Radiologic Progression in Hand Osteoarthritis (OA) Over 2.6 Years - Data From the Sekoia Trial. Emmanuel Maheu[1], Christian Cadet[2] and Francis Berenbaum[1]. [1]AP-HP, St Antoine Hospital, Paris, France, [2]Rheumatology, Paris, France

Background/Purpose: Hand OA is a frequent polyarticular disease. Few is known with respect to its radiological progression over time, which in addition is difficult to assess, considering that no radiographic scoring method has, today, proved being superior to another. The goal of this study was to assess hand OA radiological progression over 3 years using three validated scoring methods.

Methods: Data came from an international 3-year, randomized, placebo-controlled phase III trial designed to assess the effect of strontium ranelate compared to placebo on the radiographic progression of knee OA which included symptomatic primary knee OA patients (ACR criteria) at a Kellgren-Lawrence (KL) grade II or III, with a minimal joint space width (JSW) between 2.5–5 mm. During this trial, baseline and final postero-anterior radiographs of each hand were performed. Symptoms were assessed using the functional index for Hand OA (FIHOA; range 0–30) and the AUSCAN (0–300). Two independent readers scored half of the pairs of radiographs obtained each, blinded to treatment and time sequence, using the KL (range 0–128), Kallman (0–204) and Verbruggen anatomical phase (0–218) scoring methods with a good inter-rater reproducibility. Hand OA radiographic progression was studied in the placebo group by looking at 1/baseline-end changes in global scores, 2/the numbers of progressors (progression was defined for each global score by a change over each reader's smallest detectable difference (SDD)), and 3/the number of patients in whom at least 1 joint showed a deterioration (from KL0–1 to KL≥2; progression of ≥1 phase for Verbruggen score).

Results: Of 1669 patients included in the SEKOIA trial, 999 had radiologic hand OA: 73%. 297 patients in the placebo group had baseline and post-baseline radiographs. 72% were female, mean age 64±7 years, body mass index 29.5±5 kg/m^2, and initial knee JSW 3.5±0.8 mm. Baseline hand OA radiologic severity was mild: KL score 21±13, Kallman score 24±21 and Verbruggen score 13±14. FIHOA score was 4±5, Auscan global score was 96+80. Mean time interval between baseline and final radiographs was 31.5 months.

Hand OA radiographic progression over 2.6 years was modest with a mean change of 2.4±3.3 for KL score, 3.7±5.3 for Kallman score and 2.0±4.0 for Verbruggen score.

The numbers (%) of progressors (change≥SDD) were 7 (2%), 17 (6%), and 21 (7%) respectively.

The numbers (%) of patients with at least 1 worsened joint were 169 (57%) for KL and 139 (47%) for Verbruggen score, with respective means of 2.0±1.3 and 1.7±1.1 worsening joint.

Conclusion: Whatever the radiological scoring method used, and the kind of analysis performed, mild radiographic hand OA patients showed a very weak global radiological progression over 2.6 years. In future structure-modification trials in hand OA, analysing the number of patients with at least one joint worsening could be the most sensitive method.

1111

Erosive Evolution in Hand Osteoarthritis Is Associated with Incident Joint Tenderness Independent of MRI-Defined Bone Marrow Lesions and Synovitis.

Ida K. Haugen[1], Barbara Slatkowsky-Christensen[1], Pernille Boyesen[1], Sølve Sesseng[1], Désirée van der Heijde[2] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Previous studies have shown no association between increased amount of radiographic hand osteoarthritis (OA) resulting in more hand pain/disabilities. In this longitudinal study, our aim was to study whether radiographic hand OA was related to joint tenderness in cross-sectional and longitudinal settings focusing on joint-specific analyses, and whether presence of MRI-defined synovitis and bone marrow lesions (BMLs) at follow-up had an effect on the observed longitudinal associations.

Methods: We included 190 patients (173 women, mean (SD) age 61.5 (5.7) years) from the Oslo hand OA cohort with hand radiographs at baseline, of which 112 (102 women) had 7-years follow-up data. Of those, 89 had pre-/post-Gd T1w fs MRIs of the distal (DIP) and proximal interphalangeal (PIP) joints in the right hand, whereas 101 had STIR images. The bilateral DIP, PIP and carpometacarpal joints were scored for radiographic OA according to Kellgren-Lawrence scale and OARSI atlas, whereas the right hand's DIP and PIP joints were scored for synovitis and BMLs according to Oslo hand OA MRI score. Joint tenderness on palpation (absent/present) was assessed by a rheumatologist. To explore the associations between radiographic hand OA and tenderness in the same joint, we performed uni-/multivariate logistic regression analyses with Generalized Estimating Equations. In the longitudinal analyses only joints with potential for radiographic progression and without tenderness at baseline were included. Features that were associated with tenderness in univariate analyses (p<0.20) were included in a multivariate model and excluded by backward selection. All analyses were adjusted for age and sex. Using the final multivariate model from the longitudinal analyses, we did additional adjustment for presence of MRI-defined synovitis (grade 2–3) and BMLs (grade 1–3) at follow-up (only DIP and PIP joints in right hand included in these analyses).

Results: Incident erosions seemed to be the most important predictor for incident tenderness, but also progression of osteophytes and JSN remained in the final model. Sclerosis and cysts were not associated with tenderness in the multivariate models, and malalignment remained in the final multivariate model for cross-sectional data only (table). Associations between radiographic progression of osteophytes, JSN and erosions and incident joint tenderness were similar after adjustment for BMLs and synovitis at follow-up (data not shown).

Table. Associations between OA severity and joint tenderness in cross-sectional analyses and between radiographic progression and incident tenderness in longitudinal analyses (no progression as reference).

		Cross-sectional analyses (OR, 95% CI)*	Longitudinal analyses (OR, 95% CI)*
Model 1: Global score:			
Kellgren/Lawrence	Grade0	1.0 (ref.)	1.0 (ref.)
	Grade1	1.4 (1.2-1.7)	1.2 (0.7-2.0)
	Grade2	3.0 (2.4-3.7)	1.5 (0.9-2.5)
	Grade3	6.8 (4.5-10)	5.7 (3.0-11)
	Grade4	5.3 (3.3-8.6)	11 (4.0-33)

Model 2: Individual radiographic features (one multivariate model):			
Osteophyte	Grade0	1.0 (ref.)	1.0 (ref.)
	Grade1	2.4 (1.9-3.0)	1.6 (1.0-2.4)
	Grade2	2.7 (1.9-4.0)	
	Grade3	2.8 (1.7-4.5)	
Joint space narrowing	Grade0	1.0 (ref.)	1.0 (ref.)
	Grade1	0.9 (0.7-1.1)	2.1 (1.2-3.7)
	Grade2	1.4 (1.0-1.8)	
	Grade3	1.1 (0.7-1.6)	
Erosions	Grade0	1.0 (ref.)	1.0 (ref.)
	Grade1	1.6 (1.0-2.4)	1.0 (ref.)
Malalignment	Grade0	1.0 (ref.)	-
	Grade1	1.6 (1.1-2.2)	

Conclusion: Erosive development can strongly predict future joint tenderness, and the association to tenderness seemed to be independent of MRI-defined BMLs and synovitis. However, future longitudinal MRI studies are warranted.

1112

Patients with Erosive Osteoarthritis Have Less Extensive Synovitis Than Patients with Rheumatoid Arthritis On Histopathology.

Allen P. Anandarajah[1], Stephen Kates[2], Kate Burns[3] and Ellen Giampoli[4]. [1]Univ of Rochester Medical Ctr, Rochester, NY, [2]University of Rochester Medical Center, Rochester, [3]University of Rochester, Rochester, NY, [4]University of Rochester Medical Ctr, Rochester, NY

Background/Purpose: Patients with erosive osteoarthritis (EOA) often develop disfiguring deformities and associated decline in hand function. We have previously demonstrated that synovitis was a common finding on MRI and histology in patients with EOA and along with BME were associated with the presence of erosions, on MRI. Treatment of EOA with anti-rheuamtic disease modifying drugs and anti-tumor necrosis factor therapies however has not been successful. We therefore sought to identify the difference on histopathology between EOA and rheumatoid arthritis (RA).

Objective: To compare the extent of synovial inflammation, inflammatory cell infiltration, vascularity and lymphoid follicles on histopathology specimens from EOA and RA patients

Methods: This was a single center, retrospective, observational study. The records of all EOA patients from a cohort of 112 patients were reviewed for pathology or biopsy of any joint. Patients with a diagnosis of EOA had to meet the following criteria: (1) OA of hands based on the ACR criteria (2) erosions in at least 2 interphalangeal joints (IP) of which one must be a distal IP joint (3) be negative for rheumatoid factor and anti-CCP antibody (4) negative personal and family history of psoriasis and psoriatic arthritis and (5) absence of history of gout or pseudogout in hands. These were compared with synovial specimens from 15 RA patients who had elective orthopedic surgeries. The synovial tissue was graded on a scale of 0–4 (none, minimal, mild, moderate and marked) for the presence and degree of synovial lining hyperplasia, the cellularity of the synovial stroma, extent of inflammatory infiltrate, degree of vasculairy and the number of lymphoid follicles on routine hematoxylin and eosin stained slides.

Results: A total of 8 synovial specimens (6 proximal interphalangeal joints and 2 knees) were obtained from 5 patients for the EOA group and 15 specimens (5 knees, 5 wrists, 2 hips, 1 elbow, 1 shoulder and I proximal interphalangeal joint) from 14 patients was obtained for the RA group. The EOA group comprised 4 females and 1 male with a mean age of 60.4 while the RA group was comprised of 12 females and 2 males with an average age of 59.5. All RA patients were on therapy: 3 on biologic therapies, 1 on biologic and methotrexate, 7 on methotrexate monotherapy and 3 on methotrexate and hydroxychloroquine. One of the EOA patients was on hydroxychloroquine and one on methotrexate. Synovial hyperplasia and inflammatory infiltrate were noted in all RA specimens and in most EOA specimens (7 and 6) but the grading of extent revealed mean scores for hyperplasia and inflammatory infiltrate of 2.6 and 3.1 respectively for RA and 1.4 and 1.1 respectively for EOA. Synovial stroma cellularity and vascularity were also common in both conditions (14 of 15 RA and 7 of 8 EOA) but again differed on the grading from 2.5 and 2.4 for RA and 1.4 and 1 for EOA. The presence of lymphoid follicles was seen in only 1 EOA patients but noted in 7 RA subjects.

Conclusion: Synovial hypertrophy, synovial stroma cellularity, vasculiary and inflammatory cell infiltrate are commonly seen in both EOA and RA but the extent of involvement is less in EOA than in RA. The difference in

pathology may the lack of response in EOA to traditional DMARDs and anti-TNF therapies.

1113

Characterization of Lumbar Spine Individual Radiographic Features in African American and White Women and Men: The Johnston County Osteoarthritis Project. Adam P. Goode[1], Amanda E. Nelson[2], Kelli D. Allen[3], Jordan Renner[4], Timothy S. Carey[5] and Joanne M. Jordan[2]. [1]Duke University, Durham, NC, [2]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [3]Duke and Durham VA Medical Center, Durham, NC, [4]University of North Carolina, Chapel Hill, NC, [5]Cecil G. Sheps Center for Health Services Research University of North Carolina, Chapel Hill, NC

Background/Purpose: Race and gender differences have been found to exist in hip and knee osteoarthritis (OA). Whether such differences occur with lumbar spine individual radiographic features (IRF) of disc space narrowing (DSN) and vertebral osteophytes (OST) are unknown. The purposes of these analyses are to describe differences in the severity of DSN and OST among African American and Caucasian men and women.

Methods: Lumbar spine radiographs (DSN and OST) were available for 1,633 participants returning for second follow-up in the Johnston County Osteoarthritis Project from 2008-11. Participants had a mean age 68.1 (SD 9.2), and were 68.0% female and 31.7% African American (AA), with mean body mass index (BMI) 31.4 (SD 7.2). Seventy-eight percent had $>=12$ years education. Lateral lumbar spine films were graded for each level in a semi-quantitative fashion (0–3) for DSN and (0–3) for both anterior superior and inferior OST according to the Burnett Atlas. Lumbar spine IRF were coded (individually for DSN and superior and inferior OST) based upon a participant's most severely affected lumbar level. For all analyses, AAs were the referent group and results were stratified by gender. Multivariable associations were determined with proportional odds models while adjusting for age, BMI, and education.

Results: After adjustment, White women had a significantly greater odds of DSN (adjusted Odds Ratio [aOR]= 1.56 ((95% CI 1.23, 1.98)) whereas no significant association was found across race for men (aOR= 1.24 ((95% CI 0.86, 1.79)). No association was found across race for either women (aOR=1.00 ((95% CI 0.78, 1.28)) or men (aOR= 1.13 ((95% CI 0.78, 1.65)) for superior anterior OST. White women (aOR= 1.50 ((95% CI 1.16, 1.95)) and White men (aOR= 1.88 ((95% CI 1.27, 2.77)) both had a greater odds of inferior anterior vertebral OST.

Conclusion: Severity of some lumbar spine IRFs differs by race, suggesting the possibility of anatomic or developmental variation in the spine. The greater severity of DSN in White women compared to AA women is important because this IRF has been consistently associated with low back symptoms. The fact that both White women and White men had greater severity of inferior vertebral OST, compared with their AA counterparts, suggests anatomic racial differences in this region.

1114

Prevalence of Radiographic and Symptomatic Hip Osteoarthritis in an Urban US Population: The Framingham Osteoarthritis Study. Katherine D. Linsenmeyer[1], Ali Guermazi[1], Kyu-Chan Kim[1], David T. Felson[2], Mary M. Clancy[2] and Steven C. Vlad[2]. [1]Boston Medical Center, Boston, MA, [2]Boston University, Boston, MA

Background/Purpose: There are few studies of hip osteoarthritis (OA) in the United States and none in the last 35 years that have addressed the prevalence of hip OA in an urban population. Recent estimates from Europe suggest that 2–5% of the population age 50 and over has symptomatic hip OA. Our goal was to assess the prevalence of radiographic and symptomatic hip OA within the Framingham Osteoarthritis cohort.

Methods: We studied the Community sample of the Framingham Osteoarthritis study which was recruited among those 50–79 years using random digit dialing from the town of Framingham in 2002–2005. As part of this examination standing long-limb radiographs of the lower extremities including the pelvis were obtained using a near horizontal beam. In addition, subjects answered questions regarding the presence and frequency of joint symptoms and indicated on a homunculus whether they had hip joint pain on most days of the previous month. Two reviewers who received training from an expert musculoskeletal radiologist read all films and verified abnormal ones with the radiologist. Films where both hips were unreadable were excluded. Films were also assessed for Kellgren-Lawrence grade: radiographic OA (ROA) was defined as K/L $\geq$ 2 (probable joint space narrowing plus an osteophyte ' 2). Interobserver kappas were 0.72 between the readers. Persons with a hip replacement were defined as having hip OA in that joint (n=22 subjects). Symptomatic hip OA (SxOA) was defined as radiographic OA with ipsilateral hip pain.

Results: Of 1025 subjects with radiographs, 949 films could be evaluated in both hips. Mean age was 63.5 years (sd 9.0), 56% were women, mean BMI was 27.9 (sd 4.6), 98.1% were white. 16.9% had radiographic hip OA (20.8% of men, 13.8% of women). Of those with ROA, 73.1% were unilateral and 26.9% bilateral. 11.7% of subjects under 65 had ROA (67/571) as compared to 24.7% of subjects 65 and over (93/376). In subjects with BMI < 25, 19.3% (53/276) had ROA; for BMI 25–29.9, 16.3% (66/404) had ROA; for BMI $\geq$ 30, 15.2% (41/269) had ROA. Both whites and non-whites had similar rates of ROA (16.9%). Of those with ROA, 21.9% had hip joint pain, yielding a SxOA prevalence of 3.7% of the total population (4.3% of men, 3.2% of women).

Conclusion: Around 1/6 of the subjects in this population-based cohort had radiographic evidence of hip OA; 3.7% of men and women had symptomatic OA, an estimate similar to studies from Europe.

1115

Relation Between Hip Dysplasia, Pain, and Osteoarthritis in a Cohort of Patients with Hip Symptoms. Johanne Morvan[1], Ronan Bouttier[2], Bernard Mazieres[3], Evelyne Verrouil[3], Jacques Pouchot[4], Anne-Christine Rat[5], Joel Coste[6] and Alain Saraux[7]. [1]CH Quimper, Quimper, France, [2]CHU Brest, Brest, [3]Hopital de Rangueil, Toulouse, FRANCE, France, [4]Hopital Louis Mourier, Colombes, FRANCE, France, [5]Nancy Teaching Hospital, Nancy, France, [6]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F- 54 000, France, Nancy, France, [7]Université Brest Occidentale, Brest, France

Background/Purpose: The relationship between acetabular dysplasia (HD) and hip osteoarthritis remains unclear, especially for mild forms of dysplasia. Our objectives were to estimate the prevalence of HD in a population-based sample with hip symptoms and to evaluate potential associations linking HD, hip osteoarthritis, and hip pain.

Methods: Individuals 40 to 75 years of age with symptoms in one or both hips were recruited during a multiregional prevalence survey. All study participants underwent a physical examination and radiographs. Radiographs were evaluated using Kellgren and Lawrence (KL) staging (with stages $\geq$2 indicating hip osteoarthritis) and HD parameters (center-edge [CE] angle, acetabular inclination angle [HTE], acetabular depth [AD], and vertical-center-anterior margin [VCA] angle).

Results: We studied both hips of 842 individuals (1684 hips) among whom 203 had hip osteoarthritis. Compared to left hips, right hips had significantly smaller CE angles and significantly greater AD and HTE values ($P \leq 0.001$). Overall, the prevalence of HD ranged from 7.6% to 22.2% of the hips depending on the parameter used. The prevalence of HD was higher in individuals with hip osteoarthritis, with significant differences for abnormal HTE (19.1% vs. 11.4%; $P < 0.0001$) and abnormal CE (11.3% vs. 7.5%; $P = 0.04$). By logistic regression, only abnormal HTE remained associated with OA ($P = 0.05$). Hip pain was more common in individuals with HD ($P < 0.0001$) but the association was not statistically significant after stratification on osteoarthritis status ($P = 0.25$).

Conclusion: Our study confirms the relationship between osteoarthritis and HD, particularly defined based on the HTE angle. HD was not associated with hip pain.

1116

Diagnostic Value of Internal Rotation Measurement in Patients with Cam- and Pincer-Type Deformities of the Hip. Stephan Reichenbach[1], Michael Leunig[2], Stefan Werlen[3], Andreas Limacher[1], Christian W. Pfirrmann[4], Reinhold Ganz[1] and Peter Jüni[1]. [1]University of Bern, Bern, Switzerland, [2]Schulthess Clinic, Zurich, Switzerland, [3]Hospital Sonnenhof, Bern, Switzerland, [4]Balgrist University Hospital, Zurich, Switzerland

Background/Purpose: It has been proposed that femoroacetabular impingement (FAI) causes early osteoarthritis (OA) in non-dysplastic hips. FAI occurs predominantly in two different types, "cam" or "pincer". Cam impingement is due to a cam-type deformity with a non-spherical femoral head and/or a decreased anterior head-neck offset. Pincer impingement results from increased acetabular depth with over-coverage of the femoral head, while the head-neck configuration may be normal. FAI is often seen in young male athletes referred to rheumatologists or orthopaedic surgeons because of groin pain, and internal rotation in flexion is usually diminished. The aim of this study was to determine whether diminished internal rotation can be used to detect FAI in young asymptomatic males.

Methods: Study subjects were young males aged 18 to 21 undergoing compulsory conscription for the Swiss army. Participants completed questionnaires pertaining to pain, stiffness, and physical function, and internal rotation was measured on a validated examination chair. A random sample of the examined participants was invited for magnetic resonance imaging (MRI) of the hip. Cam-type deformities were graded from 0 to 3: 0=normal, 1=mild, 2=moderate, 3=severe. Pincer impingement was defined by increased acetabular depth, which was specified as the distance (in mm) between the center of the femoral neck and the line connecting the anterior and posterior acetabular rims. Values were positive if the center of the femoral neck was lateral to the acetabular rim, with ≤3 mm representing increased acetabular depth. Based on a fitted receiver operating characteristics (ROC) curve, we estimated sensitivity, specificity, positive and negative likelihood ratios (LR) for different internal rotation cutoffs for cam impingement, pincer impingement, and the combination of both, as compared with the reference group without deformity on MRI.

Results: 244 asymptomatic males underwent imaging, with a mean age of 19.9 years. Fifty-nine subjects showed definite cam-type deformity, eight increased acetabular depth, and eight a combination of both. Area under ROC-curves were 0.725 for detection of the first group, 0.549 for detection of the second, and 0.895 for detection of the third group as compared with the reference group. A cut-off value of 30° of internal rotation yielded a sensitivity of 0.63 and a specificity of 0.69 for the first group, 0.13 and 0.69 for the second, and 1.00 and 0.69 for the third. An internal rotation of ≥30° had sufficient power to rule out the combination of both types of impingement: the crude negative likelihood ratio (LR) was below 0.10. Conversely, an internal rotation of ≤20° had the required power to rule in the combination of both types of impingement, with a positive LR of 12.7.

Conclusion: Different cut-offs for internal rotation may be used to accurately rule in or rule out the combination of cam- and pincer-type impingement. Internal rotation is not useful for detecting pincer-type impingement.

1117

Association Between Hip Bone Marrow Lesions (BMLs) and Bone Mineral Density: A Cross-Sectional and Longitudinal Population-Based Study. Harbeer Ahedi[1], Dawn Dore[1], Leigh Blizzard[1], Flavia Cicuttini[2] and Graeme Jones[1]. [1]Menzies Research institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Bone marrow lesions (BMLs) have been identified one of the key pathologic features in knee osteoarthritis (OA)[1]. However, there is limited data on hip BMLs and their relation to bone mass. The aim of this study was to examine the cross-sectional and longitudinal association between hip BMLs and BMD at three different sites.

Methods: 198 subjects in the Tasmanian Older Adult Cohort (TASOAC) study (average age 64 yrs) with a right hip MRI and dual-energy x-ray absorptiometry (DXA) scans conducted at two time points, approx. 2.6 years apart, were included in this study. MR images were used to assess femoral and acetabular hip BML presence and size (cm²) by manually drawing contours around the outer edges of the BML using Osiris X (Geneva) software. DEXA scans were used to determine total hip, femoral neck and spine BMD.

Results: Fifty-five subjects (28 %) had either femoral and/or acetabular BMLs. In cross-sectional analysis, femoral BMLs were not associated with either hip or femoral neck BMD whereas acetabular BMLs were associated with lower hip BMD and femoral neck BMD *(mean diff: −0.05 g/cm², p=0.009 & mean diff: −0.06 g/cm², p<0.001 resp.)*. Neither was associated with spine BMD. Longitudinally, resolving acetabular BMLs were associated with an increase in BMD at both hip *(mean diff: +0.02 g/cm², p=0.05)* and femoral neck *(mean diff: +0.01 g/cm², p=0.02)* sites while incident femoral BMLs were associated with an increase *(mean diff: +0.03 g/cm², p<0.001)* and resolving femoral BMLs with a decrease in femoral neck BMD *(mean diff: −0.04 g/cm², p=0.04)*. Finally, change in femoral BML size was associated with change in femoral neck BMD (*βeta: +0.03, p<0.001)* and change in acetabular BML size was associated with change in femoral neck BMD (*βeta: −0.01, p=0.004)*.

Conclusion: Hip BMLs are associated with site-specific changes but not distant changes in bone mass. These results, especially in the longitudinal data, suggest this is a combination of changes related directly to the underlying BML pathology as well as changes adjacent to the disease process perhaps due to pain, disuse or paracrine effects.

Association Between Hip and Knee Cartilage Measured Using Radiographs and Magnetic Resonance Imaging: The Tasmanian Older Adult Cohort Study. Hussain Ijaz Khan[1], Dawn Dore[1], Guangju Zhai[2], Changhai Ding[3], Jean Pierre Pelletier[4], Johanne Martel-Pelletier[4], Flavia Cicuttini[5] and Graeme Jones[1]. [1]Menzies Research institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Discipline of Genetics, Faculty of Medicine, Memorial University of Newfoundland, St John's, NL, [3]Menzies research institute & Monash University, Hobart, Australia, [4]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [5]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, 3004, Australia

Background/Purpose: Cartilage loss is the key pathological feature of osteoarthritis (OA) and can be assessed indirectly using radiography or directly through magnetic resonance imaging (MRI). A number of cross-sectional studies have examined the association of hand OA with hip or knee OA, suggesting that primary generalised OA (PGOA) may be a distinct disease in which systemic predisposition is more important than local (mechanical) factors. However, despite the high frequency of involvement of the hip and the knee joints in OA, only a few studies have looked at the radiographic association of joint space narrowing (JSN) in these two joints with inconsistent results. None has done so using MRI. The aim of this study was to examine the association of hip and knee cartilage measured by both radiography and MRI.

Methods: We studied 151 participants from a cohort study of older adults. MRI was used to assess hip and knee cartilage volume and radiography was used to asses JSN at both sites. Correlation analyses were used to compare cartilage volume measurements and JSN.

Results: In adjusted analysis, there was a consistent, positive association between knee cartilage volume and hip cartilage volume which was best for total knee cartilage volume (R= 0.23–0.50, all P= <0.05). In contrast, there was no or at best a weak correlation between hip and knee JSN (R= −0.01–0.24).
Figure 1. Correlation between hip cartilage volume and total knee cartilage volume. Line of best fit, R-value and p-value were adjusted for age and sex.

Conclusion: Hip and knee cartilage volume are more strongly associated than hip and knee radiographic JSN suggesting commonality of cartilage volume at different anatomic sites. The weaker radiographic association may reflect less measurement error with MRI or the contribution of multiple structures to JSN in the knee.

1119

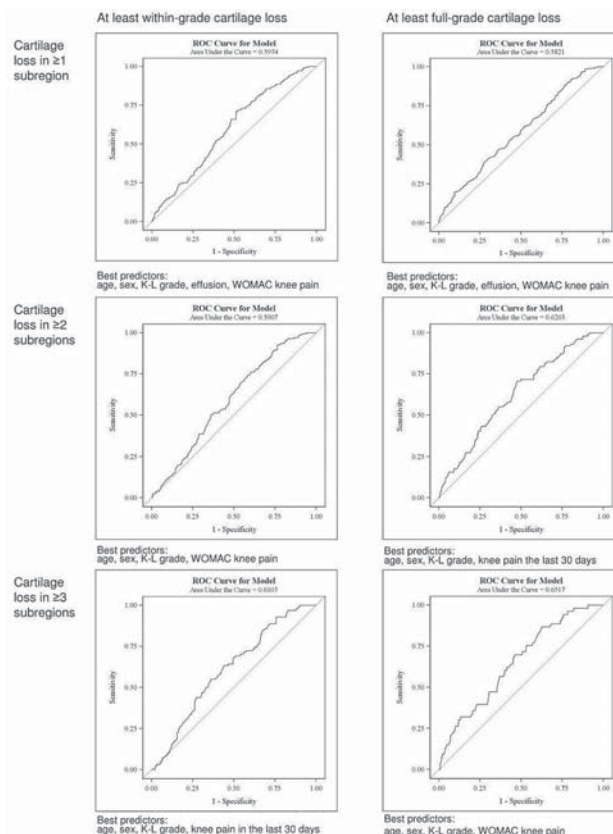
Prediction of MRI-Detected Cartilage Loss Over 30 Months Using Simplified Radiographic and Clinical Stratification: The MOST Study.

Frank Roemer[1], David T. Felson[2], Jingbo Niu[2], Yuqing Zhang[3], Michael C. Nevitt[4], Michel Crema[3], Cora E. Lewis[5], James Torner[6] and Ali Guermazi[7]. [1]Klinikum Augsburg, Augsburg, Germany, [2]Boston Univ School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]University of California-San Francisco, San Francisco, CA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA, [7]Boston University School of Medicine, Boston, MA

Background/Purpose: MRI-detected cartilage loss is the main structural outcome measure in large studies of knee OA. Definition of subjects at high risk for cartilage loss is important as this subgroup is likely to benefit most from interventional efforts and will potentially reduce subject numbers and duration of clinical trials. A simple stratification strategy is needed for pre-selecting subjects at high risk. We assessed a set of potential factors in regard to their predictive capability of cartilage loss over 30 months.

Methods: The Multicenter Osteoarthritis (MOST) Study is a longitudinal study of subjects with knee OA or at risk of OA. 1.0 T MRI was performed at baseline and 30 months follow-up in subjects with radiographic knee OA at baseline. MRIs were assessed according to the WORMS scoring system including within-grade assessment. Altogether 10 tibiofemoral subregions were scored. Cartilage loss was defined as at least within-grade increase in cartilage score in ≥1, ≥2, or ≥3 subregions. Analyses were repeated with cartilage loss defined as full grade increase. Six predictors that are commonly acquired in screening efforts, i.e., gender, age, BMI, Kellgren Lawrence (K-L) grade (0–1, 2, 3–4), joint effusion (0–1, 2–3) and knee pain (pain on most days during the past 30 days or maximal WOMAC pain score as 0, 1–2, 3–4) were assessed using a 10-fold cross-validation method. The cross-validation was repeated 10 times, and averaged receiver operating characteristics (ROC) curve, i.e., C-statistic, was calculated as a measure of the overall performance. Age and sex were forced in all models. We plotted the ROC curves for each variable selected in the final model according to cross-validation method.

Results: Of 544 knees randomly selected from the progression cohort, risk of at least within-grade cartilage loss occurring in ≥1, or ≥2, or ≥3 subregions was 53.6%, 31.6%, and 18.1%, respectively. The model contain-

ing age, sex, K-L grade, effusion, and knee pain provided the highest prediction accuracy (C-statistic 0.533) for any cartilage loss occurring in at least one subregion. The best models for prediction of at least within-grade cartilage loss of ≥2 or ≥3 included the same variables, i.e., age, sex, K-L grade and knee pain (C-statistics=0.561 for ≥2, and 0.571 for ≥3 subregions). Risk of full-grade cartilage loss in ≥1, ≥2, or ≥3 subregions was 38.8%, 18.8% and 9.7%, respectively. The same variables were included for predicting cartilage loss of a full grade in ≥1, or ≥2, or ≥3 subregions as those for at least within-grade loss. The corresponding C-statistics were 0.559, 0.599, and 0.615 (Figure 1), respectively.


Conclusion: Among knees with radiographic OA, age, sex, K-L grade and knee pain only had the moderate capability of predicting cartilage loss. Of them the strongest predictors were baseline K-L grade, followed by knee pain. The prediction accuracy of this model needs to be further validated using large databases from other populations.

Cartilage Volume Loss Occurs in Most Older Adults and the Rate of Loss Increases with Age.

Andreea M. Harsanyi[1], Dawn Dore[1], Changhai Ding[1], Jean-Pierre Pelletier[2], Johanne Martel-Pelletier[2], Flavia Cicutinni[3] and Graeme Jones[1]. [1]Menzies Research institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [2]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [3]Monash University, Melbourne, Australia, Melbourne, Australia

Background/Purpose: Radiographic data suggests knee osteoarthritis is a relatively static disease even over the long term. It is uncertain how much this is influenced by measurement error and whether it accurately reflects what is happening to the cartilage. Initial cross-sectional studies suggest little

change in cartilage volume with age but a decrease in thickness. However, longitudinal studies in younger age groups suggest the rate of cartilage volume loss increases with age. There are no longitudinal studies in older age groups.

The aim of this study was to describe cartilage loss over time and the association between age and knee cartilage volume loss in older adults.

Methods: A total of 407 randomly selected community-dwelling older adults (mean age 63.2 years, range 51–79 years; 50% female) were measured at baseline and approximately 2.7 years later. T1-weighted fat-suppressed magnetic resonance imaging (MRI) was used to measure knee cartilage volume at the tibial and femoral sites. Body mass index (BMI) and radiographic osteoarthritis (ROA) were measured by standard protocol. A real change in volume loss was assessed using the least significant criterion which takes into account measurement error and the correlation between measurements at baseline and follow up.

Results: On average, participants had 1.5% per annum tibiofemoral cartilage volume loss. Of the 407, 74% had a decrease larger than measurement error while, 14% which had a genuine increase in volume and only 12% were unchanged. After adjustment for sex, BMI and ROA, age was significantly associated with annual decrease in medial and total tibial (β −0.08 to −0.13%/yr, all P< 0.008) but not lateral tibial cartilage volume (β −0.03%/yr, P>0.05). In addition, age was associated with a decrease in medial and lateral femoral cartilage volume in males (β −0.05 to −0.06%/yr, all P <0.01) but not females (β −0.001 to 0.005%/yr, P >0.05).

Conclusion: Knee cartilage volume is rarely static even over a three year time frame. The majority of subjects lose cartilage and this rate of loss increases with age. These findings suggest radiographs are not sensitive measures of changes in cartilage volume and challenge the view that osteoarthritis is largely static over time.

Degenerative Medial Meniscal Pathology May Initiate in the Posterior Horn: Data From the Osteoarthritis Initiative. Robert J. Ward[1], Jeffrey B. Driban[1], Eric E. Wong[1], Jonathan W. Pack[1], Kunal K. Kothari[2], Grace H. Lo[3] and Timothy E. McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA, [3]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX

Background/Purpose: Meniscal pathology is highly prevalent in knee Osteoarthritis (OA). However, details regarding the distribution of pathology within the meniscus has yet to be described in patients with and without radiographic signs of OA. Cross-sectional distribution of medial meniscal pathology as it relates to the anterior horn, body, and posterior horn may be informative of the role of the meniscus in the natural history of OA.

Methods: We studied participants in the Osteoarthritis Initiative (OAI) progression subcohort who had the OAI core set of magnetic resonance (MR) images at the 24-month OAI visit and consented to participate in the Bone ancillary project. By definition, members of the progression subcohort had at least one symptomatic knee with radiographic evidence of OA.. The right knee was selected as the index knee for investigation among these participants unless there was a contraindication for MR imaging; therefore, the index knee did not have OA as a pre-requisite. A single experienced fellowship trained musculoskeletal radiologist reviewed the MR images for meniscal pathology by location (e.g. anterior, body, and posterior horn) within the medial menisci using a modified International Society of Arthroscopy, Knee Surgery, and Orthopaedic Sports Medicine (ISAKOS) meniscal tear classification system. We presented the prevalence of meniscal pathology within the medial meniscus among this sample both with and without knee OA. PA standing radiographs were obtained of the same knees and read for Kellgren-Lawrence grade.

Results: 464 knees were included in the analysis; 454 were right knees; 244 (53%) men, with a mean age of 63 years (SD). 135 (29.4%) knees had no radiographic evidence of knee OA (Kellgren-Lawrence Grade = 0 or 1). 114 (24.6%) had normal medial menisci, leaving 350 (75.4%) with some pathology in at least one region of the medial meniscus. 117 (25.2%) knees had pathologic anterior medial menisci and among those 98.3% had concurrent findings in the body or posterior horn. 272 (58.6%) medial menisci have pathologic findings in the meniscal body and among those 97.4% had concurrent findings in the anterior or posterior

meniscal horn. 336 (72.4%) medial menisci had pathologic findings in the posterior meniscus and among those 263 (78.3%) had concurrent findings in the body or anterior regions. Finally, 107 (23.1%) had pathologic findings in all three regions (regardless of type of finding).

Conclusion: Medial meniscal pathology is highly prevalent. In our sample, of those with medial menisci pathology some damage was also almost universally found in the posterior horn. Those with posterior horn damage also very commonly had concurrent pathology in the body and anterior horn. Isolated involvement of the anterior horn and body of the medial meniscus are rare. Though this is a cross-sectional study, these findings suggest that medial meniscal pathology may initiate in the posterior horn. Longitudinal studies are needed to confirm this possibility.

Identifying Radiographic Phenotypes of Early Knee Osteoarthritis Using Separate Quantitative Features Might Improve Patient Selection for More Targeted Treatment. Margot B. Kinds[1], Anne C. A. Marijnissen[1], Max A. Viergever[1], P.J. Emans[2], J.W.J. Bijlsma[1], F.P.J.G. Lafeber[1] and P.M.J. Welsing[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands

Background/Purpose: Osteoarthritis (OA) is a degenerative joint disease characterized by pain and functional disability. The expression of OA varies significantly between individuals and over time, implying the existence of different phenotypes. This study aims at identifying phenotypes of progression of radiographic knee OA and to describe their radiographic and clinical characteristics.

Methods: In individuals with early knee OA from the Cohort Hip & Cohort Knee (CHECK), baseline, two-year, and five-year follow-up radiographs were evaluated. Separate radiographic OA parameters were quantitatively measured by Knee Images Digital Analysis (KIDA). To identify phenotypes of radiographic knee OA progression, hierarchical clustering was performed using the KIDA measurements of participants with complete data at T0, T2y, and T5y (n=417 of 1002). The phenotypes were compared for development of joint space width (JSW), varus angle, osteophyte area, eminence height, bone density, and for clinical characteristics at T0. Additionally, logistic regression analysis evaluated whether baseline radiographic features predicted to which phenotype an individual belonged.

Results: Overall, the radiographic features showed OA progression during follow-up. Based on the development, five clusters were identified that were interpreted as 'severe' (n=17; most progression of all radiographic features) or 'no' (n=108) progression, 'early' (n=110; progression of all features specifically between T0 and T2y) or 'late' (n=69; progression of all features specifically between T2y and T5y) progression, or specific involvement of 'bone density' (n=113). Clinical characteristics at T0 were not evidently different between the clusters, and WOMAC scores were only slightly lower in the 'no' cluster than in the other clusters. In the evaluation of predictors for the different clusters, the area under the curve (AUC) improved when radiographic features were added to basic demographic and clinical variables. Kellgren & Lawrence grading was not a significant predictor for any of the phenotypes. The predictors for 'early', 'late', and 'no' progression phenotypes generally had an opposite effect than the predictors for the 'severe' and 'bone density' phenotypes. Larger medial JSW, varus angle, osteophyte area, eminence height, and bone density at T0 were associated with 'severe' and 'bone density' progression. The 'bone density' model had AUC=0.91. Smaller eminence height and bone density were associated with 'early' and 'late' progression (AUC= 0.79, and 0.76 respectively). Larger varus angle and smaller osteophyte area were associated with 'no' progression (AUC=0.72).

Conclusion: This is the first study to identify specific phenotypes of radiographic knee OA progression in individuals with early OA complaints. Phenotypes represented the level (severe vs. no) and phase of progression (early vs. late), and the involvement of a specific feature (bone density). Baseline radiographic features could predict the phenotypes. The phenotypes might represent relevant subgroups for the evaluation of treatment strategies in clinical trials, and with that drive the discovery of more targeted treatment.

1123

Comparison of Anatomic Knee Alignment On Physical Examination and Radiographs. Iman Hemmati[1], Eric C. Sayre[2], Ali Guermazi[3], Savvakis Nicolaou[1], Anona Thorne[4], Joel Singer[1] and Jolanda Cibere[2]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Vancouver, BC, [3]Boston University, Boston, MA, [4]Canadian Institutes of Health Research HIV Trials Network, Vancouver, BC

Background/Purpose: Severity of knee malalignment is a risk factor for osteoarthritis (OA) progression. Currently the hip-knee-angle (mechanical axis), assessed on a full-limb radiograph, is the gold standard. Direct measurement of the anatomic axis using standard knee radiographs has been validated as an alternative method. In clinical practice, examining knee alignment with a goniometer may be more practical. The aim of the current study was to 1) evaluate the correlation of knee alignment angle measured by goniometer on physical examination with the anatomic angle measured on knee radiographs and 2) to evaluate whether the relationship is confounded by clinical variables that may affect goniometric measurements.

Methods: A simple random sample (n=120) was selected from the MoDEKO (Model for the Diagnosis of Early Knee Osteoarthritis) cohort, a population-based cohort of people with knee pain, age 40–79. Knee alignment was measured to the nearest degree by two methods: 1) anatomic-axis on fixed-flexion PA knee radiographs and 2) standardized goniometer assessment on physical examination, previously shown to be reliable. In this study varus was defined as angle < 0, valgus > 0 and $0°$ as neutral. On PA radiographs anatomic axis was defined by the intersection of two lines originating from points bisecting the femur and tibia and converging at the centre of tibial spine tips. Inter- and intra-rater reliability of anatomic angle measurements from radiographs were determined by intraclass correlation coefficient (ICC) of two independent assessors. The correlation of radiographic anatomic angle with goniometer measurements was analyzed by linear regression. Western Ontario and McMaster Universities (WOMAC) pain score, body mass index (BMI) and flexion contracture were assessed as potential confounders. Analysis was weighted by stratum sampling weights.

Results: Of 120 subjects, 52% were male, with mean (SD) age of 58 (11) years and BMI of 27 (5). The mean (SD) angle measured on PA radiographs and goniometer were 2 (3.6) and 3 (2.3) degrees respectively. Intra-rater ICC for radiographic measurements was 0.93, while inter-rater ICC was 0.83. A significant correlation was found between radiographic and goniometer measurements ($r = 0.48$; $P < 0.0001$). A model was developed to predict anatomic angle based on goniometer angle: anatomic angle on PA radiographs = $0.410 + 0.749$*goniometer angle. WOMAC pain score, BMI and flexion contracture were not significantly associated with PA radiographic angle and did not significantly change the correlation of radiographic and goniometric measurements, and so these variables were dropped from the model.

Conclusion: In this study, knee alignment assessed by goniometer was significantly correlated with the anatomic axis angle on fixed-flexion PA knee radiographs. Moreover, factors such as pain, BMI and flexion contracture did not confound the relationship of goniometric with radiographic angle measurements. Given the ease of application, goniometric measurements may be preferable to x-ray, although the predictive utility of goniometric alignment measurement will require further assessment in longitudinal studies of knee OA.

Total Knee Replacement As an Osteoarthritis Study Outcome: Predictors Derived From Long-Term Observation Following a Randomized Clinical Trial. Jean-Pierre Raynauld[1], Johanne Martel-Pelletier[1], Marc Dorais[2], Boulos Haraoui[1], Denis Choquette[1], François Abram[3], André Beaulieu[4], Louis Bessette[5], Frédéric Morin[6], Lukas M. Wildi[1] and Jean Pierre Pelletier[7]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [2]StatSciences Inc., Notre-Dame de l'Île Perrot, QC, [3]Imaging Research & Development, ArthroLab Inc., Montreal, QC, [4]Faculty of Medicine, Laval University, Quebec, QC, [5]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC, [6]Centre de Recherche Musculo-squelettique, Trois-Rivières, QC, [7]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC

Background/Purpose: Using data from a 4-year follow-up of knee OA patients who formerly received treatment with chondroitin sulfate (CS) within a 6-month clinical trial, we wanted to find predictors of the incidence of total knee replacement (TKR).

Methods: Knee OA patients participating in a randomized, double-blind controlled trial evaluating the impact of CS (Bioibérica S.A., Barcelona, Spain) (400 mg BID) vs. placebo who had serial MRI acquisitions (qMRI) and clinical evaluations of the symptomatic knee[1] were contacted to evaluate retrospectively the incidence of TKR of the study knee. A sub-group of patients (n=57) who received the study medication and had all the MRI evaluations (intent to treat (ITT)) were selected for this post hoc retrospective analysis. The TKR incidence was assessed blindly to the treatment allocation with a standardized phone interview.

Results: The patients' mean age was 63.2 years, 63% were female and the average body mass index (BMI) was 30.7 kg¨ Mm[2]. A total of 13 TKRs (22.8%) were performed on this sub-population in the time frame of 4 years after completion of the original study. Interestingly, there were more TKRs performed within the placebo group (n=9) than the CS group (n=4) (69% vs. 31%, p=0.15, logistic regression). We further investigated the predictors of long-term TKRs for the target knee by comparing, within the ITT cohort, the patients who had TKR (n=13) for the target knee to those who did not (n=44), using data at baseline or the change at 1 year. Baseline values of WOMAC pain (p=0.01, logistic regression) and function (p=0.04), bone marrow lesions (BMLs) in the medial tibial plateau (p=0.0008) and global knee (0.02), and C-reactive protein (CRP) level (p=0.05) were strong predictors of TKR. Changes at 1 year in the medial cartilage volume higher than 7% (p=0.03) and the change in WOMAC pain (p=0.02) and function (p=0.02) also predicted the occurrence of TKR. Multivariate analyses controlling for age, sex, and BMI revealed that baseline presence of BML (p=0.003) and WOMAC pain (p=0.006) were independent strong predictors of TKR. Time to occurrence of the TKR from the study inception also favored the CS group vs. placebo (Log-Rank, p=0.14). Cox regressions that included age, sex, and BMI in the model indicated that baseline values of WOMAC pain (p=0.0006), presence of BML in the medial compartment (p=0.0007) and CRP (p=0.02) were the strongest independent predictors of TKR over time.

Conclusion: Treatment with CS appeared to reduce the need for TKR. There are very few OA RCTs that use qMRI to probe knee structural outcomes. According to this study, predictors of long-term occurrence of a TKR were greater levels of knee pain, lower level of function and presence of BML at baseline, and greater loss of cartilage over time. This study links MRI findings to long-term clinical outcomes.

Three Trajectories of Activity Limitations in Early Symptomatic Knee Osteoarthritis: A 5-Year Follow-up Study. Jasmijn F. M. Holla[1], Marike van der Leeden[1], Leo D. Roorda[1], Martijn W. Heymans[2], Sita M.A. Bierma-Zeinstra[3], Maarten Boers[2], Willem F. Lems[2], Martijn P.M. Steultjens[4] and Joost Dekker[2]. [1]Reade, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Erasmus MC - University Medical Center, Rotterdam, Netherlands, [4]Glasgow Caledonian University, Glasgow, Scotland

Background/Purpose: Knee osteoarthritis (OA) is one of the leading causes of activity limitations among older adults. The course of activity limitations is highly variable; some patients seem to be stable or even improve, whereas others deteriorate. The aim of the present study was to identify subgroups of knee OA patients with different trajectories of activity limitations, and to describe patient characteristics for each subgroup.

Methods: Five-year follow-up data from a sample of 713 participants with early symptomatic knee OA from the Cohort Hip and Cohort Knee (CHECK) were used. Activity limitations were measured yearly with the physical function subscale of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Latent class growth analyses (LCGA) were used to identify trajectory classes of activity limitations. Multivariable logistic regression analyses were used to examine differences in demographic, clinical and psychological characteristics between the trajectory classes.

Results: The LCGA yielded 3 trajectory classes for activity limitations. Participants in class 1 ('slight limitations'; n = 336) reported permanent low levels of activity limitations, or moved from moderate or high levels at baseline to low levels of activity limitations over 5 years. Participants in class 2 ('moderate limitations'; n = 261) reported permanent moderate levels of activity limitations, or moved from fairly high or fairly low levels to moderate levels of activity limitations over 5 years. Participants in class 3 ('severe limitations'; n = 116) reported permanent high levels of activity limitations, or moved from low or moderate levels of activity limitations to high levels of activity limitations over 5 years. Participants in class 1 ('slight limitations') were more likely to have a lower BMI, to have less than 3 comorbidities, to report a lower level of knee pain, no to have hip pain, not to have joint space narrowing, and to feel more vital, compared with participants in class 2 ('moderate limitations') (AUC: 0.75). Participants in class 3 ('severe limitations') were more likely to report a higher level of knee pain, to have bilateral knee pain, to have osteophytosis, to feel less vital, and to avoid physical activities (AUC: 0.76).

Conclusion: Three trajectory classes of activity limitations were identified using 5-year follow-up data of 713 participants with early symptomatic knee OA: 'slight limitations'; 'moderate limitations'; and 'severe limitations'. The 'slight limitations' group was characterized by a lower BMI, a lower comorbidity count, lower levels of knee pain, not having hip pain, not having joint space narrowing, and high vitality. The 'severe limitations' group was characterized by higher levels of knee pain, bilateral knee pain, osteophytosis, low vitality, and avoidance of physical activities.

1126

Comparison between Osteoartritis Initiative and CHECK study (Cohort Hip & Cohort Knee); Development of pain and function during 4 years follow-up. Janet Wesseling[1], Sita M.A. Bierma-Zeinstra[2], Margreet Kloppenburg[3], Johannes WJ Bijlsma[1] and CHECK steering group[4]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Erasmus MC - University Medical Center, Rotterdam, Netherlands, [3]Department Rheumatology and Department of Clinical Epidemiology, Leiden University Medical Centre, Leiden, The Netherlands, Leiden, Netherlands, [4]Utrecht

Background/Purpose: Pain and disability related to osteoarthritis (OA) may generally be considered to be chronic, but it is known that its course can be very different between patients. In this study, it is investigated whether there is a difference in course of pain, physical function and radiographic damage during follow-up between two OA cohorts: Osteoarthritis Initiative (OAI) and Cohort Hip & Cohort Knee study (CHECK).

Methods: For the current study, longitudinal data of four years follow-up of the CHECK study and OA Initiative were used. The CHECK study is a Dutch prospective 10-year follow-up study, initiated by the Dutch Arthritis Association, to study progression of OA in participants with early symptomatic OA of knee or hip. Individuals were eligible if they had pain of knee or hip, were aged 45–65 years, and had not yet consulted their physician for these symptoms. In the same time in the U.S. an observational 4-year follow-up study was started to create a public archive of data, biological samples and joint images to study the natural history of, and risk factors for, the onset and progression of knee OA. The WOMAC was utilized to measure pain during activities (range 0–20) and physical functioning (range 0–68). For comparison with CHECK a subgroup of the OAI Incidence cohort was selected which was comparable with the CHECK cohort. Generalized estimating equations (GEE) were used to account for correlations within individuals and all models were adjusted for gender, BMI, age, amount of working hours and baseline radiographic joint damage. Interaction terms were investigated to measure the effect of time and the effect of progression in course of pain and function.

Results: Data of 688 CHECK participants with knee pain at baseline were analyzed, mean age 56 years, BMI 25 kg/m^2 and 79% female. The subgroup of OAI Incidence cohort with infrequent or frequent knee pain consisted of 1417 participants, with a mean age of 56, BMI of 28 kg/m^2 and 64% female. At baseline CHECK had less radiographic OA (K&L $\geq$ 2) compared to OAI Incidence subgroup, but at follow-up CHECK had more radiographic progression (42% vs 15% of at least 1 K&L point increase; p< 0.001). A final longitudinal regression model with pain as outcome showed slight decrease of course of pain in both cohorts, but a consistent lower level of course of pain in OAI Incidence subgroup of 2 points (better health). In a final model with function as outcome, in both cohorts there is a slight decrease of physical function, but a consistent higher level of function of 10.2 points (worse health) in CHECK. There is no different effect of time in course of pain (p= 0.7) and function (p=0.06) for CHECK or OAI. There is also no different effect of progression of joint damage on course of pain and function (both p=0.07) for CHECK or OAI.

Conclusion: In the total group, participants of the OAI Incidence subgroup and the CHECK participants with knee pain, there is a slight decrease over time in pain and physical functioning. In CHECK participants more progression of joint damage over time was observed and these participants recorded a higher level of pain and function problems. Difference between the 2 cohorts in course of pain and function could not be explained by the effect of time or of progression of joint damage on pain and function.

1127

Dynamic Stereo X-Ray Evaluation of Knee Joint Mechanics During Downhill Walking in Subject with Knee Osteoarthritis. Shawn Farrokhi, Carrie A. Rainis, G. Kelley Fitzgerald and Scott Tashman. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Altered tibiofemoral (TF) joint kinematics and joint surface interactions have been linked with development and progression of knee osteoarthritis (OA). However, accurate in-vivo investigations of the TF joint mechanics in patients with knee OA have been difficult to perform due to limitations of conventional techniques. This study sought to accurately characterize TF joint kinematics and the interactions of the articulating joint surfaces using high-speed dynamic stereo x-ray (DSX) technology during the loading phase of downhill walking in older adults with and without knee OA.

Methods: Eleven subjects with knee OA and 10 subjects without OA participated in this study. Subjects with knee OA were included if they demonstrated a Kellgren and Lawrence radiographic OA severity of at least grade II or higher. High speed DSX images were acquired during the loading phase of a moderately declined walking condition (7% grade, 0.75 m/s) on an instrumented treadmill. Computerized tomography images were also taken to create subject-specific 3D bone models of the distal femur and proximal tibia. A previously validated model-based tracking algorithm was employed to determine 3D joint motion by matching the radiographic images with projections through the volumetric bone models. The anterior/posterior (AP) and medial/lateral (ML) positions of the TF joint contact points were estimated using the distance-weighted centroids of the region of closest bony proximity in both the medial and lateral TF compartments. ML and AP contact path lengths were determined by subtracting the minimum from the maximum AP and ML contact positions. In addition, the total contact path was determined as the algebraic summation of the ML and AP translations of the contact points in each compartment.

Results: Compared to the control group, subjects with knee OA contacted the ground with more knee flexion but moved through less flexion range of motion. Conversely, subjects with knee OA moved through more knee adduction range of motion despite contacting the ground with a near neutral frontal plane knee alignment. Additionally, the OA group demonstrated longer ML and total contact path lengths for the medial TF compartment and a longer ML contact path for the lateral TF compartment. rate of OA progression. Intervention strategies to improve knee flexion during loading while limiting excessive frontal plane motion and joint translations should be considered.

Table 1. Means and standard deviations for subject demographics, knee joint kinematics and tibiofemoral compartment contact path translations during the loading phase of downhill gait.

	Control (n = 10)	OA (n = 11)
Age (years)	67.8 ± 5.1	69.6 ± 8.0
Sex (% female)	60%	72%
BMI (Kg/m²)	25.0 ± 2.2	30.4 ± 5.3*
Knee Flexion		
Position @ Heel Contact (degrees)	0.01 ± 3.8	7.7 ± 8.7*
Total Joint Excursion (degrees)	10.2 ± 5.1	7.0 ± 4.5*
Knee Adduction(−)/Abduction(+)		
Position @ Heel Contact (degrees)	0.5 ± 3.6	−0.6 ± 8.3
Total Joint Excursion (degrees)	0.9 ± 0.4	2.0 ± 1.6*
Knee External Rotation (−)/Internal Rotation (+)		
Position @ Heel Contact (degrees)	−2.2 ± 5.9	−1.4 ± 9.3
Total Joint Excursion (degrees)	4.3 ± 2.0	4.1 ± 2.6
Medial Compartment Contact Path		
Anterior/Posterior Distance (mm)	3.0 ± 1.9	4.2 ± 2.6
Medial/Lateral Distance (mm)	0.4 ± 0.3	1.3 ± 1.4*
Total Distance (mm)	4.0 ± 1.9	6.2 ± 2.9*
Lateral Compartment Contact Path		
Anterior/Posterior Distance (mm)	3.5 ± 2.4	2.9 ± 1.6
Medial/Lateral Distance (mm)	0.6 ± 0.3	1.2 ± 0.9*
Total Distance (mm)	4.2 ± 2.6	4.6 ± 2.0

*Statistically significant differences ($p < 0.05$)

Conclusion: Consistent with previous reports, subjects with knee OA contacted the ground with more knee flexion. However, findings from this study further suggest that individuals with knee OA also move through less knee flexion range of motion which can adversely affect shock absorption. Additionally, individuals with knee OA demonstrated signs of frontal plane TF joint instability (excessive adduction motion and ML translation) and a longer medial TF compartment translation which can negatively impact the

Different of Patterns Knee Pain Trajectories: Longitudinal Data From the Osteoarthritis Initiative (OAI). Joseph Devich Jr.[1], Michael J. Hannon[2], Zhijie Wang[2], Robert M. Boudreau[3] and C. Kent Kwoh[4]. [1]UPMC Shadyside, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA

Background/Purpose: Knee osteoarthritis (KOA) is one of the most common forms of arthritis and the most common cause of disability among the elderly. Knee pain is the presenting symptom of KOA, and symptomatic knee KOA is defined as "frequent knee pain" (pain on most days of at least one month in the past 12 months) and radiographic KOA. There is little data, however, on changes in knee pain over time. The purpose of this study was to identify whether there were different patterns of knee pain trajectories over four years of follow-up using data from the Osteoarthritis Initiative (OAI).

Methods: We studied 7,543 knees from OAI from baseline to 48 months (OAI public use data sets 2.1 and 2.2). Knee pain trajectories were based on the following knee pain reports at each visit: "No Pain" (no pain or aching in the past 12 months)=0, "Some Pain" (pain but not frequent pain)=1, or "Frequent Pain" (as above)=2. Unchanging subgroups had knees with same pain report at each visit: Group 1a, always 0; Group 1b, always 1; and Group 1c, always 2. Worsening subgroups had knees with consistent progression to worse pain: Group 2a for knees going 0-->(1)-->2; Group 2b 1-->2; and Group 2c 0-->1. Improving subgroups had knees with consistent progression to less pain: Group 3a for knees going from 2-->(1)-->0; Group 3b 2-->1; and Group 3c 1-->0. Fluctuating knee pain patterns (i.e., alternating between 0, 1 or 2 from visit to visit) were excluded from this analysis. To reduce the chances that a fluctuating knee was misclassified, for the worsening and improving subgroups, knees had to have two time points at the initial level of lower/higher pain or two time points at the final lower/higher level, respectively. Knee-specific WOMAC pain scores across the five visits were compared within each knee pain group using GEE (STATA 11.2) with each model adjusted for age, sex, race, educational level, depression, hand OA, and BMI. Subgroups within a group that were not distinct from each were combined. Comparison of differences between the larger subgroups was then performed.

Results: Group 1a and Group 1b, Group 2a and Group 2b, Group 3a and Group 3b were no different from each other (p-values > 0.1). Each of these pairs was then collapsed into three respective subgroups. The results between remaining subgroups are summarized in Table 1 below. There were significant differences in the adjusted mean WOMAC pain scores at each OAI visit between the referent group (i.e., unchanging no/some pain) and the unchanging frequent pain subgroup, the worsening pain subgroups and the improving pain subgroups.

Table 1. Comparisons of Adjusted Mean WOMAC Pain Scores of the Knee Pain Trajectories

Knee Pain Frequency	Baseline	M12	M24	M36	M48	P for change over time between groups
Unchanging Pattern						
Always 0 (n = 717) or Always 1 (n = 434)	3.2055*	2.2147	2.4398	2.4167	2.2598	reference
Always 2 (n = 606)	28.5385*	28.1584*	29.8006*	29.7471*	29.1578*	0.332, 0.004, 0.001, 0.031
Worsening Pain						
0→(1)→2 (n = 200) or 1→2 (n = 231)	9.2034*	10.374*	12.1654	14.7872*	17.5806*	< 0.001 all time points
0→1 (n = 316)	2.3465*	1.788	2.3214	3.2002	4.1065*	0.247, 0.146, < .001, < .001
Improving Pain						
2→(1)→0 (n = 171) or 2→1 (n = 291)	15.8499*	12.7436*	11.5562	9.2976*	7.3585*	< 0.001 all time points
1→0 (n = 220)	4.4188*	2.3249	2.1787	1.3796	0.7486	0.005, < .001, < .001, < .001

*Different at $p < .05$ from all other groups, Tukey pairwise adjustment.
Where:
0 = "No Pain"
1 = "Sometimes Pain"
2 = "Frequent Pain"

Conclusion: We have been able to define distinct knee pain trajectories of unchanging, worsening and improving knee pain. Further work is underway to better characterize these groups. Better understanding of these knee pain trajectories may help to identify subgroups to target for specific interventions.

1129

Prevalence of Symptomatic Basilar Thumb Joint Osteoarthritis in the General Population. Jennifer Moriatis Wolf[1], Aleksandra Turkiewicz[2], Isam Atroshi[3] and Martin Englund[2]. [1]University of Connecticut Health Center, Farmington, CT, [2]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [3]Lund University, Hässleholm, Sweden

Background/Purpose: While the radiographic prevalence of basilar thumb osteoarthritis (OA) is well described, little is known about whether this translates to clinically symptomatic arthritis. The purpose of this study is to determine the prevalence of physician-diagnosed thumb carpometacarpal (CMC) arthritis.

Methods: Using healthcare register data from Skåne County, in southern Sweden (predominantly Caucasian population 1.3 million), we identified all adults aged 20 years or older who consulted a physician at least once and were given a diagnosis code for OA of the first CMC joint (ICD-10 code M18). Data were analyzed over the 13-year period between 1999 and 2011. Using cross-referencing with the Swedish population register to exclude subjects who were deceased or had relocated out of the county by end of year 2011, we obtained frequencies and point prevalence estimates by age and gender. The population was reduced with 20% to compensate for the loss of patients seen by the private care practitioners exclusively (ICD-10 codes partially forwarded to the register).

Results: The point prevalence of physician-diagnosed symptomatic OA of the basilar thumb joint in adults was estimated to 1.3% overall (2.0% in women and 0.57% in men). The prevalence peaked in women aged 65–74 with prevalence of 5.3%. The corresponding peak in men was in men aged 75–84 with a prevalence of 1.7%.

Conclusion: In a well-defined population, the clinically important prevalence of basilar thumb OA is substantially higher in women than men, with peak prevalence in women between 60–79 years of age. Thumb base OA can have a large impact on function and activities of daily living, and the high prevalence in elderly women and men is a health and economic concern in an aging population.

Women / Men — Prevalence (%) by Age group (35-44, 45-54, 55-64, 65-74, 75-84, 85+)

The Effect of Age On the Number of Osteoarthritis Flares with Continuous Versus Intermittent Celecoxib Treatment. George H. Sands. Pritha Bhadra and Margaret Noyes Essex, Pfizer, Inc, New York, NY

Background/Purpose: Continuous nonsteroidal anti-inflammatory drug (NSAID) treatment is significantly more efficacious than intermittent dosing[1] during 22-weeks in preventing flares in patients with osteoarthritis (OA) of the knee or hip who have successfully treated an initial flare. The objective was to characterize the effect of age on efficacy, as measured by the number of flares, of continuous daily celecoxib treatment versus intermittent celecoxib treatment.

Methods: An exploratory analysis of a multinational, randomized clinical trial[1]was conducted to determine if the number of OA flares during the blinded postrandomization period was different for patients aged $<$ or $\geq$ 60 years. In the trial, 858 patients aged 18 to 80 years with OA of the knee or hip, meeting American College of Rheumatology criteria, were randomized to receive celecoxib 200 mg qd either as "continuous" (daily) or "intermittent" (celecoxib 200 mg qd when needed to treat OA flare meeting predefined criteria) treatment. Analyses were performed on the intention-to-treat (ITT) population ($\geq$ 1 dose of study medication post-randomization) and flare-modified ITT population (all patients meeting criteria for ITT population plus having flare durations $\leq$ 14 $+$ 2 days), using a 2-sided type I error rate of 0.05.

Results: Mean ages were 51.3 and 67.2 years in the 2 continuous treatment groups (n = 236 and n = 195, respectively) and 51.2 and 66.7 years in the 2 intermittent treatment groups (n = 220 and n = 207, respectively). For patients aged $<$ 60 years, 0.50 flares/month (SD 0.60) were reported in the group receiving continuous treatment, while 0.89 flares/month (SD 0.98) were observed in those receiving intermittent treatment ($P < 0.0001$). For patients aged $\geq$ 60 years, the continuous treatment group had 0.59 flares/month (SD 0.87) compared with 0.97 flares/month (SD 1.04) in the intermittent group ($P < 0.0001$). These results are consistent with the primary results.[1]

In the flare-modified ITT population, patients aged $<$ 60 years receiving continuous treatment had 0.45 flares/month (SD 0.61) vs 0.87 flares/month (SD 1.15) for the intermittent group ($P < 0.0001$). The older flare-modified ITT population ($\geq$ 60 years) had similar results: 0.55 flares/month (SD 1.02) vs 1.02 flares/month (SD 1.22) for the continuous and intermittent groups, respectively ($P = 0.001$). The mean number of flares was significantly lower in the continuous group than in the intermittent group irrespective of whether the patients were aged $<$ or $\geq$ 60 years.

Conclusion: Daily celecoxib treatment was significantly more efficacious, as assessed by the number of flares/month, than intermittent use, irrespective of whether the patients were aged $<$ or $\geq$ 60 years. These data may be useful in considering the treatment of OA patients aged $\geq$ 60 years.

Intraarticular Infliximab for Knee Osteoarthritis: High Baseline Levels of Synovial Cellularity and High MRI Cartilage Injury At the Lateral Tibial Plateau Predict Improvement in Total WOMAC Score.
Jeremy R. Schue[1], Ossama Tawfik[1], Rebecca Bolce[2], Donald D. Smith[1], Gary Hinson[1], Jo A. Wick[1] and Herbert B. Lindsley[1]. [1]Kansas University Med Ctr, Kansas City, KS, [2]Crescendo Bioscience Inc., South San Francisco, CA

Background/Purpose: Synovial tissue from patients with OA often demonstrates inflammation. We hypothesized that a single intraarticular (IA) injection of an anti-TNF drug would decrease inflammatory cell infiltration (primary outcome) and ultimately reduce articular injury. These data were drawn from the infliximab (IFX) group, part of a larger study presented previously (ACR Ann Mtg, Chicago 2011; EULAR Ann Mtg, Berlin 2012). The results noted below represent new findings.

Methods: The original pilot study was a single center, 2:1:1 (IFX: MP:P) randomization, double-blind, placebo-controlled IA treatment of knee OA: infliximab (IFX) 100 mg, methylprednisolone (MP) 80 mg or saline (P) on Day 0. Subjects (n=16) had to have knee pain and show minimal to moderate OA on knee radiographs. Demographics for IFX group: Age 54 (IQR 44–62) Race AA/C=3/5; Gender F/M=5/3; BMI 28.9 (IQR 23.1–31.4). Closed needle synovial biopsies and PBMCs for flow cytometry were obtained on Days 0 and 28. Total WOMAC scores and blood samples were obtained on Days 0, 14, 28 and 56. MRI of the target knee was obtained before Day 0. Statistics: nonparametric Wilcoxon test and Spearman correlation coefficient.

Results: Total WOMAC score improved significantly only for Group IFX, comparing baseline (BL) to Day 56 (p<0.05). The BL total WOMAC scores were greater in the high vs low cellularity subgroups. When comparing subjects with high vs low cellularity (4 each), significant improvement (p<0.05) occurred only in the high cellularity subgroup (See Fig). The high cellularity subgroup had higher scores (p<0.02) for inflammatory intensity, mononuclear cells (CD68+ cells, CD3+ cells), blood vessels, Cox-2 expression and IL-1β expression. No significant baseline differences between the high and low subgroups were noted for synovial TNFα, IL-6, IL-17, or CD54+ cells, or serum levels of CRP, SAA, IL-6, TNFα, MMP-3 or COMP. BL PBMC biomarkers were compared for differences between high and low cellularity subgroups; two cell subsets trended higher (p=0.097) in the high cellularity subgroup: B cells and low-MFI CD14 CXCR3 monocytes. Higher BL Total WOMAC scores correlated with lower CD14 MFI (p=0.067, R=-0.67); no such correlation was noted with TNFα, MMP-3 or COMP. Circulating levels of IFX peaked at Day 4 with a Cmax of 6.1 ug/ml in 6 subjects; two subjects with detectable anti-IFX Ab had a lower Cmax of 1.6 ug/ml; Cmax did not differ between the two subgroups (5.5 vs 4.3 ug/ml).

WOMAC Total vs Study Day (0, 14, 28, 42, 56) for High and Low Baseline Cellularity; $P < 0.05$.
Conclusion: BL characteristics of the subjects responsive to IA anti-TNF therapy included those with higher WOMAC scores, more abnormal cartilage MRI scores at the lateral compartment, and higher levels of inflammatory cells, including T lymphocytes and macrophages, as well as more blood vessels, Cox 2 and IL-1β expression. In subjects with higher WOMAC scores and higher levels of synovial inflammation IA IFX offers promise as a symptomatic intervention.

Prevalence of Knee Pain in Ultramarathon Runners. Victoria M. Kelly[1], Martin Hoffman[2], Bharathi Lingala[1], Mihoko Bennett[1] and Eswar Krishnan[1]. [1]Stanford University, Palo Alto, CA, [2]Department of Veteran's Affairs, Northern California Health Care System and University of California Davis Medical Center, Sacramento, CA

Background/Purpose: Approximately one in four Americans suffer from frequent knee pain. While some studies have linked long-distance running with the risk for knee pain, others have not observed such associations. Since the proposed mechanism of such a link involves mechanical stress to the joints, greater lifetime running miles should be associated with a greater risk for knee pain and an earlier age of onset. We tested these expectations by cross sectional analysis of data from the baseline questionnaire of a new cohort of ultramarathon runners.

Methods: The ULTRA study is a cohort of runners who have participated in at least one ultramarathon race (≥ 50 kilometers) in their lifetime. This study has been enrolling participants since November 2011. For the purposes of this analysis, "knee pain" was defined as "any knee pain in the past 6 months", as there were almost no individuals with chronic-frequent knee pain in this cohort of high functioning individuals. To assess the impact of mileage on knee pain, we performed a logistic regression model, where the dependent variable was knee pain and independent variables were quartiles of lifetime running distance, age, body mass index (BMI) and current running status. Ex-runners were defined as those who have not run regularly in the preceding 12 months.

Results: Of the 1,083 runners included in the present analysis, 68% were men and 6% were classified as ex-runners. The mean age, and BMI were 44 years and 27 kg/square meters respectively. After adjusting for age, gender and BMI, the prevalence of knee pain was higher in those with lower lifetime mileage, both in runners and ex-runners. Overall rates of knee pain did not differ between runners and ex-runners (47% vs. 48%), and confidence intervals overlapped significantly for knee pain within each mileage group (see Figure). In the logistic regression model, runners in the highest distance quartile (>25,000 miles) were the least likely to report knee pain, OR 0.5 (CI 0.4–0.8), suggesting that lifetime running distance is inversely correlated with knee pain.
Conclusion: Knee pain was more common among low mileage runners; the causal direction of this association can be ascertained in prospective studies. There was no difference in overall knee pain between current and ex-runners.

Gait Differences Are Present in Subjects with Symptomatic Vs. Asymptomatic Mild Radiographic Hip Osteoarthritis. Samir S. Chabra[1], Najia Shakoor[2] and Kharma C. Foucher[2]. [1]University of Illinois at Chicago, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

Background/Purpose: It is known that joint mechanics are involved in the hip osteoarthritis (OA) disease process. In a previous study[1], several gait variables were lower in subjects with symptomatic hip OA compared to asymptomatic controls. In the OA subjects gait variables were significantly correlated with radiographic OA severity but not pain. It remains unclear, however, whether structural changes or clinical symptoms initiate the gait changes associated with hip OA. In this study we tested the hypothesis that gait variables are different in people with symptomatic radiographic hip OA compared to those with radiographic changes but no symptoms.

Methods: 25 subjects with mild radiographic hip OA (Kellgren-Lawrence grade 2) were identified from an IRB approved repository of gait and radiographic data. 12 had been enrolled in a study of subjects with symptomatic unilateral hip OA and 13 came from a database of asymptomatic subjects. Demographics and BMI were similar between the two groups (Table). Gait analysis was performed with standard published methods: participants completed 3 trials per limb walking at a self-selected normal speed. Kinematics and kinetics were calculated from marker positions and ground reaction forces. Standard inverse dynamics methods were used. The variables of interest were speed, dynamic hip range of motion, and peak 3D external moments normalized to body weight times height (%BWxHt). Data were averaged for the 3 trials. T-tests were used to compare gait variables between the two groups.

Results: Walking speeds were not significantly different between the two groups (Table). The peak adduction and internal rotation moments were 17% and 29% lower in the symptomatic OA group compared to the asymptomatic group (p=0.017 and p=0.044, Table). The external rotation moment was 26% lower in the symptomatic group (*trend* p=0.059). No other comparisons were statistically significant.

Table. Comparisons between subjects with mild radiographic hip OA who are symptomatic vs. asymptomatic

Variable	Symptomatic	Asymptomatic	p Value
Age (years)	53 ± 6	58 ± 10	0.166
BMI (kg/m²)	26 ± 3	28 ± 5	0.198
Sex	9 Female/3 Male	11 Female/2 Male	0.548
'Normal' walking speed (m/s)	1.16 ± 0.20	1.20 ± 0.11	0.615
Dynamic sagittal plane hip range of motion (degrees)	29.2 ± 7.4	30.8 ± 6.3	0.568
Peak Flexion Moment (%BW × Ht)	5.15 ± 1.48	5.85 ± 1.30	0.221
Peak Extension Moment (%BWxHt)	2.37 ± 0.61	2.64 ± 0.99	0.427
*Peak Adduction Moment (%BWxHt)	**3.53 ± 0.84**	**4.27 ± 0.60**	**0.017**
Peak Abduction Moment (%BWxHt)	1.84 ± 0.81	2.05 ± 1.02	0.587
*Peak Internal Rotation Moment (%BWxHt)	**0.53 ± 0.19**	**0.75 ± 0.29**	**0.044**
Peak External Rotation Moment (%BWxHt)	0.44 ± 0.13	0.60 ± 0.26	0.059

* bold text indicates p<0.05.

Conclusion: Subjects with mild *symptomatic* radiographic hip OA had different gait than subjects with mild radiographic OA alone. Notably, walking speeds were similar between groups. Thus gait differences observed were not attributable to slower speeds in the symptomatic group. The adduction, internal rotation, and external rotation moments, which each reflect aspects of hip abductor function, were reduced in the symptomatic group. This suggests that this muscle group plays an important role in early symptomatic OA. Further, these results support previous speculations that pain may be an initial stimulus that initiates joint loading alterations in hip and knee OA[1,2].

What Are the Levels of Physical Activities and Their Associations with Quality of Life in Patients with Symptomatic Hip and/or Knee Osteoarthritis? Irawati Lemonnier[1], Anne Vuillemin[2] and Anne-Christine Rat[3]. [1]Lorraine Université Paris Descartes University, EA 4360 Apemac, Nancy, France, Nancy, France, [2]Universite de Lorraine, Paris Descartes University, EA 4360 Apemac, Nancy, France, Nancy, France, [3]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy, France

Background/Purpose: Physical activities (PA) practice is recommended by numerous public health organizations. According to international recommendations, patients with hip and knee osteoarthritis (OA) should be encouraged to undertake more specific activities: regular aerobic, muscle

strengthening and range of motion exercises. However, the level of PA practice in patients with symptomatic hip and/or knee OA in a real setting is not well known and associations between PA practice and quality of life (QoL) should be clarified. The aim of the study was to study 1.the level of PA practice in patients with symptomatic hip and/or knee OA in a real setting 2. the associations between PA practice and QoL in patients with symptomatic hip and/or knee OA.

Methods: The 878 patients of the KHOALA (Knee and Hip Osteo-Arthritis Long term assessment) cohort were included in the study. KHOALA cohort is a multiregional population based study of patients aged 45–75 years with symptomatic knee or/and hip OA. The MAQ (modifiable activity questionnaire) was used to measure the PA during the past year. It includes 2 scores: the numbers of hours spend weekly for physical activities in leisure activities (PAL) and in professional activities (PAP). QoL was measured by a generic questionnaire, the SF-36; pain, function, and clinical data by the Index of Severity for Knee (ISK) and the Harris hip score. All measures were completed at baseline. Multivariate linear-regression models were constructed to identify the associations between PA and QoL. The models were adjusted on OA functional and pain scores, age, sex, BMI, current smoking status, current employment status and occupation during their life.

Results: Among the 878 patients, 222 had hip OA, 607 knee OA and 49 both. Patients with hip and knee OA were slightly older (64.7+8) than those with knee (62+8.5) or hip OA only (61.2+8.8). The average body mass index was 26.9+4.4 and 30.3+6.2 for patients with hip and knee OA respectively. 67 and 71% of the patients were women in hip and knee OA respectively. The level of PAP was of 25 hours a week in patients with hip or knee OA only and was lower (20 hours a week) in patients with both hip and knee OA. The level PAL was of 5.6, 6.2, 6.5 hours a week for hip OA, knee OA and both respectively. No relation was observed between physical activities level and QoL in patients with hip OA. For patients followed for knee OA, more hours spend on leisure activities were associated with better mental health (p=0.001), role emotional (p=0.02), social functioning (p=0.04) and vitality (p<0.001) scores in multivariate analyses. The number of hours spent on professional activities by patients who suffered from both hip and knee OA were associated with lower role emotional (p=0.03) and social functioning (p=0.04) scores.

Conclusion: These results suggest that more hours spend weekly on leisure activities may positively affect patients with symptomatic knee and/or hip OA independently of pain, function and sociodemographic variables. The associations are found for mental state and social functioning. On the other hand, physical activities for professional reasons seemed to be associated with more difficulties in social functioning of patients with both hip and knee OA.

Combined Glucosamine and Chondroitin Sulfate, Once of Three Times Daily, Provide Clinically Relevant Analgesia in Knee Osteoarthritis. Jose R. Provenza[1], Samuel K. Shinjo[2], Joyce M. Silva[3], Carla RGS. Peron[4] and Francisco AC Rocha[5]. [1]Pontifícia Universidade Católica de Campinas, Campinas, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]Sao Paulo, Brazil, [4]Laboratórios Aché Ltda, Sao Paulo, Brazil, [5]Federal University of Ceara, Fortaleza, Brazil

Background/Purpose: The analgesic efficacy of combined glucosamine and chondroitin sulfate (CS) in knee osteoarthritis (OA) remains controversial. Criticism to previous studies includes small sample size, short term evaluation and lack of intent-to-treat (ITT) analysis. Glucosamine sulfate (GS) or hydrochloride (GH) formulations and dosing schedule relevance are also not clearly defined.

Methods: 1,120 subjects with radiographic knee OA (Kellgren/Lawrence grades 2–3) and moderate-severe knee pain flare after analgesic washout were randomized (1:1:1) at 16 centers in Brazil to receive GS 500mg/CS 400mg three times daily capsules (GI) or once daily sachet (GII), or GH 500mg/CS 400mg three times daily capsules (GIII) for a 16 week trial. Acetaminophen up to 3,750mg daily was a rescue medication. Primary outcome (ITT) was patient reported pain intensity in the affected knee and variation of Lequesne's index (LI) at 16 weeks. Monthly secondary outcomes were mean changes from baseline in patient reported pain and LI, patient and physician global assessments of disease activity, acetaminophen consumption, and adherence. Sample size calculation considered a non-inferiority evaluation allowing a difference of less than 1.7 points in the LI and a decrease of pain less than 18mm in GI and GII, as compared to GIII. Safety evaluations were done at each monthly visit.

Results: The ITT population comprised 302, 301, and 306 patients in GI, GII and GIII, respectively, and 911 patients for safety. Demographic data were equally comparable in all groups. The criterion for non-inferiority analysis of GI and GII in relation to GIII, based on confidence interval (95%), was met for pain intensity and LI. The mean of pain reduction (GI: −30.9±1.5; GII: −28.7±1.5; GIII: −29.7±1.5 mm) was significant for all groups at week 16 (P<0.001). Similarly, the mean of LI decrease was significant in all groups (GI: −3.8±0.2; GII: −3.7±0.2; GIII: −3.9±0.2) (P<0.001). Moreover, reduction of acetaminophen consumption (−5, −3, and −5 weekly tablets for GI, GII, and GIII, respectively) was also significant in all groups (P<0.005). Withdrawal rate was 18.2%, 19.3%, and 19.3% for GI, II, and III. Patients that did not complete the study were 77 (44.8%) for lack of adherence, 16 (9.3%) consent withdrawal, 11 (6.4%) adverse events, 8 (4.7%) lost to follow-up, and 17 (9.9%) for other causes.

Conclusion: This is the largest study showing that GS/CS and GH/CS provide clinically meaningful and sustained analgesia in knee OA regardless of dose fractionation. GS/CS (capsule or sachet) and GH/CS formulations are equally effective and safe to treat symptomatic knee OA.

1136

Aesthetic Dissatisfaction in Hand Osteoarthritis Patients, Its Impact and Risk Factors. R. Liu, L.J.J. Beaart-van de Voorde, T.W.J. Huizinga and M. Kloppenburg. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Hand osteoarthritis (HOA) leads to aesthetic damage and is rarely studied. We aim to investigate in HOA patients the prevalence of dissatisfaction with the appearance of their hands, the impact and its risk factors.

Methods: Cross-sectional data were used of the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) study, in which consecutive patients are included, that are diagnosed by the treating rheumatologist with primary HOA. Participants underwent physical examination to assess number of joints with bony joint enlargements (0–30), deformities (0–22) and limitation in mobility (0–22).

The Michigan Hand Outcomes (MHQ) questionnaire involves a pain (range 0–100, higher scores=more pain) and an aesthetic scale, which measures satisfaction (range 1–5, lower scores=more dissatisfaction) with the appearance of the hands and its impact, namely discomfort in public, depression and/or the interference with normal social activities (range 3–12, lower scores = more impact). A score of <3 was considered as dissatisfaction and a score of <9 as experiencing impact. Scores for right and left hand were averaged.

Disability was assessed by the functional index for HOA (FIHOA) (0–30). Anxiety (0–21), depression (0–21) and illness perceptions were assessed with the Hospital Anxiety and Depression scales (HADS) and Illness Perception Questionnaire (IPQ), respectively.

Odds Ratio (OR) with 95% confidence intervals (CI) were calculated using multivariate logistic regression as measures of relative risk for reporting dissatisfaction with appearance or impact due to dissatisfaction of the appearance, adjusted for age, sex and BMI.

Results: Of 226 patients (87% women, mean age 61.5 yrs, median symptom duration 5.2(range 0.1– 58.7) yrs) 93% met ACR criteria for HOA. 25% were aesthetically dissatisfied and only 4% reported impact due to dissatisfaction. Mean pain score was 44 (SD 19) and median FIHOA score was 8 (range 0–24). Median depression and anxiety scores were 4 (range 0–18) and 2 (range 0–17), respectively.

Pain (OR 1.02 (1.00–1.04)), disability (OR 1.07 (1.01–1.12)), deformities (OR 1.24 (1.11–1.37)), number of joints with limitation in mobility (OR 1.05 (1.01–1.08) and the illness perception scale which involves negative feelings towards OA (OR 1.08 (1.02–1.15)) were associated with dissatisfaction, as well as with impact.

Bony joint enlargements (OR 1.09 (1.01–1.17)) and illness perception (belief in OA as a chronic disease) (OR 1.12 (1.01–1.23)) were associated with dissatisfaction, but not with impact.

Depression (OR 1.32 (1.13 –1.55)), anxiety levels (OR 1.37 (1.14 –1.64)) and illness perceptions (the belief in more severe consequences as a result of OA, less understanding of OA and attributing more psychological factors to their disease) were associated with impact.

Conclusion: HOA patients who consult secondary care report regularly aesthetic dissatisfaction with their hands. However, this dissatisfaction has negative impact only in a small group of patients, who also experiences more

pain, depression and anxiety and negative illness perceptions. These results have implications for management strategies in patients with HOA.

Clinimetric Properties of a New Outcome Measure: the Hand-Osteoarthritis Aesthetic Damage Index. N. Bellamy and Joan Hendrikz. The University of Queensland, Herston, Queensland, Australia

Background/Purpose: The 2006 OARSI Guidelines for hand OA clinical trials, recognised the potential value of an aesthetic damage assessment, but acknowledged the absence of any existing instrument to perform the measurement. In order to address this deficiency, a measure termed the Hand-Osteoarthritis Aesthetic Damage Index(HADIX) has been developed and its clinimetric properties explored. HADIX is a hexadimensional, Patient Reported Outcome Measure (PROM) of the aesthetic impact of hand OA (HADIX 1–6).

Methods: This study forms part of a larger longitudinal initiative involving clinical profiling, digital photography and radiography. The development of HADIX has been reported previously (1). In the current study, test-retest reliability (TRR) and construct validity of re-test HADIX data (except HADIX 4 which is a relative measure) using the Michigan Hand Outcomes Questionnaire - MHOQ, were evaluated using Pearson's rho or Kendall's tau-b. Time to completion was also examined.

Results: The study involved 28 subjects with hand OA 25 females and 3 males), who fulfilled the Altman Criteria for hand OA, with mean age last birthday70 yrs (min = 52 yrs; max = 87 yrs; SD = 9.5). TRR correlation coefficients were: HADIX1 = 0.89: HADIX2 = 0.77: HADIX3 = 0.86: HADIX4 = 0.68: HADIX5 = 0.76: HADIX6 = 0.87. Correlations between the re-test HADIX and MHOQ scores were HADIX1 = 0.55: HADIX2 = 0.52: HADIX3 = 0.44: HADIX5 = 0.72: HADIX6 = 0.45. Mean time to completion for HADIX on first presentation was 8.6 mins (min = 2.33 mins; max = 22.22 mins; SD = 4.57 mins). On the second occasion information was available for 5 patients who were 34 seconds faster on average.

Conclusion: HADIX provides a novel approach to the evaluation of the aesthetic impact of hand OA. These observations suggest that the HADIX Index is reliable, valid and feasible, and may have a role in the evaluation of structure modifying interventions in hand OA.

Nonpharmacologic and Pharmacologic Therapy Utilization by Primary Care Providers for Hand Osteoarthritis-Comparative Review by Electronic Health Record Data Mining and in-Home Visit Verification. Gale A. McCarty, President. Rheum.Ed Consulting, Harborside, ME

Background/Purpose: To compare current utilization of usual nonpharmacologic (NP) and pharmacologic (P) therapies for hand osteoarthritis (OA) by primary care providers (PCPs) and patients (Pts) based on American College of Rheumatology (ACR) 2012 Recommendations in 2 age- and gender-matched populations.

Methods: From voluntary in-home health visit (problem list, history, exam, medication reconciliation) with electronic health record assessment over 3 yrs for ascertainment of Medicare Advantage general health maintenance and quality benchmarking (Cty 1-Sacramento County CA, N = 50, and Cty 2-Cumberland County ME, N = 50), age- and gender-matched pts were identified. Pts were unaware the examiner was a rheumatologist. Discussion vs. Use vs. Source (PCP or pt) of NP recommendations (Activities of Daily Living, ADLs/Jt Protection/Assistive Device Provision for ADLs/Thermal Modalities/TrapezioMCP Splints) and P recs (Top. Capsaicin/Top. NSAIDs/PO NSAIDs/Tramadol) were queried. Descriptive statistics and/or SPlus were used where applicable: p value significance was $</=$ 0.05.

Results: Results: Behavior Risk Factor Surveillance System 2009/10 data confirmed no significant differences (nsd) from Cty 1 vs Cty 2 in: population (281,674 vs 265,012), % pop. > 65 (10.6 vs 11.2%), white ethnicity (78% vs 80%), female gender (70 vs 72%), mean age (72.4 vs 74.1 yrs-range 65–98), no. of pts. w/doctor-diagnosed arthritis b/w ages of 65 and 74 (45 vs 53%), no. of pts. w/activity limitation due to arthritis (48 vs 44%), no. of pts w/social participation restriction due to arthritis (17 vs 14%), no. of pts w/severe pain due to arthritis-non-site specified (27 vs 21%), obesity by BMI (32 vs 33%), the no. of Rheumatologists available for referral in network (6 vs 7), and the % of benchmarks attained for major health metrics (96 vs 95% capture). Latino ethnicity was statistically different (16.6 vs 1.9%). No significant differences from Cty 1 vs Cty 2 were noted for: Dx of OA-Hands (88 vs 92%); all had discussed OA as an issue with their PCPs at least once in the prior 3 yrs. Presence of hand OA was confirmed by Rheumatology exam in 88 vs 92% of pts. At least 1 NP Rec (Thermal Modalities) and 1 P Rec (Top NSAIDS) had been discussed at least once for all pts. by PCPs (100 vs 100%), but utilization was significantly different (44 vs 22%). Jt Protection and ADLs had not been discussed or utilized (80 vs 80%); only Assistive Device Provision (cane/walker) had been done (33 vs 30%). PO NSAIDs were actively discouraged even in low dose/Cox2 selective/H2 blocker usage by providers (80% vs 80%).

Conclusion: Current NP and P recommendations from OA experts are variably implemented with pts, despite confirmed presence of OA by their own PCPs as an Active Problem, and pts. reporting pain and social restriction due to arthritis.

Pediatric Rheumatology - Clinical and Therapeutic Aspects: Juvenile Idiopathic Arthritis
Monday, November 12, 2012, 9:00 AM–6:00 PM

1139

Inhaled Nitrous Oxide Facilitates Access to Intra-Articular Corticosteroid Injections in Children with Juvenile Idiopathic Arthritis. Mercedes O. Chan[1], Ruth Wyllie[2] and H. E. Foster[3]. [1]University of British Columbia and British Columbia's Children's Hospital, Vancouver, BC, [2]Newcastle Hospitals, NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom, [3]Newcastle Hospitals NHS Foundation Trust, Great North Children's Hospital and Newcastle University, Newcastle Upon Tyne, United Kingdom

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease of childhood affecting 1 in 1000 children. Medical management for arthritis often includes intra-articular corticosteroid injections. The inhalation of nitrous oxide (N_2O) in painful procedures is widely recognised in adults, yet is underused in children and young people (CYP). N_2O is quickly absorbed, having low solubility in water and fat, and rapidly eliminated from the body when inhalation stops. It is safe, fast-acting, and non-invasive, reducing apprehension and anxiety. The use of N_2O has increased access for CYP requiring painful procedures such as joint injections (JIs) that may have previously required a general anaesthetic. We aimed to describe a population of children receiving JIs with N_2O at our center and the wait time for JIs with N_2O once a decision to inject was made.

Methods: Data was collected retrospectively from available charts of children receiving JIs with N_2O from January 2002 to April 2012 at our centre. Demographics, number of JIs (including types of joints injected), and number of repeat JIs within a year were recorded. Time from decision point (DP) to JI was calculated for JIs performed in 2011–2012.

Results: 397 JIs with N_2O on 292 occasions (140 males, 152 females) were performed from 2002–2012. The median age at time of JI was 13.78 (range 6.38 to 18.97 years). The median number of JIs performed with N_2O per year was 24 (range 14–53). On 48 occasions JIs were performed subsequent to one done earlier that calendar year. The median number of repeat JIs per patient requiring them was 1.

From 2011–2012, 79 JIs were performed with N_2O. The median number of days from a DP to a JI with N_2O was 0 (range 0–87 days). 62 patients had JIs within 2 weeks; 11 between 2 and 4 weeks; 2 between 4 to 6 weeks; and, 3 after 6 weeks from DP. One patient receiving a JI after 6 weeks (87 days) from DP required imaging to confirm synovitis before proceeding with the procedure. Reasons for other JIs performed after 6 weeks from DP were unable to be elicited from charts. Documentation of a DP for JIs with N_2O was present in 77/79 patients (97.5%).

Joints most commonly injected were: knees (80.05%), ankles (14.4%), elbows (3.28%), wrists (1.26%), subtalar (0.5%), fingers (0.31%) and shoulders (0.20%). There were no major adverse events (including septic arthritis) reported. An increase in trainee procedures was seen after 2009 consistent with the introduction of a paediatric rheumatology (PRh) training program.

Conclusion: Use of N_2O for JIs in children with JIA allows for expeditious, safe and efficient sedation and analgesia. At our centre, children assessed in clinic and who need JIs may be offered one at that visit, performed by the PRh team (clinician and nurse specialist). This has benefits for clinical care (rapid access to the procedure); the patient and family (less time off school/college or work, no anaesthetic risk); health care costs (reduced need for day case access and theatre time); and, optimal use of resources (preferential access to general anaesthetic lists for younger children; or those requiring multiple JIs or use of image intensifiers; or, quick procedures reducing PRh time).

Response to Adalimumab in 40 Patients with refractory juvenile Idiopathic Arthritis-Associated Uveitis. A Multicenter Study. Vanesa Calvo-Río[1], Ricardo Blanco[1], Manuel Díaz-Llopis[2], David Salom[3], Carmen García-Vicuña[4], Miguel Cordero-Coma[5], Norberto Ortego[6], Marta Suarez-de-Figueroa[7], J. Carlos Fernandez-Cid[8], A. Fonollosa Calduch[9], Ángel M. García-Aparicio[10], Jose M. Benítez-del-Castillo[11], Jose L. Olea[12], Javier Loricera[13] and Miguel Angel González-Gay[13]. [1]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain, [2]Hospital Universitario La Fe de Valencia, Valencia, Spain, [3]Hospital Universitario La Fe de Valencia, Valencia, Spain, [4]Hospital Sant Joan de Déu, Barcelona, Barcelona, Spain, [5]Hospital de León, León, Spain, [6]Hospital Santa Cecilio, Granada, Spain, [7]Hospital Ramon y Cajal, Madrid, Spain, [8]Hospital de Pontevedra, Pontevedra, Spain, [9]Hospital de Cruces, Barakaldo, Spain, [10]Hospital Virgen Salud, Toledo, Toledo, [11]Hospital Clínico San Carlos, Madrid, [12]Hospital Son Dureta, Palma de Mallorca, Spain, [13]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain

Background/Purpose: To assess the efficacy and safety of treatment with adalimumab therapy in patients with refractory Juvenile Idiopathic Arthritis (JIA)-associated uveitis.

Methods: Multicenter study on 40 patients diagnosed as having JIA-associated uveitis refractory to treatment with corticosteroids therapy and at least other systemic immunosuppressive drug. Standard adalimumab therapy was started (40 mg subcutaneously every-other-week); for children aged between 4 and 12 years, the recommended dose was 24 mg/m[2] body surface area up to a maximum single dose of 40 mg sc every other week. The associated immunosuppressive therapy and the prednisone dose were reduced if there was no evidence of inflammation. Degree of anterior and posterior chamber inflammation (SUN criteria), corticosteroid dose, and macular thickness (optical coherence tomography) were assessed. Definite outcomes were assessed at six months in all patients. All expressed comparisons are between baseline and after 6 months of adalimumab therapy (Wilcoxon test).

Results: Forty patients (11 males, 29 females), mean age of $11,4\pm7,9$ years (range: 4 to 44 years), with active intraocular inflammation at baseline were studied. Thirty-six of 40 patients had inflammation in the anterior camera, and treatment with adalimumab achieved a significant improvement in mean tyndall from $1,8\pm1,1$ to $0,41\pm0,6$; p $=0.000001$.

Also, 17 (42,5%) patients had macular thickness with Optic Coherence Tomography (OCT)>250 microns. These cases had a significant improvement in OCT from $370,8\pm133,9$ to $249,3\pm28,0$ microns; p$=0,0007$. In addition, 9 patients with Cystoid Macular Edema (CME) (OCT>300) also had a significant improvement in OCT $(463,1\pm123,8$ to $254,4\pm30,2,$ p$=0,007)$. The dose of corticosteroids also was decreased from 0.26 ± 0.4 to 0.004 ± 0.02 mg/day (p$=0.00061$).

Adalimumab was usually well tolerated, and only local minor side-effects at the injection site were observed. Twelve patients (30%) had a mild relapse during the 6 months of therapy whereas only 2 patients (5%) had a moderate-severe relapse.

Conclusion: Adalimumab appears to be an effective and safe drug for the treatment of refractory JIA-associated uveitis and may reduce steroid requirement. Further controlled studies are warranted.

Safety of Celecoxib and Non-Selective Non-Steroidal Anti-Inflammatory Drugs in Juvenile Idiopathic Arthritis. Rachel E. Sobel[1], D. J. Lovell[2], Hermine I. Brunner[3], Jennifer E. Weiss[4], Paula W. Morris[5], Beth S. Gottlieb[6], Elizabeth C. Chalom[7], Lawrence K. Jung[8], Karen Onel[9], Lisa Petinoit[10], Donald P. Goldsmith[11], Staci Abramsky-Risman[12], James P., Young[13] and Edward H. Giannini[14]. [1]Pfizer, Inc., New York, NY, [2]Cincinnati Children's Hospital, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Hackensack Univ Med Ctr, Hackensack, NJ, [5]Univ of Arkansas for Med Sci, Little Rock, AR, [6]Cohen Children's Medical Center of New York, New Hyde Park, NY, [7]St. Barnabas Medical Center, Livingston, NJ, [8]Children's National Medical Center, Washington, DC, [9]University of Chicago, Chicago, IL, [10]'Specially for Children, Dell Children's Medical Center, Austin, TX, [11]St Christopher's Hospital for Children/Drexel College of Medicine, Philadelphia, PA, [12]Pfizer Inc, New York, NY, [13]United BioSource Corporation, Ann Arbor, MI, [14]PRCSG-Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Celecoxib, a selective COX-2 inhibitor, was approved by the FDA for the treatment of the signs and symptoms of JIA in children aged 2–17 years in December, 2006. As a condition of approval, Pfizer conducted a Phase IV study, the Safety in Idiopathic Arthritis: NSAIDs and Celebrex Evaluation Registry (SINCERE), to collect longer-term safety and developmental data on patients with JIA treated in routine clinical practice with celecoxib or non-selective NSAIDs (nsNSAIDs).

Methods: Children aged between 2 and 18 years with RF(+) or RF(−) polyarthritis, persistent or extended oligoarthritis, or systemic juvenile arthritis (without features of extra-articular features for '6 months) were enrolled into this prospective, observational, multi-centered, standard-of-care registry. To be eligible, patients had to be receiving newly or recently prescribed (≤6 months) nsNSAID or celecoxib. Duration of previous nsNSAID or celecoxib exposure, or use of concomitant DMARD or biologic therapy did not affect eligibility. Once enrolled, patients were to remain in the study whether they continued on the original NSAID, switched, or discontinued NSAIDs altogether. Visits were scheduled at 0, 4, 8, 12 months, and at 6 month intervals thereafter for a minimum of 2 years. All adverse events (AEs) regardless of severity were captured in the SINCERE database.

Results: A total of 274 patients (219 in the nsNSAID and 55 in the celecoxib group) were observed for 410 patient-years of observation (PYO) at study termination. Sixty percent of patients in the celecoxib group, and 53% in the nsNSAID group had oligoarthritis. Naproxen, meloxicam, and nabumetone were the most frequently used nsNSAIDs. At baseline, the celecoxib group had numerically longer disease duration, was older, and had a higher median weight and height. This is consistent with the practice of using celecoxib as the second or third NSAID in JIA. A numerically higher proportion of celecoxib patients had a history of intolerance to nsNSAIDs, mostly due to gastrointestinal side effects. The analysis of AEs reported during the study showed a similar incidence of AEs across groups (44 and 53/100 PYO for nsNSAID and celecoxib respectively, and 50/100 PYO for those off-NSAID [≥29 days after final dose]). AEs were those frequently observed with NSAID treatment. Two patients on nsNSAID and 2 off-NSAID experienced AEs of special interest. Twelve unique patients experienced a total of 18 serious adverse events (SAEs), the most frequent of which were infections; none were attributed to NSAID. Incidence rates (95% CI) of SAEs per 100 PYO were 3.4 (1.2, 5.6) and 2.9 (0, 7.0) for the nsNSAID and celecoxib group respectively, and 4.0 (0, 8.6) for the off-NSAID cohort. Overall, the study results indicate no important difference in the safety profiles between celecoxib and nsNSAIDs.

Conclusion: The total study population of 274 patients followed for a total of 410 PYO is one of the largest JIA NSAID cohorts, and adds substantially to the safety experience of NSAID treatment of JIA. The safety profile of celecoxib appears similar overall to that of nsNSAIDs and the benefit-risk for celecoxib treatment in JIA remains positive.

Efficacy of Biologic Agents in Juvenile Idiopathic Arthritis: A Systematic Review Using Indirect Comparisons. Janneke Anink[1], Marieke H. Otten[1], Sandra Spronk[2] and Lisette W.A. Van Suijlekom-Smit[1]. [1]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands

Background/Purpose: During the last decade the availability of biologic agents for the treatment of juvenile idiopathic arthritis (JIA) increased substantially. Because direct head-to-head trials comparing biologics are lacking, physicians face difficulties to choose between these agents. In order to provide some scientific guidance, we indirectly compared the short-term efficacy of biologic agents.

Methods: In a systematic review, all available efficacy data from randomized controlled trials performed in JIA were retrieved. The following biologics were included: etanercept, adalimumab, infliximab, abatacept, anakinra, rilonacept, canakinumab and tocilizumab. Indirect between-drug comparisons (based on the Bucher's method) were conducted only if trials were comparable with regard to design and patients' characteristics related to treatment outcome.

Results: Eleven trials that evaluated biologic agents in JIA were selected. Quality of trials varied greatly: earlier trials for registration gained best scores, trials evaluating treatment strategies performed worst. For 5 trials, no match for an indirect comparison could be found due to design and patient characteristics. The remaining trials could be divided into two networks of evidence. Network 1 included withdrawal trials that evaluated etanercept, adalimumab and abatacept in poly-articular course juvenile idiopathic arthritis. Indirect comparisons identified no significant differences in short-term efficacy. Etanercept seemed superior to adalimumab (relative risk (RR) disease flare, etanercept vs. adalimumab, 0.59, 95% CI 0.28–1.24) and abatacept better than adalimumab (RR disease flare, abatacept vs. adalimumab, 0.64, 95% CI 0.34–1.23), especially considering the case-mix of adalimumab-treated patients, associated with better outcomes. Network 2 indirectly compared anakinra, tocilizumab and canakinumab in systemic juvenile idiopathic arthritis and no differences could be identified. Canakinumab tended to be superior to tocilizumab (RR 2.44, 95% CI 0.81–7.37).

Conclusion: The short-term efficacy of etanercept, adalimumab and abatacept seemed similar for poly-articular course JIA and anakinra, canakinumab and tocilizumab seemed similar for systemic JIA. Because of the observed differences between trials, head-to-head trials comparing 2 biologic agents directly are highly needed. For now, the pediatric rheumatologist has to rely on these indirect comparisons supplemented by observational data derived from cohort studies and safety, practical, and financial arguments.

Tocilizumab Therapy in Children with Systemic Onset Juvenile Idiopathic Arthritis. Russian Experience. Ekaterina Alekseeva, Rina Denisova, Saniya Valieva, Tatyana Bzarova, Kseniya Isayeva, Alexandra Chomakhidze, Evgeniya Chistyakova, Tatyana Sleptsova and Elena Mitenko. Scientific Center of Children's Health, Moscow, Russia

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (sJIA) is classified as an acquired autoinflammatory disease. The interleukin-1 and interleukin-6 play a pivotal role in pathogenesis of this disease. The systemic manifestations as well as arthritis in sJIA are related to interleukin-6 action. Tocilizumab is promising drug for the treatment of systemic arthritis refractory to immunosuppressive drugs.

Objectives: To evaluate safety and efficacy of tocilizumab treatment in children with systemic juvenile idiopathic arthritis.

Methods: A prospective observational study in patients with sJIA taking tocilizumab. A total of 94 patients (49 boys and 45 girls) were included in this study. Median age was 5,5 years (range; 2 to 15 years) and median disease duration was 3,5 years (range; 0.5 to 12 years). Tocilizumab was administrated intravenously at a dose of 8–10 mg/kg every 2 weeks during 2 months then every 4 weeks. All patients received DMARDs. Efficacy end points included the American College of Rheumatology (ACR) Pediatric criteria for improvement 30 (ACR30), ACR50, ACR70 and criteria of inactive disease and remission.

Results: 39 of 94 patients (41%) entered 52 weeks and 69 patients - 24 weeks of continuous tocilizumab treatment. Tocilizumab treatment was discontinued in 15 patients. 40 patients continue to receive Tocilizumab therapy and have not entered 52 weeks yet. The ACR Pedi 30, 50 and 70 improvement were achieved by 100%, 100% and 75% of patients at Week 24 (n=69) and by 100%, 100% and 87% of patients at Week 52 (n=39), respectively. Inactive disease was achieved by 55% of patients at week 24 (n=69) and by 65% of patients at week 52 (n=39). Remission was achieved by 59% of patients (n=39). The mean dose of oral glucocorticoid was decreased from 0,6 (0,4; 0,5) mg/kg (n=45) to 0,2 (0,1-0,3) mg/kg (n=20) at week 52. The frequently observed non-severe adverse events were nasopharyngitis, upper respiratory tract infections and gastroenteritis. No cases of opportunistic infections, malignancies or death were reported. There were three cases of pneumonia and cellulitis. 30 patients had incidences of neutropenia. Tocilizumab treatment was discontinued in 15 patients. The causes for cancellation were relapse of disease (n=7), inefficacy (n=3), remission (n=1), parent's refusal (n=1), infusion reaction (n=2) and Crohn's disease (n=1).

Dynamics in systemic features

	Background	1 m	6 m	12 m
Number of systemic features per patient	3,1	1,1	0,5	0,2

Conclusion: The results of the annual prospective observational study have shown the high efficiency of tocilizumab in patients with the severe sJIA. Drug induced remission of extra-articular manifestations, arthritis and normalized laboratory parameters of the disease activity without initiation of treatment with oral prednisolone and increase its dose, thus avoiding severe irreversible complications of glucocorticoid therapy. Tocilizumab induced disease remission in 59% of patients at Week 52.

1144

Phenotypic Characterization of Childhood Onset Rheumatoid Arthritis. Emily G. Ferrell[1], Lori Ponder[2], Lauren Minor[3], Sheila T. Angeles-Han[3], Christine W. Kennedy[2], Kelly A. Rouster-Stevens[4], Mina Pichavant[2], Larry B. Vogler[4] and Sampath Prahalad[2]. [1]Emory University School of Medicine, Atlanta, GA, [2]Emory Children's Center, Atlanta, GA, [3]Emory University, Atlanta, GA, [4]Emory Univ School of Medicine, Atlanta, GA

Background/Purpose: Rheumatoid Factor positive polyarthritis (RF+ poly) is the JIA subtype that resembles adult seropositive RA. However, the ILAR classification criteria for RF+ polyarthritis do not capture all children with childhood onset RA due to specific exclusion criteria: lack of 2 (+) RF tests, <5 active joints in the first 6 months, family history of psoriasis, and (+) HLA-B27 in boys with onset after age 6. The ACR/EULAR criteria used for diagnosing adult RA do not have these exclusions, and they include the highly specific anti-CCP antibodies (ACPA). The current ILAR classification system does not include ACPA. Hence, children who are RF (−) but ACPA (+) may be treated less aggressively and develop complications secondary to undertreated disease. Our objectives are to 1) determine whether RF and/or ACPA (+) children meet ILAR criteria for RF+ poly JIA and 2) assess for significant differences between children who meet RF+ poly criteria and those who are classified as other subtypes.

Methods: Demographic and disease-related data were collected from charts of RF and/or ACPA (+) children. Each child was classified using ILAR criteria, and the ACR/EULAR classification was used to determine whether each child met criteria for adult RA. Children with RF+ poly JIA were compared to those with other subtypes. Nominal variables were compared using Chi square or Fisher's exact tests, and continuous variables were compared using Student's T test.

Results: Of 49 children with RF and/or ACPA (+) JIA, 29 (59%) met criteria for RF+ poly JIA (Table 1). Of the 20 who did not, 9 (45%) met criteria for undifferentiated JIA, 6 (30%) for RF- polyarthritis, 3 (15%) for persistent oligoarthritis, and 2 (10%) for extended oligoarthritis. All children with undifferentiated JIA were ACPA (+); 7 had presentations consistent with oligoarthritis, but had 2 positive RF tests; 1 had a father with psoriasis; 1 was an HLA-B27 (+) boy with onset after age 6. Comparison of children who met criteria for RF+ poly JIA to those who did not revealed significant differences in subtype distribution, number meeting ACR/EULAR criteria for RA, and use of steroids. All other features were not significantly different.

The ACR/EULAR criteria for RA captured more children with RF and/or ACPA (+) JIA than the ILAR RF+ poly classification (92% vs. 59%).

Table 1. Characteristics of ACPA and RF positive children with JIA*

	RF positive polyarticular JIA	Non-RF positive polyarticular JIA	P value**
Total number	29 (59)	20 (41)	
Age at symptom onset (mean±SD)	10.3 ± 3.4	9.3 ± 3.9	0.34
Demographic features			
Female gender	22 (76)	15 (75)	0.95
Hispanic ethnicity	7 (14)	1 (5)	0.08
African ancestry	9 (18)	8 (40)	0.52
Birth weight (kg; mean±SD)	3.4 ± 0.5	3.3 ± 0.5	0.60
ACPA value (mean±SD)	174.5 ± 100.0	163.2 ± 100.2	0.70
ILAR subtype			
RF + poly	29 (100)	0 (0)	**<0.0001**
RF - poly	0 (0)	6 (30)	**0.002**
Oligo extended	0 (0)	2 (10)	0.09
Oligo persistent	0 (0)	3 (15)	**0.03**
Undifferentiated	0 (0)	9 (45)	**<0.0001**
Meets 2010 ACR/EULAR criteria for RA	29 (100)	16 (80)	**0.01**
Imaging evidence of damage	18 (62)	7 (35)	0.07
Number of affected joints in first 6 months (mean & range)	13 (5-30)	11 (1-48)	0.48
Treatment			
Use of systemic steroids	20 (69)	7 (35)	**0.02**
Use of DMARD	28 (97)	17 (85)	0.15
Use of biologic	19 (66)	8 (40)	0.08

* All values are N(%) of those tested/reporting data for particular variables, except as indicated.
ACPA: anti-citrullinated protein antibody.
** P<0.05 was considered statistically significant

Conclusion: A significant number of children (41%) with RF and/or ACPA (+) JIA did not meet criteria for RF+ poly JIA, though many of their demographic features and disease measures were similar to children who did. The ACR/EULAR criteria allow a positive RF *or* ACPA to qualify as positive serology, and these criteria capture more children with RF and/or ACPA (+) JIA. We propose the inclusion of ACPA in future revisions of the JIA classification criteria to improve the specificity of diagnosing childhood onset RA, and we suggest replacing RF+ polyarthritis with RF/ACPA+ JIA.

Use of Non-Etanercept Biologics in Children with Juvenile Idiopathic Arthritis: Results From the Biologics for Children with Rheumatic Diseases Study. Lianne Kearsley-Fleet[1], Eileen Baildam[2], Michael Beresford[3], Rebecca Davies[1], Helen E. Foster[4], Katy Mowbray[1], Taunton R. Southwood[5], Wendy Thomson[1] and Kimme L. Hyrich[6]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [3]Institute of Translational Medicine (Child Health), Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [4]Musculoskeletal Research Group, Newcastle upon Tyne, United Kingdom, [5]University of Birmingham and Birmingham Children's Hospital, Birmingham, United Kingdom, [6]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester Academy of Health Sciences, Manchester, United Kingdom

Background/Purpose: The management of juvenile idiopathic arthritis (JIA) has been revolutionised by the introduction of biologic therapy, although the majority remain unlicensed for children. Until recently, etanercept (ETN) was the only choice of licensed therapy in the UK, with recent additions of adalimumab (age ≥ 4 years), abatacept (age ≥ 6 years) and tocilizumab (systemic arthritis). It is not yet known how and when non-ETN biologics are being prescribed in JIA. The purpose of this analysis was to describe the pattern of use of non-ETN biologics in children with JIA.

Methods: Since 2010, the Biologics for Children with Rheumatic Diseases (BCRD) study, an ongoing prospective observational cohort study, has been collecting detailed information on children <18 years newly starting a non-ETN biologic therapy for JIA. There are no other exclusion criteria. At baseline, detailed demographic and disease information, including details of past biologic therapies, are collected. The use of non-ETN therapy as a first-line or subsequent biologic therapy was compared, including patterns of prescription, use under licensed indications, ILAR subtypes and disease activity/severity using non-parametric descriptive statistics.

Results: To 06/21/2012, 136 children across the UK had been recruited: median age 10 years, 65% female. The most common ILAR subtypes were systemic arthritis (26.5%) and rheumatoid factor (RF) negative polyarthritis (27.2%) (see Table). Sixty four patients (47.1%) were starting a non-ETN biologic as first-line biologic therapy, of which 33 (51.6%) were prescribed off-license. Off-license use was more common among first-line users (p=0.047), largely accounted for by infliximab and anakinra. All patients on anakinra had systemic arthritis, whereas only 67.7% of those were prescribed tocilizumab. Forty-eight percent of first line users versus 26% of subsequent users had a history of chronic anterior uveitis (p=0.028). Of those registered at the point of starting a subsequent biologic, 71% had received prior ETN. The majority had received only 1 prior biologic although 17 children had received 2 prior biologics, 3 children had received 3 and 1 child (RF negative) had received 5 previous biologics. Disease severity was moderate to high and largely comparable between first-line and subsequent biologic users, although subsequent biologic users had a higher limited joint count.

Biologic Patients Characteristic, med(IQR) or n(%)	First Line	Subsequent	Total	p-value
n	64 (47.1)	72 (52.9)	136	
Age at Registration, years	8.5 (4.5-12)	11.5 (8-14)	10 (6-13.5)	0.0006

Licensed Use	31 (48.4)	47 (65.3)	78 (57.4)	0.047
Prior Biological Treatment				
1 previous	0	51		
2 previous	0	17		
3 previous	0	3		
5 previous	0	1		
Ever had Chronic Anterior Uveitis	31 (48.4)	19 (26.4)	50 (36.8)	0.028
Active Chronic Anterior Uveitis at Registration	25 (39.1)	17 (23.6)	42 (30.9)	0.141
Disease activity				
Active joint count	2 (0-6)	3 (1-8.5)	2 (0-7)	0.1030
Limited joint count	1 (0-6)	3 (1-8)	2 (0-7)	0.0061
Physician Global Assessment (10cm VAS)	3.1 (1.5-4.9)	3 (1.8-6)	3 (1.8-5.5)	0.5603
Parent Global Assessment of Well-being (10cm VAS)	3 (0.8-5)	4.4 (2-6)	4 (1.1-5.9)	0.3414
CHAQ	1 (0.3-2)	1.3 (0.3-1.6)	1.1 (0.3-1.8)	0.8697
Pain (10cm VAS)	3.8 (0.5-6.1)	3.7 (1-6.6)	3.7 (0.8-6.5)	0.7833
ESR, mm/hr	10 (6-42)	14 (5-52)	12 (6-50)	0.6820
CRP mg/L	5 (3-20)	5 (4-28)	5 (3-20.4)	0.7292

Conclusion: Many children are now receiving non-ETN biologics in the UK, although almost half of these are being prescribed off-license. Ongoing

follow-up will help to address the question of best choice of biologic therapy for children with JIA, both as first-line and subsequent use, as well as determine the safety of these drugs in children, for which limited clinical experience exists.

1146

Choice of Systemic JIA Treatment Among Childhood Arthritis and Rheumatology Research Alliance (CARRA) Rheumatologists.

Jennifer E. Weiss[1], Esi M. Morgan DeWitt[2], Timothy Beukelman[3], Laura E. Schanberg[4], Rayfel Schneider[5] and Yukiko Kimura[1]. [1]Joseph M. Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]Duke University Medical Center, Durham, NC, [5]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Despite recent advances in identifying effective treatments for systemic Juvenile Idiopathic Arthritis (sJIA), many pediatric rheumatologists continue to use corticosteroids and methotrexate. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed standardized consensus treatment plans (CTPs) for sJIA with the goal of comparing their effectiveness using data collected for the CARRA Registry. Since physicians will select CTPs without randomization, each CTP must be used with sufficient frequency to allow for meaningful comparisons of efficacy. We aimed to ascertain the current anticipated frequency of CTP use by CARRA pediatric rheumatologists, and whether a clear standard of care exists for sJIA treatment.

Methods: An electronic survey was sent to voting members of CARRA regarding CTP choice for new-onset sJIA which has failed NSAID therapy alone. Respondents were asked to select one or more of the following CTPs for each clinical case scenario: (a) systemic corticosteroids (CS) only; or (b) methotrexate, (c) anti-IL1 or (d) anti-IL6 therapy, each with or without CS. Respondents could choose more than one CTP if factors such as insurance limitations or family preference might affect treatment. Features of the clinical case scenarios are summarized in the Table.

Table. Clinical Cases

	Systemic symptoms	Arthritis	Anemia	Acute Phase Reactants	Disability
Case 1	+	+	+	++	+
Case 2	++	+++	+++	+++	++
Case 3	+	++++	+	+	+++
Case 4	+++	++++	++++	++++	++++

Results: 134 of 247 (54%) CARRA members responded. The figure depicts treatment selections sorted by case, demonstrating wide variability in preferred treatment for new-onset sJIA. IL1 and IL6 inhibitors have become important treatment choices. Methotrexate use increases with more prominent arthritis features; however, methotrexate and CS usage are frequent regardless of presenting disease features. Overall, concurrent CS use was indicated by the majority of respondents across all CTPs (Case 1: 74%; Case 2: 87%, Case 3: 66%; Case 4: 91%).

Figure: CTP Choices by Case
Conclusion: There is still significant variability in sJIA treatment approaches and no clear standard of care among CARRA members, with widespread use of methotrexate and CS. There is likely to be sufficient utilization of each of the CTPs for new-onset sJIA to establish comparative treatment effectiveness using the observational CARRA Registry.

1147

Definition of Improvement Thresholds in Juvenile Idiopathic Arthritis Using the JADAS.

Gerd Horneff[1] and Ingrid Kaul[2]. [1]Centre of Pediatric Rheumatology, Sankt Augustin, Germany, [2]Institute of Medical Statistics, Informatics and Epidemiology, University of Cologne, Cologne, Germany

Background/Purpose: Evaluation of disease activity in JIA is fundamental in clinical assessment. The ACR paediatric response measure used in clinical trials are validated to analyse the response to a treatment in comparison to a baseline disease activity but does not judge about the absolute disease activity or the absolute improvement.

Methods: The JADAS has been calculated in patients of the BIKER registry newly starting treatment with etanercept or MTX. The JADAS10 was preferred because it values all 4 domains equally. Physicians + parents were requested to judge on treatment efficacy as very good, good, weak, none or worse. Improvement was assumed if judgement of both were very good or good. No improvement was assumed if at least one judgement was for none or poor. Inconclusive judgements or those with a difference >1 point were excluded from analysis.

Results: Initially, ANOVA of JIA categories showed no significant differences of mean DJADAS in all baseline classes and IQRs also showed good overall limits. So, all JIA categories were combined for a joint cutoff. Analysis was restricted to the 3 month evaluation because of a time dependence of the judgement of improvement in terms of the JADAS. Restriction to the 3 month results left 1340 patients. JADAS at baseline was finally put into 4 classes, class 0 for JADAS <5, "low" for 5≤JADAS<15, "moderate" for 15 ≤JADAS<25 and "high" for 25≤JADAS≤40. An initial JADAS of <5 was assumed as only minor or no disease activity. An improvement cutoff was only defined for baseline classes "low", "moderate" and "high". Cutoffs for defining improvement were chosen by calculating interquartile ranges (IQR) of the judgement groups and considering accuracy as well as sensitivity/specificity of the resulting model. Analysis by baseline class revealed clear cutoff points. According to the baseline JADAS class the following minimum decreases of the JADAS (DJADAS) are proposed for definition of improvement: For baseline class "low": DJADAS of 4, for baseline class "moderate": DJADAS of 10, for baseline class "high": DJADAS of 15. Alternatively a relative decrease of the JADAS by 42% for JADAS class "low", by 51% for JADAS Class "moderate" and 56% for JADAS class "high" were found to define improvement (table 1).

Table 1. Inter quartile ranges of variable DJADAS10 by improvement and baseline class, absolute and relative values. Chosen cutoff for improvement and goodness-of-fit parameters. Higher DJADAS10 indicate better treatment efficacy. Only integer cutoffs were considered.

	JADAS10 baseline class				
	Low (5-15)	Moderate (15-25)	High (25-40)		
Improvement	DJadas10 absolute values IQR (n)				
Yes	4.1-9.5 (502)	10.4-17.2 (450)	17.8-27.2 (148)		
No	-31.-3.7 (85)	1.5-10.2 (94)	4.6-15.0 (35)		
Cutoff for improvement	4	10	15		
Accuracy [%]	76.2	74.8	85.8		
Sensitivity	75.9	76.2	88.5		
Specificity	76.5	73.4	74.3		
Improvement	DJadas10 relative values [%] IQR				
Yes	45-86	55-88	65-94		
No	-32-42	8-50	18-49		
Cutoff for improvement	42	51	50	53	56
Accuracy [%]	76.8	78.5	88.0	87.4	87.4
Sensitivity	77.1	78.4	90.5	88.5	87.2
Specificity	75.3	78.7	77.1	82.9	88.6

Conclusion: Disease improvement on therapy can efficiently be defined by the decrease of the JADAS depending on the initial JADAS score defining low, moderate or high disease activity. Our model demonstrates clear cut off values. After cross validation these cutoffs may be used in clinical trials and for decisions in clinical practice.

Adalimumab — Effective Control under Refractory JIA Associated Uveitis.

Ekaterina Alekseeva, Elena Mitenko, Tatyana Bzarova, Saniya Valieva, Kseniya Isayeva, Alexandra Chomakhidze, Evgeniya Chistyakova, Tatyana Sleptsova and Rina Denisova. Scientific Center of Children's Health, Moscow, Russia

Background/Purpose: Treatment of juvenile idiopathic arthritis (JIA)-associated uveitis is one of the serious problems of paediatric rheumatology. JIA associated uveitis often is refractory to MTX, CiA and topical NSAIDs and GC. Humanised anti-TNFα monoclonal antibody (adalimumab) may be effective drug for the treatment of JIA-associated uveitis refractory to immunosuppressive drugs.

Objectives: To evaluate clinical efficacy and safety of adalimumab therapy in patients with JIA-associated uveitis.

Methods: It was prospective, observational trial. 48 patients with uveitis were enrolled in the study, 8 boys and 40 girls, 32-with bilateral and 16-with unilateral uveitis, 27 had poly-, 21-oligoarthritis. Mean age of patients was 11,8 (range 4-18) y; mean of disease duration-5,7 (range 1-16) y. Before adalimumab therapy 10 patients were treated with MTX (range of dose 15–25 mg/m^2/w), 38-with MTX in combination with CiA (range of dose 4-4,5 mg/kg/d), 5—with oral GC (range of dose 5–12 mg/kg/d), all of them-with topical GC drops, NSAID drops, 27 -received retrobulbar injections of GC. Adalimumab was administrated by subcutaneous injection at dose 40 mg every 2 w during 1y. Adalimumab use was approved by the Local Ethics Committee. The efficacy of therapy was measured by ACR-pedi criteria. Changes in ocular inflammation were graded by M.J.Hogan's criteria. The main target—remission of uveitis and arthritis.

Results: Prior to administration of adalimumab, injection of conjunctiva, edema of iris, corneal precipitations, areas of inflammation in lens and optical nerve disk edema were found in all children with uveitis. After 8 w of treatment complete management of conjunctiva injection, iris edema and optical nerve disk edema were reported in 55% (44/80) of the affected eyes—corneal precipitations disappeared in 45% (36/80); inflammation-associated changes of lens—in 18% (14/80) of eyes. Treatment-associated improvement of vision was found in 63 of 80 of the affected eyes; no changes of vision acuity were reported in 33 (41%) of the affected eyes. GC eye drops were discontinued in 45% (22/48) of patients, NSAIDs eye drops—in 50% (24/48) of children; the dose of GC eye drops was reduced in 86% (41/48) of patients. The exacerbation of uveitis was persisting in 10% (8/80) of the affected eyes, subacute uveitis—in 25%(20/80); remission was found in 65%(52/80) of the affected eyes. After 24 w of treatment the cases of uveitis were not reported; subacute disease was observed in 22%(21/96) of eyes; remission was diagnosed in 78%(62/80) of the affected eyes. After 52 w of treatment remission was diagnosed in 83% of the affected eyes (66/80) The ACR-Pedi 30, 50, 70 were achieved 100%, 80%, 60% of patients at w 4, respectively. After 24 w of therapy ACR-Pedi 30,50,70 and 90 improvements rates was registrated in 100 %,92 %,78 % of patients. The remission was achieved by 63% of patient at w 52. Serious adverse events were not found.

Conclusion: Adalimumab is effective in patients with JIA associated uveitis. Reduction in uveitis activity and remission were reported in 83% of affected eyes. Remission of disease—in 63% of patients.The high efficacy of adalimumab allowed avoiding oral prednisolone and discontinuing topical GC therapy in patients with uveitis.

Disclosure: **E. Alekseeva**, None; **E. Mitenko**, None; **T. Bzarova**, None; **S. Valieva**, None; **K. Isayeva**, None; **A. Chomakhidze**, None; **E. Chistyakova**, None; **T. Sleptsova**, None; **R. Denisova**, None.

1149

Long-Term Safety of Etanercept in Patients with Juvenile Idiopathic Arthritis (JIA).

Kirsten Minden[1], Martina Niewerth[2], Jens Klotsche[3], Michael Hammer[4], Johannes Peter Haas[5], Gerd Ganser[6] and Gerd Horneff[7]. [1]German Rheumatism Research Center, a Leibniz Institute, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]German Rheumatism Research Center, a Leibniz institute, Berlin, Germany, [4]St. Josef-Stift, Sendenhorst, Germany, [5]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [6]Sankt Josef Stift, Sendenhorst, Germany, [7]Centre of Pediatric Rheumatology, Sankt Augustin, Germany

Background/Purpose: Etanercept (Eta) has been the most frequently used biologic drug in patients with JIA. In Germany, about one in three patients with polyarticular JIA received Eta in 2010. However, published data on its long-term safety are limited. The data of the German JIA biologic registers BiKeR and JuMBO were used to determine the rates of serious adverse events or events of special interest in order to assess the long-term safety of Eta.

Methods: Patients who were included at start with Eta in the BiKeR registry until March 2007 and have been half-yearly observed into adulthood were considered for this analysis. All adverse events recorded by physicians over the whole observation period (mean 7.5 years) were categorized on the basis of MedDRA. Total exposure-adjusted rates for serious adverse events (SAEs) and for events of special interest (i.e., deaths, malignancies, medically important infections [MII], and newly emerged other immune-mediated inflammatory diseases [IMID]) per 100 patient years (PY) were calculated.

Results: During the 1,815 years of Eta exposure in 386 patients (mean age 23 years, mean disease duration 14 years) 77 SAEs were recorded (4.2 SUEs/100 PY), of which 8% were possibly related to therapy. The SAE rates for each year of Eta exposure per 100 PY varied somewhat over the first nine years of treatment, but did not differ significantly (p=0.312). The JIA-associated mortality rate was 1% in this study population. Two deaths occurred in patients treated with Eta within the last three months before death, but no patient died in suspected causal relationship to Eta. Two malignancies were reported (that were already published[1]), resulting in 0.11 event per 100 PY of exposure. Twenty MII were recorded which led to drug discontinuation in five patients. 75% of the MII occurred within the first three years of Eta treatment. The exposure-adjusted MII rate was 1.1 per 100 PY. Tuberculosis or other opportunistic infections were not registered. A total of 17 incident IMID (0.9/100 PY) were reported: among them were eight cases with new onset inflammatory bowel disease (0.44/100 PY) and eight cases with uveitis (0.44/100 PY).

Conclusion: The hitherto most comprehensive study of the long-term safety of Eta confirms the good tolerability of the substance. SAEs with possible relationship to therapy occur only rarely (0.3/100 PY). However, reliable risk rates for events of particular interest can only be calculated in larger patient cohorts. Moreover, a comprehensive control group is necessary to put the results into perspective.

Adverse Events in Juvenile Idiopathic Arthritis: Results From the Enhanced Drug Safety Surveillance (EDSS) Pilot Project.

Sarah Ringold[1], Audrey F. Hendrickson[1], Carol A. Wallace[2] and Rachel E. Sobel[3]. [1]Seattle Children's Hospital, Seattle, WA, [2]Seattle Childrens Hospital, Seattle, WA, [3]Pfizer, Inc., New York, NY

Background/Purpose: There are few data available regarding the rates of serious and important medical events (SAEs and IMEs) for most of the medications used to treat JRA/JIA (Juvenile Rheumatoid Arthritis/Juvenile Idiopathic Arthritis), including nonsteroidal anti-inflammatory drugs. These data are of particular importance as the use of biologic disease modifying antirheumatic drugs (DMARDs) in JRA/JIA has increased significantly over the past several years along with the number of medications that are FDA-approved for the treatment of these diseases. While the FDA has a voluntary MedWatch reporting system in place, only a small proportion of physicians fill out these reports and these data cannot be used to calculate SAE/IME rates. The Enhanced Drug Safety Surveillance (EDSS) Pilot Project was developed in partnership with Pfizer, as one of the US FDA post-marketing commitments for celecoxib in JIA, to implement a pilot process to capture of SAEs and IMEs, and to calculate SAE/IME rates in children with JRA/JIA utilizing the CARRA (Childhood Arthritis and Rheumatology Research Alliance) physician network. The objective of this analysis is to summarize the data resulting from the 4-year (2008–2012) EDSS Pilot Project.

Methods: Physicians at participating sites were surveyed monthly to determine whether any of their JIA/JRA patients had experienced a SAE or IME during the prior month. MedWatch forms were subsequently completed for each event, including attribution to medication(s). SAEs and IMEs were categorized by the primary organ system and/or the dominant symptoms (e.g. disease flare, infusion reaction). Each site was surveyed every 6 months regarding the number

of JRA/JIA patients per site, to provide a denominator for the SAE/IME rates. Reporting rates were calculated per 100 person-years (p-y) and 95% CI were calculated based on a Poisson distribution.

Results: 37 sites with 115 physicians contributed at least one year of data. The overall response rate to the monthly surveys was 65% and the overall response to the 6 month surveys was 86%. There were a total of 139 total SAEs and 139 IMEs. The largest proportion of SAEs and IMEs occurred in children with polyarticular JIA (39% and 38%, respectively). The majority of SAEs and IMEs were reported for patients receiving biologic DMARDs (73% and 68%, respectively). NSAIDs and non-biologic DMARDs were the next most commonly reported medications, with 1 SAE and 2 IMEs attributed to celecoxib, and 12 SAEs and 11 IMEs attributed to other NSAIDs. Infection accounted for the largest proportion of both SAEs and IMEs (52% and 20%). The next most common categories of SAE were disease flare and macrophage activation syndrome. The next most common categories of IME were neurologic and elevated liver function tests. The total event rate for SAEs and IMEs combined was 1.2 SAE/IME per 100 p-y (95% CI: 1.1–1.4). The rate for SAEs was the same as IMEs (0.6 per 100 p-y; 95% CI: 0.5–0.7).

Conclusion: The EDSS provided a simple and effective tool for SAE/IME reporting. These data support the development of a long-term registry of children with JRA/JIA in North America to continue the collection of these critical data.

Low-Dose Methotrexate and the Selective Accumulation of Intracellular Aminoimidazolecarboxamide Ribotide. Ryan S. Funk, Leon van Haandel, Mara L. Becker and J.S. Leeder. Children's Mercy Hospital, Kansas City, MO

Background/Purpose: Current evidence suggests that the anti-folate methotrexate (MTX) mediates its anti-inflammatory effects through inhibition of the purine synthesis pathway causing the accumulation of aminoimidazolecarboxamide ribotide (AICAR). Meanwhile, the anti-proliferative effects of MTX have primarily been attributed to inhibition of the pyrimidine synthesis pathway, marked by the accumulation of deoxyuridine monophosphate (dUMP). Therefore, identification of factors that affect MTX selectivity for purine synthesis pathway inhibition may be important in predicting and enhancing drug response in immuno-inflammatory diseases.

Methods: K562 erythroblastoid cells (2.5×10^5 cells/mL) were exposed to 0, 10, 100 and 1000 nM MTX under normal culture conditions for up to 24 hr. Cell samples (2.5×10^6 cells) were harvested after 1, 2, 4, 8 and 24 hr of MTX exposure. Cell lysates were analyzed for AICAR, dUMP, MTX and six different oxidation/methylation states of tetrahydrofolate, including 5-methyltetrahydrofolate (5mTHF); the polyglutamate distribution was also determined for each folate species and MTX. Mean concentrations and standard deviations from three independent experiments are reported. Statistical evaluations were conducted by unpaired Student's t-tests and statistical significance was defined by a P-value < 0.05.

Results: The primary effect on intracellular folates was a depletion of 5mTHF to levels at 24 hr that were 80%, 3% and 1% of control (0 nM MTX) in response to 10, 100 and 1000 nM MTX challenge, respectively with no effect on cell viability. Similarly, intracellular dUMP accumulated to levels 29-, 343- and 486-fold greater than control after a 24 hr exposure to 10, 100 and 1000 nM MTX, respectively. In the presence of 10 nM MTX, AICAR accumulated 93-fold compared to vehicle treated cells at 24 hr, however, increasing [MTX] had a paradoxical effect, resulting in lower AICAR concentrations. Across all experimental conditions intracellular [MTX] correlated with the intracellular accumulation of dUMP ($r^2=0.854$) and depletion of 5mTHF ($r^2=0.860$), but poorly with intracellular AICAR accumulation ($r^2=0.122$).
Figure. Intracellular dUMP and AICAR in K562 cells following a 24 hr exposure to MTX (**, P-value < 0.01; ***, P-value < 0.001).

Conclusion: Under these experimental conditions, increasing concentrations of MTX beyond 10 nM did not result in concentration-dependent increases in AICAR accumulation, and higher doses of MTX appeared to minimize the effects on the purine pathway, despite having profound effects on pyrimidine synthesis. Although the mechanism for this paradoxical effect on AICAR accumulation is currently under investigation, these findings support the hypothesis that low-dose MTX selectively targets the purine biosynthesis pathway and may result in improved anti-inflammatory effects.

Improvement in Health-Related Quality of Life for Children with Juvenile Ideopathic Arthritis After Start of Treatment with Etanercept. Jens Klotsche[1], Kirsten Minden[2] and Gerd Horneff[3]. [1]German Rheumatism Research Center, a Leibniz institute, Berlin, Germany, [2]German Rheumatism Research Center, a Leibniz Institute, Berlin, Germany, [3]Centre of Pediatric Rheumatology, Sankt Augustin, Germany

Background/Purpose: The concept of Health-related quality of life (HrQoL) has been widely accepted as a burden of disease measure in recent years. The improvement in HrQoL is an important therapy goal in the treatment of patients with juvenile idiopathic arthritis (JIA). We investigated the 12-month course of HrQol in an unselected cohort of patients with JIA after therapy start with Etanercept and identified its associated factors.

Methods: Children were enrolled in the BiKer (Biologics in Paediatric Rheumatology) registry. A random subset of children completed the Pediatric Quality of Life Inventory (PedsQL) after the start of Etanercept treatment and was followed-up monthly for 6 monthly and bimonthly thereafter for up to one year. The 12-month course of the PedsQL total score and predictors for the change in HrQoL were investigated by growth curve modeling. The role of the depending predictor variables of an inactive disease and level of pain were studied in the course of HrQoL. The criteria by Wallace (2004) were applied to define inactive disease, the level of pain was assessed on a visual analogue scale (0–100) and functioning was measured by the CHAQ.

Results: Data were available for 61 patients with a mean age of 10.5 years (sd=3.9) and a mean disease duration of 3.2 years (sd=3.2). At baseline, the mean PedsQL total score was 75.5 (sd=16.7), mean number of swollen joints was 7.2 (sd=6.2), the mean rating of disease activity was 56.9 (sd=19.5) and 80% of the children reported functional restrictions indicated by a CHAQ above 0. A lower HrQol for patients at baseline was significantly associated with the number of swollen joints (beta=-1.1, p=0.016), functional restrictions (beta=-18.9, p<0.001), a high disease activity (beta=-0.31, p=0.002) and the existence of at least one comorbid condition (beta=11.5, p=0.021). The PedsQL total score increased at a rate of 2.8 units per month (p<0.001) in the first 6 months of treatment up to a level of 89.7 (sd=10.7), whereas the increase flattened (0.3 units per month, p=0.144) from 6-month to 12-month follow-up. A total of 16 (26%) children were already in remission after one year Etanercept treatment. The achievement of remission at the second month (beta=6.7, p<0.001) and fourth month (beta=5.2, p=0.029) yielded a significant increase in HrQoL. A high level of pain was associated with a lower HrQoL at each occasion.

Conclusion: HrQoL significantly improved after starting an Etanercept therapy in children with JIA. Adequate disease control and a low level of pain predicted a higher HrQoL in the 12-month course. But, both time dependent predictor variables did not fully explain the improvement in HrQoL.

1153

Perceived Health-Related Quality of Life and Its Determining Factors in Children with Recent-Onset JIA. Jens Klotsche[1], Ina Liedmann[1], Martina Niewerth[2], Gerd Horneff[3], Johannes Peter Haas[4] and Kirsten Minden[5]. [1]German Rheumatism Research Center, a Leibniz institute, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Centre of Pediatric Rheumatology, Sankt Augustin, Germany, [4]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [5]German Rheumatism Research Center, a Leibniz Institute, Berlin, Germany

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease and a major cause of chronic disability in children aged below 16 years. Health-related quality of life (HrQoL) has become an important

outcome measure for the perceived burden of disease and therapy effectiveness in the field of pediatric rheumatology. There is little knowledge about its diversification and determining factors in children with recently diagnosed JIA.

Methods: The diversification and determining factors of HrQoL were investigated by latent class analyses (LCA) in the ICON (Inception Cohort Of Newly-diagnosed patients with JIA) study, a prospective controlled observational multicentre study for long-term observation of patients diagnosed as JIA within the last 12 months. The evaluation comprised a self assessment by patients and parents via standardized questionnaires and clinical examinations by pediatric rheumatologists and ophthalmologists. HrQoL was measured by the Pediatric Quality of Life Inventory (PedsQL) 4.0 Generic Core Scales and the PedsQL 3.0 Rheumatology Module. The PedsQL was completed by patients above an age of eight years and parents. The difference between both ratings and determining factors for the difference was investigated.

Results: Information about HrQoL was available for 426 patients. Differences in the patients and parents ratings could be investigated for 198 children aged above 8 years. More than half of the children (58.4%) were assigned to a group characterized by high PedsQL scores (range: 79.4, 95% CI: 76.3;82.5 for treatment problems to 98.3, 95% CI: 97.5;99.2 for daily activity) by LCA. Only 9% of the children were classified into a group with low HrQoL scores (mean total score 50.6, 95% CI: 45.3;55.9) and were diagnosed with polyarthritis. High HrQoL scores were associated with the ILAR category oligoarthritis (p<0.001) and a low disease activity (mean 2.7 on NRS 0–10, p<0.001). Patients with high HrQoL scores had significantly less emotional difficulties as measured by the Strength and Difficulties questionnaire. Interestingly, parents of patients with higher HrQoL scores had more likely a higher educational level (57% with more than 10 years of schooling). In general, the parents rating of HrQoL was lower than the rating of the children (difference in total score = 4.1, 95%CI: 2.5;5.7). The most pronounced differences were observed in the rating of emotional problems (Δ=8.3, 95%CI: 5.3;11.2) within the age groups (Δ=6.0 for age group 8–12 years versus 1.8 for age group 13–16 years, p<0.001). Children in the two ILAR categories systemic arthritis (Δ=8.8, 95%CI: 3.6;14.1) and psoriatic arthritis (Δ=6.6; 95%CI: 1.2;13.5) reported better HrQoL compared to the parents report.

Conclusion: More than half of the children report high HrQoL scores at the beginning of JIA. Disease related parameters as well as social and personal factors independently affect the patients' overall well-being. Parents of younger children rated HrQoL remarkably lower than the children themselves, both patient- and proxy-reporting is therefore required to get a full picture of the burden of illness.

1154

Impact of FokI VDR and TNFalpha-308 Polymorphism On Disease Severity and Long Term Outcome in JIA Patients On Anti-TNF Treatment.
Jelena Vojinovic[1], Jelena Basic[2], Gordana Susic[3], Dragana Lazarevic[2] and Nemanja Damjanov[4]. [1]Prof, Nis, Serbia, [2]Dr, Nis, Serbia, [3]Dr, Belgrade, Serbia, [4]Prof, Belgrade, Serbia

Background/Purpose: Genetic contribution of SNP (single nucleotide polymorphism) of TNFα-308 promoter and FoxI for VDR (vitamin D receptor) polymorphism on disease severity and outcome in JIA is not yet well established. VDR polymorphisms correlations with different autoimmune diseases have been implicated and found to be different in some populations but data for JIA are missing. Primary endpoint of this study was to evaluate influence of these promoter polymorphisms, as possible biomarkers, on disease severity and long term outcome in JIA patients on anti-TNF treatment.

Methods: Genomic DNA was extracted and TNFα-308 promoter and FokI VDR polymorphism was evaluated using the PCR-RFLP method in 60 JIA patients included in Serbian JIA registry who donated blood samples before commencement of etanercept treatment. Time cut of point for outcome data analysis was 4 years after first dose of anti-TNF agent (etanercept).

Results: At enrolment JIA patients mean age was 14.7±4.22, disease duration 6.59±2.76, and average dose of MTX 11.91±6.68 mg/m2/week. Disease subtype distribution was 6.78% systemic, 54.24% polyRF- and extended oligo, 18.64% polyRF+, 16.95% ERA and 3.38 PsA. The distribution of TNFα308 and VDR genotypes was not significantly different among JIA subtypes. TNFα308 genotypes distribution was 6.78% AA, 30.51% GG and 62.71% GA. After 4 years treatment could be stopped (remission) in 35.14%, had to be reintroduced due to disease worsening in 16.22%, disease was in remission under medication in 21.62% or still active in 24.32% GA patients while respectively in 38.9%, 16.7%, 27.8% and 11.1% in GG patients. Average duration of etanercept treatment was 34.61±12.11 months and there was significantly shorter need for treatment duration if GG polymorphism group. VDR genotypes distribution was 51.6% FF, 38.7% Ff and 9.7% ff while in 20 healthy controls only FF (wild type) genotype was present. Presence of ff genotype significantly correlated with worse outcome and disease severity. We have found significant correlations with disease severity and presence of TNFα308 and/or FokI VDR genotypes.

Conclusion: Our results indicate that JIA patients, more frequently than healthy controls, have Ff or ff VDR FokI polymorphism. Heterozygote or homozygote presence of f variant for FokI polymorphism of VDR in JIA patients was associated with more severe disease and worse outcome. JIA patients with GG TNFα308 genotype can achieve better outcome and etanercept treatment can be stopped earlier compared to GA genotype. Both genotypes could be useful clinical predictive biomarker for disease severity and treatment response.

1155

A New Measure of Visual Function for Children with Juvenile Idiopathic Arthritis-Associated Uveitis.
Sheila T. Angeles-Han[1], Steven Yeh[1], Courtney McCracken[1], Larry B. Vogler[1], Kelly A. Rouster-Stevens[1], Christine W. Kennedy[2], Kirsten Jenkins[3], Matthew Kent[1], Scott Lambert[1], Carolyn Drews-Botsch[4] and Sampath Prahalad[2]. [1]Emory Univ School of Medicine, Atlanta, GA, [2]Emory Children's Center, Atlanta, GA, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Emory University School of Public Health, Atlanta, GA

Background/Purpose: Studies on outcomes of children with juvenile idiopathic arthritis-associated uveitis (JIA-U) focus on the clinical ocular exam and physical disability secondary to arthritis. This assessment could improve by including measures of the impact of uveitis on daily life. However, until recently, there were no instruments that measured visual function in this population. Our objective is to validate a measure of visual function, the "Effects of Youngsters' Eyesight on Quality of Life (QOL)" (EYE-Q), in children with uveitis.

Methods: Focus groups were held to modify the old EYE-Q for children with uveitis. The new EYE-Q contains items specific to uveitis. A parent-proxy version was also developed. Children with JIA, JIA-U, and idiopathic uveitis (I-U) participated. Medical record reviews were performed. Questionnaires were completed on QOL (Pediatric QOL Inventory - PedsQL), physical function (Childhood Health Assessment Questionnaire - CHAQ), and visual function (EYE-Q).

Results: Participants were 104 children with JIA, 19 with JIA-U and 9 with I-U (Table 1). There were significant differences in the child and parent EYE-Q scores in children with uveitis compared to children with JIA (Table 2). For the child report, there were mild correlations between EYE-Q scores and logmarVA (r = −0.35) and moderate correlations with the PedsQL (r = 0.50) and CHAQ (r = −0.53) (Table 3). Similar results were found with the parent report. There were strong correlations between the parent and child EYE-Q (r = 0.74), and the old and new versions of the EYE-Q (r = 0.96, r = 0.94).

Table 1. Characteristics of children with JIA-associated uveitis, JIA alone, and idiopathic uveitis

	JIA alone N = 104	JIA-U N = 19	I-U N = 9
Demographic Characteristics

[a] Effects of Youngsters Eyesight on QOL; [b] Logmar visual acuity; [c] Childhood Health Assessment Questionnaire; [d] Pediatric Quality of Life Inventory

Cronbach's α for the old EYE-Q child and parent reports was 0.89. Cronbach's α for the new EYE-Q child report was 0.91 and for the parent report was 0.90.

Conclusion: The new EYE-Q, with items specific to uveitis, is a valid measure of visual function in children with uveitis. There were differences in child and parent perception of disease hence the inclusion of both perspectives in disease assessment is important. The EYE-Q may be an important measure in the assessment of outcomes in this population and a better measure than the clinical exam and arthritis specific measures alone. Longitudinal studies examining the performance of the EYE-Q in children with JIA-U and I-U are ongoing.

Effectivity of Methotrexate in Therapy of Juvenile Idiopathic Enthesitis-Related Arthritis. Katharina Geitz and Ivan Foeldvari. Hamburger Zentrum Kinder-und Jugendrheumatologie, Hamburg, Germany

Background/Purpose: Juvenile idiopathic enthesitis related arthritis (enthJIA) represents 5 to 10% of children with JIA. Most patients present with peripheral arthritis and enthesitis. Methotrexate was not formally studied regarding effectivity for the peripheral joint involvement of this subset. Aim of our study was to assess the effectivity of methotrexate in peripheral joint involvement of enthesitis related JIA.

Methods: We conducted a chart review of patients with juvenile idiopathic enthesitis related arthritis, who have been treated at least for 3 months with MTX since 2005. The clinical and demographic parameters of the patients were assessed.

Results: We identified 73 patients with confirmed diagnosis of enthJIA, who were treated at least for 3 months with MTX. At the initiation of the therapy the average active joint count was 2,5 and the number of active enthesitis sites were 0,9. The mean CHAQ value was 0,55 and the mean pain score was 1,20 and the mean well being score was 1,26. The mean physician global was 1,74. At 3,6 and 9 months the active joint count was reduced by 18%, 44% and 53%, the number of painful joints by 22%, 36% and 47% and the number of swollen joints by 70%, 70% and 65%. The number of active enthesitis sites were reduced by 3,6 and 9 months by 44.5%, 61% and 50%. The CRP was reduced at 3,6 and 9 months by

49%, 70% and by 76%.The CHAQ score decreased at 3,6 and 9 months by 45%, 63% and 62%, the pain-score by 38%, 62% and 51% and the well-being score by 52%, 66% and 49% and the physician global by 58%, 65% and 65%.

Conclusion: In this retrospective chart review we could demonstrate the effectivity of MTX for peripheral joint involvement and for enthesitis. Interestingly only after 6 months of MTX therapy was the highest rate of improvement reached. Prospective controlled trial would be important to prove our results.

The Phenotypic Characterization of Juvenile Idiopathic Arthritis in African American Children. Lauren Minor[1], Lori Ponder[2], Emily G. Ferrell[1], Sheila Angeles-Han[1], Christine W. Kennedy[2], Kelly Rouster-Stevens[1], Mina Pichavant[2], Larry B. Vogler[1] and Sampath Prahalad[1]. [1]Emory University School of Medicine, Atlanta, GA, [2]Emory Children's Center, Atlanta, GA

Background/Purpose: JIA, a common childhood arthropathy, with an estimated prevalence of 1 in 1000 in children under the age of 16, affects children of all ages and races. There is limited data describing the characteristics of JIA in African-American (AA) children. The purpose of this study was to compare phenotypic characteristics of AA and Non-Hispanic White (NHW) JIA patients in our rheumatology clinic.

Methods: Charts of children with JIA, who were enrolled in a genetic study between June 2009 and June 2012 were reviewed. At time of enrollment, demographic and disease-related data were collected. Patients who identified as Hispanic or multi-racial were excluded. Disease characteristics compared between AA and NHW children included: age at onset and diagnosis, family history, JIA subtype, laboratory tests, associated features, medications, and radiographic changes. Fischer's exact test or Chi-Square tests were used to compare nominal variables, and student's T test was used to compare continuous variables.

Results: 150 NHW children and 62 AA children with JIA were studied. Table 1 compares demographic and disease characteristics of NHW and AA children. AA children with JIA were significantly older both at disease onset and presentation to a pediatric rheumatologist. JIA subtypes differed significantly between AA children and NHW children, with the AA being predominantly polyarticular RF+, and NHW being predominantly persistent oligoarticular. Both groups had a female predominance. Significantly more AA children had Medicaid and lived closer to their rheumatologist. AA children were less likely to have a family history of autoimmunity. Laboratory studies demonstrated that AA children were more likely to have positive RF and CCP antibodies. AA children were more likely to be treated with methotrexate at diagnosis, and more likely to have received systemic steroids during the course of their disease. These children were also more likely to have joint space narrowing and osteopenia on x-ray than NHW children. AA children were more likely to have rheumatoid nodules and chronic anemia as manifestations of their disease. The prevalence of uveitis was not significantly different between AA and NHW children with JIA. Even excluding the polyarticular RF+ subtype, AA children were older at onset and had more cumulative joints affected.

Conclusion: Using a large cohort of AA and NHW children with JIA, we confirm reports of the differences in disease characteristics reported in smaller earlier studies. AA children with JIA demonstrate significant differences in disease characteristics; they are older at disease onset, more likely to have RF/CCP + polyarthritis, more likely to use systemic steroids, more likely to have a higher joint count involvement, and more likely to have radiographic evidence of disease. These observations support earlier observations that the phenotype of JIA is different in AA children.

Development of Cut-off Values for High Disease Activity in Juvenile Idiopathic Arthritis Based On the Juvenile Arthritis Disease Activity Score. Alessandro Consolaro[1], Stefano Lanni[1], Sara Verazza[1], Maria C. Gallo[1], Marta Bertamino[1], Giulia C. Varnier[1], Serena Calandra[2], Nicolino Ruperto[3], Alberto Martini[2] and Angelo Ravelli[4]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Paediatric Rheumatology International Trials Organisation [PRINTO], Genova, Italy, [4]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: In the last decade, there have been major advances in the management of juvenile idiopathic arthritis (JIA), including the shift towards early aggressive interventions and the development of new therapeutic agents and combination treatment strategies. A reliable documentation of the advances in therapeutic effectiveness creates the need for validated and clinically useful criteria that describe precisely the clinical state of the patient. The study was aimed to determine cut-off values for the state of high disease activity (HDA) in JIA based on the Juvenile Arthritis Disease Activity Score (JADAS).

Methods: For the selection of cut-offs, data from a clinical database including 618 children with JIA followed between 2007 and 2011 were used. Patients were defined as being in HDA when one of the following therapeutic interventions was prescribed: 1) start of methotrexate; 2) intraarticular corticosteroid therapy; 3) start of a biologic medication; 4) start of systemic corticosteroid therapy. Patients were defined as having low disease activity (LDA) when they were receiving no therapy or had therapy discontinued, tapered or left unchanged for > 1 year. For each patient, 1 visit in HDA and 1 visit in LDA were retained. Optimal JADAS cut-offs were determined by calculating the 25th percentile of cumulative score distribution in patients with HDA and by assessing their ability to discriminate between the states of HDA and LDA through ROC curve analysis (including calculation of Youden index and fixed 90% specificity). Cross-validation of cut-offs was performed in 490 JIA patients enrolled in the PRINTO methotrexate trial (Ruperto et al, A&R 2004;50:2191-201) and on 358 patients followed longitudinally at study centers for a median of 1.7 years, and was based on assessment of discriminative and predictive validity.

Results: The cut-offs were calculated separately for patients with oligoarticular and polyarticular course of joint disease (irrespective of ILAR category) owing to the different severity of these 2 JIA phenotypes. Complete clinical data were available for 258 visits of patients with oligoarthritis and 289 visits of patients with polyarthritis. JADAS-10 and JADAS-71 cut-offs were 7.6 for oligoarthritis and 10.6 for polyarthritis. JADAS-27 cutoffs were 7.7 for oligoarthritis and 8.9 for polyarthritis. Validation analyses showed that at baseline visit of methotrexate trial 94.7% of patients had a JADAS higher than the proposed cut-off for JADAS. At 6-month visit, the percentage of patients with a JADAS higher

than the cut-off was 85.6% among nonresponders and 23.8% among responders. Evidence of predictive ability of the cut-offs was obtained by demonstrating that in the longitudinal patient sample, the percentage of patients with inactive disease or with a C-HAQ score of 0 at final visit was significantly lower among patients who had a JADAS above the cut-off value at first visit than among those who did not.

Conclusion: We developed the JADAS cut-offs for HDA in JIA. The cut-offs revealed strong discriminative and predictive ability in a clinical trial and are, therefore, potentially applicable in clinical practice, observational investigations, and therapeutic studies.

Reasons and Predictors of Methotrexate Discontinuation in Children with JIA: Results From the Childhood Arthritis Prospective Study (CAPS). Suzanne Verstappen[1], Lucy R. Wedderburn[2], H. E. Foster[3], Eileen Baildam[4], Janet Gardner-Medwin[5], Joyce Davidson[5], Alice Chieng[6], Wendy Thomson[7] and Kimme L. Hyrich[8]. [1]University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [2]University College London (UCL), London, United Kingdom, [3]Newcastle Hospitals NHS Foundation Trust and Great North Children's Hospital, Newcastle Upon Tyne, United Kingdom, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]Royal Hospital for Sick Children, Glasgow, United Kingdom, [6]Manchester Children's Hospital, Manchester, United Kingdom, [7]Arthritis Research UK Epidemiology Unit, Manchester, United Kingdom, [8]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester Academy of Health Sciences, Manchester, United Kingdom

Background/Purpose: Methotrexate (MTX) is the DMARD of first choice in patients with juvenile idiopathic arthritis (JIA). However, limited data is available on MTX survival, including reasons for stopping MTX, and predictors for stopping MTX.

Objectives: The objectives of this study were to i) describe survival time and reasons for stopping MTX and ii) to identify possible predictors for stopping MTX due to adverse events (AE) or inefficacy.

Methods: Consecutive children with JIA treated with MTX from the Childhood Arthritis Prospective Study (CAPS), a large prospective longitudinal inception cohort study, were included. At baseline, 6 months and at annual follow-up visits a clinical examination was performed including the physician's global assessment (PGA) and number of active and limited joints. The CHAQ, was completed by the parent or the child. Start and stop dates and reasons for stopping MTX were also collected. For the present study the following definitions were applied: 1) AE, stopped due to AE and MTX not restarted for at least one month; 2) inefficacy, stopped MTX due to inefficacy or added a biologic; 3) efficacy, stopped MTX because of efficacy and MTX not restarted for at least one year; 4) other. Kaplan Meier survival curves were calculated to determine the survival probability at two years for overall, AE, inefficacy or efficacy survival. Patients were included until the date of stopping MTX or until the last follow-up date when MTX treatment was continued. Cox proportional hazards regression analyses were applied to assess the predictive ability of demographic and clinical variables assessed at time of starting MTX treatment with AE or inefficacy. Since data on disease activity were not always collected at time of MTX therapy start, disease activity and CHAQ-score assessed for a maximum of three months prior to MTX start was used, otherwise data was defined missing.

Results: 501 children (median [IQR] age at MTX start was 8.3 [4.0-12.2] yrs) received MTX after a median time since symptom onset of 7.1 [3.5-19.1] months. 244 (49%) stopped MTX, reasons: AE (n=58), inefficacy (n=121), efficacy (n=34) and other reasons (n=31). Overall median survival time was 2.4 [1.1-4.4] yrs. The estimated survival rates at two yrs were 0.87 (95%CI 0.83 to 0.90) for AE, 0.75 (95%CI 0.70 to 0.79) for inefficacy and 0.93 (95%CI 0.88 to 0.95) for efficacy. Older children were more likely to stop MTX medication because of AE (HR 1.08, 95%CI 1.01 to 1.14) or inefficacy (HR 1.06, 95%CI 1.01 to 1.10) and a high PGA score measured at MTX start (HR 1.21, 95%CI 1.04 to 1.42 (n=236)) was associated with MTX related AE survival. No other associations with AE or inefficacy survival were found, probably due to lack of power, respectively: female gender (HR, 95%CI; 0.83 (0.48 to 1.43) and 0.98 (0.66 to 1.44)), active joint count (HR, 95%CI; 0.99 (0.95

to 1.03) and 1.02 (0.99 to 1.04) (n=323)), limited joint count (HR, 95%CI, 0.99 (0.95 to 1.04) and 1.02 (0.99 to 1.04) (n=321)), and CHAQ-score (HR, 95%CI, 0.71 (0.36 to 1.41) and 1.03 (0.64 to 1.66) (n=147)).

Conclusion: In this cohort of patients with JIA starting MTX we found that children stayed on MTX therapy for a median of 2.5 years. Older age was a predictor for stopping MTX due to AE and inefficacy.

Assessment of Subclinical Synovitis by Power Doppler Ultrasonography in Patients with Juvenile Idiopathic Arthritis. Maria Teresa Terreri[1], Vanessa M. Bugni[2], Claudio A. Len[2], Sônia de A.V. Mitraud[3], Rita NV. Furtado[4] and Jamil Natour[5]. [1]Universidade Federal de São Paulo/UNIFESP, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo/UNIFESP, São Paulo, Brazil, [3]Universidade Federal de São Paulo/UNIFESP, São Paulo, [4]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [5]Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood, leading to physical disability and poor quality of life. Advances in the treatment of JIA have led to higher remission rates. However despite clinical remission articular ultrasonography (US) can sometimes detect subclinical synovitis (SS). The aim of this study was to evaluate patients with JIA in remission and healthy controls for the presence of SS by US Power Doppler (PD), and evaluate its association with demographic and clinical variables.

Methods: Cross-sectional study of patients with JIA in remission and healthy controls, matched for age and gender. Inclusion criteria: oligoarticular and polyarticular JIA, clinical and laboratory remission (Wallace et al), between the ages 5 to 18 years. Clinical assessment: active/limited joint count, functional capacity by the Childhood Health Assessment Questionnaire (CHAQ), physician global visual analogue scale (VAS), patient global VAS, medications in use. US assessment evaluated 17 joints bilaterally. Ultrasonographic parameters included synovitis and synovial blood flow in PD. A moderate to severe degree of synovitis and/or any synovial flow present at the PD indicated the presence of SS. P-values were calculated based on the chi-square test, Fisher's exact test, student's T test and Mann-Whitney U test.

Results: Thirty-six patients (mean age 11.5 ± 3.7 years) and 36 controls (mean age 11.3 ± 3.7 years) were included and a total of 2448 joints were assessed. There were 36 JIA patients, 29 were girls, with a mean age at assessment of 11.5 ± 3.7 years and a mean age at disease onset of 4.3 ± 3.2 years. Sixteen patients had persistent oligoarticular JIA, 11 extended oligoarticular and 9 polyarticular with negative rheumatoid factor. Nine patients were off medication and 27 were on medication, with an average time of remission of 1.8 ± 2.2 years. SS was present in 46/2448 (1.8%). SS was more common in patients (41.6%) than in controls (13.9%) (p=0.009). The most frequently affected joints were the wrists (15), followed by elbows (9), ankles (8), toes (7), knees (4) and fingers (3). There were differences between patients and controls related to the presence of SS in elbows (p=0.033) and ankles (p=0.006). On ultrasonographic evaluation of JIA patients, 38/1224 (3.1%) had SS joints. Patients with JIA polyarticular/extended oligoarticular subtypes and age at onset older than 6 years old had more SS (p=0.026 and p=0.018, respectively). There were no differences in terms of gender, age at evaluation, presence of antinuclear antibodies, type of remission, duration of remission, type of medication, previous uveitis, previous intra-articular injections, physician VAS, patient VAS and CHAQ.

Conclusion: SS was present in 3.1% of joints from JIA patients considered to be in remission especially in wrists, elbows, ankles, knees, fingers and toes. Although SS was shown to be more frequent in all JIA joints than in controls, we only observed significant difference in elbows and ankles joints. SS was more common in patients with polyarticular involvement (polyarticular and extended oligoarticular) and later age of JIA onset (greater than 6 years old).

Current Evidence of Anti-TNFα Treatment Efficacy in Childhood Chronic Uveitis: A Systematic Review and Meta-Analysis Approach Comparing the Different Drugs. Gabriele Simonini[1], Kate Druce[2], Rolando Cimaz[1], Gary J. Macfarlane[2] and Gareth T. Jones[2]. [1]Anna Meyer Children's Hospital-University of Florence, Firenze, Italy, [2]University of Aberdeen, Aberdeen, United Kingdom

Background/Purpose: To summarize evidence regarding the effectiveness of anti-TNFα treatments in childhood autoimmune chronic uveitis (ACU), non responder and/or failure to previous DMARD course.

Methods: A systematic search of articles between January 2000 and June 2012 was conducted using EMBASE, Ovid MEDLINE, Evidence Based Medicine Reviews-ACP Journal Club, Cochrane libraries, and EBM Reviews. Studies were eligible for inclusion if they investigated the efficacy of anti-TNFα therapy as the first biologic modifier immunosuppressant medication, among children ('16 yrs) naïve to any anti-TNFα, therapy in the treatment of ACU, refractory to therapy with topical treatment and/or systemic treatment and at least one immunosuppressive treatment (MTX, and/or Azathioprin and/or CSA and/or Clorambucil and/or Micofenolate Mofetil). The primary outcome for this review was the proportion of patients classified as having improved intraocular inflammation, expressed as Tyndall, as defined by the Standardization of Uveitis Nomenclature (SUN) working group criteria. We determined a combined estimate of the proportion of children in the eligible studies responding to anti-TNFα treatment: Etanercept (ETA), Infliximab (INF), or Adalimumab (ADA).

Results: The initial search identified 959 articles, of which 144 were potentially eligible. 26 eligible articles, all retrospective chart reviews, but one RCT, remained in the analysis. 245 children were included in the analysis (ADA n=27; ETA n=62 and INF n=156) and the number of children in studies ranged from 1 to 47. The pooled analysis suggested that INF and ADA have favorable effects in the improvement of intraocular inflammation: the proportion of responding subjects was 82% (95% CI: 68–96%) and 68% (61–76%) for ADA and INF respectively. In contrast, only 28% (16–40%) showed improvement with ETA. There was no difference in the proportion of responders between ADA and INF (χ^2 2.17,p=0.14), although both showed superior efficacy compared to ETA (ADA *vs* ETA χ^2 =21.1, p<0.001; INF *vs* ETA χ^2=25.5, p<0.001)

Conclusion: Although randomized controlled trials are needed, the available evidence does not support the use of ETA in the treatment of childhood ACU.; ADA and INF seem instead reliable approach for their treatment.

Patients with Juvenile Idiopathic Arthritis From a Low Socio-Economic Background Perceive Their Disease Activity and Physical Limitations Higher Than Patients from a High Socio-Economic Background. Suzanne Verstappen[1], Joanna Cobb[2], H. E. Foster[3], Eileen Baildam[4], Lucy R. Wedderburn[5], Janet Gardner-Medwin[6], Alice Chieng[7], Joyce Davidson[6], Wendy Thomson[8] and Kimme L. Hyrich[9]. [1]University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [3]Newcastle Hospitals NHS Foundation Trust and Great North Children's Hospital, Newcastle Upon Tyne, United Kingdom, [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [5]University College London (UCL), London, United Kingdom, [6]Royal Hospital for Sick Children, Glasgow, United Kingdom, [7]Manchester Children's Hospital, Manchester, United Kingdom, [8]Arthritis Research UK Epidemiology Unit, Manchester, United Kingdom, [9]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester Academy of Health Sciences, Manchester, United Kingdom

Background/Purpose: It has been suggested that socio-economic status (SES) may be associated with delayed to access to rheumatology care and with worse disease severity in patients with juvenile idiopathic arthritis (JIA). The objectives of this study were to examine the association between SES and delay to rheumatology clinic and disease severity in patients with JIA in England.

Methods: Consecutive children from the Childhood Arthritis Prospective Study (CAPS), a large prospective longitudinal inception cohort study, were included. At baseline, a clinical examination was performed including the physician's global assessment (PGA), number of active and limited joints and

JADAS71. The CHAQ, pain score, the parental general evaluation (PGE) and the CHQ, including several physical and psychosocial concepts (higher scores indicate better functioning and well-being), were completed by the child or parent. Using postcode data, SES was determined by calculating the Index of Multiple Deprivation score (IMD). Based on the ranking of the IMD score, patients were included in the low SES group (lowest quartile), middle SES group (two middle quartiles) and high SES group (highest quartile). Differences in demographic and disease characteristics between these three groups were statistically tested applying the Kruskal-Wallis test or Chi-square test for gender.

Results: 934 JIA patients with a median age of 6.8 [IQR 2.9-10.9] yrs at baseline were included in this study. At baseline the percentage of patients according to the ILAR subtypes for the low, middle and high SES classes were, respectively: systemic (3.6%, 6.8%, 8.0%), oligoarthritis (54%, 51%, 48%), extended oligoarthritis (1.6%, 2.4%, 2.5%), polyarthritis RF- (13.6%, 18.4%, 19.0%), polyarthritis RF+ (4.2%, 2.9%, 2.5%), enthesitis related arthritis (4.2%, 5.8%, 5.5%), psoriatic arthritis (6.1%, 4.2%, 5.5%), undifferentiated (7.2%, 5.8%, 4.9%), other (5.5%, 3.2%, 4.3%). There was no difference in delay to first rheumatology consultation between the three SES groups. Although no significant differences in diseases activity scores assessed by the rheumatologist were observed between the three SES groups, children and/or parents of children with JIA in the low SES group recorded higher pain scores, disease activity scores and lower physical function scores than those in the high SES group. SES did not seem to impact on psycho-social outcomes as measured in the CHQ.

Table. Demographic clinical and self-reported outcomes of disease related factors in JIA patients from low, middle and high socio-economic background

	Low SES group N = 177	Middle SES group N = 419	High SES group N = 338	P-value
Age at onset, yrs	7.6 [3.5–115]	6.1 [2.5–10.8]	6.3 [2.8–10.3]	0.0103
Gender, female	211 (62%)	265 (63%)	112 (63%)	0.843
Delay to 1st rheumatology consultation, yrs	0.37 [0.19–0.86]	0.41 [0.19–0.86]	0.35 [0.17–0.91]	0.3929
JADAS71	12.2 [5.6–16.7]	10.8 [6.0–18.1]	20.3 [5.5–16.0]	0.6620
PGA, mm	28 [17–50]	29 [15–51]	29 [13–53]	0.9744
No. limited joints	1 [1–3]	1 [1–3]	1 [0–3]	0.8891
No. active joints	2 [1–5]	2 [1–5]	2 [1–4]	0.7333
CHAQ-score	0.875 [0.312–1.625]	0.625 [0.125–1.375]	0.375 [0–0.875]	0.0001
Pain score, mm	39 [14–64]	30 [6–55]	18 [4–49]	0.0003
PGE, mm	30 [7–52]	20 [3–50]	15 [4–36]	0.0013
CHQ score				
Physical functioning	56 [28–89]	72 [33–94]	89 [39–100]	0.0016
Role social limitations	50 [33–100]	75 [33–100]	86 [67–83]	0.0043
Bodily pain/discomfort	40 [20–60]	50 [20–70]	50 [30–80]	0.0081
Behaviour	73 [56–83]	68 [56–83]	77 [60–85]	0.3698
Mental health	75 [55–85]	75 [60–85]	75 [65–85]	0.3379
Self esteem	73 [54–88]	71 [50–83]	75 [67–88]	0.1167
General health perception	60 [43–75]	64 [52–73]	70 [60–81]	0.0028
Parental impact-emotional	67 [33–83]	58 [33–83]	67 [42–83]	0.4277
Parental impact - time	89 [56–100]	89 [56–100]	89 [67–100]	0.3193
Family activities	71 [48–88]	79 [50–96]	83 [58–96]	0.0176
Family cohesion	85 [60–85]	85 [60–85]	85 [60–85]	0.9630

Scores are median [IQR] or %

Conclusion: Patients from lower SES background score their disease activity and functional disability higher than patients from higher SES background, whereas no differences were found in disease activity scores obtained in clinic between the different SES groups. This study suggests that it is important to take SES background into account when patients with JIA present to the clinic for the first time.

Risk Factors for Radiologic Progression in Polyarticular Juvenile Idiopathic Arthritis Patients Treated with Biologic Agents. Tomohiro Kubota[1], Tsuyoshi Yamatou[1], Yukiko Nonaka[1], Harumi Akaike[2], Tomokazu Nagakura[3], Yuichi Yamasaki[1], Tomoko Takezaki[1], Yasuhito Nerome[1], Hiroyuki Imanaka[1] and Syuji Takei[1]. [1]Kagoshima University, Kagoshima City, Japan, [2]Kagoshima University, Kagoshima, Japan, [3]House of Megumino-seibo, Usuki, Japan

Background/Purpose: Progression of joint damage is sometimes observed in JIA patients during the biologic therapy. However, it is difficult to evaluate the radiographic progression by simple radiographs because the width of joint space and ossification varies with age. Carpal length (CL) is a useful measure component for identifying joint space narrowing due to cartilage damage of the wrist in children[1–2].

Therefore, the risk factors for radiologic progression during the biologic therapy were investigated by evaluating the CL in polyarticular JIA patients.

Methods: Forty-six polyarticular JIA patients initiating biologics were followed up prospectively for mean 3.1 years. RF was positive in 36 out of 46, and all had active arthritis in the wrist at starting biologic therapy. Duration from the onset to initiating biologics was mean 3.1 years, and the 1st biologic agents used were etanercept in 21, adalimumab in 7, infliximab in 9, and tocilizumab in 9. CL was measured from radiographs of the wrist obtained at baseline (n=46), at 1year (n=36), and at 3 year (n=20), and the standard deviation (SD) of CL calculated by Poznanski's formula established from healthy children[1] was analyzed.

Results: 1) Changes in CL (SD) from baseline (Figure).
At 1 year after starting biologics, incidence of patients with increased (improved) or sustained CL(SD) was 61%, which indicated that 61% patients had no radiographic progression of joint damage of the wrist during the first year of biologic therapy. At 3 year from baseline, 70% of patients showed no radiographic progression of joint damage.

2) Risk factors for progression of joint damage.

Background, clinical features, disease activity by $DAS28_{ESR}$, and the biologic therapy were compared between two groups of patients with improved/sustained CL(SD) and with non-improved CL(SD) to determine the risk factors for radiologic progression after 1 year biologic therapy.

As the result, incidence of the patients showed no statistical difference between the two groups as to sex (male, female), onset age (<10 y, ≥10 y), RF (positive, negative), disease duration at initiating biologic therapy (<1 y, $1-<3$ y, ≥3 y), 1st biologic agent used, and episode of switching to the 2nd biologic agent. However, the incidence of patients who attained $DAS28<2.6$ remission was significantly higher in improved/sustained CL(SD) group (100%) than that of non-improved CL(SD) group (46%) (Qui square=7.038, P=0.0080).

Conclusion: Biologics can prevent the radiologic progression of wrist in only patients who attained the $DAS28<2.6$ remission during the first year treatment. Switching to the 2nd biologic agent may be needed in polyarticular JIA patients who failed to complete the $DAS28<2.6$ remission.

Orofacial Anomalies in Children with Confirmed Juvenile Idiopathic Arthritis. Bernd Koos[1], Franka Stahl de Castrillon[2], Robert Ciesielski[1] and Nikolay Tzaribachev[3]. [1]University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, [2]Department of Orthodontics, University of Rostock, Germany, Rostock, Germany, [3]Center for Rheumatic Diseases, Bad Bramstedt, Germany

Background/Purpose: In children with juvenile idiopathic arthritis (JIA) temporomandibular joints (TMJ) are affected in up to 96% of the patients,

where TMJ arthritis is frequently asymptomatic. Despite that, orofacial anomalies occur in many patients and tend to be correlated with dysfunction and excessive mechanical strain, which may complicate treatment and aggravate TMJ destruction.

To examine the prevalence and severity of relevant orofacial anomalies in patients with JIA compared to healthy children and to assess the correlation with Gadolinium (Gd) enhanced MRI.

Methods: TMJ data of 216 consecutive JIA patients (69% female, median age 12.9 years) were compared to TMJ data of 3756 healthy children (Stahl, Grabowski et al., 2007; Hirsch et al., 2009). JIA patients were divided into group I (2-10 years) and group II (10-18 years). The following measurements were taken: occlusal relations, mandibular position, deep and open bite (group I) and TMJ noise, tenderness to palpation of the TMJ or the masticatory muscles, reduced mouth opening (group II). In a subgroup (37 consecutive JIA patients, 57% female, median age 11.1 years) Gd MRI examinations were analyzed and compared to functional measurements. Sensitivity and specificity of the functional measurements were determined.

Results: Mandibular asymmetry was found in 35% of patients (15% right, 20% left; no correlation with sex; $p = 0.76$). Inhibited mandibular growth (distocclusion) was seen in 59% of patients (no correlation with sex; $p = 0.57$). Open bite was seen in 6.5%, deep bite in 33% of the children.

TMJ arthritis was demonstrated in 81% of the children from the MRI subgroup. Pathological TMJ sounds were present in 26% of the patients, but showed no statistical significance ($p = 0.16$). TMJ and masticatory muscles tenderness were present in 46.8% and 40.2%, respectively. Limitation of the interincisal opening was found in 14.4% of the patients. A positive statistical correlation was found for these functional measures (tenderness to palpation $p \leq 0.001$ and limitation of interincisal opening $p = 0.002$), but sensitivity was low at 53% (specificity: 89%).

Conclusion: The prevalence of orofacial abnormalities is noticeably increased in JIA patients compared to healthy children, particularly inhibition of the mandibular growth and mandibular asymmetries. Clinical findings and inflammatory state of TMJ does not reliable correlate. This mandates interdisciplinary TMJ treatment including orthodontics especially with respect to the high prevalence of TMJ dysfunction.

Factors Associated with Achievement of Inactive Disease in Children with Juvenile Idiopathic Arthritis Treated with Etanercept. Nicoletta Solari[1], Elena Palmisani[1], Alessandro Consolaro[1], Sara Dalprà[1], Benedetta Schiappapietra[1], Giulia Bracciolini[1], Silvia Rosina[1], Giorgia Negro[1], Alberto Martini[2] and Angelo Ravelli[3]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: The advent of new therapies for juvenile idiopathic arthritis (JIA), particularly the introduction of biologic medications, has increased considerably the potential for treatment benefit, with clinical remission being now a realistic goal for a substantial proportion of patients. However, the assessment of remission has seldom been incorporated in clinical trials of biologics in JIA. Moreover, little information exists on predictors of the effectiveness of biologic medications. The study aim was two-fold: 1) to evaluate the rate of inactive disease (ID) in children with juvenile idiopathic arthritis (JIA) treated with etanercept (ETN); 2) to identify clinical characteristics associated with attainment of ID.

Methods: The clinical chart of all consecutive JIA patients who were given ETN between 2002 and 2011, and had a follow-up of at least 6 months after ETN start were reviewed. For each patient, all visits made from ETN initiation to the last follow-up evaluation in which the patient was still receiving ETN were examined to establish whether the patient had reached the state of ID, defined by the Wallace criteria (J Rheum 2004;31:2290-4), and to identify the first visit in which ID was documented. Clinical characteristics associated with achievement of ID were sought for by means of univariate analyses and Cox regression procedures. Predictive factors included sex, age at disease onset, age and disease duration at treatment baseline, interval between first observation at study center and start of ETN, ILAR category, antinuclear antibody status, JIA outcome measures at ETN start, joints affected before ETN start, and medications administered before ETN start and administered concomitantly during ETN therapy.

Results: A total of 173 patients who received ETN for a median of 2.2 years (range 0.5–10.5 years) were included in the study. Eighty-seven patients (50.3%) achieved ID a median of 0.6 years (range, 0.1–2.5 years) after the initiation of ETN therapy. The rate of ID was much lower in children with systemic JIA than in those with non-systemic categories altogether (29.6% vs. 54.1%). At last follow up visit, 0.5 to 10.5 years after ETN start (median, 2.2 years), 85 patients (49.1%) still had ID and 70 patients (40.5%) met the criteria for clinical remission on medication. The probability of achievement of ID after 6, 12 and 24 months of therapy was 24%, 46% and 57%, respectively. On Cox regression analysis, the attainment of ID was associated with lack of wrist involvement [HR_{Adj} (95% CI): 2.19 (1.38-3.48), p=0.0006] and an age at onset < 3.6 years [HR_{Adj} (95% CI): 1.61 (1.04- 2.49), p=0.03]. A secondary analysis made after the exclusion of the 27 children with systemic JIA led to identify the same predictors

Conclusion: Around half of our JIA patients treated with ETN in standard clinical care were able to achieve the state of ID. Children who lacked wrist involvement and had a younger age at disease onset had a greater likelihood of achieving ID during ETN administration. Thus, the presence of wrist disease and an older age at disease presentation may constitute an indication for the earlier introduction of ETN or its administration in combination with methotrexate.

Cron[16] and Angelo Ravelli[5]. [1]Istituto di Ricovero e Cura a Carattere Scientifico G. Gaslini, Genova, Italy, [2]International Investigator Consortium for MAS Diagnostic Criteria, Ankara, Turkey, [3]International Investigator Consortium for MAS Diagnostic Criteria, Newcastle upon Tyne, United Kingdom, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [5]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy, [6]University of Naples Federico II, Naples, Italy, [7]International Investigator Consortium for MAS Diagnostic Criteria, Ljubljana, Slovenia, [8]International Investigator Consortium for MAS Diagnostic Criteria, Catania, Italy, [9]International Investigator Consortium for MAS Diagnostic Criteria, Rio de Janeiro, Brazil, [10]International Investigator Consortium for MAS Diagnostic Criteria, Zurich, Switzerland, [11]International Investigator Consortium for MAS Diagnostic Criteria, Chieti, Italy, [12]International Investigator Consortium for MAS Diagnostic Criteria, Saint-Petersburg, Russia, [13]International Investigator Consortium for MAS Diagnostic Criteria, Buenos Aires, Argentina, [14]International Investigator Consortium for MAS Diagnostic Criteria, Ancona, Italy, [15]Karolinska Institutet, Karolinska University Hospital Solna, Stockholm, Sweden, [16]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: A multinational collaborative effort aimed to develop a new set of criteria for macrophage activation syndrome (MAS) complicating systemic juvenile idiopathic arthritis (sJIA) has been recently started. The first step of the project, based on a Delphi survey, has been completed (Davì S et al. J Rheumatol 2011;38:764-8). The second step, whose goal is to collect the data of a sizable sample of children with MAS and with potentially 'confusable' conditions, is currently under way. The study aim is to describe the demographic, clinical, laboratory, histopathologic, therapeutic and prognostic features of children with MAS collected so far in the data-collection phase of the project.

Methods: Investigators who participated in the Delphi survey were asked to enter the information of their patients with MAS collected retrospectively in a web-based database, developed by the Pediatric Rheumatology International Trials Organization (PRINTO).

Results: At the 31st of May, 2012, 312 patients with sJIA-associated MAS have been entered in the study website by 87 investigators from 27 countries. 181 (58%) patients were females and 131 (42%) were males. The age at onset of sJIA ranged from 0.2 to 15,9 years (median 5,1 years) and the disease duration from onset of sJIA and onset of MAS ranged from 0 to 15,6 years (median 0,3 years). MAS occurred at onset of sJIA in 50 (20,2 %)

patients. The frequency of the clinical, laboratory and histopathologic features of MAS is reported in the Table. The most frequently reported trigger of MAS was active disease (35,3%), followed by infection (26,3%) and medication toxicity (3,7%). 69 (37,1%) patients were admitted in the ICU. Therapeutic interventions included iv steroids (88.0%), oral steroids (74.1%), cyclosporine (65.5%), other immunosuppressants (13.8%), iv Ig (36.3%), etoposide (11.1%), anakinra (6.8%), and plasma exchange (5.4%). The mortality rate was 8.2%.

Table. Frequency of clinical, laboratory, histopathologic features of 312 patients with MAS.

Feature	No. with info available	Percentage
Falling platelet count ($\leq 262 \times 10^9$/l)	286	74.8
Hyperferritinemia (≥ 500 ng/ml)	256	91.4
Bone marrow hemophagocytosis	214	60.7
Increased liver enzymes (AST > 59UI/L)	275	74.9
Falling leukocyte count ($< 4 \times 10^9$/l)	285	21.1
Persistent continuous fever $\geq 38°C$	302	63.9
Hypofibrinogenemia ($\leq 2,5$ g/l)	250	48.4
Hypertrigliceridemia (≥ 265 mg/dl)	221	43.9
Central nervous system dysfunction	302	36.1
Increased D-dimer (≥ 500 ng/ml)	105	88.6
Hemorrhagic manifestations	301	20.9
Liver enlargement	305	70.5
Spleen enlargement	301	59.5

Conclusion: Hyperferritinemia, increased liver enzymes and falling platelet count were the most frequently observed laboratory abnormalities. The frequency of falling leukocyte count was unexpectedly low. Also unexpectedly, liver and spleen enlargement were recorded more frequently than persistent continuous fever. Hemophagocytosis was noticed in around two third of patients who underwent bone marrow aspirate. As expected, corticosteroids and cyclosporine were the most commonly administered medications.

Golimumab in 25 Young Adults Affected by Juvenile Idiopathic ARTHRITIS NON Responders to OTHER Biological Agents: Preliminary DATA. Irene Pontikaki[1], Orazio De Lucia[1], Maurizio Gattinara[1], Alessandra Salmaso[1] Pier Luigi Meroni[2] and Valeria Gerloni[1]. [1]Orthopedic Institute Gaetano Pini, Milano, Italy, [2]Istituto G. Pini, University of Milan, Milano, Italy

Background/Purpose: Biological agents licensed in JIA have demonstrated a favourable benefit-to-risk profile. Nevertheless, intolerance, loss and lack of efficacy or adverse events have led to try other therapeutic options. Ultrasound can help in the assessment of active synovitis. The purpose of this study was to evaluate efficacy and safety of Golimumab in young adults affected by JIA with active polyarthritis (with or without uveitis), non responders to MTX, antiCD20 and anti-IL-1 and intolerant to the first generation of antiTNF (Infliximab, Etanercept and Adalimumab) by EULAR criteria and power Doppler ultrasound (PDUS).

Methods: In our Centre, since november '99 to dicembre 2011, 288 patients affected by refractory JIA were treated with TNF inhibitors and since May 2011, 25 patients (16 F, 9 M) affected by refractory JIA, non responders to other biologic agents, were enrolled in Golimumab (Simponi).

Patients had failed MTX as monotherapy, previous TNF inhibitors, Rituximab and anti-IL1 therapy. Two patients had been treated with 8 different biologic agents, 1 patient with 7, 2 patients with 6, 5 patients with 5, 3 with 3, 7 with 2 and 3 patients with just one previous biologic agent.

Two patients had a Systemic onset of JIA, 4 polyarthritis RF negative, 3 enthesitis related arthritis, 1 psoriatic arthritis, 6 oligoarthritis persistent and 9 oligoarthritis extended. Median age was of 28.7 years, median onset age 7.3 years, median disease duration 19.8 years. All patients had active

disease according to EULAR criteria, 8 patients had a previous history of chronic Iridociclitis. Patients received Golimumab at the dose of 50 mg subcutaneously every month, as in RA. Fifteen patients receive Golimumab in association with MTX. All patients underwent basal assessment of DAS 28 and after 4 months DAS 28 and PDUS assessment of the same 28 joints. Presence of synovitis at PDUS examination was considered in presence of at least one between joint effusion, synovial thickening and power Doppler signal detected in accordance to OMERACT criteria.

Results: Seventeen patients (68%) were responders according both to DAS 28 and PDUS, 5 patients were not evaluable because of follow-up less than 12 weeks and 3 patients were non responders (1 of these 3 pts dropped-out). In non responder patients PDUS showed a higher number of joints involved. No adverse events were observed. No adverse events occured.

Conclusion: Golimumab seems to be effective and well tolerated and could be a good treatment of long lasting refractory JIA in young adults who failed other biologics. Data found are confirmed by PDUS examination. This study seem to be one of the first experiences in the use of Golimumab in young adults affected by JIA.

Cost-Effectiveness Analysis of Early Biologic Treatment in Polyarticular Juvenile Idiopathic Arthritis. Nadia Luca[1], Heather Burnett[2], Wendy Ungar[2], Timothy Beukelman[3], Brian M. Feldman[2], Gwen Schwartz[4] and Ahmed Bayoumi[5]. [1]Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]St. Michael's Hospital, Toronto, ON, [5]Keenan Research Centre of the Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, ON

Background/Purpose: The optimal timing of high cost biologic therapies in the treatment of polyarticular juvenile idiopathic arthritis (JIA) is uncertain. We evaluated the economic and health outcomes of initial compared with step-wise use of anti-tumor necrosis factor (TNF) agent, etanercept (ETN), in this setting.

Methods: We conducted a cost-utility analysis of two strategies from a Canadian health care payer perspective. In one strategy, initial therapy was with methotrexate (MTX) alone. ETN was added in a step-wise fashion for patients who did not respond to MTX. In the other strategy, initial therapy was with MTX in combination with ETN; patients who did not respond switched to another anti-TNF agent. In both strategies, third and fourth line therapies were modeled with additional biological agents. Our base case was a 12-year-old child (weight 40 kg) with newly diagnosed polyarticular JIA naïve to disease-modifying and biological agents. We simulated the course of the disease over 5 years using a Markov model with a cycle length of 1 month. Treatment response was defined as achieving an ACR Ped 70 response or better after 4 months of therapy. If this response was sustained over 12 months, without flare, patients entered a remission state. We derived model parameters, including treatment efficacy, disease flares, adverse events, costs, and quality of life weights from the medical literature. Effects were calculated as quality-adjusted life years (QALYs); costs and QALYs were discounted at a rate of 3% per year. We conducted sensitivity analyses on all model parameters to assess the robustness of our results and used a $50,000/QALY threshold for cost-effectiveness.

Results: Our model predicted that the proportion of patients entering remission after 5 years was 89% with initial MTX and 93% with initial MTX and ETN combination. Median time to remission was 20 months in the MTX monotherapy group and 16 months in the combination group. The combination of initial MTX and ETN, compared to MTX alone, resulted in a discounted incremental cost of $14,498 per patient over 5 years and yielded a discounted incremental effect of 0.15 QALYs, for an incremental cost-effectiveness ratio of $97,517 per QALY. The results were sensitive to the cost of ETN and estimates of the efficacy of initial combination therapy.

Conclusion: Our model suggests that using initial combination therapy of MTX and ETN is unlikely to be cost-effective compared to using MTX alone, but more research is needed on key model parameters, including efficacy of initial anti-TNF agents and their impact on quality of life. A reduction in the cost of ETN by 33% would make initial use of this drug cost-effective.

Obstetrical Complications in Women with Juvenile Idiopathic Arthritis.
Evelyne Vinet[1], Sasha Bernatsky[2], Mohammed Kaouache[2], Christian A. Pineau[1], Ann E. Clarke[3], Elizabeth Hazel[1], Ciaran M. Duffy[4], Anick Bérard[5] and Debbie Ehrmann Feldman[6]. [1]McGill University Health Centre, Montreal, QC, [2]Research Institute of the McGill University Health Ctre, Montreal, QC, [3]MUHC, Montreal, QC, [4]Children's Hospital of Eastern Ontario, Ottawa, ON, [5]Université de Montréal, [6]Université de Montréal, Hampstead, QC

Background/Purpose: Juvenile idiopathic arthritis (JIA) most often affects women before childbearing age. Patients with JIA and their parents often ask about the potential impact of the disease on future pregnancies. Little is known about the risk of obstetrical complications in women with JIA. In a large population-based study, we aimed to determine if women with JIA have an increased risk of obstetrical complications compared to women without JIA.

Methods: We identified all women who had a hospitalization for their first delivery after JIA diagnosis using Quebec's physician billing and hospitalization databases (1996–2008). Women were defined as JIA cases if they had ≥ 1 hospitalization with the *International Classification of Diseases, Ninth Revision* (ICD-9) code 714, as a primary or secondary diagnosis, or ≥ 2 physician visits with the ICD-9 code 714, occurring 2 months to 2 years apart, both prior to the age of 18 years and prior to the delivery. We randomly selected a general population control group, composed of women with their first delivery and matched at least 3:1 for age and year of delivery, without a preceding diagnosis of JIA.

We ascertained the length of hospitalization for delivery, the occurrence of gestational diabetes, premature rupture of membranes (PROM), preeclampsia/eclampsia, and caesarean section (c-section), at the time of hospitalization for delivery, based on relevant diagnostic or procedures codes.

Results: We identified 1406 women with JIA. Of these women, 90 had their first delivery after JIA diagnosis, during database follow-up, and were matched to 448 controls. Mean age at JIA diagnosis was 15.3 years (95% CI 14.8, 15.8) and mean age at delivery was 22.9 years (95% CI 22.3, 23.5). There was no difference in the length of hospitalization for delivery between women with JIA and controls [3.2 days (95% CI 2.9, 3.5) vs 2.8 days (95% CI 2.7, 3.0)]. Compared to controls, women with JIA did not experience more gestational diabetes [1.1% (95% CI 0.1, 6.9) vs 1.1% (95% CI 0.4, 2.7)], PROM [8.9% (95% CI 4.2, 17.3) vs 8.3% (95% CI 6.0, 11.3)], preeclampsia/eclampsia [3.3% (95% CI 0.9, 10.1) vs 4.7% (95% CI 3.0, 7.2)], or c-section [20.0% (95% CI 12.6, 30.0) vs 20.5% (95% CI 17.0, 24.6)].

Conclusion: Our findings suggest that women with JIA do not seem to have an increased risk of obstetrical complications compared to the general population. We are currently expanding this study by performing mother-child linkage to further assess neonatal outcomes in children born to women with JIA and their controls.

1170

Folate Usage in Methotrexate - Treated Juvenile Idiopathic Arthritis Patients Is Inconsistent and Highly Variable.
Gil Amarilyo[1], Ornella J. Rullo[1], Deborah K. McCurdy[1], Jennifer M.P. Woo[1] and De Furst[2]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]University of California at Los Angeles, Los Angeles, CA

Background/Purpose: Low-dose weekly methotrexate (MTX) is the first-choice second-line drug in the treatment of juvenile idiopathic arthritis (JIA). Folate (as either Folic acid (FA) or Folinic acid (FLA)) effectively ameliorates or prevents some of MTX's adverse events (AE) in adults with RA. Folate supplementation in JIA, therefore, has become the standard of care in many medical centers. Although widely used in JIA patients, including in research studies, the evidence for folate-use in JIA to prevent AEs is based on only one-43 patient, non-randomized retrospective case series. To begin defining the most commonly used folate regimens, we examined the methods of folate supplementation in MTX-treated JIA patients among pediatric rheumatologists around the globe, using an electronic survey.

Methods: An Internet-based survey was distributed among the registrants of the pediatric rheumatology list serve, an electronic forum and mailing list, which hosts 1040 subscribers worldwide. The survey was initiated between March and April 2011 and followed up with 3 subsequent electronic reminders. Chi-square tests of proportions were used to compare the distribution of responses between US and Non-US populations. A Bonferroni corrected significance level of 0.0125 was used to account for repeated testing.

Results: 214 pediatric rheumatologists from 25 countries responded to the survey (table 1). 11.7% of respondents do not routinely use ANY folate supplementation unless the patient experiences AEs during the course of treatment; 72.5% prescribe only FA; 5.1% prescribe only FLA; and 10.7% use both forms of folate supplementation.

Table 1. Folate supplementation in MTX-treated JIA

Regimen	Total (%, n=214)	US (%, n=128)	Non-US (%, n=86)	p-value
Folic acid	72.5	62.5	87.2	0.0001
Folinic acid	5.1	5.5	4.7	0.9600
Both	10.7	16.4	2.3	0.0024
None*	11.7	15.6	5.8	0.0484

* Only if the patient experiences adverse events during the course of treatment

An extremely wide spectrum of prescribing regimens (71 unique regimens) for folate supplementation was reported:
1) Folic acid (FA): Some physicians used multivitamin supplements as the source of their FA. Others used FA in doses between 400 mcgs and 10 mg daily, 6 days per week or only 24–48 hours after MTX intake.
2) Folinic Acid (FLA): FLA was generally used in dose ranges of 5–10 mg once a week (24 hours after MTX intake).

A majority of the responders (53.6%) agreed with the statement that they did not know which supplementation regimen was superior.

Conclusion: We found a high degree of variability among pediatric rheumatologists in how and whether folate supplementation is used in JIA. This variability, often arising from a lack of evidence and certainly true in this case, emphasizes the need for a well-designed clinical trial to support a rational regimen of either FA or FLA supplementation in MTX-treated JIA patients.

1171

Validation of BASDAI and BASFI in Children with Spondyloarthritis.
Alisa C. Rachlis[1], Bertha Wong[2], Kristi J. Whitney-Mahoney[2], Michelle Batthish[2], Michelle Anderson[2], JoAnne Marcuz[2], Margaret Reaume[2], Ashley DeLaurier[2], Ronald M. Laxer[2], Brian M. Feldman[2] and Shirley M. Tse[2]. [1]Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Juvenile-onset Spondyloarthritis (JSpAs), referred to as Enthesitis-Related Arthritis (ERA) subtype under the International League of Associations for Rheumatology (ILAR) classification is characterized by arthritis and enthesitis largely affecting the lower limbs. Axial involvement is uncommon at presentation, but may develop later in life. Although there are validated instruments assessing spinal disease in adults with Ankylosing Spondylitis (AS) such as the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI), there are no validated tools to measure disease activity or functional impairment in this population of children. We have previously reported excellent intra-rater reliability of the BASDAI and BASFI. The aims of the current study were to measure the validity and responsiveness of these two adult scores in ERA.

Methods: Patients diagnosed with ERA followed in the JSpA Clinic at The Hospital for Sick Children (June 2009 - June 2010) were enrolled into the study. The BASDAI and BASFI were measured prospectively at baseline and again at 4 to 6 months. At each study visit, joint and entheseal clinical exams were performed according to a standardized protocol. The data collected at baseline and follow up visit were used to assess construct validity and were expressed using Pearson's correlation coefficient. Responsiveness (sensitivity to change) was calculated in a subgroup of patients who showed changes in their joint and entheseal counts over time by dividing the mean change between the two assessments by the standard deviation of the change scores and was expressed by effect size.

Results: There were 41 patients (85% male) with a mean age at diagnosis of 12.1 ± 7.6 years and average age at enrollment of 14.5 ± 2.5 years.

Average disease duration at the time of the study was 5.1 ± 2.4 years. 46% were HLA B27 positive, 17% had a family history of Spondyloarthritis. 70% had SI involvement confirmed radiographically. The average time between baseline and follow up clinic visits was 4.6 ± 2.3 months. Correlations between both the BASDAI and the BASFI and active joint counts were found to be high ($r = 0.6$) while correlations with sites of enthesitis were found to be moderate (r = 0.3 – 0.4). Responsiveness was greatest in effect size for the BASDAI for detecting worsening arthritis (0.8) and improving enthesitis (0.7). For the BASFI, effect size was large for detecting worsening arthritis (0.9) and was moderate for improving enthesitis (0.4).

Conclusion: Our study demonstrates that the BASDAI and the BASFI show adequate construct validity and responsiveness and may be used in the evaluation of disease activity and functional impairment in children with JSpA. Correlations were higher for both measures in arthritis than in enthesitis, and sensitivity to changes over time showed the largest effect sizes for detecting worsening arthritis. For enthesitis, the BASDAI showed a larger effect size for detecting improving enthesitis than the BASFI. The results of this study illustrate that these two instruments validated in adults may become an objective addition to developing Paediatric JSpA core sets.

Background/Purpose: Intra-articular corticosteroid injection (IACI) therapy in juvenile idiopathic arthritis (JIA) is generally considered for the treatment of children with arthritis in a small number of joints, particularly large joints. However, the current place of multiple IACIs in the management of JIA is still uncertain. The aim of this study was to investigate the efficacy and safety of multiple IACIs, and to seek for factors associated with sustained remission of synovitis in injected joints.

Methods: The clinical charts off all JIA patients who received an IACI in ≥ 3 joints and had a follow-up ≥ 6 months after the IACI were reviewed. The corticosteroid preparation used was triamcinolone hexacetonide for large joints and methylprednisolone acetate for small or difficult to access joints. In each patient, the follow-up period after the IACI was censored when one of the following two events occurred: 1) first visit with flare of synovitis in ≥ 1 injected joint; 2) last follow-up visit with sustained remission of synovitis in all injected joints. Flare of synovitis was defined as recurrence (or persistence) of joint inflammation in ≥ 1 joint that required a new IACI or the initiation or change of systemic therapy, and remission of synovitis as complete resolution of all signs and symptoms of joint inflammation.

Results: A total of 220 patients (79.5% females) who underwent an IACI in 1086 joints (median 4 joints per patient) were included. The median age at IACI was 3.7 years and the median disease duration was 0.6 years. The most common ILAR categories were RF-negative polyarthritis (37.1%) and extended oligoarthritis (34.1%). The most frequently injected joints were the knee (84.5% of patients), ankle (76.4%), subtalar (30.5%), elbow (29.1%), and proximal interphalangeal (PIP) (26.4%) joints. Concomitant therapy included methotrexate in 56.8% of patients and biologic medications in 9.5% of patients. Seventy (31.8%) of patients had sustained remission in all injected joints after a median follow-up of 1 year, whereas 150 patients (68.2%) experienced flare of synovitis after a median of 0.5 years. Univariate analyses showed that patients with sustained remission had more frequently a positive ANA status (p=0.04) and an oligoarticular disease course (p=0.004), and had received more frequently general anesthesia (p=0.03) and concomitant methotrexate therapy (0.003) than did patients who experienced flare of synovitis. Flare of synovitis was seen more frequently in the ankle (45.2%), wrist (40.2%), and subtalar (34.5%) joints, than in the knee (20.8%), metacarpophalangeal (26.2%), PIP (21.3%), and elbow (15.5%) joints. Side effects occurred in only 1% of joints and were represented by skin hypopigmentation or subcutaneous atrophy.

Conclusion: Around one third of the patients who received multiple IACIs experienced long-lasting remission of synovitis in all injected joints.

General anesthesia and concomitant administration of methotrexate may increase the effectiveness of IACI procedures. The presence of ankle, subtalar and wrist joint involvement may constitute an indication to the simultaneous initiation of a more aggressive systemic therapy at the time of the injection.

Targeting Remission in Juvenile Idiopathic Arthritis in Routine Clinical Care: Experience in 175 Newly-Diagnosed Patients.
Alessandro Consolaro[1], Giorgia Negro[1], Nicoletta Solari[1], Cristina Ferrari[1], Sergio Davì[1], Silvia Pederzoli[1], Giulia Bracciolini[1], Maria C. Gallo[1], Alberto Martini[2] and Angelo Ravelli[3]. [1]Istituto Giannina Gaslini, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: The recent advances in the management of juvenile idiopathic arthritis (JIA) have increased considerably the potential to achieve disease remission or, at least, low levels of disease activity, and have consequently moved the therapeutic aims increasingly towards the attainment of an inactive disease (ID) status. Complete disease quiescence is regarded as the ideal therapeutic target because its achievement helps preventing further joint damage and disability and may enhance physical function and quality of life. These issues have led to suggest that a tight control approach be adopted in the management of children with JIA. We describe our experience with treating JIA patients to specified targets.

Methods: Starting in March 2007, a treat-to-target approach to the management of all children with JIA first seen in the senior author's clinic was implemented, setting achievement of ID as primary goal and achievement of minimal disease activity (MDA) or parent-acceptable symptom state (PASS) as secondary goal. In case primary goal was not reached, treatment was intensified as deemed necessary. For the purpose of this study, patient records were reviewed to evaluate the frequency of achievement of primary and secondary therapeutic goals at 6, 12, 18 and 24 months following initial evaluation. ID, MDA and PASS were defined according to both established criteria and Juvenile Arthritis Disease Activity Score (JADAS) cutoffs. The outcome of patients who achieved or did not achieve ID at last follow-up visit was compared by means of the Juvenile Arthritis Functionality Scale (JAFS) and the Pediatric Rheumatology Quality of Life scale (PRQL).

Results: A total of 175 patients (77.7% females) were enrolled. The most common ILAR subtypes were persistent oligoarthritis (53.1%), extended oligoarthritis (14.9%), and RF-negative polyarthritis (14.3%); 3.4% of patients had systemic arthritis. The median age at disease onset was 2.8 years. At baseline visit, the median age was 3.5 years and the median disease duration was 0.2 years. Initial therapeutic interventions included intra-articular corticosteroid injection (84%), methotrexate (28%), systemic corticosteroids (5.7%), and biologic medications (1.1%). The frequency of achievement of treatment goals at study endpoints is shown in the table. At last follow-up visit, patients who had achieved ID had better functional ability (p=0.007) and physical well-being (p=0.007) than those who did not. The frequency of clinical remission on medication was 29.2%.

	6 months N (%)	12 months N (%)	18 months N (%)	24 months N (%)
Inactive disease (ID)	50 (35.2)	48 (41)	46 (47.4)	45 (50.6)
Minimal disease activity (MDA)	62 (43.7)	71 (60.7)	60 (61.9)	53 (59.6)
Parent-acceptable symptom state(PASS)	76 (66.1)	77 (74.8)	69 (82.1)	53 (70.7)
JADAS10 ≤ 1 (ID)	43 (31.6)	46 (41.4)	43 (46.2)	33 (39.3)
JADAS10 ≤ 2/3.8 (MDA)	51 (37.5)	58 (52.3)	60 (64.5)	40 (47.6)
JADAS10 ≤ 3.5/5.4 (PASS)	64 (47.1)	66 (59.5)	67 (72)	52 (61.9)

Conclusion: At 2 years after initial visit, a substantial percentage of patients had reached the states of ID or MDA or were in PASS. Patients who achieved ID had better physical function and well-being than those who did not. These findings suggest that the implementation of a treat-to-target approach may help improve patient outcomes.

Severe Adverse Events Associated with Use of Biologic Therapy in Juvenile Idiopathic Arthritis: A Single-Center Study. Ricardo A. G. Russo[1] and Marìa M. Katsicas[2]. [1]Hospital de Pediatrìa Garrahan, Buenos Aires, Argentina, [2]Hospital de Pediatrìa Garrahan, Buenos Aires, Argentina

Background/Purpose: biologic agents have revolutionized the treatment of Juvenile Idiopathic Arthritis (JIA) and other conditions due to their high efficacy and safety. However, with the increased and prolonged use of these agents there is uncertainty regarding adverse events, especially in the long-term. The purpose of this study is to describe and analyse SAEs occurring during biologic therapy in a cohort of patients with JIA.

Methods: unicenter, retrospective longitudinal study based on review of a prospectively built, ad-hoc database and medical records. Observation period was January 2000-December 2011. Demographic data, JIA class, disease duration at start of biologic treatment, time from start of biologic treatment to occurrence of SAEs, type and dosage of biologic agents, total time of biologic therapy, concomitant methotrexate (MTX) and prednisone therapy, system involvement during SAEs, and outcomes were recorded. SAEs were defined as any untoward medical occurrence that occurs during observation and results in death, a life-threatening illness, hospitalization, persistent or significant disability or incapacity, or a medically significant event that jeopardized the health of the patient and required intervention to prevent one of the other outcomes listed.

Results: 218 biologic treatments were administered to 145 JIA patients (83 girls; 63 systemic [SJIA], 35 RF −ve poly, 22 RF +ve poly, 16 enthesitis related, 5 extended oligo and 4 psoriatic). Age at start of biologic therapy: 12 years; disease duration at start of biologic therapy: 30 months. One biologic agent was prescribed to 101 children, 2 (sequentially) to 28, 3 to 11, 4 to 5 and 5 to 2 patients. Biologics used: etanercept (ETA, 136 treatments), infliximab (INF, 29), adalimumab (ADA, 25), tocilizumab (TOC, 12), abatacept (ABA, 10), anakinra (ANA, 5), and rituximab (2). MTX was used in combination with biologic therapy in 172 (79 %) cases, prednisone in 80 (37 %). Total time of biologic therapy: 4444 months (3342 corresponding to ETA); median duration of each biologic therapy: 13 months. Eighteen SAEs were recorded in 15 children (11 SJIA): 14 infectious (6 varicella zoster), 2 hematologic, 1 systemic autoimmune, 1 anafilaxis. Symptoms compatible with macrophage activation syndrome developed in 2 patients. SAEs occurred at 3.5 (median) months after start of biologic therapy. SAEs rate was 4.9 per 100 patient-years. SAEs were observed during ETA (11 episodes, 8% of treatments), TOC (3, 25%), and INF (1, 3%), ADA (1, 4%), ABA (1, 10%), ANA (1, 20%) therapy. Median dose of concomitant MTX was 15 mg/week, prednisone 0 mg. All patients required admission (2 ICU) and eventually improved after discontinuation of biologics and appropriate therapy. One SJIA patient on ETA developed a lupus-like disease. No malignancy or TB reactivation were observed.

Conclusion: SAEs arising during biologic therapy are infrequently observed in children with JIA They usually appear during the initial months of therapy. Patients with SJIA are at a higher risk of developing SAEs. Varicella zoster is the more common infection. Multicenter studies and international registries may provide evidence on short- and longer-term, comparative safety of different biologics.

Decreased Frequency of Th17 Cells in Early Rheumatoid Arthritis. Irene Arroyo-Villa[1], M. Belén Bautista-Caro[1], Alejandro Balsa[1], Pilar Aguado[1], Laura Nuño[1], Gema Bonilla[1], Amaya Puig-Kröger[2], Emilio Martín-Mola[1] and M. Eugenia Miranda-Carús[1]. [1]Hospital La Paz-IdiPaz, Madrid, Spain, [2]Hospital Gregorio Marañon, Madrid, Spain

Background/Purpose: Our objective was to examine the frequency and phenotype of Th17 cells in the peripheral blood of early RA (eRA) patients.

Methods: CD4+ T cells were isolated from the peripheral blood of 33 eRA patients and 33 healthy controls (HC), and from the synovial fluid of 20 established RA patients (RASF), by ficoll-hypaque gradient and magnetical negative selection. After polyclonal stimulation, the frequency of Th17 and Th1 cells was determined by flow cytometry and concentrations of IL-17, IFN-g, TNF-a and IL-10 were measured by ELISA in cell-free supernatants.

Results: When all of our eRA patients were analyzed together, a significantly lower percentage of circulating Th17 cells and a lower CD4-derived IL-17 secretion were observed in comparison with HC. However, after stratifying by anti-CCP antibody status, circulating Th17 cells were decreased in anti-CCP(+) but not in anti-CCP(−)-eRA. All Th17 cells were CD45RO+CD45RA- and CCR6+. Dual Th17/Th1 cells were also exclusively decreased in anti-CCP(+)-eRA. Circulating Th17 and Th17/Th1 cells were negatively correlated with anti-CCP titres. When anti-CCP(+)-eRA patients were retested one year after initiating treatment with oral methotrexate, their circulating Th17 frequency was no longer different from HC. Of note, the percentage of circulating Th1 cells and the secretion of CD4-derived IFN-g, TNF-a and IL-10 were not different between eRA patients and HC. In RASF, both Th17 and Th1 cells were increased when compared with blood.

Conclusion: Decreased circulating Th17 levels in eRA seem to be a marker of anti-CCP seropositivity, and return to levels observed in healthy controls after treatment with methotrexate.

Galactosylation, and Not Sialylation, of Immunoglobulin G Is Associated with Improvement of Rheumatoid Arthritis During Pregnancy. Albert Bondt[1], Maurice H.J. Selman[2], André M. Deelder[2], Johanna M.W. Hazes[1], Manfred Wuhrer[2] and Radboud J.E.M. Dolhain[1]. [1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is known to improve during pregnancy and to flare after delivery [1]. Changes in the glycosylation of immunoglobulin G's fragment crystallizable (IgG-Fc) have been suggested to play a role in this phenomenon [2]. Animal studies indicate sialylation is the effector of galactosylation mediated immune suppression [3]. In this study technical advances allowed further insight into sialylation, a previously elusive feature. We aim to find new associations between IgG-Fc N-glycosylation (galactosylation and sialylation) and the improvement of rheumatoid arthritis during pregnancy, which can give more insight into RA pathogenesis.

Methods: Sera of RA patients (n=251 pregnancies) and healthy controls (n=32), all participating in a prospective cohort study on RA and pregnancy (PARA study), were collected before conception if possible, during pregnancy, and after delivery. At all time points disease activity (DAS28-CRP(3)) was measured, and medication was recorded. Using a newly developed mass spectrometric method [4] the glycosylation of IgG Fc-glycopeptides was measured in a subclass specific manner.

Results: In both patients and controls changes in glycosylation during pregnancy have been observed. In patients IgG1 galactosylation changed from 59.3 ± 1.1 to $64.9\pm1.0\%$ (mean$\pm$SEM); sialylation from 18.7 ± 0.5 to $21.4\pm0.5\%$. Similar results were obtained for IgG2/3 and IgG4. Patient galactosylation and sialylation levels are lower compared to controls. Our data show that in patients increased galactosylation, but not sialylation, is associated with lower disease activity. Increased sialylation rates are associated with higher DAS28-CRP(3).

Conclusion: In contrast to animal studies, in patients increased galactosylation, and not sialylation, is associated with low disease activity. Our data suggest sialylation could partially inhibit the positive effect of galactosylation. These data do not only have implications for understanding the pathogenesis of RA, but may also shed new light on how glycosylation determines the function of IgG. This latter could have major consequences for the development of new monoclonals to treat human disease.

Talin Is Cleaved and Expressed As a Short Form in Patients with Rheumatoid Arthritis. Kensei Tsuzaka[1], Masako Takao[1], Naoshi Shinozaki[2] and Jiro Nishida[1]. [1]Ichikawa General Hospital,TDC, Ichikawa, Chiba, Japan, [2]Ichikawa, Japan

Methods: Western Blot analysis showed that the N-terminal 32kDa and the C-terminal 15kDa of calpain1 fragment of talin (32kDa and 15kDa short-talin, respectively) was expressed predominantly in RA patients [85.7% (36/42), 83.3% (35/42)] compared with NC [0% (0/31), 0% (0/31)] and SLE patients [25.0% (5/20), 30.0% (6/20)] (Fig. 1, Fig. 2). PBMC obtained from a NC was incubated with each of 4 RA patient PBMCs, lysed with the lysis buffer, incubated with calpain1, and were electrophoresed on a SDS-PAGE gel. Membrane was blotted with H-18. As a result, the wild-type calpain1 fragment (47kDa) of talin was degraded into 32kDa short-talin after incubating with each RA patient PBMC. Moreover, GST-talin fusion protein was cleaved into the short-talin after incubating with RA patient PBMC lysate, but was not cleaved with NC PBMC lysate. Surprisingly, Western Blot analysis using H-18 also showed predominant expression of the 32kDa short-talin in RA patient plasma. findings suggest that the intracellular talin in RA patients is cleaved into short-talin and expressed predominantly in RA patient PBMC and plasma (Fig.3). This short-talin might be related to the pathogenesis of RA.

IL-6 and IL-21 in Rheumatoid Arthritis. Gustavo Carbone[1], Augusta Wilson[1], Sean Diehl[2], Janice Bunn[3], Sheldon Cooper[4] and Mercedes Rincon[1]. [1]University of Vermont College of Medicine, Burlington, VT, [2]University of Vermont College of Medicine, [3]University of Vermont, Burlington, [4]Univ Vermont College of Med, Burlington, VT

Background/Purpose: Interleukin-6 (IL-6) levels are known to be increased in patients with rheumatoid arthritis (RA). Tocilizumab, a monoclonal antibody to the IL-6 receptor (IL-6R), reduces disease activity in RA, although its mechanisms of action remain unclear. IL-6 has been shown to regulate cytokine production by CD4 T cells during activation. The objective of this study was to determine if treatment with tocilizumab altered the phenotype and cytokine production by CD4 T cells in patients with rheumatoid arthritis.

Methods: RA patients who entered a six-month open-label Phase III clinical study of tocilizumab (ACT-STAR), also consented to enter an accompanying laboratory study. Clinical parameters were obtained at each study visit. Additional blood specimens were obtained prior to the first treatment (baseline, visit 1), second infusion (visit 2), fourth infusion (visit 4), and 1 month after the sixth infusion (visit 7). CD4 CD45RA (naïve) and CD4 CD45RO (memory/activated) cells were isolated from peripheral blood of RA patients at the above time points. Production of IL-2, IL-21, IFNg, and IL-17 upon activation *in vitro* was determined. In addition, serum was also collected to determine the levels of specific immunoglobulins.

Results: There was significant reduction in tender and swollen joint counts, and DAS28 scores with tocilizumab treatment. The relative frequency of naïve and memory CD4 T cells was not altered over the treatment period. There was no change in the production of any of the examined cytokines by CD45 RA naïve T cells during the study. In contrast, there was a marked reduction of IL-21 production by memory/activated CD4 T cells with tocilizumab treatment. In addition, tocilizumab treatment led to a profound decrease in the levels of IgG4-specific anti-CCP autoantibodies. We also show that IL-21 is a powerful inducer of IgG4 production by B cells.

Conclusion: Treatment of RA with tocilizumab selectively lowers both the production of IL-21 by the memory/activated CD4 T cell population and serum IgG4-specific autoantibody levels. Since IL-21 promotes IgG4 production by B cells, these results suggest that IL-21 may play a role in B cell activation in patients with RA, and blockade of IL-6 may down-regulate this pathway.

Vitamin D Receptor Polymorphisms Are Associated with Clinical Outcomes and IgM Responses to Common Pathogens but Not Baseline Disease Activity in Early Inflammatory Arthritis. Carol A. Hitchon[1], Linda Larcombe[1], Neeloffer Mookherjee[1], Christine A. Peschken[1], Marianna M. Newkirk[2] and Hani S. El-Gabalawy[1]. [1]University of Manitoba, Winnipeg, MB, [2]McGill University Health Centre, Montreal, QC

Background/Purpose: Vitamin D (VitD) exerts immunoregulatory activities of potential importance to rheumatoid arthritis and acts by binding to nuclear vitamin D receptors (VDRs) and regulating gene expression including cathelicidin an important mediator of host innate responses to infection. VDR genetic polymorphisms (VDrP) have been variably linked to disease activity in rheumatoid arthritis and to chronic infections. Altered host response to infection may break tolerance leading to disease. We sought to assess the association of VDR polymorphisms (Fokl, Bsm1, Apa1 and Taq1) with clinical disease activity at baseline and one year, baseline serum vitD levels, and antibody responses to common pathogens in a cohort of patients with inflammatory arthritis of less than 1 year symptom duration.

Methods: VDR SNPs at the restriction sites Bsm1 (B/b (T/C)) (rs1544410), Apa1(A/a (T/G)) (rs7975232), Taqa1(T/t (T/C)) (rs731236), Fok1 (F/f (C/T)) (rs10735810) and Cdx-2 (G/A) (rs11568820) were detected by polymerase chain reaction sequencing and analyzed using genotypic (DD vs Dd vs dd), dominant (DD, Dd vs dd), and recessive (DD vs Dd, dd) models. At first visit before DMARD treatment, 25OH VitD levels, antibody titers to E Coli and P. mirabilis (IgG, IgA and IgM), and CCP2 antibodies were measured in serum by ELISA. Smoking was assessed by self report and serum cotinine levels. Associations of VDR snps with clinical disease activity at baseline and one year and achievement of remission (DAS28CRP (3variable) <2.6) or EULAR treatment response at one year were tested.

Results: Subjects (n=228) were predominantly female (72%) and Caucasian (87%), with mean age at first visit of 47.8 years (range 17–82, SD 14), a mean DAS28CRP (3variable) 3.91 (1.35), (31% low, 50% moderate 19% high disease activity) and were RF (54%) or CCP2 positive (44%). Of the 154 subjects with one year follow-up data, 67% achieved low disease activity. The VDR minor allele frequencies were Fokl 0.42, Bsm1 0.55, Apa1 0.51, and Taq1 0.37. There was an association between Taq1 dominant alleles (TT,Tt) and at least one copy of shared epitope allele (p=0.01). No robust associations were seen between VDR polymorphisims and gender, age at first visit, RF or CCP2 or baseline disease activity. Fokl dominant alleles (FF,Ff) had higher baseline anti-E.Coli IgM titers (0.51 vs 0.34 units p<0.01) and anti-proteus IgM titers (1.34 vs 1.18 units p<0.05), and at one year had higher DAS28CRP (3 variable) scores (2.92 vs 2.44 p<0.05) and were less likely to achieve remission (41% vs 73% p<0.01). In multivariate models including CCP2, rheumatoid factor, shared epitope, smoking (ever), and baseline serum VitD, only lower baseline DAS28CRP (3 variable) (p=0.001), Fokl recessive alleles (ff) (p<0.01) and higher IgM E.Coli titers (p<0.05) predicted remission at one year.

Conclusion: Vitamin D receptor polymorphisms, especially Fokl, associate with IgM immune responses to common pathogens and associate with disease outcome in EIA but do not associate with baseline disease activity. Vitamin D receptor mediated regulation of immune responses may be important for the predisposition to inflammatory arthritis by breaking immune tolerance.

The Sex-Determining Region Y Box 6 Locus: Shared Genetic Susceptibility Between Rheumatoid Arthritis and Psychotic Disorder. Tony R. Merriman[1], Nicola Dalbeth[2], Andrew Harrison[3], John Highton[4], Lisa K. Stamp[5], Malcolm D. Smith[6], Benedicte A. Lie[7], Tore K. Kvien[8], Timothy Radstake[9], Marieke J.H. Coenen[10], Barbara Franke[10], Jasper Broen[11], Piet Van Riel[10], Pilar Barrera[10], Sophia Steer[12], Marilyn E. Merriman[1], Amanda Phipps-Green[1], Ruth Topless[1], Mansour Zamanpoor[1] and Wan Rohani Wan Tain[13]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Hutt Hospital, Lower Hutt, New Zealand, [4]Univ of Otago Med Sch, Dunedin, New Zealand, [5]University of Otago, Christchurch, Christchurch, New Zealand, [6]Rheumatologist, Adelaide, Australia, [7]Oslo University Hospital, Oslo, Norway, [8]Diakonhjemmet Hospital, Oslo, Norway, [9]Radboud University Nijmegen Medical Centre, University Medical Center Utrecht, Nijmegen, Utrecht, Netherlands, [10]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [11]Department of Rheumatology & Clinical Immunology, University Medical Center, Utrecht, Netherlands, [12]1 Sloane Ct East Flat 7, London, United Kingdom, [13]Universiti Sains Malaysia, Malaysia

Background/Purpose: Rheumatoid arthritis (RA) is a common auto-immune disease and schizophrenia (SZ) is a common psychotic disorder. There is an established negative association between RA and SZ, with some evidence for a similar relationship in bipolar disorder (BPD) (Oken and Schulzer, *Schiz Bull* 25:625, 1999). We hypothesize that the negative relationship is determined by disease-specific mutually-exclusive (genetic and environmental) factors that provide input into a common pathway, driving disease progression in both the brain and immune system. An allele confer-

ring susceptibility to RA will stimulate the hypothetical disease-causing pathway in the immune system, but will protect from SZ by preventing activation of the pathway in the brain, and *vice versa*. Our hypothesis predicts a molecular pathway(s) containing shared genetic risk variant(s) driving the pathogenesis of both diseases.

Methods: We exploited genome-wide association scan (GWAS) data by comparing the top 1000 associations from the Genetic Association Information Network (GAIN) SZ dataset and the Wellcome Trust Case Control Consortium (WTCCC) RA dataset for candidate SNPs associated with both RA and SZ in the same direction of association. Replication in RA was done over Australasian, UK, Dutch and Norwegian Caucasian case-control sample sets (3755 cases and 3084 controls) using TaqManÒ technology. For psychotic disorder, replication was done *in silico* from publicly-available non-GAIN SZ and BPD datasets (3770 cases and 5269 controls).

Results: SNP *rs900865* from the chromosome 11 INSC-SOX6 region fitted the selection criteria of consistent direction of association (OR=1.14, P=0.002 in WTCCC RA and OR=1.22, P=5×10^{-4} in GAIN SZ). In replication there was evidence for association in both the meta-analyzed RA replication dataset (OR=1.09, P=0.009) and in the combined SZ/BPD replication dataset (OR=1.09, P=0.004). Meta-analysis of all datasets (psychotic disease datasets GAIN Sz, non-GAIN Sz and BPD; and RA datasets Australasian, UK, Dutch, Norwegian and WTCCC) provided evidence of association with *rs900865* at the genome-wide level of significance (OR=1.11, P=1.8×10^{-8}).

Conclusion: We conclude that the minor allele (C) of SNP *rs900865* confers susceptibility to both RA and psychotic disease. The SNP maps between the INSC *(*inscuteable homolog) and SOX6 (sex-determining region Y box 6) genes. *INSC* is not well characterized, but is known to be involved in retinal development. *SOX6* encodes a transcriptional factor that plays a role in a number of cell developmental processes including development of the central nervous system and human skeletal development (chondrogenesis), and is expressed in both the immune and central nervous systems. Whilst the mechanism is unclear, our data do suggest a genetic relationship between RA and psychosis, perhaps in a common signaling pathway.

The Role of á-Defensin-1 and Its Signal Transduction Mechanisms in the Production of IL-6, IL-8 and MMPs in Rheumatoid Fibroblast-Like Synoviocytes. Joong Kyong Ahn[1], Bo Huang[2], Eun-Jung Park[2], Jiwon Hwang[2], Jaejoon Lee[2], Chan Hong Jeon[3], Eunmi Koh[2] and Hoon-Suk Cha[2]. [1]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea

Background/Purpose: Fibroblast-like synoviocytes (FLS) play an essential role in the pathophysiology of rheumatoid arthritis (RA). Also, neutrophils are the most abundant cell type of synovial fluid (SF) in flare-up of RA patients, suggesting that this cell plays an important role in overt inflammation in RA. α-defensin-1 is released into the extracellular milieu from neutrophils during inflammation. However, little is known of the role of α-defensin-1 in RA. We investigated the effect of α-defensin-1 on the expression of IL-6, IL-8, and MMPs and the signal transduction mechanisms responsible for these expressions in RA FLS.

Methods: The concentrations of SF α-defensin-1 from 51 RA patients and 21 OA patients were measured using ELISA. In rheumatoid FLS, IL-6, IL-8, and MMPs mRNA expression was examined using real-time PCR. The activation of signaling molecules was evaluated by Western blotting and EMSA.

Results: SF α-defensin-1 concentration was significantly increased in RA patients compared to OA patients (39.3±3.5 vs. 18.0±5.6 ng/ml, p=0.002). IL-6, IL-8, MMP-1 and MMP-3 mRNA expressions were significantly increased in RA FLS after α-defensin-1 stimulation compared to control (n=5)(all p <0.05). JNK and ERK were significantly phosphorylated in FLS stimulated with α-defensin-1 compared to control (n=3)(25.2±3.4-fold,

p=0.008 and 1.42±0.24-fold, p=0.05, respectively), while no significant change was found in p38 activity. Treatment of RA FLS with ERK inhibitor prior to α-defensin-1 stimulation significantly resulted in approximately 71% and 98% reduction, respectively, in IL-6 and MMP-1 production compared with control (p <0.05 for each). Blocking JNK pathway significantly suppressed α-defensin-1-induced MMP-1 production by approximately 73% compared with control (p<0.01). α-defensin-1-induced IL-8 expression was reduced by approximately 68% and 52% by inhibition of ERK and JNK, respectively. Also, α-defensin-1-induced MMP-3 expression was reduced by approximately 22% and 50% by ERK and JNK inhibitor, respectively. However, these differences did not reach statistical significance. In addition, there was a significant induction of NF-κB DNA binding activity in response to the stimulation of α-defensin-1 in rheumatoid FLS.

Conclusion: Our results are notable to suggest that increased SF α-defensin-1 released mainly by neutrophils can induce the expression of IL-6 and MMP-1 in rheumatoid FLS and these processes were dependent on the regulation of JNK and/or ERK and NF-κB pathway. These data provide new insight regarding the mechanism by which α-defensin-1 participates in joint inflammation and destruction in RA.

Familial Aggregation and Heritability of Rheumatoid Arthritis in Taiwan: A Nationwide Population Study. Chang-Fu Kuo[1], Matthew J. Grainge[1], Kuang-Hui Yu[2], Lai-Chu See[3], Shue-Fen Luo[2], Ana M. Valdes[4], I-Jun Chou[2], Hsiao-Chun Chang[2], Weiya Zhang[1] and Michael Doherty[1]. [1]University of Nottingham, Nottingham, United Kingdom, [2]Chang Gung Memorial Hospital, Taoyuan, Taiwan, [3]Chang Gung University, Taoyuan, Taiwan, [4]St. Thomas' Hospital, King's College London, London, United Kingdom

Background/Purpose: The present study was to estimate the familial relative risk (RR) of rheumatoid arthritis (RA) in individuals with affected first-degree relatives compared to individuals with no affected first-degree relatives. We also estimated the heritability to assess the magnitude of genetic contribution to susceptibility to RA.

Methods: Using data from the National Health Insurance Research Database in Taiwan, we conducted a nationwide cross-sectional study of data collected from 11,449,138 men and 11,800,070 women in 2010. RA cases were those receiving a catastrophic illness certificate for RA. The identification of first-degree relatives of each individual was determined using the NIHRD registry for beneficiaries. This specifies relationships between the insured person who paid the insurance fee and his/her dependents, allowing first-degree relatives (father, mother, son, daughter, brother, sister, twin) to be identified directly. Full siblings were identified as individuals who shared the same parents. Twins were full siblings who shared the same date of birth. The marginal Cox proportional hazard model with an equal follow-up time, adjusting for age and sex, was used to estimate RR (95% confidence interval [95% CI]) of RA in individuals with affected first-degree relatives. This model was used to account for shared environment and case clustering within families with robust variance. Heritability was estimated using multifactorial polygenic model.

Results: There were 8,010 men (0.07%) and 30,200 women (0.26%) who had RA catastrophic illness certificate in 2010. The prevalence of RA was higher in individuals with affected first-degree relatives (0.51%) than those without (0.16%). The overall familial RR was 4.79 (95% CI, 4.08-5.63). An individual's risk for RA varied depending on which of their family members were affected. The RRs (95% CIs) for an individual with an affected twin, sibling, offspring and parent were 20.95 (6.59-66.62), 8.93 (5.59-14.27), 4.46 (3.63-5.47) and 4.60 (3.90-5.44), respectively. The RR (95% CI) increased with the number of affected first-degree relatives, from 4.65 (3.95-5.46), 44.46 (18.90-3.09) and 118.34 (13.11-1068.55) for one, two or three or more affected relatives. The heritability of RA was 0.54 (95% CI, 0.42-0.67).

Conclusion: This population-based study confirms that RA aggregates within families and the heritability of RA is high. Genetic predisposition contributes to a significant proportion of RA development.

Podoplanin-Mediated Interaction of Rheumatoid Arthritis Synovial Fibroblasts with Platelets Modulates IL-8 Expression. Manuel J. Del Rey[1], Elena Izquierdo[1], Regina Faré[1], Alicia Usategui[1], Vanessa Miranda[1], Gabriel Criado[1], J. D. Cañete[2] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Hospital Clínic de Barcelona,, Barcelona, Spain

Background/Purpose: Synovial fibroblasts (SF) are the most abundant resident stromal cells in the synovium. In rheumatoid arthritis (RA), SF expand and undergo phenotypic changes that contribute to the pathogenesis of chronic arthritis. Among these changes, expression of podoplanin, a membrane protein expressed by normal lymphatic endothelium and cancer cells, has been reported (Ekwall, Arthritis Res Ther 2011). Podoplanin is up-regulated on the invasive front of tumors and participates in tumor cell migration. The only known specific receptor for podoplanin is the platelet membrane signaling protein CLEC-2. We have analyzed the expression and potential functions of podoplanin in rheumatoid arthritis synovial fibroblasts (RASF).

Methods: Podoplanin expression was analyzed by immunohistochemistry (IHC), immunofluorecence labeling (IF), quantitative real-time polymerase chain reaction (qRT-PCR) and flow cytometry in synovial tissue and SF cultures from RA and osteoarthritis (OA) patients and healthy donors. Podoplanin RASF expression was silenced with podoplanin specific and control siRNA lentiviral expression vectors. Transduced cells were used in RASF-cartilage co-culture experiment to measure cartilage glycosaminoglycan degradation products in supernatants (Blyscan Assay; Biocolor, Northern Ireland, UK). Matrigel invasion and *in vitro* wound healing assays were performed to evaluate migration capability of silenced fibroblasts. Finally, silenced RASF were co-cultured for 24h with human platelets prepared from healthy donors and RASF RNA was extracted to quantify IL-6, IL-8, MCP-1, MMP-1 and MMP-3 mRNA expression by qRT-PCR. Quantitative data from at least three independent experiments were analyzed by Mann-Whitney U-test or t-test as required and p-value<0.05 was considered significant.

Results: Abundant podoplanin expression was detected by IHC in synovial lining and sublining fibroblasts in RA biopsies (n=40) whereas minimal or absent expression was observed in OA (n=15) or healthy synovium (n=6) respectively. Cultured SF displayed abundant podoplanin membrane expression irrespective of their source (RA, OA or healthy synovium). Treatment of cultured SF with TNF-α induced up-regulation of podoplanin mRNA and protein expression, as determined by qRT-PCR and flow cytometry. Podoplanin expression was effectively down-regulated by specific siRNA lentiviral transduction. Cell migration in matrigel and wound healing assays and *ex vivo* cartilage degradation were not modified in RASF transduced with podoplanin siRNA compared to RASF transduced with scrambled control siRNA. Co-culture of RASF with platelets induced a significant increase in IL-6 and IL-8 but no MCP-1, MMP-1 or MMP-3 mRNA expression in RASF. siRNA podoplanin silencing in RASF blocked the up-regulation of IL-8 but not IL-6 mRNA expression in response to platelet co-culture.

Conclusion: Our results confirm previous data on the up-regulation of podoplanin in RASF. Functional studies do not support a role for podoplanin on RASF migratory and invasive properties as reported in cancer cells. Podoplanin is potentially involved in the pro-inflammatory response that results from RASF/platelet interaction.

Negative Association Between Testosterone Levels and Risk of Future Rheumatoid Factor Negative Rheumatoid Arthritis in Men. Mitra Pikwer[1], Aleksander Giwercman[2], Ulf Bergström[1], Jan-Åke Nilsson[1], Lennart T.H. Jacobsson[1] and Carl Turesson[1]. [1]Lund University, Malmö, Sweden, [2]Skåne University Hospital, Malmö, Sweden

Background/Purpose: Rheumatoid arthritis (RA) is a heterogeneous disease with female predominance. Sex hormones have been suggested to play a part in the pathogenesis. We have previously identified hormonal predictors (breast-feeding and early menopause) that influence predominantly rheumatoid factor (RF) negative RA in women. The increasing incidence with age of RA in men parallels age related drops in androgens. Lower levels of testosterone have been demonstrated in men with RA compared with controls,

but it has not been known whether this pattern precedes the disease or if it is a consequence of inflammation.

Methods: A nested case-control study was performed, using information and blood samples from a community based health survey performed between 1974 and 1992, which included 22 444 males. Blood samples were drawn between 8.00 and 10.00 a.m. after an overnight fast and stored at −20 degrees Celsius. Height and weight was measured and self-reported smoking habits were noted. Incident cases of RA were identified by linking the cohort to local and national RA-registers, and verified by a structured review of their medical records. Two controls for each validated case, matched for age, sex and year of screening, were selected from the health survey. Testosterone (T), sex hormone-binding globulin (SHBG), follicle stimulating hormone (FSH) and luteinizing hormones (LH) were analysed with standard immunoassays. Free testosterone was calculated from T and SHBG levels.

Results: Serum was available from 105 cases (mean age at diagnosis 59 years; median time from screening to RA diagnosis 12.7 years (range 1–28); 73 % RF positive at diagnosis or later) and 174 matched controls. Mean age at screening was 46 years. Mean free and total T levels were lower in pre-RA cases compared to controls, in particular in the subset who subsequently developed RF negative RA. T correlated negatively with body mass index (BMI), and smokers had significantly higher levels of both free and total T, as well as FSH and LH. In conditional logistic regression models, adjusted for smoking and BMI, lower levels of T were associated with RF negative RA (Odds Ratio (OR): 0.31 per standard deviation (SD), 95% Confidence Interval (CI): 0.12–0.85), with a similar tendency for RA overall (OR: 0. 77 per SD; 95% CI: 0.52–1.12). The same patterns were seen for free T. The differences were more pronounced in individuals screened > 12.7 years before diagnosis. Compared to matched controls and adjusted for smoking, significantly higher levels of FSH were seen in pre-RF-negative RA cases (p=0.02), whereas FSH levels were lower in pre-RF-positive RA cases (p=0.02),

Conclusion: Lower levels of total and free T were predictive of RF negative RA in men, adjusted for smoking and BMI. FSH levels were higher before onset of RF-negative RA, indicating a hypothalamus-pituitary response to testicular dysfunction. By contrast, lower FSH levels were found before onset of RF-positive RA, implicating an impaired hypothalamus-pituitary function as a possible factor in the pathogenesis of RF positive RA. Our results suggest that distinct hormonal patterns are associated with different phenotypes of RA, and that changes in androgens precede the onset of RA in men.

Regulatory Role of 1, 25 Dihydroxyvitamin D3 in the Pathogenesis of Autoimmune Arthritis. Siba P. Raychaudhuri[1], Ananya Datta Mitra[2], Anupam Mitra[1], Christine Abria[2] and Smriti K. Raychaudhuri[2]. [1]VA Sacramento Medical Center/UC Davis School of Medicine, Mather, CA, [2]VA Sacramento Medical Center, Mather, CA

Background/Purpose: Fibroblast like synoviocytes (FLS) and T lymphocytes are considered as major effector cells in the pathogenesis of autoimmune arthritis (AA) such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA), due to their significant contribution in formation of pathognomonic "pannus"[1,2]. Several studies suggest deficiency of Vitamin D in RA and its correlation with disease severity[1,3]. 1,25 dihydroxyvitamin D3 (Vit D) is an active metabolite of Vitamin D3 and induces immuomodulatory effect through Vitamin D3 receptor (VDR) which is expressed on antigen presenting cells, lymphocytes, FLS. Here we are reporting the anti-proliferative and pro-apoptotic potential of Vit D in FLS and T lymphocytes of AA patients.

Methods: PBMC and FLS were isolated respectively from blood and synovial tissues of RA (n=5) and PsA (n=5) patients. $CD3^+$ T cells were magnetically sorted from PBMC. FLS were cultured in presence or absence of growth factor (PDGF), pro-inflammatory cytokine (IL-17) and Vit D (10^{-6}M) for 5 days. T cells were stimulated with CD3/CD28 cocktail and treated with Vit D (10^{-6}M) for 5 days. MTT and flow cytometric (CFSE) based proliferation assays were performed. T cell apoptosis was assessed by flow cytometry using Annexin V and propidium iodide (PI). Staurosporine was used as a positive control for apoptosis assay.

Results: In MTT assay (n=5), Vit D significantly inhibited the PDGF (OD: 0.61 $\pm$ 0.06 vs. 0.23 $\pm$ 0.01, p<0.01) and IL-17 (0.55 $\pm$ 0.05 vs. 0.32 $\pm$ 0.01, p<0.01) induced proliferation of RA-FLS (Figure 1). Similar results were observed with PsA-FLS. CD3/CD28 stimulation induced significant proliferation of $CD3^+$ T lymphocytes (17.54 $\pm$ 2.48% vs. 6.06 $\pm$ 1.13%, p<0.01) and Vit D significantly inhibited activated T lymphocytes

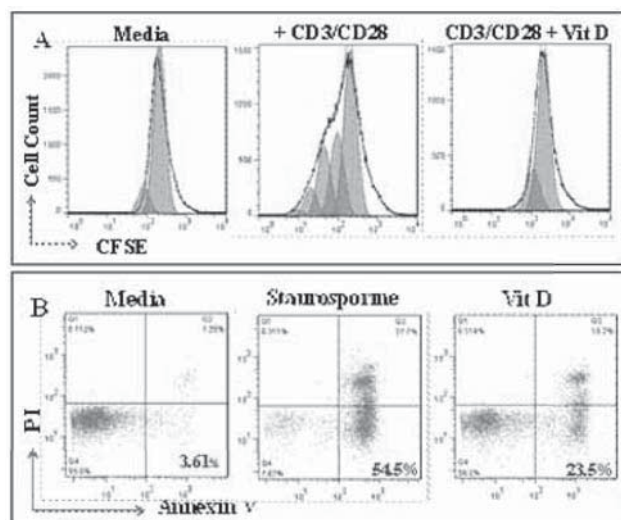
proliferation (11.21 ± 2.28 vs. $17.54 \pm 2.48\%$, $p<0.01$) (Figure 2A). We also observed that Vit D significantly induced apoptosis (Annexin V^+ PI^-) of T lymphocytes ($26.1 \pm 2.05\%$ vs. $3.28 \pm 0.17\%$, $p<0.001$) (Figure 2B).
Figure 1. Anti-proliferative effect of Vit D in RA-FLS.


Figure 2. Representative histogram showing the anti-proliferative (A) and pro-apoptotic (B) effect of Vit D.

Conclusion: This demonstrates showed that Vit D has a regulatory role in pannus formation by exerting anti-proliferative effect on two major effector cells of AA such as FLS and T lymphocytes. Moreover the pro-apoptotic effect of Vit D on activated T lymphocytes further suggests its immunomodulatory effect in AA.

1186

A Single Nucleotide Polymorphism of Tumor Necrosis Factor Receptor-Associated Factor 1 Predicts Clinical Response to Anti-Tumor Necrosis Factor Treatments in Japanese Patients with Rheumatoid Arthritis.
Tetsuya Nishimoto[1], Noriyuki Seta[1], Ryusuke Anan[1], Tatsuya Yamamoto[1], Yuko Kaneko[2], Masataka Kuwana[3] and Tsutomu Takeuchi[3]. [1]Keio university, Tokyo, Japan, [2]Keio Univ School of Medicine, Shinjuku-ku, Japan, [3]Keio University School of Medicine, Tokyo, Japan

Background/Purpose: Recent genome-wide association studies have disclosed several single nucleotide polymorphisms (SNPs) associated with rheumatoid arthritis (RA) susceptibility. Among them, it is reported that the SNP of tumor necrosis factor (TNF) receptor-associated factor 1 (TRAF1) (+16860A/G) is associated with pathophysiology of RA in both Asians and Caucasians. Therefore, in this study, we assessed the usefulness of TRAF1 genotyping as a genetic predictor of the response to anti-TNF treatments in Japanese RA patients, and examined an underlying mechanism of the association between TRAF1 polymorphism and the clinical response to anti-TNF treatments.

Methods: TRAF1 (+16860A/G) was genotyped using TaqMan® SNP genotyping assay. 101 Japanese RA patients were enrolled, and retrospectively analyzed the association between the SNP and the clinical response to treatment with anti-TNF drugs as a first biologic agent, such as infliximab, etanercept and adalimumab. The clinical response was assessed by the 28-joint Disease Activity Score (DAS28)-ESR response criteria at 24 weeks after the initiation of anti-TNF treatments. To investigate the effect of the SNP on the expression of TRAF1, $CD4^+$, $CD8^+$, $CD14^+$ or $CD19^+$ cells were isolated using magnetic activated cell sorting from peripheral blood mononuclear cells obtained from healthy subjects with AA (n=6), AG (n=6), or GG (n=3) genotype, and then the mRNA expression of TRAF1 in $CD4^+$, $CD8^+$, $CD14^+$ or $CD19^+$ cells were evaluated by TaqMan™ quantitative RT-PCR. The expression of TRAF1 was evaluated by intracellular staining in combination with staining for CD4, CD8, CD14 or CD19 using flowcytometry.

Results: In 101 RA patients received anti-TNF treatments, 63 (62.4%), 28 (27.7%), and 10 (9.9%) patients achieved good, moderate, and no response, respectively. There was no statistical difference in DAS28-ESR at baseline among each patient group with AA, AG, or GG genotype. However, the relative change in DAS28-ESR from baseline to 24 weeks after the initiation of anti-TNF treatments tended to be decreased in patients with GG genotype compared to those with AA or AG genotype (1.27 versus 2.16, P=0.057). GG genotype was more frequently detected in patients with no response compared to those with good or moderate response (30.0% versus 5.5%, P=0.031, OR 7.4, 95%CI 1.5–37.5). Patients with no response more frequently possessed G allele than those with good or moderate response (55.0% versus 25.8%, P=0.006, OR 3.5, 95%CI 1.4–9.0). Quantitative RT-PCR revealed that mRNA for TRAF1 was highly expressed in $CD8^+$ or $CD14^+$ cells with AG or GG genotype compared to those with AA genotype (P=0.045). Flowcytometric analysis also showed that the expression of TRAF1 tended to be increased in $CD14^+$ cells with AG or GG genotype compared to those with AA genotype (p = 0.09).

Conclusion: TRAF1 (+16860A/G) is possibly useful for prediction of the clinical response to anti-TNF treatments, and may contribute to resistance to anti-TNF treatments in RA patients with G allele via increased expression of TRAF1 in circulating inflammatory cells.

Smoking Status Is Associated with Inflammatory Cytokine Profile and Disease Activity in Anti-Citrullinated Protein Antibody Positive Rheumatoid Arthritis: Decreased Inflammation and Disease Improvement with Smoking Cessation?
Catriona Cramb[1], Jeremy Sokolove[2], Geoffrey M. Thiele[3], Gail S. Kerr[4], Grant W. Cannon[5], Andreas M. Reimold[6], Ted R. Mikuls[7] and William H. Robinson[8]. [1]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]Univ of Nebraska Med Ctr, Omaha, NE, [4]Washington DC VAMC and Georgetown University, Washington, DC, [5]Salt Lake City VA and Univeristy of Utah, Salt Lake City, UT, [6]Dallas VA and University of Texas Southwestern, Dallas, TX, [7]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [8]Stanford University, Palo Alto, CA

Background/Purpose: Smoking is a major risk factor for rheumatoid arthritis (RA) and has been associated with increased disease severity and lower rates disease remission. We hypothesized that levels of disease activity would be associated with smoking status and this would be related to levels of anti-citrullinated protein antibodies (ACPA) and/or serum cytokines.

Methods: The Veterans Affairs RA (VARA) registry was initiated in 2003 with routine collection of clinical demographics including disease activity score (DAS28) as well as baseline serum sampling. 1468 veterans with RA were included in the current study (76.9% anti-CCP2+, 90.7% male, mean age median age 63 (IQR 57–72), Median disease duration 8.45 years (IQR 2.8–18). Baseline serum samples were evaluated for levels of 19 distinct ACPA and 17 cytokines using the BioPlex platform on the Luminex 200 instrument. Smoking status was recorded as current, former, or never smokers. We evaluated the association of smoking status with disease activity (DAS28) by ANOVA and with levels of ACPA and cytokines using significance analysis of microarray (SAM) and output sorted based on false discovery rates (FRDs) in order to identify cytokines or autoantibodies with the greatest difference between different categories of smoking status.

Results: RA disease activity was significantly higher among current compared with former or never smokers ($P<0.01$). Among anti-CCP2 positive patients, levels of several cytokines associated with RA pathogenesis including TNFα, IL-17, IFNγ, GM-CSF, MCP-1, IL-2, and IL-7 were found to be significantly higher among current smokers compared with both former and non-smokers (FDR (q-value) <0.1%). Cytokine levels were similar between former and never smokers. Notably, levels of many ACPA were higher among current compared with never smokers, but similar between current and former smokers. Though number of subjects was smaller, the effect of smoking status on cytokine profile was not observed in the anti-CCP2 negative population.

Conclusion: Among anti-CCP2 positive RA patients, current smoking status is strongly associated with increased RA disease activity as well as elevation in several serum cytokines. This effect does not seem to be related to level of ACPA. The observation that higher levels of DAS28 and serum cytokines was only seen in current, and not former, smokers suggests that the effect of smoking may be minimized by smoking cessation. The effect of smoking cessation on RA disease activity should be evaluated in a prospective manner and multiplex cytokine profiling may provide a surrogate endpoint for efficacy of this intervention.

Fibrinogen Induced Inhibition of Osteoclastogenesis Is Reversed by Citrullination of Fibrinogen by Peptidylarginine Deiminase. Eun Young Lee[1], Ji Soo Kim[1], Hye Won Kim[1], Sung Hae Chang[1], Jin-Su Song[2], Hie-Joon Kim[2], Kyung-Hyun Park-Min[3], Lionel B. Ivashkiv[3], Eun Bong Lee[2] and Yeong Wook Song[1]. [1]Seoul National University College of Medicine, Seoul, South Korea, [2]Seoul National University, Seoul, South Korea, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: There are increasing evidences that autoantibodies and immune complexes (ICs) containing citrullinated fibrinogen are present in rheumatoid arthritis (RA) patients' sera and contribute to synovitis. We have in vitro data that fibrinogen can inhibit osteoclastogenesis from precursor cells. In this experiment, we investigated the effect of citrullinated fibrinogen, which are abundant in RA, on the in vitro osteoclastogenesis.

Methods: Fibrinogen (human and bovine; 1mg/ml) was citrullinated *in vitro* by reacting with rabbit skeletal muscle peptidylarginine deiminase (rmPAD2). Soluble fibrinogen, citrullinated or non-citrullinated, were applied with increasing doses to buffy coat-derived CD14+ cells, and osteoclastogenesis was induced in the presence of M-CSF (20 ng/ml) and RANKL (40 ng/ml). To confirm a migration shift due to citrullination, western blotting was performed. The citrullinated sites of fibrinogen were analyzed using mass spectrometry.

Results: Fibrinogen inhibited osteoclastogenesis in a dose-dependent manner. In contrast, citrullinated fibrinogen via rmPAD2 did not show inhibition of osteoclastogenesis, which were evident with non-citrullinated fibrinogen (Figure). Several osteoclastogeneisis related genes, especially DC-STAMP, were suppressed by fibrinogen during osteoclastoegenesis, but restored by citrullinated fibrinogen. Citrullination of fibrinogen was confirmed by Western blot analysis and Mass spectrometry, showing peak changes between citrullinated and non-citrullinated fibrinogen at 1576 and 1593 m/z. Western blot with anti-citrullinated antibody showed that proteins from RA synovial fluid were more citrullinated than those from osteoarthritis (OA) synovial fluid.
Conclusion: Fibrinogen was successfully citrullinated by PAD and confirmed by Western blot and Mass spectrometry. In contrast to fibrinogen, citrullinated fibrinogen did not show inhibition of osteoclastogenesis. These results may suggest that citrullinated fibrinogen can contribute to osteoclastogenesis in RA patients.

Stromal Cell Markers in the Synovial Tissue of Patients with Early Arthritis and Preclinical Rheumatoid Arthritis. Yuen Kei Choi[1], Olga N. Karpus[1], Paul Peter Tak[2], Jörg Hamann[1], Christopher D. Buckley[3], Andrew Filer[4] and Danielle M. Gerlag[1]. [1]Academic Medical Center, Amsterdam, Netherlands, [2]Division of Clinical Immunology and Rheumatology, Department of Experimental Immunology, Academic Medical Center/University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands, [3]School of Immunity and Infection, MRC Center for Immune Regulation, Birmingham, United Kingdom, [4]Rheumatology Department, Birmingham, United Kingdom

Background/Purpose: Stromal cells in synovial tissue (ST) of patients with arthritis may have an important role in the initiation and persistence of the inflammatory infiltrate. Previous studies showed increased expression of stromal markers in ST of patients with established rheumatoid arthritis (RA) *(Maia et al, Arthritis Rheum 2010:62:3595; Ekwall et al, Arthritis Res Ther 2011:13:R40)*. Here we investigated the expression of CD248, gp38, CD55 and PDI in early arthritis in relationship to diagnosis and outcome. Furthermore, these markers were tested in the ST of individuals without clinically apparent arthritis who are at risk for developing RA.

Methods: Forty-seven patients with early inflammatory arthritis (<1 year disease duration) and 19 IgM rheumatoid factor and/or anti-citrullinated peptide antibody (ACPA) positive individuals with arthralgia but without arthritis were included in this study. Of the latter group, 9 individuals developed arthritis after a mean follow-up time of 3.4 years. In the early arthritis cohort, patients were diagnosed at baseline and at 2 years follow up as gout (n = 10), psoriatic arthritis (PsA, n = 9), undifferentiated arthritis (UA-UA, n = 10), UA-RA (n = 4) and RA-RA (n = 14). Patients were also classified based on prognostic outcome after 2 years into self-limiting, persistent non-erosive and persistent erosive disease. Synovial tissue was obtained by miniarthroscopy and analyzed by immunofluorescence to detect CD248, gp38, CD55 and PDI on stromal cells.Slides were examined by confocal microscopy. Expression was quantified as pixel/um². Kruskal-Wallis test and Mann-Whitney U test were used for statistical analysis. A *P*-value <0.05 was considered statistically significant.

Results: We observed clear expression of CD248, gp38, CD55 and PDI in ST of patients with early arthritis, independent of diagnosis or outcome (table 1). In the autoantibody positive subjects at risk of developing RA, the expression of gp38 was lower compared to early RA (p = 0.0025). Expression levels were not different between individuals who developed RA after follow up (n = 9) compared to those who did not (n = 10).

Table 1. Median expression levels in early arthritis and preclinical RA

Median expression (in pixel/ um²)	Expression levels in early arthritis in relationship to diagnosis						Expression levels in early arthritis in relationship to outcome				Expression levels in preclinical RA		
	Gout	PsA	RA-RA	UA-RA	UA-UA	P*	Erosive	Non-erosive	Self limiting	P*	Arthritis+	Arthritis-	P*
CD248	0.037	0.056	0.026	0.080	0.043	ns	0.018	0.026	0.053	ns	0.015	0.051	ns
Gp38	0.007	0.030	0.008	0.003	0.009	ns	0.010	0.008	0.005	ns	0.000	0.000	ns
CD55	0.014	0.027	0.014	0.017	0.006	ns	0.016	0.011	0.016	ns	0.017	0.019	ns
PDI	0.056	0.075	0.026	0.022	0.037	ns	0.025	0.044	0.037	ns	0.004	0.004	ns

*ns: not significant, p-value ≥0.05
Arthritis +: Seropositive individuals who developed arthritis during follow-up time of 3.4 years
Arthritis −: Seropositive individuals who did not develop arthritis after a mean follow-up time of 3.4 years

Conclusion: The stromal cell markers CD248, gp38, PDI and CD55 are all expressed in the earliest stages of clinically manifest arthritis, independent of the diagnosis and outcome after follow up. In preclinical RA the expression of gp38 is lower compared to early RA. Stromal markers seem to be expressed in a stable way in the ST during the development from being at risk of RA to early RA.

Fine Specificity of Anti-Citrullinated Peptide Antibodies Discloses a Heterogeneous Antibody Population in Rheumatoid Arthritis (RA). John D. Goules, Andreas V. Goules and Athanasios G. Tzioufas. School of Medicine, National University of Athens, Athens, Greece

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are highly specific for the diagnosis of patients with RA. However, the predominant B cell epitopes have not yet been defined. The aim of this study was to examine in parallel the individual ACPA antibodies against different peptides derived from citrullinated proteins and investigate whether these antibodies constitute a homogenous population.

Methods: Sera from patients with RA (n = 141), systemic lupus erythematosus (n = 60), Sjögren's syndrome (n = 54), and healthy controls (n = 100) were tested for their reactivity against 6 citrullinated peptides (pep#2-pep#7) derived from peptidyl arginine deiminase (PAD), vimentin, alpha-enolase, fibrin, type II collagen and filaggrin respectively. A non citrullinated-control peptide derived from PAD was used as control (pep#1). Antibody reactivity was evaluated for each individual peptide by ELISA. Third generation anti-cyclic citrullinated peptide (anti-CCP3) antibodies were also determined. Specificity and sensitivity for anti-peptide antibody were tested by homologous and cross inhibitions assays. Cross reactivity between anti-peptide antibodies was evaluated, after affinity purification, by cross-inhibitions assays.

Results: Sera from patients with RA reacted diversely with the six citrullinated peptides. More specifically, pep#2 PAD (210–230aa) displayed 29.08% sensitivity, pep#3 vimentin (60–75aa) 29.08%, pep#4 alpha-enolase (5–21aa) 37.59%, pep#5 fibrin (617–631aa) 31.21%, pep#6 type II collagen (358–375aa) 29.97% and pep#7 filaggrin (306–324aa) 28.37% while control pep#1 PAD (621–640aa) showed no reactivity. All reactive peptides were found to be specific for RA (specificity: 91.59%, 93.93%, 95.33%, 95.79%, 97.20% and 97.73% respectively). The sensitivity of anti-CCP3 antibodies and antibodies against equamolar peptide mixture (containing six citrullinated peptides) for RA was 60.78% and 46.08% respectively and specificity 94.12% and 82.22%. Minimal cross reactivity between antibodies against the majority of citrullinated peptides was observed, ranging from 5.43% to 44.98%. A notable cross reaction (>60%) was observed between antibodies to pep#2 and antibodies to other peptides.

Conclusion: This study showed that ACPA in RA, using as substrates peptides from different citrullinated proteins, constitute a heterogeneous population with limited cross reactivity and without a predominant epitope. Studies to evaluate the significance of these findings are now under study in our laboratory.

Nicotinamide Adenine Dinucleotide Phosphate Oxidase Mediated Angiogenesis and Inflammation in the Arthritic Joint. Monika Biniecka[1], Wei Gao[2], Chin Teck Ng[2], Emese Balogh[2], Douglas J. Veale[2] and Ursula Fearon[2]. [1]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Translation Rheumatology Research Group, Dublin, Ireland

Background/Purpose: To examine the role of Nicotinamide Adenine Dinucleotide Phosphate Oxidase (NADPH oxidase)-derived Reactive Oxygen Species (ROS) and NADPH oxidase-dependent redox signaling events in regulating angiogenesis and inflammation in the arthritic joint. Moreover to examine the effects of hypoxia, TNFi treatment and NADPH inhibitors on NADPH oxidase mediated angiogenesis and inflammation.

Methods: Patients with inflammatory arthritis (IA; n=48) underwent arthroscopy and synovial tissue oxygen (tpO₂) measurements, synovial tissue biopsies and clinical assessment were obtained. Sixteen patients pre/post-TNFi therapy were also recruited. Macroscopic synovitis/vascularity was measured by visual analogue scale. Synovial levels of NADPH oxidase (isoform NOX2), cell-specific markers of inflammation (CD3, CD8, CD20, CD68), vascular factors (VEGF, Ang2, Factor VIII) and redox signaling factors (NF-κB, Akt, STAT3) were quantified by immunohistology/ immunofluorescence. Using IA synovial explant cultures ex-vivo, the effect of the NOX2 inhibitors (DPI and APO) on IL-8 release was measured by ELISA. NOX2 protein levels were assessed in K4 cells (immortalised human synoviocytes) under normoxia and hypoxia (3%) by Western Blot.

Results: Low in vivo pO₂ levels in the inflamed joint (median [range] 26.6 [3.2-63] mm Hg) were related to increased microscopic expression of NOX2 (p=0.01; r=-0.43). In biologic responders in vivo tpO₂ levels increased post treatment, which was associated with a significant reduction in NOX2 level (p<0.05). In contrast in non-responders where tpO2 levels remained the same or were reduced, no significant change in NOX2 expression was observed. Furthermore in vitro hypoxia (3%) induced NOX2 protein expression in K4 cells. High synovial NOX2 expression correlated with high macroscopic vascularity (p=0.005; r=0.46), synovitis (p=0.03; r=0.37), and with increased number of cell-specific markers of T cells (CD4 p=0.0001, r=0.90; CD8 p=0.002, r=0.72), B cells (CD20 p=0.003; r=0.82) and macrophages (CD68 p=0.01; r=0.44). There was a colocalisation and strong association between synovial NOX2 and expression of VEGF (p=0.005; r=0.52), Ang2 (p=0.05; r=0.32) and a number of blood vessels (p=0.004; r=0.50). In addition, synovial NOX2 expression was linked to redox activation of NF-κB, Akt, and STAT3 signaling pathways. Functionally, stimulation of synovial explants with DPI and APO alone or in combination with TNF significantly decreased secretion levels of IL-8.

Conclusion: NADPH oxidase is strongly expressed in synovial tissue and NADPH oxidase-derived ROS may mediate angiogenic and proinflammatory processes in the inflamed joint. Furthermore these effects may in part be mediated through hypoxic activation of downstream redox sensitive signaling events.

IL-21 Regulates B Cell Proliferation and Differentiation in Rheumatoid Arthritis. Lingyun Sun, Rui Liu and Xia Li. Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: Interleukin (IL)-21 is a member of type I cytokine family. Recent studies have indicated that IL-21 is an important regulator for human B cell activation, proliferation, plasma cell (PC) differentiation, immunoglobulin (Ig) production and isotype switching. Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by abnormal production of cytokines and autoantibodies including rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP), suggesting that B cells play a key role in pathogenesis of RA. The aim of this study was to investigate the effect of IL-21 on B cell proliferation and differentiation of RA patients.

Methods: Concentrations of IL-21 in serum were measured by ELISA. The correlation between serum IL-21 levels and clinical features of RA patients were assessed. The percentages of IL-21R⁺CD19⁺ cells were analyzed by flow cytometry (FACS) in peripheral blood mononuclear cells (PBMC) from RA patients and healthy controls. PBMC from RA patients were stimulated with rIL-21 (50 or 100ng/ml) after motivation with anti-CD40 and anti-IgM. The percentages of IL-21R, activation markers (CD40, CD69 and CD25) on B cells and the proliferation labeled with CFSE as well as differentiation of B cells were determined by using FACS analysis

Results: The results showed that serum IL-21 concentrations in RA patients (191.3±34.42pg/ml, n=104) were significantly higher than in healthy controls (10.33±11.43pg/ml, n=56, p<0.01). The levels of IL-21 in RA patients were positively related to RF-IgM (r=0.23, p<0.05), RF-IgA (r=0.34, p<0.05), RF-IgG (r=0.35, p<0.05) and anti-CCP (r=0.32, p<0.05). Moreover, the

percentages of IL-21R$^+$CD19$^+$ cells were found to be markedly higher in PBMC of RA patients (48.55%±2.63%, n=50) compared to healthy controls (34.12%±2.37%, n=40, p<0.01) and IL-21 could up-regulate IL-21R expression on B cells in vitro. Meanwhile, IL-21 stimulated the proliferation of B cells and activated marker expressions (CD40, CD69 and CD25). IL-21 induced more production of CD138$^+$CD19$^{+/low}$ cells in RA patients, indicating that IL-21 can promote B cell differentiation.

Conclusion: These results suggest that increased IL-21 expression from RA patients might support B cells proliferation, activation and antibody secretion. Thus, antagonizing IL-21 may be a novel strategy for treating RA.

Podoplanin Expression in Rheumatoid Stroma Correlates with Lymphoid Neogenesis and Is Downregulated by Anti-TNF-α Therapy. Regina Faré[1], Elena Izquierdo[1], Manuel J. Del Rey[1], Raquel Celis[2], Alicia Usategui[1], Juan D. Cañete[2] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Hospital Clínic of Barcelona, Barcelona, Spain

Background/Purpose: In rheumatoid arthritis (RA), synovial fibroblasts (SF) expand and undergo phenotypic changes that contribute to chronic inflammation and joint destruction. Podoplanin (Pdp) is a transmembrane glycoprotein normally expressed by lymphatic endothelium and stromal cells of the T-cell zone in lymph nodes. Recent studies have shown that Pdp is inducible by TNF-α in SF and its expression is increased in RA synovium. Pdp-deficient mice have defective development of both lymphoid organ and ectopic inflammation-associated lymphoid follicles. The aim of this study was to investigate the clinical and pathological significance of increased podoplanin expression in RA patients with particular focus on ectopic lymphoid neogenesis (LN).

Methods: Pdp expression was quantified by immunohistochemistry with specific anti-human podoplanin antibody (clone D2–40) in synovial arthroscopic biopsies from RA patients with active knee arthritis and variable disease characteristics (n=39) and healthy synovial tissues (n=6). Pdp expression was quantified as the fractional immunostained area using ImageJ software. Variation in Pdp expression was analyzed regarding the presence of LN (defined as large grade 2–3 T/B aggregates with MECA79+ high endothelial venules), pathological data including CD68, CD3, CD20 and CD31 cell density, and clinical variables such as disease duration and severity or activity variables. Changes in Pdp expression in a subgroup of 16 patients that underwent a second arthroscopic biopsy after anti-TNF-α therapy were also analyzed. Correlation between Pdp expression and other quantitative variables was analyzed by Spearman's test and changes in Pdp expression in different patient groups by Mann Whitney U-test.

Results: Pdp was abundantly expressed by lining cells of all RA synovial tissues whereas it was undetectable in healthy synovial tissues. In 54% of the patients, Pdp expression extended to sublining fibroblasts and reticular stromal cells within lymphoid aggregates of LN structures. Pdp expression was significantly increased in the group of patients (64%) with ectopic LN (13.7±2.4% vs 21.9±1.7%, mean±SEM, p=0.006). We also found significantly increased Pdp expression in the groups of patients with rheumatoid factor (14.6±2.3% vs 23.2±2.5%, p=0.02) or ACPA autoantibodies (10.7±1.9% vs 21.8±2.1%, p=0.01). No other clinical or pathological correlations were found. Therapy with TNF-α antagonists induced a significant reduction in Pdp expression (18.6±2.4% to 6.8±1.5%, p=0.0002).

Conclusion: Pdp is ectopically expressed by stromal cells of the lining and sublining in RA tissues, a phenomenon partially reversed by anti-TNF-α therapy. A higher level of Pdp expression is present in the subgroup of patients with LN providing a potential mechanistic link between stromal cell changes and LN.

1194

Prevalence of Anti-Peptidylarginine Deiminase Type 4 Antibodies in Rheumatoid Arthritis and Unaffected First-Degree Relatives in Indigenous North American Populations. Elizabeth D. Ferucci[1], Irene Smolik[2], Tammy L. Choromanski[1], David B. Robinson[2], Marianna M. Newkirk[3], Marvin J. Fritzler[4], Antony Rosen[5], Erika Darrah[5] and Hani S. El-Gabalawy[2]. [1]Alaska Native Tribal Health Consortium, Anchorage, AK, [2]University of Manitoba, Winnipeg, MB, [3]McGill University Health Centr, Montreal, QC, [4]University of Calgary, Calgary, AB, [5]The Johns Hopkins University, Baltimore, MD

Background/Purpose: Antibodies directed against peptidylarginine deiminase type 4 (PAD-4) are present in a subset of patients with rheumatoid arthritis (RA) and are associated with more severe joint destruction. These autoantibodies have been detected preceding the clinical diagnosis of RA in some patients. The objective of this study is to determine whether anti-PAD-4 antibodies are present in first-degree relatives of RA patients in two indigenous North American (INA) populations with high prevalence of RA.

Methods: Participants were recruited from two INA populations. We included RA patients (probands), their unaffected first-degree relatives (FDRs), and healthy controls, including both INA and Caucasian controls. Participants were interviewed for the presence of joint symptoms and underwent a joint examination by a rheumatologist. Sera were tested for the presence of anti-PAD-4 antibodies, anti-cyclic citrullinated peptide (CCP) antibodies, and rheumatoid factor (RF) IgM by ELISA. HLA-DRB1 subtyping was performed and participants were classified according to the presence or absence of shared epitope alleles.

Results: Antibodies to PAD-4 were detected in 27 of 82 (32.9%) RA probands; 2 of 147 (1.4%) FDRs; and 0 of 64 controls, including 20 Caucasian and 44 INA controls (p <0.0001). Anti-CCP antibodies were present in 26/27 (96.3%) of probands with anti-PAD-4, as compared to 42/54 (77.8%) of probands without anti-PAD-4 (p=0.05). In the FDRs, anti-CCP was present in 39/144 (27.1%) and there was no overlap between positivity for anti-CCP and PAD-4. None of the controls had anti-CCP antibodies detected. CCP and RF were both positive in 80.8% of the probands, but the association between RF and PAD-4 positivity was not statistically significant (p=0.14). One or more copy of an HLA-DRB1 shared epitope allele was present in 92% of probands and 82% of relatives (p=0.13), and there was no association between the presence of a shared epitope allele and PAD-4 positivity in probands (p=0.65) or relatives (p=1.0).

Conclusion: Despite a significant prevalence of anti-CCP in FDRs of INA RA patients, anti-PAD-4 antibodies were almost exclusively found in existing RA, suggesting these autoantibodies may be highly specific for RA. The prevalence of anti-PAD-4 antibodies in INA people with RA is similar to the prevalence described in other populations and these autoantibodies are strongly associated with anti-CCP in RA.

1195

Identification of Follicular Helper T Cells As a Novel Cell Population Potentially Involved in the Pathogenesis of Rheumatoid Arthritis. Sharon Ing[1], Anika Alarakhia[1], Elvira Lindwall[1], Austin Fraser[1], Jerald M. Zakem[2], William E. Davis[2], Tamika A. Webb-Detiege[3], Robert Quinet[4] and Xin Zhang[5]. [1]Ochsner Medical Center, New Orleans, LA, [2]Ochsner Clinic, New Orleans, LA, [3]Ochsner Medical Ctr, New Orleans, LA, [4]Ochsner Medical Center - New Orleans, New Orleans, LA, [5]Ochsner Clinic Foundation, New Orleans, LA

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the synovium, causing progressive joint destruction and reduction in quality of life for patients. The treatment of RA is largely based on management of the clinical consequences and manifestation of joint inflammation, which is likely to be remote from the fundamental pathophysiologic defects. Identification of cellular subsets or biomarkers that differentiate distinct clinic features according to the pathophysiologic defects is a necessary first step toward making a more accurate prognosis and better therapeutic decisions. Here, we identify a novel T cell subset, follicular helper T cells (Tfh) in RA patients and examine the hypothesis that Tfh cells may participate in the pathogenesis in RA by fostering an environment for self-reactive B cells, resulting in autoantibody production.

Methods: Peripheral blood was collected from 20 RA patients meeting 2010 ACR/EULAR RA classification criteria and age/gender matched healthy donors. Synovial fluid specimens from actively inflamed joints of RA patients were also collected. Clinical disease activity was quantified using the Disease Activity Score in 28 joints (DAS-28). RA patients were divided into remission, mild/moderate, and severe groups based on their DAS-28 score. Serum laboratory measurements including Rheumatoid factor, anti-cyclic citrullinated peptide, Erythrocyte sedimentation rate and C Reactive Protein levels were obtained. Tonsil specimens were obtained from discarded surgical tissue of non-RA patients and used as positive controls. Surface phenotype (CXCR5, CD57, ICOS, PD-1, BTLA) and intracellular cytokine (IL-21) production were used to identify Tfh cells in RA peripheral blood, RA synovial fluid, and normal tonsil by flow cytometry and/or immunohistochemical staining. Surface phenotype CD20 and CD38 were used to identify

plasmablasts. IgG production was measured by ELISA from the co-culture of autologous B cells with their respective tonsillar Tfh cells, or RA peripheral blood Tfh and non-Tfh cells.

Results: A novel T cell subset with Tfh cell surface molecule and signature cytokine was identified in both of the peripheral blood and the synovial fluid from RA patients. The percentage of these Tfh-like cells was expanded in the peripheral blood and synovial fluid of active RA patients (DAS-28 > 2.6) (P<0.05), compared to healthy donors and RA patients in remission (DAS-28 <2.6). The percentage of Tfh-like cells in CD4$^+$ T cells of the peripheral blood of RA patients correlated with the percentage of plasmablasts in the total lymphocyte population, and also with the level of pathogenic auto-antibody (anti-CCP) and DAS-28. IgG levels were significantly increased in co-culture of Tfh-like cells and peripheral blood B cells of RA patients, but not in co-culture of non-Tfh-like cells and RA peripheral B cells.

Conclusion: Identification of an expanded population of Tfh-like cells in RA patients provides evidence that a distinctive germinal center pathway maybe involved in RA pathogenesis resulting in autoimmunity. Targeting RA-Tfh-like cells may provide more precise treatment strategies.

1196

Analysis of Gene Expression Patterns in Rheumatoid Arthritis (RA) Synovial Macrophages From Patients Undergoing Disease Flare. Karen L. Berg[1], Adedayo Hanidu[1], Jon Hill[2], Xiaoyu Jiang[1], Tom Freeman[2], Jennifer Swantek[1], Anna Yarlina[3], George D. Kalliolias[3], Lionel B. Ivashkiv[3] and Gerald H. Nabozny[1]. [1]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, [2]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: Synovial macrophages play a key role in RA pathogenesis. Their numbers are greatly increased in RA synovium, their phenotype is consistent with a pro-inflammatory function, and clinical data indicate all efficacious RA therapies lead to a significant reduction of this cell type in the diseased joint. Studies probing global gene expression in RA synovial macrophages have been limited in scope. We set out to further our understanding of synovial macrophage biology—both in RA and additional arthropathies—through gene expression profiling, gene mining and pathway analysis in synovial macrophages from patients undergoing disease flare.

Methods: Synovial fluids were collected from 10 RA patients in disease flare (treatments included oral DMARDs and/or biologics), and CD14+ cells isolated by positive selection. Control macrophage samples were generated from CD14+ peripheral blood monocytes from healthy donors, and differentiated with M-CSF. Macrophages were also isolated from synovial fluid from patients with Psoriatic Arthritis and other arthropathies to allow for comparison of dysregulated genes and pathways across related diseases. RNAs were isolated, processed, and transcriptional profiling of the samples was performed using Affymetrix arrays. Statistical analysis was performed using principle component analysis (PCA) and upregulated genes defined as >2.0-fold increase in expression and an FDR p-value of <0.05. Internal genesets from cytokine-stimulated macrophages, and M1 or M2 polarized macrophages, were used as comparators to further characterize upregulated genes and pathways in RA macrophages.

Results: Approximately 1900 genes were significantly upregulated in RA synovial macrophages, and 70% demonstrated overlap with Psoriatic arthritis and other arthropathies. Forty percent of RA-upregulated genes were upregulated in M1 polarized macrophages, vs. 7% in M2 macrophages. Only 10% of RA-regulated genes were upregulated by chronic treatment of control macrophages with TNFa, indicating other factors impact gene expression to a greater extent in RA macrophages. Gene Set Enrichment and Ingenuity Pathway Analysis indicated that several immunoregulatory pathways previously linked to RA pathogenesis were upregulated in RA macrophages (including CD40, and FcR), independent of treatment. Interestingly, the LTb signaling pathway, which was highly upregulated in M1 macrophages was not significantly induced in RA macrophages indicating a unique inflammatory phenotype of these disease macrophages.

Conclusion: We performed a comprehensive study focused on identifying differentially regulated genes and pathways in synovial macrophages from patients with RA and related arthropathies. These results suggest a unique inflammatory phenotype of RA macrophages and maintenance of key inflammatory pathways during flare that is independent of treatment. These observations may shed light on novel intervention points for treatment of RA.

1197

***Porphyromonas Gingivalis* and the Pathogenesis of Rheumatoid Arthritis: Analysis of the Synovial Tissue and of Other Compartments.** Michele C. Totaro[1], Sara D'Onghia[2], Elisa Gremese[1], Luca Petricca[1], Simona Marchetti[2], Silvia Canestri[1], Barbara Tolusso[1], Stefano Alivernini[1], Paola Cattani[2] and Gianfranco Ferraccioli[1]. [1]Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy, [2]Laboratory of Clinical Analyses CIC, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: *Porphyromonas gingivalis* (Pg), a periodontal anaerobic intracellular pathogen, has been recently associated to rheumatoid arthritis (RA) and the pathogenesis of the disease, due to its unique characteristic of citrullinating host and bacterial peptides. Given the mainly intracellular life of the bacterium, the aim of the study was to evaluate the presence of Pg DNA in the synovial tissue (ST) of RA patients through synovial biopsy in comparison with patients affected by other arthritides. Possible links with clinical, immunologic and genetic features were assessed.

Methods: Peripheral blood (PB), sub-gingival dental plaque, synovial fluid (SF) and ST samples were collected from 69 patients with active knee arthritis (32 with RA and 37 with other arthritides, of which 14 with undifferentiated peripheral inflammatory arthritis–UPIA). Demographic, clinical, laboratory and immunological data were recorded. The presence of Pg DNA was evaluated through PCR. The HLA-DR haplotype was assessed for 45 patients with RA and UPIA.

Results: No differences arose in the positivity for Pg DNA in the sub-gingival plaque, PB and SF samples between RA and the cohort of other arthritides. Full PB samples showed a higher positivity for Pg DNA than plasma samples (11.8% vs. 1.5%, p = 0.04). Patients with RA showed a higher positivity for Pg DNA in the synovial tissue compared to controls (33.3% vs. 5.9%, p < 0.01). UPIA and RA patients carrying HLA DRB1*04 allele showed a higher positivity for Pg DNA in the ST compared to patients negative for the allele (57.1% vs. 16.7%, p = 0.04). RA patients positive for Pg DNA in the sub-gingival plaque had a lower disease duration and a higher peripheral blood leucocytes and neutrophils count. The presence of Pg DNA did not influence disease activity, disease disability or positivity for auto-antibodies.

Conclusion: The presence of Pg DNA in the synovial tissue of RA patients suggests a pathogenic role of the bacterium. The higher positivity of Pg DNA in full peripheral blood and synovial tissue samples compared to plasma and synovial fluid suggests a possible intracellular localization of Pg, thus contributing to the loss of tolerance, in particular in patients positive for HLA-DR4.

1198

Cardiovascular Risk Factors and Events Are More Frequent Prior to the Onset of Rheumatoid Arthritis Than in the General Population. Helen Pahau[1], Vibeke Videm[2], Sanjoy Paul[3] and Ranjeny Thomas[1]. [1]University of Queensland Diamantina Institute, Brisbane, Australia, [2]Department of Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology, and Department of Immunology and Transfusion Medicine, Trondheim University Hospital, Trondheim, Norway, [3]University of Queensland School of Population Health, Brisbane, Australia

Background/Purpose: Patients with the inflammatory autoimmune disease Rheumatoid Arthritis (RA) have a higher mortality and morbidity than the general population, predominantly related to cardiovascular disease (CVD). RA patients experience a 2-fold increased risk of myocardial infarction, due to the effects of traditional risk factors combined with inflammation. Since systemic inflammation, as determined by increases in multiple serum cytokines and chemokines, is evident prior to the onset of clinical RA but not osteoarthritis (OA), we hypothesized that cardiovascular events and risk factors would also occur more frequently prior to diagnosis of RA.

Methods: The HUNT population-based surveys were conducted in the county of Nord-Trøndelag in Norway. Detailed information pertaining to RA and OA diagnosis were obtained from 36493 subjects at baseline (HUNT 2, 1995–1997) and at 10-year follow-up (HUNT 3, 2006–2008). In subjects who did not have RA or OA at baseline, we evaluated the effects of cardiovascular and other relevant risk factors on the likelihood of developing RA or OA at follow-up. The risk factors included age, sex, smoking, BMI, blood pressure, diabetes and previous CVD.

Results: The 33567 individuals studied without RA or OA at baseline were mean (SD) age 46 (13) years old, 54% female, 50% current or ex-smokers, had BMI 26.1 (3.8) kg/m^2, 3.2% had previous CVD (angina, myocardial infarction or stroke), 1.4% had diabetes and 36% had hypertension. In this cohort, 786 (2.3%) individuals self-reported RA and 3586 (10.7%) self-reported OA at follow-up. Female were 41% and 136% more likely to develop RA and OA respectively. Individuals with previous CVD were 41% more likely to develop RA (p=0.03), but not OA. Current and previous smoking, and increased BMI, but not hypertension or diabetes, were significantly associated with both conditions. We evaluated the cardiovascular outcomes and associated risk factors in patients diagnosed with RA (n=429) or OA (n=2497) at baseline and follow-up. Adjusted for the cardiovascular risk factors, individuals with RA had 69% increased risk of stroke (p=0.02) and 45% increased risk of myocardial infarction (p=0.12) during follow-up. Individuals with OA had 35% increased risk of angina (p=0.003), but no increased risk of vascular events.

Conclusion: Although diagnosis was self-reported and not confirmed by chart review, these data suggest that individuals developing OA and RA among the Norwegian population share common cardiovascular risk factors, but only RA is pre-dated and associated with increased cardiovascular events. The development of RA at population level is associated with previous cardiovascular events and suggests the need for screening individuals with events for auto-antibodies and inflammatory features of RA.

Proteases Produced by *Porphyromonas Gingivalis* Can Cleave and Citrullinate Substrates Found in the Joint and Oral Mucosa: Implications for Autoimmunity in Rheumatoid Arthritis.
Nidhi Sofat[1], Saralili Robertson[1] and Robin Wait[2]. [1]St. George's University of London, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterised by inflammation followed by tissue rebuilding or fibrosis. Failure by the body to effectively regulate inflammation is a hallmark of RA. It has been suggested that periodontal disease is one mechanism whereby tissue inflammation is triggered in RA. One of the organisms implicated in periodontal disease: *Porphorymonas gingivalis*, is an anaerobic pathogen that is known to produce peptidyl arginine demiminase (PAD), the only known bacterial PAD which causes citrullination. Cleavage of extracellular matrix (ECM) substrates in RA is known to lead to the production of ECM damage-associated molecular patterns, or DAMPs that can then be available for citrullination, thereby mediating chronic inflammation in RA.

Methods: We investigated the ability of proteases produced by *Porphorymonas gingivalis* to cleave extracellular matrix substrates which are found in the joint and also the human oral mucosa: fibrinogen, fibronectin and type I collagen. Culture supernatants of the anaerobe *Porphorymonas gingivalis* (strain W83 from ATCC) were produced from 24 hour cultures using full anaerobic conditions (3M Concept Plus anaerobic incubator). After culture, bacterial supernatants were extracted and incubated with the substrates at 0.5 mg/ml at 37° C, with collection of digestion products from 0–320 mins. The cleavage patterns of the substrates described was evaluated by SDS-PAGE and Western blotting in the presence of selective protease inhibitors.

Results: We found that culture supernatants *from Porphorymonas gingivalis* are effective at cleaving all the substrates tested. The substrate demonstrating the most rapid digestion profile in conditions of 37° C were in order of rapidity of cleavage: fibrinogen (30 mins for complete cleavage), fibronectin (180 mins for complete cleavage) and type I collagen (320 mins for complete cleavage). In the presence of arginine inhibitor (100 micromolar NMLA, *NG-methyl-L-arginine*) and 50 nM 1400 W (a potent selective inducible NOS *inhibitor)*, digestion of all three substrates was strongly inhibited. In the presence of gingipain inihibitors KYT-1 and KYT-36, greater inhibition of cleavage was demonstrated for KYT-36 than for KYT-31.

Conclusion: Our data demonstrate that selective proteases can cleave extracellular matrix protein substrates shared in the oral mucosa and the arthritic joint. Inhibition of cleavage of such substrates may delay the production of ECM DAMPs that can then be available for citrullination in RA. Therapeutic strategies aimed at inhibiting such cleavage of ECM substrates may be a novel therapeutic target in RA.

Anti-Cyclic Citrullinated Peptide Antibodies in Idiopathic Pulmonary Fibrosis Are Not Citrulline-Specific: Implications for the Pathogenesis of Rheumatoid Arthritis.
Elena B. Lugli[1], Muslima Chowdhury[1], Peter J. Charles[1], Michael G. Crooks[2], Simon P. Hart[2], Patrick J. Venables[1] and Benjamin A. Fisher[3]. [1]Oxford University, London, United Kingdom, [2]Hull York Medical School, Cottingham, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom

Background/Purpose: The association of rheumatoid arthritis (RA) with smoking and silica exposure has led to the hypothesis that the lung is the site where RA autoimmunity is initiated. In support of this, anti-citrullinated protein/peptide antibody (ACPA) positive RA is associated with a high prevalence of lung abnormalities at presentation, and airway changes have recently been reported in subjects with ACPA in the absence of joint disease. There are also reports of ACPA occurring in lung diseases in the absence of joint symptoms. Investigation of early lung associated citrullinated antigens may therefore give insight into RA pathogenesis.

Methods: Sera from 42 patients with idiopathic pulmonary fibrosis (IPF), but no arthritis, were tested for anti-CCP2 antibodies by commercial ELISA. Sera were further tested for antibodies to immunodominant peptides from 3 citrulllinated autoantigens in RA, α-enolase (KIHA-cit-EIFDS-cit-GNPTVE), vimentin (VYAT-cit-SSAV-cit-L-cit-SSVP) and fibrinogen (NEEGFFSA-cit-GHRPLDKK), as well as filaggrin (CCP1; SHQEST-cit-G-cit-SRGRSGRSGS) by in-house ELISA, with cysteines at the end of each peptide to facilitate cyclisation. Arginine-containing control peptides for all assays were run in parallel. A549 alveolar epithelial cells and HL-60 cells were cultured and lysates citrullinated in vitro with rabbit PAD2. Citrullinated and non-citrullinated lysates were separated by SDS-PAGE and probed with the anti-CCP2 positive sera.

Results: Six patients were anti-CCP2 positive (14%) with a mean antibody level of 44 AU/ml (range 29–61; normal <25). None of these 6 sera were positive for antibodies to the α-enolase, vimentin and fibrinogen peptides and only one was positive for the CCP1 peptide. No reactivity of the anti-CCP2 positive sera against the in vitro citrullinated A549 cell lysates was observed, however with the HL-60 lysates, reactive bands were identified in 3/6 sera (molecular weight approx. 52, 60 and 62 kDa) which were not citrulline-dependent. Sera were re-tested with the arginine-containing control peptide for CCP2, using a previously published method. This demonstrated that reactivity was not citrulline-dependent. Serum from a patient with RA-associated lung disease was used as a positive-control and had antibodies to CEP-1, cVim, cFib and CCP1, reacted predominantly with the citrullinated but not uncitrullinated A549 (bands at approx. 45, 50, 102 and 300 kDa) and HL-60 lysates, and showed citrulline-dependent specificity for the CCP2 peptides.

Conclusion: Our findings suggest that anti-CCP2 antibodies occurring in lung disease are not specific for citrullinated peptides. They may represent non-specific reactions, with correspondingly low antibody levels, as has previously been reported in autoimmune hepatitis. However, it remains a possibility that immunity to native antigens might breach tolerance to citrullinated proteins, as we have previously observed in DR4 transgenic mice immunised with α-enolase. Here we have identified candidate immunoreactive bands in the HL-60 lysates. In some individuals, this autoreactivity may be followed by epitope spreading to citrullinated protein, a corresponding rise in anti-CCP2 antibody levels, and the clinical onset of RA.

Anti-Citrullinated Protein Antibody Specific Fc Glycosylation Patterns in Arthralgia Patients. Hans Ulrich Scherer[1], Yoann Rombouts[2], Ewoud Ewing[2], Lotte van de Stadt[3], Maurice H.J. Selman[2], André M. Deelder[2], Tom W.J. Huizinga[2], Manfred Wuhrer[2], D. van Schaardenburg[3] and René E.M. Toes[1]. [1]Leiden University Medical Centre, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) exhibit a specific, pro-inflammatory Fc glycosylation profile characterized by a low content of galactose and sialic acid residues. The absence of these residues from the Fc-linked core glycan could influence the biological activity of ACPA in rheumatoid arthritis. As ACPA can be detected in sera several years before disease development, we hypothesized that a change in ACPA Fc-glycosylation might precede the onset of arthritis.

Methods: Serum samples (n=300) of patients with ACPA positive arthralgia (n=184) were obtained at various time points. ACPA were isolated by affinity purification using cyclic citrullinated peptides as antigen. Isolated ACPA and total serum IgG molecules were subjected to trypsin digest, and glycan profiles of IgG1 Fc glycopeptides were analyzed by mass spectrometry. 96 patients in this cohort developed arthritis after an average duration of arthralgia of 14.7 months. At the time of the onset of arthritis, patients were defined as having rheumatoid arthritis (RA, n=51) based on the 1987 ACR criteria for RA, or undifferentiated arthritis (UA, n=45).

Results: No difference was found between ACPA-specific and total serum IgG1 Fc glycosylation patterns at the time of the patients' first presentation with arthralgia (baseline). At diagnosis of arthritis, RA patients, but not patients with undifferentiated arthritis, exhibited increased hypogalactosylation of the ACPA Fc fragment compared to healthy donors. Although a similar degree of Fc hypogalactosylation was found for total IgG in RA patients, hypogalactosylation of the ACPA Fc-tail occurred at 6 months before diagnosis, and was significantly more pronounced at 3 months before diagnosis than that of total IgG. No significant changes were noted for sialylation or fucosylation of the Fc tail.

Conclusion: ACPA acquire specific Fc-glycosylation patterns prior to disease onset, with a change towards hypogalactosylation occurring around 6 months before RA development. Of interest, ACPA hypogalactosylation was more pronounced than that of total IgG, indicating specific changes in the ACPA immune response several months before disease onset.

1202

Antibodies Against *Porphyromonas Gingivalis* Correlate with Rheumatoid Arthritis-Specific Auto-Immunity in Arthralgia Patients. M. J. de Smit[1], L. A. van de Stadt[2], J. Westra[1], B. Doornbos-van der Meer[1], K.M.J. Janssen[1], A. Vissink[1], A. J. van Winkelhoff[1], E. Brouwer[1] and D. van Schaardenburg[2]. [1]University of Groningen, University Medical Center, Groningen, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: In the disease association between rheumatoid arthrtitis (RA) and periodontitis a potential role is suggested for the periodontal pathogen *Porphyromonas gingivalis* (PG). PG is a major pathogen in periodontitis and has the unique feature of protein citrullination. Anti-cyclic-citrullinated-protein (CCP) antibodies are found not only in established RA but are also known to precede RA development. Aim of this study was to assess the levels of anti-PG antibodies in rheumatoid factor (IgM-RF) and/or anti-CCP positive arthralgia patients.

Methods: A cohort of 318 adult IgM-RF and/or anti-CCP positive arthralgia patients (mean age 50 years SD 12, 80% female) was prospectively followed for arthritis development during a median follow-up of 30 months. Patients with the possibility of a false-positive result for IgM-RF were excluded. Baseline analysis of serum samples was done by commercial (anti–CCP2; Axis-Shield) or in-house ELISA (IgM-RF, IgM-, IgG- and IgA-anti-PG). Baseline variables included age, gender, smoking, carriage of shared epitope (SE), and CRP/ESR levels by routine analysis. Anti-PG titers were compared to control subjects with severe periodontitis (disease controls, n=90) and control subjects with a healthy periodontium (healthy controls, n=23).

Results: 32% (n=103) of the patients developed arthritis, at median 15 months after baseline. After correction for age, gender, smoking and SE carriage, these patients had significantly higher mean anti-CCP levels compared to those who did not develop arthritis (p<0.001). No differences in levels of IgM-RF, anti-PG, CRP and ESR were found between groups of patients who did or did not develop arthritis.

Arthralgia patients had higher mean IgG-anti-PG levels than the healthy controls, as had the disease controls (p<0.001) (table 1). IgA anti-PG levels were only different between disease- and healthy controls (p<0.05), and no differences were seen between arthralgia patients, disease controls, and healthy controls in IgM-anti-PG levels (table 1). However, in the subgroup of arthralgia patients who developed arthritis there was a correlation of IgM-anti-PG with both anti-CCP and IgM-RF levels (ρ=0.2, p<0.05). No correlations were found between IgG- and IgA-anti-PG and anti-CCP.

Table 1. Mean (SD) anti-PG titers (mg/l) of different patient groups

Patients (n)	Arthralgia (318)	Arthritis+ (103)	Arthritis- (215)	Disease controls (90)	Healthy controls (23)
IgM-anti-PG	12.9 (12.9)	12.9 (12.4)	12.8 (13.1)	10.3 (8.71)	9.5 (7.44)
IgG-anti-PG	8.78 (17.5)**	7.94 (19.9)**	13.4 (29.6)**	23.8 (45.5)**	6.27 (23.6)
IgA-anti-PG	6.2 (11.5)	5.5 (15.5)	19.3 (133)	59.1 (292)*	8.88 (31)

** p<0.001 or *p<0.05 compared to healthy controls
Arthritis+: arthralgia patients who developed arthritis
Arthritis−: arthralgia patients who did not develop arthritis

Conclusion: IgM-RF and/or anti-CCP positive arthralgia patients have elevated IgG-anti-PG titers, and there is a significant correlation of IgM-anti-PG and RA-specific auto-antibodies in arthralgia patients who developed arthritis. This might indicate a role for the periodontal pathogen *P. gingivalis* in arthritis development.

High Expression of Genes in the Toll-Like Receptor and Interferon Pathways Are Associated with Radiographic Damage in African-Americans with ACPA-Positive RA. Maria I. Danila[1], A. D. Steg[2], Xiangqin Cui[2], David Redden[3], M. R. Johnson[2], Richard J. Reynolds[3], D. van der Heijde[4], Doyt L. Conn[5], Beth L. Jonas[6], Leigh F. Callahan[7], Larry W. Moreland[8], P. K. Gregersen[9] and S. Louis Bridges Jr.[10]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Emory Univ School of Medicine, Atlanta, GA, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]University of North Carolina, Chapel Hill, NC, [8]University of Pittsburgh, Pittsburgh, PA, [9]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [10]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: The clinical phenotype of rheumatoid arthritis (RA) ranges from mild joint inflammation to severe joint destruction, but molecular factors responsible for variability are incompletely understood, particularly in African-Americans. We tested the hypotheses that expression of immune-related genes in PBMCs differ in: a) severe vs mild radiographic damage; b) early or longstanding disease; c) RA vs control.

Methods: We analyzed total RNA from the PBMC of 60 African Americans from the CLEAR Registry (of a total of ~1,060 RA patients and 550 controls). Extremes of phenotype were analyzed: 10 RA with early disease/low damage (EL); 10 RA with early disease/high damage (EH); 10 RA with late disease/low damage (LL); late disease/high damage (LH) and 20 age, race and gender matched healthy controls. Early disease was defined as disease duration < 2 years. Late disease ranged from 9.5 to >60 years duration (Table 1). Radiographic severity was defined as total Sharp/van der Heijde scores of hands/feet. All participants had ACPA positive RA. We performed TaqMan qRT-PCR for 165 independent genes using panels based on specific pathways: SAB Innate and Adaptive Immune Signaling, and AB Immune Panel. The normalized gene expression levels (dCt) were compared between each RA group and the controls using a two-group t test.

Table 1. Clinical and demographic characteristics.

Variable	Control Group	EH Group	EL Group	LH Group	LL Group
Age (years)	35–69	23–75	34–62	35–76	47–68
Disease duration (months)	NA	2–23	0–5	114–522	189–339
Anti-CCP antibody status (ACPA)	Negative	Positive	Positive	Positive	Positive
Total Sharp/van der Heijde score	NA	11–53	0	181–341	0

Results: Preliminary results (Table 2) indicate a statistically significant increase (compared to controls) in gene expression in the EH category for the following genes: *TLR2, TLR4, TLR8, INFGR1, INFGR2, MAPK14*. In addition, EH subjects had lower expression of *MIF* and *IKBKB*. High expression of *TLR8* was associated with the LH group, while low expression of *TOLLIP* was associated with both the EL and LL groups. The expression of these genes is rarely increased in mild disease, especially in the LL goup. These preliminary results suggest that high expression of genes in the Toll-like receptor and interferon pathways are associated with radiographic damage in African-Americans with RA.

Table 2. Gene expression difference between RA groups and the control group*.

Gene	Control	EH Group		EL Group		LH Group		LL Group	
	dCT	dCT	p value	dCT	p value	dCT	p value	dCT	p value
TLR2	2.608	1.278	*0.00012*	2.561	0.9	2.244	0.32	2.234	0.31
TLR4	2.909	1.679	*0.0011*	2.345	0.13	2.334	0.12	2.247	0.076
TLR8	2.797	1.689	*0.00012*	2.391	0.17	2.129	*0.029*	2.402	0.19
TOLLIP	2.233	2.452	0.54	3.153	*0.012*	2.657	0.25	3.049	*0.027*
IFNGR1	2.58	1.364	*0.00048*	2.21	0.28	2.023	0.11	2.329	0.47
IFNGR2	2.171	1.447	*0.018*	2.2	0.92	1.83	0.24	2.284	0.7
MAPK14	2.548	1.641	*0.0011*	2.333	0.42	2.086	0.089	2.323	0.41
MIF	1.896	2.661	*0.012*	2.187	0.32	2.402	0.09	2.174	0.35
IKBKB	2.182	3.513	*0.0011*	2.767	0.14	2.509	0.41	2.464	0.48

*The CT values from qRT-PCR experiment were normalized against multiple house-keeping genes to obtain dCT values. Each RA group was compared with the control group. P values less than 0.05 are shown in italics.

Conclusion: These results will inform further studies of predictors of RA severity in African Americans using ~300 subjects from the CLEAR Registry, and have important implications regarding pathogenesis of radiographic damage of RA.

1204

Porphyromonas Gingivalis Antibody Responses and Clinical Associations in Patients with Early Rheumatoid Arthritis.
Sheila L. Arvikar[1], Klemen Strle[1], Deborah S. Collier[1], Mark C. Fisher[1], Gail McHugh[1], Toshihisa Kawai[2], Alpdogan Kantarci[2] and Allen C. Steere[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Forsyth Institute, Cambridge, MA

Background/Purpose: Three prior studies have demonstrated an increased frequency of antibody responses to *P. gingivalis* (*Pg*), a leading agent of periodontal disease (PD), in RA patients, lending further evidence for a "mouth-joint connection" in RA pathogenesis. However, in these studies, patients had longstanding disease and were receiving DMARD therapy, which may affect serum antibody responses to *Pg* as well as infection with PD pathogens. Our goal was to determine the frequency of *Pg* antibody responses and their clinical associations early in the course of RA, prior to DMARD therapy.

Methods: We have established an early RA cohort study. To date, 45 adult patients with <1 year of symptoms have been enrolled prior to DMARD treatment and enrollment is ongoing. Sera from the early RA patients and 60 healthy controls were tested for *Pg* IgG antibodies by ELISA using sonicate antigen of whole *Pg* (ATCC 33277). A positive *Pg* antibody response was defined as >2SD above the mean absorbance of the 60 control subjects.

Results: The 45 early RA patients were typical of an RA cohort; 73% were female and 80% had positive test results for anti-CCP antibodies or rheumatoid factor (RF). Thirteen (29%) had a smoking history, but only 6 (13%) were current smokers. At study entry, 14 of the 45 patients (31%) had positive IgG antibody responses to *Pg* and the levels were significantly higher compared to healthy controls (P<0.0001). History of smoking was slightly lower in patients with *Pg* antibodies (3/13, 23%) than in those without such antibody responses (13/32, 41%), and median levels of *Pg* antibodies were not different between these groups. At study entry, early RA patients with *Pg* antibodies tended to have higher DAS-28-ESR scores (median values, 5.2 versus 4.3), more frequent anti-CCP antibody responses (86% versus 68%), and higher ESR values (median values 35 versus 20 mm/h, P=0.05) than those without *Pg* antibodies. Moreover, the magnitude of *Pg* antibody responses correlated directly with anti-CCP antibody levels (R^2=0.147, P=0.009) and ESR values (R^2=0.179, P=0.004), while showing no correlation with RF or CRP levels. During 12 months of DMARD therapy, DAS-28-ESR scores and *Pg* antibody responses declined in most patients, and no patient who had a negative *Pg* antibody response at entry became seropositive. At 12 months, there was still a trend toward higher DAS-28-ESR scores in patients with *Pg* antibody responses than those without *Pg* antibody (median score, 3.9 versus 2.4, P=0.08), and fewer patients in the Pg+ group achieved DAS remission (31% versus 56%).

Conclusion: A subset of patients with early untreated RA had IgG antibody reactivity to *Pg*. The high *Pg* antibody responses at this time demonstrate that immunosuppressive therapy does not explain the *Pg* antibody reactivity. In these patients, higher anti-CCP antibody responses and ESR values suggested that *Pg* infection may be associated with a specific inflammatory response. Finally, *Pg* antibody positivity was associated with a trend toward greater disease activity and less likelihood of achieving remission by 12 months. These findings support a role for *Pg* in both the initiation and persistence of disease activity in a subset of patients with early RA.

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with increased cardiovascular (CV) mortality. Since *CD40-CD154* binding has direct consequences on inflammation process initiation, we aimed to replicate previous findings related to disease susceptibility in Spanish RA population. Furthermore, as the major complication in RA disease patients is the development of CV events due to accelerated atherosclerosis, and elevated levels of CD40L/CD154 are present in patients with acute myocardial infarction, we assessed the potential association of the *CD40* (rs1883832, rs4810485 and rs1535045) and *CD154/CD40L* (rs3092952 and rs3092920) gene variants with CV risk in Spanish RA patients.

Methods: One thousand five hundred and seventy-five patients fulfilling the 1987 ACR classification criteria for RA and 1600 matched controls were genotyped for the *CD40* rs1883832, rs4810485 and rs1535045 and *CD154* rs3092952 and rs3092920 gene polymorphisms, using predesigned TaqMan single nucleotide polymorphism genotyping assays. Afterwards, we investigated the influence of *CD40-CD154* gene variants in the development of CV events. Also, in a subgroup of 273 patients without history of CV events, we

assessed the influence of these polymorphisms in the risk of subclinical atherosclerosis determined by carotid ultrasonography.

Results: Statistically significant differences in the allele frequencies for the rs1883832 CD40 gene promoter polymorphism between RA patients and controls were found. Although we did not observe a significant association of CD40-CD154 gene variants with the development of CV events, an ANCOVA model adjusted for sex, age at the time of the ultrasonography assessment, follow-up time, traditional CV risk factors and anti-cyclic citrullinated peptide antibodies disclosed a significant association between CD40 rs1535045 polymorphism and carotid intima media thickness, a surrogate marker of atherosclerosis (p= 0.0047).

Conclusion: Our data indicate a potential association of rs1883832 *CD40* gene polymorphism with susceptibility to RA. Also, the *CD40* rs1535045 gene variant may influence development of subclinical atherosclerosis in RA patients.

Gp96 Exacerbate the Inflammation of Rheumatoid Arthritis. Qi Quan Huang[1], Robert Birkett[2], J.-P. Jin[3] and Richard M. Pope[4]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Wayne State University, Detroit, MI, [4]Northwestern Univ Med School, Chicago, IL

Background/Purpose: The mechanisms that contribute to the persistent activation of macrophages in rheumatoid arthritis (RA) are incompletely understood. Toll-like receptors (TLRs) have been implicated in the regulation of innate immunity and inflammation, and to play an important role in the pathogenesis of RA. We have recently identified that gp96 as an endogenous TLR2 ligand that contributes to the persistent inflammation of RA. Employing RA synovial fluid (SF) macrophages, we demonstrated synergistic activation between the microbial TLR2 ligand peptidoglycan (PGN) and the TLR4 ligand lipopolysaccharide (LPS). This study was performed to determine the synergistic effect of gp96 in macrophages activation and in the K/BxN serum transfer model of arthritis.

Methods: Recombinant N' terminal fragment (aa 22–337) of gp96 was expressed from *E.coli* and purified with extensive endotoxin removing procedures (final product < 1EU/mg protein). Suboptimal concentrations of LPS, Pam3CSK4, PGN, and RA SFs containing low concentrations of gp96 (<300ng/ml) were employed individually or in combination to activate control or RA SF macrophages. Except when LPS was added, cell activation was performed in media supplemented with endotoxin inhibitor Polymyxin-B. Macrophage activation was determined by the expression of TNFa mRNA employing quantitative RT-PCR or by examining culture supernatants for TNFa and IL6 by ELISA. Arthritis was induced employing the K/BxN serum transfer model in wild type C57Bl/6 mice. Gp96 (20 mg/in 5ml of PBS) was injected intraarticularly into mice on days 3 and 10, with/without injection of K/BxN serum on day 0. Heat inactivated gp96 (65°c for 2 hour) severed as the negative control. Arthritis was evaluated by ankle swelling and clinical score from day 0 to 17 post-induction.

Results: Macrophage activation by low concentrations of gp96 (2.5–5 mg/ml) were synergistically enhanced by very low or trace amount of LPS, Pam3CSK4 and PGN. Pre-incubation of RA SFs (10% in RPMI medium) with gp96 (1mg/ml) synergistically increased TNFa expression in control and RA SF macrophages, compared with SF only or SF preincubated with heat inactivated gp96. C57Bl/6 mice that received K/BxN serum plus gp96 intraarticularly developed more severe arthritis, compared with the group received K/BxN serum plus heat inactivated gp96. Although gp96 or heat inactivated gp96 was administered at day 3 and boosted at day 10 post arthritis induction, the difference between these two groups was not observed until day 10 and afterward. Gp96 or heat inactive gp96 ankle injection alone only caused mild ankle swelling at 24 hours that resolved in 2–3 days.

Conclusion: These observations suggest that gp96 synergizes with low levels of microbial TLR2 and TLR4 ligands in promoting of macrophage activation. The intraarticular injection of gp96 exacerbated serum transfer arthritis. Gp96 may also interact with endogenous TLR ligands or other inflammatory molecules present in RA SF resulting in enhanced macrophage

activation. These observations suggest that gp96 does not act alone, but cooperates with other factors within the joint to promote inflammation and joint destruction.

Impact of Anti Tumor Necrosis Factor-Alpha Therapy in Rheumatoid Arthritis On Osteoclast Activation and B Cells. Ezinma Ezealah[1], Jennifer Hossler[1], Jamie Biear[1], Christopher A. Cistrone[1], Teresa Owen[1], Nida Meednu[1], Kelly Callahan[1], Arumugam Palanichamy[1], Ignacio Sanz[2], Allen P. Anandarajah[1], Ralf G. Thiele[1], Darren Tabechian[1], R. John Looney[1] and Jennifer H. Anolik[1]. [1]University of Rochester Medical Center, Rochester, NY, [2]Emory University, Atlanta, GA

Background/Purpose: Serum receptor activator of NFkB ligand (RANKL) and its natural decoy receptor, osteoprotegerin (OPG), play key roles in osteoclast activation. In a group of patients with active RA, we tested the hypothesis that initiation of TNF blockade would improve osteoclast activation (reflected by the serum OPG:RANKL ratio). DAS response was correlated with markers of B cell activation and musculoskeletal ultrasound.

Methods: 18 patients with RA failing methotrexate therapy (disease activity score (DAS) > 4.4) were randomized to receive either etanercept or adalimumab as part of a larger NIH sponsored Autoimmunity of Excellence (ACE) study (n=60). Soluble serum RANKL and OPG were measured by ELISA at baseline, 24, and 52 wk (pg/ml). RA disease activity was followed by DAS28 at baseline, 12 and 24 weeks. Peripheral blood (PB) B cells were phenotyped by flow cytometry using the following surface markers: CD19, IgD, CD27, CD24, CD38, CD95, and CD21. High frequency gray scale (GS) and power Doppler (PD) musculoskeletal ultrasound (MSK US) was performed on a subset of subjects (n=8) on the wrists, MCP, and PIP joints of both hands according to EULAR guidelines by a rheumatologist (DT and RT) certified in MSK US at baseline 4, 12, and 24 wk. GS US and PD US were scored semiquantitatively (on a severity scale from 0–3).

Results: In the current analysis of the Rochester cohort (n=18), 61% of patients were good DAS responders, 28% moderate responders, and 11% non-responders at 24 weeks. Good DAS responders had higher baseline RANKL levels than moderate/non-responders (2653 vs. 1218). Serum RANKL decreased significantly with anti-TNF treatment (2381+3025 at baseline vs. 921+1630 at 52 wk, p=0.03, n=8 longitudinal), as did OPG (150+92 at baseline vs. 82+51 at 52 wk, p=0.01), regardless of DAS response. Interestingly, the OPG:RANKL ratio was very low in these active RA patients (0.76+1.2 compared to historic healthy controls 3.0) and did not change significantly with anti-TNF treatment. On MSK US, the higher the baseline # of GS+ joints the less likely patients were to achieve a good DAS response. Additionally good DAS responders tended to have a low # of GS+ joints/absent PD on follow-up US (12 and 24 wk) in contrast to moderate/non-responders. Finally, RA patients at baseline had an expansion of activated memory B cells in the PB (CD95+ on CD27+IgD- memory in RA [n=13] 50.5+19.5% vs. HC [n=14] 29.6+9.5%, p=0.001; also significant for CD95+ on CD27-IgD- memory p<0.0001 and CD21- on CD27+IgD- memory p=0.02). There was a strong negative correlation between OPG:RANKL ratio and B cell activation (R2=−0.62 for correlation with CD95+ on CD27-IgD- memory), suggesting that activated B cells may contribute to RANKL activation. Longitudinal assessment of B cell subsets in response to anti-TNF is underway.

Conclusion: In our study, the OPG:RANKL ratio was considerably lower than the ratio reported for control subjects and similar to that observed in patients with multiple myeloma. B cell activation was characteristic of active RA and correlated with RANKL activation. These results support the notion that OPG:RANKL and B cells have a central role in RA-associated joint destruction.

Stable Synovial Fluid Phenotype for Anti Citrullinated-Protein Antibodies in Established Rheumatoid Arthritis. Vijay Joshua[1], Lena Israelsson[2], Lars Klareskog[2], Anca Irinel Catrina[1] and Vivianne Malmström[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden

Background/Purpose: Presence of anti citrullinated-protein antibodies (ACPA) in the peripheral blood of patients with rheumatoid arthritis is a validated disease biomarker. We have previously shown local synovial production of these antibodies in the synovial fluid of active RA. We aimed to investigate longitudinal stability of ACPA and ACPA fine specificities in SF of active established RA patients.

Methods: A cohort of 30 RA patients (n=30) with established RA (median disease duration 11 years at inclusion) was followed up for a median of 9 years. Half of the included patients were testing positive for CCP2 ELISA in the SF when screened at one arbitrary time point and half were negative. Longitudinal SF samples of these patients (a median of 5 samples/patient, median follow-up time of 9 years) were analyzed for the presence of anti CCP2 antibodies and for fine ACPA specificities using ELISA against citrullinated forms of alpha-enolase (aa5–21; cep-1), fibrinogen (aa566–580; cit-fib573) and vimentin (aa60–75; cit-vim60–75) peptides. Cut off of these ELISAs were set at the 98th percentile, based on analysis of sera from healthy controls.

Results: SF ACPA quantification using the CCP2 ELISA kit demonstrates a highly stable phenotype during time, with all patients selected on the basis of ACPA positivity at one time point (15/30, 100%) being positive on all tested occasions. The same was true for ACPA negative SF (15/30, 100%). Among fine specificities presence of anti citrullinated a-enolase was stable (with 5/30 positive and 25/30 negative patients on all tested occasions). Same trend was observed for antibodies against citrullinated vimentin with 25/30 patients being either positive (3) or negative (22) on all tested occasions and citrullinated fibrinogen with 28/30 patients being either positive (3) or negative (24) on all tested occasions.

Conclusion: We demonstrate that both ACPA and ACPA fine specificities have a stable phenotype in SF of patients with longstanding RA suggesting continuous local production of antibodies during disease progression.

Functional Role of Chondrogenic Progenitor Cells in Rheumatoid Arthritis. Sabine Blaschke[1], Sandra Trautmann[1], Alexander W. Beham[2], Burkhard Mai[3], Sebastian Koelling[1], Caroline Breysach[4], Gabriele Wolf[1], Gerhard A. Mueller[1] and Nicolai Miosge[5]. [1]University Medical Center Goettingen, Goettingen, Germany, [2]Department of Surgery, Germany, [3]Vitos Orthopaedic Clinic Kassel, Kassel, Germany, [4]Department of Surgery, Goettingen, Germany, [5]Dept. of Prosthodontics, Goettingen, Germany

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease of still unknown etiology leading to progressive cartilage and bone destruction. Proinflammatory cytokines, immunoregulatory cells and synoviocytes were previously shown to play an important role in RA pathogenesis. Recently, a novel progenitor cell population, termed chondrogenic progenitor cells (CPCs), were isolated from repair tissue in later stages of osteoarthritis (OA). In this study, we analyzed the presence and functional characteristics of this cell type in human RA.

Methods: Cartilage tissue specimens were obtained from 10 RA patients (age 44–85y) after total joint replacement surgery. All patients met the American College of Rheumatology criteria for established RA. The study was approved by the local ethics committee. CPCs were isolated as previously described (1) and subjected to flow cytometry and immunocytochemistry for stem cell surface markers and the interleukin-17 receptors (IL-17RA/RC). Expression of transcription factors was analyzed by quantitative RT-PCR and multipotency was characterized by in vitro chondrogenic, osteogenic and adipogenic differentiation. Functionally, in vitro effects of IL-17A/F-stimulation (50ng/ml for 24h) in RA-CPCs were assessed.

Results: RA-CPCs could be isolated from tissue specimens in 10/10 RA cases. Flow cytometry revealed the expression of cell surface markers CD13, CD29, CD44, CD73, CD90 and CD105, but CPCs were negative for CD34 and CD45. Furthermore, RA-CPCs were shown to express the IL-17RA and -RC receptor. Transcription factors RUNX-2 and SOX-9 were detected by quantitative RT-PCR and immunocytochemistry. Multipotency differentia-

tion revealed that RA-CPCs harbour a chondrogenic, osteogenic and adipogenic potential. In vitro stimulation with IL-17A/F resulted in significant upregulation of NF-kB, TRAF-6, MMP-3 and IL-6.

Conclusion: Our study results demonstrate that CPCs are also present in RA cartilage tissue and express stem cell characteristics already described for OA-CPCs. Functional analysis revealed that these cells may also play a role in RA pathogenesis by IL-17-induced upregulation of MMP- and proinflammatory cytokine expression.

1210

Effect of HLA-DRB1*0901 Suggest Distinctive Mechanisms of Rheumatoid Arthritis Susceptibility. So-Young Bang[1], Hye-Soon Lee[2], Kyung Wha Lee[3] and Sang-Cheol Bae[4]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Hanyang University Guri Hospital, Guri, South Korea, [3]Hallym Institute for Genome Application, Hallym University Sacred Heart Hospital, Anyang, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea

Background/Purpose: Although HLA-DRB1 shared epitope (SE) alleles and DRB1*0901 have repeatedly been shown to be associated with RA susceptibility, the effect of each allele on levels of anti-cyclic citrullinated peptide autoantibodies (anti-CCP) and interaction with smoking in RA remains to be fully defined. We aimed to investigate whether DRB1 risk alleles influence anti-CCP levels and whether each allele interacts with smoking in anti-CCP positive or negative RA.

Methods: All RA patients (n =1,924) and controls (n = 1,119) were Korean. Odds ratios and biologic interactions as departure from additivity or multiplicity were analyzed by logistic regression.

Results: The *0901 allele significantly decreased anti-CCP levels in both the SE-negative and SE-positive group. We found a hierarchy of anti-CCP levels depending upon the combination of RA risk alleles ($P=5.55\times10^{-11}$). In the hierarchy, individuals carrying SE/SE had the highest (614 units/ml) and *0901/*0901 had the lowest levels (189 units/ml). The SE alleles interacted with smoking strongly in anti-CCP positive RA (AP=0.48 [0.25–0.71] and slightly in anti-CCP negative RA (AP=0.43 [0.02–0.81]). In addition, each of the SE alleles significantly interacted with smoking in anti-CCP positive RA. In anti-CCP negative RA, only *1001 interacted with smoking. However, DRB1*0901 did not interacted with smoking in both anti-CCP positive and negative RA groups. Interestingly, interactions between the two most significant risk alleles, *0405 and *0901, (AP=0.68 [0.46–0.89], multiplicity p=0.012) significantly increased RA susceptibility regardless of anti-CCP and smoking status. Moreover, smoking amplified the risk for RA by significant synergistic interaction with the heterozygote *0405/*0901 in anti-CCP negative RA (AP=0.80 [0.32–1.28]) but not in anti-CCP positive RA.

Table 1. Risk of anti-CCP positive and anti-CCP negative RA according to HLA-DRB1 and smoking

HLA-DRB1/ Smoking	anti-CCP positive RA		anti-CCP negative RA	
	No. of cases/ controls	OR† (95% CI)	No. of cases/ controls	O† (95% CI)

Table 2. Synergistic effect of having *0405 and *0901 alleles in RA according to anti-CCP status

Genotype	anti-CCP positive RA		anti-CCP negative RA	
	No. of cases/ controls	OR† (95% CI)	No. of cases/ controls	OR† (95% CI)
non-risk/non-risk	220/574	reference	71/574	reference
*0901/non-risk	173/151	2.94 (2.24–3.87)	31/151	1.63 (1.03–2.59)
*0405/non-risk	359/135	7.54 (5.82–9.77)	51/135	3.11 (2.07–4.67)
*0901/*0901	29/11	6.92 (3.36–14.24)	2/11	1.44 (0.31–6.64)§
*0405/*0405	61/9	20.22 (9.77–41.82)	2/9	1.85 (0.39–8.74)§
*0405/*0901	90/10	28.03 (14.17–55.45)	16/10	13.66 (5.93–31.44)
AP‡		0.66 (0.43–0.89)		0.73 (0.49–0.96)
RERI‡		18.69 (−0.28–37.66)		9.98 (−1.23–21.20)
S‡		3.19 (1.57–6.52)		4.63 (1.75–12.26)
Multiplicity‡		$P = 0.025$		$P = 4.32 \times 10^{-4}$

† All odds ratios (OR) and 95% confidence intervals (95% CI) were calculated by comparing each group with the corresponding reference group [individuals without SE &*0901] adjusted for age and sex.

Conclusion: DRB1*0901 differs from SE alleles regarding to anti-CCP levels and interaction with smoking, suggesting a distinct mechanism of *0901 in RA pathogenesis, which may bypass anti-CCP formation. In addition, significant increase of *0405/*0901 heterozygote in RA susceptibility may be attributable to the synergistic contribution of two different pathways in which two alleles participate independently.

ANTI-Cyclic Citrullinated Protein Antibodies Induce Inflammation and Oxidative Stress in WHITE Blood CELLS of Rheumatoid Arthritis Patients. Chary Lopez-Pedrera[1], Carlos Perez-Sanchez[2], Patricia Ruiz-Limon[1], Mª Angeles Aguirre[1], Rosario M. Carretero-Prieto[1], Antonio Rodriguez-Ariza[1], Nuria Barbarroja[3], Pilar Font[1], Francisco Martinez[1], Inmaculada Gomez-Gracia[1], Mª Jose Cuadrado[4] and Eduardo Collantes-Estevez[1]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]Research Unit, IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [3]IMABIS and Virgen de la Victoria Hospital, Malaga, Spain, [4]The Rayne Institute, London, United Kingdom

Background/Purpose: Anti-cyclic citrulinated protein antibodies (anti-CCP) are the most specific autoantibody markers in rheumatoid arthritis (RA) patients. However no previous studies have evaluated their role in the atherogenic process and cardiovascular (CV) risk in RA. The aim of this study was to investigate the role of anti-CCP antibodies in the induction of a pro-oxidative and inflammatory status in white blood cells, and their relationship with chronic inflammation and early atherogenesis in RA.

Methods: Fifty three RA patients and 31 healthy donors were included. Tissue factor (TF), protease activated receptors (PARs) expression, peroxides and peroxinitrites levels, and mitochondrial membrane potential (MMP), were analyzed by flow cytometry in white blood cells; glutathione peroxidase activity (GPx) was evaluated in cell lysates. Atherosclerosis/CV risk markers were also evaluated. RT-PCR was performed to elucidate the cellular origin of plasma inflammatory molecules. The carotid-intimate media thickness (CIMT) was measured as a surrogate marker of atherosclerosis. In parallel in vitro studies, isolated monocytes, lymphocytes, or neutrophils were incubated with non-specific human IgG or with purified anti-CCP antibodies.

Results: Increased expression of TF and PAR2 was found in neutrophils from RA patients, with higher plasma levels of VEGF, tPA, MCP1, MIP1α, TNFα, IL-2, -6, -8, -17A and -23. RA monocytes and neutrophils had higher peroxides and peroxynitrite levels, more depolarised mitochondria and lower GPx activity. Significantly higher levels of mRNA MCP-1, IL-1β, -6, -8, and TF were found in monocytes, pointing to the main cell sources of inflammatory molecules in RA. Notably, augmented titres of anti-CCPs were not only directly related to increased expression of protrombotic, pro-inflammatory and oxidative stress markers, but also to increased CIMT. Moreover, in vitro treatment with anti-CCP increased peroxide production in monocytes and neutrophils, as well as on the percentage of cells with increased MMP. Anti-CCP treatment in monocytes induced elevated cell surface TF expression and increased mRNA levels of MCP-1, IL-1β, -6, and -8 while in lymphocytes provoked increased IL-1β, -2, -6, -8, TNFα, and VEGF mRNA expression levels. No changes in cytokine mRNAs were found in neutrophils.

Conclusion: 1) Anti-CCP antibodies directly induce inflammation and oxidative stress in RA patients. 2) Monocytes and lymphocytes are key mediators of the anti-CCP-induced inflammatory state by expressing particular cytokines, which may constitute promising therapeutical targets for the

prevention of atherosclerosis and CVD in RA patients. Support: JA0246/2009, P08-CVI-04234, PS09/01809, Spanish Foundation of Rheumatology.

Elevated Fecal Secretory Immunoglobulin A, Anti-Cyclic Citrullinated Peptide Antibodies, and Cytokine Levels in Rheumatoid Arthritis Patients. Sam Dalvi, Jose U. Scher*, Mukundan Attur, Jyoti Patel and Steven B. Abramson. NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Rheumatoid arthritis (RA) is a complex auto-immune disease with genetic and environmental contributions. There has been increasing interest in the microbiome and its potential contribution to the pathogenesis of the inflammatory arthritides. Our recent study suggest that RA patients have altered intestinal microbiota compared to healthy controls. Here we aimed to investigate the local immunologic response in the intestinal tract of RA patients, including humoral signatures and pro-inflammatory cytokine profile. Mucosal response against enteric bacteria may offer insights into the pathogenesis of RA and the potential identification of subsets of patients amenable to therapeutic interventions.

Methods: *RA status, clinical activity and sociodemographic factors were determined in patients with New-onset RA (NORA; n=15), Chronic-established RA (CRA; n=14), and matched healthy subjects (n=14).* Fecal samples were obtained and total protein was extracted. ELISA assays were performed to determine concentrations of secretory (s) IgA, anti-cyclic citrullinated peptides antibodies (anti-CCP3.1), and various pro-inflammatory cytokines by multiplex assay**.**

Results: RA patients show aberrant intestinal humoral responses manifested by elevated fecal sIgA levels. Elevated levels of anti-CCP antibodies were found in fecal samples of these patients (mean= 64.9 Units vs 14.7 Units in healthy controls; P=0.03), suggesting that the intestinal tract is a potential site for peptide citrullination. Intriguingly, the gut anti-CCP3.1 levels in CRA patients were higher compared to NORA (p=0.10). NORA patients have significantly elevated fecal IL-1β compared to controls (mean= 4.2 pg/ml vs 1.67, p=0.02) as well as other pro-inflammatory cytokines including TNFa. These changes are associated with an intestinal microbiota alteration in NORA patients, characterized by a higher prevalence of Prevotella spp.

Conclusion: Our results show evidence of an amplified adaptive immune response and subclinical inflammation within the intestinal tract of patients with RA. To our knowledge, detection of the aforementioned fecal immunoglobulins and cytokines in RA patients has not been previously described. These findings suggest that immunologic defense mechanisms against intestinal bacteria may play a role in the pathogenesis of RA and that the intestinal tract is a potential site of peptide citrullination. Further studies are warranted to validate our findings.

The Serum Cytokine Profile of Interstitial Lung Disease in Rheumatoid Arthritis. Jose Felix Restrepo[1], Inmaculada del Rincon[2], Roy Haas[3], Daniel F. Battafarano[4] and Agustin Escalante[5]. [1]University of Texas Health Science Center, San Antonio, TX, [2]University Of Texas, Health Science Center, San Antonio, TX, [3]TX, [4]Brooke Army Medical Ctr, San Antonio, TX, [5]University of Texas Health Science Center at San Antonio, San Antonio, TX

Background/Purpose: Interstitial lung disease (ILD) is associated with significant morbidity and mortality in rheumatoid arthritis (RA). There are currently no proven biomarkers for ILD in RA. Cytokines, because of their important role in RA pathogenesis, as promising candidates to serve as biomarkers for ILD. In the current analysis, we examined the association between multiple cytokines and ILD in an RA cohort.

Methods: We studied members of an RA cohort recruited during a visit to a rheumatologist. All patients had comprehensive assessments at baseline

and annual follow-up, including collection of a serum sample which was stored. Medical records, including imaging reports, were reviewed thoroughly to assess comorbidity. We considered ILD to be present if an X-ray or computed tomography of the chest, or a lung biopsy were diagnostic of ILD. We measured the concentration of 38 cytokines in stored serum, using ELISA. We used stepwise logistic regression to identify cytokines associated with ILD, adjusting for age and sex as covariates. We show odds ratios (95% CI) to show strength of association.

Results: We studied 1328 patients, of whom 1204 had a stored serum sample for cytokine measurement. Of these, 86 had ILD (6.5%). Using stepwise logistic regression, the concentration of six cytokines was independently associated with ILD. The following three were associated with increased odds of ILD: growth-related oncogene (GRO), 2.14 (1.33, 3.44); tumor necrosis factor-alpha (TNF-a), 1.56 (1.12, 2.17); and interleukin-2 (IL-2), 1.73 (1.4, 2.15). The following three were associated with decreased odds of ILD: macrophage inflammatory protein-1-alpha (MIP1-a), 0.79 (0.62, 1.00); macrophage-derived chemokine (MDC) 0.48 (0.32, 0.72); and granulocyte colony stimulating factor (GCSF), 0.51 (0.34, 0.78). (Table 1). The area under the ROC curve for a model containing these cytokines plus age and sex was 0.776, while that for a model containing only age and sex was 0.63.

Table 1. Cytokines in RA-ILD patients.

Cytokine	OR (95% CI)	P-Value
GRO	2.14 (1.33, 3.44)	0.004
IL-2	1.73 (1.40, 2.15)	≤0.001
TNF-A	1.56 (1.12, 2.17)	0.021
MIP 1A	0.79 (0.62, 1.00)	0.043
GCSF	0.51 (0.34, 0.78)	0.006
MDC	0.48 (0.22, 0.72)	0.001

Conclusion: The profile of serum cytokine concentrations is significantly associated with the presence of ILD, with some cytokines being associated with increased risk, others with decreased risk. These findings may indicate the potential pathogenic of these cytokines in ILD among RA patients. In addition, these cytokines offer promise as potential biomarkers that could be used for the early identification of patients at risk for developing ILD.

The Impact of Periodontal Disease On Early Inflammatory Arthritis Persists Even After All Teeth Are Lost. Gisela Westhoff[1], Paola de Pablo[2], Thomas Dietrich[3], Georg Schett[4] and Angela Zink[5]. [1]German Rheumatism Research Center Berlin, Berlin, Germany, [2]University of Birmingham, Birmingham, United Kingdom, [3]The School of Dentistry, University of Birmingham, Birmingham, UK, Birmingham, United Kingdom, [4]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [5]German Rheumatism Research Center and Charité University Medicine, Berlin, Germany

Background/Purpose: Data suggests that individuals with periodontal disease (PD) may be more likely to develop rheumatoid arthritis (RA) and have worse disease activity. PD is a common inflammatory disease characterized by gingival accumulation of inflammatory cells with endothelial cell proliferation and matrix degradation that may worsen joint inflammation. Since PD is a major cause of tooth loss, tooth loss may be a surrogate marker for chronic PD, an inflammatory process that may possibly end when the last tooth is lost. We therefore hypothesized that partial vs. complete tooth loss (edentulism) may be differentially associated with disease activity in persons with early arthritis naive to DMARD-therapy.

Methods: The study sample included 1,009 patients with early arthritis (<6 months) naive to DMARD-treatment, enrolled in an ongoing longitudinal study (CAPEA 2010–2013). Data collection included disease activity (DAS28 calculated by TJC28, SJC28, ESR and Patient Global (PG; NRS 0–10)), the 2010 ACR-EULAR RA classification criteria and self-reported number of teeth. Patients were categorized according to number of teeth at study entry (no teeth, 1–19, 21–27, all teeth). Analysis of covariance was done to determine baseline disease activity by number of teeth.

Results: Study participants (65% female) were 55 ±14 years old and had mean symptom duration of 12 ±7 weeks. 56% were RF and/or ACPA positive and 66% fulfilled the 2010 criteria for RA. No patient had received any DMARDs at baseline. Sample characteristics by tooth loss categories are shown on Table 1. Significantly more participants with edentulism met ACR/EULAR classification compared with those with complete dentition (OR 1.9, 95% CI 1.01–3.35; adjusted for age, sex, BMI, smoking, and DAS28). Edentulous patients had neither lower nor higher disease activity (DAS28) than patients with considerable tooth loss (1–19 teeth left). However, compared with those with moderate tooth loss (20–27; P = 0.046) or complete dentition (P = 0.006), they had significantly worse disease activity.

Number of teeth	N	%	Age*	§RF/ ACPA pos. %	# RA %	& ESR*	~CRP mg/l*	TJC28*	PG*	DAS28 ESR*# (95% CI)
edentulous	77	7.6	68.2	65	75	45	28	10.0	5.5	5.2 (4.8–5.5)
1–19	289	28.6	63.7	54	70	39	27	10.0	5.3	5.3 (5.1–5.4)
20–27	401	39.7	53.6	55	65	28	18	7.8	4.9	4.8 (4.7–4.9)

P = no vs. 1–19 teeth			0.001	0.055	0.270	0.080	0.828	0.955	0.578	0.470
P = no vs. all teeth			<0.001	0.101	0.011	<0.001	0.017	0.013	0.055	0.006

§ rheumatoid factor and/or anti citrullinated peptide antibody; # ACR-EULAR RA classification criteria points (0–10; ≥6 =RA);; & erythrocyte sedimentation rate; ~ C-reactive protein; *means, adjusted to 55.0 years of age

Conclusion: Tooth loss was associated with disease activity at disease onset in a large cohort of patients with early inflammatory arthritis (IA) naïve to DMARD-therapy. Contrary to the assumption that exposure to periodontal disease ends once all affected teeth are lost, edentulism does not improve the interrelation of dental health and IA. The impact of PD on IA starts before IA onset, and obviously persists even after all teeth have been lost. The data also support the notion that there might be a common underlying pathobiology for both conditions.

Rates of Orthopaedic Interventions for Rheumatoid Arthritis Have Changed Over the Last 25 Years. A Report From Two UK Inception Cohorts Reflecting Treatment Changes From Sequential DMARD Monotherapy to Anti-TNF Agents (1986–2011). Elena Nikiphorou[1], Lewis Carpenter[2], Sam Norton[3], David James[4], Patrick D. Kiely[5], David Walsh[6], Richard Williams[7] and Adam Young[3]. [1]ERAS, St Albans City Hospital and University College London (UCL), London, United Kingdom, [2]University of Hertfordshire, Hatfield, United Kingdom, [3]ERAS, St Albans City Hospital, St Albans, United Kingdom, [4]Diana Princess of Wales Hospital, Grimsby, United Kingdom, [5]St. Georges Hospital, London, United Kingdom, [6]City Hospital, Nottingham, United Kingdom, [7]County Hospital, Hereford, United Kingdom

Background/Purpose: Orthopaedic surgery is considered an important, although uncommonly reported, outcome measure in rheumatoid arthritis (RA) and a surrogate marker for joint destruction. The expectation is that orthopaedic surgical rates will decline over time with greater and earlier use of more intensive treatments for RA.

Methods: The Early RA Study (ERAS) recruited from 1986–1999 (n=1465), the Early RA Network (ERAN) from 2002–2011 (n=1236). Standardised clinical, laboratory and X-ray measures were performed at baseline prior to initiation of DMARD therapy and then yearly in both cohorts. Treatment of patients included disease modifying, steroid and biologic therapies according to standard UK practices for management of hospital based RA patients, based on sequential published guidelines over 1986–2011. Source data of all orthopaedic interventions included clinical datasets (patient reports and medical records from 1986), and national data from Hospital Episode Statistics and the National Joint Registry. Length of follow up was based on the National Death Registry. For the analysis, recruitment years were grouped into 6 periods and interventions categorized into major (large joint replacements), intermediate (mainly synovectomies and arthroplasties of wrist/hand, hind/forefoot), and minor (soft tissue/ tendon surgery).

Results: A total of 1602 procedures were performed in 770 patients (29%) over maximum 25 year follow up. The 25 year cumulative incidence rate of major interventions was 21.7% (19.4–24.0%), and 21.5% (17.8–25.5%) for intermediate. Secular changes in orthopaedic surgical rates per year from 1987–2011 will be displayed graphically, showing a small, non-significant decline in major interventions (0.02%; p>0.05), but the regression model fitted for intermediate interventions indicated a significant decline (0.03%, p <0.05), and a small but non-significant increase for minor interventions (0.02%; p>0.05). There were only minor differences in demographic and baseline features over the recruitment periods examined, but definite treatment trends showed a gradual change from sequential monotherapy to combination therapies and biologics, and greater and earlier use of methotrexate and steroids in later recruitment periods. Methotrexate

and combination therapies as first DMARD were used in 1% and less than 1% respectively in recruitment period 1986–1989, and in 70% and 13% in 2006–2011. Anti-TNF agents were used in the first 3 years of disease only the latter two recruitment periods: 2002–2005, 7.8% and 2006–2011, 19.4%.

Conclusion: Orthopaedic surgery is an important and common outcome in RA by 10years. Only hand/foot surgery rates showed a consistent decline from 1986–2011. Possible explanations include differences in pathophysiological processes affecting joints; variations in responses to therapy between large and small joint destructive processes; changes in service provision and thresholds for different types of orthopaedic surgery over time.

Flare Self Management Strategies Used by Patients with Rheumatoid Arthritis. Susan J. Bartlett[1], Clifton O. Bingham III[2], Juan Xiong[3], Ernest Choy[4], Gilles Boire[5], Carol A. Hitchon[6], Janet E. Pope[7], J. Carter Thorne[8], Diane Tin[8], Boulos Haraoui[9], E. Keystone[10], Vivian P. Bykerk[11], OMERACT Flare Working Group[12] and CATCH[13]. [1]McGill University, Montreal, QC, [2]Johns Hopkins University, Baltimore, MD, [3]Mount Sinai Hospital, Toronto, ON, [4]Cardiff University School of Medicine, Cardiff, United Kingdom, [5]CHUS - Sherbrooke University, Sherbrooke, QC, [6]University of Manitoba, Winnipeg, MB, [7]Western University of Canada, St. Joseph's Health Care, London, ON, [8]Southlake Regional Health Centre, Newmarket, ON, [9]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [10]University of Toronto, Toronto, ON, [11]Hospital for Special Surgery, New York, NY, [12]Ottawa, [13]Toronto, ON

Background/Purpose: Though disease flares are common, very little is known about strategies RA patients use for self management (SM) of flares. We asked patients to identify SM strategies and explored potential predictors of strategies.

Methods: 512 patients in the Canadian early ArThritis CoHort (CATCH) completed the OMERACT preliminary flare questionnaire (PFQ) at clinic visits from 11–2011 through 4–2012. Patients who self-identified as being in a flare provided ratings of flare severity, pain, disability (HAQ) and identified SM strategies they were using. Strategies were selected from those previously reported during OMERACT RA Flare patient focus groups. Rheumatologists rated whether their patient was in a flare and performed joint counts. Groups were stratified based on Patient-MD agreement of flare status and compared using ANOVA. Multivariable logistic regression was used to identify potential predictors of flare SM.

Results: 512 patients with early RA who were mostly female (75%), white (82%) and well educated (57% > HS) answered the PFQ. Patients had a mean (SD) age of 53 (14) yr, 18% smoked, 65% RF+, 53% CCP+ and 24% had erosions. Mean HAQ was 1.03 (.70) and pain was 56 (27). 149 (29%) patients self-identified flare whereas MDs identified 169 cases of flare (31%); patients and MDs agreed about flare status 72% of the time (K=.34). Patients who were female, current smokers, RF+, Anti-CCP+, minority, living alone and ≤ HS education were significantly (p<.05) more likely to be classified as being in a flare.

The most common SM strategy was taking more analgesics (51%); in contrast, few patients reported taking more steroids (5%) and 34% tried to manage the flare without medications. Other strategies differed by patient/MD agreement on flare status (see Table). When patients and MDs agreed the patient was in a flare, 87% reported using SM strategies; whereas when patients but not MDs identified flare, 65% used SM strategies (p=.001). Patient/MD agreement about flare status was also associated with a significantly (p<.05) greater likelihood of activity reduction/avoidance. Although few patients contacted the care team for help prior to the visit, patient/MD agreement about flare status was associated with >5 fold increase in asking for help. Across strategies, predictors of SM included patient/MD agreement, female sex, and higher disability; other sociodemographic and disease characteristics were not reliably associated with SM.

As a result of this flare, I:	Patient Flare MD Flare (n=86)	Patient Flare MD Non-Flare (n=63)	p-value
Didn't do anything different	11 (13%)	22 (35%)	.001
Reduced the amount of activities	49 (57%)	24 (38%)	.023
Avoided doing activities that I had planned to do	32 (37%)	15 (24%)	.082
Tried to manage my flare without medications	28 (33%)	23 (37%)	.616
Took more painkillers	48 (56%)	28 (44%)	.170
Took more steroid tablets	6 (7%)	2 (3%)	.468
Asked for help from nurse or my rheumatologist	14 (16%)	2 (3%)	.014

Conclusion: Disease flares are common at routine care visits in early RA. Most patients recognize when they are flaring and their rheumatologists agree. Patients report using several flare SM strategies including taking more analgesics and reducing activities. Patient/MD agreement, female sex and higher disability are predictors of flare SM efforts. Notably, few patients (11%) experiencing flare in this early RA sample reported asking care providers for help prior to the routine clinic visit.

Decreased Survival in Rheumatoid Arthritis Complicated with Bronchiectasis: A Family-Based Cohort Study. Xavier Puéchal[1], Emmanuelle Génin[2], Thierry Bienvenu[1] and Daniel J. Dusser[1]. [1]Hôpital Cochin, AP-HP, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [2]INSERM UMR-S946, Université Paris Diderot, Paris, France

Background/Purpose: In cystic fibrosis, mutations of the cystic fibrosis transmembrane conductance regulator (*CFTR*) gene lead to diffuse bronchiectasis (DB) and decreased survival. DB is also associated with rheumatoid arthritis (RA), in which the role of *CFTR* mutations in predisposition to DB has been established (Puéchal et al. ARD 2011,70: 653–9). The prognosis of RA-associated DB (RA-DB) has not been well described.

Methods: We report on long-term mortality in a French nationwide prospectively followed, well-characterized, family-based association study of patients with a diagnosis of RA, DB or RA-DB. Families of probands with RA-DB were included if one first-degree relative had RA and/or DB. We assessed the overall mortality according to clinical characteristics and *CFTR* mutations among 138 subjects from 24 kindreds enrolled in the cohort. The association of potential risk factors with death was tested by Cox proportional-hazard analysis.

Results: During a median follow-up time after the inclusion of 10.6 years, 18 patients in the study cohort died, mainly due to respiratory involvement. The survival of RA-DB patients was significantly lower than the one of the RA patients and DB patients (P=0.006) (Fig A). In RA patients, the presence of DB was the main poor prognostic factor (hazard ratio for death, 8.7; 95% CI, 1.6 to 48.5; P=0.01). Among the RA-DB patients, an early onset of DB (hazard ratio, 18.6; 95% CI, 2.2 to 156.9; P<0.01) and *CFTR* mutation (hazard ratio, 8.3; 95% CI, 1.5 to 45.7; P=0.02) had an independent, significant association with decreased survival (Fig B and C). A *CFTR* mutation in RA patients with early-onset DB defined a subgroup of patients with increased mortality (hazard ratio, 9.4; 95% CI, 2.5 to 35.0; P<0.001).
Figure A. Survival curves in RA patients using Cox proportional Hazard model and two strata (with and without DB) (p=0.006).
Figure B. Cox survival curves in RA patients with DB according to age of DB onset.
Figure C. Cox survival curves in RA patients with DB according to *CFTR* mutational status.

Conclusion: In this prospective family cohort, DB in RA patients was associated with decreased overall survival. *CFTR* mutation in early-onset DB was strongly associated with shortened survival in RA patients and provides a new biomarker for risk stratification and design of future therapeutic interventions.

Genetic Markers of Functional Stress Response in Patients with Rheumatoid Arthritis. Olga Malysheva and Christoph G. Baerwald. University Hospital, Leipzig, Germany

Background/Purpose: Stress is recognized as an important risk factor in the pathogenesis of rheumatoid arthritis (RA). However, it is still incompletely understood how the stress response and interactions between the autonomic nervous system, the hypothalamus-pituitary-adrenal axis and the immune system contributes to the pathogenesis of RA. The purpose of our study was to characterise neuroimmune interactions common variants in the genes of the beta2-adrenergic receptor (beta2AR) and corticotropin releasing hormone (CRH) together with functional stress responses in RA patients and controls.

Methods: An allele-specific polymerase chain reaction was used to determine the polymorphisms of the beta2AR at position 16, 27, and 164, as well as the polymorphic sequences in the 5' flanking region of the human CRH gene in patients with RA (n = 310) and ethnically matched healthy controls (n = 305). In a subgroup of RA patients (n = 100) the autonomic response upon various standardised stressors was performed by utilising the heart rate variability (HRV) test (ProSciCard III, Version 2.2a, Medi-Syst GmbH, Germany) and compared to 45 age and sex matched osteoarthritis patients. To evaluate the impact of CRH promoter polymorphisms on the stress response in a subgroup of RA patients (n=18) an insulin hypoglycaemia test (IHT) was performed studying the dynamics of blood glucose levels, CRH, adrenocorticotropin (ACTH) and cortisol production.

Results: There was a highly significant distortion in the distribution of the beta2AR polymorphism at codon 16 between RA patients and controls, contributing to the genetic background of RA. Arginine (Arg) at codon 16 was present in 89.7 % of RA patients compared to 66.2 % controls (OR 4.43, 95 % CI 2.81 to 7.02, p = 0.00001). Stratifying RA patients for the amino acid sequence at position 16 and their autonomic reactivity revealed a statistically significant decrease of parasympathetic activity, in particular for the deep breathing test, in patients with homozygosity for Glycine (Gly) 16 compared to RA patients being heterozygous (Arg16Gly). However, RA patients with homozygosity for Glycine 16 showed a normalisation of the sympathetic reactivity upon mental stress test. On the other hand, polymorphisms of CRH 5' regulating region are differentially distributed in RA patients and healthy subjects. The CRH promoter polymorphisms exerted a significant influence on the stress response of RA patients undergoing an IHT. The integrated cortisol response to hypoglycaemia expressed as area under the curve was significantly lower in RA patients bearing the A1B1 allele (64154 ± 5768 nmol/l) compared to the A2B2 allele (91273 ± 7298 nmol/l, p=0.016).

Conclusion: Polymorphisms of the beta2AR and CRH contribute to the genetic background of RA and is associated with disturbed functional stress reactivity on various levels in these patients. Further studies are warranted to determine the role of genetic factors on stress response in the disease process of RA.

Periodontal Disease Is Associated with Rheumatoid Arthritis but Its Severity Is Not Correlated with Rheumatoid Arthritis Disease Activity.
In Ah Choi[1], Jin-Hee Kim[2], Kyung Hwa Kim[2], Hye Won Kim[1], Myeong Jae Yoon[1], Bon Seung Ku[1], Hyejin Oh[1], Joo Youn Lee[1], Eun Young Lee[1], Eun Bong Lee[1], Yong-Moo Lee[2] and Young Wook Song[1]. [1]Department of Internal Medicine, School of Medicine, Seoul National University, Seoul, South Korea, [2]Department of Periodontology, School of Dentistry, Seoul National University, Seoul, South Korea

Background/Purpose: The prevalence of periodontal disease is known to be increased in patients with rheumatoid arthritis (RA) compared to the general population. We investigated whether severity of periodontal disease is associated with RA and correlated with RA disease activity, ACPA status or treatment medication.

Methods: We conducted a cross-sectional study comparing 295 RA patients and 88 non-arthritis controls. In RA patients, serum RF, anti-CCP antibody, CRP and ESR were measured. Clinical parameters including tender joint count (TJC), swollen joint count (SJC), DAS28 and presence of erosive changes in X- ray were evaluated at the time point obtaining samples. In all subjects, a number of teeth (0~28, 3rd molars excluded) was checked. Subjects who had 15 or more teeth were evaluated for dental exam and checked for P. gingivalis antibody. Plaque index (PI) was evaluated as a marker of dental hygiene and gingival index (GI), probing pocket depth (PPD), bleeding on probing (BOP) and clinical attachment loss (CAL) were evaluated as index of periodontitis. Periodontitis was defined as mild (CAL 1~2 mm), moderate (CAL 3~4 mm) and severe (CAL ≥ 5mm) by American Academy of Periodontology 2004 Classification.

Results: The mean number of teeth (±SD) in 295 RA patients and 88 controls were 23.4 ± 6.2 vs. 25.8 ± 2.9, respectively (p= 0.001). Among 290 RA patients, 28 patients (8.8%) had less than 15 teeth and 3 patients had ongoing dental care, both were excluded from the dental exam. Mean PI in 264 RA patients and 88 controls were 0.84 ± 0.49 and 0.70 ± 0.34

(p=0.014), mean GI 0.51 ± 0.43 vs. 0.15 ± 0.18 (*p < 0.001*), mean PPD 2.0 ± 0.4 vs. 1.7 ± 0.2 (*p < 0.001*) and mean CAL 3.2 ± 0.8 vs. 2.9 ± 0.5 (*p < 0.001*). The prevalence of moderate or severe periodontitis was significantly higher in RA patients compared to controls (63.6% vs. 33.3%, *p*< 0.001). Mean P. gingivalis antibody level (±SD) was higher in RA compared to control (34227 ± 55100 vs. 18341 ± 13147 unit/mL, p< 0.001). In RA patients, presence of dry mouth was associated with higher BOP (*p*= 0.022). Disease duration was associated with higher GI (r^2= 0.044, *p*= 0.002) and BOP (r^2= 0.022, *p*= 0.016). The patients with high positive anti-CCP antibody (≥ 15 IU/mL) showed higher GI than patients with negative (< 5 IU/mL, *p*= 0.002) or low positive (≥ 5 and < 15 IU/mL, *p*=0.046) anti-CCP antibody. There was no significant association between severity of periodontitis and RA disease activity markers (TJC, SJC, ESR, CRP, DAS28), presence of bone erosion, rheumatoid factor or use of steroid or biologic agents.

Conclusion: Patients with RA had more severe periodontal index than controls. Severity of periodontitis was associated with the presence of dry mouth, anti-CCP antibody and RA disease duration but not with disease activity.

Occurrence and Morbidity of Lower Extremity Ulcer in Rheumatoid Arthritis - A Population Based Study. Adlene Jebakumar, Cynthia S. Crowson, Prabhu D. Udayakumar, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Lower extremity (LE) ulcer is a known complication of rheumatoid arthritis (RA). However, little is known regarding the magnitude and morbidity associated with this complication. We aimed to assess the occurrence, risk factors, morbidity and mortality associated with LE ulcers in RA.

Methods: We retrospectively reviewed a population-based incidence cohort of patients who fulfilled 1987 ACR criteria for RA in 1980–2007. All subjects were longitudinally followed through their complete community medical records until death, migration or April 2012. Ulcers in the lower extremities that developed after the diagnosis of RA were included. Foot ulcers due to surgery, biopsy, burns, animal bites, ingrowing toe nail, toe nail removal, abrasion, cellulitis, foreign body or herpes zoster were excluded. Cumulative incidence of lower extremity ulcers adjusted for the competing risk of death was estimated. Cox models were used to assess risk factors for LE ulcers and their impact on mortality.

Results: The study population included 813 patients, 537 (66%) were rheumatoid factor positive; during follow-up, 33% had rheumatoid nodules and 53% had erosive joint disease. During 9771 total person-years of follow-up (mean 12.0 years per patient), 125 patients developed LE ulcers with total occurrence of 171 episodes. The cumulative incidence of LE ulcers in RA patients was 4.8 % (± 0.8%) at 5 years after diagnosis of RA and increased to 26.2% (± 2.5%) by 25 years. Mean age of RA patients with at first LE ulcer occurrence was 73.5 years (74% female). The most common ulcer locations were between ankle and knee (58 ulcers, 34%) and in the tips of toes (46 ulcers, 27%). Majority were pressure (62 ulcers, 36%) or traumatic (49 ulcers, 29%) in etiology; 22 (13%) were ischemic ulcers and only 2 (1%) were vasculitic ulcers. The incidence of LE ulcers was higher among patients diagnosed with RA in 1995–2007 compared to those diagnosed in 1980–1994 (hazard ratio [HR] 2.03; p=0.001). Median time for the LE ulcer to heal was 30 days. 10 (6%) of 171 episodes lead to amputation. LE ulcers in RA were associated with increased mortality (HR 2.42; p < 0.001) adjusted for age, sex and calendar year.

Risk factors for LE ulcers in RA were: age (HR 1.90 per 10 year increase; p<0.001); current smoking (HR 1.51; p = 0.048); diabetes mellitus (HR 1.65; p = 0.015); coronary heart disease or heart failure (HR1.56; p = 0.035); presence of rheumatoid nodules (HR 1.64; p = 0.010); ESR ≥ 60 mm/hour on three occasions (HR 1.78; p = 0.022); venous thromboembolism (HR 2.08; p = 0.014); severe extra-articular manifestations (HR 1.67; p = 0.048). 79 (46%) of 171 ulcer episodes occurred in patents on corticosteroid therapy.

Conclusion: LE ulcers are common among patients with RA. The cumulative incidence increased by 1% per year, and the incidence of LE ulcers in RA has doubled in the recent years. A significant number require amputation. LE ulcers are associated with double the mortality rate in RA patients. Clinicians should be aware of the significance of LE ulcers in RA for better management of these patients.

Low Muscle Density in Rheumatoid Arthritis and Modified Association with Total Fat Mass, Results of a Pilot Study. Joshua Baker[1], Joan Marie Von Feldt[2] and Mary Beth Leonard[3]. [1]University of Pennsylvania, Philadelphia, PA, [2]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA, [3]The Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: Fatty infiltration of muscle (*myosteatosis*) results in a decrease in muscle density. Prior studies documented that skeletal muscle attenuation determined by CT was associated with skeletal muscle lipid content on tissue biopsy. Low muscle density is associated with insulin resistance and is independently associated with an increased fracture risk. We evaluated muscle density as measured by peripheral quantitative CT (pQCT) in 28 subjects with rheumatoid arthritis (RA) compared to 464 well-characterized controls.

Methods: RA subjects and healthy controls from the Philadelphia area underwent whole-body Dual X-ray Absorptiometry (DXA) and pQCT of the tibia. The pQCT measure of muscle density (mg/cm^3) was used as a composite index of intra and extra-myocellular fat content as previously described. Edge-detection and threshold techniques were used to separate tissues (fat, muscle, and bone) based on attenuation characteristics. Images were filtered prior to being analyzed using contour mode 3 (-101 mg/cm^3) to find skin, and peel mode 2 (40 mg/cm^3) to separate adipose and muscle/bone, respectively. Whole body DXA measures of total fat mass were converted to an index to adjust for height (kg/m^2). Muscle density was compared between RA and controls after adjusting for age, sex, and race using multivariable linear regression analysis. Linear regression was further utilized to assess for differences in RA and controls after adjustment for differences in total fat mass and to evaluate for modification of the association between fat and muscle density among RA subjects.

Results: Adjusted mean muscle density in RA and controls was 73.3 (2.08) and 74.5 (2.01), respectively (p=0.003). There was significant modification of the effect of fat mass on muscle density in RA [Interaction β: 0.0038 (0.0018–0.0057) p<0.001]. In healthy controls, muscle density was negatively associated with total fat mass index (FMI), while among RA, there was no such association (Figure 1). This interaction suggested that differences in muscle density between RA and controls were most pronounced among subjects with lower fat mass. Use of steroids, use of biologics, disability scores, C-Reactive Protein (CRP) and disease activity (DAS28) were not significantly associated with muscle density in this small sample of RA.
Figure 1. Association between DXA fat mass index (FMI) and muscle density among Healthy Controls and Rheumatoid Arthritis after adjustment for age, sex, and race.

Conclusion: Muscle density is lower in RA subjects compared to healthy controls of similar age, sex, and race. Differences in muscle density are not dependent on the greater fat mass observed among RA subjects. The interaction observed between RA status and FMI suggests that the mechanism of myosteatosis in RA may be distinct from that of healthy controls.

Incidence and Time Trends of Malignancy in Rheumatoid Arthritis: A Population Based Study 1980–2007. Kerry Wright, Cynthia S. Crowson, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: to determine the incidence and time trends of malignancy in patients with rheumatoid arthritis (RA) in 1980–2007 compared to individuals without RA from the same population.

Methods: A population based inception cohort of patients with RA who fulfilled 1987 ACR criteria in 1980–2007 and an age and sex matched cohort of non-RA subjects from the same population was assembled and followed until death, migration or 12/31/2008. Incidence rates of overall and site specific malignancy were collected. Cumulative incidence of malignancy adjusted for the competing risk of death was estimated for RA and non-RA subjects and compared using Gray's test.

Results: The study consisted of 813 RA and non-RA subjects (mean age 55.9 years, 68% female, 66% rheumatoid factor positive). Prior to RA incidence/non-RA index date, 53 RA and 66 non-RA subjects had a malignancy (p=0.22). The prevalence of hematologic malignancy was lower among RA subjects compared with non-RA subjects prior to the incidence/index date, (n=0 vs n=7, p=0.015). Excluding patients with prior malignancies, the remaining RA patients were followed for a mean of 9.1 years (mean 10.3 years for non-RA) during which 109 RA and 94 non-RA subjects developed a malignancy. The cumulative incidence for hematologic malignancy was higher among RA than non-RA subjects (2.0% ± 0.6% vs 0.7% ± 0.3% at 10 years, p=0.009). There was no significant difference in the cumulative incidence of overall malignancy between RA and non-RA subjects (13.0% ± 1.5% vs 9.1% ±1.2% at 10 years, p=0.10). There was no significant difference in the rate of lung or colon cancer in RA subjects relative to non-RA subjects. The cumulative incidence of breast cancer was lower among RA subjects compared to non-RA in the first 10 years after diagnosis of RA (2.9% ± 0.8% vs 1.6% ± 0.7% at 10 years), but this difference did not achieve statistical significance (p=0.63). Individuals diagnosed with RA more recently (1995–2007) were more likely to develop a hematologic malignancy compared with RA subjects diagnosed in earlier years (1980–1994) (hazard ratio [HR]: 2.28; 95% CI 0.95, 5.51). Similar changes were not seen over the same time period among subjects without RA.

Conclusion: Patients diagnosed with RA more recently appear to be at higher risk of developing a malignancy relative to patients diagnosed in earlier years. There was no significant difference in the rate of solid organ malignancies including breast, lung and colon cancer between RA and non-RA subjects in this population. The rate of hematologic malignancy is higher among patients with RA relative to non-RA subjects.

Frequency of Deep Vein Thromboses and Pulmonary Emboli in Rheumatoid Arthritis. Christian A. Pineau[1], Evelyne Vinet[1] and Sasha Bernatsky[2]. [1]McGill University Health Centre, Montreal, QC, [2]Research Institute of the McGill University Health Ctre, Montreal, QC

Background/Purpose: There are few data regarding the frequency of deep vein thromboses (DVTs) and pulmonary emboli (PE's) in patients with rheumatoid arthritis (RA). To determine the frequency of DVTs and PE's within RA patients in a population-based sample from Quebec, Canada.

Methods: We conducted a study using Quebec's provincial administrative health care databases (including physician billing claims and hospitalization records for all eligible Quebec residents (over 7.8 million individuals) from 1996 to 2008.

Cohort definition: The definition for RA was based on at least 2 physician billing diagnoses for RA (ICD-9 code 714, ICD-10 code M05), at least 8 weeks apart but within 2 years, OR at least one hospitalization code (primary or secondary) with an RA diagnostic code. Of these subjects, we excluded any with subsequent evidence (based on 2 billing codes or a hospitalization) of a different systemic rheumatic disease (including seronegative arthropathies and connective tissue diseases). We also excluded any patients who had seen a rheumatologist but who did not have the RA diagnosis confirmed on at least one of the rheumatology visits.

Outcome definitions: Our outcome definition for DVT was: Two or more physician billing diagnoses for ICD-9 code 451 or 453 (ICD10 code 180.2], or at least one hospitalization diagnosis (primary or secondary) indicating one

of these codes. Our outcome definition for PE was: Two or more physician billing diagnoses for ICD-9 code 415.1 (ICD-10 code I26) or one or more hospitalization diagnoses (primary or secondary), based on the same ICD codes.

We compared the number of observed events, to the number of events that would be expected, based on recent estimates of thromboembolic events (DVT's and PE's) within a general population (which were also based on physician billing and hospitalization administrative data sources. * The ratio of observed to expected events provides the standardized incidence ratio, and 95% confidence intervals were generated assuming a Poisson distribution for the observed events.

Results: In total over the period of study, we identified 170,021 Quebec residents who met our RA definition (suggesting a period prevalence of about 2%). The subjects were followed for a total of 1,074,854 patient-years, averaging 6.3 years (standard deviation 3.9) of observation per subject. Within this time, 12278 RA subjects had at least one event (1.18 events per 100 person-years), with 9,846 DVT's being recorded over the interval (0.94 events per 100 person-years), and 3756 PE's (0.35 events per 100 person-years).

RA cohort experience	Observed events	Expected Events*	Standardized Incidence rate	95%	CI
Any event	12278	9054	1.36	1.33	1.38
DVT	9846	7229	1.36	1.34	1.39
PE	3756	2996	1.25	1.21	1.29

* Expected rates generated from Boulet et al, ARCH INTERN MED 2010: 170 (19)

Conclusion: Our preliminary work suggests that patients with RA have about a 30% increase in thromboembolic events, compared to published general population rates. Further work is in progress to provide results stratified by age and sex.

Rheumatoid Arthritis Disease Activity During Pregnancy Affects the Postnatal Catch-up Growth of the Child. Florentien D.O. de Steenwinkel[1], Anita C.S. Hokken-Koelega[2], Maria A.J. de Ridder[1], Johanna M.W. Hazes[1] and Radboud J.E.M. Dolhain[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus Medical Center- Sophia Children's Hospital, Rotterdam, Netherlands

Background/Purpose: Active rheumatoid arthritis (RA) during pregnancy is associated with lower birth weight. Active RA during pregnancy can be treated with prednisone. However, studies have shown that prednisone use during pregnancy reduces gestational age thereby indirectly creates lower birth weight[1]. In general, newborns with a lower birth weight will catch-up in growth after they are born. Literature shows that a fast catch-up growth pattern of the child is associated with cardiovascular risk and metabolic disorders in early adulthood[2]. The purpose of this study: "Is maternal RA and/or prednisone use during pregnancy associated with fast catch-up growth in the first 2 years of the child?"

Methods: Current study is a continuation of a prospective nationwide study on RA during pregnancy. Growth charts were collected from children born from mothers participating in this study. Dependent variable: height standard deviation score (SDS) and weight SDS on different time points. Independent variable: prednisone use and RA disease activity (DAS28) during pregnancy.

Results: 161 growth charts were analyzed; 67 women used prednisone at some point during their pregnancy. The mean DAS28 during pregnancy was significantly higher in the prednisone group, 3.88 (SD: 1.01) than in the group without prednisone 3.02 (SD: 1.03) (p<0.0001).

An association was found between elevated DAS28 during pregnancy and fast catch-up growth (>0.50 SDS) of the child within the first half year. An increase of one point DAS28 during pregnancy resulted in a catch-up weight of 0.16 (p=0.03) and a catch-up height of 0.12 (p=0.04) at the age of 3 months. No effect was shown for prednisone use.

Conclusion: Our study suggests that elevated RA disease activity during pregnancy is associated with fast catch-up growth. This might have lifelong consequences for the child. Minimizing the disease activity during pregnancy is therefore crucial and should be striven at all times.

Self Reported Comorbidity Is Common in Early Inflammatory Arthritis and Associated with Poorer Function and Quality of Life and Greater Disease Activity: Results From the Canadian Early Arthritis Cohort.
Carol A. Hitchon[1], Gilles Boire[2], Boulos Haraoui[3], Edward Keystone[4], Janet E. Pope[5], Vivian P. Bykerk[6] and Canadian Early Arthritis Cohort (CATCH) Investigators[7]. [1]University of Manitoba, Winnipeg, MB, [2]CHUS - Sherbrooke University, Sherbrooke, QC, [3]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [4]University of Toronto, Toronto, ON, [5]Univ of Western Ontario, London, ON, [6]Hospital for Special Surgery, New York, NY, [7]Toronto

Background/Purpose: Chronic comorbid medical conditions may contribute to poor outcomes in rheumatoid arthritis. The extent of comorbidity, in particular cardiovascular disease (CVD), may be related to the burden of inflammation and may influence initial treatment choice. We report the association of baseline comorbidity with clinical disease activity, functional status and quality of life in early inflammatory arthritis (EIA) using data from the Canadian Early Arthritis Cohort (CATCH).

Methods: Subjects (n=779) with EIA of symptom duration 6–52 weeks, $\geq$ 2 effused joints *or* 1 swollen MCP or PIP and $\geq$ 2 of: +RF, +CCP, morning stiffness > 45 minutes, response to NSAIDS, or painful MTP squeeze test report comorbid medical conditions at baseline, quality of life indices (SF12) annually, and functional status (HAQ), pain visual analogue scale, detailed arthritis clinical assessments and arthritis treatment at each visit. Although there is no formal treatment protocol, participating rheumatologists aim for minimal disease activity. The influence of baseline comorbidity on outcomes while controlling for age and disease duration was tested by linear regression.

Results: Comorbidity was reported by 538 subjects (69%; median conditions 1 range 0–8). Patients with vs without comorbidity were older (45 vs 54 years p<0.0001) and had higher baseline disease activity primarily due to ESR (37 vs 21 p<0.001) and CRP (14 vs 11 p<0.02). Associations between CVD and higher DASCRP3v (4.42(1.3) vs 4.18(1.3) p=0.03) and worse HAQ (1.13(0.73) vs 0.94(0.71) p<0.001) at baseline were not significant after correcting for age. Baseline SF12 scores (all patients) were below population averages (Physical Composite Score (PCS) 37(11) and Mental Composite Score (MCS) 47(12)). SF12 correlated with the number of comorbidities: PCS (−0.2 p<0.0001); MCS (−0.11 p=0.003). All domain scores were significantly worse in patients with any comorbidity vs without. Patients with CVD (vs without) (34 (10) vs 38 (11) p<0.0001) endocrine disease (diabetes, thyroid, dyslipidemia) (35(11) vs 38(11) p=0.001), GI or renal (stomach bowel, liver disease, hepatitis or renal; 35(11) vs 38(11) p=0.03) and respiratory (asthma, bronchitis) (p=0.005) had poorer PCS. Patients with neurologic (migraine, parkinson, seizures) (44(12) vs 47(11) p=0.03), mental health (depression or other)(39 (11) vs 48 (39) p<0.0001) and GI or renal (43(12) vs 47(11) p=0.005) comorbidities were associated with poorer MCS. Patients with any baseline comorbidity had higher DASCRP3v scores (3.15 (8.1) vs 2.94 (9.1) p=0.004), worse functional status (HAQ 0.67 (0.54) vs 0.47 (0.46) p<0.0001), and more pain (3.6 (2) vs 3.2 (2.1) p=0.001), averaged over the first year, than those without baseline comorbidity. Renal or GI disease had worse DASCRP3v (p<0.001) over the first year. Baseline cardiovascular disease was not associated with poorer outcomes. The number of comorbid conditions at baseline was inversely associated with one year PCS and MCS.

Conclusion: Patients with comorbid medical conditions have greater disease activity, poorer functional status and lower self reported quality of life over the first year of followup. This observation has implications for treatment of early arthritis.

1226

Transition Time to Osteoporosis in Patients with Rheumatoid Arthritis.
Jiwon Hwang[1], Joong Kyong Ahn[2], Ji Young Chai[3], Hoon-Suk Cha[1], Jaejoon Lee[1] and Eunmi Koh[1]. [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Jesang Hospital, Seongnam-si Gyeonggi-do, South Korea

Background/Purpose: Rheumatoid arthritis (RA) is an independent risk factor for osteoporosis. Although bone mineral density (BMD) testing is routinely performed in patients with RA, the optimal interval between BMD tests remains undetermined. The aim of this study was to evaluate the transition time to osteoporosis in RA patients with normal BMD and in those with osteopenia at baseline, and to estimate the optimal BMD testing interval.

Methods: We retrospectively analyzed 548 consecutive RA patients at a single tertiary hospital who underwent BMD testing on two or more occasions during October 1994 and December 2011. Patients were sorted into 5 groups; normal baseline BMD (T score, −1.00 or higher), mild osteopenia (T score, −1.01 to −1.49), moderate osteopenia (T score, −1.50 to −1.99), severe osteopenia (T score, −2.00 to −2.49) or osteoporosis (T score −2.50 or lower). The transition time to osteoporosis was defined as the estimated time for 10% of patients to make the transition to osteoporosis from normal BMD or from each subgroup of osteopenia. Risk factors for osteoporosis on initial BMD test were also assessed.

Results: Patients were mostly women (96.4%) and the mean age was 55.6 ± 10.6 years. The mean follow-up duration of RA was 8.8 ± 4.3 years. At initial visit, 9.1% of patients had a past history of steroid use for diseases other than RA. Rheumatoid factor was positive in 330 of 531 patients (62.1%) and anti-CCP antibodies in 138 of 206 patients (67%). The mean duration between the initial visit and the first BMD screening was 32.7 ± 40.2 months and the prevalence of osteoporosis was 31.7% at screening (95% confidence interval (CI) 27.6 to 36.1). Estimated transition time to osteoporosis was 72 months (95% CI 36 to 90) for patients with normal BMD, 62 months (95% CI 28 to 126) for patients with mild osteopenia, 34 months (95% CI 16 to 60) for patients with moderate osteopenia, and 17 months (95% CI 10 to 21) for patients with severe osteopenia. The adjusted odds ratio (OR) for osteoporosis at initial BMD testing was high for older age (OR 1.066, 95% CI 1.029 to 1.105, p < 0.0001), past steroid use (OR 2.033, 95% CI 1.174 to 3.520, p = 0.0159), and current steroid use (OR 3.987, 95% CI 2.092 to 7.597, p < 0.0001).

Conclusion: Our data indicate that osteoporosis would develop in less than 10% of RA patients within 6 years for patients with normal bone density, 5 years for patients with mild osteopenia, 2.5 years for patient with moderate osteopenia, and 1 year for patients with advanced osteopenia at baseline. Therefore, the interval for rescreening BMD testing should be adjusted based on the initial BMD result in patients with RA.

1227

Rheumatoid Arthritis-Associated Interstitial LUNG Disease: Clinical Spectrum of A Large Cohort From A Respiratory Referral Center.
Joshua J. Solomon[1], Gloria M. Russell[2], Jill B. Ketzer[3], Amy L. Olson[4], Evans R. Fernandez-Perez[4], Tristan J. Huie[4], Jeffrey J. Swigris[4], Kevin K. Brown[5] and Aryeh Fischer[4]. [1]Denver, [2]Pontificia Universidad Católica Madre y Maestra, Santiago, Dominican Republic, [3]National Jewish Health, Denver, [4]National Jewish Health, Denver, CO, [5]National Jewish Hospital, Denver, CO

Background/Purpose: Rheumatoid arthritis (RA) has a myriad of pulmonary manifestations and RA-associated interstitial lung disease (RA-ILD) causes the most clinical concern. Subclinical ILD may be identified in up to 60% of individuals with RA, and lung disease is responsible for 10–20% of overall deaths and 80% of deaths in those with clinically significant lung disease. Known risk factors for RA lung disease include smoking and male gender. In this study, we sought to describe a large cohort of RA-ILD evaluated at our center.

Methods: We identified all subjects with a diagnosis of RA and ILD at our center between January 1987 and June 2012 (N=350). All subjects were confirmed to have RA by their treating rheumatologist. Patients without a high resolution computed tomography (HRCT) or surgical lung biopsy were excluded. The final cohort consisted of 135 subjects. All data were extracted from comprehensive medical review. Kaplan Meier survival analysis was performed on those with usual interstitial pneumonia (UIP) and non-specific interstitial pneumonia (NSIP).

Results: Table 1 displays the cohort characteristics as a whole and Table 2 displays the comparison of those with UIP and NSIP. There was no significant difference among those with UIP (median 100.3 months) compared to NSIP (median 58.3 months) (p=0.5).

Table 1. Baseline Demographics and Pulmonary Function Tests

Age at Initial Visit	63 (21 to 90)
Gender (%male)	42%
Current or Past Smokers	67%
RF Positivity	79%
RF Level	822 (0 to 13300)
CCP Positivity	76%
CCP Level	134 (0 to 323)
ANA positivity	14%
%FEV1	67% (22 to 113%)
%FVC	66% (30 to 122%)
%TLC	84% (45 to 143%)
%DLCO	70% (31 to 127%)
ILD Subtypes	
Usual Interstitial Pneumonia	31% (43)
Nonspecific Interstitial Pneumonia	30% (41)
Fibrosis NOS	12% (17)
Cryptogenic Organizing Pneumonia	2% (3)
Other	22.5% (31)

Table 2. Usual Interstitial Pneumonia vs Nonspecific Pneumonia

	Usual Interstitial Pneumonia	Nonspecific Interstitial Pneumonia
Age at initial visit	63 (39–84)	62 (26–84)
Gender (% male)	70%	22%
Past or current smokers	63%	60%
RF positivity	100%	76%
CCP positivity	83%	68%
%FVC	59% (30–100%)	67% (32–112%)
%DLCO	62% (39–96%)	75% (31–111%)
%TLC	76% (53–105%)	80% (45–128%)

Conclusion: In contrast to prior studies that suggest UIP is the most common pattern in RA-ILD, equal numbers of subjects with UIP and NSIP were identified in our large cohort. We also found a significant number of subjects in whom lung disease was either too mild to classify or had fibrotic features both of NSIP and UIP (28% of our cohort). Furthermore, in contrast to prior studies that suggest RA-UIP has worse survival than RA-NSIP, underlying histologic pattern did not impact survival in our cohort. Prospective studies are needed to further understand the impact of histopathology on the natural history of RA-ILD.

Contributions of Inflammation, Inactivity, and Low Dose Prednisone Use to Skeletal Muscle Insulin Resistance in Well-Controlled Rheumatoid Arthritis. Hiba Abouassi, Lori Bateman, Gary E. McDaniel, Lorraine Elliott-Penry, Michael Muehlbauer, E. William St. Clair, William E. Kraus and Kim M. Huffman. Duke University Medical Center, Durham, NC

Background/Purpose: Rheumatoid arthritis (RA) is associated with a high prevalence of insulin resistance. Most prior investigations of insulin resistance in RA have examined fasting glucose and insulin. However, because glucose uptake is performed predominantly by skeletal muscle, skeletal muscle insulin resistance is best assessed with a glucose challenge. We determined if persons with RA exhibit more skeletal muscle insulin resistance than age, gender, race, and BMI–matched controls, and if inflammation, inactivity, and low dose prednisone use mediated skeletal muscle insulin resistance.

Methods: We enrolled 50 participants with RA and 50 matched controls; all had no history of diabetes or cardiovascular disease. The patients with RA had not changed their anti-rheumatic therapy in the previous 3months and may have been taking low doses of prednisone (5 mg or less per day); any steroid tapers were completed at least three weeks prior to study enrollment. Participants completed questionnaires for medication information, a visual analog scale for health rating, and the Stanford Brief Activity Survey for physical activity. Each underwent anthropomorphic measures, a 28 joint exam, and fasting blood collection for glucose, insulin, and an erythrocyte sedimentation rate (ESR), used to compute a disease activity score (DAS-28). Fasting glucose and insulin were used to calculate the Homeostasis Model of Assessment (HOMA). A frequently-sampled

intravenous glucose tolerance test was performed with glucose and insulin measured in each sample. Bergman's minimal model was used to determine insulin sensitivity (SI), indicative of skeletal muscle insulin sensitivity. SI was logarithmically transformed prior to group comparisons with a t-test and predictor identification with linear modeling.

Results: Persons with RA reported less physical activity (P=0.046) than controls, and had a slightly higher median (IQR) ESR [4 (1, 5) vs. 8 (1, 18) mm/h, P=0.05]. The median (IQR) DAS-28 was 2.9 (2.1, 3.8). Daily low dose prednisone use was reported by 27%.

Persons with RA were more insulin resistant than controls (geometric mean (SD) 4.4 (2.39) versus $4.8(2.1)*10^{-5}\text{min}^{-1}/[\text{pmol/l}]$), but this difference was not statistically significant (P=0.37). Prednisone use was related to SI independent of the contributions of BMI, fasting insulin, HOMA, gender and physical activity ($R^2 = 0.56$, model P<0.0001, prednisone use, partial R^2=0.10, P=0.03). Prednisone use was associated with more than a 41% lower SI. There was a trend for an independent relation for physical activity with SI (partial R^2=0.03, P=0.09). Age, ESR, DAS-28, NSAID, DMARD, or biologic use did not contribute to SI in the aforementioned model.

Conclusion: Although persons with RA showed higher insulin resistance, this difference did not achieve statistical significance. However, in persons with RA, the use of low dose prednisone therapy did appear to increase skeletal muscle insulin resistance independent of BMI and physical activity. Future studies should determine if interventions, such as regular physical activity, can counteract the effect of low dose prednisone use on skeletal muscle insulin resistance.

1229

Rheumatoid Arthritis and Risks of Malignant Lymphoma - Are Risks Still Increased? Karin Hellgren[1], Eva Baecklund[2], Karin E Smedby[3], Carin Backlin[4], Christer Sundstrom[5] and Johan Askling[6]. [1]Unit of Rheumatology, Stockholm, Sweden, [2]Unit of Rheumatology, Uppsala, Sweden, [3]Clinical Epidemiology Unit, Stockholm, Sweden, [4]Department of Medical Sciences, Uppsala, Sweden, [5]Department of Genetics and Pathology, Uppsala, Sweden, [6]Rheumatology Unit & Clinical Epidemiology Unit, Stockholm, Sweden

Background/Purpose: Patients with established Rheumatoid Arthritis (RA) are at increased risk of malignant lymphomas. We have previously demonstrated a strong association between inflammatory intensity and lymphoma risk in a historical RA cohort, but also that the lymphoma risk was increased in patients diagnosed 1997 and followed through 2006. Given the dramatic changes in treatment strategies and goals over the last decade, it may be that lymphoma risks in more recently diagnosed patients have changed. We therefore aimed at assessing lymphoma risks in a more contemporary patient population with respect to year of RA onset and duration of RA disease.

Methods: 10,367 patients with incident RA (ACR criteria, >18 years age, symptom duration ≤ 13 months) diagnosed 1997 through 2010 were identified within the national Swedish Rheumatology Register (SRQ) including information on disease characteristics, disease activity, and therapy. Each patient was matched to 5 general population comparators, by gender, age and residence (n=49,825).To identify the lymphomas, all individuals were linked to the nationwide Swedish Cancer Register. Relative risks (RR) of lymphoma were assessed using Cox models. The RA lymphomas were reviewed and reclassified (WHO classification).

Results: Overall, the risk of lymphoma in RA was almost doubled (RR= 1.7 (95% CI 1.2–2.4)), based on 45 lymphomas in RA versus 126 in the general population comparator cohort (person time 58,825 versus 283,903). When stratified by RA disease duration, a statistically significantly increased risk (p value=0.04) was noted > 5 years after RA diagnosis. When relative risks were cross-tabulated according to year of RA onset and time since RA diagnosis, we noted that this risk increase was significant only among patients in calendar period 1997–2001. Short-term risks for lymphoma were similar across calendar periods. (see Table).

Calender Period, years of inclusion in SRQ RR (95% CI) (No. of events)	Time period since RA diagnosis (years) RR (95% CI) (No. of events)			
	0-<3	3-<6	6–14	Total
1997–2001	1.3 (0.5–3.7) (4/13)	1.3 (0.5–3.3) (5/21)	2.7 (1.4–4.9) (15/27)	1.9 (1.2–3.1) (24/61)
2002–2005	1.2 (0.4–3.3) (4/16)	1.7 (0.8–3.8) (7/17)	2.0 (0.6–6.7) (3/8)	1.6 (0.9–3.0) (14/41)
2006–2010	1.6 (0.7–3.7) (6/20)	1.3 (0.2–9.4) (1/4)	not applicable	1.4 (0.6–3.3) (7/24)
Total study period 1997–2010	1.2 (0.7–2.1) (14/49)	1.6 (0.9–2.9) (13/42)	2.9 (1.7–4.7) (18/35)	1.7 (1.2–2.4) (45/126)

Conclusion: Overall, the risk increase for malignant lymphomas in RA patients diagnosed 1997–2010 was of a similar magnitude as that reported from historical RA cohorts. Whereas our results suggested a declining point estimates for lymphoma risk in successive calendar periods of RA diagnosis 1997–2010, this observation was confounded by differences in length of follow-up, i.e., that risks increased with RA duration. It will be an important task to monitor future risks over longer follow-up time.

1230

The Role of Sleep Problems in Conditioned Pain Modulation in Rheumatoid Arthritis.
Yvonne C. Lee[1], Bing Lu[2], Robert R. Edwards[3], Ajay Wasan[4], Nicholas Nassikas[1], Daniel J. Clauw[5], Daniel H. Solomon[6] and Elizabeth W. Karlson[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Brigham & Womens Hospital, Chestnut Hill, MA, [4]Brigham and Women's Hospital, Chestnut Hill, MA, [5]University of Michigan, Ann Arbor, MI, [6]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA

Background/Purpose: Among rheumatoid arthritis (RA) patients, pain may exist out of proportion to peripheral inflammation. This observation suggests that central nervous system pain amplification mechanisms, such as diminished conditioned pain modulation (CPM), may play a role in enhancing pain perception among some RA patients. We examined CPM, pressure pain threshold and pressure pain tolerance among RA patients compared to controls.

Methods: Fifty-eight female RA patients and 54 age-matched controls without chronic pain underwent quantitative sensory testing to assess CPM, pressure pain threshold and pressure pain tolerance. We induced CPM using a cold water bath, and we assessed pain threshold (when patients first felt pain) and tolerance (when pain was too much to bear) with an algometer. Associations between RA and quantitative sensory testing measures were analyzed using linear regression models. Sleep problems, mental health and inflammation were assessed as mediators of the relationship between RA and quantitative sensory testing measures, according to the Baron and Kenny criteria (J Pers Soc Psychol 1986).

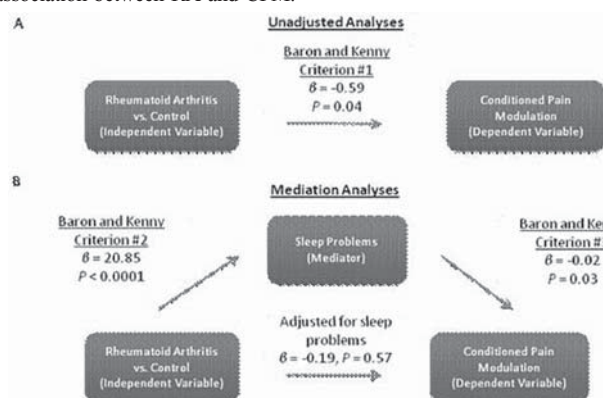
Results: Median CPM levels were 0.5 kg/cm^2 (interquartile range (IQR) -0.1, 1.6) among RA patients compared to 1.5 kg/cm^2 (IQR -0.1, 2.5) among controls ($P = 0.04$). Relative to controls, RA patients had lower pain threshold ($P = 0.03$) and tolerance ($P \leq 0.004$) at the wrists and knees. Spearman's correlations between clinical pain scores and quantitative sensory testing measures of pain varied from -0.08 for CPM to -0.31 for wrist tolerance. Compared to controls, RA patients had greater problems with sleep, catastrophizing, depression and anxiety ($P < 0.0001$). Mediation analyses showed significant associations between: 1) RA and CPM (Baron and Kenny criterion #1), 2) RA and sleep problems (Baron and Kenny criterion #2) and 3) sleep problems and CPM, adjusted for RA (Baron and Kenny criterion #3) (Figure 1). Catastrophizing, depression and anxiety did not mediate the association between RA and CPM.


Figure 1. A. Unadjusted association between RA and conditioned pain modulation. B. Mediation analyses for the role of sleep problems in the association between RA and conditioned pain modulation. The change in β between the unadjusted analyses and the analyses adjusted for sleep problems indicates potential mediation, which is supported by the Baron and Kenny criteria: 1) the significant unadjusted association between RA and conditioned pain modulation, 2) the significant association between RA and sleep problems and 3) the significant association between sleep problems and conditioned pain modulation, adjusted for RA.

Conclusion: RA patients have impaired CPM relative to pain-free controls. Sleep problems may contribute to low CPM levels. Future studies are needed to determine whether interventions to improve sleep may improve pain in RA.

1231

Rheumatoid Arthritis Is Associated with Likelihood of Being Overweight in Women.
Irum-Mona Idrees[1], H. Lester Kirchner[2] and Androniki Bili[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Danville, PA

Background/Purpose: Adipose tissue is metabolically active producing adipokines, which, along with locally attracted cytokines, are active participants in inflammation and its regulation. Since RA a systemic inflammatory disease, we postulated that obesity might be a risk factor for developing RA. The objective of this study was to evaluate the association of obesity with risk of incident RA.

Methods: We conducted a case control study using incident RA cases from 2001 to 2011 in a health system using electronic health records. Patients with a primary care physician in the health system with at least 3 documented body mass index (BMI, in kg/m^2) measurements were eligible. A 1:5 (case:control) age, gender, and calendar year match design was performed. An index date was created such that for cases it was the date of RA diagnosis and for the controls it was the date of RA diagnosed in the matching case. Current obesity was defined using the most recent prior, BMI measurement to the index date. History of obesity was defined using all historical BMI measurements, prior to the index date. Any prior BMI >30 was considered as meeting criteria. This was repeated for current and history of overweight classification (BMI > 25). The association between BMI in RA patients and the controls was calculated using a conditional logistic regression model adjusting for current smoking status.

Results: 523 patients with incident RA and 2615 age, gender, calendar year matched controls were included in the analysis. The baseline characteristics revealed similar average BMI measurements in the two groups; current and past smoking was more prevalent in the RA group than controls. Of the RA patients, 63% and 41% were positive for RF and ACPA, respectively. The odds ratio (OR) for the association between RA and obesity or overweight overall, and stratified by gender, is shown in Table 1. Subgroup analysis according to RF positivity is shown in Table 2. Similar results were found for ACPA positivity.

Table 1. Odds of obesity or overweight in RA patients according to gender

	All		**Female**		**Male**	
	OR (95% CI)	P-Value	OR (95% CI)	P-Value	OR (95% CI)	P-Value
BMI	1.01 (0.99, 1.02)	0.19	1.01 (1.00, 1.03)	0.12	0.99 (0.96, 1.03)	0.73
Current Obesity	1.07 (0.88, 1.29)	0.50	1.21 (0.97, 1.51)	0.10	0.79 (0.56, 1.12)	0.19
History of Obesity	1.18 (0.98, 1.43)	0.08	1.24 (0.99, 1.56)	0.06	1.04 (0.74, 1.48)	0.81
Current Overweight	**1.31 (1.03, 1.66)**	**0.03**	**1.38 (1.05, 1.82)**	**0.02**	1.11 (0.68, 1.80)	0.67
History of Overweight	**1.43 (1.09, 1.88)**	**0.01**	**1.60 (1.17, 2.18)**	**0.003**	0.92 (0.52, 1.62)	0.77

Table 2. Odds of RF positivity in RA patients according to gender

	RF-negative vs. Control		**RF-positive vs. Control**	
	OR (95% CI)	P-Value	OR (95% CI)	P-Value
BMI	1.03 (1.00, 1.05)	0.04	1.00 (0.99, 1.02)	0.72
Current Obesity	1.18 (0.86, 1.62)	0.30	1.01 (0.79, 1.29)	0.93
History of Obesity	**1.44 (1.04, 2.01)**	**0.03**	1.05 (0.83, 1.34)	0.69
Currently Overweight	**1.68 (1.09, 2.58)**	**0.02**	1.15 (0.85, 1.54)	0.37
History of Overweight	**1.72 (1.06, 2.78)**	**0.03**	1.22 (0.87, 1.71)	0.25

Conclusion: RA is associated with 43% and 31% increase in odds of historical or current overweight status in women. This is consistent with other previously reported data and it is a significant observation that can help shed light in the pathogenesis of RA. Further, the observed association of being currently overweight or historically overweight or obese with specifically

sero-negative RA may be relevant to the reported protective effect of a higher BMI on joint erosion in RA. These results need to be replicated in prospective RA cohorts.

Association of Actometer Assessed Physical Activity and Fatigue in Patients with Rheumatoid Arthritis: Patients with a Lower Daily Activity Have More Fatigue. Sanne van Dartel, Han Repping-Wuts, Dewy van Hoogmoed, Hans Knoop, Gijs Bleijenberg, Piet L.C. van Riel and J. Fransen. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Fatigue in rheumatoid arthritis (RA) is related to pain and disability, and several psycho-social factors such as coping strategies. In Chronic Fatigue Syndrome (CFS), increased fatigue is associated with reduced physical activity. Apparently, cognitive behavioral therapy and exercise are the only effective interventions in CFS. It is unclear whether, also in RA, fatigue and physical activity are related. Therefore, the objective of this study was to investigate whether there is an association between objectively measured physical activity and patient assessed fatigue in RA patients.

Methods: Consecutive RA patients of the rheumatology clinic of the Radboud University Nijmegen Medical Centre (N=181) were enrolled. Fatigue severity was measured using the fatigue severity subscale (CIS-fatigue) of the Checklist Individual Strength (CIS20). Physical activity was measured during 12 consecutive days with an ankle-worn actometer and a daily activity score was calculated from the number of accelerations. The group mean of the physical activity score over the 12-day period acted as predefined reference score. All patients with at least 10 daily measurements of activity were included in the analyses. Patients with at least 90% of their daily activity scores below the group mean were classified as pervasively passive, while the remaining patients were labeled as active. Linear regression was performed with CIS-fatigue as dependent and physical activity as independent variable with correction for confounders. Fatigue was also analyzed classified as severely fatigued (CIS-fatigue score $\geq$ 35) and not severely fatigued (CIS-fatigue score $<$ 35).

Results: A total of 167 patients had at least 10 daily measurements of activity and were included in the analysis. Mean activity score ($\pm$SD) of all 167 patients was 73$\pm$27, and 42 (25%) patients were classified as pervasively passive and 125 (75%) patients were classified as active. Active patients showed less fatigue: the mean ($\pm$SD) CIS-fatigue was 30.9 (12.3) in active patients and 35.7 (12.8) in pervasively passive patients (p=0.028). Similarly, there was a significantly higher percentage of severely fatigued patients in the passive group (60%) compared to the active group (38%), (p=0.017). The relation between activity and fatigue was linear ($\beta=$ -0.077) and significant (p=0.012), with correction for the confounders age, gender and pain.
Figure 1. Box plots: bold horizontal bars indicates the medians, the end of the boxes indicates the quartiles.

Conclusion: In RA, a higher level of physical activity was associated with less fatigue. Active patients had a significantly lower CIS-fatigue score than the pervasively passive patients. To study whether this relationship is causal

and clinically relevant, an intervention trial aiming at increasing activity may be performed.

Effect of Insoles On the Rheumatoid Foot. Emilia Moreira[1], Anamaria Jones[1], Hilda A. Oliveira[1], Fabio Jennings[1], Artur R.C. Fernandes[2] and Jamil Natour[3]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease characterized by peripheral polyarthritis, which may cause joint destruction and deformities, resulting in reduced function and disability. The joint involvement of the foot occurs in 85–100% of the patients with RA. The use of insoles has been a routine in the treatment of rheumatoid feet, despite the weak evidence of its use in randomized controlled trials. The aim of the present study were to evaluate the effectiveness of the use of insoles for foot pain, function, gait, foot load distribution, quality of life and patient satisfaction regarding the use of the insoles in patients with RA.

Methods: Eligible patients included women classified as RA according to the ACR criteria, aged 18–65 years old with pain in feet between 3 and 8 on a 10-cm pain scale (VAS) for walking; functional classes I, II, and III. Of the 208 patients evaluated, 80 met the eligibility criteria and were randomized into experimental (EG) or control groups (CG). The EG group made use of EVA insoles with medial arch and retrocapital support, and CG group employed flat insoles during the study. Pacients were evaluated for pain (VAS) when walking and at rest, function (HAQ), function of the feet (FFI), quality of life (SF-36), 6-minute walk test, satisfaction with the treatment (Likert scale) and dynamics baropodometry (Pro FootWalk, AMcube®, Gargas, France) at baseline, 45 days (T45), 90 days (T90) and 180 days after randomization by a blinded evaluator.

Results: Thirty-nine and 41 patients were randomly divided into EG and CG groups, respectively. The groups were homogeneous at baseline regarding clinical and demographic characteristics. In the comparison between the groups over time, we found better results for the EG with a statistical difference for pain during walking and at rest on the right and left foot (p $<$0.001), stride length (p $=$ 0.001), and satisfaction with the treatment (p $=$ 0.039). For other variables, we found no statistically significant difference between groups.

Conclusion: The use of insoles with medial arch and retrocapital support is effective in reducing pain during walking and at rest on both feet, increasing stride length and satisfaction with the use of insoles.

Barriers, Benefits and Preferences for Exercise in RA Patients: A Cross Sectional Study. Yves Henchoz[1], Pascal Zufferey[2] and Alexander So[2]. [1]Université du Québec à Trois-Rivières, Trois-Rivières, QC, [2]Lausanne University Hospital, Lausanne, Switzerland

Background/Purpose: Physical exercise is safe and effective as an adjunctive nonpharmacological treatment modality in the management of rheumatoid arthritis (RA). It is well established that patients with RA are less active compared to healthy controls. The transtheoretical model of health promotion, based on five stages of change, provides a useful framework to better understand patients' motivation towards regular exercise. The purpose of this study was to determine the distribution of exercise stages of change in a RA cohort, and to examine barriers, benefits and preferences for exercise.

Methods: One hundred and twenty consecutive patients with RA followed at a hospital-based rheumatology practice were invited to participate in the study. Those who accepted to participate filled in a questionnaire to determine their exercise stage of change, their perceived benefits and barriers to exercise, and their preferences for various features of exercise. Disease activity was measured using the disease activity score (DAS28). Other variables included the Health Assessment Questionnaire (HAQ), the short version of the Arthritis Impact Measurement Scales 2 (AIMS2-SF), pain and

fatigue visual analogue scales (VAS), the number of comorbidities and demographic characteristics. Characteristics of patients in the maintenance and precontemplation stages of change were compared using two-sample t tests, Wilcoxon rank-sum tests and Chi-square tests.

Results: Eighty nine (74%) patients were finally included in the analyses. Mean age was 58.4 (SD 11.7) years, mean RA duration was 10.1 (9.8) years and mean DAS28 was 2.8 (1.2). The distribution of exercise stages of change was as follows: precontemplation (n=30, 34%), contemplation (n=11, 13%), preparation (n=5, 6%), action (n=2, 2%), and maintenance (n=39, 45%). Compared to patients in the maintenance stage of change, precontemplators were less often at work (P<0.05), exhibited a higher body mass index (P<0.01), poorer HAQ (P<0.01), higher pain VAS (P<0.05), poorer scores of physical (P<0.001), symptom (P<0.01), affect (P<0.01) and role (P<0.01) dimensions of the AIMS2-SF, and reported less exercise benefits (P<0.05) and more barriers to exercise (p<0.01). Most participants preferred exercising alone (40%), at home (29%), at a moderate intensity (64%), with advice provided by a rheumatologist (34%) or a specialist in exercise and RA (34%). Walking was by far the preferred type of exercise, in both the summer (86%) and the winter (51%).

Conclusion: This study provides new insight into how RA interferes with exercise participation. Our cohort of patients with RA was essentially distributed across the precontemplation and maintenance exercise stages of change. These subgroups of patients exhibit psychological and functional differences that make their needs in terms of exercise counseling different. Walking appears to be a simple but promising way of promoting physical activity among RA patients.

Orthopedic Surgery Among Patients with Rheumatoid Arthritis 1980–2007: A Population-Based Study to Identify Predictors of Large Joint Vs Small Joint Surgeries. Ashima Makol, Cynthia S. Crowson and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Despite improvements in medical management of rheumatoid arthritis (RA) in recent years, arthritis related orthopedic surgery is often needed to relieve pain and improve function. We aimed to identify risk factors for orthopedic surgery in RA, and ascertain if predictors for large joint surgery differ from those for small joint surgery and soft-tissue procedures.

Methods: A population-based inception cohort of patients fulfilling 1987 ACR criteria for RA between 1980–2007 was assembled and followed until death, migration or 12–31–2008. A retrospective medical record review was performed of all orthopedic surgeries since RA incidence, including primary total joint arthroplasty (TJA), large joint surgery (LJS), small joint surgery (SJS) and soft tissue procedures (STP). Demographics, clinical characteristics of RA, extra-articular manifestations and comorbidities were recorded. Risk factors for surgery were examined using Cox models adjusted for age, sex and calendar year.

Results: The study included 813 RA patients (mean age 56 years; 68 % female; mean follow-up 9.6 years), 189 of who underwent ≥1 joint surgeries during follow-up.

Age was associated with a significantly higher risk of TJA (hazard ratio [HR] per 10 years 1.18; p=0.01) and hip/knee surgery (HR 1.3; p<0.001) but lower risk of SJS (HR 0.84; p=0.03). Female sex (HR 1.38; p=0.05) was predictive of a higher risk for any joint surgery. Obesity at incidence was predictive of higher rates of TJA (HR 2.0; p=0.001), LJS (HR=1.8; p=0.001) and hip/knee surgery (HR=2.6; p<0.001), but not SJS (HR=0.8; p=0.4) or STP (HR=1.0; p=0.9). ESR at RA incidence was associated with increased risk for any joint surgery (HR per 10 mm/hr 1.12; p=0.002), TJA (HR=1.2; p<0.001) and LJS (HR=1.15; p=0.001) but not SJS (HR=1.0; p=0.7). Presence of rheumatoid factor (HR=2.0; p<0.001) and radiographic erosions (HR 3.1; p<0.001) predicted a significantly higher risk for any joint surgery.

Large joint swelling was associated with elevated risk of TJA (HR 1.85; p=0.02), LJS (HR 2.1; p=0.001) and STP (HR 2.0; p=0.02) but not SJS. Rheumatoid nodulosis was predictive of SJS (HR 3.3; p<0.001) and STP (HR 3.0; p<0.001) but not LJS (HR=1.3; p=0.2). Severe extra-articular manifestations of RA were marginally associated with a higher risk of SJS (HR 1.8; 95% confidence interval [CI] 0.93–3.6) but not LJS (HR 1.0; p=0.98). Smoking history predicted a marginally higher risk for STP (HR 1.57; 95% CI 0.98–2.5) but not other procedures.

Conclusion: Women with RA are more likely than men to undergo joint surgery. Female sex, increasing age and obesity were predictive of LJS (especially hip and knee TJA) in RA, similar to the general population. Older patients were less likely to undergo SJS. Rheumatoid nodulosis and radiographic erosions are strong predictors especially for SJS and STP but are also associated with increased risk for any joint surgery. These results indicate that need for LJS in patients with RA is similar to the general population, and that SJS is less desirable for older patients despite long standing disease. Aggressive control of disease activity in the early years after RA incidence to lessen development of erosive changes may decrease future need for joint surgery.

1236

Important Prognostic Factor in Rheumatoid Arthritis Patients with Interstitial Lung Disease Is Not Usual Interstitial Pneumonia Pattern but Interstitial Lung Disease Extent On Chest High-Resolution Computed Tomography. Hwajeong Lee[1], Jung-Yoon Choe[1], Seong-Kyu Kim[1], Sung Hoon Park[1], Ji Hun Kim[1], Dae Sung Hyun[2], Kyung Jae Jung[3] and Jisuk Bae[4]. [1]Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]Division of Pulmonology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, South Korea, [3]Radiology, Catholic University of Daegu School of Medicine, South Korea, [4]Department of Preventive Medicine, Catholic University of Daegu School of Medicine, South Korea

Background/Purpose: Interstitial lung disease (ILD) is a common pulmonary manifestation of rheumatoid arthritis (RA), and an important cause of morbidity and mortality in RA patients. We categorized ILD to two groups, as the usual interstitial pneumonia (UIP) pattern and the nonspecific interstitial pneumonia (NSIP) pattern, using chest high-resolution computed tomography (HRCT) scanning. We compared demographic and clinical characteristics of UIP pattern and NSIP pattern in rheumatoid arthritis patients and determined the important prognostic factors that influence the survival of RA-ILD patients.

Methods: We enrolled 51 RA patients (male n=21, female n=30) with ILD underwent HRCT, between January 2002 and December 2011 in Catholic University Hospital of Daegu.

Results: Demographics and the clinical characteristics of the 51 RA-ILD patients showed no significant difference between the UIP pattern and NSIP pattern. Comparing the two groups, there were no differences in age at which RA was diagnosed, age at which ILD was diagnosed, RA duration, ILD duration, proportion of steroid and DMARD medication, laboratory study, pulmonary function test and ILD extent on chest HRCT. But RA-NSIP group was younger than RA-UIP group (62.3±11.7 vs 68.2±8.4).

Of the 51 RA-ILD patients, 21(UIP pattern 16 cases, NSIP pattern 5 cases) patients died. More patients died in UIP pattern, but there were no significant differences in survival time between RA-UIP pattern and RA-NSIP pattern (Log rank p=0.985).

Cox's regression analysis was performed to find out prognostic factors that affects survival of RA-ILD patients. ILD extent on chest HRCT was strongly associated with mortality (HR=1.044, 95% CI 1.019–1.069). Patients that was diagnosed ILD in older age (HR=1.518, 95% CI 1.109–2.077), high LDH(HR=1.007, 95% CI 1.000–1.014) and high rheumatoid factor (HR=1.004, 95% CI 1.000–1.008), the use of MTX (HR=5.539, 1.332–23.041) were associated with worse survival time. UIP pattern on HRCT, age, sex, smoking history, anti-CCP antibody didn't have an effect on survival. We divided the extent of the lung disease in to 4 groups; 1–15%, 16–20%, 21–25%, >25% and compared the survival rate. Comparing four groups, there were significant differences in survival estimates (Log-rank p value= 0.0) based on ILD extent of 15%. The median survival time for ILD extent of less than 15% was 89.4 months, ILD extent of excess of 15% was 49 months.

Conclusion: Our case studies reveal that the relationship of the UIP pattern to survival is unclear but the extent of ILD on chest HRCT was found to be significantly associated with poor prognosis of RA-ILD patients.

Baseline Evaluation of Insulin Resistance in Patients with early Non-Treated Rheumatoid Arthritis. Sara Manrique-Arija[1], María América López-Lasanta[1], Pilar Espiño- Lorenzo[1], Pedro Valdivielso[2], José Rioja[2], Inmaculada Ureña[1], Francisco Gabriel Jimenez- Núñez[1], Carmen M. Romero-Barco[1], Veronica Rodríguez-García[1], Laura Nieves[1], Mari Carmen Ordoñez-Cañizares[1], Laura Cano[1], Maria Victoria Irigoyen[1] and Antonio Fernández-Nebro[1]. [1]Hospital Carlos Haya. University of Malaga, Malaga, Spain, [2]Department of Medicine. University of Malaga, Malaga, Spain

Background/Purpose: High levels of inflammatory cytokines are associated with insulin resistance syndrome in long-standing AR. The aim was to analyze insulin resistance (IR), adipokines, inflammatory cytokines and baseline clinical and laboratory features in patients with early rheumatoid arthritis (ERA) who have not received any treatment for their underlying disease.

Methods: Cross-sectional, case-control, study. Forty-six consecutively patients with ERA (disease duration <1 year) according to 2010 ACR/EULAR criteria, older than 16 years of age and 45 sex and age-matched controls were included. Patients with Diabetes (2010 ADA Criteria) and in prior or current treatment with DMARDs or corticosteroids were excluded. All participants signed an informed consent. Baseline blood and urine samples were collected; Glucose, lipid profile, RF, anti-CCP, ESR, CRP and other parameters were measured in fresh samples; serum was stored at −80°C for later analysis of insulin, ultrasensitive CRP, IL6, TNFα, resistin, adiponectin y leptin. Insuline resistance was estimated by the Homeostasis model assesment for insulin resistance (HOMA-IR), HOMA β, McAuley and QUICKI index. A cardiovascular risk factors (CVRF) questionnaire and a dietary survey were also completed. Measurement of abdominal and hip circumference was performed. Statistical analysis: T-test or Mann Whitney test and Pearson or Spearson's correlation analysis were performed.

Results: Among 103 subjects twelve were excluded (6 were other types of arthritis, 6 had type 2 diabetes) and finally, 91 subjects were included; 46 had RA (50.5%) and 45 were healthy controls (49.5%). Most of them were women (~76%) and there were not differences in age, sex and BMI, between groups but hypertension was higher in patients than controls (30 vs 13%, p < 0.05). Regarding baseline characteristics of patients with RA, the average time of evolution of RA was 6 months, and more than 70% had positive RF and anti-CCP. Concerning laboratory parameters, CRP and ESR were higher in RA patients than in controls (p<0,001). In relation to CVRF and IR, total cholesterol was higher in controls [215 (SD±40,3) mg/dl vs 195(SD±39,5) mg/dl (p< 0,05)], and HDL cholesterol lower in RA patients [52(SD±14,8)mg/dl Vs 59 (SD±16,7) mg/dl(p< 0,05)], and also levels of cytokines such as IL6, TNF-alpha and Resistin in blood were higher in patients than controls. No statistically significant differences were found in leptin, adiponectin or atherogenic index between cases and controls neither in insulin resistance estimated by HOMA-RI, HOMA β, QUICKI nor McAuley. Bivariate analysis revealed a statistically significant correlation between the different indices of IR and parameters of inflammatory activity (PCR, TNF), leptin and body composition.

Conclusion: Although patients showed higher blood pressure, total cholesterol and resistin levels and lower HDL cholesterol than age, sex and BMI matched controls, we were unable to show differences in leptin, adiponectin and any of the insulin resistance indexes assessed, in spite of the expected high levels of systemic inflammatory molecules, such as TNFα and IL-6 in patients group. Lack of association between AR and IR indexes might be due to the short course of the disease.

1238

Effects of Stress On Clinical Presentation of Patients with Early Rheumatoid Arthritis. Yun A. Kim[1], Jane E. Salmon[2], Juan Xiong[3], Boulos Haraoui[4], Carol A. Hitchon[5], Edward Keystone[6], Janet Pope[7], Diane Tin[8], J. Carter Thorne[8], Gilles Boire[9], Vivian P. Bykerk[2] and CATCH[10]. [1]Hospital for Special Surgery (and Kwangju Christian Hospital, Gwangju, Korea), New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Mount Sinai Hospital, Toronto, ON, [4]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]University of Toronto, Toronto, ON, [7]Schulich School of Medicine and Dentistry, Western University, London, ON, [8]Southlake Regional Health Centre, Newmarket, ON, [9]CHUS - Sherbrooke University, Sherbrooke, QC, [10]Toronto

Background/Purpose: Stress is related to pathogenesis and progression of inflammatory autoimmune disorders. The aim of this study is to evaluate the role of patient (pt) self reported stress within a year of clinical presentation, particularly pt reported outcomes (PROs) in patients (pts) with early rheumatoid arthritis (ERA).

Methods: 951 pts in CATCH (Canadian Early Arthritis Cohort), a prospective multicentre observational cohort, who answered a modified stress & life events questionnaire, were included. Psychological (Psych) stress was defined as death of family member, divorce, separation, family stress and financial stress. Physical stress was defined as motor vehicle accident, surgery, major illness and infection. Differences in baseline characteristics and PROs in pts at 6 months and 1 year reporting exposure or not to stress were compared. Differences were compared using Chi-Square tests for categorical and Wilcoxon rank sum test for continuous variables.

Results: Mean age (SD) was 53.8(14.2). Mean symptom duration (SD) was 6.0 (3.1) months, 83% were Caucasian, 73% female and 18% smokers. Features distinguishing pts with exposure to either stress vs. none are noted in Table 1. More pts reporting psych stress were female, living alone, employed and fatigued (p<0.05). More pts reporting physical stress and were female, older, had a higher HAQ score, and more co-morbidities (p<0.05). Symptom duration, AM stiffness, smoking, race, education, income and marital status were not associated with stress. Pain, fatigue and HAQ scores were elevated at 0,6 and 12 months in patients exposed to stress vs. non-exposed though these improved to a similar degree in both groups. (Table2).

Table 1. Patients reporting exposure to psychological or physical stress versus no stress

Variables	No stress n=454	Psychological stress n=307	Physical stress n=69
Age	54.2 ± 15.0	53.0 ± 12.49	**58.5 ± 12.8***
Female sex	318 (70.0%)	**239 (77.9%)***	**39 (56.5%)***
Living alone, n (%)	51 (11.4%)	**54 (17.7%)***	11 (16.2%)

DAS28 score	3.3 ± 1.5	3.3 ± 1.5	3.0 ± 1.5	2.9 ± 1.3
HAQ score	**0.6 ± 0.6***	0.5 ± 0.6	**0.5 ± 0.6***	0.4 ± 0.6

* p <.05, Values are mean ± SD unless indicated

Conclusion: Exposure to stress in ERA pts negatively affects PROs. Given that patient self report of stress may be affected by recall bias and attribution prospective studies on the prevalence and impact of stress in early inflammatory arthritis are needed. Stress may be a significant contextual factor to consider when assessing PROs in long term observational studies of RA.

Soluble Glycoprotein VI: A Novel Risk Marker for Thrombosis in Patients with Inflammatory Arthritis. Leann Bell[1], Anne M. Madigan[1], Paul A. MacMullan[1], Eimear Dunne[2], Dermot Kenny[2] and Geraldine M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland

Background/Purpose: Patients with inflammatory arthritis (IA) such as rheumatoid arthritis (RA) are at high risk of cardiovascular mortality. Increased platelet reactivity is a risk marker for adverse cardiovascular events.

We and others have demonstrated that there is increased platelet reactivity in blood from patients with IA. Recent data has shown that platelets amplify inflammation in the joint in IA via the collagen receptor, glycoprotein(GP)VI followed by the production of proinflammatory platelet microparticles[1]. When platelets are activated, the GPVI receptor is shed and detectable in plasma as soluble GPVI (sGPVI) Our hypothesis was that both plasma and synovial fluid (SF) sGPVI would be raised in patients with IA compared to those with osteoarthritis (OA).

Methods: Following ethics approval and informed consent healthy normal donors (n=20) were compared to 43 consecutively recruited patients (OA, n=15, IA, n=28). SF samples were obtained from knee joints when indicated for clinical evaluation and/or joint injection. Plasma and SF samples were centrifuged at 720g and then 20000g to ensure that no platelets or platelet derived microparticles were present in the sample and sGPVI levels were measured by ELISA[2].

Results: Mean plasma sGPVI was similar in normal controls and patients with OA (30$\pm$6 ng/ml vs 31$\pm$6 ng/ml respectively). In contrast, mean plasma sGPVI was 51$\pm$14 ng/ml in patients with IA compared to both normal and OA individuals (P<0.005). SF sGPVI was assayed in 14 patients (IA, n=8, OA, n=6). Seven patients (IA n=4, OA, n=3) had plasma and synovial fluid samples taken simultaneously. SF sGPVI was significantly elevated in patients with IA compared to those with OA. Moreover plasma levels of sGPVI closely correlated with SF levels in these matched samples (rs = 0.995).

Conclusion: Our data shows that sGPVI is easily measured in both plasma and SF. It also suggests the potential value of sGPVI as a marker of both disease activity and platelet reactivity in arthritis. Finally, it further supports an active role of platelets in promoting inflammation locally within the joint.

Serum Anti-Müllerian Hormone Can Be Used to Determine Ovarian Reserve in Women with Rheumatoid Arthritis. Jenny Brouwer, Johanna M.W. Hazes, Joop S.E. Laven, Izaäk Schipper and Radboud J.E.M. Dolhain. Erasmus Medical Center, Rotterdam, Netherlands

Background/Purpose: Planning of pregnancy is important in women with rheumatoid arthritis (RA). It is preferred to start a pregnancy after adjustment of medication and when disease activity is low. Therefore, it is important to know the ovarian reserve in these women, since a reduced ovarian reserve is associated with subfertility and early menopause. It has been shown in healthy women, that anti-Müllerian hormone (AMH) is a good biomarker for ovarian reserve. Prior to using AMH for this purpose in women with RA, the influence of disease activity and medication use, in particular methotrexate, should be assessed.

Methods: Serum levels of anti-Müllerian hormone were measured in women aged 18 to 42 years with recent onset RA (according to the 2010 ACR/EULAR rheumatoid arthritis classification criteria) at time of diagnosis (before treatment was started) and six months later. The control group existed of 509 healthy women aged 18 to 42 years. The relationships between AMH and presence of rheumatoid factor (RF), anti-cyclic citrullinated peptide (anti-CCP), erosions, values of C-reactive protein (CRP), disease activity (measured by DAS28) and use of methotrexate (MTX) were assessed.

Results: Serum samples were available for 72 patients at time of diagnosis. Patients were older (median age 35,1 years (IQR 30,1–39,2)) than controls (29,4 years (IQR 23,8–34,4)) (p<0,001). Serum values of AMH, adjusted for age, did not differ significantly between patients (1,71 μg/L (IQR 0,81–4,39 μg/L)) and controls (2,82 μg/L (IQR 1,64–4,38 μg/L)) (p=0,254). AMH levels were not related to the presence of RF (p=0,487), anti-CCP (p=0,686) or erosions (p=0,350) and did not show a significant correlation with serum CRP levels (r = $-$0,207, p=0,083) or disease activity scores (DAS28, r = 0,007, p=0,955).

After six months of treatment, serum was available for 53 patients, of whom 31 patients (58%) were prescribed MTX. AMH levels after six months were significantly lower in these patients (1,92 μg/L (IQR 0,84–3,75)) than at

time of diagnosis (2,57 μg/L (IQR 0,90–5,30)) (p<0,001), but did not differ from the controls after adjustment for age (p=0,741). There was no significant difference in AMH values after six months of treatment between patients who did or did not receive MTX (p=0,287).
Serum values of anti-Müllerian hormone in women with recent onset rheumatoid arthritis at time of diagnosis compared to the 10th, 50th and 90th percentile lines of healthy controls

Conclusion: In women with recent onset RA, serum AMH levels are not affected by disease activity or short term use of methotrexate. Therefore, serum AMH levels can be used as a marker for ovarian reserve in women with RA. AMH levels are not reduced in women with recent onset RA compared to controls. Further research is needed to study the long term effects of rheumatologic disease and medication use on ovarian reserve in women with RA.

Glucocorticoid use Is associated with increase in HDL in Rheumatoid Arthritis Patients. Lisa L. Schroeder[1], Xiaoqin Tang[2], Mary Chester Wasko[3] and Androniki Bili[4]. [1]Geisinger Health System, Danville, PA, [2]Geisinger Center for Health Research, Danville, PA, [3]Temple University School of Medicine, Pittsburgh, PA, [4]Geisinger Medical Center, Danville, PA

Background/Purpose: Atherogenic lipid profiles are common in active RA, with most common being decreased HDL. Glucocorticoids (GC) use is reported to have variable associations with lipid profiles in RA, and the potential differential effect of GC dose on lipid levels is unknown. We sought to evaluate the association of GC dose with lipid changes in RA.

Methods: Patients with RA diagnosed between 1/1/01–11/30/11, receiving oral or intravenous GC and having lipid levels tested prior to and at least 1 year after treatment with ongoing GC were identified. A cohort of RA patients not on GC was constructed for comparison. GC exposure was calculated as a weighted daily dosage in prednisone equivalents. GC exposure was analyzed as a continuous and as a dichotomous <7.5mg/day (low) vs. $\geq$7.5mg/day (high) GC dose. Primary outcome was change in HDL in the low vs. high GC groups. Secondary outcomes were changes in LDL, total cholesterol (TC), triglycerides (TG) and TC/HDL in the same fashion. A similar analysis between the patients on GC vs. not on GC was performed. Linear regression models were used to calculate the outcome, adjusting for age, gender, body mass index (BMI), diabetes, HTN, hyperlipidemia, RF, ESR, statin, NSAID, methotrexate (MTX), hydroxychloroquine (HCQ) and TNF-α inhibitor use.

Results: 202 patients on GC and 463 patients not on GC were included. Baseline characteristics are shown in Table 1. The changes in lipid levels according to GC use are shown in Table 2. Any GC and high dose GC use were associated with increased HDL, but no other significant lipid changes,

compared to non-GC users. There were no significant differences in HDL or other lipids between the low vs. high GC groups. Sensitivity analysis, excluding patients on statins, showed similar results.

Table 1. Baseline patient characteristics

	Patients on GC			**No GC**
	All **N=202**	**GC <7.5** **N=87**	**GC ≥7.5** **N=115**	**No GC** **N=463**

Anti-TNF use	23 11.4)	10 (11.5)	13 (11.3)	47 (10.8)
MTX use	107 (53.0)	49 (56.3)	58 (50.4)	184 (42.2)

Table 2. Change in lipids according to GC use [1]

	Any GC	**GC <7.5**	**GC ≥ 7.5**	**No GC**
Pre-treatment HDL	52.4 (15.8)	55.4 (16.0)	50.1 (15.4)	52.2 (15.3)
Highest post-treatment HDL	58.1 (16.6)	60.1 (15.6)	56.5 (17.2)	55.4 (16.0)
Change in HDL	5.7 (11.6)*	4.7 (12.1)	6.5 (11.3)*	3.2 (10.5)*
Pre-treatment TC	191 (43)	197 (34)	187 (48)	194 (43)
Lowest post-treatment TC	189 (41)	193 (36)	186 (45)	186 (41)
Change in TC	2.4 (36.5)	3.6 (3.9)	1.5 (40.3)	7.8 (37.7)
Pre-treatment TC/HDL	3.9 (1.2)	3.8 (1.2)	4.0 (1.2)	4.0 (1.2)
Lowest post-treatment TC/HDL	3.5 (1.0)	3.4 (1.0)	3.5 (1.1)	3.6 (1.2)
Change in TC/HDL	0.39 (0.91)	0.37 (0.94)	0.40 (0.89)	0.35 (0.93)
Pre-treatment LDL	106 (35)	110 (33)	103 (36)	110 (35)
Lowest post-treatment LDL	96 (33)	103 (30)	97 (34)	100 (33)
Change in LDL	6.4 (32.3)	6.9 (28.5)	6.0 (34.8)	9.9 (32.6)
Pre-treatment TG	160 (113)	151 (84.1)	167 (130)	157 (90)
Lowest post-treatment TG	149 (81)	147 (81)	152 (82)	149 (83)
Change in TG	11.1 (90.3)	4.3 (78.4)	16.2 (98.3)	7.8 (68.4)

*Statistically significant findings p-value<0.05:
GC vs. No GC: change in HDL: p=0.006
High GC dose vs. No GC: change in HDL: p=0.012
[1]Adjusted for age, gender, BMI, ESR, RF, DM, HTN, hyperlipidemia, and use of TNF-α inhibitors, MTX, statins, HCQ, and NSAIDs

Conclusion: In this RA cohort, any GC and high dose GC (median 10.4 mg/day) use were associated with increased HDL, whereas low dose was not. Although our results need to be replicated in other RA cohorts, these findings are reassuring in this patient population at high risk for cardiovascular disease.

Use of Anti-Tumor Necrosis Factor Therapy Is Associated with Reduced Cardiovascular Event Risk in Rheumatoid Arthritis. Mike Nurmohamed[1], Yanjun Bao[2], James Signorovitch[3], Parvez M. Mulani[2] and Daniel E. Furst[4]. [1]VU University Medical Center & Jan van Breemen Research Institute, Amsterdam, Netherlands, [2]Abbott Laboratories, Abbott Park, IL, [3]Analysis Group, Inc., Boston, MA, [4]David Geffen School of Medicine at UCLA, Los Angeles, CA

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risks for cardiovascular (CV) comorbidities because of an increased prevalence of traditional CV risk factors and the underlying chronic inflammatory process. We assessed the effects of treatment with anti–tumor necrosis factor (anti-TNF) therapy, methotrexate (MTX), or other nonbiologic DMARDs on CV event risk in patients with RA.

Methods: Adult patients with ≥2 RA diagnoses (ICD-9 CM: 714.xx) and ≥1 filled prescription of anti-TNF therapy, MTX, or other nonbiologic DMARD were identified in the Thomson Reuters MarketScan® database

(2003–2010). Patients were assessed from index fill date to first inpatient CV diagnosis of myocardial infarction (MI), stroke, unstable angina, or congestive heart failure (CHF) to the end of health plan enrollment or to 6 months after the discontinuation of their index drug, whichever came first. Cox proportional-hazards models assessed the effect of cumulative exposure to anti-TNF therapy, MTX, and other nonbiologic DMARDs on occurrence of CV events. We adjusted for baseline (ie, 1 year before index prescription) demographics, use of therapies for RA (eg, MTX, corticosteroid), CV-related medications and smoking deterrents, comorbidities (eg, dyslipidemia, hypertension, diabetes), history of CV events, and medical resource use. Subgroup and sensitivity analyses also were conducted.

Results: The study identified 109,462 patients with 105,920 total patient-years (PYs) of follow-up, including 48,621 PYs of exposure to anti-TNF therapies (31,466 as monotherapy), 35,480 PYs of exposure to MTX (18,325 as monotherapy) and 52,994 PYs of exposure to other nonbiologic DMARDs (9,441 as monotherapy). A total of 1743 patients (1.6%) had a CV event after their index prescription. In the multivariate regression model, each additional 6 months of anti-TNF therapy significantly reduced the risk for any study CV event (hazard ratio [HR]=0.87, 95% confidence interval [CI]=0.80–0.96, P=.005) and for MI (HR=0.80, CI=0.67–0.95, P=.013), compared with patients without anti-TNF biologics. The effects of cumulative use of MTX and other nonbiologic DMARDs were not statistically significant. In the subgroup analyses, each additional 6 months of anti-TNF therapy use was significantly associated with a reduction in CV events in patients aged ≥50 years (HR=0.86, CI=0.77–0.96, P=.007) and in those without prior MTX use (HR=0.85, CI=0.73–0.98, P=.022). When assessed individually, significant event risk reduction was also observed with MI, unstable angina, and CHF for patients with longer exposure to anti-TNF therapies compared with nonuse of anti-TNF therapies. In the full sample, the model predicted that cumulative use of anti-TNF therapy for 1, 2, or 3 years would reduce CV event risks by 24%, 42%, and 56%, respectively, compared to nonuse of anti-TNF therapies.

Conclusion: Use of anti-TNF therapies vs. nonuse was associated with significantly lower risks for CV events (ie, inpatient diagnoses for MI, stroke, unstable angina, or HF) in patients with RA, older patients with RA, and patients without prior exposure to MTX, adjusting for use of MTX and other nonbiologic DMARDs.

Effect of Tocilizumab Treatment On Regional Left Ventricular Function, As Assessed by Cardiac Magnetic Resonance Imaging, in Rheumatoid Arthritis Patients without Cardiac Symptoms. Hitomi Kobayashi[1], Isamu Yokoe[1], Hiroshi Sato[1] and Yasuyuki Kobayashi[2]. [1]Itabashi Chuo Medical Center, Tokyo, Japan, [2]St Marianna Univ Sch of Med, Kawasaki, Japan

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of congestive heart failure, possibly via shared mechanisms of inflammation. This study was undertaken to test the hypothesis that the powerful anti-inflammatory effect of anti-interleukin 6 (tocilizumab: TCZ) therapy might lead to a reduction in left ventricular (LV) dysfunction in patients (pts) with RA. We sought to measure LV regional function by using a cardiac magnetic resonance imaging (CMR) approach in RA pts without cardiac symptoms, and also to evaluate the changes in these measurements at 52 wks of TCZ treatment.

Methods: This was an open-label prospective pilot study to directly evaluate the effect of TCZ on LV function in RA pts without a clinical diagnosis of cardiovascular disease. Consecutive RA pts with active disease and healthy control subjects were enrolled. The RA pts each had inadequate clinical response to non-biologic DMARDs or non-TNF directed therapy, and were prescribed TCZ therapy (8 mg/kg IV every 4 wks). All subjects underwent baseline evaluation of LV function, as measured by non-contrast CMR on a 1.5 T scanner. Peak systolic regional radial strain (Err, %) was calculated by feature tracking of cine MRI in the six segments of the mid-slice of LV. After the baseline (BL) CMR, treatment with the prescribed TCZ was initiated and pts were followed for 52 wks. Pts underwent follow-up CMR evaluation at 52 wks of treatment with TCZ. We examined the differences in peak Err between the control subjects and RA pts. We compared peak Err of RA pts at BL and at 52 wks, and determined the association of peak Err with disease activity and severity measures.

Results: All RA pts received TCZ treatment for 52 wks. We compared 11 RA pts (100% female; mean age 52.6±10.4 y) at BL and at 52 wks, with 10 non-RA controls (100% female; mean age 55.7±4.6 y). DAS28-ESR, SDAI, and Swollen Joint Count (SJC) were significantly lower in RA pts at 52 wks than at BL ($p<0.0001$, $p<0.0001$, $p=0.003$, respectively). Mean peak Err in RA pts at BL was significantly lower than in normal subjects (0.58±0.13 vs. 0.69±0.10; $p=0.04$); mean peak Err in RA pts at 52 wks was not significantly different from those of normal subjects (0.65±0.12 vs. 0.69±0.10; $p=0.56$) (figure). Mean peak Err tended to be lower at BL than at 52 wks, but not significantly ($p=0.26$). Percentage change of mean peak Err in RA pts was significantly associated with percentage change of SJC ($r=0.74$, $p=0.009$) and DAS28-ESR ($r=0.70$, $p=0.017$).

Peak Err in control subjects, in patients at baseline and after 52 weeks of TCZ treatment
Conclusion: Our findings suggested sub-clinical LV regional dysfunction in RA pts without cardiac symptoms. Furthermore, we demonstrated that improvements in LV regional function by TCZ treatment correlated with reduction in measures of systemic inflammation and RA disease activity. This suggests that systemic inflammation contributes to myocardial dysfunction in RA.

Group Cycling in Rheumatoid Arthritis: Positive Effects On Aerobic Capacity and Blood Pressure. Lars Ångström, Kristina Hörnberg and Solveig Wållberg Jonsson. Dept of Rheumatology, Umeå, Sweden

Background/Purpose: Cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA) (1). Strong evidence shows that exercise reduces the CVD risk in the general population (2). In the present study we examined the effect of group cycling on risk factors for CVD in patients with RA.

Methods: 13 subjects (12 women and 1 man, median age 57 years) with RA exercised on stationary bikes at medium to high intensity for 45 min, 3 times a week for 10 weeks. A control group of 10 subjects continued their previous activities. The following measurements were made at baseline, at 10 weeks and at 25 weeks: Aerobic capacity calculated by a sub-maximal ergometer test according to Åstrand; Visual analogue scale (VAS) for self-assessment of pain and general health; self-assessments of functional ability, using the health assessment questionnaire (HAQ), and the number of tender and swollen joints (28-joint count). Analyses of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), lipids (cholesterol, % high density lipoprotein (HDL), low density lipoprotein (LDL), triglycerides), insulin and glucose according to routine methods; Body mass index (BMI) and disease activity score (DAS 28) were calculated; Pulse wave analysis (PWA) (Arteriograph™) was used to register augmentation index (AIx), a measure reflecting early endothelial dysfunction shown to predict future cardiovascular events, pulse wave velocity (PWV), a proxy for arterial stiffness, and systolic blood pressure in aorta (SBPao) besides peripheral blood pressure.

Results: In the exercise group there were significant improvements at 10 weeks compared to baseline regarding aerobic capacity (33 vs 26 ml O2/kg ×

min; $p<0.05$), systolic (126 vs 137.8 mm Hg; $p<0.01$) and diastolic (73 vs 83.8 mm Hg, $p<0.05$) peripheral blood pressure, SBPao (118 vs 137.7 mm Hg; $p<0.01$) and tender joint count ($p<0.05$). The improvement of the diastolic blood pressure was significantly larger in the exercise group compared to the controls at 10 weeks (-7.0 vs $+2.6$ mm Hg; $p<0.05$). Low aerobic capacity at baseline correlated with high disease activity (ESR; $r_s=-.687$, $p<0.01$, CRP; $r_s=-.727$, $p<0.01$) and low physical function (HAQ; $r_s=-.572$, $p<0.05$) at baseline. Swollen joint count at baseline correlated with AIx at 10 weeks ($r_s=.641$, $p<0.05$). Improvements in blood pressure correlated with high physical function (HAQ) at baseline and at 10 weeks and with low disease activity (tender joints, VAS pain, CRP, DAS 28) at 10 weeks.

Conclusion: Regular exercise on stationary bikes on medium to high intensity for 10 weeks increased aerobic capacity in a group of RA-subjects and produced changes of blood pressure to a level that is described to be clinically relevant (3). Subjects also reported fewer tender joints after the exercise period.

1245

Age-Specific Association Between Disease-Related Measures and Incident Cardiovascular Events and All-Cause Mortality in Early Rheumatoid Arthritis. Sofia Ajeganova[1], Maria LE Andersson[2], Johan Frostegård[3] and Ingiäld Hafström[1]. [1]Karolinska Institutet, Unit of Rheumatology, Department of Medicine Huddinge, Stockholm, Sweden, [2]R&D Center, Spenshult Hospital, Oskarström, Sweden, [3]Karolinska Institutet, Section of Immunology and chronic disease, Institute of Environmental Medicine, Stockholm, Sweden

Background/Purpose: Increased risk of cardiovascular disease (CVD) and premature mortality in rheumatoid arthritis (RA) has been established, but the impact of inflammatory and disease related factors has been inconsistent across studies.

Here, we determined if occurrence of subsequent CVD and mortality outcomes was influenced by disease related factors at RA onset and the first years of disease, and if the impact of these factors differed between age groups. Further we investigated the role of antibodies against phosporylcholine (anti-PC), a promising atheroprotective biomarker.

Methods: This is a cohort study derived from the BARFOT inception RA cohort, to which patients were consecutively recruited from 1994 through 1999, disease duration <13 months. Participants with prevalent CVD at study enrollment or aged <20 years were excluded. The outcomes were an incident CVD event (myocardial infarction, cardiac arrest, angina pectoris, peripheral arterial disease, coronary or vascular surgery, stroke and transient ischemic attack) and all-cause mortality, and were tracked through the Swedish Hospital Discharge Registry and the National Cause of Death Registry until December 2010.

Area under the curve (AUC) was calculated for disease measures assessed at inclusion and after 1 and 2 years, and differences (D) between inclusion and 1 year after enrollment. IgM anti-PC was determined by ELISA.

Cox proportional regression models in age groups <65 and ≥65 years at RA onset, adjusted for age, gender, smoking, presence of hypertension, diabetes or hyperlipidemia, and Kaplan Meier analysis were used for statistical tests.

Results: The study population comprised 741 patients with early RA, whose mean age at entry was 55 years (SD 14.7), range 20–93 years, 67.5% of the participants were women, and 60% were RF positive. The median observation was 13 years (range 2–17). During follow-up, 177 patients developed an incident CVD event, and 151 deceased, corresponding rates of 2.1 (1.8–2.4) and 1.7 (1.4–1.9) per 100 person-years.

Only in the younger individuals, RF or ACPA positivity, CRP-AUC, ESR-AUC, and VAS pain-AUC were associated with higher risk of CVD event, adjusted hazard ratios (HRs) 2.72 (95% CI, 1.48–5.02), 1.87 (1.01–3.34), 1.07 (1.01–1.14), 1.10 (1.02–1.17), and 1.06 (1.00–1.13), respectively. On the other hand, only in the older patients, DCRP, DESR, DHAQ, and also regular use of methotrexate and daily oral glucocorticoids were associated with incident CVD, respective HRs 0.94 (0.89–1.00), 0.90 (0.82–0.97), 0.71/0.52–0.97), 0.64 (0.43–0.96), and 1.69 (1.13–2.51). Similarly, RF or ACPA positivity and VAS pain-AUC were associated with higher death risk

in the younger patients, while CRP-AUC, ESR-AUC and HAQ-AUC were independently related to risk of death in both age groups.

CVD outcome but not mortality was associated with the levels of anti-PC at baseline, the 10-year CVD event-free survival rates were 66%, 74% and 76% in the first (lowest), second and third anti-PC tertiles, respectively, p=0.024.

Conclusion: In early RA, age stratification could improve evaluation of risk factors for CVD and mortality. The IgM anti-PC antibodies may perform atheroprotective in RA.

Cardiovascular Risk Assessment in Rheumatoid Arthritis (RA) Patients Treated by Biologic Response Modifiers. Majed M. Khraishi[1], Rana Aslanov[2] and Katie Doyle[1]. [1]Memorial University of Newfoundland, St Johns, NF, [2]Memorial University of Newfoundland, St.John's, NF

Background/Purpose: We aimed to assess the 10-year CV event risk in patients with RA at the baseline and 1 year after the initiation of treatment with biologic DMARDs.

Methods: RA patients receiving biologic therapy were included. Participants were divided into 2 groups aged 21 to 49 years and 50 to 84. The Framingham Risk Score (FRS) was used for the assessment of 10-year CVD risk. The presence of CV risk factors (fasting serum TC, HDL levels, history of HTN, DM and Dyslipidemia, and CV events) were ascertained by a medical records review and throughout a 1 year follow-up. Regression analyses of the relationship between lipids and inflammatory indices (CRP & DAS28) before and after treatment, as well as of biologic modifiers were performed.

Results: The mean (SD) age of 215 patients (73.5% females) was 55.6 (12) years. The age at RA diagnosis was 41.6 (13.3) years with a mean (SD) duration of symptoms at 14 (8.7) years. 7 cases with previously documented MI and 3 cases with TIA/Stroke were analysed. All patients had their CV events prior to the initiation of treatment with biologics with predicted 10-year CVD risk more than 30%. Smoking was documented in 19% of patients (61% females) at baseline and 1-year. TJC and SJC were significantly reduced after 12 months of treatment (12.5 ± 8.6 vs. 9.0 ± 7.5; $p<0.001$ and 4.3 ± 3.8 vs. 1.9 ± 2.4; $p<0.001$, respectively). The means of TC, HDL and the Atherogenic Index (AI) at the baseline and 12 months were compared: TC was not significantly increased from 3.1 ± 2.8 to 3.3 ± 2.6 (p=0.185); HDL increased from 0.7 ± 0.7 to 0.9 ± 0.7 (p=0.005); and AI was significantly reduced from 4.6 ± 1.7 to 4.0 ± 1.2 ($p<0.001$). CRP, ESR and DAS28 levels were significantly reduced from baseline (p=0.002; $p<0.001$ and $p<0.001$, respectively). Patients were grouped by their 10-year CVD risk level: Low Risk ($<10\%$), Moderate Risk (10% to 19%), High Risk (20% and more). The trend analysis of 10-year CVD risk by gender showed that 7% of men in a 12-month period moved from the low/moderate risk to the high risk (38.6% vs. 45.6%; $p<0.001$) while 4% of females significantly lowered their risk from the high to the moderate/low (11.4% vs. 7.6%; $p<0.001$). The analysis of relationship between lipids and inflammation indices as well as biologics did not show significance at the baseline and 1 year follow-up.

RA Characteristics and lipid levels at baseline and 12-month

RA Characteristics	Baseline, mean (SD)	1-year F-Up, mean (SD)	P
Total Joint Count (TJC)	12.47 (8.550)	8.97 (7.52)	<0.001
Swollen Joint Count (SJC)	4.33 (3.77)	1.94 (2.43)	<0.001
C-Reactive Protein (CRP), mg/l	16.24 (29.73)	9.92 (15.81)	0.002
ESR, mm/h	30.67 (23.20)	22.86 (20.77)	<0.001
DAS28 score	3.95 (1.34)	3.39 (1.25)	<0.001
CDAI score	17.44 (9.90)	13.00 (10.00)	<0.001
HAQ score	1.18 (0.73)	1.08 (0.75)	0.007
Total Cholesterol, mmol/l	3.10 (2.80)	3.30 (2.62)	0.185
HDL Cholesterol, mmol/l	0.73 (0.70)	0.86 (0.71)	0.005
Atherogenic Index (TC/HDL)	4.64 (1.68)	3.99 (1.18)	<0.001

Conclusion: Our results showed a trend in reducing a 10-year CV event risk over 12-month of treatment with biologic disease modifiers. No serious cardiovascular events were observed during the study period. This improvement was influenced by many factors such as lipid-lowering treatment (30.7% of patients) and proper control of blood pressure and plasma glucose level

(28.4% and 11.6% of patients, respectively). Females appeared to be more successful in reducing the CVD risk. Biologic DMARDs effectively decreased inflammation and possibly played a pivotal role in reducing the risk for CV event in patients with chronic RA.

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to be at increased risk for cardiovascular diseases. Inflammation as well as traditional risk factors contributes to this risk and adequate control of the disease activity of RA will decrease it. We investigated whether earlier diagnosis and earlier initiation of treatment would decrease the risk of cardiovascular diseases in patients with RA.

Methods: RA patients from the KORONA (Korean Observational Study Network for Arthritis) prospective multicenter cohort were assessed. Information on RA onset to diagnosis, disease duration, disease activity, functional impairment, smoking status, cardiovascular comorbidities, and cardiovascular risk using SCORE (Systematic Coronary Risk Evaluation) risk chart were obtained from questionnaires and medical records. Regression models were used to assess the association between delay in diagnosis of RA and cardiovascular risk, adjusting for disease duration, disease activity, radiographic damage, functional impairment, body-mass index, and methotrexate, steroids, NSAIDs, and biologics use.

Results: The mean delay from RA onset to diagnosis was 1.8 ± 4.1 years. A total of 2,465 patients were diagnosed within a year from onset with a mean delay of 0.2 ± 0.3 years and diagnosis was delayed more than a year in 1,023 patients with a mean of 5.5 ± 6.1 years. Patients with delayed diagnosis were significantly older at assessment, younger at diagnosis, and had longer disease duration. There was no difference in current disease activity assessed by DAS28, but patients with delayed diagnosis showed significantly higher functional impairment (p < 0.01). Proportion of patients smoking, taking corticosteroids and/or NSAIDs were significantly lower in the delayed diagnosis group (p < 0.01, p = 0.03, p <0.01, respectively). SCORE risk score was significantly higher in patients with delayed diagnosis with 1.3 ± 1.7 compared to 1.1 ± 1.7 in patients with diagnosis within a year (p < 0.01). The association between delay in diagnosis of RA and increase in cardiovascular risk calculated by SCORE risk score remained significant in women after adjustment (p < 0.01), but it was lost in men (p = 0.12).

Conclusion: Delay in diagnosis of rheumatoid arthritis can lead to increase in major cardiovascular risk, especially in women.

Accelerated Aging Influences Cardiovascular Disease Risk in Rheumatoid Arthritis. Cynthia S. Crowson, Terry M. Therneau, John M. Davis III, Veronique L. Roger, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Background/Purpose: People with rheumatoid arthritis (RA) suffer an excess burden of cardiovascular disease (CVD), yet standard risk assessments designed for the general population do not accurately predict their CVD risk. The purpose of this study was to identify traditional CVD risk factors that have a significantly different impact on CVD development in the presence of RA. Recognition of potentially distinctive contributions of CVD risk factors in RA could inform the development of improved CVD risk assessment tools for patient management.

Methods: A population-based inception cohort of RA subjects aged ≥ 30 years who fulfilled 1987 ACR criteria for RA between 1-1-1988 and 1-1-2008 was assembled and followed until death, migration, or 12-31-2008. Medical records were reviewed to ascertain the presence of CVD risk factors (age, blood pressure, lipids, smoking, and diabetes mellitus) at RA incidence and to ascertain the development of CVD (myocardial infarction, CVD death, angina, heart failure, stroke and intermittent claudication) during follow-up. The 10-year Framingham risk score (FRS) for CVD was calculated. Cox models were used to examine the effects of CVD risk factors included in the FRS in patients with RA, and whether RA disease characteristics (e.g., rheumatoid factor [RF] positivity, acute phase reactants, extra-articular manifestations) modify the effects of CVD risk factors. Models were adjusted for the FRS and stratified by sex.

Results: The study included 525 patients with RA without prior CVD (mean age: 55 years, 71% women; 68% RF positive). The patients were followed for a mean of 8.4 years, during which 84 developed CVD (47 women, 37 men). The FRS predicted only 45.7 events (23.3 women, 22.4 men). Essentially all of the excess events (37.2 of 38.3) were among the RF-positive patients. Analysis of CVD risk factors revealed a greater effect of age on the risk of developing CVD among RF-positive but not RF-negative patients. As estimated by the FRS, the effect of age on CVD risk in the RF-positive group was nearly double its effect in the general population (p<0.001). The impact of this additional aging effect was negligible for patients younger than 50 years, when CVD risk in the general population is generally low. However, the impact was observed to increase exponentially as CVD risk rose with age. For example, patients over 65 years with RF-positive RA had similar CVD risk as persons in the general population aged >90 years. The unique influence of age in RF-positive RA was not explained by other CVD risk factors or RA disease characteristics. Acute phase reactants and severe extra-articular manifestations also appear to influence CVD risk in RF positive RA after accounting for this additional age effect.

Conclusion: The results revealed an exponentially increasing effect of age on CVD risk in patients who have seropositive RA, supporting prior reports of accelerated aging in this disease. In contrast, the impact of age on CVD risk among RF-negative patients was similar to the general population. These findings suggest that the advent of CVD risk scores that better account for accelerated aging and other factors in RF-positive patients could improve CVD risk assessment for persons with RA.

The Impact of Statin Use On Lipid Levels in Statin-Naive Patients with Rheumatoid Arthritis (RA) Vs. Non-RA Subjects: Results From a Population-Based Study. Elena Myasoedova, Cynthia S. Crowson, Abigail B. Green, Eric L. Matteson and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Background/Purpose: Dyslipidemia in patients with rheumatoid arthritis (RA) is well recognized. The impact of lipid-lowering medications on lipid levels in patients with RA vs non-RA subjects has not been comprehensively studied in large population-based cohorts. We aimed to examine lipid profiles among statin naive patients with RA and those without RA before and after the initiation of statins.

Methods: Lipid measures were abstracted in a population-based incident cohort of RA patients (1987 ACR criteria first met between 1/1/1988 and 1/1/2008) and in a cohort of non-RA subjects from the same underlying population. Information regarding statin use was gathered in both cohorts. Only patients with no history of statin use who started a statin for dyslipidemia between 1 year prior to RA diagnosis/index date and last follow-up were included. Target lipid levels for both cohorts were defined as follows: total cholesterol (TC) <200 mg/dL, low density lipoprotein cholesterol (LDL) <160 mg/dL, triglycerides <150 mg/dL, high density lipoprotein (HDL) ≥ 50 mg/dL. T-tests and linear regression models were used to compare changes in lipid profiles between the RA and non-RA cohorts.

Results: The study included a cohort of 161 patients with RA (mean age 56.3 years, 57% female, 66% rheumatoid factor positive) and 221 non-RA subjects (mean age 56.0 years, 66% female). Prior to the start of statins, the levels of TC (mean+/−standard deviation, 225.3+/−54.7 mg/dL) and LDL (141.0+/−53.4 mg/dL) in the RA cohort were significantly lower than in the non-RA cohort (TC: 242.3+/−45.8 mg/dL, p<0.001, and LDL: 155.2+/−40.6 mg/dL, p=0.004). The decrease in absolute LDL values after at least 90 days of statin use was less pronounced in the RA vs non-RA cohort (−33.7+/−42.8 mg/dL vs −44.7+/−38.5 mg/dL, respectively, p=0.025); a similar trend was observed for TC (−35.6+/−46.3 mg/dL vs −43.5+/−41.4 mg/dL, p=0.08). There were no significant differences in baseline and/or follow-up levels of triglycerides, HDL, and TC/HDL in RA vs non-RA cohorts. During the 90-day follow-up, the percentage change in LDL, but not in other lipids, was significantly smaller (by 9%) in RA than in the non-RA cohort (p=0.039), adjusting for age, sex, smoking, diabetes mellitus, hypertension, and coronary heart disease. However, RA patients with altered lipid levels were as likely to reach lipid targets with statin use as non-RA subjects (all p > 0.05). A total of 89% of RA vs 91% of non-RA subjects met the target levels for LDL after 90 days of statin use (p=0.53). There were no apparent changes in the use of disease-modifying antirheumatic drugs and biologics in RA patients during the study period.

Conclusion: Before statin initiation, patients with RA had significantly lower TC and LDL levels than non-RA subjects. Absolute and relative decreases in LDL values following statin initiation were smaller in RA than in non-RA subjects. Nonetheless, patients with RA were as likely to achieve conventional lipid goals as non-RA subjects suggesting the potential for clinical benefits of statins in RA. More studies are needed to determine the impact of improvement in lipid profile with statin use on cardiovascular risk reduction in RA.

Heightened Aortic Wall Inflammation in Patients with Rheumatoid Arthritis Versus Patients with Established Coronary Artery Disease without Autoimmune Disease. Jeffrey D. Greenberg[1], Zahi Fayad[2], Victoria Furer[3], Michael Farkouh[2], Michael J. Colin[3], Pamela B. Rosenthal[3], Jonathan Samuels[3], Svetlana Krasnokutsky Samuels[4], Soumya M. Reddy[3], Peter M. Izmirly[3], Cheongeun Oh[3], Manish Jain[3] and Venkatesh Mani[2]. [1]New York University School of Medicine, New York, NY, [2]Mount Sinai School of Medicine, New York, NY, [3]NYU School of Medicine, New York, NY, [4]NYU School of Medicine, New York

Background/Purpose: Rheumatoid arthritis (RA) has been associated with premature atherosclerosis and increased prevalence of cardiovascular disease. 18-fluoro-deoxyglucose positron emission tomography (18-FDG-PET) is a promising imaging technique that has been used previously to evaluate vascular inflammation. Individuals with coronary artery disease (CAD) have been shown to have increased 18-FDG-PET uptake in previous studies. In this study we compare vascular inflammation in individuals with RA with inflammation versus patients with established CAD without underlying autoimmune disease.

Methods: 27 RA patients (aged 35–64)and 70 CAD patients (aged 41–76) without autoimmune disease were recruited as two separate cohorts and underwent PET scans after injection of 10mCi of FDG to measure vascular inflammation. Metrics of PET uptake, the mean, maximum and most diseased segment (MDS) target to background ratios (TBR) were computed

for the aorta and carotid arteries and compared across the two groups. Multivariate regression models were run to adjust for differences in age, gender and BMI between the groups. P-values < 0.05 were considered significant.

Results: The RA cohort had a mean disease duration of 11.3 years and mean DAS28 of 4.6, with 10 (37%) on biologic DMARDs. None of the RA patients had a history of CAD, MI or stroke. The table shows the median +/− standard deviations of the mean, maximum and MDS FDG-PET uptake (TBR values) in the two groups both without and with adjustments for age gender and BMI. For the carotids, no differences were detected in mean, maximum or MDS comparisons in adjusted models. For the aorta, we found that the mean, maximum and MDS TBR values were significantly higher in RA patients than CAD patients in both unadjusted and adjusted analyses.

Table. Comparison of RA Patients versus CAD Patients Target to Background Ratios

Target to Background Ratio (TBR) Measures	RA patients (median ± SD)	CAD Patients (median ±SD)	p-value (unadjusted)	p-value (adjusted)*
Aorta Mean TBR	1.46 ± 0.40	1.25 ± 0.12	**0.003**	**<0.0001**
Aorta Max TBR	2.08 ± 0.57	1.75 ± 0.22	**0.014**	**<0.0001**
Aorta MDS TBR	2.23 ± 0.62	1.87 ± 0.27	**0.015**	**0.0004**
Carotids Mean TBR	1.47 ± 0.19	1.47 ± 0.21	0.261	NS
Carotids Max TBR	1.69 ± 0.25	1.84 ± 0.30	**0.018**	NS
Carotids MDS TBR	1.79 ± 0.25	1.87 ± 0.31	**0.005**	NS

* Adjusted for age, gender and BMI; **bold font** indicates significant differences

Conclusion: Our data indicates that RA patients without known CVD have heightened aortic wall inflammation and similar levels of carotid wall inflammation when compared to CAD patients without autoimmune disease. Increased aortic inflammation might be a mechanism for increased risk for atherosclerosis in RA patients.

Vulnerability Features Are Common in Coronary Plaques of Asymptomatic Patients with Rheumatoid Arthritis Compared to Controls: Associations with Lipid and Oxidative Stress Biomarkers. George A. Karpouzas[1], Jennifer Malpeso[2], Tae-Young Choi[2], Silvia Munoz[1] and Matthew Budoff[2]. [1]Harbor-UCLA, Torrance, CA, [2]Harbor-UCLA Medical Center, Torrance, CA

Background/Purpose: Computed tomography angiography (CTA) reliably evaluates coronary plaque presence, severity, burden, and composition. CT characteristics of culprit lesions in acute coronary syndromes (ACS) include low attenuation plaques (LAP) consistent with necrotic core, positive remodeling (PR) and spotty calcifications. Increasing numbers of those vulnerability features yields progressively higher risk for future ACS (within 2 years) compared to their absence. We studied 150 asymptomatic, patients with Rheumatoid Arthritis (RA) and an equal number of age and sex-matched controls for plaque vulnerability features using CTA.

Methods: A standard 15-segment American Heart Association model was used for evaluation. Plaque composition was defined as non-calcified (NCP), mixed- partially calcified (MP), or fully calcified (CP). Plaques in both groups were evaluated for all 3 vulnerability features. Fasting lipid assessments, including total Cholesterol (TC), HDL-c, LDL-c, VLDL-c, particle sizes thereof, and apolipoproteins B100 and A1 were completed. Both IgG and IgM antibodies against oxidized LDL in relative light units (RLU), as well as oxidized phospholipids on apoB100 particles were measured as indicators of oxidative stress. Non-parametric ANOVA and Fisher's tests were used as appropriate for comparisons among groups.

Results: In the RA group, 107 (71%) patients had a total of 303 plaques, compared to 68 (45%) in the controls with 135 plaques (p<0.0001). Twenty-four (16%) RA subjects had 41 plaques with ≥1 vulnerable characteristic (VP+) compared to none in the control group (p<0.0001, table); 8 (5.3%) had plaques with≥2, and 6 (4%) had all 3 characteristics. Thirty-one of 84 (37%) MP in RA had ≥1 VP characteristic, compared to 10/156 (6.4%) of NCP (p<0.0001); higher numbers of VP features were only present on MP. In general, VP were moderately sized and 66% rendered <50% luminal stenosis. Subjects with vulnerable plaque features (VP+) had higher Framingham scores, TC/HDL-c (pro-atherogenic index), small particle LDL

(LDL4), and apoB/A1 ratio, compared to those with plaque lacking vulnerability characteristics (VP-), or those without plaque (table).

Parameter	VP (+)	VP (−)	Plaque (−)	p-value
RA-n patients=150	24	83	43	**<0.0001**
Controls-n patients=150	0	68	82	
RA-n plaques=303	41	262	n/a	**<0.0001**
Controls-n plaques=135	0	135	n/a	
Parameters in subjects with RA (mean± SEM)				
Framingham Score	6.3 ± 1.3	3.6 ± 0.5	2 ± 0.5	**<0.0001**
Total Cholesterol (mg/dl)	175.7 ± 8.2	170.2 ± 3.9	161.5 ± 4.8	0.26
HDL-c (mg/dl)	46.7 ± 2.5	53.2 ± 1.5	49.9 ± 2.4	0.07
Total Chol/HDL ratio	3.92 ± 0.21	3.36 ± 0.11	3.43 ± 0.14	**0.026**
HDL2 (md/dl)	12.1 ± 1.2	15.2 ± 0.8	13.5 ± 1.1	0.06
HDL3 (mg/dl)	34.7 ± 1.5	38.1 ± 0.8	36.3 ± 1.4	0.15
LDL-total (mg/dl)	104 ± 6.5	94.6 ± 3.7	92.6 ± 3.6	0.2
LDL1 (mg/dl)	14.2 ± 1.4	13.2 ± 0.8	12.8 ± 0.9	0.7
LDL2 (mg/dl)	21 ± 2.7	21.9 ± 1.4	22.7 ± 1.7	0.7
LDL3 (mg/dl)	37.1 ± 2.8	30.6 ± 1.5	31.4 ± 1.6	0.09
LDL4 (mg/dl)	12.5 ± 1.5	9.1 ± 0.7	8.4 ± 1.1	**0.01**
Triglycerides (mg/dl)	163.4 ± 20.5	142.5 ± 10	144.7 ± 11.9	0.6
VLDL1, 2 (mg/dl)	11.3 ± 1.3	9.9 ± 0.5	9.5 ± 0.5	0.5
VLDL3 (mg/dl)	13.7 ± 0.8	12.7 ± 0.4	11.7 ± 0.4	0.1
ApoB/A1 ratio	0.64 ± 0.03	0.56 ± 0.02	0.59 ± 0.02	**0.045**
OxPL/apoB100 (NanoM PC)	11.4 ± 1.2	11.7 ± 0.5	11.4 ± 0.9	0.7
Ox-MDA-LDL IgG (RLU)	14,366 ± 2,490	11,095 ± 707	10,587 ± 1,011	0.7
Ox-MDA-LDL IgM (RLU)	28,195 ± 2,833	28,082 ± 1,169	27,036 ± 1,365	1

Conclusion: Coronary plaques of asymptomatic patients with RA frequently display vulnerability features, by contrast to controls, and increasing numbers of those segregate preferentially on moderate sized, non-occlusive MP. Their presence associates with higher Framingham scores, pro-atherogenic index, smaller sized oxidation-prone LDL, and apoB/A1 ratios.

Association of Paraoxonase 1 Gene Polymorphisms and Enzyme Activity with Carotid Plaque in Rheumatoid Arthritis. Christina Charles-Schoeman, Yuen Yin Lee, Veena K. Ranganath, John D. FitzGerald, Mihaela B. Taylor, Maureen A. McMahon, David Elashoff and Srinivasa T. Reddy. University of California, Los Angeles, CA

Background/Purpose: Paraoxonase 1 (PON1) is a high density lipoprotein (HDL) associated enzyme, which promotes the anti-oxidant and anti-inflammatory properties of HDL. PON1 polymorphisms and enzyme activity have previously been associated with cardiovascular (CV) events in the general population. Since abnormal HDL function has been proposed to contribute to CV risk in patients with rheumatoid arthritis (RA), the current work investigated the relationship of genetic and biochemical determinants of PON1 activity with carotid plaque as a surrogate marker of CV risk in RA patients.

Methods: PON1 activity, PON1 genotype (for the functional polymorphism at position 192), and carotid plaque presence were determined in 168 patients with RA. Fasting blood was collected for lipoprotein analysis, and PON1 activity was measured using paraoxon as the substrate. Genotyping for the PON1 Q192R polymorphism (SNP rs662) was done for all patients as described previously (Bhattacharyya et al. *JAMA* 2008). Lipoprotein cholesterol levels were measured by standard methods and traditional cardiovascular risk factors, medication use, and RA disease characteristics were assessed for all patients.

Results: The PON1 genotype demonstrated a significant dose dependent association with PON1 activity (RR192 > QR192 > QQ192) (p<0.001). Compared to patients with either the PON1 QQ192 or QR192 genotype, patients with the RR192 genotype demonstrated decreased risk of carotid plaque in multivariate analysis controlling for traditional CV risk factors, high-sensitivity C-reactive protein levels, prednisone use, and cholesterol lowering medication use (p<0.05). Separate multivariate logistic regression analysis controlling for the above factors also revealed a significant association of plasma PON1 activity with carotid plaque in RA patients. Lower plasma PON1 activity was associated with increased risk of carotid plaque (p <0.05).

Conclusion: The current work suggests a relationship between the genetic determinants and activity of PON1 with cardiovascular risk in RA patients as assessed by the presence or absence of carotid plaque. Further CV outcome studies may be warranted to determine if PON1 is a useful biomarker of CV risk in patients with RA.

Identifying Vulnerable Plaque in Rheumatoid Arthritis: A Pilot Study Using Novel Microbubble-Contrast Enhanced Carotid Ultrasonography.
Kimberly P. Liang, Douglas P. Landsittel. Suresh R. Mulukutla, Steven E. Reis, Marc C. Levesque, Flordeliza S. Villanueva, Hunter C. Champion and Larry W. Moreland, University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Rheumatoid arthritis (RA) is independently associated with a higher risk of cardiovascular disease (CVD). Markers of systemic inflammation, as seen in RA, are associated with plaque vulnerability. Recently, increased vasa vasorum neovascularization has been identified as a common feature of inflammation and plaque vulnerability, and independently predicts future CV events in the non-RA general population. Excess CVD risk in RA may be caused by disease-related factors leading to vulnerable plaque characterized by increased vasa vasorum neovascularization, which is not assessed by traditional imaging modalities. Microbubble contrast-enhanced carotid ultrasound (CU) is a novel imaging technique that has been validated in detecting measures of vulnerable plaque, namely increased adventitial vasa vasorum density (aVVD), in non-RA subjects.

Our objective was to establish feasibility of measuring aVVD in RA patients; to determine whether RA patients have higher aVVD compared to non-RA controls, and whether disease-related RA measures correlate with increased aVVD, using CU.

Methods: We performed a preliminary cross-sectional study of 23 RA cases and 28 non-RA controls; this project is ongoing. All 51 subjects underwent CU with measurement of intima-media thickness (IMT, using maximum of both sides) and the mean common carotid artery adventitial to lumen videointensity ratio (using maximum of both sides) to quantify aVVD. Demographic and CV risk factor data were collected on all subjects, and tested for differences between cases and controls, using the Wilcoxon rank-sum test for continuous data and Fisher's exact test for categorical data. RA disease activity measures (CDAI and DAS28), erythrocyte sedimentation rate, high sensitivity C-reactive protein (CRP), rheumatoid factor (RF), and anti-cyclic citrullinated peptide (CCP), were collected systematically on RA subjects. Spearman correlations were assessed between disease activity measures and aVVD and IMT within RA cases.

Results: Demographic and CV risk factors between RA and controls were similar, except for mean age (58.0 years in RA, 66.1 years in controls; p<0.01); systolic blood pressure (138 in RA, 120 in controls; p<0.01); and race (91.3% white in RA, 64.3% white in controls; p=0.02). We successfully measured aVVD, which was higher in RA (mean=0.634; SD=0.097) versus controls (mean=0.595; SD=0.112), although so far non-significantly (p=0.31). IMT was also higher, although again non-significantly so far (p=0.65), in RA (mean = 0.85; SD=0.28) versus controls (mean=0.80; SD=0.18). After adjusting for age and personal history of CVD, results did not qualitatively change. As expected, CRP, RF and CCP were all significantly higher in RA than controls (p<0.001). No correlations between disease activity measures with aVVD and IMT were significant.

Conclusion: Measurement of aVVD to quantify plaque vulnerability in RA patients is feasible utilizing the novel CU technique. In this pilot study, the aVVD was slightly higher in RA than control subjects, though not significantly. Our study is ongoing, with plans for targeted enrollment of larger numbers of subjects and further adjustment for differences in demographic and CV risk factors.

In Treatment-Naive Early RA the Left Ventricular Function Is Correlated to CRP, Doctors Global and Anti-CCP Status.
BB Løgstrup[1], LD Kristensen[1], A. Hedemann-Andersen[1] and Torkell Ellingsen[2]. [1]Diagnostic Centre Region Hospital Silkeborg Denmark, Silkeborg, Denmark, [2]Diagnostic Centre Regional Hospital Silkeborg, 8600 Silkeborg, Denmark

Background/Purpose: The role of inflammation and anti-CCP status in the pathogenesis of cardiovascular disease in RA remains unclear. Previous studies have suggested that both disease activities as well as disease duration are associated with atherosclerosis and a higher mortality rate caused by coronary artery disease.

We wanted to investigate how disease activity and anti-CCP status in treatment-naive early RA impacts the left ventricular (LV) systolic function.

Methods: 41 patients (18 men, median age 60 range (28–81)) with steroid and DMARD-naive early RA. Disease activity was scored by the use of the Danish national DANBIO registry (number of swollen joints (NSJ) (28), number of tender joints (NTJ) (28), CRP, HAQ. Visual analog scales 1–100 was used to assess pain, fatigue and global assessment by the patient as well as global assessment by doctor and as composite score DAS28(CRP)). IgMRF and anti-CCP titers were evaluated by standardized techniques. One experienced senior rheumatologist and one experienced cardiologist performed all the clinical assessments as well as all the transthoracical echocardiography (TTE). We performed an extensively TTE measuring conventional measurements of LV systolic function including the novel technology, global longitudinal strain (GLS) analysis.

Results: Disease activity before treatment at baseline NSJ(28) median 7 range (1–16), NTJ(28) 8 (1–15), CRP 9 mg/l (0–42), HAQ 2.625 (0.5–2.625), pain VAS 54 (7–100), fatigue VAS 48 (2–100), doctor global assessment 55 (28–79), DAS28(CRP) 4.7 (3.3–6.2), pulse 65 (50–87), diastolic blood pressure (BP) 88 mmHg (66–158), systolic BP 147 mmHg (78–158). 18 (43.9%) patients was IgMRF positive and 26(63.4%) was anti-CCP positive.

We found LV systolic function by conventional Ejection Fraction (EF), median 52% (24–74), non-significant correlated to disease activity (CRP: r= 0.19, p=0.23; baseline NSJ: r=-0.11, p=0.5; NTJ: r=-0.04, p=0.81; HAQ: r=0.27, p=0.1; pain VAS: r=-0.1, p=0.53; fatigue VAS: r=0.1, p=0.56; doctor global assessment: r=-0.07, p=0.67 and DAS28: r=0.03, p=0.86). However using a more sensitive measurement of the longitudinal systolic LV function (s') we found a significant correlation, in means of CRP (r=0.40; p=0.015) and doctor global assessment VAS (r=0.47; p=0.003), to disease activity; both corrected for relevant confounders (age, gender, pulse and blood pressure). Furthermore using strain analysis of LV function we found a significant difference in global LV GLS values in 11(26.8%) patients with high values of anti-CCP (values ≥ 340 (GLS: −18.7% (−20.6–14.4)) vs. in 30(73.2%) patients with anti-CCP <340; p=0.04. For patients with high IgMRF the result was non-significant.

Conclusion: We observed a significant correlation between increasing CRP, doctors global, anti-CCP anti-CCP <340 and increased longitudinal LV systolic function.

Vascular Calcification On Hand and Feet X-Rays, VFA Imaging of the Spine, and Cardiovascular Disease in Rheumatoid Arthritis.
Ausaf Mohammad[1], Collette English[1], Derek Lohan[1], Diane Bergin[1], Sarah Mooney[1], John Newell[2], Martin O'Donnell[1], Robert J. Coughlan[1] and John J. Carey[1]. [1]Galway University Hospitals, Galway, Ireland, [2]National University of Ireland, Galway, Ireland

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of osteoporosis (OP) and cardiovascular disease (CVD), and have increased cardiovascular mortality compared with the general population. Vascular calcification (VC) is independent predictor of incident CVD and mortality in RA patients. While VC may be present on plain films of the hands and feet, little is known about the significance of this entity in RA patients. We evaluated the prevalence of VC on hands and feet radiographs, the association with VFA-detected abdominal aortic calcification (AAC) and other CVD risk factors, and the prevalence of CVD in RA patients.

Methods: We conducted a cross-sectional study on our RA subjects ≥40 years of age, who met 1987 ACR criteria for RA classification, and had hands and feet radiographs available for analysis. Risk factors and details of CVD were recorded, and DXA and VFA scans were reviewed where available. Study was approved by local I.R.B. Two blinded musculoskeletal radiologists examined all radiographs for the presence of VC as either "present" or "absent", and VFA scans to detect and quantify the presence of AAC. We compared the prevalence of VC between RA patients with and without CVD using multivariable logistic regression, and determined if VC on hands and feet radiographs was independently associated with VFA-detected AAC and prevalent CVD.

Results: 854 RA patients met the inclusion criteria, 603 of whom also had a VFA scan available for analysis: 69% female mean age 59 years and 77% seropositive (Table 1). 230 subjects had ≥1 documented CVD event. VC was observed on radiographs in 94(11%) and a higher proportion of subjects had prevalent CVD (49% Vs 24%). Of the 603 who had a VFA scan available, 211(35%) of the subjects had AAC. A greater proportion of those with VC on plain films had AAC on VFA (36% Vs 23%). In multivariable analyses, VC presence was significantly and independently associated with AAC (OR 1.80; 95% CI 1.55 to 1.98; p< 0.05) and prevalent CVD (OR 2.30; 95% CI 1.8 to 2.8; p<0.05).

Table 1. Demographics and Clinical Features of 854 RA Patients According to the Presence of VC on Hand and Feet X-rays

Variables	VC positive (n = 94)	VC negative (n = 760)	p Value
Age (years)	59 ± 12.74	56 ± 9.67	0.012
Women–n (%)	65 (69)	525 (69)	0.890
Smokers–n (%)	60 (64)	396 (52)	0.003
RA duration (years)	15 ± 9	13 ± 6	0.006
Family history of CVD–n (%)	39 (41)	200 (26)	0.003
Diabetes–n (%)	15 (16)	112 (15)	0.540
Dyslipidemia–n (%)	41 (43)	260 (34)	0.003
Prevalent CVD	46 (49)	184 (24)	<0.001
Hypertension–n (%)	45 (48)	167 (22)	<0.001
Glucocorticoid use–n (%)	23 (24)	120 (16)	0.017
RF positive–n (%)	69 (73)	590 (78)	0.021
Anti-CCP positive–n (%)	71 (76)	540 (71)	0.013
C-reactive protein (mg/l)	5.50 ± 3.52	3.31 ± 1.86	<0.001
DAS28, mean ± SD	2.98 ± 0.90	1.92 ± 0.86	<0.001
AAC on VFA–n (%)	34 (36)	177 (23)	0.034

Conclusion: We found a significant association between VC on hands and feet radiographs and abdominal aortic calcification and CVD in our RA cohort. The presence of VC should alert physicians to the presence of CVD in patients with RA.

1256

High Inflammation May Condition the Antiatherogenic Function of Small, Dense HDL in Patients with Active Rheumatoid Arthritis. Carla Saucedo[1], Leonardo gomez Rosso[2], Tomas Meroño[2], Fernando Brites[2], Anatol Kontush[3], Luis J. Catoggio[1], Enrique Soriano[4], Laurent Camont[5], Marie Lhomme[5], Veronica Malah[6], Patricia Sorroche[7], Sandrine Chantepie[5], Paul Robillard[8] and John Chapman[5]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Laboratory of Lipids and Lipoproteins, School of Pharmacy and Biochemistry, Buenos Aires, Argentina, [3]Université Pierre et Marie Curie-Paris, Paris, France, [4]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [5]Université Pierre et Marie Curie, Paris, France, [6]Rheumatology section, Hospital de Clínicas "José de San Martín", Buenos Aires, Argentina, [7]Central Laboratory, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [8]Université Pierre et Marie Curie, Paris, Argentina

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased mortality, mainly due to cardiovascular disease. High grade inflammation might drive to premature atherosclerosis. High-density lipoprotein (HDL) possesses multiple biological activities, including antioxidative actions. Small, dense HDL3c particles exert potent antiatherogenic activities, which can be compromised under conditions of chronic inflammation. It remains indeterminate as to whether the level of such functional HDL deficiency is related to the degree of inflammation. Our objective was to evaluate HDL antioxidative function in normolipidemic RA active patients and controls.

Methods: serum from normolipidemic female patients with active RA (DAS28 >3.2; n=12) and normolipidemic age-matched female controls (n=10) was analized. Plasma levels of total cholesterol (TC), triglycerides (TG), HDL, LDL, apo-A, apo-B, plasma C-reactive protein (PCR), and serum amyloid A (SAA), subfractions of LDL and HDL were obtained. Small, dense HDL3b and 3c particles were isolated by density gradient ultracentrifugation. The capacity to protect LDL from oxidative stress induced by free radicals was assessed in small, dense HDL3b and HDL3c subpopulations, and in total HDL.

Results: sera from 12 active female RA patients and 10 age-matched female controls were analized. No significant differences were observed in plasma levels of TC, TG, LDL, HDL, apo-A and apo-B. Active RA patients exhibited a wide range of plasma C-reactive protein (CRP) levels, which were elevated relative to controls (8.4 mg/l, CI 3.5–11.4 vs. 0.47 mg/l, CI 0.30–0.89, p<0.001). Antioxidative activity and total chemical composition of small, dense HDL did not differ between RA patients and controls (p>0.05). Nonetheless, subgroup analyses revealed that RA patients featuring high levels of inflammation (CRP>10mg/l) possessed small, dense HDL with reduced antioxidative activities (up to −23%, p<0.01). Furthermore, antioxidative activity of HDL was inversely correlated with plasma CRP and SAA levels. HDL3b and 3c were depleted of free cholesterol (FC) in high-inflammated RA patients. This FC depleted HDL particles were less efficient in preventing LDL oxidation.

Conclusion: only RA patients who displayed high circulating levels of inflammatory biomarkers (CRP and SAA) possessed small, dense HDL3 particles with reduced antioxidative activity. This reduction in antioxidative action of HDL3 particles, along with reduced capacity of HDL to promote cholesterol efflux, and depletion of free cholesterol in HDL, may enhance development of atherosclerosis in active RA patients. These pathophysiological features are intimately linked to the inflammatory state, supporting that uncontrolled chronic inflammation leads to increased cardiovascular risk.

1257

Subclinical Atherosclerosis in Hispanic Patients with Rheumatoid Arthritis. Correlation with the Presence of Anti-Oxidized LDL Antibodies and Serum Levels of CD40L. Yurilis Fuentes-Silva[1], Soham Al Snih[2], Natali Serra-Bonett[1], Juan De Sanctis[3] and Martin A. Rodriguez[4]. [1]Centro Nacional de Enfermedades Reumáticas, Caracas, Venezuela, [2]University of Texas Medical Branch, Galveston, TX, [3]Instituto de Inmunología, Caracas, Venezuela, [4]Hospital Universitario de Caracas, Caracas, Venezuela

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease, associated with an excess of cardiovascular morbidity and mortality due to accelerated atherosclerosis. The appearance of antibodies (Abs) against anti-oxLDL may be a pathogenic link between inflammation and atherosclerosis. An excessive CD40L/CD40 interaction is thought to play a pathogenic role in RA. The aim of this study was to search for the presence of subclinical atherosclerosis in a group of Venezuelan patients with RA and examine its correlation with anti-oxLDL Abs and serum levels of CD40L.

Methods: Sixty-five RA patients and 26 healthy volunteers participated in the study. The presence and total serum levels of anti-oxLDL Abs and CD40L were examined by ELISA. The biologically active CD40L was measured by an assay testing induction of nitric oxide production in vitro by RAW mouse 264.7 cells. The presence of subclinical atherosclerosis was detected by the measurement of intima-media-thickness (IMT) of the common carotid arteries using a Doppler ultrasound system (Esaote MyLab, 12 Mhz). Subclinical atherosclerosis was defined by an IMT ≥ 0.6 mm. Statistical analysis was performed by Student's t test and Chi-square and the Exact Fisher's test for continuous and dichotomous variables, respectively. The study was approved by our hospital Ethics Committee and all patients signed an informed consent.

Results: We compared 65 RA patients (92.3% female; mean age 50,58±8,96) with 26 healthy controls (96.15% female; mean age 43.42±9.62). DMARDs and DMARDs plus biologics were received by 98.46% and 18.46% of patients, respectively. Mean disease duration was 7.32±6.04 years and mean and Disease Activity Score (DAS) 28-ESR was 3.19±1.5. Serum levels of anti-oxLDL were significantly higher in the RA patients than in healthy controls (34.48±9.83 vs. 24.74±6.4; P= 0,01). Serum levels of total CD40L and biologically active CD40L were also significantly higher in RA patients than in controls (9.13±2.74 vs. 3.86±1.21; P < 0,0001 and 3.81±1.94 vs. 1.6±1.11; P = 0,002). Patients with RA showed a higher proportion of an IMT ≥ 0.6 mm (P = 0,006). There was no correlation between serum levels of anti-oxLDL or CD40L with IMT.

Conclusion: To our knowledge this is the first study showing the presence of subclinical atherosclerosis in Hispanic patients with RA. Elevated serum titers of anti-oxLDL Abs and both total and soluble CD40L were features observed in this patient population suggesting their potential utility as biomarkers in this disease. Our preliminary results do not support a role for anti-oxLDL Abs or CD40L in the premature atherosclerosis observed in RA patients.

1258

Association Between Low Vitamin D Levels and Indicators of Osteoporosis and Atherosclerosis.
Barry J. Sheane[1], Ruth Dunne[2], Ken Scott[3], Mary Hall[2], Michelle O'Connor[2], Martin Healy[2], John Feely[2], J.B. Walsh[2] and Gaye Cunnane[2]. [1]St. James's Hospital, Dublin, Ireland, [2]St James's Hospital, Dublin, Ireland, [3]Trinity College Dublin, Dublin 8, Ireland

Background/Purpose: Osteoporosis and cardiovascular disease are complications of chronic rheumatoid arthritis (RA). It is not known if these processes share pathogenetic mechanisms. Low levels of vitamin D predispose to bone fragility. Recent data suggest that they may also be linked to vascular disease.

Methods: A cross-sectional study of RA patients and age-/sex-matched controls was carried out. None had any history of cardiovascular disease or diabetes mellitus. Levels of 25-hydroxy vitamin D were recorded and DXA scans were performed. Evidence of sub-clinical atherosclerosis was obtained with pulse wave analysis (PWA) and carotid intimal-medial thickness (CIMT). Serum markers of vascular disease (ICAM1, oxidized LDL, HSP60, IL6), a lipid profile and body mass index (BMI) were measured. Early RA was defined as those with disease duration less than 2 years. Data were analysed using SPSS 16.0.

Results: 99 people were included in this study (74 RA and 25 controls). Fifty-two (70%) of the RA group and 8 (31%) of the control group were taking calcium/vitamin D supplements (average vitamin D level 400iu/day). Only 12 (13%) had normal vitamin D levels (>80nmol/l). Vitamin D levels were deficient (<25nmol/l) in 21% and insufficient (>25 <80nmol/l) in 65%. All patients with early RA were vitamin D deplete (n = 18); 33% had insufficient levels and 67% deficient amounts. In contrast, 20% (n = 11) of those with established RA had normal vitamin D levels, while 65% had insufficient and 15% deficient levels. Mean vitamin D measurements were 38.5nmol/l in early RA versus 58nmol/l in established RA (p = 0.02).

Bone mineral density was similar between RA and controls. In the RA cohort, 29% had evidence of osteoporosis, while 46% had osteopenia and 25% had a normal DXA scan. In those with early RA, osteoporosis was present in 3 (18%) versus 16 (32%) patients with chronic RA (p = 0.3)

In RA, there was a negative correlation between vitamin D levels and DXA T-scores (p = 0.02), and BMI (p = 0.007). While RA patients had significantly greater levels of serum markers of vascular disease (IL6, ICAM1, oxidized LDL, HSP60) compared with controls, there was no correlation with vitamin D levels. CIMT measurements correlated negatively with vitamin D (p=0.06). Using multiple linear regression controlling for age, CIMT and DXA T-scores, and calcium/vitamin D supplements, vitamin D levels were negatively correlated with PWV (p=0.04), across the entire study group. Triglyceride levels were inversely related to vitamin D across the study group (cc −0.3, p<0.01).

Conclusion: Low levels of vitamin D were common in this population, particularly in those with early RA. Vitamin D supplementation at current dosages does not achieve normal vitamin D levels. The association between low vitamin D levels and markers of both osteoporosis and atherosclerosis needs to be further explored. In particular, a lack of sunlight in relation to insufficient exercise exposure may be relevant in exploring this link.

Disclosure: B. J. Sheane, None; **R. Dunne**, None; **K. Scott**, None; **M. Hall**, None; **M. O'Connor**, None; **M. Healy**, None; **J. Feely**, None; **J. B. Walsh**, None; **G. Cunnane**, None.

1259

Association Between Subclinical Atherosclerosis and Bone Mineral Density in Rheumatoid Arthritis.
Barry J. Sheane[1], Ruth Dunne[2], Ken Scott[3], Mary Hall[2], Michelle O'Connor[2], Martin Healy[4], John Feely[2], J.B. Walsh[5] and Gaye Cunnane[6]. [1]St. James Hospital, Dublin, Ireland, [2]St James's Hospital, Dublin 8, Ireland, [3]Trinity College Dublin, Dublin 8, Ireland, [4]Central Pathology Laboratory, Dublin 8, Ireland, [5]Medicine for the Elderly, Dublin 8, Ireland, [6]St James's Hospital, Dublin, Ireland

Background/Purpose: Rheumatoid arthritis (RA) is associated with a higher risk of osteoporosis (OP) and cardiovascular disease (CVD). This cross-sectional study was undertaken to identify links between the subclinical evidence of these processes.

Methods: RA patients without known cardiovascular disease or diabetes were included. Measures of osteoporosis risk (DXA, bone turnover markers) and sub-clinical atherosclerosis (pulse wave analysis, carotid intimal-medial thickness (CIMT)) were recorded in addition to serum markers of systemic inflammation and lipid profiles. Data were analysed using SPSS 16.0 for Windows.

Results: Seventy four RA patients and 26 controls were included in the analysis. Gender and age were similar between RA and controls and between sub-groups of RA duration. The RA group had significantly higher oxidized LDL titres (p<0.001), interleukin-6 (p<0.001), heat shock protein (HSP) 60 (p=0.008), and soluble ICAM-1 (p=0.016) compared with controls. HDL levels were significantly lower in those with RA for <10 years (p=0.026), while LDL (p = 0.014) and HSP60 levels (p = 0.024) were higher. Levels of vitamin D (p = 0.008), TNFα (0.016) and P1NP, a marker of bone formation (p = 0.03), were higher in those with long-standing RA.

In RA, femur T-scores were inversely related to mean CIMT (cc −0.3, p=0.02), mean common carotid artery IMT (cc −0.3, p=0.02), aortic augmentation index (AAIx) (cc −0.3, p=0.01), CRP (cc −0.4, p=0.002), oxLDL (cc −0.3, p=0.01) and anti-CCP antibody titre (cc −0.25, p=0.046). T-scores for the spine were also negatively correlated with AAIx (cc −0.4, p<0.001), anti-CCP antibody (cc −0.3, p=0.03), and oxLDL (cc −0.25, p=0.04). For those with osteoporosis, oxLDL was significantly higher compared to those with normal bone density (p=0.016). However, femur T-scores correlated positively with BMI (cc 0.5, p<0.001), waist (cc 0.4, p=0.002) and hip (cc 0.6, p<0.001) circumference, total fat mass (cc 0.4, p=0.01) and trunk fat mass (cc 0.4, p=0.02). T-scores for the spine also correlated with BMI (cc 0.3, p=0.008), waist (cc 0.4, p=0.002) and hip (cc 0.3, p=0.03) circumference.

Conclusion: Disease duration in RA correlated significantly with risk factors for atherosclerosis, independent of age. Furthermore, reduced bone mineral density was associated with evidence of sub-clinical atherosclerosis. These results suggest that early recognition of such complications may help to improve quality of life and longevity in patients with RA.

Hydroxychloroquine Reduces the Risk of Coronary Artery Disease in Patients with Rheumatoid Arthritis.
Li Chun[1], Mu Rong[1], Su Yin[1], Li Xiaofeng[2], Wang Yongfu[3], Wang Guochun[4], Zhu Ping[5], Liu Xiangyuan[4], Chen Haiying[6], Cui Liufu[7], Zhang Zhuoli[4], Li Zhenbin[6], Li Junfang[8], Zhang Fengxiao[9], Han Shuling[4], Lin Jinying[10], Liu Xiaomin[4], Hu Shaoxian[11], Yang Xiuyan[12], Huang Cibo Sr.[13], Li Xingfu[14], Wang Yi[15] and Li Zhanguo[1]. [1]Peking University People's Hospital, Beijing, China, [2]Taiyuan, China, [3]Baotou, China, [4]Beijing, China, [5]Xian, China, [6]Shijiazhuang, China, [7]Tangshan, China, [8]Handan, China, [9]China, [10]Nanning, China, [11]Wuhan, China, [12]Guangzhou, China, [13]Beijing Hospital, Ministry of Health, Beijing, China, [14]Jinan, China, [15]Lanzhou, China

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) can alter cardiovascular risk in RA by inflammation or by influencing cardiovascular risk factors indirectly. However, previous studies predominantly focused on methotrexate(MTX) and ignore the other major conventional DMARDs, such as hydroxychloroquine (HCQ).To assess the complication of coronary artery disease (CAD) and identify the risk factors of CAD in a large population of RA in China.

Methods: One thousand and ninety-six patients were enrolled in the study. Data were obtained from a retrospective survey of patients with RA, randomly selected from rheumatology practice of 21 university hospitals in China. The patients' social conditions, clinical conditions, medications associated with RA such as DMARDs, non-steroidal anti-inflammatory drugs (NSAIDs), glucocorticoid, biologic agents were collected. The χ^2test was used to compare the frequency of CAD risk factor, manifestations and medications of RA. Logistic regression modeling was used to examine the influence of risk factors on the development of CAD outcomes.

Results: Of the 1096 patients 34 developed CAD with a incidence of 3.1%. Compared to the control group, the CAD group patients had higher age (64.8±9.3yrs *vs* 52.0±14.1yrs, *P*=0.000), longer disease duration (13.3±11.4yrs *vs* 8.0±8.9yrs, *P*= 0.011), higher prevalence of diabetes

mellitus (29.4% *vs* 7.0%, *P*=0.000), hypertension (38.2% *vs* 16.2%, *P*=0.001), rheumatoid nodules (14.7% *vs* 2.7%, *P*=0.003) and lung interstitial disease (17.6% *vs* 7.0%, *P*=0.023). Patients with CAD were less likely to use hydroxychloroquine (HCQ)(5.9% *vs* 20.3%, *P*=0.038). Multivariate analysis showed higher age and rheumatoid nodules were independent predictors of CAD and HCQ was a protective factor of CAD.

Conclusion: CAD is a major concern for RA patients. HCQ reduces the risk of CAD in RA patients, higher age and rheumatoid nodules are independent risk factors for CAD in RA.

1261

Epicardial Adipose Tissue Is Associated with Cardiometabolic Risk and the Metabolic Syndrome in Patients with Rheumatoid Arthritis. Michelle J. Ormseth[1], Aliza Lipson[2], Nikolaos Alexopoulos[2], Gregory R. Hartlage[2], Annette M. Oeser[1], Aihua Bian[1], Tebeb Gebretsadik[1], Ayumi Shintani[1], Paolo Raggi[2] and C. Michael Stein[1]. [1]Vanderbilt Medical Center, Nashville, TN, [2]Emory University, Atlanta, GA

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased coronary atherosclerosis and this may be related to their increased prevalence of visceral adiposity, insulin resistance, and metabolic syndrome. Epicardial adipose tissue (EAT), a type of visceral fat, may contribute to insulin resistance, and through local paracrine effects, to coronary atherosclerosis. We measured EAT volume in patients with RA (n=162) and a matched control group (n=89) to define the relationship between EAT and markers of cardiometabolic risk in RA.

Methods: Clinical characteristics, inflammatory cytokines, lipids, fasting insulin and glucose, and homocysteine were measured. The homeostatic model of insulin resistance (HOMA) was calculated as a measure of insulin resistance and presence of metabolic syndrome defined by the National Cholesterol Education Program Adult Treatment Panel III criteria. EAT volume and coronary artery calcium score were measured by non-contrast cardiac computed tomography. EAT volume was compared in RA patients and controls, and the relationships between EAT volume and markers of cardiometabolic risk in RA defined.

Results: EAT volume was 108.2 cm^3 [77–144.6] (median [IQR]) in patients with RA and 93.9 cm^3 [69.9–133.1] in controls (P=0.06). RA patients with metabolic syndrome had significantly higher EAT volume than those without (P<0.001) and each increase in metabolic syndrome criteria count was associated with a 20% increase (95% CI, 14–26%) in EAT volume (p<0.001) independent of age, race and sex. Among RA patients, EAT volume was positively associated with IL-6 (P=0.03), triglycerides (P=0.004), presence of hypertension (P=0.01), HOMA (P<0.001), smoking history (P=0.04), and homocysteine (P=0.001) and negatively associated with HDL (P=0.005) after adjustment for age, race and sex. However, there was no significant association between EAT volume and current use and cumulative dose of corticosteroids (P=0.72 and P=0.90, respectively) or coronary artery calcium score (P=0.24), after adjustment for age, race and sex. With further adjustment for waist circumference as a measure of visceral obesity, EAT was independently positively associated with triglycerides, HOMA, current smoking and homocysteine (all P<0.05).

Conclusion: In patients with RA, EAT volume is associated with metabolic syndrome and independently associated with cardiometabolic risk factors including: insulin resistance, triglycerides, current smoking, and homocysteine levels, but not with coronary artery calcium.

Rheumatoid Arthritis Patients with Higher Disease Severity and Subclinical Carotid Plaque Experience More Cardiovascular Events Despite a Favorable Conventional Cadiovascular Risk Profiles. Yeon-Ah Lee[1], Somi Kim[1], Sang-Hoon Lee[2], Ran Song[2], Hyung In Yang[2] and Seung-Jae Hong[1]. [1]Kyung Hee University, Seoul, South Korea, [2]Hospital at GANG-DONG, Kyung Hee University, Seoul, South Korea

Background/Purpose: It has been shown that patients with rheumatoid arthritis (RA) experience cardiovascular (CV) events more often than expected. Increased risks of CV diseases in RA patients cannot be fully explained by conventional CV risk factors. This raises the possibility that the systemic inflammatory burden in RA may bring about its high CV event rate by causing accelerated atherosclerosis. This study was designed to evaluate the extent of subclinical atherosclerosis by measuring intima-media thickness of the carotid arteries (C-IMT) and the presence of plaque among RA patients and controls and to determine whether subclinical atherosclerosis, RA associated features, and other conventional CV risk factors are associated with later development of CV diseases (CVDs) in RA patients.

Methods: C-IMT was measured in 126 RA patients and 85 OA patients as controls who had no experience of CV events. The C-IMT was evaluated at common carotid arteries (CCAs), carotid bifurcation (BF) and internal carotid arteries (ICAs), bilaterally. Mean and maximal (max) IMTs were calculated from three measurements at each site. The following data were obtained for every patient: age, sex, body mass index (BMI), presence of bone erosions, rheumatoid factor, anti-CCP, medications, hypertension, hypercholesterolemia, diabetes mellitus, smoking status, family history of CVDs, ESR and CRP levels. Thereafter, these patients have been followed-up and examined the CV event rate during seven years. The CVD was defined as myocardial infarction, unstable angina, cardiac arrest, or death due to ischemic heart diseases.

Results: Although CV risks were fewer in RA than in OA, the mean and max C-IMT did not show a significant difference between two diseases groups. We found the higher presence of carotid plaques in RA patients than in OA patients. During follow-up, 21 patients experienced CV events. The incidence of CV events was higher in RA than OA (15.0% vs. 3.5%, p=0.004). But, the conventional CV risk factors such as DM, hypertension and high BMI were fewer in RA than in OA (10.3%, 27.7%, 34.1% vs. 28.2%, 55.2%, 57.6%, p=0.000). More CV events occurred in RA patients who initially showed the presence of subclinical plaques. The duration of CV event-free survival was shorter in RA patients with carotid plaque than those without (10 vs. 31 months, p=0.051). The RA patients who developed CVD later had more bony erosions, higher positivity for rheumatoid factor or anti-CCP, higher doses of steroid and higher levels of ESR and CRP, than those who did not.

Conclusion: Despite a favorable conventional CV risk profile, RA patients had a significantly higher incidence rate of CVD than OA patients. RA itself was an independent risk factor for CVD. Especially, RA patients with carotid plaque, seropositivity, bony erosion, higher ESR and CRP are at higher risk of CVD.

1263

Carotid Arterial Wall Inflammation Is Associated with a Specific Profile of Inflammatory Biomarkers and Anti-Citrullinated Protein Antibodies in Rheumatoid Arthritis Patients. Caroline Grönwall[1], Gregg Silverman[1], Zahi Fayad[2], Venkatesh Mani[2], Victoria Furer[1], Michael Farkouh[2], Manish Jain[1], Cheongeun Oh[1], John Todd[3], Mukundan Attur[4], Steven B. Abramson[4] and Jeffrey D. Greenberg[5]. [1]NYU School of Medicine, New York, NY, [2]Mount Sinai Hospital, New York, NY, [3]Singulex, Alameda, California, Alameda, CA, [4]NYU Hospital for Joint Diseases, New York, NY, [5]New York University School of Medicine, New York, NY

Background/Purpose: Patients with RA are at increased risk of cardiovascular (CV) comorbidity and premature mortality. While generally attributed to accelerated atherosclerosis, the pathogenesis remains poorly understood.

Methods: To investigate cardiovascular disease in RA, we measured carotid and aortic wall inflammation by 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) uptake and vessel wall morphology by MRI in a cross-sectional study (N=30 pts). We calculated Mean and Maximum Target to Background Ratio (TBR) values as measures of arterial wall inflammation. Left and right carotid TBRs were combined as mean carotid values. Inflammation-related serum analytes were measured by commercial ELISA (sRAGE), and with a custom plasma panel for inflammation-related proteins, including cytokines, matrix metalloproteinases (MMPs), MMP inhibitors and trophic factors (Singulex Inc.). High-sensitivity cardiac troponin I (cTn-I) was also measured (Singulex Inc) as a marker of myocardial injury. IgG antibodies to citrullinated (cit) peptides from fibrinogen (Fib), histone 2A, filaggrin, a-enolase, and vimentin were determined by quantitative ELISA, and CCP3 using a commercial clinical assay (Inova

Diagnostics Inc.). Protein peptide-specific ACPA assays were validated with a panel of sera from RA, OA and healthy individuals.

Results: The mean age was 51.2 years, mean DAS28 score 6.7 (range 2.2–6.7), 80% female and 11(36%) were on biologic DMARDs. Carotid Max TBR was associated with higher levels of cTn-I ($r=0.566$, $p=0.01$), indicating an association of carotid wall inflammation with subclinical myocardial injury. Of the 15 inflammatory biomarkers assessed, carotid max TBR values was associated with elevations of sRAGE, VEGF, MMP8, proMMP9 and IL-1b. **(Table 1)**. Similar results were obtained for carotid mean TBR. Strikingly, there was a strong correlation between carotid max TBR and cit-Fib IgG ($R=0.72$, $p=0.0005$). Furthermore, patients with a positive Cit-Fib IgG test ($n=10$) had higher levels of carotid wall inflammation [max TBR (p-0.04), mean TBR ($p=0.03$)] than Cit-Fib IgG negative pts. No correlation was found between carotid TBR values and levels of IgG CCP3. Neither IgG antibodies nor any of the inflammatory biomarkers correlated with aorta TBR measures. By MRI, we found significant correlations between wall thickness and ACPA IgGs specific for citrullinated fibrinogen, filaggrin, and enolase, as well as plasma hsCRP and pMMP9.levels ($p<0.05$).

Table. Associations of carotid wall inflammation (max TBR) and biomarkers

Biomarker	Spearman (r)	P-value
cTn-I	0.57	0.01
sRAGE	0.43	0.07
VEGF	0.59	0.008
MMP8	0.62	0.004
pMMP9	0.58	0.008
IL1β	0.48	0.03
IgG anti-Cit-Fib	0.72	0.0005

Conclusion: These FDG-PET studies indicate that a subset of RA patients exhibit inflammatory carotid artery disease. Carotid inflammation was associated with elevations of a distinct profile of innate inflammatory markers and citrullinated self-protein-specific IgG. These data may provide insights into the immunopathogenesis of RA-associated CV disease.

Vascular Age in Rheumatoid Arthritis Patients. Jl Rosales-Alexander. César Magro Checa, Juan Salvatierra, Silvia Montes García, Jesús Cantero Hinojosa and Enrique Raya Álvarez, University Hospital San Cecilio, Granada, Spain

Background/Purpose: The European League Against Rheumatism (EULAR) recommends cardiovascular risk (CV) assessment using the systematic coronary risk evaluation (SCORE) chart in rheumatoid arthritis (RA) patients. However, the absolute 10 years CV risk is a statistical and epidemiological concept that could be difficult to understand by our patients, resulting in a lack of adherence to treatment. The Framinghan heart study (FHS) incorporated the concept of vascular age, as the age of the arteries, a concept more easily understood by all patients. Recently, a calibrated vascular age chart (VAC) according to the SCORE scales was published for european people.

Objectives: To assess vascular age (VA) in RA patients without CV risk factors/previous ischemic events using the VAC comparing it with healthy controls. To assess the correlation of several clinical and serological variables with VA.

Methods: We included 101 consecutive RA patients, according to the 1987 ACR classification criteria, without CV risk factors neither previous ischemic events and matched to 98 healthy controls according to sex, age and gender. We recorded demographic data, clinical and laboratory parameters of disease activity like ESR, CRP, tender and swollen joint counts, DAS28, patient global assessment by visual analogue scale, lipid profile and RA characteristics. We assessed VA using the VAC. Data was analyzed with the statistical software SPSS 15. Descriptive data were shown as percentages and mean±SD. To analyze data, we use simple lineal regression test with correlation and the multiple lineal regression analysis. The limit of statistical significance was located in the α error of 0,05.

Results: In RA patients, the median chronologic age (CA) was 53,83±8,28 years, VA was 56,67±9,84 and absolute CV risk was 1,43±1,1. Of these patients, 20% fulfilled EULAR criteria for higher CV risk (20% had more than 10 years of disease, 9% had extra articular manifestations, 77% were positive RF and 48% had ACPA). In controls, CA was 53,52±8,37, VA

was 55,78±9,82 and absolute CV risk was 1,1±1. After applying lineal regression test, VA was correlated with CA (beta 1.096, $p=0.000$); however, there were not differences in VA between both groups (beta −0.62, $p=0,232$). Of interest, after adjusting for confounding factors, VA seem to be correlated with presence anti-citrullinated peptide antibodies (ACPA) $p<0,021$.

Conclusion: In our study we did not find differences between VA in RA patients without CV risk factors in comparison to healthy controls, but we found a well correlation between VA and the CA. Presence of ACPA seems to predict higher vascular age.

Lipoprotein Subclass Particles and Small Vessel Elasticity As a Potential Marker for Early Atherosclerosis in Rheumatoid Arthritis: a Prospective, Controlled Study. Marty T. Mertens[1] and Elie Gertner[2]. [1]University of Minnesota, Minneapolis, MN, [2]Regions Hospital and University of Minnesota Medical School, St. Paul, MN

Background/Purpose: Rheumatoid arthritis (RA) has increased rates of cardiovascular (CV) events. However, standard CV risk factors, such as routine lipid profiles, are not different in RA patients. It is still unclear how to best evaluate CV risk in RA.

Lipoprotein subclass determination differentiates lipoproteins by size and density. Small, dense LDL particles have been associated with an increased risk of CV disease in a number of population studies. Recently, small, dense HDL particles have been shown to be potentially anti-atherogenic. In RA, lipoprotein subclasses have been evaluated in three studies with conflicting results. No studies have prospectively evaluated lipoprotein subclasses in RA. Further, no studies have attempted to correlate these findings with a marker of endothelial function.

In this study, we evaluated lipoprotein subclasses and small arterial elasticity (SAE) in patients with RA over a 12 month period in comparison to healthy controls. SAE is a marker for vascular function and reduction in SAE is predictive of development of atherosclerosis.

Methods: Thirty-five seropositive RA and thirty-one control subjects without a history of coronary artery disease, diabetes mellitus, or active statin therapy were recruited. DAS28-CRP was measured as a marker for disease activity. Lipoprotein subclass concentrations were measured by nuclear magnetic resonance spectroscopy. SAE was measured from pulse-wave analysis by radial artery tonometry. After 12 months, the RA group underwent repeat DAS28-CRP, lipoprotein subclass determination, and SAE evaluations.

Results:

1. There was no significant difference between the RA and control groups in small arterial elasticity.
2. The RA group had significantly lower total LDL and lower small LDL particle concentration as compared to the control group.
3. Average HDL size was significantly larger in the RA group compared to controls.
4. Within the RA group, there was a statistically significant correlation of increased DAS28-CRP with a lesser number of small HDL particles ($R = -0.07$, $p = 0.047$). No significant correlations were seen between changes in DAS28-CRP with small LDL particles or HDL size. Changes in small LDL, small HDL particles, HDL size and DAS28-CRP did not correlate with changes in SAE.

	Rheumatoid Arthritis (SD) N = 35	Controls (SD) N = 31	p-value
Small Arterial Elasticity (ml/mmHg ×100)	5.90 (2.74)	6.48 (2.68)	0.42
Total LDL (nmol/L)	1008 (317)	1210 (389)	**0.028**
Small LDL (nmol/L)	504 (308)	753 (445)	**0.012**
LDL size (nm)	21.4 (0.7)	21.1 (0.8)	0.085
Total HDL (nmol/L)	32.5 (5.4)	33.3 (5.3)	0.57
Small HDL (nmol/L)	18.5 (5.2)	19.6 (5.9)	0.38
HDL size (nm)	9.3 (0.4)	9.1 (0.5)	**0.039**

Conclusion:

1. In the RA group, there was lower total LDL and lower small LDL particle concentration as compared to controls. HDL size was significantly larger in the RA group as compared to controls.

2. Within the RA group, increased disease activity significantly correlated with a reduced number of small HDL particles.
3. Small arterial elasticity did not differentiate RA from controls in assessing potential cardiovascular risk. SAE was not affected by changes in lipoprotein subclasses.

Alterations in LDL subclass populations may not account for the increased cardiovascular risk seen in RA. However, reduction in the potentially anti-atherogenic small HDL particles may be a potential factor.

Disclosure: **M. T. Mertens**, None; **E. Gertner**, None.

Evaluation of Metabolic Syndrome in 97 Patients with Rheumatoid Arthritis. Fernanda G. G Chaer[1], Juliana Lucena[1], Rogerio Castro Reis[1], Fabiola Brasil[1], Murilo Melo[2], Amanda Callegari[2] and Branca Souza[2]. [1]Irmandade da Santa Casa de Misericordia de Sao Paulo, São Paulo, Brazil, [2]Irmandade da Santa Casa de Misericordia de São Paulo, São Paulo, Brazil

Background/Purpose: Rheumatoid arthritis (RA) is an independent risk factor for cardiovascular disease (CVD), which is the leading cause of death in this group. Thus, the investigation of metabolic syndrome (MS) is critical, as designating a number of other cardiovascular risk factors: abdominal obesity, dyslipidemia, hypertension and hyperglycemia.To evaluate the frequency of MS in patients with RA and their relationship with disease activity and the different therapies used, in particular blocking tumor necrosis factor alpha (anti-TNF).

Methods: We selected 107 consecutive patients diagnosed with RA and included only patients with data necessary for determining the MS according to NCEP-ATPIII. Disease activity was determined using the 28-joint Disease Activity Score (DAS28). Score greater than 3.2 and was considered the cutoff point for disease activity.

Results: The study included 97 patients. 47 (48.5%) were using anti-TNF in combination with methotrexate (MTX). 50 (51.5%) patients were using only synthetic DMARDs: 36 (72 %) MTX, 22 (44%), leflunomide, 19 (38%) chloroquine and 8 (16%) sulphasalazine. The overall frequency of MS was 37.1%. There was no significant difference between the prevalence of MS in patients using synthetic DMARDs only or anti-TNF. We did not observe any association between RA disease activity and MS in our study. The use of chloroquine was associated with a lower frequency of MS (p = 0.005), and BMI was higher in this group (p <0.001). In multivariate analysis including all variables with p <0.200, only the use of chloroquine and BMI remained in the model (r = 0.465, p <0.001).

Conclusion: The use of anti-TNF was not associated with lower incidence of MS compared to the use of synthetic DMARDs only, and among these, chloroquine was associated with a lower frequency of MS. Considering these results, the safety profile and low cost, chloroquine remains a valuable adjuvant therapy in this patient population at high risk for CVD.

1267

Inflammatory Burden Predicts Progression of Carotid Plaque in Rheumatoid Arthritis: A 24-Month Longitudinal Analysis. Churl Hyun Im, Na Ri Kim, Jong Wan Kang, Young Ji Kim, Kyung Hye Kim, Eon Jeong Nam and Young Mo Kang. Kyungpook National University School of Medicine, Daegu, South Korea

Background/Purpose: Carotid atherosclerosis, which is associated with the increased risk of cardiovascular (CV) disease, is increased in rheumatoid arthritis (RA) patients. In our previous study, an inflammatory burden, measured by area under the curve of erythrocyte sedimentation rate (ESR-AUC), increases the risk of carotid plaque formation in RA, independently with traditional CV risk factors. The aim of this study was to evaluate the role of inflammatory burden in the progression of carotid plaques during 2 years of follow up in a RA patient cohort.

Methods: We measured the intima-media thickness (IMT) and plaques using carotid artery ultrasound at baseline and after 2 years in 279 RA patients, who were enrolled in the Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort. Surveys for traditional CV risk factors were performed using the same questionnaire. Clinical and laboratory variables relevant to RA activity were obtained. To assess inflammatory burden, ESR-AUC during 2 years of follow up (ESR-AUC2), 5 years before baseline enrollment (ESR-AUC5, 140 females, ≥ 40 years old), and summation of these two periods (ESR-AUC7) were calculated.

Results: The study population included 227 females and 52 males RA patients. Mean and maximal common carotid IMT was increased during 2 years of follow up (0.799 ± 0.173 vs. 0.809 ± 0.173 mm; $P = 0.010$ and 0.918 ± 0.214 vs. 0.936 ± 0.210 mm; $P = 0.002$, respectively). Frequency and number of carotid plaque were also increased from 34.7% to 46.4% ($P < 0.001$) and from 0.7 ± 1.3 to 1.0 ± 1.7 ($P < 0.001$), respectively. Plaque presence at 2 years of follow up was associated with tender joint count (TJC), swollen joint count (SJC), disease activity score (DAS) 28, and ESR level at baseline, after the adjustment with age and gender. ESR-AUC2, ESR-AUC5, and ESR-AUC7 were significantly associated plaque at 2 years ($P = 0.035$, $P = 0.018$, and $P = 0.025$ respectively), after the adjustment with age and gender). After multivariate logistic regression analysis, the factors found to be significantly associated with plaque at 2 years were ESR-AUC5 ($P = 0.015$) and TJC28 at baseline ($P = 0.048$). In the second step analysis of 71 patients with newly developed plaque at 2 years (33 patients with no plaque at baseline and 38 patients with increased number of plaques from baseline), the factor significantly associated with plaque progression was ESR-AUC5 ($P = 0.038$) in multivariate logistic regression analysis.

Conclusion: Our findings indicate that residual inflammatory burden increases the risk of carotid plaque progression during 2 years of follow up in RA.

Lipid Alterations and Measurement of Arterial Stiffness in Rheumatoid Arthritis. Marina Scolnik[1], Carla Saucedo[1], David A. Navarta[1], Leandro Ferreyra Garrott[1], Erika Catay[1], Maria L. Acosta Felquer[1], Eliana Lancioni[1], Cristian Quiroz[1], Federica Varela Guidetti[1], Zaida Bedran[1], Mirtha Sabelli[1], Javier Rosa[1], Maria Victoria Garcia[1], Patricia M. Imamura[1], Patricia Sorroche[2], Jose Alfie[3], Margarita Morales[3], Gabriel Waisman[3], Luis J. Catoggio[1] and Enrique Soriano[4]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Central Laboratory, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Hypertension Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease. Increased arterial stiffness, an independent risk factor for premature coronary artery disease, has been reported in patients with RA. The objectives of this study were first to assess, in patients with RA and controls, the prevalence of lipid alterations and to measure arterial stiffness. And second, to investigate the relationship between arterial stiffness, disease activity, disease duration and other traditional cardiovascular (CV) risks factors.

Methods: Between January 2010 and May 2011, 91 consecutive adult RA patients (fulfilling 2010 ACR/EULAR criteria) and 79 controls (patients seen at the rheumatology section with diagnoses of non-inflammatory diseases) were included. Exclusion criteria were previous history of cardiovascular disease, using of lipid-altering drugs and uncontrolled hypothyroidism. Data from each patient of smoking, blood pressure, weight, height, body mass index (BMI), waist size, glucose levels, HDL cholesterol, LDL cholesterol, triglycerides (TG), total cholesterol (TC), DAS28, sedimentation rate (ESR) and medication were obtained. Carotid femoral pulse wave velocity (PWV) was measured in 56 RA patients and 25 controls. RA patients were divided in active patients (DAS28>=2.6, n=39) or patients in remission (DAS28<2.6, n=17). Reference values for PWV were those published by the European Society of Cardiology. Patients with PWV over the value expected for age and optimal blood pressure were considered to have arterial stiffness.

Results: Patients characteristics are shown in table 1. Mean RA duration was 7.5 years (SD 4.5). RA patients and controls had similar values of lipids and other classic CV risk factors (table 1). Arterial stiffness measured by PWV was found in 1 control (4%) and 6 RA patients (10.7%) (p=0.3). Mean carotid femoral PWV was 8,78 m/s (SD 2.1) for controls and 9.3 m/s (SD 2,6) for RA patients (p=0.4). PWV was similar in remission RA patients and active RA patients, means 9,23 m/s (SD 3.4) and 9.3 m/s (SD 2.3) respectively (p=0,9). Patients with hypertension had an increased PWV compared with non-hypertensive patients (p=0.0003). In fact in multivariate analysis, only arterial hypertension correlated independently with arterial stiffness (OR 19.9, CI 2.2–178). No relationship was found between carotid femoral velocity and DAS 28, ESR, disease duration, medications or other CV risk factors.

Table 1.

	CONTROLS (n=79)	RA PATIENTS (n=91)	P value
Age, years (SD)	58.6 (12.6)	58.4 (12.4)	0.92
Female, % (CI)	94.9 (87.5–98.6)	93.4 (86.2–97.5)	0.67
Hypertension, % (CI)	53.2 (41.6–64.5)	46.1 (37.4–57)	0.36
Hyperglycemia, % (CI)	6.5 (CI 2.1–14.5)	5.5 (CI 1.5–13.4)	0.8
Current smokers, % (CI)	19 (11–29.4)	11.3 (5.3–20.3)	0.17
BMI (SD)	27.9 (5.6)	26.02 (5.3)	0.02
Waist perimeter, cm (SD)	94.31 (14.08)	88.76 (14.28)	0.01
HDL <40 mmol/L, % (CI)	6.4 (2.1–14.3)	6.6 (1.8–15.9)	0.97
LDL >= 160 mmol/L, % (CI)	17.9 (10.2–28.3)	15.5 (7.3–27.4)	0.7
TG > 150 mmol/L, % (CI)	16.7 (9.2–26.8)	7.1 (2–17.3)	0.1
TC> 200 mmol/L, % (CI)	41 (30–52.7)	50.6 (39.4–61.8)	0.22
Dyslipidemia, % (CI)	58.2% (IC 46,6–69,2)	51.7% (IC 40,8–62,4)	0.39

Conclusion: in this cohort, RA patients and controls had similar CV risk factors and we found no differences in PWV between them. In RA patients, neither disease duration nor disease activity, measured by DAS28, was related to increased arterial stiffness. Arterial hypertension was the only CV risk factor associated with arterial stiffness. We did not find increased pulse wave velocity in RA patients as has been previously reported.

1269

Serum Cytokines Associated with Carotid Atherosclerosis in Rheumatoid Arthritis. Inmaculada del Rincon[1], Roy W. Haas[1], Daniel H. O'Leary[2], Joseph F. Polak[2], Daniel F. Battafarano[3] and Agustin Escalante[1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Tufts University-Boston Campus, Boston, MA, [3]Brooke Army Medical Ctr, San Antonio, TX

Background/Purpose: The mechanism for the increased cardiovascular morbidity and mortality in rheumatoid arthritis (RA) is incompletely understood. In a previous analysis, we found that both the erythrocyte sedimentation rate and the C-reactive protein were associated with the carotid intima-media thickness (IMT) in RA patients, suggesting that systemic inflammation plays a role. Cytokines are important mediators in inflammation and can be measured in the serum. We examined the association between the serum concentration of cytokines/chemokines and the carotid IMT in patients with RA.

Methods: We performed a high-resolution carotid ultrasound in patients with RA for measurement of the internal and common carotid IMT, expressed as a composite. A subset of patients returned for a repeat ultrasound of the common carotid IMT, following a protocol designed to assess change. A stored sample of patients' serum at baseline was used to measure 38 cytokines using a multiplex ELISA technique. We used a multivariable stepwise selection process to identify cytokines associated cross-sectionally with the composite carotid IMT, and with rapid progression of the common carotid IMT.

Results: A baseline scan was performed on 1,162 RA patients, 873 of whom were women. The mean composite carotid IMT was 1.040 mm (SD 0.181 mm). A subset of 566 patients was eligible for a follow-up scan, which we performed in 487 (86%). The mean (SD) common carotid IMT at baseline was 0.571 mm (0.151), and after a 3 year follow-up, the common carotid IMT increased to a mean of 0.621 mm (0.171), an increase of 0.050 mm (0.055), P < 0.001. Among patients in the highest progression quartile, the common carotid IMT increased by 0.119 mm (0.062). The following serum cytokines were independently associated with the cross-sectional composite IMT, adjusted for age and sex: IL-8, 0.047 (0.018, 0.076); soluble IL-2 receptor-alpha, 0.054 (0.020, 0.089); IL1-receptor antagonist, −0.053, −0.087, −0.018); and macrophage-derived chemokine −0.027 (−0.052, −0.001). Values shown are regression coefficients in mm per SD (95%CI). Few cytokines were associated with rapid progression of the common carotid IMT, with only the IL-12p40 reaching statistical significance with an odds ratio of 1.67 per SD, 95% CI (1.14, 2.29).

Conclusion: A number of inflammatory cytokines measured in the serum, notably IL-8, were significantly associated with the carotid IMT. However, in contrast with other RA outcomes, the number of cytokines and the strength of their association with the carotid IMT were modest. This may indicate that cytokines and chemokines exert their effect at the level of the vascular wall rather than though the systemic circulation. These findings help clarify the role of inflammation in rheumatoid atherosclerosis.

Role of Inflammation, Serologic Status and Low Density Lipoprotein in Coronary Heart Disease Among Patients with Rheumatoid Arthritis: Data From the National Veterans Health Administration. Iris Navarro-Millan[1], Shuo Yang[2], Scott L. DuVall[3], Lang Chen[2], John Baddley[2], Grant W. Cannon[4], Elizabeth S. Delzell[2], Jie Zhang[2], Monika M. Safford[2], Nivedita M. Patkar[5], Ted R. Mikuls[6], Jasvinder A. Singh[2] and Jeffrey Curtis[2]. [1]University of Alabama Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [4]Salt Lake City VA and Univeristy of Utah, Salt Lake City, UT, [5]Univ of Alabama-Birmingham, Birmingham, AL, [6]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Rheumatoid arthritis (RA) increases the risk for coronary heart disease and ischemic events like myocardial infarction (MI). The association between traditional cardiovascular risk factors in this population remains unknown. Objective: To determine the association between myocardial infarction (MI), low density lipoprotein (LDL), seropositive RA and inflammation as determined by C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) among patients with RA.

Methods: Retrospective data from the national Veterans Health Administration (VHA) from 1998–2011 was used for this study. Identification of the RA population and incident hospitalized MI was done using a validated algorithm using ICD-9 codes for RA from outpatient rheumatology visits and MI primary diagnosis code on hospitalization. Patients eligible for this analysis included RA patients with no previous MI. Baseline characteristics were determined during the first 12 months of observation in the VHA system, after which follow-up time for this analysis began. Laboratory data was examined in a time-varying fashion and updated on a daily basis and assessed at each event time. Seropositivitiy was characterized by having either positive rheumatoid factor (RF) or anti-cyclic citrullinated peptide (CCP) antibody. Cox proportional hazard models were used to determine the hazard ratios (HR) between first hospitalized MI and LDL (in quartiles and using ATP III cutpoints); CRP, ESR in quartiles (to avoid assumptions of linearity) and seropositivity using age as the time axis.

Results: A total of 38,694 VHA patients with RA were identified. They were 90.3% male; mean ± SD age was 63.5 (± 12.1) years. Mean CRP, ESR and LDL levels at baseline were 10.4 mg/L (± 20.5), 30.1 mm/h (SD ± 24.9) and 100 mg/dL (SD ± 31.7) respectively; 85% of the RA cohort was seropositive. The baseline prevalence of diabetes was 12.5% and hypertension 33.9%.

The number of usable MI events varied according conditional on the availability of laboratory results. The crude rates of MI by each exposure variable are listed (table). A strong relationship was seen with increasing ESR. Trends in MI rates associated with increasing CRP were observed only for the 4th quartile. Higher HDL appeared protective, and patients in the lowest LDL quartile had the highest rates of MI.

Table. Myocardial Infarction Incident rates by ESR, CRP, LDL, High Density Lipoprotein (HDL) and Serologic Status by Quartiles

ESR (mm/hour) Quartile	MI Events	Person Years	Iincident Rate per 1,000 Person year
1st (<11)	80	2406	3.3
2nd (≥11 and <23)	87	21131	4.1
3rd (≥23 and <42)	133	20247	6.6
4th (>42)	171	18896	9.0
CRP (mg/L) Quartile			
1st (< 0.89)	26	4975	5.2
2nd (≥ 0.89 and <3.1)	17	4302	4.0
3rd (≥3.1 and <9.5)	20	3941	5.1
4th (>9.5)	30	3483	8.6
LDL 9mg/dL) Quartile			
1st (< 77.4)	245	31437	7.8
2nd (≥ 77.4 and ≤ 97.2)	184	32797	5.6
3rd (≥ 97.2 and ≤ 121)	143	31965	4.5
4th (>121)	162	30392	5.3
HDL (mg/dL) Quartile			
1st (< 34.4)	220	27241	8.1
2nd (≥ 34.4 and 41.0)	190	30203	6.3
3rd (≥ 41.0 and ≤ 50.4)	180	35294	5.1
4th (>50.4)	153	34345	4.5
Serologic status (RF/CCP)			
Seronegative	43	14588	2.9
Seropositive	443	84193	5.3

After controlling for age, the HR for ESR (comparing the highest to lowest quartile) was 2.4 (p < 0.001), and the HR for CRP (highest to lowest quartile) was 1.6 (p = 0.08). The HR for sepositive RA was 1.7 (p < 0.001). HR for LDL ≥160 mg/dL compared to LDL < 100 was 1.2 (p= 0.30).

Conclusion: In this U.S., predominantly male RA cohort, ESR and seropositivity were significantly associated with a risk for MI and trends suggested CRP was as well. Higher LDL was not associated with a significantly increased risk for MI.

Two-Year Drug Survival and Treatment Effect of Abatacept and Tocilizumab in the Treatment of Rheumatoid Arthritis in Routine Care. Results From the Nationwide Danish Danbio Registry. HC Leffers[1], Mikkel Østergaard[1], Bente Glintborg[2], Niels Steen Krogh[3], Ulrik Tarp[4], Tove Lorenzen[5], Annette Hansen[2], Michael Sejer Hansen[2], Lene Dreyer[2], Martin S. Jakobsen[2] and Merete L. Hetland[6]. [1]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Glostrup, Denmark, [2]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Copenhagen, Denmark, [3]ZiteLab ApS, Copenhagen, Denmark, [4]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Aarhus, Denmark, [5]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Silkeborg, Denmark, [6]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Abatacept and tocilizumab have been shown to be efficacious for the treatment of rheumatoid arthritis (RA), even in patients refractory to tumor necrosis factor inhibitor (TNFi). However, reports on their long term efficacy in clinical practice are scarce. The aim of this study was to describe two-year drug survival and clinical response in RA patients treated with abatacept or tocilizumab in routine care. It is an extension of previously published 48-week data[1], based on data from the nationwide Danish DAN-BIO registry

Methods: In the DANBIO registry we identified 230 and 447 RA patients treated with abatacept and tocilizumab, respectively. The clinical efficacy was assessed by drug survival and by changes in DAS28 and EULAR response rates after 48 and 96 weeks. No imputation of missing values was done. No direct comparison of the 2 drugs was made.

Results: Of the patients receiving abatacept and tocilizumab, respectively, 22%/25% (abatacept/tocilizumab) were male, median (interquartile range, IQR) age 55(45–64)/57(46–65) years, disease duration 5(1–13)/5(1–11) years and number of previous biological drugs 2(2–3)/2(1–3), >99%>/99% of patients, had previously received ≥1 TNFi. Rheumatoid factor was positive in 79% and 77% of patients with available data (143/230 and 290/447), respectively.

After 48 and 96 weeks, 54%/66% and 39%/58% of patients treated with abatacept/tocilizumab were still receiving the drug, respectively.

Among patients with available response data, median DAS28 was in the abatacept group 5.2, 3.2 and 2.9 at baseline, week 48 and week 96, respectively, while 5.3, 2.7 and 3.0 in the tocilizumab group.

At week 48 and 96, the remission rates for abatacept/tocilizumab were 29%/49% and 38%/41%, respectively and rates of good-or-moderate EULAR response was 76%/87% and 79%/97% at week 48 and 96. Response rates after correction for proportion of patients still on drug (LUNDEX values[2]) are presented in **figure 1**.

Conclusion: In RA patients (>99% TNFi failures) treated with abatacept and tocilizumab, 54%-66% of patients were still receiving the drug after 48 weeks, and 39%-58% after 96 weeks. Due to the non-randomised study

design, no direct comparison of the drugs were made. Both drugs significantly decreased the disease activity, and a good-or-moderate EULAR response was seen in the majority (76%-87%) of patients after 48 weeks (87%-97% after 96 weeks). After correction for patients who had withdrawn, response rates were lower. This stresses the importance of transparency in the reporting of observational data.

1272

Rheumatoid Arthritis (RA) Incomplete Secondary Responders to TNF-Alpha Safely Achieve Efficacy by Switching to Certolizumab Pegol in a 24-Week Study: A Phase IV, Randomized Multicenter, Double-Blind, Twelve-Week Study Followed by a 12 -Week Open-Label Phase. M. Schiff[1], Ronald Goldblum[2] and John RP Tesser[3]. [1]University of Colorado, Denver, CO, [2]CPC, Inc, Carlsbad, CA, [3]AZ Arthritis Rheum Assoc, Paradise Valley, AZ

Background/Purpose: Certolizumab pegol (CZP), an inhibitor of TNF-alpha, has demonstrated rapid and sustained efficacy in RA patients. Switching from one anti-TNF therapy to another has been investigated in many open-label (OL) uncontrolled studies, but in few controlled trials. This 24-week study (12 weeks double-blind (DB) CZP or placebo followed by 12 weeks OL CZP) examined the effect of treatment with CZP or placebo on measures of disease activity in patients with active RA on stable concomitant DMARD therapy who had discontinued a TNF-alpha inhibitor other than CZP due to a secondary loss of efficacy.

Methods: The initial 12-week phase randomized 37 subjects (2:1 ratio) who were secondary non-responders (primary non-responders were excluded) or intolerant of TNF-alpha inhibitors to either CZP (27 subjects) or placebo (10 subjects) in addition to background MTX or other DMARDs. CZP was administered subcutaneously in approved doses. The pre-specified primary endpoint was the ACR 20 response at Week 12. After the Week 12 visit, all subjects could continue (blinded to initial treatment) with OL CZP for an additional 12 weeks. (NCT01147341).

Results: 37 subjects were randomized; 35 (26 on CZP and 9 on placebo) completing at least 4 weeks of dosing were analyzed for efficacy. Demographic/baseline characteristics (mean) of the 2 treatment groups were similar: age 56 vs 59 years, disease duration 12 vs 14 years, MTX dose 16.4 vs 16.1 mg/week, and DAS-CRP 5.48 vs 5.44 (placebo vs active). Efficacy results (initial 12 weeks) are as follows:

Efficacy Endpoints	Placebo n/N (%)	CZP n/N (%)	p-value*
ACR 20 (primary)	0/9 (0)	16/26 (61.5)	0.001
CDAI Decrease ≥10	2/9 (22.2)	22/26 (84.6)	0.001
ACR 50	0/9 (0)	5/26 (19.2)	N.S.
CDAI LDAS+Remission	0/9 (0)	6/26 (23.1)	N.S.
EULAR good and moderate	0/9 (0)	17/26 (65.4)	0.001
DAS28 (CRP) ≥1.2 Decrease	0/9 (0)	17/26 (65.4)	0.001
CDAI ≥13.9 Decrease	0/9 (0)	17/26 (65.4)	0.001

* two-sided p-value from Fisher's exact test

24-Week Data: 8 of the 9 subjects randomized to placebo (all non-responders) continued into OL; 5/8 (67%) attained ACR 20, 7/8 (87.5%) of these had CDAI improvement ≥13.9 after the switch to CZP. Five of the CZP-treated subjects who were initially ACR 20, but not ACR 50, responders improved to ACR 50 or 70 responses with OL treatment.

In the initial 12 weeks, adverse events occurred in 16/27 (59.3%) CZP subjects and 4/10 (40%) placebo subjects. One serious adverse event of G-I bleeding (considered unrelated to CZP) occurred in the open-label phase.

There were no other serious adverse events, deaths, neoplasms, opportunistic or serious infections.

Conclusion: In this controlled study of secondary non-responders to TNF inhibitors, the primary efficacy endpoint (ACR 20) and most secondary endpoints showed significant improvement with CZP compared to placebo. The ACR 20 response rate observed with CZP (>60%) is higher than that reported in most previous studies of incomplete TNF responders. With OL CZP dosing for the final 12 weeks, improved efficacy was seen in most subjects who had previously received placebo. In addition, CZP demonstrated good safety and tolerability. This study supports the use of CZP in RA patients who are secondary non-responders to anti-TNF therapies or intolerant to them.

1273

Can Response Duration After the First Rituximab Treatment Be Used in Timing of Rituximab Retreatment?
Noortje van Herwaarden[1], Aatke van der Maas[1], Tim L. Jansen[2], Ellen Dutmer[3], Andre Hartkamp[4], Piet L.C.M. van Riel[2], Wietske Kievit[2], Bart J.F. van den Bemt[1] and Alfons A. den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Gelderse Vallei Hospital, Ede, Netherlands, [4]Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands

Background/Purpose: The optimal retreatment strategy for rituximab is not clear[1]. Different strategies are being used in clinical practice, including: on demand retreatment when disease activity increases and fixed interval retreatment. We investigated whether the response duration after the first rituximab course might be used for timing of retreatment by assessing the intra-individual variation in response duration after two subsequent rituximab courses in patients with rheumatoid arthritis (RA).

Methods: In this retrospective study, RA patients treated with at least three rituximab courses, according to the on demand retreatment strategy, were included. Difference in first and second interval between infusions and between duration until loss of response were analysed with student's paired t-test, Spearman correlation coefficient and limits of agreement. Date of loss of response was determined by two research physicians based on chart review.

Results: Seventy patients were included (table 1). The dosage of the first rituximab treatment cycle was 2 × 1000 mg in 69 patients (in 1 patient unknown), and of the second rituximab cycle 2 × 1000 mg in 57 patients, 2 × 500 mg in 6 patients and 1 × 1000 mg in 7 patients. Concomitant DMARD treatment changes were infrequent and comparable between first and second interval. Forty patients were treated with systemic corticosteroids at baseline; changes in systemic steroid treatment were also comparable between first and second interval.

Table 1. Baseline characteristics

	n = 70
Age, years (SD)	58 (10.2)
Woman, n (%)	57 (81)
Disease duration, years median [p25-p75]	13 [6 – 18]
Rheumatoid factor positive, n (%)	61 (87)
Anti-CCP positive, n (%)	53/65 (76)
DAS28 at first RTX (SD)	5.1 (0.99)
Previous DMARDs, n median [p25-p75]	5 [3 – 6]
Previous biologicals n, median [p25-p75]	2 [2 – 3]
Concomitant DMARD, n (%)	32 (46)
Concomitant MTX, n (%)	21 (30)
Concomitant corticosteroid, n (%)	40 (57)
Corticosteroid dose, mg (SD)	10 (4.0)
Concomitant statin, n (%)	7 (10)

anti-CCP= anti-cyclic citrullinated peptide; DAS28 = 28 joints disease activity score; RTX = rituximab; DMARD = disease-modifying antirheumatic drug; MTX = methotrexate

The mean interval in days was 301 (SD 95) and 341 (SD 123) days for the first and second rituximab interval. Mean time until loss of response was 252 (SD 93) and 307 (SD 126) days respectively. Limits of agreement between 1st and 2nd infusion intervals were large, −190 and +272 days (figure 1). Of note, the second interval between infusions was longer than the first (40 days (SD 119) p = 0.003).
Figure 1. Difference against mean for RTX interval 1 and 2

Conclusion: Duration of response after the first rituximab course is not a useful parameter in timing of retreatment, because of the large intra-individual variation in response duration. The second rituximab interval seems to be longer than the first, which could lead to increasing overtreatment when fixed schedule retreatment is used.

1274

Relationship Between Morning Stiffness Duration and Severity, Pain Intensity, and Measures of Disease Activity in a 12 Week Efficacy Study of a Modified (Delayed-Release) Prednisone Plus Disease-Modifying Antirheumatic Drugs in Rheumatoid Arthritis.
Frank Buttgereit[1], John R. Kirwan[2], Kenneth G. Saag[3], Reike Alten[4], Amy Grahn[5], Patricia Rice[6] and Maarten Boers[7]. [1]Charite University Medicine, Berlin, Germany, [2]Bristol Royal Infirmary, Bristol, United Kingdom, [3]Univ of Alabama-Birmingham, Birmingham, AL, [4]Charité Univ Medicine, Berlin, Germany, [5]Horizon Pharma, Deerfield, IL, [6]CliniRx Research, Naperville, IL, [7]VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: RA patients typically present with pain and morning stiffness (MS). MS is predictive of both functional disability and escalated RA care, but the best way to evaluate MS in RA has yet to be determined. Data evaluating MS duration (MSD), MS severity (MSS), and pain intensity (PI) upon awakening with other RA measures representing disease progression and response would help to determine if one is more clearly related to disease activity. Chronotherapy with a modified (delayed)-release (MR) prednisone tablet given at bedtime has shown MS reduction compared to conventional, immediate-release (IR) prednisone with a sustainable effect up to 12 months. Data from the Circadian Administration of Prednisone in Rheumatoid Arthritis-2 (CAPRA-2) study in patients with active RA and on stable DMARD therapy provide the opportunity to evaluate possible relationships between measures of MS and PI with ACR20, DAS28 and HAQ-DI response criteria.

Methods: CAPRA-2 was a 12-week, double-blind, PBO-controlled study that randomized 350 RA patients to 5 mg MR-prednisone (n=231) or PBO (n=119) taken once daily at bedtime (eg, 10pm) in addition to their standard DMARD treatment (Buttgereit, ARD 2012). The primary endpoint was the proportion of patients achieving an ACR20 response after 12 weeks. A key secondary objective was reduction of MS at week 12, as measured in patient diaries. Pearson Correlations were performed to evaluate the relationships between change from baseline in MSD (minutes), MSS (VAS) or PI with DAS28 and HAQ-DI. Furthermore a Wilcoxon rank sum analysis was completed between responders and nonresponders based on ACR20, DAS28 (score < 2.6) and HAQ-DI (% change from baseline < −0.22) and MSD.

Results: MSD, MSS and PI showed correlation with DAS28 and HAQ-DI in all group analyses (p<0.0001). Stronger absolute correlations

were seen with MSS and PI than with MSD, whether the study groups were analyzed separately or together (all treatment, Table 1). Specifically, a moderately strong correlation (≥ 0.5) was seen between DAS28 and MSS and PI in the treatment and PBO groups. MSS and PI were strongly correlated (0.9). The ranges of correlations found are similar to previous studies showing joint impairment is moderately correlated with disability (0.42–0.50) as measured by self-report questionnaires (Yazici, J Rheumatol 2004). Responders had a greater relative reduction in MSD than non-responders, especially the MR-prednisone patients (Table 2).

Table 1. Change from Baseline Correlation between MSD, MSS, and PI with Disease Activity Measures

	All Treatment	MR-Prednisone + DMARD	PBO + DMARD
DAS28			
MSD	0.28	0.21	0.37
MSS	0.48	0.43	0.51
PI	0.47	0.42	0.50
HAQ-DI			
MSD	0.25	0.21	0.27
MSS	0.39	0.35	0.40
PI	0.43	0.41	0.41

Table 2. Analysis of MSD and Responder Status

	MR Prednisone + DMARD			PBO + DMARD		
	Responder	Non-responder	p-value	Responder	Non-responder	p-value
ACR20						
N	109	107		34	73	
Reduction MSD (%)	86.0	34.0	<0.0001	46.3	17.9	<0.001
DAS28						
N	25	101		8	99	
Reduction MSD (%)	100.0	50.8	<0.0001	67.3	31.0	0.1221
HAQ-DI						
N	110	106		32	75	
Reduction MSD (%)	73.9	48.1	<0.01	42.7	19.7	<0.01

Conclusion: MSD, MSS and PI are correlated with DAS28 and HAQ-DI in placebo and MR-prednisone treated patients on DMARDs, with stronger correlations seen with MSS and PI. Patients meeting ACR20, DAS28 and HAQ-DI response criteria had a significantly greater reduction in MS than non-responders. Morning pain and stiffness severity in addition to duration of morning stiffness are key patient reported outcomes for both treatment response and disease progression in RA patients.

1275

Fast Remission Response to Etanercept At Week 4 Predicts Better Long-Term Outcomes in Early and Established Rheumatoid Arthritis Compared to Slower Response At Week 12. Bernd Raffeiner, Costantino Botsios, Francesca Ometto, Mariagrazia Canova, Livio Bernardi, Cristiana Vezzari, Silvano Todesco, Paolo Sfriso and Leonardo Punzi. Rheumatology Unit - University of Padova, Padova, Italy

Background/Purpose: Achievement of clinical remission not only early in disease course but also early in treatment course may be critical for functional outcome of patients with rheumatoid arthritis (RA). Patients showing clinical response to certolizumab at week 6 demonstrated greater ACR responses, higher rates of remission, and improved patient-reported outcomes after 1 year compared to patients who had a response at week 12. Response to treatment as early as week 6 predicted continuation of treatment with TNFα blockers in long-term follow-up. Objective of study was to establish rate of patients on etanercept (ETA) achieving clinical remission at week 4 (fast) or week 12 of treatment (slow remission responders). To

determine effects of fast versus slow remission response on clinical and radiographic remission. To identify predictors for fast remission response.

Methods: Retrospective case control study was performed on RA patients who started ETA from 2004 to 2010 due to moderate-severe disease activity despite DMARDs. Patients having available control at first and third month were enrolled. Patients achieving DAS28 remission by first month were defined as fast remission responders. Patients reaching DAS28 remission at three month as slow remission responders. Patients not reaching remission within 3 months or not maintaining remission for at least one year were excluded because considered unresponsive. Fast remission responders were compared with slow responders regarding maintenance of clinical remission on ETA in longterm follow-up. Arrest of radiolgraphic progression was determined by Total Sharp Score modified van der Heijde (TSS) on X-rays performed at baseline and after 1 year. Clinical and therapeutic baseline characteristics were compared between fast and slow remission responders. Statistical analysis was performed by Student T-test and Pearson test as appropriate. Multivariate logistic regression was applied to find predictors for fast remission response.

Results: 74 of total 186 RA patients identified reached DAS28 remission within the first treatment month with ETA and were classified as fast remission responders (39.7%). Only 8 of 74 fast remission responders (10.8%) lost disease control by ETA in follow-up (mean 3.5 years) compared with 25% of slow remission responders (28 out of 112, p < 0.05). Considering patients with early RA (disease duration ' 1 year) difference was even more significant (14.3 vs 64.7%, p <0.05). Radiographic progression (ΔTSS>1) occurred in 5.8% of fast but 16.3% of slow remission responders (p < 0.05). No difference was found for analyzed patients' baseline characteristics or past and concomitant therapy. None of the baseline characteristics was predictive for fast remission response.

Conclusion: Fast remission response to ETA at week 4 was achieved in 39.7% of RA patients with early and established disease, and determined better outcome by greater maintenance of clinical and radiographic remission compared to slow remission responders at week 12. Fast remission response resulted to be an independent factor for outcome as it could not be predicted by other parameters but only clinically assessed by tight control.

1276

Changes in B Cell Populations and Serum Immunoglobulins and Their Relationship to Infections in a One Year, Uncontrolled Open Label Study of Tabalumab. Maria W. Greenwald[1], Melissa Veenhuizen[2], Wendy Komocsar[2], Rebecca Jones-Taha[3], Chin H. Lee[2] and Pierre-Yves Berclaz[2]. [1]Desert Medical Advances, Palm Desert, CA, [2]Eli Lilly & Company, Indianapolis, IN, [3]PharmaNet/i3, Blue Bell, PA

Background/Purpose: B cell activating factor (BAFF) is an important modulator of B cell development and proliferation and is secreted by neutrophils, monocytes, macrophages and dendritic cells. Tabalumab, a monoclonal antibody that neutralizes both membrane-bound and soluble BAFF, has previously been shown to reduce the signs and symptoms of rheumatoid arthritis (RA)[1,2]. In this open label, uncontrolled, extension study, we examined the effect of tabalumab on B cell populations, serum immunoglobulins (Ig) and the relationship between these parameters and infections.

Methods: One hundred eighty-six patients (pts) who completed one of two 24 week phase 2 trials of tabalumab versus placebo were elligible for this study, and 182 (98%) of those pts enrolled. Pts were methotrexate or TNF antagonist inadequate responders. All pts received open label 60 mg subcutaneous tabalumab every 4 weeks for 48 weeks. The dose could be increased to 120 mg and, if necessary, decreased to 60 mg one time at the investigators' discretion. B cell populations and serum Igs were compared to their pre-treatment baseline from the initial phase 2 studies. Total B cell counts were monitored during a post study follow-up period.

Results: Sixty pts (33%) received 60 mg throughout the study, and 121 pts (66%) escalated to 120 mg at different times (60/120 mg group). One pt escalated to 120 mg then returned to 60 mg. In all groups, total B cell and mature naïve B cell counts gradually declined over time but were not depleted at week 52 (table). Memory B cells increased $\sim$ 100% over baseline at week 12 and returned to $\sim$ 60–70% over baseline at week 52. Sixty-six pts had total B cell counts < 43 cells/μl and < 50% of baseline at week 52 or after and the Kaplan-Meier estimate of median time to recovery after the last injection was 40.6 weeks (CI: 39.6–51.3). All of these pts who completed follow up (n=47) recovered by 66 weeks. Among pts whose B cells decreased below

50% of baseline at any time during the treatment period, 37% had infections compared to 53% among pts whose B cells did not. Serum Igs (IgA, IgM, IgG) decreased for all groups at week 52 (table). Eleven pts had treatment-emergent serum Ig levels below the lower limit of normal (LLN) during the treatment period with no concurrent infections.

Change from Baseline in B Cell Populations and Serum Immunoglobulins at Week 52†

	60 mg (N=60)	60/120 mg (N=121)	All pts* (N=182)
Total B cells (CD20+)	(n=59) -41.1 %	(n=118) -34.7 %	(n=178) -37.1 %
Mature naïve B cells (CD19+ IgD+ CD27-)	(n=59) -65.8 %	(n=118) -72.0 %	(n=178) -70.1 %
Memory B cells (CD19+ IgD- CD27+)	(n=59) 58.4 %	(n=118) 78.6 %	(n=178) 71.8 %
Serum IgA	(n=57) −14.7 %	(n=121) -13.5 %	(n=179) -13.8 %
Serum IgG	(n=57) −10.9 %	(n=121) -11.2 %	(n=179) -11.1 %
Serum IgM	(n=57) −18.7 %	(n=121) -19.4 %	(n=179) -19.1 %

† Last observation carried forward method was used to impute missing values at week 52. Small 'n' indicates the number of patients with both baseline and post baseline assessments
* 1 pt that had dose escalated to 120 mg and decreased back to 60 mg is included in 'all pts' category

Conclusion: Tabalumab treatment reduced total B cells, mature naïve B cells and serum Igs, while memory B cells were increased. Total B cells were only partially depleted and recovered in all pts during the post treatment follow-up period. There was no indication that reductions in B cells or in serum Igs below the LLN were associated with an increased frequency of infections. Additional studies will help further understand the effect of tabalumab treatment on B cells, serum Igs and adverse events.

Tofacitinib, an Oral Janus Kinase Inhibitor, in Combination with Methotrexate Reduced the Progression of Structural Damage in Patients with Rheumatoid Arthritis: Year 2 Efficacy and Safety Results From a 24-Month Phase 3 Study. D. van der Heijde[1], Y. Tanaka[2], R. M. Fleischmann[3], E. Keystone[4], J. M. Kremer[5], C. Zerbini[6], M. H. Cardiel[7], S. B. Cohen[8], P. T. Nash[9], Y. Song[10], D. Tegzova[11], B. Wyman[12], D. Gruben[12], B. Benda[13], G. Wallenstein[12], S. Krishnaswami[12], S. H. Zwillich[12], J. Bradley[12], C. A. Connell[12] and ORAL Scan Investigators[14]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Mount Sinai Hospital, Toronto, ON, [5]Albany Medical College, Albany, NY, [6]CEPIC–Centro Paulista de Investigação Clínica, São Paulo-SP, Sao Paulo, Brazil, [7]Centro de Investigacion Clinica de Morelia, Morelia, Mexico, [8]Metroplex Clinical Research Centre, Dallas, TX, [9]Nambour Hospital, Sunshine Coast, Australia, [10]Seoul National University Hospital, Seoul, South Korea, [11]Institute of Rheumatology, Prague, Czech Republic, [12]Pfizer Inc., Groton, CT, [13]Pfizer Inc., Collegeville, PA, [14]Groton

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. This 24-month (Mo) Phase 3 study compared efficacy, including inhibition of structural damage, and safety of tofacitinib vs placebo (PBO) in patients (pts) with active RA with inadequate response to methotrexate (MTX). Here we report 24-mo data to assess consistency of efficacy and safety.

Methods: Pts on stable-dose MTX were randomized 4:4:1:1 to one of four sequences (NCT00847613): tofacitinib 5 mg twice daily (BID); 10 mg BID; PBO advanced to 5 mg BID; PBO advanced to 10 mg BID. Pts on PBO advanced at Mo 6 or at Mo 3 if non-responsive (<20% reduction from baseline (BL) in swollen and tender joint counts). In the primary analysis, PBO structure data were imputed through linear extrapolation from the time of advancement (Mo 3 or Mo 6). As there is less relevance of imputing data long-term, mean change from BL for the modified Total Sharp Scores (mTSS) as well as ACR response and DAS28-4(ESR) <2.6 rates are shown with and without imputation.

Results: 797 pts were randomized and treated; 535 (67.1%) completed the 24-mo study. Pt treatment sequences were similar for BL characteristics including mTSS and its components. Primary efficacy endpoints and Mo 12 data have been reported previously;[1] here we report Mo 24 data. Only descriptive statistics are presented for these selected secondary endpoints (Table 1). Efficacy was maintained through Mo 24 as measured by ACR response, DAS28-4(ESR) <2.6, HAQ-DI and mTSS suggesting that pts maintain their response to tofacitinib for at least 2 years. Adverse events (AEs), serious AEs and serious infection events are shown in Table 2. Most AEs were mild or moderate and resolved while continuing tofacitinib treatment. During the 24-mo study, 36 pts (11.2%) on 5 mg BID, 37 pts (11.7%) on 10 mg BID, 8 pts (9.9%) on PBO to 5 mg BID, and 10 pts (12.7%) on PBO to 10 mg withdrew due to AEs related to study drug. There was one opportunistic infection (8 in total over 24 mo) and four deaths (all 5 mg BID; one considered not related: acute myocardial infarction; three considered related by the investigator: cardio-respiratory arrest; cardiac failure; congestive cardiac and renal failure) occurring after Mo 12. The incidence of laboratory abnormalities was similar in all treatment sequences.

Table 1. Selected secondary efficacy endpoints at Mo 12 and Mo 24

	Mo 12		Mo 24	
	NRI	Observed	NRI	Observed

Placebo → 10 mg BID	−0.48 (63)		−0.59 (52)	
mTSS *mean change from BL*	LEP Δ (N)	Observed Δ (N)	LEP Δ (N)	Observed Δ (N)
Tofacitinib 5 mg BID	0.45 (287)	0.31 (252)	0.87 (287)	0.48 (210)
Tofacitinib 10 mg BID	0.10 (298)	0.20 (261)	0.36 (298)	0.23 (216)
Placebo → 5 mg BID	0.59 (71)	0.51 (62)	1.18 (71)	0.63 (52)
Placebo → 10 mg BID	0.65 (68)	0.16 (61)	1.31 (68)	0.37 (49)

All data are from the full analysis set; [a]mixed-effect, longitudinal model; BID, twice daily; BL, baseline; LEP, imputation using linear extrapolation; N, number of patients in each group; NRI, non-responder imputation (with advancement penalty); Observed, no imputation

Table 2. Treatment-related adverse events over the final 18-month study period, Mo 6–24

Adverse events, n (%)

Tofacitinib 5 mg BID (N = 321)	160 (49.8)
Tofacitinib 10 mg BID (N = 316)	165 (52.2)
Placebo → 5 mg BID (N = 81)	30 (37.0)
Placebo → 10 mg BID (N = 79)	36 (45.6)

Serious adverse events, n (%)

Tofacitinib 5 mg BID (N = 321)	18 (5.6)
Tofacitinib 10 mg BID (N = 316)	18 (5.7)
Placebo → 5 mg BID (N = 81)	3 (3.7)
Placebo → 10 mg BID (N = 79)	6 (7.6)

Serious infection events, n (%)

Tofacitinib 5 mg BID (N = 321)	9 (2.8)
Tofacitinib 10 mg BID (N = 316)	13 (4.1)
Placebo → 5 mg BID (N = 81)	1 (1.2)
Placebo → 10 mg BID (N = 79)	3 (3.8)

BID, twice daily

Conclusion: RA pts treated with tofacitinib 5 or 10 mg BID on stable background MTX maintained efficacy, including inhibition of structural damage, through 24 mo. No new safety signals emerged.

Tuberculosis and Tofacitinib Therapy in Patients with Rheumatoid Arthritis. Kevin L. Winthrop[1], S.-H. Park[2], A. Gul[3], M. Cardiel[4], JJ Gomez-Reino[5], D. Ponce de Leon[6], R. Riese[7], R. Chew[7], T. Kawabata[7], E. Mortensen[6] and H. Valdez[8]. [1]Oregon Health & Science University, Portland, OR, [2]The Catholic University of Korea, Seoul, South Korea, [3]Istanbul University, Istanbul, Turkey, [4]Centro de Investigación Clínica de Morelia SC, Morelia, Mexico, [5]Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain, [6]Pfizer Inc., Collegeville, PA, [7]Pfizer Inc., Groton, CT, [8]Pfizer Inc., New York, NY

Background/Purpose: Biologic therapies that block tumor necrosis factor-alpha (TNF) increase the risk of tuberculosis (TB), and screening for latent tuberculosis infection (LTBI) before their initiation can prevent LTBI progression to active TB disease. Tofacitinib, a novel oral Janus kinase inhibitor investigated as a targeted immunomodulator and disease-modifying therapy for RA, partially and reversibly inhibits cytokine signaling thought to be important in TB immunity. It was shown recently that incidence rates for TB in patients (pts) treated with tofacitinib are consistent with those of TNF inhibitors in RA.[1]

Methods: Phase 2, 3, and long-term extension (LTE) clinical trial data from the tofacitinib RA program were reviewed. Before study entry, potential participants were screened for TB per protocol with Quantiferon-TB Gold® or, if unavailable, a Mantoux PPD skin test (5 mm cutoff), and chest radiography performed within 3 months of screening. In Phase 3 trials, patients diagnosed with LTBI were allowed trial entry after completing 1 month of a planned 9-month isoniazid preventive therapy regimen. Active TB cases, reported by study investigators as of September 29, 2011, were identified and TB incidence rates (IRs; per 100 pt-years [95% CI]) calculated for patients exposed to tofacitinib, stratified by their region of enrollment. Regions were categorized according to background TB IR (per 100 person-years): low (≤0.01), medium (>0.01 to ≤0.05), and high (>0.05).[2]

Results: Twelve pts with active TB were identified in 4791 (0.25%) total subjects enrolled. Median time between drug start and TB diagnosis for all TB cases was 38 weeks (range 22–137 weeks). Ten cases (83%) occurred in countries with high background TB IR; 11 cases (92%) occurred in pts with negative screening results at study entry (Mantoux PPD skin test or Quantiferon-TB Gold®), and 4 cases (33%) were extrapulmonary or disseminated. Demographic characteristics and use of concomitant medications, including methotrexate and corticosteroids, were similar to those of the entire program population. Overall, the TB IR (95% CI) for tofacitinib-treated pts was 0.173 (0.098, 0.305), which varied according to regional background TB IR: low 0.037 (0.005, 0.261); medium 0.034 (0.005, 0.242); high 0.781 (0.420, 1.452). In Phase 3 studies, 209 tofacitinib-treated pts received concomitant isoniazid therapy for treatment of LTBI. None of these pts developed active TB and there was no apparent difference in the safety profile (eg elevated transaminases) in these pts.

Conclusion: Within the large global tofacitinib development program for RA, TB was rare in regions of low and medium TB incidence and occurred most frequently in pts receiving higher doses of tofacitinib in endemic regions. As with biologic therapy, pts should be screened for TB before tofacitinib treatment using either Quantiferon-TB Gold® or tuberculin skin test. Initial data indicate that pts diagnosed with LTBI can be successfully and safely treated with isoniazid while receiving tofacitinib.

First in Human Study with Recombinant Anti-IL-21 Monoclonal Antibody in Healthy Subjects and Patients with Rheumatoid Arthritis. Stanislav Ignatenko[1], Birte K. Skrumsager[2], Adam Steensberg[2] and Ulrik Mouritzen[2]. [1]Charité Research Organization GmBH, Berlin, Germany, [2]Novo Nordisk A/S, Copenhagen, Denmark

Background/Purpose: Interleukin-21 (IL-21), a cytokine produced by activated T cells (especially T$_{17}$ and T$_{FH}$ cells), has a proinflammatory and pleiotropic nature, and drives mainly activation and differentiation of adaptive immune cells. Both IL-21 and the IL-21 receptor (IL-21R) have been shown to be upregulated in patients with rheumatoid arthritis (RA). NNC0114-0005 is a human recombinant monoclonal immunoglobulin G1 (IgG1) antibody that binds to and neutralizes IL-21. It is currently in development for the treatment of RA. The primary objective of this trial was to assess safety and tolerability of single intravenous (i.v.) and subcutaneous (s.c.) doses of NNC0114-0005 in healthy subjects (HS) and patients with RA.

Methods: A phase 1, randomized, single-center, placebo-controlled, double-blind, single-dose, dose-escalation trial was conducted in male HS (n=44) aged 18–60 and patients with RA (n=20) aged 18–75 on stable methotrexate treatment (7–25 mg/wk for ≥4 wks) with a DAS28-CRP score >3.2. HS were randomized (3:1 active to placebo) to 8 increasing i.v. dose levels (range: 0.0025–25 mg/kg) and 3 s.c. dose levels (0.1, 1 and 4 mg/kg). Patients with RA were randomized (3:1) to 3 i.v. dose levels (0.25, 4 and 25 mg/kg). Key safety parameters included adverse events (AEs), injection-site reactions and detection of neutralizing antibodies against NNC0114-0005. Pharmacokinetic (PK), pharmacodynamic and efficacy parameters were also assessed.

Results: In total, 55 AEs were reported in 31/64 (48%) subjects: 32 AEs in 16/32 HS on i.v. treatment; 16 AEs in 10/20 RA patients on i.v. treatment; and 7 AEs in 5/12 HS on s.c. treatment. The most commonly reported AEs were headache (22%) and nasopharyngitis (16%). No dose dependency was detected for AEs. One serious AE (eczema) was reported 91 days post-dosing for a patient with RA exposed to 4 mg/kg NNC0114-0005; it was evaluated as unlikely related to the trial product by the investigator. No injection-site reactions or clinically significant antibodies against NNC0114-0005 were detected. No clinically relevant changes in laboratory parameters, vital signs or ECG were observed. Pharmacokinetic dose proportionality of the area under the curve (AUC) was shown after i.v. and s.c. dosing in HS and patients with RA. The mean terminal elimination half-life of NNC0114-0005 was ~3 weeks. Overall, no clinically relevant changes in lymphocyte subsets, B-cell subsets or total IL-21R expression on lymphocyte subsets were observed after NNC0114-0005 treatment. The reduction in DAS28-CRP was numerically favorable (but not statistically significant) for patients with RA treated with 25 mg/kg NNC0114-0005 compared to placebo.

Conclusion: NNC0114-0005 was safe and well tolerated in HS and patients with RA and did not raise any safety concerns during the trial. Linear PK of NNC0114-0005 was demonstrated in HS and patients with RA and the PK properties were similar for both populations. The improvements in DAS28-CRP for patients with RA at the highest dose level may suggest biologic and clinical activity of NNC0114-0005.

1280

Sustained Efficacy Responses and a Consistent Safety Profile with Rituximab Repeat Treatment Over 5 Years in Patients with Rheumatoid Arthritis and an Inadequate Response to Tumour Necrosis Factor Inhibitors. Edward Keystone[1], Stanley B. Cohen[2], Paul Emery[3], Joel M. Kremer[4], Maxime R. Dougados[5], James E. Loveless[6], Carol Chung[7], Pamela Wong[7], Patrica B. Lehane[8] and Helen Tyrrell[8]. [1]Mount Sinai Hospital, Toronto, ON, [2]Metroplex Clinical Research Center, Dallas, TX, [3]University of Leeds, Leeds, United Kingdom, [4]Albany Medical College, Albany, NY, [5]René Descartes University, Paris, France, [6]St Luke's Rheumatology, Boise, ID, [7]Genentech, Inc., South San Francisco, CA, [8]Roche Products Limited, Welwyn Garden City, United Kingdom

Background/Purpose: In the REFLEX study conducted in anti-TNF inadequate responder (TNF-IR) patients with RA, a single course of rituximab (RTX) in combination with methotrexate (MTX) significantly improved disease activity at 24 weeks vs placebo (PBO) + MTX. Patients were eligible for continued RTX treatment in an open-label extension (OLE). Efficacy and safety outcomes from REFLEX and its OLE over 5 years are presented.

Methods: This was an observational, post-hoc analysis of REFLEX from baseline to 5 years, open label from the second study treatment. Patients originally randomized to PBO were rescued with RTX as appropriate and included in the OLE. Patients with a response to initial RTX treatment were eligible for further RTX treatment courses. RTX retreatment was administered as needed based on SJC and TJC ≥ 8 and at the discretion of the physician (≥ 24 weeks following first RTX course and ≥ 16 weeks following additional courses). PBO patients were re-baselined prior to their first RTX treatment and for this analysis PBO data were pooled with RTX patient data from time of first RTX treatment. Efficacy outcomes 24 weeks after each RTX course were calculated relative to first RTX pre-treatment baseline. No imputations were made for missing data. Safety data included rates of AEs, serious AEs (SAEs), infections, and serious infections (SIEs).

Results: Overall, 480 patients received at least one course of RTX. Subsequent RTX courses were given to 317 (≥ 2 courses), 259 (≥ 3 courses), 195 (≥ 4 courses), and 122 (≥ 5 courses) patients. Most withdrawals occurred after course 1, mainly for non-safety reasons. ACR responses were improved after the first course of RTX and were maintained over 5 courses (Table) with a similar trend observed for EULAR responses.

ACR response rates (% patients) at 24 weeks after each course

Clinical measure	Course 1 (n=400)	Course 2 (n=279)	Course 3 (n=225)	Course 4 (n=161)	Course 5 (n=91)
ACR20	62.0	72.8	72.4	65.8	70.3
ACR50	30.8	41.2	47.6	44.7	41.8
ACR70	13.0	19.4	26.2	24.2	22.0

The proportion of patients achieving a minimal clinically important difference in HAQ-DI was maintained over 5 courses (66.0–71.1%). Over the 5 years, rates of AEs, SAEs, and infections did not increase and generally remained stable in the RTX-treated population (1768 pt-yrs), with overall rates per 100 pt-yrs (95% CI) of 344.87 (336.32–353.64) for AEs, 22.34 (20.24–24.65) for SAEs, 97.50 (93.01–102.21) for all infections, and 5.60 (4.60–6.82) for SIEs. The most frequent SIE was pneumonia, affecting 2% of RTX patients.

Conclusion: This post-hoc analysis shows that RTX repeat treatment is associated with 24-week clinical efficacy responses, sustained to 5 courses, with a trend towards improved efficacy over time. The safety profile of RTX was comparable with published RTX long-term safety data and with that of other biologics in RA populations. No increased incidence of significant AEs was observed in spite of RTX exposure and peripheral B-cell depletion over many years. The results confirm RTX as an effective long-term treatment option in this refractory RA population.

IL-6 Signaling Inhibition Improves Abnormal Bone Homeostasis in Active Rheumatoid Arthritis. Masayasu Kitano[1], Sachie Kitano[1], Chieri Sato[1], Kazuyuki Fujita[1], Takahiro Yoshikawa[1], Yuki Katashima[1], Masahiro Sekiguchi[1], Naoto Azuma[1], Naoaki Hashimoto[1], Shinichiro Tsunoda[1], Kiyoshi Matsui[1] and Hajime Sano[1]. [1]Hyogo College of Medicine, Nishinomiya-city, Japan

Background/Purpose: Tocilizumab (TCZ) is a humanized monoclonal anti-IL-6 receptor antibody. TCZ has demonstrated efficacy in moderate to severe active rheumatoid arthritis (RA) with inadequate clinical response to disease-modifying anti-rheumatic drugs (DMARDs) or TNF inhibitors. Moreover, it is reported that TCZ combined with MTX reduces systemic bone resorption in RA. However, the detailed mechanism about improvement effect by TCZ on abnormal bone homeostasis in RA is poorly understood. In this study, we investigated the effect of TCZ on biomarkers of bone metabolism, soluble receptor activator of NF-kappa B ligand (sRANKL), osteoprotegerin (OPG), Dickkopf-1 (DKK-1), and osteopontin (OPN) in active RA.

Methods: Thirty four patients with active RA (25 females, 9 males; age 51.9 ± 7.9 years; disease duration 12.4 ± 12.6 years; DAS28-ESR 5.6 ± 1.6) were started on treatment with TCZ 8mg/kg intravenously every 4 weeks. All patients were treated with methotrexate, other DMARDs and prednisolone, and the treatments continued at the stable pretreatment doses. After 12 weeks of treatment with TCZ, we evaluated an effectiveness using DAS28-ESR. We appreciated DAS28-ESR<2.6 as a remission group and DAS28-ESR$\geq$a2.6 as a no-remission group, respectively. Additionally, we measured serum biochemical markers such as osteocalcin, type I collagen cross-linked N-telopeptides (NTx), sRANKL, OPG, and DKK-1 and plasma OPN by ELISA at baseline and 12 weeks.

Results: At 12 weeks after the treatment of TCZ, a disease activity reduced significantly from the baseline (DAS28-ESR 5.6 ± 1.6 vs 3.1 ± 1.7; p<0.01). Fifteen patients achieved the remission. In the analysis of bone metabolic markers at 12 weeks, average of serum NTx levels decreased significantly from the baseline (18.91nmol BCE/l vs 17.16nmol BCE/l; p<0.05) and osteocalcin levels increased significantly from the baseline (5.78ng/ml vs 6.68ng/ml; p<0.05). In addition, average of serum sRANKL, DKK-1, and plasma OPN levels decreased significantly from the baseline (sRANKL: 0.570pmol/l vs 0.480pmol/l; p<0.05, DKK-1: 2806pg/ml vs 2282pg/ml; p<0.01, and OPN: 117.0ng/ml vs 77.1ng/ml; p<0.01 respectively), however average of OPG levels did not change significantly from the baseline. TCZ decreased NTx, sRANKL, DKK-1, and OPN levels and increased osteocalcin levels regardless of remission group or no-remission group. Moreover, average of OPG levels in remission group increased significantly from the base line. Therefore, OPG/RANKL ratio tended to increase in remission group compared with no-remission group.

Conclusion: These findings suggest that TCZ therapy improves abnormal bone homeostasis in patient with active RA. We consider that this mechanism may result from the regulation of osteoclastic-bone destruction via the control of RANKL induced-osteoclastogenesis and OPN induced-osteoclast attachment of bone surface and the promotion of osteoblastic-bone formation via the regulation of DKK-1.

Tofacitinib, an Oral Janus Kinase Inhibitor, in the Treatment of Rheumatoid Arthritis: Open-Label, Long-Term Extension Safety and Efficacy up to 48 Months. Jurgen Wollenhaupt[1], Joel C. Silverfield[2], Eun Bong Lee[3], Susan P. Wood[4], Koshika Soma[4], Lisy Wang[4], Hiroyuki Nakamura[5], Yoshihiro Komuro[5], Chudi I. Nduaka[4], David Gruben[4], Birgitta Benda[6], Samuel H. Zwillich[4], Richard Riese[4] and John D. Bradley[4]. [1]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, [2]Tampa Medical Group, Tampa, FL, [3]Seoul National University, Seoul, South Korea, [4]Pfizer Inc., Groton, CT, [5]Pfizer Japan Inc., Tokyo, Japan, [6]Pfizer Inc., Collegeville, PA

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy in RA. Here we report the safety and tolerability of tofacitinib and the durability of response up to 48 months (mo) in long-term extension (LTE) studies.

Methods: Data were pooled from two open-label studies (NCT00413699, NCT00661661) involving patients (pts) who had participated in randomized Phase (P)2 or P3 studies of tofacitinib. Treatment was initiated with tofacitinib 5 or 10 mg twice-daily (BID); data from doses are pooled. Baseline was that of the P2 or P3 study for pts enrolling within 14 days of participation; if enrollment was >14 days after participation, baseline was the start of the LTE study. Primary endpoints were adverse events (AE) and confirmed laboratory safety data. Secondary endpoints included ACR responses, DAS28-4(ESR), and HAQ-DI. Safety data were included over 60 mo of observation but efficacy data were only available up to Mo 48 (limited pt numbers [n=58] post-Mo 48).

Results: 4102 pts were treated for a total duration of 6034 patient-years (pt-y); mean (maximum) treatment duration was 531 (1844) days. 852 pts (20.8%) discontinued (AEs: 440 [10.7%]; lack of efficacy: 83 [2.0%]; other: 329 [8.1%]). The most commonly reported classes of AEs were infections and infestations (50.8%), gastrointestinal disorders (23.6%), musculoskeletal/connective tissue disorders (23.4%), and investigations (16.1%). The most frequent investigator-reported AEs (%) were nasopharyngitis (12.7%), upper respiratory tract infection (10.5%), and urinary tract infection (6.6%). Serious AEs (SAEs) were reported in 15.4% of pts with an incidence rate (IR) of 11.11 per 100 pt-y (95% CI 10.28, 12.02). Serious infection events (SIEs) were reported in 4.5% of pts with an IR of 3.07 per 100 pt-y (95% CI 2.66, 3.55). IRs for SAEs and SIEs did not increase between 36- and 48-mo observations.

Decreased hemoglobin (Hgb; ≥ 2 g/dL from baseline, or Hgb <8 g/dL) was observed in 3.5% of pts. Raised aminotransferases (>3 × upper limit of normal) were observed in 3.2% (ALT) and 1.5% (AST) of pts. Moderate-to-severe neutropenia (absolute neutrophil count [ANC] $0.5-1.5 \times 10^3/mm^3$) was reported in 0.7% of pts; there were no cases of confirmed ANC <0.5 × $10^3/mm^3$. Increases (>50% from baseline) in creatinine were noted in 3.2% of pts. Mean values for laboratory safety measures were consistent with observations in P2 and P3 studies, and were stable over time.

Efficacy was maintained through Mo 48. ACR20, ACR50, and ACR70 responses in pts treated with tofacitinib 5 and 10 mg BID (results pooled) at Mo 1 and Mo 48 were 67% and 69%, 44% and 47%, and 25% and 31%, respectively. Mean DAS28-4(ESR) was 6.2 at baseline, and was reduced to 3.8 at Mo 1, and 3.6 at Mo 48. Mean HAQ-DI score was 1.4 at baseline and improved to 0.85 at Mo 1, and 0.81 at Mo 48.

Safety and efficacy were similar for pts receiving tofacitinib as monotherapy or with background DMARDs.

Conclusion: Tofacitinib dosed at 5 or 10 mg BID in pts with RA demonstrated a consistent safety profile and sustained efficacy over 48 mo in open-label LTE studies.

Effects of Tofacitinib On Patient-Reported Outcomes in Patients with Active Rheumatoid Arthritis Receiving Stable-Dose Methotrexate: Results of Two Phase 3 Studies.

Gerd R. Burmester[1], Désirée van der Heijde[2], Vibeke Strand[3], Cristiano A. F. Zerbini[4], Carol A. Connell[5], Charles A. Mebus[5], Samuel H. Zwillich[5], John D. Bradley[5], David Gruben[5] and Gene Wallenstein[5]. [1]Charité–University Medicine Berlin, Berlin, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Stanford University, Palo Alto, CA, [4]Centro Paulista de Investigação Clinica, Sao Paulo, Brazil, [5]Pfizer Inc., Groton, CT

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. The efficacy and safety of tofacitinib were evaluated in patients (pts) with active RA in Phase 3 trials. Primary efficacy analyses have previously been described.[1,2] Here we show patient-reported outcomes (PROs) from two Phase 3 studies.

Methods: Pts on stable-dose methotrexate (MTX) from the ORAL Step (NCT00960440; tumor necrosis factor inhibitor-inadequate responder [TNFi-IR] pts) and ORAL Scan (NCT00847613; MTX-IR pts) studies were randomized to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or placebo (PBO) advanced to either tofacitinib 5 mg BID or 10 mg BID. All PBO pts in ORAL Step advanced at Month 3. In the ORAL Scan study, non-responder PBO pts (<20% reduction from baseline in swollen/tender joint counts) were advanced to tofacitinib 5 or 10 mg BID at Month 3, and all remaining PBO pts were advanced to tofacitinib at Month 6. Non-responding tofacitinib patients remained on the same treatment and dose. Excepting the Health Assessment Questionnaire-Disability Index, the PROs were secondary endpoints and included patient global assessment of disease activity (visual analog scale [VAS]), pain (VAS), health-related quality of life (Medical Outcomes Study Short-Form [36-Item] Health Survey), and fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue).

Results: In total, 1196 pts received treatment (399 in ORAL Step and 797 in ORAL Scan). Within each study, baseline demographic and disease characteristics were generally similar across treatment groups; differences were noted between studies: ORAL Step pts were required to have failed at least one TNFi and had longer RA disease duration and higher disease activity at baseline relative to pts in ORAL Scan. Treatment with tofacitinib 5 and 10 mg BID resulted in significant improvements in all PROs when compared with PBO (Table 1). Improvements with both tofacitinib doses were observed at 3 months and continued through study end. Based on pts reporting improvements $\geq$ minimally clinically important differences, numbers needed to treat at Mo 3 for tofacitinib 5 and 10 mg BID, were 3.7–7.8 and 3.1–10.6, respectively, across various PROs in both studies.

Table 1. PROs at Month 3 (least squares means of change from baseline)

Evaluation of Influenza and Pneumococcal Vaccine Responses in Patients with Rheumatoid Arthritis Receiving Tofacitinib. K. L. Winthrop[1], A. Racewicz[2], E. B. Lee[3], B. Wilkinson[4], S. H. Zwillich[4], K. Soma[4], S. Rottinghaus[4], T. Kawabata[4], R. Riese[4], S. Wood[4], J. Bradley[4] and C. O. Bingham III[5]. [1]Oregon Health and Science University, Portland, OR, [2]Department of Internal Medicine and Osteoarthrology, Bialystok Regional Hospital, Bialystok, Poland, [3]Seoul National University, Seoul, South Korea, [4]Pfizer Inc., Groton, CT, [5]Johns Hopkins University, Baltimore, MD

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. Clinical guidelines recommend the use of influenza and pneumococcal vaccines in patients with RA; however, the effect of tofacitinib on vaccine immunogenicity is unknown.

Methods: Patients with RA taking tofacitinib 10 mg twice daily (BID) were recruited from an open-label, long-term extension trial (NCT00413699). In this vaccine substudy, participants were randomized into 2 groups and stratified by methotrexate (MTX) use: 1) those who continued tofacitinib 10 mg BID during and after randomization ("continuous"); or 2) those who interrupted tofacitinib use for 1 week prior to and 1 week after vaccination ("withdrawn"). Vaccination baseline serum pneumococcal and influenza antibody titers were measured and all patients were vaccinated with the 2011–2012 influenza vaccine and PNEU-MOVAX® 23 (PCV23, Merck & Co., Inc) at 1 week post-randomization; antibody titers were measured at 35 days post-vaccination. The primary endpoint was the proportion of continuous and withdrawn patients who achieved a satisfactory humoral response to (a) pneumococcal vaccine (≥2-fold increase in antibody concentrations against ≥6 of 12 pneumococcal antigens [serotypes 1, 3, 4, 5, 6B, 7F, 9V, 14, 19A, 19F, 23F, 18C]) and (b) influenza vaccine (≥4-fold increase in antibody titers against at least 2 of 3 influenza antigens). Secondary endpoints included comparison of pre- and post-vaccine hemaglutination titers (HI), and influenza and pneumococcal serotype-specific Geometric Mean Fold Rise (GMFR) between groups.

Results: Of 199 patients enrolled, 183 (continuous, N=92; withdrawn, N=91) completed vaccination and antibody titer evaluations and were included in the analysis. The proportion of patients achieving a satisfactory humoral response to pneumococcal and influenza vaccines was similar between patients who continued tofacitinib and those who were temporarily withdrawn (Table). Post-vaccination pneumococcal antigen GMFRs trended higher in patients withdrawn from tofacitinib, while GMFRs were similar between groups for influenza (Table). Protective influenza HI titers (≥1:40 influenza antibody titer in ≥2 of three antigens) were similar for continuous (75%) and withdrawn patients (82%) at 35 days post-vaccination.

H1N1	92	7.94	(5.96, 10.58)	91	6.71	(4.94, 9.12)
H3N2	92	7.80	(5.58, 10.91)	91	8.51	(6.45, 11.21)

*Primary endpoints, 35 days post-vaccination; BID, twice daily; BL, baseline; CI, confidence interval; GMFR, Geometric Mean Fold Rise; MTX, methotrexate; PCV23, PNEUMOVAX®, influenza vaccine for 2011–2012

Conclusion: Among patients with RA, continuous tofacitinib use did not significantly impair overall responsiveness to pneumococcal and influenza vaccines, although the pneumococcal antigen GMFRs trended higher in patients who discontinued tofacitinib. A study limitation is the absence of a MTX-only control group or group lacking tofacitinib exposure. These data suggest that it is not necessary to discontinue tofacitinib in order to attain meaningful responses to pneumococcal and influenza vaccines.

Short-Term Efficacy of Etanercept Plus Methotrexate Vs.Various Disease-Modifying Anti-Rheumatic Combinations with Methotrexate in Established Rheumatoid Arthritis. Roy Fleischmann[1], Andrew S. Koenig[2], Annette Szumski[2], Henk Nab[3], Lisa Marshall[2] and Eustratios Bananis[2]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Pfizer Inc., Collegeville, PA, [3]Pfizer Europe, Rome, Italy

Background/Purpose: The objective of this study was to assess the short-term benefit of etanercept (ETN) + methotrexate (MTX) vs. various disease-modifying anti-rheumatic drugs (DMARDs; hydroxychloroquine [HCQ], leflunomide [LEF], or sulfasalazine [SSZ]) + MTX in subjects with established rheumatoid arthritis (RA).

Methods: Data from subjects with moderate-to-severe RA and an inadequate response to MTX were pooled from the APPEAL[1] (ETN 25 mg twice weekly + MTX or DMARD + MTX) and LatinRA[2, 3] (ETN 50mg once weekly + MTX or DMARD + MTX) studies. At week 16, proportions of subjects for each pair of treatments were compared using Fisher's exact test for the following endpoints: American College of Rheumatology (ACR) 20, 50 and 70 responses, disease activity score in 28 joints (DAS28, both C-reactive protein [CRP; DAS28-CRP] and erythrocyte sedimentation rate [ESR; DAS28-ESR] methods) low disease activity (LDA; DAS28-CRP or DAS28-ESR ≤3.2), remission (DAS28-CRP or DAS28-ESR <2.6), Clinical Disease Activity Index (CDAI) of LDA (CDAI ≤10), CDAI remission (CDAI <2.8), and a Health Assessment Questionnaire (HAQ) score of ≤0.5.

Results: 478 subjects received ETN + MTX and 245 subjects received a DMARD + MTX (HCQ + MTX, n=81; LEF + MTX, n=69; SSZ + MTX, n=95). Baseline demographics were similar between the 2 treatment groups, with a mean age of 48.5 years (standard deviation [SD], 11.7; p=0.983) and disease duration of 7.6 years (SD, 7.5; p=0.437). At week 16, significantly more subjects receiving ETN + MTX achieved ACR 20/50/70, DAS28-CRP LDA and remission, DAS28-ESR LDA and remission, CDAI LDA and remission, and HAQ ≤0.5 compared with subjects on DMARDs + MTX (**Table**). Significantly greater proportions of subjects in the ETN + MTX group vs. the HCQ + MTX, LEF + MTX, and SSZ + MTX groups reached these endpoints with the exception of CDAI remission for all DMARD types and DAS28-CRP LDA, DAS28-ESR remission, CDAI LDA, and HAQ ≤0.5 in the LEF + MTX group. In addition, significantly more subjects on LEF + MTX achieved ACR50, DAS28-CRP LDA, DAS28-CRP remission, and CDAI LDA than subjects on SSZ + MTX.

Table. Proportions (%) of Subjects Achieving Endpoints at Week 16

Endpoint	ETN + MTX (N = 478)	DMARD + MTX			
		Overall (N = 245)	HCQ + MTX (N = 81)	LEF + MTX (N = 69)	SSZ + MTX (N = 95)
ACR 20	82	58[a]	59[a]	62[a]	54[a]
ACR 50	56	29[a]	31[a]	38[b,c]	20[a]
ACR 70	24	8[a]	12[d]	7[a]	6[a]
DAS28-CRP LDA	53	28[a]	28[a]	43[e]	17[a]
DAS28-CRP remission	35	15[a]	16[a]	22[c,d]	9[a]
DAS28-ESR LDA	39	18[a]	20[f]	20[b]	14[a]
DAS28-ESR remission	18	7[a]	7[d]	9	4[a]
CDAI LDA	54	29[a]	30[a]	42[e]	18[a]
CDAI remission	7	3[d]	2	3	3
HAQ ≤0.5	48	34[a]	32[d]	37	34[d]

[a]p < 0.001 vs. ETN + MTX; [b]p < 0.01 vs. ETN + MTX; [c]p < 0.05 vs. SSZ + MTX; [d]p < 0.05 vs. ETN + MTX; [e]p < 0.001 vs. SSZ + MTX; [f]p = 0.001 vs. ETN + MTX; p values calculated using Fisher's exact test.

Conclusion: Combination ETN + MTX was more effective in treating subjects with established moderate-to-severe RA regardless of the DMARD combination (HCQ, LEF, or SSZ) + MTX. LEF + MTX and HCQ + MTX had some greater benefits over SSZ + MTX at 16 weeks.

Antibodies to Etanercept and Adalimumab in Rheumatoid Arthritis Inadequate Responders and Clinical Outcomes After an Active Switch to Infliximab.

Chad Pool[1], Gopi Shankar[2], Allen Schantz[2], George Gunn[2], Rebecca Bolce[3], Marjatta Leirisalo-Repo[4], Jim Wang[5], John A. Goldman[6], Raphael J. DeHoratius[1], Roy M. Fleischmann[7] and Dennis Decktor[1]. [1]Janssen Services, LLC, Horsham, PA, [2]Janssen R&D, LLC, PA, [3]Crescendo Bioscience Inc., South San Francisco, CA, [4]Helsinki University Central Hospital, Helsinki, Finland, [5]Janssen Services, LLC, Horsham, [6]Medical Quarters #293, Atlanta, GA, [7]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX

Background/Purpose: To determine if RA patients (pts) who had an inadequate response to etanercept(ETN) or adalimumab(ADA) and developed antibodies (Abs) to ETN or ADA responded clinically in the RESTART Trial after switching without a washout to infliximab(IFX) and if the presence of Abs to ETN or ADA correlated with differences in the levels of IFX or Abs to infliximab(ATI) compared to pts who had not developed Abs to ETN or ADA.

Methods: RESTART is a Phase 4, multicenter, open-label, assessor-blinded, active switch study of IFX+MTX (methotrexate) in pts with active RA who had an inadequate response (DAS28 score ≥3.6 and ≥6 SJC and TJC) to ETN or ADA+MTX. EULAR response was evaluated at wk 10 post-induction (1° endpoint). Pts adequately responding by EULAR criteria remained on IFX 3 mg/kg; incremental increases in IFX dose in pts not achieving/maintaining EULAR response occurred at wks 14 and/or 22, with a final efficacy assessment at wk 26. Assays were developed to measure Abs against ADA, ETN and IFX. Antibodies to anti-TNFs were measured at wks 0, 14 and 26 for ADA and wks 0, 6, 14 and 26 for ETN and IFX. IFX levels were measured at wks 0, 6, 14 and 26.

Results: Among the evaluated patients, 40.3% (50/124) of previously treated ETN pts and 46.8% (37/79) of the previously treated ADA pts of ADA pts demonstrated measureable Abs before exposure to IFX. No cross-reactivity was observed between anti-ADA Abs and IFX. By Week 26, 71% (88/124) of ETN inadequate responders demonstrated Abs to ETN (median titer = 1280) and 50.6% (40/79) of ADA inadequate responders had demonstrated Abs to ADA (median titer = 320). Of these pts, 195 pts had samples available for ATI testing, of which 24 pts (12.3%) had detectable ATI. Of these 24 pts, 23 had evidence of prior Abs to ETN (12/12) or ADA (11/12). Interestingly, the median wk26 serum conc of IFX was significantly lower in those pts who had developed Abs to ADA vs those who had not (2.1 mg/mL vs 11.9 ug/mL; p<0.0001) and contrasted with pts with or without Abs to ETN (8.8 ug/ml vs 11.7 ug/ml, respectively; p = 0.4768). Also, in pts who received IFX dose escalation to 5 or 7 mg/kg, the anti-ADA⁺ pts who were ATI⁻ had a median wk26 IFX serum conc (1.8ug/ml) lower than that observed for the dose escalated pts who were anti-ADA⁻ (13.9ug/ml). Overall, the combined EULAR responses at wks 10 and 26 were 49.7% and 51.8%, resp. Pts with Abs to ADA showed lower EULAR responses to IFX early on, but following incremental dose increases of IFX, these pts reached responses by wk26 (55.3%) similar to pts who were anti-ADA⁻ (59%).

Conclusion: Although Abs develop in 6% and 5% of adult pts treated with ETN and ADA (ETN PI 2011, ADA PI 2012, resp), in this pt population of refractory RA pts who had an inadequate response to either ADA or ETN, the majority of pts had developed moderate to high titer Abs to either ETN or ADA. In these pts, 12.3% developed ATI through 26wks after switching to IFX. Since no cross-reactivity was observed between anti-ADA Abs and IFX, the data suggest that some pts who developed Abs to ADA cleared IFX more rapidly than those pts who were anti-ADA⁻ and did so independent of ATI. Overall, a majority of IFX-treated pts demonstrated a EULAR response by wk26 regardless of the presence of Abs to ETN, ADA or IFX.

1287

Rheumatoid Arthritis Comparison of Active Therapies in Methotrexate Suboptimal Responders: Validation of the Strategy of Conventional Disease Modifying Anti-Rheumatic Drugs Before Biologicals.

James R. O'Dell[1], Ted R. Mikuls[1], Thomas Taylor[2], Vandana Ahluwalia[3], Mary Brophy[4], Stuart Warren[5], Robert Lew[6], Ciaran Phibbs[7], Aslam H. Anis[8], Amy C. Cannella[1], Gary A. Kunkel[9], Alan R. Erickson[10], Edward Keystone[11] and the CSP551 RACAT Research Group[12]. [1]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [2]VA Medical Center, White River Junction, VT, [3]William Osler Health Center, Mississauga, ON, [4]VA Boston Healthcare System, Boston, MA, [5]VA CSP Clinical Research Pharmacy Coordinating Center, Albuquerque, NM, [6]VA Boston HealthCare System, Boston, MA, [7]Palo Alto VA Health Care System, Menlo Park, CA, [8]Univ of British Columbia, Vancouver, BC, [9]George Wahlen Veterans Affairs Medical Center, Salt Lake City, UT, [10]Omaha VA and University of Nebraska Medical Center, LaVista, NE, [11]University of Toronto, Toronto, ON, [12]Boston

Background/Purpose: Double-blind placebo controlled randomized trials have demonstrated the efficacy of 15 different therapies in RA patients with active disease despite methotrexate (MTX). No blinded trials have compared conventional combination therapy to biologicals. Biologicals are roughly 100-fold more expensive than conventional therapy and have a different toxicity profile. We examine the strategy of starting conventional combination therapy followed by switch to a biological only in the subset of non-responders.

Methods: This multinational double-blind non-inferiority trial randomized 353 patients with active disease despite MTX equally to treatment with triple therapy (MTX, sulfasalazine and hydroxychloroquine) or etanercept plus MTX. Treatment continued for 48 weeks, with blinded treatment switch at 24 weeks allowed for patients in both groups if their DAS28 had failed to improve by a clinically significant amount (ΔDAS28 of <1.2). The primary end point of the trial was DAS28 improvement at week 48 based on the initial randomization group. Radiographs were obtained at 0, 24 and 48 weeks and scored by the modified Sharp method (secondary endpoint). Patients were enrolled from 16 VA centers, 12 other US sites and 8 sites in Canada.

Results: Study population baseline: mean age 57 yrs., 54% males, DAS28 = 5.8, disease duration 5.2 years and mean initial MTX dose of 19.6 mg week. There was no significant difference between groups at baseline. Both groups improved significantly from 0 to 24 weeks (p=0.001). The percentage of patients who switched therapy at 24 weeks was nearly identical (27.9% for triple therapy group vs. 27.0% for etanercept group). In those patients who switched both groups had significant improvement after the switch (p <0.0001) and the response was not different across therapies (p=0.08). At 48 weeks Δ DAS28 was not different between the groups (−2.1 [triple] and- 2.3 [etanercept]). Importantly, in patients in both groups who did respond and continued on their original assignment (73% of the patients in both groups) the response was maintained at 48 weeks. Radiographic progression (week 0 to week 48) was not different between the groups (+ 0.87 for triple vs. + 0.23 for etanercept, [p=0.09]). Secondary patient-reported outcomes including HAQII and pain were also not different between groups. Toxicities were similar across groups.

Conclusion: The strategy of conventional combination therapy before biological therapy provides benefit, both clinically and radiographically, that are similar to initial use of etanercept. For the first time data support the premise that patients who respond poorly to MTX and a biological (etanercept) have significant improvement with conventional DMARD combinations (triple therapy) and vice versa. At the health system level, the cost-saving potential and ultimately the cost-effectiveness of the

strategy of starting with conventional DMARD combinations and then switching to biologicals in those who do not respond is enormous.

1288

A Significant Number of Patients with Chronic Arthritis Received a Reduced Dosage of Biological Drugs: an Observational Study in Clinical Practice. Jose Inciarte-Mundo[1], Maria Victoria Hernández[1], Violeta Rosario[1], Sonia Cabrera[2], Virginia Ruiz-Esquide[1], Maria Eugenia Gomez-Caballero[1], Jose A. Gómez-Puerta[1], Julio Ramirez[1], Juan D. Cañete[1] and Raimon Sanmarti[1]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Hospital Clínic of Barcelona., Barcelona, Spain

Background/Purpose: Biological agents are used to treat chronic arthritis according to the standard dosages from phase III clinical trials. However, in some patients, a good response to treatment may allow the dosage to be reduced, the timing lengthened, and costs reduced. Our objective was to analyze a strategy of dosage reduction of biological agents in patients with chronic arthritis attended by the rheumatology department of a tertiary hospital.

Methods: Cross-sectional study which included all patients attended consecutively between June 2011 and November 2011 by a single clinician, and who had received ≥1 dose of a biological agent in 2011. Data analyzed were: demographic characteristics, diagnosis and disease duration, DMARD therapy, dosage, type and duration of biological agent used; time on reduced dosage and reason for dosage reduction. In rheumatoid arthritis (RA) patients we also analyzed disease activity (DAS28 score) and serum levels of C-reactive protein (CRP). The reduced dosage was defined as a lower dosage than recommended in the summary of product characteristics and was not based on a structured protocol.

Results: We included 170 patients (67% female); mean age: 51.1 ± 14.3 years. Diagnoses were: 56.5% RA, 18.8% ankylosing spondylitis (AS), 11.8% psoriatic arthritis (PsA) and 12.9% miscellaneous (MISC), including 9 juvenile idiopathic arthritis, 3 undifferentiated spondyloarthropathy, 3 uveitis, 2 connective tissue disorder and 1 SAPHO. Mean disease duration was 14.5 ± 8 years, with no differences between diagnoses. Mean duration of current biological therapy was 47.7 ± 35.6 months, with 134 patients receiving TNF blockers and 36 patients receiving non anti-TNF (abatacept, rituximab and tocilizumab). 53% of patients received concomitant therapy with DMARDs, mainly in the RA group, and 28.2% had received ≥1 biological agent. At the time of analysis, 76 patients (44.7%) were receiving low dosages of biologicals (56% of etanercept patients, 55% adalimumab, 45% tocilizumab, 39% infliximab and 11% abatacept). Of the 76 patients, 51.3% had RA, 23.7% AS, 13.2% PsA and 11.8% MISC. Most commonly used low dosages were 50 mg every 15 days for etanercept, 40 mg every 3 weeks for adalimumab, 5mg every 9–10 weeks for infliximab and 6 mg every 4 weeks for tocilizumab. The reason for dosage reduction was disease remission in 68 patients (89.5%) and low activity in 8 (10.5%). Mean time of dosage reduction was 17.2 ± 21.1 months. In RA patients, mean DAS28 score and CRP levels were lower in patients with reduced dosage than in patients with standard dosage (2.57 vs 3.47, p=0.09) and (0.37 vs 1.09, p=0.007), respectively, and the percentage of remission was higher (76.3% vs 30.7%, p=0.000). The medical decision at the time of data collection was to maintain low-dosage biological treatment in 63 patients (82.9%) due to low disease activity and/or remission, assessed by clinical judgment and regular scores.

Conclusion: Near half our chronic arthritis patients receiving biological therapy were able to reduce the dosage to below that of established clinical guidelines, preserving remission or low disease activity in many cases. This dosage reduction was observed both in RA and spondyloarthropathies, and with different biological drugs.

1289

Abatacept Biologic-Free Remission Study in Established Rheumatoid Arthritis Patients. Orion Study. Tsutomu Takeuchi[1], Tsukasa Matsubara[2], Shuji Ohta[3], Masaya Mukai[4], Koichi Amano[5], Shigeto Tohma[6], Yoshiya Tanaka[7], Hisashi Yamanaka[8] and Nobuyuki Miyasaka[9]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Matsubara Mayflower Hospital, Hyogo, Japan, [3]Taga General Hospital, Ibaraki, Japan, [4]Sapporo City General Hospital, Sapporo, Japan, [5]Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan, [6]Sagamihara National Hospital, Sagamihara City, Japan, [7]University of Occupational and Environmental Health, Kitakyushu, Japan, [8]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [9]Tokyo Medical and Dental University, Tokyo, Japan

Background/Purpose: Abatacept (ABA) has comparable efficacy to TNF inhibitors in achieving clinical remission in rheumatoid arthritis (RA) patients. However, although clinical evidence suggests that biologic-free remission is achievable for RA patients treated with TNF inhibitors, no evidence for biologic-free remission is available for ABA. To evaluate the efficacy of ABA in terms of biologic-free remission in RA patients who achieved clinical remission with ABA.

Methods: We conducted a multi-center, non-randomized, 12-month, prospective observational study that recruited RA patients who achieved DAS28-CRP < 2.3 at the end of a Japanese phase II/III study. ABA was continued or discontinued based on the patients' decision. During a 12 month follow-up period, ABA treatment was restarted in patients who experienced disease flare (DAS28-CRP >2.7 at two consecutive visits) or according to doctors' decisions. The primary endpoint was the proportion of patients who maintained biologic-free remission 1 year after ABA discontinuation. DAS28-CRP and change in van der Heijde-modified Sharp Score (ΔTSS) were compared between the discontinuation and continuation groups.

Results: A total of 51 RA patients were enrolled in the study, of which 34 discontinued and 17 continued ABA treatment. The mean age was 57.1 ± 11.3 and 61.4 ± 9.4 years, mean disease duration at entry was 6.6 ± 5.3 and 12.0 ± 10.5 years, and mean duration of ABA treatment was 3.3 ± 0.3 and 3.3 ± 0.3 years for the discontinuation and continuation groups, respectively. Twelve patients (35.3%) in the discontinuation group maintained biologic-free remission for 12 months. Among the other 21 patients in the discontinuation group, 14 patients experienced disease flare, with 9 of them restarted ABA treatment. Seven patients dropped out from the study and one was excluded due to data deficiency, even though the patient discontinued ABA during the entire follow-up period (included in the analysis). The overall remission rate at month 12 for the discontinuation and continuation groups did not significantly differ (p=0.058, 23.5% and 52.9%, respectively). The least square mean (LS) means for DAS28-CRP at month 12 were 3.1 and 2.1 in the discontinuation and continuation groups, respectively, and the longitudinal profiles of the two groups were significantly different (P=0.030). ΔTSS of the discontinuation and continuation groups was 0.64 and 0.32, respectively, which did not statistically differ (p=0.19). The proportion of patients with non-radiological progression (ΔTSS≤0.5) was 52.9% and 70.6%, respectively, and no marked differences in HAQ-DI at month 12 were detected (0.68 and 0.56, respectively; p=0.46).

Conclusion: Biologic-free remission occurred in 35.3% of ABA discontinuation patients, with over 50% of both groups achieving non-radiographic progression. Moreover, functional remission was also maintained among patients in biologic-free remission compared to those in the continuation group. Our findings suggest that ABA may achieve biologic-free remission in RA patients.

1290

Effects of Tofacitinib On Lipid Profiles and Cholesterol and Lipoprotein Kinetics in Patients with Rheumatoid Arthritis.
Christina Charles-Schoeman[1], Roy M. Fleischmann[2], Jean Davignon[3], Howard Schwartz[4], Scott Turner[5], Carine Beysen[5], Mark Milad[6], Zheng Luo[7], John Bradley[7], Irina Kaplan[7], Richard Riese[7], Andrea Zuckerman[7] and Iain B. McInnes[8]. [1]University of California, Los Angeles, CA, [2]Metroplex Clinical Research Center, Dallas, TX, [3]University of Montreal, Montreal, [4]Miami Research Associates, Miami, FL, [5]KineMed Inc., Emeryville, CA, [6]Milad Pharmaceutical Consulting LLC, Plymouth, MI, [7]Pfizer Inc., Groton, CT, [8]University of Glasgow, Glasgow, United Kingdom

Background/Purpose: Tofacitinib is a novel oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. In RA patients (pts), suppression of total (TC), high-density lipoprotein (HDL), and low-density lipoprotein (LDL) cholesterol levels during inflammation has been described. Tofacitinib has shown significant efficacy in reducing RA disease activity and inflammation in Phase 2/3 studies, during which a proportion of pts displayed increases in cholesterol levels. This Phase 1 study aimed to understand the mechanisms for suppression of cholesterol levels in active RA pts compared with healthy controls, and to investigate changes in cholesterol and lipoprotein kinetics following 6 weeks of tofacitinib treatment in RA pts.

Methods: Baseline lipid profiles and cholesterol and lipoprotein kinetics were assessed in 36 RA pts and 33 matched healthy controls (of similar age, race, sex, and menopausal status) and were repeated in RA pts after treatment with oral tofacitinib 10 mg twice daily for 6 weeks. Fasting blood samples were collected for apolipoprotein (Apo) and lipoprotein cholesterol concentrations, HDL and LDL particle size, and biomarkers of HDL dysfunction. In vivo cholesterol and lipoprotein kinetics were assessed with a 22-hour infusion of [^{13}C]cholesterol and [^{13}C]leucine.

Results: At baseline, HDL cholesterol, LDL cholesterol, TC and ApoA1 concentrations in RA pts were lower than in controls (Table). The cholesterol ester (CE) fractional catabolic rate (FCR) was significantly greater in RA pts vs controls without differences in cholesteryl ester transfer protein mass/activity or CE production rate. HDL-ApoA1 and LDL-ApoB100 FCR were similar between the groups. HDL biomarkers indicated HDL dysfunction in RA pts compared with controls as shown by higher HDL-associated serum amyloid A and myeloperoxidase, and lower in vitro lecithin cholesterol acyltransferase activity/mass. After tofacitinib therapy, the HDL-ApoA1 production rate was increased. Additionally, the CE FCR and cholesterol levels approached levels of controls with increases in plasma ApoA1 and ApoB concentrations. Increased CE FCR in the absence of changes in HDL-ApoA1 or LDL-ApoB100 FCR suggests increased selective CE uptake by scavenger receptor Class B Type 1 in RA pts, which was normalized by tofacitinib. Total HDL particle number and LDL size increased, and markers of HDL dysfunction improved after tofacitinib.

Table. Lipid parameters, cholesterol kinetics, and particle size in RA pts before and after treatment with tofacitinib, and in healthy controls

Mean (standard deviation)	RA patients Baseline	RA patients Tofacitinib-treated[a]	Baseline healthy controls
Lipid and lipoprotein concentrations			
Total cholesterol (mg/dL)	194 (33)†	220 (41)*	222 (42)
CE (mg/dL)	106 (20)†	122 (23)*	123 (30)
LDL-cholesterol (mg/dL)	125 (29)†	143 (39)*	145 (36)
HDL-cholesterol (mg/dL)	54 (13)†	62 (15)*	63 (17)
ApoB1 (mg/dL)	81 (42)	93 (42)*	82 (48)
ApoA1 (mg/dL)	117 (56)†	135 (58)*	128 (68)
Cholesterol and lipoprotein kinetics			
CE FCR (%/h)	2.43 (0.39)†	2.23 (0.31)*	2.17 (0.36)
CE production rate (mg/kg BW/h)	1.09 (0.24)	1.12 (0.24)	1.11 (0.26)
LDL-ApoB100 FCR (%/h)	1.61 (0.37)	1.57 (0.41)	1.50 (0.35)
LDL-ApoB100 production rate (mg/kg BW/h)	0.49 (0.12)	0.52 (0.12)	0.50 (0.13)
HDL-ApoA1 FCR (%/h)	1.08 (0.22)	1.11 (0.28)	1.02 (0.22)
HDL-ApoA1 production rate (mg/kg BW/h)	0.57 (0.11)	0.65 (0.15)*	0.59 (0.16)
HDL dysfunction			
HDL serum amyloid A (mg/L)	35 (63)†	18 (35)	3 (2)
Myeloperoxidase (pmol/L)	1092 (1017)†	943 (943)	736 (345)
LCAT activity (nmol/mL/h)	596 (139)†	642 (134)*	688 (121)
Particle size			
Total HDL particles (μmol/L)	30.7 (4.8)†	33.9 (5.51)*	35.0 (5.92)
LDL size (nm)	21.0 (0.85)	21.2 (0.97)*	21.4 (0.89)

*p < 0.05 vs baseline for RA pts; †p < 0.05 paired difference vs healthy controls
[a]Tofacitinib 10 mg twice daily for 6 weeks
Note: all pts had a body mass index <40 kg/m^2. Apo, apolipoprotein; BW, body weight; CE, cholesterol ester; FCR, fractional catabolic rate; HDL, high-density lipoprotein; LCAT, lecithin cholesterol acyltransferase; LDL, low-density lipoprotein

Conclusion: This is the first study to assess cholesterol and lipoprotein kinetics in pts with active RA and matched healthy controls. The data suggest that low cholesterol levels in RA pts with active disease may be explained by increases in CE catabolism. Treatment with tofacitinib decreased CE catabolism and normalized cholesterol levels to those of healthy controls while improving markers of HDL function, including increased HDL-ApoA1 production.

1291

A Phase Ib Clinical Trial with F8-IL10, an Anti-Inflammatory Immunocytokine for the Treatment of Rheumatoid Arthritis (RA), Used in Combination with Methotrexate (MTX).
Mauro Galeazzi[1], Caterina Baldi[1], Elena Prisco[2], Marco Bardelli[1], Dario Neri[3], Leonardo Giovannoni[4], Enrico Selvi[1] and Roberto Caporali[2]. [1]University of Siena, Siena, Italy, [2]University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [3]Swiss Federal Institute of Technology Zurich, Zurich, Switzerland, [4]Philogen S.p.A., Siena, Italy

Background/Purpose: Interleukin 10 (IL10) is an anti-inflammatory cytokine potentially efficacious for RA. F8-IL10 is a fusion protein in which the cytokine is fused with the antibody F8 specific to the alternatively-spliced EDA domain of fibronectin, a marker of angiogenesis. The conjugation of IL10 to the antibody F8 allows the selective delivery and accumulation of the cytokine to sites of inflammation, therefore increasing the therapeutic index. In mouse models of collagen-induced arthritis, F8-IL10 was able to selectively localize at sites of inflammation and showed a clear therapeutic activity by drastically reducing paw swelling when combined with MTX. A Phase Ib clinical trial is now on-going involving the administration of F8-IL10 in combination with MTX in patients with RA who have previously failed at least one TNF blocker. Objectives of the study are to establish the maximum tolerated dose of the combined treatment (F8-IL10 + MTX), to study safety and tolerability, to obtain preliminary information on efficacy and to assess the pharmacokinetic behavior of the drug. Here, we report the results obtained in 5 patients who have already completed the study. A sixth patient is under treatment at the time of writing.

Methods: Cohorts of 3–6 patients with active RA are assigned to receive escalating doses of F8-IL10 (6, 15, 30, 60 μg/kg respectively) in combination with 15mg of MTX. The treatment is given as once weekly sc injection for up

to 8 weeks. Safety evaluation performed on days 1 through 28, including AEs, SAEs, and standard laboratory assessments, are used to determine the dose limiting toxicity. Response is assessed after 4 and 8 weeks of treatment according to ACR and DAS28 criteria. The pharmacokinetic profile and formation of human anti-fusion protein antibodies are measured using standard methods.

Results: All three patients enrolled in the first cohort (6 μg/kg weekly of F8-IL10) achieved an ACR 50 response at more than one evaluation time point. In cohort 2 (15 μg/kg weekly of F8-IL10), patient I005 even resulted in ACR 70 response whereas patient I004 did not reach ACR20, however a moderate EULAR response was seen and treatment stopped after only 4 weeks. ACR responses are summarized in the attached table. DAS 28 significantly improved in all patients but to a lesser extent in pt I004. An excellent tolerability of F8-IL10, at the doses used, was observed in all treated patients, as of now no grade ≥2 adverse drug reactions have been reported.

ACR RESPONSE TO THE TREATMENT

Patient ID	week 5	week 9	F.U. 1 (week 14)	F.U. 2 (week 22)	Cohort and Dose Level
I001	ACR0	ACR0	ACR50	ACR50	Cohort 1, 6 μg/kg weekly
I902	ACR0	ACR50	ACR50	ACR20	Cohort 1, 6 μg/kg weekly
I903	ACR0	ACR50	ACR50	ongoing	Cohort 1, 6 μg/kg weekly
I004	ACR0	-	-	-	Cohort 2, 15 μg/kg weekly
I005	ACR50	ACR70	ACR70	ongoing	Cohort 2, 15 μg/kg weekly
I006	ongoing				Cohort 2, 15 μg/kg weekly

Conclusion: The promising safety data regarding the clinical use of F8-IL10, together with preliminary positive signs of activity may be favored by the targeted delivery of IL10 to the site of inflammation. These results also warrant future developments of the product in randomized clinical trials, which are currently in planning. An update of clinical data will be presented at the ACR meeting.

1292

Fatigue Is an Independent Variable Predicting Physical Function and Disease Activity Score-28 Remission for Patients with Rheumatoid Arthritis Treated with Intravenously Administered Golimumab: Results From Phase 3, Placebo Controlled Clinical Trial. Rene Westhovens[1], Michael Weinblatt[2], Chenglong Han[3], Tim Gathany[3], Lilianne Kim[4], Michael Mack[5], Jiandong Lu[5], Daniel Baker[5], Alan Mendelsohn[5] and Clifton O. Bingham[6]. [1]University Hospital KU Leuven, Leuven, Belgium, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [3]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [4]Janssen Research & Development, LLC, Malvern, PA, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Johns Hopkins University, Baltimore, MD

Background/Purpose: To evaluate the association of fatigue with physical function and disease activity in patients with rheumatoid arthritis (RA), and the impact of treatment with intravenously administered golimumab (GLM) on fatigue using data from the Phase III clinical trial GO- FURTHER.

Methods: GO-FURTHER was a multicenter, randomized, placebo-controlled study. Adult patients with active RA despite MTX therapy were randomized to placebo + MTX (placebo group) or GLM 2mg/kg plus MTX (GLM group) at week 0, 2, and every 8 week thereafter. Patients in placebo group with <10% improvement in tender and swollen joint count from baseline at week 16 entered early escape and received a 2 mg/kg GLM infusion at Weeks 16 and 20. Impact on physical function was assessed using the disability index of the Health Assessment Questionnaire (HAQ). Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) questionnaire, and clinically meaningful improvement in FACIT-Fatigue was defined as ≥ 4 points increase in the scores. Correlation of FACIT-Fatigue with HAQ and disease activity and remission (DAS28 using CRP<2.6) were analyzed using Pearson correlation, or multiple linear and logistic regression models to adjust for other confounding variables (age,

CRP, swollen and tender joints counts). Comparisons between groups were performed using ANOVA on van der Waerden normal scores for continuous outcomes or Chi-square test for binary outcomes.

Results: At baseline, mean (SD) FACIT-Fatigue score was 25.5 (10.54), indicating significant fatigue. Significant correlations of FACIT-Fatigue with HAQ (r=-0.62, p<0.01) and DAS28 score (r=-0.42, p<0.01) were observed at baseline. In multiple regression models, baseline FACIT-Fatigue score or change in FACIT-Fatigue at week 24 were correlated with change in HAQ and DAS28 score. Patients with higher FACIT-Fatigue scores at baseline were more likely to achieve DAS28 remission at week 24 (p=0.024). Compared to the placebo group, GLM-treated patients had significantly greater improvement in FACIT-fatigue at week 12 (5.4 ± 10.3 vs. 2.1 ± 9.0), which was sustained through week 16 (7.5 ± 10.5 vs. 2.2 ± 9.7) and 24 (8.0 ± 10.8 vs. 2.5 ± 10.2) (all p-values<0.001). Compared with the placebo group, a greater proportion of patients in the GLM group achieved clinically meaningful improvement in FACIT-Fatigue score at week 12 (57.5% vs. 42.8%) and at week 24 (65.8% vs. 40.3) (all p-values<0.001).

Conclusion: RA patients inadequately responsive to MTX experienced severe fatigue. Fatigue was a significant independent predictor of physical function and disease activity in patients with RA. Treatment with intravenously administered GLM significantly improved clinical symptoms of fatigue in patients with RA inadequately responsive to MTX.

1293

Importance of Steady-State Trough Concentrations After Intravenous Golimumab with Concomitant Methotrexate in Subjects with Active Rheumatoid Arthritis. J. H. Leu, Z. Xu, C. Hu, Alan Mendelsohn, J. Ford, Hugh M. Davis and H. Zhou. Janssen Research and Development, LLC, Spring House, PA

Background/Purpose: To determine an optimized dosing regimen for IV golimumab in subjects with active RA using population pharmacokinetic (PK) modeling and simulation.

Methods: Two Phase 3 trials were performed for IV golimumab. In the first trial, IV infusions of 2 mg/kg golimumab every 12 weeks (Q12W) or 4 mg/kg Q12W with concomitant methotrexate (MTX) were investigated in RA subjects. Population PK modeling was conducted using data from this first trial. Simulations were performed to identify an optimized IV regimen that would result in steady-state trough golimumab concentrations similar to the approved subcutaneous (SC) dosing regimen of 50 mg Q4W. Absolute bioavailability of 50% and Ka of 0.658 day^{-1} were used for simulating the SC golimumab profile. The dosing regimen for the second trial was then modified to shorten the dosing interval to Q8W.

Results: In the first trial, although there were strong trends towards clinical benefit, the primary endpoint (ACR 50) was marginally missed. It was found that Q12W dosing was inadequate to maintain adequate trough golimumab concentrations at the later part of the dosing interval. Using population PK analysis, a two-compartment IV infusion model with first-order elimination was developed. Parameter estimates for the model were: CL: 0.654 L/day; V1: 4.33 L; V2: 2.82 L and Q: 0.215 L/day. Simulations showed that IV golimumab 2 mg/kg Q8W + MTX and currently approved SC golimumab 50 mg Q4W + MTX resulted in similar steady-state trough golimumab concentrations. When the IV regimen of 2 mg/kg golimumab at Weeks 0, 4 followed by Q8W was studied in the second trial, the primary efficacy endpoint (ACR 20) was achieved.

Conclusion: Population PK modeling and simulation aided in the determination of an optimized dosing regimen for IV golimumab in subjects with active RA. Both observed data and population PK modeling and simulation corroborate the importance of maintaining adequate steady-state trough concentrations of golimumab for robust clinical efficacy.

A Phase Ib Multiple Ascending Dose Study Evaluating Safety, Pharmacokinetics, and Early Clinical Response of Brodalumab (AMG 827), a Human Anti-Interleukin 17 Receptor (IL-17R) Antibody, in Rheumatoid Arthritis.

Melvin A. Churchill[1], Luis F. Flores-Suarez[2], Daniel J. Wallace[3], Kristine Phillips[4], Richard W. Martin[5], Mario H. Cardiel[6], Jeffrey Kaine[7], Edgar Bautista[8], David H. Salinger[9], Erin Stevens[9], Christopher B. Russell[9] and David A. Martin[9]. [1]Arthritis Center of Nebraska, Lincoln, NE, [2]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of Michigan Medical School, Ann Arbor, MI, [5]Michigan State University College of Human Medicine, Grand Rapids, MI, [6]Hospital, Morelia, Mexico, [7]Sarasota Arthritis Research Center, Sarasota, FL, [8]Amgen, Thousand Oaks, CA, [9]Amgen, Seattle, WA

Background/Purpose: The cytokine IL-17A is an innate inflammatory cytokine implicated in the pathogenesis of several human autoimmune diseases including rheumatoid arthritis (RA). Brodalumab is a human, immunoglobulin G2 (IgG2) monoclonal antibody that binds with high affinity to human IL 17RA and blocks the biological activity of IL 17A, IL-17F, IL-17A/F heterodimers, and IL-25. Increased levels of IL-17A have been detected in the synovial fluid of patients with RA and furthermore, blockade of IL-17A signaling can inhibit osteoclast formation induced by culture media of RA synovial tissues. The aim of this study was to evaluate safety, pharmacokinetics, and preliminary efficacy of brodalumab in subjects with moderate to severe RA.

Methods: This phase Ib, randomized, placebo-controlled, double-blind multiple ascending dose study enrolled subjects with a moderate to severe RA (>6/66 swollen and >8/68 tender joints). Subjects were randomized 3:1 to receive multiple doses of brodalumab (50mg, 140mg or 210mg subcutaneously every two weeks for 6 doses, or 420mg or 700mg intravenously every 4 weeks for two doses) or placebo. The primary endpoint was safety and tolerability of brodalumab, including incidence of adverse events (AEs). Multiple dose pharmacokinetics was a secondary endpoint. Exploratory endpoints included pharmacodynamics, and improvements in RA clinical metrics. Assessments were performed up to end of study on day 127.

Results: 40 subjects were randomized and received at least one dose; there was one dropout on day 85 due to worsening RA (placebo). Treatment with brodalumab resulted in receptor occupancy by brodalumab on circulating leukocytes and inhibition of IL-17 receptor signaling. Dose-dependent increases in the magnitude and duration of mean receptor occupancy were observed. Treatment-related AEs were reported by 3 (30.0%) of 10 placebo subjects and 7 (23.0%) of 30 brodalumab subjects. The most common treatment-related adverse event was headache (20%) for placebo subjects and leukocytosis (7%) for brodalumab subjects. Serious AEs occurred in 2 subjects during the study [complicated migraine (placebo) and non-cardiac chest pain (brodalumab, 420 mg IV)]; neither was considered by the investigator related to investigational product. On day 85 (week 13) ACR20 was achieved by 11 (36.7%) of 30 subjects receiving brodalumab and 2 (22.0%) of 9 subjects receiving placebo. Few ACR50 or ACR70 responses were observed in either active or placebo group at day 85.

Conclusion: This small ascending dose phase 1b study demonstrates that multiple dose administration of brodalumab was tolerated in subjects with active RA. Conclusions about efficacy cannot be reached given the study design.

Effectiveness and Tolerability of Subcutaneous Tocilizumab in Rheumatoid Arthritis Patients Switched From Intravenous Tocilizumab: Results From the Extension Period of the Musashi Study.

Atsushi Ogata[1] and the MUSASHI study group[2]. [1]Osaka University Graduate School of Medicine, Suita, Japan, [2]Japan

Background/Purpose: In the MUSASHI study (i.e., Double-blind, parallel-group, Phase III non-inferiority study comparing subcutaneous tocilizumab [SC-TCZ] monotherapy versus intravenous tocilizumab [IV-TCZ] monotherapy), the effectiveness and safety of SC-TCZ monotherapy were proved to be comparable to those of IV-TCZ monotherapy in Japanese patients with rheumatoid arthritis (RA). The aim of the current study was to investigate the effectiveness and safety of SC-TCZ in the patients who had received IV-TCZ in the MUSASHI study.

Methods: This study enrolled RA patients who had received TCZ monotherapy for 24 weeks in the MUSASHI study (prior-IV group: 8 mg/kg IV-TCZ every 4 weeks; prior-SC group: 162 mg SC-TCZ every 2 weeks). They received open label SC-TCZ (162 mg every 2 weeks) starting at Week 24 without any concomitant use of synthetic or biologic DMARDs. Disease activity as measured by DAS28-ESR and ACR response rates and safety were assessed.

Results: A total of 319 patients (160 patients in the prior-IV group and 159 patients in the prior-SC group) were enrolled. Baseline demographics were comparable between the prior-IV group and the prior-SC group: body weight (kg, mean $\pm$ SD), 54.3 ± 10.1 vs. 53.9 ± 8.8; proportion of patients who previously used TNF-α inhibitors before the MUSASHI study, 23.1% vs. 18.2%. At 12 weeks after starting the extension period (36 weeks after the beginning of the MUSASHI study), 158 patients in the prior-IV group and 157 patients in the prior-SC group were still receiving SC-TCZ. The mean change of DAS28-ESR in the prior-IV group was comparable to that in the prior-SC group over the whole 36 weeks, and was maintained after switching from IV-TCZ to SC-TCZ (Table). ACR response rates at Week 24 were also maintained for the 12 weeks following the switch from IV-TCZ to SC-TCZ. The incidences of new onset AEs and SAEs between Weeks 24 and 36 were, respectively, 59.4% (95/160) and 4.4% (7/160) in the prior-IV group and 57.9% (92/159) and 2.5% (4/159) in the prior-SC group. The safety profiles in both groups were comparable. Among AEs, the incidence of new onset injection-site reactions (ISRs) was 5.6% (9/160) in the prior-IV group. No case of serious ISR was seen during the extension period in the prior-IV group and the prior-SC group. Anti-TCZ antibodies were detected in 1 patient who switched from IV to SC administration. However this patient had no case of serious anaphylaxis or anaphylactoid reactions.

Table. DAS28-ESR over time (mean $\pm$ SD)

week	Double blind period			Extension period
	0	12	24	36
Prior-SC[*1]	6.1 ± 0.9	3.1 ± 1.2	2.7 ± 1.3	2.6 ± 1.4
Prior-IV[*2]	6.2 ± 0.9	2.8 ± 1.0	2.5 ± 1.1	2.6 ± 1.2

[*1]Prior-SC: SC-TCZ 162 mg q2w
[*2]Prior-IV: IV-TCZ 8 mg/kg q4w for 24 weeks and then switched to SC-TCZ 162 mg q2w

Conclusion: There was no sign of effectiveness being reduced after switching to SC-TCZ in this short extension period. Switching of TCZ treatment from IV-TCZ to SC-TCZ was tolerable. These findings are useful consideration for the clinical application of SC-TCZ.

An Interim Analysis of the Efficacy of Abatacept in Japanese Biologics-naïve Rheumatoid Arthritis Patients (results from ABROAD study): Comparison of CRP and MMP-3 Level After Treatment with Abatacept Versus Anti-TNF Agents.

Background/Purpose: Abatacept (ABA) is a recombinant fusion protein consisting of the extracellular domain of human CTLA-4, binding to

CD80/86 on antigen presenting cells (APCs) and thereby inhibits the interaction between these molecules and CD28 on T cells. ABA suppresses T cell activation and has been reported to have the therapeutic benefit for patients with rheumatoid arthritis (RA). However, there are limited data to compare the efficacy of ABA and anti-TNF agents. We conducted the ABROAD study (Abatacept Research Outcomes as a first-line biological Agent in the real worlD) in collaboration with 37 institutions in Japan. In this study, we confirmed the efficacy of ABA and compared CRP and MMP-3 levels after treatment with ABA versus anti-TNF agents in Japanese biologics-naïve RA patients.

Methods: We analyzed multicenter 100 biologics-naïve RA patients treated with ABA (ABROAD study) from January 2010 to May 2012. Patients received 500mg of abatacept for patients weighted less than 60kg or 750mg for patients with more than 60kg with or without MTX (mean dosage:6.0±3.7mg/week) for 24 weeks. To evaluate the efficacy of the treatment, we measured SDAI, DAS28-CRP (DAS), CRP and MMP-3 levels at week 0, 4, and 24 after treatment. We also compared CRP and MMP-3 levels after treatment with ABA versus anti-TNF agents using propensity score matching of sex, age and duration of the disease in 48 biologic-naïve RA patients, respectively.

Results: At week 0, 4, and 24 after ABA treatment, the mean SDAI/DAS score and CRP/MMP-3 levels were SDAI (26.2±14.9→16.6±11.1→10.4±9.6), DAS (4.5±1.3→3.5±1.2→2.8±1.2), CRP (2.1±2.2→1.1±1.6→0.8±1.8 mg/dl), and MMP-3 (219.1±202.5→169.7±140.3→114.1±117.0 ng/dl), respectively. We observed statistically significant reduction of SDAI/DAS/CRP/MMP-3 levels at week 4 compared to those of the baseline. The proportions of patients who achieved low disease activity or remission at week 24 were 65.7% and 17.2% based on SDAI score, and 49.0% and 39.2% based on DAS, respectively. In the comparison of propensity score matching 96 biologics-naïve RA patients (48 patients received ABA: ABROAD group; 48 patients received anti-TNF agents: anti-TNF group), the mean CRP levels at week 0, 4 and 24 after treatment were (1.75±1.99→0.71±0.88→0.39±0.67 mg/dl) in ABROAD group and (1.60±1.78→0.52±1.24→0.45±0.78 mg/dl) in anti-TNF group, respectively. The mean MMP-3 levels at week 0, 4 and 24 after treatment were (217.4±194.5→166.3±124.7→90.7±64.0 ng/dl) in ABROAD group and (225.9±163.8→164.4±177.2→127.9±128.2 ng/dl) in anti-TNF group, respectively. Although statistically not significant, CRP and MMP-3 levels in ABROAD group were lower than those in anti-TNF group at week 24 after treatment.

Conclusion: We observed the efficacy of ABA at week 4 after treatment of biologic-naïve RA patients. We also observed that CRP and MMP-3 levels in ABROAD group were lower than those in anti-TNF group at week 24 after treatment. These results indicate the possibility that ABA could become as a first-line biologic for the treatment of RA patients.

Tofacitinib and Adalimumab Achieve Similar Rates of Low Disease Activity in Rheumatoid Arthritis—Lack of Improvement in Disease Activity Score by 3 Months Predicts Low Likelihood of Low Disease Activity At 1 Year.
Ronald F. van Vollenhoven[1], Sriram Krishnaswami[2], Birgitta Benda[3], David Gruben[2], Bethanie Wilkinson[2], Charles A. Mebus[2], Samuel H. Zwillich[2] and John Bradley[2]. [1]Karolinska Institute, Stockholm, Sweden, [2]Pfizer Inc., Groton, CT, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Tofacitinib is a novel oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. This post-hoc analysis of the Phase 3 active-controlled randomized ORAL Standard trial (NCT00853385) determined the relationship between changes in the Disease Activity Score (28 joints, 4 components, ESR; DAS28) during the first 3 months (mo) of treatment with tofacitinib or adalimumab (ADA), and the likelihood of achieving low disease activity (LDA) at Mo 6 or Mo 12 in patients (pts) with RA.

Methods: Pts on stable background methotrexate (MTX) were randomized 4:4:4:1:1 to one of five sequences: tofacitinib 5 mg twice daily (BID); 10 mg BID; ADA 40 mg sc biweekly (q2w); placebo (PBO) advanced to tofacitinib 5 mg BID; or PBO advanced to 10 mg BID. All pts self-administered injections q2w (ADA or PBO). Pts on PBO advanced to tofacitinib at Mo 6, or at Mo 3 if they did not show ≥20% reduction from baseline (BL) in swollen/tender joint counts.

Results: Overall, 717 pts were treated. Primary results have been reported previously.[1] Mean BL DAS28 values across sequences were 6.4–6.6. Tofacitinib 5 and 10 mg BID and ADA all showed statistical superiority to PBO at Mo 3 and Mo 6, and achieved numerically similar responses, including rates of LDA (DAS28 ≤3.2) (Table). In the current analysis of pts with a DAS28 improvement from BL <0.6 by Mo 1, less than 5% receiving tofacitinib 5 mg BID and approximately 10% receiving tofacitinib 10 mg BID achieved LDA at Mo 12. In pts with a DAS28 improvement from BL <0.6 by Mo 3, none achieved LDA at Mo 6 or Mo 12 on either dose of tofacitinib, while approximately 10% (n=2) of ADA pts with DAS28 improvement <0.6 by Mo 3 achieved LDA at Mo 12 (Table).

Endpoint	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID	Adalimumab 40 mg q2w	Placebo
LDA (%), all pts[a]				
Mo 3	14.7**	13.6**	14.6**	2.2
Mo 6	17.0*	19.3**	15.7*	4.4
Mo 12	17.5	22.7	26.4	NA
LDA (n/N) at Mo 12 in pts achieving <0.6 DAS28 improvement from BL at Mo 1	1/42	5/49	8/54	NA
LDA (n/N) at Mo 12 in pts achieving <0.6 DAS28 improvement from BL at Mo 3	0/19	0/19	2/21	NA

*p≤0.001; **p≤0.0001 vs placebo. [a]Non-responder imputation BL, baseline; DAS28, Disease Activity Score (28 joints, 4 components, erythrocyte sedimentation rate); LDA, low disease activity defined as DAS28≤3.2; Mo, month; n, number of patients achieving LDA; N, total number of patients with DAS28 improvement from baseline < 0.6; NA, not applicable

Conclusion: LDA rates were similar between tofacitinib and ADA. In this post-hoc analysis of the ORAL Standard study, failure to achieve ≥0.6 improvement from baseline in DAS28 within the first 3 months of tofacitinib treatment was predictive of a low probability of achieving LDA at 1 year.

Improvement of Treatment Outcome of Rheumatoid Arthritis with Salazosulfapyridine by Pharmacogenetic Approach.
Shunichi Kumagai[1], Yoshiaki Hagiwara[2], Yoshihide Ichise[1], Sho Sendo[1], Nobuhiko Okada[1], Jun Saegusa[2] and Goh Tsuji[3]. [1]Shinko hospital, Kobe, Japan, [2]Kobe University Graduate School of Medicine, Kobe, Japan, [3]Shinko Hospital, Kobe, Japan

Background/Purpose: Salazosulfapyridine (SASP) is acetylated in liver by N-acetyltransferase2 (NAT2) in the track of metabolism. Previous studies have shown that genotyping of NAT2 is adequate to classify its acetylation activity into fast (FA), intermediate (IA), and slow acetylator (SA). Prediction of SASP efficacy/adverse events (AEs) based on NAT2 genotype has been demonstrated in retrospective studies, but has not been validated by prospective study. Thus, the purpose of this study is to investigate the association of efficacy and NAT2 genotype prospectively.

Methods: NAT2 genotype was determined by typing following SNPs, C341T, G590A, and G857A, using Q-probe method (i-densy; Arkray Inc.). Wilcoxon rank-sum test and Pearson's chi-square test were used for statistical analysis.

1.) Retrospective Study: AEs and efficacy were retrospectively investigated based on physician's reports and medical records for 102 RA patients (male/female; 29/73, mean age; 60.2±14.6 years), whose mean DAS28-CRP (DAS28) was 4.26±1.08 at baseline.

2.) Prospective Study: Forty three RA patients who initiated SASP between Jan 2010 and Mar 2012 (male/female; 15/28, mean age; 64.4ΔDAS28 was significantly greater in IA than that of FA (FA; −1.03±0.86, IA; −1.88

Results: Between Oct 2001 and Apr 2012, 9,905 CORRONA patients initiated biologic therapy for RA, of which 40% were previously bio naïve. Demographics and disease activity characteristics in the Bio naïve and Bio

experienced patients respectively were as follows; age (years; mean±SD): 57±14 vs 57±13, females: 76% vs 81%, duration of RA (years; mean±SD): 8±9 vs 13±10, seropositivity: 75% vs 73%, and CDAI (mean±SD): 19± 14 vs 22± 15.

Of the 9,905 patients, 25% received Bio MT and 75% received Bio CMB. Among patients that were previously bio naïve, 19% initiated a biologic as MT whereas MT initiation rates for patients who had received one prior biologic was 29%; two prior biologics, 26%; and three or more prior biologics, 31%. Higher rates of MT initiations were observed with prior Bio experience (unadjusted OR 2.01 [95% CI 1.70, 2.37]). Higher proportion of patients starting their biologic therapy after 2006 received MT as compared to those who started their biologic therapy prior to 2006 but was not statistically significant (unadjusted OR 1.20 [95% CI 0.99, 1.45]).

In the multivariate model (Table 1), Bio experienced patients continued to be significantly more likely to receive MT as compared Bio naïve. Median odds ratio showing the effect of individual physician's prescribing patterns on initiating bio MT was 2.40 [95% CI 2.08, 2.86].

Table 1. Adjusted Odds ratios for initiating Bio MT versus Bio CMB

	OR (95% CI) for initiating Bio MT vs Bio CMB
Prior number of biologics	1
0 (reference)	2.12 (1.76, 2.54)
1	1.63 (1.30, 2.04)
2	2.20 (1.68, 2.89)
≥3	
After 2006 vs. up to 2006	1.03 (0.84, 1.25)
Effect of physician prescribing patterns	2.40 (2.08, 2.86)

Abbreviations: Bio–biologic, MT–monotherapy, CMB–combination therapy.

Conclusion: Monotherapy remains a common strategy of biologic prescription to treat RA. Prior biologic experience and individual physician's prescribing patterns were associated with increased likelihood of initiating a biologic as monotherapy warranting further investigation to understand factors influencing decisions to initiate biologic monotherapy.

1299

Rituximab Versus Abatacept in Rheumatoid Arthritis Patients with an Inadequate Response to Prior Biologic Therapy: A Retrospective, Single-Center Study. Edward Keystone, Juan Xiong, Deborah Weber and Ye Sun. Mount Sinai Hospital, Toronto, ON

Background/Purpose: Patients with RA who experience an inadequate response to TNF inhibitor (TNFi) therapy (TNF-IR) may be successfully treated using an alternative TNFi or a biologic with a different mode of action such as rituximab (RTX) or abatacept (ABA). The relative effectiveness of these approaches has not been determined in head-to-head trials. Evidence from real-world experience would help to guide treatment decisions for TNF-IR patients.

Methods: This was a retrospective chart review of patients from a single site (Rebecca MacDonald Center) with ACR-defined RA who initiated RTX or ABA after failure of at least one TNFi. The relative effectiveness of RTX and ABA was evaluated by analyzing drug survival distribution. Kaplan-Meier survival curves were compared using the log rank test (p-values <0.05 indicated statistical significance).

Results: The study cohort comprised 61 patients, of whom 37 and 24 were treated with RTX and ABA, respectively. In the RTX group, 10 patients had also received prior therapy with ABA. Demographics and disease characteristics were generally similar in the two groups, although RTX patients had higher disease activity compared with ABA patients (mean CDAI: RTX 32.5 vs ABA 26.9) and had received more prior TNFis (1.8 vs 1.7) and/or ABA (2.1 vs 1.7). After excluding the 10 RTX patients who had received prior ABA, survival rates over time were generally better with RTX vs ABA (table).

Estimated survival rates

Time (years)	RTX (n=27)	ABA (n=24)
0.5	0.92	0.83
1.0	0.79	0.74
1.5	0.74	0.54
2.0	0.68	0.54
3.0	0.68	0.54
4.0	0.68	0.41

Overall survival distribution (figure) was not significantly different between the RTX and ABA groups (p=0.658); however, RTX patients who had also failed ABA had significantly reduced survival compared with those who had not received ABA (p=0.015).
Stratification of survival data according to number of prior TNFi failures indicated that RTX (excluding patients with prior ABA) was superior to ABA among patients who had failed 3 TNFis. Survival was also numerically greater with RTX vs ABA in patients who had failed 1 prior TNFi. Finally, survival was better on both RTX and ABA when compared with that seen in a separate cohort of patients (n=88) who received a second TNFi after first TNFi failure.

Conclusion: These results from real-life practice suggest that in RA patients who have failed one or more TNFi, RTX may have better long-term survival than either ABA or an alternative TNFi. Prior ABA appears to reduce the efficacy of RTX. Further data are needed.

1300

Characteristics Associated with Biologic Initiation As Monotherapy Versus Combination Therapy in Patients with Rheumatoid Arthritis (RA) in a US Registry Population. Dimitrios A. Pappas,[1] George W. Reed,[2] Katherine C. Saunders,[3] Ani John, [3] Ashwini Shewede,[3] Jenny Devenport,[4] Jeffrey D. Greenberg,[5] and Joel M. Kremer.[6] [1]Columbia University, College of Physicians and Surgeons, New York, NY, [2]University of Massachusetts Medical School, Worcester, MA, [3]CORRONA, Inc., Southborough, MA, [4]Genentech Inc., South San Francisco, CA, [5]NYU Hospital for Joint Diseases, New York, NY, [6]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Approximately one-third of RA patients were prescribed biologic (Bio) monotherapy (MT) i.e. without concomitant disease-modifying anti-rheumatic drugs (DMARD) (Yazici et al., 2008). The purpose of this abstract is to summarize characteristics associated with Bio MT and Bio combination therapy (CMB) initiation in a cohort of previously bio naïve and experienced RA patients in US and evaluate if previous treatments, increased availability of biologics approved for MT after 2006, and individual physician-prescribing patterns influence the decisions to initiate Bio MT and Bio CMB.

Methods: Data were obtained from the Consortium of Rheumatology Researchers of North America (CORRONA) registry, an independent prospective observational cohort with >30,000 RA patients enrolled from over 100 academic and private practices across the US. Odds ratios (OR) (adjusted and unadjusted) for initiating MT in Bio experienced compared to Bio naïve patients were estimated using logistic regression models. A Median OR to account for random effects from variation in individual physician's prescribing patterns and the effect of the availability of more biologics approved for MT after 2006 were also estimated.

Results: Between Oct 2001 an Apr 2012, 9,905 CORRONA patients initiated biologic therapy for RA, of which 40% were previously bio naïve. Demographics and disease activity characteristics in the Bio naïve and Bio experienced patients respectively were as follows; age (years; mean±SD): 57±14 vs 57±13, females: 76% vs 81%, duration of RA (years; mean±SD): 8±9 vs 13±10, seropositivity: 75% vs 73%, and CDAI (mean±SD): 19±14 vs 22±15.

Of the 9,905 patients, 25% received Bio MT and 75% received Bio CMB. Among patients that were previously bio naïve, 19% initiated a biologic as MT whereas MT initiation rates for patients who had received one prior biologic was 29%; two prior biologics, 26%; and three or more prior biologics, 31%. Higher rates of MT initiations were observed with prior Bio experience (unadjusted OR 2.01 [95% CI 1.70, 2.37]). Higher proportion of patients starting their biologic therapy after 2006 received MT as compared to those who started their biologic therapy prior to 2006 but was not statistically significant (unadjusted OR 1.20 [95% CI 0.99, 1.45]).

In the multivariate model (Table 1), Bio experienced patients continued to be significantly more likely to receive MT as compared Bio naïve. Median odds ratio showing the effect of individual physician's prescribing patterns on initiating bio MT was 2.40 [95% CI 2.08, 2.86].

Table 1. Adjusted Odds ratios for initiating Bio MT versus Bio CMB

	OR (95% CI) for initiating Bio MT vs Bio CMB
Prior number of biologics	1
0 (reference)	2.12 (1.76, 2.54)
1	1.63 (1.30, 2.04)
2	2.20 (1.68, 2.89)
≥3	
After 2006 vs. up to 2006	1.03 (0.84, 1.25)
Effect of physician prescribing patterns	1.40 (1.08, 2.86)

Abbreviations: Bio - biologic, MT - monotherapy, CMB - combination therapy.

Conclusion: Monotherapy remains a common strategy of biologic prescription to treat RA. Prior biologic experience and individual physician's prescribing patterns were associated with increased likelihood of initiating a biologic as monotherapy warranting further investigation to understand factors influencing decisions to initiate biologic monotherapy.

1301

Predictors of Significant Disease Activity Score-28 (Using C-reactive protein) Remission Achieved with Intravenous Golimumab in Patients with Active Rheumatoid Arthritis Despite Methotrexate Therapy: Results of the Phase 3, Multicenter, Double-Blind, Placebo-Controlled Trial. Clifton O. Bingham III[1], Michael Weinblatt[2], Alan Mendelsohn[3], Lilianne Kim[3], Michael Mack[3], Jiandong Lu[3], Daniel Baker[3] and Rene Westhovens[4]. [1]Johns Hopkins University, Baltimore, MD, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [3]Janssen Research & Development, LLC, Spring House, PA, [4]University Hospital KU Leuven, Leuven, Belgium

Background/Purpose: To evaluate the efficacy of intravenous(IV) golimumab(GLM) 2mg/kg+ methotrexate(MTX) in patients(pts) with active RA despite MTX in achievement of DAS remission and ACR/EULAR remission.

Methods: Pts (n=592) with active RA (≥6/66 swollen joints, ≥6/68 tender joints, CRP≥1.0mg/dL, RF and/or anti-CCP antibody-positive) despite ≥3months of MTX(15–25mg/wk) participated in this multicenter, randomized, double-blind, placebo(PBO)-controlled phase 3 study. Pts were randomized (2:1) to receive IV GLM 2mg/kg or PBO at wks0&4 and q8wks; all pts continued their stable MTX regimen. Clinical remission was defined by DAS28-CRP score <2.6 (prespecified; not validated) and recently developed ACR/EULAR remission[1] using SDAI≤3.3 (post hoc; validated). DAS28-CRP analyses used last-observation-carried-forward.

Results: Statistically significantly higher DAS28-CRP remission rates were observed with GLM+MTX vs. PBO+MTX at Wk14 (15.4% vs. 4.6%, respectively; p<0.001) and Wk24 (17.7% vs. 5.1%, respectively; p<0.001). Similar trends were seen when remission was defined by a SDAI score ≤3.3 (Wk14: 4.8% vs.1.0%, respectively; p<0.05 and Wk24: 7.3% vs. 2.0%, respectively; p<0.01). Moderate (approx.10%-15%) increases in Wk24 DAS28-CRP remission rates were observed among subgroups of pts defined by HAQ score <1.625 (24%) vs ≥1.625 (12%), baseline physical Functional Class I (27%) vs Class II and III (17% each), swollen joint count <12 (23%) vs ≥12 (14%), tender joint count <24 (25%) vs ≥24 (11%), and CRP <1.5 mg/dL (29%) vs ≥1.5 mg/dL (15%).

Table. No. (%) of pts achieving DAS28-CRP <2.6 at Wk24 by baseline characteristics*

No. randomized GLM pts	495
Age (yrs): < 65/≥ 65	61/336 (18%)/9/59 (15%)
Sex: Female/Male	58/326 (18%)/12/69 (17%)
Body weight (median: 70kg): < 70 kg/≥ 70 kg	34/198 (17%)/36/197 (18%)
Disease duration (median:4.7yrs):< 4.7yrs/≥ 4.7yrs	35/196 (18%)/35/199 (18%)
Functional class: I/II/III	9/33 (27%)/48/284 (17%)/13/78 (17%)
Rheumatoid factor: Negative/Positive	6/30 (20%)/64/365 (18%)
Anti-CCP: Negative/Positive	6/32 (19%)/64/362 (18%)
CRP (mg/dL): ≤ 1.5/> 1.5	20/69 (29%)/50/326 (15%)
Swollen joint count (median: 12): < 12/≥ 12	40/174 (23%)/30/221 (14%)
Tender joint count (median: 24): < 24/≥ 24	48/195 (25%)/22/200 (11%)
HAQ score (median 1.625): < 1.625/≥ 1.625	46/193 (24%)/24/202 (12%)
Oral corticosteroids at baseline: Yes/No	38/251 (16%)/32/144 (22%)
DMARDs at baseline: Yes/No	38/206 (18%)/32/189 (17%)
NSAIDs at baseline: Yes/No	57/323 (18%)/13/72 (18%)
Methotrexate at baseline (mg/wk): <15/≥ 15	46/268 (17%)/24/127 (19%)

* Cutpoints for baseline characteristic subgroups were determined by the median value among patients randomized to GLM+MTX

Conclusion: In pts with active RA despite ongoing MTX, IV GLM 2 mg/kg+MTX yielded significantly higher DAS28-CRP remission rates and higher ACR/EULAR remission rates vs PBO at Wk14 and Wk24. Achievement of DAS28-CRP remission appeared to be enhanced in pts with lower levels of baseline physical function impairment and lower joint counts. Confirmation of these hypothesis-generating data are required.

1302

Early Neutropenia Is Associated with Clinical Response in Patients Receiving Tocilizumab in Rheumatoid Arthritis. Marie Kostine[1], Thomas Barnetche[2], Elodie Ardouin[3], Marlene Joly[4], Emilie Rabois[5], Baptiste Glace Sr.[6], Delphine Nigon[7], Thierry Schaeverbeke[8] and Christophe Richez[9]. [1]Rheumatology, CHU Pellegrin, Bordeaux, France, [2]CHU Bordeaux Pellegrin, Bordeaux, France, [3]Rheumatology, Limoges University Hospital, Limoges, France, [4]Rheumatology, Montpellier University Hospital, Montpellier, France, [5]CHU Gabriel Montpied, Clermont-Ferrand, France, [6]Rheumatology CHU Gabriel Montpied, Clermont-Ferrand, France, [7]CHU Purpan, Toulouse, France, [8]Groupe Hospitalier Pellegrin, Bordeaux, France, [9]Hôpital Pellegrin and Université Victor Segalen Bordeaux, France

Background/Purpose: A reduction in peripheral blood neutrophils count is usually observed with the anti-interleukin (IL) 6 receptor antibody tocilizumab. This often appears few days after first administration, but mechanisms are not completely established. Objective is to evaluate the evolution of neutrophils count under tocilizumab (anti IL-6R) treatment for rheumatoid arthritis affected patients and to correlate this evolution with clinical response.

Methods: We performed a multicentric retrospective study including patients with RA treated by tocilizumab +/− DMARDs in 5 University French Centers (Bordeaux, Clermont-Ferrand, Limoges, Montpellier and Toulouse). Neutrophils, inflammatory parameters and DAS28 (ESR) were recorded at baseline, and after one and three months of treatment. The comparisons were performed using Student's t-test or Mann-Whitney test when appropriate. A statistical significant p-value of 0,05 was selected.

Results: 158 patients were included with mean age of $59,7 \pm 12,6$ years-old and a mean disease duration of $13,4 \pm 8,8$ years. The mean DAS28 (ESR) at inclusion was about $5,32 \pm 1,27$, and decreased significantly after one month of treatment to $3,74 \pm 1,38$ ($p<10^{-4}$), and to $3,18 \pm 1,33$ ($p<10^{-4}$) after three months of treatment. According to the EULAR response criteria, 3 patients were classified as good responders (1,9%), 126 as moderate responders (79,7%) and 29 as non-responders (19,4%). The neutrophils count shows a significant decrease between the introduction of tocilizumab therapy and after one month of treatment ($5972 \pm 2736/\text{mm}^3$ vs. $3972 \pm 2436/\text{mm}^3$, $p<10^{-4}$), whereas it stays at the same level between the first and the third month of treatment ($3972 \pm 2436/\text{mm}^3$ vs. $3963 \pm 2255/\text{mm}^3$, p=0,94). The frequency of neutropenia (neutrophils$<=1500/\text{mm}^3$) was about 1,3% (2/155) at inclusion, 5,9% (9/154) after one month and 3,5% (5/142) after three months of treatment.

The neutrophils count decreases significantly between the inclusion and first month of treatment in the subgroup of Month 3 responders ($6095 \pm 2823/\text{mm}^3$ vs. 3946 ± 2450, $p<10^{-4}$ with Mann-Whitney test), whereas this decrease is not significant in the subgroup of month 3 non-responders ($5438 \pm 2292/\text{mm}^3$ vs. $4087 \pm 2415/\text{mm}^3$, p=0,05 with Mann-Whitney test). The DAS (ESR) difference between Month 0 and Month 3 was positively correlated with the difference of the neutrophils count between Month 0 and Month 1 (p=0,03; r=0,19)

Conclusion: This study reveals correlation between neutrophils decrease and clinical response during tocilizumab therapy. Accordingly with our previous report showing decrease of myeloid dendritic cells and monocytes during tocilizumab therapy, these new data suggest a specific effect of tocilizumab on cells from myeloid lineage.

1303

Achieving Comprehensive Disease Control in Long-Standing or Early Rheumatoid Arthritis Patients Treated with Adalimumab Plus Methotrexate Versus Methotrexate Alone. Edward C. Keystone[1], Ferdinand C. Breedveld[2], Désirée van der Heijde[2], Ronald F. van Vollenhoven[3], Stefan Florentinus[4], Freddy Faccin[5], Shufang Liu[5], Hartmut Kupper[6] and Arthur Kavanaugh[7]. [1]University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Karolinska Institute, Stockholm, Sweden, [4]Abbott, Rungis, France, [5]Abbott, Abbott Park, IL, [6]Abbott GmbH and Co. KG, Ludwigshafen, Germany, [7]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Effective treatment of rheumatoid arthritis (RA) patients (pts) aims to suppress inflammation, preserve physical function, and prevent structural damage, which together represent the hallmarks of comprehensive disease control (CDC).[1] Advances in therapies and application of targeted approaches to disease management have made CDC a realistic treatment goal for many pts.[2] The present analysis evaluated CDC attainment following 1 year of treatment with adalimumab (ADA) + methotrexate (MTX) vs MTX alone in 3 different randomized, controlled trials (RCTs).

Methods: Pt data originate from the DE019, OPTIMA, and PREMIER RCTs. DE019 enrolled pts with long-standing RA (mean =11 years) and an inadequate response (IR) to MTX; OPTIMA and PREMIER enrolled early RA (mean =0.4 and 0.7 years, respectively) and MTX-naïve pts. All studies included a comparison of ADA+MTX vs placebo (PBO)+MTX and were of at least 1 year duration. Changes to assigned treatment strategy were not allowed in DE019 or PREMIER but were made on the basis of achieving a stable low disease activity [LDA, DAS28(CRP) <3.2] target at weeks 22 and 26 in OPTIMA; PBO+MTX-IR could receive open-label (OL) ADA+MTX for an additional 52 weeks (Rescue ADA arm). CDC was defined for this analysis as the simultaneous achievement of LDA, normal function (HAQ-DI <0.5), and the absence of radiographic progression (ΔmTSS ≤0.5). This post hoc analysis assessed the proportion of pts achieving CDC and the individual criteria following 1 year of treatment with ADA+MTX combination therapy or MTX monotherapy in DE019, in the Rescue ADA arm of OPTIMA, or in PREMIER.

Results: Approximately one-fifth (19%) of ADA+MTX-treated pts in DE019 achieved CDC at 1 year vs 5% of PBO+MTX-treated pts ($P <.001$, **Table**). The addition of OL ADA+MTX to PBO+MTX-IR in the Rescue ADA arm of OPTIMA permitted 29% (n/N=102/348) of early RA pts to achieve CDC following 1 year of treatment, a proportion that was comparable with the proportion of MTX-naïve early RA pts treated with ADA+MTX in PREMIER achieving CDC at 1 year (32%, n/N=87/268). Significant differences between treatment groups in DE019 and PREMIER were still apparent when the disease activity component was replaced by DAS28(CRP) remission (<2.6).

Table. Attainment of Individual and Composite Criteria for Comprehensive Disease Control (CDC) Following 1 Year of Treatment With ADA + MTX or MTX Alone

Study	DE019		OPTIMA	PREMIER	
Outcome	ADA + MTX (N = 207)	PBO + MTX (N = 200)	Rescue ADA (N = 348)	ADA + MTX (N = 268)	MTX (N = 257)
DAS28 (CRP)[a], n (%)					
<3.2 (LDA)	100(48)	29 (15)***	209 (60)	171 (64)	91 (35)***
<2.6 (remission)	56 (27)	12 (6)***	154 (44)	125 (47)	56 (22)***
HAQ-DI <0.5[a], n (%)	77 (37)	35 (18)***	136 (39)	157 (59)	99 (39)***
ΔmTSS ≤0.5[b], n (%)	164 (79)	116 (58)***	287 (82)	169 (63)	89 (35)***
CDC[c], n (%)					
LDA	40 (19)	10 (5)***	102 (29)	87 (32)	29 (11)***
remission	28 (14)	5 (3)***	82 (24)	67 (25)	22 (9)***

[a]Last observation carried forward.
[b]Linear extrapolation, with nonresponder imputation for patients with no data.
[c]Comprehensive disease control, the simultaneous attainment of LDA [DAS28(CRP) <3.2] or remission [DAS28(CRP)<2.6], normal function (HAQ-DI <0.5), and no radiographic progression (ΔmTSS ≤0.5).
***$P < .001$ for differences between initial treatments from chi-square; no comparisons were made with the Rescue ADAgroup from OPTIMA.
ADA, adalimumab; MTX, methotrexate; PBO, placebo; DAS28 (CRP), 28-joint disease activity score with C-reactive protein; LDA, low disease activity; HAQ-DI, disability index of the health assessment questionnaire; ΔmTSS, change in modified total Sharp score.

Conclusion: CDC appears to be a realistic treatment goal in RA. Treatment with the combination of ADA+MTX led to significantly higher rates of CDC following 1 year than treatment with MTX alone, and earlier treatment appeared to increase the likelihood of CDC. A targeted treatment approach aiming at stable LDA at 6 months enabled MTX-IR who received OL ADA+MTX for an additional 1 year to achieve CDC in a proportion that was comparable with MTX-naïve early RA pts initiated with ADA+MTX, underscoring the utility of treat-to-target approaches in maximizing long-term outcomes.

1304

Long-Term Use of Adalimumab As Monotherapy Following Attainment of Low Disease Activity with Adalimumab Plus Methotrexate. Edward C. Keystone[1], Ferdinand C. Breedveld[2], Hartmut Kupper[3], Shufang Liu[4] and Stefan Florentinus[5]. [1]University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Abbott GmbH and Co. KG, Ludwigshafen, Germany, [4]Abbott, Abbott Park, IL, [5]Abbott, Rungis, France

Background/Purpose: There has been increased interest in understanding whether biologics can be safely withdrawn from patients (pts) receiving combination therapy with MTX once a clinical target has been achieved. The ability of the biologic to maintain the target as monotherapy following MTX withdrawal has received less consideration. The purpose of this analysis was to evaluate long-term clinical, functional, and radiographic outcomes in pts

treated with open-label (OL) adalimumab (ADA) as monotherapy following attainment of low disease activity (LDA) with ADA+MTX.

Methods: PREMIER was a 2-year (yr), phase 3, randomized, controlled trial (RCT) in MTX-naïve pts with early RA who were randomized to MTX, ADA, or ADA+MTX.[1] Pts completing the RCT were eligible to receive OL ADA for up to an additional 8 yrs (this trial is ongoing); MTX could be added at the investigator's discretion. This post hoc analysis included data from pts treated with ADA+MTX during the RCT who reached at least an LDA state [defined as DAS28(CRP) <3.2] at Yr 2 (ie, the end of the RCT) and received OL ADA as monotherapy up to Yr 5. The percentages of pts remaining in LDA or with normal function (HAQ-DI <0.5) at Yr 5 were summarized using non-responder imputation based on the population entering the OL period and as observed for pts with data available at Yr 5. Mean ΔmTSS and the proportion without radiographic progression (ΔmTSS ≤0.5) from Yrs 2–5 were summarized as observed. Conditional logistic regression analysis based on propensity score matching was used to identify variables significantly associated with MTX use.

Results: Of the 183 ADA+MTX-treated pts who enrolled in the OL extension, 140 (83%) reached an LDA state at Yr 2. Among the LDA responders, 84 (60%) received ADA as monotherapy during the OL period, and 56 (40%) reinitiated MTX during the OL extension (time to 1st MTX use: mean/median=28/5 weeks). Higher physician's global assessment appeared to predict MTX use during the OL extension (P <.01). A total of 60 pts (75%) completed 3 yrs of OL ADA monotherapy. Adverse events were the most frequently cited reason for study discontinuation (n=9); no pt withdrew citing loss of efficacy. The majority of pts retained LDA at Yr 5 with ADA monotherapy (63%; **Table**); 50% of the 84 pts were in DAS28(CRP) remission and 58% had normal function at Yr 5. Of the pts with Yr 5 data available, 88% were in LDA. Further, OL ADA monotherapy was associated with clinically insignificant radiographic progression for pts completing Yr 5 (mean annual mTSS progression rate from Yrs 2–5 =0.5 units/yr).

Table. Year 5 Outcomes for Year-2 LDA Responders Who Received Up to 3 Years of Treatment With Open-label ADA Monotherapy

Assessment Parameter	OL ADA Monotherapy	
	Non-responder imputation[a]	Observed
DAS28(CRP), mean ± SD	N/A	2.3 ± 0.9
DAS28 (CRP) <3.2, % (n/N)	63 (53/84)	88 (53/60)
HAQ-DI, mean ± SD	N/A	0.3 ± 0.5
HAQ-DI <0.5, % (n/N)	58 (49/84)	78 (49/63)
ΔmTSS, mean ± SD	N/A	1.5 ± 5.6
ΔmTSS ≤0.5, % (n/N)	50 (42/84)	72 (42/58)

[a]Patients with missing data at the Yr 5 assessment were imputed as non-responders.
LDA, low disease activity; ADA, adalimumab; OL, open-label; DAS28(CRP), 28-joint disease activity score with C- reactive protein; SD, standard deviation; N/A, not applicable; HAQ-DI, disability index of the health assessment questionnaire; ΔmTSS, change in modified total Sharp score from Year 2.

Conclusion: Following attainment of an LDA state at Yr 2 with ADA+MTX combination therapy, treatment with OL ADA as monotherapy for 3 yrs was sufficient for most pts to retain LDA and have minimal radiographic progression. Thus, MTX withdrawal appears possible for some pts whose disease activity is responsive to ADA monotherapy.

1305

Three-Year Follow-up of Rituximab in Rheumatoid Arthritis: Results From the Belgian MIRA (MabThera in Rheumatoid Arthritis) Registry.
Filip De Keyser[1], Patrick Durez[2], Rene Westhovens[3], marie-Joelle Kaiser[4] and Ilse Hoffman[5]. [1]Universitair Ziekenhuis Gent, Gent, Belgium, [2]Université Catholique de Louvain, Brussels, Belgium, [3]University Hospital KU Leuven, Leuven, Belgium, [4]Dept Rheumatology, University Hospital Liege, Belgium, Belgium, [5]Dept Rheumatology, GZA St-Augustinus Hospital Antwerp, Belgium

Background/Purpose: The MIRA registry was set up to collect safety, efficacy and (re)treatment practice data for Belgian RA patients treated with rituximab.

Methods: All rheumatologists from Belgium and Luxemburg were invited to participate in the study. Patient demographics were collected at baseline. Follow-up data included disease activity measures, attrition and reasons for discontinuation. Evolution of disease activity is reported here for the subpopulation followed for at least 3 years. Data are presented as mean±standard error (SE) or as percentages. Data analysis was performed with SPSS 20.0 software.

Results: The MIRA registry includes 649 patients (treated by 80 rheumatologists in 52 centers), who started rituximab therapy between November 2006 and October 2011. The study population consisted for 75% of females; 55.3% were RF positive and 33.9% anti-CCP positive. Patients starting rituximab were on average 57.4±0.5 years old with a mean disease duration of 12.8±0.4 years. Patients received on average 2.82±0.07 (range 1–9) rituximab treatments, over a median follow up time of 82 weeks (range 0–254 weeks). At database lock, 433 patients (66.72%) were still on rituximab treatment, 182 (28.04%) had stopped, and 34 patients (5.24%) were lost to follow up.

Over the study period, a clear evolution was observed in the baseline characteristics of patients starting rituximab treatment. The number of previously failed anti-TNF drugs used before starting rituximab significantly decreased over time (chi-square p<0.001). In 2006, 50.0 % of patients had previously been treated with more than one anti-TNF, whereas in 2011 only 33.4% of patients had received more than one anti-TNF before switching to rituximab. In parallel, the DAS28 values at baseline significantly decreased, from 6.31±0.59 in 2006 to 5.65±0.17 in 2011 (ANOVA, p<0.001).

Evolution of disease activity was analysed in a subset of 139 patients who were followed for at least 3 years. DAS28 showed significant changes over the study period (ANOVA, p<0.001), declining in the first 8 weeks after rituximab treatment, and stabilising afterwards. DAS28 in this subgroup with 3-year follow-up at weeks 0, 8, 52, 104 and 156 respectively were 6,16±0.09, 4.47±0.45, 3.79±0.18, 3.85±0.29 and 3.58±0.42.

Conclusion: Data from the MIRA registry shows that over the last 5 years, less alternative anti-TNF treatments were used in Belgium before switching RA patients to rituximab. Additionally, rituximab treatment tended to be started in patients with lower disease activity. Furthermore, this clinical practice study demonstrates that rituximab treatment results in adequate long-term disease control.

1306

How well Do Patients with Rheumatoid and Psoriatic Arthritis Tolerate Methotrexate? A Retrospective Review of Discontinuation Data From a Large UK Cohort.
Calum T. Goudie[1], John D. Fitzpatrick[1], Anshuman P. Malaviya[2] and Andrew J. Ostor[2]. [1]University of Cambridge Medical School, Cambridge, United Kingdom, [2]Addenbrooke's Hospital, Cambridge, United Kingdom

Background/Purpose: Due to its efficacy and safety, methotrexate (MTX) has become the first-line disease-modifying drug for rheumatoid (RA) and psoriatic arthritis (PsA). Although deemed safe, few studies have analysed MTX tolerability. The objective of our study was to ascertain the proportion of RA and PsA patients that discontinue MTX and the reasons for this.

Methods: A retrospective review of the Rheumatology departments electronic database was undertaken to identify all patients who had received MTX for RA or PsA. This was followed by review of both the electronic and paper records to identify patients in whom MTX had been discontinued. The reasons for this were then classified into several categories. Every effort was made to ensure that the correct reasons for drug withdrawal were documented. Discrepancies were discussed with a senior member of the team. Cases with insufficient data were excluded from the final analysis.

Results: 1257 patients on MTX were identified. Of these 762 had RA and 193 had PsA. MTX had been stopped in 260 patients with RA and 71 patients with PsA. In RA patients, the mean dose at the time of discontinuation of MTX was 14.1mg/week (dose range 5–30mg, SD 5.6mg) and in PsA patients 13.6mg/week (dose range 5–25mg, SD 5.0mg) (missing data in 80 and 26 patients respectively). The reasons for discontinuation and differences between the rheumatoid and psoriatic arthritis groups are highlighted in Table 1 & 2. Our data suggests that about a third of patients with RA and PsA eventually stop methotrexate, most of whom cite intolerance as a reason. In addition a statistically significant difference between the RA and PsA cohorts was seen, with abnormalities in blood counts (leucopenia and thrombocyto-

penia) being reported more frequently in RA patients (11.5% vs 6.8%; p<0.05) and more PsA patients having liver enzyme abnormalities (27% vs 12%; p<0.05).

Table 1. Reasons for methotrexate discontinuation in patients with RA and PsA

Reason for discontinuation	RA (% of all withdrawals)	PsA (% of all withdrawals)	p-value (X^2-test)
Adverse events	200 (77.5)	44 (62.0)	0.4430
Ineffective	32 (12.4)	13 (18.3)	0.2061
No longer indicated	17 (6.6)	1 (1.4)	–
Patient choice	13(5.0)	10 (14.1)	0.0117
No reason stated	14 (5.4)	6 (8.5)	0.4168

Table 2. Side-effects leading to methotrexate discontinuation

	RA (% of all withdrawals) n=260	PSA (% of all withdrawals) n=71	p-value (X^2-test)
All gastrointestinal symptoms	65 (32.5)	12 (27.3)	0.93
Nausea	41 (20.5)	7 (15.9)	
Oral ulceration	12 (6.0)	1 (2.3)	
Diarrhoea	6 (3.0)	3 (6.8)	
Vomiting	4 (2.0)	2 (4.5)	
Abdominal pain	2 (1.0)	3 (6.8)

Alopecia	2 (1.0)	1 (2.3)	
Miscellaneous AEs	7 (3.5)	6 (13.6)	
Non-specific intolerance	19 (9.5)	5 (11.4)	

Conclusion: Our data demonstrates that although MTX is safe, it is not well tolerated. The differences between MTX tolerability in RA and PsA is likely to be disease rather than therapy specific. We were unable to characterise patients who suffer from side-effects but continue therapy. Thus, the magnitude of the problem is likely to be substantially greater. Poor tolerability is also likely to impact on adherence and in these patients biologic therapy may be indicated.

1307

Anti-IL-6 Receptor Nanobody (ALX-0061) Seamless "First-in-Human" Phase I/II POC Study in Patients with Active RA On Stable MTX Treatment.
Steven De Bruyn[1], Béla Gachályi[2], Bernadette Rojkovich[3], Slavomir Bruk[4], Petr Sramek[5], Mariusz Korkosz[6], Krzysztof Krause[7], Pieter Schoen[1], Laura Sargentini-Maier[1], Joke D'Artois[1], Katrien Verschueren[1], Katelijne De Swert[1], Gerhard Arold[8] and Josefin-Beate Holz[1]. [1]Ablynx N.V., Zwijnaarde, Belgium, [2]Péterfy Sándor Utcai Kórház, Budapest, Hungary, [3]Budai Irgalmasrendi Kórház Kht., Budapest, Hungary, [4]Nemocnice Trinec, Trinec, Czech Republic, [5]Pharmaceutical Research Associates CZ, Praha, Czech Republic, [6]Szpital Uniwersytecki w Krakowie, Krakow, Poland, [7]Wojewodzki Szpital, Wroclaw, Poland, [8]PRA International GmbH, Berlin, Germany

Background/Purpose: ALX-0061 is a 26kD bispecific IL-6R targeting Nanobody® with monovalent binding to IL-6R and serum albumin. It effectively neutralizes IL-6 pathway activity in-*vitro* and in-*vivo*. Translational studies (PK/PD modelling) resulted in a novel FIM design combining single ascending dose (SAD), multiple ascending dose (MAD) and clinical POC using PK, biomarker and early clinical read-outs as decision tools.

Methods: Multicentre (6 sites in CEE), randomized, double-blind, placebo (PLC) controlled, dose escalation, Phase I/II study in patients with active RA on stable MTX therapy. Five treatment groups are tested in the SAD part and primary objectives are safety and tolerability of single ascending doses, MTD and/or biological effective doses (BED). Following SAD completion, an interim PK/PD analysis was performed to confirm the adequacy of the anticipated dosing regimen in MAD. Monthly or bi-monthly doses of ALX-0061 up to 12 and 24 weeks are tested in MAD with roll-over of PLC subjects after 12 weeks interim efficacy assessment to enrich the safety and efficacy population of ALX-0061. Biological and clinical efficacy is assessed with PK/PD, radiographic (MRI) and clinical scores at 12 weeks and end of study and correlated with pre-clinical modelling and literature data on IL-6R pathway inhibition.

Results: 28 patients with active RA were included in the SAD part and received single injections of 0.3mg/kg (2 pat), 1mg/kg (6 pat), 3mg/kg (6 pat), 6mg/kg (6 pat) and PLC (8 pat). Average age (52y) and BMI (25.6) were balanced between the groups; compared with PLC group, patients in ALX-0061 arm had higher disease activity (ACR Class II/III 85% vs 62.5%; DAS high disease activity 45% vs 12.5%). Safety: ALX-0061 was well tolerated. One subject reported an acute hypersensitivity event, no further SAEs were reported and no DLT occurred. The MTD was not reached. No clear increase in frequency or severity of AEs with increased doses of ALX-0061 observed. PK: Serum ALX-0061 concentrations and corresponding drug exposure increased with escalated dose. PD: CRP, ESR, fibrinogen and serum amyloid A showed rapid and marked decrease with highest effect observed at highest dose levels (3 and 6mg/kg). IL-6 and sIL-6R plasma concentrations increased with dose, representing a marker to monitor the biological effect of ALX-0061 on its target. Clinical effect: Following single injection, 16 ALX-0061 subjects (80%) and 3 PLC subjects (37.5%) achieved moderate/good EULAR response at 2 months. 10 ALX-0061 subjects (50%) achieved LDA (6 pat) or DAS28 remission (4 pat), 2 PLC subjects (25%) achieved LDA (1 pat) or DAS28 remission (1pat). Based on PK/PD modelling, three dose levels were selected for the MAD: 1 mg/kg Q4W, 3 mg/kg Q4W and 6 mg/kg Q8W. 36 patients are treated in MAD part and completion is expected before end of 2012.

Conclusion: Single injections of ALX-0061 were well tolerated at BED. The pre-clinical PK/PD modelling was confirmed and dose-dependent changes of early inflammation biomarkers were consistent with inhibition of the IL-6 pathway. The MAD study part will further assess early effect of ALX-0061 on disease activity with radiographic and clinical disease score evaluations.

[1]Strasbourg University Hospital, Strasbourg, France, [2]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [3]Hôpital Lariboisière, Paris, France, [4]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [5]Place du Docteur Baylac, Toulouse, France, [6]Hopital Lapeyronie, Montpellier, France, [7]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [8]Hopital R Salengro CHRU, Lille CEDEX, France, [9]Service de médecine interne, Université Paris Est Créteil, AP-HP, Hôpital Mondor Créteil, France, Creteil, France, [10]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [11]CHU de ROUEN, Rouen, France, [12]Department of Internal Medicine, Claude Huriez Hospital, University of Lille, Lille CEDEX, France, [13]Groupe Hospitalier Pellegrin, Bordeaux, France, [14]CHU Hautepierre, Strasbourg, France, [15]Hotel Dieu University Hospital Paris, France, [16]Strasbourg, France, [17]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: Therapy with biological agents may be associated with opportunistic infections (OIs). Data on the occurrence of OIs in patients with RA treated with rituximab (RTX) are limited.
Objective: To describe the spectrum of OIs associated with RTX therapy.
Methods: The AutoImmunity and Rituximab (AIR) registry was set up by the French Society of Rheumatology. Patients are followed up every 6

months during 7 years. Data regarding serious infections are validated by the 2 coordinators of the study using chart copies.

Results: 1975 patients had already had at least 1 follow-up visit. The follow-up was 4937 patient/years on January 1st, 13 OIs occurred (0.3 OIs/100 patient years). 23.0% of OIs were due to intra-cellular bacterial (1 tuberculosis, 1 atypical mycobacteriosis, 1 non-typhoid salmonellosis), 38.6% were viral (2 severe herpes zoster, 1 varicella, 2 disseminated cytomegalovirus infections), 30.8% were fungal (2 pneumocystosis, 1 echinococcosis, 1 Scedosporium infection) and 7.6% were parasitic (1 disseminated scabies). 1 patient required admission to the intensive care unit and died from herpetic hepatitis.

Conclusion: Even in real life patients, the risk of tuberculosis remains very low in patients treated with RTX in Western Europe. However, some various and serious OIs, especially those with intracellular micro-organisms, may unfrequently develop in patients receiving RTX. This risk requires to be reevaluated with a longer follow-up.

1309

Predictive Risk Factors of Serious Infections in RA Patients Treated with Abatacept in Real Life: Results in the Orencia and Rheumatoid Arthritis (ORA) Registry. Jacques-Eric Gottenberg[1], Philippe Ravaud[2], Alain G. Cantagrel[3], Bernard Combe[4], René-Marc Flipo[5], Thierry Schaeverbeke[6], Eric Houvenagel[7], Philippe Gaudin[8], Damien Loeuille[9], Stephanie Rist[10], Maxime Dougados[11], Jean Sibilia[12], Xavier Le Loet[13], Christian Marcelli[14], Thomas Bardin[15], Isabelle Pane[16], Elodie Perrodeau[17], Gabriel Baron[18] and Xavier Mariette[19]. [1]Strasbourg University Hospital, Strasbourg, France, [2]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [3]Place du Docteur Baylac, Toulouse, France, [4]Hopital Lapeyronie, Montpellier, France, [5]Rheumatology Department, Lille University Hospital, Lille, France, [6]Groupe Hospitalier Pellegrin, Bordeaux, France, [7]St Philibert Hospital, Lomme 59462, France, [8]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [9]CHU Brabois, Vandoeuvre les Nancy, France, [10]Hospital University Orléans, France, [11]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [12]CHU Hautepierre, Strasbourg, France, [13]CHU de ROUEN, Rouen, France, [14]Rheumatology Department, Caen University Hospital, [15]Hôpital Lariboisière, Paris, France, [16]Hotel Dieu University Hospital Paris, France, [17]Epidemiologist, Paris, France, [18]Epidemiology, Paris, France, [19]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: Little data is available regarding the rate and predicting factors of serious infections in patients with rheumatoid arthritis treated with abatacept (ABA) in daily practice. We therefore addressed this issue using real-life data from the Orencia and Rheumatoid Arthritis (ORA) registry.

Methods: ORA is an independent registry promoted by the French Society of Rheumatology which includes RA patients treated with abatacept. At baseline, 3, 6 months and every 6 months or at disease relapse, during 5 years, standardized information are prospectively collected by trained clinical nurses in each center. Central reviewing of charts of patients with SAEs is performed by the two coordinators of the study.

Results:

–Baseline characteristics and comorbidities

1032 patients (79.1% of women) were included in the ORA registry. Median age of patients was 58 years and median disease duration was 15 years. 5.8% of patients had a history of cancer, 34.6% a record of serious infection, and 11.8% had diabetes. 12.9% of patient had not received any anti-TNF prior to ABA. 29.8% of patients had previously received rituximab.

–Rate of serious infections

Among the 977 patients with a follow-up of at least 3 months (median follow-up of 1766 patient-years (PY)), 118 serious infections occurred in 99 patients during treatment with ABA (64 infections) and/or within the 6 months following ABA discontinuation (54 infections). Thus, 6.7 serious infections/100 PY were observed (3.6/100 PY during treatment with ABA and 3.1/100 PY within the 6 months following discontinuation of ABA).

–Predicting factors of severe infections

On univariate analysis, an older age, record of previous serious or recurrent infections, diabetes, chronic lung disease, a lower number of previous anti-TNF, and a higher corticosteroid dosage at initiation of ABA were associated with a higher risk of serious infections. Disease duration, previous treatment with rituximab, concomitant treatment with a synthetic DMARD, disease activity were not significantly associated with an increased risk of serious infections. On

multivariate analysis, only age (OR 1.5 CI95% [1.2–1.7], P<0.001) and record of previous serious or recurrent infections (2.2 [1.5–3.5], P< 0.001) were significantly associated with a higher risk of serious infections.

Conclusion: In ORA registry, severe infections in patients treated with abatacept were slightly more frequent than in clinical trials. This might be related to the fact that a high proportion of patients with comorbidities, who would have been excluded from controlled trials, are treated with ABA in real life. Characteristics of RA (duration, previous treatments including anti-TNF or rituximab, disease activity) were not associated with serious infections. Predictive risk factors of serious infections in patients treated for RA with ABA in common practice included age and previous record of serious infections.

1310

Analysis of Anti-JC Polyomavirus T-Cell Immune Response with JC-Feron in Patients with Rheumatoid Arthritis Treated with Rituximab or Anti-TNF. Raphaèle Seror[1], Houria Chavez[2], anne-Aurélie Mazet[1], Jeremie Sellam[3], Bruno Fautrel[4], Maxime Dougados[5], Yassine Taoufik[2] and Xavier Mariette[6]. [1]Bicetre university hospital, LE Kremlin-Bicetre, France, [2]Hopital Bicetre, Université Paris Sud, AP-HP, France, [3]Hopital Saint-Antoine, Pierre et Marie Curie University Paris 6, AP-HP, 75012, France, [4]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [5]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [6]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: Some cases of progressive multifocal leukoencephalopathy (PML) have been described in patients with autoimmune diseases with profound immunosuppression, due to replication of JC polyomavirus within the CNS. Biologics such as natalizumab and efalzimab have been clearly associated with an increased risk of PML. Rare cases of PML have also been described in patients treated with rituximab (RTX), without any idea of the mechanisms which could support this association. Our objectives were to analyze JC viral load and anti-JC T-cell response in rheumatoid arthritis (RA) patients treated with RTX or anti-TNF.

Methods: In four French rheumatology departments, RA patients starting a new biological therapy with either RTX or anti-TNF were recruited to participate in this prospective study. All patients were screened at baseline, 3 to 6 months and 12 to 18 months after the beginning of biologic therapy during for JC tests, including urine, PBMC and plasma viral load (with quantitative PCR method) and specific IFN-g Elispot for JC (Elipsot was performed after overnight activation of T cells with purified JCV). It was planned to include half of patients treated with RTX and half with anti-TNF, and to compare evolution of anti-JCV T cell response and JC viral load between these 2 groups.

Results: Between February 2010 and January 2011, 42 patients were included: 19 received RTX and 23 anti-TNF (etanercept n= 15; adalimumab n=3; infliximab n=4; golimumab n=1). At baseline and during the whole follow-up, all patients had negative PBMC and plasma viral load, 19/42 (45.2%) had positive and stable urine viral load. At baseline, 5 patients had positive JCV Elispot, 2 before anti-TNF and 3 before RTX, 2 out of these 5 patients having also positive urine viral load, one in each group. To assess reproducibility of the JCV Elispot, at baseline 4 patients had been tested twice a few days apart, results were similar (3 had negative and one had positive results).

38/42 patients had a follow-up visit. The evolution of JCV Elispot is reported the table. Overall, 9 patients had a positive JCV Elispot once, 5 at baseline, 2 after RTX and 2 after anti-TNF during the follow-up, including 3 who with positive urine viral load, which remained positive during the whole follow-up.

Table. Evolution of JC-feron positive patients

Treatment	Evolution		JC virus IFNγ Elispot			
			Baseline	4–6 months	9–18 months	Urine JC viral load
Rituximab	Positive to negative	Patient 1	Positive	ND	Negative	Positive (6 log)
		Patient 2	Positive	Negative	Negative	Negative
		Patient 3	Positive	Positive	Negative	Positive (6 log)
	Negative to positive	Patient 4	Negative	Negative	Positive	Negative
		Patient 5	Negative	Positive	Negative	Negative
Anti-TNF	Positive to negative	Patient 6	Positive	ND	Negative	Negative
	Negative to positive	Patient 7	Negative	Negative	Positive	Negative
		Patient 8	Negative	Positive	ND	Positive (1.3 log)
	Always positive	Patient 9	Positive	Positive	Positive	Negative

Conclusion: The presence of anti-JCV T cell response has been found positive at least once in 9/42 (21%) of patients with RA treated with anti TNF or rituximab without any link with the use of one or the other type of biologics. These results suggest that in patients chronically infected with JC virus with long duration RA treated or not with biologics, transient reactivation of JC may occur leading to T-cell response Our data do not support a link with RTX or anti-TNF use. Long term follow up in larger cohorts of patients is necessary for indicating if a positive JCV Elispot could be predictive of further central neurological complication of JC virus.

1311

A Novel Individualized Treatment Approach in Open-Label Extension Study of Ozoralizumab (ATN-103) in Subjects with Rheumatoid Arthritis On a Background of Methotrexate. Roy M. Fleischmann[1], Steven De Bruyn[2], Christian Duby[2], Katrien Verschueren[2], Judith Baumeister[2], Laura Sargentini-Maier[2], Cedric Ververken[2] and Josefin-Beate Holz[2]. [1]University of Texas, Dallas, TX, [2]Ablynx N.V., Zwijnaarde, Belgium

Background/Purpose: Ozoralizumab (ATN-103), a novel TNFα inhibitor, is a trivalent, bispecific Nanobody® that potently neutralises TNF and binds to human serum albumin to increase its in vivo half-life. 2 singe ascending dose (SAD)/multiple ascending dose (MAD) studies in 313 patients (world-wide and Japan) with active RA on stable MTX background evaluated ozoralizumab's clinical activity and safety during 12 weeks of treatment. The 80mg Q4W dosing regimen significantly improved disease activity measures compared with placebo. Patients completing the MAD trials were allowed to enrol in this 48-week open-label extension (OLE) study to evaluate the long-term safety and tolerability of ATN-103. An innovative dosing concept with individual dose escalation from 10mg to max. 80mg during first 12 weeks of treatment was tested in this OLE.

Methods: Study start was defined as completion of 20-week follow-up visit in the MAD trials. Individualized dosing regimen was introduced with all patients starting on active treatment at 10mg SC monthly. Subsequently, dose escalation to 30mg and 80mg monthly SC was dependent on patient's CDAI and safety. Primary objective was long-term safety and tolerability of ATN-103. Efficacy measures, as well as PK/PD, were included as exploratory endpoints.

Results: 266/313 pat (85%) enrolled in the OLE. Baseline mean age was 52y, 80% female, DAS 6.11 and CDAI 42. Dropout rate was low with 13% and 231/266 pat completed the study. 93% of pat reached individual final dose at or before week 12, 56% completed at 80 mg, 29% at 30mg and 15% remained on the starting dose of 10mg. Safety: Treatment was well tolerated, most common AEs were infections (37.6%) with serious events in 3/100 pat years. Efficacy: At study endpoint, ACR20, 50 and 70 scores were 84%, 63% and 32% respectively; 38% had DAS28_CRP <2.6; 132/230 pat (57%) had low or no disease activity; EULAR good/moderate response rate was 97% with rapid and marked improvement of pain (47%) and morning stiffness (90%). 7/266 pat tested positive for neutralizing anti-drug antibodies (nADA) at any time during trial, all completed the study and 57% (4/7) had DAS28 <2.6. 0.75% of patients remained positive for nADA at end of study without effect on patient's safety or ability to achieve remission or improvement of disease activity.

Conclusion: The novel anti-TNFα inhibitor ATN-103 enabled highly effective and well-tolerated individualized treatment. Specific molecular features of Nanobodies (small size, low immunogenicity potential, manufacturability) contributed to the desired treatment outcome with the majority of patients showing marked improvement in their disease activity and, moreover, once induced remission could be maintained at doses less than 80mg monthly. This treatment approach could prove beneficial to patients and minimize treatment costs.

1312

Clinical Response At 12 Weeks Predicts Long-Term Remission and the Extent of Radiographic Progression in Japanese Patients with Rheumatoid Arthritis Treated with Certolizumab Pegol with and without Methotrexate Coadministration. Tsutomu Takeuchi[1], Kazuhiko Yamamoto[2], Hisashi Yamanaka[3], Naoki Ishiguro[4], Yoshiya Tanaka[5], Katsumi Eguchi[6], Akira Watanabe[7], Hideki Origasa[8], Toshiharu Shoji[9], Nobuyuki Miyasaka[10] and Takao Koike[11]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [5]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [6]Sasebo City General Hospital, Sasebo, Nagasaki, Japan, [7]Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi, Japan, [8]University of Toyama School of Medicine, Toyama, Toyama, Japan, [9]Otsuka Pharmaceutical Co., Ltd, Shinagawa-ku, Tokyo, Japan, [10]Tokyo Medical and Dental University, Tokyo, Japan, [11]Sapporo medical center NTT EC, Sapporo, Japan

Background/Purpose: The majority of patients (pts) with active rheumatoid arthritis (RA) have previously been shown to respond during the first 12 weeks (wks) of certolizumab pegol (CZP) treatment; additionally, a lack of DAS28 improvement by Wk12 predicts failure to achieve low disease activity (LDA) at later timepoints.[1] This post hoc analysis investigated whether the magnitude of DAS28(ESR) nonresponse to CZP at Wk12 of therapy can predict the likelihood of achieving remission (DAS28(ESR)<2.6) and extent of radiographic progression after 1 year (yr) (52–56 wks) of CZP treatment in Japanese pts receiving coadministered MTX (JRAPID, NCT00851318), DMARDs other than MTX or CZP monotherapy (HIKARI, NCT00850343).

Methods: Both studies included a 24 Wk double blind phase (CZP 400mg Wks 0, 2, 4, then CZP 200mg every other week (Q2W)), followed by open-label treatment for 28 Wks with CZP 200mg Q2W or CZP 400mg every 4 wks (Q4W). The mean change in mTSS and the proportion of pts who achieved remission at 1 yr was assessed according to the level of DAS28 response (ie, DAS28(ESR) change from baseline [CFB] ≥0.6 and ≥1.2 units) at Wk12. Last observation carried forward (LOCF) imputation was used for pts who withdrew.

Results: 82 J-RAPID and 116 HIKARI CZP treated pts were included. J-RAPID and HIKARI pts had a mean baseline DAS28(ESR) of 6.19 and 6.09, and mean mTSS total of 50.4 and 36.5, respectively. Overall, 77% of J-RAPID pts and 74% of HIKARI pts had a ≥1.2 DAS28(ESR) response at Wk12. Remission was achieved by 32.9% and 27.6% of the original J-RAPID and HIKARI CZP ITT populations at 1 yr. Pts who did not achieve a DAS28(ESR) change of ≥1.2 at Wk12, had a <7% chance of achieving remission at Wk52 (Table) and had greater radiographic progression at 1 yr than responders. Failure to achieve remission at 1 yr and the extent of radiographic progression was also dependent on the magnitude of DAS28(ESR) change at Wk12. Pts with a DAS28(ESR) response of <0.6 had a lower rate of remission and greater radiographic progression at 1 yr compared to pts with a DAS28(ESR) response of <1.2 (Table). Similar results were observed in both the J-RAPID and HIKARI populations.

Table. Wk 12 response predicts remission rate and mean mTSS total score change after 1 year

Change in DAS28 (ESR) at Wk 12	J-RAPID CZP 200 mg Q2W + MTX (N = 82)				HIKARI CZP 200 mg Q2W (N = 116)			
	N	DAS28 (ESR) remission rate n (%)	N	Mean change in mTSS total score	N	DAS28 (ESR) remission rate n (%)	N	Mean change in mTSS total score
<0.6	10	0 (0)	10	4.20	13	0 (0)	12	3.46
≥0.6	72	27 (37.5)	71	0.26	103	32 (31.1)	102	1.39
<1.2	19	1 (5.3)	19	2.23	30	2 (6.7)	28	2.79
≥1.2	63	26 (41.3)	62	0.29	86	30 (34.9)	86	1.23

Conclusion: The majority of Japanese pts responded to treatment with CZP at Wk12 in the broad pt population represented by these studies.

Likelihood of remission and extent of radiographic progression after 1 year could be predicted at Wk12 based on the magnitude of change in DAS28(ESR) in pts.

Background/Purpose: Data regarding tolerance of biologics in patients with a history of cancer are very limited. We therefore analyzed tolerance of rituximab (RTX) in patients with a history of cancer included in the AIR ("Autoimmunity and Rituximab") registry.

Methods: The French Society of Rheumatology has set up a nationwide prospective 7-year registry, AIR to investigate the long-term safety and efficacy in real life of RTX.

Results: Among the 2000 patients enrolled, 272 patients (13.6%) treated with RTX had a history of cancer prior to RTX. 33% of them had a history of breast cancer with a median duration of 6 years, 15% of skin cancer (6% melanoma), 14% of lymphoma, 7% a prostate cancer, 6% an uterus cancer, 5% a colorectal cancer, 3% a thyroid cancer and 17% another cancer (kidney, bladder, lung, blood malignancies, brain). The main baseline characteristics of these patients (disease duration 15 years, record of serious or recurrent infections: 35.2%, proportion of patients treated without a concomitant synthetic DMARD:38.2%) were comparable to those of patients without a history of cancer, except an older age (63 vs 58 years), a higher proportion of patients without anti-TNF prior to RTX (55% vs 83%) and a lower disease activity (median DAS28: 5.2 vs 5.6). The median time between the diagnosis of cancer and the first infusion was 4 [0–46] years. 270 patients with a history of cancer had at least 1 follow-up visit respectively, with a median follow-up period of 2.8 years (756 patient/years) and 1709 patients without a history of cancer had a follow-up visit with a median follow-up of 2.8 years (4785 patient/years).

–Cancers: Among the patients with a history of cancer, 20 patients had a recurrence of cancer or a second cancer (2.6 cancers/100 patient/years). 13 (5%, 1.7/100 patient/years) developed metastases or recurrence of their previous cancer (breast: 3, colon: 1, liver: 2, lung: 2, myeloma: 1, skin: 1, uterus: 1, bladder: 1, kidney: 1) and 7 (2.6%, 0.9 cancer/100 PY).) developed a new cancer (skin: 3, bladder: 2, colon: 1, pancreas: 1). Among the patients without a history of cancer, 43 cancers (0.9 cancer/100 patient/years) (skin: 10, breast: 6, lung: 5, prostate: 4, others: 18) occurred after a median duration of 22 months after the 1st RTX infusion.

–Serious infections: 25 and 214 patients with/without history of cancer had a serious infection (3.3 and 4.5 serious infections/100 patient/years, respectively).

–Deaths: 15 and 64 patients with/without history of cancer died (1.9 and 1.3 deaths/100 patient/years, respectively).

Conclusion: RTX is often used in common practice in patients with history of cancer, although data are limited except for lymphomas. After nearly 3 years of follow-up, overall safety of RTX seems comparable in patients with or without history of cancer. The risk of a new cancer is the same than in patients without any previous cancer. The risk of cancer recurrence is difficult to evaluate in the absence of a control group of RA patients with cancers of matched histology, severity and duration, non-treated with RTX. Collaboration between registries might help to address this issue.

Validation of Algorithms Using Genome-Wide SNP Analysis for Prediction of Remission or Low Disease Activity for Infliximab or Etanercept-Treated RA Patients. Tsukasa Matsubara[1], Satoru Koyano[2], Keiko Funahashi[2], James E. Middleton[2], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Akira Sagawa[3], Takeo Sakurai[4], Hiroaki Matsuno[5], Tomomaro Izumihara[6], Eisuke Shono[7], Kou Katayama[8], Toyomitsu Tsuchida[9], Mitsuyoshi Iwahashi[10], Tomomi Tsuru[11] and Motohiro Oribe[12]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [4]Inoue Hospital, Takasaki, Japan, [5]Toyama, Japan, [6]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [7]Shono Rheumatology Clinic, Fukuoka, Japan, [8]Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan, [9]Tsuchida Clinic, Chiba, Japan, [10]Higashi-Hiroshima Memorial Hospital, Higashi-hiroshima, Japan, [11]PS Clinic, Fukuoka, Japan, [12]Oribe Rheumatism and Internal Medicine Clinic, Oita, Japan

Background/Purpose: Achievement of remission or low disease activity with infliximab (IFX) and etanercept (ETN) treatment is currently one of the most important matters in RA treatment. However, there is no method for prediction of remission or low disease activity. Previously, we established and validated SNP algorithms for prediction of remission or non-remission among IFX or ETN-treated RA patients (Matsubara T, et al., *The 75th annual meeting of the American College of Rheumatology (ACR)*. Chicago, IL, USA (2011)). In this study, in order to predict remission or low disease activity with these biologics, we validated a third population sample by using the first and second population algorithms.

Methods: The first population sample included 187 RA patients, the second, 206 patients, and the third, 145 patients, for a total of 538 patients from eleven hospitals in different regions of Japan. Remission criteria and low disease activity were determined by DAS28(CRP) within 24–30 weeks after the initiation of treatment with the biologics. Case-control analyses between 285,548 SNPs and remission or low disease activity was examined by Fisher's exact test. For each biologic, IFX or ETN, we selected 10 SNPs associated with remission or low disease activity which were common in the analyses of both the first and second population ($p < 0.05$). We then scored the relationship between each SNP and responsiveness, the estimated total score of 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in remission: +1 point, hetero allele: 0 points, and homo allele in the majority of non-remission: −1 point), and then examined relationship between remission, non-remission, and the total score.

Results: In the validation of the third population sample, accuracy ((true positive+true negative)/total) for prediction of IFX remission or low disease activity using the two combined algorithms was 88.9%. Also, in the validation of the third population sample, accuracy of prediction of ETN remission or low disease activity using two combined algorithms was 76.7%. Therefore, the accuracy of prediction of remission or low disease activity using the two combined algorithms is exponentially better than that of remission or low disease activity algorithms alone.

Conclusion: These highly accurate algorithms using SNP analysis may be useful in the prediction of remission or low disease activity before treatment with IFX or ETN, and in this way can contribute to future tailor-made treatment with biologic agents.

Gene Expression Profiling and Pathway Changes Associated with Clinical Response to Tabalumab Blockade of Membrane Bound and Soluble B Cell Activating Factor in Rheumatoid Arthritis.

Wendy J. Komocsar[1], Mark C. Genovese[2], Ernst R. Dow[1], Poulabi Banerjee[1], Michelle A. Penny[1], Eric P. Nantz[1], Sergey Stepaniants[3], Anne Ho[3], Pierre-Yves Berclaz[1] and Robert W. Hoffman[1]. [1]Eli Lilly and Company, Indianapolis, IN, [2]Stanford University Medical Center, Palo Alto, CA, [3]Covance Genomics Laboratory LLC, Seattle, WA

Background/Purpose: Tabalumab, a monoclonal antibody neutralizing membrane bound and soluble B cell activating Factor (BAFF), has been shown to reduce the signs and symptoms of rheumatoid arthritis (RA)[1.] To better define tabalumab's molecular mechanism of action, gene expression profiling of whole blood RNA was performed to characterize individual gene expression signatures and to map the associated pathways involved with BAFF blockage in RA.

Methods: Whole blood RNA was obtained from 158 RA subjects with inadequate response to methotrexate enrolled in a phase 2 randomized trial in which patients received subcutaneous placebo, 1, 3, 10, 30, 60 or 120 mg of tabalumab every 4 weeks (wks) over 24 wks. At total of 669 RNA samples were obtained at baseline, wk 1, 4 and 16, and follow up visits at wk 32 and 44. Samples from 30 healthy blood donors controls were analyzed. Affymetrix U133 Plus 2.0 expression arrays were used to measure gene expression. Data were normalized using Robust Multichip Average (RMA) algorithm[2]. Following quality analysis a total of 676 samples were profiled. B cells from peripheral blood were enumerated using flow cytometry. Total serum IgG, A and M, rheumatoid factor (RF) and ACPA were measured using nepholometry. Statistical analyses were performed using a mixed effect model and p-values were adjusted for multiple hypotheses testing using False Discovery Rate (FDR) and Bonferroni techniques. Paired t-tests were used to generate a list of biologically relevant genes whose transcripts exhibited consistent changes in response to tabalumab treatment.

Results: The genes demonstrating significant changes with treatment over time are listed in the table. Many of these genes are represented by multiple probe sets. Most were down regulated. Several of these have been previously reported to be associated with RA susceptibility. The use of gene ontology, pathway and literature mining revealed that the most significant changes were related to B cell development and signaling. Changes in CD19 expression were correlated with CD19 enumeration. Additional genes related to B cell development and signaling were associated with changes in CD19 expression. Consistent with these changes, serum immunoglobulins IgM, IgA decreased significantly from baseline and IgG had a numerical decrease over time. There were no statistically significant changes in RF or ACPA levels from baseline.

Table. Top candidate genes whose gene expression changes were significant following treatment with tabalumab

Gene	Raw p-value/ Multiplicity Adjusted p-value	Gene	Raw p-value/ Multiplicity Adjusted p-value
T-cell leukemia/lymphoma 1A, TCL1A	5.40E-18/ 2.90E-13	phosphatidic acid phosphatase type 2 domain containing 1B, PPAPDC1B	6.00E-08/ 3.30E-03

CD200 molecule, CD200	9.80E-07/ 2.20E-03	sorting nexin 22, SNX22	6.70E-07/ 1.70E-03
coronin, actin binding protein, 2B, CORO2B	1.10 E-06/ 4.90 E-03	Fc receptor-like 2, FCRL2	2.40E-06/ 5.30E-03
probe 243780_at near the BAFF Receptor, BAFF-R	2.90E-06/ 5.50E-03	Fc receptor-like 1, FCR1	3.50E-06/ 6.30E-03

Conclusion: Using RNA gene expression profiling and pathway analysis, significant gene changes associated with the clinical response to tabalumab were identified. We observed changes in genes related to B cell development and maturation which is consistent with tabalumab's mechanism of action. These data may provide additional potential targets or biomarkers for future studies in RA.

Long-Term Safety and Efficacy of 4-Weekly Certolizumab Pegol Combination and Monotherapy in Rheumatoid Arthritis: 5 Year Results from an Open Label Extension Study.

Roy M. Fleischmann[1], Ronald F. van Vollenhoven[2], Jiri Vencovsky[3], Rieke Alten[4], Owen Davies[5], Christian Stach[6], Marc de Longueville[5], Brenda Van Lunen[7] and Ernest Choy[8]. [1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [2]Karolinska Institute, Stockholm, Sweden, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Schlosspark Klinik, University Medicine Berlin, Berlin, Germany, [5]UCB Pharma, Brussels, Belgium, [6]UCB Pharma, Monheim, Germany, [7]UCB Pharma, Raleigh, NC, [8]Cardiff University School of Medicine, Cardiff, United Kingdom

Background/Purpose: Certolizumab pegol (CZP) has been shown to be efficacious and have an acceptable safety profile when administered every 4 weeks (Q4W) as monotherapy (FAST4WARD, NCT00548834) or in combination with methotrexate (MTX) (Study 014, NCT00544154) for the treatment of rheumatoid arthritis (RA).[1,2] This post-hoc analysis evaluated long-term safety and efficacy of 400mg CZP Q4W monotherapy and in combination with MTX for RA over 5 years.

Methods: The open label extension (OLE) study (NCT00160693) enrolled patients (pts) who withdrew or completed the 24 week (Wk) FAST4WARD or 014 studies. The primary OLE objective was to monitor safety. Pts were permitted to take DMARDs in OLE. Pt retention rates and efficacy are reported up to Wk280 (5.4yrs) (last time point all sites open) and safety up to Wk364 (final data cut-point) of the OLE. Safety population included all pts who received CZP in OLE (patients completing or withdrawing early from either feeder study who entered OLE and those originally randomized to PBO in the double-blind phase [all pts N=402, all monotherapy pts N=126]). Analyzed efficacy population consisted of (1) FAST4WARD and 014 Wk 24 completers from CZP group who entered OLE (N=71; CZP completers) and (2) FAST4WARD completers from CZP group who entered OLE and did not receive MTX or another DMARD at any point (N=48; CZP monotherapy completers).

Results: 50% of the CZP monotherapy completers remained in OLE at Wk280 (Figure). These retention rates were similar to all CZP completers (Figure). For all monotherapy pts, the event rates per 100-pt yrs (ERs) for all adverse events (323.4), injection site reactions (2.8), all serious AEs (16.5) and serious neoplasms (0.8) were lower than for all pts (416.4, 3.6, 24.4 and 1.6). ER of serious infections, AEs leading to withdrawal and AEs leading to death were low and similar between populations (Table). In CZP completers and CZP monotherapy completers, respectively, DAS28-3(CRP) mean (SD) change from feeder study baseline was −1.8 (1.2) and −1.9 (1.4) at OLE entry, and −3.0 (1.4) and −3.1 (1.6) at Wk280. HAQ mean (SD) change from feeder baseline for the same groups were −0.4 (0.5) and −0.6 (0.7) at OLE entry, and −0.5 (0.6) and −0.7 (0.8) at Wk280, respectively.

A. Kaplan Meier plot showing drop-out rates due to any reason for CZP all patients and CZP monotherapy pts who completed 24-wks of double-blind CZP therapy
B. Safety of CZP: all patients compared to monotherapy subgroup (includes pts who completed or withdrew from either feeder and entered OLE, and pts who were originally on PBO)

Summary of adverse events	All pts in OLE N=402	All monotherapy in OLE N=126
ER-event rate per 100 pt-yrs		
Any AE	416.4	323.4
Injection site reaction	3.6	2.8
Any serious AE	24.4	16.5
Serious infection	4.4	4.2
Serious neoplasm*	1.6	0.8
AEs leading to withdrawal	6.7	6.3
AEs leading to death	0.6	0.6

*Neoplasms could be benign or malignant

Conclusion: Use of CZP 400mg Q4W monotherapy has been confirmed to have an acceptable long-term safety profile. Some AEs seem to be lower in the monotherapy subgroup than for all pts, but this requires confirmation as it could be a consequence of selection bias. Long-term CZP monotherapy is associated with similar improvement in disease activity and physical function to a population where the majority of pts received combination therapy. CZP monotherapy pts had a similar retention rate in the OLE to the overall population.

One-Year Results From the Canadian Methotrexate and Etanercept Outcome Study: A Randomized Trial of Etanercept and Methotrexate Versus Etanercept Alone in Rheumatoid Arthritis.

Janet E. Pope[1], Boulos Haraoui[2], J. Carter Thorne[3], Melanie Poulin-Costello[4], Andrew Vieira[4] and Edward Keystone[5]. [1]St. Joseph's Health Care, London, ON, [2]Institut de Rhumatologie de Montréal, Montreal, QC, [3]Southlake Regional Health Centre, Newmarket, ON, [4]Amgen Canada Inc., Mississauga, ON, [5]University of Toronto, Toronto, ON

Background/Purpose: Combination therapy with a biologic and methotrexate (MTX) usually yields better outcomes than biologic monotherapy in rheumatoid arthritis (RA).[1,2,3] However, patients may be intolerant to MTX, or prefer fewer medications if doing well. As well, some data suggest monotherapy with etanercept (ETN) may be sufficient.[4] The objective of this open label, RA trial was to determine if withdrawing MTX after 6 months of combination ETN+MTX, in MTX inadequate responders, is as effective as continuing ETN+MTX.

Methods: TNF inhibitor naïve, RA patients with active disease ($\geq$3 swollen joints, DAS28$\geq$3.2) despite stable MTX therapy ($\geq$15 mg/wk, or 10 mg/wk if intolerant) for >12 weeks were enrolled. Combination therapy with ETN (50 mg/wk sc)+MTX was initiated for 6 months, followed by randomization of the patients to either continue with ETN+MTX or switch to ETN monotherapy for an additional 18 months. The primary end point was to show non-inferiority of ETN vs ETN+MTX, based on the change in DAS28-ESR, 6 months after randomization (non-inferiority margin in DAS28-ESR (-0.6)), with pre-specified analyses of subsets by disease activity (DAS28<3.2 vs DAS28$\geq$3.2).

Results: 258 patients with active RA were enrolled (76% female; mean age 54.7$\pm$12.5 yrs; DAS28 5.4$\pm$1.1; duration of RA 8.9$\pm$8.4 yrs). Mean duration of prior MTX treatment was 4.9$\pm$4.7 yrs; 48.4% of patients used $\geq$2 prior DMARDs and 43.8% used sc MTX. From baseline to 6 months, disease activity improved, with a change in mean DAS28 [95% CI] of -1.9 [-2.1, -1.7]. At 6 months, 205 patients were randomized with similar baseline characterisitics. Of 53 non-randomized patients, 40% discontinued treatment due to disease progression, 26% due to adverse events and 34% for other reasons. From 6 to 12 months, DAS28 was maintained in patients on ETN+MTX and increased slightly in patients on ETN monotherapy, (Table 1). The primary endpoint of non-inferiority was not achieved. However, if a low disease activity (LDA) was achieved (DAS28<3.2) at 6 months, the change in DAS28 from 6 to 12 months was similar for ETN+MTX and ETN (Figure 1). Conversely, for patients on ETN+MTX with DAS28$\geq$3.2 at 6 months disease activity continued to improve from 6 to 12 months, while patients on ETN monotherapy had slightly iincreased disease activity at 12 months (Figure 1).

Table 1. Change in DAS28 from 6 and 12 months (Intent to Treat–All randomized subjects)

	Total		Primary Non-Inferiority Endpoint (Adjusted difference between 6 to 12 months DAS28 change in ETN vs ETN+MTX)
	ETN (n = 98)	**ETN+MTX (n = 107)**	
Mean DAS28 [95%CI] 12 months	4.0 [3.7, 4.3]	3.6 [3.2, 3.8]	-0.4 [-0.7, -0.12]
Change [95%CI] from month 6 to 12 in mean DAS28	0.5 [0.3, 0.7]	0.04 [-0.2, 0.3]	
Figure 1. Mean DAS28–6 Month Randomization to 12 Months (Intent to Treat Analysis)

Conclusion: Patients who achieve DAS28<3.2 by 6 months on ETN+MTX have similar disease activity at 12 months, whether they continue or stop MTX. It is possible to discontinue MTX in the subset of patients who reach LDA, while it is preferable to continue MTX in those who do not achieve LDA.

Long-Term Benefits of 4-Weekly Certolizumab Pegol Combination and Monotherapy On Household Productivity and Social Participation in Rheumatoid Arthritis: 5 Year Results from an Open Label Extension Study. Vibeke Strand[1], Oana Purcaru[2], Ronald F. van Vollenhoven[3], Ernest Choy[4] and Roy Fleischmann[5]. [1]Stanford University, Portola Valley, CA, [2]UCB Pharma, Brussels, Belgium, [3]Karolinska Institute, Stockholm, Sweden, [4]Cardiff University School of Medicine, Cardiff, United Kingdom, [5]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Certolizumab pegol (CZP) monotherapy administered every 4 weeks (Q4W) for rheumatoid arthritis (RA) has been shown to be associated with rapid and sustainable improvements in productivity up to 2 years.[1] The current analysis evaluates the long-term impact on household productivity and social participation of CZP 400mg Q4W combination and monotherapy over 5 years.

Methods: In this open-label extension (OLE) (NCT00160693) patients (pts) originally enrolled in FAST4WARD (NCT00548834) or study 014 (NCT00544154) received CZP 400 mg Q4W for 24 weeks (wks). Pts who completed or withdrew on/after Wk12 in either study were eligible and were permitted to take DMARDs in OLE. Household productivity and social participation were assessed through the RA-specific Work Productivity Survey (WPS-RA); results are reported up to Wk268 (5.2yrs). The analyzed population consisted of (1) Wk 24 CZP completers from FAST4WARD or 014 who entered the OLE (all pts group) and (2) CZP completers from FAST4WARD who entered OLE and did not receive MTX or another DMARD at any point (monotherapy subgroup).

Results: From the CZP groups of the FAST4WARD (N=111) and 014 (N=124) feeder studies, 75 and 96 pts, respectively, completed the studies and entered the OLE. 48 pts who completed FAST4WARD and entered the OLE remained on monotherapy throughout their time in the OLE, and of these 26 remained in OLE at Wk268. In both populations analyzed, a rapid reduction in the number of days missed of household work per month was seen from feeder study baseline (BL, 7.4 and 11.1 mean days respectively) over 24wks of the feeder studies to OLE entry (3.5 and 4.1 mean days respectively) and continued to decline over time, up to Week 268 (1.2 and 1.4 mean days respectively; Table). A similar decrease was reported in the number of household days with reduced productivity per month, and in the rate of RA interference with household productivity per month (Table). Increased participation in family/social/leisure activities was reported in both populations, with a decrease in the number of days missed per month from feeder study baseline (4.4 and 6.2 mean days, respectively), to entry to OLE, at a mean of 1.3 and 1.1 days respectively for the 2 groups; these improvements continued over the 5 years to 0.4 and 0.2 days on average in the 2 populations respectively.

Table. Productivity at home and daily activities of CZP 400mg Q4W combination and monotherapy patients over 5 years[a]

Week	All pts					Monotherapy subgroup*				
	BL feeder study	Entry OLE	52	160	268	BL feeder study	Entry OLE	52	160	268
Number of subjects*	171	171	157	112	95	48	46	42	31	26
Household work days missed per month; mean [median/Q8]	7.4 [4/10]	3.5 [0/5]	1.7 [0/1.7]	1.3 [0/1.3]	1.2 [0/1.3]	11.1 [7/20]	4.1 [1.5/5]	1.6 [0/1.7]	0.9 [0/1]	1.4 [0.2/1.7]
Household work days with reduced productivity per month; mean [median/Q8]	10.2 [8.0/15]	3.8 [0/5]	2.4 [0/2.3]	1.3 [0/1.2]	1.6 [0/1.3]	11.9 [9/22.5]	3.6 [0.5/4]	2 [0/1.3]	0.8 [0/1]	1.2 [0/1.7]
Rate of RA interference with household productivity per month; mean [median/Q8]	5.5 [5/7]	3.2 [3/5]	2.8 [3/4]	2.3 [2/4]	2.4 [2/4]	5.9 [5/9]	3.2 [2.5/5]	2.6 [1.5/5]	1.8 [1/4]	2.3 [0.5/5]
Days missed of family/social/ leisure activities per month; mean [median/Q8]	4.4 [1.5/5]	1.3 [0/1]	0.5 [0/0.3]	0.3 [0/0]	0.4 [0/0]	6.2 [2.5/6.5]	1.1 [0/2]	0.9 [0/0.7]	0.3 [0/0.7]	0.2 [0/0]

Observed data; *Total possible pts at each time point shown, actual number of survey respondents may differ; 0–10 scale, 0 = no interference, 10 = complete interference; Pts from FAST4WARD who remain on monotherapy throughout the CLE

Conclusion: CZP treatment, in combination with MTX/DMARDs or as monotherapy, improved household productivity and increased participation in social/family/leisure activities, as shown by the decrease in the number of household work or social/family/leisure days missed or the number of days with reduced productivity per month. These improvements were maintained up to 5 years with open-label CZP following 24 wks double-blind CZP therapy.

Certolizumab Pegol Plus Methotrexate Is Similarly Effective in Active Rheumatoid Arthritis Secondary Non-Responders to Anti-TNF Inhibitors: Post-Hoc Analysis of a Phase Iiib Trial. Daniel Furst[1], Saeed A. Shaikh[2], Maria W. Greenwald[3], Michael H. Schiff[4], Barbara Bennett[5], Owen Davies[6], Fabienne Staelens[6], Will Koetse[7] and Philippe Bertin[8]. [1]University of California at Los Angeles, Los Angeles, CA, [2]McMaster University, St Catharines, ON, [3]Desert Medical Advances, Palm Desert, CA, [4]University of Colorado, Denver, CO, [5]BABennett Consulting, LLC, Marietta, GA, [6]UCB Pharma, Brussels, Belgium, [7]UCB Pharma, Rtp, NC, [8]Dupuytren Hospital, Limoges, France

Background/Purpose: Certolizumab pegol (CZP) has demonstrated efficacy in patients (pts) with prior TNF inhibitor exposure.[1] In the Doseflex trial two maintenance dosing regimens of CZP were comparable at maintaining response and significantly better than placebo (PBO).[1] Data from pts with and without prior TNF inhibitor exposure are presented.

Methods: Doseflex was a 34 Wk Phase IIIb, open-label run-in and double-blind (DB) PBO-controlled randomized study in pts with active RA on stable dose MTX (NCT00580840). Secondary TNF inhibitor non-responders were included. All pts received 400 mg CZP at wks 0, 2, and 4 and 200 mg CZP every 2 wks (Q2W) to Wk16 + MTX. Wk16 ACR20 responders were randomized 1:1:1 at Wk18 to MTX plus 200 mg CZP Q2W, 400 mg CZP every 4 wks (Q4W) or PBO (CZP withdrawn) for 16 Wks. Primary end-point was ACR20 at Wk34; ACR responses and CDAI/SDAI/DAS28(ESR) remission were assessed using NRI for missing data imputation.

Results: Of 333 pts entering the run-in 91.9% were from the US and 53.5% had prior TNF inhibitor use. Mean DAS28(ESR), SDAI and CDAI at baseline were 6.4, 40.4 and 38.4. At Wk16, responder rates for pts with and without prior TNF inhibitor exposure were; ACR20 60.7% vs. 61.9%; ACR50 34.8% vs. 41.3%; ACR70 14.0% vs. 18.7%. Of pts randomized at Wk18, 42.0%, 61.4% and 55.7% had prior TNF inhibitor use in PBO, CZP 200 mg and CZP 400mg groups. Baseline characteristics were similar for randomized pts with and without prior TNF inhibitor exposure. At Wk34, ACR20/50/70 response rates were comparable between 200mg and 400mg groups (67.1/50.0/30.0% and 65.2/52.2/37.7%) and significantly higher than CZP→PBO (44.9/30.4/15.9%, p<0.05 for all). ACR20 at Wk34 in pts with vs. without prior TNF exposure was 37.9% vs. 50.0% with PBO, 74.4% vs. 55.6% with CZP 200 mg Q2W and 61.5% vs. 70.0% with CZP 400 mg Q4W. ACR50/70 and remission rates were similar in CZP pts with and without prior TNF inhibitor exposure receiving both dosage regimens; however, with PBO they were considerably lower for pts with prior TNF inhibitor exposure vs. without (Figure). CZP was well tolerated (adverse event (AE) rates in DB phase: 62.3% vs 62.9% vs 60.9%; serious AE rates: 0% vs 7.1% vs. 2.9% in the CZP→PBO, CZP 200mg and 400mg groups). The most common SAEs were infections and infestations (4.3% in the CZP 200mg groups; 0 in the other groups).

Figure. ACR50 response, CDAI and SDAI remission rates by prior TNF inhibitor at wk 34 in ACR20 responders at wk 18
Conclusion: In RA pts with active disease and incomplete response to MTX, CZP 200mg Q2W and CZP 400mg Q4W showed comparable efficacy in maintaining clinical response to Wk34 following a 16 Wk run-in. CZP demonstrated similar efficacy in RA pts with or without prior exposure to TNF inhibitors over 34 Wks. When CZP was withdrawn at Wk16 in ACR20 responders (pts randomized to PBO), there appeared to be a greater maintenance of response in pts who had no prior TNF inhibitor exposure.

Sarilumab, a Subcutaneously-Administered, Fully-Human Monoclonal Antibody Inhibitor of the IL-6 Receptor: Effects On Hemoglobin Levels in a Clinical Trial for the Treatment of Moderate-to-Severe Rheumatoid Arthritis.

Mark C. Genovese[1], Roy M. Fleischmann[2], Martine Jasson[3], Allen R. Radin[4], Jennifer Hamilton[5] and Tom W.J. Huizinga[6]. [1]Stanford University Medical Center, Palo Alto, CA, [2]University of Texas, Dallas, TX, [3]Sanofi, Paris, France, [4]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [5]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [6]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Anemia of chronic disease, a common extra-articular manifestation of rheumatoid arthritis (RA), which has a substantial impact on patient function, is driven in part by proinflammatory cytokines such as IL-6. Sarilumab, the first fully human monoclonal antibody directed against the alpha subunit of the IL-6 receptor (IL-6Rα), blocks receptor binding of IL-6. In the phase 2 MOBILITY Part A trial, sarilumab administered subcutaneously demonstrated significant and clinically relevant improvements in ACR20 at Week 12 relative to placebo in patients with active RA receiving methotrexate (MTX). The current analysis evaluated the effects of sarilumab on hemoglobin (Hb) levels.

Methods: MOBILITY Part A was a phase 2, 12-week, double-blind, placebo-controlled trial of adults with active RA despite MTX. Patients continued MTX and were equally randomized to placebo or 1 of 5 sarilumab doses: 100 mg every other week (q2w); 150 mg q2w; 100 mg weekly (qw); 200 mg q2w; or 150 mg qw. Blood samples collected at baseline and every 2 weeks during treatment were analyzed for Hb levels (ANCOVA model comparing Hb change over 12 weeks for each sarilumab group vs. placebo) and high sensitivity C-reactive protein (hs-CRP), an inflammatory marker.

Results: 306 patients were randomized. Baseline characteristics were similar across all groups: mean age 52.2 ± 12.3 years; 79% female; mean disease duration 7.8 ± 8.1 years; RF+ 79.7%; mean hs-CRP 2.8 ± 3.0 mg/dL. Week 0 Hb data were available for 295 patients: mean baseline Hb 12.6 ± 1.6 mg/dL; 25.4% of patients had low Hb, defined as ≤12.5 mg/dL. Increase in Hb levels was observed as early as Week 2 in all sarilumab groups, with significant increases vs. placebo ($P\leq0.0002$) at Week 12 (Figure). The effect was greatest with the 150 mg qw dose, followed by 200 mg q2w. All placebo patients who had low baseline Hb (n=17) still had low Hb at Week 12; 65.5% of the sarilumab patients low at baseline (n=58) had normalized Hb (n=38) at Week 12. Mean hs-CRP levels were ≤0.8 mg/dL by Week 12 in all treatment groups except placebo (2.6 mg/dL) and sarilumab 100 mg q2w (1.8 mg/dL); reductions in hs-CRP at Week 12 were also significant relative to placebo ($P<0.0001$), except for 100 mg q2w ($P=0.0661$). The most common treatment emergent adverse events (AEs) reported in the sarilumab arms were infections (non-serious) 12–26%, neutropenia 0–20%, and ALT increase 0–6%. Eight patients (3 receiving sarilumab 100 mg q2w, 3 receiving 100 mg qw, and 2 receiving placebo) experienced at least 1 treatment emergent serious AE (SAE); of these, 6 led to permanent treatment discontinuation, including 1 death in the sarilumab 100 mg q2w group (acute respiratory distress syndrome, cerebrovascular accident). There were no infection-related SAEs in patients with grade 3 or 4 neutropenia.
*P≤0.0002, change from baseline at week 12 for each dose group vs placebo

Conclusion: Sarilumab treatment for RA over 12 weeks resulted in significant improvements in hemoglobin relative to placebo.

C-Type Lectin Domain Family 4, Member C Gene Expression Level Helps Predict Future Clinical Response to Tabalumab Blockade of B Cell Activating Factor in Rheumatoid Arthritis.

Ernst R. Dow[1], Poulabi Banerjee[1], Michelle A. Penny[1], Eric P. Nantz[1], Sergey Stepaniants[2], Anne Ho[2], Wendy J. Komocsar[1], Pierre-Yves Berclaz[1] and Robert W. Hoffman[1]. [1]Eli Lilly and Company, Indianapolis, IN, [2]Covance Genomics Laboratory LLC, Seattle, WA

Background/Purpose: Patients with rheumatoid arthritis (RA) exhibit substantial variability in both the magnitude and duration of their clinical response to treatment. Despite considerable research, no biomarker has reproducibly been shown to predict likelihood of clinical response to biologic therapy. There remains significant unmet medical need to identify patients who will have a meaningful response to treatment prior to drug exposure. We have recently shown the efficacy of tabalumab (previously known as LY2127399), a monocolonal antibody neutralizing membrane bound and soluble B cell activating factor (BAFF) in RA[1]. We have now used gene expression profiling of whole blood mRNA, obtained prior to drug exposure, to identify a predictive gene expression pattern that helps identify patients that are highly likely to respond to treatment with tabalumab.

Methods: Whole blood mRNA was obtained at baseline from 158 RA subjects with an inadequate response to methotrexate enrolled in a phase 2 randomized trial in which patients received placebo, 1, 3, 10, 30, 60 or 120 mg of tabalumab every 4 weeks over 24 weeks. Clinical results of BAFF blockade in RA of this study have recently been reported[1]. In addition to the RA subjects (152 samples passed quality control), samples from 30 healthy blood donor controls were analyzed using Affymetrix U133 Plus 2.0 expression arrays to determine gene expression, and data were compared after normalization using Robust Multichip Average (RMA) algorithm[2]. C-type Lectin Domain Family 4, Member C (CLEC4C) qPCR was performed in validated assays at Covance Genomics Seattle using primers and probes obtained from ABI. Statistical analyses were performed using Messina[3], two sample t-test and or regression modeling.

Results: There was a bimodal distribution of CLEC4C mRNA in whole blood from RA patients and controls at baseline. The mean level of CLEC4C gene expression measured by Affymetrix was lower in patients than in controls. Mean expression after normalization for patients (n=152) is 5.79 with a range of 3.18 to 9.69. Mean expression for control healthy blood donors (n=30) is 6.88, range is 4.36 to 9.02. Among patients, those with higher levels of CLEC4C gene expression were more likely to respond to tabalumab (as measured by ACR-N). Messina analysis[2] at baseline identified both CLEC4C probe sets as having the largest margin when comparing responder and non-responder group outcome at week 16 using ACR-N/DAS28. A two sample t-test on the same data was significant (p<0.0007). These expression findings from selected Affymetrix probe sets were validated using qPCR; for CLEC4C the change in threshold cycle versus ACR-N was statically significant after correction for multiple comparisons using False Discovery Rate (FDR) and Bonferroni techniques (FDR p=0.013, Bonferroni p=0.013).

Conclusion: The subgroup of RA patients with higher levels of CLEC4C mRNA expression at baseline were significantly more likely to respond to treatment with tabalumab. Independent replication of these hypothesis generating findings is now in progress in a large phase 3 clinical trial of tabalumab.

Coadministration of ASP015K, a Novel Janus Kinase Inhibitor with Methotrexate Demonstrates Tolerability and Lack of Pharmacokinetic Interactions in Patients with Rheumatoid Arthritis. Tong Zhu[1], Kazuo Oda[2], Udaya Valluri[1], Bogie Moore[1], Ying Cao[1], Vishala Chindalore[3] and Bola Akinlade[1]. [1]Astellas Pharma Global Development, Inc., Northbrook, IL, [2]Astellas Pharma Inc., Osaka, Japan, [3]Pinnacle Research Group/Anniston Medical Clinic, Anniston, AL

Background/Purpose: ASP015K is an oral Janus kinase (JAK) inhibitor with selectivity for JAK1/3 in development for treatment of rheumatoid arthritis (RA) and other autoimmune diseases. Methotrexate (MTX) is the most common non-biologic DMARD therapy and recommended as first-line therapy in RA treatment guidelines. In humans, MTX is primarily excreted unchanged into urine. Transporter-mediated renal tubular secretion of MTX is thought to be a major mechanism of PK interaction with other drugs. In vitro experiments were performed to evaluate the effects of ASP015K on renal transporters. A clinical drug-drug interaction study was also conducted to evaluate the effect of multiple-dose of ASP015K on MTX PK, and the short-term safety and tolerability of coadministration in RA patients.

Methods: In vitro experiments were conducted to assess the inhibitory potency of ASP015K on human multidrug resistance-associated protein 2/4 (MRP2/4) and organic anion transporter 1/3 (OAT1/3). A phase 1, open-label, single-sequence study was conducted to confirm the in vivo effect of ASP015K on the PK of MTX, a substrate of MRP2/4 and OAT1/3. Fifteen subjects diagnosed with RA for ≥ 6 months and had been treated with MTX (15 to 25 mg weekly) for ≥ 28 days were enrolled. Subjects received their usual prescribed dose of MTX on day 1. They then received ASP015K 100 mg BID for 6.5 days (day 3 through the morning of day 9), and a second prescribed dose of MTX in combination with ASP015K on day 8. Serial blood samples were collected for MTX concentration assay after dosing on day 1 (MTX alone) and 8 (MTX+ASP), and for ASP015K concentration assay after dosing on day 7 (ASP alone) and 8 (MTX+ASP). Predose concentrations (C_{tough}) of ASP015K were measured on days 3, 4, 5, 6, 7 and 8. Urinary excretion of MTX was also assessed.

Results: ASP015K demonstrated no in vitro inhibitory effect on MRP2/4 or OAT1 ($IC_{50} > 100$ μM); it inhibited OAT3 with an IC_{50} of 5 μM. Fourteen subjects completed the phase 1 study for PK evaluation. Results showed that MTX exposure was not affected by coadministration of ASP015K; AUC_{inf} ratio (MTX+ASP/MTX alone) was 103% [90% confidence interval (CI) 93, 113]; C_{max} ratio was 92% [90% CI 83, 103]. Analysis of C_{trough} indicated ASP015K levels reached steady state on day 5. ASP015K $AUC_{12,ss}$ was not affected by coadministration of MTX with a ratio (MTX+ASP/ASP alone) of 98% [90% CI, 91, 106]. ASP015K C_{max} decreased by 8% with a ratio (MTX+ASP/ASP alone) of 92% [90% CI, 78, 108], which was considered not to be clinically significant. The unbound C_{max} of ASP015K at 100 mg BID was estimated to be $<1/10^{th}$ of the IC_{50} for OAT3 in vitro suggesting that ASP015K would not affect MTX PK. ASP015K was well tolerated when coadministed with MTX. One subject experienced an SAE (urinary tract infection) before receiving study drug and subsequently a second SAE (gastroenteritis) after receiving MTX on day 1 but before receiving ASP015K. This subject was discontinued from the study.

Conclusion: Coadministration of ASP015K and MTX was well tolerated in this short-term study exhibiting no clinically significant effect on the PK profile of either drug. Efficacy and safety of ASP015K/MTX combination therapy is being assessed in ongoing phase 2 trials in RA patients.

Effects of Dose Escalation of Tocilizumab in Combination with Nonbiologic Disease-Modifying Antirheumatic Drugs: Sub-Analysis of a 24-Week Study in a United States Population. M. E. Weinblatt[1], Herbert S. B. Baraf[2], Ara H. Dikranian[3], Andrew M. Anisfeld[4], Jenny Devenport[4] and Sheldon Cooper[5]. [1]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [2]Arthritis & Rheumatism Associates, Wheaton, MD, [3]San Diego Arthritis Medical Clinic, San Diego, CA, [4]Genentech, South San Francisco, CA, [5]Univ Vermont College of Med, Burlington, VT

Background/Purpose: In the US, the recommended starting dose of Tocilizumab (TCZ) is 4 mg/kg (q4w) with an increase to 8 mg/kg (q4w) based on clinical response. However, analyses of responses experienced by patients increasing TCZ dose from 4 mg/kg to 8 mg/kg have been limited by a uniform escape escalation criterion used across phase III trials: patients randomized to 4 mg/kg who did not experience a 20% improvement in TJC and SJC at Week 16 increased the dose to 8 mg/kg. This sub-analysis of the ACTSTAR study evaluated the response of patients following an increase in TCZ dose after or at Week 8 based on joint counts or investigator discretion, respectively. Safety and efficacy outcomes of the full study were reported previously.

Methods: ACT-STAR was a phase 3b, 24-wk, open-label, multicenter US study that evaluated adults with active RA who had an inadequate clinical response or safety/tolerability issues with prior DMARD therapy. This sub-analysis examined patients initiating TCZ 4 mg/kg who continued their current synthetic DMARD. Per study protocol, patients who did not achieve $\geq 20\%$ improvement in TJC and SJC at Week 8 were to increase TCZ dose to 8 mg/kg. After Week 8, the protocol allowed TCZ dose escalation to 8 mg/kg per physician discretion. Study visits occurred at BL and 4 weeks after each infusion.

Results: Of the 363 patients randomized to receive TCZ 4 mg/kg, 68 increased to 8 mg/kg *after* Week 8, 142 patients increased to 8 mg/kg *at* Week 8 and 152 patients received only 4 mg/kg (1 patient was not dosed). Among patients who increased dose *after* Week 8, ACR20 response at Week 24 was achieved by 58.8% of patients, ACR50 by 36.8% of patients and ACR70 11.8% of patients. Mean DAS28 decreased from 5.76 at BL to 4.45, 4.20 and 3.77 at Weeks 8, 16 and 24, respectively. ACR core components improved initially and continued to improve following dose escalation (Table). Of these patients who escalated at Week 8, which was enriched for non-responders due to study design, ACR20, 50 and 70 responses were achieved in 30.3%, 12.0% and 3.5% of patients at Week 24. Mean DAS28 decreased from 5.69 at BL to 5.39 at Week 8 (prior to protocol defined dose escalation) and to 4.32 and 4.17 at Weeks 16 and 24 (after dose escalation), respectively. Similar improvements across ACR core components were observed (Table). The most common serious adverse events pre- and post-dose increase were serious infections (SI); 1/142 (0.7%) patient experienced SI prior to dose increase, 0 patients who escalated after Week 8 experienced SIs and 3/142 (2.1%) patients experienced SI post Week 8 dose increase. Eight patients withdrew from the study due to adverse events; 2 patients who escalated after Week 8 and 6 patients who increased at Week 8.

Table.

	Baseline	Change from baseline		
		Week 8	Week 16	Week 24
Patients who increased dose from 4 mg/kg to 8 mg/kg after Week 8 (n = 68)				
DAS28, mean (SD)–	5.76 (0.97) [68]	-1.29 (1.1) [66]	-1.59 (1.3) [66]	-1.95 (1.4) [61]
CRP, mg/dL (SD)–	1.08 (1.3) [68]	-0.19 (1.3) [66]	-0.36 (1.5) [67]	-0.62 (2.8) [62]
TJC, mean (SD)–	29.57 (13.5) [68]	-12.73 (10.0) [67]	-13.12 (14.3) [67]	-15.33 (14.3) [67]
SJC, mean (SD)–	19.32 (11.6) [68]	-9.07 (8.1) [67]	-8.72 (13.2) [67]	-10.34 (12.4) [67]
Patient Global VAS (SD)–	63.91 (20.7) [68]	-19.37 (22.8) [67]	-20.10 (26.3) [67]	-25.00 (25.3) [67]
Physician Global VAS (SD)–	64.93 (18.2) [68]	-24.12 (22.3) [67]	-22.36 (24.3) [66]	-29.82 (23.8) [67]
Patients who increased dose from 4 mg/kg to 8 mg/kg at Week 8 (n = 142)				
DAS28, mean (SD)–	5.69 (1.03) [142]	-0.31 (0.9) [139]	-1.38 (1.1) [134]	-1.47 (1.2) [120]
CRP, mg/dL (SD)–	1.64 (2.5) [142]	-0.15 (2.0) [139]	-1.19 (2.6) [134]	-1.02 (2.7) [120]
TJC, mean (SD)–	28.73 (14.6) [142]	0.27 (10.5) [142]	-8.33 (14.3) [138]	-9.37 (13.5) [127]
SJC, mean (SD)–	18.06 (11.0) [142]	0.56 (8.2) [142]	-5.10 (8.1) [138]	-5.96 (9.2) [127]
Patient Global VAS (SD)–	65.17 (19.4) [142]	-5.32 (20.4) [142]	-14.60 (23.4) [138]	-16.63 (23.5) [127]
Physician Global VAS (SD)–	63.91 (17.9) [142]	-8.45 (22.2) [142]	-23.02 (26.1) [133]	-25.92 (25.5) [127]

Conclusion: Patients who escalated TCZ dose from 4 mg/kg to 8 mg/kg after or at Week 8 based on joint counts or investigator discretion were observed to have improvements in DAS28 and ACR core components following dose escalation.

Golimumab, A Human Anti-TNF Monoclonal Antibody, Administered Subcutaneously Every Four Weeks As Monotherapy in Patients with Active Rheumatoid Arthritis Despite Disease Modifying Antirheumatic Drug Therapy: Week 104 Results of Clinical, Radiographic and Safety Assessments.

Tsutomu Takeuchi[1], Masayoshi Harigai[2], Yoshiya Tanaka[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Kazuhiko Yamamoto[6], Minoru Kanazawa[7], Yoshinori Murakami[8], Toru Yoshinari[9], Daniel Baker[10], Nobuyuki Miyasaka[2] and Takao Koike[11]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [6]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [7]Director of Respiratory Center Professor of Respiratory, Medicine Saitama Medical University, Moroyama, Iruma-Gun, Saimata, Japan, [8]Janssen Pharmaceutical KK, Tokyo, Japan, [9]Mitsubishi Tanabe Pharma Corporation, Osaka, Japan, [10]Janssen Research and Development, LLC, Spring House, PA, [11]Sapporo medical center NTT EC, Sapporo, Japan

Background/Purpose: To assess the long-term efficacy and safety of golimumab (GLM) as monotherapy in Japanese patients (pts) with active rheumatoid arthritis (RA) despite DMARD therapy.

Methods: GO-MONO is a multicenter, randomized, double-blind, placebo (PBO)-controlled study in pts with active RA despite treatment with DMARDs. Pts were randomized to SC PBO, GLM50 mg, or GLM100 mg q4wks as monotherapy. At wk16, pts in the PBO group (grp) crossed over (CO) GLM50 mg q4wks. Treatment with GLM continued to wk120. Primary endpoint was the proportion of pts achieving ACR20 at wk14. Secondary endpoints included ACR50, ACR70, and ACR-N, DAS28 and HAQ and changes from BL to wks 24/52/104/120 in total modified vdH-Sharp (vdH-S) score. Data were analyzed using all patients receiving ≥ 1 dose of study treatment. Missing clinical response data were not imputed. For vdH-S score, treatment grp comparisons at wks 52/104 were based on initial randomized grps. Missing data were imputed using median change from BL in total vdH-S scores (TSS) of all pts or by linear extrapolation. Wk52 data have been reported; wk104 results of efficacy are now reported. Safety data from all treatment period are reported as incidence per 100-patient-years.

Results: Long-term efficacy and safety data are shown in the Table. Clinical remission was defined as DAS28(ESR) < 2.6 and HAQ remission was defined as HAQ < 0.5 maintained between wk52 and wk104. Median changes from baseline to wk52 were 1.0 in PBO and GLM 50mg, and 0 in GLM100 mg. Median changes from baseline to wk104 in PBO, GLM 50 and 100 mg were 1.5, 1.25 and 1.0, respectively. The proportions of pts with changes in TSS greater than the smallest detectable change (SDC) were also maintained from wk52 and wk104. Proportion of pts with no progression (change in TSS≤ 0) were slightly decrease from wk52 to wk104 in both of GLM 50 mg and 100 mg. Safety finding are also summarized in the Table. Two deaths were reported, one in GLM 50 mg (brain stem haemorrhage) and one in 100 mg (pancreatic carcinoma). Incidences of SAEs and AEs leading to discontinuation in GLM 50 mg were higher than 100 mg. There were no cases of tuberculosis or lymphoma reported.

	Evaluation at	PBO[a]	GLM 50 mg	GLM 100 mg
Efficacy results				
DAS(ESR) remission (<2.6)	Wk 52	17/85 (20.0)	18/84 (21.4)	26/94 (27.7)
n/N(%)	Wk 104	27/78 (34.6)	29/74 (39.2)	32/90 (35.6)
HAQ remission (<0.5)	Wk 52	46/85 (54.1)	37/84 (44.0)	52/94 (55.3)
n/N(%)	Wk 104	51/78 (65.4)	46/74 (62.2)	53/90 (58.9)
Change from BL in TSS[b]	Wk 52	83	82	93
n	Wk 104	2.81 (7.139)	3.31 (6.192)	1.56 (5.093)
Mean (SD)		1	1	0
Median		83	82	93
		3.61 (8.922)	4.34 (7.720)	2.64 (6.507)
		1.5	1.25	1
Pts with progression based on TSS >SDC[c]	Wk 52	17/83 (20.5)	16/82 (19.5)	16/92 (17.4)
n/N(%)	Wk 104	16/75 (21.3)	16/72 (22.2)	21/89 (23.6)
Pts with change ≤ 0 in TSS from baseline	Wk 52	37/105 (35.2)	46/101 (45.5)	54/102 (52.9)
n/N(%)	Wk 104	28/75 (37.3)	22/72 (30.6)	40/89 (44.9)
Safety results from all treatment period				
Avg duration of follow-up (wks)		15	97.1	110.9
Incidence per 100 patient-years (95%CI)		0.00 (0.00, 9.88)	0.28 (0.01, 1.55)	0.46 (0.01, 2.56)
Deaths		6.63 (0.80, 23.94)	14.47 (10.74, 19.08)	7.92 (4.61, 12.68)
SAEs		9.95 (2.05, 29.09)	7.83 (5.20, 11.32)	5.07 (2.53, 9.07)
Patients with AEs leading to discontinuation		3.30 (0.08, 18.38)	3.09 (1.54, 5.53)	3.75 (1.62, 7.39)
Patients with 1 or more serious infections				

a) All patients received placebo crossed over to GLM50 mg afer wk 16.
b) Missing data were imputed using median change from BL of all pts or by linear extrapolation.
c) SDC = 5.18 at wk 52, SDC = 5.65 at wk 104

Conclusion: Treatment with GLM50 mg and 100 mg monotherapy sustained the efficacy of signs/symptoms during 104wks. Inhibition of structural damage in GLM 100 mg was relatively greater than GLM 50mg, however the progression went on slowly during 104wks in both of the GLM groups. The GLM safety profile was similar to other anti-TNF agents.

Prevention of Joint Destruction in Patients with High Disease Activity or High C-Reactive Protein.

Yoshiya Tanaka[1], Masayoshi Harigai[2], Tsutomu Takeuchi[3], Hisashi Yamanaka[4], Naoki Ishiguro[5], Kazuhiko Yamamoto[6], Yutaka Ishii[7], Daniel Baker[8], Nobuyuki Miyasaka[2] and Takao Koike[9]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [5]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan, [6]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [7]Janssen Pharmaceutical K.K, Tokyo, Japan, [8]Janssen Research and Development, LLC, Spring House, PA, [9]Sapporo medical center NTT EC, Sapporo, Japan

Background/Purpose: In Japan, 2 doses (50mg and 100mg) of golimumab (GLM) were approved for the treatment of rheumatoid arthritis (RA) patients (pts), used with methotrexate (MTX), based on the results from GO-FORTH study. However, differences in joint destruction between the GLM 100mg and 50mg groups remain unclear. In a sub analysis of the GO-FORTH study, we assessed the difference of suppression on joint destruction progression between 100mg and 50mg based on the baseline disease activity or CRP.

Methods: GO-FORTH is a multicenter, randomized, double-blind, placebo(PBO)-controlled study in pts with active RA despite MTX. Pts were randomized to SC PBO, GLM50 mg, or GLM100 mg q4wks. All pts received MTX 6–8 mg orally/wk. Pts with <20% improvement in SJC/TJC entered early escape(EE) at wk 16 so that PBO→GLM50 mg and GLM50 mg→GLM100 mg. Pts who did not enter EE continued initial therapy until wk 24. The ΔTSS and inhibition rates (IR, ΔTSS ≤ 0) on progression of joint destruction through wk 24 in MTX-resistant pts (n=261) by baseline DAS28ESR and CRP were compared. High disease activity pts (HDA) and high CRP pts were defined as DAS28ESR > 5.1 or CRP $\geq$ 1.5mg/dL, and moderate disease activity pts (MDA) and low CRP were defined as 3.2 < DAS28 (ESR) $\leq$ 5.1 or CRP < 1.5mg/dL.

Results: Mean ΔTSS (median) in placebo + MTX with HDA (n=57) or high CRP (n=40) were 3.48 (1.0) and 3.41 (1.0) which were higher than those in MDA (0.76 (0.0) (n=29)) and low CRP (1.76 (0.0) (n=48)), respectively (Table). In HDA and high CRP, mean ΔTSS in GLM 100mg + MTX was lower compared with GLM 50mg + MTX in HDA and high CRP individually, although MDA and low CRP were not. IR on progression in HDA and high CRP were 40.4% in placebo + MTX (n=57), 43.1% in GLM 50mg +

MTX (n=51) and 69.8% in 100mg + MTX (n=53) by HDA, and 40.0% (n=40), 38.2% (n=34) and 61.5% (n=26) by high CRP, respectively. IR on progression in MDA and low CRP were 69.0% (n=29), 81.8% (n=33) and 70.6% (n=34) by MDA and 58.3% (n=48), 73.1% (n=52) and 73.8% (n=61) by low CRP, respectively. Group differences in IR were only observed between GLM 50mg + MTX and 100mg + MTX in HDA or high CRP. The suppression on joint destruction in GLM 50mg + MTX was effective in MDA or low CRP, however it was not effective in HAD or high CRP. Pts whose ΔTSS >0 in GLM 50mg + MTX with HAD or high CRP had short disease duration and small TSS as baseline characteristics in comparison with pts whose ΔTSS ≤ 0.

Table. Change from baseline in vdH-S through wk 24.

		Placebo + MTX†	50mg + MTX	100mg + MTX
Overall	number of patients	88	86	87
	Δtotal vdH-S score			
	mean (SD)	2.51 (5.52)	1.05 (3.71)	0.33 (2.66)

	p value	–	0.1127	0.0012
	Change in vdH-S score ≤ 0	23 (40.4%)	22 (43.1%)	37 (69.8%)
	p value	–	0.7069	0.0019
CRP (mg/dL) <1.5	number of patients	48	52	61
	Δtotal vdH-S score			
	mean	1.76	−0.04	0.02
	median (min, max)	0.00 [-1.5, 19.5]	0.00 [-6.3, 5.5]	0.00 [-3.5, 7.0]
	p value	–	0.0010	0.0007
	Change in vdH-S score ≤ 0	28 (58.3%)	38 (73.1%)	45 (73.8%)
	p value	–	0.1200	0.0889
≥1.5	number of patients	40	34	26
	Δtotal vdH-S scor			
	mean	3.41	2.71	1.15
	median (min, max)	1.00 [-8.5, 33.5]	1.00 [-4.5, 225]	0.00 [-2.0, 19.0]
	p value	–	0.6021	0.1151
	Change in vdH-S score ≤ 0	16 (40.0%)	13 (38.2%)	16 (61.5%)
	p value	–	0.8768	0.0871

Data shown are number (%) of patients or mean ±SD, median [range].
P values derived from comparisons versus placebo+MTX. Δtotal vdH-S score was tested by van der Waerden normal scores. Changes in vdH-S score ≤ 0 was tested by chi-square test.
† Pts with <20% improvement in SJC/TJC entered early escape(EE) at wk 16 so that PBO→GLM50 mg and GLM50 mg→GLM100 mg.

Conclusion: In the GO-FORTH study, joint destruction progression in RA pts with HAD or high CRP at baseline was more rapid than in RA pts with MDA or low CRP. GLM 100mg was more effective in preventing joint destruction than GLM 50mg, especially in RA pts with early and high disease activity or high CRP.

Efficacy of Different Biologic Agents for Improving Physical Function As Measured by the Health Assessment Questionnaire: A Meta-Analysis with Indirect Comparisons.
Lillian J. Barra[1], Andrew Ha[2], Louise Sun[3], Catarina Fonseca[4] and Janet Pope[1]. [1]Schulich School of Medicine and Dentistry, Western University, London, ON, [2]The University of Toronto, Toronto, ON, [3]University of Ottawa, Ottawa, ON, [4]Universidade de Lisboa, Lisbon, Portugal

Background/Purpose: The Health Assessment Questionnaire (HAQ) is a patient-centred, validated measure of physical function. It is predictive for disability, morbidity and mortality. The efficacy of various biologics agents for improving HAQ in patients with Rheumatoid arthritis (RA) has been demonstrated in numerous trials. However, head-to-head comparisons of biologic agents are scarce. The objective of this study was to determine the comparative efficacy of biologic agents for improving HAQ in patients with established RA who failed Disease Modifying Anti-Rheumatic Drugs (DMARDs) or anti-Tumour Necrosis Factor alpha (TNF) agents and in patients with early RA (ERA).

Methods: We performed random effects meta-analyses (Mantel-Haenszel method) of randomized, placebo-controlled trials. Inclusion criteria were: age >15 years, clinically utilized biologic agents, HAQ score at baseline and 6 or 12 months. We searched PubMed, EMBASE and the Cochrane Library. Outcome was the mean difference in change in HAQ for biologic agents compared to controls (ΔHAQ_B-ΔHAQ_C). Indirect comparisons of the different biologic drugs compared to the control group were conducted using the Q-test based on analysis of variance. Meta-regression was performed using the method of moments.

Results: 31 trials were included: 23 with DMARD-failures; 5 with anti-TNF-failures and 6 ERA. The following biologics were represented: abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. In established RA patients with DMARD failures: ΔHAQ_B-ΔHAQ_C = −0.28; 95%CI:-0.324, −0.237 (I^2=64%); abatacept and infliximab were less effective compared to the other anti-TNF agents and tocilizumab (p<0.01). In anti-TNF-failures: ΔHAQ_B-ΔHAQ_C was −0.254; 95%CI: −0.46, −0.049 (I^2=92%); golimumab was not effective compared to control and abatacept was superior to tocilizumab (p=0.0184); rituximab was equivalent to abatacept and tocilizumab. Heterogeneity was predominately due to differences in the efficacy of the different biologic agents. In ERA trials: ΔHAQ_B-ΔHAQ_C = −0.231; 95% CI: −0.323, −0.14 (I^2=0%); adalimumab, etanercept, infliximab and rituximab were equally effective. Using meta-regression, baseline HAQ did not significantly effect HAQ improvement.

Conclusion: Biologic agents were efficacious at lowering HAQ in established RA and ERA by at least the minimally clinically important difference of 0.22. However, infliximab and abatacept were less effective in DMARD-failures. The role of anti-TNF agents in anti-TNF failures and of biologics in DMARD-naïve patients remains unclear.

Comparison of Four Different Intensive Treatment Strategies in Patients with Early Rheumatoid Arthritis in Korea.
Mi-Il Kang, Yoon Kang, Hee-Jin Park, Hyang-Sun Lee, Sang-Won Lee, Yong-Beom Park and Soo-Kon Lee. Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea

Background/Purpose: The previous studies reported that intensive treatment-strategies, including biological agents and glucocorticoids, can improve the severity of early rheumatoid arthritis. However, there was no report on their efficacy in Korean patients with early rheumatoid arthritis. Hence, in this study, we investigated the clinical efficacy of intensive treatments in patients with early rheumatoid arthritis in Korea.

Methods: A total of 135 patients with rheumatoid arthritis (RA), who had not receive disease modifying anti-rheumatic drugs (DMARDs) and who had presented with joint symptoms within 1 year, were prospectively enrolled. Clinical outcome measurements and laboratory tests were performed monthly during one-year study period for adjusting treatment in order to achieve remission (Disease Activity Score in 28 joints, DAS28 (ESR) <2.6). All patients were randomly distributed to four treatment groups. Treatment groups were as followings: group1 = a step-up regimen starting with initial methotrexate (MTX) monotherapy and subsequent addition of sulfasalazine (SSZ) and hydroxychloroquine (HCQ); group 2 = initial triple therapy (MTX/SSZ/HCQ); group 3= initial high dose prednisolone with rapid-tapering schedule, combined with MTX; group 4 = initial tumor necrosis factor (TNF)-α blockades combined with MTX. At 12 months, functional ability (Health Assessment Questionnaire (HAQ)), mean differences in the DAS28 (ESR) score, proportion of patients meeting the American College of Rheumatology criteria for 50% improvement (ACR50) and DAS28 (ESR) remission were evaluated. Radiological progression was assessed by the modified Sharp scores after 12 months.

Results: Patients in group 3 and 4 had significantly lower HAQ score than those in group 1 or 2 at 6 months (0.06 and 0.14 vs 0.39 and 0.36, respectively, p=0.008). Furthermore, HAQ scores were still low in patients in group 3 and 4, compared to those in group 1 and 2 after 12 months, but they did not significantly differ (0.07 and 0.10 vs 0.27 and 0.23, respectively, p=0.056). Mean differences in DAS28 (ESR) scores between initial and final assessments were significantly greater in patients in group 3 and 4 than those in group 1 and 2 (-3.6 and -3.3 vs -2.3 and -2.9, respectively, p=0.029). Also ACR50 proportion of group 3 or 4 was significantly higher than that of group 1 or 2 (85 or 95% vs 54 or 76%, respectively, p=0.013). The percentages of patients fulfilling DAS28 (ESR) remission criteria or radiologic progression among study groups showed no significant differences.

Conclusion: In Korean patients with early RA, intensive initial therapy of either high dose prednisolone or TNF-α blockades exhibited rapid functional improvement and excellent disease control at 1 year, compared to a step-up regimen starting with initial MTX monotherapy or parallel triple therapy. Also the efficacy of prednisolone combination therapy was comparable to that of TNF-α blockades combination therapy. Further clinical studies are needed to evaluate whether the initial clinical efficacies of combination therapy including either high dose prednisolone or a TNF-α blockades could be maintained during the long-term follow-up of patients with early rheumatoid arthritis.

The Higher and Faster Increasing Schedule of Methotrexate May Not Be the Best: The Accumulation of Intracellular Longer Chain Methotrexate Polyglutamates Was Facilitated by the Extra-Low-Dose Methotrexate Treatment. Yoshinobu Koyama[1], Kazunori Hase[2], Daisuke Hidaka[2], Shuji Nagano[2], Toshiyuki Ota[2] and Ayumi Uchino[2]. [1]Okayama Red Cross General Hospital, Okayama, Japan, [2]Iizuka Hospital, Iizuka, Japan

Background/Purpose: Although data are conflicting with regard to the clinical utility of MTX polyglutamates (PGs) measurements as a predictor of the efficacy or toxicity in the treatment of rheumatoid arthritis (RA), it is considered to be essential for the therapeutic effect to achieve necessary concentrations of intracellular MTX-PGs. However, there is no universally accepted method of the optimal schedule for dose initiation and escalation. The higher starting dosage and faster increasing schedule is considered to be beneficial so far. In Japan, the officially approved dosage of MTX for RA treatment had been fixed up to 8mg/wk from 1996 to 2011, whereas the maximum doses of 20 to 30mg/wk were commonly used in the rest of world. As a result, we have very unique experience of extra-low-dose MTX (ExLD-MTX) treatment for RA. In this report, we evaluate the efficacy of ExLD-MTX treatment for RA, and we also investigate the concentrations of intracellular MTX-PGs after ExLD-MTX treatment.

Methods: RA cases treated with ExLD-MTX (n=133) were retrospectively investigated. After 12 months of the treatment, the rates of achieving remission criteria and of withdrawing from the initial treatment were calculated. Next, the concentrations of MTXGlu1–7 in red blood cell (RBC) lysates of 91 patients receiving long-term oral ExLD-MTX were quantitated with using HPLC method.

Results: After 12 months of ExLD-MTX treatment (mean MTX dosage: 6.68 ± 1.72 mg/wk), 72.2% of cases were still maintained with the same treatment. The remission criteria for DAS28 (<2.6) were achieved 31.4% of cases, which is comparable to those of MTX monotherapy arm (mean MTX dosage: 16.9mg/wk) in PREMIER study. The rates of withdrawal because of adverse events and of insufficient efficacy were 2.2% and 25.6% in ExLD-MTX group, while 7.4% and 17.9% in MTX monotherapy arm in PREMIER study. The analysis of intracellular MTX-PG after ExLD-MTX treatment revealed distinct distribution of MTX-PG subtypes, i.e., $88.2\pm19.5\%$ of MTX-PG was MTX-PG6–7, whereas the rate of MTX-PG6–7 was reported to be less than 1% after conventional MTX treatments. Although it did not reach statistical significance, the total concentrations of MTX-PG1–7 (nmoles/1g of Hb) after ExLD-MTX treatment were 8.3 ± 3.8 (range: 3.3–15.4) in the DAS<2.6 group and 6.55 ± 4.25 (range: 1.7–17.6) in the DAS>3.2 group. The percentages of low MTX-PG1–7 concentration (<5.0 nmoles/1g of Hb) were 7.7% in the DAS<2.6 group versus 44.8% in the DAS>3.2 group.

Conclusion: Although the higher starting dosage and faster increasing schedule for MTX has been considered to be better, we found that the efficacy of ExLD-MTX treatment is comparable to conventional MTX treatments. Since MTX exposure was known to induce up-regulation of folylpolyglutamate hydrolase, which removes glutamic acid from MTX-PG, the ExLD-MTX treatment could be favorable for accumulation of the longer-chain MTX-PG. Although it seems to be beneficial to escalate the MTX dosage for some of patients with active disease (DAS>3.2) after ExLD-MTX treatment, a majority of them may have already sufficient MTX-PG concentration to predict its maximal efficacy. Our findings prompt a re-evaluation of the conventional methods for dose initiation and escalation of MTX.

Differential Effect of 4 and 8 Mg/Kg Tocilizumab in Combination with Methotrexate On Serum Biomarkers of Cartilage, Connective Tissue and Bone Turnover. Anne C. Bay-Jensen[1], Inger Byrjalsen[2], Andrew Kenwright[3], Thierry Sornasse[4], Claus Christiansen[5] and Morten Asser Karsdal[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark, [3]Roche, Welwyn Garden City, United Kingdom, [4]Genentech, South San Francisco, [5]CCBR, Ballerup, Denmark

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by poly-articular inflammation, cartilage loss, synovial inflammation, subchondral bone erosion, and joint space narrowing. In this analysis, we investigated the effect of tocilizumab (TCZ; anti-IL-6R mAb) in combination with methotrexate (MTX) on serum biomarkers of bone, cartilage, and synovium turn over in patients with moderate to severe RA enrolled in the LITHE study.

Methods: The LITHE study (Roche WA17823) was a 2-year phase III, 3-arm randomized (1:1:1), double-blind, placebo-controlled, parallel group study of TCZ in moderate to severely active RA with inadequate response to MTX. 1196 patients were randomized to receive stable doses of MTX (10–25 mg/week) plus placebo, TCZ at 4 mg/kg (TCZ4), or TCZ at 8 mg/kg (TCZ8) every 4 weeks for 52 weeks. Patients who experienced less than 20% improvement in both swollen (SJC)/tender joint counts (TJC) at week 16 were given escape therapy. Serum samples were collected at baseline and week 2, 4, 16, 24, and 52. Following biomarkers were measured: C2M (cartilage degradation), C3M (synovial inflammation), MMP3, total CRP, CRPM (MMP-degraded CRP), VICM (Citrullinated and MMP degraded Vimentin), ICTP (MMP destroyed type I collagen), osteocalcin (bone formation) and CTX-I (Bone resorption). Analysis of dose- and time-dependent effect of TCZ on the release of biomarkers compared to placebo both including and excluding the escape patients was done by two-way ANOVA.

Results: In the TCZ8 group, the cartilage degradation marker C2M was rapidly reduced as compared to placebo (week 2: -12%) and remained low through weeks 4, 16, 24, and 52 (-13 to -16%, p<0.001). A similar pattern was observed for C3M, VICM, and CRPM, which were reduced at week 4 by -28, -50, and -30% (p<0.0001), respectively. The levels of these 4 markers were not affected in the TCZ4 group or in the placebo group. In contrast, MMP3 levels were strongly reduced in both TCZ4 and TCZ8 groups. The circulating level of total CRP was completely inhibited by TCZ8, but only inhibited by 50% in the TCZ4 group. Osteocalcin and CTX-I were both increased in response to TCZ8, but only osteocalcin was increased in response to TCZ4. No change in ICTP was observed. There was a significant difference (p<0.001) in the biomarker profiles between escape patients, non-responders and responders.

Conclusion: TCZ8 strongly inhibited serum markers of cartilage degradation, synovial inflammation, and inflammation mediated tissue turnover suggesting that TCZ actively suppresses key pathobiological processes at the site of inflammation in RA patients. TCZ4, on the other hand, had limited effect on the release of the markers. This might indicate that TCZ8 had a more beneficial effect on the joint health as compared to TCZ4. Furthermore, the difference in the biomarkers profiles of responders and non-responders were markedly different indicating that predictive profiles for responders and non-responders may exist.

High Body Mass Index Is Associated with Decreased Response to Initial Combination Therapy in Recent Onset RA Patients. Marianne van den Broek[1], L. Heimans[1], S. le Cessie[1], B. Siegerink[1], H.K Ronday[2], K.H. Han[3], P.J.S.M. Kerstens[4], T.W.J. Huizinga[1], W.F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]MCRZ hospital, Rotterdam, Netherlands, [4]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: A diminished response to combination treatment with a fixed dose of TNF-blocker infliximab (IFX) has been reported in patients with established RA and a high BMI. The association between BMI and response to therapy might also exist for other treatment regimens through inflammation and/or pain.

The association between high body mass index (BMI) and treatment response was assessed in a treat to target cohort with recent onset RA patients.

Methods: All patients from the BeSt study (n=508), in which patients were randomized to initial monotherapy or combination therapy with prednisone or infliximab (IFX) were included in the analyses. Response (DAS≤2.4) to disease activity steered treatment (first dose and after 1 year) was compared between patients with a BMI <25 and ≥25, using Poisson regression analyses. Several components of disease activity and functional ability during the first year were compared using linear mixed models. Joint damage progression in year 1 and over 8 years of treatment was compared using radiographs scored with the Sharp/van der Heijde Score.

Results: High BMI was independently associated with decreased treatment response to initial therapy, RR: 1.20 (95% C.I. 1.05–1.37). After stratification for initial treatment group, the effect was found for combination therapy with prednisone: RR 1.55 (1.06–2.28) and for combination therapy with IFX, RR 1.42 (0.98–2.06). The RRs for failure after one year in these groups were 1.46 (0.75–2.83) and 2.20 (0.99–4.92) respectively. A similar association was found for response to delayed combination therapy with IFX, after adjustment for selection bias related to previous failure on DMARDs. In the first year of treatment, patients with a high BMI had higher disease activity and worse functional ability, with more tender joints and a higher VAS global health, but not more swollen joints and similar systemic inflammation. Patients with high BMI did not have more damage progression over time (figure 1).
Figure 1. functional ability and joint damage progression in year 1 for patients with normal and high BMI

Conclusion: High BMI was independently associated with decreased response to initial combination therapy with prednisone and to initial and delayed treatment with infliximab, During DAS≤2.4 targeted treatment, patients with a high BMI experienced more pain, but not more swelling or systemic inflammation. Joint damage progression over 8 years was similar for patients with high and normal BMI.

Once Daily High Dose Regimens of GLPG0634 in Healthy Volunteers Are Safe and Provide Continuous Inhibition of JAK1 but Not JAK2. Florence Namour[1], René Galien[1], Lien Gheyle[2], Frédéric Vanhoutte[3], Béatrice Vayssière[1], Annegret Van der Aa[3], Bart Smets[3] and Gerben van 't Klooster[3]. [1]Galapagos SASU, Romainville, France, [2]SGS Clinical Pharmacology Unit, Antwerp, Belgium, [3]Galapagos NV, Mechelen, Belgium

Background/Purpose: GLPG0634 is an orally-available, selective inhibitor of Janus kinase 1 (JAK1) with an IC_{50} of 0.6 μM and a 30-fold selectivity over JAK2 in human whole blood. Non-selective JAK inhibitors have shown long-term efficacy in treating rheumatoid arthritis (RA). However, doses and thereby efficacy are limited by JAK2-driven side effects. Selective inhibition of JAK1 may result in a cleaner safety profile while maintaining clinical efficacy. Based on its pharmacokinetic (PK) half life, both once-daily (QD) and twice-daily (BID) dosing regimens have been explored. In patients with active RA on methotrexate, 4 weeks daily dosing of 200 mg GLPG0634 has shown highly encouraging efficacy and safety.

Objectives: Evaluate the safety, PK, JAK pharmacodynamics (PD) and -selectivity of GLPG0634 at high dose QD regimens in healthy volunteers.

Methods: In a single-center Phase I study, 3 panels of 8 male healthy volunteers (2 on placebo) received QD dosing of 200 mg, 300 mg and 450 mg GLPG0634 for 10 days. Safety was monitored continuously and followed until 7 days after the last dose. Day profiles for PK and PD were evaluated on Days 1 and 10. GLPG0634 plasma concentrations were assessed by LC-MS/MS. Inhibition of JAK1 was measured by *ex vivo* IL-6 induced STAT1 phosphorylation (pSTAT1) in $CD4^+$ cells, and JAK2 by GM-CSF induced pSTAT5 in $CD33^+$ cells.

Results: GLPG0634 was safe and well-tolerated for 200 mg, 300 mg and 450 mg QD, following 10 days of dosing. Treatment-emergent adverse events over all dose groups were typical Phase I findings (mild and transient headache and abdominal discomfort), with a comparable incidence in GLPG0634- and placebo- treated subjects. There were no relevant findings regarding hematology (including reticulocytes), biochemistry (including LDL cholesterol, ALT/AST or creatinine) or other safety parameters (ECG and vital signs, including blood pressure). A maximal tolerated dose was not reached.

Steady state PK was dose proportional up to 450 mg QD, with an apparent mean half-life of 8 hours. The PK was similar in RA patients and healthy volunteers. There was no accumulation to steady state with low trough levels relative to GLPG0634's IC_{50}. Still, JAK1 signaling remained suppressed up to 24 hours from drug intake, whereas JAK2 signaling was not influenced up to the high dose of 450 mg QD.

GLPG0634 Steady state PK	RA patients (n=6) 200 mg QD	Healthy volunteers (n=6/cohort) 300 mg QD	450 mg QD	200 mg QD
C_{max} (ng/mL)	1,430	1,200	1,380	2,580
C_{24h} (ng/mL)	24	6.0	9.9	18
AUC_{24h} (ng.h/mL)	5,380	4,490	4,400	10,200

Conclusion: At high doses, exceeding those showing high level efficacy in a 4-week RA patient study, GLPG0634 was well tolerated and safe in healthy volunteers. No safety signals were found with GLPG0634; typical findings reported within 2 weeks of dosing of non-selective JAK inhibitors were not observed. Up to 450 mg QD, GLPG0634 was highly selective for inhibition of JAK1 over JAK2. The data suggest the PD half life to be longer than that for PK.

Ongoing studies in RA patients will determine the efficacy of low doses of GLPG0634 (30 mg QD) and the safety of high doses (300 mg QD).

The Incidence of Exacerbation of Pre-Existing Interstitial Lung Disease (ILD) Is Higher in TNF Blockers Than in Non-TNF Blockers in RA. Tamao Nakashita[1], Shinji Motojima[2], Natsuki Fujio[2] and Akira Jibatake[2]. [1]Kameda Medical Center, Kamogawa City, Japan, [2]Kameda Medical Center, Kamogawa city, Japan

Background/Purpose: Exacerbation of interstitial lung disease (ILD) is a problem when biologics are administrated in patients with RA, and not a few fatal cases have been reported in Japan. According to the post-marketing surveillance report of TNF blockers, the development/exacerbation rate of ILD was 0.5 %. In our department, however, the rate was 5 % probably because we have many RA cases with ILD. We have shown that in patients with pre-existing ILD, the rate is nearly 30%. In japan there are 6 biologics available for the treatment of RA, 4 of which are TNF blockers and 2 are non-TNF blockers. Here we compared the incidence of exacerbation of pre-existing ILD in patients administrated with TNF blockers and non-TNF blockers.

Methods: Subjects were 58 patients with RA, with the mean age of 66. As a part of workup before administration of biologics, chest CT scan was done. After administration of biologics, chest X-ray film (CXR) was taken at least every 3 months. When newly developed shadows were found on CXR or when patients complained of respiratory symptoms for more than 2 weeks, chest CT scan was done again. The severity of ILD was graded into 3, grades 1 to grade 3, according to the extent of ILD on chest CT. The biologics administrated were infliximab (IFX) for 8, etanercept (ETN) for 36, adalimumab (ADA) for 2, tocilizumab (TCZ) for 9 and abatacept (ABT), respectively. The duration of observation was 12 months, except when the biologics were withdrawn because of exacerbation of ILD.

Results: The ILD of 30, 22 and 6 patients were graded into grade 1, 2 and 3, respectively. The ILD exacerbated in 14 subjects (24.1 %); the duration from the introduction of biologics to the exacerbation was from 1 to 12 months with the median of 7 months. The biologics used at the exacerbation of ILD were IFX in 5, ETN in 8, ADA in 1, TCZ in 0 and ABT in 0, respectively. The incidence of ILD exacerbation with TNF blockers and non-TNF blockers were 30.4 % (14/46) and 0 % (0/12), respectively, and there was a significant difference between them (p = 0.024).There were no differences between the subjects with ILD exacerbation and those without it in age, gender, RF titer, the ILD grade, KL-6 concentration, and the dose of prednisolone and MTX. The KL-6 concentration increased significantly when ILD exacerbated (p < 0.05). The biologics were withdrawn in 11 of 14 subjects with ILD exacerbation, and 2 subjects with ILD grade 2 and 3 died due to respiratory failure.

Conclusion: The exacerbation rate was high in patients with pre-existing ILD when TNF blockers were administrated.

The Predictive Value of CD64 Counts for Infectious Disease in Patients Treated with Tocilizumab On the Infectious Disease Risk Management Cohort (ACT4U-study). Atsushi Ihata[1], Hiroyuki Hagiyama[2], Shouhei Naga-oka[3], Junichi Obata[4], Kiyomitsu Miyachi[5], Hidehiro Yamada[6], Shunsei Hirohata[7], Norihiko Koido[8], Masaomi Yamasaki[9], Kenichi Miyagi[10], Shigeru Ohno[11], Daiga Kishimoto[1], Reikou Watanabe[1], Takeaki Uehara[1], Kaoru Takase[1], Maasa Hama[1], Ryusuke Yoshimi[1], Atsuhisa Ueda[1], Mitsuhiro Takeno[1] and Yoshiaki Ishigatsubo[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama-city Bay Red Cross Hospital, Yokohama, Japan, [3]Yokohama Minami Kyosai Hospital, Yoko-hama, Japan, [4]Hikarichuo Clinic, Kawasaki, Japan, [5]Keigu Clinic, Kawasaki, Japan, [6]St. Marianna University, Kawasaki, Japan, [7]Kitasato University School of Medicine, Sagamihara, Japan, [8]Kawasaki Rheumatism & Internal Medecine Clinic, Kawasaki, [9]St Marianna University, Yokohama City Seibu Hospital, Yokohama, Japan, [10]Miyagi Naika Clinic, Yokohama, [11]Yokohama City University Medical Center, Yokohama, Japan

Background/Purpose: An administration of tocilizumab (TCZ) rapidly suppresses inflammatory markers such as CRP and ESR, which makes the diagnosis of infection difficult. There is a real need to establish the surrogate marker of infectious disease and to find how to reduce the infection risk./To validate the specificity of CD64 on polymorphonuclear neutrophils (CD64) and procalcitonin (PCT) levels as parameters for serious infection (SI) and deterrence effect of infectious disease risk management (IDRM) in RA patients with TCZ.

Methods: Forty-nine RA patients with were enrolled from 4 universities and affiliated clinics (Table). They were required to comply with IDRM policy during observation period. CD64 and PCT were measured at week 0, 4, 8 and the occurrence of infectious disease. Primary endpoint was occurrence frequency of SI (OFSI) and rate of increase in CD64 and PCT. Secondary endpoint was admission due to infection, the dose of concomitant medicines, CDAI and persistence rate of TCZ.

Table. Baseline characteristics of RA subjects at cohort entry

Cases (Male/Female)	49 (5/44)
Age (yr)	57.9 ± 2.1
Weight	8.0 ± 1.4 (6.0)
Steinblocker's Stage (1/2/3/4)	18.8/35.4/22.9/22.9
Steinblocker's Class (1/2/3/4)	22.9/62.5/14.6/0
Smoking	14.3%
Steroid use	± 0.6
Methotrexate use	± 0.5

Results: CD64 was 1477.3±199 and 1456.1±96.7 before and after TCZ administration, respectively. There was no significant difference of CD64 and PCT at baseline between patients with infectious disease and without infectious disease (1104.8±228.3 vs. 1501.4±191.5). Although the increase of CD64 was found in patients with infectious disease at week 8 compared with patients having no infectious disease, there were no significant difference between two groups (2091.2±934.9 vs. 1405.2±157.9). CRP was not as sensitive as CD64, which increased more than 2,000 when infection was complicated in some, but not all cases.

Neither pneumonia nor cellulitis occurred in 17 events of infection and 3 events of SI. CDAI was changed from 61.1±3.7 to 18.3±4.4 (Figure). The dose of CS was reduced by 41.8%. Persistence rate of TCZ was 69.4% at 48 weeks (Figure).
Conclusion: The present study showed that CD64 more sensitively moved than CRP at the complication with infection, suggesting that CD64 was a promising surrogate marker to detect infectious events in patients treated with TCZ. In spite of higher frequency of concomitant lung disease, the incidence of respiratory infection and OFSI were lower in our study than PMS, indicating that IDRM could contribute to reduction of OFSI especially in respiratory infection.

Intra-Articular Etanercept Treatment in Inflammatory Arthritis: A Randomized Double-Blind Placebo-Controlled Trial. Caroline J. Aal-bers[1], Danielle M. Gerlag[1], Koen Vos[1], Gertjan Wolbink[2], R. Landewe[1] and Paul P. Tak[3]. [1]Academic Medical Center/University of Amsterdam, Amster-dam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [3]Academic Medical Center, University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: The use of intra-articular (IA) corticosteroid injections has been widely accepted as a therapy to control local inflamma-tion. Studies on the use of IA TNF inhibitors revealed conflicting results. Case-reports suggested long-term efficacy of single or repeated injections in inflammatory arthritides. Randomized controlled trials comparing the use of IA TNF inhibitors to IA corticosteroids, showed either inferior or comparable efficacy. It is unknown if IA TNF blockade is more effective than placebo treatment. The objective of this trial was to investigate efficacy and safety of a single IA etanercept injection in comparison to placebo.

Methods: Patients with rheumatoid arthritis (RA) (revised 1987 ACR criteria) or psoriatic arthritis (PsA) (CASPAR classification criteria) and arthritis of knee, ankle, wrist, elbow or MPC joint despite a stable dose of methotrexate and/or prednisone were included. Patients were randomized to receive an IA injection of etanercept (25 mg) or placebo (0.9% NaCl) in a 2:1 ratio. Target joint improvement was determined by a composite change index (CCI; score 0–10), including a visual analogue scale (VAS) for pain, clinical assessments (tenderness, swelling and disability, scored 0–3) and patient's and doctor's assessment of treatment effect. To evaluate the effect of treatment on the CCI as a dependent variable, generalised estimating equations was used with age, gender, disease duration, CRP at baseline and TJC at baseline as covariates, and an exchangeable working correlation structure was chosen. Safety and general disease activity parameters were evaluated weekly up to week 6, as well as systemic CRP level, ESR and etanercept levels.

Results: Thirty-two patients (RA=12; PsA=20) were included, 22 received etanercept and 9 placebo. At baseline both groups were comparable. Treatment with etanercept resulted in a prompt and statistically significant improvement of the CCI (p<0.001) in comparison with placebo, as well as a

decrease in general parameters. When analysed over time, this beneficial effect was transient and only statistically significant at week 1 and 2 after IA injection (Figure 1). Joint tenderness remained decreased up to week 6 (p < 0.01). Maximum serum etanercept levels measured after 1 week were 1.39 ± 0.46 ug/ml. Levels were comparable between CCI 'good'- and 'non-responders'. Mild transient adverse events were reported for 7 (32%) patients treated with etanercept and 2 (25%) with placebo (p=0,55). No serious adverse events were reported.
Figure 1. Effect over time of treatment on the composite change index (CCI). The CCI is calculated relative to the baseline visit. Etanercept has a significant effect on the CCI at 1 and 2 weeks after intra-articular injection. *p < 0.05; **p < 0.01.

Conclusion: A single IA etanercept injection is feasible and safe and results in transient improvement of disease activity in the target joint as well as general parameters. This treatment can benefit patients who do not respond to or do not tolerate IA corticosteroids. Due to the high costs associated with anti-TNF treatment, IA corticosteroids remain the preferred treatment option.

Remission Induction in Early Active Rheumatoid Arthritis: Comparison of Tocilizumab Versus Methotrexate Monotherapy. Patrick Durez, Geneviève Depresseux, Marie Avaux, Adrien Nzeusseu Toukap, Bernard Lauwerys, Laurent Meric de Bellefon, Maria S. Stoenoiu and Frédéric A. Houssiau. Université catholique de Louvain, Brussels, Belgium

Background/Purpose: Tocilizumab (TCZ), as monotherapy and in combination with methotrexate (MTX), has been shown to be efficacious for rheumatoid arthritis patients with insufficient response to MTX or other disease-modifying antirheumatic drugs. These observations were extended to patients with early rheumatoid arthritis (ERA) or refractory to tumor necrosis factor inhibitors. This study was designed to compare the rate of remission induction and the cardiorespiratory endurance (CRE) in early RA patients treated with TCZ or MTX.

Methods: Eligible patients had disease duration ≤2 years, were MTX-naive, and had active RA (DAS28 ≥3.2). Thirty (23 women and 7 men) RA patients were randomized to received either TCZ 8 mg/kg every month or MTX 20 mg weekly for 6 months. After this first period, all patients were treated with MTX for an additional 6 months period. Baseline demographics did not differ between groups: mean age +/− SD (56.9 +/− 10.4) vs (49.4 +/− 14.0), mean disease duration (0.49 +/− 1.3) vs (0.99 +/− 2.3), mean DAS 28-CRP (4.7 +/− 1.3) vs (4.4 +/− 1.0), mean HAQ (1.4 +/− 0.7) vs (0.9 +/− 0.6). ACR and EULAR core set values were evaluated monthly by an independent joint assessor. Differences were statistically tested using Mann-Whitney or Wilcoxon rank tests.

Results: 13 and 17 ERA patients were included in the MTX and TCZ arm, DAS 28CRP promptly improved with a between group statistically significant difference observed at month 3 and 6. At week 24, respectively 76.5% (13/17), 75% (12/16) of patients in the TCZ group achieved DAS28CRP remission (<2.6) and SDAI remission (<3.3) vs 41.7% (5/12), 50% (6/12) in the MTX group. Interestingly, a SJC of 0 was achieved at 6, 9 and 12 month in a significantly greater proportion of patients in the TCZ group (88%) compared to the MTX group (36%) (p<0.012). According to the new ACR/EULAR Boolean definition, remission was achieved in **31.3% (5/16) of TCZ patients and 0% (0/13) of MTX patients** (p<0.048). The proportion of patients achieving HAQ scores within the norm (£0.5) was not significantly greater in the TCZ group (70.5% [12/17]) than in the MTX group (33.3% [4/12]). For the submaximal CRE test, 13 patients were excluded from the analysis because they were unable to perform the 3rd stage. The work capacity during the active treatment was not statistically improved at 6 months (W65%/kg: 1.86 +/−0.85 vs 1.57 +/−0.60 watts/kg for the MTX group and 1.55 +/−0.60 vs 1.57 +/− 0.49 for the TCZ group). Serious AEs were reported by only one patient in the TCZ group who developed an episode of diverticulitis at 24 weeks.

Conclusion: These results demonstrate that remission is a realistic therapeutic goal when TCZ monotherapy is administered early in the RA disease process. In this population of naive DMARDs ERA patients, TCZ was superior to MTX alone in producing prolonged clinical remission. We failed to demonstrate that early RA patients intensively treated with TCZ or MTX could restore their CRE despite a large clinical response.

1336

Changes in the Levels of Anti-Cyclic Citrullinated Protein Antibody and Immunoglobulins in Rheumatoid Arthritis Patients After Administration of Tocilizumab. Masao Sato, Masao Takemura, Ryuki Shinohe, Tsuneo Watanabe and Katsuji Shimizu. Gifu University, Gifu, Japan

Background/Purpose: The recently established scoring system of American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) early arthritis diagnosis criteria have assigned scores of 0, 1, and 2, respectively, for negative, positive (low titer), and positive (high titer) results of anti-cyclic citrullinated protein (anti-CCP) antibody tests. Thus, high anti-CCP antibody titer is unfavorable in the pathological condition of rheumatoid arthritis (RA). We investigated the changes of anti-CCP antibody and immunoglobulin titers after treatment using tocilizumab (TCZ), which is the biological product of an interleukin (IL)-6 inhibitor agent.

Methods: Subjects were 40 RA patients (6 men, 34 women). The patient backgrounds were as follows: age, 25–76 years; mean age, 58.1 ± 11.8 years; mean disease duration, 8.8 ± 8.4 years (range, 1–45 years). TCZ 8 mg/kg was intravenously administered every 4 weeks and was continued for 52 weeks. Evaluations were performed at 3 time points: at the start of the treatment, after 12 weeks, and after 52 weeks. The methods of evaluations were as follows: after calculation of the patient's disease activity score (DAS28), quantitative determination of serum C-reactive protein (CRP) and immunoglobulin levels was performed by TIA. Anti-CCP antibody was measured using CL-JACK with a designated reagent and an anti-CCP test kit. IL-6 was evaluated using CLEIA. In addition, lymphocyte phenotypes were analyzed for CD3/CD19, CD4/CD25, and CD8/CD11 levels with the corresponding antibodies by using a flow cytometer.

Results: Of the 40 RA patients, 34 patients showed effective improvement in the DAS28; further, although effective, 6 patients showed insufficient DAS28. All CRP values of effective cases after the 12-week evaluation were less than the cut-off value (0.02 μg/ml). Comparison of the immunoglobulin levels at the start of the treatment and after 52 weeks of treatment were respectively as follows: IgG, 1550.1 ± 518.9 mg/ml and 1162.2 ± 431.9 mg/ml, p < 0.0006; IgA, 287.9 ± 112.2 mg/ml and 234.7 ± 89.9 mg/ml, p < 0.002; IgM, 119.9 ± 68.0 mg/ml and 111.9 ± 59.1 mg/ml, not significant (NS). A significant decrease was observed in IgG and IgA levels. No changes were observed in the CD3 (68.2 ± 11.7% and 65.2 ± 11.2%; NS), CD19 (12.5 ± 8.1 and 14.3 ± 8.7%; NS), and number of lymphocytes. The results at the beginning and after 52 weeks of treatment for anti-CCP antibody were 207.0 ± 281.2 U/ml and 253.6 ± 336.4 U/ml (NS) and IL-6, 22.7 ± 35.6 pg/ml and 31.8 ± 40.1 pg/ml (NS). No statistically significant differences were observed.

Conclusion: It can be confirmed from our study results that administration of TCZ decreases immunoglobulin levels in all patients. This result is understood clearly by blocking the differentiation-inducing effect from B-cell lymphocytes to plasma cells, which originally is an action of IL-6. Despite the

possibility that a decrease in the levels of anti-CCP antibodies can be misinterpreted, no such observations were noted. A suppressive action on B-cell differentiation is assumed because of the changes in lymphocytes (CD19+) in the patient blood samples. However, TCZ is considered to have no suppressive action on anti-CCP antibody production at the local inflammation sites in RA patients.

Sarilumab, a Subcutaneously-Administered, Fully-Human Monoclonal Antibody Inhibitor of the IL-6 Receptor: Pharmacokinetic Profile and Its Relationship to Changes in Pharmacodynamic Markers in Patients with Rheumatoid Arthritis. Pavel Belomestnov[1], Jennifer Hamilton[1], A. Thomas DiCioccio[1], Martine Jasson[2] and Allen R. Radin[3]. [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Sanofi, Paris, France, [3]Regeneron Pharmaceuticals Inc, Tarrytown, NY

Background/Purpose: Sarilumab, a fully human monoclonal antibody targeting interleukin-6 receptor alpha (IL-6Rα), is being evaluated for the treatment of rheumatoid arthritis (RA) based on the role of IL-6 in RA pathogenesis. This study aims to characterize the pharmacokinetic (PK) profile of single subcutaneous (SC) doses of sarilumab, and determine its relationship to markers of pharmacodynamic (PD) effects in patients (pts) with RA.

Methods: In this phase 1 parallel group study, pts with active RA (N=32) on background methotrexate (MTX) received a single SC dose of 50, 100, or 200 mg sarilumab or placebo (PBO). Blood samples were drawn at baseline and post-treatment days 1, 4, 8, 12, 15, 22, 29, 36, and 43. The serum obtained was analyzed for concentrations of functional sarilumab, defined as antibody with 0 or 1 of the 2 binding sites occupied by soluble IL-6Rα, using a validated enzyme-linked immunosorbent assay (ELISA). Pharmacokinetic parameters were determined using non-compartmental methods. The PD markers IL-6, high sensitivity C-reactive protein (hsCRP), and serum amyloid A (SAA) were assessed in parallel. Safety and tolerability were evaluated based on incidence of adverse events (AEs) and clinical/laboratory assessments.

Results: All pts were white and female; age ranged from 45.5–55.4 years and RA duration from 7.9–10.3 years. PK is characterized as non-linear with target-mediated elimination. An initial absorption phase, followed by a saturating beta phase and a terminal target-mediated elimination phase were observed. Patients in the higher dose groups had higher concentrations of functional sarilumab, and these concentrations were detectable for a longer period (Table). A greater than dose-proportional increase in the area under the concentration-time profile (AUC) and maximum serum concentration (C_{max}) was observed. The beta phase was well defined in the 200 mg dose group. While no meaningful changes over time were observed in hsCRP, SAA, or IL-6 with PBO, changes in the sarilumab groups reflected both the dose and PK profile. Reductions in hsCRP and SAA and increases in IL-6 were greater and of longer duration at higher doses, and were statistically significant compared to placebo. The largest % changes were seen in the 200 mg group: hsCRP −91.7%, SAA −92.5%, and IL-6 +647%. The most commonly reported treatment-related AEs in the combined sarilumab groups were neutropenia, increased alanine aminotransferase, and increased aspartate aminotransferase, which were transient and not associated with clinical sequelae. One pt receiving sarilumab 50 mg had a serious AE of RA flare requiring hospitalization.

Pharmacokinetic variable	Sarilumab 50 mg SC + MTX (n = 8)	Sarilumab 100 mg SC + MTX (n = 8)	Sarilumab 200 mg SC + MTX (n = 8)
C_{max}, mg/L	0.52 ± 0.26 (144)	3.96 ± 0.96 (68.2)	12.9 ± 1.7 (37.5)
C_{max}/Dose, 1/L	0.010 ± 0.005 (144)	0.040 ± 0.010 (68.2)	0.064 ± 0.009 (37.5)
t_{max}, days	2.56 ± 0.37 (24.7)[a]	3.77 ± 0.47 (35.4)	3.67 ± 0.49 (37.8)
C_{last}, mg/L	1.38 ± 0.23 (29.4)[a]	1.83 ± 0.55 (85.0)	2.55 ± 1.21 (134)
t_{last}, days	2.56 ± 0.37 (24.7)[a]	6.53 ± 0.53 (23.0)	15.9 ± 3.83 (68.1)
AUC_{all}, day · mg/L	1.79 ± 0.92 (145)	21.2 ± 5.43 (72.5)	102 ± 20.1 (55.6)
AUC_{all}/Dose, day/L	0.036 ± 0.018 (145)	0.21 ± 0.05 (72.5)	0.51 ± 0.10 (55.6)

Mean ± standard error (coefficient of variation %)

C_{max}, maximum plasma concentration; t_{max}, time to reach C_{max}; C_{last}, concentration at time of last positive evaluation; t_{last}, time of last positive drug evaluation; AUC_{all}, area under the curve from time zero to the last concentration
[a]Five patients who had concentrations < lower limit of quantitation were excluded from this analysis.

Conclusion: Sarilumab has a nonlinear PK profile with parallel linear and target-mediated elimination. PD effects were dose-dependent, consistent with the PK profile, and showed substantial reductions in acute phase reactants relative to placebo.

Anti-Tumor Necrosis Factor Therapy Reduces Serum Levels of Chemerin in Rheumatoid Arthritis: A New Mechanism by which Anti-Tumor Necrosis Factor Might Reduce Inflammation. M.M. Herenius[1], A.S.F. Oliveira[1], C.A. Wijbrandts[1], D. Gerlag[1], Paul P. Tak[2] and Maria C. Lebre[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: Chemerin is a specific chemoattractant for macrophages and dendritic cells (DC). In addition, it can rapidly stimulate macrophage adhesion to extracellular matrix proteins and adhesion molecules and is able to activate fibroblast-like synoviocytes (FLS), suggesting a role in the pathogenesis of rheumatoid arthritis (RA). Chemerin is also an adipocytokine that has been related to the inflammatory state of endothelial cells and as such could be involved in the changes in endothelial cells in RA and perhaps increased cardiovascular morbidity. We investigated whether anti-TNF treatment affects chimeric levels.

Methods: 49 patients with active RA (disease activity score evaluated in 28 joints (DAS28)) ≥3.2) were started on adalimumab therapy. Blood was drawn from patients while fasting at baseline and 16 weeks after treatment. Chemerin serum levels were measured by ELISA and related to disease activity, mediators of inflammation and known risk factors for cardiovascular disease

Results: Adalimumab therapy significantly reduced chemerin serum levels, which was correlated with the reduction in DAS28 ($r=0.37$, $p=0.009$), ESR ($r=0.55$ $p<0.001$), CRP ($r=0.40$, $p=0.005$). In addition, the decrease in chemerin serum levels after anti-TNF treatment was associated with the decrease in serum levels of IL-6 ($r=0.39$, $p=0.033$) and macrophage migration inhibitory factor (MIF) ($r=0.31$, $p=0.049$). Baseline chemerin serum levels were not related to traditional risk factors for atherosclerosis, except perhaps for smoking ($p=0.07$).

Conclusion: The present study suggests that anti-TNF therapy may exert its beneficial effects on synovial inflammation and cardiovascular morbidity in part via an effect on chemerin levels.

1339

A Pilot Study Investigating the Tolerability and Pharmacodynamic Effect of Single Intravenous/Subcutaneous Doses of Olokizumab, an Anti-Interleukin-6 Monoclonal Antibody, in Patients with Rheumatoid Arthritis. Roy Fleischmann[1], Alan J. Kivitz[2], Frank Wagner[3], Jeffrey A. Feinstein[4], Uwe Fuhr[5], Jürgen Rech[6], Jagdev Sidhu[7], Philip L. Hill[8], Ruth Oliver[8] and Kosmas Kretsos[9]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Charité Research Org GmbH, Berlin, Germany, [4]San Antonio, TX, [5]Hospital of the University of Cologne (AöR), Köln, Germany, [6]University of Erlangen-Nuremberg, Erlangen, Germany, [7]CSL Limited, Parkville, Australia, [8]UCB Celltech, Slough, United Kingdom, [9]UCB, Slough, United Kingdom

Background/Purpose: Olokizumab is a novel IL-6 inhibitor that selectively blocks the final assembly of the IL-6 signaling complex (gp80+gp130+IL-6). We report the safety, PK, and PD results from a pilot single-dose study in patients with rheumatoid arthritis (RA).

Methods: This was a randomized, double-blind, placebo-controlled study of RA patients who: were diagnosed by the 1987 ACR criteria; had >6 months' disease duration; were treated with methotrexate 5–25 mg/week for at least 3 months prior to screening; had an elevated baseline high-sensitivity C-reactive protein (CRP; median 3.37, range 0.6–27.2 mg/L) with a reasonable spread that allowed robust characterization of the PD effect. At baseline, the mean DAS28 (CRP) was 3.07 (olokizumab) and 2.87 (placebo). Patients were randomized (3:1) to a single dose of olokizumab, either iv (0.1 or 1.0 mg/kg) or sc (1.0 or 3.0 mg/kg), or placebo. Primary objectives of the study

included evaluating the PK/PD relationship between olokizumab and CRP, and the safety and tolerability of olokizumab over 12 weeks post dose.

Results: Of 40 randomized patients, 38 completed the 12-week follow-up. Dose-dependent and sustained suppression of plasma CRP followed all doses of olokizumab until the end of the study (except for the 0.1 mg/kg iv group). IL-6 levels were markedly reduced after olokizumab exposure, remaining suppressed for the duration of the study. Commonly reported AEs in olokizumab recipients included headache, infection, decreased white blood cells (WBC), and abnormal liver function tests (LFT), with no dose relationship to severity, grade, or frequency of reported events. Laboratory abnormalities included: reductions in WBC and elevated LFT, cholesterol, and triglycerides. Two serious AEs were reported: 1 for placebo (grade 2 Bowen's disease) and 1 for olokizumab 1.0 mg/kg sc (worsening of RA). Two patients withdrew: 1 placebo (worsening of RA) and 1 olokizumab 1.0 mg/kg sc (protocol deviation). Dose-related reductions in complement C3 and C4 were seen. The terminal elimination $t_{1/2}$ of olokizumab in plasma was consistent regardless of route of administration or dose, with an overall median of 31 days. For the 1.0 and 3.0 mg/kg sc dose groups, the mean C_{max} was 6.29 and 19.1 μg/mL, achieved within a median t_{max} of 13 and 7 days, respectively. Bioavailability determined from PK/PD modeling, pooling data from the first-in-human study[1] and this study, was 76%. Non-compartmental analysis, based solely on data from this study, yielded a bioavailability of 66%.
Conclusion: In RA patients, single doses of $\leq$3mg/kg sc olokizumab demonstrated prolonged suppression of CRP, a marker of inflammation, although CRP in the 0.1 mg/kg iv group showed some recovery after 28 days; all doses were well tolerated. These results provided the rationale for a further study to investigate the clinical efficacy of olokizumab in RA.

Effects of Subcutaneous Abatacept or Adalimumab On Remission and Associated Changes in Physical Function and Radiographic Outcomes: One Year Results From the Ample (Abatacept Versus Adalimumab Comparison in Biologic-Naive RA Subjects with Background Methotrexate) Trial. Roy Fleischmann[1], Michael H. Schiff[2], Michael E. Weinblatt[3], Michael A. Maldonado[4], Elena M. Massarotti[5] and Yusuf Yazici[6]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Colorado, Denver, CO, [3]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [4]Bristol-Myers Squibb, Princeton, NJ, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [6]New York University, New York, NY

Background/Purpose: Advancements in the understanding of Rheumatoid Arthritis (RA) have led to the development of novel therapeutics and treatment guidelines that target remission as an achievable goal in RA.

Further, this has created a debate on the definition and dimensions of remission in RA. We report here, the impact of treatment with subcutaneous abatacept (ABA) or adalimumab (ADA) on remission in the AMPLE (**A**batacept Versus Adali**m**umab Com**p**arison in Bio**l**ogic Naiv**e** RA Subjects with Background Methotrexate) study, the first head-to-head trial in RA patients with inadequate response to methotrexate (MTX). AMPLE provides a novel opportunity to compare biologic agents with different mechanisms of action and their ability to achieve remission defined by multiple criteria.

Methods: AMPLE is an ongoing, phase IIIb, randomized, investigator-blinded study of 24 months duration with a 12 month primary efficacy endpoint. Biologic-naïve RA patients with an inadequate response to MTX were randomized to 125 mg ABA weekly or 40 mg ADA bi-weekly, in combination with a stable dose of MTX. The proportions of patients achieving remission defined as DAS28-CRP <2.6, SDAI ≤3.3, CDAI ≤2.8, RAPID3 <1, and Boolean score ≤1 were assessed. Patient function (assessed with the health assessment questionnaire disability index [HAQ-DI - responders defined as reduction ≥ 0.3]) and radiographic non-progression (defined as change in modified total Sharp score of ≤ 0.5 or ≤ 2.8, change in erosion or joint space narrowing score of ≤ 0.5) were then analyzed in patients achieving remission at 1 year.

Results: The baseline clinical characteristics of ABA (n = 318) and ADA (n = 328) treatment groups were balanced, as was clinical, functional and radiographic efficacy and safety at 1 year with minor differences. The proportions of patients meeting each of the remission criteria at 1 year were generally equal for both groups, but significantly more patients achieved DAS28-CRP remission compared to CDAI, SDAI or RAPID3 remission, and the smallest proportion achieved Boolean remission (Table). Across all assessed remission criteria, 76–85% of patients in both treatment arms were HAQ responders at year 1. Furthermore, 63–100% of patients were radiographic non-progressors depending on the remission criteria employed; however, similar radiographic outcomes were seen in both treatment arms.

Remission Criteria	SC Abatacept	Adalimumab
DAS28-CRP ≤ 2.6, n/m (%)	119/275 (43.3%)	112/267 (41.9%)
RAPID3 = 0–1.0	74/272 (27.2%)	66/263 (25.1%)
CDAI ≤ 2.8	65/277 (23.5%)	64/267 (24.0%)
SDAI ≤ 3.3	64/275 (23.3%)	66/266 (24.8%)
Boolean	6/275 (2.2%)	15/267 (5.6%)

Conclusion: Patients treated with SC abatacept or adalimumab in the AMPLE trial achieved comparable rates of remission as assessed across multiple criteria. Similar improvements in physical function and radiographic outcomes were observed in patients that achieved remission. Data reported here further highlight the difference in remission rates depending on the measure used and help illustrate the relationship between remission and functional and radiographic outcomes independent of choice of effective treatment in RA.

1341

Beneficial Effect of Anti-TNF Therapy in the Lipoprotein Atherogenic Risk Profile in Comparison with DMARD Standard Therapy in RA Patients. Jaime Calvo-Alen[1], Ignacio Villa[2], Victor M. Martinez-Taboada[3], Jose Luis Peña-Sagredo[4], Mario Agudo[4], Ana Carmen García[5] and Juan Gomez-Gerique[6]. [1]Hospital Universitario Sierrallana, Torrelavega, Spain, [2]Hospital Sierrallana, Torrelavega, Spain, [3]Hospital Universitario Marques de Valdecilla. IFIMAV, Santander, Spain, [4]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [5]Fundación 12 de Octubre, Madrid, Spain, [6]Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background/Purpose: RA patients portend a greater risk of cardiovascular complications than general population. Although most probably diverse mechanisms are implicated, quantity and quality changes in the lipoproteins appear to have an important role.

Methods: RA patients in stable treatment with anti-TNF therapy at least during the last six months and a matched (by age, gender and rheumatoid factor status) with stable doses of standard DMARDs (most of them using methotrexate) were clinically evaluated using DAS28, as activity marker and MHAQ to assess disability. In addition, a complete standard lipid profile, a comprehensive lipoprotein assessment was carried out including: Lipoprotein, and apolipoprotein A1 (ApoA1) and B (ApoB) levels (total and lipoprotein specific), levels of paroxonase 1 (PON1), HDL, LDL, VLDL and total cholesterol, triglycerides and phospholipids levels as well as number of molecules of these lipids (mc, mt and mf respectively) in each lipoprotein, total mass (M) and number of particles (np) of the before mentioned lipoproteins, levels of PCSK9 receptor. Results of both subsets of patients were performed with standard statistical tests.

Results: Sixty-seven RA patients on anti-TNF and 63 matched RA patients on DMARD, mean age (58.7 ± 12.3 and 61 ± 12.1 years), gender distribution (81% females in both cases), disease duration (140 ± 165 and 143 ± 276 months) and RF status (64% in both cases) were comparable. Patients on DMARD were more active (DAS28 4.42 ± 1.35 vs 3.57 ± 1.27 and hsCRP 9.4 ± 15.2 vs 3.8 ± 5.8 mg/l respectively. Main findings in the lipoprotein analysis are shown in table 1.

	Apo-A (mg/dl)	MVLDL (mg/dl)	np VLDL
Anti-TNF	169.7	913.5	89513.1
DMARD	156.2	1360.8	112898.3
p value	.008	.001	.017

Multivariate analysis were performed with the three variables entering DAS28 as covariate and in all cases anti-TNF therapy remained as unique explicative variable.

Conclusion: RA patients treated with anti-TNF, regardless that they show lower levels of clinical activity, they have an improvement in their atherogenic risk profile showing higher levels of ApoA1 and therefore greater antioxidant capacity as well as lower levels of total mass and number of particles of VLDL which are atherogenic risk factors.

Changes in Patient Reported Outcomes in Response to Subcutaneous Abatacept or Adalimumab in Rheumatoid Arthritis: Results From the Ample (Abatacept Versus Adalimumab Comparison in Biologic Naive RA Subjects with Background Methotrexate) Trial. Roy Fleischmann[1], Michael E. Weinblatt[2], Michael H. Schiff[3], Dinesh Khanna[4], Daniel Furst[5] and Michael A. Maldonado[6]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [3]University of Colorado, Denver, CO, [4]University of Michigan, Ann Arbor, MI, [5]University of California at Los Angeles, Los Angeles, CA, [6]Bristol-Myers Squibb, Princeton, NJ

Background/Purpose: Rheumatoid arthritis (RA) is associated with pain, fatigue, disability and functional loss, which can significantly impact a patient's health-related quality of life (HRQoL). Patient-Reported Outcomes (PROs) are critical since patients and caregivers do not always perceive treatment effects equally. To highlight the patient's perspective, we report multiple PROs from the first head-to-head study, AMPLE (**A**batacept Versus Adali**m**umab Com**p**arison in Bio**l**ogic Naiv**e** RA Subjects with Background Methotrexate) comparing subcutaneous abatacept (ABA) and adalimumab (ADA) on background methotrexate (MTX).

Methods: AMPLE is an ongoing, phase IIIb, randomized, investigator-blinded study of 24 months duration with a 12 month efficacy primary endpoint. Biologic-naïve patients with active RA and inadequate response to MTX were randomized to either 125 mg ABA weekly or 40 mg ADA bi-weekly in combination with MTX. PROs assessed were patient pain, patient global assessment (PtGA), and fatigue, all assessed by 100mm visual analog scale (VAS), with a higher score indicating worse outcome (Minimal Clinically Important Difference [MCID]: reduction $\geq$10mm). Physical function was evaluated with the health assessment questionnaire disability index (HAQ-DI; MCID reduction $\geq$0.3). HRQoL was assessed using the SF-36 (including Physical and Mental Component Summary subscores [PCS and MCS]; MCID: improvement $\geq$5). The Routine Assessment of Patient Index Data (RAPID3), an index of 3 patient-reported core dataset measures (physical function, pain, and patient global estimate of status), was also assessed (MCID: reduction $\geq$2.0).

Results: A total of 646 patients were randomized and treated with ABA (n=318) or ADA (n=328) on background MTX. Patient characteristics were balanced. A similar proportion of patients achieved a HAQ-DI response from baseline to year 1 (60.4% patients in the ABA arm vs. 57.0% patients in the ADA arm). Improvements in patient pain (mean% $\pm$ SE) were 46.5 ± 4.2% vs. 35.6 ± 4.1% at 6 months, and 53 ± 6.1% vs. 39.2 ± 6.0% at 1 year for ABA and ADA, respectively. Improvements in PtGA were 40.2 ± 7.3% vs. 27.6 ± 7.2% and 46.1 ± 3.5% vs. 41.2 ± 3.4% for ABA and ADA at 6 months and 1 year. Fatigue decreased from baseline by -22.4 ± 1.5% vs. -19.9 ± 1.5% at 6 months, and -23.2 ± 1.5% vs. -21.4 ± 1.5% at 1 year for ABA and ADA respectively. Improvements in all domains of the SF-36 including PCS and MCS observed at 6 months were maintained at 1 year (Figure). For RAPID3, the ABA and ADA-treated groups demonstrated improvements (mean $\pm$ SE) of -2.7 ± 0.1 vs. -2.5 ± 0.1 at 6 months and -2.9 ± 0.1 vs. -2.7 ± 0.1 at 1 year.
Figure 1. Mean Change from Baseline to Year 1 in Short From-36 Scores

Conclusion: In this first head-to-head comparison, subcutaneous abatacept demonstrated significant improvements with similar kinetics of response in patient-reported outcomes and HRQoL measures over 1 year which were comparable to adalimumab.

EARLY Improvements in the Lower Limbs Enthesis by Ultrasound Predicting Later Favorable Responses in TNF Inhibotors-Treated Patients with Spondyloarthritis. Kensuke Kume[1], Kanzo Amano[1], Kuniki Amano[2], Hiroyuki Ohta[3] and Noriko Kuwaba[4]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Sky Clinic, Hiroshima, Japan, [3]Hiroshima, Japan, [4]Sanki Clinical Link, Hiroshima, Japan

Background/Purpose: Lower limbs enthesis by ultrasound (US) detects inflammatory activity in patients with spondyloarthritis(SpA) and is a diagnostic tool of early SpA. The present objective was to follow SpA patients starting anti-TNF inhibitors with US and clinical assessments to

explore whether any variable in baseline or early stage could predict later favorable responses.

Methods: This study is prospective and US reader and clinical physician blinded study. Patients with SpA starting anti-TNF inhibitors were consecutively included and examined at baseline and, after 1 and 12 weeks with standardized bilateral ultrasound of six enthesis (Madrid sonography enthesitis index (MASEI)). In addition, the patients were assessed clinically with ASDAS, assessor global VAS (study nurse), ESR and CRP. Patients with ASDAS clinical important improvement at the 12 weeks examination was defined as responders. The results of US score (MASEI), clinical and laboratory assessments at baseline and after 1 week were explored by Mann-Whitney tests to examine for associations with the responders.

Results: A total of 45 patients were included (mean (SD) age 60.3 (25.2) years, disease duration 14.2 (6) years, and 35% women, with 73% using infliximab and 27% adalimumab). A total of 69 % of the patients were defined as ASDAS responders, and they had significantly lower US score (MASEI) (p=0.03), assessor global VAS (study nurse) (p=0.02), and CRP (p=0.02) at the 12 weeks examination. Baseline US score (MASEI), ASDAS, assessor global VAS, ESR or CRP did not separate between responders and non-responders. At 1 week examination the only variable differing between responders and non-responders was the US score (MASEI), with a significant reduction in US score (MASEI) in the responders versus non-responders 12.6 (5.4) versus 2.3(3.3) (p=0.03).

Conclusion: US enthesis images at 1 week after TNF inhibitors in patients with SpA are useful to identify later good responders.

Diagnostic Value of High Sensitivity C Reactive Protein for Early Axial Spondyloarthritis: Results From the Devenir Des Spondylarthopathies Indifferenciees Recentes Cohort. Victoria Navarro-Compán[1], Désirée van der Heijde[1], Bernard Combe[2], Claudine Cosson[3] and Floris van Gaalen[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Hopital Lapeyronie, Montpellier, France, [3]Hôpital Bicêtre, Assistance Publique Hôpitaux de Paris, Paris, France

Background/Purpose: The average delay in spondyloarthritis (SpA) diagnosis after symptom onset is one of the longest among the inflammatory rheumatic diseases. Elevated C-reactive protein (CRP) has been incorporated as one of the features for ASAS axial SpA criteria and in the Berlin diagnostic algorithm. However, CRP levels are elevated in only a minority of early SpA patients which limits its potential diagnostic value. More sensitive tests called high-sensitivity CRP (hsCRP) have been developed and can detect lower concentrations of CRP compared with traditional methods. Therefore, hsCRP could be more sensitive than traditional CRP for diagnosis in axial SpA. The aim of this study was to assess if hsCRP measurement contributes to early axial SpA diagnosis compared with traditional CRP measurement.

Methods: Baseline data from 648 patients with inflammatory back pain (IBP) duration >3 months but <3 years from DESIR cohort was used. Design and inclusion criteria have previously been reported (1). Levels of CRP and hsCRP were measured in serum at baseline. The cut-off values selected to define positive hsCRP and CRP were ≥ 2 mg/l and ≥ 5 mg/l, respectively.

Results: Based on the ASAS axial SpA criteria, 444 (69%) patients were classified as SpA and 203 (31%) patients as no SpA. Patients' characteristics and lab results are shown in table 1. Serum levels of CRP and hsCRP were higher in SpA versus no SpA. In the subgroup of patients with a negative CRP, mean serum levels of hsCRP were also higher in SpA patients compared with no SpA patients (1.7 mg/L vs 1.5 mg/L, p 0.03). Moreover, after dichotomizing hsCRP, more patients within the SpA group had a positive hsCRP versus the no SpA group, although this difference was not statistically significant (p=0.06) (table 2).

Table 1. Characteristics of patients

	SpA n=444 (69%)	No SpA n=203 (31%)	P value
Age (years)	32.4 ± 8.6	34.8 ± 8.3	0.001
Male	223 (50%)	76 (37%)	0.01
Caucasoid	400 (90%)	159 (88%)	0.5
Back pain duration	1.0 ± 0.9	0.9 ± 8.4	0.03
HLA-B27 positive	368 (83%)	8 (4%)	<0.0001
Sacroiliitis on MRI	106 (52%)	0 (0%)	<0.0001
Sacroiliitis on X-Ray	107 (24%)	0 (0%)	<0.0001
CRP (mg/L)	3.9 (1–8.6)	2.6 (1–5)	<0.0001
hsCRP (mg/L)	2.8 (1.1–8.1)	1.6 (0.3–3.6)	<0.0001

Table 2. Serum levels of hs-CRP in patients with normal CRP values (<5 mg/L)

hsCRP	SpA (n=260)	No SpA (n=152)
<2	174 (66.9%)	110 (72.4%)
≥2–<3	41 (15.8%)	30 (19.7%)
≥3–<4	34 (13.1%)	11 (7.2%)
≥4–<5	7 (2.7%)	0
≥ 5	4 (1.5%)	1 (0.7%)

Finally, we investigated how many extra patients from the no SpA group (n=203) would be classified as SpA substituting the traditional CRP by hsCRP in the clinical arm (HLA-B27 arm) of the ASAS axial SpA criteria. Only 4 (2%) extra patients had 2 axial SpA features instead of only 1 feature (IBP) substituting hsCRP by CRP (195 vs 191 patients), but none of them was HLA-B27 positive. Consequently, none of the no SpA patients met ASAS criteria applying this modification.

Conclusion: In patients with a normal CRP, hsCRP is increased in axial SpA patients compared with patients without SpA. However, hsCRP measurement in patients with IBP may not add any extra value for early axial SpA diagnose compared with CRP measured by traditional method.

Validation of the Health Assessment Questionnaire for Spondyloarthritis in Patients with Non-Radiographic Axial Spondyloarthritis. Dennis Revicki[1], Wen-Hung Chen[1], Ying Jin[1], Sumati Rao[2], Philip Mease[3] and Mary Cifaldi[2]. [1]United Biosource Corporation, Bethesda, MD, [2]Abbott Laboratories, Abbott Park, IL, [3]Swedish Rheumatology Research Group, Seattle, WA

Background/Purpose: To evaluate the psychometric properties of the Health Assessment Questionnaire for Spondyloarthritis (HAQ-S) in patients with non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: Data from 185 nr-axSpA patients receiving the human anti-TNF monoclonal antibody adalimumab (ABILITY-1-trial) were analyzed. Internal consistency and test–retest reliability were assessed using Cronbach's alpha and intraclass correlation coefficient (ICC), respectively. Convergent validity was assessed by correlating HAQ-S with Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), EQ-5D™, Patient and Clinical Global Assessment of Disease Activity Visual Analog Scales (PGA-VAS and CGA-VAS), and Patient's Global Assessment of Pain (PAIN-VAS). Known-groups validity and ability to detect changes were assessed based on Patient Acceptable Symptom State Questionnaire (PASS) and PGA-VAS using analysis of variance. PASS, PGA-VAS, and CGA-VAS were used as anchors to determine the minimally important difference (MID).

Results: The HAQ-S Global and Activity scores demonstrated internal consistency, with good Cronbach's alpha (0.95 and 0.78, respectively), but Cronbach's alpha was lower for Driving scores (0.63). The HAQ-S Global, Activity, Driving, and Stiffness scores all demonstrated test–retest reliability, with good ICCs (0.90, 0.82, 0.71, and 0.87, respectively). The HAQ-S Global, Activity, and Stiffness scores demonstrated good convergent validity, as indicated by the moderate to high correlations with BASFI, BASDAI, EQ-5D™, PGA-VAS, and PAIN-VAS at baseline (0.31–0.76) and week 12 (0.53–0.89). Correlations between the HAQ-S Driving score and the criterion measures were lower (0.24–0.46 at baseline; 0.41–0.63 at week 12). For known-groups validity, mean HAQ-S Global, Activity, Driving, and Stiffness

scores at week 12 were significantly different for patients with different PASS responses (P<0.001). The HAQ-S Global, Activity, and Stiffness scores were significantly different for patients with PGA-VAS scores below and above the sample median at baseline and at week 12 (P<0.001). The HAQ-S Global, Activity, Driving, and Stiffness scores demonstrated significantly larger changes for responders (PASS="Yes" at week 12) than for non-responders (PASS="No"), and for responders (PGA-VAS decreased ≥30% at week 12) than for non-responders (PGA-VAS decrease <30% or increased), indicating the ability to detect changes in clinical status. Using anchor-based methods (based on PASS, PGA-VAS, and CGA-VAS), MIDs ranged from −0.17 to −0.42 for HAQ-S Global score, −0.09 to −0.57 for HAQ-S Activity score, 0.10 to −0.29 for HAQ-S Driving score, and −8.8 to −32.7 for HAQ-S Stiffness score. The MID for the HAQ-S Global score should be 0.26 calculated as the average of the MIDs based on PGA-VAS and CGA-VAS anchors.

Conclusion: This study of the HAQ-S indicated that Global, Activity, and Stiffness scores were reliable and valid measures of functional ability in patients with nr-axSpA. The HAQ-S scores also demonstrated ability to detect change in clinical status.

Background/Purpose: The majority of patients with PsA have psoriasis prior to arthritis and there is evidence that a significant proportion of patients in dermatology clinics have undiagnosed PsA. Multiple screening questionnaires have been developed and tested for the early detection of PsA but there has been no direct comparison to identify which is the optimal screening questionnaire. The aim of this study was to compare three existing PsA screening questionnaires (PASE, PEST, TOPAS) in a head-to-head study in secondary care dermatology clinics using the CASPAR criteria as the gold standard.

Methods: This study recruited from 10 UK secondary care dermatology clinics. Patients with a diagnosis of psoriasis, not previously diagnosed as PsA, were given a pack containing study information, and all 3 questionnaires in a random order. The completed questionnaires were compiled and scored by a study co-ordinator and all patients who were positive on any of the questionnaires were invited for a rheumatological assessment where consent was obtained. This assessment included physical examination of joints, entheses, dactylitis, spine, skin and nails. Where available, rheumatoid factor positivity and radiographic reports were collected. Receiver operator characteristic (ROC) curves were used to compare the sensitivity, specificity and area under the curve (AUC) of the 3 questionnaires with their diagnosis according to CASPAR criteria.

Results: In total, 938 patients with psoriasis were invited to participate and given a screening pack. Of these, 657 (70%) patients returned the screening questionnaires. One or more questionnaires were positive in 314

patients (48%) and these were invited for rheumatological assessment. Of these positive patients, 119 (37%) declined to attend for examination, leaving 195 (63%) patients with positive questionnaires who were assessed. There were 47 patients diagnosed with PsA according to the CASPAR Criteria, equating to 24% of those with positive questionnaires who attended for examination. The proportion of patients found to have PsA increased with the number of positive questionnaires (1 questionnaire = 19.1%, 2 questionnaires = 34.0%, 3 questionnaires = 46.8%). Sensitivities and specificities for the three questionnaires are shown in the table below. A positive non-PsA diagnosis was made in 54 subjects: 40 of these had degenerative tendinopathy or osteoarthritis.

Questionnaire	Sensitivity	Specificity	AUC	P value
PASE	74.5	38.5	0.594	0.052
PEST	76.6	37.2	0.610	0.023
TOPAS	76.6	29.7	0.554	0.267

Conclusion: Both the PEST and TOPAS questionnaires performed slightly better than the PASE questionnaire at identifying PsA but discriminatory capacity overall was best for the PEST questionnaire. As patients scoring negative for the questionnaires were not examined these results are likely to overestimate the sensitivity and underestimate the specificity. Nevertheless, these screening tools do identify many cases of musculoskeletal disease other than PsA.

1347

Anti-TNFα Discontinuation in Psoriatic Arthritis: Is It Possible After Achieving Minimal Disease Activity? Amir Haddad, Arane Thavaneswaran, Vinod Chandran and Dafna D. Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Remission in Psoriatic Arthritis, defined as a period of at least 3 consecutive visits with no actively inflamed joints, occurs in about 17 percent of patients with PsA. Achieving a state of Minimal Disease Activity (MDA) can lead to reduction in joint damage progression. In clinical practice, we face a dilemma in terms of future management when a patient achieves MDA while being on anti-TNF therapy. The aim of this study was to identify and describe PsA patients who discontinued or reduced the dose of anti-TNF agent and continued to remain in a state of MDA.

Methods: Patients were identified from a large single centre psoriatic arthritis cohort. We included patients who achieved MDA (according to slightly modified criteria proposed by Coates et al) and discontinued their anti-TNF treatment or reduced the dose and continued to remain in MDA. No predetermined protocol was used for dose reduction and in most cases it was left to patient preference. MDA was defined when fulfilling at least 5 of the 7 following outcome measures: tender joint count ≤1; swollen joint count ≤1; psoriasis activity and severity index (PASI) ≤1 or body surface area ≤3; patient pain numerical rating scale (NRS) score of ≤ 2; patient global disease activity numerical rating scale (NRS) score of ≤2; Health Assessment Questionnaire (HAQ) score ≤0.5; and tender entheseal points ≤1. Baseline demographic and clinical characteristics at the first visit and before commencing anti-TNF therapy were collected including sex, age at diagnosis of psoriasis and PsA, disease manifestation (peripheral joint involvement, axial disease, the presence of enthesitis, dactylitis and tenosynovitis), previous disease-modifying anti-rheumatic drug use, the number of active and damaged joint counts, patient global assessment, C-reactive protein (CRP), ESR as well as the health assessment questionnaire (HAQ) and SF 36 PCS. Descriptive analyses were conducted.

Results: Of the 307 patients treated with anti-TNF agents in our cohort, 17 patients were identified who were able to reduce the dose of anti-TNF agents with a total of 22 observation periods and continued to be in MDA for a mean duration of 23.7 ± 18.6 months. 15 patients were on etanercept and 2 on adalimumab. Most patients were not treated concurrently with DMARDs at the time they reduced/stopped the dose of anti-TNF agent. 8 patients reduced their dose and did not flare for a mean duration of 38.7 ± 16.3

months, while 9 patients flared after a mean duration of 13.2 ± 11.2 months. Patients stopped the medications for the following reasons: 11 patients were in remission, 3 patients due to infection, 2 cases due to patient preference and one case due to non improvement in skin disease.

Conclusion: In this study, we identified a group of patients who have stopped or reduced the dose of anti-TNF medications after being in remission. Eight patients have reduced the dose with no evidence of disease exacerbation. The data support the need for randomized controlled trials to better define the duration of anti-TNF therapy in psoriatic arthritis.

Diffuse Idiopathic Skeletal Hyperostosis (DISH) in Psoriatic Arthritis.
Amir Haddad[1], Arane Thavaneswaran[1], Sergio M.A. Toloza[2], Vinod Chandran[1] and Dafna D. Gladman[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Hospital San Juan Bautista, Catamarca, Argentina

Background/Purpose: Spondylitis in Psoriatic Arthritis (PsA) sometimes resembles DISH because of the presence of juxta-vertebral calcification that resemble syndesmophytes. Distinguishing spondylitis from DISH has therapeutic and prognostic implications. The purpose of this study was to determine the prevalence of DISH in PsA patients and to identify features associated with its occurrence.

Methods: PsA patients were recruited from a single centre prospective observational cohort initiated on 1978. All patients fulfilled the CASPAR criteria and were assessed every 6–12 months according to a standard protocol which included a detailed history, physical examination and laboratory evaluation. Radiographs of peripheral joints and spine were obtained every 2 years. DISH was defined as flowing bony bridges in at least 4 contiguous thoracic vertebrae irrespective of the presence of radiographic sacroiliitis on the last radiographic assessment. Each PsA patient with DISH was matched by sex to 3 PsA patients without DISH recruited to the clinic within a year. Demographics and disease characteristics were compared in both groups including age, disease duration, BMI, comorbidities (myocardial infarction, angina, diabetes, hypertension), uric acid levels, ESR and CRP. The radiographic features that were assessed included the presence of sacroiliitis, syndesmophytes at cervical, thoracic and lumbar spine, and calcaneal spurs. Descriptive analyses and comparisons were conducted using McNemar test, Fisher's exact test and Chi-squared test for categorical variables and paired t-test for continuous variables. Logistic regression analyses using univariate and multivariate models with stepwise regression were conducted.

Results: Of 938 PsA patients, DISH was observed in 78 patients with a prevalence of 8.3%. Patients with DISH were older (62.9 vs 49.3, P<0.0001), had a longer disease duration (15.1 vs 12.8 years, P<0.003), a higher BMI (32.9 vs 28.7, P<0.0001), had more diabetes (28% vs 9.8%, P<0.0001), hypertension (50% vs 24.9%, P<0.0001) and higher uric acid levels (16% vs 7%, P=0.02).The modified Steinbrocker score was also higher in patients with DISH (32.0 ± 39.8 vs. 19.5 ± 31.4, P=0.0001). The presence of inflammatory back pain, HLA-B*27 allele and sacroiliitis was similar in both groups. The difference in ESR and CRP was not clinically significant. However, patients with DISH had more syndesmophytes (38.5% vs 18.7%, P<0.0001) and calcaneal spurs (83.3% vs 60.9%, P<0.0001). Patients with DISH and syndesmophytes had more sacroiliitis (65% vs 38%, P=0.02) than patients with no syndesmophytes. Older age, higher BMI and the presence of radiographic damage to peripheral joints were associated with DISH in the multivariate analysis with an odds ratio of 1.13 95%CI(1.07–1.19), 1.19 95%CI(1.09–1.29) and 5.22 95%CI(1.35–20.13) respectively.

Conclusion: DISH was associated with known DISH related factors including older age and high BMI, as well as the presence of radiographic damage to peripheral joints. The diagnosis of DISH is possible in the presence of psoriatic spondylitis. The presence of sacroiliitis was similar but syndesmophytes were higher in patients with DISH.

1349

Trends in Incidence and Clinical Features of Ankylosing Spondylitis in Olmsted County (1980–2009): A Population Based Study.
Kerry Wright, Cynthia S. Crowson, Clement J. Michet and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: To determine trends in the incidence and clinical presentation of ankylosing spondylitis (AS) among residents of a geograph-ically defined area first diagnosed 1980–2009 and to describe survival among these patients.

Methods: A population-based inception cohort of patients with AS was assembled by screening all medical records of residents of a geographical area with any diagnosis consistent with AS. We identified residents aged 18 years or older first diagnosed between January 1, 1980 and December 31, 2009. Cases were included if they fulfilled the modified New York criteria for AS or the ASAS criteria for axial spondyloarthritis and the date at which the criteria was fulfilled was considered the date of diagnosis. Incidence rates were estimated and were age- and sex-adjusted to the 2000 US white population. All identified cases were followed until death, migration or December 31, 2011. Cases with psoriasis, inflammatory bowel disease (IBD) and reactive arthritis were identified. Survival was estimated using the Kaplan-Meier method and compared to expected survival for persons of the same age, sex and calendar year estimated using US population life tables.

Results: 95 patients were newly diagnosed with AS between 1980–2009 (25 women and 72 men) based on ASAS criteria for axial spondyloarthritis. 92 (97%) patients met modified New York criteria. The overall age and sex-adjusted incidence for AS was 3.9 per 100,000 population (95% CI 3.1, 4.6). The age- adjusted incidence in men was more than three times that of women: 6.0 (95% CI 4.6, 7.4) vs 1.8 (95% CI (1.0, 2.5) per 100,000 population. The mean age at diagnosis was 35 years (min: 18 max: 69). Patients diagnosed in the 1990s (mean 39 years) were older than those diagnosed in the 1980s (mean 32 years) or the 2000s (mean 34 years). The median interval between symptom onset and diagnosis was 4.0 years (min: 0, max: 36 years) with no significant difference over the study period (p = 0.539). The incidence of AS was highest in the 25–34 age group at 8.0 per 100,000. Of 75 patients tested for HLA-B27 antigen, 65 (87%) were positive. Inflammatory back pain was the most common presenting manifestation and was seen in 92% of patients. Twenty nine patients (32%) had peripheral arthritis at diagnosis which was more common in patients diagnosed in the 1990s (50%) compared to the 1980s (36%) or the 2000s (20%; p=0.034). Ten patients (11%) also had psoriasis and 10 (11%) had IBD. Uveitis was the most common extra-articular manifestation, seen in 31 patients (33%) with no significant change over the study period (p=0.22). Uveitis occurred more often in women (56% vs 25%; p=0.005). There were 3 deaths during a median follow up duration of 8.5 yrs. (total 998 person-years). This was consistent with the 4.4 expected deaths (standardized mortality ratio: 0.68; 95% CI 0.14, 2.00).

Conclusion: AS occurs in about 4 persons per 100,000 per year. Patients diagnosed in the 1990s had more peripheral arthritis and were slightly older at diagnosis than patients in any other decade. Clinical features, extra-articular manifestations and interval from symptom onset to diagnosis have remained constant in this population over the study period.

Inflammatory Biomarkers in Psoriatic Arthritis.
Ibrahim AlHomood, Arane Thavaneswaran, D. D. Gladman and Vinod Chandran. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis that may progress rapidly and result in joint damage and disability. The aim of this study was to establish the frequency of raised inflammatory markers (ESR and CRP) in PsA and to investigate their association with disease activity and progression.

Methods: At the PsA Clinic patients are followed prospectively and are evaluated according to a standard protocol which includes a detailed clinical history, physical examination, laboratory and radiological assessments every 6–12 months.ESR levels are recorded as normal or raised (15 mm/hour for male patients, 20 mm/hour for female patients) as well as CRP as normal or raised (0–3). X-rays are done every two years. Patients followed between 2006 and 2011 were included.

ESR and CRP were measured at baseline in all patients included in this study, and correlated with other disease features at baseline. Pearson correlation coefficient was used for correlations between the continuous variables. We also constructed univariate and multivariate models based on information at baseline to detect the variables that associate with disease activity and severity. The covariates were age at onset of PsA, sex, duration of PsA, use of biologics, infection and BMI.

Results: A total of 253 patients with PsA (107 male and 146 female with mean duration of PsA 5.2±7.6 years) were included.ESR level ranged from 0 to 121 mm/hr at baseline. Mean ESR was 18.3±21.2 (median 11) and was

elevated in 28.1%. CRP level ranged from 3 to 132 mg/l. Mean CRP was 14.3±20.7 (median 5) mg/l and was elevated in 54.9%.

Correlation between ESR and CRP with the variables

	Active joint count		Damaged joint count		BASDAI		PASI	
	Correlation	P-value	Correlation	P-value	Correlation	P-value	Correlation	P-value
ESR	0.14	P=0.02	0.16	P=0.01	0.17	P=0.05	0.23	P=0.0004
CRP	0.07	P=0.26	0.03	P=0.63	0.23	P=0.008	0.31	P<0.0001

The association between ESR and CRP and different variables

	ESR		CRP	
variable	Univariate analysis p-value	Multivariate linear regression p-value	Univariate analysis p-value	Multivariate linear regression p-value
Active joints	0.02	0.006	0.26	0.67
Damage joints	0.01	0.07	0.63	0.32
PASI	0.0004	0.004	<0.0001	0.13
BASDI	0.05	0.28	0.008	0.30
Radiogical damage	0.12	0.68	0.04	0.16

Conclusion: Increased ESR was observed in 28.1% of PsA and was correlated with active and damaged joint count and PASI. Increased CRP was observed in 54.9% of PsA and was correlated with PASI. Inflammatory markers are associated with disease activity and progression.

Ultrasonographic Entheseal Abnormalities Among Patients with Psoriatic Arthritis, Psoriasis Alone and Healthy Individuals and Their Correlation with Disease-Related Variables. Lihi Eder[1], Jai Jayakar[2], Arane Thavaneswaran[3], Amir Haddad[3], Daniel Pereira[3], Sutharshini Shanmugarajah[3], David Salonen[4], Cheryl Rosen[3], Vinod Chandran[3] and Dafna D. Gladman[3]. [1]Carmel Medical Center, Haifa, Israel, [2]University of Western Ontario, London, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON, [4]University Health Network, Toronto, ON

Background/Purpose: Enthesitis is an important manifestation of psoriatic arthritis (PsA). We aimed to compare the frequency of ultrasonographic (US) entheseal abnormalities between patients with PsA, psoriasis without arthritis (PsC) and healthy controls and to assess the correlation between disease-related variables and the extent of US enthesitis.

Methods: PsA and PsC patients who were part of two large prospective cohorts were recruited. PsC patients were assessed by a rheumatologist to exclude inflammatory arthritis. Healthy controls were recruited from hospital personnel. Ultrasound examinations were performed using a MyLab 70 XVG device equipped with 6–18 MHz linear transducer and Doppler frequency of 7.1–14.3 MHz. The following entheseal insertion sites were examined: patella (at insertions of the quadriceps and patellar tendons), tibial tuberosity, Achilles tendon and plantar fascia insertions to the calcaneous and triceps tendon insertion to the olecranon. Two scoring systems for US enthesitis (MAdrid Sonographic Enthesitis Index (MASEI) and Glasgow Enthesitis Scoring System (GUESS)) were used to generate scores that reflect the severity of entheseal abnormalities in each patient. Analysis of variance was used to compare GUESS and MASEI scores across the groups. Chi square test was used to compare the frequencies of entheseal abnormalities between the groups. The correlation between disease-related variables and enthesitis scores was assessed by Pearson correlation coefficients (r).

Results: A total of 59 PsA patients, 79 PsC patients and 60 healthy controls were assessed. The frequency of US entheseal abnormalities was high with 98.3% of PsA patients, 97.5% of PsC patients and 86.7% of healthy controls having at least one abnormality. However, the extent of US abnormalities showed a trend with the highest score found in PsA patients followed by PsC patients and lowest in the controls (GUESS 8.9±4.6, 5.6±3.5 and 4.4±3.9, respectively p<0.001, MASEI 18.5±13, 9.9±7.4 and 7.7±9.2, respectively p<0.001). GUESS and MASEI correlated significantly with age (p<0.001 for each score) and Body Mass Index (p<0.001 for each score) and after adjusting for these variables the difference in enthesitis scores across the groups were not significant. The frequency of individuals who had tendon hypoechogenicity (p<0.001) and thickening (p<0.001), bony erosions (p<0.001) and positive Doppler signal (p=0.04) at the entheses was highest in PsA patients compared to both PsC and healthy control. No

difference was observed in the frequency of individuals with calcifications or bursitis at the entheses. Among patients with PsA, C-reactive protein (CRP) and modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) correlated with GUESS (r=0.45, p=0.002 and r=0.44, p=0.004, respectively) and with MASEI (r=0.51, p=0.0007 and r=0.56, p=0.0005, respectively).

Conclusion: The prevalence of US entheseal abnormalities is high even among healthy individuals. However, their severity is highest in PsA patients followed by PsC and is lowest in healthy controls. Such abnormalities are associated with age, obesity, CRP and in PsA with the severity of radiographic axial damage.

Adalimumab Significantly Reduces Recurrence Rate of Anterior Uveitis in Patients with Ankylosing Spondylitis. J. Christiaan van Denderen[1], Ingrid M. Visman[1], M. T. Nurmohamed[2], Maria S.A. Suttorp-Schulten[3] and Irene E. van der Horst-Bruinsma[4]. [1]Jan van Breemen Research Institute/Reade, Amsterdam, Netherlands, [2]VU University Medical Center/Jan van Bremen Research Institute, Amsterdam, Netherlands, [3]Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands, [4]VU University Medical Centre, Department of Rheumatology, Amsterdam, Netherlands

Background/Purpose: A high percentage (30–40%) of patients with Ankylosing Spondylitis (AS) suffer from acute anterior uveitis (AAU) attacks. Local treatment with corticosteroids is a beneficial treatment, but not always sufficient. The objective of this study is to examine whether the use of adalimumab decreases the frequency of attacks of AAU in patients with AS, who receive this treatment for their spinal disease activity.

Methods: Consecutive AS patients, who were treated for at least 12 weeks with 40 mg of adalimumab every other week, were enrolled. The number of attacks of AAU in the year before start and during adalimumab treatment was assessed by ophthalmological controls at baseline and yearly thereafter. Follow-up ended at January First, 2012, or upon discontinuation of adalimumab treatment for any reason.

Results: In total 77 patients were enrolled of whom 67 (87%) were seen by the ophthalmologist at baseline and 44 (57%) during follow-up. The other data were retrieved from protocol visits to the research physician. Out of these 77 patients:

51 (66%) did not have attacks of uveitis in the year before (and during) treatment,

16 (21%) had uveitis before, but not during treatment,

10 (13%) had attacks of uveitis before and during treatment

No one developed uveitis for the first time during adalimumab treatment.

Figure 1 Uveitis before and after start adalimumab
In total 26 patients (34%) suffered from recurrent flares of uveitis in the year before start of adalimumab treatment, with a median of 2.0 uveitis

attacks per year (IQR: 1.0–3.5). The median follow-up period of all patients was 1.74 years (IQR: 0.80–2.57). During follow-up only 10 patients (13%) had attacks of uveitis with a median of 0.56 uveitis attacks per year (IQR: 0.30–0.75). This constitutes a 62% drop in the number of patients with uveitis attacks. The number of patients with uveitis as well as the number of attacks/year dropped significantly (p<0.0001), compared with the year before adalimumab. Even the patient with a very high number of attacks of AAU (12 attacks/year) was completely free of uveitis attacks after start of adalimumab, during his entire 4 years of follow-up.

Conclusion: A significant and substantial reduction of recurrence rate of flares of anterior uveitis during adalimumab treatment was found, even in patients with a high recurrence rate of attacks. The majority (87%) of patients remained completely free of uveitis attacks for the entire follow-up period.

Improvement in Physical Function, Health-Related Quality of Life, and Work Productivity with Adalimumab Treatment in Nonradiographic Axial Spa: Wk-52 Results From Ability-1. Désirée van der Heijde[1], Philip Mease[2], Aileen L. Pangan[3], Sumati Rao[4], Naijun Chen[4] and Mary A. Cifaldi[4]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Swedish Rheumatology Research Group, Seattle, WA, [3]Abbott, Abbott Park, IL, [4]Abbott Laboratories, Abbott Park, IL

Background/Purpose: To evaluate long-term effects of adalimumab (ADA) treatment on patient reported outcomes (PROs) in nonradiographic axial spondyloarthritis (nr-axSpA).

Methods: Ability-1 is an ongoing Phase III, multicenter, randomized, controlled trial of ADA vs. placebo (PBO) in patients with nr-axSpA (fulfilling ASAS axial SpA criteria but not modified New York criteria for AS). Following the 12-wk double-blind phase, all patients were switched to open-label (OL) ADA (represented by ADA/ADA and PBO/ADA groups) for 144 wks. This post hoc analysis evaluated physical function, health-related quality of life (HRQOL), and work productivity until Wk 52. Physical function was assessed using the disability index of the Health Assessment Questionnaire for Spondyloarthropathies (HAQ-S) and HRQOL using the Short Form 36 Health Survey (SF-36) Physical Component Summary (PCS) score. Productivity was assessed using the overall work impairment domain of the Work Productivity and Activity Impairment Questionnaire. Changes from baseline to Wk 12 were compared between groups using ANCOVA with adjustment for baseline scores and with treatment as a factor. Analyses were conducted on the intent-to-treat (ITT) population excluding 7 subjects from a noncompliant site and the OL population (patients who had at least 1 dose of OL ADA).

Results: After 12 wks of therapy in the double-blind period, the ADA group experienced statistically significant improvements in HAQ-S (p<0.02) and SF-36 PCS (p<0.001) compared with PBO. A total of 179 patients entered the OL period (87/91 and 92/94 from the original ADA and PBO arms, respectively) and 150/151/81 patients completed the HAQ-S, SF-36 PCS, and work productivity questionnaires, respectively, at Wk 52 (**table**). At Wk 52, approximately 62% of the patients met the minimum important difference (MID) for HAQ-S of 0.26 and 77% met the MID for SF-36 PCS of 3.0. Nearly 65% of the patients also met the MID for work productivity of 7% at Wk 52. PBO patients who switched to OL ADA experienced improvements in HRQOL and work productivity levels comparable to patients who received ADA through Wk 52. By Wk 52, patients in both groups achieved SF-36 scores (42.8 and 44.1 for the PBO/ADA and ADA/ADA groups, respectively) that approached the US general population norm of 50.

Change From Baseline Through Wk 52 in Physical Function, HRQL, and Work Productivity in Patients With nr-axSpA.

	Wk 12 (ITT)	Wk 24 (OL Population)			Wk 52 (OL Population)	
	PBO	ADA[a]	PBO/ADA[a]	ADA/ADA	PBO/ADA	ADA/ADA
HAQ-S (mean ± SD)[b,c]	n = 90	n = 88	n = 89	n = 82	n = 78	n = 72
	−0.14 ± 0.43	−0.28 ± 0.50	−0.38 ± 0.56	−0.40 ± 0.39	−0.48 ± 0.52	−0.41 ± 0.45
SF-36 (PCS) (mean ± SD)[b,c]	n = 93	n = 91	n = 90	n = 87	n = 79	n = 72
	2.0 ± 7.04	5.5 ± 8.98	7.0 ± 9.42	7.4 ± 9.66	9.4 ± 10.42	9.9 ± 9.82
Work productivity (mean ± SD)[b,c]	n = 47	n = 49	n = 46	n = 49	n = 43	n = 38
	−5.7 ± 28.63	−12.1 ± 28.84	−20.8 ± 27.75	−18.5 ± 26.34	−21.0 ± 35.55	−24.7 ± 27.56

[a]Corresponds to 12 wks of ADA treatment.
[b]n = number of subjects with nonmissing values for both baseline and the respective visit. Baseline was defined as the last nonmissing value prior to the first dose of study drug.
[c]MID thresholds are −0.26, 3.0, and 7.0% for HAQ-S, SF-36 (PCS), and work productivity, respectively.

Conclusion: Patients who remained on ADA therapy for 52 wks had sustained improvement in PRO and productivity. Likewise, patients who received PBO and switched to ADA in the OL period showed improvement in physical function, HRQOL, and work productivity that was maintained through Wk 52.

1354

The Prevalence of Psoriatic Arthritis Based On Rheumatologists' Clinical Assessment Before and After Laboratory and Radiographic Tests in Psoriasis Patients in European/North American Dermatology Clinics. Dafna D. Gladman[1], Philip J. Mease[2], Rafat Y. Faraawi[3], Eustratios Bananis[4], Andrew S. Koenig[4], Robert Northington[4], Joanne Fuiman[4] and Daniel Alvarez[4]. [1]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [2]Swedish Medical Center, Seattle, WA, [3]McMaster University, Kitchener, ON, [4]Pfizer Inc., Collegeville, PA

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease with a heterogeneous presentation that is associated with impaired quality of life, joint damage, and limited ability to work.[1–3] Diagnosis of PsA is often challenging and may require close collaboration between dermatologists and rheumatologists. Reliance on laboratory and/or radiographic tests to diagnose PsA varies among rheumatologists. The PREPARE trial (NCT01147874) was conducted to estimate PsA prevalence as determined by rheumatologists' evaluation of psoriasis patients presenting to dermatologists' offices. The objective of the secondary analysis presented here was to estimate the prevalence of PsA in psoriasis patients based on clinical assessment by rheumatologists using medical history and physical examination before and after review of supplemental laboratory and radiographic tests.

Methods: Unselected, consecutive psoriasis patients, ≥18 years of age, were initially assessed for plaque psoriasis by dermatologists at 34 dermatology centers in 7 European and North American countries. After psoriasis was confirmed, patients were evaluated for PsA by rheumatologists based on medical history and physical examination alone. Rheumatologists reassessed their diagnoses after receiving laboratory test results (eg, C-reactive protein, erythrocyte sedimentation rate, or rheumatoid factor). In a patient subgroup undergoing radiographic evaluation of hands and feet, rheumatologists conducted a 2nd reassessment after x-rays were provided.

Results: In 949 psoriasis patients who were subsequently evaluated with the inclusion of laboratory tests, 281 (29.6%) were initially diagnosed with PsA based on medical history and physical examination alone (table). In comparison, 285 (30.0%) received clinical PsA diagnoses from rheumatologists based on medical history, physical examination, and laboratory results. In 183 psoriasis patients in the radiographic subgroup, 74 (40.4%) received a PsA diagnosis based on medical history, physical examination, and laboratory results, whereas 71 (38.8%) received this diagnosis based on medical history, physical examination, laboratory results, and radiographic findings.

Table. PsA prevalence based on different clinical assessment approaches in the PREPARE study

Clinical Assessments	Prevalence n (%) (95% CI)	Change in PsA Diagnosis n (%)	
		Negative to Positive	Positive to Negative
All Patients (N = 949)			
Medical history + physical examination	281 (29.6%) (26.7, 32.6)		
Medical history + physical examination + laboratory results	285 (30.0%) (27.1, 33.1)	8 (0.8)*	4 (0.4)*
Patients in Radiographic Subgroup (n = 183)			
Medical history + physical examination + laboratory results	74 (40.4%) (33.3, 47.9)		
Medical history + physical examination + laboratory results + radiographic results	71 (38.8%) (31.7, 46.3)	2 (1.1)†	5 (2.7)†

*Number (%) of patients whose diagnosis changed when laboratory tests were added to the initial clinical assessment based on medical history and physical examination.
†Number (%) of patients whose diagnosis changed when radiographic results were added to the clinical assessment based on medical history, physical examination, and laboratory results.

Conclusion: In this large, multinational prevalence study, approximately one-third of psoriasis patients had PsA based on rheumatologists' clinical assessment. This analysis confirms the ability of rheumatologists to diagnosis PsA based on medical history and physical examination alone. However, laboratory and radiographic results may assist in excluding and/or confirming the diagnosis in some patients.

Hand Bone Loss Is Arrested in Early Psoriatic Arthritis but Not in Rheumatoid Arthritis Following Anti-Rheumatic Treatment Assessed by Digital X-Ray Radiogrammetry. Agnes Szentpetery[1], Muhammad Haroon[2], Phil Gallagher[3], Martina Cooney[1], Eric J. Heffernan[4] and Oliver M. FitzGerald[5]. [1]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland, [2]Dublin Academic Medical Center, St. Vincent's University Hospital, Dublin, Ireland, [3]Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [4]Department of Radiology, St. Vincent's University Hospital, Dublin, Ireland, [5]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Periarticular bone loss is an early feature of both psoriatic arthritis (PsA) and rheumatoid arthritis (RA). Digital X-ray radiogrammetry (DXR) is a sensitive method for quantifying changes in periarticular bone mineral density (DXR-BMD) in the early phase of the disease. Only a few studies have examined the effect of anti-rheumatic drugs on hand bone loss as measured by DXR in RA and even less in PsA. To our knowledge there is no prospective study designed for capturing differences in hand bone loss between recent onset PsA and RA patients following intervention with anti-rheumatic treatments.

The aim of this study was to: (1) investigate DXR-BMD changes in early PsA and RA prior to and 3 and 12 months after introducing an anti-rheumatic drug; and (2) to explore associations between disease-related variables and DXR-BMD.

Methods: Recent-onset (<12 months), treatment naive PsA and RA patients with active disease were recruited. Hand BMD was assessed by DXR calculated from digitized radiographs (Sectra, Sweden) measuring the cortical thickness of the 2nd, 3rd and 4th metacarpal bones. Mean DXR-BMD (mg/cm^2) values and changes from baseline in DXR-BMD (mg/cm^2/month) were calculated and compared between the two groups at baseline, 3 and 12 months. Clinical parameters were correlated with DXR-BMD including ESR, CRP, TJC, SJC, DAS28-CRP4v and HAQ.

Results: 64 patients (31 PsA, 33 RA) were included with median age 43 years (18–71). 96.6% of the patients were commenced on a DMARD therapy (93.2% methotrexate) at baseline; 18.6% of the patients (12.1% of RA; 19% of PsA) were also started on a TNF inhibitor.

Mean DXR-BMD was significantly higher in PsA at 12 months compared to 3 months (p=0.0137). In contrast mean DXR-BMD was lower in RA at both 3 and 12 months compared to baseline (p=0.0347 and p=0.0302) and at 12 months compared to 3 months (p=0.0159). Highly elevated bone loss (>2.5 mg/cm^2/month) was only present in the RA cohort (6%). Changes from baseline and 3 months to 12 months were significantly less marked in PsA compared to RA (p=0.0084 and p=0.004). Similarly, comparing treatment responders only, changes from baseline to 12 months were less marked in the PsA responder group (p=0.0209). Disease activity scores were lower in PsA than in RA at all time points reaching significance at baseline and 3 months. ESR, CRP, TJC, SJC, DAS28-CRP4v and HAQ improved significantly in both diseases during the study. Mean DXR-BMD correlated with ESR at 3 months in PsA (r = −0.59; p= 0.013) and with CRP at baseline in RA (r = −0.448; p= 0.025). Similarly, significant inverse correlations were found between mean DXR-BMD and ESR and CRP at baseline in the entire group.

Conclusion: Hand bone loss is arrested by 12 months of intervention of appropriate DMARD therapy in PsA but not in RA. Higher disease activity is associated with accelerated cortical bone loss in both diseases. Changes in DXR-BMD were less marked in PsA supporting the hypothesis of different pathogenetic mechanisms being involved in hand bone resorption/formation balance in PsA.

Gender Differences Among Spondylitis Associated with Psoriasis, Inflammatory Bowel Disease and Primary Ankylosing Spondylitis. Margarita Landi[1], Hernan Maldonado-Ficco[1], Jose A. Maldonado-Cocco[1], Gustavo Citera[2], Pablo Arturi[1], Percival Sampaio-Barros[3], Diana Flores[4], Ruben Burgos-Vargas[5], Helena Santos[6], Jose Chavez-Corrales[7], Daniel Palleiro[8], Miguel A. Gutierrez[9], Elsa Vieira-Sousa[10], Fernando Pimentel-Santos[11], Sergio O. Paira[12], Alberto Berman Sr.[13], Janitzia Vazquez-Mellado[14], Eduardo Collantes-Estevez[15] and On behalf of RESPONDIA Group[16]. [1]Instituto de Rehabilitacion Psicofisica and Fundacion Reumatologica Argentina, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica., Buenos Aires, Argentina, [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil, [4]Hospital Universitario "Dr. José Eleuterio González", Monterrey, Mexico, [5]Hospital General de Mexico, Mexico DF, Mexico, [6]Instituto Português de Reumatologia, Lisboa, Portugal, [7]Hospital Nacional E. Rebaglliti-ESSALUD, Lima, Peru, [8]Instituto Nacional de Reumatologia, Montevideo, Uruguay, [9]Pontificia Universidad Catolica de Chile, Santiago, Chile, [10]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [11]Centro Hospitalar de Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, [12]Hospital Jose Maria Cullen, Santa Fe SFE S3000BFP, Argentina, [13]Hospital Padilla, Tucuman, Argentina, [14]Hospital General de Mexico, Mexico city, Mexico, [15]IMIBIC-Reina Sofia Hospital, Cordoba 14012, Spain, [16]Buenos Aires

Background/Purpose: Differences regarding gender in primary Ankylosing Spondylitis are well known. However, there is less evidence regarding Spondylitis Associated with Psoriasis and that associated with Inflammatory Bowel Disease. To compare clinical manifestations, disease activity, functional capacity, spinal mobility and radiological findings among women and men from a multicenter, multiethnic cohort, of Ibero-American patients with Spondyloarthritis.

Methods: This observational cross-section study included 2044 consecutive spondyloarthritis (SpA) patients (ESSG criteria). Demographic, clinical, disease activity, functional ability, quality of life, work status and radiologic data were evaluated and collected by RESPONDIA members from different Ibero-American countries between June and December 2006. For this analysis patients were selected only if they met modified New York criteria for AS. Data was transmitted on-line and stored in the Spanish SpA Registry (REGISPONSER) website. Categorial data were compared by X^2 or Fisher's exact tests and continuous variables by ANOVA with post-hoc tests.

Results: Out of 2044 patients, 1264 met New York criteria; 73% were male, (mean age 43 years, SD=15.8), and 27% were female (mean age 45,8 years, SD=12.6). 1072 had primary Ankylosing Spondylitis (AS), 147 Spondylitis Associated to Psoriasis (PsSp) and 45 Spondilytis associated to Inflammatory Bowel Disease (IBDSp). Overall, male patients were significantly younger, had longer diagnostic delay, lower disease activity (BASDAI), less swollen joints, worse spinal mobility (BASMI), better quality of life although worse total BASRI. Frequency of dactylitis and enthesitis was significantly more common among women. Analysing only AS, there was marked male predominance (76.2%). Male patients were also significantly younger, had lower disease activity, worse BASMI, better quality of life and less frequence of dactylitis, yet worse total BASRI. When reading only BASRI in the spine, still it was significantly higher in male patients (mean 7.3 vs 5.8 p=0.000). However, among patients with PsSp male predominance was lower (57.8%), had significantly worse total BASRI and spinal BASRI and worse spinal mobility (BASMI). Among the 45 patients with IBDSp there was a slight female predominance (51.1%) and only differed in less lateral lumbar flexion in males (p=0.015). Regarding work disability in the total population, men had higher permanent work disability (13.2 vs. 6.9 p<0.05). These differences were maintained when subdividing patients according to primary AS but were no differences in PsSp. There were no patient with IBDSp and permanent work disability.

Conclusion: In this gender comparative analysis among Psoriatic, IBD and primary AS, male patients were significantly younger, had longer diagnostic delay, worse total BASRI, higher BASMI, strikingly lower disease activity (BASDAI) and better quality of life. In both primary AS and PsSp groups, women had better spinal mobility and less radiographic damage.

Psoriatic Arthritis and Biologic Therapy: Treatment Response, Drug Survival and Outcome After Switching.

Dinny Wallis[1], Deepak Jadon[2], William Tillett[2], Nicola Waldron[2], Charlotte Cavill[3], Neil McHugh[2] and Eleanor Korendowych[2]. [1]Royal National Hospital for Rheumatic Diseases NHS Foundation Trust, Bath, United Kingdom, [2]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [3]Bath Institute for Rheumatic Disease, Bath, United Kingdom

Background/Purpose: Data on longer term efficacy and tolerance of biologic therapies in psoriatic arthritis (PsA) are emerging. Persistence with the first TNF inhibitor (TNFi) at one year is estimated at 70–87%. Data on the benefit of switching between TNFi are limited but persistence with a second agent at one year is reported as 74–81%. We aimed to investigate the treatment response, drug survival and outcome with the first and subsequent biologic agents in patients with PsA.

Methods: Data were collected from a prospective single-centre cohort of PsA patients who started a biologic agent between 1stJan 2003–1st Sept 2010.

Results: Seventy-one patients started a biologic agent of whom 96% had polyarticular disease. The median follow-up was 36 months, median age at start of biologic 47y and median disease duration 10y. The most frequently prescribed first biologic agent was etanercept (58%) followed by adalimumab (35%) and infliximab (7%).

Thirty-six percent started a biologic agent as monotherapy, 49% started in combination with one DMARD and 13% with two DMARDs. Ninety-six percent fulfilled the Psoriatic Arthritis Response Criteria (PsARC) where completed.

Persistence with the first biologic was 92% at 6 months, 87% at 12 months, 74% at 24 months and 70% at 36 months. Six patients (8.4%) stopped due to secondary inefficacy (after 12 weeks) and 16 (23%) stopped due to adverse event.

Nineteen patients switched to a second biologic agent (6 due to secondary inefficiency and 13 due to an adverse event). Persistence was 67% at 6 months and 53% at 12 months. One patient stopped due to primary inefficacy, 2 due to secondary inefficacy and 7 had an adverse event. Of the 6 patients who had switched to a second agent because of secondary inefficacy, one continued on the second agent, one switched again because of primary inefficacy, 2 switched again because of secondary inefficacy and 2 switched again because of an adverse event. Of the 13 patients who switched to a second agent because of an adverse event, 8 continued on the second agent, one stopped biologic therapy and 3 switched again because of an adverse event. One patient was pending switch to a third biologic at the time of analysis.

Eight patients switched to a third biologic. Six continued on the third agent (median follow up after switching 26 months). Two switched to a 4th agent (ustekinumab) because of secondary inefficacy and remained on the 4thagent at 4 and 11 months follow up respectively.

Median percentage improvements with the first biologic at 12 and 24 months respectively were 79% and 100% in swollen joint count, 77% and 83% in tender joint count, 50% and 56% in Health Assessment Questionnaire, 67% and 61% in Psoriasis Area and Severity Index, 89% and 100% in Dermatology Life Quality Index and 100% and 100% in the Bath Nail Score.

Conclusion: Persistence with the first biologic agent in this cohort was 87% at 12 months, 74% at 24 months and 70% at 36 months. The response to the first biologic agent was sustained at 24 months across joint, skin, nail and quality of life measures. Persistence with the second biologic agent was 53% at 12 months. Patients who switched to a second biologic agent because of adverse event were more likely to continue with the second agent than those who switched because of secondary inefficacy.

Performance of Remission Criteria and Activity Indices in Psoriatic Arthritis.

Maria L. Acosta Felquer[1], Leandro Ferreyra Garrott[1], Erika Catay[1], Josefina Marin[2], Marina Scolnik[2], Maria Victoria Garcia[2], Santiago Ruta[2], Mirtha Sabelli[3], Zaida Bedran[3], Javier Rosa[1], Luis J. Catoggio[4] and Enrique R. Soriano[4]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM. Catoggio, Buenos Aires, Argentina

Background/Purpose: Remission criteria and activity indices used in rheumatoid arthritis (RA) are often applied in psoriatic arthritis (PsA). Although indices have been specifically developed for PsA: CPDAI (Composite Psoriatic Disease Activity Index), PASE (Psoriatic Arthritis Screening and Evaluation), DAPSA (Disease Activity index for Psoriatic Arthritis) and MDA (minimal disease activity criteria in Psoriatic Arthritis), few studies have compared their performance in PsA patients.

The Objective was to evaluate the performance of different remission criteria and activity indices in PsA.

Methods: 55 consecutive patients with PsA (CASPAR criteria) were included. At study entry visit, information necessary to complete the following indices was captured: CPDAI, DAPSA, PASE, MDA, DAS28, SDAI, CDAI, and ACR/EULAR Boolean RA remission criteria. The following assessments were also included: HAQ, BASDAI, BASFI and PASI (Psoriatic Assessment of Skin Index).

Results: Mean age was 53 years (SD=12), and 35 (63.6%) were males. Mean PsA disease duration was 5.9 (SD=8.5) years and mean psoriasis duration was 15.9 (SD= 12.6). Mean number of swollen and tender joint count was 2.4 (SD= 3) and 4.3 (SD=6) respectively. Mean PASI was 1.9 (SD=2.7). In 33 patients (60%) the treating rheumatologist indicated a change in treatment.

Table 1. Percentage of patients in remission and different levels of activity according to the different indices

Index	Percentage in remission (95% CI)	Low disease activity (95%CI)	Moderate disease activity (95% CI)	High disease activity (95% CI)
DAS28	33 (20–45)	11 (4–22)	43 (30–58)	13 (5–24)
SDAI	4 (0.4–14)	34 (21–49)	36 (23–51)	26 (15–40)
CDAI	9 (1–17)	36 (24–50)	35 (22–48)	20 (10–33)
CPDAI	0	78 (65–88)	20 (10–33)	2 (0.04–10)
ACR/EULAR (Boolean)	9 (1–17)	–	–	–
MDA	29 (18–43)	–	–	–

Table 2. Correlation coefficients between different indices (Pearson).

Index	DAS28	CDAI	SDAI	CPDAI	PASE	HAQ	BASDAI	BASFI
DAS28	1	0.83	0.75	0.58	0.75	0.71	0.68	0.66
CDAI	0.83	1	0.76	0.57	0.75	0.70	0.63	0.62
SDAI	0.75	0.76	1	0.42	0.61	0.61	0.52	0.64
CPDAI	0.60	0.57	0.42	1	0.44	0.53	0.38	0.39
PASE	0.75	0.75	0.61	0.44	1	0.84	0.84	0.72
HAQ	0.71	0.70	0.61	0.53	0.84	1	0.76	0.79
BASDAI	0.68	0.63	0.52	0.38	0.84	0.76	1	0.82
BASFI	0.66	0.62	0.64	0.39	0.72	0.79	0.82	1

Table 3. Comparison of mean indices values between patients with and without change in treatment.

Index	Not changing treatment (n=22)	Initiating/Changing treatment (n=33)	P value (Mann-Whitney)
Mean PASE (SD)	29.5 (8.5)	42.2 (14.1)	0.0004
Mean CPDAI (SD)	2 (0.9)	4.7 (3.6)	0.0013
Mean DAPSA (SD)	6 (4.5)	11.7 (6.1)	0.0008
Mean DAS28 (SD)	2.3 (0.9)	4.3 (1.2)	<0.0001
Mean SDAI (SD)	8.7 (8)	29.2 (24.6)	0.0005
Mean CDAI (SD)	5.3 (3.5)	19.4 (11.8)	<0.0001

All indices showed good discriminative power for a change in treatment in the ROC curve: PASE- AUC (area under curve) = 0.78 (95% CI:

0.65–0.9); CPDAI -AUC= 0.81 (95%CI: 0.7–0.9); DAPSA–AUC=0.78 (95% CI: 0.65–0.91).DAS28- AUC= 0.92 (95%CI: 0.89–1); CDAI-AUC= 0.93 (95%CI: 0.87–0.99); SDAI- AUC= 0.89 (95% CI: 0.79–0.99).

Conclusion: There were differences in the percentage of patients classified as in remission by the different remission criteria. Particularly, DAS28 and MDA seemed to be less stringent in PsA than the other indices. Of the specific indices studied CPDAI showed the poorest correlation with all the other activity measurements.

1359

Comparison of Sacroiliac MRI Evaluation Versus Sacroiliac x-Rays in Peripheral Psoriatic Arthritis: Evidence of Silent Disease and Lack of Association to HLA-B27. Jose Luis Fernandez-Sueiro[1], JA Pinto[1], S. Pertega-Diaz[1], E. Gonzalez[1] and Francisco J. Blanco[2]. [1]Complejo Hospitalario Universitario La Coruña, La Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain

Background/Purpose: Although there are no consensus on how to define spinal involvement in axial psoriatic artritis (axPsA), our data suggest that the presence of spinal symptoms (defined as a combination of inflammatory back pain plus back stiffness) can be sufficient. However x-ray evaluation of sacroiliac joints may be normal at the first stage of the disease. Objetive: to evaluate the negative predictive value of sacroiliac x-rays versus MRI to rule out the diagnosis of sacroiliitis in peripheral PsA.

Methods: cross sectional descriptive and observational study of PsA patients classified according to CASPAR criteria. All patients had peripheral arthritis not spinal back pain and normal or grade I sacroiliac involvement determined by x-rays. All patients were evaluated according to current standard care. HLA-B27 was determined in all patients. Sacroiliac MRI was performed with either a Tesla 1.5 Gyroscan Intera (Philips MS) or Tesla 1.5 Signa-Excite with the following coronal sequences T1-TSE, T2-TGE and STIR with slices of 4mm of thickness, criteria for lesions were as ASAS proposal. The negative predictive value of x-rays versus MRI was determined as well as the 95% CI. Patients' characteristics were compared according to MRI results, by means of Mann-Whitney U test, chi-squared test and Fisher's exact test.

Results: sacroiliac MRI was performed in 59 patients from a total of 97 PsA patients with peripheral arthritis. There were not significant differences in both groups of patients. MRI patients had a medium age of 49,2±12,9 years, a time of evolution of the disease of 9,4±7,6 years. 96,4% patients had a normal sacroiliac x-rays, 2 had grade I unilateral and bilateral sacroiliitis respectively. HLA-B27 was negative in 93,2%(n=55) patients. 20,3% (n=12) showed active inflammatory lesions (1 with x-rays grade I bilateral). All patients were HLA-B27 negative. There were not significant clinical differences between MRI positive/negative patients, the exception was the occiput to wall distance (p=0,032). The negative predictive value of sacroiliac x-rays versus sacroiliac MRI was of 79,7% (95%IC: 68,5%-90,8%)

Conclusion: Conventional x-rays versus MRI for the evaluation of sacroiliitis had a negative predictive value of 79,7%. In this study the sacroiliac involvement in PsA does not depend on the presence of spinal pain, HLA-B27 or radiological sacroiliitis.

1360

Spinal Involvement in Axial Psoriatic Artritis Is Not Determined by the Presence of HLA-B27. Is the HLA-B27 Arm of the Axial Spa Criteria Reliable for Classifying Axial Psoriatic Arthritis? Jose Luis Fernandez-Sueiro[1], JA Pinto[1], S. Pertega-Diaz[1], E. Gonzalez[1], Ignacio Rego-Perez[2], Francisco J. de Toro-Santos[3] and Francisco J. Blanco[4]. [1]Complejo Hospitalario Universitario La Coruña, La Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña. Genomic Group. Rheumatology Division., A Coruña, Spain, [3]Complejo Hospitalario Universitario Juan Canalejo, Universidad de la Coruña, La Coruña, Spain, [4]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain

Background/Purpose: There is a debate whether axial psoriatic arthritis (axPsA) is an ankylosing spondylitis with psoriasis, however due to the fact that PsA has characteristic clinical features, this concept is debatable. On the other hand HLA-B27 is a key component of the clinical arm of the new ASAS criteria for axial SpA. Objective: to determine the prevalence of HLA-B27 in PsA and to analyze its prevalence according to the clinical forms

Methods: Cross-sectional prevalence study of HLA-B27. HLA-B27 was determined in the following populations: a) healthy controls (HC) (n= 308) and AS (n=106) (1), b) cutaneous psoriasis (n=113), c) PsA (n=172). axPsA was defined according to our previous definition (2,3). HLA-B27 was determined wit a commercial kit: Invitrogen®, Allset Gold B27 Low and High Res SSP. For each group of patients, HLA-B27 prevalence was determined, together with its 95% confidence interval. Using data from the Galician population as reference, prevalence ratio and odds ratio values were estimated from a logistic regression model. Comparisons among groups were performed by using the Mann-Whitney U, chi-squared and Fisher's exact tests.

Results: The prevalence of HLA-B27 was: HC 9,4%, AS 94,3% (p<0,001), cutaneous psoriasis 9,7% (p=0,921), PsA whole group 14,5% (p=0,099), peripheral PsA 8,2% (p=0,708), axPsA (mixed/"pure") (n=68) 23,5% (p=0,002), axPsA "mixed" (n=61) 18% (p=0,052), axPsA (pure) (n=7) 71,4% (p=<0,001),]. HLA-B27+ PsA patients had a diagnosis of the disease at an earlier age, 39,2±14,14 vs 45,3±13,52 years (p=0,036). Comparing axPsA (mixed/"pure") HLA-B27- (n=52) vs HLA-B27+ (n=16) there were no significant differences in the following: epidemiological, clinical, metrological, inflammatory, function and structural damage assessed by BASRI. The only exception was the occiput to wall distance (1,1 cm vs 4,7 cm; p=0,036)

Conclusion: The prevalence of HLA-B27 in PsA is similar to the general population. HLA-B27+ seemed to determine the age of presentation of PsA. There seems to be two populations with spinal involvement in axPsA, HLA-B27+/−, being the most prevalent the HLA-B27-. These data question the hypothesis that axPsA is a primary AS and question the reliability of HLA-B27 for classifying axPsA patients using the new ASAS criteria for axial SpA.

Disease Burden Is Comparable in Patients with Non-Radiographic Axial Spondyloarthritis and Ankylosing Spondylitis. Joachim Sieper Male[1], Désirée van der Heijde[2], Dirk Elewaut[3], Aileen L. Pangan[4] and Jaclyn K. Anderson[4]. [1]Charité Universitätesmedizin Berlin, Berlin, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Ghent University Hospital, Ghent, Belgium, [4]Abbott Laboratories, Abbott Park, IL

Background/Purpose: Chronic back pain and functional impairment are disease characteristics common to all patients (pts) with axial spondyloarthritis (SpA), regardless of the presence of radiographic sacroiliitis in ankylosing spondylitis (AS) or its absence in non-radiographic axial SpA (nr-axSpA). This analysis compares baseline disease characteristics of pts with nr-axSpA and AS in registries and randomized clinical trials (RCT) with adalimumab (ADA).

Methods: Registry data in this analysis include the German SpA Inception Cohort (GESPIC)[1] that compared pts with AS by modified New York criteria (divided into >5 yrs and ≤5 yrs) and nr-axSpA (≤5 yrs) meeting modified ESSG criteria and a prospective cohort of TNF-naïve SpA pts meeting ASAS criteria for axial SpA.[2] ADA RCT data were derived from the ATLAS study[3] in AS pts, and the ABILITY-1[4] and Haibel[5] studies in nr-axSpA pts. Pts in RCTs were selected based on a pre-specified level of disease activity and inadequate response to non-steroidal anti-inflammatory drugs.

Results: Mean age was similar in nr-axSpA and AS pts, ranging from 36–42 yrs (table). A higher proportion of AS pts had elevated CRP as compared to nr-axSpA pts and gender differences were observed, with nr-axSpA pts being predominantly female and AS pts primarily male. Symptomatic pts with nr-axSpA and AS often went undiagnosed for years. Similar levels of disease activity as measured by the BASDAI, pain scores, and pt and physician global assessments of disease activity were seen between nr-axSpA and AS pts in registries and RCTs, with levels of disease activity generally higher in RCT pts due to minimum levels of baseline disease activity required for study eligibility.

Table. nr-axSpA and AS baseline disease characteristics

| | Registries | | | | | RCTs | | |
| | GESPIC | | | Kiltz | | ATLAS | ABILITY-1 | Haibel |
	All AS N=236	AS ≤5 yrs N=119	nr-axSpA ≤5 yrs N=226	AS N=56	nr-axSpA N=44	AS N=315	nr-axSpA N=185	nr-axSpA N=46
Age, yrs	35.6	36.1	36.1	41.2	39.1	42.2	38.0	37.5
Female, %	36.0	34.5	57.1	23.2	68.2	25.1	54.6	54.3
HLA-B27 +, %	88.2	73.1	74.7	89.1	86.4	78.7	75.1	67.4
Symptom duration, yrs	5.2	3.0	2.6	12.8	9.4	-	10.1	7.5
Duration since diagnosis, yrs	2.8	1.7	1.7	7.5	5.0	10.6	2.9	–
BASDAI, 0–10	4.0	4.0	3.9	4.2	3.6	6.3	6.5	6.3
Abnormal CRP, %	51.9	49.6	29.8	69.1	29.5	67.6	35.7	37.8
Total back pain, VAS 0–10	–	–	–	–	–	6.5	6.9	–
Total pain, VAS 0–10	5.0	4.8	4.8	4.7	4.0	–	6.8	7.2
PtGA of disease activity, VAS 0–10	5.0	5.0	4.9	4.6	4.0	6.3	6.8	6.6
PhGA of disease activity, VAS 0–10	4.5	4.4	3.6	3.5	2.7	5.7	5.7	5.9

Values are the mean unless otherwise indicated. AS, ankylosing spondylitis; BASDAI, Bath AS Disease Activity Index; CRP, C-reactive protein; nr-axSpA, non-radiographic axial spondyloarthritis; PhGA, physician global assessment; PtGA, patient global assessment; RCT, randomized clinical trial; VAS, visual analog scale.

Conclusion: Registry and clinical trial data demonstrate that both nr-axSpA and AS patients have comparable burden of disease. These findings suggest that all patients with axial spondyloarthritis can present with similar debilitating signs and symptoms requiring treatment regardless of the extent of radiographic damage.

Evaluation of Spondyloarthritis activity by the Patients and the Physicians: ASDAS, Basdai, PASS and Flare.

Marie Godfrin-Valnet[1], Clément Prati[2], Marc Puyraveau[1], Eric Toussirot[3], Helene Letho-Gyselinck[4] and Daniel Wendling[4]. [1]CHU, Besançon, France, [2]CHU J Minjoz, Besancon, France, [3]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France, [4]Minjoz University Hospital, Besançon, France

Background/Purpose: Objectives: to define thresholds of the ASDAS corresponding to the PASS (Pateint Acceptable Symptomatic State) and to the thresholds of activity of the disease through what the patients feel. Correlate these levels of activity to the presence of a depressive syndrome and determine a threshold ASDAS and BASDAI corresponding to a flare in spondyloarthritis (SpA).

Methods: A prospective study of SpA patients (ASAS criteria) from February 2011 until February 2012. Various scores (BASDAI, ASDAS, BASFI) as well as the evaluation of the PASS and the depressive syndrome were measured. Determination of ASDAS thresholds corresponding to the PASS, to the various thresholds of activity according to the patients, and to flare was performed using ROC curves. The Kappa coefficient was calculated to estimate the correlation between the physician's and the patient's evaluation of the flare.

Results: 200 SpA patients, mean age 44.4 ± 12.5 years (duration 12.9 ± 10.5 years) were included. The average scores were respectively 4.1 ± 2.2 for the BASDAI and of 2.4 ± 1 for the ASDAS-CRP and of 3.3 ± 2.7 for the BASFI. 58.9 % of the patients were considered in PASS. The PASS corresponded to a BASDAI ≤ 4.1 and to an ASDAS-CRP ≤2.3. Concerning the impression of the disease by the patients: a weakly active disease corresponded to a BASDAI ≤3.8 and to an ASDAS-CRP ≤2.3, and a strongly active disease in a BASDAI >5.2 and an ASDAS-CRP > 3.1. When the disease was considered as strongly active, 64.5 % of patients had a score of severe depressive syndrome on Beck's scale. A flare was considered by 36.9 % of the patients versus 28.3 % of the physicians. The threshold BASDAI "flare" was ≥5.2 and the threshold ASDAS-CRP "flare" was ≥2.3. The concordance between the evaluation of the flare according to the physician and the patient was good (Kappa: 0.61).

Conclusion: Our results report a significant link between the level of activity of the disease and the severity of the depressive syndrome. Our study confirms a good concordance between the BASDAI and the ASDAS. Thresholds of BASDAI and ASDAS are proposed for PASS and flare in SpA.

Validation of the Self-Administered Comorbidity Questionnaire in Patients with Ankylosing Spondylitis.

Carmen Stolwijk[1], A.M. Van Tubergen[1], Sofia Ramiro[2], Ivette Essers[1], Marc Blaauw[1], Désirée van der Heijde[3], Robert B. M. Landewé[4], Filip Van den Bosch[5], Maxime Dougados[6] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Academic Medical Center/University of Amsterdam & Atrium Medical Center, Amsterdam, Netherlands, [5]Ghent University Hospital, Ghent, Belgium, [6]Paris-Descartes University, APHP, Cochin Hospital, Paris, France

Background/Purpose: Comorbidities can importantly influence the results of clinical studies on functional outcomes as they may act as confounders or effect modifiers. The generic self-administered comorbidity questionnaire (SCQ) is a frequently used instrument to assess common comorbidities which might impact functioning but has never been validated for use in ankylosing spondylitis (AS). Objective was to measure the agreement between SCQ-responses and medical records diagnosis, and to assess construct- and concurrent validity of the SCQ in patients with AS.

Methods: The SCQ (range 0–45) asks about the presence, treatment and functional limitations of 12 common comorbidities and three additional non-specified medical problems. The SCQ, demographics and indices of disease activity (Bath AS Disease Activity Index [BASDAI]; AS Disease Activity Score- C-reactive protein); physical function (Bath AS Functional Index) and health-related quality of life (HR-QoL; Short form-36 [SF-36], Ankylosing Spondylitis Quality of Life [ASQoL], EuroQoL-VAS), were administered to 98 patients with AS who were followed in the Outcome in Ankylosing Spondylitis International Study (OASIS). The agreement between the SCQ-items and comorbidities retrieved from medical records was calculated by two independent extractors. Concurrent validity was assessed by the correlation with two other comorbidity indices: the Charlson index, a record-based comorbidity index which predicts mortality, and the Michaud/Wolfe index, which predicts functional outcomes. Construct validity was assessed by testing the hypothesis that a valid comorbidity index should correlate with age, function and overall HRQoL. An adapted version of the SCQ (adapted SCQ) was created and validated after removing items on rheumatic diseases (osteoarthritis, back pain, chronic rheumatic disease) because they were conceptually overlapping with the index disease.

Results: The median SCQ-score was 5 (range 0–19) and the median adapted-SCQ-score was 2 (range 0–13). Frequently reported non-rheumatic comorbidities were hypertension (27.6%), inflammatory bowel disease (10.2%) and depression (9.2%). Agreement between self-report and medical records was moderate to perfect for all diseases included in the SCQ (kappa 0.47–1.00), except for stomach disease, depression, and osteoarthritis (kappa

0.14–0.15). The correlations of the SCQ with the Michaud/Wolfe index and the Charlson index were 0.39 and 0.24 respectively, and of the adapted-SCQ with both indices 0.53 and 0.36 respectively. The SCQ correlated weakly with age (r=0.24) and disease activity (BASDAI r=0.27), and moderately with function (r=0.43) and HRQoL (SF-36 physical r=-0.45; AsQoL r=0.43). The adapted SCQ correlated weakly with age (r=0.28), and moderately with function (r=0.41) and HRQoL (SF-36 physical r=-0.41, ASQoL r=0.32), but not with measures of disease activity.

Conclusion: The SCQ can be used to measure comorbidities which have impact on functional outcomes in AS, but the rheumatic items showed low agreement. Exclusion of these items improved construct and concurrent validity.

Development, Sensibility and Reliability of a New Case-Finding Questionnaire, the Toronto Axial Spondyloarthritis Questionnaire in Inflammatory Bowel Disease. Khalid A. Alnaqbi[1], Zahi Touma[1], Laura A. Passalent[1], Sindhu R. Johnson[1], George A. Tomlinson[2], Adele Carty[1] and R. D. Inman[1]. [1]Toronto Western Hospital, Toronto, ON, [2]Toronto General Hospital, Toronto, ON

Background/Purpose: Inflammatory bowel disease (IBD) encompasses Crohn's disease, ulcerative colitis, and indeterminate colitis. Articular involvement [(peripheral arthritis and axial spondyloarthritis (axSpA)] is the most common extra-intestinal manifestation. There is an unacceptable delay in diagnosis of axSpA by 8–11 years. Our aim was to develop a sensible and reliable questionnaire that identifies undetected axSpA among IBD patients and facilitates timely referral to rheumatologists.

Methods: Literature review facilitated identification of 3 domains:1) IBD, 2) inflammatory back symptoms, and 3) extra-axial features. Items of the Toronto Axial Spondyloarthritis Questionnaire (TASQ) were evaluated for sensibility among SpA team, 2 general rheumatologists, and axSpA patients. Sensibility assessment was related to purpose and framework (clinical function, clinical justification, clinical applicability), face validity, comprehensibility (oligovariability, transparency), replicability, content validity, and feasibility. For the test-retest reliability study, the final version of TASQ was mailed to 77 patients with established IBD and axSpA, who were followed at the Spondylitis clinic. Patients were instructed to complete the questionnaire on 2 occasions 1–2 weeks apart. Calculated sample size was 23 for reliability. Kappa statistics were calculated for the binary response options of each item.

Results: Item modification and reduction led to drafting version 4 of TASQ consisting of 16 items on a one-page double-sided document with a diagram of the back. Of the 77 patients, 34 responded to the TASQ. Responders and non-responders did not differ in terms of age, sex, level of education, types of IBD, BASDAI, BASFI, ESR and CRP levels. Kappa agreement coefficient ranged from 0.81 to 1.00 indicating almost perfect agreement. Absolute agreement of all items ranged from 91 to 100%.

Double-Blind, Placebo-Controlled, 28-Week Trial of Efficacy and Safety of Infliximab Plus Naproxen Vs Naproxen Alone: Results From the Infliximab As First Line Therapy in Patients with Early, Active Axial Spondyloarthritis Trial, Part I. Joachim Sieper[1], Jan Lenaerts[2], Jürgen Wollenhaupt[3], Vadim Mazurov[4], L. Myasoutova[5], Sung-Hwan Park[6], Yeong W. Song[7], Ruji Yao[8], Denesh Chitkara[8] and Nathan Vastesaeger[9]. [1]Charité, University Medicine Berlin, Berlin, Germany, [2]Reuma-instituut, Hasselt, Belgium, [3]Schön-Klinik, Hamburg, Germany, [4]St. Petersburg Medical Academy, St. Petersburg, Russia, [5]Kazan State Medical University, Kazan, Russia, [6]Catholic University of Korea, Seoul, South Korea, [7]Seoul National University, Seoul, South Korea, [8]Merck Sharp and Dohme, Kenilworth, NJ, [9]Merck Sharp and Dohme, Brussels, Belgium

Background/Purpose: Efficacy of anti–tumor necrosis factor (TNF) therapy in patients with axial spondyloarthritis (SpA) has been tested only in patients who are refractory to NSAIDs.

Objectives: To determine whether combination infliximab (IFX)+NSAID therapy is superior to NSAID monotherapy for achieving better clinical outcomes in patients with early, active axial SpA who were naïve to NSAIDs or had a submaximal dose of NSAIDs.

Methods: The INFAST trial was a double-blind, randomized controlled trial of IFX in biologic-naïve patients 18–48 years of age with early, active axial SpA (ASAS criteria, disease duration ≤3 years with chronic back pain and active inflammatory lesions of the sacroiliac [SI] joints on MRI). Patients naïve to NSAIDs or treated with a submaximal dose of NSAIDs were randomized (2:1) to receive 28 weeks of treatment with either IV IFX 5 mg/kg (weeks 0, 2, 6, 12, 18, and 24)+naproxen (NPX) 1000 mg/d or IV placebo (PBO)+NPX 1000 mg/d. The primary endpoint was the percentage of subjects meeting ASAS partial remission criteria at week 28. Treatment group differences were analyzed using Fisher exact tests or analysis of covariance.

Results: 106 patients were randomized to IFX+NPX and 52 to PBO+NPX. At baseline, mean BASDAI scores (100 mm VAS) were 64.4 (SD=15.37) mm and 63.0 (SD=15.43) mm and HLA-B27–positive statuses were 82.1% and 90.4% in the IFX+NPX and PBO+NPX groups, respectively. The primary endpoint, ASAS partial remission at week 28, was achieved by more patients treated with IFX+NPX (61.9%) than PBO+NPX (35.3%), P=0.0021. Partial remission rates increased steadily through weeks 2, 6, 16, and 28 in both the IFX+NPX group (28.6%, 41%, 51.4%, and 61.9%) and the PBO+NPX group (11.8%, 15.7%, 25.5%, 35.3%), with greater partial remission in the IFX+NPX group at each visit (all P <0.05). Improvements in BASDAI, ASDAS, and ESR were considerable and were significantly greater in the IFX+NPX group than the PBO+NPX group (**Table 1**). The observed CRP decrease was greater in the IFX+NPX group

than the PBO+NPX group, but did not reach statistical significance. A greater number of patients in the IFX+NPX group (51.4%) than the PBO+NPX group (19.6%), $P=0.0001$, achieved inactive disease, defined as ASDAS-CRP <1.3.

Table 1. Change in Efficacy Outcomes from Baseline to Week 28 by Treatment Group

Outcome	IFX+NPX (N=105)			PBO+NPX (N=51)			P Value
	Baseline, mean	Week 28, mean	Change, mean (SD)	Baseline, mean	Week 28, mean	Change, mean (SD)	
BASDAI (100 mm VAS)	64.4	18.0	−46.6 (22.38)	63.0	32.2	−30.2 (24.34)	0.0001
ASDAS	3.8	1.4	−2.4 (1.16)	3.9	2.4	−1.5 (1.13)	<0.0001
ESR (mm/hr)	23.0	7.1	−16.0 (16.11)	28.3	19.0	−9.4 (13.18)	<0.0001
CRP (mg/dL)	2.02	0.91	−1.24 (6.209)	1.65	1.15	−0.55 (1.315)	0.5943

Serious adverse events were reported in 5 (4.8%) patients in the IFX+NPX group (possibly related to study medication in 3 [2.9%] patients) and 3 (5.8%) patients in the PBO+NPX group (possibly related in 2 [3.8%] patients). No deaths occurred.

Conclusion: Patients with early, active axial SpA who were treated with IFX+NPX had greater rates of ASAS partial remission and were more likely to have lower or inactive disease (as measured by BASDAI and ASDAS) than those treated with PBO+NPX. Patients who were treated with PBO+NPX had good response but still had moderately active disease. The safety profile was consistent with that of other anti-TNF biologics.

Golimumab Administered Subcutaneously Every 4 Weeks in Chinese Patients with Active Ankylosing Spondylitis: Week 24 Safety and Efficacy Results From a Randomized, Placebo - Controlled Study.

Chunde Bao[1], Feng Huang[2], Muhammad Asim Khan[3], Kaiyin Fei[4], Zhong Wu[4] and Elizabeth C. Hsia[5]. [1]Shanghai Renji Hospital, Shanghai, China, [2]Chinese PLA General Hospital, Beijing, China, [3]Case Western Reserve University Hospital, Cleveland, OH, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Janssen Research & Development, LLC/U of Penn, Spring House/Phila, PA

Background/Purpose: This multicenter, randomized, placebo (PBO)-controlled study was conducted to evaluate the efficacy and safety of golimumab (GLM) in Chinese patients with active ankylosing spondylitis (AS).

Methods: Patients ≥18yrs of age with a diagnosis of active AS for ≥3 months prior to screening and symptoms of active disease (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] '4, and a visual analogue scale [VAS] for total back pain ≥4, each on a scale of 0 to 10cm) were eligible to be enrolled for study screening. Patients with prior exposure to biologic anti-tumor necrosis factor alpha (TNF) agents and patients with complete ankylosis of the spine were not permitted to be included in the study. Patients who passed study screening were randomized in 1:1 ratio to receive sub-cutaneous (SC) injections of GLM 50mg or PBO q4wks through wk20. At wk16, all patients randomized to PBO that met early escape criteria (<20% improvement from baseline in both total back pain and morning stiffness measures) began receiving GLM 50mg SC injections in a blinded fashion at wk16 and q4wks thereafter through wk48; all other patients still receiving placebo injections began receiving GLM 50 mg SC injection at wk24 and q4wks thereafter through wk48; all patients randomized to GLM continued receiving GLM 50 mg SC at wk24 and q4wk through wk48 regardless of the status of early escape.The primary efficacy endpoint was the proportion of patients with ≥ 20% improvement in the ASsessment in AS (ASAS) criteria at wk14.

Results: 213 patients were randomized to treatment; baseline demographics were comparable between groups with median age of 29yrs, median weight of 62.0kg, and 83.1% male. The primary endpoint and major secondary endpoints were achieved (Table). Adverse events through 24 wks were reported in 38.9% of GLM-treated and 34.3% of PBO-treated patients.

Serious adverse events were reported in 0.9% (1 ovarian epithelial cancer) and 0.0% of GLM and PBO-treated patients, respectively. Infections were reported in 22.2% and 19.0% of GLM and PBO-treated patients, respectively (primarily upper respiratory tract infections). No serious infections, TB or opportunistic infections, or deaths were reported. Antibodies to GLM were not detected in GLM-treated patients through wk24.

Table.

	Placebo	Golimumab 50 mg

Clinical Features and Treatment Results of Japanese Patients with SAPHO (Synovitis-Acne-Pustulosis-Hyperostosis-Osteitis) Syndrome.

Hiroki Yabe[1], Takashi Kuroiwa[1], Aya Nonaka[1], Tomomi Tsutsumi[1], Tadashi Sakurai[1], Masato Moriguchi[1], Hisaji Oshima[2], Kensuke Ochi[3] and Chihiro Terai[1]. [1]Jichi Medical University Saitama Medeical Center, Saitama City, Japan, [2]Tokyo Medical Ctr, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: SAPHO syndrome is a disorder characterized by pustular skin lesions and osteoarticular lesions, which was proposed by Chamot et al. in 1987. Clinical studies based on the diagnostic criteria of SAPHO syndrome are mainly reported from Europe, and still limited in East-Asia.

Methods: We investigated the clinical features and treatment results in 31 Japanese patients with SAPHO syndrome (male 10, female 21) diagnosed and treated between 2003 and 2011. HLA-A and -B typing was performed in 30 patients, and their allele frequencies were compared with those in the healthy Japanese controls, using Fisher's exact test.

Results: The age at onset was ranged between 16 and 68 years old (y.o.) (average: 48.3), and the age at diagnosis from 16 to 74 y.o. (average: 53.8). The average follow-up period was 42 months. Sternocostoclavicular hyper-ostosis was the main manifestation and recognized in 29 cases (94%). Pustular dermatitis including palmoplantar pustulosis was seen in 26 cases (84%). As other manifestations, recurrent oral ulceration was seen in 6 cases (19%), and inflammatory bowel disease in 2 cases. Most patients had intermittent attacks of pain, therefore oral NSAIDs were needed in all cases and oral prednisolone (PSL) in 14 cases (45%). The oral NSAIDs and/or PSLwere effective for temporary pain relief. DMARDs (SSZ and/or MTX) were used in 14 cases (45%) with recurrent chronic pain. Pain relief more than 50% was seen in only 4 cases (29%) out of DMARDs users. In two refractory cases with severe spondylitis, adalimumab (ADA) was tried. Both cases showed immediate pain-relief and ADA was effective during at least one

year. HLA tests revealed that the allele frequencies of HLA-B27 and HLA-B51were respectively 0% and 12%, which were similar with those in healthy Japanese controls. On the other hand, the frequency of HLA-B61 was 27 % and significantly higher than that (12%) in healthy controls.

Conclusion: Mucosal lesions seem to be a rather frequent complication of SAPHO syndrome in our study. The efficacy of DMARDs (SSZ and/or MTX) was observed in a small number of patients. ADA was effective in two refractory cases with severe spondylitis. This study revealed that HLA-B61 was significantly increased in Japanese patients with SAPHO syndrome.

Psoriatic Arthritis in South Asians- Comparison with Caucasians of European Descent. Vinod Chandran. Arane Thavaneswaran and Dafna D. Gladman Gladman, Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: The prevalence of psoriatic arthritis (PsA) varies substantially world-wideand is highest among Caucasians of European descent. Studies from India suggest that patients with PsA have a milder disease. Comparing disease phenotype across ethnicities can provide insight into mechanisms underlying disease severity. We aimed to determine whether demographic and disease characteristics differed in PsA patients of South Asian ethnicity compared to those of European ethnicity.

Methods: The study was conducted at a PsA clinic in a North American city with a diverse ethnic composition. Patients are assessed every 6–12 months according to a standard protocol. Prospectively collected data were retrieved from the clinic database. The distribution of ethnicities within the cohort was determined. The demographic and disease characteristics of those with South Asian ethnicity were compared to those of European ethnicity using chi-squared tests and unpaired t-test. Subsequently, each patient of South Asian ethnicity was matched by gender, age, duration of PsA and year of entry to clinic, to 3 patients of European ethnicity and the disease characteristics compared using McNemar and paired t-tests.

Results: The distribution of the 1184 patients in the cohort were as follows: European 1037 (88%), South Asian 59 (5%), Chinese 26 (2.2%), Black 12 (1%), Filipino 12 (1%), Hispanic 7 (0.6%), South-east Asian 4 (0.3%), Korean 2 (0.2%), Aboriginal 1 (0.1%) and other/mixed 24 (2%). Overall patients of South Asian descent had shorter duration of psoriasis, lower family history of psoriasis, lower family history of PsA, lower prevalence of obesity, lower exposure to biologic agents and NSAIDs as well as lower prevalence of nail psoriasis and severe radiographic damage (defined as grade 4 damage according to the Steinbrocker method) compared to patients of European descent. The summary of results of the matched analysis comparing patients of South Asian descent to those of European descent is presented in Table 1. Patients of South Asian descent had lower tender joint counts, less number of joints with severe damage, lower frequency of treatment with biologics, lower frequency of HLA*B27 and worse SF-36 MCS scores, compared to matched patients of European descent. Although they had lower prevalence of obesity, the prevalence of diabetes and hyperlipidemia was higher.

Table 1. Summary of the results of the matched-pair analyses between subjects of South Asian ethnicity and those of European ethnicity

Variable	South Asian (N=49)	Caucasian (N=147)	p-value
Active joint count	12.3 (12.8)	10.5 (8.0)	0.10
Tender joint count	10.2 (11.7)	7.5 (6.1)	0.01
Damaged joint count	4.3 (4.2)	6.0 (6.6)	0.06
No. of joints with grade 3 damage	9 (18.4%)	40 (27.2%)	0.09
No. of joints with grade 4 damage	1 (2.0%)	17 (11.6%)	0.003
HAQ	0.73 (0.75)	0.58 (0.59)	0.10
SF-36 MCS	43.9 (12.1)	46.4 (12.3)	0.03
Obesity	5 (17.9%)	34 (34.7%)	0.09
Diabetes	5 (11.1%)	7 (5.9%)	0.02
Hyperlipidemia	4 (9.3%)	3 (2.8%)	0.01
Biologics ever	8 (20.0%)	45 (40.9%)	0.0006
DMARDs ever	32 (72.7%)	78 (59.1%)	0.08
HLA-B*27	3 (8.6%)	23 (20.0%)	0.09

Conclusion: Although PsA patients of South Asian descent report higher HAQ scores, and have more tender joints, radiographic joint damage appears

to be less severe and they are less likely to be treated with biologic agents than patients of European descent. Although less likely to be obese, they have higher prevalence of diabetes and hyperlipidemia. Ethnic differences in disease manifestations may have an impact on long-term outcomes of patients with PsA.

Severe Joint Damage in Psoriatic Arthritis: Mutilans and Ankylosis. Amir Haddad, Arane Thavaneswaran, Dafna D. Gladman Gladman and Vinod Chandran. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Patients with Psoriatic arthritis (PsA) who develop severe joint damage have severe functional disability and increased mortality risk. The most severe form of PsA is termed arthritis mutilans and is associated with severe erosions, osteolysis and pencil-in-cup change. Ankylosis is also a feature of severe PsA. The modified Steinbrocker method of scoring radiographic damage to peripheral joints in PsA recognizes grade 4 damage as severe damage, but does not explicitly distinguish between severe erosions, pencil-in-cup change, subluxation and ankylosis. We aimed to describe the prevalence and disease association of these features of severe joint damage in a cohort of patients with early PsA.

Methods: Patients presenting to a large PsA clinic with PsA duration of < 5years were identified. Patients are evaluated every 6–12 months and plain radiographs are obtained every 2 years. Radiographs are reviewed according to the modified Steinbrocker method by consensus of at least 2 rheumatologists. For this study radiographs that were scored as 4 were retrieved and rescored to indicate disorganization (4.0), subluxation (4.1), pencil-in-cup (4.2) and ankylosis (4.0). Subsequently, the clinical characteristics at first visit of patients who developed at least 1 joint with severe joint damage were compared to those without such damage.

Results: 664 patients who were enrolled within 5 years of diagnosis were the subjects of this study. 116/664 (17.5%) were observed to have at least one joint with 4.0, 4.1, 4.2 or 4.3 of the 42 scored. The demographic and disease characteristics at first visit of the patients who were observed to develop such damage compared to those who did not are reported in table 1. Patients with severe joint damage were older at diagnosis of psoriasis and had longer PsA duration, but shorter psoriasis duration. They had higher active and damaged joint counts and ESR. There was a trend towards higher prevalence of female sex, axial disease and HLA-B*27 in those with severe damage. Of the 116 patients observed to develop severe damage, 34 (29%), 63 (54%), 36 (31%), 58 (50%) patients were observed to have '4.0', '4.1', '4.2' and '4.3', respectively at baseline or during follow-up. The mean (sd) number of joints with '4.0', '4.1', '4.2' and '4.3', were 0.3 (0.7), 1.1 (2.1), 0.6 (2.0) and 0.7 (1.4), respectively. Only 15 (13%) patients were observed to have ankylosis without lysis. These patients had lower modified Steinbrocker score [mean, (sd) 31 (18) vs. 53 (43) p=0.001] compared to those with subluxation or pencil-in-cup change.

Table 1. Demographics and Disease Characteristics at baseline

Variable	Patients with severe joint damage N=116	Patients without severe joint damage N=548	p-value
Gender (Males)	58 (50.0%)	322 (58.8%)	0.08
Age	43.8 (13.9)	41.7(12.9)	0.11
Age at diagnosis of Psoriasis	33.9 (15.5)	29.0 (14.6)	0.002
Age at diagnosis of PsA	41.4 (14.1)	39.8 (13.0)	0.27
Duration of Psoriasis	9.9 (10.1)	12.7 (11.6)	0.02
Duration of PsA	2.3 (1.6)	1.9 (1.7)	0.02
ESR	30.2 (20.5)	20.9 (19.6)	<0.0001
PASI score	6.3 (9.1)	5.9 (8.4)	0.76
Active joint count	12.9 (10.5)	9.4 (8.7)	0.001
Swollen joint count	5.7 (5.7)	4.7 (5.1)	0.09
Damage joint count	5.8 (5.2)	3.1 (4.0)	0.0008
Axial disease	41 (35.3%)	148 (27.0%)	0.07
HLA B*27	21 (22.6%)	59 (14.0%)	0.06
Follow-up time (radiographic visits)	11.6 (9.3)	5.3 (7.4)	<0.0001

Conclusion: Patients with PsA who develop severe joint damage have higher disease activity at presentation. The most common form of severe joint

damage observed is subluxation. Only 13% have exclusive ankylosis. Further phenotypic characteristic of radiographic damage in PsA will facilitate genetic and mechanistic studies.

Clinical and Ultrasonographic Features of Nail Disease in Psoriasis and Psoriatic Arthritis. Amir Haddad, Arane Thavaneswaran, Vinod Chandran and Dafna D. Gladman Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: The purpose of this study was to investigate the association between clinical and unltrasonographic features of psoriatic nail disease and to identify specific nail features associated with psoriatic arthritis (PsA).
Methods: Patients with PsA and Psoriasis without arthritis (PsC) were recruited from prospective cohorts in a single centre. Healthy volunteers were also recruited. Subjects with co-existing OA or history of nail trauma were excluded. A detailed nail assessment according to the modified Nail Psoriasis Severity Index (mNAPSI) for the presence of onhycolysis, nail pitting, nail plate crumbling, leukonychia, splinter hemorrhages, nail bed hyperkeratosis and red spots in the lunula was completed for each participant. All participants underwent an ultrasound evaluation of the nail apparatus at each finger with detailed recording of loss of definition of the ventral or dorsal plates, thickness of the nail bed or matrix and the presence of increased vascularity in the nail bed or matrix using a 10-MHz linear array transducer. Doppler signal was standardized with a pulse repetition frequency of 400 Hz, a gain of 20 dB and a low wall filter. Descriptive analyses and comparisons were conducted using Kruskal Wallis for continuous variables and Fisher's exact test for categorical variables. Logistic regression analyses using GEE model was used to compare between the groups due to repeated observations for each patient.
Results: 10 patients were recruited into each group and the results are reported in the following tables:

Table 1. Demographic Characteristics (n=30) between Controls, PsC and PsA

Frequency (%) or Mean (sd)

Controls	Controls (n=10)	PsC (n=10)	PsA (n=10)	p-value
Gender (Males)	3 (30.0%)	9 (90.0%)	7 (77.8%)	0.02
Age	29.0 (4.4)	46.0 (16.1)	54.7 (12.6)	0.0006
Age at diagnosis of Psoriasis	–	33.0 (21.9)	33.4 (13.8)	0.60
Duration of Psoriasis	–	13.0 (13.9)	21.1 (11.7)	0.10
mNAPSI score	0	6.2 (5.8)	3.8 (4.6)	0.01

Table 2. Summary & Comparison of Fingers Affected by Nail Feature for the three groups

Nail Feature	Controls	PsC	PsA	p-value*	p-value**
Loss of definition of the ventral plate	6/100	24/100	29/100	<0.0001	0.42
Hyperechoioc focal involvement of the ventral plate	0/100	23/100	16/100	<0.0001	0.21
Thickening of both the and dorsal and ventral plates	0/100	8/100	2/100	0.005	0.052
Nail bed thickness (mm)	14.1 (1.2)	16.0 (2.9)	15.9 (3.0)	<0.0001	0.81
Nail matrix thickness (mm)	15.8 (0.92)	17.5 (2.9)	18.8 (3.0)	<0.0001	0.002
Nail bed vascularity	2/100	14/100	18/100	0.001	0.44
Nail matrix vascularity	16/100	30/100	34/100	0.01	0.54
Onycholysis and oil drop dyschromia (Some vs. none)	0/100	13/100	5/100	0.0005	0.048
Pitting Some vs. none	0/100	28/100	20/100	<0.0001	0.19
Nail bed crumbling (Some vs. none)	0/100	8/100	0/100	0.0003	0.004
Leukonychia	0/100	3/100	2/100	0.24	0.65
Splinter hemorrhage	0/100	0/100	0/100	NS	NS
Nail bed hyperkeratosis	0/100	0/100	0/100	NS	NS
Red spots in the lunula	0/100	0/100	1/100	0.37	0.32

P-value* is between the 3 groups, p-value** is between the PsC and PsA.

None of the nail's sonographic or clinical covariates were found to statistically different in between PsA and PsC groups after adjusting for repeated measurements.
Conclusion: This proof of concept study shows that ultrasounds can be used as a tool for assessment of psoriatic nail disease. Patients with psoriatic disease had increased nail bed and matrix thickness as well as vascularity compared to healthy controls. However, whether these microanatomical nail structures could be predictors for evolution of psoriatic arthritis is yet to be determined.

Predictors of Erosion-Free Psoriatic Arthritis. Zahi Touma, Arane Thavaneswaran, Vinod Chandran and D. D. Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: A number of patients with psoriatic arthritis (PsA) remain erosion-free despite years of disease. We aimed to determine the prevalence, characteristics and predictors of erosion-free patients (EFP) as compared to erosion-present patient (EPP) in PsA patients.
Methods: This is a retrospective analysis conducted on all PsA patients with at least a 10 year period of follow-up in single centre PsA cohort.
Radiographs at 1–2 year intervals were scored (modified Steinbrocker): 0-normal, 1-soft tissue swelling/osteopenia, 2-erosions (E), 3- E plus joint space narrowing and 4- total joint destruction. EPP was defined as any joint with ≥ grade 2 (EFP could not have erosions at any visit).
T-tests, Chi-squared and Fisher's exact test were used for comparison between groups. Baseline characteristics were used to predict the development of E with logistic regression models (reduced model using stepwise selection). The time to development of erosions was assessed with Kaplan-Meier estimator.
Results: Among 290 patients, 12.4% were EFP and 87.6% EPP. EFP were diagnosed with psoriasis at a younger age compared to EPP patients, 22.5±14.7 and 27.6±12.1 years respectively (p=0.02). Of the 243 EPP patients, 97 (39.9%) have no E at first visit and develop it later. The remaining 146 (60%) already had E at first visit. There was no statistically significant difference in ethnicities, gender, age at diagnosis of PsA and duration of psoriasis and PsA among groups.
At baseline, EPP displayed a greater number of actively inflamed joints (10.1±9.1) compared to EFP (4.8±5.3) (p=0.0007). 40.6% of EPP had damaged joints compared to 8.3% in EFP (p=0.0002). EPP had a higher BMI compared to EFP (p=0.03). More EPP were on NSAIDs and sulfasalazine; p=0.04 and p=0.02 respectively. EFP were all employed vs. 69.8% EPP (p=0.05). 93% of EPP had active joints as compared to 72% EFP (p<0.0001). Similar differences in characteristics among EPP and EFP were also present at the last follow-up visit. In particular EPP have a higher percentage of unemployment as compared to EFP; 25% vs. 52% respectively (p=0.02).
Univariate analyses showed that actively inflamed joint count (OR=1.12, p=0.001), damage joint count (OR=2.35, p=0.02) and use of DMARDs/NSAIDs (OR=2.73, p=0.02) were associated with the development of E. In the multivariate analysis actively inflamed joint count (OR=1.09, p=0.01) and damage joint count (OR=2.43, p=0.02) were predictive of the development of E whereas a longer duration of psoriasis at baseline decreased the odds of developing E (OR=0.96, p=0.03). The mean time to development of E was 2.96±5.23 years (Figure 1).
Figure 1. Time to Development of Erosions

Conclusion: Among patients with PsA followed for at least 10 years 12% never develop E.

Presence of actively inflamed and damaged joints at baseline increases the odds of development of E. A longer duration of psoriasis at baseline has a protective effect of development of E.

Increased Participation in Daily Activities After 24 Weeks of Certolizumab Pegol Treatment of Axial Spondyloarthritis Patients, Including Patients with Ankylosing Spondylitis: Results of a Phase 3 Double-Blind Randomized Placebo-Controlled Study. Désirée van der Heijde[1], Jurgen Braun[2], Martin Rudwaleit[3], Oana Purcaru[4] and Arthur Kavanaugh[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Endokrinologikum Berlin, Berlin, Germany, [4]UCB Pharma, Braine, Belgium, [5]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Axial spondyloarthritis (axSpA) includes both ankylosing spondylitis (AS) and non-radiographic axial SpA (nr-axSpA). AS significantly affects patients' (pts) work productivity.[1] The impact of the entire spectrum of axSpA on work productivity is still poorly researched. RAPID-axSpA (NCT01087762) is the first report of the effect of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, on paid and household work productivity, and daily activities, in pts with axSpA.

Methods: Recruited pts had adult-onset active axSpA as defined by the ASAS criteria,[1] BASDAI ≥4, spinal pain ≥4 on a 10 point scale, CRP > upper limit of normal or sacroillitis on MRI. Pts must have failed ≥1 NSAID. Up to 40% of pts could have experienced secondary failure to 1 previous anti-TNF. The pt population reflected the broad axSpA population, including AS pts also meeting the modified New York criteria and nr-axSpA pts who met the ASAS MRI or clinical criteria. Pts were randomized 1:1:1 to PBO, or CZP 400mg at Week (Wk) 0, 2 and 4 (loading dose, LD) followed by either CZP 200mg every 2 wks (Q2W) or CZP 400mg every 4 wks (Q4W). Pts receiving PBO who failed to achieve an ASAS20 response at both Wks 14 and 16 were rescued and randomized at Wk16 to receive CZP 200mg Q2W or CZP 400mg Q4W following LD. The arthritis-specific Work Productivity Survey (WPS) assessed the impact of axSpA on workplace and household productivity. WPS was administered every 4 wks. WPS responses (last observation carried forward imputation) were compared between treatment arms using a non-parametric bootstrap-t method.

Results: 325 pts were randomized. 63.2%, 69.4%, and 74.8% of pts in the PBO, CZP 200mg Q2W, and CZP 400mg Q4W treatment groups were employed at study BL; 11%-13% of pts were unable to work due to axSpA; 4%-9% were students; 3%-8% were retired. Treatment groups were comparable at BL in terms of workplace and household productivity. At BL the burden of axSpA on absenteeism, presenteeism, household productivity and social activities was high (Table). Compared to PBO, pts employed in both CZP groups reported reduced absenteeism, presenteeism, and axSpA interference with work from Wk4 through to Wk24 (Table). CZP groups also reported greater reductions vs PBO in days lost of household work and of family/social/leisure activities per month, in days with reduced household productivity and in axSpA interference with household duties as early as Wk4 through to Wk 24 (Table).

Table. Work and household productivity in RAPID-axSpA study (FAS population, LOCF data)

WPS		PBO	CZP 200mg Q2W	CZP 400mg Q4W
Productivity at workplace[a]				
	BL	67	77	80
n	Wk4	68	78	79
	Wk24	66	80	81
	BL	2.4	2.3	1.4
Work days missed due to arthritis per month	Wk4	1.9	1.4	0.8*
	Wk24	2.0	1.1	0.6*
Days with work productivity reduced by ≥50% due to arthritis per month[b]	BL	5.3	5.8	4.7
	Wk4	3.2	2.7	3.2
	Wk24	4.4	2.4	2.7
	BL	4.8	4.5	4.6
Rate of arthritis interference with work productivity per month[c]	Wk3.9	3.1*	3.1*	
	Wk24	3.5	2.2*	2.0*

		All	107	111	107
Productivity at home and daily activities					
n	BL	6.9	5.8	4.7	
Household work days missed due to arthritis per month	Wk4	5.4	3*	3.2*	
	Wk24	5.6	2.3*	2.2*	
Household work days with productivity reduced by ≥50% due to arthritis per month[b]	BL	5.3	4.4	3.6	
	Wk4	6.5	5	4.9	
	Wk24	5.9	3.5*	3*	
Days missed of family, social, or leisure activities due to arthritis per month	BL	5.3	4.4	3.6	
	Wk4	4.1	2.3*	2.4*	
	Wk24	3.0	1.1*	1.9	
Days with outside help hired due to arthritis per month	BL	2.7	2	1.5	
	Wk4	2.2	1.6	1.1	
	Wk24	1.8	1.1	0.6*	
Rate of arthritis interference with household work productivity per month[c]	BL	5.0	5	4.6	
	Wk4	4.4	3.6*	3.3*	
	Wk24	4.2	2.4*	2.2*	

[a]Based only on employed pts; [b]Does not include work days missed counted in the previous question;
[c]0–10 scale, where 0 = no interference and 10 = complete interference; *p-value ≤0.05 vs PBO

Conclusion: CZP improved workplace productivity in pts with axSpA by reducing absenteeism, presenteeism and axSpA interference with work. CPZ also improved household productivity and increased participation in social and daily activities.

Influence of Early Onset On the Clinical Characteristics and Prognosis of Ankylosing Spondylitis. Maria Aparicio[1], Jesús Rodríguez-Moreno[1], Paula Estrada[1], Irene Martín-Esteve[1], Laura López-Vives[1], Vicenç Torrente[2], Jordi Anton[3], Joan Miquel Nolla[1] and Xavier Juanola[1]. [1]Hospital Universitari de Bellvitge, Barcelona, Spain, [2]Hospital Sant Joan de Déu, Barcelona, Spain, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: To determine the influence of early onset (≤ 16 years) on the clinical characteristics and prognosis of ankylosing spondylitis (AS).

Methods: We revised patients diagnosed with AS according to the New York criteria included in our database. Age at symptom onset was taken from the patient's clinical history. Other data recorded were current: age, time of evolution, gender, form of onset, form of evolution, HLA B27, BASRI (cervical, lumbar column, sacroiliacs and hips), metrology (Schober test, modified Schober test, thoracic expansion and occipuci-wall distance), VSG and PCR (last measurements), uveitis development, surgery of the locomotive apparatus and treatment provided with special attention to the need for biological drugs in order to establish prognosis.

To ensure that the differences were no solely related to the time of evolution of the disease, we created a Control Group (CG) comprising, two randomly paired patients for each patient with early onset (EO), with an age of onset between 20 and 30 years and a time of evolution of the disease (± 5 years) similar to those with EO. The results were analyzed by means of the SPSS 15.0 statistical package. The differences between EO and CG were studied by means of χ^2 and ANOVA or Fisher's test depending on the characteristics of the variables.

Results: We revised 324 patients with EA; 35 (10.8%) had an age of onset ≤ 16 years. The chart shows the main characteristics of the patients from both groups. Significant differences in the development of uveitis and HLA B27 positivity were observed, as well as a tendency towards greater hip involvement and indication for hip prosthesis in the EO group.

	≤ 16 years (n= 35)	> 16 years (n = 66)	p		≤ 16 years (n = 35)	< 16 years (n = 66)	p
Age of onset (years)	14.9 ± 2.2	27.1 ± 9.1	<0.000	Form axial onset	77%	84%	ns
Male gender	89%	81%	ns	Form axial evolution	60%	72%	ns
Time of evolution (years)	34.6 ± 13.4	31 ± 12.7	ns	HLA B27 positive	100%	85%	< 0.05
Axial BASRI (cm)	6.4 ± 3.4	7 ± 3.3	ns	Uveitis	40%	17%	< 0.05
Hips BASRI (cm)	1.38	0.87	ns	Prosthesis indication	14%	5%	ns
Schober (cm)	2.7 ± 2.5	2.6 ± 1.6	ns	AINE use continuos	49%	49%	ns
Modified Schober (cm)	4.2 ± 2.1	3.8 ±3.1	ns	FAME use	29%	23%	ns
Thoracic expansion (cm)	4.7 ± 2	3.7 ± 1.6	ns	AntiTNF actual o pass use	29%	23%	ns
Occip-wall (cm)	5.2 ± 8.1	7.1 ± 7.6	ns				

Conclusion: AS patients with early onset were more likely to be positive for HLA B27 and to present more ocular involvement (uveitis). AS patients with EO also presented trend towards more serious radiological damage in the hips and a higher indication for hip prosthesis, although the differences were not significant.

Value of C-Reactive Protein Level At Diagnosis of Psoriatic Arthritis in Predicting the Future Need for Treatment with Tumor Necrosis Factor-á Inhibitors. Yair Molad[1] and Shachaf Ofer-Shiber[2]. [1]Beilinson Hospital, Rabin Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Petah-Tikva, Israel, [2]Beilinson Hospital, Rabin Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Petah Tikva, Israel

Background/Purpose: To determine the value of acute-phase reactant levels at diagnosis of psoriatic arthritis in predicting the risk of failure of conventional treatment with disease-modifying anti-rheumatic drugs (DMARDs) and the–consequent need for biologic treatment with a tumor necrosis factor (TNF) inhibitor.

Methods: Clinical, laboratory, and treatment data were collected from the medical files of a real-life inception cohort of 71 consecutive patients diagnosed with psoriatic arthritis (CASPAR criteria) in 2000–2011 at the rheumatology clinic of a tertiary medical center. A logistic regression model was used to identify laboratory variables associated with TNF inhibitor use during the disease course.

Results: The cohort included 38 female (53.5%) and 33 male patients of mean age 41 ± 10.4 years; 66 (93%) Jewish and 5 (7%) Arabic. Mean disease duration was 11.56 ± 6.58 years. The most common clinical feature was symmetric polyarthritis (40.8%). All patients were treated with one or more DMARDs, mainly methotrexate (81.6%). Thirty-seven patients (52.11%) had an inadequate response and received at least one TNF inhibitor, at the discretion of the attending rheumatologist. C-reactive protein (CRP) level at diagnosis was positively correlated with need for a TNF inhibitor (p=0.009; hazard ratio = 1.8 95% CI 1.27–1.85). Patients with CRP >0.9 mg/dl at diagnosis started biologic treatment significantly earlier in the disease course than patients with a lower level (p=0.003, hazard ratio = 2.62 95% CI 0.393–2.5).

Conclusion: In patients with psoriatic arthritis, CRP ≥0.9mg/dl at diagnosis significantly predicts an inadequate response to conventional DMARDs and the probability that a TNF inhibitor will be needed to achieve disease control.

Depression and Anxiety in Psoriatic Disease: Prevalence and Associated Factors. Emily McDonough[1], Arane Thavaneswaran[2], Adele Carty[3], Suthar-shini Shanmugarajah[2], Renise Ayearst[2], Lihi Eder[4], Vinod Chandran[5], Cheryl Rosen[2] and Dafna Gladman[2]. [1]University of Toronto, Ontario, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Hospital, Toronto, ON, [4]Carmel Medical Center, Haifa, Israel, [5]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Psoriatic arthritis (PsA) affects approximately 30% of patients with psoriasis and has the potential to cause severe joint damage. Research into the prevalence of depression and anxiety in PsA patients, and the contribution of joint disease to mental health in psoriatic disease, is limited. The objectives were: 1) To determine the prevalence of depression and anxiety in PsA patients and identify associated demographic and disease-related factors. 2) To determine if there is a difference between patients with PsA and those with psoriasis without PsA (PsC).

Methods: Consecutive patients attending PsA and PsC clinics were assessed for depression and anxiety using the Hospital Anxiety and Depression Scale (HADS). Patients with PsA satisfied CASPAR criteria and those with PsC had dermatologist confirmed psoriasis and PsA excluded by a rheumatologist. Patients underwent a clinical assessment according to a standard protocol and completed questionnaires assessing their health and quality of life. T-tests, ANOVA, univariate, and multivariate models were used to compare depression and anxiety prevalence between patient cohorts and determine factors associated with depression and anxiety.

Results: A total of 306 PsA and 135 PsC patients were assessed. The mean age of PsA and PsC patients was 53.8 and 52.4 years respectively. There were significantly more men in the PsA group (61.4% vs. 48% for PsC) and they were more likely to be unemployed (40% vs. 29.1%). The prevalence of both anxiety and depression was higher in PsA patients (36.6% and 22.2% respectively) compared to PsC (24.4% and 9.6%) (p = 0.012, 0.002). Factors associated with a higher likelihood of depression and/or anxiety included unemployment, female gender, and higher active joint count. Patient reported factors such as disability, pain, and fatigue were highly correlated with an increased likelihood of both depression and anxiety (p < 0.0001). In the univariate analyses, the protective factors for depression included having only PsC, drinking socially, and being employed. Factors associated with a higher odds ratio (OR) for depression included current smoking, a higher pain rating, higher patient reported physical disability, and a higher level of fatigue. In the multivariate reduced model, employment was protective for depression (OR 0.36) and a 1 unit increase on the fatigue severity scale (FSS) was associated with depression (OR 1.5).

Conclusion: The rate of depression and anxiety is significantly higher in PsA patients than in PsC patients. The factors most closely associated with higher rates of depression and anxiety are those in which patients express the negative effects PsA has on their quality of life, such as ratings of pain, disability and fatigue. The major limitation of this study is that it is not able to determine causation. Nonetheless, these results indicate the importance of addressing patients' perceptions of their own health and functioning, as well as objective measures of disease severity, when treating depression and anxiety in psoriatic disease. A deeper understanding of these factors is important for planning and evaluating future treatments.

Development of A Health Index for Patients with Ankylosing Spondylitis - First Steps of A Global Initiative Based On the ICF Guided by ASAS. Uta Kiltz[1], Désirée van der Heijde[2], Annelies Boonen[3], Alarcos Cieza[4], Gerold Stucki[5], Muhammad Asim Khan[6], Walter P. Maksymowych[7], Helena Marzo-Ortega[8], John D. Reveille[9], William Taylor[10], Cristina Bostan[11] and Jügen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University Hospital Maastricht, Maastricht, Netherlands, [4]Munich, Germany, [5]University of Lucerne, Lucerne, Switzerland, [6]CASE at MetroHealth Med Center, Cleveland, OH, [7]University of Alberta, Edmonton, AB, [8]University of Leeds, Leeds, United Kingdom, [9]Univ of Texas Health Science Center at Houston, Houston, TX, [10]University of Otago, Wellington, New Zealand, [11]Paraplegic Research Unit, Nottwil, Switzerland

Background/Purpose: The burden of ankylosing spondylitis (AS) can be considerable. The patients suffer from pain, stiffness and fatigue, and they are limited in their activities and restricted in social participation. The International Classification of Functioning, Disability and Health (ICF), a model to systematically classify and describe functioning, disability and health in human beings, has been used by the Assessments of SpondyloArthritis international Society (ASAS) as a basis to define a core set of items that are typical and relevant for patients with AS. However, no ICF-based patient-reported outcome measure has been developed for AS patients. The objective is To develop a measure to assess the overall impact of AS on health based on the ICF Core Set for ankylosing spondylitis (add the ref) which can be

considered as the external standard of categories that are relevant and typical for AS and contains categories within the bio-medical as well as contextual part of the ICF model for health.

Methods: Development is being performed in five phases. *I* development of an item pool using categories of the ICF Core Set for AS as the domain structure; *II* Item exploration based on Rasch analyses for the items fitting the bio-medical categories and correlation analyses for the contextual factors; *III* - Agreement on item reduction; *IV* Validation of the draft version; *V* Agreement on a final version

Table 1. Phases of development for the ASAS Health Index

	Phase	Objectives	Methods
I	Preparatory	Development of a pool of items representing the categories of the Comprehensive ICF Core Set	Linkage of various assessment tools for functioning and health to ICF categories
II	1st postal patient survey	Item reduction	Factor Analysis, Rasch Analysis, Spearman rank correlation coefficient
III	Expert consultation	Agreement on item reduction	Nominal Consensus Process
IV	2nd postal patient survey	Validation of the draft version and further item reduction	Testing psychometric properties Rasch Analysis
V	Consensus Meeting	Agreement on a final version	Nominal Consensus Process

Results: Phase 1: The item pool contained 251 items in 44 categories. It was formed from various instruments (identified through literature search) which focus on symptoms and functioning in patients with AS. Phase 2: An international cross sectional study with 1915 AS patients (mean age 51.2±3.6, 53% male, BASDAI 5.5±2.4) was conducted in 4 continents. In 82 items of the *functioning* part a unidimensional scale, fit to the Rasch model and absence of Differential Item Function could be confirmed. 32 items of the *environmental factors* part showed a significant correlation between person score and ICF category (correlation coefficient between 0.04–0.45). Phase 3: Based on results of the analyses in step 2, an expert committee selected 50 functioning items and 16 environmental factor items using predefined selection criteria (clinimetric properties, ease of wording, coverage of the whole range of ability). Phase iV: The draft version are being tested in a 2nd cross sectional survey. Rasch analysis will help to choose those items which represents the full spectrum of functioning

Conclusion: The item pool has been successfully reduced to 66 items. In covering much of the ICF Core Set for AS, these items represent a whole range of abilities of patients with AS. This draft version will be tested in a second survey to create a first version of the ASAS Health Index. The final measure can be used in clinical trials and cohort studies as a new composite index that captures relevant information on the health status of the patients.

Prevalence of Spondyloarthritis-Related Comorbidities, Osteoporosis and Fractures in Ankylosing Spondylitis: a Systematic Literature Review. Carmen Stolwijk[1], A.M. Van Tubergen[1], Jose Dionisio Castillo-Ortiz[2] and Annelies Boonen[1]. [1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico

Background/Purpose: Comorbidities, both related and unrelated to the concept of spondyloarthritis (SpA), are common in patients with ankylosing spondylitis (AS) and may have substantial influence on health outcomes. However, data on the prevalence of these comorbidities in AS vary substantially. Objective of the study was to review the literature on the prevalence of SpA-related comorbidities uveitis, psoriasis and inflammatory bowel disease (IBD), as well as on prevalence of osteoporosis and vertebral fractures in patients with AS.

Methods: Medline, Embase and Cochrane were searched systematically up to November 2011, supplemented by a hand search of references. Specific MeSH headings and key words were used to identify all relevant studies without restriction of languages. Articles were eligible if reporting original data on the prevalence of one of the above mentioned comorbidities in studies on adult patients with AS. Study quality was assessed independently by 2 authors using a predefined criteria list. Demographic and prevalence data were extracted and studies were combined to express prevalence with 95% confidence intervals (CI) weighted for the number of patients included in the studies.

Results: Out of 7817 studies initially retrieved, 188 met the inclusion criteria. Additionally, 13 studies were found by hand search. The prevalence of uveitis, psoriasis, IBD, osteoporosis and vertebral fractures could be calculated in respectively 137 (40141 patients), 53 (25695 patients), 66 (30410 patients), 24 (2786 patients), and 17 articles (2285 patients). The overall (weighted) mean age was 43.9 (SD 6.9) years, mean disease duration 16.7 (SD 6.2) years and 63.7% were men. The weighted prevalence of uveitis was 30.3% (95% CI 30.2–30.4) for a mean disease duration of 16.4 (SD 6.4) years but increased with longer disease duration (from 19.4% for a disease duration of <10 years to 36.5% for a duration of >20 years). Prevalence of uveitis was also higher for studies using self-report compared to medical records (39.2% vs. 27.4%, p<0.001). Weighted prevalence of psoriasis was 11.3% (95% CI 11.2–11.4) for a mean disease duration of 18.0 (SD 6.3) years and prevalence of IBD was 7.2% (95% CI 7.1–7.2) for a mean disease duration of 17.8 (SD 6.4) years, without a clear relation to disease duration for both comorbidities. Prevalence of osteoporosis was 20.5% (19.4–21.6) in the lumbar spine, 10.9% (10.4–11.4) at the femoral neck and 29.2% (28.2–30.1) at both anatomical sites for a mean disease duration of 12.4 (SD 5.2) years in studies that screened for radiological evidence. The overall prevalence of osteoporosis increased with longer disease duration. Osteoporosis was diagnosed in 3.4% according to medical records data (936 patients). Vertebral fractures were present on 21.8% (21.0–22.4) of the radiographs for a mean disease duration of 19.5 (SD 6.1) years, and prevalence was 5.8% in studies using self-report (1071 patients).

Conclusion: SpA-related comorbidities, osteoporosis and vertebral fractures are very common in patients with AS but may vary with disease duration and method of investigation. Given the high prevalence, attention for comorbidities in relation to outcome in AS is recommended.

1378

Validity of Ankylosing Spondylitis Disease Activity Score (ASDAS) in Patients with Early Spondyloarthritis. Cruz Fernández-Espartero[1], Eugenio De Miguel[2], Milena Gobbo[3], Carmen Martínez[4], Miguel A. Descalzo[3], Estíbaliz Loza Sr.[5] and Esperanza Group[6]. [1]Hospital Universitario de Móstoles, Madrid, Spain, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Spanish Society of Rheumatology, Madrid, Spain, [4]Sociedad Española de Reumatología, Madrid, Spain, [5]Research Unit. Sociedad Española de Reumatología, Madrid, Spain, [6]Madrid

Background/Purpose: Recently, a Working Group of the SpondyloArthritis International Society (ASAS) has proposed a composite disease activity score, the Ankylosing Spondylitis Disease Activity Score (ASDAS), for patients with ankylosing spondylitis (AS), for improved and feasible measures of disease activity and treatment response in patients with spondyloarthritis (SpA).

Objective: To evaluate the validity of the Ankylosing Spondylitis Disease Activity Score (ASDAS) as clinical tool for measurement of disease activity in early spondyloarthritis (SpA) in comparison with conventional clinical measures of disease activity. To assess the discriminative ability and correlation of the ASDAS and Bath Ankylosing Spondylitis Activity Disease Activity Index (BASDAI) with disease activity in early SpA.

Methods: Patients with early SpA were selected from ESPeranza database (n=676). To test concurrent validity of the indices, correlations of the two indices with activity variables were calculated in ESPeranza database. Patients were categorised into high and low disease activity states based on patient and physician global assessment scores and physician's decision to start on a disease-modifying anti-rheumatic drug or tumour necrosis factor blocker. Discriminatory ability of the indices was compared using the approach of standardised mean difference between subgroups of patients with high vs low disease activity.

Results: ASDAS-B and C showed good correlation with BASDAI (0.79, 0.74, p<0.001). Both scores correlated well with disease activity as reflected by the patient global assessment (BASDAI 0.71, ASDAS-B 0.70, ASDAS-C 0.70, p <0.001) and the physician global score (r=0.44 for BASDAI, r=0.46 for ASDAS-B, r=0.47 for ASDAS-C, p <0.001). CRP and ESR showed poor correlation with patient- and physician-derived disease activity scores.

ASDAS and BASDAI scores show good and moderate discriminative ability with different constructs of disease activity.

Conclusion: ASDAS is a disease activity index valid in early Spa. ASDAS and BASDAI scores show good and moderate discriminative ability and correlation with different constructs of disease activity. In early Spa, ASDAS showed a slight superiority to BASDAI in its ability to discriminate between high and low disease activity states.

1379

Ultrasonographic Is More Sensitive Than Traditional Clinical Evaluation in the Detection of Hands and Wrists Synovitis and Digital Soft Tissue Involvement in Early Psoriatic Arthritis. Francesca Bandinelli[1], Valentina Denaro[1], Francesca Prignano[2], Diletta Bonciani[2], Ledio Collaku[3] and Marco Matucci-Cerinic[1]. [1]University of Florence, Florence, Italy, [2]Florence, Italy, [3]University of Tirana, Tirana, Albania

Background/Purpose: Background: Clinical measures are widely used in established psoriatic arthritis (PsA) but in early phase of disease, often fail to identify the joint and tendons involvement. Purpose: To investigate the ultrasonography (US) abnormalities in hands and wrists of early PsA patients and to compare them with clinical evaluation

Methods: We performed a retrospective study on 112 early PsA (onset of inflammatory symptoms lower than one year) in the period 2008–2010, diagnosed with CASPAR criteria (1).

Data were carried out by the analysis of medical records of all patients, completed of demographic data, historical information, clinical (swollen joints and dactylitis count) and MyLab70 Xview (linear probe 15 MHz and PFR 1 Mhz) and US (Power doppler [PD] positive synovitis, erosions, tenosynovitis and PD in soft tissue around flexor finger tendons) hands and wrists assessment.

Results: Out of 224 wrists and 1120 MCP, 1120 PIP and 1120 DIP totally observed, synovitis was more frequently found on wrist (50/224; 22,3%) and US resulted more sensitive than clinical evaluation (swollen joints): in wrists 50/224 (22,3%) vs 42/224 (18,7%), in MCP 28/1220 (2,5%) vs 11/1120 (1%), in IPP 24/1120 (2,1%) vs 15/1120 (1,3%), in IPD 3/1120 (0,3%) vs 1/1120 (0,09%). Also erosions were present only in MCP (mostly II e III MCP) in 10/1120 joints (0,9%). At US, PD signal in soft tissue around tendons (68/1120, 6,1%) was more frequent than tenosynovitis of flexors (29/1120, 2,6%) and were both found also in patients without clinical dactilitis (55/68 PD [80,8] of soft tissue and 18/29 [62%] of tenosynovitis).

Conclusion: US showed more frequently synovitis of wrists but also erosions and PD signals in soft tissue are present in early phase of PsA. In all cases, US seemed more sensitive than clinical evaluation for synovitis and dactilytis.

A Spondyloarthritis Research Consortium of Canada Score Cut-off ≥3 As Best Match for the Assessment of Spondyloarthritis International Society Definition of a Positive MRI of the Sacroiliac Joints. Rosaline van den Berg, Manouk de Hooge, Victoria Navarro-Compán, Monique Reijnierse, Floris van Gaalen, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The definition of a 'positive' or 'negative' MRI of the sacroiliac joints (MRI-SIJ) according to ASAS is recommended for use in daily practice[1]. However, in several clinical trials the Spondyloarthritis Research Consortium of Canada (SPARCC)-score is used[2]. It would be useful to know which SPARCC-score is the best cut-off value as surrogate for the ASAS definition. Therefore, we investigated which SPARCC cut-off value best matches the ASAS definition for a positive MRI-SIJ.

Methods: All MRI-SIJs of two time points of patients included in the SPondyloArthritis Caught Early (SPACE)-cohort in the Leiden University Medical Center (LUMC) were scored independently by 3 readers. The readers, blinded to the time sequence, scored the MRI-SIJs according to the ASAS definition (ASAS-pos) and the SPARCC-score. An MRI-SIJ was marked ASAS-pos if 2/3 readers scored positive. In this analysis, mean SPARCC-scores of the readers that also scored ASAS-pos for that particular case were used. Cross-tabs were used to analyse agreement between several SPARCC-score cut-off values (≥1, ≥2, ≥3 and ≥4) and ASAS-pos, which served as external standard in this comparison.

Results: All available MRI-SIJs were used (n=238 in total; n=148 baseline MRI-SIJs; n=90 follow-up MRI-SIJs). The results of the different tested SPARCC cut-off values are presented in the table. A SPARCC cut-off value ≥1 resulted in 39 (16.4%) false-positive classifications and a cut-off value ≥2 resulted in 11 (4.6%) and both cut-off values had no false-negative classifications compared to ASAS-pos. A SPARCC cut-off value ≥3 resulted in 1 (0.4%) false-positive classification and 4 (1.7%) false-negative classifications, and a SPARCC cut-off value ≥4 resulted in 9 (3.8%) false-negative and 1 (0.4%) false-positive classifications. We found very similar results if baseline MRI-SIJs and follow-up MRI-SIJs were analysed separately.

	ASAS negative, n (%)	ASAS positive, n (%)
SPARCC <1, n (%)	143 (60.1)	0 (0.0)
SPARCC ≥1, n (%)	39 (16.4)	56 (23.5)
Agreement		**83.6%**
SPARCC <2, n (%)	171 (71.9)	0 (0.0)
SPARCC ≥2, n (%)	11 (4.6)	56 (23.5)
Agreement		**95.4%**
SPARCC <3, n (%)	181 (76.1)	4 (1.7)
SPARCC ≥3, n (%)	1 (0.4)	52 (21.8)
Agreement		**97.9%**
SPARCC <4, n (%)	181 (76.1)	9 (3.8)
SPARCC ≥4, n (%)	1 (0.4)	47 (19.7)
Agreement		**95.8%**

Conclusion: SPARCC cut-off values of ≥2, ≥3 or ≥4 have all high percentages of correctly classified patients (95.4%, 97.9% and 95.8%, respectively). A SPARCC cut-off value ≥3 shows the most balanced misclassification and the highest agreement with the ASAS definition for a positive MRI-SIJ.

Non-Radiographic Spondyloarthritis Has Greater Work Instability Than Other Spondyloarthritis Subtypes in a National Database. Sherry Rohekar[1], Robert D. Inman[2], Renise Ayearst[3], Proton Rahman[4], Walter P. Maksymowych[5] and Dafna D. Gladman[6]. [1]St. Joseph's Hospital, London, ON, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON, [4]Memorial University, St. Johns, NF, [5]University of Alberta, Edmonton, AB, [6]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON

Background/Purpose: Clinical subsets of spondyloarthritis (SpA), such as ankylosing spondylitis (AS) and psoriatic arthritis (PsA) can be associated with significant impact on work performance and attendance. Prior to becoming completely work disabled, patients' functional abilities do not match their work demands. This period of time is one of work instability (WI). The aim of this study was to determine the characteristics of WI in a large population of patients with SpA.

Methods: Patients were recruited from two large, well established cohorts of AS and PsA. WI was evaluated using a validated questionnaire, the AS-WIS, in which higher scores denote more WI, which may be stratified into low, medium and high risk of future job loss. Standard protocols were completed at the time of completion of the AS-WIS which included a detailed history, physical examination, physician-reported outcome measures and patient-reported outcome measures.

Results: 414 patients responded (222 PsA, 160 AS, 18 undifferentiated SpA [uSpa], 12 non-radiographic SpA [nr-axSpA] and 2 reactive arthritis [ReA]). Mean age was 47.2 (SD 14.4), 66.9% male. Mean duration of PsA was 17.4 years; AS was 11.9 years. Mean WIS scores were low in AS (8.0, SD 6.1), PsA (6.7, SD 6.0), ReA (7.5, SD 9.2) and uSpA (8.0, SD 6.9). However, those with nr-axSpA had significantly greater WIS scores than the other groups, placing them in the moderate risk category (mean 12.6, SD 6.6). Higher WIS scores were significantly correlated with female gender, lower education, lung disease, gastrointestinal (GI) disease, diabetes, peripheral joint involvement, NSAID use, tender joint count, fibromyalgia tender point count (FMTP), MD global assessment of disease activity, EQ5D, Dermatology Life Quality Index, pain, stiffness, Health Assessment Questionnaire, Fatigue Severity Score, Bath AS-Global, Bath AS Disease Activity Index, Bath AS Functional Index, AS Quality of Life, Functional Assessment of Chronic Illness Therapy, SF-Physical Component Scale, SF-Mental Component Scale, and patient global assessment of disease activity. Linear regression revealed that sex, lower education level, history of GI disease, diabetes, NSAID use and FMTP were significantly associated with higher WIS scores. Multinomial logistic regression was carried out on WIS risk level (low, medium or high) with low risk as the reference category. Medium WIS risk scores were significantly associated with education level, history of GI disease, diabetes, NSAID use and FMTP. High WIS risk scores were significantly associated with education level and history of GI disease.

Conclusion: WI was significantly higher in those with nr-axSpA than other types of SpA, suggesting that these patients have a greater mismatch between their functional abilities and job demands. Education level, history of GI disease, NSAID use and higher FMTP were associated with higher levels of WI. The highest risk of WI was associated with education level and history of GI disease.

1382

A Comparison of Three Methods of Measuring Intermalleolar Distance in Patients with Ankylosing Spondylitis. Buse Ozata[1], Burak Uyar[2], Dilek Solmaz[2], Ismail Sari[2], Servet Akar[3] and Nurullah Akkoc[4]. [1]Dokuz Eylul University School of Medicine, Izmir, [2]Dokuz Eylul University School of Medicine, Izmir, Turkey, [3]Dokuz Eylul University School of Medicine Department of Internal Medicine Division of Rheumatology, Izmir, Turkey, [4]Dokuz Eylul University School Of Medicine, Department Of Internal Medicine, Division Of Rheumatology, Izmir, Turkey

Background/Purpose: Involvement of the hips are relatively common in AS and associated with a higher degrees of disability and worse prognosis. The measurements of spinal mobility could be used for predicting clinical involvement and monitoring disease severity. In this regard, intermalleolar distance (IMD) < 100 cm suggests hip disease in AS. There are two reccommended methods of measuring IMD. First, distance between the two medial malleoli is measured, with the patient lying in a supine position with the hips fully abducted. Second, the patient stands and separates the legs as far as possible and the distance between the medial malleoli is measured. Alternatively, some physicians measure IMD in sitting position, while keeping knees and the legs straight in contact with the resting surface, patient is then asked to take legs as far apart as possible, and the distance between the medial malleoli is measured. Today, it is not known whether these three methods are in agreement with each other. In this study, we evaluated the agreement of IMD measurement methods performed during standing, sitting and supine positions.

Methods: In total of 61 consecutive AS patients (44.1±12.3 years; 35 male, and 26 female), were included in the study. Each patient was examined independently by two observers. Reproducibility of the methods and reliability of observers were evaluated by means of the single measures intraclass correlation coefficient (ICC) values. For the analysis of intra- and interobserver variability, ten randomly chosen patients were reexamined by the observers on two different occasions (2 weeks apart). An ICC value of > 0.75 indicated good agreement.

Results: The three measurement methods of IMD showed good agreement between each other (Table 1). The ICCs obtained by each observer were as follows: 1- measurements performed by the observer 1: 0.81 (95% CI= 0.73–0.88), and 2- measurements performed by observer 2: 0.81 (95%CI= 0.72–0.87). Both intra- and interobserver reliability of the observers also showed good agreement (Table 1).

Table 1. Comparison of agreement between three methods of IMD measurements and intra- and inter-observer reliability of the examiners.

	Observer 1	Observer 2
Comparison of agreement between three methods of IMD measurements	0.81 (0.73–0.88)	0.81 (0.72–0.87)
Intra-observer reliability of observers		
Supine	0.98 (0.91–0.99)	0.99 (0.97–0.99)
Standing	0.97 (0.88–0.99)	0.99 (0.97–0.99)
Sitting	0.88 (0.6–0.97)	0.98 (0.94–0.99)
Inter-observer reliability of observers		
Supine		0.96 (0.85–0.99)
Standing		0.99 (0.98–0.99)
Sitting		0.99 (0.97–0.99)

Conclusion: In this study we showed that IMD measurements (supine, standing and sitting) were in good agreement with each other. It is not of note that this finding obtained independently by both observers who had also good intra- and interobserver reliability. According to the results of our study investigators can reliably use any IMD measurement methods in their studies.

1383

The Burden of Ankylosing Spondylitis and the Cost-Effectiveness of Anti-Tumor Necrosis Factor α Agents in Romania. Ioan Ancuta[1], Catalin Codreanu[2], Ruxandra Ionescu[3], Magda Parvu[4] and Mihai Bojinca[1]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [3]Clinic Hospital Sf. Maria, Bucharest, Romania, [4]"N.Gh. Lupu" Clinical Hospital, Bucharest, Romania

Background/Purpose: Ankylosing Spondylitis (AS) usually affects young males, severely impairing their quality of life. Chronic treatment of AS using anti-TNF α agents is costly and represents a main concern for the national health insurance system, currently covering costs for three drugs: Adalimumab (ADA), Etanercept (ETA) and Infliximab (INF). Limited budget prompted the need to find optimal therapeutic approach. We aimed to identify the best cost/efficiency ratio when comparing clinical outcomes of anti-TNF α agents ADA/ETA/INF and to develop future treatment guidelines.

Methods: In a longitudinal, population-based study we retrospectively investigated, as of June 2012, the clinical files of 320 patients treated with ADA (n=70, 40 mg/2 weeks), ETA (n=50, 50 mg/week) and INF (n=200, 5 mg/kg at week 0, 2 and 6 then at every 6 to 8 weeks), out of 1859 AS patients on record in database (2008–2012) of state health insurance system. Costs were calculated in local currency (RON), according to standard clinical practice prescribed doses and reimbursed drug list prices, no infusions or other additional costs were included. We used multiple analysis of variance (MANOVA) and chi-squared tests to analyze statistically significant differences (p<0.05) in treatment efficacy.

Results: Concomitant use of disease modifying therapy (DMARD) was similar in all groups. Treatment efficacy was assessed and compared using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), tender joints count (TJC) and swollen joints count (SJC), C Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR). Assessments were made at 6 month intervals over a maximum period of 54 months after treatment initiation. In our nationally representative cohort, 266 (83.1%) patients were male. Overall, mean age was 37.4±9.8 years and average disease evolution 7.6±6.1 years. Sacroiliitis was present in 34 (10.6%) patients, calcaneum was affected in 45(14.1%), as confirmed on MRI scans, 27(8.4%) showed ophthalmic symptoms of auto-immune disease, 188 (58.8%) suffered from axial AS and 132 (41.2%) were diagnosed with mixed AS. Median baseline BASDAI values were 8.02±0.78, 8.07±0.92 and 8.13±0.82, in ADA, ETA and INF groups, respectively. We found statistical difference (p<0.0001) in CRP values at 6 months from baseline, but no difference at any other assessment. Similarly, there were no statistically significant differences between groups at any assessments for ESR, TJC and SJC. In contrast, drug cost analysis showed INF as the most expensive followed by ADA and by ETA.

anti-TNF α agent	Median price (RON)	Difference vs. most expensive (%)	Average price (RON)	Difference in average price (all patients) vs. average price per therapy (%)
INF	58.933	0	65.195	8.36
ADA	52.248	−12.80	52.248	−14.34
ETA	48.420	−21.71	48.420	−23.38

1 USD = 3.5766 RON

Conclusion: For the vast majority of endpoints, including BASDAI index, there were no statistically significant differences in treatment efficacy between the investigated groups at any assessment. Therefore, we suggest that treatment cost, rather than active compound, might be taken into consideration when choosing between these three anti-TNF α drugs for treatment of autoimmune AS.

The Frequency of Non-Radiographic Axial Spondyloarthritis in Relation to Symptom Duration in Patients Referred Because of Chronic Back Pain: Results From the Berlin Early Spondyloarthritis Clinic. Denis Poddubnyy[1], Henning Brandt[1], Janis Vahldiek[1], Inge Spiller[1], In-Ho Song[1], Martin Rudwaleit[2] and Joachim Sieper[3]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Endokrinologikum Berlin, Berlin, Germany, [3]Charité Universitätesmedizin Berlin, Berlin, Germany

Background/Purpose: Non-radiographic axial spondyloarthritis (nr-axSpA) and radiographic axial SpA (=ankylosing spondylitis–AS) are considered currently as two stages of axial SpA. We reported recently that about 12% of the patients with non-radiographic axial SpA progress in AS over 2 years [1]. Although it can be expected that in the first years after back pain onset non-radiographic (without definite sacroiliitis on the x-ray) SpA is more likely to see than established AS, their frequencies and their ratio in relation to back pain duration at the referral time point is not known.

This study was aimed at investigating of the frequencies of non-radiographic axial SpA (nr-axSpA) and ankylosing spondylitis (AS) diagnoses and their ratios in relation to symptom duration in patients referred because of chronic back pain and suspicion of axial SpA.

Methods: In this monocenter study performed in Berlin [2] orthopaedists and primary care physicians were requested to refer patients with chronic low back pain (duration >3 months) and onset of back pain before <45 years of age to a SpA-specialized rheumatology outpatient clinic for further diagnostic investigation if at least one of the following screening parameters was present: 1) inflammatory back pain, 2) positive HLA-B27, and 3) sacroiliitis detected by imaging. The final diagnosis was made according to the opinion of rheumatologist.

Results: A diagnosis of definite axial SpA was made in 43.7% of the referred patients (n = 522). Axial SpA was diagnosed in a similar percentage of about 50% if back pain duration was <9 years but decreased to 36% if symptom duration was >9 years. Nr-axSpA represented the majority of patient (67.3%) only if duration of back pain was 1 year and less at the time of referral. Between 1 and 6 years of back pain duration the probability of nr-axSpA and AS was nearly equal (1–3 years: 52.5% and 47.5%, respectively; 3–6 years: 53.7% and 46.3%, respectively). In patients with back pain duration of 6–9 years, AS was more likely (61.1%) to be diagnosed than nr-axSpA (38.9%), and this increased further over time - figure.
Figure. Ratio of nr-axSpA to AS among referred patients who were diagnosed with definite axial SpA.

Conclusion: Non-radiographic axial SpA represents an important diagnosis in the structure of reasons of back pain, especially in patients with recent symptom onset.

Increased Body Mass Index in Ankylosing Spondylitis Is Associated with a Greater Burden of Symptoms and Poor Perceptions of the Benefits of Exercise. Laura J. Durcan[1], Fiona Wilson[2], Richard Conway[1], Gaye Cunnane[1] and Finbar (Barry) D. O'Shea[1]. [1]St James's Hospital, Dublin, Ireland, [2]Trinity College, Dublin, Ireland

Background/Purpose: In Ankylosing Spondylitis (AS) the effect of obesity on disease characteristics and exercise perceptions is unknown. Exercise is an essential component in the management of AS. This study was undertaken to assess the attitudes of our AS patients to exercise and to evaluate the effect an increased BMI has on symptoms and disease activity.

Methods: AS patients fulfilling the New York diagnostic criteria were recruited consecutively from our dedicated AS clinic. Demographic data and disease characteristics were collected. Disease activity, symptomatology and functional disability were examined using standard AS questionnaires. Body mass index (BMI) was calculated using standardised methods as kg/m^2. Co-morbidity was analysed using the Charlson co-morbidity index. Patient's attitudes towards exercise were assessed using the exercise benefits and barriers scale (EBBS). The total EBBS score was used to assess their overall perception of exercise and the barriers component was used to evaluate their conceptual barriers to exercise. We then compared the disease characteristics, perceptions regarding exercise and functional limitations in AS patients who were overweight to those who had a normal BMI. Continuous variables were compared using a t-test and categorical variables were assessed using chi squared testing.

Results: Forty six AS patients were included. The mean disease duration in the group was 12.8 years (SD 10.2), 76.1% (N=35) were male, and 69.6% (N=32) were taking biologic therapy. There were 37% (N=17) either current or ex-smokers in the group. The mean BMI was 27.4 kg/m^2(SD 4.0). 67.5% (N=32) were overweight or obese. There was a statistically significant difference between those who are overweight and those with a normal BMI regarding their perceptions of exercise (EBBS 124.7 Vs 136.6 (p=0.006)) indicating that those who are overweight have a worse perception of the benefits of exercise. With regards to those who were overweight versus those with a normal BMI there were significant differences in both BASFI and HAQ (BASFI 4.7 Vs 2.5 (p=0.009), HAQ 0.88 Vs 0.26, (p=0.002)). The disease activity in the groups were also significantly different (BASDAI 4.8 Vs 2.9 (p=0.007) and patient global score 5.0 Vs 2.7 (p=0.007)). There was no difference between the groups in terms of their co-morbid conditions as measured by the Charlson index (p=0.3), smoking (p=0.29), disease duration (p=0.78), gender (p=0.71), or treatment (p=0.89).

Conclusion: The majority of AS patients in this cohort are overweight. These overweight patients have a greater burden of symptoms, worse perceptions regarding the benefits of exercise and enhanced awareness of their barriers to exercising. This is of particular concern in a disease where exercise plays a crucial role.

ACR/ARHP Poster Session B
Systemic Lupus Erythematosus: Clinical Aspects
Monday, November 12, 2012, 9:00 AM–6:00 PM

1386

Genetic Variation and Coronary Atherosclerosis in Patients with Systemic Lupus Erythematosus. Cecilia P. Chung[1], Joseph F. Solus[1], Annette Oeser[1], Chun Li[1], Paolo Raggi[2], Jeffrey R. Smith[1] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Emory University, Atlanta, GA

Background/Purpose: Premature coronary artery disease is a major cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). However, this is not explained by traditional cardiovascular risk

factors or markers of inflammation. Little is known about the contribution of genetic variation to atherosclerosis in this patient population. Therefore, we examined the hypothesis that, in patients with SLE, candidate gene polymorphisms were associated with the presence of coronary atherosclerosis.

Methods: One hundred and twenty five patients with SLE, enrolled in an ongoing study to evaluate the prevalence and associated risk factors of coronary atherosclerosis in SLE, were studied. Patients fulfilled the 1997 American College of Rheumatology classification criteria for SLE and were 18 years or older. Coronary artery calcium (CAC), a non-invasive measurement of coronary atherosclerosis, was measured by electron beam computed tomography. Using the Illumina Goldengate platform, we determined the genotype of 714 single-nucleotide polymorphisms (SNPs) in 176 selected candidate genes. Candidate genes were selected because of their relevance to autoimmune or cardiovascular risk. The associations between the presence of CAC and individual SNPs were assessed with logistic regression, adjusted for age, gender, and race. To account for multiple comparisons, a false discovery rate (FDR) threshold of 20% was specified.

Results: Patients with SLE were 41 ± 12 years old, 91% were women and 64% were Caucasian. The presence of CAC was detected in 33 patients (26%). After adjustment for age, race, and sex, associations were detected for *CSF1, ADIPOQ, REST, VCAM1, MIF, TNFSF4, INS, IRF5, TH* and *HMOX1* (Table). However, none of these associations remained significant after FDR correction.

Table. Genetic Association with Coronary Atherosclerosis in Patients with SLE

SNP	Gene	Major, minor allele	Minor allele frequency	Odds ratio* (95% CI)	p-value
rs333947	*CSF1*	G,A	0.18	4.71 (1.93–11.53)	0.001
rs7649121	*ADIPOQ*	A,T	0.20	0.05 (0.01–0.30)	0.001
rs1862513	*REST*	C,G	0.31	2.94 (1.47–5.93)	0.002
rs3917009	*VCAM1*	C,T	0.07	3.75 (1.53–9.22)	0.004
rs875643	*MIF*	G,A	0.41	0.36 (0.17–0.74)	0.005
rs333970	*CSF1*	C,A	0.45	0.39 (0.20–0.77)	0.006
rs738806	*MIF*	A,G	0.25	3.24 (1.41–7.45)	0.006
rs34124816	*REST*	A,C	0.06	6.69 (1.51–29.72)	0.012
rs3850641	*TNFSF4*	A,G	0.14	3.15 (1.28–7.78)	0.013
rs3842748	*INS*	C,G	0.29	0.35 (0.15–0.80)	0.013
rs3745369	*REST*	G,C	0.41	2.49 (1.20–5.15)	0.014
rs1874328	*IRF5*	A,G	0.39	0.38 (0.17–0.83)	0.015
rs2070762	*TH*	A,G	0.44	2.43 (1.18–4.98)	0.015
rs333968	*CSF1*	C,T	0.26	0.41 (0.19–0.88)	0.022
rs11912889	*HMOX1*	G,A	0.15	0.32 (0.12–0.85)	0.022
rs3093037	*CSF1*	C,T	0.10	0.21 (0.06–0.81)	0.024

* Odds ratios for the comparison between minor and major allele.

Conclusion: Our results suggest that polymorphisms of genes coding CSF-1, adiponectin, resistin, VCAM-1, MIF, TNFSF-4, insulin, IRF-5, TH, and HMOX-1 may be associated with the presence of coronary atherosclerosis in patients with SLE. Studies in additional cohorts will be informative.

Hospitalizations and Reasons for Admission in a Clinical SLE Cohort. Alaa Dekis[1], Kenjey Chan[1], Christian A. Pineau[2], Evelyne Vinet[2], Emil P. Nashi[2], Sasha Bernatsky[3] and Ann E. Clarke[3]. [1]McGill University, Montreal, QC, [2]McGill University Health Centre, Montreal, QC, [3]Research Institute of the McGill University Health Centre, Montreal, QC

Background/Purpose: Data published from several countries have suggested that patients affected by systemic lupus erythematous (SLE) may have high annual hospitalization rates. However, there is a lack of data regarding the incidence and causes of hospitalization in Canadian SLE patients. Our objective was to provide recent estimates for hospitalization rates, and reasons for admission, in a clinical systemic lupus (SLE) cohort.

Methods: We preformed a retrospective study of patients followed at the McGill University Health Center Lupus Clinic from the year 2000 till 2006. Each patient undergoes a yearly clinical assessment, which includes documentation of hospital admissions in the past year.

Results: Our SLE cohort consisted of 316 female patients and 27 males, with an average age of 46.3 years. Over the interval studied, there were 234 reported admissions. SLE-related causes accounted for the highest proportion of hospitalizations (29.5%), and infections were the next most common

reason for hospitalization (13.8%). Other categories included surgical and gynecological reasons for hospitalization (12.9% each), hospitalizations for cardiac and gastrointestinal causes (7.9% each) and other causes.

Conclusion: Canadian annual hospitalization rates are approximately 1.1 hospitalizations per 10,000 residents. Our results suggest much high hospitalization rates in SLE. Previous authors have emphasized disease flares and infections as common reasons for hospitalizations in SLE, and our data seems consistent with this. Further work is in progress, to provide more detailed comparisons with general population data.

Diagnostic Accuracy of Anti-dsDNA Antibodies in Unselected Patients with Recent Onset of Rheumatic Symptoms. Michele Compagno[1], Søren Jacobsen[2], Ole Petter Rekvig[3], Lennart Truedsson[4], Niels H. H. Heegaard[5], Johannes C. Nossent[6], Andreas Jönsen[1], Rasmus Sleimann Jacobsen[2], Gro Østli Eilertsen[6], Gunnar K. Sturfelt[1] and Anders Bengtsson[1]. [1]Lund University, Lund, Sweden, [2]Copenhagen University Hospital, Copenhagen, Denmark, [3]University Hospital, Tromsø, Norway, [4]Department of Laboratory Medicine, Section of Microbiology, Immunology and Glycobiology, Lund, Sweden, [5]Statens Serum Institut, Copenhagen S, Denmark, [6]University of Tromsø, Tromso, Norway

Background/Purpose: Anti-dsDNA antibodies are widely used in diagnostic settings when SLE is suspected. Crithidia Luciliae Immunofluorescence Test (CLIFT) and Enzyme Linked ImmunoSorbent Assay (ELISA) are commonly used assays to detect anti-dsDNA antibodies in clinical practice. The aim of the present study was to evaluate the diagnostic accuracy of CLIFT and ELISA in unselected patients with recent onset of rheumatic symptoms.

Methods: In the three participating centres, 1073 consecutive patients were locally screened for ANA. A total of 292 ANA positive patients and 292 matching ANA negative patients were selected. Anti-dsDNA antibodies were assessed at study entry by different laboratories with CLIFT (totally four times using two different commercial kits) and with ELISA (totally four times with three different commercial kits). The results of the laboratory tests were related to the clinical diagnosis formulated at study entry and verified after a long term follow-up period (median 4.8 years).

Results: Discrepant results were obtained from the different assessments regardless of the assay used, with kappa statistics value ranging between 0.25 and 0.75. At least one anti-dsDNA analysis was positive in 164 patients, but in only seven patients the positivity was confirmed by all the assessments. SLE diagnosis was initially made in 65 patients, of which 40 were anti-dsDNA positive. A wide spectrum of other diagnoses was observed among anti-dsDNA positive patients. Overall, about one third of anti-dsDNA positive patients were ANA negative. At follow-up after approximately 5 years, SLE diagnosis was unchanged in 63 patients (39 anti-dsDNA positive) and changed in only two (one anti-dsDNA positive). Among the 120 anti-dsDNA positive patients not diagnosed with SLE at study entry, only one developed SLE during the follow-up period.

Conclusion: Regardless of the assay used, assessment of anti-dsDNA antibodies was not reliable as diagnostic tool in our cohort of unselected patients with rheumatic symptoms. ANA showed poor reliability as screening test before anti-dsDNA analysis. Anti-dsDNA antibodies had surprisingly low positive predictive value for SLE diagnosis, despite their high specificity. For non SLE patients, being anti-dsDNA positive poses little risk of developing SLE within 5 years.

Erythrocyte Sedimentation Rate Is a Predictor of Renal and Overall Systemic Lupus Erythematosus Disease Activity. George Stojan[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: To assess whether ESR levels correlate with the level of disease activity at each visit and whether a change in ESR could be useful in predicting changes in disease activity.

Methods: 34000 visits in a prospective SLE cohort were analyzed for the association of ESR and level of disease activity. Follow-up visits when patients had cancer, infection, pregnancy or were in renal failure were excluded.

Results: After adjusting for confounding factors, ESR correlated with the SELENA-SLEDAI, the physician global assessment (PGA), fatigue, renal, joint, rash, serositis, and hematologic visual analogue scales (VAS) and proteinuria (p<0.0001). A change in ESR between two visits was highly correlated with a concurrent change in physician global assessment (PGA), renal, fatigue and joint VAS (p<0.0001) (Table). There was no statistically significant correlation between change in ESR between two visits and a future change in disease activity.

Table. Mean change in disease activity between two consecutive clinic visits, per 1 standard deviation change (27 mm/hr) in ESR.

Change in Disease Activity Measure	Adjusted[1] Difference in mean activity level (95% CI)	P-value
SLEDAI	0.09 (0.00, 0.19)	0.043
PGA	0.05 (0.03, 0.07)	<0.0001
Fatigue VAS	0.016 (0.008, 0.024)	0.0001
Neuro VAS	−0.005 (−0.012, 0.002)	0.19
Rash VAS	0.006 (−0.006, 0.019)	0.33
Renal VAS	0.030 (0.018, 0.043)	<0.0001
Joints VAS	0.030 (0.013, 0.046)	0.0004
Pulmonary VAS	−0.001 (−0.004, 0.002)	0.65
Hematology VAS	0.001 (−0.007, 0.010)	0.79
Serositis VAS	0.005 (−0.002, 0.011)	0.16
Hematuria	−0.000 (−0.000, 0.000)	0.36
Proteinuria	0.009 (0.002, 0.016)	0.013

[1] Adjusted for age, race, sex, and changes in: weight, c3, c4, hematocrit, andti-dsDNA, prednisone use, plaquenil use, and immunosuppresant use.

Conclusion: ESR is associated with disease activity in SLE measured by the SELENA-SLEDAI, the physician global assessment (PGA), and with organ specific activity including serositis, rash, joint, renal and hematologic visual analogue scales. A change in ESR between two visits was highly correlated with a change in physician global assessment (PGA), renal, fatigue and joint visual analogue scale (VAS). However, change in ESR between two visits did not predict the disease activity at the next (third) visit. Until more specific biomarkers are validated, serial ESR does have utility in following disease activity, in particular renal, in SLE.

Vitamin D Deficiency Is Not Associated with Nor Does It Predict Progression of Coronary Artery Calcium or Carotid Intima-Media Thickness in Systemic Lupus Erythematosus. Adnan Kiani[1], Hong Fang[1], Ehtisham Akhter[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: In the general population, vitamin D deficiency is associated with cardiovascular disease including myocardial infarction and stroke. In SLE, Vitamin D deficiency has been associated with carotid plaque. We investigated whether low vitamin D would predict change in subclinical measures of atherosclerosis over 2 years.

Methods: 167 SLE patients (93% female, 63% Caucasian, 32% African-American, mean age 45 yrs) had measurement of coronary artery calcium and carotid intima-media thickness IMT (IMT)) and vitamin D.

Results:

Table 1. shows the baseline characteristics by vitamin D status.

Variable	Number (%) with the characteristic Vitamin D <32 (n=133)	Vitamin D ≥32 (n=34)	p-value
Age			
18–30	14 (11%)	4 (12%)	0.80
31–49	75 (56%)	17 (50%)	
50+	44 (33%)	13 (38%)	
Ethnicity			
Caucasian	79 (59%)	27 (79%)	0.066
African-American	47 (35%)	5 (15%)	
Other	7 (5%)	2 (6%)	
Gender			
Female	124 (93%)	31 (91%)	0.68
Male	9 (7%)	3 (9%)	

Table 2. Changes in coronary artery calcium (CAC) and carotid intima-media thickness (IMT)

Measure	Mean at baseline	Mean after 2 years	Mean Change	p-value for change	Difference in change (95% CI)*	p-value for difference between groups**
Log$_e$(CAC score+1)						
Vitamin D <32	1.18	1.23	0.05	0.63	−0.14 (−0.58,0.30)	0.69
Vitamin D ≥32	1.11	1.30	0.19	0.25		
Carotid IMT						
Vitamin D <32	0.58	0.66	0.08	<0.0001	0.01 (−0.02,0.04)	0.59
Vitamin D ≥32	0.58	0.65	0.07	<0.0001		

This table is based on the 123 patients with vitamin D <32 and the 32 patients with vitamin D ≥32 for whom there were both baseline and follow-up measures.
* Difference in change: measure in vitamin D <32 group minus measure in vitamin D ≥32 group.
** Adjusted for ethnicity.

Conclusion: Vitamin D deficiency was not associated with any measure of subclinical atherosclerosis in SLE. Another study by Bruce et al (Rheumatology:2012) did not show an association of low Vitamin D in SLE with carotid IMT or plaque either. Vitamin D deficiency did not predict progression of subclinical atherosclerosis over 2 years. Future studies with larger sample size and longer follow up are needed to confirm our findings.

1391

Anti-Ku Autoantibodies in Systemic Lupus Erythematosus Versus Autoimmune Myositis As Measured by a Novel Chemiluminescence Assay. Michael Mahler[1], Jason Wu[2], Magdalena Szmyrka-Kaczmarek[3], Andreas Swart[4], Marvin J. Fritzler[5], Jean-Luc Senécal[6] and John G. Hanly[7]. [1]INOVA Diagnostics, Inc., San Diego, CA, [2]INOVA Diagnostics, San Diego, [3]Wroclaw Medical University, Wroclaw, Poland, [4]Rheumatology clinic Neuss, Neuss, Germany, [5]University of Calgary, Calgary, AB, [6]Hôpital Notre-Dame du CHUM, Montréal, QC, [7]Dalhousie University and Capital Health, Halifax, NS

Background/Purpose: Autoantibodies targeting Ku, an abundant nuclear protein with DNA helicase activity, have been reported in patients with systemic autoimmune rheumatic diseases. Little is known about the clinical association of anti-Ku antibodies, especially when tested using novel technologies. The objective of the present study was to analyze the prevalence of anti-Ku antibodies in different pathologies using a novel chemiluminescence immunoassay (CIA) on the BIO-FLASH®, a fully random access automated immunoanalyzer.

Methods: Serum samples from adult patients with systemic lupus erythematosus (SLE, n=305) and autoimmune myositis patients (AIM, n=109) were used. **Results** were compared to disease controls (rheumatoid arthritis, n=30; infectious diseases, n=17) and healthy adults (HA, n=167). In addition, samples from patients referred to a rheumatology clinic submitted for routine autoantibody testing (n=1078) were studied. All samples were tested for anti-Ku antibodies by QUANTA Flash Ku (research use only, INOVA Diagnostics, San Diego, CA, USA) using recombinant Ku coupled to paramagnetic beads. SLE patient samples were also tested for other connective tissue disease associated autoantibodies using the respective QUANTA Lite® ELISAs (INOVA Diagnostics). Clinical data of anti-Ku positive patients (high titers) from the referral study were collected by retrospective chart review. Statistical analysis (Fisher exact test, receiver operating characteristics [ROC] analysis) was done with ANALYSE-IT version 2.03.

Results: At cut-off values of 10,000 or 15,000 relative light units (RLU), 43/305 (14.1%) or 30/305 (9.8%) SLE patients and 4/109 (3.7%) AIM patients were positive, respectively. The 4 positive AIM patients had myositis in overlap, including 2 patients with SLE and myositis. In the control cohorts, 4/167 (2.4%) or 2/167 (1.2%) HA (all low titer), respectively, 0/30 (0.0%) rheumatoid arthritis and 0/17 (0.0%) infectious disease patients were positive. The area under the curve values were: 0.65 for SLE vs. controls and 0.37 for AIM vs. controls. In three SLE patients, anti-Ku antibodies were the only detectable autoantibody. In the rheumatology clinic referral cohort, 12/1078 (1.1%) were positive for anti-Ku antibodies, 9 showing low and 3 high titers. The diagnoses of the 3 high positive anti-Ku positive patients were: suspected SLE, mixed connective tissue disease, and rheumatoid arthritis treated with anti-TNF in a patient with a positive ANA.

Conclusion: Anti-Ku antibodies detected by CIA are present in 14.1% or 9.8% of SLE, but in only 3.7% of AIM patients, 50% of whom have SLE.

This suggests that anti-Ku antibodies are associated with SLE rather than with AIM. This association may have been missed in previous studies due to the past use of indirect immunofluorescence screening assays or the high sensitivity of the current CIA assay.

Clinical Correlation with Anti Double Stranded Deoxyribonucleic Acid Via Enzyme Linked Immunoassay Versus Multiplex Immunoassay.
Megan L. Krause, Melissa R. Snyder, Cynthia S. Crowson, Abigail B. Green and Kevin G. Moder. Mayo Clinic, Rochester, MN

Background/Purpose: In systemic lupus erythematosus (SLE), antibodies to double-stranded DNA (dsDNA) are utilized for disease classification and assessment of activity. Enzyme immunoassays (EIAs) and multiplex immunoassays (MIAs) are frequently used. However, anti-dsDNA antibody assays are not well-standardized with previously reported low concordance rates. In this study, clinical factors and laboratory data were evaluated for their association with anti-dsDNA antibody testing performed by EIA and MIA.

Methods: Patients from a single institution (n=102) underwent anti-dsDNA antibody testing by EIA (INOVA Diagnostics) and MIA (BioRad Laboratories). Clinical diagnoses, SLE disease activity index (SLEDAI), medication exposure, and laboratory data (serologies, complement values, and inflammatory markers) were abstracted. Qualitative concordance between the two methods was defined as both methods being classified as "negative" or "positive" according to the manufacturer's recommended reference ranges. Discordance was defined as one method having different categorization than the other, "positive," "borderline/indeterminate," or "negative."

Results: Within the total cohort, 35% and 44% of patients were positive for anti-dsDNA antibodies by EIA and MIA, respectively. Further, 54 had a diagnosis of definite, probable, or cutaneous SLE with 63% positive by MIA and 50% by EIA. In addition, only 6% of these patients had negative concordance, while 37% demonstrated positive concordance (p=0.02). Of those negative by both methods, none had lupus nephritis. In patients with lupus nephritis, 35% demonstrated positive concordance. The remaining demonstrated discordance with a higher qualitative value of MIA in 52% compared to 13% with EIA higher (p=0.14). The mean SLEDAI score calculated without the anti-dsDNA value was 3.3 in patients with negative concordance and 7.7 with positive concordance. In comparison, patients with discordant higher MIA had a mean SLEDAI score of 5.9 compared to 2.9 in patients with higher EIA (p=0.1). No patients with negative concordance had low complement values. In contrast, in patients who were positive by both methods, a low C3 or C4 was observed in 46% (p<0.01) and 62% (p=0.01), respectively. Of patients with positive concordance, 53% were positive for anti-SS-A antibodies and anti-RNP antibodies compared to 8% and 23% of patients with negative concordance, respectively. In patients with positive MIA, 80% were currently on at least one medication for SLE, compared to 37% with negative and 39% with borderline MIA results (p<0.01). In patients with positive MIA, they were more likely to have been treated with cyclophosphamide and hydroxychloroquine. In contrast, 73% of patients with positive EIA were currently on at least one medication for SLE compared to 43% and 63% of patients with negative or borderline results (p=0.09).

Conclusion: The association between clinical factors and anti-dsDNA antibodies may be determined, in part, by the specific methodology. Further clarification of these relationships could assist with interpretation of anti-dsDNA antibody results as well as choice of a method for a specific clinical scenario.

1393

Predictors of Panniculitis in Systemic Lupus Erythematosus.
Ashika Odhav[1], Michelle Petri[2] and Hong Fang[2]. [1]University of Missouri Kansas City School of Medicine, Kansas, MO, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Panniculitis is a rare, but devastating manifestation of SLE. We examined associates of panniculitis in a large SLE cohort.

Methods: 52 out of 2,149 SLE patients in the cohort had panniculitis (2.4%). The mean age at last assessment was 49 ± 15 years. The patients were 46% African-American, 46% Caucasian, and 96% female. Other SLE manifestations were determined at baseline by history, physical examination, and chart review; patients were then seen quarterly in follow-up.

Results: The table shows the association of demographics, SLE manifestations and serologies with panniculitis. Panniculitis was strongly associated with discoid lupus and leg ulcers. It was also associated with serositis, seizures, myositis, alopecia, and vasculitis. Proteinuria was significantly less frequent in those with panniculitis.

Association between Various Factors and Panniculitis in SLE

Characteristics/ Manifestations	Panniculitis (%, N=52)	No panniculitis (%, N=2097)	Odds Ratio (95% CI)	Adjusted P-value§
History of smoking	48.1	37.8	1.3 (0.7, 2.3)	0.34
Disability	40.4	21.8	2.1 (1.1, 3.7)	0.016
Malar rash	57.7	51.0	1.3 (0.7, 2.3)	0.41
Discoid	50.0	19.0	3.8 (2.1, 6.9)	<.0001
Photosensitivity	63.5	53.7	1.4 (0.8, 2.6)	0.22
Mouth ulcers	61.5	51.2	1.5 (0.9, 2.7)	0.15
Arthritis	80.8	73.5	1.2 (0.6, 2.5)	0.57
Serositis	67.3	48.9	2.0 (1.1, 3.7)	0.020
Proteinuria	28.9	44.3	0.4 (0.2, 0.8)	0.0062
Hematologic disorder	75.0	65.7	1.4 (0.8, 2.7)	0.27
ANA positivity	98.1	96.5	1.7 (0.2, 12.8)	0.59
Myositis	19.2	7.7	2.3 (1.1, 4.9)	0.023
Alopecia	73.1	53.1	2.0 (1.0, 3.8)	0.040
Vasculitis	28.9	14.2	2.2 (1.2, 4.2)	0.012
Leg ulcers	17.3	2.5	7.1 (3.2, 15.7)	<.0001
Seizure	19.2	9.5	2.4 (1.2, 4.8)	0.019
Peripheral Neuropathy	11.5	3.7	2.5 (1.0, 6.4)	0.046
Leukopenia	59.6	43.9	1.8 (1.0, 3.2)	0.044
Lupus Anticoagulant	26.0	27.2	0.9 (0.5, 1.7)	0.73
Low C3	46.2	55.6	0.6 (0.4, 1.1)	0.12
Low C4	36.5	48.3	0.6 (0.3, 1.1)	0.10
Increased ESR	82.7	74.9	1.4 (0.6, 3.0)	0.41
Anti- Sm	11.5	19.4	0.6 (0.2, 1.4)	0.20
Anti-DNA	63.5	63.0	1.0 (0.5, 1.7)	0.88
Anti-Ro	38.5	30.6	1.4 (0.8, 2.6)	0.21
Anti-La	15.4	12.9	1.3 (0.6, 2.8)	0.52

§ Adjusted for ethnicity, gender, age at last assessment, and duration of SLE at last assessment

Conclusion: In contrast to photosensitive cutaneous lupus, panniculitis is not associated with anti-Ro, anti-La, or smoking. It is strongly associated with discoid (discoid lesions often overlay panniculitis areas). It is not associated with any serologic test, and, in fact, is less frequent in those with renal lupus. The impact of panniculitis has been unrecognized, with 40% becoming disabled due to it.

Health Status Burden and Impact of Fatigue On Patient Functioning in SLE Patients From a Phase 1b Study.
Michelle Petri[1], Ariane K. Kawata[2], Ancilla W. Fernandes[3], Kavita Gajria[3], Warren Greth[4] and Asha Hareendran[5]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]United Biosource Corporation, Bethesda, MD, [3]MedImmune LLC, Gaithersburg, MD, [4]MedImmune, LLC, Gaithersburg, MD, [5]United Biosource Corporation, London, United Kingdom

Background/Purpose: Systemic Lupus Erythematosus (SLE) has a significant impact on patient's quality of life. Fatigue is the most common symptom of SLE and affects between 50–80% of SLE patients (Cleanthous et al. 2012; Tench et al. 2000; Krupp et al. 1990). Our objective was to evaluate the health related quality of life burden in SLE in a clinical trial and to explore the relationship between fatigue and overall health status.

Methods: Pooled treatment group data from a Phase Ib dose-escalation clinical trial study of adult patients with moderate to severe SLE were analyzed. Clinical trial outcomes included clinician-reported global assessment of disease severity (MGDA) and PRO measures: Short Form 36-item Health Survey, Version 2 (SF-36v2), Fatigue Severity Scale (FSS), and patient numeric rating scale (NRS) global assessment. Descriptive analyses were conducted to characterize overall burden of SLE

compared to US general population. The relationship between fatigue and overall health status was evaluated by comparing SF-36v2, patient and physician global assessments changes at endpoint from baseline between fatigue responders and non-responders. A fatigue response was defined as FSS change score ≤-1.0.

Results: There were 161 patients, predominantly female (96%) and white (72%), with average age of 43±11 years (range: 18–71). Mean SF-36v2 subscale scores ranged from 34.5 (SD=9.6) for general health (GH) to 42.1 (SD=13.2) for mental health (MH); summary component scores reflected overall problems with physical (PCS; mean=35.2, SD=9.7) and mental health (MCS; mean=40.9, SD=12.9). SLE patients had worse health status on all SF-36v2 subscale domains than US general population and comparable age and gender norms (effect size [ES] = −0.51 to −2.15; Figure 1). A comparison of change scores between fatigue responders and non-responders showed that fatigue responders had greater improvement on SF-36v2 and patient and physician global assessments than non-responders. Fatigue responders had larger ES improvements than non-responders on SF-36v2 bodily pain (BP; ES=0.6 vs. 0.2), physical functioning (PF; ES=0.6 vs. 0.1), social functioning (SF; ES=0.6 vs. 0.0), and PCS (ES=0.7 vs. 0.1), patient global assessment NRS (ES=−0.7 vs. 0.0), and MDGA (ES=−1.6 vs. −0.7).
Figure 1. Comparison of Mean Baseline SF-36v2 Subscale Scores in the SLE Clinical Study to US Population Norms

Conclusion: SLE patients had poor HRQL in this study. All SF-36 domains including physical and mental health components were worse than general population averages. Improvement in fatigue was associated with improvements in the individual SF-36 domains as well as the physician's global assessment of disease activity.

1395

The Validation of a New Simple Disease Activity Tool in Systemic Lupus Erythematosus (SLE): The Lupus Activity Scoring Tool (LAST) As Compared to the Sledai Selena Modification. Majed M. Khraishi[1], Rana Aslanov[2] and Krista Fudge[3]. [1]Memorial University of Newfoundland, St Johns, NF, [2]Memorial University of Newfoundland, St.John's, NF, [3]Corner Brook, NF

Background/Purpose: SLE is a chronic autoimmune disease with variable manifestations. New developments in the understanding and treatment of SLE mandated closer monitoring of the disease activity and its response to treatment. Current disease activity indices (e.g. SLEDAI SELENA, BILAG & SLAM) have their own limitations. We designed a new disease activity evaluation tool: the Lupus Activity Scoring Tool (LAST) that simplifies the approach to quantify SLE activity while maintaining high sensitivity. We have also developed an easy to use electronic application of this tool.

Primary: To validate a SLE activity tool with it correlation to the SLEDAI SELENA modification. Secondary: To test the usability and the accuracy of electronic applications of the same tool in clinical settings.

Methods: The new disease activity tracking and evaluating tool included patient global assessment of disease activity (PGA), physician global assessment of disease activity (PHGA), and a formula incorporating the current immuno-modulating medication used as an indication of SLE activity. The LAST included C3, C4 and Anti-ds Anti-DNA titer abnormalities as activity indicators. Patients who met the SLE ACR 1997 criteria update were seen in a rheumatology clinic

within the last 12 months and had the laboratory investigations done within 2 weeks of their visit. The SLEDAI was calculated for each visit. Five different systems (algorithms) of weighting the different variables of disease activity were calculated. Apple iPad and Windows web-based applications were developed for the LAST and a clinical only LAST (without incorporating serological values). Descriptive statistics and correlation bivariates (Pearson's & Spearman's) were conducted. Each algorithm result and the disease activity of patients with multiple assessments were compared to the SLEDAI SELENA scores.

Results: Twenty three patients (91% females) with 43 assessments were included. Scores from 5 algorithms of the variables in addition to the SLEDAI SELENA scores were obtained at each visit. The mean (SD) age was 47.97 (14.61) years and the mean (SD) of disease duration was 12.26 (6.47) years. The mean (SD) SLEDAI score was 6.30 (4.01). The mean (SD) LAST (with C3, C4 and Anti-ds DNA) score was 39.85 (18.67). The correlation between the two new activity indices was very high: 0.920 with p<0.001. The SLEDAI scores were consistent with the LAST scores at the baseline and follow-up visits: SLEDAI scores 0–4 corresponded to the LAST scores of 0–30 while SLEDAI scores of 8 or higher corresponded to 50 and higher, respectively. The electronic applications of the LAST were easy to use and no errors were found with their results as compared to the manually obtained scores.

Conclusion: The Lupus Activity Scoring Tool (LAST) is a new disease activity index correlated well with the SLEDAI SELENA modification. The use of simple clinical variables as a measure of SLE activity seems to be valid. The development of easy to use electronic apps will make the use of these activity tracking tools easier to calculate and can be possibly utilized in non-specialist settings.

1396

Associates of a History of Thrombosis in Systemic Lupus Erythematosus. Melissa Nastacio[1], Hong Fang[1], Thomas Kickler[1], Jayesh Jani[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Thrombosis in SLE is highly associated with anti-phospholipid antibodies, yet the majority of those with antiphospholipid antibodies never have a thrombotic event. Plasma microparticles have been identified as a risk factor for atherosclerosis. D-dimers are elevated in the setting of deep venous thrombosis. Endogenous thrombin potential (ETP) measures the thrombin formation capacity of plasma and may be elevated in hypercoagulable states.

Methods: We measured plasma microparticles by their functional capacity to generate thrombin, ETP, and D-dimer levels in 986 SLE patients. The relationship between these biomarkers and history of thrombosis was estimated.

Results: The patients were 92% female, 37% African American, 55% Caucasian with mean age 48.1 ±13.1 years. Of the 986 patients, 258 had at least one thrombotic event, including deep venous thrombosis (113), stroke (75), myocardial infarction (26), other venous (21), and other arterial thrombosis (13). Elevated levels of D-dimer (> 0.88 mg/L) were not associated with thrombosis. Thrombin generated microparticles were associated with history of a thrombotic event (Table). In subanalyses, we found that this association was only found with respect to venous (but not arterial) events. Low ETP was associated with a higher likelihood of a history of thrombosis. However, controlling for antiocoagulant use, this association disappeared, suggesting that the association was due to the fact that those with a history of thrombosis were put on anticoagulants which reduced their ETP.

Table 1. Life-time rates of thrombotic events in SLE patients by biomarker levels

	Group	# events	# of person-years at risk	Rate per 1000 person years	Risk Ratio (95% Confidence Interval)	P-value	Adjusted[1] Risk Ratio (95% Confidence Interval)	P-value
Everyone		258	42,513	6.1				
Ddimer (High/Low)	<0.88	173	28,305	6.1	1.0 (Ref Group)	.91	1.0 (Ref Group)	.52
	0.88+	85	14,208	6.0	1.0 (0.8, 1.3)		0.9 (0.7, 1.2)	
Thrombin generated microparticles (High/Low)	<5	76	14,262	5.3	1.0 (Ref Group)	.044	1.0 (Ref. Group)	.0075
	5+	165	25,845	6.4	1.3 (1.0, 1.7)		1.5 (1.1, 1.9)	
ETP quartiles	<343	111	9,699	11.4	1.0 (Ref. Group)	<.0001	1.0 (Ref. Group)	.61
	343–.395	42	10,486	4.0	0.3 (0.2, 0.5)	<.0001	0.9 (0.6, 1.4)[2]	.81
	395–.436	36	10,030	3.6	0.3 (0.2, 0.4)	<.0001	0.9 (0.6,1.5)[2]	.50
	436+	52	10,545	4.9	0.4 (0.3, 0.6)		1.2 (0.8, 1.8)[2]	

[1] Adjusting for ever having a positive ACL or RVVT test unless specified
[2] Adjusting for ever having a positive ACL or RVVT test and use of anti-coagulants.

Conclusion: Thrombin generated plasma microparticles increase the risk of thrombosis at levels >5. These data indicated that hypercoagulability in SLE can be further characterized beyond antiphospholipid antibodies, allowing prophylactic therapy to be given to the subset at greatest risk.

1397

Risk Factors Associated with Early Central Nervous System Damage Detected Through Perfusion MRI in Patients with Systemic Lupus Erythematosus. Paola Tomietto[1], Federica Casagrande[2], Maja Ukmar[2], Luca Weis[2], Pia Morassi[1], Rita Moretti[3], Gianni Biolo[3], Carlo Giansante[3] and Maria Assunta Cova[2]. [1]AOU Ospedali Riuniti di Trieste, Trieste, Italy, [2]Radiology Department, University of Trieste, Trieste, Italy, [3]Internal Medicine Department, University of Trieste, Trieste, Italy

Background/Purpose: Antiphospholipid antibodies (aPL), hypertension and accumulated damage (SLICC-DI) have been associated to the severity of cerebral MRI lesions and to cognitive deficits in SLE. Perfusion weighted MRI (PWI) is a sensitive technique that assess the capillary microcirculation and might allow to detect an early vascular damage, eventually preceding the appearance of structural damage in conventional MRI. The aim of this study was to determine the main factors affecting CNS damage detected through perfusion MRI in SLE.

Methods: 20 consecutive SLE patients underwent a clinical evaluation to characterize central nervous system involvement (NPSLE) including the clinical history, a 45-minutes neuropsychological battery and the Hospital Anxiety and Depression Scale (HADS). All the patients underwent MRI examination performed on a 1.5T magnet. In all of them conventional (cMRI) and dynamic susceptibility contrast (DSC) sequences were performed. Cerebral blood flow (CBF), cerebral blood volume (CBV), mean transit time (MTT) and time to peak (TTP) maps were reconstructed for 19 patients. Region of interest (ROI) were placed symmetrically on normal appearing white matter (NAWM) in 12 areas (frontal and parietal WM, amygdala, corpus callosum and middle cerebellar peduncles). ROI relevant to distinguish patients with NPSLE vs patients without were selected on the basis of the receiver operating characteristic (ROC) curve analysis. SLEDAI, SLICC-DI, generic cardiovascular risk factors, positivity for Raynaud's phenomenon, livaedo reticularis, cutaneous vasculitis, aPL, anti-RNP and anti-DNA were determined for all the patients and included as independent variables in several stepwise regression analysis to determine which of them affected changes in CBF, CBV MTT and TTP of NAWM.

Results: Measures of CBV of right frontal WM (sensitivity 83,3%, specificity 71,4%) and of MTT in left frontal (sensitivity 58,3%, specificity 100%) and parietal WM (sensitivity 66,6%, specificity 85,7%) showed moderate accuracy (AUC 0,72) in distinguishing patients with and without NPSLE, according to the clinical classification. Among generic cardiovascular risk factors, smoking resulted as an independent factor affecting CBF and CBV in frontal and parietal subcortical NAWM, while cholesterol and hypertension were independent variables associated to MTT respectively of the fronto-parietal NAWM and corpus callosum. Among SLE-related factors, aPL and livaedo reticularis were independent factors affecting MTT of corpus callosum. Finally SLICC-DI resulted as an independent factor affecting all the parameters of PWI in fronto-parietal NAWM and corpus callosum.

Conclusion: This preliminary analysis showed as some cardiovascular risk factors, (smoking, hypertension, cholesterol levels), and some SLE-related factors (aPL, SLICC-DI, livaedo reticularis), previously reported as related to NPSLE, are associated to early changes of cerebral perfusion in fronto-parietal subcortical normal appearing white matter and corpus callosum. These data, if confirmed, suggest the importance of a tight control of cardiovascular risk factors, aPL and of the disease activity to prevent early central nervous system damage in SLE.

Disclosure: **P. Tomietto**, None; **F. Casagrande**, None; **M. Ukmar**, None; **L. Weis**, None; **P. Morassi**, None; **R. Moretti**, None; **G. Biolo**, None; **C. Giansante**, None; **M. A. Cova**, None.

1398

Inflammatory Back Pain Is Increased in SLE and Associated with Anti-Sm Antibodies. Neslihan Yilmaz[1], Ayten Yazici[2], Sibel Z. Aydin[3] and Sule Yavuz[4]. [1]Marmara University, Faculty of Medicine, Istanbul, Turkey, [2]Sakarya Research and Training Hospital, Sakarya, Turkey, [3]Medeniyet University, Goztepe Training and Research Hospital, Istanbul, Turkey, [4]Marmara University, Istanbul, Turkey

Background/Purpose: Growing evidence suggest that autoantibodies may present in patients with ankylosing spondylitis. Here, we aim to determine the association of inflammatory back pain and autoantibodies in patients with systemic lupus erythematosus (SLE) which is a protype autoimmune disease.

Methods: One hundred thirty two SLE patients (130 females, 2 males) and 100 healthy controls (98 females,2 males) were questionnaired for having inflammatory low back pain (LBP). The SI joints of SLE patients with LBP were evaluated by conventional radiography followed by color and duplex Doppler ultrasonography (CDDUS) examination. X-Rays were scored according to the modified New York criteria. CDDUS evaluations included the presence of a vessel in and/or around the SI joints and measurement of the RI, which is expected to decrease by inflammation of the joint. The CDDUS results of 44 SLE patients (88 SI joints) were compared with 17 healthy controls (HC) (34 SI joints) without any low back pain.

Results: The incidence of LBP was 58/132 (43.9%) in SLE patients and 15/100 (15%) in HC (p<0.05). Forty four of SLE patients gave consent to participate the study. Within these patients 20/132 (15%) had inflammatory, 24/132 (18%) had noninflammatory LBP. None of the HC has inflammatory LBP. The mean age was 38.6±11.3 years and mean disease duration was 6.8±5.7 years. Mean SLEDAI was 1.94±1.94, BASDAI was 4.11±1.63. In SLE patients; Anti ds-DNA seropositivity was 17(38.6%), anti Sm was 6 (13.6%), anti RNP was 14 (31.8%), anti Ro was 9 (20.5%) and Anti La was 6 (13.6).Two of 16 (12.5%) HC had unilateral grade 1 sacroiliitis and 11/44 (25%) patients had unilateral, 2/44 (4.5%) patients had bilateral grade 1–2 sacroiliitis on X-ray of the SI joints. Vascularisation inside or around the SI joints was seen in 25/44 (56.8%) SLE patients with 41 of 88 SI joints (46.5%) and 12/17 (70.6%) HC with 18 of 34 SI joints (52.9%) (p>0.05). The mean RI of the SI joints was 0.66 ± 0.11 in SLE patients and 0.64 ± 0.07 in HC with no significant difference between the groups (p>0.05). Prevalence of sacroiliitis on X ray and power Doppler signal inside the SI joints on CDDUS examination had no correlation (Pearson: 0.06). Clinical features and autoantibody seropositivity were not related to sacroiliitis (p>0.05), except anti Sm antibodies (p=0.026).

Conclusion: Although a significant subset of SLE patients had inflammatory LBP, most patients had no severe radiological or CDDUS evidence of sacroiliitis implicating a mild axial disease. The association with anti-Sm antibodies needs further evaluation.

1399

Regional Fat Distribution Is Independently Associated with Damage Accrual in Systemic Lupus Erythematosus Female Patients. Manuel F. Ugarte-Gil, Rocio V. Gamboa-Cardenas, Karim E. Diaz-Deza, Mariela Medina-Chinchon, J. Mariano Cucho-Venegas, Risto A. Perich-Campos, Jose L. Alfaro-Lozano, Alfredo A. Sanchez-Torres, Zoila Rodriguez-Bellido, Sheyla Rodriguez-Ulloa and Cesar A. Pastor-Asurza. Hospital Almenara, Lima, Peru

Background/Purpose: In general population, a higher trunk fat and the ratio of trunk fat to leg fat (trunk-leg ratio) increase the risk for a cardiovascular event, and a higher leg fat decreases this risk. The purpose of this study is to determine if level of disease cumulative damage in Systemic Lupus Erythematosus (SLE) as measured by the SLICC/ACR damage index (SDI) is independently associated with body fat distribution in female patients with SLE.

Methods: In a cross-sectional single center study, we evaluated 101 consecutives SLE female patients who were seen at the Rheumatology department of our hospital. SLE was defined using the ACR criteria; body composition analysis was assessed by dual energy X-ray absorptiometry (DXA). A chart review, clinical evaluation and laboratory exams were performed. We defined damage using SDI. Disease activity was measured using SLEDAI. Body fat percentage and fat distribution was reported as trunk fat percentage, leg fat percentage and trunk-to-leg fat ratio. For the univariate analysis we performed a simple linear regression model, after that, we performed a logistic regression model adjusted to disease activity, metabolic syndrome, body mass index, age, disease duration, time of exposure to prednisone and current dose of prednisone.

Results: One hundred and one SLE patients with an average age of 42.64 (SD: 12.77) years were evaluated. Almost all of them were mestizo, only one

was African Latin-American. Disease duration was 8.32 (SD: 7.20) years. Percent total body fat was 36.4% (SD: 7.0%), percent trunk fat 36.4% (SD: 8.1%), percent leg fat 37.8% (SD: 7.4%), trunk-to-leg ratio 1.72 (SD: 0.68). SDI was 0.86 (SD: 1.27), SLEDAI was 5.82 (SD: 4.26). Body mass index was 27.11 (SD: 5.20) kg/m2. Forty-four (43.6%) patients had metabolic syndrome. Current dose of prednisone was 8.43 (SD: 5.18) mg/d and the time of exposure to prednisone was 8.11 (SD: 6.79) years. SDI correlate with trunk-to-leg fat ratio (β: 0.41, p<0.001) and percent leg fat (β: −0.22, p: 0.03), but not with percent total body fat (β: −0.10, p: 0.31) or percent trunk fat (β: −0.04, p: 0.71). After adjustment for disease activity, metabolic syndrome, body mass index, age, disease duration, time of exposure to prednisone and current dose of prednisone, SDI remained associated with trunk-to-leg fat ratio (β: 0.50, p<0.001) and leg fat (β: −0.25, p:0.009).

Conclusion: In SLE female patients, a higher level of disease damage is associated with a higher trunk-to-leg fat ratio and a lower leg fat, independently of disease activity, metabolic syndrome, body mass index, age, disease duration, time of exposure to prednisone and current dose of prednisone.

Predictors of Obesity in Systemic Lupus Erythematosus. Michelle Petri, Sesha Adusumilli and Hong Fang. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Hypertension and obesity are the two most important traditional cardiovascular risk factors in the prediction of subclinical measures of atherosclerosis in SLE. Obesity is the most important associate of hsCRP in SLE, as well. We analyzed predictors of obesity in a longitudinal SLE cohort.

Methods: Body mass index (BMI) was calculated at baseline and at last visit in a longitudinal cohort. 2,016 SLE patients with 48,163 visits were analyzed. Obesity was defined as BMI > 30.

Results: The patients were 92.6% female, with average age on 1/1/12 of 47.6 years. 37.4% were African-American and 55.6% Caucasian. The average BMI at cohort entry was 27.5 ± 7.9 and at last visit 28.2 ± 8.1. At cohort entry 28.1% were obese and at cohort end 32.5% were obese. 8.7% became obese and 4.4% who were obese became not obese. The table shows prediction of new obesity over cohort follow-up in a multivariate model.

Factor	Coefficient	P-value
Prednisone (mgs)–maximum dose	−0.009	**0.0249**
African-American ethnicity	0.057	0.5696
Education (years)	−0.010	0.7680
Private Insurance	−0.064	0.5612
Age at Diagnosis	0.009	0.2484
Current smoker	0.228	**0.0401**
Current drug abuser	0.107	0.6532
Discoid lupus	0.086	0.4112
Alopecia	0.081	0.3826
Proteinuria	−0.043	0.6655
Anemia	−0.043	0.6909
Lupus anticoagulant (RVVT)	0.246	**0.0072**
Dry mouth	−0.171	0.2257
Cardiac murmur	0.193	**0.0371**
Anti-dsDNA positive	0.008	0.9402
Low C4	0.015	0.8798
ESR	0.293	**0.0301**
Hyperglycemia	0.020	0.8266

Conclusion: New obesity developed in 8.7% during follow-up. Surprisingly, both maximum and mean (data not shown) prednisone dose had negative coefficients. The lupus anticoagulant and ESR were both predictors of obesity. Demographic factors (African-American race, lack of private insurance, smoking) were all predictive of new obesity. These data suggest that demographic variables can identify the subsets most at risk, for preemptive dietitian consulting and lifestyle intervention. However, the reason why some laboratory tests (lupus anticoagulant and ESR) are predictors is unknown. Ironically, prednisone dose was NOT a positive predictor in the multivariate model.

1401

Characterization of Clinical Photosensitivity in Cutaneous Lupus Erythematosus. Kristen Foering[1], Aileen Y. Chang[2], Evan W. Piette[2], Joyce Okawa[3] and Victoria P. Werth[4]. [1]University of Pennsylvania, Philadelphia VAMC, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Perelman School of Medicine at the University of Pennsylvania and Philadelphia V.A. Medical Center, Philadelphia, PA, [4]University of Pennsylvania and Philadelphia V.A. Medical Center, Philadelphia, PA

Background/Purpose: Photosensitivity (PS) is one of the most common manifestations of systemic lupus erythematosus (SLE), and is 1 of only 11 criteria used to make the diagnosis of SLE. However, the definition of photosensitivity is vague and its pathophysiology is not well understood. There is a need to better define the clinical aspects of photosensitivity in lupus, to enhance further study of this difficult problem. The objective of this study was to characterize self-reported photosensitivity phenotypes among a primarily cutaneous lupus (CLE) population.

Methods: A novel photosensitivity questionnaire provided a framework for characterizing subjects' experience of sun sensitivity. The PS questionnaire was based on information gathered over a 9-month period of subject interviews pertaining to sun exposure. Recurring themes of self-reported photosensitivity relating to morphology, characteristics, and timing of reactions were identified and incorporated into a brief PS questionnaire. The PS questionnaire was used to classify subject responses into five PS phenotypes: sun-induced CLE exacerbation (directCLE); general worsening of CLE in summer (genCLE); PMLE-like reactions (genSkin); general pruritus/paresthesia (genRxn); and systemic symptoms, e.g. headache, arthralgia (genSys). 100 subjects with CLE alone or both CLE and SLE were interviewed.

Results: 83% of subjects ascribed to any and 66% reported more than one PS phenotype. 47% cited direct examples of sun-induced CLE [directCLE]. Other PS phenotypes were reported as follows: 22% genCLE, 38% genSkin, 36% genRxn, and 37% genSys. The genSys phenotype was reported by fewer discoid and subacute cutaneous LE compared with acute and tumid LE subjects, χ^2=13.0, p<0.05. Subjects with both CLE and SLE reported more paresthesias/pruritus (51% vs 23%) and systemic symptoms (50% vs 26%) compared to those without SLE, p<0.05. Subjects with PMLE-like reactions had lower CLE Disease Area and Severity Index (CLASI) activity scores compared to other PS phenotypes (6.4 ± 5.4 vs 11.5 ± 11.11, p=0.02).

Conclusion: Self-reported photosensitivity in lupus ranges from CLE-specific reactions to generalized cutaneous eruptions to systemic symptoms. Clinical PS phenotypes are associated with CLE subtype, SLE diagnosis, and CLASI activity scores. Recognition of various PS phenotypes in CLE will permit improved definitions of clinical photosensitivity and allow for more precise investigation into the pathophysiology of photosensitivity in lupus.

Anti-ApoA1 Antibodies Associate with Disease Activity in Lupus and Are Lower in Patients Taking Hydroxychloroquine: A Longitudinal Analysis of 398 Samples. Sara Croca, Ian Giles, David A. Isenberg, Yiannis Ioannou and Anisur Rahman. University College London, London, United Kingdom

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a significantly increased risk of developing cardiovascular disease. The presence of chronic inflammation which characterizes SLE disease activity may contribute to this risk. Apolipoprotein A1 (ApoA1) plays a protective role against atherosclerosis. Anti-ApoA1 antibodies have been described in patients with coronary disease. Our previous cross-sectional studies showed that anti-apoA1 levels are raised in patients with current and persistent disease activity but there are few longitudinal data. This abstract describes the result of longitudinal studies of anti-ApoA1 levels and measures of disease activity, serological profile and treatment in patients with SLE.

Methods: Longitudinal serum samples (n= 398) were selected retrospectively from a cohort of 49 patients with SLE with a mean of 8 samples per patient (SD 2.16; min 3; max 14) and a mean follow-up of 89 months (SD 46; min 14; max 180). Serum from 40 healthy controls and 15 patients with rheumatoid arthritis (RA) was also tested. Anti-ApoA1 levels were measured using a direct ELISA. Using the British Isles Lupus Assessment Group (BILAG) index, we categorized the samples by disease activity as follows. Current activity was defined as high if global BILAG score was ≥5 and

low if it was <5). Disease activity over the most recent 4 assessments was characterized as persistently low (all systems BILAG C, D or E) or persistently moderate-high (A or ≥1 B in any BILAG system on at least 2/4 occasions). 90% of all samples fell into one of those two categories and the rest were excluded.

Anti-dsDNA was defined as high or normal based on a cut-off of 50IU/ml. C3 was defined as low or normal based on a cut-off of 0.9g/l.

Data on the treatment at the time of each individual sample were also obtained, considering prednisolone dose and whether either immunosuppressants (IS) or hydroxychloroquine (HCQ) were used.

Results: 42% of the samples tested were positive for anti-ApoA1 (greater than mean + 3SD of healthy controls). Patients with SLE had significantly higher anti-ApoA1 levels than healthy controls and patients with RA (p< 0.0001). No association between either sex or ethnicity and anti-ApoA1 levels was found. Higher anti-ApoA1 levels were significantly associated with the following factors:
- Low complement levels (p= 0.017).
- Persistent disease activity (p=0.04)
- Disease activity on date of sample (p=0.04)
- Not being on HCQ (p<0.0001)
- Prednisolone dose< 5mg/day (p= 0.0067)

We found no association between anti-ApoA1 and positivity for anti-dsDNA or ENA and no significant association with use of IS.

Conclusion: The presence of anti-ApoA1 antibodies has been shown in patients with SLE and may play a role in disturbing the normal lipid homeostasis which in turn may contribute to the increased cardiovascular risk associated with this disease. We have found that anti-ApoA1 levels are increased in patients with SLE compared to healthy controls and patients with RA. Anti-ApoA1 levels appear to be associated with both clinical and serological disease activity measures. The use of HCQ seems to be associated with lower anti-ApoA1 levels.

1403

Anti-Nucleosome Antibodies Are Associated with Disease Activity and Hydroxychloroquine Use in Patients with Lupus: A Longitudinal, Multivariate Analysis of 398 Samples. Sara Croca, Ian Giles, David A. Isenberg, Yiannis Ioannou and Anisur Rahman. University College London, London, United Kingdom

Background/Purpose: Impaired apoptotic clearance appears to play a pivotal role in the pathogenesis of SLE leading to the accumulation of nuclear debris, such as nucleosomes, ultimately stimulating the production of autoantibodies. Both nucleosomes and anti-nucleosome antibodies (AN) have been found in serum of patients with SLE and appear to correlate with disease activity. AN have been particularly associated with renal and skin disease. This abstract describes the result of longitudinal studies of AN levels, ethnicity, autoantibody profile, treatment and measures of disease activity in patients with SLE.

Methods: Longitudinal serum samples (n= 398) were selected retrospectively from a cohort of 49 patients with SLE with a mean of 8 samples per patient (SD 2.16; min 3; max 14) and a mean follow-up of 89 months (SD 46; min 14; max 180). Sera from 40 healthy controls were also tested. OD values were converted to standard absorbance units (AU) by comparison to a positive control serum sample loaded on every plate. AN levels were measured using a direct ELISA and a positive result was defined as mean + 3SD of the healthy controls (0.17). Using the British Isles Lupus Assessment Group (BILAG) index, we categorized the samples by disease activity as follows.

Current activity was defined as high if global BILAG score was ≥5 and low if it was <5. Disease activity over the most recent 4 assessments was characterized as persistently low activity (all systems BILAG C, D or E) or persistently moderate-high activity (A or ≥1 B in any BILAG system on at least 2/4 occasions). 90% of all samples fell into one of those two categories and the rest were excluded.

Anti-dsDNA was defined as high or normal based on a cut-off of 50IU/ml. C3 was defined as low or normal based on a cut-off of 0.9g/l.

Data on the treatment at the time of each individual sample were also obtained, considering prednisolone dose and whether either immunosuppressants (IS) or hydroxychloroquine (HCQ) were used.

Results: Table 1 shows that higher AN levels were significantly associated with low C3 and high anti-dsDNA levels as well as with higher

current or persistent disease activity defined by the BILAG index. We found no association between AN levels and ethnicity, ENA positivity or flares in individual organs. Patients who were taking HCQ and those on low dose steroids (≤5mg/day) had significantly lower AN levels (p< 0.0001). No differences were found with regards to presence or absence of IS.

	Number of samples (*n*)	Mean (SD) AN level	*p*-value (high vs. low)
Persistently moderate-high activity	209	59.1 (99.4)	0.0243
Persistently low activity	166	49.1 (84.0)	
BILAG< 5	166	49.1 (84.0)	0.0243
BILAG≥ 5	209	59.0 (99.4)	
Anti-dsDNA			
High (>50IU/ml)	177	37.5 (75.2)	<0.0001
Normal (≥50IU/ml)	170	78.5 (112.5)	
Complement (C3)			
Normal (≤0.9g/l)	209	50.1 (90.4)	0.04
Low (>0.9g/l)	138	68.9 (105.6)	
Hydroxychloroquine			
Yes	174	43.46 (76.9)	>0.0001
No	223	65.15 (105.4)	
Predisolone			
>5mg/day	209	40.2 (76.9)	>0.0001
≤5mg/day	188	72.8 (108.4)	

Conclusion: AN levels were significantly associated with disease activity assessed both by clinical and serological measures. In addition, it appears that the type of treatment used, namely the use of HCQ may influence the levels of AN.

1404

There Is an Association Between Disease Activity and Risk of Thromboembolism in SLE. Reem Jan, Emily E. Lewis, Ting Ting Lu, Emily Siegwald and W. Joseph McCune. University of Michigan, Ann Arbor, MI

Background/Purpose: Venous thromboembolism is a recognized complication of systemic lupus erythematosus (SLE). The role of antiphospholipid antibodies (aPL) in thrombogenesis is well documented; much less is known about the potential for an increased risk of thromboembolic disease in the absence of these markers. Inflammatory stimuli are prothrombotic, with apoptotic endothelial cells identified as a potential trigger through tissue-factor dependent pathways. We aim to determine whether venous thromboembolic events (VTE) in patients with SLE correlate with periods of enhanced disease activity.

Methods: A retrospective chart review was performed on 837 patients enrolled in the Michigan Lupus Cohort to identify patients diagnosed with VTE. Patients satisfied ≥4 ACR criteria for SLE. Diagnosis of VTE was defined as a positive venous doppler, CT scan of the thorax, or high probability VQ scan.

Risk factors for VTE were noted including: use of oral contraceptives within 3 months of the event, pregnancy/6 weeks postpartum, surgery within 3 months, smoking, inherited thrombophilia, malignancy, and the presence of nephrotic-range proteinuria. We also noted the presence of aPL positivity (defined by positive lupus anticoagulant or antibodies to cardiolipin or beta-2 glycoprotein-1 IgG, IgM or IgA at >99% percentile of assay).

Disease activity was measured by the Systemic Lupus Disease Activity Index (SLEDAI).

Markers of disease activity at the time of VTE were recorded using the closest SLEDAI score within 3 months before, or up to 1 month after the event. Comparisons were made between the SLEDAI score at the time of the event and a baseline SLEDAI collected up to 12 months prior to the event for each patient.

Results: 72 patients were identified as having sustained a VTE (8.6%). Of these patients, 36 had serial SLEDAI data available. The most frequently detected confounding risk factors were recent surgery (30.6%; p= 0.012) and the presence of aPL (25%; p= 0.033). If aPL positivity was required to be present on two separate occasions, this no longer became a statistically significant association.

There was a significant association between VTE and disease activity, with a mean increase in SLEDAI score of 1.72 at the time of event (p= 0.021; 95% CI 0.274–3.471).
Figure 1. The difference for each patient between the SLEDAI score at the time of VTE compared with the score 4–12 months previously.

Conclusion: Our results show a statistically significant association between disease activity and VTE, independent of the presence of aPL. This has implications for the management of patients with active SLE, including decisions regarding the safety of estrogens for contraception and the threshold for anticoagulation in high-risk situations such as pregnancy. It may also lend clinical support to a growing body of basic science research that suggests an association between inflammation and thrombosis.

1405

Real World Experience Comparing Multiplex Immunobead Assay versus Immunoflorescence Assay for Anti-Nuclear Antibody Detection At a University Hospital. Neha Dang, Brock E. Harper, Emilio B. Gonzalez, Silvia S. Pierangeli, Trisha M. Parekh, Michael J. Loeffelholz and Kimberly K. Bufton. University of Texas Medical Branch, Galveston, TX

Background/Purpose: Anti-nuclear antibody (ANA) is considered a screening method for diagnosis of autoimmune disorders. Immunoflorescence ANA assay (IF) remains the gold standard for detection of ANA as per the 2011 ACR position statement. Many laboratories perform immunoassays for detection of ANA as it is less labor-intensive to perform.

Methods: We collected data prospectively on patients tested for ANA by multiplex immunobead assay MIA (BioPlex ANA screen, Bio-Rad Laboratories, Hercules, CA, USA) and IF assay (HEp-2000 (Immuno Concepts, Sacramento, CA, USA) from chart review of rheumatology patients from March 2011 to May 2012. Patients were separated into 4 groups based on positive and negative ANA by MIA and IF assay. Data were collected by individual chart review including age, gender, ethnicity, and indication for ANA testing. Sensitivity and specificity of the immuno assay were determined using the IF results as the "gold standard".

Results: One hundred and ten (110) patient samples were tested for both assays. Multiplex immunobead assay (MIA) were considered positive based on the manufacturer's instructions, and IF was considered positive at a titer $\geq 1{:}160$; 12 (10%) were positive by both assays and were considered true positives (TP), 74 (67%) were negative by both or true negatives (TN); 15 (14%) were positive by IF and negative by MIA and were false negatives (FN); 9 (8%) were positive by MIA and negative by IF, or false positives (FP) (Table 1). Indications for ANA testing in the false negative group included systemic sclerosis, polymyositis, rheumatoid arthritis on treatment with anti-TNF therapy, undifferentiated connective tissue disorders, and polyarthralgias (Table 2). Sensitivity and specificity for the multiplex immunoassay was 44%, and 89%, respectively.

Table 1. Comparison of ANA MIA and IF

	IF positive ($\geq 1{:}160$)	IF negative
Multiplex positive n (%)	12 (10%) TP	9 (8%) FP
Multiplex negative n (%)	15 (14%) FN	74 (67%) TN

Sample size 110

Table 2. Baseline Demographic comparison

	Multiplex +, IF+ (TP)	Multiplex −, IF − (TN)	Multiplex +, IF − (FP)	Multiplex −, IF + (FN)
Age (mean±SD)yrs	45±13	48±15	47±18	48±16
Females n (%)	11 (91%)	59 (79%)	8 (89%)	13 (86%)
Ethnicity*(%)	AA (16%) C (25%) H (50%)	AA (13%) C (70%) H (9%)	AA (33%) C (44%) H (11%)	AA (46%) C (46%)
Indication for testing/ Clinical diagnosis (n)				
SLE	5	1	1	-
Sjogren's	1	-	-	-
RA	1	9	1	2
Systemic sclerosis/PM/DM	-	-	-	2
Polyarthralgias	2	30	2	6
UCTD	2	-	-	3
Others	2	32	5	1

*AA African American, C Caucasian, H Hispanic

Conclusion: Our study reveals a low sensitivity with high rate of false negatives when MIA is used for ANA screening compared to IF in a real world rheumatology setting of patients presenting with a variety of autoimmune diseases. Patients misclassified by the MIA included patients with definite ANA-associated autoimmune diseases. These data suggest that screening with an immuno assay would result in misclassification and potential delay or missed diagnoses of certain systemic autoimmune diseases. Immunoflorescence assay should remain the preferred assay for ANA testing in patients with suspicion of autoimmune disorders until until high sensitivity platforms are developed.

1406

The Cost of Management of Adult Active Systemic Lupus Erythematosus in the UK. Munther A. Khamashta[1], Christina Donatti[2], Ian N. Bruce[3], Caroline Gordon[4], David A. Isenberg[5] and Ateka-Barrutia Oier[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]IMS Health, United Kingdom, [3]Arthritis Research UK Epidemiology Unit and NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom, [4]University of Birmingham, Birmingham, United Kingdom, [5]University College London, London, United Kingdom

Background/Purpose: Several international studies have shown that systemic lupus erythematosus (SLE) has a considerable financial burden on patients and the health-care economy. Little recent information is available in most European countries about the cost of SLE care (treatment strategies, healthcare pathways, medical resource utilization), especially for patients with moderate to severe disease to make valid comparison with other countries. The aim of this study was to evaluate the annual direct medical costs of the management of adult SLE with active disease in the UK.

Methods: A multi-centre retrospective chart review involving four specialist lupus centres in the UK recruited 86 SLE patients: 38 severe and 48 non severe patients. At inclusion, patients had to have: 1) at least one change (increase in dose and/or new treatment) in treatment related to current SLE activity, and/or a new manifestations and/or worsening of clinical symptoms of SLE; or, 2) presence of at least one biomarker of SLE activity and concurrently, the presence of at least one clinical and/or hematological feature of SLE. Two-year direct costs were obtained by summarizing all the health resource costs related to laboratory and imaging tests, medical treatment, visits to doctors, day hospitalization, day surgery, emergency room visits, inpatient stays and rehabilitation stays.

Results: Of the patients studied, 68 (94.4%) were female. The mean age was 45.5 ($\pm$13.9) years and the mean duration of SLE was 11.9 ($\pm$8.3) years. At baseline, 48/86 (55.8%) of patients had relapsing-remitting SLE and 29/86 (33.7%) had chronically active SLE; 73/86 (84.9%) of patients received corticosteroids, 63/86 (73.3%) antimalarials, 48/86 (55.8%) immunosuppressants and 17/86 (19.8%) NSAIDS. No biological drugs were prescribed at inclusion. The mean (SD) SELENA-SLEDAI score was 7.7 (5.7), and was statistically significantly greater in severe patients (9.6 vs 6.1, p=0.004). Organ damage was present in 34/86 (39.5%) of patients. Anti-dsDNA antibodies were tested in 83/86 (96.5%) at baseline; of which 53/83 (63.9%) were positive.

The median annual direct medical cost of management of adult SLE patients with active autoantibody positive disease on medication for SLE was £2855.87 (US$4389.02) (mean [SD]: £3230.65 [£2333.21] (US$4,964.98 [US$3585.77]). The minimum and maximum costs (min: £389.06 (US$597.92), max: £9701.52 (US$14909.66) respectively) showed the wide range of costs, associated with a wide spectrum of disease activity and complications needing intervention in these lupus patients. The mean annual direct medical cost was 2.2 times higher in severe than in non-severe SLE patients (p<0.001).

Conclusion: The trend in terms of direct costs for treating active SLE patients and the marked gradient associated with increasing disease severity are consistent with Sutcliffe et al (2001), which calculated direct costs at £2613 and higher disease activity was associated with increased costs. There are very few published studies attempting to calculate the direct costs of SLE and this study provides current and reliable source of cost data for active SLE patients in the UK and comparable healthcare systems.

The Effect of the Antiphospholipid Syndrome (APS) On Survival in Chinese Patients with SLE: A Prospective Study of 679 Patients. Chi Chiu Mok, Ling Yin Ho, Ka Lung Yu and Chi Hung To. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To study the effect of the antiphospholipid syndrome (APS) on survival in Chinese patients with SLE

Methods: A cohort of 679 southern Chinese patients who fulfill at least 4 of the ACR criteria for SLE from 1995 to 2011 was studied. The status of the patients at last clinical visits (alive or death) was evaluated. The cumulative survival rate over time was studied by Kaplan-Miere's plot. For those who died during the course of their disease, data were censored at the time of their deaths whereas data of other patients were censored at the time of last clinic visits. APS was defined by the modified Sydney criteria in 2006, ie. The presence of arterial or venous thrombosis, or miscarrages (recurrent abortion or intra-uterine death) plus any one of the following positive twice at least 12 weeks part: (1) lupus anticoagulant; (2) moderate to high titers of anticardiolipin antibodies (IgG or IgM); or (3) beta-2-glycoprotein-I. Comparison of the survival of patients with and without APS was made.

Results: 679 SLE patients (92% women; age of disease onset 32.5±14 years) were prospectively followed for 9.7±7.3 years. Sixty-eight (10%) patients died and 33 (4.9%) patients were lost to follow-up. The main contributing causes of death in these patients were: infection (53%), cardiovascular events (6%), cerebrovascular events (15%), and cancer (9%). Forty-four (6.5%) patients qualified the criteria for APS, manifested as: ischemic stroke (55%), deep venous thrombosis (32%), obstetric morbidity (14%), cardiovascular events (9%) and peripheral vascular disease (9%). Twenty-three (52%) patients developed APS after the diagnosis of SLE, 16 (36%) patients had concomitant APS diagnosed at the same time as SLE and 5 (11%) patients had APS preceding SLE diagnosis. Nine (20%) APS patients died, which was significantly more frequent than the non-APS SLE patients (59/635[9%]; p=0.02). Patients with the APS died at an older age than those without APS (54.0±11.4 vs 45.1±18.2; p=0.07). The duration of SLE at the time of death was also longer in patients with the APS than those without (13.9±10.4 vs 7.47±7.4 years; p=0.11). The cumulative mortality of patients with APS was 4.6% at 5 years, 7.8% at 10 years and 22.2% at 15 years, which was not significantly higher than that of non-APS patients (5.4% at 5 years, 9.2% at 10 years and 11.3% at 15 years; p=0.14). However, if only patients with APS caused by arterial thrombosis were considered, the presence of APS was significantly associated with mortality (HR 2.29 [1.13–4.64]; p=0.02).

Conclusion: The presence of APS increases the mortality risk of patients with SLE, which is mainly contributed by arterial thrombotic events that occur late in the disease course.

Monitoring Patients with Systemic Lupus Erythematosus in Clinical Practice: Have You Already Checked the Vaccination Status in Your Patients? Olga Malysheva, Jean-Philipp Ivanov, Sybille Arnold and Christoph G. Baerwald. University Hospital, Leipzig, Germany

Background/Purpose: Infection is one of the main causes of morbidity and increased mortality in patients with systemic lupus erythematodes (SLE). Information about vaccination history and updating vaccinations on a regular basis is an economical way to avoid complications of various infections. Ideally vaccinations should be done prior to starting immunosuppressive treatment. Influenza, pneumococcal and tetanus vaccines are safe and do not lead to SLE flares while the majority of patients develop protective antibodies. Recommendations for hepatitis B and varicella herpes zoster (VZV) vaccination have not yet been validated in SLE patients. The purpose of study was to assess the vaccination rates against common infections and to determine the incidence of hepatitis B and VZV infections in patients with SLE attending a rheumatology outpatient clinic.

Methods: Data collected included age, duration of disease and treatment (systemic corticosteroids, methotrexate, azathioprine, hydroxychloroquine). According to the recommendations for vaccination in patients with rheumatic diseases derived from The European League against Rheumatism (EULAR) and the German Robert Koch Institute for Infection Control vaccination history was taken for MMR (measles, mumps and rubella), poliomyelitis, pertussis, diphtheria, influenza, human papillomavirus, hepatitis A, hepatitis B, tetanus, meningococcal and pneumococcal vaccines. A simple questionnaire was designed and 68 SLE patients were asked to provide their vaccination records. Patients were also tested for hepatitis B (anti-HBc, anti-HBs) and VZV (IgG) status.

Results: 95.6 % of SLE patients presented a vaccination card. Of interest, 75 % patients did not receive the influenza vaccine in the previous year. Only 12 patients (19 %) in total and 30 % in the age group > 60 years have ever received the pneumococcal vaccination. The vaccination rate for tetanus (combined vaccination with diphtheria and pertussis) was 51 %. For the remaining vaccinations the following picture emerged: vaccination was complete for 66 % against poliomyelitis, 11.8 % for hepatitis A, 1.5 % for meningococcus, 2.6 % for MMR. Only 1.6 % of SLE patients were vaccinated against human papillomavirus (only 12.5 % of the patients < 27 years). Patients with SLE do not have an increased incidence of hepatitis B and we did not detect any patient with an active hepatitis B. Only 14.7 % patients with SLE had a vaccination against hepatitis B. 2 SLE patients (3.6%) exhibited an abnormal hepatitis serology (increase of anti-HBc + anti-HBs-Titre, or anti-HBc) and only one of them had a moderate increase of liver enzymes. 97% SLE patients were positive for VZV IgG and 23 SLE patients (33.8%) had a history of VZV infection with postherpetic neuralgia. Therefore, 60% of SLE patients may be considered for herpes zoster vaccination; however, no patient was vaccinated against VZV.

Conclusion: In SLE patients with stable disease the vaccination rate was low. More careful monitoring of SLE patients concerning vaccination is necessary. In particular with new therapies being directed against B-lymphocytes a timely update of the vaccination status is mandatory for every individual patient with SLE.

A Multicentre Clinical Study of Umbilical Cord Mesenchymal Stem Cells Transplantation in Active Systemic Lupus Erythematosus. Lingyun Sun[1], Dandan Wang[1], Jing Li[2], Miao Zhang[3], Yu Zhang[4] and Xia Li[1]. [1]Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Department of Rheumatology, Affiliated Hospital of Jiangsu University, Zhenjiang, China, [3]Department of Rheumatology, Jiangsu Provincial People's Hospital, Nanjing, China, [4]Department of Rheumatology, Subei People's Hospital of Jiangsu Province, Yangzhou, China

Background/Purpose: Umbilical cord (UC) derived mesenchymal stem cells (MSCs) have shown safety profile and therapeutic effect in severe and refractory systemic lupus erythematosus (SLE) in our single-centre pilot study. The present multicentre clinical trial was undertaken in China to assess the efficacy and safety of allogenic UC MSCs transplantation (MSCT) in active SLE patients.

Methods: Forty patients (aged ≥16 years) with active SLE (SLE Disease Activity Index >6) were enrolled from 4 clinical centres in China. All patients gave informed consents before transplantation, and allogenic UC MSCs were infused intravenously on days 0 and 7. Adverse event was monitored during and after MSCs transplantation. Primary efficacy endpoints were major clinical response (MCR), partial clinical response (PCR) and relapse at 6 and 12 months. Secondary endpoints were improvement in SLEDAI score, British Isles Lupus Assessment Group (BILAG) score, serum levels of creatinine, urea nitrogen, complements and albumin pre- and post-MSCT.

Results: Fourteen and fifteen patients achieved MCR (14/40, 35.0%) and PCR (15/40, 37.5%) at 6 months follow-up, respectively. Three and four patients experienced disease relapse at 9 (7.5%) and 12 (10%) months follow-up, respectively, after a prior clinical response. SLEDAI score significantly decreased at 3 (7.43±3.93), 6 (6.30±3.63), 9 (6.40±3.84) and 12 months (6.48±3.52) follow-up (P all <0.05 vs. baseline 10.83±4.63). Total BILAG score markedly decreased 3 months after MSCT, and continued to decrease in the following visit times. BILAG score for renal and hematopoietic system significantly improved. For those with lupus nephritis, 24-hour proteinuria declined after transplantation, with statistical differences at 9 (1.24±1.09 mg) and 12 months (1.41±1.33 mg, P<0.05 vs. baseline 2.24±1.43 mg). Serum creatinine and urea nitrogen decreased to the lowest level at 6 months, while slightly increased at 9 and 12 months due to the 7 relapsed cases. Additionally, Serum levels of albumin, complements 3 and 4 increased after MSCT, peaked at 6 months visit, then slight declined at 9 and 12 months. Serum anti-nuclear antibody (ANA) and anti-double strand DNA (dsDNA) antibody decreased after MSCT, with statistical differences at 3 months follow-up. Furthermore, hemoglobin and platelet counts increased after MSCT in those with hematopoietic involvement. UC-MSCT was well tolerated and no adverse event was observed.

Conclusion: Our findings indicate that UC MSCT results in satisfactory clinical responses in SLE. However, several cases experienced disease relapse after 6 months visit, which suggests the necessity for repeated MSCT after 6 months in some patients.

Relationship Between Individual Organ Damage and Mortality of Systemic Lupus Erythematosus (SLE): A Prospective Cohort Study of 679 Patients. Chi Chiu Mok, Ling Yin Ho and Ka Lung Yu. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To study the relationship between damage in different organ systems and mortality in patients with SLE.

Methods: 679 patients who fulfilled at least 4 of the ACR criteria for SLE between 1995 and 2011 were prospectively followed. The cumulative rate of survival was studied by Kaplan-Meier's plot. For those who died during the disease course, data were censored at the time of death. For other patients, including those who were lost follow-up, data were censored at the time of last clinic visits. Organ damage was assessed by the ACR SLICC damage scores (SDI). Cox regression models were established to study the association between damage in individual systems and mortality in this cohort of patients.

Results: 679 SLE patients were studied (623 women, 92%). All were ethnic Chinese. The mean age of onset of SLE was 32.5±13.6 years and the mean follow-up time of the entire cohort of patients was 117±89 months. 67 (9.9%) patients died during the course of illness and 33 (4.9%) patients were lost to follow-up. 23 (3.4%) patients developed end stage renal failure (ESRF). The main contributing causes of death were: infection (51%), cardiovascular events (12%), cerebrovascular events (16%), cancer (9%), suicide (3%) and others (8%). Infective complications were the commonest causes of death both in patients with disease duration of less (55%) and more than 5 years (47%). In patients with SLE for less than 5 years, 19% of all deaths were caused by vascular events, which was lower than those with disease for more than 5 years (36%). The cumulative survival rate of the patients was 94.8% at 5 years, 91.3% at 10 years and 88% at 15 years. 301 (44%) patients had organ damage (SDI score $\geq$1). Among patients who had organ damage, the frequency of damage in individual systems was, in decreasing order: neuropsychiatric (N=102, 15%), musculoskeletal (N=93, 14%), renal (N=78, 11%), ocular (N=46, 6.8%), cardiovascular (N=38, 5.6%), pulmonary (N=36, 5.3%), gonadal (N=32, 4.7%), endocrine (N=23, 3.4%), peripheral vascular (N=22, 3.2%), malignancy (N=19, 2.8%) and gastrointestinal (N=8, 1.1%). Within the first 5 years of onset of SLE, neuropsychiatric damage was most frequent (10%), followed by renal (7.9%) and dermatological (7%) damage. In patients with SLE duration of more than 5 years, the commonest cause of damage was in the musculoskeletal system (18.4%), followed by neuropsychiatric (17%) and renal damage (13.3%). The presence of any organ damage was strongly and significantly associated with mortality (HR 6.42[3.05–13.5]; p<0.001). Cox regression analysis revealed that damage in the neuropsychiatric system (HR 1.74[1.31–2.32]; p<0.001), renal (HR 1.97 [1.61–2.42]; p<0.001), cardiovascular (HR 1.75 [1.21–2.53]; p=0.03) and pulmonary (HR 2.63 [1.50–4.62]; p=0.001) systems was significantly associated with mortality.

Conclusion: In patients with SLE, organ damage predicts mortality, in particular damage in the renal, nervous, cardiovascular and pulmonary systems. Neuropsychiatric damage is most common in early disease while musculoskeletal damage is most frequent in long-standing disease. Prevention of infective and cardiovascular complications, and minimization of renal damage is important in improving the survival of SLE.

Background/Purpose: Due to observed disparities in health outcomes in Systemic Lupus Erythematosus (SLE) across racial/ethnic groups, socioeconomic status, or health care systems, studies on group comparisons can highlight important contextual influences on health outcomes. However, comparative research requires the measurement tool used to quantitate such health outcomes to have similar measurement qualities across settings (Measurement Equivalence). This property focuses on the internal structure of multi-item instruments. Currently measurement equivalence data is not available on any of the SLE specific patient reported outcome tools. Herein, we present measurement equivalence properties of various language versions of the LupusPRO that were tested across nations.

Methods: Data from the SOUL study (Study of Outcomes in Lupus) collected during cross-cultural validation studies of the LupusPRO in various languages were utilized: English [USA (n=180), Canada (n=123), Philippines (n=100)], Spanish [USA (n=121), Mexico (n=34), Argentina (n=56)] and Turkish (Turkey n=102). Confirmatory factor analysis (CFA) was conducted with the LupusPRO ítem responses using a robust weighted least squares estimator. The goodness of fit parameters used were the Comparative Fit Index (CFI) and Tucker-Lewis Index (TLI). In addition, item to factor loadings were tested. For measurement equivalence, a logistic regression approach was used to test for differential Item functioning (DIF) in each LupusPRO scale item across languages, while conditioning on the aggregate sum score for each LupusPRO score. The magnitude of DIF was quantified by a pseudo R^2 difference measure and $\geq$2 % variance was considered significant DIF across languages

Results: Results of the CFA lend empirical support for the conceptual framework of the LupusPRO across languages. The model fit for the hypothesized item to scale relationships was good (CFI=0.94–0.98, TLI=0.95–0.99). In addition, item to factor representing the hypothesized item to scale relationships were also satisfactory. In general, items loaded >0.6 with their respective factor. Of the 43 LupusPRO items, only 6 items showed a marginal DIF: (1) woke up feeling worn out, (2) worried about losing income, (3) lacked control over appearance, (4) ability to plan activities and schedule events, (5) received comfort/strength from spiritual/religious beliefs, and (6) doctor was accessible when I had questions. Some of these could be due to cultural differences.

Conclusion: Since the LupusPRO demonstrates measurement equivalence across languages, it can now be used for comparative research

studies to gain better insight into health outcomes disparities or effects of interventions across various groups of SLE patients in cross-national studies. Further evaluation and analysis of the items showing DIF are ongoing.

Vascular Cell Adhesion Molecule (VCAM-1) and Angiostatin in Systemic Lupus Erythematosus. Adnan Kiani[1], Hong Fang[1], Tianfu Wu[2], Chandra Mohan[3] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [3]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Vascular cell adhesion molecule-1 (VCAM-1), an adhesion molecule, is involved in the progression of glomerular and tubulo-interstitial injury. High levels of VCAM-1 have been found in the urine of patients with active lupus nephritis. Angiostatin, due to its anti-inflammatory action, has been shown to improve kidney function in murine models. Over expression of angiostatin inhibits leukocyte and macrophage migration and recruitment. We investigated both VCAM-1 and angiostatin as potential biomarkers for lupus nephritis.

Methods: VCAM-1 and angiostatin were measured during 2 to 16 clinic visits in 17 SLE patients (82% female, 42% African-American, 45% Caucasian, and 13% others) for a total of 88 visits by ELISA (R&D). Mean age was 38 years. We analyzed the relationship between these potential urine biomarkers and the urine protein/creatinine ratio (urine Pr/Cr), the SLICC Renal Activity Score, SLEDAI renal descriptors and other clinical variables.

Results:

Table 1. Mean (SD) Log-transformed and Normalized (by urine creatinine) VCAM-1 and Angiostatin, by Clinical Variables at Each Visit

	Clinical Variables at Each Visit	VCAM-1		Angiostatin	
		Mean (SD)	P-value*	Mean (SD)	P-value*
Age, years	21–.44 (n=65)	9.1 (2.4)	0.99	5.1 (1.6)	0.019
	45–.70 (n=23)	9.2 (1.2)		6.1 (1.8)	
Sex	Female (n=72)	9.2 (2.3)	0.63	5.4 (1.6)	0.77

Pyuria	Present (n=10)	9.7 (1.4)	0.94	5.2 (1.4)	0.74
	Absent (n=78)	9.0 (2.2)		5.4 (1.8)	
Anti-dsDNA	Present (n=37)	9.9 (0.9)	0.088	5.6 (1.8)	0.31
	Absent (n=51)	8.6 (2.5)		5.2 (1.6)	
Low C3 or C4	Present (n=31)	10.1 (1.0)	0.059	5.6 (1.9)	0.12
	Absent (n=55)	8.6 (2.4)		5.3 (1.6)	
Urine Protein/ Creatinine Ratio	≥0.5 (n=64)	9.6 (1.2)	0.022	5.9 (1.6)	<0.0001
	<0.5 (n=22)	8.0 (2.9)		3.8 (1.0)	
Renal Failure	Ever (n=3)	7.8 (1.1)	0.28	4.6 (1.2)	0.12
	Never (n=85)	9.2 (2.1)		5.4 (1.7)	
Hydroxychloroquine	Yes (n=66)	8.9 (2.3)	0.22	5.4 (1.8)	0.41
	No (n=22)	9.8 (1.2)		5.5 (1.6)	
Diabetes mellitus	Present (n=9)	9.9 (1.1)	0.38	6.7 (1.3)	0.096
	Absent (n=79)	9.0 (2.2)		5.2 (1.7)	
Use of ACE/ARB inhibitor	Yes (n=64)	9.2 (2.1)	0.36	5.5 (1.7)	0.79
	No (n=24)	8.9 (2.3)		5.1 (1.7)	
SLICC Renal Activity Score	≥4 (n=51)	9.8 (1.1)	0.036	6.1 (1.6)	<0.0001
	<4 (n=29)	8.4 (2.7)		4.2 (1.3)	

*P-values are based on a mixed effects model to account for the fact that some patients contributed multiple observations.

Conclusion: Both urine VCAM-1 and angiostatin had a strong association with multiple renal activity descriptors. However, in contrast to a previous murine study which showed angiostatin may improve kidney function, our study showed the reverse (Am J Physiol Renal Physiol 2009:F145–152). Further studies of urinary VCAM-1 and angiostatin with larger sample size, and long-term renal outcomes ARE justified.

Clinical Presentation, Treatment and Outcome of Membranous Nephropathy in SLE: A Comparison with Proliferative Lupus Glomerulonephritis in 141 Patients. Chi Chiu Mok, Ling Yin Ho and Ka Lung Yu. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To study the presentation and outcome of membranous nephropathy in SLE in comparison with proliferative lupus glomerulonephritis.

Methods: Patients with biopsy firmed active lupus nephritis who were recruited in our randomized comparative trial of mycophenolate mofetil (MMF) vs tacrolimus (Tac) were studied. Participants were divided into 3 groups: group 1 (pure membranous lupus Gn: RPS/ISN class V); group 2 (mixed membranous and proliferative Gn: class V+III or IVS/IVG) and group 3 (proliferative lupus Gn: IVS/IVG). The clinical presentation, treatment response, outcome and complications were compared.

Results: 141 patients were studied (92% women; age 35.2±12.8 years; SLE duration 49.3±62 months at renal biopsy). There were 25 patients (18%), 31 patients (22%) and 85 patients (60%) in group 1, 2 and 3, respectively. At presentation, group 1/2 patients had significantly higher hemoglobin level (11.3±1.8 vs 9.9±1.7g/dL), creatinine clearance (CrCl) (90.0±31 vs 69.7±27ml/min), complement C3 level (0.62±0.27 vs 0.42±0.16g/L) but lower serum Cr (70.8±25 vs 91.5±33umol/L) and anti-dsDNA titer (166±116 vs 234±89IU/ml;p<0.001) than that of group 3 patients (p<0.001 in all). 18 (32%) patients in group 1/2 had normal range C3 or anti-dsDNA, compared to 3 (4%) patients in group 3 (p<0.001). Nephrotic syndrome was more common in group 1/2 than group 3 (46% vs 32%; p=0.08). Blood pressure and serum albumin level was similar among the 3 groups. SLE disease activity index (SLEDAI) score was significantly lower in group 1/2 than group 3 patients (13.5±4.9 vs 18.0±5.3 points; p<0.001). Extra-renal activity was less common in group 1/2 than group 3 patients, but the difference was only statistically significant for arthritis (25% vs 42%; p=0.04). All patients were treated with high-dose prednisolone and either MMF (N=72) or Tac (N=69), followed by low-dose prednisolone and azathioprine for maintenance. Complete response to induction treatment at 6 months, defined as urine P/Cr of <1.0, resolution of active urine sediments, improvement in lupus serology and stabilization of CrCl, was less common with group 1/2 than group 3 patients (45% vs 62%; p=0.10). After a mean of 48.5±21 months, the cumulative risk of loss in 30% of CrCl compared to baseline was 4.6% at year 1, 6.3% at year 3 and 18% at year 5. Group 1/2 patients did not differ significantly from group 3 patients in terms of decline in CrCl (HR 0.46[0.15–1.46];p=0.19, adjusted for age, sex, SLE duration, initial CrCl and treatment arms). There were 4 arterial events (2 acute coronary syndrome; 2 cerebrovascular accidents) and 1 venous event (deep vein thrombosis) - all occurred in group 1/2 patients (compared with group 3; p=0.01). Infections (major and minor) were numerically more common in group 1/2 than group 3 patients.

Conclusion: The presence of histological membranous component in lupus nephritis is associated with heavier proteinuria, better renal function but less active lupus serology or extra-renal activity such as arthritis. One-third of patients have either normal complements or anti-dsDNA. Renal function decline in membranous lupus nephropathy is no different from proliferative lupus nephritis at 5 years, but thrombotic complications are more frequent.

1414

Combination of Mycophenolate Mofetil and Tacrolimus for Refractory Lupus Nephritis: A 12-Month Open-Labeled Trial. Chi Chiu Mok, Pak To Chan, Ling Yin Ho and Ka Lung Yu. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To evaluate the efficacy and tolerability of a combination of mycophenolate mofetil (MMF) and tacrolimus (Tac) for refractory lupus nephritis

Methods: Patients with refractory lupus nephritis were recruited. Inclusion criteria: (1) Active nephritis documented by renal biopsy within 24

months; (2) Failure to respond to =2 regimens which consisted of high-dose corticosteroid combined with another non-corticosteroid immunosuppressive agent together with ACE inhibitors. Each regimen should be used for [3]4 months at the maximally tolerated dosages of drugs. Exclusion criteria: (1) Previous intolerance to either MMF/Tac; and (2) Scr >200umol/L. Treatment failure to previous regimens, defined as any one of the following: (1) Failure of proteinuria to improve to <3g/day or urine protein-to-creatinine (uP/Cr) ratio to <3.0; or <50% of pre-treatment values; (2) Deteriorating Scr by [3]20% or loss in creatinine clearance (CrCl) by [3]30% not accounted by causes other than active nephritis; (3) Persistently active urinary sediments (RBC, active cellular casts [3]5/HPF). While prednisolone (£10mg/day) and ACE inhibitors were continued, other immunosuppressive agents were replaced by combined MMF (1g/day) and Tac (4mg/day). Patients were followed 2-monthly for the primary end-point (clinical response) at 12 months and adverse events.

Results: 18 patients (17 women) were recruited. The mean age of these patients was 35.3±9.9 years and the mean SLE duration was 112±46 months. The distribution of the ISN/RPS histological classes of lupus nephritis were: class IV/III (33%), pure V (39%), V+III/IV (28%). Previous treatment regimens were: high-dose prednisolone (100%), CYC (pulse/oral) (39%), AZA (89%), MMF (89%), CSA (28%) and Tac (39%). The mean Scr, CrCl, uP/Cr, and serum albumin was 83.6±29umol/L, 83.9±30ml/min (56% <90ml/min), 3.00±1.3 and 29.4±5.7g/L, respectively. Twelve (67%) patients had active urinary sediments and 13 (72%) patients had active lupus serology. After 12 months, 7 (39%) patients had very good response (uP/Cr<0.5; return of lupus serology to baseline; improvement/stabilization of CrCl; and resolution of urinary sediments), 1 (6%) patient had good response (uP/Cr<1.0; improvement in lupus serology and urinary sediments; and stabilization of CrCl) and 3 (17%) patients had partial response (50% improvement in uP/Cr and to <3.0; improvement in serology and urinary sediments; and stabilization of CrCl). Seven (39%) did not respond to the protocol and required further salvage treatment. For those patients who responded to treatment, significantly improvement in uP/Cr, serum albumin and anti-dsDNA titer was observed. CrCl in these patients did not change significantly. 27 adverse events were reported: major infection (7%), minor infection including herpes zoster (41%), diarrhea (7%), dyspepsia/anorexia (7%), transient increase in serum Cr (7%), cramps (7%), alopecia (4%), facial twitching (4%), diabetes mellitus (4%) and others (11%). None of these had led to protocol withdrawal.

Conclusion: Combined MMF and Tac is a viable option for refractory lupus nephritis, with 61% patients improves after 12 months without significant adverse effects.

1415

Effect of Renal Disease On Survival of Patients with Systemic Lupus Erythematosus: A Prospective Cohort Study of 694 Patients.
Chi Chiu Mok[1], Raymond Kwok[2] and Paul Yip[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]University of Hong Kong, Hong Kong, Hong Kong

Background/Purpose: To study the effect of renal disease on survival and life expectancy of patients with systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled >=4 ACR criteria for SLE who were prospectively followed in our unit from 1995 to 2011 were studied. The cumulative survival rate was calculated using Kaplan Miere's plot. The standardized mortality ratios (SMR) (adjusted for age and sex) compared to the general population within the same period of time was worked out. The effect of renal involvement, different histological classes, renal damage and end stage renal failure on survival of SLE was also evaluated by the Cox proportional hazard models, with adjustment for age, sex and use of various immunosuppressive drugs.

Results: 694 patients were studied (92% women; mean age of onset of SLE 32.9±13.4 years). 368 (53%) had evidence of renal disease according to the ACR definition (persistent proteinuria of >=0.5g/day; cellular casts or histological evidence). 285 (77%) patients had undergone renal biopsy for at least 1 time. The distribution of histological classes (ISN/RPS) was: class I (1%), class II (6%), class III (19%), class III+V (10%), class IV (47%), class V (16%) and others (1%). The mean follow-up time was 9.6±7.3 years, 79 (11%) had renal damage as assessed by the SLE damage index (SDI) and 24 (3%) patients developed end stage renal failure (ESRF). The cumulative 5, 10 and 15 year survival of patients with renal involvement was 92.3%, 88.8% and 84.3%, respectively (significantly lower than that of patients without renal disease [97.0%, 93.7% and 91.6%, respectively; log rank test p=0.004]). Cox regression demonstrated the age and sex adjusted hazard ratio (HR) of

mortality in patients with renal disease and renal damage compared with those without renal was 2.23 [1.29–3.85] (p=0.004) and 3.59 [2.20–5.87] (p<0.001), respectively. The corresponding HR ratio for mortality in patients who developed ESRF was 9.20 [4.92–17.2] (p<0.001). Patients with proliferative types of lupus nephritis (class III, IV±V) had significantly increased mortality (adjusted HR 2.28[1.22–4.24]; p=0.01). In contrast, pure membranous lupus nephropathy was not associated with increased mortality (adjusted HR 1.09 [0.38–3.14]; p=0.88). The age and sex adjusted SMRs of all SLE patients, SLE patients with renal disease, proliferative nephritis, pure membranous nephropathy, renal damage and renal failure compared to the general population were 7.3[5.7–9.3], 9.1[6.7–12.0], 9.8[6.5–14.1], 6.2[2.0–14.4], 13.9[9.1–20.4] and 63.1[33.6–108], respectively. All patients with proliferative or membranous lupus nephritis were treated with glucocorticoids, and the proportion of patients who had ever received other immunosuppressive agents in combination was: azathioprine (89%), cyclophosphamide (51%), MMF (50%), cyclosporin A (31%), tacrolimus (38%) and hydroxychloroquine (68%). Adjustment for the use of immunosuppressive regimens in the Cox regression models above did not materially affect the overall hazard ratios for mortality.

Conclusion: The presence of renal disease, in particular proliferative types of nephritis causing renal function impairment, significantly increases the mortality risk of patients with SLE.

1416

Tumor Necrosis Factor Alpha Is Associated with Mood Disorders in Patients with Systemic Lupus Erythematosus.
Mariana Postal[1], Aline T. Lapa[1], Nailu A. Sinicato[1], Karina Peliçari[1], Lilian Costallat[2] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Brazil, [3]State University of Campinas, São Paulo, Brazil

Background/Purpose: Elevated serum levels of tumor necrosis factor alpha (TNF-α) have been reported in patients with major depressive disorder and in patients with depression in multiple sclerosis. However, the association between activation of the immune system, levels of proinflammatory cytokines and mood disorders is still unknown in systemic lupus erythematosus (SLE).

Objective: To determine if increased serum levels of TNF-α are associated with mood disorders in SLE.

Methods: We included 153 SLE patients (women 148; mean age 32.16±14.49; range 10–67) and 41 healthy (women 32; mean age 31±12.04; range 12–59) age and sex matched controls. Mood disorders were determined through Becks Depression and Becks Anxiety Inventory in all participants. The total score ranges from 0 to 63 for BDI and BAI. The cutoffs used for the BDI were: 0–13: no/minimal depression; 14–19: mild depression; 20–28: moderate depression; and 29–63: severe depression and for the BAI: 0–7: no/minimal level of anxiety; 8–15: mild anxiety; 16–25: moderate anxiety; 26–63: severe anxiety. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Serum samples were obtained from all participants in the absence of infections. TNF-α levels were measured by enzyme-linked immunosorbent assay using commercial kits from R&D Systems. Mann-Whitney Test was used to compare TNF-α concentrations between groups. Multivariate analysis was performed including sex, age, SLE duration, disease activity, and cumulative damage, severity of depression and anxiety and current drug exposures.

Results: Depression was identified in 70 (45.7%) SLE and in 10 (25%) controls (p<0.001). Anxiety was identified in 93 (60.7%) SLE and in 17 controls (41.5%) (p<0.001). Serum TNF-α levels were increased in individuals with depression (p<0.001) and with anxiety (p=0.037). A direct correlation between the severity of depression and serum TNF-α levels (r=0.15; p=0.023) was observed. TNF-α levels were significantly increased in patients with active disease (SLEDAI≥3) (p=0.007) and with current prednisone dosage (p<0.001). In addition, we observed a correlation between serum TNF-α levels and SLEDAI (r=0.23, p=0.004) and with current prednisone dosage (r=0.18; p=0.031). No association between TNF-α levels and other clinical, laboratory variable and SDI scores was observed. No difference in TNF-α levels was observed between patients with and without hydroxicloroquine or other immunosuppressants. In the multivariate analysis, serum TNF-α levels were independently associated with depression (OR=3.1; 95%CI 1.8–5.6) and with disease activity (OR=4.4; 95%CI 1.3–7.1).

Conclusion: Serum TNF-α levels are elevated in individuals with mood disorders. In SLE, serum TNF-α levels were independently associated with

depression and with disease activity. The etiology of mood disorders is still debated in SLE, but our findings suggest the presence of immunological basis for depression in SLE.

Favorable Response to Belimumab At Three Months. Katrina M. Shum[1], Jill P. Buyon[1], H. Michael Belmont[1], Andrew G. Franks[2], Richard Furie[3], Diane L. Kamen[4], Susan Manzi[5], Michelle Petri[6], Rosalind Ramsey-Goldman[7], Chung-E Tseng[1], Ronald F. van Vollenhoven[8], Daniel Wallace[9] and Anca Askanase[1]. [1]NYU School of Medicine, New York, NY, [2]New York University, New York, NY, [3]North Shore-LIJ Health System, Lake Success, NY, [4]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC, [5]West Penn Allegheny Health System, Pittsburgh, PA, [6]Johns Hopkins University School of Medicine, Baltimore, MD, [7]Northwestern University Feinberg School of Medicine, Chicago, IL, [8]The Karolinska Institute, Stockholm, Sweden, [9]Cedars-Sinai/UCLA, Los Angeles, CA

Background/Purpose: Belimumab (Benlysta) is a monoclonal antibody that inhibits soluble B-Lymphocyte Stimulator and improves SLE disease activity. This study was initiated to evaluate the use of Belimumab in academic SLE clinical practices.

Methods: An invitation to participate was sent to 16 physicians experienced in SLE Phase III clinical trials. All agreeing to participate completed a one page questionnaire for each patient prescribed Belimumab. The questionnaire contained demographic information on each patient (age, gender, race/ethnicity), SLE data (duration of disease, SELENA-SLEDAI, clinical manifestation(s) targeted, background medications), and Belimumab information (start date, clinical response, side effects). Clinical response was defined as the investigator's impression of a ≥50% improvement in the initial manifestation being treated and no worsening in other organ systems.

Results: Of 16 invitations sent, ten investigators accepted to participate in the study. Questionnaires on 83 treated patients were returned. The mean age was 43.9±11.2 years old, 94% were female, 65.1% White, 24.1% Black, 8.4% Asian, and 6.0% Hispanic. The average SLE disease duration was 11.1±8.4 years. All patients were ANA positive. Concomitant medications included: antimalarials in 74.7% immunosuppressants in 75.9% (Azathioprine 19.3%, Mycophenolate Mofetil 43.4%, Methotrexate 13.3%), and prednisone in 72.3% (average dose of 11.3±11.5 mg, 63.3% on ≥10 mg). Only 2.4% of patients were not on background SLE medications. The dominant clinical manifestation driving treatment was arthritis (74.7%) followed by rash (41.0%) and serositis (15.7%). Other SLE manifestations included renal (7.2%, 4 membranous, 2 proliferative), hematological (8.4%), and inability to taper steroids (8.4%). Approximately half of patients (55.4%) had two or more active manifestations. Forty-two patients were on Benlysta for at least 3 months. Of those, 23 (55%) patients clinically responded by 3 months with marked improvement in arthritis and/or rash. Twenty-three patients were on Benlysta for at least 6 months. Of those, 14 (60.9%) patients clinically responded with improvements in arthritis and/or rash. Of the 6 patients in whom Benlysta was discontinued, 2 had CNS lupus, 1 MI, 1 infection, 1 infusion reaction, and 1 elective surgery.

Conclusion: These early data support the use of Benlysta across all ethnic groups and efficacy similar to that reported in the Phase III trials. Relevant to physician and patient decision making, improvement was observed within 3 months.

Directed Intuitive Assessment of Lupus (the DIAL system for real world clinics) Correlates Well with BILAG and SLEDAI. Anca D. Askanase[1], Katrina M. Shum[1], Stan Kamp[2], Fredonna C. Carthen[2], Teresa J. Aberle[2] and J.T. Merrill[2]. [1]NYU School of Medicine, New York, NY, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Disease activity measures used in SLE clinical studies, including the SLEDAI (SLE Disease Activity Index) and BILAG (British Isles Lupus Assessment Group) index are challenging due to potential scoring pitfalls, and require extensive training and experience. This leaves a busy clinician with limited tools for tracking SLE patients to ensure quality care and documentation of treatment targets. The SLEDAI physician's global assessment (PGA) is simple to learn and efficient to use, but compresses assessment of moderate to severe disease into a small region of the scale, limiting the ability to evaluate change. Also, no organ specific evaluation is performed.

Directed Intuitive Assessment of Lupus (DIAL) is a pilot application composed of seven anchored visual analogue scores (0–100mm each) representing the most common organs affected by SLE: mucocutaneous, neuropsychiatric, musculoskeletal, cardiorespiratory, renal, hematologic, or other (for more rare conditions). The physician selects the scale(s) for active organ(s) and rates disease severity using simple anchored landmarks based on the SLEDAI system: 0=no disease, 1=mild, 2=moderate, and 3=severe. Only features due to active SLE are rated. The total DIAL score is the sum of scores for active organs. This enables both organ-specific distinctions and a wider spectrum of change.

This study was initiated to compare BILAG, SLEDAI and DIAL scores.

Methods: A prospective real world clinic exercise was performed by evaluating 91 consecutive SLE patients in two rheumatology clinics. SLEDAI, BILAG, and DIAL scores were recorded. The level of agreement was determined by the strength of Spearman rank correlations.

Results: The study included 86 women and 5 men, mean age 42.1 years, 54% Caucasian, 31% African, 14% Asian, 24% Hispanic. 70(77%) patients were taking antimalarials, 53(58%) immunomodulators, and 40(44%) prednisone (11>10 mg). 17(19%) were rated as flaring at the time of the assessment. The median (range) SLEDAI was 4.0(0–28), BILAG 2004 score 8.0(0–32) representing a broad spectrum from minimal to severe disease. The median PGA (on 100mm scale) was 38(4–92) vs the total DIAL score 50(0–268). 33 patients were rated moderate-severe (≥1.5 on PGA) and their median PGA was 66(50–92) vs DIAL 100(50–268) confirming a wider distinction potential of comparative scores. The total DIAL score correlated well with the PGA, SLEDAI, and BILAG summary scores (correlation coefficients of 0.90, 0.82, and 0.93 respectively, p<0.0000002 for all). The DIAL scores for musculoskeletal and mucocutaneous domains correlated with the corresponding BILAG domain scores at 0.92 and 0.94 (p<0.0000002). The DIAL index took only a few seconds to score.

Conclusion: This simple, intuitive measurement of disease severity performed reliably at two clinics. The advantage over the PGA is ability to distinguish involvement of different systems and more range to assess change in moderate/severe disease. Community input, refinement and formal validation of the DIAL system is planned. The final product of this work (which could be amenable to paper or encrypted electronic applications) could improve treatment justification, documentation of progress and standard of care for lupus patients.

Infections Increase Risk of Arterial and Venous Thromboses in Systemic Lupus Erythematosus Patients: 4925 Patient Years of Follow-up. Renata Baronaite Hansen[1] and Søren Jacobsen[2]. [1]Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark, [2]Copenhagen University Hospital, Copenhagen, Denmark

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk of developing coronary heart disease as well as infections. Acute infections have been recognized to be associated with the development of arterial coronary events and previous studies have also demonstrated an increased risk of deep venous thrombosis and pulmonary embolism following an infection in general population. Our aim was to determine if there is an association between infections and risk of arterial and venous thrombotic events in patients with SLE.

Methods: Based on both retrospectively and prospectively collected data on 571 adult SLE patients fulfilling the ACR classification criteria, we identified all cases of acute infections requiring hospitalization, cutaneous herpes zoster, as well as arterial and venous thrombotic events. For each patient, the start of follow-up was the date of SLE diagnosis, and the end of follow-up was date of death or most recent information recorded.

Patients were divided into 3 groups based on infection type: respiratory, cutaneous herpes zoster and other (urinary tract, cerebral, gastrointestinal, gynecological, cutaneous infections, bacteremia and bacterial endocarditis). Period of interest (POI) was defined as one year following an infection. Poisson regression analysis was used to estimate relative risks (RR) and their 95% confidence intervals (CI).

Results: Of the 571 enrolled patients 89% were female and the mean age at diagnosis was 36 ± 16 years. The mean length of follow-up was 8.9 ± 7.6 years. The total amount of patient years of follow-up was 4925 years. 271 infections (104 acute respiratory, 41 cutaneous herpes zoster and 126 other acute infections),

as well as 98 arterial and 61 venous thromboses were identified. The table presents number of infections, number of thromboses during and outside POI, RR and corresponding 95% CI for arterial and venous thromboses in patients with different infection types.

Table 1. Association between infections and thrombotic events in SLE patients

Type of infection	Infection, n	Arterial thromboses during POI, n/ Months at risk, n	Arterial thromboses outside POI, n/Months at risk, n	Arterial thromboses RR (95% CI)	Venous thromboses during POI, n/ Months at risk, n	Venous thromboses outside POI, n/ Months at risk, n	Venous thromboses RR (95% CI)
Respiratory	104	5/1078	93/60162	3.00 (1.22–.7.38)	6/1078	55/60162	6.09 (2.62–.14.1)
Other	126	5/1299	93/59941	2.48 (0.99–.6.21)	2/1299	59/59941	1.56 (0.37–.6.59)
Cutaneous herpes zoster	41	2/409	96/60831	3.10 (0.89–.12.9)	0/409	61/60831	Not calculated

Conclusion: Our data showed that SLE patients were at increased risk of developing an arterial thrombosis within 12 months following a respiratory infection, and similar risk was observed for cutaneous herpes zoster and other infections. For venous thrombosis, the risk was increased following respiratory infections, but not following cutaneous herpes zoster or other infections. These data suggest that the increased risk of thromboses observed in SLE patients may also be partly explained by infections. To our knowledge, this is the first study describing an association between infections and risk of thromboses in SLE patients.

1420

Ethnicity and B Cell Depletion Therapy in Systemic Lupus Erythematosus. A. Lois-Iglesias[1], J. Ishorari[2] and D.A. Isenberg[2]. [1]University Hospital Ramón y Cajal, Madrid, Spain. University College London, London, United Kingdom, [2]University College London, London, United Kingdom

Background/Purpose: The aim of this study was to determine if there is any relation between ethnicity and outcome in patients with SLE treated with B cell depletion therapy (BCDT).

Methods: Between June 2000 and December 2011, 102 SLE patients received BCDT in our centre. The mean age was 31 years old. 92,2% were female. 41.2 % of them (42) received at least two cycles. It was administered intravenously, each cycle consisting of: cyclophosphamide 750–1500 mg, methylprednisolone 125–250 mg and rituximab 1 g, on 2 occasions, 2 weeks apart.

In this observational study we reviewed the disease activity assessments at the time of BCDT and six and twelve months later using the British Isles Lupus Assessment Group (BILAG) activity index, and the serological markers C3 and anti-dsDNA antibody levels.

Complete remission (CR) was defined as the loss of all BILAG A or B scores (to a C or D score). Partial remission (PR) was a change from a BILAG A or B score to a C or D score in at least 1 system, but with the persistence of 1 or more A or B scores in another system. No improvement was defined as a BILAG A or B score that remained unchanged after treatment. Worsening was also noted (no improvement and worsening = other, see below).

Results: In our cohort at the time of the initial BCDT 46 patients (45.1%) were Caucasian (C), 28 (27.4%) Afrocaribbean (AC), 21 (20.6%) Asian (As) and 7 (6.8%) Oriental (O). In the second cycle 13 (31%) were C, 16 (38.1%) AC, 11 (26.1%) As and 2 (4.8%) O.

There were no statistically significant differences between the ethnic groups in terms of gender, mean age and mean BILAG total score at the time of BCDT.

For our analysis we excluded the Oriental patients because of their small number. We had sufficiently complete data on 80 patients for the analysis.

After the first and second cycle of BCDT the rates of complete remission, partial remission and other outcomes including worsening (CR/PR/other) were as follows:

	6 months after BCDT 1st cycle	12 months after BCDT 1st cycle	6 months after BCDT 2nd cycle	12 months after BCDT 2nd cycle
C	37.5%/22.5%/40%	37.8%/24.3%/37.8%	38.5%/7.7%/53.8%	33.3%/16.7%/50%
AC	38.1%/9.5%/52.4%	45%/5%/50%	28.6%/28.6%/42.9%	53.9%/7.7%/38.5%
As	36.8%/15.8%/47.4%	42.1%/15.8%/42.1%	33.3%/22.2%/44.4%	16.7%/33.3%/50%

These differences between the ethnicities were not statistically significant (p>0.05) and there were no significant differences between groups with respect to the number of patients who increased their C3 by 25% from baseline or decreased their anti-dsDNA antibody level by 50% or more.

Conclusion: Our data suggest that BCDT is equally effective in SLE patients of Caucasian, Afrocaribbean and Asian. However, a larger sample size is recommended to confirm this.

1421

Antimalarials Protect Systemic Lupus Erythematosus Patients From Damage Accrual During the First Five Years of the Disease. Ioana Ruiz-Arruza, D. D. Gladman, Dominique Ibanez and Murray B. Urowitz. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Studies in the last 20 years have demonstrated that antimalarials (AM) prevent flares, protect from damage accrual, reduce the risk of thrombosis and increase survival, making them one of the cornerstone treatments for lupus. The aim of this study was to examine whether damage accrual, measured with the SLICC/ACR DI, over a 5 year period is reduced with the previous use of AM.

Methods: The present study was designed as a nested case-control embedded in an inception cohort of patients with SLE from our Lupus Clinic database, a long term prospective observational cohort study. All subjects fulfilled 4 of the ACR classification criteria or 3 ACR criteria plus having a histological lesion indicative of SLE.

All patients who had SLICC/ACR DI of 0 at inception and developed first damage in the time between the initial and the last follow-up visit at 5 years were considered cases. Two controls, comprising lupus patients in whom damage did not develop, were identified for each case and matched for known confounders for the development of damage: age, sex and disease activity at enrolment measured by the SLEDAI-2K.

AM exposure was classified as *never* or *ever* if patients were on either chloroquine or hydroxychloroquine at any visit prior to the onset of damage or during the 5 year interval for the controls.

Comparisons between cases and controls were made using descriptive statistics. Time to presence of damage was compared using Kaplan-Meier curves and time-dependent covariate proportional hazard models.

Results: 719 patients constituted the inception cohort. 490 had the first SLICC/ACR DI measure available within the first year and equal to 0. From the 354 who had at least 5 year follow-up in the clinic, 77 developed damage during the study period and 75 could be matched to 150 controls with no damage.

At first clinic visit, there were 84% women in both groups, with a mean age of 38.5 years in both groups and a SLEDAI-2K of 10.9 in the cases and 9.5 in the controls.

In the univariate analysis AM use was associated with a protective effect for the development of damage (cases 49.3% vs controls 70.7% p=0.002).

Analyzing the damage free survival with Kaplan-Meier curve, AM prolonged the time to damage accrual.
In the proportional hazard regression model, AM usage prior to the onset of damage reduced the probability for damage (HR 0.60 95%CI 0.38–0.95 p=0.03).

In further adjusting for potential risk factors (sex, age at diagnosis, disease duration, SLEDAI-2K) in the time-to-event regression analysis, AM was protective (HR 0.62 95%CI 0.39–0.99 p<0.05) and SLEDAI-2K at each visit increased the risk of damage (HR 1.05 95%CI 1.02–1.09 p<0.005).

Conclusion: AM is protective for damage accrual in SLE patients during the first five years of the disease, supporting their use at diagnosis of SLE.

1422

Clinical Associations of Anti-Smith Antibodies in Profile: A Multiethnic Lupus Cohort. Yesenia C. Santiago-Casas[1], Luis M. Vila[1], Gerald McGwin Jr.[2], Ryan S. Cantor[2], Michelle Petri[3], Rosalind Ramsey-Goldman[4], John D. Reveille[5], Robert P. Kimberly[2], Graciela S. Alarcon[2] and Elizabeth E. Brown[2]. [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Univ of Texas Health Science Center at Houston, Houston, TX

Background/Purpose: Anti-Smith (anti-Sm) antibodies are highly specific for systemic lupus erythematosus (SLE) and have an important value in the diagnosis of this disease. However, whether these autoantibodies are associated to a specific subset of clinical manifestations or if they convey a prognostic value in lupus remains controversial. The aim of this study was to determine the association between anti-Sm antibodies and clinical manifestations, comorbidities, and disease damage in a large multiethnic SLE cohort.

Methods: SLE patients (per ACR criteria), age $\geq$ 16 years, disease duration $\leq$ 10 years at enrollment, and defined ethnicity (African American, Hispanic or Caucasian), from a longitudinal cohort were studied. Socioeconomic-demographic features, cumulative clinical manifestations, comorbidities, and disease damage [as per the Systemic Lupus International Collaborating Clinics Damage Index (SDI)] were determined. The association of the anti-Sm antibodies with clinical features was examined using multivariable logistic regression adjusting for age, gender, race/ethnicity, disease duration, education, smoking, and type of medical insurance.

Results: A total of 2,322 SLE patients were studied. The mean (standard deviation, SD) age at diagnosis was 34.4 (12.8) years and the mean (SD) disease duration was 9.0 (7.9) years; 2,127 (91.6%) were women. Anti-Sm antibodies were present in 579 (24.9%) patients. In the multivariable analysis, SLE patients with anti-Sm antibodies were more likely to have serositis (odds ratio [OR] 1.51, 95% confidence interval [95% CI] 1.23–1.84), renal involvement (OR 1.33, 95% CI 1.08–1.64), neurologic involvement (OR 1.51, 95% CI 1.12–2.04), psychosis (OR 1.60, 95% CI 1.01–2.53), vasculitis (OR 1.50, 95% CI 1.17–1.94), Raynaud's phenomenon (OR 1.64, 95% CI 1.34–2.00), hemolytic anemia (OR 1.73, 95% CI 1.28–2.35), leukopenia (OR 1.56, 95% CI 1.28–1.91), lymphopenia (OR 1.76, 95% CI 1.43–2.16), and arterial hypertension (OR 1.32, 95% CI 1.07–1.62). No significant associations were found for mucocutaneous manifestations and damage accrual.

Conclusion: In this cohort of SLE patients, anti-Sm antibodies were associated with several clinical features including serious manifestations such as renal disease, neurologic involvement, hemolytic anemia and vasculitis.

1423

Vascular Thrombosis and Pregnancy Morbidity in Patients with Systemic Lupus Erythematosus with Positive Antiphospholipid Profile and Thrombocytopenia. Amir Haddad, Murray B. Urowitz, Dominique Ibanez and D. D. Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: The trigger for a thrombotic in patients with antiphospholipid antibodies is unknown. Thrombocytopenia is among the most common clinical manifestations of the Antiphospholipid antibody syndrome (APS). The purpose of this study was to investigate whether patients with lupus and positive antiphospholipid profile with thrombocytopenia are at more risk to have obstetric or thrombotic events than patients with antiphospholipid but without thrombocytopenia.

Methods: Patients with SLE and positive antiphospholipid (aPL) profile (Lupus anticoagulant (LA), anticardiolipin (aCL) antibody of IgG and/or IgM isotype or anti-β_2 glycoprotein-I antibody of IgG and/or IgM isotype) and chronic thrombocytopenia (Platelet count<100,000) confirmed for 2 consecutive clinic visits followed at the prospective longitudinal lupus cohort since 1996 were recruited (study group). As controls a group of patients with SLE with positive aPL without thrombocytopenia were selected and matched by sex, age of SLE diagnosis, age at study start, disease duration and length of follow up period. Patients in the lupus cohort are followed at 2–6 month intervals according to a standard protocol which documented the presence of thrombotic events and obstetric morbidity as defined by the revised Sapporo

criteria of APS. Descriptive analysis was used to describe the patients. Kaplan-Meier (KM) curves was used to compare time to 1st event between study groups.

Results: The study group included 21 patients and 63 controls, 81% were females with a mean age of 39.8 $\pm$ 13.0 years and age of SLE diagnosis at 31.7 $\pm$ 14.7 years. The mean disease duration was 8.1 $\pm$ 7.8 years and they were followed for an average of 12.1 $\pm$ 9.3 years.

During the study period, the medication used by cases and controls respectively were: on steroids 86% vs 79% (p=.075); on antimalarials 43% vs 68% (p=0.07); on immunosuppressants 52% vs 43% (p=0.46); on ASA 20% vs 22% (p=1.00); and on anticoagulants 5% vs 10% (p=0.67).

16 events occurred in the study group compared to 43 events in the controls and included 6 Obstetrical morbidities in 2 patients in the study groups compared to 4 events in 2 patients in the controls (KM p=0.17), 9 arterial thrombosis in 4 patients in the study group compared to 24 events in 17 patients in the controls (KM p=0.19) and 1 event of venous thrombosis in 1 patient in the study group compared to 15 events in 10 patients in the controls (KM p=0.19).
Figure 1. The Kaplan-Meier curve for time to 1st event after Study Start.

Conclusion: Thrombocytopenia in patients with antiphospholipid antibodies in SLE is not associated with increased thrombotic events.

Background/Purpose: Infection is a major cause of morbidity and mortality in systemic lupus erythematosus (SLE). Immunosuppression, co-

morbidities, and the disease itself makes patients with SLE susceptible to severe infections (SInf) but the relative contribution each of this factors are not well known. We retrospectively assess the prevalence of SInf and potential differences between patients with or without SInf in a multicentric SLE cohort.

Methods: Patients with SLE on active follow up, with enough data about infection, from the first 684 patients registered on RELESSER. Cumulative clinical data were collected at the moment of the last assessment. SInf was defined by the need for hospitalization. Charlson index (ChI) was use to evaluate comorbidity, and SLICC/ACR/DI (SDI) and Katz index (ISK) to assess damage and SLE severity respectively. We analyzed the impact of infection on SLE mortality in the entire cohort.

Results: 583 SLE patients (92% ≥4 ACR criteria) were included; 88.3% females, mean age: 45.5 years, median SLE duration: 111 months (IQR: 47.8–188.4). 80 patients (14.5%) suffered ≥ 1 SInf (any time). Median SInf: 1(IQR: 1–2). First SInf localization: respiratory: 51.2%, urinary: 16.2% and bloodstream (8.7%), with a predominant bacterial aetiology (42.5%). However, we found an elevated rate of non-isolations (48.7%), likely related to the predominance of respiratory infections. Comparing with patients without SInf, patients with SLE and SInf were older: 50(39–61) [median (P25–75)] vs. 43(34–53) years, p <0.0001, had longer duration of SLE:170 (83–253) vs.103(42–174) months (p <0.0001), more ISK: 4(2–5) vs. 2(1–3), p <0.0001, more SDI:1(0–3) vs. 0(0–1), p <0.0001 and a higher ChI: 3(1–4) vs. 1(1–2), p <0.0001. Furthermore, ≥ 2 SInf also associated with more SDI (p= 0.003), more ISK (p=0.027) and more ChI (p<0.001) comparing with only 1 SInf. In addition, patients with InfG were more frequently hospitalized by SLE (excluding by infection): 80.0% vs. 45.0%, p <0.0001 and treated with corticosteroids (CE): 98.7% vs. 87.6%, p= 0.004, cyclophosphamide (CPM): 40.8% vs.17.3%, p<0.0001, or mycophenolate m. (MPM):33.8% vs. 17.1%, p =0.001(any time), without differences in antimalarials use. At the moment of the first infection, 41 patients (77.4%) were treated with CE, 25(48.1%) with immunosupressors, 5(20%) with CPM and 4(16.0%) with MPM, figures higher than the prevalence of these treatments in the last assessment available in RELESSER, i.e., GC: 51.8%, CPM: 1.1 % and MPM: 12.3%. Only 3 of 24 (12.5%) deceased patients, died by SInf. Excluding patients died by infection, the mortality was higher in SLE with history of SInf (9.6 vs. 1.7%, p<0.000; χ2 Pearson).

Conclusion: Despite being a low-severity cohort, the cumulative incidence of serious infection is high in our SLE patients. These data confirm the respiratory infection as the most common localization of SInf in SLE. An antecedent of severe infection seem to associate to more severe SLE, more mortality and increased comorbidity, although these associations could be related with a longer disease exposure y/or older age.

Circulating Free Protein S Levels May Be Linked to Cardiovascular Events and Venous Thrombosis in SLE.
Gregg J. Silverman[1], John Jung[1], Ehtisham Akhter[2], Michelle Petri[2] and Caroline Grönwall[1]. [1]NYU School of Medicine, New York, NY, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: SLE patients are at risk for diverse organ systems involvement, which increases the challenges for diagnosis and predictions for the development of specific clinical features. In recent studies we have compared traditional and novel serologic markers and identified profiles that correlate with levels of overall clinical disease activity, and for specific organ system involvement (1). In the current studies we extended our studies to surveys of levels of Protein S, a vitamin K dependent factor implicated both in the coagulation cascade and as a ligand for the TAM receptor tyrosine kinase family that regulates inflammatory responses and apoptotic cell clearance.

Methods: In cross-sectional surveys of 90 SLE patients, we assessed levels of free Protein S with a commercial immunoassay. All clinical and experimental data was imported into a customized database where multivariate methods were used to seek natural divisions in the sample set based on a panel of IgM and IgG lupus/apoptosis-associated natural autoantibodies and to relate them to various clinical parameters.

Results: Low Protein S levels correlated with a history of DVT/PE (N=12, Spearman, P<0.0007, R=0.41)(Sens. 0.92, Spec.0.56). These correlations had greater significance than for well known lab correlates, that include high levels of IgG anti-cardiolipin (P=0.007, R=−0.29), IgG anti-β2-GPI (P=0.03, r=−0.23), and RVVT (P=0.001, R=−0.34). Patients with a hx of MI/CVA also had significantly lower levels of free Protein S (N=17, P=0.001 R=−0.34) (Sens. 0.76, Spec.0.56). We found no correlations between protein S and overall SLE disease activity levels by SELENA-SLEDAI, physician's global assessment, or organ damage by the SLICC index, or for nephritis. Although the vitamin K antagonist, coumadin, is reported to affect Protein S levels, we found no significant difference in Protein S levels between those with and without coumadin. For MI/CVA affected patients not treated with coumadin, we found significantly lower levels of Protein S compared to clinically unaffected SLE pts (P<0.01).

Conclusion: Significantly lower levels of free Protein S were found in the subsets of SLE patients with clinical DVT/PE and for MI/CVA events. These findings support the hypothesis that disturbance in levels of the anti-coagulant Protein S may play roles in both venous thrombopathy and cardiovascular events.

Collectively, this study describes a potential biomarker, free Protein S, which identifies a specific SLE subgroup that may be at increased risk for pathogenic mechanisms responsible for thrombotic events and serious CV events. Further investigations of this topic may allow for the development of better diagnostic and prognostic tests and personalized therapies in patients afflicted by SLE.

The Clinical Relevance of a "False Negative" Enzyme Linked Immuno-assay: Which Antinuclear Antibody Screening Test Is Preferred by Rheumatologists in an Integrated Health System?
Rachita Bansal, David Bulbin, Alfred E. Denio, Sandi Kelsey and Harold Harrison. Geisinger Medical Center, Danville, PA

Background/Purpose: Historically, Immunofluorescence Assay (IFA) methodology has been the gold standard for ANA screening. Most clinical laboratories in recent years utilize the Enzyme Linked Immunoassay (ELISA) to screen for ANA rather than IFA as ELISA is automated and less expensive. Studies have suggested the sensitivity and specificity of the two methods are comparable but most of these studies were retrospective and not done in populations of patients referred to rheumatologists. There has been concern among rheumatologists that there may be a high "false negative" rate for ELISA when compared to IFA, potentially affecting a rheumatologist's ability to diagnose patients with connective tissue disorders. We studied the incidence and clinical relevance of a negative ANA by ELISA when the IFA is positive and when ordered by a rheumatologist.

Methods: We conducted a prospective study in a 12 person integrated health system rheumatology practice to determine the rate of "false negative" ANA by ELISA. 200 consecutive negative ELISA ANA's ordered by rheumatologists were subsequently reanalyzed with IFA. We reviewed medical records of these patients and surveyed their rheumatologists regarding the clinical relevance of the positive IFA ANA finding for each patient identified. After their experience with the "false negative" ELISA and after providing the rheumatologists with the lab's comparative costs of the 2 methodologies, their opinion about the most cost effective ANA screening strategy was solicited.

Results: Of 200 consecutive ELISA negative ANA's ordered by rheumatologists reanalyzed using IFA, 15% were positive by IFA. Six% had titers of 1:160 or greater. One was 1:10240. The rheumatologist survey demonstrated that of the 30 patients with false negative ANA by ELISA, the clinical suspicion of an underlying connective tissue disorder remained medium or high in 17 despite the negative ANA. In 8 patients, the clinical suspicion for a connective tissue disorder increased following the finding of a positive ANA by IFA and in 4 patients led to additional testing or start of treatment for a connective tissue disorder. The surveyed rheumatologists by a large majority felt that the abnormal ANA cut off titer should remain 1:160. After experience with each "false negative" ELISA patient and after being provided with cost differences for the IFA and ELISA methodologies, the rheumatologists by a slim majority (14 to 13) recommended continuation of the current lab's practice of screening all ANAs with ELISA rather than the option of

screening rheumatology ordered ANAs with IFA (added lab cost $3,323.50/yr.) No one felt the entire system's ANAs screening should be done by IFA (added cost to lab *$33,465.20/yr.*)

Conclusion: Use of IFA rather than ELISA as initial screening ANA test would rarely change a rheumatologist's patient management decisions. With knowledge of the "false negative" ELISA rate, the system's cost differences between the ELISA and IFA, and experience with their own patients who have had a "false negative", rheumatologists in an integrated health system prefer the ELISA methodology over IFA as initial ANA screen.

Late Onset Systemic Lupus Erythematosus: Is It Actually A Milder Variant?

Juan G. Ovalles-Bonilla[1], Julia Martínez-Barrio[1], Javier Lopez-Longo[1], Inmaculada de la Torre[1], Carlos Gonzalez Fernandez[1], María Montoro Álvarez[1], Francisco Aramburu[1], Carolina Marin[1], Lina Martinez-Estupiñan[1], Juan C. Nieto[2], Michelle Hinojosa[1], Natalia Bello[1], Indalecio Monteagudo[1] and Luis Carreño[1]. [1]Gregorio Marañon Hospital, Madrid, Spain, [2]Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Classically, late onset Systemic Lupus Erythematosus (SLE) has been described as a milder variant of the disease. The objective of this study is to describe the clinical and immunological features, the damage accrual and mortality of late onset compared with adult onset SLE.

Methods: The data was obtained from a long term prospective cohort of 353 patients diagnosed with SLE in the Rheumatology Department of Gregorio Marañon Hospital in Madrid, Spain. Demographic, clinical, and laboratory data were collected at disease onset and during it's course from 1986 to 2006. Patients were divided into 2 groups: adult onset 19–49 years (n=276) and late onset ≥50 years (n=77). Organ damage was scored using the Systemic Lupus International Collaborative Clinics/American College of Rheumatology (SLICC/ACR) Damage Index. Damage accrual was defined as an SLICC/ACR score ≥1. The groups were compared using the chi-square, Fisher-Holton and t-student tests.

Results: A total of 353 patients were recruited, with a following mean time of 11 years. The female to male ratio differed significantly (p=0.005) between groups. At diagnosis, the late-onset group presented cutaneous manifestations less frequently (p<0.001). During follow-up, the late-onset group presented a lower incidence of arthritis (p=0.02), malar rash (p=0.001), photosensitivity (p=0.04), fever (p=0.03), low serum complement (p=0.001), hematologic (p=0.03) and renal (p=0.01) manifestations. The late-onset group had significantly more hypertension (p=0.03), neoplasms (p=0.02), damage accrual (p=0.007) and mortality (p=0.006). As for autoantibody profile, no statistically significant differences were found.

CHARACTERISTICS	Adult Onset 19–49 Years (n=276)	Late Onset ≥50 Years (n=77)	p
At Disease Onset			
DEMOGRAPHIC			
Female/Male Ratio	8.9 (248/28)	3.5 (60/13)	0.005
Age at diagnosis, (range)	31.9 (19–.50)	61.2 (51–.86)	<0.001
CLINICAL MANIFESTATIONS (%)			
Cutaneous	93 (33.7)	8 (10.4)	<0.001
During Follow-up			
CLINICAL MANIFESTATIONS (%)			
Arthritis	254 (92)	64 (83.1)	0.02
Malar Rash	130 (47.1)	17 (22.1)	<0.001
Photosensitivity	147 (53.3)	31 (40.3)	0.04
Fever	103 (37.3)	19 (24.7)	0.03
Hematologic Manifestations	228 (82.6)	55 (71.4)	0.03
Renal Manifestations	124 (44.9)	22 (28.6)	0.01
Hypertension	77 (27.9)	31 (40.3)	0.03
Neoplasms	13 (4.7)	9 (11.7)	0.02
SLICC/ACR (mean ± SD)	1.7 ± 2.1	2.5 ± 2.5	0.007
Mortality	17 (6.2)	13 (16.9)	0.006
Disease duration time (mean ± SD)	12.6 ± 8.6	9.9 ± 7.5	0.01
Low serum complement	220 (81.2)	40 (58)	<0.001

Conclusion: Late onset SLE is clinically different with less arthritis, fever, low serum complement, cutaneous, hematologic and renal manifestations, but with higher mortality and organ damage rates, compared with the adult onset group. The higher frequency of damage accrual, mortality and hypertension observed in the late-onset group can be affected by aging-related factors other than disease activity or duration.

1428

Long-Term Outcomes of Children Born to Women with Systemic Lupus Erythematosus.

Evelyne Vinet[1], Mohammed Kaouache[2], Christian A. Pineau[1], Ann E. Clarke[3], Caroline P. Gordon[4], Robert W. Platt[5] and Sasha Bernatsky[2]. [1]McGill University Health Centre, Montreal, QC, [2]Research Institute of the McGill University Health Ctre, Montreal, QC, [3]MUHC, Montreal, QC, [4]Medical School, Birmingham, United Kingdom, [5]McGill University, Montreal, QC

Background/Purpose: SLE can cause considerable morbidity during pregnancy. Although several studies have evaluated foetal outcome in lupus pregnancy, very few have examined the long-term outcome of children born to mothers with SLE. In a large population-based study, we aimed to determine if children born to women with SLE have an increased risk of major congenital anomalies, serious infections, and cardiac conduction disturbances compared to children born to women without SLE.

Methods: We identified all women who had ≥ 1 hospitalization for delivery after SLE diagnosis using Quebec's physician billing and hospitalization databases (1989–2009). Women were defined as SLE cases if they had any of the following: 1) ≥ 1 hospitalization with a diagnosis of SLE prior to the delivery, 2) a diagnosis of SLE recorded at the time of their hospitalization for delivery, or 3) ≥ 2 physician visits with a diagnosis of SLE, occurring 2–24 months apart, prior to the delivery. We randomly selected a general population control group, composed of women matched at least 4:1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery.

We identified children born live to SLE cases and their matched controls, and ascertained major congenital anomalies (i.e. ≥ 1 hospitalization or physician visit for a major congenital anomaly < 12 months of life), serious infections (i.e. ≥ 1 hospitalization with a primary diagnosis of infection), and cardiac conduction disturbances (i.e. ≥ 1 hospitalization or 2 physician visits occurring 2–24 months apart) through to end of database follow-up.

We performed multivariate analyses to adjust for maternal demographics, sex and birth order of child, major maternal co-morbidities, obstetrical complications, and relevant maternal medication.

Results: 507 women with SLE had 721 children, while 5862 matched controls had 8561 children. Compared to controls, children born to women with SLE experienced slightly more major congenital anomalies [13.6% (95% CI 11.3, 16.3) vs 10.4% (95% CI 9.7, 11.1)], serious infections [31.5% (95% CI 28.2, 35.0) vs 26.0% (95% CI 25.1, 26.9)], and cardiac conduction disturbances [3.1% (95% CI 2.0, 4.6) vs 1.2% (95% CI 1.0, 1.4)]. Mean age at the time of serious infection was 1.8 (95% CI 1.6, 2.0) year for children born to women with SLE and 2.1 (95% CI 2.0, 2.2) years for controls, while mean age at the time of cardiac conduction disturbance was 0.2 (95% CI 0.17, 0.22) year for children born to women with SLE and 1.8 (95% CI 1.7, 1.8) year for controls.

In multivariate analyses, children born to women with SLE had substantially increased rates of serious infections (HR 1.76, 95% CI 1.21, 2.56) and cardiac conduction disturbances (HR 1.90, 95% CI 1.03, 3.52) compared to controls. There was also a trend for an increased risk of major congenital anomalies in children born to women with SLE compared to controls (OR 1.24, 95% CI 0.98, 1.58).

Conclusion: Compared to children from the general population, children born to women with SLE have increased rates of serious infections and cardiac conduction disturbances. Our findings suggest that children born to mothers with SLE might also be at slightly increased risk of major congenital anomalies and prompt further research to elucidate this issue.

1429

Women with Systemic Lupus Erythematosus (SLE) May Have Different Predictors of Risk for Progression of Aorta Calcium (AS) Than Women without SLE. Apinya Lertratanakul[1], Peggy W. Wu[1], Alan Dyer[1], William Pearce[1], George Kondos[2], Daniel Edmundowicz[3], James Carr[4] and Rosalind Ramsey-Goldman[4]. [1]Northwestern University, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]Temple University School of Medicine, Philadelphia, [4]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: Women with SLE have increased rates of subclinical atherosclerosis and cardiovascular (CV) events. We investigated which risk factors may be significant in the rate of subclinical atherosclerosis progression, as measured by AS, in women with (cases) and without (controls) SLE.

Methods: Baseline data were collected on cases and controls including demographics, self-reported and measured Framingham CV risk factors. SLE factors collected included the modified SLICC/ACR-DI Damage Index (SDI) (excluding CV outcomes). AS was measured by electron beam or multi-dimensional computed tomography at baseline and at 1 follow-up visit in the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE). A high risk AS was defined as AS>100 and progression in AS at follow-up was defined as an AS>100 and an increase of >10% compared to baseline. A low risk AS was defined as AS<100. Univariate regression models of AS with risk factors were examined, and also adjusted for age. Presence of hypertension (HTN) was defined as systolic blood pressure (BP) ≥ 140 or diastolic BP ≥ 90 or on anti-HTN medication.

Results: At the baseline visit in 142 cases, their age was 43.3 ± 9.9 yrs, disease duration was 12.0 ± 8.4 yrs, SLEDAI was 3.8 ± 3.5, SDI was 1.5 ± 1.6 (mean ± SD). Imaging data with AS at baseline and follow-up were available on 106 cases; baseline AS scans were not performed in 36 cases. In 120 controls, their age was 46.7 ± 10.1 yrs (mean ± SD). Imaging data with AS at baseline and follow-up were available on 118 controls; 2 were missing baseline AS measurements. Mean ± SD follow-up time between imaging studies in 106 cases and 118 controls was 3.26 ± 0.35 yrs and 3.37 ± 0.41 yrs, respectively. Follow-up time was slightly different between cases and controls (p=0.05).

In 106 cases, 67 (63%) had low risk AS at baseline and at follow-up, 11 (10.4%) had low risk AS at baseline with progression at follow-up, 4 (3.8%) with high risk AS at baseline regressed to low risk at follow-up, and 0 with low risk AS at baseline progressed at follow-up.

In 118 controls, 87 (73%) had low risk AS at baseline and at follow-up, 7 (5.9%) had low risk AS at baseline with progression at follow-up, 2 (1.7%) with high risk AS at baseline regressed to low risk at follow-up, and 0 with high risk AS at baseline progressed at follow-up.

In the women with SLE, AS progression was univariately associated with HTN, current smoking, older age, and higher SDI. After adjustment, only increased SDI remained significant (OR 1.60, 95% CI 1.22–2.16). In controls, AS progression was univariately associated with HTN, current smoking status, older age, and higher BMI. After adjustment, only current smoking status remained significant (OR 6.65, 95% CI 1.55–31.29).

Conclusion: In cases and controls, traditional CV risk factors are univariately associated with the progression of subclinical atherosclerosis as measured by AS. In cases, SLE damage is significantly associated with progression. While aging mediates the effect of many traditional CV risk factors for AS progression in women with and without SLE, increased risk due to SLE damage is independent of age. Further investigation with multivariate models is needed.

1430

Women with Systemic Lupus Erythematosus (SLE) May Have Different Predictors of Risk for Progression of Coronary Artery Calcium (CA) Than Women without SLE. Apinya Lertratanakul[1], Peggy W. Wu[1], Alan Dyer[1], William Pearce[1], George Kondos[2], Daniel Edmundowicz[3], James Carr[4] and Rosalind Ramsey-Goldman[4]. [1]Northwestern University, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]Temple University School of Medicine, Philadelphia, [4]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: Women with SLE have increased rates of subclinical atherosclerosis and cardiovascular (CV) events. We sought to deter-mine which risk factors may be significant in the rate of subclinical atherosclerosis progression, as measured by coronary artery calcium score (CAC) in women with (cases) and without (controls) SLE.

Methods: Baseline data were collected on cases and controls including demographics, self-reported and measured traditional CV risk factors. SLE factors collected included modified SLICC/ACR-DI Damage Index (SDI) (excluding CV outcomes). CAC was measured by electron beam or multi-dimensional computed tomography at baseline and at 1 follow-up visit in the Study of Lupus Vascular and Bone Long-Term Endpoints (SOLVABLE). A high risk CAC was defined as CAC>10 and progression in CAC at follow-up was defined as a CAC>10 and an increase of >10% compared to baseline. Low risk CAC was defined as CAC<10. Univariate regression models of CAC with risk factors were examined. These models were further adjusted for age.

Results: At the baseline visit in 142 cases, the age was 43.3 ± 9.9 yrs, disease duration was 12.0 ± 8.4 yrs, SLEDAI was 3.8 ± 3.5, SDI was 1.5 ± 1.6 (mean ± SD). In 120 controls, the age was 46.7 ± 10.1 yrs (mean ± SD). Follow-up time between imaging studies in 142 cases and 120 controls was 3.25 ± 0.35 yrs and 3.37 ± 0.41 yrs (mean ± SD), respectively. Follow-up time was longer in controls than in cases (p=0.02).

In 142 cases, 103 (73%) had low risk CAC at baseline and at follow-up, 12 (8.5%) had low risk CAC at baseline with progression at follow-up, 2 (1.4%) with low risk CAC at baseline had regression to low risk at follow-up, and 21 (14.8%) with high risk CAC at baseline and progression at follow-up. Four (2.8%) had high risk CAC at baseline and follow-up without progression.

In 120 controls, 100 (83%) had low risk CAC at baseline and at follow-up, 7 (5.8%) had low risk CAC at baseline with progression at follow-up, 3 (2.5%) with high risk CAC at baseline had regression to low risk at follow-up, and 10 (8.3%) with high risk CAC at baseline and progression at follow-up.

In cases, progression in CAC was univariately associated with presence of diabetes, older age, and higher BMI. After adjustment for age, only SDI remained associated with CAC progression (Table 1). In controls, presence of hypertension and older age were univariately associated with CAC progression. After adjustment for age, no risk factors remained significant.

Table 1. Risk Factors Associated with Coronary Artery Calcium Progression in Cases and Controls, Adjusted for Age

Risk Factor	Cases OR (95% CI)	Controls OR (95% CI)
HTN*	1.06 (0.44–2.53)	0.93 (0.24–3.28)
Smoking	0.75 (0.15–2.79)	2.60 (0.46–12.69)
Diabetes	3.42 (0.912–12.88)	NA**
Total cholesterol	1.01 (0.63–1.60)	1.20 (0.67–2.16)
BMI	1.48 (1.00–2.22)	1.16 (0.64–2.07)
SDI	1.56 (1.21–2.05)	NA

*HTN = systolic blood pressure≥90 or on an anti-HTN medication **1 control subject noted having diabetes

Conclusion: In cases and controls, traditional CV risk factors are univariately associated with the progression of subclinical atherosclerosis as measured by CAC. In cases, SLE damage is significantly associated with progression. While aging mediates the effect of many traditional CV risk factors for CAC progression in women with and without SLE, increased risk due to SLE damage is independent of age. Further investigation with multivariate models is needed.

Single Photon Emission Computed Tomography Contributes to Clinical Assessments in Neuropsychiatric Systemic Lupus Erythematosus Patients. Maasa Hama, Mitsuhiro Takeno, Atsushi Ihata, Daiga Kishimoto, Reikou Watanabe, Takeaki Uehara, Ryusuke Yoshimi, Yukiko Asami, Atsuhisa Ueda and Yoshiaki Ishigatsubo. Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background/Purpose: Because the clinical manifestations of NPSLE are diverse, multifaceted approaches are necessary to evaluate the disease activity

and therapeutic responses. We investigated contribution of various CNS examinations to clinical assessment in each subtype of NPSLE.

Methods: We retrospectively analyzed clinical features and the findings of CSF, EEG, CNS imaging modalities including MRI and SPECT in 41 patients (6 male, 35 female) who met ACR 1997 SLE classification criteria with neuropsychiatric symptoms from 2000 to 2011. The patients were categorized into 3 groups according to ACR-defined NPSLE syndromes at 1999; Patients with neurological symptoms (Group N), those with psychiatric symptoms (Group P), and those with the both (Group N+P).

Results: Median age at onset of SLE was 25 years old (range 5–63). About a half of the patients developed neuropsychiatric symptoms within a year from SLE onset. Based on the clinical symptoms such as cognitive dysfunction (37%), acute confusional state (32%), seizure (29%), headache (22%), aseptic meningitis (20%), and cerebrovascular disease (15%), the patients were classified into Group N (16 patients, 39%), Group P (13 patients, 32%), and Group N+P (12 patients, 29%). Pleocytosis and increased protein in CSF were the most frequently found in Group N, whereas increased protein with high IgG index was also observed in a part of patients in Group P. EEG abnormality, especially emergence of slow waves, was more prevalent in group P and N+P than group N. MRI showed any abnormalities in 85 %. Diffuse white matter (WM) high intensity signals in Group N, and cerebral parenchymal atrophy and focal WM high intensity signals in group P and N+P were common. SPECT revealed the hypoperfusion, particularly in the frontal and parietal lobes in all patients but one, even in those having normal MRI. Most patients received potent immunosuppressive therapies including steroid pulse and IVCY, leading to clinical improvement in 69% of Group N but 37.5% of Group P and N+P, irrespective of pre-therapeutic clinical parameters. In 19 patients having follow-up examinations of SPECT, brain perfusion was restored with clinical amelioration responding the therapy in 4 out of 5 patients of Group N. In contrast, hypoperfusion was unchanged or decreased in about 75%, 50% of Group P, N+P, respectively. In the two groups, there was a discrepancy between SPECT findings and clinical course in 5 of 14 patients.

follow-up SPECT
Conclusion: Cerebral hypoperfusion in SPECT was associated with NP lesions in SLE and the findings were closely correlated with disease activity especially in neurological deficits rather than psychiatric symptoms.

1432

Safety and Efficacy of Etanercept in Systemic LUPUS Erythematosus.
Josefina Cortes-Hernandez[1], Natalia Egri[1], Miquel Vilardell-Tarres[1] and Josep Ordi-Ros[2]. [1]Hospital Universitari Vall dxHebron, Institut de Recerca (VHIR), Barcelona, Spain, [2]Vall De Hebron General Hospt, Barcelona, Spain

Background/Purpose: TNF is a strong mediator of inflammation with a controversial role in SLE. Whereas few open-label studies have shown efficacy of anti-TNFα agents in patients with SLE arthritis and renal disease, many others have reported its potential risk of autoantibody formation. The aim of the study was to evaluate the efficacy and safety of etanercept in patients with moderate active SLE without renal involvement.

Methods: In this open-label study, 42 SLE patients with cardiopulmonary and/or articular involvement (10 with serositis, 6 with shrinking lung syndrome (SLS) and 35 with arthritis) refractory to other therapies were given etanercept (50 mg/weekly) in addition to conventional immunosuppression therapy. Clinical response was categorized in complete response when a complete resolution of the symptoms and/or SLEDAI score <4 was achieved; partial response when there was a 50% clinical improvement and no response when there was no clinical improvement.

Results: Forty two lupus patients (34 female and 8 male, mean age 38.2 (18–60) were included and followed up prospectively for 24 months (3–6). Two of them withdrew from the study due to significant local reactions. Of the remaining patients, clinical improvement was observed in 38 of them (95%). Six patients had to be switched to adalimumab due to etanercept side-effects or lack of efficacy. Eight of the ten patients (90%) with pleuropericarditis achieved clinical remission in a mean period of 5.67±2.65 weeks. In four patients (80%) with SLS, FVC (%) rose from 43±12 to 58±16 (p<0.05) at the end of treatment. Thirty-five patients (92%) with joint involvement achieved remission of arthritis. Relapse was frequent after stopping medication and occurred 8–11 weeks after stopping treatment. The main adverse effects were local reactions (14%) and urinary tract infection (5%). Levels of ANA and/or anti-dsDNA rose in 6 patients (14%), but were not associated with lupus flare.

Conclusion: Anti-TNF agents are safe and efficacious in SLE and did not lead to an increase SLE activity. In view of their anti-inflammatory properties they can be a therapeutical alternative for refractory serositis and SLS.

Persistent Dyslipidemia Is a Risk Factor of Progression to Chronic Kidney Disease in Patients with Lupus Nephritis.
Dong-Jin Park, Kyung-Eun Lee, Tae-Jong Kim, Yong-Wook Park and Shin-Seok Lee. Chonnam National University Medical School, Gwangju, South Korea

Background/Purpose: To investigate the effect of dyslipidemia at baseline and during follow-up period on the progression to chronic kidney disease (CKD) in patients with biopsy-proven lupus nephritis (LN).

Methods: We studied 68 patients who had kidney biopsy prior to the start of induction treatment, and who subsequently were treated with immunosuppressive drugs for at least 6 months. Sociodemographic, clinical, laboratory including lipid profile, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by reviewing patients' charts. In addition, lipid profile data were collected at 6 months and 1 year of follow-up periods. Patients were divided into two groups based on mean levels of LDL cholesterol: the ≥100 mg/dl group with 25 patients and the < 100 mg/dl group with 43 patients. Cox- proportional regression analyses were performed to identify independent predictors of progression to CKD in these patients.

Results: The higher LDL cholesterol group had a significantly older age at onset of LN, had higher WBC counts, and excreted more 24-hour urine protein than the lower LDL cholesterol group (p=0.010, p=0.035, and p=0.048, respectively). The high LDL cholesterol levels during the follow-up period was a significant predictor of CKD in LN patients in unadjusted model (hazard ratio [HR] 3.997, 95% CI 1.193-13.388, p=0.025), and this association remained significant after adjustment for confounders including estimated glomerular filtration rate (HR 3.592, 95% CI 1.067-12.094, p=0.039).

Conclusion: Our findings suggested that persistent dyslipidemia during 1-year follow-up after the onset of LN was an independent risk factor to predict the development of CKD in LN patients. Therefore, lipid profile should be monitored regularly and dyslipidemia should be managed aggressively to prevent deterioration of kidney function in these patients.

Cardiovascular Morbidity in a Long-Term Follow-up Cohort of Systemic Lupus Erythematosus Patients in Southern Sweden.
Ragnar Ingvarsson[1], Ola Nived[2], Gunnar Sturfelt[1], Anders Bengtsson[3] and Andreas Jönsen[4]. [1]Department of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, [2]University Hospital - Lund, Lund, Sweden, [3]University Hospital Lund, Lund, Sweden, [4]Section of Rheumatology, Lund, Sweden

Background/Purpose: The main objective was to study the incidence of myocardial infarction in a cohort of patients with Systemic Lupus Erythem-

atosus (SLE) assembled prospectively over 25 years within a geographically defined area in Southern Sweden.

Methods: All SLE patients living within a defined geographical area in Southern Sweden between 1981–2006 were included in the study. The patients were observed prospectively within a structured follow-up program. Myocardial infarctions (AMI) were registered according to the definitions in the SLICC/ACR organ damage index during follow-up. The frequency of AMI was compared with the general population in the same area. Population data on AMI in the study period 1981–2006 were obtained through central databases (Socialstyrelsen). Data were stratified for age and sex.

Results: The health care district of Lund-Orup had a mean population during 1981–2006 of 176.460 persons (>15 yrs of age). One-hundred seventy-five new cases were diagnosed with SLE from 1981–2006. There were 148 women and 27 male patients that received the diagnosis of SLE, with a mean age of diagnosis at 44.3 years. Average follow-up time was 12,4 years from the time of diagnosis. There were 23 cardiovascular related deaths during the study period. Females between the ages 45–54 had an increased risk for acute AMI compared to healthy paired controls (SIR 12,4 (95%CI 1.4–45). In the other 10-year age groups, both for males and females, no significant differences were found.

Conclusion: Acute myocardial infarction is more prevalent in females between the ages 45–54 with SLE compared with the population in a geographically defined area in southern Sweden.

1435

Identifying Systemic Lupus Erythematosus Patients At Higher Risk of Coronary Artery Disease. Dominique Ibanez, D. D. Gladman and Murray B. Urowitz. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: There is a high prevalence of premature atherosclerosis among patients with SLE. The traditional Framingham risk score (FRS) identifies few of the SLE patients who go on to develop coronary artery disease (CAD). This is particularly true among patients aged 30 to 70. It has been suggested that a modified Framingham risk score (mFRS) where each item is multiplied by 2 more accurately identifies patients at Moderate/High risk of CAD, and more accurately predicts subsequent CAD. Moreover FRS predicts outcomes at 10 years. In a clinic setting, FRS and mFRS can be assessed more than once over time. The aim of this study was to determine whether the mFRS more accurately identifies patients at higher risk of CAD then FRS when the Risk Scores are assessed repeatedly through time.

Methods: Patients aged 30 to 70, seen at a large lupus clinic with multiple clinic visits, and in whom all of the variables necessary for the evaluation of FRS and mFRS were available, were included. FRS and mFRS were assessed for each visit and subsequent development of CAD was determined. CAD was defined as presence of myocardial infarction or angina. Descriptive statistics were used to characterize the survey population. Time-dependent covariate proportional hazard models were used to evaluate the Hazard Ratio associated with FRS and with mFRS for the development of future CAD. Adjustments were made in the models for disease activity at each clinic visit using SLEDAI-2K.

Results: A total of 630 patients were seen for 8098 visits where FRS and mFRS were assessed. 575 (91.3%) were female and their age at SLE diagnosis was 31.4 ± 11.2 years. At first visit in the study, the mean age was 42.4 ± 11.2 with disease duration of 11.1 ± 9.1 years. FRS and mFRS were evaluated for an average of 12.9 ± 9.6 visits per patient. The mean time from study start to the development of CAD or last clinic visit is 12.3 ± 9.7 years. A total of 37 patients went on to develop CAD.

FRS was classified as Moderate/High for 1.2% of all visits and for 16.4% of all visits when using mFRS. 31 (4.9%) patients were classified as Moderate/High at least once in their follow-up compared to 221 (35.1%) for mFRS.

Table 1. Hazard Ratio for the prediction of CAD

	Risk Score: FRS HR (95% CI)	p value	Risk Score: mFRS HR	p value
Risk Score	2.66 (0.63,11.33)	0.18	3.10 (1.76,6.58)	0.0003
Models adjusting for Disease Activity				
Risk Score	2.96 (0.70,12.58)	0.14	3.50 (1.81,6.77)	0.0002
SLEDAI-2K	1.08 (1.02,1.15)	0.01	1.08 (1.02,1.15)	0.01

Conclusion: The Modified Framingham Risk Score can better identify patients with Moderate/High risk for CAD. Being applied over multiple visits through time, it better selects patients who are more likely to benefit from more intensive risk factors control.

Application of European League Against Rheumatism Recommendations for the Management of Systemic Lupus Erythematosus Patients with Neuropsychiatric Involvement May Limit Unnecessary Diagnostic Testing and Curve Intensification of Immunosuppressive Therapy of Unclear Benefit. Cristina Pamfil[1], Antonios Fanouriakis[2], Argyro Repa[2], Maria Melissourgaki[2], Prodromos Sidiropoulos[2], Ileana Filipescu[3], Mirela Rinzis[3], Simona Rednic[3], George Bertsias[2] and Dimitrios Boumpas[4]. [1]University of Medicine and Pharmacy, Cluj, Romania, [2]University of Crete, Iraklion, Greece, [3]Emergency County Clinical Hospital Cluj Napoca, Cluj-Napoca, Romania, [4]Panepistimio Kritis, Rethymnon, Greece

Background/Purpose: Systemic lupus erythematosus (SLE) patients may experience a wide variety of neurological and psychiatric manifestations (neuropsychiatric [NP] SLE [NPSLE]), which pose diagnostic and therapeutic challenges to clinicians leading to significant heterogeneity in their management. We have recently published evidence and expert based recommendations on NPSLE. We sought to measure them against usual care by auditing the management in our centers prior to issuing these recommendations.

Methods: NPSLE events were reviewed in two lupus centers in Iraklio, Greece and Cluj, Romania. Non-SLE-related events were excluded. We compared the diagnostic and treatment decisions in our cohort with the recommendations issued by the European League Against Rheumatism (EULAR) for specific NPSLE manifestations.

Results: A total of 105 NP events attributed to SLE were recorded in 89 patients (89% female, mean age 41.1 years, mean time from SLE onset to NPSLE 5.2 years) by cxahrt review over the last decade (2001–11). Most common events included cerebrovascular disease (n=19, 18%), cognitive dysfunction (n=17, 16%), intractable headache (n=10, 9.5%), psychosis (n=10, 9.5%), and transverse myelitis (n=10, 9.5%). Overall, the concordance between clinical decisions and the recommendations was 74% for diagnostic work-up and 67% for treatment of NPSLE (**Table 1**). Regarding diagnosis, lower concordance rates were noted in cases of cognitive dysfunction with only 5/17 (29%) SLE patients undergoing the recommended neuropsychological testing, and also in mood disorder where 4/7 (57%) patients had brain neuroimaging despite limited evidence for its usefulness. In contrast, the diagnostic work-up of major NPSLE such as seizure disorders, cranial neuropathy, and peripheral neuropathy, was generally in accordance with the recommendations. In terms of treatment, 40% of patients with seizure disorder and 40% of patients with cerebrovascular disease underwent intensification of immunosuppressive therapy without clear evidence of generalized SLE activity, as the recommendations suggest. Antiplatelet or anticoagulant treatment was initiated in 34/39 (87%) of patients with NPSLE and positive antiphospholipid antibodies in accordance with EULAR recommendations. In contrast, the management of cognitive dysfunction did not include the recommended psycho-educational support in the majority of cases.

Table 1. Concordance of clinical practice with recommendations

	N	Diagnostic work-up	Treatment
Cardiovascular disease	19 (18%)	14/19 (74%)[a]	9/19 (47.3%)[b], 6/11 (55.5%)[d]
Cognitive disorder	17 (16%)	5/17 (29.4%)[f]	17/17 (100%)[g], 1/17 (6%)[h]
Psychosis	10 (9.5%)	7/10 (70%)[a]	8/8 (100%)[b]
Seizure disorder	9 (8.5%)	8/9 (88.9%)[c]	3/5 (60%)[b], 0/2 (0%)[d]
Mood disorder	7 (6.6%)	4/7 (57%)[a]	5/7 (71%)[b]
Transverse myelitis	10 (9.5%)	7/10 (70%), 8/10 (80%)[e]	6/10 (70%), 7/10 (80%)[b]
Cranial neuropathy	8 (7.5%)	2/2 (100%)[i]	2/2 (100%)[b]
Peripheral neuropathy	6 (5.7%)	6/6 (100%)[j]	5/6 (83%)[b]

Abbreviations: a, brain imaging; b, glucocorticoids and immunosuppressants; c, MRI and EEG; d, antiplatelet/anticoagulation; e, MRI and CSF; f, neuropsychological tests; g, disease and risk management; h, psycho-educational support. i: ophtalmological evaluation, j: electromyography and nerve conduction studies

Conclusion: The diagnostic and therapeutic decisions in NPSLE patients managed in two European centers were often not in concordance with the existing EULAR recommendations. Applications of these recommendations

may decrease unnecessary testing and curve intensifications of immunosuppressive therapy in cases no clear benefit has been documented. Longitudinal studies to further validate the impact of these recommendations in improving outcomes are needed.

Majority of Lupusqol Domains Are Negatively Correlated with Systemic Lupus Activity Questionnaire (SLAQ) Score. Wendy Marder[1], Martha Ganser[1], Margaret Hyzy[2] and Emily C. Somers[1]. [1]University of Michigan, Ann Arbor, MI, [2]Universitiy of Michigan, Ann Arbor, MI

Background/Purpose: Systemic lupus erythematosus (SLE) disease activity measures such as the SLEDAI and BILAG require real time physician and laboratory assessment of patients, making them difficult to use in large, epidemiologic studies. The Systemic Lupus Activity Questionnaire (SLAQ) is a self-administered tool developed specifically for screening purposes and epidemiologic studies, and takes a lupus patient < 5 minutes to complete. While the SLAQ is not intended for clinical management or in lieu of physician assessment for disease management purposes, it has been validated in a large community based cohort in response to other health indices such as SF12 and SF 36. We assessed correlations between these two self-administered SLE disease measures in a cohort of well characterized SLE patients at a large tertiary care outpatient setting.

Methods: SLE patients from the University of Michigan rheumatology clinics who met 4 or more ACR criteria and age 18 years or older were enrolled. Patients completed SLAQ and LupusQoL questionnaires, as well as sociodemographic data. The total SLAQ score is calculated on a scale of 0–47, with groups of symptoms aggregated and assigned different weights. LupusQOL consists of 34 items, grouped as 8 domains. Pearson's correlation was utilized to assess the strength of associations between overall disease activity and individual QOL domains.

Results: 100 adult SLE patients responded, including 89 females and 11 males. Mean age was 40 years (sd 13 range 18–71). Patients were 66% White, 21% Black, 11% Other, 2% not reported. Mean SLAQ score was 13.3 (SD 9.0, range 0 to 39). SLAQ score (0–47 scale) was negatively associated with all QOL domains except body image, including physical health, pain, planning, intimate relationships, burden to others, emotional health, and fatigue. Pearson correlation coefficients ranged between -0.39 and -0.70.

Conclusion: Using lupus-specific self-report measues, increased disease activity (by SLAQ) is associated with reduced QOL (by LupusQOL) in 7 of 8 domains. While QOL measures have been examined more thoroughly in the context of physician-measured disease activity measures, data are needed in relation to patient-reported lupus activity in order to provide the basis for more extensive evaluation of these concepts in the epidemiologic setting. The total SLAQ score is negatively associated with nearly all domains of the LupusQoL questionnaire, supporting its utility in self-report SLE disease assessment.

Development of Systemic Lupus Erythematosus (SLE) in NZM 2328 Mice in the Absence of Any Single BAFF Receptor. Chaim O. Jacob[1], Ning Yu[2], Shunhua Guo[2], Noam Jacob[2], William J. Quinn III[3], Michael P. Cancro[3], Beatrice Goilav[4], Chaim Putterman[5], Thi-Sau Migone[6] and William Stohl[2]. [1]Department of Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA, [3]University of Pennsylvania School of Medicine, Philadelphia, PA, [4]Children's Hospital at Montefiore, Bronx, NY, [5]Albert Einstein College of Medicine, Bronx, NY, [6]Human Genome Sciences, Rockville, MD

Background/Purpose: To determine the necessity for any individual BAFF receptor in the development of SLE.

Methods: NZM 2328 wild-type (WT), NZM.$Bcma^{-/-}$, NZM.$Taci^{-/-}$, and NZM.$Br3^{-/-}$ mice were evaluated for lymphocyte phenotype and BAFF receptor expression by flow cytometry, for serum BAFF and total IgG and IgG anti-dsDNA levels by ELISA, for glomerular deposition of IgG and C3 by immunofluorescence, for renal histopathology, and for clinical disease.

Results: The phenotypes of NZM mice deficient in a single BAFF receptor were highly divergent. In comparison to WT mice, NZM.$Bcma^{-/-}$ and NZM.$Taci^{-/-}$ mice harbored increased spleen B cells, T cells, and plasma cells (PC), whereas serum total IgG and IgG anti-dsDNA levels were similar to WT levels. Although B cells were markedly reduced in NZM.$Br3^{-/-}$ mice, they nonetheless harbored increased T cells as well as WT-like numbers of PC and levels of IgG anti-dsDNA. Serum BAFF levels were increased in NZM.$Taci^{-/-}$ and NZM.$Br3^{-/-}$ mice but were decreased in NZM.$Bcma^{-/-}$ mice. Expression of TACI on B cells and of BCMA and TACI on bone marrow (BM) PC was reduced in NZM.$Br3^{-/-}$ mice, and expression of BR3 and TACI on BM PC was markedly diminished in NZM.$Taci^{-/-}$ mice. Despite their phenotypic differences, renal immunopathology in NZM.$Bcma^{-/-}$, NZM.$Taci^{-/-}$, and NZM.$Br3^{-/-}$ mice, including robust glomerular deposition of IgG and C3 and development of glomerular hypercellularity, glomerular crescents, mesangial matrix deposition, interstitial inflammation and fibrosis, tubular atrophy, and perivascular leukocyte infiltration, was at least as severe as in WT mice. Moreover, clinical disease was indistinguishable among the four cohorts of mice. Severe proteinuria began to develop in each of the cohorts at 4–5 months of age, and ₋90% of the mice in each cohort was affected by 12 months of age. Mortality in each of the cohorts was noted as early as 6–7 months of age, with ₋90% of the mice in each cohort being dead by 12 months of age.

Conclusion: Any single BAFF receptor, including BR3, is dispensable to development of full-blown clinical SLE in NZM mice. The development of disease in NZM.$Br3^{-/-}$ mice demonstrates that BAFF/BCMA and/or BAFF/TACI interactions importantly contribute to SLE. Moreover, development of disease in NZM.$Br3^{-/-}$ mice demonstrates that profound, chronic reduction in B cells does not equate with protection from SLE. As such, NZM.$Br3^{-/-}$ mice may serve as a useful model in elucidating why the efficacy of B cell-depletion therapy in human SLE is limited.

CTL-Promoting Effects of IL-21 Results in B Cell Elimination and Disease Improvement in a Murine Model of Lupus. Vinh Nguyen[1], Daniel Veizaga-Udaeta[2], Horea Rus[3] and Violeta Rus[3]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]University of Maryland at Baltimore County, MD, [3]University of Maryland School of Medicine and Veteran Affairs Medical Center, Baltimore, MD

Background/Purpose: IL-21 is a member of the type I cytokine family with pleiotropic activities. IL-21 enhances CD8 T cells maturation into cytotoxic T lymphocytes (CTL), promotes the differentiation of T follicular helper (T_{FH}) and Th17 cells while downregulating Tregulatory (Treg) cells and regulates B-cell proliferation and survival, Ig production and class switching. In humans, an association of IL-21 and IL-21R polymorphisms with SLE were reported, while studies in murine models of lupus have indicated that IL-21 blockade was beneficial in MRL-Fas^{lpr}, BXSB-Yaa and chronic graft versus host disease (cGVHD) mice. Furthermore, we have shown that in the cGVHD model, IL-21 promotes the autoimmune phenotype by both B and CD4 T cell intrinsic mechanisms. The relative importance of IL-21R signaling in CD8 T cells on autoimmune parameters in murine lupus has not yet been assessed. In this study we set to determine whether the effect of IL-21 in promoting CD8 T cell differentiation into CTL, leads to the elimination of autoreactive B cells and subsequently the attenuation of autoimmune parameters in murine lupus.

Methods: To address this question we have used two established models of chronic and acute GVHD to dissect the effect on autoimmune parameters of IL-21R signaling in donor CD8 T cells. Specifically, IL-21R sufficient and deficient mice were used as donors in the B6-into-F1 model of acute (a)GVHD. In addition, the effect of exogenous IL-21 on autoimmune parameters was assessed in the DBA-into-F1 lupus-like model of cGVHD that is characterized by defective CTL activity resulting in the persistence of autoreactive B cells. In both models, parameters of acute and cGVHD including donor CD4 and CD8 T cell engraftment, host B cell number and

activation, anti-ssDNA autoAb production, in vivo donor anti-host CTL activity were assessed at two weeks after disease induction.

Results: Acute GVHD induced by injection of IL-21R$^{-/-}$ splenocytes on the B6 background into B6D2F1 hosts, resulted in the conversion of acute to chronic GVHD phenotype, as demonstrated by increased autoAb production, decreased host B cell elimination (57%±6 vs. 90%±0.3; p=0.03) and impaired in vivo CTL activity along with significant decrease in donor (d)CD4 and dCD8 cell expansion. In contrast, DBA-into-F1 cGVHD mice that received rmIL-21 exhibited attenuated autoimmune parameters with respect to host B cell expansion and activation, anti-ssDNA autoAb production along with enhanced donor CD8 expansion and donor anti-host CTL activity. In both models, IL-21/IL-21R interaction on donor CD8 cells resulted in their increased proliferation, expansion and differentiation into CTLs that expressed higher levels of granzyme B and IFNg levels, but nor perforin.

Conclusion: These results suggest that lack of IL-21/IL-21R interaction on CD8 T cells converts acute to chronic GVHD by impairing B cell elimination, while in cGVHD, IL-21 administration attenuates the humoral component by enhancing CTL generation and subsequently host B cells elimination. Therefore, IL-21R signaling on CD8 T cells attenuates disease phenotype in murine lupus, thus opposing the enhancing effects of IL-21R signaling on CD4 T cells and B cells.

Lupus-Prone Mice Demonstrate Enhanced Neutrophil Extracellular Trap Formation: Implications for Autoantibody Formation and Organ Damage.

Jason S. Knight[1], Alexander A. O'Dell[1]. Wenpu Zhao[1], Ritika Khandpur[1], Srilakshmi Yalavarthi[2] and Mariana J. Kaplan[2], [1]University of Michigan Rheumatology, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

Background/Purpose: Recent evidence suggests that enhanced neutrophil extracellular trap (NET) formation—the programmed release of chromatin fibers decorated with granular antimicrobial peptides—is as an important activator of plasmacytoid dendritic cells in systemic lupus erythematosus (SLE). We have proposed that NETosis is also linked to skin, kidney, and premature vascular damage in human SLE. Understanding the role of NETosis in murine models of lupus will be crucial to further investigations of the pathogenic role of this process in autoimmune diseases.

Methods: The New Zealand Mixed (NZM) 2328 model of murine lupus was utilized, with BALB/c and C57BL/6 mice as non-autoimmune controls. Percentage of neutrophils undergoing NETosis was assayed both at baseline and upon exposure to NZM or control serum. Autoantibodies (autoAbs) to NET proteins were characterized by immunofluorescence, western blotting, and in-house ELISAs for Abs to the LL-37 mouse orthologue CRAMP and to NET proteins in general. Glomerular and skin NET-like material were detected by immunofluorescence analysis.

Results: NZM neutrophils demonstrated enhanced spontaneous NETosis (7.13% ± 1.16 vs. 1.83% ± 0.25; p=0.0008) as compared to control BALB/c neutrophils; further, incubation of control neutrophils with NZM serum increased NETosis percentage to levels observed in NZM neutrophils. The NET-stimulating effect of NZM serum was also robust in type I interferon receptor-knockout neutrophils, suggesting that serum factors other than these cytokines contribute to the phenotype. NZM mice develop anti-NET autoAbs. Immunofluorescence analysis using NZM serum as primary Ab demonstrated a granular pattern of reactivity with NETs, which in many places co-localized with anti-myeloperoxidase (MPO) and anti-neutrophil elastase (NE) staining. Using similar methodology, western blotting revealed NZM serum reactivity with specific proteins derived from NETs. By ELISA, NZM serum reacted more strongly with CRAMP (1.98 ± 0.19 vs. 1.00 ± 0.14; p=0.017) and NET proteins (1.85 ± 0.16 vs. 1.00 ± 0.090; p=0.014) than age-matched control serum. NET-like material—consisting of DNA, MPO, and NE—was detected in nephritic NZM kidneys and in non-affected NZM skin, but not in control mice.

Conclusion: The NZM2328 murine model of lupus replicates a number of the features of human SLE with regards to aberrant neutrophil function. These include enhanced NETosis, anti-NET autoAb formation, and the potential for organ damage attributable to NETs. Future studies should better dissect the role of NETosis both in driving lupus pathogenesis and in contributing to organ damage such as skin disease, nephritis, and accelerated atherosclerosis.

Epstein Barr Virus CD40 Functional Mimic Latent Membrane Protein-1 Drives Cellular Molecular Mimicry in the Presence of Epstein Barr Virus Nuclear Antigen-1 in a Novel Murine Model of Lupus-Like Disease.

Melissa E. Munroe[1], Jourdan R. Anderson[1]. Timothy F. Gross[1], Laura L. Stunz[2], Gail A. Bishop[2] and Judith A. James[3], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]The University of Iowa, Iowa City, IA, [3]Oklahoma Medical Research Foundation; University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background/Purpose: Immune dysregulation underlies the complex pathogenesis of SLE. Infection with Epstein Barr Virus (EBV) and expression of latent protein Epstein Barr Virus Nuclear Antigen-1 (EBNA-1, a humoral molecular mimic with SLE associated autoantigens) has been linked with SLE. Acting in an enhanced and sustained manner, the Latent Membrane Protein-1 (LMP1, another major EBV latent protein) cytoplasmic tail is necessary and sufficient as a functional mimic of the TNF Receptor, B cell stimulatory molecule CD40. Mice were created expressing a transgene (Tg) for the chimeric molecule mCD40-LMP1 (containing the cytoplasmic tail of LMP1) and bred onto a CD40$^{-/-}$ background to remove endogenous CD40. The mCD40-LMP1 Tg mice have normal T-dependent antibody responses, spontaneous germinal center formation, and autoantibodies by 2–3 months of age. However, no overt autoimmune disease or early death develops in this model. This study evaluates the nature of the immune response to EBNA-1 in mCD40-LMP1 Tg mice and whether the addition of a molecular mimic in this model could accelerate lupus pathogenesis.

Methods: mCD40-LMP1 Tg, full length mCD40 Tg (Tg strain control), and congenic C57Bl/6 (B6) mice (8–12 weeks of age) were immunized (in CFA) and boosted (in IFA) with EBNA-1 over an 8-week course. Saline/adjuvant and naïve control mice were also employed. Draining lymph node cells were cultured in antigen-recall assays stimulated with EBNA-1, the EBNA-1 antigenic epitope PPPGRRP (GRR), the cross-reactive autoantigen Sm, or the Sm antigenic epitope PPPGMRPP (GMR). Proliferation was measured by ^{3}H-Thymidine incorporation and culture supernatant cytokines by xMAP multiplex assay. Serum antibodies to EBNA-1, autoantibodies, and BUN and creatinine levels were also assessed.

Results: Anti-EBNA-1 antibody levels are comparable in mCD40-LMP1 Tg, mCD40 Tg and B6 congenic mice. EBNA-1 specific proliferative and inflammatory cytokine responses, including IL-6, IL-17, IFN-γ, and TNF-α, are significantly enhanced ($p < 0.0001$) in mCD40-LMP1 Tg compared to mCD40 Tg, B6 mice, and adjuvant and naïve control mice. In addition, mCD40-LMP1 Tg mice immunized with EBNA-1 exhibit significantly enhanced cellular responses ($p < 0.0001$) to the EBNA-1 antigenic epitope GRR and cross-react to the autoantigen Sm, as well as its antigenic epitope GMR. The cross-reactive cellular response to GRR and Sm starts within 10 days post-immunization with EBNA-1 in mCD40-LMP1 Tg mice. Cross-reactivity to the Sm epitope GMR occurs within 4 weeks after initial immunization. Enhanced cellular immune dysregulation with EBNA-1 immunization in mCD40-LMP1 mice is accompanied by enhanced splenomegaly, increased serum BUN and creatinine levels, and elevated anti-dsDNA and ANA autoantibody levels (p <0.0001 compared to mCD40 Tg and B6 mice, $p < 0.01$ compared to adjuvant and naïve mCD40-LMP1 mice).

Conclusion: Mice Tg for mCD40-LMP1 exhibit enhanced cellular responses to EBNA-1. In the presence of LMP1, EBNA-1 induces cellular molecular mimicry to the SLE associated autoantigen Sm. These data suggest that expression of EBV latent proteins EBNA-1 and LMP1 may contribute to immune dysregulation that leads to pathogenic autoantigen-specific inflammation in lupus.

IRF-1 Deficient Lupus-Prone MRL/Lpr Mice Show Reduced Glomerulonephritis but Develop Severe Interstitial Nephritis, Renal Vasculitis and Pulmonary Granulomas with Propensity for Th2 Polarity.

Hidemaru Sekine[1], Takeshi Machida[1], Natsumi Sakamoto[1], Eiji Suzuki[2], Xian Zhang[3], Christopher Reilly[4] and Gary S. Gilkeson[2]. [1]Fukushima Medical University, Fukushima, Japan, [2]Medical University of South Carolina, Charleston, SC, [3]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC, [4]Virginia Tech, Blacksburg, VA

Background/Purpose: The transcription factor interferon regulatory factor-4 (IRF-4) and -1 (IRF-1) are members of the IRF family of transcrip-

tion regulators and involved in the development of Th2/Th17 and Th1 cells, respectively. MRL/*lpr* mice, a murine model of human SLE, spontaneously develop lupus-like disease. At ACR 2011, we reported that *Irf4*$^{-/-}$ MRL/*lpr* mice, which lacked serum autoantibodies and Th17 cells, developed proliferative glomerulonephritis but minimal to no interstitial nephritis or renal vasculitis. *Irf4*$^{-/-}$ MRL/*lpr* mice also developed granulomas containing Langhans-type multinucleated giant cells (MGCs) in multiple organs with significantly increased numbers of IFN-γ producing CD4$^+$ T cells, suggesting autoreactive Th1 cell-mediated mechanisms for their pathogenesis. To further define the role of autoreactive CD4$^+$ T cells in murine lupus, we generated *Irf1*$^{-/-}$ MRL/*lpr* mice and assessed their disease.

Methods: *Irf1-KO* MRL/*lpr* mice were generated by backcrossing *Irf1-KO* C57BL/6 mice onto MRL/*lpr* background for 7 generations by using speed congenic strategy. Mice were sacrificed at 18 weeks of age and histopathological analysis in multiple organs was performed. Infiltration of CD4$^+$ T cells and CD68$^+$ macrophages/monocytes in tissues was detected by immunofluorescence or immunohistochemical staining. Splenic immune cell populations were analyzed by flow. To determine Th1/Th2/Th17 cell numbers, splenic CD4$^+$T cells were cultured with PMA/ionomycin, and IFN-γ, IL-4 or IL-17 production was detected by intracellular staining and flow analysis.

Results: Unlike WT or *Irf4*$^{-/-}$ MRL/*lpr* mice, *Irf1*$^{-/-}$ MRL/*lpr* mice showed severe inflammation in their renal intersititum and blood vessels characterized by predominant infiltration of CD4$^+$ T cells. In contrast, minimal to no inflammation was observed in their glomeruli, suggesting independent mechanisms for development of interstitial nephritis and renal vasculitis. *Irf1*$^{-/-}$ MRL/*lpr* mice also developed pulmonary granulomas characterized by predominant infiltration of CD68$^+$ macrophages/epithelioid cells with formation of foreign body-type and Langhans-type MGCs. No granuloma was observed in age-matched WT MRL/*lpr* or *Irf1*$^{-/-}$ C57BL/6 mice. Different appearances of renal disease and granulomas between *Irf4*$^{-/-}$ and *Irf1*$^{-/-}$ MRL/*lpr* mice are summarized in the table. Intracellular cytokine analysis showed that there was significantly increased population of IL-4-producing CD4$^+$ T cells in the spleens of *Irf1*$^{-/-}$ MRL/*lpr* and C57BL/6 mice than their WT controls.

Mouse	CD4$^+$ T cell polarity	Renal disease Glomerular change	Interstitial inflammation	Vasculitis	Granulomas Lung	Liver	Spleen	Lymph node
Irf4$^{-/-}$ MRL/*lpr*	Th1	±~++ (Proliferative GN)	–~±	None	CD4$^+$ T cell predominant infiltration with formation of Langhans-type MGCs	CD4$^+$ T cell predominant infiltration with formation of Langhans-type MGCs	CD4$^+$ T cell predominant infiltration with formation of few Langhans-type MGCs	CD4$^+$ T cell predominant infiltration with formation of few Langhans-type MGCs
Irf1$^{-/-}$ MRL/*lpr*	Th2	–~±	+++ CD4$^+$ T cell predominant infiltration	+++ CD4$^+$ T cell predominant infiltration	CD68$^+$ macrophages predominant infiltration with formation of foreign body-type and Langhans-type MGCs	Focal granulomatous lesions with formation of foreign body-type MGCs	No granulomas	No granulomas

Conclusion: Our results indicate that IRF-1 plays an important role in the regulation of Th2 polarity in MRL/*lpr* and C57BL/6 mice. Development of inflammatory renal disease and pulmonary granulomas not in *Irf1*$^{-/-}$ C57BL/6 mice but in lupus-prone *Irf1*$^{-/-}$ MRL/*lpr* mice with significantly increased numbers of IL-4 producing CD4$^+$ T cells suggests autoreactive Th2 cell-mediated mechanisms for their pathogenesis.

Caspase-1 Modulates Endothelial Dysfunction and Vascular Repair in Murine Lupus. J. Michelle Kahlenberg, Wenpu Zhao, Srilakshmi Yalavarthi and Mariana J. Kaplan. University of Michigan, Ann Arbor, MI

Background/Purpose: Premature cardiovascular disease (CVD) represents a significant cause of morbidity and mortality in systemic lupus erythematosus (SLE). We recently proposed that type I interferon (IFN) modulation of the inflammasome and resultant IL-18 production contribute to dysfunction of endothelial progenitor cells (EPC) in SLE patients. This phenomenon may promote an imbalance of vascular damage and repair and increase CV risk. Thus, we hypothesize that activation of the inflammasome may play an important role in CVD development in SLE. In order to determine the role of caspase-1, the central enzyme of the inflammasome and activator of IL-18 and IL-1beta, in the enhanced risk of CVD in SLE, we utilized the type-I IFN dependent, pristane-induced model of murine lupus in wild type and caspase-1 deficient mice.

Methods: 8 week old C57Bl/6 (WT) mice or C57Bl/6 caspase-1 $-/-$ (KO) mice were injected intraperitoneally with 0.5 ml pristane or 0.5 ml PBS, and euthanized 6 months post injection. Aortic rings were assessed for relaxation following acetylcholine (Ach) exposure as a measure of endothelial function. Bone marrow EPCs were quantified by FACs and their capacity to differentiate into mature endothelial cells (ECs) was assessed by fluorescent microscopy. Lupus phenotype was also quantified.

Results: Aortas isolated from pristane-exposed wild type mice had dysfunctional relaxation, similar to what has been described in other lupus models and in SLE patients. In contrast, endothelial relaxation in caspase-1 KO mice exposed to pristane was significantly improved when compared to that observed in pristane treated wild-type mice. This suggests that caspase-1 is required for SLE mediated endothelial dysfunction. Bone marrow EPC numbers trended toward a reduction in numbers in pristane exposed wild type but not caspase-1 knockout mice. Additionally, the capacity of these cells to differentiate into mature ECs was significantly preserved in pristane treated caspase-1 KO mice compared to pristane treated WT mice. This indicates that caspase-1 contributes to lupus-induced aberrant EPC function in vivo. Lupus phenotype is currently being compared between the two groups.

Conclusion: In pristane-induced lupus, the absence of caspase-1 is protective against endothelial dysfunction and aberrant EPC function. This observation implicates inflammasome modulation by type I IFNs as an important contributor to cardiovascular damage in SLE.

HLA-DR3 Controls Autoantibody Response to Sm in NZM2328. DR3+.AE0 Transgenic Mice. Vaidehi R. Chowdhary[1], Chao Dai[2], Shu Man Fu[2] and Chella S. David[1]. [1]Mayo Clinic, Rochester, MN, [2]University of Virginia Health System, Charlottesville, VA

Background/Purpose: Large genome wide scans have confirmed the strong association of HLA -DR3 with risk of developing SLE and antibody response to Sm which is specific to lupus. To understand the role of HLA-DR3 in pathogenesis of lupus and anti-Sm response, we generated NZM2328 mice transgenically expressing HLA-DR3 and devoid of endogenous mouse class II (AE0). Female NZM2328 spontaneously develop anti-dsDNA and severe glomerulonephritis whereas incidence of glomerulonephritis is less in male mice.

Methods: HLA DR3.AE0 transgenic mice were repeatedly backcrossed to NZM2328 mice for 6 generations. Mice were genotyped by PCR and Flow cytometry. Various cohorts of mice were followed monthly for proteinuria using Albustix and sera collected. Urinary protein greater than 300 mg/dL (3+ or more) was considered significant. Anti-Sm antibodies were determined by ELISA and immunoprecipitation.

Results: The overall incidence of proteinuria in female NZM2328. DR3+.AE0 and NZM2328 mice at 12 months was 58% and 62% respectively (p=0.38) whereas male mice, as expected, had low incidence of proteinuria namely 11% in NZM2328 and 19% in NZM2328.DR3+.AE0. No proteinuria was seen in DR3+.AE0 and AE0 mice. Both NZM2328 and NZM2328.DR3+.AE0 developed anti-dsDNA antibodies. NZM2328 males and females, AE0 and DR3+AE0 did not develop anti-Sm antibodies whereas both male and female NZM2328.DR3+.AE0 mice developed anti-Sm antibodies. Preliminary results from immunoprecipitation in few samples also confirm presence of anti-Sm antibody in NZM2328.DR3+.AE0 mice. These mice develop glomerulonephritis and kidney scores are shown in Table 1.

Table 1. Severity of glomerulonephritis in NZM2328 and NZM2328.DR3*.AE° mice

Group	Mesangial Expansion	Endocapillary Proliferation	Glomerular deposits	Extracapillary proliferation
NZM2328 Proteinuric	2.2 ± 0.75	1.8 ± 0.5	2 ± 0.9	0.16 ± 0.41
NZM.DR3+.AE0 Proteinuric	3 ± 0	2.8 ± 0.5	3.5 ± 0.6	0
NZM2328 Non-proteinuric	1.7 ± 0.9	1.6 ± 1.2	0	
NZM.DR3+.AE0 Non-proteinuric	2 ± 1.2	1.2 ± 1.3	1.5 ± 1.1	0.16 ± 0.4

Total number of spleen cells, CD4+, CD8+, B220+ and Mac1+ cells were enumerated in NZM2328, NZM2328.DR3+ AE0 mice and were not

significantly different. Similarly the total numbers of thymocytes, CD4, CD8 double negative, double positive, single positives were also not different in both the groups. Certain CD4+, CD8+ T cell Vβ families were increased in NZM2328 and NZM2328. DR3+.AE0 mice compared to DR3+AE0 mice.

Conclusion: These results strongly support that that HLA-DR3, in an autoimmune prone background, plays an important role in generating an immune response to Sm and development of glomerulonephritis.

Shared and Unique Molecular Features of Nephritis in 3 Models of Murine SLE. Ramalingam Bethunaickan[1], Celine C. Berthier[2], Matthias Kretzler[3] and Anne Davidson[4]. [1]Feinstein Institute for Medical research, Manhasset, NY, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, MI, [4]Feinstein Institute for Medical Research, Manhasset, NY

Background/Purpose: Mouse models are useful for studying the pathogenesis of SLE nephritis but it is not clear which model is the most appropriate for understanding human disease. The goal of this study was to understand both shared and unique features of SLE nephritis in mouse models of proliferative and glomerulosclerotic renal disease.

Methods: Perfused kidneys from NZB/W F1, NZW/BXSB and NZM2410 mice were harvested before and after nephritis onset. Affymetrix based expression profiles of whole kidney RNA were analyzed using Genomatix Pathway Systems and Ingenuity Pathway Analysis software. Fold-change ≥1.4 for the up-regulated genes and ≤ 0.7 for the down-regulated genes and q <0.001 were chosen as cut-off values. Only those genes with human orthologs were analyzed. Confirmation of gene expression patterns was performed using real-time PCR.

Results: 955, 1168 and 835 genes were regulated in the kidneys of nephritic NZB/W F1, NZW/BXSB and NZM2410 mice respectively. 263 genes were regulated in all three strains reflecting immune cell infiltration, endothelial cell activation, fibrinolysis, complement activation and cytokine signaling. STAT3 was the top transcription factor having a binding site in the regulated gene promoter and IL-6 signaling was a top pathway in the ingenuity analysis. Each strain also expressed a unique pattern of genes. NZB/W mice had dominant T cell and IL-1 signatures whereas NZW/BXSB mice had prominent integrin, complement signatures and p53 signatures. NZM2410 mice that have severe glomerulosclerosis and scant lymphocytic infiltrates had a dominant metabolic and mitochondrial dysfunction signature; part of this signature was shared with NZB/W mice. The two strains with proliferative disease NZB/W and NZW/BXSB shared a macrophage/DC infiltration and activation signature. Importantly, overlapping signatures with human SLE biopsies were observed for all three mouse strains.

Using real-time PCR we confirmed these gene expression profiles and showed significant differences in the inflammatory response between strains. For example regulatory T cells infiltrated the kidneys of NZB/W mice but not the other two strains. NZM2410 mice had features of renal macrophage activation but lacked dendritic cell infiltration and had less endothelial cell activation than the other two strains. Loss of nephrin, indicating podocyte death, was most marked in the NZM2410 strain and was not observed in NZW/BXSB mice. Robust markers of interstitial disease/remodeling and hypoxia were shared between nephritic mice of all three strains. IL1F6, a marker of tubular dysfunction was an earlier marker of proteinuria than Lcn2.

Conclusion: These findings among genetically related strains of SLE prone mice illustrate the heterogeneity of renal responses to immune complex deposition and inflammation and suggest that individualized targeting of effector mechanisms might need to be based on biopsy findings. These findings further suggest that the progression of renal impairment in SLE shares many common mechanisms with other non-immune–mediated renal diseases and that strategies currently being applied in other diseases to prevent tissue hypoxia and remodeling may also be useful in SLE.

The Granulocyte Signature and Organ Inflammation in TLR7 Responsive Mice Is RNA and Type 1 Interferon Dependent. Xizhang Sun[1], Alice Wiedeman[2], Thomas H. Teal[2], Nalini Agrawal[2], Jeffrey Duggan[2], Matt B. Buechler[3], Jeffrey A. Ledbetter[2], Denny Liggitt[2], Jessica A. Hamerman[4] and Keith B. Elkon[2]. [1]Division of Rheumatology, Department of Medicine, University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA, [3]Benaroya Research Institute at Virginia Mason, Seattle, WA, Seattle, [4]Benaroya Research Institute at Virginia Mason, Seattle, WA

Background/Purpose: Microarray expression analysis of blood taken from patients with Systemic Lupus Erythematosus (SLE) has revealed two characteristic signatures: one that reflects exposure to type 1 interferon (IFN) and the other reflective of immature circulating granulocytes. Whereas the IFN signature is thought to arise predominantly from the activation of TLR7 in plasmacytoid dendritic cells (pDC) by RNA containing nucleoprotein immune complexes (ICs), the generation of the granulocyte signature is uncertain. Mice that overexpress TLR7 (TLR7 transgenic (Tg) mice) not only develop a lupus-like syndrome, but also a myeloid expansion in the spleen.

Goals: A) To determine the relationship between the myeloid expansion and the pathology in TLR7 Tg mice. B) To determine whether the myeloid expansion and immunopathology is driven by the TLR7 ligand, RNA, and whether it is also IFN dependent.

Methods: Granulocytes (CD11bhigh Ly6Ghigh Ly6Chigh) and inflammatory monocytes (CD11bhigh Ly6Chigh Ly6Gnegative) were flow sorted from the spleen. Microarray analysis on RNA isolated from whole spleen was performed using Illumina's MouseWG-6 v2.0 Expression BeadChips. Chips were scanned on an Illumina HiScanSQ System and >2.0-fold changes in gene expression by TLR7 Tg compared with B6 were analyzed by Ingenuity software. To create TLR7 mice that either overexpressed RNase A or were deficient in the type 1 interferon receptor (IFNAR), TLR7 mice were crossed to RNase Tg or IFNAR deficient mice respectively. Parenchymal organs were examined by light microscopy, Mac2 staining and by other methods as appropriate.

Results: Transcript profiling of TLR7 Tg and B6 spleens (n=10 in each group) revealed a striking granulocyte signature in the TLR7 Tg spleen (e.g. proteinase 3, myeloperoxidase and elastase were expressed at 16 × wild type). Surprisingly, Q-PCR of flow sorted subpopulations revealed that it was the inflammatory monocytes rather than the granulocytes that expressed high levels of these genes. These myeloid populations from TLR7 Tg mice expressed 5–10-fold more TLR7 mRNA compared to B6 mice and the inflammatory monocytes from TLR7 Tg mice expressed more inflammatory cytokines in response to the TLR7 agonist gardiquimod. Pathologic studies of TLR7 Tg mice revealed only mild kidney disease whereas a striking inflammatory infiltrate predominantly of myeloid cells was observed in the liver. This infiltrate was associated with hepatic necrosis. The inflammatory infiltrate was markedly reduced in double mutant TLR7 Tg mice that either co-expressed RNase or that were deficient in IFNAR expression.

Conclusion: Our results indicate that TLR7 Tg mice express a granulocyte signature similar to that observed in humans with SLE. This signature was a consequence of high expression of neutrophil genes in inflammatory monocytes which is likely explained by increased numbers of immature cells released by the bone marrow suggestive of altered myelopoiesis. Attenuation of disease in the double mutant mice indicate that myelopoiesis and/or activation of myeloid cells is caused by exposure to RNA in an IFN dependent process. These results have important implications for therapy.

1447

A Synthetic Triterpenoid CDDO-Me Prevents and Reverses Murine Lupus Nephritis. Tianfu Wu[1], Yujin Ye[1], Mei Yan[1], Xin J. Zhou[2], Michael Andreef[3] and Chandra Mohan[1]. [1]University of Texas, Southwestern Medical Center at Dallas, Dallas, TX, [2]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [3]The University of Texas M. D. Anderson Cancer Center, Houston, TX

Background/Purpose: Current treatment options for lupus are far from optimal. Previously, we have reported that PI3K/AKT/mTOR, MEK1/Erk1,2, p38, STAT3, STAT5, NF-κB, multiple Bcl-2 family members, and various cell cycle molecules were overexpressed in splenic B-cells in an age-

dependent and gene-dose-dependent manner in mouse strains with spontaneous lupus. As the synthetic triterpenoid methyl-2-cyano-3,12-dioxooleana-1,9-dien-28-oate (CDDO-Me) has been shown to inhibit AKT, MEK1/2, and NF-κB, and to induce caspase-mediated apoptosis, we proceeded to test the therapeutic potential of CDDO-Me on murine lupus.

Methods: In a preventive study, CDDO-Me or placebo were administered to 2 month old *B6.Sle1.Sle3* mice (n=10 per group) at a dose of 3mg/kg, 3 times a week for 2 months. In the treatment study, diseased NZM2410 (age = 7mo; n = 4–7 per group) were treated with CDDO-Me at a dose of 3mg/kg, 5 times a week for 2 months. Proteinuria, BUN, autoantibody levels, cellularity and renal disease were examined to determine the efficacy of this agent.

Results: Splenic cellularity was reduced after CDDO-me treatment. Particularly, the percentage of splenic CD4+ T cells was decreased (12.1 $\pm$ 0.35% vs 15.1 $\pm$ 1.2%, P = 0.021), while the percentage of CD8+ T cells was increased (9.73 $\pm$ 0.4% vs 6.8 $\pm$ 1.1%, P = 0.023) in the CDDO-Me treated group compared to the placebo group. In addition, CDDO-Me-treated mice exhibited significant reductions in serum autoantibody levels, including anti-dsDNA and anti-glomerular antibodies. Finally, CDDO-Me treatment attenuated renal disease in mice, as revealed by reduced 24-hour proteinuria, blood urea nitrogen, and glomerulonephritis. In order to confirm the therapeutic efficacy of CDDO-Me, we carried out a treatment study by administering CDDO-Me to a different lupus strain (NZM2410, age = 7mo; N = 4–7 per group) for a period of 2 months. These mice were already proteinuric at the beginning of the study. Once again, CDDO-Me was remarkably effective in improving survival, and reducing cellularity, circulating antibodies and proteinuria. Thus, we have established that CDDO-Me is therapeutically effective, even when administered after disease onset. In terms of the underlying molecular mechanisms, we demonstrated that CDDO-Me treatment dampened MEK1/2, ERK, and STAT3 signaling within lymphocytes. Importantly, the NF-E2-Related Factor 2 (Nrf2) pathway was activated after CDDO-Me treatment, indicating that CDDO-Me can attenuate renal damage in lupus via the inhibition of oxidative stress. Collectively, these findings underscore the importance of AKT/MEK1/2/NF-κB signaling in engendering murine lupus.

Conclusion: CDDO-me may effectively prevent the hematological, autoimmune and pathological manifestations of lupus via the blockade of multiple signaling nodes and oxidative stress.

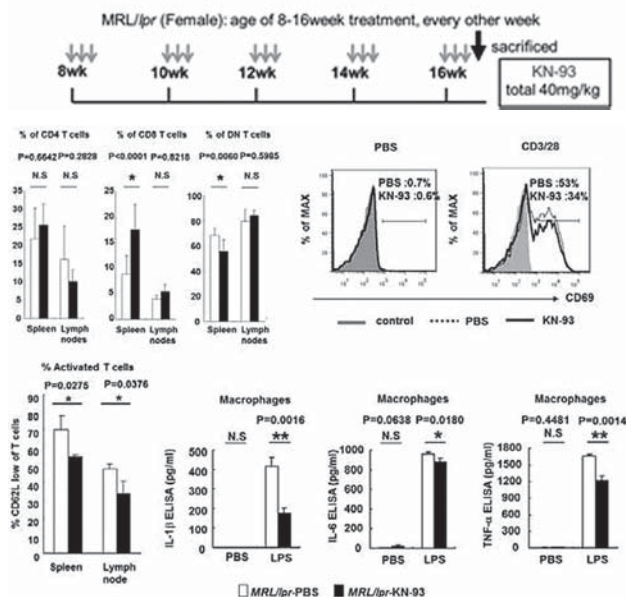
Inhibition of Calcium/Calmodulin-Dependent Protein Kinase IV Suppresses the Autoimmunity in Lupus-Prone Mice. Kunihiro Ichinose[1], Atsushi Kawakami[1] and George C. Tsokos[2]. [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease associated with abnormal immune cell function.SLE T cells express high levels of calcium/calmodulin-dependent protein kinase IV (CaMKIV). We have shown previously that pharmacologic (Arthritis Rheum. 2011) or genetic silencing of Camkiv (J Immunol. 2011) suppresses lupus nephritis in lupus-prone mice. The purpose of this study was to determine whether pharmacologic inhibition of CaMKIV would improve immune function abnormalities.

Methods: We treated MRL/lpr mice with KN-93, a CaMKIV inhibitor. The agent was administered by intraperitoneal injections at a dosage of 2.67 ug/gm of body weight per mouse 3 times a week, starting at week 8 of age through week 16. We evaluated the presence of CD4+, CD8+, CD3+CD4-CD8- (double negative, DN) and CD62L low T cells and proinflammatory cytokine production. We also determined the effect of inhibition or silencing of CaMKIV on proinflammatory cytokine production by human T cells and macrophages.

Results: CaMKIV inhibition in MRL/lpr mice resulted in significant suppression of DN and CD62L low of T cells population and IFN-γ production by T cells. In human activated T cells and macrophages, pharmacologic inhibition of CaMKIV resulted in suppression of IFN-γ production and CD69 expression by T cells and IL-1β, IL-6 and TNF-α by macrophages. Silencing of CaMKIV in human activated T cells showed increased expression of FoxP3 mRNA level and decreased IL-17A mRNA level.


Conclusion: We conclude that pharmacologic inhibition of CaMKIV suppresses cell activation and cytokine production in lupus-prone mice. Our data justify the development of small-molecule CaMKIV inhibitors or silencing CaMKIV for the treatment of patients with SLE.

Numbers of Splenic Long-Lived Plasma Cells in Autoimmune and Pre-Autoimmune Lupus Mice Are Linked to a Hyper-Responsive Variant of the Thrombopoietin Receptor and Enhanced Megakaryopoiesis. Oliver Winter[1], Katrin Moser[2], Rudolf A. Manz[3] and Falk Hiepe[4]. [1]Charité - University Medicine Berlin, Berlin, Germany, [2]German Arthritis Research Center (DRFZ Berlin), Berlin, Germany, [3]University of Lübeck, Lübeck, Germany, [4]Charité University Hospital Berlin, Berlin, Germany

Background/Purpose: Autoantibodies contribute to the pathogenesis of the autoimmune disease Systemic Lupus Erythematosus (SLE) by stimulating the immune response. Further, deposits of immune complexes in the kidneys can lead to severe nephritis. The autoantibodies are secreted by short- and long-lived plasma cells located in the bone marrow and in the spleen. In NZB/W mice - a mouse model for SLE - both parental strains New Zealand Black (NZB) and New Zealand White (NZW) contribute different *sle-loci* to the formation of SLE. The NZB strain passes the *sle2c locus* in which the gene for the Thrombopoietin (TPO)-receptor (*c-mpl*) is located.

According to the relevance of megakaryocytes for the plasma cell niche and the correlation between plasma cell and megakaryocyte numbers, we wanted to elucidate whether c-Mpl and/or megakaryopoiesis is altered in auto-immune mice.

Methods: Therefore, we examined in wild type, NZB and NZW mice the amount of megakaryocytes and plasma cells in spleen and bone marrow, the occurrence of genetic variations for *c-mpl* and the degree of megakaryopoiesis upon TPO stimulation by histological survey, flow-cytometric and genetic analysis and by *in vitro* studies.

Results: We found, that in the spleen of NZB mice the number of long-lived plasma cells and megakaryocytes are 10-times higher than in wild type while in NZW mice the numbers are equal. We detected a missense mutation in the *c-mpl* gene of NZB mice leading to an amino acid replacement within the essential TPO-binding site. Upon TPO stimulation of splenocyte and bone marrow cultures NZB cultures responded significantly stronger resulting in the double amount of megakaryocytes compared to NZW cultures.

Conclusion: In summary, our data indicate that the mutated *c-mpl* gene located within the *sle2c-locus* is leading to an augmented megakaryopoiesis which enables the accumulation of a greater number of autoreactive plasma cells and thus is contributing to the development of SLE.

1450

MEDI-551 Depletes a Majority of Murine B Cells and Reduces Serum Titers of Autoantibodies in the SLE1-huCD19 TG Mice. Sandra Gallagher, Yue Wang, Isharat Yusuf, Thomas McCaughtry, Ronald Herbst and Laura Carter. MedImmune, Gaithersburg, MD

Background/Purpose: Systemic Lupus Erythematosus (SLE) is characterized by chronic inflammation that can affect various organs. Hyperactive B cells appear to be key drivers in SLE disease. Although some monoclonal antibody (MAb) therapies targeting B cells have shown positive therapeutic effect, these therapies do not effectively deplete plasma cells or autoantibodies. MEDI-551 is an antibody-dependent cellular cytotoxicity (ADCC)-enhanced, humanized, anti-CD19 MAb. Previous studies demonstrated that MEDI-551 can effectively deplete a broad range of tissue B cells in naïve mice. In immunized mice, MEDI-551 led to depletion of tissue plasma cells and a reduction of serum titers of responding antibodies. In this study, we examined the ability of MEDI-551 to deplete B cells in the SLE1-huCD19 TG mice and the impact on the autoimmune phenotype.

Methods: SLE1-huCD19 TG mice were given either a single IV dose of MEDI-551 or repeated doses biweekly for up to twelve weeks. The number of B cells in the blood, spleen and bone marrow (BM) were detected by flow cytometry staining. In the spleen and bone marrow, the number of antibody secreting cells (ASC) specific for total IgG and IgM as well as anti-dsDNA IgG and IgM were determined by ELIspot. Serum autoantibody and total immunoglobulin levels were determined by ELISA.

Results: Aged SLE1-huCD19 TG mice display classical autoimmune symptoms, including antibodies against self antigens and hyper-activation of B and T cells. A single dose of 10mg/kg MEDI-551 led to depletion of 90% of B cells in spleen, BM, and blood at day 7 post injection. Spleen germinal center B cells and plasma cells (PC) were largely sensitive to MEDI-551, and their numbers were reduced by 72%. BM PC, with numbers 80% less than spleen PC, were not significantly affected. In a follow-up longitudinal study, the SLE1-huCD19 TG mice were given biweekly dosing of MEDI-551 or PBS for up to twelve weeks. Repeated dosing of MEDI-551 resulted in significant (>90%) and sustained B cell depletion throughout the duration of the experiment. At week 12, spleen ASC were reduced by ≥90%; whereas, only dsDNA IgM BM ASC were reduced (70%). This reduction in spleen PC was correlated with a 40–80% reduction in autoantibodies specific for dsDNA, histone, and ANA. Total serum immunoglobulins were reduced ~50% compared to control by 12 weeks.

Conclusion: In the autoimmune SLE1-huCD19 TG model, MEDI-551 is able to eliminate naïve as well as activated germinal center B cells and PC in spleen, but spared a majority of BM PC. MEDI-551 dosing resulted in a robust reduction of autoantibodies, whereas total Ig was moderately reduced. Thus, MEDI-551's novel ability to remove a broad range of B cells and eliminate most disease-driving autoantibodies in an SLE model warrants continued research.

Estrogen Receptor Alpha Deficiency Protects Against Cognitive Defects in Murine Lupus. Melissa A. Cunningham[1], Osama S. Naga[2], Heather A. Boger[2], Ann-Charlotte E. Granholm-Bentley[2] and Gary S. Gilkeson[3]. [1]MUSC, Charleston, SC, [2]Medical University of SC, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC

Background/Purpose: Up to 80% of SLE patients have cognitive defects or affective disorders. The mechanism of CNS injury responsible for cognitive impairment is unknown. Anti-dsDNA antibodies cross-reacting with NMDA receptors in the brain mediate excitotoxic cell death, causing behavioral changes in lupus–prone mice. A breach in the blood-brain barrier (BBB) is required for these effects. Data suggest that BBB breakdown, pathogenic autoantibodies, and subsequent neuronal damage in key areas are critical to the development of neuropsychiatric SLE. We previously showed that estrogen receptor alpha (ERa) deficiency significantly reduced renal disease and increased survival in murine lupus. We hypothesized that ERa also plays a role in modulating BBB integrity and/or neuroinflammation leading to CNS dysfunction in lupus prone MRL/lpr mice.

Methods: MRL/lpr lupus mice (n=28) were ovariectomized at 4wks, received 90d-release estradiol pellets at 6wks, and underwent behavioral testing beginning at 8wks with radial arm water maze (RAWM) and novel object recognition (NOR). Mice were sacrificed at 12wks, or after re-testing at 20wks. Hippocampus, pre-frontal cortex, ventral striatum and parietal cortex were dissected. Western blotting and IHC were used to evaluate tight junction proteins, BBB and inflammatory mediators.

Results: MRL/lpr ERa−/− mice (n=9) performed significantly better in RAWM testing than WT MRL/lpr mice (n=11). There was a significant reduction in working memory errors (2.33 vs. 5.64, p=0.041), reference memory errors (8.22 vs. 12.73, p=0.033) and start arm errors (1.67 vs. 5.18, p=0.048) in ERa−/− mice at 8–10wks. There were no significant differences in NOR testing in discrimination index or latency to novel object, but ERa−/− mice spent significantly more time with both objects compared to WT MRL/lpr. Eight of 20 brains were processed and analyzed to date, with no significant differences seen in tight junction proteins (Zo-1 or occludin), however there is a trend towards reduced Zo-1 in hippocampus and cortex from ERa−/− mice. GFAP (astrogliosis marker) was not significantly different between groups, but there was a trend towards reduced Iba1 (microgliosis marker) in hippocampus.
Conclusion: Preliminary data suggest a trend towards reduced microgliosis as a marker of inflammation in the hippocampus of ERa−/− mice. Most notably, ERa deficiency provides profound protection against cognitive deficits in MRL/lpr mice as early as 8wks of age.

Inherent Strain-Based Differences in Qualitative CD4 T Cell Responses Determine Lupus Severity. Kateryna Soloviova, Maksym Puliaiev and Charles S. Via. Uniformed Services University of Health Sciences, Bethesda, MD

Background/Purpose: A lupus-like disease can be induced in B6D2F1 mice by the transfer of parental DBA/2 splenocytes (DBA->F1). Transfer of splenocytes from the other parent (B6->F1) results in B6 anti-F1 CD8 cytotoxic T lymphocytes (CTL) that abort lupus by eliminating host lymphocytes, particularly B cells (acute graft-vs.-host disease)(GVHD). In DBA-

>F1 mice, donor anti-host CTL fail to develop allowing donor CD4 T cell help to B cells and autoantibody production to proceed unchecked (chronic GVHD). Depletion of donor CD8 T cells (i.e. transfer of purified CD4 T cells) from either parent results in lupus although renal disease is milder with B6 CD4 T cells.

Methods: To determine whether CD4 T cells exhibit strain-based differences in lupus inducing capacity, disease was induced in B6D2F1 mice following transfer of equal numbers of purified parental CD4 T cells. B10.D2 splenocytes (which behave like B6 splenocytes) were substituted for B6 donors to ensure that both donor populations recognized H-2[b]. Because the F1 strain is constant, differences in disease expression can be ascribed to the donor strain.

Results: Long term, DBA CD4->F1 mice exhibited more severe lupus renal disease (histology, proteinuria, mortality) and significantly greater T follicular helper cells (donor and host) and IL-21 gene expression vs. B6 CD4->F1. Short term (< 2 weeks), B6 CD4->F1 mice exhibited greater donor CD4 intracellular IFN-g and TNF and greater host CD8a+ DC expansion vs. DBA CD4->F1 mice however, DBA CD4->F1 mice exhibited significantly greater expansion of plasmacytoid DC and IL-21 gene expression. To address the mechanism of defective DBA CD8 CTL maturation, purified CD4 and CD8 T cells from both donors were matched or mixed prior to transfer. For matched injections, both B10.D2 CD4 +B10.D2 CD8 (D2+D2->F1) mice and DBA+DBA->F1 mice exhibited the expected acute and chronic GVHD phenotype respectively at 2 weeks. For mixed subsets, D2+ DBA->F1 exhibited a phenotype not significantly different from control acute GVHD indicating that normal (D2) CD4 T cell help could correct intrinsic DBA CD8 CTL defects e.g., poor KRLG-1 upregulation. By contrast, DBA+D2->F1 mice exhibited an intermediate phenotype significantly different from either control group indicating that normal D2 CD8 CTL maturation was significantly impaired with DBA CD4 help. Long term, only DBA+DBA->F1 and DBA+D2->F1 mice exhibited significant lupus autoantibodies or renal disease.

Conclusion: Following an experimental loss of tolerance, B10.D2 CD4 T cells skew towards a strong Th1 cell mediated immune response that mitigates lupus expression whereas DBA CD4 T cells exhibit weak Th1 skewing but are strongly lupus prone by virtue of: 1) greater help for autoreactive B cells, 2) greater pDC and IL-21 expression, and 3) poorer help for down regulatory CD8 CTL. These data indicate that inherent strain differences in qualitative CD4 T cell responses to the same F1 alloantigens determine lupus expression in this model. Similar qualitative differences in CD4 T cell responses to a lupus trigger in humans could also contribute to disease expression.

Estrogen Receptor Alpha Impacts Th17 Expansion in Murine Lupus.
Melissa A. Cunningham[1], Osama S. Naga[2], Jackie G. Eudaly[2] and Gary S. Gilkeson[3]. [1]MUSC, Charleston, SC, [2]Medical University of SC, Charleston, SC, [3]Medical University of South Carolina, Charleston, SC

Background/Purpose: Systemic lupus erythematosus is a disease that disproportionately affects females. The mechanisms underlying the female predominance in this disease are largely unknown. We previously showed that estrogen receptor alpha (ERα) deficiency resulted in significantly reduced renal disease and increased survival in murine lupus. More recently we showed a role for ERα in TLR induction of the IL-23/IL-17 inflammatory pathway. TLR7 and TLR9 agonists induced significant increases in IL-1β and IL-23 expression in dendritic cells derived from ERα+/+, but not ERα-/- mice. Additionally, TLR7 and TLR9 stimulation upregulated IL-23R, which is critical for the stabilization of the Th17 cell phenotype, but this effect could not be demonstrated in the absence of ERα. We hypothesized that the capacity to expand/stabilize Th17 cells is partially regulated by ERα.

Methods: NZM2410 lupus-prone mice (n=19) were sacrificed at 17–19wks and spleens were harvested. T cells were isolated and analyzed prior to and after 4–5d Th17 polarizing conditions (stimulated with CD3/CD28 beads, +TGFβ, +IL-6, +anti-IFNγ, +anti-IL-4; +IL-23 on d3). Flow cytometry, ELISA and RT-PCR were used to evaluate IL-17/CD4 positivity, and IL-21, ICOS, IL-23R message levels, respectively.

Results: Consistent with previous experiments that demonstrated reduced IL-17-producing *ex vivo* spleen cells from ERα deficient mice, we

now show that T cells isolated from NZM2410 ERα-/- mice also produce less IL-17 and have reduced IL-21, ICOS, and IL23R mRNA levels compared with WT NZM2410. In addition, under Th17 polarizing conditions, fewer Th17 (IL17+/CD4+) cells were attained from NZM2410 ERα-/- mice.

Conclusion: T cells from lupus-prone ERα-/- mice express less IL-17 and other markers of Th17 development and stabilization. Taken together, our previous and current data suggest that ERα impacts the IL-23/IL-17 inflammatory pathway. A reduction in Th17 cells may partially explain the decrease in inflammatory renal damage and increased survival in ERα deficient animals.

Characterization of Renal Mononuclear Phagocyte Populations in Murine SLE Nephritis.
Ranjit Sahu[1], Ramalingam Bethunaickan[2] and Anne Davidson[1]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Feinstein Institute for Medical research, Manhasset, NY

Background/Purpose: Macrophages and dendritic cells contribute to renal damage in chronic renal diseases including lupus nephritis. However owing to their multiple phenotypic and functional variations, the role of these cells in organ pathology is still not defined. The present work examines the phenotype and functional characteristics of renal macrophages and dendritic cells in two murine lupus nephritis models.

Methods: A bead based enrichment step followed by cell sorting was used to isolate populations of interest. Cells were cultured in M-CSF or GM-CSF +/- LPS/IFN¥ and analyzed by microscopy and for arginase activity and nitrite production. Antigen presentation capability was measured in mixed lymphocyte reactions. Flow cytometry was performed using multiple phenotypic markers. Gene expression was performed using real-time PCR.

Results: We identified two populations of macrophages and three populations of dendritic cells in both SLE models, with a large increase in the number of cells belonging to two of these five populations during active nephritis. F4/80[hi] monocyte derived macrophages, that are normally resident in the kidneys and increase in number during nephritis, do not differentiate into either M1 or M2 macrophages upon cytokine stimulation and acquire a mixed pro and anti-inflammatory functional phenotype during nephritis in both SLE strains that resembles the constitutively activated phenotype of gut F4/80[hi] macrophages. F4/80[lo] macrophages are infrequent in the kidneys of both strains and do not alter their phenotype during nephritis. CD11c[hi]/CD103[-] DCs accumulate in large numbers during nephritis. These cells have a myeloid DC phenotype and can easily be distinguished from resident renal CD103+ DCs on the basis of morphology, motility and cell surface phenotype. Patterns of TLR expression and chemokine receptors differ between subsets.

Conclusion: This study highlights the heterogeneity of the macrophage/DC infiltrate in chronic SLE nephritis and provides an initial phenotypic and functional analysis of the different cellular components that can now be used to define the role of each subset in nephritis progression or amelioration.

Mitochondrial Dysfunction in the Liver of Lupus-Prone MRL/Lpr Mice Prior to Disease Onset.
Zachary A. Oaks[1], Tiffany Telarico[2] and Andras Perl[3]. [1]SUNY, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY, [3]Upstate Medical University, Syracuse, NY

Background/Purpose: Liver dysfunction, characterized by serum elevation of liver enzymes, is detectable in 20% of patients with systemic lupus erythematosus (SLE.) Males had a higher prevalence of liver dysfunction (12/33: 36%) than females (65/387; 18%; p=0.014; Yu and Perl submitted). Patients with SLE have mitochondrial dysfunction with increased mitochondrial mass and transmembrane potential, yet the biochemical consequences of mitochondrial accumulation in SLE have yet

to be determined. ATP generation is reduced in SLE, a process which is regulated by O_2 consumption through the electron transport chain (ETC) of mitochondria. Here, we characterize utilization of O_2 through the ETC and the generation of oxidative stress in pre-disease lupus-prone MRL/lpr mice to determine whether mitochondrial dysfunction precedes onset of SLE.

Methods: Mitochondrial ETC activity of isolated liver mitochondria was assessed in 4-week-old MRL/lpr lupus-prone mice as well as C57BL/6, MRL/MpJ, and Black 6/lpr age and gender-matched controls mice. ETC was measured O_2 with a Clark electrode. State IV respiration, a measurement of O_2 consumption through complex II, was measured by addition of succinate, ADP, and inorganic phosphate to isolated mitochondria. Hydrogen peroxide (DCF-DA), superoxide (HE), peroxynitrite (DAR-4M), nitric oxide (DAF-FM), mitochondrial potential (JC-1, TMRM), and mitochondrial mass (NAO) were measured by flow cytometry of isolated liver mitochondria. Statistical analysis of data was done by paired t-tests and Pearson's correlation analysis using GraphPad 5.0 software, with a cutoff of $p < 0.05$ considered significant.

Results: 4 week old male MRL/lpr mice exhibited increased mitochondrial respiratory capacity, measured by complex II respiration, in comparison to C57BL/6 (25.8%, p=.03) and Black 6/lpr (11.4%, p=.004) control strains. Mitochondrial mass was increased in male MRL/lpr mice in comparison to C57BL/6 (+26.5%, p=.04) and Black 6/lpr (+55.5%, p=.001). Male MRL/lpr mitochondria also had increased mitochondrial potential (+64.2%, p=.006), production of hydrogen peroxide (+60.0%, p=.02), superoxide (+72.4%, p=.03), nitric oxide (56.1%, p=.0004), and peroxynitrite (107.9%, p=.0005) relative to Black 6/lpr controls. Mitochondrial potential positively correlated with production of hydrogen peroxide (r= 0.883, p=0.047), superoxide (r= 0.881, p=0.049), and peroxynitrite (r= 0.912, p=0.031). MRL/lpr females had increased complex II state 4 respiration (+51.2%, p=0.02) relative to Black 6 controls.

Conclusion: Mitochondrial dysfunction, characterized by increased respiratory capacity and increased mitochondrial mass, precedes disease onset in lupus-prone MRL/lpr mice. We show these changes correlate with increased production of reactive oxygen and nitrogen intermediates, which cause oxidative stress in SLE. Mitochondrial dysfunction in MRL/lpr was more robust in males than females that may account for a higher prevalence of liver disease in men than women with SLE.

A Tolerogenic Peptide Down-Regulates the Expression of Interferon-a in Murine and Human Systemic Lupus Erythematosus. Zev M. Sthoeger[1], Heidy Zinger[2], Amir Sharabi[2], Ilan Asher[1] and Edna Mozes[2]. [1]Kaplan Hospital, Rehovot, Israel, [2]The Weizmann institute of Science, Rehovot, Israel

Background/Purpose: The tolerogenic peptide, designated hCDR1, was shown to ameliorate manifestations of systemic lupus erythematosus (SLE) via down-regulation of pro-inflammatory cytokines, up-regulation of immunosuppressive cytokines and molecules and the induction of regulatory T cells. Because type I interferon (IFN-a) has been implicated to play a major role in the pathogenesis of SLE, in the present studies we investigated the effects of hCDR1 on IFN-a in a murine model of SLE and in human lupus.

Methods: (NZBxNZW)F1 female mice with established SLE manifestations were treated with hCDR1 (10 weekly subcutaneously injections) or with the vehicle alone. The effects on anti-dsDNA antibody levels, proteinuria and kidney immunohistology were assessed. Splenocytes were obtained for gene expression studies. Peripheral blood lymphocytes (PBL) of lupus patients (10), primary anti-phospholipid syndrome (APS) patients (5) and healthy controls (5) were incubated in vitro for 48 hours with hCDR1 or medium prior to gene expression assays. Lupus patients were treated for 26 weeks with hCDR1 (5) or placebo (4) in a Phase II clinical trial by weekly subcutaneous injections. Disease activity was assessed using SLEDAI-2K and BILAG scores [1]. Blood samples were collected, before and after treatment, in PAXgene tubes and frozen until mRNA isolation. Gene expression of IFN-a was determined by real-time RT-PCR.

Results: Treatment of (NZBxNZW)F1 SLE afflicted mice with hCDR1 down-regulated significantly IFN-a gene expression (73% inhibition compared to vehicle, p= 0.002). The latter was associated with diminished anti-dsDNA titers as well as proteinuria and glomerular

immune complex deposit levels. Further, hCDR1 reduced, in vitro, the IFN-a gene expression in PBL of lupus patients (74% inhibition compared to medium, p=0.002). hCDR1 had no significant effects on the expression levels of IFN-a in PBL of primary APS patients or of healthy controls. Moreover, a significant reduction in IFN-a was determined in PBL of lupus patients that were treated with hCDR1 for 26 weeks (64.4% inhibition compared to pretreatment expression levels, p=0.015). No inhibition of IFN-a expression was observed in PBL of placebo treated patients. In agreement, as previously reported, treatment with hCDR1, but not with placebo, resulted in a significant decrease of disease activity as determined by the BILAG and SLEDAI-2K scores [1].

Conclusion: Treatment with hCDR1 resulted in a significant amelioration of lupus manifestations in murine models. Studies of a limited number of lupus patients indicated beneficial effects in hCDR1 treated patients. We reported previously that hCDR1 affected various cell types and immune pathways involved in the pathogenesis of SLE. The present studies demonstrate that hCDR1 is also capable of down-regulating significantly (and specifically to lupus) IFN-a that has been recently considered as a target for SLE therapy. Thus, hCDR1 has a potential role as a novel, disease specific treatment for human lupus.

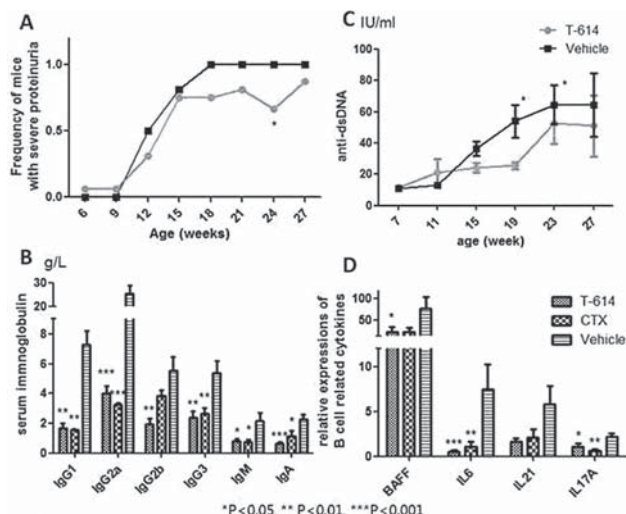
A Novel Small Molecular Anti-Rheumatic Drug, T-614, Ameliorates Lupus-Like Disease in MRL/Lpr Mice by Suppressing B Cell Functions. Qingran Yan, Fang Du and Chunde Bao. Renji Hospital, Shanghai, China

Background/Purpose: T-614 is a small molecular drug that has multiple immunomodulatory effects and has been used for treating rheumatoid arthritis. Previous work has revealed this agent may have inhibitory effects on B cells. Since excessive B cell activation is a characteristic of systemic lupus erythematosus (SLE), here we investigated efficacy of T-614 on lupus-like disease and its potential mechanism in MRL/lpr mouse, a classic lupus model.

Methods: Female MRL/lpr mice were randomly given T-614 (30mg/kgμd), vehicle solution or cyclophosphamide (CTX, 20mg/kg w) as controls before their disease onset. 24-hour-urine and blood samples were collected regularly. Kidney and spleen samples of each mouse were collected at the end point of observation. Urine protein concentrations were measured by bicinchoninic acid protein assay, serum C3 and immunoglobulin were detected by ELISA, anti double strand DNA (dsDNA) antibody titers were quantified by radioimmunoassay and serum alanine transaminase (ALT), creatinine and blood cell counts were analyzed by auto analyzer. Expressions of B cell related cytokines by splenic cells were determined by real-time polymerase chain reaction, CD20+ B cell invasions in kidney were detected by immunohistochemistry, immune complex deposition in kidney was determined by immunofluorescence, and kidney injury was blindly scored by a renal pathologist.

Results: T-614 ameliorated lupus-like disease activity in MRL/lpr mice. Mice in T-614 group had lower frequency of severe proteinuria (over 20mg/24h, Figure A), lower serum creatinine (15.53 ±0.5845 vs 19.19 ±0.9184 μmol/L, P=0.025) and higher levels of serum C3 (2.027 ±0.1807 vs 1.296 ±0.0866 g/L, P=0.026) than vehicle controls. Kineys from T-614 treated mice had less lymphocyte invasions, creasants, casts in tubula and vasculitis changes than those from controls. Glomerular injury scores showed statistically significant difference (median: 1.46, QR 1.35–3.745 vs median: 3.37, QR 2.17–4.0, P=0.0381) between these two groups. Immunofluorescence also showed less immune complex depositions in kidneys from T-614 group. For B cells, T-614 remarkably reduced serum immunoglobulin (Figure B), anti-dsDNA antibody titers (Figure C) and B cell related cytokine (Figure D) expressions in splenic cells. Notably, effects of T-614 on immunoglobulin and B cell cytokines were comparable to CTX. Furthermore, mice from T-614 group had less CD20+ B cell invasions in their kidneys than vehicle group (mdian: 1.0, QR 0.875–2.0 vs mdian: 2.0,QR 2.0–3.0, P=0.0157). Lastly, overt adverse effects, including infection, elevated serum ALT or abnormal peripheral blood cell counts, were not observed.

*P<0.05, ** P<0.01, ***P<0.001


Conclusion: T-614 can ameliorate lupus-like disease in MRL/lpr mice mostlikely through B cell suppression without overt toxicity. Our results suggest that T-614 has potential for the therapy of SLE.

Left Ventricular Diastolic Dysfunction May Play a Role in Pathophysiology and Poor Prognosis of Pulmonary Arterial Hypertension Associated with Systemic Sclerosis. Sumiaki Tanaka[1], Eisuke Ogawa[1], Tatsuhiko Wada[1], Tatsuo Nagai[1], Jun Okada[2] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Kitasato University, Sagamihara, Japan

Background/Purpose: Cardio-pulmonary involvements of systemic sclerosis (SSc), including cardiomyopathy, interstitial lung disease, and pulmonary arterial hypertension (PAH) are leading causes of SSc-related deaths. Several potent effective PAH-specific therapies have recently been recently available, improving survival of patients with overall PAH. However, the survival of patients with PAH associated with SSc (SSc-PAH) is still poorer than that of patients with PAH associate with other connective tissue diseases (CTDs). To explore the characteristics relevant to poor survival of SSc-PAH patients, we analyzed hemodynamics data.

Methods: We analyzed 157 right heart catheter data obtained from 66 patients with PAH associated with CTDs, including 30 patients with SSc, and 36 non-SSc-CTD patients (17 patients with SLE,13 patients with MCTD and 6 patients with other CTDs), who had been followed between January 1980 and April 2012 in our hospital. We compared mean pulmonary artery pressure (mPAP), cardiac output (CO), pulmonary capillary wedge pressure (PCWP) and pulmonary vascular resistance (PVR) between SSc-PAH patients and non-SSc-PAH patients. Survival from the date of the initial diagnosis of PAH was measured, and analyzed using Cox's proportional hazard model.

Results: The values (mean $\pm$ SD) of mPAP, CO, PCWP, and PVR at the initial diagnosis of PAH were 37.7 $\pm$ 11.3 mmHg, 4.6 $\pm$ 1.2 L/min, 7.7 $\pm$ 3.5 mmHg, and 6.9 $\pm$ 3.8 Wood's units, respectively. Thirty-six of the 66 patients died. Cox's proportional hazard model estimated that lower CO, higher PVR and higher PCWP, but not mPAP in hemodynamics at the initial diagnosis of PAH appeared to be risk factors for death (**Table**). Of the 36 patients who died, 20 were SSc-PAH patients. Moreover, PCWP measured throughout the course of PAH was significantly higher in SSc-PAH patients than that in non-SSc-PAH patients (8.66 $\pm$ 3.93 mmHg, 6.79 $\pm$ 2.73 mmHg, respectively; p=0.0354) (**figure**).

Table. Hazard ratios for death in hemodynamics at the initial diagnosis of PAH in patients with CTDs estimated by Cox's proportional hazard model

Covariant	HR for death	95%CI	p
mPAP (mmHg)	1.011	0.979 - 1.043	0.4817
PCWP (mmHg)	1.122	0.984 - 1.258	0.0840
CO (L/min)	0.580	0.396 - 0.815	0.0012
PVR (Wood's unit)	1.151	1.045 - 1.265	0.0051

| P value | 0.6294 | 0.0354 | 0.2227 | 0.8826 |
Figure. Hemodynamics data obtained from 157 right heart catheter test from 30 SSc-PAH patients and 36 non SSC-PAH patients.

Conclusion: These results demonstrate that the presence of left ventricular diastolic dysfunction as evidenced by the elevation of PCWP plays a role in pathophysiology and poor prognosis of SSc-PAH. The data therefore suggest the importance of care for left ventricular diastolic dysfunction under management using PAH-specific therapies in order to improve prognosis in SSc patients.

Limited Utility of Pulmonary Function Tests and B-Type Natriuretic Peptide As Screening Tools for Pre-Capillary Pulmonary Hypertension in Patients with Systemic Sclerosis. Yuichiro Shirai[1], Yuichi Tamura[1], Hidekata Yasuoka[1], Tsutomu Takeuchi[1], Toru Satoh[2] and Masataka Kuwana[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Kyorin University School of Medicine, Tokyo, Japan

Background/Purpose: A series of recent studies indicate that early detection of pulmonary hypertension (PH) improves a survival in patients with systemic sclerosis (SSc). Thus, annual screening based on echocardiography combined with Doppler procedure is recommended in SSc patients. On the other hand, pulmonary function test (PFT) and B-type natriuretic peptide (BNP) are also reported to be useful for identifying patients with PH, but roles of these tests in routine PH screening remain unclear. We evaluated if PFT parameters and BNP, in combination with or without echocardiography, are useful as screening tools for PH in patients with SSc.

Methods: This single-center observational study enrolled 94 consecutive SSc patients who visited our center between January 2008 and June 2012, and underwent PFTs, serum BNP measurement, and echocardiography for PH screening. Our routine screening program consists of two steps: i) selection of patients suspected to have PH based on dyspnea symptoms and echocardiography that assesses morphology and estimated systolic pulmonary arterial pressure (esPAP) calculated from tricuspid regurgitation velocity and presumptive right atrial pressure (5 mmHg), and ii) diagnostic confirmation by right heart catheterization (RHC) in patients with esPAP >50 mmHg, esPAP 37–50 mmHg with echocardiographic variables suggestive of PH, or unexplained dyspnea. Patients with mean pulmonary arterial pressure $\geq$25 mmHg at rest and pulmonary capillary wedge pressure <15 mmHg were diagnosed as having pre-capillary PH (pre-PH). We also enrolled 14 incident SSc cases with pre-PH. PFT variables recorded were %FVC, %DLCO, %DLCO/VA, and a ratio of %FVC and %DLCO or %DLCO/VA. Receiver-operating characteristic (ROC) curve analysis was performed to obtain area under the curve (AUC) and optimal cut-off values.

Results: Of 94 patients screened, 19 underwent RHC, resulting in diagnosis of pre-PH in 5 patients. Individual screening parameters were compared between 89 patients without pre-PH and 19 with pre-PH consisting of 14 incident and 5 newly identified cases. There were significant differences in %DLCO, %DLCO/VA, %FVC/%DLCO ratio, %FVC/%DLCO/VA ratio,

and serum BNP between PH and non-PH groups (P <0.01 for all comparisons). ROC analysis revealed that %FVC/%DLCO was the best PFT parameter that discriminated PH and non-PH cases (AUC 0.76), while BNP and esPAP gave the higher AUC (0.93 and 0.98, respectively). The %FVC/%DLCO ratio provided sensitivity of 79% and specificity of 76% when cut-off was set at 2.45, while BNP gave sensitivity of 84% and specificity of 91% with the cut-off of 86 pg/mL. Diagnostic utility of these two tests was apparently inferior to esPAP, which provided sensitivity of 100% and specificity of 93% with the cut-off of 45 mmHg. When %FVC/%DLCO ratio and BNP were combined with esPAP, the specificity was increased from 93% to 96% without decrease of sensitivity.

Conclusion: Our results clearly indicate PFT or BNP alone was inappropriate for PH screening in SSc. Simultaneous measurement of PFT and BNP with echocardiography slightly improves diagnostic accuracy, indicating limited utility of these tests in current echocardiography-based screening program.

Unmasking Latent Pulmonary Arterial Hypertension by Fluid Challenge in Patients with Systemic Sclerosis. Amee Sonigra[1], Melanie Hurford[2], Patricia Lewis[3], David Kilpatrick[1], Nathan Dwyer[1] and Jane Zochling[3]. [1]Royal Hobart Hospital, Hobart, Australia, [2]Menzies Research Institute, Hobart, Australia, [3]Menzies Research Institute Tasmania, Hobart, Australia

Background/Purpose: Pulmonary arterial hypertension (PAH) is associated with high morbidity and mortality in Systemic Sclerosis. Early diagnosis and treatment leads to substantial improvements in quality of life, prognosis and mortality. Right heart catheterization remains the only test that can diagnose PAH and differentiate it from pulmonary venous hypertension or diastolic dysfunction. Controversies exist in unmasking PAH with exercise or fluid challenge during right heart catheterization. However, there are no studies so far to identify them as one of the means of early diagnosis.

Methods: Our study includes 173 Systemic sclerosis patients enrolled in the Tasmanian Systemic Sclerosis Epidemiology (TASSIE) study, recruited from rheumatologists, physicians, cardiologists, general practitioners and other health professionals across Tasmania since 2007. Echocardiogram and pulmonary function tests were routinely performed on each patient at screening and at annual follow up. Right heart catheter was performed when clinically indicated. A proportion of symptomatic patients underwent right heart catheterization with fluid challenge based on clinical suspicion of PAH or diastolic dysfunction. Treatment for PAH was initiated in all patients who qualified under current regulations. Treatment effects on their six minute walk test (6MWT) and quality of life were studied at the end of two years.

Results: Seventy-eight of the cohort (45.1%) were diagnosed with PAH. Thirty-seven (21.4%) were diagnosed by standard RHC and 41 (23.7%) had latent PAH unmasked by the fluid challenge on RHC. Patients with PAH showed female predominance, and those who had diagnosis on fluid challenge were younger than those who were diagnosed without fluid challenge (57.5–vs-59.8, p < 0.05). More patients with limited SSc than diffuse disease had PAH (51-vs-27). Improvements in 6MWT were observed in both groups at 6 months and 12 months after treatment commencement for PAH (Table).

	PAH on RHC	PAH on fluid challenge	Any form of PAH
Total	37 (21.4%)	41 (23.7%)	78 (45.1%)
Sex (M:F)	8:29	4:37	12:66
Age (Mean yrs)	59.8	57.5	59
Diffuse	16	11	27
Limited	21	30	51
Mean % improvement from baseline in 6MWT at 6 months	14.34%	11.33%	13.33%
Mean % improvement from baseline in 6MWT at 12 months	12.96%	15.84%	14.4%

Conclusion: Fluid challenge is a sensitive measure of early diagnosis of pulmonary arterial hypertension secondary to systemic sclerosis. Early diagnosis has led to improved treatment outcome in our small cohort.

Clinical Outcomes of Scleroderma Patients At High Risk for Pulmonary Hypertension. Analysis of the Pulmonary Hyparternsion Assessment and Recognition of Outcomes in Scleroderma Registry. Avram Z. Goldberg[1], Vivien M. Hsu[2] and Virginia D. Steen[3]. [1]North Shore-LIJ Health System, Lake Success, NY, [2]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ, [3]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Pulmonary hypertension (PH) is the most frequent cause of death in Systemic Sclerosis (SSc). It is critical to identify patients early to begin treatment before onset of irreversible heart failure. The PHAROS registry is a prospective observational longitudinal cohort study to better understand the natural history of this problem. This analysis looks at outcomes of patients at high risk for developing PH, the Pre PAH group.

Methods: Pre-PAH is defined by one of the following entry criteria: echocardiogram systolic pulmonary arterial pressure (sPAP) of ≥40mmHg, or DLCO<55% predicted or FVC%/DLCO% ratio >1.6. PFTs, 6 minute walk test (6MW), and sPAP were performed yearly. If PH was clinically suspected, a right heart catheterization was performed. A mean pulmonary artery pressure (MPAP) ≥25 mmHg on right-heart catheterization (RHC) was required for the diagnosis of PH. Descriptive statistics, changes in baseline studies, such as PFTs and 6MWT, at the time of diagnosis of PH, Kaplan-Meier estimate of the time to PH diagnosis and survival of the Pre PAH group were studied.

Results: 253 patients were enrolled in the Pre-PAH group: 35 developed PH at follow-up (New PH), 21 PAH (Group 1), 11 pulmonary venous hypertension (WHO Group 2) and 3 PH secondary to interstitial fibrosis (WHO Group 3). By 4 years, PH developed in 24% of these high risk patients. There was no difference in the age, sex, disease duration or SSc subgroup in patients with New PH and those with no PH. All patients had long disease duration (mean 11.7 years of Raynaud's) and 64% had limited SSc. The baseline DLCO was low in both groups (46.66 in New PH group vs 51.3 in the no-PH group) but there was not a further significant decrease in those who had a repeat DLCO at the time of diagnosis of PH. there was no difference in 6MW distance at baseline, but patients with New PH had a significant decrease in the mean 6MW distance of 60.27 meters at the time of the diagnosis of PH, compared to the no PH group (−13m) (p<0.01) Those that progressed to PH also exhibited significant oxygen desaturation during 6MW (saturation < 92%) both at baseline and at time of diagnosis of PH which was not experienced by the no PAH group (p<0.01). There were 22 deaths in the pre PAH group: 3 year survival was 92%. Three of the 35 New PH patients died of PH, 6 pre-PAH died of interstitial lung disease, 6 had multisystem SSc deaths, and 7 others were either non SSc or unknown. Patients who died had lower DLCO at baseline than those who were still living, 35% vs 51% (p<0.01)

Conclusion: We show that 24% of the prePAH SSc patients developed PH by 4 years. In addition to the known high risk features of long standing limited scleroderma and a low DLCO, patients had a decreasing 6MW distance and significant 02 desaturation prior to the diagnosis of PH by RHC. Overall, 3 year survival of these patients at 92% was fair, but deaths in these high risk patients were associated with a very low DLCO. Our study shows the usefulness of the serial 6MW distance and exercise induced hypoxia to determine patients that may progress to PH. We hope that early identification and treatment of SSc -PH will significantly alter the long-term outcome of these patients.

Expert Consensus for Performing Right Heart Catheterization in Suspicion of Pulmonary Arterial Hypertension Associated with Systemic Sclerosis: A Delphi Consensus Study with Cluster Analysis From the Eposs Group. Jerome Avouac[1], Dörte Huscher[2], Daniel E. Furst[3], Oliver Distler[4] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [3]UCLA Medical School, Los Angeles, CA, [4]University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Pulmonary hypertension (PH) has emerged as a critical cause of death in systemic sclerosis (SSc). Recent data have highlighted the poorer outcomes of SSc associated PAH as compared to the idiopathic forms. Therefore, the management of SSc patients at risk of PAH risk must be improved to allow early diagnosis. However, there is presently no guideline regarding the parameters that should lead the physician to perform right heart catheterization, the only tool unequivocally establishing

the correct diagnosis. Our aim was, by consensus, to identify the most appropriate indications for RHC in patients with SSc.

Methods: A three-stage Delphi exercise involving worldwide PH experts was designed to answer the following question: "based on which parameters, performed on the basis of an annual screening of SSc patients in clinical practice, do you decide to refer patients for RHC?". The Delphi exercise was performed between March 2011 and December 2011.

The aim of the first stage was to obtain a comprehensive list of domains and tools to be considered before referring a SSc patient for RHC. This list combined evidence-based indications extracted from published reports on SSc-PH and expert opinions. For the second stage, experts were asked to rate each item proposed in the list, using a 5-point scale (1 indicates "not important/appropriate at all" and 5 indicates "very important/appropriate"). For the third stage, experts were asked to rate the items accepted after the second round, using the same 5-point scale. After each of stages 2 and 3, the number of domains and tools was reduced according to a cluster analysis. The number of clusters was generated by an automatic cluster algorithm using Bayes information criterion.

Results: 77 experts were contacted by e-mail to participate in this Delphi procedure. 47 (61%) participated in stage 1, 50 (65% of the 77) in stage 2, and 48 (62% of the 77) in stage 3. The list obtained after the first stage consisted on 7 domains (clinical, biomarkers, pulmonary function tests, echocardiography, cardiopulmonary exercise, imaging and EKG) containing a total of 142 tools. Cluster analysis performed after the second stage allowed discarding of 63 of the 142 initial tools. Cluster analysis performed after stage 3 reduced the EPOSS instrument to 3 domains containing 8 items (see table).

Domains	Tools	Mean ratings (5-point scale)
Clinical tools	*Progressive dyspnea over the last 3 months	4.4
	*Unexplained dyspnea	4.3
	*Worsening in WHO dyspnea functional class	4.4
	*Any finding on physical examination suggestive of elevated right heart pressures (Jugular venous distension, accentuated S2, TR murmur, etc)	4.4
	*Any sign of right heart failure	4.8
Echocardiography	*sPAP>45 mmHg	4.3
	* Dilation of right ventricle	4.3
Pulmonary function tests	*DLCO<50% without pulmonary fibrosis	4.4

Conclusion: Among experts in PH-SSc, a core set of indications for clinical practice has been defined to refer SSc patients to RHC in case of PH suspicion. This EPOSS instrument is the first expert guidelines for PH detection that is based on validated consensus methods. Although these indications are recommended by this expert group, it is an interim tool. It will be necessary to formally validate and extend the EPOSS instrument in further studies, both for clinical practice and in terms of additional research.

Pulmonary Hypertension and Interstitial Lung Disease within Pharos: Impact of Extent of Fibrosis and Pulmonary Physiology On Cardiac Hemodynamic Parameters. Aryeh Fischer[1], Stephen C. Mathai[2], Marcy B. Bolster[3], Lorinda Chung[4], Mary Ellen Csuka[5], Robyn T. Domsic[6], Tracy M. Frech[7], Monique E. Hinchcliff[8], Vivien M. Hsu[9], Laura K. Hummers[2], Jason R. Kolfenbach[10], Mardi Gomberg-Maitland[11], Aida Manu[12], Robert W. Simms[13] and Virginia D. Steen[14]. [1]National Jewish Health, Denver, CO, [2]Johns Hopkins University, Baltimore, MD, [3]Medical Univ of South Carolina, Charleston, SC, [4]Stanford Univ Medical Center, Palo Alto, CA, [5]Medical College of Wisconsin, Milwaukee, WI, [6]University of Pittsburgh, Pittsburgh, PA, [7]University of Utah School of Medicine, SLC, UT, [8]Northwestern Univ Med School, Chicago, IL, [9]RWJ Med Schl Scleroderma Prog, New Brunswick, NJ, [10]Univ of Colorado School of Med, Aurora, CO, [11]University of Chicago, Chicago, [12]Rheumatology, Georgetown University Medical Center, Disrict of Columbia, [13]Boston University School of Medicine, Boston, MA, [14]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are the leading causes of mortality in systemic sclerosis (SSc). Many SSc patients have both pulmonary hypertension (PH) and ILD and it can be difficult to distinguish PAH from PH secondary to chronic ILD (PH-ILD). In addition, it is not known to what degree the extent of ILD or pulmonary physiology impact cardiac hemodynamic parameters of PAH. The purpose of this study was to determine the impact that extent of ILD and degree of pulmonary physiologic restriction have on specific cardiac hemodynamic parameters within a subset of the PHAROS cohort.

Methods: We identified PHAROS subjects with right-heart catheter-proven PH that had a forced vital capacity (FVC) < 70% predicted or that had ILD reported on computed tomography (CT) scans. Subjects with pulmonary venous hypertension (wedge pressure >15mmHg) were excluded. Baseline CT scans were scored by the investigator at each site by a standardized system that graded severity of ILD as none (0), mild (1), moderate (2), or severe (3) at 5 specific zones distributed throughout the lungs. A cumulative score based on summation of the score for all 5 zones was generated from each CT scan and defined as none-mild (sum=0–5), moderate (sum=6–10), or severe (sum=11–15).

Results: Sixty subjects met the inclusion criteria and had CT scoring performed: 19 had none-mild, 26 had moderate, and 15 had severe ILD. There were no differences between groups with respect to age (mean 57+/−11) or SSc type (43% diffuse). None-mild ILD was associated with higher mean pulmonary artery pressures (mPAP) (41.8+/−10.7) than moderate (32.7+/−8.4; p=0.002) and severe ILD (mPAP 34.3+/−8.1; p=0.03) or the combination of moderate and severe ILD (33.3+/−8.2; p=0.001). None-mild ILD was also associated with higher pulmonary vascular resistance (PVR) (623+/−340) than seen with combined moderate and severe ILD (361+/−227; p=0.001). There were no differences in mPAP or PVR between moderate and severe ILD or between the combinations of none-mild-moderate ILD compared with severe ILD. In contrast, when stratified by FVC, no differences in mean PAP or PVR were identified. FVC was not a reliable predictor of the extent of ILD in this cohort: 29% of those with FVC% less than 70 had none-mild ILD, and in those with FVC% greater than 70, 54% had moderate and 16% had severe ILD.

Conclusion: Within this PHAROS subset, significant differences in cardiac hemodynamics were associated with varied extent of ILD but not with degree of restriction estimated by FVC. Furthermore, FVC was not a reliable predictor of degree of ILD. Further studies, incorporating CT extent of ILD along with pulmonary physiology, are needed to help determine ways to distinguish PAH from PH-ILD.

Comparison of Baseline Characteristics of the Combined Response Index for Systemic Sclerosis (CRISS) Cohort to Patients Enrolled in Clinical Trials of Diffuse Systemic Sclerosis. Heather Gladue[1], De Furst[2], Veronica Berrocal[1], James R. Seibold[3], Peter A. Merkel[4], Maureen D. Mayes[5], Kristine Phillips[6], Robert W. Simms[7], Shervin Assassi[8], Philip J. Clements[9], Paul Maranian[10] and Dinesh Khanna[1]. [1]University of Michigan, Ann Arbor, MI, [2]University of California at Los Angeles, Los Angeles, CA, [3]Scleroderma Research Consultants LLC, Avon, CT, [4]University of Pennsylvania, Philadelphia, PA, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]University of Michigan Medical School, Ann Arbor, MI, [7]Boston University School of Medicine, Boston, MA, [8]Univ of Texas Health Science Houston, Houston, TX, [9]UCLA School of Medicine, Los Angeles, CA, [10]UCLA Medical School, Los Angeles, CA

Background/Purpose: Randomized clinical trials (RCTs) of treatment of diffuse systemic sclerosis (dcSSc) would benefit from a composite index that predicted efficacy better than current standard measures that are based on single organ systems. As a first step to achieve the goal of a validated composite index, a longitudinal observational registry was launched in the U.S.: the combined response index for SSc (CRISS) cohort. We aim to compare the baseline characteristics of the 200 patient CRISS cohort with those of 3 large dSSc clinical trials to ascertain whether the CRISS patients are representative of the patients in dSSc clinical trials.

Methods: We compared the baseline clinical characteristics of the 200 patients enrolled in the CRISS cohort to patients who participated in 3 large RCTs in dcSSc: the Oral Collagen, the D-Penicillamine, and the Relaxin trials. Patients were enrolled into the CRISS cohort from 4 scleroderma

centers and all study patients have early dcSSc (< 5 years from first non-Raynaud's sign or symptom).

Results: The Table provides comparison between CRISS and the 3 RCTs. The CRISS cohort is similar across all 3 trials for most of the 15 selected measures. The CRISS cohort is similar to the Oral Collagen trial being statistically not different for 13 of 15 measures; it is similar to the D-Pen cohort for 11 of 15 measures and similar to the Relaxin cohort for 9 of 15 measures. While statistical differences existed for age, gender, BMI, tender joints, DLCO and MD global in some comparisons, majority were not clinically meaningful.

Table. Baseline data for study subjects in the CRISS cohort and comparison clinical trials

	CRISS (n=200)	Collagen (n=165)	D-Pen (n=134)	Relaxin (n=196)
Age (years), mean (SD)	50 (12)	51 (12)	44 (12)*	47 (10)*
Female, n (%)	149 (75)	132 (80)	104 (78)	167 (85)*
Race: Caucasian, n (%)	141 (71)	116 (70)	91 (68)	145 (74)
BMI, mean (SD)	25.4 (5.7)	29.1 (6.9)*	25.4 (4.7)	25.3 (4.7)
Disease duration[a], mean (SD)	32.4 (17.8)	41.9 (32.8)	9.5 (4.1)*	26.4 (16.4)*
MRSS, mean (SD)	20.6(10.3)	26.3 (7.7)*	21.0 (8.0)	27.3 (6.9)*
Tender joints count, mean (SD)	2.8(4.2)	NA	1.5 (2.4)*	1.2 (1.9)*
Active digital ulcers (present), mean (SD)	0.2 (0.7)	NA	0.1 (0.3)	NA
MD global assessment (0–100), mean (SD)	43.0 (21.7)	43.7 (22.6)	NA	49.4, (20.4)*
Pt global assessment (0–100), mean (SD)	39.6(26.9)	38.6(29.3)	NA	50.7 (23.4)*
HAQ-DI (0–3), mean (SD)	1.2 (0.8)	1.3 (0.7)	1.0 (0.7)	1.2 (0.7)
FVC predicted %, mean (SD)	82.4 (18.4)	85.1 (18.2)	83.6 (16.9)	84.9 (15.7)
DLCO predicted %, mean (SD)	66.3 (21.3)	67.9 (20.8)	75.3 (18.4)*	69.3 (21.3)
Serum CPK (U/L), mean (SD)	167 (403)	132 (245)	82 (124)	132 (193)
Serum Creatinine (md/dl), mean (SD)	0.90 (0.95)	0.78 (0.36)	0.90 (0.19)	0.67 (0.22)*

D-Pen=D-Penicillamine; MRSS=Modified Rodnan skin score; Pt=patient; NA=data not available
*Time since first non-Raynaud's symptoms/signs (months)
*p<0.05 for difference between CRISS cohort and the 3 RCTs

Conclusion: The CRISS cohort is generally representative of patients enrolled in large multicenter RCTs of dcSSc and will be fit for the purpose of developing a composite response index. The CRISS cohort will also be a valuable resource for studying the clinical characteristics of patients with early dsSSc followed at major academic centers and treated according to the current standards of care.

1465

World Health Organization Classification of Pulmonary Hypertension and Survival in Systemic Sclerosis Patients in the Pharos Cohort. Jessica K. Gordon[1], Lorinda Chung[2], Robyn T. Domsic[3], Wei-Ti Huang[4], Stephen L. Lyman[1], Evelyn M. Horn[5], Virginia D. Steen[6] and PHAROS Investigators[7]. [1]Hospital for Special Surgery, New York, NY, [2]Stanford Univ Medical Center, Palo Alto, CA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Hospital for Special Surgery, New York, [5]New York Presbyterian Hospital/Weill Cornell Medical College, New York, NY, [6]Georgetown Univ Medical Center, Washington, DC, [7]Washington, DC

Background/Purpose: Pulmonary hypertension (PH) is a leading cause of death in patients (pts) with Systemic Sclerosis (SSc). The World Health Organization (WHO) classifies PH into groups: pulmonary arterial hypertension (PAH - Group 1); PH secondary to left heart dysfunction or pulmonary venous hypertension (PVH - Group 2); and PH secondary to pulmonary disease (PH-ILD - Group 3). Our objective was to compare the clinical features and survival among the 3 PH groups.

Methods: Pts in the PHAROS database with PH, defined by a mean PAP≥25 mmHg on initial right heart catheterization (RHC), were categorized by WHO criteria. A pulmonary capillary wedge pressure (PCWP) <15 mmHg differentiated Group 1 and 2. Pts with ILD with a forced vital capacity (FVC) <65% predicted or significant fibrosis on chest CT with a normal PCWP were included in group 3. Statistical analysis was carried out using ANOVA, logistic regression, and Kaplan-Meier estimates.

Results: There are 248 pts with PH in the PHAROS database: PAH − 160, PVH − 49, and PH-ILD Π39. Demographic and clinical differences are summarized in the table below. PAH pts are slightly older, more likely to be anti-centromere (ACA) positive, and to have limited SSc. Pts with PVH are more likely to be African-American (AA).

Pts have been observed for up to 6.5 yrs. The median period of observation is: PAH 5.02, PVH 1.86, and PH-ILD 2.82 yrs. The 1-year survivals were as follows: PAH 91.8%, PVH 95.2%, and PH-ILD 81.3%, and the 3-year survivals were: PAH 79.4%, PVH 79.1%, and PH-ILD 61.3%. Although the PH-ILD had only a 61% 3 year survival, Kaplan-Meier analysis did not show a significant difference in time to death between the groups, p=0.28, and Cox regression analysis did not show a difference between the groups with respect to survival. Using univariate logistic regression, we assessed the following baseline features as predictors of death: age, gender, race, antibody, disease duration, SSc subtype, RHC parameters, and pericardial effusion. Diffuse subtype was a predictor of death with OR of 1.9 (95% CI 1.008, 3.82), p =0.047. Higher mPAP on RHC was statistically significant with an OR 1.03 (1.005, 1.064) p =0.026. The presence of an effusion missed statistical significance (OR 1.93 (0.977, 3.796), p=0.058).

Survival Analysis stratified by PH_TYPE

Variable	WHO 1	WHO 2	WHO 3	p-value (overall)	p-value (1 v 2)	p-value (1 v3)	p-value (2 v 3)
Age (years)	60.4 (10.3)	54.4 (12.5)	56.2 (11.7)	0.027	0.0048	0.1023	0.7489
% female	85.2	77.3	69.4	0.0702	Overall Insignificant		
% white	81.2	59.1	75.0	0.0357	0.0428	0.268	0.1998
% AA	11.0	27.2	17.1				
Antibody	37.6	13.3	8.33	0.0004	0.024	<0.001	0.672
%aca	8.1	22.2	30.6				
%scl70	22.8	24.4	13.9				
% nuc ANA							
%limited	70.5	51	43.6	0.0109	0.0418	0.0064	0.7812
Disease Duration (yrs)	10.7 (9.2)	7.7 (5.5)	10.2 (8.6)	0.1134	Overall Insignificant		
Right Heart Catheterization Parameters							
mPAP	37.3 (10.5)	34.4 (9.6)	33.8 (10.6)	0.0693	Overall Insignificant		
pulmonary capillary wedge pressure	10.0 (3.3)	20.6 (4.1)	10.0 (4.4)	<0.001	<0.001	0.9987	<0.001
cardiac output	5.0 (1.5)	5.7 (1.8)	5.3 (1.8)	0.0419	0.0365	0.5566	0.5407
pulmonary vascular resistance	506.7 (365.6)	249.7 (183.4)	338.8 (272.2)	<0.001	<0.001	0.1119	0.1222
Pulmonary Function Test Parameters							
FVC % predicted	81.8 (16.1)	66.0 (18.8)	54.1 (13.9)	<0.001	<0.001	<0.001	0.0029
DLCO % predicted	42.2 (16.9)	40.0 (17.1)	28.6 (10.3)	<0.001	0.721	<0.001	0.0052
TLC % predicted	80.5 (16.2)	70.4 (20.1)	60.0 (16.1)	<0.001	0.0053	<0.001	0.0173
FVC:DLCO ratio	2.2 (0.9)	1.8 (0.6)	2.1 (0.7)	0.0249	0.0193	0.6179	0.3977

Conclusion: Overall survival in the PH patients enrolled in PHAROS is better in this observational cohort than in other recent studies, but WHO Group classification did not affect survival over the present period of observation. How these categorizations affect the prognosis of PH pts will continue to be studied in the long-term follow-up of the PHAROS cohort.

1466

Patients with Systemic Sclerosis Are Dying of Non-Systemic Sclerosis Related Causes, However Interstitial Lung Disease Remains the Predominant Systemic Sclerosis Related Cause of Death. Rebecca L. Batten and Bridget Griffiths. Freeman Hospital, Newcastle Upon Tyne, United Kingdom

Background/Purpose: Studies suggest that despite aggressive treatment of interstitial lung disease (ILD) secondary to systemic sclerosis with

cyclophosphamide, over one third of patients will experience a decline in lung function, death or require a lung transplant. The objective of this retrospective cohort is to document the causes of mortality in a UK based population with systemic sclerosis based in a tertiary centre in the North East of England over a period of seven years, and to review the causes of death in those patients treated aggressively with cyclophosphamide.

Methods: All patients attending a North East of England Tertiary Medical Centre with a diagnosis of systemic sclerosis were identified using the departmental database. From this group, all patients who died between 2003 and 2010 were identified. Medical records were reviewed and government death certificates were obtained for these patients. Patients were excluded from the study if either of these resources were not available.

Results: Of the twenty patients identified, five were male and fifteen were female. Four patients had a diagnosis of diffuse systemic sclerosis. Sixteen had a diagnosis of limited disease.

	Cause of death	Diffuse	%	Limited	%
NSR	Cancer	2	50	3	18.8
	Infection	1	25	2	12.5
	Other	1	25	3	18.8
SR	Multiorgan	0	0	1	6.25
	ILD	0	0	6	37.5
	PH	0	0	1	6.25

More patients died of non-systemic sclerosis related (NSR) causes (55%) than systemic sclerosis related (SR) causes. These included cancer (not related to cyclophosphamide) (25%), infection (15%), and other chronic disease (15%). Of the eleven patients treated with cyclophosphamide therapy, nine (82%) died of their underlying lung disease. The leading scleroderma related cause of death in our cohort was ILD (30% of all deaths), followed by pulmonary hypertension (10% of all deaths).

Conclusion: This highlights the importance of screening for organ complications of systemic sclerosis. Patients are, however more likely to die of non-systemic sclerosis related diseases. Physicians should therefore also remain vigilant for NSR disease such as malignancy, which accounted for 25% of deaths.

1467

Association of Gastroesophageal Factors and Progression of Interstitial Lung Disease in the Canadian Scleroderma Research Group, a Large, Multicenter Database.

Xuli Jerry Zhang[1], Ashley Bonner[2], Murray Baron[3], Marie Hudson[4], Janet E. Pope[5] and Canadian Scleroderma Research Group[6]. [1]Western University, London, ON, [2]McMaster University, Hamilton, ON, [3]Jewish General Hospital, Montreal, QC, [4]McGill University, Montreal, QC, [5]Western University of Canada, St. Joseph's Health Care, London, ON, [6]Montreal

Background/Purpose: Interstitial lung disease (ILD) is a common complication of systemic sclerosis (SSc) and is a leading contributor to mortality in SSc patients. Once lung fibrosis occurs, lung function disease course may become stable or progressively decline. While some demographic and SSc-related factors have been associated with development of ILD, little is known about what contributes to progression. We studied the clinical manifestations of SSc-gastroesophageal (GE) involvement in relation to ILD status to determine associations between GE involvement and ILD progression in SSc. Our objective was to determine if GE reflux and dysphagia are associated with progressive ILD as measured by PFTs over three years.

Methods: Canadian Scleroderma Research Group (CSRG), a multi-center database of adult SSc patients, annually evaluates and collects patient information including demographics, skin manifestations, internal organ involvement and function assessment data. Using indicators of GE involvement and annual pulmonary function test results from the CSRG database, comparisons were made between no ILD, stable ILD and progressive ILD groups based on FVC% predicted. Univariate and multivariate analysis were used to determine association between GE factors and ILD development and progression.

Results: The study included data of 1043 SSc patients with mean age of 55.7 years and mean disease duration of 10.8 years. Among the variables of interest, physician indicators such as esophageal dysmotility (P=0.009) and post-esophageal dilatation (P=0.041) along with patient indicators such as difficulty swallowing (P=0.016), waking up choking (P=0.026) appeared to significantly increase risk of developing ILD. In comparing progressive vs. stable ILD patients, early satiety (p=0.018) a combination term composed of post-dilatation*choking (p=0.042) increased risk of ILD progression.

Table 1. Logistic regression models for dysphagia and GERD indicators

Moderate/Severe ILD vs. No/mild ILD			Single Effects					Interaction Effects	
COVARIATES	Model 1 Dilatation	Model 2 Dysmotility	Model 3 Difficulty Swallowing	Model 4 Choking	Model 5 Heartburn	Model 6 Food/Acid	Model 7 Early Satiety	Model 8 Dilatation* Difficulty Swallowing	Model 9 Dilatation* Choking

Progressive vs. Stable			Single Effects					Interaction Effects	
COVARIATES	Model 1 Dilatation	Model 2 Dysmotility	Model 3 Difficulty Swallowing	Model 4 Choking	Model 5 Heartburn	Model 6 Food/Acid	Model 7 Early Satiety	Model 8 Dilatation* Difficulty Swallowing	Model 9 Dilatation* Choking
Age	1.066 (.014)	1.068 (.0110	1.069 (.013)	1.067 (.013)	1.062 (.021)	1.071 (.011)	1.072 (.010)	1.069 (.012)	1.075 (.011)
Telangiectasia	0.124 (.036)	.126 (.033)	0.122 (.028)	0.127 (0.34)	0.138 (.044)	.124 (.040)	.073 (0.17)	0.142 (.052)	0.095 (.028)
GI variable of interest	2.150 (.263)	-	2.045 (.248)	1.325 (.653)	2.680 (.098)	3.009 (.072)	4.573 (.018)	0.367 (.677)	29.075 (.042)

Results are **OR (P-value). GI variable of interest is what each model studied (listed under each Model). Covariates with P<0.1 from univariate logistic regression were included for each comparison. Odds ratio are indicated as OR (p-value). P<0.05 was considered to be significant. (−) indicates that multivariate analysis could not be performed. Pulmonary arterial hypertension (PAH)=physician answering yes to 'Has the patient ever had pulmonary hypertension? * indicates interaction term between indicated variables.**

Conclusion: Indicators of esophageal dysmotility and GERD studied appear to be associated with ILD in SSc, with some factors specifically related to progressive ILD. Further, the strong association of an interaction term of both dysmotility and GERD with progressive ILD illustrates a potential dose-response phenomenon. These results hold important implications for management of ILD in SSc.

1468

Patient Perspective Informs Core Sets, Constructs of Metrics and Communication Tools for Patients with Connective Tissue Disease Related Interstitial Lung Disease.

Shikha Mittoo[1], Sid Frankel[2], Daphne LeSage[3], Flavia V. Castelino[4], Lisa Christopher-Stine[5], Sonye Danoff[6], Aryeh Fischer[7], Laura K. Hummers[5], Ami A. Shah[5], Jeffery J. Swigris[7], Spohia Cena[8], Sancia Ferguson[9], Ignacio Garcia-Valladares[8], Maithy Tran[1], Harmanjot K. Grewal[10] and Lesley Ann Saketkoo[8]. [1]University of Toronto, Toronto, ON, [2]University of Manitoba, Winnipeg, [3]Center for CCH at State of Louisiana, New Orleans, LA, [4]Massachusetts General Hospital, Boston, MA, [5]Johns Hopkins University, Baltimore, MD, [6]Johns Hopkins School of Medicine, Baltimore, MD, [7]National Jewish Health, Denver, CO, [8]Louisiana State University Health Science Center, New Orleans, LA, [9]Tulane University School of Medicine, [10]Lousiana State University Health Sciences Center, New Orleans, LA

Background/Purpose: Limited information on the patient experience exists in CTD-ILD. Herein supports that the patients' perspective is essential to informing clinical practice and in developing optimal outcome measures for CTD-ILD.

Methods: Focus groups were dedicated to patients with each of the following ILD subtypes: rheumatoid arthritis, idiopathic inflammatory myositis, systemic sclerosis, and various CTD subtypes. Focus groups were followed with patient questionnaires and/or patient interview. Institutional review board approval was attained at all participating institutions.

Included were English speaking adults with a diagnosis of ILD by either histologic or computed tomography (CT) evidence with either a) symptoms of cough and/or dyspnea or b) restrictive pulmonary physiology or c) resting or exertion-related peripheral oxygen desaturation. CTD diagnoses were by rheumatologists based on accepted criteria. Patients with pulmonary hypertension or hypersensitivity pneumonitis made were excluded.

The script included 2 questions ("How have you experienced your disease since the diagnosis of ILD?", "How has the disease changed?"), with the WHO-100 domains as back-up to insure comprehensiveness. Data were analyzed through inductive development. The thematic structures of 5 independent analysts were triangulated, including 1 patient for each transcript.

Results: Six focus groups of 6–9 (total 45) participants per group across 5centres (University of Manitoba, University of Toronto, Louisiana State University, Johns Hopkins University, Massachusetts General/Brigham and Womens) and two countries (Canada and USA) were conducted; the following themes that emerged from preliminary findings from a subset analysis.

I. Biophysiologic Sphere:
   A. Cough:
      i. Universal and relevant patient experience
      ii. Patients described types of coughs and its triggers
   B. Dyspnea:
      i. Reference to breath/breathing rarely used
      ii. Often described within context of functional limitation or loss of pleasurable activity and/or connectedness (eg. reading to children)
II. Psychological Sphere:
   A. Living with Uncertainty:
      i. Perpetuated by inadequate physician communication
      ii. Unknown and unpredictable disease course in the immediate and long-term (death)
      iii. Conflicts in management between CTD and ILD
   B. Struggle Over the New Self:
      i. Maintaining an autonomy
      ii. Parenting and grand-parenting roles were a central concern
   C. Development Of Resilience Through Coping (Self-Efficacy)

Conclusion: Patient experts have informed our understanding around communication and promising, relevant outcome measures in CTD-ILD. Medical expert consensus identified 5 domains in CTD-ILD for outcome measures. While dyspnea remained a core outcome measure for both patient and medical experts, cough was relevant to patients but not medical experts. A discordant language related to dyspnea exists between clinicians and patients and may impact performance of current and potential metrics related to dyspnea.

1469

Heterogeneity of Autoantibodies in Systemic Sclerosis: Reconsidering Current Paradigms. Sonal Mehra[1], Murray Baron[2], Mat Stephenson[1], Marie Hudson[3], Janet E. Pope[4], Canadian Scleroderma Research Group[5] and Marvin J. Fritzler[1]. [1]University of Calgary, Calgary, AB, [2]Jewish General Hospital, Montreal, QC, [3]McGill University, Montreal, QC, [4]St. Joseph's Health Care London, London, ON, [5]Montreal

Background/Purpose: One of the hallmarks of systemic sclerosis (SSc) is the presence of disease specific autoantibodies (aab): anti-centromere (CENP), anti-topoisomerase I (TopoI), anti-RNA polymerase III (RNAP), and anti-fibrillarin (Fib). Current paradigms suggest that SSc aab profiles are relatively monospecific and that SSc-specific aab are mutually exclusive. We undertook a study using array technologies to evaluate the spectrum and interrelations of aab in SSc

Methods: Sera from 805 SSc patients enrolled in the a multi-centre cohort biobanked at −80C were used for this study. Aab to Topo I, CENP, RNAP, Fib, NOR90, Th/To, Pm100, Pm75, Ku, platelet derived growth factor (PDGFR), and Ro-52/TRIM21 were detected by line immunoassay (LIA). Addressable laser bead immunoassay (ALBIA) was used to detect other antibodies to Extractable Nuclear Antigens Jo-1, Sm, UI1RNP, SSA/Ro60, SSB/La, Rib P. The frequency of each aab occurring individually or associated with other aab was calculated, tabulated and plotted as a heat map derived from an Excel database.

Results: In order of decreasing overall frequency, anti-CENP was positive in 38.5%, anti-RNAP 23.2%, anti-Topo I 21.4% and anti-Fib 7.2%. In contrast to current paradigms, the SSc-related aab overlapped with other SSc-specific aab: anti-CENP 8.9%; anti-Topo I 4.7%; anti-RNAP 9.8%; anti-Fib 6.6%. SSc-specific aab also overlapped with the broader spectrum of aab: anti-CENP 73%, anti-Topo I 60%, anti-RNAP 63% and anti-Fib 88%. Accordingly, 'monospecific' aab (i.e. no other detectable aab) to

CENP, RNAP, U1RNP, Topo-I, and Fib, I were detected in 26.7%, 36.8%, 18%, and 39.3%, 13.8% and 12%, respectively. Likewise, the majority of sera with aab to Ku, Th/To, Sm and SSB/La also overlapped with other aab. Aab to PM-Scl 75/100, NOR-90, SSA and Fib were observed in 12%, 77 9.5%, 8.5%, 7.2%, respectively. Anti-U1RNP and Ku (both 5.4%), anti-PDGFR (2%), anti-Jo-1 (0.5%) were the least common. Of note, 8.6% of the SSc sera did not have any aab detectable by LIA or ALBIA.

Conclusion: Our study indicates that the majority of SSc sera have multiple aab and independent segregation of the SSc-specific or SSc-related autoantibodies is not as clear-cut as current literature suggests. Furthermore, studies of clinical correlations with certain aab in SSc should be reconsidered in light of the complexity of the serological profiles of individual patients.

1470

Clinical Features Associated with Anti-Th/to in Non-Scleroderma Patients - Sine Scleroderma? Ann D. Chauffe, Minoru Satoh, Angela Ceribelli, Edward K.L. Chan, Yi Li, Eric S. Sobel, Westley H. Reeves and Michael R. Bubb. University of Florida, Gainesville, FL

Background/Purpose: Autoantibodies in scleroderma (systemic sclerosis, SSc) such as anti-topoisomerase I (Scl-70), RNA polymerase III, centromere, U3RNP/fibrillarin, and Th/To are associated with a unique subset of the disease and useful biomarkers in diagnosis and management. Among these, anti-Th/To is found in 4–13% of SSc patients and believed to be relatively specific for SSc, however, some reports show the detection of anti-Th/To in patients without SSc or some specific features such as interstitial lung disease (ILD). We sought to further characterize the clinical significance of anti-Th/To by focusing on non-SSc patients in an unselected cohort of rheumatology patients.

Methods: Patients enrolled in the registry from 2000 to 2012 were studied. All sera collected at the initial visit of each patient were tested by immunoprecipitation of ^{35}S-methionine-labeled K562 cell extracts. In addition, 132 SSc and 45 non-SSc sera that had predominant nucleolar staining reported from diagnostic laboratories were tested by urea-PAGE and silver staining for RNA component analysis. Anti-Th/To was defined based on detection of 7–2 and 8–2 RNA in the immunoprecipitates. The clinical information of anti-Th/To positive patients were collected from the database and analyzed.

Results: Overall, 16 patients were found to have anti-Th/To; 7 had sclerodermatous skin changes (SSc group) while 9 patients had neither sclerodermatous skin changes nor a diagnosis of SSc (non-SSc group). All except one in the non-SSc group were female and 7/7 SSc and 7/9 non-SSc were Caucasians (2 in non-SSc were African Americans). In the SSc group, 5 had limited cutaneous (lcSSc) disease and 2 had the diffuse cutaneous (dcSSc) variant. In the non-SSc group, there was 1 SLE with Sjogren's (SjS), 1 with polymyositis (PM) and 2 with primary SjS. Other patients had a diagnosis based on organ involvement or symptoms, such as ILD, pulmonary hypertension (PH), and/or Raynaud's phenomenon (RP). Most non-SSc group patients had features typically associated with SSc: 5/9 RP, 2/9 pitting scars, 3/9 telangiectasias, 3/9 ILD, 2/9 PH. No SSc patients had ILD or PH. 4/9 patients in the non-SSc group may be considered sine scleroderma; 2 with ILD and RP (one also with PH) and 1 with PH and telangiectasias. Another patient had SjS, Hashimoto's thyroiditis and ILD complicated by diffuse alveolar hemorrhage that resulted in his death.

	Scleroderma (n = 7)	No scleroderma (n = 9)
Female, Caucasian	7/7, 7/7	8/9, 7/9
Age (mean)	48	48
Raynaud's	86% (6/7)	56% (5/9)
Pitting scars	0% (0/7)	22% (2/9)
Telangiectasia	71% (5/7)	33% (3/9)
Interstitial Lung Disease	0% (0/7)	33% (3/9)
Pulmonary Hypertension	0% (0/7)	22% (2/9)
Esophageal Dysmotility	43% (3/7)	0% (0/9)
Pericardial effusion	14% (1/7)	22% (2/9)

Conclusion: A significant number of patients with anti-Th/To did not have a diagnosis of SSc. However, most of these patients were found to have other features associated with SSc, many of which may be considered the sine

scleroderma variant. In particular, non-SSc patients with anti-Th/To were found to be enriched for ILD and PH when compared to SSc patients with anti-Th/To. It may be worth testing for anti-Th/To in patients with ILD or PH and anti-nucleolar antibodies. Further studies on the clinical significance of anti-Th/To in non-SSc patients are warranted.

1471

Differential Expression of Hepatocyte Growth Factor (HGF) in Patients with Systemic Sclerosis-Associated Pulmonary Arterial Hypertension.

Lorinda Chung[1], Catriona Cramb[2], William H. Robinson[3], Virginia D. Steen[4] and Roham T. Zamanian[3]. [1]Stanford Univ Medical Center, Palo Alto, CA, [2]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [3]Stanford University, Palo Alto, CA, [4]Georgetown Univ Medical Center, Washington, DC

Background/Purpose: Pulmonary arterial hypertension (PAH) is one of the leading causes of death in patients with systemic sclerosis (SSc). Non-invasive biomarkers are needed to identify patients with early PAH who may benefit from early intervention. We sought to identify novel cytokines that differentiate patients with incident right heart catheterization (RHC)-confirmed SSc-PAH from SSc patients who are at high risk for PAH.

Methods: The Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS) Registry is a registry of SSc patients at high risk for or with incident RHC-confirmed PAH that includes 23 centers throughout the US. Pre-PAH patients fulfill at least one of the following criteria: pulmonary artery systolic pressure (PASP) $\geq$ 40 mmHg on transthoracic echocardiogram (TTE), diffusing capacity of carbon monoxide (DLCO) $<$ 55% predicted, or forced vital capacity (FVC)/DLCO ratio $>$ 1.6. Patients with definite incident PAH have a mean pulmonary artery pressure $\geq$ 25 mmHg and a pulmonary capillary wedge pressure $\leq$ 15 mmHg (without significant interstitial lung disease) on RHC performed $\leq$ 6 months from enrollment. Cytokine and chemokine profiling of 17 cytokines/chemokines measured by Bio-Plex™ bead arrays was performed comparing serum samples from 10 pre-PAH patients to 9 definite PAH patients. Significance Analysis of Microarrays (SAM) was used to identify statistical differences in cytokines/chemokines between the groups with a false discovery rate (q) $<$0.1%. We also evaluated for longitudinal changes in cytokine profiles from 3 pre-PAH patients who subsequently developed definite PAH during follow-up.

Results: All patients were female with a mean age of 52 ± 12 years and disease duration from first Raynaud's symptom of 13 ± 10 years. Two-thirds of patients had limited cutaneous disease, 37% were anti-centromere antibody positive, 32% had a nucleolar ANA, and 16% were anti-U1RNP antibody positive. Mean FVC and DLCO were 82 ± 20% and 45 ± 13% predicted, respectively. Clinical features in the pre- vs. definite PAH groups were not significantly different except with respect to PASP on TTE (34 ± 7 vs. 45 ± 8 mmHg, p=0.006) and 6 minute walk distance (508 ± 115 vs. 393 ± 70 m, p=0.02). Profiling of the pre-PAH vs. definite PAH group identified only one cytokine whose expression levels significantly differed between the groups—hepatocyte growth factor (HGF) levels were significantly higher in the definite PAH group (q$<$0.1%). Evaluation of cytokine profiling from longitudinal samples of pre- to definite-PAH patients did not identify any cytokines with significant changes in expression levels over time.

Conclusion: We found that patients with definite incident PAH from the PHAROS registry expressed higher levels of HGF than patients at high risk for PAH. HGF is a potent pro-angiogenic and anti-fibrotic factor, and has been shown to correlate significantly with right ventricular systolic pressure on echocardiogram as well as a diagnosis of PAH based on RHC. Our findings suggest that HGF expression levels may provide predictive information regarding the risk for PAH in patients with SSc in addition to clinical parameters such as DLCO and PASP on TTE.

1472

Enhanced Liver Fibrosis Test: A Further Step Toward Depiction of Fibrotic Process in Very Early Diagnosis of Systemic Sclerosis.

Francesca Ingegnoli[1], Roberta Gualtierotti[1], Tommaso Schioppo[1], Annalisa Orenti[2], Patrizia Boracchi[2], Chiara Lubatti[1], Sara Lodi Rizzini[1], Antonella Murgo[1], Silvana Zeni[1], Claudio Mastaglio[3], Valentina Galbiati[3], Claudia Grossi[4], Maria Borghi[4], William M. Rosenberg[5] and Pier Luigi Meroni[6]. [1]Division of Rheumatology, Istituto G. Pini, University of Milan, Milano, Italy, [2]Medical Statistics and Biometry, University of Milan, Milano, Italy, [3]Rheumatology Unit, Ospedale Moriggia-Pelascini, Italia Hospital, Gravedona, Italy, [4]Lab of immunology, IRCCS Istituto Auxologico Italiano, Milano, Italy, [5]Centre for Hepatology - UCL, London, United Kingdom, [6]Istituto G. Pini, University of Milan, Milano, Italy

Background/Purpose: Enhanced Liver Fibrosis (ELF) test is derived from an algorithm of 3 serum biomarkers of fibrosis (*i.e.* tissue inhibitors of matrix metalloproteinases, hyaluronic acid and aminoterminal propeptide of type III procollagen), it has been suggested as a sensitive/predictive tool for liver fibrosis. Aim of the study was to evaluate whether ELF may help in differentiating primary Raynaud's phenomenon (Rp) from very early Systemic Sclerosis (SSc) in a cross-sectional multi-center study.

Methods: 110 consecutive adult subjects with "isolated" Rp (*i.e.* without any symptoms/signs suggesting a connective tissue disease) referring to 3 Italian Rheumatology Centers in approximately 6 months time were enrolled. Patients underwent as first screening nailfold capillaroscopy (NC) and were tested for anti-nuclear antibodies (ANA) by IFF and blotting and classified as primary Rp (pRp) (*i.e.* NC and ANA negative), very early SSc (*i.e.* ANA and NC positive), or Rp with NC or ANA positive. Patients with any other fibrosing disorder and treated with interferon were excluded. 15 limited cutaneous (lc)-SSc and 15 diffuse cutaneous (dc)-SSc with disease duration $<$5 years were also studied. ELF score was determined blindly by an independent commercial service (iQur, UK). Statistical analysis was performed by regression modelling this score as a function of the diagnosis and age. The discriminant performance was evaluate by ROC curve analysis adjusting for age.

Results: 60 subjects had pRp (mean age 43.1 yrs), 35 had Rp with positive ANA only (mean age 43.6 yrs), 4 had Rp with NC scleroderma pattern only (mean age 38.2 yrs) and 10 had a diagnosis of very early SSc (mean age 59.7 yrs). There were significantly differences between ELF scores in subjects with pRp (mean 7.84) vs patients with very early SSc (mean 8.44), lc-SSc (mean 8.68) and dc-SSc (mean 9.00) (p 0.03, 0.001 and $<$0.0001 respectively). ELF score in pRp and Rp with positive ANA or NC scleroderma pattern only was not statistically different, although a progressive increase was observed (mean 7.84, 7.90 and 7.95 respectively). Considering patients with and without SSc, the area under the ROC curve was 0.7465 (CI 95%: 0.6578–0.8351). When adjusting for age the AUC for youngest patients was 0.77 and it significantly decreased for the older patients. A correlation was observed between ELF score and age.

Conclusion: ELF score shows unbalanced fibrosis biomarkers in very early SSc; it may represent useful potential tool in identifying Rp associated with a scleroderma signature.

1473

Sub-Analysis of ELF Score Biomarkers Components Indicates a Specific Correlation with Different Organ Involvement in Systemic Sclerosis.

Giuseppina Abignano[1], Giovanna Cuomo[2], Maya H. Buch[1], William M. Rosenberg[3], Gabriele Valentini[2], Paul Emery[1] and Francesco Del Galdo[1]. [1]University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom, [2]Second University of Naples, Rheumatology Unit, Naples, Italy, [3]Centre for Hepatology - UCL, London, United Kingdom

Background/Purpose: A recent large multicenter study has identified an algorithm, known as Enhanced Liver Fibrosis (ELF), by combining the serum concentrations of amino-terminal propeptide of procollagen type III (PIIINP), tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) and hyaluronic acid (HA) in a weighted average developed to match liver fibrosis pathology scoring The algorithm has been shown to predict liver related outcomes in patients with chronic liver diseases and recently it has been shown to correlate with several measures of fibrosis in SSc including modified Rodnan Skin

Score, presence of ILD, DLCO as well as age, disease activity and different aspects of disease severity. The aim of this study was to compare the performance of ELF with its single components in correlating with the different clinical and instrumental variables in SSc, to determine whether any of the three biomarkers could have a specific predictive value as surrogate outcome measure in SSc.

Methods: The serum concentrations of the three biomarkers were analysed in 129 SSc patients employing the same platform used to calculate the ELF score (siemens, advia centaur). All patients were investigated for clinical and serological subset, disease duration, skin and internal organ involvement, HAQ-DI, disease severity and activity. Correlations were calculated using Spearman correlation test. Mann-Whitney test was used to perform comparison between groups. Statistical analysis was performed using GraphPrism software.

Results: Median, correlation coefficient and statistical significance of ELF and its single analytes are summarised in table 1. All three components of ELF showed a similar strong correlation with mRSS and HAQ-DI, confirming a strong predictive value on skin involvement. Interestingly, the concentration of HA was the only parameter correlating with Age, muscle severity and Heart severity, whereas it did not correlate with DLCO% or lung severity. In this regard the biomarker with better performance on Lung involvement was TIMP-1, which showed a strong correlation with DLCO and lung Severity. Furthermore SSc patients with interstitial lung disease (ILD) showed significant higher levels of TIMP-1 (P=0.0136) and TIMP-1 was the only biomarker to correlate with the EScSG-Activity Index. On the contrary, PIIINP was the only one to correlate with Joint and kidney severity.

Coefficient correlation (rho) between ELF score and single serum markers with clinical parameters in 129 SSc patients

	ELF score	PIIINP (ng/mL)	TIMP-1 (ng/mL)	HA (ng/mL)
Serum values (median, range)	8.84, 6.49–.10.84 rho	6.25, 2.63–.33.06 rho	215.3, 88.5–.531.2 rho	41.53, 4.69–.236.4 rho
Age	0.34***	0.05	0.11	0.42***
mRSS	0.26**	0.30***	0.33***	0.19*
DLCO, absolute value	−0.26**	−0.1	−0.28**	−0.20*

*P<0.05; **P<0.01; ***P<0.001

Conclusion: Subanalysis of the single serum markers included in the ELF score algorithm suggests that the different biomarkers may function as surrogate outcome measure of specific organ involvement in SSc. In this regard, longitudinal studies confirming the predictive value and sensitivity to change over time of the single biomarkers may pave the way to develop specific algorithms tailored to carry the maximum predictive value on specific organ involvement in SSc.

Interferon-Inducible Chemokines Correlate with Disease Severity in Systemic Sclerosis.
Xiaochun Liu[1], Maureen D. Mayes[1], Filemon K. Tan[1], Minghua Wu[1], John D. Reveille[2], Brock E. Harper[3], Hilda T. Draeger[4], Emilio B. Gonzalez[3] and Shervin Assassi[5]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]Univ of Texas Health Science Center at Houston, Houston, TX, [3]University of Texas Medical Branch, Galveston, TX, [4]Univ of TX Health Sci Ctr, San Antonio, TX, [5]Univ of Texas Health Science Houston, Houston, TX

Background/Purpose: The most prominent gene expression profile in the peripheral blood of patients with systemic sclerosis (SSc) is an interferon (IFN) inducible signature. A large scale correlation of this signature with disease subtypes and features has not been performed due to scarcity of RNA samples. Herein, we identify plasma chemokines that correlate strongly with the IFN gene signature and investigate their correlation with disease features in a large early SSc cohort.

Methods: We examined the correlation of IFNγ-inducible protein-10 (IP-10/CXCL10), IFN-inducible T cell alpha chemoattractant (I-TAC/CXCL11), and monocyte chemoattractant protein-1 (MCP-1/CCL2) with the IFN gene expression signature. We generated an IFN-inducible chemokine score with the correlated chemokines, IP-10 and I-TAC, and compared it in 266 patients enrolled in the GENISOS cohort (disease duration<5 years, 59% diffuse cutaneous involvement) to that of 97 matched controls. Subsequently, the correlation between the baseline chemokine score and markers of disease severity was assessed. Finally, the course of chemokine score over time was examined in 63 follow-up plasma samples prospectively.

Results: The plasma IFN-inducible chemokine score highly correlated with the IFN-inducible gene expression signature (r_s=0.612, p=0.0015) and was significantly higher in SSc patients than matched controls (p<0.001). When the chemokine level was dichotomized based on the 95th percentile level in unaffected controls, 39.2% of patients had a positive chemokine score, which is more prevalent than any SSc-related autoantibody. Furthermore, the chemokine score was associated with the presence of anti–U1 ribonucleoprotein antibodies (RNP) (p<0.001) and absence of anti–RNA polymerase III antibodies (p=0.002), but not disease duration, disease type, or other autoantibodies. As shown in Table 1, the chemokine score correlated with the concomitantly obtained muscle, skin and lung components of the Medsger Severity Index, as well as, FVC, DLco, creatine kinase independent of anti-RNP or other potential confounders (age, gender, ethnicity, disease duration, and treatment with immunosuppressive agents). Finally, there were no significant changes in the chemokine scores over time while their baseline levels correlated significantly with those on the follow-up visits (r=0.39, p=0.002). This indicates that the chemokine score is a stable marker of disease severity and does not fluctuate in a consistent time-dependent manner.

Table 1. Correlation of plasma IFN-inducible chemokines with disease severity

	IFN-inducible chemokine score				
	r	p	pm†	β	95CI

* Components of Medsger Severity Index. † Multivariable model after adjustment for age at enrollment, gender, ethnicity, disease duration, and treatment with immunosuppressive agents. Abbreviations: Percent predicted forced vital capacity; DLco: Percent predicted diffusing capacity; mRSS: modified Rodnan Skin Score; CK: Creatine Kinase. r: Correlation coefficient; β = regression coefficient.

Conclusion: The IFN-inducible chemokine score is a stable marker of more severe subtype of SSc. This composite score may be useful for risk stratification regardless of disease type, serology or duration. It also might identify the subgroup of patients that benefit from treatments targeting IFN pathways.

Does Skin Gene Expression Profile Predict Response to Imatinib?
Shervin Assassi[1], Jeffrey T. Chang[1], Dinesh Khanna[2], Xiaochun Liu[1], Daniel Furst[3] and Maureen D. Mayes[1]. [1]Univ of Texas Health Science Center at Houston, Houston, TX, [2]University of Michigan, Ann Arbor, MI, [3]University of California at Los Angeles, Los Angeles, CA

Background/Purpose: Imatinib is a potent inhibitor of TGF-β signaling. Furthermore, a subgroup of SSc patients shows a prominent TGF-β gene expression signature in skin biopsy samples. We examined whether baseline TGF-β skin gene expression signature or other previously described signatures differentiate responders from non-responders to imatinib treatment.

Methods: Patients with SSc were enrolled in a 1-year open-label pilot study of imatinib (Khanna D, A&R 2011). All patients had active interstitial lung disease defined as forced vital capacity (FVC) < 85% predicted, dyspnea on exertion, and presence of a ground glass opacity on HRCT. Percent changes in the modified Rodnan Skin Score (mRSS) and % predicted FVC were calculated based on the baseline and last measurement in the study.

Baseline skin biopsies were available in five patients (3 diffuse and 2 limited cutaneous involvement) who completed a 12 month course of treatment. Additional 3 patients had 3 month data available who stopped due to adverse events. Percent change in mRSS ranged from 53% worsening to 33% improvement while percent change in FVC ranged from 9% worsening to 5% improvement. Global gene expression profiling was performed on Illumina HumanHT-12 arrays in the baseline patient samples and 36 unaffected controls. All patient and control samples were processed according to the same procedures and the microarrays were performed in one batch. Previously described TGF-β, IL-13, and diffuse proliferative gene signatures (Milano et al. PLoS ONE 2008) were examined. We also developed an IFN-α gene signature using control fibroblasts treated with IFNa. Unsupervised hierarchical clustering was performed after selecting genes that were present in the above gene signatures in separate analyses. The goal of our analysis was to examine whether clustering based on these gene lists separate responders from non-responders.

Results: As shown in Figure 1, these five patients clustered separately from the majority of control samples when the transcript list was filtered based on TGF-β responsive genes. However, there was no clear separation between responders and non-responders in regard to skin (Figure 1) or lung disease. Similarly, patients clustered separately from the majority of control samples when the transcript list was selected based on IL-13, diffuse proliferative, or IFN-α gene signatures. However, there was again no clear separation between responders and non-responders to treatment with imatinib. The findings were similar when additional 3 patients with 3 month data were included in the analysis.

Unsupervised hierarchical clustering of patient and control samples –
Numbers indicate percent change in mRSS after treatment
Figure 1.

Conclusion: This pilot study confirms presence of distinct gene signatures in skin biopsy samples of patients with SSc. However, neither the TGF-β signature nor the other investigated transcript signatures were able to predict response to imatinib.

Caveolin-1 Deficiency May Play a Role in the Predisposition of African Americans to SSc ILD. Elena Tourkina[1], Charles Reese[2], Beth Perry[2], Shanice Dyer[2], Michael Bonner[2], Richard P. Visconti[2], Jing Zhang[2], Richard M. Silver[3] and Stanley Hoffman[3]. [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of SC, Charleston, SC, [3]Medical University of SC, Charleston

Background/Purpose: Scleroderma-associated Interstitial Lung Disease (SSc-ILD) is more prevalent and more severe in African Americans (AA) than in Caucasian (C) patients, but little is known of the factors underlying this health disparity. In the course of studies comparing caveolin-1 function in SSc and healthy blood monocytes, we made the striking observation that healthy AA monocytes share abnormalities with SSc monocytes including low caveolin-1 levels. The aim of this study was to determine the consequences of low caveolin-1 expression in AA and SSc monocytes,

Methods: The study was approved by the university's IRB for Human Subject Research. Monocytes were isolated from the blood of SSc-ILD patients and healthy donors using negative selection. SSc patients fulfilled the ACR criteria for the classification of systemic sclerosis. Monocyte migration was assayed in Multiwell Chemotaxis Chambers, with or without treatment with caveolin-1 scaffolding domain (CSD) peptide and control peptides. CD14, CXCR4, alpha-smooth muscle actin (ASMA), and caveolin-1 levels were determined by Western blot analysis and immunostaining. For fibrocyte differentiation, peripheral blood mononuclear cells (PBMC) isolated from 40 ml of blood were incubated for 14 days in 20 ml DMEM/20 % FBS on fibronectin-coated plates with or without treatment with CSD.

Results: Like SSc-ILD monocytes, healthy AA monocytes differ from healthy C monocytes in signaling and in function. Healthy AA monocytes contained only 49 % as much caveolin-1 as healthy C monocytes (n = 7). The percentage of AA monocytes that migrated in response to the CXCR-4 ligand, CXCL12, was almost three-fold enhanced (19 ± 2.5 vs 57 ± 4.3) compared to C monocytes (n = 10). Like SSc monocytes, when healthy AA monocytes were treated with CSD to restore caveolin-1 function, migration in response to CXCL12 was inhibited by at least 70%. When we compared the ability of healthy C monocytes, healthy AA monocytes, and SSc monocytes to differentiate into fibrocytes, we observed a three-fold increase (quantified in terms of number of spindle-shaped cells per high-power field) in both the SSc and healthy AA samples compared to the healthy C samples (C = 6.4 ± 2.1, AA = 17.3 ± 3.8, SSc = 16.5 ± 4.0; n = 12). In all three cell types, CSD treatment inhibited fibrocyte differentiation by >50%. Although fibrocyte differentiation is enhanced in both healthy AA and SSc, there are phenotypic differences between these two groups. When the CD14- population is isolated by FACS from each source, then cultured on fibronectin-coated coverslips, the level of collagen I and caveolin-1 is similar for all three groups, CXCR4 was upregulated in both the AA and SSc fibrocytes, and ASMA was upregulated only in the SSc fibrocytes.

Conclusion: Our results support the notion that low caveolin-1 levels may play a role in the predisposition of the AA population to SSc-ILD through effects both on the migration of fibrocytes and fibrocyte precursors into damaged tissue and on fibrocyte differentiation.

Skin Autofluorescence As a Measure of Oxidative Stress in Systemic Sclerosis Is Not Affected by Skin Thickness, Erythema or Melanin. Andrea Murray[1], T. Moore[1], J. Manning[2], Christopher E.M Griffiths[3] and Ariane Herrick[1]. [1]School of Translational Medicine, University of Manchester, Manchester Academic Health Science Centre, Salford Royal NHS Foundation Trust, Manchester, United Kingdom, [2]Department of Clinical Rheumatology, Salford Royal NHS Foundation Trust, Salford, United Kingdom, [3]Dermatology Centre, University of Manchester, Manchester Academic Health Science Centre, Salford Royal NHS Foundation Trust, Manchester, United Kingdom

Background/Purpose: Skin autofluorescence (AF) has been suggested as a non-invasive measure of oxidative stress in patients with diabetes and other diseases. We have previously shown that skin AF is also increased in patients with systemic sclerosis (SSc). As part of the disease process, patients with SSc undergo fundamental changes in their skin properties including skin thickening, alteration in perfusion secondary to microvascular dysfunction, and altered pigmentation. There are concerns that these might influence AF. The aim of this study was to determine whether skin AF is altered by these changes and thus to assess whether skin AF is a valid non-invasive technique to measure oxidative stress in SSc. This is a key question given the increasing evidence implicating oxidative stress in pathophysiology.

Methods: Twenty healthy controls (HC [2 males, median 45 (interquartile range 39–52) years]), 20 patients with limited cutaneous (LcSSc, [2 males, 55 (50–67) years]) and 20 with diffuse cutaneous SSc (DcSSc, [6 males, 56 (52–66) years]) participated. Skin AF, induced by ultra-violet light was measured at 10 body sites (distal and proximal digit (dorsal aspect), dorsum of hand, lower and upper arm (dorsal aspect), forehead, anterior chest and abdomen, calf and foot (dorsal aspect)). Each of the following assessments was also made: 1) dermal (skin) thickness, by high frequency ultrasound, 2) erythema index (EI, an indirect measure of blood flow) and 3) melanin index (MI, a measure of pigmentation). EI and MI were both calculated from white light reflection measurements with a spectrometer. Linear regression was used to assess the relationships between AF, skin thickness, EI and MI and SSc subtype.

Results: Linear regression confirmed previous findings that fluorescence is increased in patients with SSc as compared to controls. Patients with DcSSc showed a higher increase in AF than patients with LcSSc; data shown for one exemplar (forearm) in Table 1. Linear regression showed no associations between skin fluorescence and skin thickness, EI or MI (as shown on the last row of Table 1). No consistent differences for values of EI or MI were found between groups.

Table 1. Data for forearm for HC, LcSSc and DcSSc: mean (inter-quartile range); and linear regression at the forearm.

Group/Method	AF (intensity, arbitrary units)	Skin thickness (micrometers)	EI (arbitrary units)	MI (arbitrary units)
HC	0.034 (0.030–0.048)	88 (82–103)	10.36 (7.02–11.16)	59.21 (55.32–63.23)
LcSSc	0.040 (0.030–0.051)	81 (62–99)	9.82 (7.77–14.05)	63.96 (55.25–66.28)
DcSSc	0.045 (0.034–0.060)	109 (76–126)	10.73 (9.20–14.33)	58.23 (53.40–64.80)
Linear regression: Difference from AF (95% confidence intervals); p-value	n/a	-3.95×10^{-05} (-2.30×10^{-04} to 1.51×10^{-04}); 0.680	7.95×10^{-04} (-3.84×10^{-04} to 1.97×10^{-03}); 0.182	-5.11×10^{-04} (-1.05×10^{-03} to 2.57×10^{-05}); 0.062

Conclusion: The skin changes observed in patients with SSc, as measured by high frequency ultrasound and white light reflection, do not appear to influence skin AF measurements, i.e. skin AF is independent of skin thickness, EI and MI and should therefore be a valid technique for use in the assessment of oxidative stress in SSc.

1478

Gender-Associated Differences in Disease Characteristics and Outcome in Systemic Sclerosis. Svetlana I. Nihtyanova[1], Voon H. Ong[2] and Christopher P. Denton[3]. [1]Royal Free Hospital, Medical School, London, England, [2]UCL Medical School, London, England, [3]UCL, London, United Kingdom

Background/Purpose: Although significant female gender predominance is seen in majority of large systemic sclerosis (SSc) cohorts, multiple studies have suggested that male gender generally associates with more severe disease and worse outcome. We explore disease characteristics, morbidity and mortality in male and female patients with SSc from a large single centre cohort.

Methods: We analysed a cohort of incident cases of SSc that developed over a period of 5 years and were followed up over a decade. Basic demographic, clinical and serological characteristics were recorded and comparison of survival and cumulative incidence of clinically-significant organ complications was made between male and female patients.

Results: A total of 398 SSc patients were included. Of those 54 (14%) were male. Age at onset was very similar in both male (mean±SD 50±13 years) and female (mean±SD 48±13 years) patients. A higher proportion of men had diffuse cutaneous (dc) subset of SSc compared to women − 48% (n=26) v 35% (n=120), although the difference showed only a trend towards statistical significance (p=0.069). Duration of Raynaud's phenomenon (RP) with relation to onset of first non-RP symptom of SSc was significantly shorter in male patients with mean (range) of 40 (−12 to 576) months compared to 85 (−29 to 744) months in females (p=0.004). Comparison between frequencies of autoantibodies demonstrated significant differences only in anti-centromere antibody (ACA) positivity, which was twice as common among women – 28% (n=96) compared to 15% (n=8) in men (p=0.046).

There was a significantly higher proportion of male patients with some degree of pulmonary fibrosis (PF) confirmed on HRCT compared to females − 72% (n=39) v 49% (n=168), p=0.002. Analysis of cumulative incidence of clinically significant PF also demonstrated significantly higher frequencies among men. At 5 and 10 years from disease onset 32% and 43% of men had developed significant PF compared to 21% and 26% of women (p=0.017). There were no differences in incidence of pulmonary hypertension (PH), cardiac involvement or scleroderma renal crisis (SRC) between genders. At 5 years 6% of men and 4% of women had developed PH, 2% of men and 3% of women – cardiac SSc and 4% of men and 6% of women – SRC while at 10 years PH was found in 16% of men and 13% of women, SRC in 4% of men and 7% of women and there were no new cases of cardiac SSc in either group.

There was also no difference in survival between genders with 91% of both male and female patients being alive at 5 years. Mortality rate among men increased slightly between 5 and 10 years compared to women, although

the difference did not reach statistical significance and at 10 years survival was 79% in women and 70% in men. There was also no difference in survival from development of significant organ complications between the genders.

Conclusion: Although male patients have significantly higher incidence of PF, reflected by the lower frequency of ACA and show a trend towards greater frequency of diffuse SSc subset compared to females, there was no significant increase in overall mortality.

Early Versus Late Onset Systemic Sclerosis: Analysis of 1037 Patients From Rescle Registry. Marco A. Alba[1], Juan Carlos Mejia[2], Gerard Espinosa[3], María-Victoria Egurbide[4], Carles Tolosa[5], Luis Trapiella[6], Carmen Pilar Simeon[7], Vicent Fonollosa[8] and And RESCLE investigators[9]. [1]Vasculitis Research Unit. Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain, [2]Hospital Clinic University Barcelona, Barcelona, Spain, [3]Hospital Clínic of Barcelona, Barcelona, Spain, [4]Hospital de Cruces, UPV/EHU, Barakaldo, Spain, Barakaldo, Spain, [5]Corporación Sanitaria Universitaria Parc Taulí, Barcelona, Spain, [6]Hospital Universitario Central de Asturias, Asturias, Spain, [7]Hospital Valle de Hebron, Barcelona, Spain, [8]Hospital Vall dxHebron, Barcelona, Spain, [9]RESCLE, Barcelona, Spain

Background/Purpose: Systemic sclerosis (SSc) is characterized by extensive fibrosis, vascular dysfunction and the presence of several autoantibodies. As in other autoimmune diseases, age at disease onset seems to modify initial and cumulative clinical manifestations. The aim of this study was to determine if the age at disease onset may modulate the clinical characteristics and evolution of patients with SSc.

Methods: The Spanish Network for Systemic Sclerosis recruited 1037 patients with a mean follow-up of 5.2±6.8 years. Based on the mean ± 1SD of age at disease onset (45±16 years), patients were classified in 3 groups; Group 1: age equal or below 30 years (early onset); Group 2: age between 31 and 58 years, and Group 3: age equal or older than 59 years (late onset). We compared the initial clinical presentation, capillaroscopy pattern, immunological features, cumulative clinical manifestations and death rates between the three groups.

Results: One hundred and ninety five patients belonged to group 1, 651 to group 2 and 191 to group 3. Female distribution was similar between the three groups (91%, 86%, and 88%). Interestingly, time from disease onset to diagnosis was significantly higher in patients with early onset (group 1) (12±13, 5.8±6.7, and 2.4±3.6 years; p<0.001). Raynaud's phenomenon was the most frequent initial manifestation without differences between the three groups (88%, 84%, and 78%; p=0.134). Patients with early onset SSc had higher prevalence of myositis (11%, 7.2%, and 2.9%; p=0.009), esophageal involvement (72%, 67%, and 56%; p=0.004) and lower prevalence of centromeric antibodies (33%, 46%, and 47%; p=0.007). In contrast, patients with late onset SSc was characterized by lower prevalence of digital ulcers (54%, 41%, and 34%; p<0.001) but higher rates of heart conduction system alterations (8.7%, 13%, and 21%; p=0.004), and pulmonary hypertension (12%, 19%, and 25%; p=0.048). Mortality tended to be higher in late onset patients (9.7%, 15%, and 18%; p=0.053) and the Kaplan-Meier survival curves were significantly different (p<0.0001) for the three groups of patients.

Conclusion: Age at disease onset is associated with differences in clinical presentation and outcome in patients with SSc.

1480

The 15% Rule in Scleroderma: A Systematic Review of the Frequency of Organ Complications in Systemic Sclerosis. Chayawee Muangchan[1], Murray Baron[2], Janet E. Pope[3] and Canadian Scleroderma Research Group[4]. [1]Mahidol University, Siriraj Hospital, Bangkok, Thailand, [2]Jewish General Hospital, Montreal, QC, [3]St. Joseph Health Care London, London, ON, [4]Montreal, QC

Background/Purpose: The prevalence of each organ complication in scleroderma (SSc) varies by definition used. However, it is important to be aware of several complications that can be detected and treated. A simple rule of prevalence of organ complications in SSc can be helpful for clinicians. This study was done to determine the frequency of several SSc features including

organ involvement (lung, heart, digital ulcers {DU}, scleroderma renal crisis {SRC}, pulmonary arterial hypertensions {PAH}).

Methods: A comprehensive literature search of the Medline-OVID/ EMBASE, Pub Med, and Scopus databases from 1980 to November 30th, 2011 was conducted to identify relevant articles with at least 50 SSc patients. Search words were within organ systems such as lung, heart, pulmonary artery, kidney, digital ulcers, arthritis, myopathy and secondary Sjogren's. Study quality was assessed using the STROBE checklist. Prevalence of each organ complication was extracted from studies. Pooled prevalence and odds ratios (ORs) were calculated using the random effects method, and between-study heterogeneity was quantified using the I-squared statistic.

Results: 5916 articles were identified (913 from Embase, 1009 from PubMed and 3994 from Scopus). 5665 were excluded of which 4912 were irrelevant, 237 did not report organ prevalence, 183 were case reports, 193 were reviews, 111 had less than 50 patients,24 were not in English and 5 were not obtained; leaving 251 articles for full text review with 80 included in the meta-analysis. Where available, frequencies were also included from the Canadian Scleroderma Research Group (a database with more than 1000 SSc patients). There were no GI complications at a prevalence of 15% (GERD and dysphagia are far higher) and RP is nearly 100%. Xray ILD was common but significant restrictive ILD on PFTs occurred in approximately 15%.

SSc Feature	# of studies	# of patients total	Frequency	95% CI
Cardiac (CHF, low LEVF, pericarditis)	2	1024	15%	6–24%
Arrhythmia from SSc	11	15790	16%	13–18%
Diastolic dysfunction	5	15134	15%	14–16%
SRC in SSc	21	23103	3%	2–4%
SRC in dcSSc	6	2848	12%	5–19%
PAH by R heart catheter or echo	15	7426	14%	10–17%
PAH by R heart catheter	7	6571	14%	8–20%
ILD				
FVC<80%	5	1070	17%	13–22%
FVC<70%	4	2774	13%	10–16%
FVC<55%	3	1427	14%	7–21%
Myopathy	14	4419	13%	10–16%
Arthritis	7	19834	14%	11–16%
Digital ulcer prevalent	10	6895	17%	12–21%
Complications DU	4	1756	12%	8–16%
Sjogren's	5	2036	13%	11–16%

Conclusion: Many complications in SSc occur 15% of the time including low FVC, PAH, diastolic dysfunction, clinical and echo cardiac changes, arrhythmias, inflammatory arthritis, myopathy, Sjogren's and digital ulcers. 15% of digital ulcers have complications. SRC is uncommon but occurs in almost 15% of dcSSc. This is a helpful rule for frequency of organ involvement in SSc.

1481

A Double-Blind Placebo-Controlled Crossover Trial of the Alpha-$_{2C}$ Adrenoceptor Antagonist Orm-12741 for Prevention of Cold-Induced Vasospasm in Patients with Systemic Sclerosis. Ariane Herrick[1], Andrea Murray[1], Angela Ruck[2], Juha Rouru[3], Tonia Moore[1], John Whiteside[2], Pasi Hakulinen[3], Fredrick M. Wigley[4] and Amir Snapir[3]. [1]School of Translational Medicine, University of Manchester, Manchester Academic Health Science Centre, Salford Royal NHS Foundation Trust, Manchester, United Kingdom, [2]Orion Pharma UK, Research & Development, Nottingham, United Kingdom, [3]Orion Corporation Orion Pharma, Turku, Finland, [4]Johns Hopkins University, Baltimore, MD

Background/Purpose: The alpha-$_{2C}$ adrenoceptor is thought to play a key role in mediating cold-induced vasospasm in the digits. A previous study suggested that in patients with systemic sclerosis (SSc), treatment with the alpha-$_{2C}$ adrenoceptor antagonist OPC-23826 improved recovery of finger skin perfusion following a cold challenge. Our primary purpose was to evaluate the efficacy of the high potency alpha-$_{2C}$adrenoceptor antagonist ORM-12741 in the attenuation of a cold-induced reduction in finger blood flow and temperature in patients with Raynaud's phenomenon secondary to SSc. Secondary objectives were to assess safety and tolerability.

Methods: This was a phase IIa, randomised, double-blind, crossover, single-dose placebo-controlled, single-centre study. Patients attended 5 times: screen, treatment visits 1–3 (each at least one week apart), and an end of study visit 1–2 weeks after the last treatment. At each treatment visit, each subject

after acclimatisation received a single oral dose of 30mg or 100mg of ORM-12741 or placebo. 30 minutes later s/he underwent a cold challenge (the hand was placed in a cold chamber cooled to −18°C until the finger temperature reached 12°C or until the subject could no longer tolerate the cold). Blood flow to the fingers was assessed by 3 methods (temperature by probe, laser Doppler imaging [LDI] and infrared thermography) performed before, during and after the cold challenge, until 70% of the drop in skin temperature had been recovered (but no longer than 45 minutes).

Results: 12 patients (10 female, mean age 58 years) were included. Recovery from cold challenge was faster after placebo treatment than with either dose of ORM-12741 as measured by temperature probe and LDI (Table 1). In 10 out of 12 subjects the area under the time-LDI curve was greater with placebo than with either ORM-12741 dose. Overall ORM-12741 was well tolerated. Headache was the most common adverse effect with 8 events (3 placebo, 5 active treatment) in 4 patients.

1. P= 0.045 versus placebo
2. P = 0.023 versus placebo

Table 1. Mean (standard deviation) blood flow results by the 3 different methods

	Placebo	ORM-12741 30mg	ORM-12741 100mg
Time to 70% temperature recovery (by probe) (minutes)	21.4 (12.4)	25.7 (12.2)	26.9 (13.9)
LDI (Area under the curve, right index finger) (arbitrary flux units × time)	20.5 (13.7)	11.2 (10.6)[1]	9.6 (7.0)[2]
Thermography (area under the curve) (°C × time)	288.4 (172.2)	280.0 (108.8)	305.8 (136.3)

Conclusion: ORM-12741 did not expedite recovery from a cold challenge in the fingers of patients with SSc.

Laser Speckle Contrast Imaging May Help in the Differential Diagnosis of Raynaud's Phenomenon. Alessandra Della Rossa[1], Massimiliano Cazzato[1], Walter Bencivelli[1], Anna d'Ascanio[2], Marta Mosca[1] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy

Background/Purpose: to investigate blood flow and microvascular reactivity by laser speckle perfusion imager (Perimed, Jarfalla) in consecutive patients affected by Raynaud's phenomenon at baseline and following dynamic stimulations.

Methods: skin blood flow in the dorsum of the hand was measured at baseline and after cold test and post-occlusive hyperemia test in 56 consecutive subjects affected by Raynaud's phenomenon who attended the Rheumatology clinic of the university of Pisa between June 2011 and May 2012. 20 Healthy subjects (HS) were studied as controls. The protocol was approved by local ethic committee. All the subjects signed informed consent prior to the study. Statistical analysis was performed by ANOVA and logistic regression, both univariate and multivariate (SPSS). In view of the high number of comparisons inolved, Bonferroni correction was applied.

Results: Raynaud's subjects were divided into two cathegories: 20 primary Raynaud's phenomenon (PRP) defined according to LeRoy criteria and 36 Raynaud's secondary to Systemic sclerosis (SSc-RP). 28 SSc patients fulfilled American college of rheumatology criteria for diagnosis of SSc (4 diffuse cutaneous subset and 24 limited cutaneous subset) and 8 were classified according to very early diagnosis criteria for SSc (VEDOSS). After cold test SSc RP had a significant reduction of blood flow (−58%) as compared to HS (−19%) (p= 0.01). Time to rescue of the basal value was significantly higher in SSc-RP (58 minutes) as compared to HS (18 minutes) and PRP (19 minutes) (p=0.002). Peak flow after ischemic test was significant reduced in SSc-RP (+237%) and in HS (+258%) as compared to PRP (+485%) (p=0.03, p=0.008). Post-ischemic AUC flow showed a significant difference between SSc-RP (+79%) and PRP (+167%) (p=0.01). Patchy pattern of flux distribution was significantly different between HS (5%), PRP (20%), and SSc-RP (84%) (p< 0.0001). Differences between groups sorted out by univariate analysis were entered in a multivariate model

to outline items that independently discriminated between groups. Peak flow after ischemic test and patchy pattern of flux distribution independently discriminated between HS and PRP and SSc-RP.Within SSc patients, a significant difference in peak flow after ischemic test (543% vs 150% p=0.002), in the post-occlusive hyperemic response (158 vs 58 % p=0.005) and in duration of hyperemic response after ischemic test (711 seconds vs 171 seconds p=0.02) was shown between patients with very early SSc (VEDOSS) versus patients with definite SSc. No difference in the dynamic of microcirculation was noticed between diffuse and limited disease.

Conclusion: our preliminary results indicate a clearcut alteration in the dynamic of microcirculation in SSc-RP as compared to PRP and HS. Within SSc patients, early disease seem to have a different pattern of microvascular reactivity as compared to estabilished disease.

Predictors of Digital Ulcers in Systemic Sclerosis: Correlation Between Clinical and Hemodynamic Features, Capillaroscopy, Endothelium Dysfunction and Angiogenesis Biomarkers. Ivone Silva[1], Isabel Almeida[1], António Marinho[2] and Carlos Vasconcelos[3]. [1]Raynaud Clinics, Porto, Portugal, [2]Unidade de Imunologia Clínica, Porto, Portugal, [3]Hospital Geral Santo Antonio, Porto, Portugal

Background/Purpose: Digital Ulcers (DU) are a major disabling complication of Systemic Sclerosis (SSc) interfering with personal and professional life of our patients. The aim of our study was to analyze functional dysfunction of endothelium, capillaroscopy and angiogenesis biomarkers in patients with SSc, with or without peripheral microvascular complications, in order to try to predict the development of digital ulcers in these patients.

Methods: This is a prospective study of a cohort of Systemic Sclerosis (SSc) and primary Raynaud Phenomenon (RP) patients attending our Raynaud's Clinic (n= 108). Demographic and epidemiological data, autoimmune serological screening, inflammatory protein screening, Flow mediated dilation (FMD) and end diastolic volume (EDV), capillaroscopy, Endothelin-1 (ET-1), ADMA, VEGF and Endoglin were analyzed and compared to a control group (n=31). Statistical calculations were performed using SPSS (v 20.0). Comparison and distribution between groups were performed using Kruskal-Wallis test. The Mann-Witney test was used to compare continuous variables wit nominal variables. A p value ≤ 0.05 was considered significant.

Results: Flow mediated dilation (FMD) was reduced in patients with digital ulcers. The brachial artery diameter at 60 s after cuff deflation had statistical differences (P<0.001) between SSc patients with digital ulcers compared to SSc patients without DU or primary Raynaud phenomenon (RP). End diastolic volume was significantly different between groups (P<0.001) suggesting an increase in peripheral resistance in patients with DU. FMD was more reduced in patients with late pattern (Cutolo's classification) in capillaroscopy and a statistical differences (P<0.001) between early and late pattern (P<0.007) was found. Endothelin-1 and ADMA were increased in patients with DU (P<0.001) which might explain an excessive vasoconstrictor tone in these patients in association with occlusion of distal digital circulation (avascular areas incapillaroscopy) leading to the reduced FMD in patients with DU. VEGF was increased in SSc patients without DU, we found no difference with primary RP (P<0.168). A statistical differences (P<0.002) between patients with DU and SSc patients with no DU or with primary RP was found in VEGF. Endoglin was increased in patients with DU (p<0,001). Patients with Cutolo's late pattern in capillaroscopy had a increase in the angiostatic biomarker endoglin in comparison with the other groups (p<0,005).

Conclusion: In our cohort, we identified patients at risk of developing DUs: Ssc 70 positive, decreased FMD and low EDV, late pattern of Cutolo's classification, increased ET-1, ADMA and endoglin and a reduced VEGF. Microvascular lesions and an increase in the peripheral resistance associated to endothelial dysfunction and a impaired angiogenesis with an imbalance in favor of increased angiostatic biomarkers may be behind the underling mechanism of DU. These data may help us identify patients with high risk of developing digital ulcers and defining a correct target therapy at an early stage.

Investigating Determinants of Subjective and Objective Assessments of Peripheral Vascular Function in Primary Raynaud's Phenomenon and Systemic Sclerosis. John D. Pauling, Jacqueline A. Shipley, Nigel Harris and Neil McHugh. Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

Background/Purpose: The Raynaud's condition score (RCS) diary is recommended for use in clinical trials of Raynaud's phenomenon (RP) and systemic sclerosis (SSc). We report the findings of a cross-sectional study exploring determinants of the RCS diary in patients with primary RP and SSc. We report associations between the RCS diary and objective assessment of digital vascular function using infrared thermography (IRT) and laser speckle contrast imaging (LSCI).

Methods: Patients with primary RP and SSc were recruited between December 2010 and February 2012. All patients underwent a standardized local cold challenge (15°C for 60s) with simultaneous assessment of digital vascular perfusion using IRT and LSCI. Patients with SSc completed a Scleroderma Health Assessment Questionnaire (SHAQ) and had disease characteristics documented. Baseline demographics and medication usage were recorded for all subjects. Patients received training on the completion of a 2-week RCS diary enabling calculation of the mean daily frequency, duration and impact (10-point RCS score) of RP attacks.

Results: Twenty-five patients with SSc and 18 patients with primary RP took part. Four (9.3%) patients failed to adequately complete the RCS diary. A similar number of patients were recruited between October-March (n=21) compared with April-September and the distribution of primary RP vs. SSc was similar in each group. There was a high correlation between individual components of the RCS diary (Spearman's Rho 0.62–0.78, p<0.001 for all comparisons). The RCS score was higher in patients taking vasodilator therapy (median 2.14 vs. 1.57, p=0.058). There was moderate correlation between the RCS and the HAQ-Disability Index (Rho 0.51, p=0.013). There was moderate to high correlation between components of the RCS diary and the SHAQ RP Visual Analogue Scale (VAS, Rho 0.54–0.83, p<0.05). There were no associations between RCS diary endpoints and a history of digital ulceration (DU) or the SHAQ DU VAS (Rho 0.26–0.46) in patients with SSc. The daily frequency of RP attacks was significantly higher in females (median 1.93 vs. 0.82, p=0.031). The RCS score was significantly higher in October-March compared with April-September (median 2.29 vs.1.57, p=0.024). There were moderate to high correlations between IRT and LSCI (Spearman's Rho 0.577–0.837, p<0.01 for all comparisons). There was no correlation between individual components of the RCS diary and objective non-invasive microvascular imaging, using either IRT or LSCI. Perfusion of the digits was significantly lower in females for all IRT assessments and the majority of assessments using LSCI. Temperature of the palmer aspect of the digits was higher during April-September (p<0.05). LSCI and IRT assessment of perfusion at other regions of the fingers was not influenced by season.

Conclusion: Subjective and objective assessment tools provide differing information on digital vascular function and impact of disease in RP and SSc. This is the first study to demonstrate the influence of gender and seasonal variation on both patient self-report and objective non-invasive microvascular imaging assessment of RP. These findings must be considered when using such tools as outcome measures in clinical trials of RP and SSc.

Patients with Very Early Diagnosis of Systemic Sclerosis (VEDOSS) Present Esophageal and Anorectal Involvement: Data From a Single Centre. Gemma Lepri[1], Silvia Bellando-Randone[2]. Serena Guiducci[1], Iacopo Giani[3], Cosimo Bruni[1], Giulia Carnesecchi[4], Jelena Blagojevic[2], Alessandra Radicati[2], Filippo Pucciani[5] and Marco Matucci Cerinic[1], [1]Department of Biomedicine, Division of Rheumatology AOUC, Excellence Centre for Research, Florence, Italy, [2]University of Florence, Florence, Italy, [3]General Surgery, ASL 8, Arezzo, Italy, Arezzo, Italy, [4]Department of Internal Medicine, Rheumatology Section, University of Florence, Florence, Italy, [5]General and Urgency Surgery, University of Florence, Florence, Italy, Florence, Italy

Background/Purpose: Systemic Sclerosis (SSc) affects gastrointestinal tract in more than 80% of patients. Esophageal involvement is the most common manifestation with a prevalence ranging between 50–90%, followed by anorectal involvement (prevalence of 50–70%) that had a high impact on

patients quality of life. Objectives of the study: evaluation of esophageal and anorectal involvement and of their correlations in very early SSc patients.

Methods: 56 VEDOSS patients (55 females), mean age 49,2 ± 14, were evaluated with esophageal and anorectal manometry. The demographic data, esophageal and anorectal symptoms (dysphagia, typical GERD symptoms and fecal incontinence and constipation), Raynaud phenomenon (presence/absence, duration) autoantibodies profile (anticentromere antibodies [ACA], antinuclear antibodies [ANA], anti-Scl70 [Scl70]), videocapillaroscopy patterns (Normal, Early, Active, Late), puffy fingers, digital ulcers were recorded for all patients.

Results: Esophageal body dysmotility (absence of peristalsis or abnormal mean pressure of peristalsis) was present in 49 patients (94,2%) and it was associated with an hypotensive lower esophageal sphincter (LES) in 26 (53,1%). Anorectal manometry was abnormal in 85% of patients and in all these patients an esophageal involvement was found (absence of peristalsis in 29% of patients and an abnormal peristalsis in 67,7% of patients). Esophageal symptoms were present in 26 patients (50%). 22 patients (42,3%) showed puffy fingers that were associated with a smaller area of LES (p-value: 0,011). Only five patients (12,5%) complained anorectal symptoms. In 4 patients esophageal manometry was not performed because of scarce tolerance of the procedure and in 16 patients anorectal manometry was not performed for the same reason.

Conclusion: In VEDOSS patients esophageal and anorectal disorders are frequently detected even in asymptomatic patients. Our data showed that VEDOSS is characterized by simultaneous esophageal and anorectal involvement. Esophageal disorders seem to correlate with the presence of puffy fingers.

Poor Outcome in Patients with Systemic Sclerosis and Myocardial Involvement: A Combined Approach Based On Clinical and Laboratory Findings, EKG-Holter and Cardiac Magnetic Resonance. Silvia Laura Bosello, Giacomo De Luca, Antonella Laria, Giorgia Berardi and Gianfranco Ferraccioli. Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: Cardiac involvement is a relevant prognostic determinant in Systemic Sclerosis (SSc), but the diagnosis is often delayed due to the lack of a specific diagnostic algorithm. Objective of the present study is to define the role of a combined approach, based on evaluation of clinical symptoms, laboratory findings, EKG-holter and cardiac magnetic resonance (CMR), to characterize cardiac involvement in SSc-patients.

Methods: Twenty-five SSc-patients with symptoms of cardiac involvement (dyspnea, palpitation) or signs of cardiac failure and elevation of cardiac enzymes (MB-CK and/or troponin T) underwent EKG-holter and cardiac magnetic resonance (CMR). Median follow-up was 24±0.2 months.

Results: Major EKG-holter modifications were present in 45% of patients. CMR study demonstrated T2 hyperintensity in 2 patients while none of the patients presented early gadolinium enhancement and 16 (64.0%) patients presented late gadolinium enhancement (LGE). We identified 3 different patterns of distribution of LGE: subepicardial, midwall and subedocardial. Sixteen (64.0%) patients presented almost one pattern of distribution, while 9 patients presented more than one: 81.3% of patients presented a midwall distribution of LGE, 50% of patients presented a subepicardial LGE with a linear distribution pattern and 37.5% presented a subendocardial LGE distribution. 28% of patients showed hypokinetic area and only one patient an akinetic area. The ejection fraction (EF), corrected for the age, was decreased in 7 patients (28%). The mean EF of left ventricle was 60.2±11.1%, and of right ventricle was 55.1±10.2%. Hypokinetic and akinetic area corresponded with the LGE area. The subepicardial distribution pattern was more frequent in patients with an early disease, while patients with diffuse skin involvement presented more frequently with the subendocardial pattern. This latest distribution pattern was also associated with a reduction of EF and with major-EKG abnormalities. The extension of LGE on CMR was evaluated according to a standardized left-ventricular segmentation (Cerqueira et al; Circulation 2002, 105:539–542). Patients with major abnormalities on EKG-holter presented a higher number of myocardial segments involved on CMR (4.8±2.3) with respect to the patients without EKG-abnormalities(2.7±0.9) (p=0.041). A weak correlation was found between NYHA-dyspnea class and the number of involved myocardial segments on CMR (R=0.5, p=0.02). After a mean follow-up of 24±0.2 months, 4

patients(16%) died for arrhythmias or heart failure. All patients who died at follow-up had severe dyspnea, elevated cardiac enzymes, myosytis, major EKG-holter abnormalities, reduction of EF and LGE on CMR at baseline; 75% of patients who died had a subendocardial distribution pattern of LGE on CMR.

Conclusion: Our study suggests that a combined approach, based on clinical presentation, laboratory findings, EKG-holter examination and study of distribution of LGE on CMR, is useful to characterize the extension of myocardial damage and to identify patients with a poor outcome related to heart involvement in SSc.

1487

Incidence of Fibromyalgia Syndrome in Systemic Sclerosis and Rheumatoid Arthritis. Comparative Results According to Clinical Diagnosis, Screening Test with Fibromyalgia Rapid Screening Tool, Diagnosis with ACR1990 and ACR 2010 Criteria. Serge Perrot[1], Mariana Peixoto[2], Philippe Dieude[3], Eric Hachulla[4], Sébastien Ottaviani[5] and Yannick Allanore[6]. [1]Hopital Hotel Dieu, Paris, France, [2]Cochin Hospital, Paris, France, [3]APHP, Hopital Bichat, Paris, France, [4]Department of Internal Medicine, Claude Huriez Hospital, University of Lille, Lille CEDEX, France, [5]APHP, Paris, France, [6]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France

Background/Purpose: Fibromyalgia (FMS) is a chronic widespread pain condition that may be associated with inflammatory chronic disorders like rheumatoid arthritis (RA) and systemic sclerosis (SSc). In these latter, it is important to detect associated FMS since it may interfere with disease specific assessment. Moreover, in some studies, associated FMS could be related with the occurence of Secondary Sjogren's Syndrome (SSS). FMS diagnosis is frequently established by clinical analysis, although there are newly validated screening tools (Fibromyalgia Rapid Screening Tool (FiRST)) and diagnostic criteria (ACR 2010 criteria) that may confirm clinical impression.

The aims of the study was i) to estimate the incidence rate of FMS in RA and SSc, ii) to compare these rates according to clinical diagnosis, screening tool (FiRST), diagnostic criteria (ACR 1990 and 2010), iii) to test if FMS was associated with the occurrence of SSS.

Methods: Consecutive adult patients with confirmed RA or SSc (international classification criteria), visiting 4 university hospitals were included. Demographic characteristics were collected and FMS diagnosis was established by several consecutive methods: (i) FMS clinical impression, (ii) FMS screening by FiRST questionnaire, (iii) FMS diagnosis by ACR 1990 classification criteria and ACR 2010 diagnostic criteria. Cohen's Kappa correlation coefficient (K) was calculated for inter-agreement between diagnostic tools.

Results: In total, 274 patients were recruited: FMS was diagnosed (ACR2010) in 22.4% of the cases, without significant difference between RA and SSc (p=0.11). In global and each group, FMS occurrence was not associated with a SSS.

-In the RA group, 172 patients (12.2 % men, 54.4 ± 15.11 years old) were recruited.

FMS clinical diagnosis was proposed in 32.5%, detected by the FiRST in 22.6%, confirmed with ACR 1990 criteria in 22.1% and with ACR 2010 criteria in 19.1% of the RA patients.

In RA, considering ACR 2010 criteria as the current gold standard, K was: 0.66 with clinical diagnosis, 0.47 with FiRST and 0.41 with ACR 1990 classification criteria.

-In the SSc group, 122 patients (13.9% men, 58.2 ± 12.1 years old) were recruited: 54 with limited SSc and 66 with diffuse SSc. Clinical diagnosis of FMS was proposed in 39.3%, detected by the FiRST in 27.9%, confirmed with ACR 1990 criteria in 30.3% and with ACR 2010 criteria in 27.0% of the SSc patients.

In SSc, considering ACR 2010 criteria as the gold standard, K was 0.64 with clinical diagnosis, 0.63 with FiRST questionnaire, 0.50 with ACR 1990 classification criteria.

Conclusion: Our results reveal an unknown high prevalence of SSc associated FMS, which will need to be taken into account in the assessment of the patients who often report a heavy burden of pain. Both in SSc and RA, occurrence of FMS is not related to SSS. In both groups, there was a good correlation between FiRST and ACR FMS 2010 criteria. FiRST may represent a simple method to detect FMS in various rheumatological conditions. Further studies are needed to analyze FMS association with specific RA and SSc phenotypes.

Prevalence and Risk Factors of Low Bone Mineral Density in Chinese Patients with Systemic Sclerosis: A Case-Control Study. Chi Chiu Mok, Pak To Chan, Kar Li Chan, Ling Yin Ho and Chi Hung To. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To study the prevalence and risk factors of low bone mineral density (BMD) in patients with systemic sclerosis (SSc).

Methods: Consecutive patients who fulfilled the ACR criteria for SSc were screened for BMD and BC (fat and lean mass) by DXA scan. An equal number of age and gender matched healthy controls were also recruited for the same measurements. Data on risk factors for osteoporosis were also compared between patients and controls. In SSc patients, the extent of skin involvement was assessed by the modified Rodnan skin score (mRSS) and organ damage was evaluated by the Medsger SSc severity index. Risk factors for low BMD in SSc patients were studied by linear regression analyses.

Results: 84 patients with SSc were studied (89% women; age 49.4 ± 11.3 years; disease duration 7.8 ± 6.4 years). Eighteen (21%) patients had diffuse cutaneous SSc while the other 66 (79%) patients had limited cutaneous SSc according to the LeRoy classification. Nineteen(23%) SSc patients had been treated with glucocorticoids. The mean$\pm$SD and median (IQR) mRSS score of the SSc patients was 11.2 ± 9.8 (range 0–40) and 8 (IQR 4–14), respectively. The highest mean Medsger severity score was observed for involvement of skin (1.33 ± 0.83), followed by joint/tendon (0.89 ± 1.44), peripheral vascular system (0.86 ± 1.00), lung (0.68 ± 1.04), heart (0.23 ± 0.68) and the kidney (0.14 ± 0.60). Four (5%) SSc patients required aids for walking and 4(5%) other patients were chair-bound. Except for significantly lower body mass index (BMI) and body weight in SSc patients, the frequency of osteoporosis risk factors was similar to that of controls. The BMD of the lumbar spine, total hip, femoral neck and whole body was significantly lower in SSc patients than controls after adjustment for age, sex, BMI and menopausal status. Fourteen (17%) patients with SSc had low BMD of the lumbar spine expected for their age (Z score < -2.0) and 5 (6%) patients had a total hip Z score of < -2.0. Osteopenia of the lumbar spine, total hip and femoral neck, defined as a Z score of between -1.0 and -2.0, occurred in 37%, 45% and 40% of the SSc patients, respectively. Four (7%) patients reported a personal history of fracture (all non-vertebral; two arose from low impact injury). The proportion of patients with osteopenia of the hip, femoral neck and lumbar spine was significantly higher in SSc patients than controls. Linear regression analyses revealed that increasing age was an independent risk factor for lower BMD in all sites. Low BMI was independently associated with low BMD of the total hip and femoral neck, whereas menopause was an independent associated factor of low BMD at the lumbar spine. Other covariates such as the subtype of SSc (diffuse vs limited SSc), parity, smoking, drinking, female sex, disease duration, menopause, ever use of glucocorticoids and family history of fractures were not significantly associated with lower BMD at these sites. The skin score and disease severity scores in any organs were not significantly associated with the BMD values.

Conclusion: BMD of the spine and hip is significantly lower in SSc patients than healthy subjects, which is independent of age, sex, menopause, low BMI and altered body composition.

Peripheral Neuropathy: A Complication of Systemic Sclerosis. Melissa Reily[1], Tracy M. Frech[2], Maureen Murtaugh[2], Jason Penrod[3] and Barry M. Stults[4]. [1]University of Utah, Salt Lake City, UT, [2]University of Utah School of Medicine, SLC, UT, [3]University of Utah, Salt Lake City, [4]Salt Lake City Veterans Affairs Medical Center and University of Utah, Salt Lake City, UT

Background/Purpose: We performed bedside testing for peripheral neuropathy in our Systemic Sclerosis (SSc) population to determine whether foot care guidelines should be developed for SSc.

Methods: Twenty consecutive SSc patients and 20 healthy control patients were evaluated for peripheral neuropathy in both feet using the 10-g Semmes-Weinstein monofilament examination [SWME] three times on four sites bilaterally and vibration sensation using the on-off method on the dorsum of the 1st toe just below the nail with 128-Hz tuning fork eight times. Independent blinded evaluations were performed on each subject by two investigators who had completed a training session to standardize each exam. Abnormal SWME testing was defined as at least one pedal site failing three monofilament assessments twice. Abnormal vibratory sensation was defined

as inability to determine pressure from vibration, or as having 5 of 8 tests abnormal on the on-off methodology. Statistics were performed on SAS 9.3. We examined the inter-rater variability using Cohen's Kappa. We compared SWME and vibratory sensation in SSc to healthy controls using Fischer's exact. T-test was used look at duration of disease and modified Rodnan skin score (mRSS) for those with abnormal SWME and vibratory sensation.

Results: Mean age was 56.2 years for the SSc population and 49.4 years for the healthy control population (p: 0.7). Disease distribution included 8 diffuse and 12 limited cutaneous SSc patients. Two of 20 SSc patients reported sensory foot symptoms consistent with peripheral neuropathy, prior to the examination. Inter-rater agreement of SWME and vibration sensation was strong (kappa: 0.72 and 0.83, respectively). Two healthy controls and 12 SSc patients demonstrated abnormal vibration sense (one-sided Fishers' exact, $p < 0.002$). No healthy controls and 4 of the SSc had abnormal monofilament exam (one-sided Fishers exact, $p = 0.053$). The mRSS and duration of SSc did not differ between those with peripheral neuropathy as those without as diagnosed by these modalities (p: 0.07).

Conclusion: Patients with SSc have a high prevalence of pedal peripheral neuropathy, which may be asymptomatic and place them at risk for neuropathic complications. Similar to persons with diabetes, SSc patients should be screened annually for peripheral neuropathy. Those with significant abnormalities should be referred for routine podiatry care.

Dysregulation of Angiogenic Homeostasis in Systemic Sclerosis. Naglaa Y. Assaf[1], Hanan M. Farouk[2] and Iman M. Aly[1]. [1]Faculty of Medicine, Ain-Shams University, Cairo, Egypt, [2]Ain-Shams University, Cairo, Egypt

Background/Purpose: systemic sclerosis (SSc) is a connective tissue disorder characterized by tissue hypoxia and excessive fibrosis of skin and internal organs. The present study was planned to evaluate the possible role of angiogenesis imbalance in the pathogenesis of SSc.

Methods: 25 SSc patients, 20 age and sex matched healthy controls were included. Assay of serum vascular endothelial growth factor (VEGF) and endostatin was done for all patients and controls using ELISA. Patients were subjected to modified Rodnan skin score (mRss), pulmonary function tests (PFTS), and skin biopsies for histopathological skin thickness score assessment.

Results: There was significant increase in the mean levels of serum VEGF and endostatin in SSc patients compared to controls (t=4.07, p<0.001), mean values of serum endostatin is significantly increased in late compared to early stage of disease (t=6.65, p<0.01). A significant positive correlation was found between serum levels of endostatin, mRss and histopathological skin thickness score (r=0.99, 0.94 respectively p<0.01). SSc patients with ischemic manifestations had significantly higher levels of serum endostatin compared to those without ischemic manifestations (t=6.27, p<0.001). SSc patients with restricted PFTS had significantly higher levels of serum endostatin compared to those without pulmonary affection (t=4.3, p<0.001).

Conclusion: Angiogenic inhibitor (endostatin) is induced and outweighs angiogenic inducer (VEGF) in late stage of SSc. Increased serum endostatin is associated with skin sclerosis severity and pulmonary fibrosis and favors SSc disease progression.

Systemic Sclerosis – Effects of Agonistic Autoantibodies Directed Against the Angiotensin Receptor Type 1 and the Endothelin Receptor Type A On Effector Cells. Jeannine Guenther[1], Angela Kill[2], Mike O. Becker[3] and Gabriela Riemekasten[4]. [1]Charite University Hosptial, Berlin, Germany, [2]Charité University Hospital and German Rheumatism Research Centre, a Leibniz Institute, Berlin, Germany, [3]Charité University Hospital, Berlin, Germany, [4]Charité University Hospital, German Rheumatology Research Center, a Leibniz Institute, Berlin, Germany

Background/Purpose: Autoimmunity, vasculopathy and fibrosis are features of systemic sclerosis (SSc). The functional link between these three pathophysiological components is still missing. Research suggests an involvement of endothelin-1 and angiotensin II, and of the activation of their receptors by the natural ligands as well as by agonistic autoantibodies against these receptors in SSc–associated vasculopathy and fibrosis [1]. Autoantibodies against the angiotensin receptor type 1 (AT1R) and the endothelin receptor type A (ETAR) are present in the majority of SSc patients and high levels of the antibodies are associated with severe organ manifestations [1]. AT1R and ETAR are expressed in various cell types such as endothelial cells, fibroblasts, as well as cells of the adaptive and innate immune system. The aim of the present study was to identify the effects of these antibodies on those effector cells and establish a link to SSc pathogenesis.

Methods: Human microvascular endothelial cells, fibroblast, and peripheral blood mononuclear cells (PBMCs) from healthy donors were stimulated in vitro by affinity-purified IgG from sera of SSc patients containing anti-AT1R and anti-ETAR antibodies as well as by affinity-purified IgG from sera of healthy donors. Effects of the antibodies were measured by ELISA, migration assay, and PCR. To To prove that the IgG effects are specifically due to AT1R and ETAR activation, specific receptor blockers were used. Cytokine expression was correlated with clinical data from the IgG donors.

Results: In endothelial cells, anti-AT1R and anti-ETAR ab induced adhesion molecules and IL-8 expression as well as further pro-fibrotic and inflammatory cytokines. IL-8 levels in the supernatants correlated with the antibody levels in the IgG fractions. In fibroblasts, collagen-I expression was induced. At a molecular level, c-Jun expression, known to play a role in SSc, was upregulated. The antibodies increased the migration of neutrophils as well as of PBMC. Stimulation of PBMCs by IgG from SSc patients resulted in a significantly increased expression and secretion of IL-8 and, in most cultures, of CCL18 compared to the stimulation by IgG of healthy donors. All the effects were significantly reduced or completely blocked by commercial AT1R and ETAR antagonists. Correlation analyses with clinical data of the SSc IgG donors revealed correlations between cytokine expression, induced by the antibodies, and clinical findings.

Conclusion: As shown in vitro, anti-AT1R and anti-ETAR antibodies exhibit effects on inflammation, immune regulation, migration of cells, and on fibrosis. Based on the broad expression of the receptors on various effector cell types, the antibodies may link the adaptive and innate immune system as well as resident cells in order to produce the typical features vasculopathy, fibrosis, and autoimmunity.

IL-13 Receptors and Signaling in the Dermal Fibroblasts From Patients with Systemic Sclerosis.
Yuko Ota[1], Yasushi Kawaguchi[1], Atsushi Kitani[2], Kae Takagi[1], Hisae Ichida[1], Yasuhiro Katsumata[1], Takahisa Gono[1], Masanori Hanaoka[1], Yuko Okamoto[1] and Hisashi Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Mucosal Immunity Section, NIAID/NIH, Bethesda, MD

Background/Purpose: Interleukin (IL)-13 is a pleiotropic cytokine involved in T helper type 2 cell immune response and in the development of fibrotic conditions such as liver cirrhosis, and pulmonary fibrosis and also implicated in systemic sclerosis (SSc). Although elevated serum levels of IL-13 has been reported in SSc and recently CD8 T cells was found as a producing subset of IL-13, IL-13 effect of effector phase in the skin fibroblasts has not been well characterized in SSc. The aim of the present study was to investigate the fibrotic effects of IL-13 on the collagen production by skin fibroblasts from patients with SSc. We also evaluated the signal transduction of IL-13 in the cultured skin fibroblasts.

Methods: We examined the expression of IL-13Rα1 and IL-13Rα2 on skin fibroblasts by flow cytometry and Western blot analyses. Skin fibroblasts from patients with diffuse cutaneous SSc were cultured with indicated concentrations of IL-13 and TNFα for various periods. Procollagen type I C-peptide and TGF-β1 levels were then measured using commercial ELISA kits. mRNA expression of COlA1, ColA2, TGF-b1, CTGF were also measured by standard real-time qPCR. The phosphorylation of STAT6 and various MAPK and Akt pathways have been evaluated by Phospho-Kinase Arrays. Various specific inhibitors for STAT6-mediated pathways, U0126 (Erk1/2 inhibitor), LY294002 (PI3K inhibitor), JAK inhibitor, and Tyk inhibitor (RO495) were used for evaluation of IL-13-mediated signaling.

Results: With the flow cytometric analysis, we revealed the expression of IL-13Ra2, but did't detect IL-13 Ra1 with confirmation of the same Ra1 mAb detecting neutrophil expression of IL-13 Ra1. We also found that IL-13Rα2 expression was increased by TNF-α stimulation (13% vs 20%). On the contrary, Western blot analysis revealed both expression of IL-13 Ra1 and Ra2. With IL-13 stimulation, the phosphorylation of STAT6 and Akt was induced, and IL-13 plus Jak/Tyk inhibitor(s) suppressed the phosphorylation of STAT6, suggesting IL-13Rα1 was functional, though flow cytometry pattern does not show positive. Treatment with U0126 (Erk1/2 inhibitor) or LY294002 (PI3K inhibitor) did not suppress the phosphorylation of STAT6. We observed IL-13 increased collagen production in 72 hours (p = 0.009) compared to no stimuli. On the contrary, TNF-a decreased COLA1, COL A2, and CTGF mRNA compared to no stimuli.

Conclusion: Our results suggest that IL-13 may be a potent stimulator of collagen production in skin fibroblast derived from patients with SSc and IL-13 signaling pathway would be a potential target for the new treatment of SSc. TNF-a may have inhibitory effect on fibrotic development and the use of TNF blocking biological reagents in SSc would not be recommended in SSc.

Transforming Growth Factor-β and Endothelin-1 Induce Endothelial-to-Mesenchymal Transition in Cultured Human Endothelial Cells.
Stefano Soldano[1], Paola Montagna[1], Renata Brizzolara[1], Barbara Villaggio[2], Alberto Sulli[1] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, Genova, Italy, [2]Research Laboratory of Nephrology, Department of Internal Medicine, University of Genova, Genova, Italy

Background/Purpose: The endothelial/microvascular injury and the myofibroblast activation are crucial events that seem to contribute to the development of fibrosis in connective tissue diseases such as systemic sclerosis (SSc), which is characterized by increased local transforming growth factor-β (TGF-β) and endothelin-1 (ET-1) levels (1,2). Recently it was shown that myofibroblast activation from altered microvasculature may arise through the transition of endothelial to mesenchymal cells (EndoMT), thus expressing α-smooth muscle actin (α-SMA), vimentin and fibrillar collagens (3).

To investigate the possible involvement of TGF-β and ET-1 in the early step of EndoMT in cultures of human endothelial cells.

Methods: Human umbilical vein endothelial cells (HUVEC) were cultured in collagen-coated dishes with EGM-2 medium and used between the third and fifth passages. The cells were treated with ET-1 (100 nM) or TGF-β (10 ng/ml) for 1, 3 and 6 days. Untreated endothelial cells were used as controls (cnt). Cell proliferation was evaluated by methyl-tetrazolium salt test (MTT) after 1 day. The expression of α-SMA as marker of myofibroblast phenotype, and platelet endothelial cell adhesion molecule (PECAM-1 or CD31), as marker of endothelial phenotype, was evaluated after 3 and 6 days of treatment by immunofluorescence (IF) and western blot analysis (WB) according to recent evidences (4). Data were obtained by eight different experiments and statistical analysis was carried out by a non-parametric Friedman test.

Results: After 6 days of treatment, TGF-β induced the α-SMA expression in cultured human endothelial cells, which maintain their capability to express CD31.

Interestingly, also ET-1 was able to stimulate the endothelial cells to express α-SMA after 6 days of treatment. The data were obtained by IF and confirmed by WB analysis.

In addition, MTT test showed that both TGF-β and ET-1 induced a statistically significant increase of proliferation of human endothelial cells vs. cnt (p<0.001).

Conclusion: These preliminary results show that both ET-1 and TGF-β seem to share similar effects in inducing the α-SMA expression and cell proliferation in human endothelial cells thus supporting a possible direct involvement in promoting the transition from endothelial to myofibroblast phenotype (2, 4–6). The implications in the fibrotic process that characterize SSc are matter of further evaluations.

CD40 Signaling Results in Microvascular Endothelial Dysfunction: A Possible Clue to the Pathogenesis of Scleroderma Vasculopathy. Bashar Kahaleh and Yongqing Wang. University of Toledo, Toledo, OH

Background/Purpose: Increased expression of CD40 in SSc- Microvascular Endothelial Cells (MVEC) was noted on a gene expression array and increased concentrations of soluble CD40 ligand (sCD40L) was reported in scleroderma. In this study we investigated the effect of CD40 ligation on MVEC apoptosis, activation and dysfunction.

Methods: MVEC were isolated from involved SSc skin and from matched healthy control subjects. MVEC apoptosis was assessed by flow cytometry, caspases3/7 activity and cell viability. MVEC genes expression was determined by real-time-PCR and results were confirmed by western blot analysis. Endothelial permeability was assessed by FITC-Dextran permeability assay.

Results: Significant increase in CD40 expression of was noted in SSc-MVEC (3.2 folds $\pm$ 0.3 in SSc vs. control MVEC). Similar increase in expression level was noted in SS skin biopsies (2.4 folds $\pm$ 0.3 in SSc skin vs. control skin biopsies, n=3 each).

The addition of CD40 ligand to MVEC resulted in the following observations:

1. Reduction in nitric oxide synthase (*NOS3*) expression (80%$\pm$6 reduction in control-MVEC and 82%$\pm$ 8 in SSc-MVEC, mean 4 cell lines $\pm$SD) and in prostacyclin synthase (*PTGS1*), 64% $\pm$ 3.0 reduction in control-MVEC and 79% $\pm$ 4.5 reduction in SSc-MVEC, mean 4 cell lines $\pm$SD). While Endothelin 1 expression was significantly increased by 2.2$\pm$ 0.12 folds in control MVEC and by 2.8 $\pm$0.31 folds in SSc MVEC.
2. Increase EC *p*ermeability (2.2$\pm$ 0.3 in control-MVEC and 2.8 $\pm$ 0.34 in SSc-MVEC, folds$\pm$SD)
3. Significant Increase expression of the CC and CXC chemokines including CCL2, interleukin-8, CXCL3, 5, 6 and 9.
4. Increase expression of IL1B, hepatocyte growth factor and adhesion molecules particularly ICAM1.
5. Significant down regulation of c-fos induced growth factor (FGIF, vascular endothelial growth factor D), epidermal growth factor, Insulin-like growth factor 1 and metallopeptidase inhibitor TIMP2.
6. The addition of CD40L to MVEC cultured in 0.5% serum resulted in a dose dependent apoptosis of MVEC. SSc-MVEC were more susceptible to apoptosis than control MVEC, thus at 10 μg concentration of CD40L, MVEC apoptosis was 45% $\pm$ 5 and 20% $\pm$ 3 in SSc vs. control MVEC respectively (mean $\pm$ SD of 4 cell lines). Apoptosis was confirmed by increase caspase 3/7 activity 2.2 folds in control and 3.0 folds in SSc-MVEC.

Conclusion: The study demonstrates increase expression of CD40 in SSc skin and in SSc-MVEC. CD40 ligation led to reduce expression of vasodilatory and increase expression of vasoconstrictive genes. Moreover, addition of CD40L increased endothelial permeability and the acquisition of an activated/dysfunctional phenotype in association with increase MVEC apoptosis. In all instances, SSc MVEC were more *susceptible* to CD40 signaling effects than control MVEC. The results suggest that the blockade of CD40/CD40 ligand interaction could be an effective therapeutic strategy in SSc.

Platelet Aggregability, Eicosanoid Biosynthesis and Oxidative Stress in Primary Raynaud's Phenomenon and Systemic Sclerosis. John D. Pauling and Neil McHugh. Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

Background/Purpose: Increased platelet activation, endothelial dysfunction and oxidative stress are all thought to contribute to the pathogenesis of Raynaud's phenomenon (RP), particularly in the context of systemic sclerosis (SSc). We report the findings of a cross-sectional study evaluating platelet function, endothelial production of prostacyclin and a novel biomarker of oxidative stress in patients with primary RP and SSc.

Methods: Patients with primary RP and SSc who were not taking anti-platelet or non-steroidal anti-inflammatory drugs were included in the study. All patients had their disease characteristics and medication use documented. Platelet number and structure (mean platelet volume, platelet distribution width and plateletcrit) were assessed using automated haematology analysis. Platelet function was assessed using light transmission aggregometry (maximum % aggregation over 5 minutes and maximum gradient of aggregation) to adenosine diphosphate (ADP, 1.25–10μl/L) and arachidonic acid (AA, 0.82–1.64mmol/L). Fasting levels of the major urinary metabolite of thromboxane (11-dehydro-TxB2), prostacyclin (2,3-dinor-6-keto-PGF1α) and non-enzymatic markers of lipid peroxidation and oxidative stress (F2-isoprostanes) were assessed using Gas Chromatography/Mass Spectrometry (GC/MS) analysis.

Results: Seventeen patients with primary RP and 17 with systemic sclerosis were recruited to the study. Age, gender, smoking status and use of vasodilator therapy were similar in each group (p>0.05). Platelet number and structure did not differ between groups. Maximum % aggregation to low concentration ADP (0.125–0.5μl/L) was significantly greater in SSc compared to primary RP (p<0.05 for all comparisons). Percent aggregation to high concentration ADP (10μl/L) and AA (1.64 and 0.82mmol/L) did not differ between groups, possibly representing a ceiling effect. The maximum gradient of aggregation was significantly greater for 1.64mmol/L AA in SSc compared with primary RP. Urinary metabolites of thromboxane (medians 425 vs. 382 pg/mg creatinine [Cr]), prostacyclin (160 vs. 122 pg/mg Cr) and F2-isoprostanes (1.00 vs. 1.12 ng/ml Cr) did not differ between SSc and primary RP (p>0.05 for all comparisons). There were moderate correlations between urinary 11-dehydro-TxB2 and both 2,3-dinor-6-keto-PGF1α and F2-isoprostanes (Spearman's Rho 0.537 and 0.612 respectively, p≤0.001). A history of digital ulceration was associated with increased aggregation to 5μl/L ADP in SSc. There were no associations between disease characteristics and eicosanoid biosynthesis in SSc.

Conclusion: This pilot study has identified increased *ex vivo* platelet reactivity in SSc compared with primary RP. *In vivo* lipid biomarkers of platelet activation, endothelial function and oxidative stress did not differ between groups. Biosynthesis of thromboxane (a potent vasoconstrictor) is associated with increased oxidative stress and increased synthesis of prostacyclin (a potent vasodilator) in RP. Additional work evaluating the clinical associations of platelet function and eicosanoid biosynthesis in a larger cohort of patients with primary RP and SSc may help guide the use of anti-platelet therapy in these patient groups.

Downregulated Expression of Metallothionein Genes in Response to the Gadolinium Contrast Agent Omniscan in Normal Human Differentiated Macrophages and Dermal Fibroblasts. Peter J. Wermuth[1], Francesco Del Galdo[2], Sankar Addya[3], Paolo Fortina[3] and Sergio A. Jimenez[1]. [1]Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center,Thomas Jefferson University, Philadelphia, PA, [2]University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom, [3]Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Metallothioneins bind heavy metals with high affinity and can serve as storage proteins for labile Zn^{2+} which in turn can regulate immune system activity through interactions with Toll-like receptor (TLR) signal transduction. Nephrogenic Systemic Fibrosis (NSF) is a generalized progressive fibrotic disorder described in some patients with renal insufficiency exposed to various gadolinium based contrast agents (GdBCA). The GdBCA Omniscan activates expression and production of several proinflammatory and profibrotic cytokines and growth factors in normal differentiated human macrophages via TLR4 and TLR7.signaling. Since some GdBCA are capable of inducing transmetallation by displacing Zn^{2+} from proteins the effect of GdBCA on expression levels of metallothionein genes in normal human macrophages and fibroblasts was examined in this study.

Methods: Terminally differentiated macrophages generated from two normal buffy coats were exposed for 24 hour to either 50 mM Omnisan or saline. Total RNA was isolated, labeled and hybridized to Affymetrix human U133 2.0 Plus microarrays. Volcano plots were used to identify differentially expressed genes between Omniscan treated and saline treated cells employing parametric testing assuming equal variances. Differential gene expression was confirmed by real-time PCR on the same RNA samples. Validation experi-

ments utilizing 3 additional differentiated macrophage isolates and two early passage (<6) normal human dermal fibroblasts examined the effect 1 mM Omniscan on the expression of metallothionein genes.

Results: Microarray analyses showed marked downregulation (~1.5 to 4 fold) of expression of multiple metallothionein genes (MT1E, MT1F, MT1G, MT1H, MT1M, MT1X and MT2A) in cells treated with 50 mM Omniscan compared to saline treated controls. These results were confirmed by real time-PCR analysis. Lower doses (1 mM) of Omniscan also downregulated the expression of these same genes as well as MT3 and MT4 whereas the expression of MT1A and MT1B was upregulated in normal human differentiated macrophages as well as in normal human dermal fibroblasts.

Conclusion: Global gene expression microarrays and real-time PCR analysis showed that exposure of terminally differentiated normal human macrophages to 50 mM Omniscan downregulated expression of multiple metallothionein genes in comparison to saline treated controls. Exposure of differentiated macrophages and normal human dermal fibroblasts to 1 mM Omniscan also decreased expression of these genes but increased expression of MT1A and MT1B suggesting that changes in metallothionein expression following GdBCA exposure in macrophages and dermal fibroblasts may play a role in the pathogenesis of the severe fibrotic process of NSF pathogenesis.

1497

Activation of Sirt1 Attenuates Bleomycin Induced Scleroderma Through Inhibiting Mammalian Target of Rapamycin Activation. Xiaoxia Zhu[1], Jianhua Qiu[2], Qiong Liu[3], Minrui Liang[4] and Hejian Zou[5]. [1]Huashan Hospital, Fudan University, Shanghai, China, [2]Neuroscience Center, Massachusetts General Hospital, Harvard Medical School, Massachusetts, USA, Boston, MA, [3]Institute of Rheumatology, Immunology and Allergy,Shanghai Medical College, Fudan University, Shanghai, China, [4]Huashan Hospital,Fudan University, Shanghai, Shanghai, China, [5]Huashan Hospital, Shanghai, China

Background/Purpose: Scleroderma is an autoimmune disease, characterized by progressive fibrosis of skin and internal organs. Inflammation is one of the main manifestations of scleroderma, especially at the early stage. Inflammation is also an important initiating agent of fibrosis, suppression of inflammation may be a promising resolution to attenuate scleroderma. Sirt1 (a NAD[+] dependent deacetylase) and its potent activator, resveratrol, both have been shown to have important role in regulation of inflammation.

Methods: In this study, we investigated the anti-inflammation role of Sirt1 and resveratrol in TNF-α treated fibroblasts and bleomycin induced mice experimental scleroderma, and further explore the anti-inflammatory mechanisms of Sirt1 and resveratrol in fibroblasts.

Results: Upregulation of matrix metalloproteinases 9 (MMP9), interleukin-1beta (IL-1β), IL-6 and inducible nitric oxide synthase (iNOS) were observed in the 3T3/NIH fibroblasts after being treated by TNF-α. Resveratrol suppressed the upregulation of inflammatory factors induced by TNF-α in a dose-dependent manner. And the suppression was significantly decreased if resveratrol was applied after the inflammation being induced. In the scleroderma mice model, bleomycin induced significant inflammation and fibrosis in the skin where infiltrated inflammatory cells, increased fiber bundles, upregulated collagen deposition were examined by HE staining and Masson's trichrome staining. But the pathological changes in were then notably attenuated by resveratrol treatment in time and dose dependent manner. The bleomycin induced upregulation of inflammatory factors were also inhibited by resveratrol treatment in the mice skin. We further explored the potential anti-inflammatory mechanisms of resveratrol in vitro. We blocked Sirt1 expression by Sirt1 siRNA transfection in 3T3/NIH fibroblasts, and investigated that knockdown of Sirt1 caused cell sensitizing to TNF-α stimulation and diminished the inflammatory inhibition of resveratrol. Furthermore, in this study, we also found that resveratrol inhibited the phosphorylation of both mammalian target of rapamycin (mTOR) and S6 ribosomal protein (S6RP) while ameliorating the inflammation in TNF-α treated fibroblasts. And rapamycin, the specific inhibitor of mTOR, attenuated the TNF-α induced inflammation in the fibroblasts.

Conclusion: The results suggest that Sirt1 is an efficient target for suppression of inflammation and fibrosis in scleroderma. As a Sirt1 activator, resveratrol may be used for therapy in scleroderma. Suppression of mTOR/S6RP phosphorylation may be involved in the mechanisms. This study provides a novel insight or treatment of scleroderma and other inflammation-related diseases.

Wisp-1 Neutralization Reduces Gvhd-Induced Skin Fibrosis by Altering TSLP-OX40L Axis-Dependent Th2 Responses. Raphael Lemaire, Tim Burwell, Rachel Griffin, Julie Bakken, Joseph Madary, Lynne Murray, Ronald Herbst and Jane Connor. MedImmune LLC, Gaithersburg, MD

Background/Purpose: There is accumulating evidence for a role of Wnt-signaling pathway activation in connective tissue disorders, including dermal and lung fibrosis. In particular, expression of WNT1-inducible signaling protein–1 (WISP1) is increased in human scleroderma skin and idiopathic pulmonary fibrosis (IPF) lung. A recent study showed that WISP-1 mediates lung fibrosis in mice. In the current study, we investigated the function of WISP-1 in dermal fibrosis.

Methods: There is accumulating evidence for a role of Wnt-signaling pathway activation in connective tissue disorders, including dermal and lung fibrosis. In particular, expression of WNT1-inducible signaling protein–1 (WISP1) is increased in human scleroderma skin and idiopathic pulmonary fibrosis (IPF) lung. A recent study showed that WISP-1 mediates lung fibrosis in mice. In the current study, we investigated the function of WISP-1 in dermal fibrosis.

Results: Anti-WISP-1 mAb treatment reduced skin fibrosis in the GVHD model, as documented by reduction of hydroxyproline content and Masson's trichrome staining in skin at week 4 post-graft. Gene expression analysis showed a concomitant reduction of GVHD-associated Th2 responses in skin, including cytokine/receptor (IL-13, IL-4Rα) and chemokines (CCL2, CCL17 and CCL22). This Th2 profile reduction was associated with a broad-based reduction of the pro-Th2 TSLP-OX40L axis (TSLP, TSLPR, IL-7R, OX40L), suggesting that the TSLP/OX40L pathway may in part mediate the effect of WISP-1 on the Th2 response in GVHD. This view was supported with data generated from a separate study showing that anti-TSLP mAb treatment in GVHD-induced fibrosis reduces levels of Th2 (IL-13, IL-4) but not Th1 (IFN-γ) cytokines in skin and blood. TSLP neutralization also fully reduced GVHD-induced WISP-1 expression, further substantiating a functional link between WISP-1 and the TSLP/OX40L axis in fibrosis.

Conclusion: Consistent with the role of Wnt signaling pathways in fibrosis, WISP-1 neutralization reduces GVHD-induced skin fibrosis in part by affecting TSLP-OX40L-based Th2 responses. Interestingly, scleroderma shows increased dermal TSLP level and OX40L polymorphisms, suggesting that targeting WISP-1 may offer a valuable therapeutic strategy for the treatment of scleroderma and other skin fibrosis disorders.

The Soluble Guanylate Cyclase Mediates Its Anti-Fibrotic Effects by Inhibiting TGF-β Signaling. Christian Beyer[1], Sonia C. Schindler[2], Alfiya Distler[1], Clara Dees[1], Helena Reichert[2], Hümeyra Akan[2], Peter Sandner[3], Oliver Distler[4], Georg Schett[5] and Joerg HW Distler[6]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Bayer Health Care, Global Drug Discovery – Common Mechanism Research, Wuppertal, Germany, [4]University Hospital Zurich, Zurich, Switzerland, [5]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [6]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: We have recently demonstrated that stimulation of the soluble guanylate cyclase (sGC) has potent anti-fibrotic activity in different models of fibrosis. sGC stimulation increases levels of cGMP, which acts as a second messenger to induce various cellular effects. The molecular mechanisms, however, by which sGC stimulation exerts its anti-fibrotic effects have not been characterized yet. In the present work, we investigated interactions between sGC signaling and the TGF-β pathway.

Methods: Normal and SSc fibroblasts as well as sGC-knockout fibroblasts were pre-treated with the sGC stimulator BAY41–2272 or 8-Bromo-cGMP and stimulated with TGF-β. sGC-knockout fibroblasts were generated by isolation of dermal fibroblasts from sGCI[fl/fl] mice and recombination induced by Cre-adenovirus. In vivo, we studied anti-fibrotic effects of BAY41–2272 in mice challenged with either bleomycin or an adenovirus expressing a constitutively active TGFβI receptor (TBR model).

Results: sGC stimulation by BAY41–2272 effectively inhibited TGFβ-dependent collagen release (mRNA and protein levels) from normal and SSc

dermal fibroblasts. In sGC-knockout fibroblasts, pre-treatment with the sGC stimulator BAY41–2272 did not reduce collagen release, demonstrating that the anti-fibrotic effects of BAY41–2272 are indeed mediated exclusively via sGC. To demonstrate that the second messenger cGMP is the central mediator of the sGC effects, we used the stable cGMP analogon 8-Bromo-cGMP. 8-Bromo-cGMP was effective in reducing TGFβ-dependent increase of collagen mRNA levels and collagen release in normal and SSc fibroblasts as well as in sGC-knockout fibroblasts. To further elucidate the novel link between sGC- and TGFβ-signaling, we studied nuclear p-smad2/3 levels: BAY41–2272 or 8-Bromo-cGMP prevented the TGFβ-induced increase in nuclear p-smad2/3 in normal and SSc fibroblasts. In sGC-knockout fibroblasts, only 8-Bromo-cGMP reduced p-smad2/3 levels, while BAY41–2272 had no effects. In vivo, we examined the antifibrotic effects of sGC stimulation in TGFβ-dependent, experimental dermal fibrosis (TBR model). BAY41–2272 dose-dependently reduced dermal thickening, hydroxyproline content and myofibroblast counts as well as p-smad2/3 levels, suggesting that sGC stimulation inhibited fibrogenesis via blocking TGFβ-signaling. We confirmed these findings in the more general disease model of bleomycin-induced dermal fibrosis, in which TGFβ is one of several important pro-fibrotic mediators.

Conclusion: We elucidated the molecular mechanisms underlying the anti-fibrotic effects of sGC signaling. Stimulation of sGC increases cGMP levels, which inhibits smad phosphorylation and results in decreased fibroblast activation and collagen release. Importantly, sGC stimulators have vasodilatory and anti-remodeling effects and are in phase 3 clinical trials for pulmonary arterial hypertension (PAH). Thus, sGC stimulators may soon become available for clinical trials and may provide simultaneous treatment of vascular disease and fibrosis in SSc.

1500

Activation of Pregnane X Receptor Induces Regression of Experimental Dermal Fibrosis. Christian Beyer[1], Alla Skapenko[2], Alfiya Distler[1], Clara Dees[1], Helena Reichert[3], Louis E. Munoz[3], Jan Leipe[4], Hendrik Schulze-Koops[2], Oliver Distler[5], Georg Schett[6] and Joerg HW Distler[7]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Munich, Munich, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]Division of Rheumatology and Clinical Immunology, Munich, Germany, [5]University Hospital Zurich, Zurich, Switzerland, [6]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [7]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Pregnane-X-receptor (PXR) belongs to a super-family of nuclear receptors that function as ligand-activated transcriptional factors. Although endogenous ligands have not yet been identified, PXR is a well-established master regulator of endobiotic metabolism as well as glucose and lipid homeostasis. Herein, we studied the role of PXR in experimental dermal fibrosis.

Methods: Mice were challenged with subcutaneous bleomycin injections and treated with 5-Pregnen-3β-ol-20-one-16α-carbonitrile (PCN) to activate PXR (i.p. once daily, conc. 25 mg/kg). After treatment, murine skin samples were analyzed for skin thickness, hydroxyproline content, α-smooth muscle actin (α-SMA)-positive myofibroblast counts, and phosphorylated smad2/3 (p-smad2/3) levels. Interleukin (IL)-13 was measured by multiplex bead array technology in murine skin. In vitro, murine fibroblasts were treated with PCN prior to stimulation with TGFβ to determine direct effects of PXR on collagen release. To study the release of the Th$_2$ cytokines IL-4 and IL-13 from murine CD4$^+$ T cells, murine T cells were isolated from FVB mice, kept in Th$_0$ and Th$_2$ conditions, and treated with PCN.

Results: We found that PXR activation effectively prevented bleomycin-induced dermal fibrosis as shown by reduced skin thickening (by 85.9 ± 7.5 %; $p = 0.002$), hydroxyproline content (by 50.5 ± 6.4 %; $p = 0.002$) and myofibroblast counts (by 77.0 ± 12.0 %; $p = 0.005$). Apart from preventing fibrosis, PXR stimulation induced regression of established bleomycin-induced dermal fibrosis in a modified treatment model with significant reductions of skin thickening, hydroxyproline content and myofibroblast

counts below pre-treatment levels. When elucidating the molecular mechanisms of the anti-fibrotic activity of PXR, we found that PXR activation reduced p-smad2/3 levels by 62.5 ± 9.2 % ($p = 0.010$) in the skin of bleomycin-challenged mice, suggesting that PXR activity inhibited pro-fibrotic canonical TGF-β signaling. Although PXR was expressed in low levels in dermal fibroblasts, PCN treatment did not change TGF-β-induced collagen release in vitro. This suggested indirect anti-fibrotic effects of PXR on the collagen release from fibroblasts. We therefore examined the effects of PXR stimulation on the release of Th$_2$ cytokines from murine CD4$^+$-positive lymphocytes, which are well-established pro-fibrotic mediators in fibrotic disease. We found that PXR activation reduced the expression of pro-fibrotic T$_{H2}$ cytokine IL-13 by 60.0 ± 13.1 % ($p = 0.010$ for 100 μM PCN). Of note, we could confirm these results in vivo since PXR stimulation significantly reduced IL-13 levels by 166 ± 17.3 % ($p = 0.001$) in the skin from mice challenged with bleomycin.

Conclusion: In summary, we are the first to establish potent anti-fibrotic effects of the nuclear receptor PXR. Pharmacological activation of PXR interferes with IL-13 release from T$_{H2}$ cells, which leads to inhibition of pro-fibrotic TGF-β signaling and results in decreased fibroblast activation and collagen release. These findings suggest that activation of PXR might be a novel anti-fibrotic approach in particular for early, inflammatory stages of SSc and other fibrotic diseases.

1501

Increased Periostin Levels in Patients with Systemic Sclerosis. Yukie Yamaguchi[1], Junya Ono[2], Miho Masuoka[3], Shoichiro Ohta[4], Kenji Izuhara[3], Zenro Ikezawa[5], Michiko Aihara[1] and Kazuo Takahashi[1]. [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Shino-Test Corporation, Sagamihara, Japan, [3]Saga Medical School, Saga, Japan, [4]Saga medical School, Saga, Japan, [5]International University of Health and Welfare Atami Hospital, Atami, Japan

Background/Purpose: Systemic sclerosis (SSc) results in significant morbidity and mortality due to organ fibrosis characterized by increased deposition of extracellular matrix (ECM). Periostin is one of the matricellular proteins, a class of ECM-related molecules defined by their ability to modulate cell–matrix interactions. Recent studies revealed that periostin serves as a critical regulator of wound healing, epithelial mesenchymal transition, and fibrosis. However, the role of periostin in the pathogenesis of SSc is unknown. In this study, we determined periostin levels in association with clinical characteristics, including severity of skin sclerosis and disease duration in patients with SSc.

Methods: Expression of periostin was examined in primary fibroblasts and the skin obtained from SSc patients using immunoblotting and immunohistochemistry respectively. Enzyme-linked immunosorbent assay was performed to evaluate serum periostin levels in association with clinical characteristics in 56 patients with SSc (diffuse cutaneous SSc (dSSc); n=16, limited cutaneous SSc (lSSc); n=40) and 66 healthy controls. In addition, the sensitivity and specificity of serum periostin levels for detecting SSc were analyzed using a receiver operating characteristic (ROC) curve.

Results: Periostin was strongly expressed in the affected dermis and primary fibroblasts obtained from SSc patients. Serum levels of periostin in dSSc patients were markedly elevated compared to those in lSSc patients and control subjects. Patients with lSSc had increased periostin levels compared with healthy controls. In addition, significantly higher levels of periostin were observed in dSSc patients with disease duration £5 years compared with those with disease duration >5 years. No significant difference was found in serum periostin levels between SSc patients with interstitial lung disease (ILD) and those without ILD. Furthermore, the modified Rodnan total skin thickness score (MRSS) was positively correlated with periostin levels in SSc patients. Serial analysis revealed the relevance of MRSS and periostin levels in some dSSc patients during their course of the disease. Finally, ROC analysis demonstrated that measurement of serum periostin by ELISA would be useful to distinguish SSc patients from healthy controls.

Conclusion: An elevated periostin level in SSc patients was correlated with severity of skin sclerosis. Periostin may be a potential biomarker reflecting for disease severity in patients with SSc.

Hedgehog Signaling in Murine Chronic Sclerodermatous Graft-Versus-Host Disease.
Pawel Zerr[1], Katrin Palumbo-Zerr[1], Alfiya Distler[1], Michal Tomcik[2], Stefan Vollath[1], Louis E. Munoz[1], Christian Beyer[1], Clara Dees[1], Friederike Egberts[3], Ilaria Tinazzi[4], Francesco Del Galdo[4], Oliver Distler[5], Georg Schett[1], Bernd M. Spriewald[6] and Joerg HW Distler[7]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, [3]Department of Dermatology, Schleswig-Holstein University Hospital, Campus Kiel, Kiel, Germany, [4]Scleroderma Research Program, Leeds Institute of Molecular Medicine, Division of Musculoskeletal Diseases, University of Leeds, Leeds, United Kingdom, [5]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology, University Hospital Zurich, Zurich, Switzerland, [6]Department of Internal Medicine V, University of Erlangen-Nuremberg, Erlangen, Germany, [7]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Sclerodermatous chronic graft-versus-host disease (cGvHD) is a prognosis limiting complication of allogeneic bone marrow transplantation. cGVHD can manifest on virtually every organ system. However, the skin is most commonly affected with progressive skin fibrosis resembling the findings in systemic sclerosis (SSc). The hedgehog pathway plays a critical role in cellular differentiation during embryogenesis, but also for tissue homeostasis in adult. The prominent role of hedgehog signaling in various tumors prompted the development of small molecule inhibitors, some of which have already been successfully tested in clinical trials.

Methods: Sublethally irradiated recipient mice received miHAg-mismatched bone marrow to induce sclerodermatous cGvHD. Activation of sonic hedgehog (Shh) pathway in cGvHD was analyzed by immunohistochemistry for Shh and its downstream transcription factors Gli-1 and Gli-2 in human and murine skin. Smoothened (Smo) inhibitor LDE223 was used to investigate the efficacy of hedgehog inhibition for prevention and treatment of murine cGvHD. Skin samples were analyzed for dermal thickness, myofibroblast counts and hydroxyproline content. The effect of Shh on cultured fibroblasts was analyzed by quantification of stress fibers formation, real time PCR for Col1a2 and the collagen content in supernatants.

Results: Hedgehog signaling was activated in human and murine cGvHD with increased expression of Shh, Gli-1 and Gli-2. Inhibition of coreceptor Smo with LDE223 was well tolerated without evidence of toxicity. LDE223 effectively reduced cGvHD in both preventive and therapeutic regime without decreasing the desired graft versus leukemia effect. Treatment with LDE223 initiated either before disease onset or after first clinical signs of cGvHD, significantly reduced clinical signs such as weight loss, alopecia and skin ulcers. Moreover, inhibition of Smo effectively ameliorated the histological changes of cGvHD. Preventive as well as therapeutic regime of LDE223 significantly decreased the dermal thickness, the number of myofibroblasts and the hydroxyproline content compared to control mice. Of note, therapeutic regime of LDE223 did not only stop progression, but induced histological regression of cGvHD. While LDE223 did not ameliorate leukocyte infiltration, B- or T cell activation, incubation of human dermal fibroblasts with Shh induced fibroblast activation with increased release of collagen and myofibroblast differentiation, suggesting a direct inhibitory effect on fibroblasts as mechanism of action.

Conclusion: This is the first study on the role of hedgehog signaling in sclerodermatous cGvHD. We demonstrate that hedgehog signaling is activated in cGvHD and stimulates progression of cGvHD by activating resident fibroblasts. Considering the potent therapeutic effects of Smo inhibition in preventive as well as therapeutic settings, good tolerance and lack of interference with the desired GVL and the availability of Smo inhibitors for clinical trials, our findings might have direct translational implications and stimulate clinical trials with Smo inhibitors in cGvHD and other fibrotic diseases such as SSc.

Effect of Thiol Antioxidants On the Profibrotic Phenotype of Scleroderma Dermal Fibroblasts.
Pei-Suen Tsou, Beatrix Balogh, Adam J. Pinney, Elena Schiopu, Dinesh Khanna and Alisa E. Koch. University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: Systemic sclerosis (Scleroderma, SSc) is a connective tissue disease characterized by vasculopathy and fibrosis of the skin and organs. Increase in superoxide production and platelet-derived growth factor receptor (PDGFR) activation promote collagen I (Col I) production, leading to fibrosis in SSc. Protein tyrosine phosphatases (PTPs), which are responsible for terminating the PDGFR pathway, are oxidatively inactivated in SSc dermal fibroblasts. In addition, these cells exhibit myofibroblast characteristics with increased α-smooth muscle actin (αSMA) expression. The goal of this study is to determine the effect of two thiol antioxidants, N-acetylcysteine (NAC) and dihydrolipoic acid (DHLA), on the phenotype of SSc fibroblasts, namely PDGFR stimulation, Col I synthesis, superoxide levels, phosphatase activities, αSMA expression, and matrix metalloproteinase 1 (MMP-1) production.

Methods: Punch biopsies (4 mm) from distal skin were obtained from patients with SSc (n=5). Normal (NL) skin tissue was obtained from the tissue procurement service of the University of Michigan. Superoxide levels were measured using dihydroethidium. PDGFR phosphorylation was determined by immunoprecipitation and Western blotting. Quantitative PCR was performed with primers for Col I and β-actin. Immunofluorescence was performed to probe for Col I and αSMA. An enzyme linked immunosorbent assay was completed to detect MMP-1. Phosphatase activities were measured using the amount of phosphate released as an end point.

Results: Addition of NAC decreased superoxide in SSc dermal fibroblasts while DHLA did not. Both NAC and DHLA decreased PDGFR phosphorylation in SSc fibroblasts. Col I mRNA was increased in SSc fibroblasts compared to normal (NL) at basal level, while NAC and DHLA decreased both Col I mRNA and protein levels. SSc fibroblasts produced lower levels of MMP-1 compared to NL, but the levels increased after NAC or DHLA incubation. DHLA not only decreased the expression of αSMA in SSc dermal fibroblasts, but also restored the activities of phosphatases that inactivate the PDGFR, including PTP1B, SHP-2, and DEP-1. Almost as effective was NAC which restored PTP1B and DEP-1 activity, but not SHP-2.

Conclusion: Our results show that thiol antioxidants are beneficial for SSc dermal fibroblasts due to their ability to reverse the profibrotic phenotype of these cells. Thiol antioxidants decrease PDGFR activation, possibly by restoring the activities of phosphatases, and hence decrease Col I production. In addition, they increase MMP-1 production, which degrades Col I. Moreover, DHLA lowered the expression of αSMA, suggesting that it could reverse the myofibroblast phenotype of SSc dermal fibroblasts. Hence thiol antioxidants could prove to be an effective treatment in SSc.

A Possible Contribution of Visfatin to the Resolution of Skin Sclerosis in Patients with Diffuse Cutaneous Systemic Sclerosis Via a Direct Anti-Fibrotic Effect On Dermal Fibroblasts and Th1 Polarization of the Immune Response.
Tetsuo Toyama, Yoshihide Asano, Yuri Masui, Sayaka Shibata, Kaname Akamata, Shinji Noda, Naohiko Aozasa, Takashi Taniguchi, Takehiro Takahashi, Yohei Ichimura, Hayakazu Sumida, Koichi Yanaba, Takafumi Kadono and Shinichi Sato. University of Tokyo Graduate School of Medicine, Tokyo, Japan

Background/Purpose: Our latest studies have demonstrated that adipocytokines, including adiponectin, apelin, and retinol-binding protein-4, are potentially involved in the development of complicated clinical symptoms associated with systemic sclerosis (SSc). Visfatin is another member of adipocytokines with pro-fibrotic, pro-inflammatory, and immunomodulating properties, having been implicated in the pathogenesis of certain fibrotic and inflammatory autoimmune diseases. As an initial step of a series of studies regarding the role of visfatin in the pathogenesis of SSc, we herein investigated the clinical significance of serum visfatin levels and its contribution to the developmental process in this disorder.

Methods: Serum visfatin levels were determined by a specific ELISA in 57 SSc patients and 19 healthy controls. The effects of visfatin on the mRNA

levels of a2(I) collagen (COL1A2) and matrix metalloproteinase-1 (MMP-1) genes were examined in normal and SSc dermal fibroblasts by reverse-transcript real-time PCR. The levels of IL-12p70 produced by THP-1 cells differentiated with IFN-g plus LPS in the presence or absence of visfatin were measured by a specific ELISA.

Results: Serum visfatin levels were comparable among total SSc, diffuse cutaneous SSc, limited cutaneous SSc, and healthy controls. The only finding in a series of analyses regarding the correlation of serum visfatin levels with clinical symptoms and laboratory data was the significantly longer disease duration in dcSSc with elevated serum visfatin levels than in those with normal levels. Consistently, serum visfatin levels were significantly elevated in late stage dcSSc (disease duration of > 6 years), but not in early and mid-stage dcSSc, compared with healthy controls, suggesting the possible contribution of visfatin to the resolution of skin sclerosis in late stage dcSSc. To assess this hypothesis, two sets of *in vitro* experiments were carried out using dermal fibroblasts and THP-1 cells. Visfatin suppressed the mRNA levels of COL1A2 gene, while increasing the mRNA levels of MMP-1 gene, in a dose-dependent manner in SSc dermal fibroblasts, whereas the mRNA levels of these genes were not affected by visfatin at all in normal dermal fibroblasts, indicating the direct anti-fibrotic effect of visfatin on SSc dermal fibroblasts. Furthermore, visfatin increased the production of IL-12p70 in THP-1 cells differentiated with IFN-g plus LPS in a dose-dependent manner, suggesting the promotion of Th1 immune responses by visfatin.

Conclusion: Visfatin may contribute to the resolution of skin sclerosis in late stage dcSSc via the direct anti-fibrotic effect on dermal fibroblasts and Th1 polarization of the immune response.

1505

Inactivation of Tankyrases Ameliorates Canonical Wnt Signaling and Prevents Experimental Fibrosis. Alfiya Distler[1], Lisa Deloch[2], Jingang Huang[2], Clara Dees[1], Neng Yu Lin[2], Christian Beyer[1], Oliver Distler[3], Georg A. Schett[4] and Joerg HW Distler[4]. [1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]University Hospital Zurich, Zurich, Switzerland, [4]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Systemic sclerosis (SSc) is characterized by aberrant activation of fibroblasts with increased release of extracellular matrix components. Canonical Wnt signaling has recently emerged as a key mediator of fibroblasts activation and tissue fibrosis in SSc. However, targeting of canonical Wnt signaling has so far been complicated by the lack of pathway components that are amenable to pharmacological inhibition. However, tankyrases have recently demonstrated to regulate Wnt signalling by stimulating the proteasomal degradation of axin. In the present study, we evaluated the tankyrases as a potential novel target for the treatment of fibrosis in SSc.

Methods: The anti-fibrotic effects of the selective tankyrase inhibitor XAV-939 or of siRNA mediated knockdown of tankyrases were evaluated in the mouse models of bleomycin-induced dermal fibrosis and in experimental fibrosis induced by adenoviral overexpression of a constitutively active TGF-β receptor I (adTBR). Dermal thickness, α-smooth muscle actin (αSMA) and hydroxyproline content were determined by haematoxylin-eosin and trichrome stainings, by immunohistostaining for αSMA and by hydroxyproline assay respectively. Activation of canonical Wnt signaling was assessed by quantification of nuclear β-catenin and analyses of the target gene c-myc.

Results: Inactivation of tankyrases either by XAV-939 or by siRNA mediated knockdown of tankyrases prevented the activation of canonical Wnt signaling in experimental fibrosis and reduced the nuclear accumulation of β-catenin and the mRNA levels of the target gene c-myc. Pharmacologic inhibition of tankyrases was well tolerated without any clinical signs of toxicity. Treatment with XAV-939 potently reduced bleomycin-induced dermal thickening by 50 % compared to sham-treated mice (p = 0.0007). XAV-939 also significantly reduced the differentiation of resting fibroblasts into myofibroblasts and accumulation of collagen. XAV-939 also exerted potent anti-fibrotic effects in adTBR driven skin fibrosis with reduced dermal thickening, decreased myofibroblast counts and reduced accumulation of collagen compared to sham-treated mice. siRNA mediated knockdown of

tankyrases in the skin also exerted potent anti-fibrotic effects confirming that the anti-fibrotic effects of XAV-939 were not due to off-target effects.

Conclusion: Inactivation of tankyrases abrogated the activation of canonical Wnt signaling and demonstrated potent anti-fibrotic effects in different preclinical models of SSc without evidence of toxicity. Considering the great medical need, the potent anti-fibrotic effects, the good tolerability and first clinical trials with tankyrase inhibitors, tankyrases might be potential candidates for targeted therapies in SSc and other fibrotic diseases.

1506

Primary Human Scleroderma Dermal Endothelial Cells Exhibit Defective Angiogenesis. Pei-Suen Tsou[1], Bradley J. Rabquer[1], Beatrix Balogh[1], Ann Kendzicky[1], Bashar Kahaleh[2], Elena Schiopu[1], Dinesh Khanna[1] and Alisa E. Koch[1]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Toledo, Toledo, OH

Background/Purpose: Angiogenesis, the formation of new blood vessels, plays a critical role in a number of pathological processes including systemic sclerosis (scleroderma, SSc). SSc is a multifactoral disorder that is characterized by early inflammation, excessive extracellular matrix deposition, and vascular abnormalities. In this study we determined if the endothelial cells (ECs) isolated from SSc skin mount a proangiogenic response towards angiogenic chemokines, including growth-regulated protein-γ (Gro-γ/CXCL3), granulocyte chemotactic protein-2 (GCP-2/CXCL6), and CXCL16. The expression of transcription factors inhibitor of DNA-binding protein 1 and 3 (Id-1 and 3), which are required for ECs to mount an angiogenic response, were also examined.

Methods: Skin biopsies from the distal forearm (more involved) were obtained from patients with SSc. Normal (NL) skin tissue was obtained from the tissue procurement service of the University of Michigan. ECs were isolated from skin biopsies via magnetic selection. Immunofluorescence staining of EC markers such as CD31 and von Willebrand factor (vWF), as well as fibroblast markers such as collagen I and α-smooth muscle actin (αSMA) was performed. To determine if chemokines mediate specific angiogenic events in SSc ECs, chemotaxis assays were performed. ECs were stimulated with chemokines to determine which signaling pathways were activated. The expression of Id-1 and 3 were quantified by quantitative PCR.

Results: Both NL and SSc ECs stained positive for EC markers while they did not stain for fibroblast markers. SSc ECs migrated toward phorbol-12-myristate-13-acetate (PMA) but not to basic fibroblast growth factor (bFGF) compared to their corresponding controls, dimethyl sulfoxide (DMSO) or phosphate buffered saline (PBS). GCP-2/CXCL6 dose dependently induced both NL and SSc EC migration. In contrast, the ability of Gro-γ/CXCL3 and CXCL16 to promote cell migration was hampered in SSc ECs compared to NL ECs. GCP-2/CXCL6 stimulated the phosphorylation of Akt, cJun, Erk1/2, NFkB p65, and p38 kinases in a dose dependent manner in NL ECs, while only cJun, Erk1/2, and p38 kinases in SSc ECs. CXCL16 stimulated Akt, Erk1/2, NFkB p65, and p38 kinases phosphorylation in NL ECs, while only cJun, Erk1/2, and p38 kinases in SSc ECs. The mRNA levels of Id-1 and Id-3 in SSc ECs were 2.5 and 2.1 fold lower compared to NLs (n=3).

Conclusion: Our results show that Gro-γ/CXCL3 and CXCL16 induce anigogenic activity in NL but not SSc ECs. This might be due to the differences in the signaling pathways activated by these chemokines in NL vs. SSc ECs. In addition, the lower expression of transcription factors Id-1 and Id-3 might also decrease the angiogenic response in these cells. The inability of proangiogenic chemokines to promote EC migration provides an additional mechanism for the impaired angiogenesis that characterizes SSc.

1507

Propylthiouracil Reduces Fibrosis in Chronic Oxidant Stress Mouse Model of Scleroderma.

Gianluca Bagnato[1], Alessandra Bitto[1], Natasha Irrera[1], Gabriele Pizzino[1], Neal Roberts[2], Maurizio Cinquegrani[1], Donatella Sangari[1], Francesco Squadrito[1], Gianfilippo Bagnato[1] and Antonino Saitta[1]. [1]University of Messina, Messina, Italy, [2]Medical College of Virginia, Richmond, VA

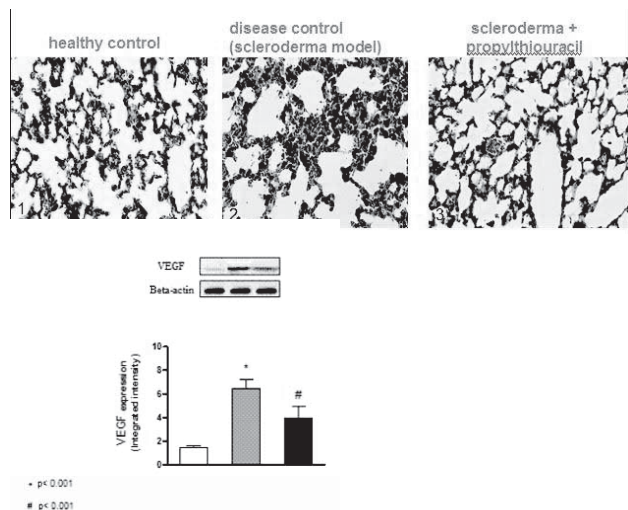
Background/Purpose: Systemic sclerosis (SSc) is characterized by fibrosis of skin and visceral organs; vascular damage and resultant ischemia; and immunological dysregulation manifested by autoantibodies. Hypothyroidism, induced by either propylthiouracil (PTU) or thyroidectomy, has been shown to induce regression of pulmonary hypertension in the sumatinib/hypoxia rat model involving blockade of vascular endothelial growth factor (VEGF). The aim of this study was therefore to evaluate the effect of PTU in another murine model closer to human SSc, a mouse model of diffuse SSc reported to cause the development of anti-topoisomerase antibodies.

Methods: SSc was induced in BALB/c mice by daily subcutaneous injections of HOCl as an oxidant stress for 6 weeks (Batteux F, Kavian N, Servettaz A. New insights on chemically induced animal models of systemic sclerosis.Curr Opin Rheumatol. 2011 Nov;23(6):511–8). Mice (n=25) were randomized in three arms to treatment with either HOCl (n=10); HOCl plus PTU (n=10); or vehicle alone (n=5). PTU treatment was initiated 30 minutes after HOCl subcutaneous injection (12 mg/kg) continuing daily for the 6 weeks. Skin and lung fibrosis were evaluated by histological methods. The severity of fibrosis was assessed using ordinal or nominal scales in both tissues and the results compared nonparametrically.

Results: Injections of HOCl induced both cutaneous and lung fibrosis in BALB/c mice, as reported in the model. Concomitant PTU treatment reduced skin thickness by 77% (images not shown) and reduced pulmonary fibrosis below the level of histological detectability, in effect preventing it entirely in this model. Pulmonary concentrations of VEGF were significantly higher in mice exposed to HOCl (p<0.001) and were reduced by concomitant treatment with PTU (p<0.001). Its downstream mediator ERK (extracellular signal-related kinase) followed the same pattern (images not shown).

healthy control | disease control (scleroderma model) | scleroderma + propylthiouracil

VEGF
Beta-actin

* p< 0.001
# p< 0.001


Conclusion: PTU-induced hypothyroidism (or the PTU itself, via another mechanism of action not related to hypothyroidism, such as antioxidant effect) reduced significantly the development of fibrosis in the HOCl mouse model of SSc. No confirmatory thyroidectomy experiments were performed in this model, in contrast to those reported in the previous rat model. Further studies are therefore needed to investigate both the roles of thyroid function and reactive oxygen species in scleroderma pathogenesis, including analysis of any direct antioxidant effect of PTU, independent of its effect upon thyroid status.

1508

Simvastatin Attenuates Pulmonary Fibrosis in a Murine Model of Systemic Sclerosis.

Gianluca Bagnato[1], Alessandra Bitto[1], Natasha Irrera[1], Gabriele Pizzino[1], Donatella Sangari[1], Maurizio Cinquegrani[1], Neal Roberts[2], Gianfilippo Bagnato[1], Francesco Squadrito[1] and Antonino Saitta[1]. [1]University of Messina, Messina, Italy, [2]Medical College of Virginia, Richmond, VA

Background/Purpose: Simvastatin is best known for its antilipidemic action due to its inhibition of 3-hydroxy-3-methylglutaryl CoenzymeA (HMG CoA) reductase. Inhibition of biological precursors in this pathway also enables pleiotrophic immunomodulatory and anti-inflammatory capabilities. The antifibrotic effect of simvastatin has been shown in human lung fibroblasts. This study aimed to measure beneficial effects of simvastatin, and to explore mechanisms of, development of pulmonary fibrosis and skin thickening in a murine model of systemic sclerosis.

Methods: Chronic oxidant stress SSc was induced in BALB/c mice by daily subcutaneous injections of HOCl for 6 weeks as characterized in detail as the Cochin chronic oxidant stress model of SSc (Batteux F, Kavian N, Servettaz A. New insights on chemically induced animal models of systemic sclerosis.Curr Opin Rheumatol. 2011 Nov;23(6):511–8). Mice (n=24) were randomized in three arms: treatment with either simvastatin plus HOCl (n=9): vehicle plus HOCl (n=10), or vehicle alone (n=5). Statin treatment (40 mg/kg) was initiated 30 minutes after HOCl subcutaneous injection and continued daily for the 6 weeks. Skin and lung fibrosis were evaluated by histological methods. The severity of fibrosis was assessed using ordinal or nominal scales in both tissues and the results compared nonparametrically

Results: Injections of HOCl induced cutaneous and lung fibrosis in BALB/c mice as demonstrated by routine histological analysis. Simvastatin treatment both reduced skin thickness by 55% (upper row of 3 representative photomicrographs) and attenuated the histopathological change of HOCl-induced pulmonary fibrosis as shown in the lower series.

S1=normal healthy control | SH_3 = HOCl disease model without intervention | ss9 = HOCl + simvastatin

healthy control | disease control (scleroderma model) | scleroderma + simvastatin
Conclusion: Simvastatin reduces the development of pulmonary fibrosis potentially modulating adverse lung parenchymal remodeling as shown by the reduced deposition of collagen in alveolar septae in this murine model. Simvastatin also reduces skin thickness in the model. The histological evidence from these experiments suggests that—given the low, 1 per million death rate from statin prescriptions and the morbidity and mortality of SSC pulmonary disease—consideration of human trials is warranted to determine the potential safety and efficacy of simvastatin for treatment of pulmonary fibrosis.

Correlates of Skin Gene Expression Profile in Systemic Sclerosis.

Shervin Assassi[1], Jeffrey T. Chang[1], Filemon K. Tan[1], Minghua Wu[1], Gloria A. Salazar Cintora[1], Irum Zaheer[2], Dinesh Khanna[3], Daniel E. Furst[4] and Maureen D. Mayes[1]. [1]Univ of Texas Health Science at Houston, Houston, TX, [2]Methodist Hospital, Houston, TX, [3]University of Michigan, Ann Arbor, MI, [4]David Geffen School of Medicine at UCLA, Los Angeles, CA

Background/Purpose: Skin global gene expression profiling indicates presence of distinct gene expression signatures in patients with systemic sclerosis (SSc). We examine the correlation of the skin gene expression profiles with clinical subsets of disease in a large sample of SSc patients.

Methods: In this study, 61 SSc patients (61% diffuse disease, mean disease duration: 7.7 years) and 36 gender, ethnicity, and age matched controls were examined. All skin biopsies were obtained from subjects' arm and processed according to the same procedures. In 40 SSc patients, the skin was affected at the biopsy site. Global gene expression profiling was performed by Illumina HumanHT-12 arrays in one batch. Only 1 biopsy per subject was analyzed. Differentially expressed (DE) genes were detected in multivariable analysis with False Discovery Rate of 10% at the confidence level of 80%. Involved Canonical Pathways were identified by Ingenuity Pathway Analysis. Unsupervised hierarchical clustering was performed with all expressed genes and after filtering the gene list with the previously published TGF-β, IL-13, and diffuse proliferative (Milano et al. 2008) signatures. We also generated an interferon-α (IFN-α) inducible gene signature using control fibroblast treated with IFNa.

Results: The transcriptome of the majority of SSc patients differed from controls. Specifically, 2525 DE genes were identified, belonging to fibrotic, leukocyte extravasation, and oxidative phosphorylation pathways. However, there was significant heterogeneity among the SSc samples. We examined whether the observed heterogeneity correlated with known clinical subtypes of SSc. However, we could not identify any significant differential expression when patients were subgrouped by disease type (limited versus diffuse), antibody subtypes, treatment status (immunosuppression versus no immunosuppression), or disease duration. The presence of anti-RNP antibodies was the exception. Comparison of anti-RNP positive to the anti-RNP negative patients resulted in 188 DE genes, belonging mainly to IFN pathways. However, we detected prominent gene expression differences among SSc patients who have affected vs. unaffected skin at the biopsy site. This comparison resulted in 378 DE expressed genes, belonging to fibrotic and leukocyte extravasation pathways. This was further underscored by the fact that comparison of SSc affected skin to controls resulted in 3458 genes while comparing patients wit unaffected skin to controls resulted in only 38 DE genes. We next filtered our gene list by TGF-β, IL-13, diffuse proliferative, and IFN-α gene signatures in separate unsupervised clustering analyses. While these gene signatures were helpful in separating the majority of patients from controls, they did not correspond to known clinical subtypes of SSc including disease type and treatment status.

Conclusion: The majority of SSc patients have distinct (but heterogeneous) global gene expression profile when compared to controls. Within SSc group, the status of skin at the biopsy site is a major source of variability (affected versus unaffected skin). The observed heterogeneity in SSc transcriptomes does not correspond to the known clinical subtypes of disease.

Critical Role of the Adhesion Receptor Dnax Accessory Molecule-1 (DNAM-1) in the Development of Inflammation-Driven Dermal Fibrosis in Mouse Model of Systemic Sclerosis.
Jerome Avouac[1], Muriel Elhai[2], Michal Tomcik[3], Manuel Friese[4], Marco Colonna[5], Günter Bernhardt[6], Andre Kahan[1], Gilles Chiocchia[7], Joerg HW Distler[8] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Paris Descartes University, INSERM U1016, Institut Cochin, Sorbonne Paris Cité, Paris, France, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic, [4]Zentrum für Molekulare Neurobiologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [5]Department of Immunology, St. Louis, MO, [6]Institute of Immunology, Hannover Medical School, Hannover, Germany, [7]Institut Cochin - INSERM U1016 - CNRS (UMR 8104), Paris, France, [8]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: DNAX accessory molecule 1 (DNAM-1) is an adhesion factor involved in the adhesion and co-stimulation of T cells. DNAM-1 has been recently identified as a genetic susceptibility factor to systemic sclerosis (SSc) and also to other autoimmune diseases. Our aim was to investigate the contribution of DNAM-1 in the development of dermal fibrosis upon gene inactivation and targeted molecular strategies.

Methods: Human skin expression of DNAM-1 was determined by immunohistochemistry. Mice deficient for DNAM-1 (dnam1$^{-/-}$) and wild-type controls (dnam1$^{+/+}$) were injected with bleomycin or NaCl. Infiltrating leukocytes, T cells, B cells and monocytes were quantified respectively on hematoxylin and eosin stained sections and by immunohistochemistry for CD3, CD22 and CD68. Inflammatory cytokines were measured in lesional skin of dnam1$^{-/-}$ and dnam1$^{+/+}$ mice by flow cytometry. The anti-fibrotic potential of a DNAM-1 neutralizing monoclonal antibody (mAb) was also evaluated in the mouse model of bleomycin-induced dermal fibrosis.

Results: Overexpression of DNAM-1 was detected in the lesional skin of SSc patients, especially in perivascular inflammatory cells. Dnam1$^{-/-}$ mice were protected from bleomycin-induced dermal fibrosis with reduced dermal thickening ($75\pm5\%$ reduction, p=0.02), hydroxyproline content ($46\pm8\%$ decrease, p=0.02) and myofibroblast counts ($39\pm5\%$ reduction, p=0.04). The numbers infiltrating T cells were decreased in lesional skin of dnam1$^{-/-}$ mice by $69\pm15\%$ (p=0.009). The number of B cells and monocytes was not significantly different in dnam1$^{-/-}$ and dnam1$^{+/+}$ mice upon bleomycin challenge. Moreover, dnam1$^{-/-}$ mice displayed in lesional skin decreased levels of inflammatory cytokines, such as IL-6 ($59\pm12\%$, p=0.001 decrease), and TNFα ($60\pm15\%$, p=0.03). Treatment with anti-DNAM-1 mAb significantly reduced dermal thickening by $64\pm6\%$ (p=0.01), hydroxyproline content by $61\pm8\%$ (p=0.001), and myofibroblast counts by $83\pm12\%$ (P=0.03). These results were similar to those observed in DNAM-1 deficient mice.

Conclusion: We demonstrate with two complementary approaches that inhibition of DNAM-1 significantly ameliorates dermal inflammation-driven fibrosis. DNAM-1 displays profibrotic effects by promoting the infiltration of T cells, into lesional skin and by stimulating the release of inflammatory cytokines. In addition, molecular targeting strategy using a DNAM-1 neutralizing mAb confirmed potent antifibrotic properties of DNAM-1 inhibition. Our findings might have direct translational implications and inhibition of DNAM-1 might be a promising new approach for the treatment of SSc and potentially other fibrotic diseases.

Low Circulating Endothelial Progenitor Cell Levels and High VEGF Serum Levels Are Associated with the Late Nailfold Capillaroscopic Pattern in Systemic Sclerosis.
Jerome Avouac[1], Maeva Vallucci[2], Vanessa Smith[3], Barbara Ruiz[2], Alberto Sulli[4], Carmen Pizzorni[4], Gilles Chiocchia[5], Maurizio Cutolo[4] and Yannick Allanore[1]. [1]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [2]Paris Descartes University, INSERM U1016, Institut Cochin, Sorbonne Paris Cité, Paris, France, [3]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [4]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [5]Institut Cochin - INSERM U1016 - CNRS (UMR 8104), Paris, France

Background/Purpose: To assess whether nailfold videocapillaroscopy (NVC) changes are associated with peripheral blood or serum levels of angiogenic biomarkers in systemic sclerosis (SSc).

Methods: Endothelial markers were assessed in a cohort of 60 SSc patients consecutively recruited. Circulating endothelial progenitor cells (EPCs) were quantified in peripheral blood by flow cytometry after cell sorting, as previously described (1). Serum levels of vascular endothelial growth factor (VEGF), placenta growth factor (PlGF), soluble vascular adhesion molecule (sVCAM), endothelin-1 (ET1), angiopoietin-2, endoglin, endostatin and Tie-2, were measured by quantitative sandwich enzyme-linked immunosorbent assay (ELISA) technique (Quantikine kits, R&D systems). Capillaroscopy was performed on 8 fingers, at $200\times$ magnification, by a single examiner (JA), on two consecutive fields extending over 1 mm, in the middle of the nailfold. Images were analysed anonymously by four investigators (VS, AS, CP and MC), blinded for the clinical and serum status of SSc patients and classified as early, active and late pattern (2).

Results: The mean $\pm$ standard deviation (SD) age of the 60 patients (46 women) was 56 ± 13 year old and the mean $\pm$ SD disease duration was 9 ± 8 years at baseline. Thirty-six patients had the diffuse cutaneous subset, and 24 the limited. Fourteen patients had an early, 22 an active, and 24 a late NVC pattern. By univariate analysis focused on biomarkers, patients with late NVC pattern exhibited significantly lower EPC levels

and higher VEGF serum levels than patients with early and active patterns (p=0.001 and p=0.01, respectively). Endothelin serum levels were significantly higher in the active pattern compared to early and late patterns (p=0.02). In multivariate multiple regression analysis, lower EPC and higher VEGF levels were independently associated with the late capillaroscopic pattern (p=0.007 and p=0.0008 respectively). In an alternate model including these 2 biomarkers and SSc-related disease characteristics, lower EPC counts, higher VEGF levels, and a modified Rodnan skin (mRSS) score >14, were independently associated, in multiple regression analysis, with the late capillaroscopic pattern (p=0.02, p=0.0001 and p=0.0003, respectively).

Conclusion: Our data revealed decreased EPC counts in patients with the late capillaroscopic pattern, suggesting that deficient vasculogenesis may contribute to the severe loss of capillaries observed in this pattern. VEGF upregulation in the late pattern may appear as a compensatory mechanism to stimulate this deficient vasculogenesis and could be implicated in the altered vessel morphology observed in this pattern. In addition, a mRSS>14 was independently associated with the late NVC pattern, highlighting from the clinical side the fibrotic component of this pattern. Further studies are now needed to determine the predictive value of capillaroscopy, in combination with these biomarkers, for the development of the vascular complications of SSc.

Bleomycin Delivery by Osmotic Pump: A Superior Model for Human ILD. Rebecca Lee, Michael Bonner, Charles Reese, Elena Tourkina, Zoltan Hajdu, Jing Zhang, Richard Visconti and Stanley Hoffman. Medical University of South Carolina, Charleston, SC

Background/Purpose: Interstitial lung disease (ILD) represents a group of chronic, progressive, irreversible diseases associated with pulmonary fibrosis, including systemic sclerosis and idiopathic pulmonary fibrosis. In ILD, pulmonary fibrosis is accompanied by alveolar epithelia cell injury, inflammatory cell accumulation, fibroblast and myofibroblast proliferation, loss of the master regulatory protein caveolin-1 from fibroblasts and inflammatory cells, and excessive deposition of extracellular matrix (ECM) resulting in impairment of pulmonary function. Fibrosis in ILD is predominantly localized in the subpleural region of the lung. ILD is modeled in rodents by bleomycin treatment. In most studies, bleomycin has been delivered directly into the lungs by intratracheal or intraoral administration; however, bleomycin has also been delivered using subcutaneous osmotic pumps. Here we have compared the effects in mice of bleomycin delivered by "Pump" or by the "Direct" route to determine which is a better model for human ILD.

Methods: Male CD1 mice (ten weeks old) are treated with bleomycin either by the "Direct" route (a single intraoral administration of 2 U/kg) and sacrificed on day 14, or by "Pump" (the pump delivers 100 U/kg continuously over 7 days, then is removed) and sacrificed on day 35. Tissue sections are stained histochemically and immunohistochemically for caveolin-1, inflammatory cell markers, several ECM proteins, and proteins associated with fibrosis. Other methods are used to analyze the progression of inflammation and fibrosis including Western blotting, gelatin zymography, collection of BAL fluid, and flow cytometry. The role of the loss of caveolin-1 in the progression of inflammation and fibrosis is determined by using the caveolin-1 scaffolding domain peptide to restore caveolin-1 function.

Results: The Pump model provides a much higher level of subpleural fibrosis than the Direct model as evaluated by Masson's Trichrome stain and immunohistochemistry for the ECM proteins collagen I, tenascin-C, and periostin, and the collagen chaperone HSP47 (Figs. 1 and 2). Conversely, there is a much higher level of inflammatory cell accumulation, weight loss, and death in the Direct model. There is a striking absence of caveolin-1 from the HSP47-positive cells in the Pump model. Experiments are underway to determine the effects of replacing caveolin-1 function in the Pump model.
Figure 1. Comparison of tissue morphology in mice treated wih bleomycin by the "Direct" and "Pump" methods. Sections are stained with H&E or Masson's trichrome stain. Images are all 20X.
Figure 2. Immunofluorescent staining in lung tissue sections from mice treated with bleomycin by "Pump" methods. Images are all 20X.

Conclusion: The Pump model is superior to the Direct model because: 1) The resulting disease more accurately recapitulates human ILD, and 2) It is more convenient because there is less animal weight loss and death.

TSLP Receptor Deficiency Reduces IL-13 Expression and Prevents Fibrosis in Experimental Scleroderma. Alicia Usategui[1], Vanessa Miranda[1], Gabriel Criado[1], Manuel J. Del Rey[1], Elena Izquierdo[1], Warren J. Leonard[2] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by progressive fibrosis of the skin and internal organs. Although SSc shares pathogenetic features with other autoimmune diseases, the participation of profibrotic Th2 cytokines is unique to SSc. However, the reasons for Th2 cytokine skewing are unknown. Thymic Stromal Lymphopoietin (TSLP) is a pivotal cytokine in induction of Th2 responses in allergic skin and lung inflammation. We have previously observed TSLP overexpres-

sion in human and experimental scleroderma (Arthritis Rheum 2011; 63: S904). To understand its function in this context, we have analyzed the contribution of TSLP to Th2 cytokine expression and fibrosis in a mouse model of scleroderma.

Methods: Skin fibrosis was induced in 6 week old female C57BL/6 TSLP receptor (TSLPR) deficient and wild type (WT) mice by subcutaneous injections of bleomycin (1mg/ml) into the shaved back skin daily for 4 weeks. Treated skin was harvested and histological examination and collagen content were determined by Masson's trichrome staining and total hydroxyproline content. Analysis of cytokines mRNA and protein expression in the skin was performed by quantitative RT-PCR, immunohistochemistry and ELISA. Quantitative data were compared by Mann-Whitney U-test and p-value<0.05 was considered significant.

Results: Bleomycin induced dermal fibrosis and an increase in the collagen content of the skin in both TSLPR deficient and WT mice. The fractional collagen area of the dermis and the total collagen protein content of the skin were significantly reduced in TSLPR deficient mice compared to WT mice. A significant increase in the expression of IL-13 and IL-17 but no IL-4 and IFN-γ mRNA in the skin was observed in bleomycin- injected compared to saline-injected WT mice. Expression of IL-13 and IL-17 mRNA in fibrotic skin was significantly reduced in TSLPR deficient mice compared to WT mice. An increase in the number of IL-13-positive cells by IHC was observed in bleomycin-injected skin compared to saline-injected controls. This response was significantly reduced in TSLPR deficient compared to WT mice. Bleomycin did not increase IL-17 protein expression in either group of mice.

Conclusion: These data provide the first evidence of TSLP contribution to a non-allergic fibrotic process. TSLP profibrotic role is potentially medidated by specific changes in the local cytokine milieu. Thus, modulating TSLP may have anti-fibrotic therapeutic implications.

Disclosure: **A. Usategui**, None; **V. Miranda**, None; **G. Criado**, None; **M. J. Del Rey**, None; **E. Izquierdo**, None; **W. J. Leonard**, None; **J. L. Pablos**, None.

1514

Differences in the Activation Levels and Expression Patterns of the Molecular Targets of Tyrosine Kinase Inhibitors May Account for the Heterogeneous Treatment Responses. Britta Maurer[1], Alfiya Akhmetshina[2], Renate E. Gay[1], Beat A. Michel[1], Steffen Gay[3], Joerg HW Distler[2] and Oliver Distler[1]. [1]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Switzerland, Zurich, Switzerland

Background/Purpose: In SSc, treatment responses to tyrosine kinase inhibitors (TKI) are less distinct compared to animal models. Therefore, we assessed whether the heterogeneous therapeutic effects could be related to differences in the activation level of the TKI targets c-abl and PDGFRβ.

Methods: Skin sections of bleomycin treated (n=10), Fra-2 transgenic (tg) (n=6), non-bleomycin treated (n=10) and wt mice (n=6), of diffuse (n=10) and limited (n=28) SSc patients and healthy controls (n=8) were analyzed by Masson's trichrome stain and immunohistochemistry (IHC) using antibodies against p-PDGFRβ and p-c-abl. Subgroups of bleomycin treated (n=8) and Fra-2 tg mice (n=6) were treated with nilotinib. The bleomycin model reflects early pro-inflammatory stages, whereas the Fra-2 model displays features of vasculopathy-induced fibrosis. Parametric non-related data were expressed as mean$\pm$SEM, nonparametric non-related data as median$_{(Q1,Q3)}$.

Results: In bleomycin treated mice compared to non-bleomycin controls, the dermal expression of both activated PDGFRβ ($10.4_{(10,11)}$ vs. $3.1_{(2,5)}$% cells/HPF) and c-abl ($9.1_{(9,10)}$ vs. $1.5_{(1,2)}$% cells/HPF) was strongly upregulated (p<0.05), whereas in Fra-2 tg compared to wt mice, the expression of p-PDGFRβ ($8.2_{(6,12)}$ vs. $5.4_{(4,7)}$% cells/HPF) and p-c-abl ($2.3_{(1,6)}$ vs. $5.0_{(4,7)}$% cells/HPF) was not significantly increased (p=0.1). In accordance with the strong activation of PDGFRβ and c-abl in the bleomycin model, nilotinib was effective by reducing the increased dermal thickness ($293.5\pm13.3\mu$m) back ($226.4\pm20.6\mu$m) to non-bleomycin levels ($224.3\pm9.3\mu$m, p<0.05). In Fra-2 tg mice, in accordance with the moderate expression of p-PDGFRβ and p-c-abl, nilotinib did not decrease dermal thickness. Given the correlation of activation level and treatment response in the animal models, we examined potential differences in the dermal activation status in subsets of SSc patients and healthy controls. Compared to healthy controls, in limited SSc, there was no significantly increased expression of p-PDGFRβ (3.1 ± 0.2 vs. 7.0 ± 1.2% cells/HPF, p=0.08) and p-c-abl (1.3 ± 0.3 vs. 1.3 ± 0.3% cells/HPF, p=0.9).

Interestingly, in diffuse SSc compared to healthy controls and limited SSc, the activation status of both PDGFRβ (8.0 ± 0.9% cells/HPF) and c-abl (3.9 ± 1.2% cells/HPF) was significantly increased (p<0.05). Whereas in the bleomycin model activated PDGFRβ and c-abl were ubiquitously expressed, particularly in skin fibroblasts, in Fra-2 tg mice there was a vascular predominance which might explain the lacking effect of nilotinib on skin fibrosis. In SSc patients, double staining showed that p-PDGFRβ and p-c-abl were most abundantly expressed in vascular smooth muscle cells (SM22α+) and endothelial cells (vWF+), but only occasionally in scattered dermal fibroblasts(prolylhydroxylase+).

Conclusion: Our study suggests that the activation level and the cellular expression pattern of target molecules are able to predict treatment responses in animal models of fibrosis. The predominant vascular expression of TKI targets in SSc patients might account for the minor anti-fibrotic effects of imatinib in clinical SSc trials.

Pharmacological Blockade of Adenosine A2A Receptors (A$_{2A}$R) Prevents Radiation-Induced Dermal Injury. Miguel Perez Aso[1], Yee C. Low[2], Obinna Ezeamuzie[2], Jamie Levine[2] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]New York Univ Medical Center, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Ionizing radiation is a commonly used therapeutic modality and following irradiation dermal changes, including fibrosis and atrophy, may lead to such problems as contractures. The molecular basis for radiation fibrosis is not well understood. We have previously found that adenosine, acting at adenosine A$_{2A}$ receptors (A$_{2A}$R), stimulates collagen production by human dermal fibroblasts and plays a central role in the development of dermal fibrosis in a murine model of scleroderma (bleomycin-induced dermal fibrosis). We therefore tested the hypothesis that A$_{2A}$R play a role in radiation-induced fibrosis and studied the effect of adenosine A$_{2A}$R blockade on development of radiation-induced changes of the skin.

Methods: After targeted irradiation (40Gy) to the skin on the dorsum of each mouse, the A$_{2A}$R antagonist ZM241385 (2.5mg/ml in Carboxymethylcellulose 3%) was applied daily for 28 days. To determine the effect of irradiation on skin we measured skin, dermal and epithelial thickness, collagen alignment with SiriusRed stain, collagen deposition with the hydroxyproline assay and myofibroblast content by immunostaining for α-SMA.

Results: When compared to non-irradiated skin, irradiation induced an increase of the epidermal thickness (33.9 ± 9.8 vs $94.2\pm13.3\mu$m; p<0.01 N=4) but did not affect the skin fold or dermal thickness. In contrast, high dose ZM241385 (2.5mg/ml) completely prevented radiation-induced epidermal thickening ($42.7\pm7.8\mu$m; p<0.001 vs vehicle N=8). Direct measurement of collagen content (hydroxyproline) shows that the collagen increase after the radiation insult (control: 15.2 ± 1.3 vs radiation: 21.6 ± 1.4 μg/ml; p<0.05 N=5) is partially prevented by ZM241385 application (18.7 ± 1.5 μg/mg N=8). Collagen alignment and packaging analysis by SiriusRed stain reveals that irradiation promotes a dramatic increase in loose packed collagen fibrils (421 ± 104% of Control: p<0.05 N=9), which is significantly diminished by ZM241385 application (75 ± 21% of Control; p<0.01 vs vehicle N=7). After irradiation-induced fibrosis, we detected an increase on myofibroblasts (α-SMA$^+$ cells; 34 ± 3 vs 83 ± 10 cells per field; p<0.01 N=5) which was again prevented by ZM241385 application (57 ± 5 cells per field; p<0.05 vs vehicle N=8).

Conclusion: Taken together, these data indicate that pharmacological blockade of A$_{2A}$R prevents skin thickening in a murine model of irradiation-induced fibrosis, and suggests that topical application of an A$_{2A}$R antagonist may be useful in the prevention or amelioration of radiation changes in the skin.

TSLP Upregulation in Human SSc Skin and Induction of Overlapping Profibrotic Genes and Intracellular Signaling with IL-13 and TGFb.
Romy Christmann, Allison Mathes, Giuseppina Stifano, Alsya J. Affandi, Andreea Bujor, Cristina Padilla and Robert Lafyatis. Boston University, Boston, MA

Background/Purpose: to investigate the expression of Thymic Stromal Lymphopoietin (TSLP) in diffuse cutaneous systemic sclerosis (dcSSc) patients and explore its effects in vivo and in vitro comparing with IL-13 and TGF-beta stimulations.

Methods: Skin biopsies [dcSSc; n=13 and healthy controls (HC); n=12] were used for immunohistochemistry (IHC) and immunofluorescence studies using TSLP, $CD4^+$, $CD8^+$, $CD31^+$, and $CD163^+$ markers. Wild type (WT) and IL4Ra1-deficient mice (IL4Ra1-ko) were treated with TGF-beta, IL-13, Poly(I:C), or TSLP. Human fibroblasts and peripheral blood mononuclear cells (PBMCs) were stimulated with the same cytokines. Gene expression (microarray and rt-PCR) and protein levels of phospho-Smad2 were tested.

Results: TSLP was highly expressed in skin of dcSSc patients, stronger in perivascular areas, where we observed inflammatory cell infiltrates, and in interstitial cells. TSLP expression was co-localized with immune cells, such as $CD4^+$, $CD8^+$, although mainly produced by $CD163^+$ cells. Skin of TSLP-treated mice showed upregulated clusters of genes that overlapped with IL-13 and TGFb-treated mice. In addition, a specific TSLP-cluster showed upregulation of CXCL9, proteasomes, and other interferon-regulated genes. In PBMCs, TSLP alone upregulated mannose-receptor-1 (MRC1), an alternatively-activated macrophage marker, to a similar degree as after IL-13 stimulation. MRC1 was also highly expressed in dcSSc skin compared to controls. TSLP kinetics, along 24 hours of stimulation in PBMCs, showed an early induction of TNF, MX1, and INFg, followed by an induction of CXCL9 and MRC1 gene-expression. Human fibroblasts and skin of mice-treated with TSLP showed TGF-beta-canonical pathway activation with phosphorylation of Smad2. The lack of IL4Ra1 in TSLP-treated mice promotes similar cutaneous inflammation and upregulation of profibrotic markers (PAI-1 and CXCL5). Poly(I:C)-treated mice, a SSc-like murine model, showed high levels of TSLP in similar areas as seen in the skin of dcSSc patients and also mainly in infiltrating immune cells, shown by IHC.

Conclusion: TSLP is highly expressed in skin of dcSSc patients, mainly produced by macrophages, and regulates similar genes as other profibrotic cytokines (TGF-beta and IL-13), strongly suggesting that it promotes SSc fibrosis directly or by stimulating production or activation of these cytokines. TSLP also promotes a proinflammmatory effect, which might explain this dual finding in SSc patients.

TLR9 Signaling in Fibroblasts Promotes Pro-Fibrotic Responses Via TGF-Beta.
Yang Yang[1], Feng Fang[2], Lei Liu[1], Junjie Shangguan[2], Boping Ye[1] and John Varga[2]. [1]China Pharmaceutical University, Nanjing, China, [2]Northwestern University, Chicago, IL

Background/Purpose: Systemic sclerosis (SSc) is associated with progressive fibrosis and transforming growth factor β (TGF-β) is implicated in its pathogenesis. Toll-like receptors (TLR) respond to microbial pathogens or injury-associated endogenous danger signals, and aberrant TLR9 signaling is implicated in chronic inflammation, autoimmunity and pulmonary fibrosis. However, the role of TLR9 in fibrogenesis, and the underlying mechanism of action are still unknown.

Methods: TLR9 expression in explanted fibroblasts and mouse skin biopsies was determined. Regulation of fibrotic gene expression and TGF-β signaling by the TLR9 ligand CpG was examined by real-time PCR, Western blot, transient transfection and immunofluorescence assays. Inhibitors of TLR9 were used to examine the antifibrotic response in vitro.

Results: TLR9 was detected in explanted normal and scleroderma skin fibroblasts, and the skin from mice with bleomycin-induced scleroderma. The TLR9 ligand CpG caused dose-dependent stimulation of collagen and α-smooth muscle actin (ASMA) gene expression along with inflammatory genes. Induction of fibrotic responses was blocked by the TLR9 antagonist iCpG. Moreover, CpG stimulated TGF-β production, TGF-β-mediated responses and canonical Smad signaling, and a neutralizing antibody to TGF-β abolished CpG-induced fibrotic responses. The proteasome inhibitor Bort-

ezomib abrogated CpG-induced stimulation of collagen and ASMA gene expression by disrupting intracellular TLR9 trafficking.

Conclusion: TLR9 activation in fibroblasts is associated with TGF-β-mediated fibrotic responses. Novel small molecule inhibitors of TLR9 already in clinical trial for lupus are sufficient to abrogate these responses, suggesting a potential therapeutic strategy for blocking TLR9 in fibrosis.

Damage-Associated Endogenous TLR4 Ligand Fibronectin-EDA Is Overexpressed in Scleroderma and Drives Persistent Fibrosis Via TLR4 and Inhibition of TLR4 Prevents and Reverses Experimental Dermal Fibrosis: Novel Target for Scleroderma Therapy.
Swati Bhattacharyya[1], Zenshiro Tamaki[2], Wenxia Wang[3], Paul Hoover[3], Adam Booth[4], Alyssa Dreffs[5], Monique E. Hinchcliff[1], Feng Fang[3], Spiro Getsios[3], Hang Yin[6], Eric S. White[5] and John Varga[7]. [1]Northwestern Univ Med School, Chicago, IL, [2]Northwestern Univ Med School, Chicago, IL, Chicago, IL, [3]Northwestern University, Chicago, IL, [4]Ann Arbor, MI, [5]University of Michigan Medical School, Ann Arbor, MI, [6]University of Colorado at Boulder, Boulder, CO, [7]Northwestern University Medical School, Chicago, IL

Background/Purpose: Recent studies implicate innate immune signaling and Toll like receptor-4 (TLR4) in fibrogenesis. We hypothesized that injury in scleroderma leads to tissue accumulation of damage-associated molecules such as fibronectin-EDA (Fn-EDA), which serve as endogenous ligands for TLR4. We sought to characterize the expression, mechanism of action and potential fibrogenic role of Fn-EDA. We further investigated the effect of pharmacological inhibition of TLR4 signaling on fibrogenesis.

Methods: TLR4 expression and Fn-EDA production and accumulation were evaluated in scleroderma skin biopsies and sera, in explanted normal and scleroderma skin fibroblasts, and in mouse models of scleroderma. The fibrogenic effect of Fn-EDA-TLR4 signaling was evaluated in explanted normal and scleroderma skin fibroblasts and in human organotypic skin raft cultures. The role of Fn-EDA in fibrogenesis was further evaluated using Fn-EDA-null mice. The effect of pharmacological inhibition of TLR4 signaling was evaluated in experimental models of dermal fibrosis and in explanted scleroderma fibroblasts.

Results: Fn-EDA was markedly elevated in scleroderma serum and skin biopsies, and in lesional tissues from mice with bleomycin-induced scleroderma. Microarray analysis showed elevated Fn-EDA mRNA levels in skin biopsies from patients with diffuse cutaneous scleroderma. Explanted scleroderma fibroblasts in organotypic skin raft cultures produced elevated Fn-EDA and deposited it into the matrix. Fn-EDA stimulated collagen synthesis and myofibroblasts differentiation in vitro, and induced dermal sclerosis in the skin equivalent. The profibrotic effects of Fn-EDA were TLR4-dependent and mediated via the microRNA miR29. Pharmacological TLR4 disruption using a novel small molecule inhibitor, or genetic deletion of Fn-EDA, protected mice from the development of skin fibrosis.

Conclusion: Together, these complementary in vitro and in vivo experiments firmly implicate TLR4-mediated innate immune signaling and aberrant Fn-EDA production and accumulation in driving persistent fibroblast activation and progressive fibrogenesis. Disrupting the TLR4-Fn-EDA axis by either preventing Fn-EDA accumulation, or blocking TLR4 signaling using selective small molecule inhibitors, represent appealing novel strategies for treating scleroderma.

Heterogeneous Nuclear RNP-K Is a Novel Cold-Related Autoantigen in Patients with Raynaud's Phenomenon.
Satoshi Serada, Minoru Fujimoto and Tetsuji Naka. National Institute of Biomedical Innovation, Ibaraki, Japan

Background/Purpose: Raynaud's phenomenon (RP) is a vasospastic disorder and shows discoloration of the fingers, toes, and occasionally other areas. RP affects 3–9% of the general population, but more frequently of patients with connective tissue diseases. In particular, more than 90% of systemic sclerosis (SSc) patients suffer from RP. While a variety of stress

including cold and emotional stress have been reported to influence both cellular and humoral immune function, the pathogenesis of the RP is not fully understood. The aim of study was to identify a novel autoantigen related to cold-induced RP.

Methods: Cold-induced surface proteome alterations in human normal dermal microvascular endothelial cells (dHMVECs) were identified by iTRAQ (isobaric tag for relative and absolute quantitation) analysis. Autoantigens were screened by serological proteome analysis (SERPA) using the sera from patients with SSc-associated RP.

Results: By proteomic analyses combining iTRAQ and SERPA approach, heterogeneous nuclear RNP-K (hnRNP-K) was identified as a candidate autoantigen for patients with SSc-associated RP. Cold-induced translocation of hnRNP-K to cell surface was verified by western blot (WB) and flow cytometric analysis. The presence of anti-hnRNP-K autoantibody in patients' sera with SSc-associated RP was confirmed by WB. ELISA analysis revealed that the prevalence of anti-hnRNP-K autoantibody in patients with SSc-associated RP was 30.70% (35 of 114), which was significantly higher than that of SSc patients without RP (7.14%, 2 of 28, P = 0.0027) and healthy controls (0%, 0 of 27, P = 0.0001).

Conclusion: Autoantibody against hnRNP-K is a potential marker for detecting a subset of SSc-associated RP. Cold stimulation may exacerbate RP by revealing autoantigens including hnRNP-K and inducing autoimmune reaction in vascular endothelia.

Role of 12/15-Lipoxygenase(LOX) in Patients with Systemic Sclerosis.
Hirahito Endo, Makoto Kabraki, Koutarou Shikano, Sei Muraoka, Nahoko Tanaka, Tatsuhiro Yamamoto, Kanako Kitahara, Kaichi Kaneko, Yoshie Kusunoki, Natsuko Kusunoki, Kenji Takagi, Tomoko Hasunuma and Shinichi Kawai. School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan

Background/Purpose: Recently 12/15-lipoxygenase (LOX) and it's metabolites have a prominent anti-fibrotic role during dermal fibrosis in scleroderma experimental model using 12/15-LOX deficient mice were reported (Ann Rheum Dis. 2012,71,1081). To evaluate the role of 12/15-lipoxygenase (LOX) in patients with systemic sclerosis(SSc) we measured 12/15-LOX and these enzyme metabolites.

Methods: SSc 32 patients:age57±10.3years old, disease duration 6.4±4.9years. dcSSc: lcSSc 20:12. control:RA 20 patients, normal healthy subjects 20. We measured the level of 12-LOX, 15-LOX mRNA in peripheral blood mononuclear cells(PBMC)of patients with SSc by real time quantitative PCR. 12-LOX and 15-LOX metabolites 12-(S)-Hydroxytetraenoic acid (HETE), 15-(S)-HETE and lipoin A_4(LXA$_4$)were measured by ELISA in plasma and bronchoalveolar lavage fluid (BALF) of patients with SSc. 15-LOX/12-LOX expression was measured by immunohistological analysis in biopsy specimens of dermal and interstitial pneumonia of patients with SSc.

Results: Level of plasma 12-(S)-HETE of SSc was significantly higher than that of RA and normal subjects(SSc10.76±3.22, RA 4.08±1.22, Control 3.77±1.26 ng/ml, P<0.01). Level of plasma lipoxin A_4 of SSc was also higher than that of RA and control (SSc, 3.39±1.79, RA 0.75±0.35, normal 0.77±0.30 ng/ml). On the other hand level of plasma 15-(S)-HETE in SSc was lower than that of control (SSc2.07±1.18,RA3.76±1.82, normal2.39±0.98ng/ml). Plasma 12-(S)-HETE, LXA$_4$ levels in dcSSc patients were higher than that of lcSSc (dcSSc 4.1±1.6, lcSSc 1.86±0.85 ng/ml). Expression of 12-LOXmRNA in PBMC of patients with SSc was higher than normal (SSc 4.7, control 1). Expression of 15LOX was not higher than SSc. BALF LXA$_4$ and 15-LOX in lung biopsy specimens were lower than that of other interstitial pneumonia.

Conclusion: Expression of platelet type 12-LOX was correlated with the progression of fibrotic lesion in patients with SSc. These data suggested that platelet type 12-LOX and 12-(S)-HETE may be increased for the negative feedback mechanisms for fibrosis because these enzymes and metabolites had anti-fibrotic effects. 12/15-LOX systems may contribute a new therapeutic approach in skin and organ involvement in patients with SSc.

A Possible Contribution of Decreased Cathepsin V Expression to the Development of Dermal Fibrosis, Proliferative Vasculopathy, and Altered Keratinocyte Phenotype in Systemic Sclerosis.
Yoshihide Asano, Shinji Noda, Takehiro Takahashi, Sayaka Shibata, Kaname Akamata, Naohiko Aozasa, Takashi Taniguchi, Yohei Ichimura, Tetsuo Toyama, Hayakazu Sumida, Yoshihiro Kuwano, Koichi Yanaba and Shinichi Sato. University of Tokyo Graduate School of Medicine, Tokyo, Japan

Background/Purpose: Cathepsin V (CTSV) is a proteolytic enzyme potentially modulating angiogenic processes, collagen degradation, and keratinocyte differentiation. Although our latest paper demonstrated that cathepsin B, another member of cathepsin family, is potentially involved in the developmental process of dermal fibrosis and vasculopathy in systemic sclerosis (SSc), the role of cathepsin V, to the best of our knowledge, has not been well studies so far in this disorder. Therefore, we herein investigated the clinical correlation of serum CTSV levels and the expression levels of CTSV in skin sections among SSc patients.

Methods: Serum CTSV levels were determined by enzyme-linked immunosorbent assay in 51 SSc patients and 18 normal controls. The expression levels of CTSV protein in normal and SSc skin were evaluated by immunohistochemistry. The contribution of transcription factor Friend leukemia virus integration 1 (Fli1), whose deficiency is associated with the developmental process of SSc, to the altered expression of CTSV in SSc skin was examined in cultured dermal fibroblasts, dermal microvascular endothelial cells, and keratinocytes by reverse-transcript real-time PCR.

Results: Serum CTSV levels were significantly lower in diffuse cutaneous SSc (dcSSc) and limited cutaneous SSc (lcSSc) patients than in healthy controls. In early-stage dcSSc, serum CTSV levels were remarkably and uniformly decreased compared with healthy controls. The decrease in serum CTSV levels in mid- and late-stage dcSSc and in lcSSc was linked to the development of proliferative obliterative vasculopathy. In immunohistochemistry, CTSV expression was decreased in microvascular endothelial cells, pericytes/vascular smooth muscle cells, and keratinocytes of dcSSc and lcSSc skin and in dermal fibroblasts of dcSSc skin compared with control skin. Consistently, mRNA levels of CTSV gene were decreased in cultured dermal fibroblasts from early-stage dcSSc and in normal dermal fibroblasts treated with TGF-β1. Furthermore, Fli1 gene silencing by siRNA, which potentially reproduces SSc phenotype in microvascular endothelial cells and keratinocytes, reduced the mRNA levels of CTSV gene in human dermal microvascular endothelial cells and normal human keratinocytes.

Conclusion: Loss of CTSV expression may contribute to the specific phenotype of fibroblasts, endothelial cells, and keratinocytes in SSc, suggesting the possible involvement of decreased CTSV expression to the developmental process of this disorder.

Differential Response to Endoplasmic Reticulum Stress Between Alveolar Epithelial Cells and Lung Fibroblasts in Systemic Sclerosis.
Jun Liang[1], Tanjina Akter[1], Ilia Atanelishvili[1], Richard M. Silver[2] and Galina S. Bogatkevich[1]. [1]Medical University of SC, Charleston, SC, [2]Medical University of SC, Charleston

Background/Purpose: Interstitial lung disease is a prevalent and worrisome complication of systemic sclerosis (SSc), which is now the leading cause of death in SSc. There is growing recognition that endoplasmic reticulum (ER) stress plays a pathogenic role in SSc-associated interstitial lung disease (SSc-ILD) and in other interstitial lung diseases. However, the nature of the response during ER stress in alveolar epithelial cells (AEC) and lung fibroblasts, two key players in pulmonary fibrosis, remains unknown. Here we demonstrate that differential ER stress response in these two cell types depends upon the expression of the pro-apoptotic C/EBP homologous protein or "CHOP", an important ER stress marker.

Methods: Lung tissues were collected postmortem from control subjects and from SSc patients who fulfilled the ACR preliminary criteria for SSc and had evidence of lung involvement. SSc-ILD was confirmed by histological examination of postmortem lung tissue. Additionally, lung tissues were obtained from mice with bleomycin-induced pulmonary fibrosis and from control animals. AEC and lung fibroblasts were isolated using standard

procedures. Lung tissues were analyzed by immunohistochemistry. Protein expression in AEC and lung fibroblasts was determined by immunoblotting; apoptosis was measured by enzyme-linked immunosorbent assay; *chop* promoter activity was analyzed by luciferase assay.

Results: We demonstrate for the first time that CHOP expression is profoundly increased in AEC surrounded by fibrotic tissues in SSc-ILD patients, but not in normal lung tissues. We observed staining for CHOP exclusively in AEC surrounded by fibrotic tissues. CHOP expression was also noted to be localized to thickened alveolar septae in SSc-ILD patients and in bleomycin-treated mice, but not in normal lung tissues from human or murine controls. In contrast, myofibroblasts (positively stained for α-SMA) show no significant immunoreactivity for CHOP. Thrombin, known to be elevated in SSc-ILD patients and in the bleomycin murine model of ILD, had no observable effect on CHOP expression in lung fibroblasts. However, thrombin was noted to upregulate CHOP expression in primary AEC and in A549 cells via an Ets1-dependent pathway. Importantly, we demonstrate that lung myofibroblasts from SSc-ILD patients and from mice treated with bleomycin, which are resistant to apoptosis, lose the resistance to apoptosis when transfected with CHOP.

Conclusion: AEC and lung myofibroblasts in SSc-ILD exhibit a differential response to ER stress, which may confer the differential fate of these two cell types, i.e., the susceptibility to apoptosis of AEC and the resistance to apoptosis of lung myofibroblasts. The ER stress marker CHOP is involved in regulating apoptotic mechanisms in fibrotic lung tissue downstream of two key mediators, thrombin and TGF-β, making CHOP a possible novel target for the treatment of SSc-ILD.

ACR/ARHP Poster Session B
Vasculitis
Monday, November 12, 2012, 9:00 AM–6:00 PM

1523

Systemic Vasculitis and Pregnancy: a Multicenter Study On Maternal and Neonatal Outcome of 43 Prospectively Followed Pregnancies.
Micaela Fredi[1], Maria Grazia Lazzaroni[1], Chiari Tani[2], Véronique Ramoni[3], Maria Gerosa[4], Flora Inverardi[5], Laura Andreoli[1], Laura Trespidi[6], Mario Motta[7], Andrea Lojacono[8], Renato Sinico[9], Antonio Brucato[10], Roberto Caporali[5], Pier Luigi Meroni[4], Carlomaurizio Montecucco[5], Marta Mosca[2] and Angela Tincani[1]. [1]Rheumatology Unit, University of Brescia, Brescia, Italy, [2]Rheumatology Unit, Internal Medicine, University of Pisa, Pisa, Italy, [3]IRCCS Policlinico San Matteo Foundation and University of Pavia and USC Internal Medicine, Bergamo, Italy, [4]Division of Rheumatology, Istituto Ortopedico Gaetano Pini, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, [5]Division of Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [6]Milan, [7]Neonathology and NICU, Spedali Civili, Brescia, Italy, [8]Obstetric and Gynecology of Brescia, Brescia, Italy, [9]Ospedale San Carlo Borromeo, Milano, Italy, [10]USC Internal Medicine, Ospedali Riuniti, Bergamo, Italy

Background/Purpose: Systemic Vasculitis (SV) are rare diseases that may affect females during childbearing age. Quite a few data are available in literature, and mostly from case reports. Aim of our study is to evaluate the maternal/neonatal outcome, the activity of maternal disease before, during and after pregnancy in patients with diagnosis of SV followed in five Italian Institutions.

Methods: Our study is a retrospective analysis of 43 pregnancies (prospectively followed by a multispecialistic team, with a least 1 documented visit each trimester) in 33 patients with diagnosis of SV, according to Chapel Hill Consensus Conference and/or ACR Criteria for SV. We collected: Takayasu Arteritis (TA) (6pregnancies in 4 patients), Churg-Strauss Syndrome (CS) (6 in 6 pt), Polyarteritis Nodosa (PA) (3 in 2 pt), Behcet's Disease (BD) (20 in 16 pt), Wegener Granulomatosis (WG) (3 in 3 pt), Henoch-Schönlein (HS) (2 in 1 pt) and ANCA associated-neuropathy (3 in 1 pt). Data regarding the duration of disease, serological and clinical features, pregnancy outcome, neonatal and maternal complications and therapy during pregnancy were collected from clinical charts.

Results: The mean age of the patients at the onset of the disease was 24.7yrs (with standard deviation (SD) of 6.9 yrs) and at the diagnosis was 26yrs (SD6.1yrs); our patients were Caucasians (28), afro-americans (2), Asians (2) and African (1). The mean duration of SV before pregnancy was 6,5 yrs (SD 5yrs). 5 patients were ANCA positive. 11 patients had been treated with cytotoxic or embriotoxic drugs but none of the pregnancies were exposed to such drugs. 1 out the 3 patients previously treated with cyclofosphamide had primary ovarian failure (POF). Five pregnancies were obtained by in vitro fertilization (all because of female infertility), one by oocyte donation in the patient with POF. During the 43 pregnancies, 6 flares of SV occurred during the first trimester (13.9%), 7 (20%) occurred in the 35 evaluable in the second trimester and 3 in 33 (9%) whose data are available in the third trimester. The onset of BD at 10°week of gestation was reported in one patient. Pregnancy-related complications occurred in 14 pregnancies, among which 4 cases of gestational diabetes. The mean week of delivery was 37.7 (SD 3 weeks) with 5 preterm delivery (before the 34°week). The pregnancy outcome was 33 live births (2 twins pregnancy), 8 miscarriages (1in a twin pregnancy), 1 fetal death. 2 pregnancies are still ongoing. 6 newborns had neonatal complications. Data about the postpartum period were available for 34 pregnancies:11 flares (32.3%) occurred.

Conclusion: Our data show that a strict multidisciplinary monitoring does not prevent maternal/neonatal complications in patients with Systemic Vasculitis. In addition puerperium should be regarded as a risk period for vasculitis flares, similarly to other systemic autoimmune diseases.

1524

The Use of the International Classification of Function, Disability and Health As a Conceptual Framework for Comparison of the Content of Core Outcome Instruments with the Patient Perspective in Vasculitis.
Nataliya Milman[1], Peter A. Merkel[2], Annelies Boonen[3], Lee Strunin[4], Ryan Borg[4] and Peter Tugwell[5]. [1]Ottawa Hospital, Riverside Campus, Ottawa, ON, [2]University of Pennsylvania, Philadelphia, PA, [3]University Hospital Maastricht, Maastricht, Netherlands, [4]Boston University School of Public Health, Boston, MA, [5]University of Ottawa, Ottawa General Hospital, Ottawa, ON

Background/Purpose: The International Classification of Functioning, Disability and Health (ICF) is a general health model endorsed by the World Health Organization. It describes health along 4 domains: body functions, body structures, activities and participation, and environmental factors. There is interest in applying ICF to human disease states to determine what domains of health are captured by current disease assessment tools.

In 2010 the OMERACT (Outcome Measures in Rheumatology Clinical Trials) initiative endorsed the Core Set of outcome measures for ANCA-associated vasculitis (AAV). The Core Set includes a choice of 3 disease activity measures (Birmingham Vasculitis Activity Score (BVAS), BVASv.3, BVAS for Wegener's Granulomatosis), 1 damage measure (Vasculitis Damage Index (VDI)), 1 patient-reported outcome (Short Form-36 (SF36)), and death. This study examined the extent to which the AAV Core Set captures the impact of AAV relevant to patients, using the ICF classification.

Methods: Outcome measures included in the OMERACT Core Set for AAV were linked to the corresponding ICF categories according to the previously established ICF linkage rules.

Two focus groups involving 9 patients were conducted. Patients identified aspects of disease that have an important impact on their lives. Focus group transcripts were analyzed according to standard qualitative analytic techniques. Identified concepts were linked to ICF categories. Coverage of various ICF domains by the Core Set tools was compared to coverage by the items identified by patients.

Results: All items of the Core Set's measures of disease activity and damage linked to categories of the ICF domains 'body functions' and 'body structures'. In contrast, the majority of items of SF36 linked to categories of the ICF domain 'activities and participation', with the remaining smaller number of items linking to categories of 'body functions' domain.

AAV Core Set instruments and patients focus on different aspects of the domain 'body functions'. The Core Set covers specific organ functions (e.g. hearing) while patients focus on sensations associated with these functions (e.g. ear fullness); similarly, the Core Set covers pain in specific body parts, while patients identify generalized and multifocal pain as most relevant. Sleep, temperament and personality, and exercise tolerance were areas in the 'body functions' domain identified by patients as important but not measured by any of the Core Set tools.

One broad area in the domain 'activities and participation' that was identified as crucial by patients but not covered by the Core Set is "interpersonal interactions and relationships". Similarly, environmental factors are not part of the AAV Core Set, while for patients a number of such factors are relevant in establishing the impact of AAV (various products and technology, support and relationships, attitudes, and services).

Conclusion: The ICF model is useful for identifying areas of health important for capturing the impact of AAV from patients' perspective but not covered by the currently utilized AAV outcome tools. These observations support the ongoing initiatives to expand the scope of outcome assessment in AAV, especially to include patient-reported outcomes.

1525

Determinants of Poor Quality of Life in ANCA Associated Vasculitis (AAV). Neil Basu[1], Andrew McClean[2], Raashid Luqmani[3], Lorraine Harper[2], Oliver Flossmann[4], David Jayne[5], Mark Little[6], Esther N. Amft[7], Neeraj Dhaun[8], John McLaren[9], Vinod Kumar[10], Lars Erwig[1], Gareth T. Jones[1], David M. Reid[1] and Gary J. Macfarlane[1]. [1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Birmingham, Birmingham, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]Royal Berkshire Hospital, Reading, United Kingdom, [5]Addenbrookes Hospital University of Cambridge, Cambridge, United Kingdom, [6]Trinity College Dublin, Dublin, Ireland, [7]Western General Hospital, Edinburgh, United Kingdom, [8]Edinburgh Royal Infirmary, Edinburgh, United Kingdom, [9]NHS Fife, Whyteman's Brae Hospital, Kirkcaldy, United Kingdom, [10]Ninewells Hospital, Dundee, United Kingdom

Background/Purpose: Patients with ANCA associated vasculitis (AAV) report significantly reduced quality of life (QOL), however the precise causes of such impairments are poorly understood.

This large study aimed to identify the determinants of poor QOL amongst AAV patients with view to informing future interventions designed to modify this crucial outcome.

Methods: A cross-sectional study was conducted. AAV cases were recruited from rheumatology and renal departments across the UK according to consecutive clinic attendance and classified using the EMEA vasculitis algorithm. Participants completed a questionnaire which determined physical- and mental-health related QOL (SF36 physical and mental component summary scores; PCS and MCS, respectively). In addition, data on putative psychosocial determinants of poor QOL was collected, including depression, anxiety (Hospital and Anxiety Depression Scale), fatigue (Chalder Fatigue Scale), sleep disturbance (Estimation of sleep problems questionnaire), coping (Brief Cope) and pain (body manikins). Concurrently, putative clinical determinants were measured, including assessments of disease activity (Birmingham Vasculitis Activity Score 3, BVAS), disease damage (Vasculitis Damage Index), co-morbidity (Charlson index), immunosuppressant exposure, laboratory tests (ANCA, haemoglobin, albumin, renal function, CRP) and system involvement. Measures were categorised and 2 multivariable explanatory models of poor PCS and MCS (defined as scores below general population mean) were developed using forward stepwise logistic regression. The relative importance, in population terms, of the identified associations was further quantified using population attributable risks.

Results: Of 486 invited patients, 410 participated (86%): 49% male, median age 63.5 years (Inter-quartile range 51.8–72.4 years), 19.3% recording active disease (BVAS>0). The final multivariable models identified a number of clinical and psychosocial factors found to be independently and significantly associated with poor PCS and MCS (Table). Fatigue was the only factor to be independently associated with both PCS and MCS and was also, by far, the greatest contributor to poor QOL in population terms across both models.

Table. Multivariable explanatory models of poor Quality of Life (QOL) amongst AAV patients

	Odds Ratio (95% CI)	Population attributable risk
Poor Physical related QOL (PCS) model		
High Fatigue (CFS)	3.2 (1.5–6.9)	24.6%
High Sleep Distrubance (ESQ)	5.3 (2.3–12.1)	13.1%
Pain	3.6 (1.7–7.8)	11.5%
High current PRED do se (>5mg)	3.8 (1.5–9.7)	5.3%
Old Aged (>69 years)	3.5 (1.4–8.9)	5%
Raised CRP	4.1 (1.6–10.6)	5%
Nervous system involvement (ever)	2.2 (0.6–7.2)	1.2%
Poor Mental related QOL (MCS) model		
High Fatigue (CFS)	4.0 (1.8–8.9)	47.4%
Self distraction (BC)	3.2 (1.6–6.6)	19.3%
Low Positive reframing (BC)	3.0 (1.5–6.3)	16.1%
Hypoalbuminemia	2.9 (1.3–6.6)	15.0%
Self blame (BC)	4.3 (1.8–10.4)	8.0%
Anxiety (HADS)	5.7 (2.1–15.0)	7.3%
Depression (HADS)	5.6 (2.0–15.8)	6.3%
Behavioural disengagement (BC)	2.1 (0.9–4.6)	5.5%
Unemployment	8.1 (2.2–30.3)	5.5%
Substance dependence (BC)	2.1 (0.9–4.6)	3.2%

*Dichotomised at general population mean; CFS Chalder Fatigue Scale; HADS Hospital Anxiety and Depression scale; BC Brief Cope; ESQ Estimation of Sleep Problems Questionnaire; PCS SF 36 Physical Component Summary; MCS SF36 Mental Component Summary

Conclusion: Poor QOL amongst AAV patients is determined by multiple clinical and psychosocial factors, however, fatigue appears to be the most important. Clinically, optimal control of underlying inflammation and neurological manifestations are likely to improve aspects of QOL, however multidisciplinary interventions targeting psychosocial determinants may offer even greater gains. Further work is required to develop treatment strategies specific to alleviating fatigue.

1526

Patient Reported Outcomes in ANCA-Associated Vasculitis. A Prospective Comparison Between Birmingham Vasculitis Activity Score and Routine Assessment of Patient Index Data 3. Osama ElSallabi, Joel A. Block and Antoine Sreih. Rush University Medical Center, Chicago, IL

Background/Purpose: ANCA-associated vasculitis (AAV) is a rare group of diseases comprising Granulomatosis with polyangiitis (Wegener's; GPA), Microscopic Polyangiitis (MPA), and Churg-Strauss Syndrome (CSS). These diseases often result in severe morbidity and frequent relapses. The Birmingham Vasculitis Activity Score v3 (BVAS) is a well-established and validated tool to measure AAV activity. However, current tools do not include patient-reported outcomes to assess for disease activity. The Multi-Dimensional Health Assessment Questionnaire (MDHAQ) has been documented to be effective in many rheumatic diseases. Therefore, we compared BVAS scores to a patient-only index termed the "Routine Assessment of Patient Index Data 3" (RAPID3) on an MDHAQ.

Methods: Patients with AAV treated by one rheumatologist at Rush University Medical Center in Chicago, IL from Jan 2010 to May 2012 were asked to participate and given MDHAQ to complete for 4 consecutive visits approximately every 6 months. An independent investigator scored RAPID3, which comprises 3 Core Data Set measures on the MDHAQ for function, pain, and patient global assessment (PATGL) and takes 5 seconds to score; scores range from 0 to 30, with higher scores being worse. BVAS was calculated at each patient visit; scores range from 0 to 63, with worse disease being higher. Both scores were compared using Spearman non-parametric correlations. BVAS was also compared to PATGL, which is a visual analogue scale from 0 to 10 and is one of the Core Data Set measures in RAPID3. Linear regression was used to adjust for age, sex, ethnicity, RAPID3 version language, type of the disease, duration of the disease, years of schooling and type of insurance. $P \leq 0.5$ was considered significant. The institutional Review Board approved the study.

Results: Twenty-nine patients with AAV consented and were included in the study, 22 had GPA, 5 MPA and 2 CSS. The mean age was 54.1 years, 77% were females, 69% Caucasians, 23% Hispanics, and 8% African-Americans. The mean duration of disease was 4.3 years. The mean BVAS at first visit was 6.1 ± 0.9 (range: 0–17), RAPID3 was 8 ± 1.3 (range: 0–22.7), and PTGA was 3.6 ± 0.5. RAPID3 correlated with BVAS at each visit (rho $= 0.45, 0.75, 0.73, 0.54$ with p values of 0.02, <0.0001, 0.002, and 0.05 for visits 1 to 4, respectively) and PATGL correlated with BVAS at 3 out of 4 visits, independently of RAPID3 (rho$= 0.24, 0.75, 0.64, 0.59$ with p values of 0.23, <0.0001, 0.01, 0.01 for visits 1 to 4, respectively).

Conclusion: RAPID3, a patient-only index, is correlated significantly with the BVAS. RAPID3 can be calculated in 5 seconds and does not require physician input, laboratory or imaging information. PATGL, a one simple measure of patient global assessment, may also reflect disease activity. As patient-relevant outcomes become increasingly important to insurers and to society, it is critical to identify valid patient-reported markers of vasculitis activity; RAPID3 permit longitudinal assessments of disease activity at any medical facility by any physician or even away from physician's offices. In the face of increased expenses and busy practices, such instruments may help document patient status and add to clinical decisions.

Patient Global Assessments for Disease Activity Are Predictive of Future Flare in Granulomatosis with Polyangiitis (Wegener's). Gunnar Tomasson[1], John C. Davis Jr.[2], Gary S. Hoffman[3], W. Joseph McCune[4], Ulrich Specks[5], Robert F. Spiera[6], E. William St. Clair[7], John H. Stone[8] and Peter A. Merkel[9]. [1]University of Iceland, Reykjavik, Iceland, [2]Genentech, Inc, South San Francisco, CA, [3]Cleveland Clinic, Cleveland, OH, [4]University of Michigan, Ann Arbor, MI, [5]Mayo Clinic, Rochester, MN, [6]Hospital for Special Surgery, New York, NY, [7]Duke University Medical Center, Durham, NC, [8]Massachusetts General Hospital, Boston, MA, [9]University of Pennsylvania, Philadelphia, PA

Background/Purpose: In granulomatosis with polyangiitis GPA), disease activity is assessed by physician-based measures. In some other rheumatic diseases, such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS), the patient global assessment for disease activity (PtGA) contributes to composite disease activity scores such as the DAS28 (RA) and ASDAS (AS). The purpose of this study was i) to describe distribution of PtGA scores in patients with GPA enrolled in a clinical trial, ii) explore discordance between PtGA and physician global assessments for disease activity (MDglobal), and iii) determine if PtGA during disease remission is associated with future disease relapse.

Methods: Subjects were participants in a therapeutic clinical trial. Patients had active disease at enrollment, with study visits occurring at baseline, 6 weeks and every 3 months thereafter. PtgA was assessed on a visual analog scale (0–100) with the question: *"Please mark the line below indicating how active you believe your Wegener's granulomatosis has been in the past 28 days. Consider only how much your Wegener's (the disease itself) is causing you problems. Do not count the effects of other medical problems or side effects of medications".* Disease activity was assessed with the Birmingham Vasculitis Activity Sore for WG (BVAS/WG). Remission was defined as BVAS/WG=0 and disease relapse was defined as BVAS/WG>0 after remission was achieved. MDglobal was assessed on a visual analog scale (0–100mm). PtGA-MDglobal discordance was defined as difference of 20 millimeters (mm) between PtGA and MDglobal scores. Logistic regression was used to explore association of PtGA-MDglobal discordance with demographic and disease associated factors. Mixed linear models were used to explore difference in PtGA scores between study visits during remission, but immediately prior to overt relapse, and other study visits during remission.

Results: Data from 180 subjects seen for total of 1719 study visits were used. At baseline mean PtGA was 64.2 (sd=27.4) and mean MDglobal was 55.5 (sd=23.4). At baseline, there was modest, but significant, correlation between PtGA and MDglobal scores (r=0.30, p<0.001); 54.4% of patients had a $\geq$20mm PtGA-MDglobal discordance. PtGA-MDglobal discordance at baseline was associated with relapsing (vs. new-onset) disease at baseline (OR 2.70, 95%CI: 1.47–1.96) but not associated with age, sex, or presence of renal or pulmonary disease. During follow-up, subjects were in disease remission during 1058 study visits, of which 103 immediately preceded disease relapse. At remission visits immediately preceding relapse the mean PtGA was 20.4 and at visits not followed by disease relapse the mean PtGA was 15.9, a difference of 4.5 (95% CI 0.66–8.4, p=0.02).

Conclusion: In GPA, patient and physician assessments are frequently discordant. Higher PtGA during apparent remission is associated with future overt disease relapse. These data imply that PtGA captures aspects of disease activity missed by physician-based measures. PtGA could contribute to a composite measure of disease activity in GPA.

1528

Assessing Fatigue in Systemic Vasculitis From the Patient's Perspective. Peter C. Grayson[1], Naomi Amudala[1], Carol McAlear[2], Renée Leduc[3], Denise Shereff[3], Rachel Richesson[3], Liana Fraenkel[4] and Peter A. Merkel[5]. [1]Boston University Medical Center, Boston, MA, [2]Vasculitis Clinical Research Consortium, University of Pennsylvania, Philadelphia, [3]University of South Florida, Tampa, FL, [4]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [5]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Fatigue is considered an important disease burden by patients with vasculitis, yet mechanisms underlying fatigue are poorly understood. *Physician-derived* measures of vasculitis disease activity do not correlate with fatigue. The aim was to determine if fatigue is associated with *patient-reported* measures of disease activity and/or illness perceptions, defined as the cognitive beliefs that patients have about their illness.

Methods: Participants were recruited from an online patient contact registry in vasculitis. Disease activity (remission vs active), disease extent (presence of a defined severe manifestation), disease duration, remission duration, and clinical variables (age, sex, race, depression, sleep disturbance) were assessed per patient-report. Fatigue was measured using the general subscale of the Multidimensional Fatigue Inventory (MFI) with scores $\geq$13 indicating severe fatigue. Illness perceptions were assessed using the revised Illness Perception Questionnaire (IPQ-R). The IPQ-R measures illness perceptions in specific dimensions: *identity, timeline, timeline-cyclical, consequences, personal* and *treatment control, emotional representations, and coherence* [see **Table** for definitions]. Disease status, clinical variables, and IPQ-R dimensions were assessed in relation to MFI scores using linear regression in 3 sequential, additive models with model-fit comparisons.

Results: 692 people with 9 different forms of vasculitis completed the IPQ-R. Disease status characteristics included current disease remission (45%), severe disease manifestation (54%), median disease duration (7.4 years), and remission duration $\geq$ 1 year (27%). Mean MFI score was 15.0 ($\pm$3.9). Disease activity, remission duration, age, race, depression, sleep disturbance, and all IPQ-R dimensions except timeline were significantly associated with MFI scores (**Table**). Sequential models demonstrated that IPQ-R dimensions explained an additional 18% of variability in fatigue scores after accounting for disease status and clinical variables. 56% of variability in fatigue scores remained unexplained in the full model.

Table. Association of fatigue scores with disease status, clinical variables, and IPQ-R dimensions in three sequential, additive linear models.

Step One: Disease Status		Step Two: Add Clinical Variables		Step Three: Add IPQ-R Dimensions	
Disease Activity *(active vs remission)*	$\beta = 1.01$**	Age *(per year)*	$\beta = 0.01$**	Identity	$\beta = 0.07$*
Disease Extent *(severe vs not)*	$\beta = 0.33$	Sex *(female vs male)*	$\beta = -0.43$	Timeline	$\beta = 0.23$
Disease Duration *(continuous)*	$\beta = -0.03$	Race *(white vs other)*	$\beta = -2.28$*	Timeline-cyclical	$\beta = 0.43$ *
Remission Duration	$\beta = -1.03$**	Depression *(yes vs. no)*	$\beta = 1.63$**	Consequences	$\beta = 1.23$**
(0, <1 year, $\geq$1 year)		Sleep Disturbed *(yes vs. no)*	$\beta = 0.81$ *	Personal control	$\beta = -0.42$*
				Treatment control	$\beta = -0.73$*
				Emotional Representations	$\beta = 0.38$*
				Coherence	$\beta = 0.40$*
F = 24.16** Adjusted R^2 = 0.18		F = 15.03** Adjusted R^2 = 0.26 R^2 change = 0.08		F = 16.03** Adjusted R^2 = 0.44 R^2 change = 0.18	

*p<0.05 **p<0.0001.
Outcome=MFI score (continuous, higher scores indicate greater fatigue). High scores on the identity, timeline, cyclical, consequences, and emotional dimensions represent strongly held beliefs about the number of symptoms attributed to the illness, the chronicity of the condition, the cyclical nature of the condition, the negative consequences of the illness, and the negative emotional impact of disease. High scores on the personal control, treatment control and coherence dimensions represent positive beliefs about the controllability of the illness and personal understanding of the condition.

Conclusion: Patient-reported measures of disease activity and remission duration are associated with fatigue, suggesting that patients consider fatigue a manifestation of active vasculitis. Illness perceptions significantly explain differences in fatigue scores beyond what can be explained by measures of disease status and depression. These data suggest that in vasculitis i) fatigue is a major domain of illness only partially related to disease activity as currently assessed; ii) illness perceptions may have a causal role in fatigue; and iii) the mechanisms underlying fatigue are complex and multifactorial. These findings have important implications for the incorporation of fatigue measures into overall outcome assessment in vasculitis.

Upper Airway Gene Expression Profiling in Granulomatosis with Polyangiitis. Peter C. Grayson[1], Katrina Steiling[1], Paul A. Monach[2], Ji Xiao[3], Xiaohui Zhang[1], Yuriy Alekseyev[1], Stephano Monti[3], Avrum Spira[1] and Peter A. Merkel[4]. [1]Boston University Medical Center, Boston, MA, [2]Boston University, Boston, MA, [3]Boston University Medial Center, Boston, MA, [4]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Nasal disease occurs in the majority of patients with granulomatosis with polyangiitis (Wegener's, GPA) and is often a presenting symptom of the disease. The objectives of this study were to use gene expression profiling techniques to gain insight into the biology of upper airway disease in GPA and explore the potential utility of genome-wide gene expression signatures as measures of nasal disease activity.

Methods: Nasal brushings of the inferior turbinate were obtained from 32 subjects with GPA (n=10 active nasal disease, n=13 prior nasal disease, n=9 never nasal disease) and 35 comparator subjects with and without inflammatory nasal disease (n=12 healthy, n=15 sarcoidosis, n=8 allergic rhinitis). RNA extracted from the brushings was processed and hybridized to Affymetrix Human Gene 1.0 ST Arrays. Gene expression changes associated with nasal disease activity were identified with a linear mixed effects model controlling for microarray batch, use of prednisone, and use of other immunosuppressant medication. Significant differences were defined at a threshold of false discovery rate (FDR) <0.1 and fold change > 1.5. Functional enrichment of biologic pathways among the gene expression profiles associated with nasal disease activity was determined using Gene Set Enrichment Analysis (GSEA) (FDR$_{GSEA}$ <0.25). The relationship of nasal gene expression profiles to peripheral blood mononuclear and neutrophil gene expression levels associated with GPA (*Cheadle et al A&R 2010*) was determined using GSEA.

Results: The expression levels of 452 genes were associated with active nasal disease, 309 with prior nasal disease, and 20 never nasal disease in subjects with GPA. GSEA revealed enrichment of several biologic pathways among genes associated with nasal disease activity. The 20 most significantly enriched pathways among subjects with active nasal disease were also significantly enriched among subjects with prior nasal disease and included pathways related to immune response (eg HSA04679 Leukocyte Transendothelial Migration) and thrombosis (eg HSA04610 Complement And Coagulation Cascade). There was no overlap between biologic pathways enriched in subjects with never nasal disease, and pathways enriched among subjects with active or prior nasal disease. Peripheral blood neutrophil and mononuclear gene expression levels associated with GPA were similarly altered in the nasal gene expression profiles of subjects with active or prior nasal disease, but were not significantly enriched in subjects with never nasal disease.

Conclusion: Nasal gene expression profiles are associated with nasal disease activity in subjects with GPA. Pathways analysis suggests that the biologic functions of genes altered in subjects with active nasal disease are similar to subjects with prior nasal disease, and distinct from subjects with never nasal disease. Upper airway gene expression profiles in subjects with active and prior nasal disease were similar to patterns of gene expression changes derived from fractionated peripheral blood in GPA, suggesting that nasal gene expression profiles in GPA may reflect systemic disease activity.

Plasma Cell Analysis As a Biomarker for Disease Activity in Patients with Granulomatosis with Polyangiitis. Bimba F. Hoyer[1], Adriano Taddeo[2], Maika Rothkegel[2], Gerd R. Burmester[3], Andreas H. Radbruch[2] and Falk Hiepe[4]. [1]Charite University Hospital, Berlin, Germany, [2]Deutsches Rheumaforschungszentrum, Berlin, Germany, [3]Charité – University Medicine Berlin, Berlin, Germany, [4]Charité University Hospital Berlin, Berlin, Germany

Background/Purpose: B cells are thought to play an important role in granulomatosis with polyangiitis (GPA) due to the presence of autoantibodies reacting with specific neutrophil granular enzymes (ANCA) in a vast majority of patients as well as the success of B cell depleting therapies in GPA. Renal manifestations in GPA are considered to be directly ANCA –mediated (Flak, RJ, 2002) whereas the granulomatous inflammation appears to be mediated by CD4 T cells.

Onto better understand the possible role of B cells in ANCA-associated vasculitis we analyzed the B cell subsets in the peripheral blood of patients with GPA and found marked changes correlating with disease activity as measured by the BVAS (Birmingham vasculitis activity score) as well as ANCA-levels.

Methods: 14 patients with GPA (7 with active disease, 7 with inactive disease) were analyzed by flow cytometry as compared to 17 healthy donors. Staining for CD27, Cd20, CD19, MHCII, CD3, 4 and 8 was analyzed using flowjo software. Statistical analysis was performed using graph pad prism, and p-values of < 0,05 were considered as significant. The ethics committee of the Charité approved the study, and all patients had signed informed consent.

Results: Marked differences (p=0,0018) could be observed in plasma cell counts as well as frequencies in GPA patients with a BVAS-score > 0 as compared to those with a BVAS-score =0 (2,52± 1,6/μl) or healthy persons (2,27±1,15/μl). Plasma cell numbers as well as the frequency of plasma cells within all B cells correlated with the BVAS (r= 0,9135, p<0,0001) as well as the ANCA-level in the serum (r= 0,8316, p=0,0013). No significant differences could be observed for naive and memory B cells or the overall B cell numbers as compared to healthy donors.

Regarding T cells, there was a significant reduction of CD3 (p=0,01) and CD4 T (p=0,012) cells in patients with active GPA as compared to patients in remission, whereas CD8 T cells did not show any significant changes.

Conclusion: Plasma cell counts are increased in patients with active GPA which implies a role for plasma cell mediated effects in active GPA. This is probably due to B cell hyperactivity in GPA. Presumably, their main role is the production of autoantibodies, but also cytokine production. Independent of their direct contribution to the disease, they may serve as a biomarker of disease activity as they highly correlate with the BVAS.

1531

Comparative Proteomic Analysis of Neutrophils Between Microscopic Polyangiitis and Granulomatosis with Polyangiitis. Teisuke Uchida[1], Kouhei Nagai[2], Toshiyuki Sato[1], Mitsumi Arito[1], Nobuko Iizuka, Manae Kurokawa[1], Naoya Suematsu[2], Kazuki Okamoto[2], Shoichi Ozaki[4] and Tomohiro Kato[2]. [1]Clinical Proteomics and Molecular Medicine, St. Marianna University Graduate School of Medicine,, Kawasaki, Japan, [2]St. Mariannna University Graduate School of Medicine., Kawasaki, Japan, [3]St. Marianna University School of Medicine., Kawasaki, Japan

Background/Purpose: Both microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) belong to ANCA-associated vasculitis (AAV), in which dysfunction of polymorphonuclear cells (PMN) is thought to be involved in their pathology. Clinically, it is often difficult to distinguish MPA from GPA. In this study, proteomic profiles of PMN of MPA and GPA patients and healthy controls (HC) were analyzed using two-dimensional difference gel electrophoresis (2D-DIGE), in order to know whether the profiles are useful to discriminate between AAV and HC, or MPA and GPA.

Methods: Proteins extracted from PMN obtained from 11 MPA patients, 9 GPA patients, and 10 HC were separated by 2D-DIGE. Differentially expressed protein spots were identified by MALDI-TOF MS. Then the obtained protein profiles were subjected to the multivariate data analysis by SIMCA-P+® containing principal component analysis (PCA) and orthogonal partial-least-squares-discriminate analysis (OPLS-DA).

Results: In all the 864 protein spots detected, intensity of 55 spots were found to be significantly different ($p < 0.05$) among the three groups by an ANOVA analysis. 31 out of the 55 spots were identified by mass spectrom-

etry. The protein spots whose intensity as higher in MPA than in GPA included cytoskeletal proteins, while the proteins whose intensity as higher in GPA than MPA included protein inhibitors and anti-microbial proteins. The OPLS-DA analysis revealed that the expression profile of the 55 protein spots discriminated completely the AAV group from the HC group with a sufficiently high R^2 (0.903) and Q^2 (0.445) values, and also discriminated completely the MPA group from the GPA group with a sufficiently high R^2 (0.947) and Q^2 (0.626) values.

Conclusion: These results indicated that the profile of PMN proteins may be used as a biomarker that can discriminate AAV from HC, and MPA from GPA.

Serum Angiopoietin-2 Level Reflects the Disease Activity and Renal Function in Antineutrophilic Cytoplasmic Antibody-Associated Vasculitis. Yoko Wada[1], Hiroe Sato[1], Takeshi Nakatsue[1], Shuichi Murakami[1], Takeshi Kuroda[2], Masaaki Nakano[3] and Ichiei Narita[1]. [1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Niigata University, Niigata, Japan, [3]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan

Background/Purpose: Angiopoietin-2 (Ang-2) has emerged as a key mediator of endothelial cell activation. Ang-1 and Ang-2 are antagonistic ligands which bind with similar affinity to the extracellular domain of the tyrosine kinase with Ig-like and epidermal growth factor-like domains 2 (Tie-2) receptor, which is almost exclusively expressed by endothelial cells. Ang-1/Tie-2 signalling maintains vessel integrity, inhibits vascular leakage, suppresses inflammatory gene expression and prevents recruitment and transmigration of leukocytes. In contrast, binding of Ang-2 disrupts protective Ang-1/Tie-2 signalling and facilitates endothelial inflammation. Recently, serum Ang-2 levels have been reported to be elevated in autoimmune disorders such as rheumatoid arthritis, systemic lupus erythematosus, and ANCA-associated vasculitis (AAV). The purpose of this study is to examine the serum Ang-2 levels in patients with AAV, and investigate the relationship with the clinical and laboratory findings.

Methods: Fifty-nine patients with AAV (microscopic polyangitis (MPA, n=27), granulomatosis with polyangiitis (GPA, n=15), Churg-Strauss syndrome (CSS, n=14), others (n=3)), who had been referred to Niigata University Medical and Dental Hospital between 2000 and 2011, were enrolled in this study. Written informed consent was obtained from each participant. The patients were divided into 2 groups according to their disease activities using *Birmingham* vasculitis activity score (BVAS) (active disease group (AD group, n=45) and remission disease group (RD group, n=14)) Serum Ang-2 levels and laboratory findings were examined in each subject, and the data were compared between these 2 groups. The data from all subjects were analyzed using Spearman's rank correlation coefficient to determine the relationship with serum Ang-2 levels. Next, the patients with AD group were divided into 2 groups in accordance with their stages of chronic kidney diseases (CKD) (CKD<3 group, n=19, and CKD≥3 group, n=26), and the data were compared to examine the impact of renal function in this study.

Results: The serum Ang-2 level, C-reactive protein (CRP), white blood cell count, and urinary protein excretion were significantly higher in AD group compared with those in RD group. In Spearman's rank correlation coefficient analysis using data from all subjects, the serum Ang-2 level was positively correlated with BVAS (r=0.62, p < 0.0001), CRP (r=0.47, p=0.0003), serum creatinine (Cr) (r=0.38, p=0.005), and urinary protein excretion (UP) (r=0.55, p < 0.0001), and negatively correlated with estimated glomerular filtration rate (r=−0.37, p=0.005). In the next analysis, patients in CKD≥3 were significantly elder and BVAS was significantly higher compared to those with patients in CKD<3 group. Ang-2 was elevated in CKD≥3 group without statistical significance. In Spearman's rank correlation coefficient analysis, Ang-2 was positively correlated with CRP and BVAS in CKD<3 group, while it was correlated with UP, e-GFR, Cr, and CRP in CKD≥3 group.

Conclusion: Serum Ang-2 level was strongly correlated with the disease activity and renal function in AAV. These results indicated the possible role of Ang-2 in the development of AAV through endothelial injuries.

Increased *FoxP3*[+] T-Cells in Patients with Granulomatosis with Polyangiitis Are Attributed to an Increase in the Non-Suppressor FoxP3^{Low} CD45RO$^+$ T$_{Reg}$ Cell Subpopulation. Wayel H. Abdulahad[1], Coen A. Stegeman[1], Minke G. Huitema[1], Abraham Rutgers[1], Peter Heeringa[2], Pieter C. Limburg[1] and Cees G.M. Kallenberg[1]. [1]University Medical Center Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Netherlands

Background/Purpose: Human *FoxP3*[+]T-cells are functionally heterogeneous, and can be classified into three phenotypically distinct subpopulations based on the expression levels of *FoxP3* and the memory T-cell marker CD45RO. These three subpopulations can be defined as: activated suppressor T$_{Regs}$ (*FoxP3*^{High}CD45RO$^+$; $_{AS}$T$_{Reg}$), resting suppressor T$_{Regs}$ (*FoxP3*^{Low}CD45RO$^-$; $_{RS}$T$_{Reg}$), and cytokine-secreting non-suppressor T$_{Regs}$ (*FoxP3*^{Low}CD45RO$^+$; $_{NON}$T$_{Reg}$).

This study aimed to evaluate the identity of the elevated frequency of *FoxP3*[+]T-cells in patients with granulomatosis with polyangiitis (GPA).

Methods: Peripheral blood mononuclear cells were isolated from 46 GPA-patients (27 ANCA-positief and 19 ANCA-negative at the time of inclusion) in remission and from 22 age- and sex-matched HCs. Expression of CD4, CD45RO, and *FoxP3* was determined by flow cytometric analysis. The expression levels of *FoxP3* and CD45RO were used for distinction between $_{AS}$T$_{Reg}$, $_{RS}$T$_{Reg}$, and $_{NON}$T$_{Reg}$ *FoxP3*[+]T-cells. Next, frequencies of intracellular production of IL-17 within the FoxP3[+] cell subpopulations were analyzed by flow cytometry in peripheral blood of ANCA-positive (n=10) and ANCA-negatieve (n=9) GPA-patients and matched HCs (n=12) upon ex vivo stimulation with *phorbol-myristate-acetate and calcium ionophore in the presence of brefeldin A.*

Results: A significant increase in the frequency of *FoxP3*[+]T$_{Reg}$ cells was observed in GPA-patients as compared with HCs. No differences were detected in $_{RS}$T$_{Reg}$- and $_{AS}$T$_{Reg}$ cells between GPA-patients and HCs, whereas the $_{NON}$T$_{Reg}$ cells were significantly increased in GPA-patients. The distribution of $_{RS}$T$_{Reg}$- and $_{NON}$T$_{Reg}$ cells did not differ between ANCA-negative and ANCA-positive patients, whereas lower percentages of $_{AS}$T$_{Reg}$ cells were observed in ANCA-positive patients as compared to ANCA-negative patients and HCs. In addition, *frequencies of IL-17[+] T-cells were significantly increased within the $_{NON}$T$_{Reg}$ subset from ANCA-positive patients in comparison with ANCA-negative patients and HCs, whereas no such difference was found between ANCA-negative patients and HCs.*

Conclusion: Increased *FoxP3* expression in CD4[+]T-cells from GPA-patients is related to an increase in a subset of non-suppressive T-cells that produce higher levels of IL-17 and display low expression of *FoxP3*. Plasticity of CD4[+]T-cells in GPA points towards FoxP3[+]IL-17[+] effector cells and decrease in suppressive T$_{Reg}$ cells in relation to ANCA production.

IgG4 Plasma Cell Infiltration in Granulomatosis with Polyangiitis (formerly Wegener's) Lung Biopsies. Mollie Carruthers, Shweta Shinagare, Arezou Khosroshahi, Vikram Deshpande and John H. Stone. Massachusetts General Hospital, Boston, MA

Background/Purpose: Granulomatosis with polyangiitis (GPA) and IgG4-related disease (IgG4-RD) are both immune-mediated conditions that can involve multiple organ systems. In GPA, IgG4-positive plasma cell infiltration has been reported in the kidneys and upper respiratory tract, leading to potential confusion between these two disorders. We sought to determine the degree of IgG4-positive plasma cell infiltration within lung biopsies from patients with ANCA-positive and ANCA-negative GPA, and compared the histopathological and immunohistochemical findings in GPA to biopsies from patients with IgG4-related pulmonary disease.

Methods: Patients with GPA (n=154) were identified by searching the pathology database of the Massachusetts General Hospital (MGH) for search terms "lung" and "Wegener's". Nine ANCA-positive and 4 ANCA-negative patients with wedge biopsy samples of the lung were selected for further analysis. Their clinical, radiologic, and pathologic data were compared to those of 5 patients with IgG4-related pulmonary disease. Hematoxylin and eosin (H&E) stained slides were reviewed in a blinded manner. Immunohistochemistry was performed using antibodies to IgG4 and IgG and subsequently counted by averaging 3 high-power fields (hpf). The histopathologic features were compared using Fisher's exact test and IgG4+ plasma cells counts by unpaired t-tests.

Results: The mean number of IgG4+ plasma cells in lung biopsy samples was higher among the IgG4-RD patients compared to those with GPA. The mean

for the IgG4-RD biopsies was 101 IgG4+ plasma cells/hpf (range: 13–240 IgG4+ cells), compared with 25 cells (range: 0–135) for the GPA patients (P=0.035). IgG4+ plasma cells were numerically higher among GPA patients who were ANCA-positive as opposed to ANCA-negative (40 vs. 11 cells, respectively). Three of the 9 ANCA-positive GPA patients had IgG4+ plasma cell infiltrates that exceeded the minimum number considered characteristic of IgG4-RD in the lung (>50 IgG4+ plasma cells/hpf).

Comparisons of the histopathologic features between GPA and IgG4-RD are shown in Table 1. Two sets of findings were critical in distinguishing the pulmonary pathology of ANCA-positive GPA and IgG4-RD: 1) Obliterative phlebitis, present in 80% of the IgG4-RD biopsies, was not observed in any GPA cases; and, 2) Features of granulomatous inflammation – histiocytes, granulomas, and multi-nucleated giant cells – were absent in IgG4-RD.

Table 1. Lung Histopathologic Features: Granulomatosis with polyangiitis (GPA) versus IgG4-related disease (IgG4-RD)

Pathology Features	GPA	IgG4-RD	P-Value
GPA			
Neutrophilic Abscesses	6/9 (67%)	0/5 (0)	0.03*
Histiocytes	8/9 (89%)	0/5 (0)	0.003*
Giant cells	8/9 (89%)	0/5 (0)	0.003*
Granulomas	8/9 (89%)	0/5 (0)	0.003*
Necrotizing granulomas	2/9 (22%)	0/5 (0)	NS
Vasculitis	3/9 (33%)	0/5 (0)	NS
Hemorrhage	5/9 (56%)	0/5 (0)	NS
IgG4-RD			
Lymphoplasmacytic infiltrate	8/9 (89%)	5/5 (100%)	NS
Tissue eosinophilia	3/9 (33%)	3/5 (60%)	NS
Storiform fibrosis	3/9 (33%)	5/5 (100%)	0.03*
Obliterative phlebitis	0 (0)	4/5 (80%)	0.005*

Conclusion: Lung biopsies from both IgG4-RD and GPA patients are characterized by lymphoplasmacytic infiltrates and IgG4+ plasma cells. Histopathological features, particularly the finding of obliterative phlebitis in IgG4-RD and the absence of granulomatous inflammation, are essential in distinguishing between these conditions.

Genetic Background of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis in a Japanese Population: Association of *STAT4* with Myeloperoxidase Antineutrophil Cytoplasmic Antibody-Positive Vasculitis. Aya Kawasaki[1], Naoya Inoue[1], Chihiro Ajimi[1], Ikue Ito[1], Ken-ei Sada[2], Shigeto Kobayashi[3], Hidehiro Yamada[4], Hiroshi Furukawa[5], Makoto Tomita[6], Takayuki Sumida[1], Shigeto Tohma[5], Nobuyuki Miyasaka[6], Shoichi Ozaki[4], Hiroshi Hashimoto[7], Hiroshi Makino[2], Masayoshi Harigai[6] and Naoyuki Tsuchiya[1]. [1]University of Tsukuba, Tsukuba, Japan, [2]Okayama University, Okayama, Japan, [3]Juntendo University Koshigaya Hospital, Tokyo, Japan, [4]St. Marianna University, Kawasaki, Japan, [5]Sagamihara National Hospital, National Hospital Organization, Sagamihara, Japan, [6]Tokyo Medical and Dental University, Tokyo, Japan, [7]Juntendo University School of Medicine, Tokyo, Japan

Background/Purpose: In antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), geographic difference in the type of vasculitis is well known. While granulomatosis with polyangiitis (GPA) is the most common form of AAV in northern European populations, microscopic polyangiitis (MPA) accounts for the majority of AAV in Japan, suggesting that the genetic background may play a role in the occurrence of these diseases. Due to low prevalence in European populations, little is known on the genetics of MPA or myeloperoxidase (MPO)-ANCA positive vasculitis. We started a multicenter collaborative study on the genetics of AAV in a Japanese population in 1999. Thus far, we reported a significant association of *HLA-DRB1*09:01* with MPA. *HLA-DRB1*09:01*, one of the most common *HLA-DRB1* alleles in the Asian but rare in the Caucasian populations, has been shown to be associated with multiple autoimmune diseases in Japan.

We have also demonstrated that *STAT4*, *IRF5* and *BLK* were associated with systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and systemic sclerosis (SSc) in a Japanese population, indicating that these genes are shared susceptibility genes to multiple autoimmune diseases. Thus far, association between these genes and MPA or MPO-ANCA positive vasculitis has not been reported. In this study, we examined association of these genes with Japanese AAV, mainly consisting of MPO-ANCA positive vasculitis.

Methods: Association of *STAT4* rs7574865, *IRF5* rs2280714 and *BLK* rs13277113, all previously shown to be associated with other autoimmune diseases in a Japanese population, was examined in 177 Japanese patients with AAV including 127 MPA, 31 GPA and 14 eosinophilic granulomatosis with

polyangiitis (EGPA), as well as in 511 healthy individuals. Among the patients, 155 were positive for MPO-ANCA. The genotypes were determined using TaqMan genotyping assay and direct sequencing.

Results: The frequency of *STAT4* rs7574865 T/T genotype, the risk genotype for SLE, RA and SSc, was significantly increased in MPO-ANCA positive patients (18.7%) as compared with healthy controls (10.4%, P=0.0058, odds ratio [OR] 1.98, 95% condidence interval [CI] 1.22–3.23). A tendency toward association was also observed in MPA (16.5%, P=0.053, OR 1.71, 95%CI 0.99–2.94), GPA (P=0.12, OR 2.07, 95%CI 0.83–5.18) and EGPA (P=0.013, OR 4.79, 95%CI 1.71–13.4).

With respect to *IRF5*, rs2280714 A allele showed a tendency toward decrease in MPA, although the difference did not reach statistical significance (A allele frequency in MPA: 49.2%, controls: 55.5%, P=0.072, OR 0.78, 95%CI 0.59–1.02). No evidence for association of *BLK* was detected.

Conclusion: *STAT4* rs7574865 T/T was associated with MPO-ANCA positive vasculitis. Our observations suggested that *STAT4* is a shared susceptibility gene for SLE, RA, SSc and AAV.

Clinical Features of Patients with Anti-Neutrophil Cytoplasmic Autoantibodies Targeting Native Myeloperoxidase Antigen. Yuji Yamanishi[1], Toshiko Ito-Ihara[2], Shigeto Kobayashi[3], Peter Y. Shane[4], Gary S. Firestein[5], Hiroshi Hashimoto[6] and Kazuo Suzuki[7]. [1]Hiroshima Rheumatology Clinic, Hiroshima, Japan, [2]Kyoto University Hospital, Kyoto, Japan, [3]Juntendo University Koshigaya Hospital, Tokyo, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]UCSD School of Medicine, La Jolla, CA, [6]Juntendo Tokyo Koto Geriatric Center, Tokyo, Japan, [7]National Institute of Infectious Diseases, Tokyo, Japan

Background/Purpose: ANCA is a useful diagnostic marker in systemic vasculitic disorders with small-vessel involvement, but depending on the particular test the myeloperoxidase (MPO)-ANCA results are variable. Unfortunately, the exact origins of the antigens used in most commercial assays are confidential. In the present study, we performed a comparative analysis between a novel MPO-ANCA assay that targets the native MPO (nMPO) antigen and commercially available assays using sera of patients with clinical features of ANCA-associated vasculitis (AAV).

Methods: Serum samples from 24 patients strongly suspected of having AAV were tested for the presence of MPO-ANCAs by the novel nMPO-ANCA assay and by other commercial-based MPO-ANCA assays. These results were correlated to indirect immunofluorescence microscopy staining patterns and patient clinical parameters.

Results: Eighteen out of 24 patients (75%) were positive for nMPO-ANCA compared to 13 out of 24 patients (54%) by one of the most frequently used commercial-based MPO-ANCA ELISA assays in Japan. Interestingly, the patients that tested positive with our nMPO-ANCA assay alone showed clinical features of AAV marked by prolonged fever, polyarthritis, and mild nephritis. The titers of nMPO-ANCA decreased in association with clinical improvement after treatment.

Conclusion: Our data suggest that a positive nMPO-ANCA result, which identifies antibodies to human native MPO antigen, identifies patients with a subset of patients with AAV and a distinct clinical profile. In addition, the titer appeared to correlate with AAV disease activity. While additional studies in larger patient populations will be needed, the nMPO-ANCA test could have clinical utility in detecting AAV-affected patients who have tested negative using commercially available assays.

Pathogenesis of Atherosclerosis in Granulomatosis Polyangiitis. Rula Hajj-Ali[1], Roy L. Silverstein[2], Gary S. Hoffman[3] and Carol A. Langford[4]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Cleveland Clinic Found A50, Cleveland, OH, [4]Cleveland Clinic, Cleveland, OH

Background/Purpose: Previous studies from our group suggested that the inflammatory events that occur during relapses in patients with Granulo-

matosis with Polyangiitis (GPA, Wegener's) may have a direct role in the pathogenesis of atherosclerosis. We also showed that circulating microparticle (MPs) levels were elevated during relapse and correlated with platelet reactivity. We further elucidated possible mechanisms by which MPs act at the interface between inflammation and atherosclerosis in GPA.

Methods: Human dermal microvascular endothelial cells (huDMVEC, Clonetics CAMBREX) were cultured in EGm-2MV media from Lonza. MPs isolated from plasma from GPA patients, healthy controls or derived from THP-1 human monocytic cells in vitro, were added at various ratios to the huDMVEC and incubated for timed periods. Cells were then detached, washed, and re-suspended in buffer and analyzed by immunofluorescence flow cytometry with anti-ICAM-1 IgG to detect endothelial cell activation. An isotope-matched control IgG was used as control. In addition, fluorescent tagged normal human platelets were incubated with GPA patient-derived MPs (MP/platelet ratio of 10:1) and platelet activation was detected by flow cytometry with PAC-1, an antibody to the activated form of the $\alpha2b\beta3$ integrin.

Results: GPA patient-derived MPs, when incubated for 4h with huDMVEC, induced surface expression of ICAM-1. MP depleted plasma was used as a control and did not influence ICAM-1 expression. ICAM-1 induction by MPs was blocked by cycloheximide indicating a requirement for new protein synthesis and showing that the ICAM-1 was not transferred to the cells by the MPs. MPs isolated from control subjects or from cultured THP-1 cells exerted a similar activating effect on huDMVEC, suggesting that the effect of MP on EC activation was a general feature of MPs. Platelet surface expression of activated $\alpha2b\beta3$ integrin was also significantly enhanced when platelets from healthy donors were pre-incubated with patient-derived MPs and then exposed to low doses of ADP (1μM).

Conclusion: Our findings demonstrate that MPs isolated from plasma of GPA patients can activate platelets and vascular endothelial cells. These findings suggest possible roles for MPs as an interface between inflammation and athero-thrombosis in GPA.

ANCA-Associated Vasculitis in Hispanic Americans: An Unrecognized Severity. Ranadeep Mandhadi[1], Fadi Aldaghlawi[2], Asad Khan[2], Vajiha Irshad[3], Joel A. Block[2] and Antoine Sreih[2]. [1]Mount Sinai Hospital, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Stroger Hospital of Cook County, Chicago, IL

Background/Purpose: ANCA-associated vasculitis, once a disease thought to predominate in Caucasians, is now increasingly recognized in diverse ethnic populations. However, there has been little systematic analysis of ANCA-associated vasculitis among minorities in the United States, particularly among Hispanics. We have observed anecdotally that Hispanics appeared to present with systemic disease and severe renal involvement. Here, we describe the clinical severity and disease outcome in a group of Hispanic patients with ANCA-associated vasculitides, and we test the hypothesis that Hispanics have more severe disease relative to an age- and gender-matched Caucasian population living in the same geographical area.

Methods: We identified 21 Hispanic and 25 Caucasian patients treated for ANCA-associated vasculitis at Stroger Hospital of Cook County and Rush University Medical Center in Chicago, IL from January 2006 to December 2011. Ethnicity was determined by self-report. The definition and diagnosis of Granulomatosis with Polyangiitis (Wegener's; GPA), Microscopic Polyangiitis (MPA), and Churg-Strauss Syndrome (CSS) followed the American College of Rheumatology criteria and the 1992 Chapel Hill Consensus Conference criteria. Patient demographics, laboratory data, Birmingham Vasculitis Activity Score (BVAS), and Vasculitis Damage Index (VDI) were analyzed. The presence of renal involvement was defined by: elevated serum creatinine, hematuria >10RBC/hpf, RBC casts, and/or proteinuria> 1+. Student's t-test and chi-square tests were employed, p<=0.05 was considered significant.

Results: Of the 46 patients, 27 had GPA, 11 had MPA, 7 had CSS, and 1 renal-limited vasculitis. There was no difference between Hispanics and Caucasians in the median age at diagnosis (49.5 years in Hispanics and 50.3 years in Caucasians, p=0.36), time to diagnosis (263 days in Hispanics and 288 days in Caucasians, p=0.72), nor in the gender distribution (47.6% females among Hispanics versus 64% among Caucasians, p=0.37). As opposed to Caucasians, Hispanics had a higher mean BVAS at presentation (16.75 ± 7.7 versus 12.4 ± 6.7, p=0.03), a higher mean VDI at presentation (2.9 ± 1.5 versus 1.9 ± 1.2, p=0.03) and a cumulative mean VDI (3.9 ± 1.7 versus 2.5 ± 1.9, p=0.01) in Hispanics versus Caucasians respectively. In addition, there was a trend towards higher prevalence of renal involvement in Hispanics (89% of Hispanics vs. 56%

of Caucasians, p=0.06). Seventy percent of Hispanics had acute renal failure (Mean highest creatinine= 4.01 ± 3.01 mg/dl) of whom half required dialysis, versus 29% of Caucasians (Mean highest creatinine= 1.98 ± 1.67 mg/dl, p=0.05) and only two patients requiring dialysis. Two Hispanic patients died shortly after presentation. There were no deaths among Caucasians.

Conclusion: In contrast to Caucasians, who tended to have a limited form of vasculitis at presentation, Hispanics with ANCA-associated vasculitis presented with more systemic and severe disease with higher damage indices. Whether these differences are due to genetic, socio-economic, or healthcare access disparities is yet to be studied. Early detection and intervention in these patients may alter the course of the disease and reduce morbidity and mortality.

Microscopic Polyangiitis: A Large Single Center Series. Leslie D. Wilke[1], Guy P. Fiocco[2] and Marilyn Prince-Fiocco[3]. [1]Scott & White Memorial Center, Temple, TX, [2]Scott & White Clinic, Temple, TX, [3]Temple, TX

Background/Purpose: Microscopic polyangiitis (MPA) is a rare systemic, ANCA (anti-neutrophil cytoplasmic antibody)-associated vasculitis of unclear etiology, characterized by necrotizing small vessel involvement with few or no immune complex deposits. Necrotizing glomerulonephritis is common. Pulmonary capillaritis causing alveolar hemorrhage and hemoptysis is well-recognized, but most case series are reported in the nephrology literature and emphasize renal considerations (1). We present a single center 10-year retrospective review of 40 patients meeting the Chapel Hill Consensus Conference case definition of MPA, with specific p-ANCA and MPO (myeloperoxidase) positivity, with emphasis on initial and subsequent pulmonary manifestations.

Methods: We searched the electronic data base as well as separate databases in our laboratory within our large integrated clinic-hospital system and reviewed charts of all patients with related ICD-9 codes for "vasculitis" in the last 10 years. Patients included in the study were both p-ANCA and MPO positive and met clinical and pathologic criteria for MPA. Patients with only c-ANCA disease or significant granulomata on pathologic evaluation were excluded. Several variables were reviewed (Table 1).

Characteristic	N = 40
Mean Age at Diagnosis	58.9 years *(range:14–83 years)*
Gender	
Male	37.5% (15)
Female	62.5% (25)
Male:Female ratio	1:1.6
Race	
White	73% (29)
Black	5% (2)
Hispanic	20% (8)
Other	2.5% (1)
Vital status as of 2011	
Alive	60% (24)
Deceased	30% (12)
Unknown	10% (4)
Smoking history prior to diagnosis	50% (20)
Patients who underwent pulmonary function testing	42.5% (17)
FEV1/FVC >70	70.5% (12 of 17)
Pulmonary involvement only	5% (2)
Renal involvement only	12.5% (5)
Pulmonary and renal involvement	75% (30)
Hemoptysis	40% (16)
Concomitant Medical History	
Positive ANA	18 (45%)
Hypertension	57.5% (23)
Diabetes mellitus	20% (8)
Cr >1.5 at time of diagnosis	62.5% (25)
Progression to hemodialysis	27.5% (11)
Diagnostic modalities	
Bronchoscopy	60% (24)
Renal Biopsy	60% (24)
Lung Biopsy	12.5% (5)
Other Biopsy	10% (4)
Clinical Diagnosis	15% (6)
Treatment	
Cyclophosphamide + Corticosteroids	60% (24)
Corticosteroids Alone	10% (4)
Azathioprine Alone	5% (2)
Azathioprine + Corticosteroids	10 (4)
Rituximab	5% (2)
Mycophenolate mofetil	12.5% (5)
Cyclophosphamide + Corticosteroids + Plasmapheresis	5% (2)
Corticosteroids + Rituximab + Mycophenolate + Plasmapheresis	2.5% (1)
No Treatment	2.5% (1)

Results: Onset of illness was usually abrupt and included respiratory symptoms. Most common presenting complaint was cough. Hemoptysis occurred during the course of illness in 40%.

Pulmonary evaluation included bronchoscopy in 60% and surgical lung biopsy in 12%, usually related to pulmonary hemorrhage.

Treatment doses and duration were quite variable but included combination corticosteroids and cytotoxic therapy in 60%. Therapy was directed by nephrology in 52.5%. Rheumatology and Pulmonary directed therapy in 22.5% patients each. One patient did not undergo therapy.

The course of illness was variable, with few significant pulmonary relapses. Hemodialysis occurred in 28%. Known deaths occurred in twelve, with none directly attributable to the disease process.

Conclusion:

1) Pulmonary involvement is much more frequent than the current literature report of 25–50% when features in addition to hemorrhage are recorded. (1,2)

2) MPA at onset usually includes respiratory symptoms. Demographic and medical variables failed to identify predisposing factors.

3) No clear guidelines direct the evaluation and management of MPA patients. Consistent communication between pulmonary, nephrology, and rheumatology services could improve our understanding of the disease process.

Practice Patterns in the Treatment of ANCA-Associated Vasculitis: Exploring Differences Among Subspecialties At a Single Academic Medical Center. Lindsy J. Forbess[1], Kenneth W. Griffin[2] and Robert F. Spiera[3]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Weill Cornell Medical College, New York, NY, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: Randomized controlled trial evidence helps guide physician treatment choices for ANCA-Associated Vasculitis (AAV). Data for remission maintenance therapy following rituximab (RTX) in generalized disease, as well as the use of RTX in limited disease, however, is currently lacking. In the absence of such data, treatment choices are largely driven by physician preferences. Our aim was to examine AAV treatment preferences to determine if patient gender and age and physician subspecialty affect treatment choices.

Methods: We invited rheumatologists, nephrologists and pulmonologists from an academic medical center to participate in a web-based survey. Three scenarios (remission induction in generalized disease; remission maintenance in generalized disease; remission induction in limited disease) were presented for 4 patient profiles (28 and 68 year old female/male). Physician treatment choices and reasons for these choices (efficacy, toxicity, cost/availability, comfort with use) were obtained. Differences between groups were analyzed using Chi-Square and Fisher's exact tests.

Results: Of 117 surveys sent, 46 were completed by 29 rheumatologists (63%), 8 pulmonologists (17%) and 9 nephrologists (19%).

For remission induction in generalized disease, 52% of physicians selected RTX, 42% CTX, 3% mycophenolate mofetil, and 3% no preference. Physicians were significantly more likely to choose RTX for young females compared with young males (p=0.039), older males (p<0.001), and older females (p<0.001). Toxicity was the most common reason for this choice. There was a trend toward rheumatologists choosing RTX over CTX compared with the other subspecialties.

Most physicians switched to a less toxic agent for remission maintenance (Table 1), but there was little agreement as to choice of maintenance therapy among subspecialties. It did appear, however, that pulmonologists were significantly less likely to choose azathioprine (AZA) (p=0.002) and nephrologists methotrexate (MTX) (p=0.007) than the other subspecialties.

Table 1. Physician Treatment Preferences for Remission Maintenance Therapy in Generalized ANCA-Associated Vasculitis

	AZA*, N (%)	Follow Expectantly, N (%)	MTX*, N (%)	MMF*, N (%)	RTX*, N (%)	CTX*, N (%)	TMP/SMX*, N (%)	LFN*, N (%)	No Preference, N (%)
After All Induction (N=128)	45 (35)	27 (21)	20 (16)	12 (9)	9 (7)	5 (4)	4 (3)	0 (0)	6 (5)
After CTX* Induction (N=56)	13 (23)	9 (16)	16 (29)	8 (14)	3 (5)	5 (9)	0 (0)	0 (0)	2 (4)
After RTX* Induction (N=64)	29 (46)	20 (31)	4 (6)	1 (2)	4 (6)	0 (0)	4 (6)	0 (0)	2 (3)

*AZA=azathioprine, MTX=methotrexate, MMF=mycophenolate mofetil, RTX=rituximab, CTX= cyclophosphamide, LFN=leflunomide, TMP/SMX= trimethoprim/sulfamethoxazole

For remission induction in limited disease, most chose RTX (36%), particularly for young females, followed by CTX (26%), MTX (24%), AZA (6%), trimethoprim/sulfamethoxazole (4%) and 4% no preference. Efficacy was the most common reason for selecting RTX. Rheumatologists chose RTX (34%) and MTX (31%) about equally, whereas pulmonologists chose RTX (67%) and nephrologists chose CTX (40%) most often.

Conclusion: Most physicians favor RTX for remission induction in young females with generalized disease because of toxicity issues, with a trend toward rheumatologists prescribing RTX more frequently than other subspecialties in this setting. Surprisingly, most physicians preferred RTX for remission induction even for limited disease, despite lack of clinical trial data supporting its use in this context. There was less agreement as to choice of remission maintenance therapy among subspecialties.

Does Leflunomide Have a Place As Remission Maintenance Therapy in ANCA-Associated Vasculitis? A Bayesian Network Meta-Analysis with Hypothesis Driven Sensitivity Analyses to Adjust for Potential Biases. Glen S. Hazlewood[1], Claudia Metzler[2], George A. Tomlinson[1], Wolfgang L. Gross[3], Brian M. Feldman[4], Loic Guillevin[5] and Christian Pagnoux[6]. [1]University of Toronto, Toronto, ON, [2]University of Lubeck, Bad Branstedy, Germany, [3]Medical University at Lubeck, Lubeck, Germany, [4]The Hospital for Sick Children, Toronto, ON, [5]Cochin University Hospital, Paris, France, [6]Mount Sinai Hospital, Toronto, ON

Background/Purpose: *Primary:* To determine the relative treatment effects of maintenance therapy in adult patients with ANCA-associated vasculitis who have achieved remission, using a Bayesian network meta-analysis of randomized controlled trials (RCT). *Secondary:* To model the impact of *a priori* hypotheses about potential biases in a RCT comparing leflunomide (LEF) to methotrexate (MTX) on the relative treatment effects.

Methods: *Study selection:* RCTs identified from an existing systematic review and updated PUBMED and MEDLINE searches comparing at least 2 of the following maintenance agents: MTX, LEF, azathioprine (AZA) or mycophenolate mofetil (MMF). *Population:* Adult patients (age>18) with ANCA-associated vasculitis who have achieved clinical remission. *Outcome:* Relapse-free survival. *Data analysis:* A Bayesian arms-based fixed-effects network meta-analysis was performed using hazard ratio data. Sensitivity analyses were performed by down-weighting the effect of LEF in the LEF-MTX RCT because of the early trial termination (using a published meta-analysis of the impact of early termination) and by modeling the removal of early methotrexate relapses, as the initial dose titration of MTX in this trial was slow.

Results: Three trials were available (LEF-MTX; MTX-AZA; AZA-MMF). In the primary analysis, LEF was superior to MMF (HR:0.26 [0.08, 0.87]) and showed a trend towards superiority to AZA (HR:0.43 [0.14, 1.36]) and MTX (HR:0.47 [0.18, 1.22]). The probability that each treatment was the best was: LEF 90%, AZA 6%, MTX 4% and MMF <1%. The probability that LEF was the best decreased to 74% after the treatment effect for LEF/MTX was down-weighted for early trial termination in the LEF-MTX RCT. LEF remained the highest ranked treatment unless >6/13 of the initial MTX relapses (all relapses within the first 7 months) were censored.

Conclusion: Based on indirect evidence, there is a high probability that LEF is an effective maintenance therapy for ANCA-associated vasculitis after adjusting for potential study biases. Further RCTs of LEF should be considered to provide direct evidence.

1542

The Efficacy of Rituximab Vs Cyclophosphamide for Treatment of Renal Disease in ANCA-Associated Vasculitis: The RAVE Trial Geetha D, Fervenza FC for the RAVE-Itn Research Group. Duvuru Geetha[1] and Fernando Fervenza[2]. [1]Johns Hopkins University, Baltimore, MD, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Rituximab (RTX) is non-inferior to cyclophosphamide (CYC) followed by azathioprine (AZA) for remission-induction in severe ANCA associated vasculitis (AAV) but details of outcomes among patients with renal involvement have not been reported. We present the long-term outcomes of patients who had renal involvement at baseline in the RAVE trial.

Methods: Patients with renal involvement defined by a Birmingham Vasculitis Activity Score/Wegener's Granulomatosis (BVAS/WG) renal item score ≥ 3 at baseline were included. Glomerular filtration rate was estimated (e-GFR) by Cockcroft-Gault formula. Complete remission (CR) was defined by BVAS/WG $= 0$, off prednisone; Renal flare by renal BVAS/WG ≥ 3. Remission rates, slopes of eGFR and renal flares were compared between treatment groups.

Results: 102 of the 197 (52%) patients had renal involvement at entry (GPA: 68; MPA: 34; PR3-ANCA: 58; MPO-ANCA: 44; new diagnosis: 58; relapsing disease: 44). The mean age was 55 years, 52% were males. 51 patients each received RTX or CYC/AZA. Except for lower mean baseline e-GFR in the RTX group (53 ml/min vs 69ml/min p=0.01), there were no clinical differences between the treatment groups. 60.8 % patients treated with RTX and 62.7 % patients treated with CYC/AZA achieved CR by 6 months, and 74.5 % and 76.5% at any time on the originally assigned treatment, respectively. Median times to CR were similar in both groups. The mean e-GFR increased in parallel in the two groups during the 18 months. The number of renal flares did not differ between the two groups at 6, 12, or 18 months. When stratified by ANCA or AAV type or new vs relapsing disease, there were no differences in remission rates or slopes of e-GFR increase at 18 months. Four MPA patients treated with RTX without maintenance therapy had a total of 5 renal flares by month 18 vs none treated with CYC/AZA (p=0.04).

Conclusion: A single course of RTX is as effective as 18 months of therapy with CYC/AZA for induction and maintenance of remission in patients with AAV with renal disease. MPA patients treated with RTX and no maintenance therapy may be more likely to experience a renal flare following B cell reconstitution.

Rituximab for ANCA-Associated Vasculitis: A Meta-Analysis of Randomized Trials. Carolina Mejia[1] and Carlos J. Lozada[2]. [1]Mount Sinai Medical Center, Miami, FL, [2]University of Miami Miller School of Medicine, Miami, FL

Background/Purpose: Over the past 40 years, cyclophosphamide/glucocorticoids combination therapy has been the standard regimen for remission induction in ANCA-associated vasculitis. Although a major advance in the treatment of these entities and a superior regimen to the glucocorticoid monotherapy regimens that preceeded it, non-responders and the potential for significant adverse effects have been major drawbacks.

The search for new therapeutic options has led to the investigation of anti-B cell therapies. Rituximab, an anti-CD20 monoclonal antibody, has compared favorably to cyclophosphamide-based regimens in remission induction in clinical trials, leading to formal approval by the Food and Drug Administration for this indication. It has also been able to maintain remission for many months of follow up without the need for medication-based maintenance regimens such as azathioprine which is standard in cyclophosphamide-based regimens.

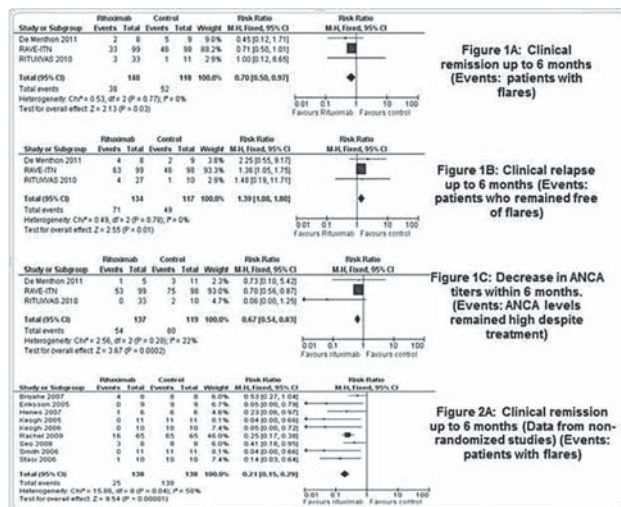
Methods: All randomized controlled trials of rituximab on patients with ANCA-associated vasculitis were sought in PubMed, EMBASE, and Cochrane databases during June 2012. Significant non-randomized controlled trials were also reviewed for a separate analysis. Data was extracted by 2 reviewers and analyzed with RevMan 5 software.

Results: Three randomized controlled trials were found. In all, rituximab was demonstrated more efficacious in achieving remission, preventing relapse and decreasing ANCA titers (Figures 1A, 1B, 1C). There was also a trend favoring rituximab in achieving remission in nine non-randomized studies that were analyzed separately (Figure 2A).

Figure 1A: Clinical remission up to 6 months (Events: patients with flares)

Figure 1B: Clinical relapse up to 6 months (Events: patients who remained free of flares)

Figure 1C: Decrease in ANCA titers with 6 months. (Events: ANCA levels remained high despite treatment)

Figure 2A: Clinical remission up to 6 months (Data from non-randomized studies) (Events: patients with flares)


Conclusion: Rituximab has been shown a new and effective alternative for achieving remission in ANCA-associated vasculitides when compared to standard cyclophosphamide-based treatment.

Long-Term Outcome of Patients with Granulomatosis with Polyangiitis (Wegener's) Treated with Rituximab. Lama Azar, Jason Springer, Meng Xu, Tiffany M. Clark, Carol A. Langford and Gary S. Hoffman. Cleveland Clinic Foundation, Cleveland, OH

Background/Purpose: Rituximab (RTX) is an efficacious alternative to cyclophosphamide for treatment of granulomatosis with polyangiitis (GPA). However, relapses have been observed, long-term efficacy is not known and strategies to reduce risk of relapses after RTX-induced remission are just beginning to be explored. This study was performed to evaluate long-term efficacy and risks of RTX when used alone or in conjunction with another immunosuppressive agent other than steroids.

Methods: Single center retrospective review: patients (pts) with GPA who fulfilled 1990 ACR criteria and were treated with at least 1 course of RTX. Subset analysis included the effect of receiving a 2nd immunosuppressive agent, other than steroids. Remission defined as BVAS/WG=0.

Results: Total of 110 pts, 56 F, 54 M, received 211 courses of RTX. In 77% of cases, 2 infusions of 1gm were given 2 weeks apart. Mean age at 1st RTX (RTX1) was 50 yrs. Indications for RTX1 were: new onset (5), relapsing (85), persistent disease (15) and remission maintenance (5). At the time of RTX1, median BVAS/WG was 4 (range 1–11). Median follow up after RTX1 was 23 months (mo) (range 1–137). Apart from 3 pts with worsening or persistent lung involvement, complete remission was achieved in 99/102 pts with active disease and available information. 45 pts (42%) received only 1 course of RTX and remained in remission during follow up (median 10mo); 66% of these pts were on 2nd agent after RTX1. Among 21 pts followed >2 years after RTX1, 38% sustained long-lasting remissions, for up to 6 yrs. Fifty pts experienced 79 relapses after RTX1. Median time to 1st relapse was 13mo (range 2.5–66). Median dose of prednisone at time of relapse vs without relapse was 5 mg (range 0–30) vs 3.5 mg (range 0–25), respectively. The incidence of relapse over time after RTX1 was lower in patients who received a 2nd agent (figure; p=0.006). Among pts who received a 2nd agent (52), 42% relapsed vs.

65% of those who did not receive a 2nd agent (43). The 2nd agents used were: AZA (29), MTX (15) and MMF (8). Median follow up in the 2 groups was 13 and 11mo and median time to relapse was 16mo vs 11mo, respectively. Of pts who relapsed while on a 2nd agent, 27% had at least 1 major organ involved per BVAS/WG vs 39% of pts who were not on a 2nd agent. Serious adverse events did not differ between groups. Serious infections occurred after RTX1 in 7.6% (2nd agent subset) and 6.9% (no 2nd agent subset), respectively. At the time of relapse, 42.2% of pts were peripheral blood B cell depleted (data for 45 relapses in 31 pts).
Conclusion: RTX is a very effective remission-inducing agent for GPA. 97% of treated pts achieved remission. Within a subset treated once and followed for > 2 yrs, remissions endured for 2–6 yrs in 38%. While 46% of pts had ≥1 relapses, use of a 2nd immunosuppressive agent diminished likelihood of relapse. A 2nd agent did not result in a greater number of serious adverse events.

1545

Long-Term Follow-up of 118 Polyarteritis Nodosa and Microscopic Polyangiitis without Poor-Prognosis Factors. Maxime Samson[1], Xavier Puechal[2], Hervé Devilliers[3], Camillo Ribi[4], Pascal Cohen[5], Boris Bienvenu[6], Christian Pagnoux[7], Luc Mouthon[8], Loic Guillevin[9] and French Vasculitis Study Group FVSG[5]. [1]Hôpital Cochin, University Paris Descartes, Paris, France, [2]Hôpital Cochin, Paris, France, [3]CHU Dijon, Dijon, France, [4]Hôpital Universitaire Cantonal de Genève, Geneve, Switzerland, [5]Service de médecine interne, Centre de Références des Vascularites, Université Paris Descartes, APHP, Hôpital Cochin, 75005 Paris, France., Paris, France, [6]Division of Internal Medicine, Centre Hospitalier Régional Universitaire de Caen, Côte de Nacre, Caen, France, [7]Mount Sinai Hospital, Toronto, ON, [8]Hopital Cochim, Paris, France, [9]Division of Internal Medicine, Hôpital Cochin, University Paris Descartes, Paris, France

Background/Purpose: Polyarteritis nodosa (PAN) and microscopic polyangiitis (MPA) are 2 vasculitides characterized by necrotizing inflammation of the vessel wall. They share several clinical features and may be treated similarly. Nonsevere manifestations, as defined by the Five-Factor Score (FFS), respond to corticosteroids (CS) alone. This study aimed to describe the long-term follow-up of PAN and MPA patients without poor-prognosis factors.

Methods: Data from patients included in a prospective trial[1] were updated in 2012. New Chapel Hill criteria were applied to classify PAN and MPA. The following definitions were used: relapses, the recurrence and/or new appearance of ≥1 vasculitis manifestation(s) after remission lasting ≥3 months; major relapses, the emergence of major organ involvement (FFS≥1, 30% creatinine-level rise, pulmonary hemorrhage, threatened vision, new multifocal neurological lesions or mononeuritis multiplex, gastrointestinal hemorrhage or perforation and/or gangrene); failure, the absence of clinical remission with the assigned treatment. Times to relapse and/or death were calculated from that of treatment onset. Time to first event (failure, minor or major relapse and/or death) defined the disease-free survival.

Results: Among the 124 patients screened, 6 were excluded (2 FFS≥1, 4 other vasculitides). Mean±SD overall follow-up was 98.2±41.9 months. For the 118 patients (61 MPA and 57 PAN), mean age at diagnosis was 55.6±16.5 years, mean Birmingham Vasculitis Activity Score 2003 11.8±5.5; ANCA-positivity: 3 (5.3%) PAN (cANCA⁺, anti-proteinase-3 and

-myeloperoxidase negative) and 31 (50.8%) MPA (pANCA⁺, 77.4% myeloperoxidase-specific). After CS alone, 97/118 (82.2%, 49 MPA and 48 PAN) achieved remission; 21/118 (17.8%, 12 MPA, 9 PAN) failed on CS and received a second- or third-line therapy with immunosuppressant(s) (IS) that achieved remission in 19 cases (11 MPA, 8 PAN), and 2 patients (1.7%, 1 PAN, 1 MPA) died before remission. After remission, 61/116 (52.6%, 35 MPA, 26 PAN) patients relapsed 25.6±27.9 months after starting treatment, 30 (25.9%, 20 MPA, 10 PAN) experiencing ≥1 major relapse after 47.8±36.2 months of follow-up. The respective 5-, 7- and 8-year overall survival rates were 92%, 85% and 81%, with no significant difference between PAN and MPA patients (p=0.289). Relapse-free survival and major relapse-free survival tended to be shorter for MPA than PAN patients (p=0.174 and 0.06, respectively). Disease-free survival was significantly shorter for MPA than PAN patients (p=0.021). Throughout follow-up, 46.6% of patients required ≥1 IS. At the last follow-up visit, 44% were still taking CS, 15% an IS and the mean vasculitis damage index score was 1.9±1.9, with the most frequent sequelae being peripheral neuropathy, hypertension and osteoporosis.

Conclusion: For PAN or MPA patients with FFS=0 at diagnosis, overall survival at 120 months was good, with first-line CS alone able to achieve remission in >80% of them. However, relapses remained frequent, especially of MPA, meaning that 46.6% of the patients required immunosuppressant(s).

Rhinosinusits and Nasal Polyps in the Diagnosis and Follow up of Patients with Eosinophilic Granulomatosis with Polyangitis (ex-Churg Strauss Syndrome). Chiara Baldini[1], Veronica Seccia[2], Manuela Latorre[3], Paolo Iannicelli[2], Daniela Martini[1], Francesco Ferro[1], Nicoletta Luciano[1], Antonio Tavoni[1], Stefano Sellari Franceschini[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Unit of Otorhinolaryngology, Department of Neuroscience, University of Pisa, Pisa, Italy, Pisa, Italy, [3]Pneumology Unit, Italy

Background/Purpose: Chronic rhinosinusitis with nasal polyposis (CRSwP) is a common manifestation of granulomatosis with polyangiitis (EGPA), and may represent an invalidating feature of the disease, causing nasal blockage and loss of smell. The aim of this study was to determine the frequency of CRSwP in a series of patients with EGPA and the impact of sino-nasal involvement on the patients' quality of life.

Methods: Consecutive patients with EGPA (ACR criteria) were prospectively enrolled in this observational cross-sectional study. Patients' cumulative clinical and serological features were collected including: ANCA status, blood eosinophilia, total IgE, IL-2, IL-4, IL-5 and eosinophil cationic protein levels (ECP). Nasal polyps were graded according to the Lund nasal endoscopy scoring system. To evaluate the impact of the sino-nasal symptoms on the quality of life (QOL), the short form (SF)-36 and the Sino-Nasal Outcome Test (SNOT-22) were used. Correlations between the different variables were analyzed using linear regression and the Spearman coefficient (p < 0.05).

Results: Twenty-six EGPA patients (12F:14M, 57±15yrs, mean follow-up =6±5yrs) were enrolled in the study. About one third of the patients (32%) was allergic to one or more common aero-allergen and high levels of IgE were found in 10/26 EGPA patients; 3/26 patients referred aspirin hypersensitivity and 3/26 patients were current smokers. Endoscopic intranasal evaluation identified: CRSwP in 14/26 cases, chronic rhinosinusitis (CRS) in 5/26, non-allergic rhinitis (NAR) in 4/26 and allergic rhinitis (AR) in 2/26 patients. One patient had a normal nasal endoscopy examination. The diagnosis of sino-nasal involvement preceded the diagnosis of EGPA of a mean period of 23±21 yrs. Surgery was needed in 13/26 cases, with 5/13 patients undergoing polypectomy, 2/13 septoplasty and 6/13 functional endoscopic sinus surgery. Polyps recurred in 9/13 EGPA patients over the follow-up. No correlation was found among CRSwP or Lund scores and ANCA status, blood eosinophilia, total IgE, IL-2, IL-4, IL-5 and ECP. Significant correlations were observed among CRSwP, LUND score and chronic use of nasal corticosteroids and between SNOT-22 and SF-36 questionnaire. There was no correlation between Lund and SNOT-22 scores.

Conclusion: Nasal polyps may represent the initial feature of EGPA, and may have a great impact on the patients' quality of life. The Lund score correlates well with CRSwP severity and chronic use of nasal corticosteroids but measures a different aspect of disease to "subjective" symptom scores.

This demonstrates the strengths and limitations of a commonly used staging system in EGPA and CRSwP.

A 4 Plus 2 Infusion Protocol of Rituximab Provides Long-Term Beneficial Effects in Patients with HCV-Associated Mixed Cryoglobulinemia with Membranoproliferative Nephritis and Severe Polyneuropathy.
Dario Roccatello[1], Savino Sciascia[2], Simone Baldovino[1] and Daniela Rossi[1]. [1]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare (CMID), Università di Torino, Torino, Italy, [2]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom

Background/Purpose: Mixed cryoglobulinemia syndrome (MCs) is a systemic vasculitis characterized by multiple organ involvement due to the vascular deposition of immune-complexes, mainly the cryoglobulins. B cells expansion frequently triggered by HCV infection plays a central role in MCs. The long term effects of B-cells depletion in MCs are still on debate

Methods: Twenty seven patients, (mean age 60.2 [range 35–78] years, HCV infection in 96% of cases) with symptomatic type-II MCs with systemic manifestations, including renal involvement (diffuse membranoproliferative glomerulonephritis in 15 cases), peripheral neuropathy (26 cases) and large skin ulcers (9 case, in 7 necrotizing) were considered eligible for Rituximab (RTX) therapy. RTX was administered at a dose of 375 mg/m^2 on days 1, 8, 15 and 22. Two more doses were administered 1 and 2 months later. No other immunosuppressive drugs were added. Response was evaluated by assessing the changes in clinical signs, symptoms, laboratory parameters and electromyographic indices for a very long term follow-up (mean 54.3 months [12–96])

Results: Complete remission of pre-treatment active manifestations was observed in all the cases of skin purpuric lesions and non-healing vasculitic leg ulcers, and in 80% of the peripheral neuropathy, mainly paresthesias. A significant improvement in the clinical neuropathy disability score was observed. Electromyography examination revealed that the amplitude of compound motor action potential had increased. Cryoglobulinemic nephropathy, observed in 15 patients, significantly improved during the follow-up starting from the second month after RTX (serum creatinine from 2.2 ± 1.9SD to 1.6 ± 1.2SD mg/dl, $p\leq.05$; 24-hour proteinuria from 2.3 ± 2.1SD to 0.9 ± 1.9SD g/24h, $p\leq.05$). Improvement of cryoglobulinemic serological hallmarks, such as cryocrit and low complement C4, were reported. The safety of RTX was confirmed by the absence of side effects recorded during the mean 54-month follow-up. Re-induction was performed in 9 relapsed cases (after a mean of 31.1 months, range 12–54) with resolutive beneficial effects

Conclusion: In this open prospective study, RTX appeared to be effective and safe in the treatment of patients with MCs-associated neuropathy and membranoproliferative nephritis

Cutaneous Vasculitis as a Paraneoplastic Syndrome.
Javier Loricera, Vanesa Calvo-Rio, Francisco Ortiz Sanjuan, Marcos Antonio Gonzalez-Lopez, Hector Fernandez-Llaca, Javier Rueda-Gotor, Carmen Gonzalez-Vela, Cristina Mata-Arnaiz, Miguel A. Gonzalez-Gay and Ricardo Blanco. Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain

Background/Purpose: Cutaneous Leukocytoclastic Vasculitis (CLV) may be associated with malignancies, and sometimes it behaves as a paraneoplastic syndrome. This association has been reported in a variable proportion of CLV patients (from 0 to 8 %) depending on population selection. Our aim was to assess the frequency and features of CLV associated to neoplasia in a wide and unselected series of CLV.

Methods: Study of CV associated to neoplasia in a series of 877 patients diagnosed as having CLV in the Rheumatology and Dermatology Divisions from a University Hospital.

Results: 16 out of 877 patients (1.82 %) presenting with CLV were finally diagnosed as having an underlying malignancy. There were 9 hematological and 7 solid malignacies. In all of them, skin lesions were the first clinical manifestation

and the median interval to the diagnosis of the malignancy from the onset of CLV was 17 days (range 8 –50 days). The most frequent skin lesions were palpable purpura (13 patients), legs ulcers (2 patients), urticaria (2 patient) and erythema (1 patient). Other manifestations were constitutional syndrome (10 patients) and arthralgias and/or arthritis (6 cases). There was no serious visceral vasculitic involvement. Cytopenia was frequently observed in the full blood cell count (11 cases), especially in those cases of vasculitis associated to hematological malignancies. Immature peripheral blood cells were observed in 9 cases. Immunological testing (ANA, Rheumatoid factor, C3, C4, and ANCA) were negative or within normal range in all cases. 10 patients died due to the malignancy and 6 patients recovered following malignancy therapy.

Case	Age/sex	Main clinical features	Peripheral blood smear	Skin biopsy	Diagnosis
1	40/F	Urticarial lesions, fever, polyarthritis	Anemia, immature cells	Leukocytoclastic Vasculitis	Megakaryocytic leukemia
2	52/F	Palpable purpura, constitutional symptoms	Pancytopenia, immature cells	Leukocytoclastic Vasculitis	Myelodysplastic Syndrome
3	56/M	Palpable purpura, constitutional symptoms, fever	Anemia, leukopenia, immature cells	Leukocytoclastic Vasculitis	Myelodysplastic Syndrome
4	70/M	Palpable purpura, constitutional symptoms,, polyarthritis	anemia, leukopenia, immature cells	Leukocytoclastic Vasculitis	Non- Hodgkin Lymphoma
5	78/M	Palpable purpura, constitutional symptoms, fever, arthralgias, abdominal pain	Anemia	Leukocytoclastic Vasculitis	Waldestrom's Macroglobulinemia
6	83/M	Palpable purpura, necrotic ulcer, constitutional symptoms	Anemia, leukopenia	Leukocytoclastic Vasculitis	Myelodysplastic Syndrome
7	61/F	Palpable purpura, hematuria, polyneuopathy	Anemia	Leukocytoclastic Vasculitis	Waldestrom's Macroglobulinemia
8	76/M	Palpable purpura, urticarial lesions, constitutional syptoms, fever	Pancytopenia, immature cells	Leukocytoclastic Vasculitis	Hairy cell leukemia
9	81/F	Palpable purpura, erythema, constitutional symptoms, fever	Anemia, immature cells	Leukocytoclastic Vasculitis	Mantle cell lymphoma
10	82/M	Palpable purpura, abdominal pain, fecal occult blood, hematuria	Normal	Leukocytoclastic Vasculitis	Oropharyngeal Squamous cell Carcinoma
11	49/F	Palpable purpura, constitutional symptoms, fever	Anemia	Leukocytoclastic Vasculitis	Infiltrating Breast Carcinoma
12	80/M	Palpable purpura, constitutional symptoms	Anemia	Leukocytoclastic Vasculitis	Lung Adenocarcinoma
13	85/F	Palpable purpura, ulcers	Normal	Leukocytoclastic Vasculitis	Breast Carcinoma
14	53/M	Palpable purpura, arthralgias	Normal	Leukocytoclastic Vasculitis	Pyriform sinus squamous cell carcinoma
15	71/M	Palpable purpura, constitutional syptoms	Normal	Leukocytoclastic Vasculitis	Bladder carcinoma
16	70/M	Palpable purpura	Normal	Leukocytoclastic Vasculitis	Glottic squamous cell carcinoma

Conclusion: CLV presenting as a paraneoplastic syndrome is a rare condition. The most common underlying malignancy is generally hematological. The prognosis depends on the underlying neplasia.

Sibling Relative Risk and Heritability of Kawasaki Disease: A Nationwide Population Study in Taiwan.
I-Jun Chou[1], Chang-Fu Kuo[2], Jing-Long Huang[1], Chang-Teng Wu[1], Shao-Hsuan Hsia[1] and Hsiao-Chun Chang[1]. [1]Chang Gung Memorial Hospital, Taoyuan, Taiwan, [2]University of Nottingham, Nottingham, United Kingdom

Background/Purpose: Kawasaki disease (KD) is an autoimmune disease involving primarily medium-sized vessels and is the leading cause of acquired cardiac disease in children. The pathogenesis is still unknown and the

evidence for familial aggregation in Kawasaki disease is rare. The aims of this study was to estimate sibling relative risk (RR) and heritability of KD.

Methods: Using data from the National Health Insurance Research Database in Taiwan, we conducted a nationwide cross-sectional study of 2,683,174 males and 2,483,901 females who were younger than 20 years in 2010. KD was defined as children < 20 years of age hospitalised with a primary or secondary diagnosis of KD between 1996 and 2010. We identified individuals with a full sibling affected by KD and compared the prevalence of the disease between individuals with and without an affected sibling. The identification of sibling of each individual was determined using the NIHRD registry for beneficiaries, which specifies relationships between the insured person who paid the insurance fee and his/her dependents and allows first-degree relatives (father, mother, son, daughter, brother, sister, twin) to be identified directly. Full siblings were identified as individuals who shared the same parents. The marginal Cox proportional hazard model with an equal follow-up time for all subjects was used to estimate RR and the 95% confidence interval (CI). This model was used to account for shared environment and case clustering within families with robust variance, and to adjust for age, place of residence, income levels and occupation. The RR was estimated for different first-degree relative categories and for the number of first-degree relatives affected by gout. Heritability (h2) was estimated using the multifactorial polygenic model.

Results: There were 7,443 male and 4,558 female individuals who had KD between 1996 and 2010. Individuals with an affected sibling with KD had a higher prevalence of KD (1.53%) than those without (0.23%). The risk of KD in individuals with an affected sibling was 6.39 (95% CI, 4.63–8.83) times greater than that in individuals without an affect sibling. The sibling RR (95% CI) was slightly higher among female individuals with affected siblings (6.79, 4.50–10.27) than male ones (6.11, 4.19–8.90). The heritability of KD was 0.45 (95% CI, 0.36–0.55).

Conclusion: The present study provides population-based estimate for sibling RR and demonstrates familial aggregation of KD. The results suggest a significant genetic contribution to the KD susceptibility.

Long-Term Outcomes of Patients with Reversible Cerebral Vasoconstriction Syndromes (RCVS). Seby John, Leonard H. Calabrese, Stewart Tepper, Mark Stillman, Ken Uchino and Rula Hajj-Ali. Cleveland Clinic Foundation, Cleveland, OH

Background/Purpose: RCVS is a syndrome characterized by acute onset of severe headaches, with or without neurologic deficit with evidence of reversible cerebral vasoconstriction. Natural history and long term outcome of RCVS has not been thoroughly investigated. To date, three main series of RCVS have been reported and long term outcomes were not readily available.

Objectives: i) To assess long term neurologic outcome of patients with RCVS using validated outcome measures for stroke and headache ii) To determine the impact of RCVS on patient's health related quality of life (QoL).

Methods: After approval from the institutional review board, prospective cohort analysis of patients recruited from our RCVS database registry was conducted. Validated questionnaires were mailed to the patients on a one-time-basis. The forms included: Headache screening questionnaire, Headache Impact Test-6 (HIT-6), Barthel index (BI), Patient Health Questionnaire (PHQ-9) and European QoL Questionnaire (EQ-5D-5L).

Results: A total of 57 patients were present in the RCVS registry. Of these patients, 3 refused to participate in the study, 26 were inaccessible or lost to follow-up, 11 agreed to participate but never returned the forms, and 17 returned the questionnaires (5 incomplete). Mean follow-up time from diagnosis to answering questionnaires was 112 months (range 10–254 months). Of the 17 patients, 8 (47%) continued to have headaches, but majority (88%) reported improvement in the character of headaches with only 1 patient having worsening. 3 (38%) patients reported that the headaches were similar to the initial headache during onset of RCVS. Headache impact on life as measured by the HIT-6 showed that only 2 patients (17%) had a severe impact (HIT score > 60), while 3 patients each (25%) reported substantial impact (56–59) or some impact (50–55); and 4 (33%) reported no impact (<50). The mean MIDAS score was 11.83 and only 2 (17%) had severe disabling headaches (MIDAS score > 21). 13(93%) patients were independent per BI scores > 85 (8 patients scored 100). EQ-5D-5L measurements showed that 9 (69%), 11 (85%)

and 9(69%) patients had no problems with mobility, self-care and leisure respectively. However, 10 (77%) and 7(54%) patients had slight to severe problems with pain and anxiety respectively. Scoring per the PHQ-9 questionnaire revealed that only 1 (7%) patient had severe depression (PHQ score 20–27), while 7(50%), 3(21%), 1(7%) and 3(21%) patients had no/minimal (0–4), mild (5–9), moderate (10–14) and moderately severe (15–19) depression.

Conclusion: This is the first study looking at the long term outcomes of patients with RCVS. Although limited by small numbers, preliminary data suggests that patients with RCVS have favorable outcomes both in terms of headaches and stroke. Although close to half (47%) of patients continued to have chronic headaches, most had improved in character with only 17% reporting severe headache by MIDAS and HIT-6 scoring. Majority of patients were also independent (93%) and had no problems with mobility or self-care, but pain and anxiety decreased the QoL. Severe and moderately-severe depression was present in 28% of patients. Additional studies are needed to determine if similar results are observed in other RCVS patients.

Background/Purpose: Primary angiitis of the central nervous system (PACNS) is rare and only 1 pediatric and 1 adult large cohorts including >30 PACNS patients have been published, both from North America. The French Vasculitis Study Group, in collaboration with the French NeuroVascular Society and Internal Medicine Society, initiated a multicenter cohort study to describe a new and large adult PACNS population.

Methods: Patients with PACNS, diagnosed recently or within the past 20 years, with follow-up >6 months after diagnosis (unless they died earlier) and negative diagnostic work-ups for alternative diagnoses or secondary CNS vasculitis, were eligible for inclusion. A multidisciplinary committee (internists, neuroradiologists, neurologists and pathologists) systematically analyzed all medical charts to validate patients' diagnoses, characteristics and outcomes. Poor outcomes were defined as no disease control and/or PACNS relapse or death.

Results: Eighteen months after cohort initiation, 52 patients (30 M/22 F; median age at diagnosis, 43.5 [18–79] yr) from 21 French hospitals have been included. Thirty-one (60%) underwent brain biopsy, which showed vasculitis features in 19 (37% biopsy-proven PACNS). All 12 patients with normal or non-contributive biopsies and the remaining 21 without brain biopsies, had persistent (>6 months) conventional cerebral angiography suggesting PACNS (33 [63%] angiography-diagnosed

PACNS). The most frequent initial manifestations were focal neurological deficits (83%), headaches (54%), cognitive impairment (35%), aphasia (35%) and/or seizures (33%). Compared to biopsy-proven PACNS, angiography-diagnosed PACNS patients had more frequent focal neurological deficits (p=0.004) and bilateral infarctions on MRI (p=0.04) but less frequent encephalitic manifestations, like seizures or cognitive disorders (p=0.003 and 0.04, respectively). Twenty-two (52%) of the 42 MRI with gadolinium injection showed enhanced-parenchymatous/meningeal (22/10) lesions. All but 1 patient received corticosteroids (CS) and 44 cyclophosphamide (CYC). At the time of this analysis (median follow-up, 35 [6–148] mo), 3 (6%) patients had died; 20 (51%) of the 49 survivors had poor outcomes (13 [27%] relapsed, 7 [13%] had no disease control) and 40 (77%) had some persistent neurological damage. Patients with gadolinium leptomeningeal enhancement responded promptly to therapy but relapsed more often (80%) than those without (14%; p<0.0001). Multivariable analysis retained only intraparenchymatous and meningeal gadolinium uptakes at diagnosis as independent predictors of poor prognosis or relapse (HR=2.45 [95% CI, 0.99–6.08] and 1.88 [95% CI, 0.80–4.46], respectively).

Conclusion: In this PACNS cohort, more than half the patients responded to CS–CYC and had good outcomes at 3 yr, but neurological damage was frequent. Leptomeningeal and intraparenchymatous enhancements on MRI were associated with a poorer outcome. Comparisons of the different ongoing cohorts should help identify subgroups with poorer outcomes.

Clinical Correlates, Treatment Outcomes and Predictors of Vasculitis Associated with Rheumatoid Arthritis in the 'Biologic Era': A Case-Control Study. Ashima Makol, Cynthia S. Crowson, Eric L. Matteson and Kenneth J. Warrington. Mayo Clinic, Rochester, MN

Background/Purpose: 1.To determine the clinical presentation, treatment and outcomes of vasculitis (RV) associated with rheumatoid arthritis (RA) in the era of biologic use. 2. To identify risk factors associated with the development of RV.

Methods: A retrospective cohort of patients with RV evaluated at Mayo Clinic Rochester in 2000–2009 was identified. RV was defined as histopathological evidence of and/or a definitive clinical or radiological diagnosis of vasculitis made by a rheumatologist in a patient meeting the 1987 ACR classification criteria for RA. In a case-control study to identify risk factors for RV, RV cases were compared in a 1:2 ratio to controls (RA without RV).

Results: Eighty-six patients (58% women, 88% white) with RV were identified. All met the 1984 Scott and Bacon criteria for systemic RV. Histopathological confirmation was available for 58%. RV manifestations included cutaneous vasculitis (65%), vasculitic neuropathy (35%), CNS vasculitis (8%), mesenteric vasculitis (2%), scleritis/episcleritis (2%), pulmonary angiitis (1%) and necrotizing glomerulonephritis (1%). Median age at RV diagnosis was 63 y (IQR 51–71 y) and median duration of RA was 10.8 y (IQR 2.7–21 y). 29% were current smokers at RV diagnosis. Majority had a positive rheumatoid factor (84%), anti-CCP antibody (67%), elevated ESR (66%) and CRP (69%). For treatment, 99% received corticosteroids, 29% cyclophosphamide, 55% other DMARDs and 28% biologic response modifiers (BRM). At 6 months, 38% patients achieved complete remission, 52% had partial improvement, while 10% noted no clinical improvement. Median follow up was 16 months (IQR 2.4 –59) during which 21% patients died and 30% had a relapse of RV. Predictors of relapse included smoking at RV diagnosis, lower mean ESR at presentation, and cyclophosphamide use. Among RV patients, those treated with a BRM for their RA were younger (56 vs 65 y, p=0.004) and had a lower incidence of vasculitic neuropathy (21% vs 47%, p = 0.015) than those treated without a BRM. In none of the 34 patients treated with a BRM prior to RV, was the BRM conclusively implicated to be a trigger for RV.

The 86 RV cases were compared to 172 RA controls. After adjusting for age and disease duration, increased RV risk was associated with male sex, current smoking at RA diagnosis, coexistent peripheral vascular disease (PVD) and cerebrovascular disease. Patients with high disease severity characterized by a composite index of erosions, nodulosis and 1 or more joint surgery had a significantly higher risk of RV (Odds ratio 2.0, 95% CI 1.1–3.7). Biologic use also increased the odds for RV while use of hydroxychloroquine (OR 0.54, p=0.03) and low dose aspirin for cardioprotection (OR 0.42, p=0.02) were associated with lower odds of developing RV.

Conclusion: In this large series of patients with RV, the predominant clinical manifestations were cutaneous vasculitis and vasculitic neuropathy. Male sex, smoking, RA severity, PVD and cerebrovascular disease increased the odds of developing RV. Among patients with RV, use of BRM was associated with a lower frequency of vasculitic neuropathy. Even in the 'biologic era', RV remains a serious complication of RA and is associated with significant mortality.

The Effect of Knee Replacement On Participation Outcomes: The Multicenter Osteoarthritis Study and Osteoarthritis Initiative. Jessica L. Maxwell[1], Jingbo Niu[2], Julie J. Keysor[1], Tuhina Neogi[2], Tianzhong Yang[2], Michael C. Nevitt[3], Jasvinder A. Singh[4], Laura Frey-Law[5] and David T. Felson[2]. [1]Boston Univ Sargent College, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA, [3]University of California-San Francisco, San Francisco, CA, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of Iowa, Iowa City, IA

Background/Purpose: Little research has explored participation outcomes, defined as involvement in life situations, among persons following knee replacement (KR). We recently reported (OARSI 2012) that persons undergoing KR did not necessarily show improvement in participation after surgery. These findings, however, could be due to confounding by indication, thus we sought to examine whether participation restriction differed among persons following KR compared to similarly matched group with symptomatic knee osteoarthritis (OA).

Methods: Subjects were selected from the Multicenter Osteoarthritis (MOST) Study and the Osteoarthritis Initiative (OAI). We took the pre-KR pain and physical function WOMAC scores of MOST and OAI subjects who were at least one year after KR and matched each of these by quartiles to 1–2 subjects with symptomatic knee OA, (defined as radiographic evidence of knee OA and frequent knee pain over the last 30 days). Participation was measured using the Late Life Disability Instrument (LLDI) at the 60 month visit in MOST and at 48 months in OAI; restriction was defined using a previously established cut-point of < 69/100 on the Instrumental Limitation subscale of the LLDI (LLDI-IL). Data on covariates was collected at the pre-KR/index visit.

We compared the proportion of subjects with participation restrictions for each group overall and stratified by sex, race, age (< 65, 65–74, ≥75 years), # of comorbidities (> 1), and depressive symptoms (> 16 on CES-D) using chi square analyses. We evaluated the association between KR status and participation restrictions while adjusting for the above covariates, as well as body mass index, educational level, and presence of lower limb or back pain, using conditional logistic regression.

Results: Participation restriction was assessed on average 3 years post-KR and was common in both the post-KR group (45%) and in those with SxOA who had comparable pain/function (43%). There were no statistical differences in the proportion of participation restriction among subjects in each KR group overall or after stratification. The SxOA group had more younger subjects, fewer Whites and more with other lower limb pain (Table 1). After adjusting for these differences in groups, there was no difference in the odds of participation restriction among subjects with KR compared to those with SxOA (OR 1.0 (0.6, 1.6). Other factors independently associated with participation restrictions included male sex and increased depressive symptoms (Table 2).

Table 1. Demographic and clinical status of study subjects at pre-KR visit

Independent Variable	Knee Replacement Group	Symptomatic Osteoarthritis Group	p-value
Total, n	277	552	
Sex: Women, %	66	64	.5
Race: White, %	86	76	.0007
Age: <65 years, %	46	55	.01
65–74 years, %	45	35	.006
75+ years, %	9	10	0.8
Body Mass Index, mean (SD)	32.2 (6.4)	32.4 (6.6)	.99
Comorbidities: > 1, %	43	43	0.9
Depressive Symptoms: > 16, %	15	17	0.3
Education: < High School, %	5	6	0.6
Pain in lower limbs/back, %	75	83	.01
WOMAC physical function, mean (SD), range 0–68	26.2 (11.7)*	26.1 (11.8)*	0.8
WOMAC pain, mean (SD), range 0–20	8.1 (3.8)*	8.1 (3.8)*	0.9

* Knee replacement and symptomatic OA group matched on these variables

Table 2. Effect of Demographic and Clinical Factors on Participation Restrictions

Independent Variable	Unadjusted OR (95%CI)	Adjusted OR (95% CI)**
Knee Replacement Status (ref=SxOA)	0.9 (0.6, 1.4)	1.0 (0.6, 1.6)
Sex (ref=male)	0.7 (0.4, 1.1)	0.6 (0.4, 1.0)
Race (ref= White)	1.3 (1.2, 1.3)	0.9 (0.5, 1.8)
Age at KR: (ref= <65)	ref	ref
65–74	1.5 (1.0, 2.3)	1.4 (0.9, 2.3)
75+	0.4 (0.2, 1.0)	0.8 (0.3, 1.9)
Educational status (ref < High school)	1.2 (0.5, 2.9)	1.1 (0.4, 2.6)
Number of Comorbidities (ref ≤ 1)	1.7 (1.1, 2.7)	1.5 (0.9, 2.5)
Body Mass Index (ref <30)	1.8 (1.1, 2.7)	1.6 (0.9, 2.6)
Depressive Symptoms (ref'16)	2.9 (1.5, 5.3)	2.3 (1.2, 4.5)
Lower Limb and Back Pain	1.4 (0.8, 2.5)	1.3 (0.7, 2.5)

**Adjusted for KR group, sex, race, age category, educational status, # of comorbidities, bmi, depressive symptoms, lower limb and back pain

Conclusion: Despite prior evidence of improvements in pain and function after knee replacement, the current study demonstrates that after KR, there is no clear difference between those who underwent KR and those who still have SxOA in terms of participation in life activities. Other factors such as sex and depressive symptoms may play more of a role in one's involvement in life situations.

Clusters of Fatigue—a Comparison Between Persons with Systemic Lupus Erythematosus and Age and Gender Matched Controls. Susanne Pettersson[1], Karin Eriksson[2], Carina Boström[2], Elisabet Svenungsson[3], Iva Gunnarsson[3] and Elisabet MB Welin Henriksson[4]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Division of Physiotherapy, Karolinska Institutet Huddinge, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institutet Rheum, Stockholm, Sweden

Background/Purpose: The aim (1) of this study was to explore fatigue in patients with SLE with age and gender match controls using cluster analysis and (2) analyze the clusters concerning health related quality of life (HRQoL), anxiety, depression and life-style habits.

Methods: This cross-sectional study included patients with SLE and paired controls (age and gender). The respondents answered self-assessment of fatigue: Fatigue severity scale (FSS), Vitality (VT) from SF-36 and Multidimensional Assessment of Fatigue scale (MAF). All three questionnaires were answered by 616 persons (mean age 47 years, SD 14.6, range 18–84) and hierarchic cluster analysis were used to form homogeneous groups of fatigue. Further the Medical Short Form-36 (SF-36) were used to collect data on HRQoL and The Hospital Anxiety and Depression Scale (HADS) with the two sub-scales, anxiety (HADS-A) and depression (HADS-D).

Results: Patients with SLE had higher levels of fatigue than the controls on all three fatigue questionnaires as well as all dimensions of HRQoL and depression. The hierarchic cluster analysis identified three divergent clusters of fatigue with significantly different levels of fatigue. The clusters were denominated by their levels of fatigue. The persons in the High fatigue cluster (n=221) were dominated by patients (80%) and most affected by depression

and anxiety, had lowest levels of HRQoL. This cluster had the lowest proportion of persons working ≥ 50% and they lived more often without a partner. The Low fatigue cluster (n= 240) was dominated by the controls (78%) and included persons with highest perceived HRQoL, lowest distribution of anxiety and no detected depression (p < 0.001). They represented the lowest proportion of smoker (13% vs 20%, both High and Intermediate). Persons in the Intermediate fatigue cluster (n=155) had smoking habits similar to the High fatigue cluster, and sleeping habits towards the Low fatigue cluster. The intermediate fatigue cluster had the most equal distribution at 48% patients and 52% controls, their level of fatigue were more moderate. There were no differences in gender distribution, age or sedentary behavior between the three clusters.

Comparing patients in the three clusters no significant difference was found regarding the number of ACR criteria, disease duration, or organ damage (SLICC/ACR). However, patients in the High fatigue cluster had more disease activity (SLAM) (mean 9.0, CI 8.3–9.7) than both the Low fatigue cluster (mean 4.2, CI 3.3–5.2, p < 0.001) and the Intermediate fatigue cluster (mean 5.3, CI 4.7–6.0, p < 0.001). However, there was no difference in disease activity between the Low fatigue cluster and the Intermediate fatigue cluster.

Conclusion: The analysis confirmed that a high number of patients with SLE are affected by fatigue but also that non-SLE persons were clustered together with the patients (6%) in the High fatigue cluster. Notable is that in this cross-sectional study a minority (7%) of patients with SLE report low levels of fatigue, high wellbeing and healthier life-style habits e.g interestingly less smoker.

1555

Minimal Clinically Important Difference for Seven Measures of Fatigue in Patients with Systemic Lupus Erythematosus – Results From a Swedish Setting. Susanne Pettersson[1], Ingrid E. Lundberg[2] and Elisabet MB Welin Henriksson[3]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institutet Rheum, Stockholm, Sweden

Background/Purpose: The objective of this study was to estimate the minimal clinically important difference (MCID) of seven self-administered measures assessing fatigue in persons with systemic lupus erythematosus (SLE).

Methods: The respondents (n=51, women 98%, age 52.8 ± 12.1 years, disease duration 18.7 ± 13.6 years) met in groups sessions with six to nine participants. After initial self-assessment with the seven fatigue questionnaires (Chalder Fatigue Scale, Vitality from SF-36, Fatigue Severity Scale, Multidimensional Assessment of Fatigue, Multidimensional Fatigue Inventory, Functional Assessment of Chronic Illness Therapy–Fatigue, and a single numeric rating scale), each respondent had a minimum of five face-to-face discussions, all followed by an individual comparative assessment of his or her own level of fatigue (7-grade scale: Much More, Somewhat More, Little More, About the Same, Little Less, Somewhat less, Much Less). This method resulted in 260 contrasting assessments; MCIDs were first calculated using paired differences and then established by a regression approach. Patients were offered the opportunity to provide additional free comments regarding the questionnaires.

Results: In total seven group sessions was hold with the 51 respondents (98% women). Correlations with the raw fatigue score for the seven questionnaires and patients' assessment of disease activity varied between 0.421 (p < 0.01) and 0.641 (p < 0.001). The self-reported disease activity and fatigue correlations of the patients varied between 0.504 and 0.562 (p<0.001 for all). No correlations were found between fatigue and age (r = −0.134–0.059) or fatigue and disease duration (r = −0.113–0.01).

The result was divided into contrast groups, based on the individual comparative assessment (the 7-grade scale). For most instruments, the mean paired difference followed a slope where the contrast groups represented a reasonable and increasing level of fatigue, compared to the neighboring contrast group. The mean paired difference for the patients scoring "about the same fatigue" ranged from 1.4 for Chalder Fatigue Scale fatigue scale to 3.4 for Functional Assessment of Chronic Illness Therapy – Fatigue. The means for the "about the same" groups were used to standardise the estimates. Except for the Chalder Fatigue Scale, the estimates for the MCID relative to "little *less* fatigue" tended to be smaller than those for "little *more* fatigue". The paired approach (contrast group: "Little more fatigue") varied from 4.6 to 17.0, and the regression approach varied from 4.45 to 10.75. Estimates in the regression approach were

consistently higher than in the paired model. The MCID estimates were least favorable for the single numeric rating scale. In the free comments section fewer respondents supported the use of the single-question measure compared to the other questionnaires.

Conclusion: Based on our results, all seven instruments are adequate for detecting clinically important differences of fatigue in patients with SLE. However, the use of a single-question measure was not supported by the MCID estimates or by comments from the respondents.

1556

The Effect of Ginger Therapy On Symptoms of Osteoarthritis: An Open Pilot Study. Tessa Therkleson. Edith Cowan University, Perth, Australia

Background/Purpose: Osteoarthritis (OA) is a painful, progressive disease of synovial joints characterised by deterioration of cartilage and bone and inflammation. Osteoarthritis of the knee and hip joints is common and a major cause of musculoskeletal pain and disability in older adults. In addition to conventional pharmacological management, people with OA often use complementary and alternative treatments. In vitro studies find ginger extract inhibits the inflammatory enzymes COX-2 and 5-lipoxygenase. Ginger seems to be absorbed after topical application by a compress that provides heat and relaxation therapy. European hospitals specialising in traditional therapies routinely use ginger compresses applied to the lower back for treatment of inflammatory conditions. In order for topical ginger treatments to be used more widely, a pre-packaged ginger patch was developed. This pilot study assessed the effects of the ginger compress and standardised ginger patch and the potential effect size of the treatments.

Methods: Twenty adult volunteers with osteoarthritis aged 35 – 90 years, recruited from medical centres and the community, were randomly assigned using a block size of 4, to ginger treatment with ginger compress (GC) or ginger patch (GP). Both treatments were provided daily for seven consecutive days at medical centres by trained nurses. While lying supine either a warm GC or GP was secured on the mid back for 45 minutes. All participants were offered a supply of the GP for self-treatment at home for the following 24 weeks. The 5-item modified Health Assessment Questionnaire (MHAQ) was used to assess pain, global effect, fatigue, functional status and health satisfaction. The MHAQ was completed once a week for 3 weeks and 4 weekly for 24 weeks.

Results: Participants (mean age 64 years, 80% female) had a mean pain score at baseline of 2.1, with 3 being the most extreme pain. Most participants had OA of the hips and/or knees (17/20, 85%). All participants had a reduction in pain one week after ginger therapy, with a mean pain score 1.1. A comparison of MHAQ scores for the GC and GP groups show a strong co-relation, with p = 0.98 at baseline and p = 0.97 at 7 days. After seven days of ginger treatment the MHAQ mean total scores for all participants for pain, fatigue, global effect and functional status were reduced by 48%, 49%, 40% and 31% respectively, with scores progressively declining over the following 24 weeks. Pain, fatigue, global effect and functional status were all statistically significantly reduced from baseline to 7 days, 12 weeks and 24 weeks after therapy (p < 0.001). Health status satisfaction improved for both GC and GP, with 80% dissatisfied 7 days before therapy to 70% satisfied 7 days after therapy and 82% satisfied 24 weeks after therapy.

Conclusion: This pilot study suggests ginger therapy using both the ginger compress and ginger patch has the potential to relieve symptoms and increase independence for people with osteoarthritis. These data will be utilised in the design of a randomised placebo-controlled trial of the ginger patch.

1557

What Percentage of Postmenopausal Women Younger Than Age 65 Years Have Low Bone Mineral Density At a Family Health Center? Marvin Vaishnani and Feyrouz T. Al-Ashkar. Cleveland Clinic,Lorain Institute, Lorain, OH

Background/Purpose: Many younger women, < 65 years of age may have low bone mineral density (BMD) that remains undetected in clinical practice due to following Medicare age guidelines of 65 years and older for BMD test and other factors. Prevalence of low BMD is a growing public health issue in the population but these have not been well quantified in this younger age group of women. This study aims to describe prevalence of low

BMD at a family health center in postmenopausal women younger than 65 years and identifying common risk factors noted in this age group.

Methods: Retrospective chart review was done of patients who had dual-energy x-ray absorptiometry (DXA) scan performed at family health center between Jan 2010 to May 2012, on Hologic® DXA machine. Postmenopausal women less than 65 years of age were included (amenorrhea ≥ 12 months). Patients who have been on osteoporosis medication therapy and used estrogen postmenopausal were also included in this study. The data of risk factors was collected from patient questionnaire present in medical charts. Patients were grouped into those with low T-score < −1.0, T-score ≤ −2.0, and T-score ≤ −2.5. T-scores of the spine (following the International Society for Clinical Densitometry guidelines), femoral neck, total hip, one-third radius (when available) was reviewed and from these the lowest T-score was used in the results.

Results: A total of 702 patient charts were reviewed. The age ranges from 30 to 64 years and average age of patients was 56.74 years. We found 71.93% of patients have T-score < −1.0, 35.47% of patients have T-score ≤ −2.0, and 17.52% of patients have T-score ≤ −2.5. The risk factors noted among T-score < −1.0 are summarized in figure-2 below and 88.51% were found to have at least 1 or more risk factors out of five.
Figure 1. This figure represents percentage of patients in a T-score group. (n=702).
Figure 2. This figure represents percentage of patients among T-score <−1.0 have this risk factors.(n=505)

Conclusion: The results show high prevalence of low BMD in postmenopausal women younger than age 65 years at this family health center. Although population prevalence cannot be calculated from this study, findings

suggest that low BMD is fairly prevalent in this age group. A larger study would be needed to further evaluate low BMD in postmenopausal women younger than 65 years of age. If confirmed this should alarm clinicians to obtain BMD testing in women earlier than age 65 years and especially so in those who have the identified risk factors and to identify the younger age group women with undiagnosed osteoporosis.

Disclosure: **M. Vaishnani**, None; **F. T. Al-Ashkar**, None.

"It Gets Me Down Every Single Day": Are Men with Rheumatoid Arthritis Getting the Support They Need? Caroline A. Flurey[1], Marianne Morris[1], Jon Pollock[1], Rodney A. Hughes[2], Pamela Richards[3] and Sarah Hewlett[1]. [1]University of the West of England, Bristol, United Kingdom, [2]St. Peters Hospital, Chertsey Surrey, United Kingdom, [3]University of Bristol, Bristol, United Kingdom

Background/Purpose: Daily life with RA has been explained as unpredictable and full of uncertainty. However, most research about daily life with RA was conducted before current more aggressive medications, and in women. The purpose is to explore daily life on modern therapies.

Methods: Q-Methodology: 30 RA patients sorted 39 statements (generated from previous qualitative interviews) about daily life with RA across a forced distribution, in ranked order of agreement. Data were analysed using centroid factor analysis with varimax rotation (i.e. the participants and not the items are the variables). Demographic and clinical data were collected and patients completed comments booklets about their rationale for sorting the statements.

Results: Three factors were generated, which explained 33% of the study variance and accounted for 23 of the 30 participants. None of the Q-sorts were confounded (loading on more than one factor). A participant loading of 0.41 reached significance at $p<.01$. Factor A (Taking Control: "Just a fact of life") and Factor B (Keeping RA in its place: "It's a very small part of you") were predominately female participants (86%, 100%) and have been reported previously.

Factor C: Struggling Through: "It gets me down every single day" comprised 8 participants, 63% male: mean disease duration 15.3yrs (SD 14.3), age 55.5yrs (SD 7.1), HAQ score 1.3 (SD 0.9), patient global 4.8 (SD 2.5), 50% on biologic therapies. These predominantly male patients are never symptom free, experiencing pain and fatigue daily: *"It's like feeling ill all the time"*, they describe fatigue as *"the worst symptom"*. They worry and get angry and frustrated about their RA: *"I get very frustrated with it, the problem is then I get irritated and take it out on the wife"*. This group report being unable to effectively manage their symptoms, some *"don't know what to avoid"*, whilst others use unadvisable methods: *"I find cocaine numbs the pain"*. They report being unable to be spontaneous or to exercise and they struggle to explain their experience to their family. These patients feel their body has let them down, life is unfair: *"Why me? Why now?"* and the idea that they are lucky in comparison to others is *"ridiculous"*.

We re-examined the preceding qualitative interviews that generated these Q-statements, and this clarified these men's views further. Having RA means men's traditional masculine coping strategies have to be adapted: *"you can't go and thump a wall because you end up with a flare and you can't go and kick a football around or anything like that, so you need to find an outlet and talking is the outlet I suppose"*. At the same time, they reject those traditional, more female-gendered RA support mechanisms: *"The self help groups don't confront it enough, it might be all lovey dovey [sweet and gentle] but sometimes you have got to be quite hard about it"*.

Conclusion: Whilst some patients cope well with their RA, others struggle to accept and adapt to their condition; the majority of these being male. These findings indicate a need to address the unique support needs of men with RA and to consider providing support that is acceptable to their masculine identities.

Treatment Outcomes From a Nurse-Led Rheumatology Clinic in Monitoring of anti-TNF Therapy – a Randomised Controlled Trial. Ingrid Larsson[1], Bengt Fridlund[1], Barbro Arvidsson[2], Annika Teleman[3] and Stefan Bergman[4]. [1]School of Health Sciences, Jönköping University, Jönköping, Sweden, [2]School of Social and Health Sciences, Halmstad University, Halmstad, Sweden, [3]Spenshults Hosp of Rheum Dis, Oskarstrom, Sweden, [4]R&D Center, Spenshult Hospital, Oskarström, Sweden

Background/Purpose: Patients with chronic inflammatory arthritis (CIA) treated with anti-TNF therapy are usually followed up by rheumatologists. Nurse-led rheumatology clinics have been proposed for patients with low disease activity or in remission. The purpose of this trial was to compare treatment outcomes from a nurse-led rheumatology clinic and a rheumatologist clinic for patients undergoing anti-TNF therapy with low disease activity or in remission.

Methods: A randomized controlled trial (RCT) with a 12-month follow-up was conducted with 107 patients randomised into two groups with a 6-month follow up to a nurse-led rheumatology clinic based on a person-centred care (intervention group; n=53) or to a rheumatologist-led clinic (control group; n=54). The intention of the interventional trial was to replace one of the two annual rheumatologist monitoring visits by a nurse-led rheumatology monitoring visit for patients undergoing anti-TNF therapy. Inclusion criteria were patients undergoing anti-TNF therapy and Disease Activity Score 28 (DAS28) ≤3.2. The hypothesis was that the outcomes from nurse-led clinic will not be inferior to those obtained by rheumatologist-led clinic at 12-month follow-up. Primary outcome was disease activity measured by DAS28.

Results: After 12 months 47 patients in the intervention group and 50 patients in the control group completed the trial and there were no differences (p=0.66) in mean change of DAS28 between the intervention or control group. There were no differences (p>0.05) in mean change in Visual Analogue Scales (VAS) for pain, Health Assessment Questionnaire (HAQ), satisfaction or security with the rheumatology care between the two groups, see table.

Table. Mean difference of changes after 12 months between intervention group (Nurse-led rheumatology clinic) (n=47) and control group (Rheumatologist-led clinic) (n=50)

	Nurse-led rheumatology clinic-Rheumatologist-led clinic Mean difference of changes (Std Error Difference)	*p*
DAS28(mean)	−0.06 (0.14)	0.66
ESR (mm/h)	−1.05 (1.47)	0.47
Swollen joints(28)	0.13 (0.24)	0.60
Tender joints(28)	0.33 (0.40)	0.42
Global Health VAS(mm)	4.29 (3.46)	0.22
HAQ	0.02 (0.06)	0.79
Pain VAS(mm)	−0.24 (3.85)	0.95

student t-test

Conclusion: In monitoring of anti-TNF therapy treatment outcomes for patients at a nurse-led rheumatology clinic are not inferior to those obtained by rheumatologist-led clinic at 12-month follow-up. The follow-up care of anti-TNF therapy may advantageously be performed by a nurse-led clinic based on a person-centred care. The results from this trial demonstrated that patients with CIA undergoing anti-TNF therapy, with low disease activity or in remission, could be monitored by a nurse-led rheumatology clinic without any differences in outcome as measured by DAS28.

What Will Determine Adherence to Pharmaceutical Treatment for Rheumatoid Arthritis? A Systematic Review. Annelieke Pasma[1], Adriaan van 't Spijker[2], Jan van Busschbach[2], Johanna M.W. Hazes[3] and Jolanda J. Luime[2]. [1]Erasmus MC University Medical Centre, Rotterdam, Netherlands, [2]Erasmus MC - University Medical Center, Rotterdam, Netherlands, [3]Erasmus Medical Center, Rotterdam, Netherlands

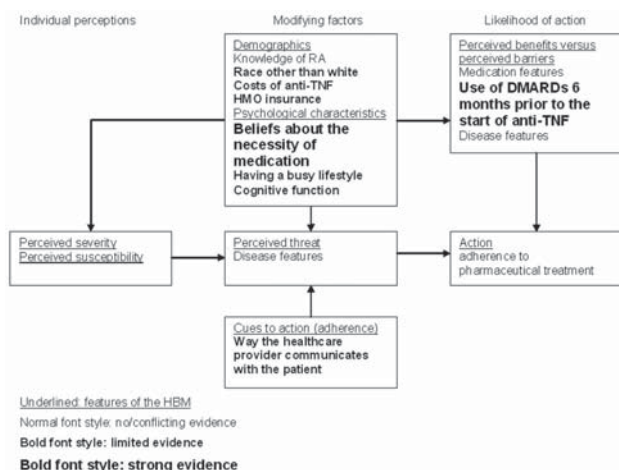
Background/Purpose: In the early stages of Rheumatoid Arthritis (RA), adherence to the prescribed treatment is important to prevent irreversible joint damage. However, medication adherence rates in RA patients can be improved. To explain the suboptimal adherence, factors that influence adherence should be elucidated. These factors were last reviewed in 1982. Since then, treatment strategies for RA have changed, which means that nowadays different factors might play a role. Our aim is therefore to review adherence rates reported in the literature, to identify factors associated with adherence, to review the strength of the association between these factors and adherence and to cluster the identified factors according to the Health Belief Model (HBM) (Figure 1).


Figure 1. Health Belief Model

Methods: PubMed, PsycINFO, EMbase and CINAHL databases were systematically searched from inception to February 2011. Articles were included if they addressed medication adherence, used a reproducible definition, determinants and its statistical relationship. Methodological quality was assessed using a quality assessment list for observational studies derived from recommendations from Sanderson, Tatt and Higgins (2007). The strength of evidence for factors associated with adherence was assessed by defining 5 levels of evidence. Resulting factors were interpreted using the HBM.

Results: 18 out of the 1479 identified studies remained. Adherence rates ranged between 49.5% and 98.5%. 64 factors were identified and grouped according the HBM into demographic and psychosocial characteristics, cues to action and perceived benefits versus perceived barriers. The belief that the medication is necessary and DMARD use prior to the use of anti-TNF had strong evidence for a positive association with adherence. There is limited evidence for positive associations between adherence and race other than White, general cognition, satisfactory contact with the healthcare provider and the provision of adequate information from the healthcare provider. There is limited evidence for negative associations between adherence and having HMO insurance, weekly costs of TNF-I, having a busy lifestyle, receiving contradictory information or delivered information in an insensitive way by the rheumatologist. 18 factors were unrelated to adherence. The results are presented in figure 1.

Conclusion: The strongest relation with adherence is found for prior use of DMARDs before using anti-TNF and beliefs about medication. Because the last one is modifiable, this provides hope to improve medication adherence. Since research on factors influencing adherence has mostly focussed on demographic and disease futures, future studies should use a theoretical framework to explore the role of interpersonal and other relevant factors.

Factors Influencing Implementation of Intensive Treatment Strategies for Early Rheumatoid Arthritis. Sabrina Meyfroidt[1], Diederik De Cock[1], Kristien Van der Elst[1], Laura van Hulst[2], Marlies Hulscher[2], Johan Joly[1], Rene Westhovens[1] and Patrick Verschueren[1]. [1]University Hospitals KU Leuven, Leuven, Belgium, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Despite the availability and demonstrated effectiveness of intensive treatment strategies for early rheumatoid arthritis (RA), a discrepancy seems to exist between theoretical acceptance and practical implementation. Limited studies have looked at factors influencing the implementation of intensive treatment strategies for early RA in daily practice. The purpose of this study was to explore and identify these factors across different healthcare settings in Flanders.

Methods: This study involved rheumatologists, nurses and patients participating in the CareRA trial, a multicentre RCT comparing different intensive treatment strategies for early RA based on the original Cobra step down schedule with conventional DMARDs (MTX+Sulphasalazine, MTX+Leflunomide, MTX monotherapy) plus step-down glucocorticoids.

Two qualitative research methods were used, including semi-structured interviews and observations at outpatient clinics. Each interview was recorded, transcribed literally and analyzed thematically.

Results: We interviewed 26 rheumatologists, 6 nurses and 24 RA patients and observed interactions between 5 rheumatologists and their patients at consultation. Greatest facilitators reported by rheumatologists and nurses included available scientific evidence, personal faith in treatment strategy, colleague support and low cost of medication. For patients, trust in caregiver was a facilitator, as well as faith in the treatment strategy. Rheumatologists had no doubts about the value of MTX but some questioned the combination strategy, others the effectiveness or/and the dosage of individual compounds. Patients were only in doubt of glucocorticoids and MTX. Additional barriers for rheumatologists included fear for patients' preconceptions, concerns of applicability to the individual patient, break in routine, interference with organizational structures and processes, time constraints and lack of financial support.

Conclusion: The factors emerging from our study highlight the complexity of implementing intensive treatment strategies for early RA in daily clinical practice. Future improvement strategies should capitalize on the facilitators identified while at the same time addressing the barriers. The generalizability of these findings to other health care systems needs further examination.

Benign Joint Hypermobility Syndrome More Common Than Expected, Both in Controls and in SLE Patients. Pia Malcus-Johnsson[1], Lotta Köhlin[1], Gunnar K. Sturfelt[2] and Ola Nived[3]. [1]Department of Rheumatology, University Hospital, Lund, Sweden, [2]Lund University, Lund, Sweden, [3]University Hospital - Lund, Lund, Sweden

Background/Purpose: Benign joint hypermobility syndrome (BJHS) in connection to rheumatic disease is sparsely investigated. It has been postulated that BJHS is more frequent in SLE than in the healthy population. The aim of this study was to investigate the frequency of BJHS in SLE patients.

Methods: Seventy-one female individuals with SLE, age 18–65, were consecutively according to age groups, enrolled to the study and were matched by healthy female controls of the same age. The study required one visit to the clinic. All individuals were examined by physician (ON/GS) for Brighton criteria and medical symptoms, by physical therapist (LK) and occupational therapist (PMJ) for Beighton scores and manifestations in body structures and body functions.

Results: Thirty-nine (55 %) individuals in SLE group and 22 (31%) in the control group satisfied Brighton criteria for BJHS (p<.004), most commonly satisfying one major and two minor criterias, whereas 16 (23%) individuals with SLE and 19 (27%) healthy controls had Beighton score ≥4 (ns). Brighton criteria to show significant differences between the groups were arthralgia major n 44/9 (p<.000), soft tissue leasions n 35/7 (p<.000), eye signs n 17/32 (p<.008), and in addition depression n 15/6 p<.033. Six individuals in the SLE group and seven in the control group had Beighton score of four or more, but did not satisfy Brighton criteria.

Within the SLE group differences between satisfying Brighton criteria or not consisted of significant differences in arthralgia major (p<.000), soft tissue rheumatism (p<.000), abnormal skin (p<.041), eye signs (p<.000) and varicose veins or prolapse (p<.005). There was in addition a significant difference in disease activity (p<.009) and in pelvic pain (p<.035). No significant differences were found in Beighton scores or other factors constituting Brighton criteria.

In physical therapist protocol, within SLE-group, significant differences were detected in being clumsy or stumble (p<.003), standing still for a while (p<.033), jaw luxation (p<.002) and experiencing problems in shoulders (p<.009), knee (p<.001), foot (p<.033) and back (p<.033).

In occupational therapist protocol, within SLE-group, significant differences were found in estimating hand function on VAS (right p<.014, left p<.029), grip force (right p<.001, left p<.002), pinch force (right p<.000, left p<.000) and in right hand dexterity (p<.005) and estimating hand pain at work on VAS (p<.025). No differences were found in deformities of the hand.

According to age, within SLE-group, there was no significant difference in satisfying Brighton criteria but a significant difference (p<.019) in ≥ 4 Beighton score with higher scores in younger individuals, cut off point 45 years. Older individuals had significantly higher rates of Beighton 1,2,3

(p<.005), arthralgia minor (p<.014) and in addition symptoms from bowel (p<.008).

Conclusion: From this study no certain conclusion can be drawn whether SLE and BJHS are related, but for both cases and controls BJHS was much more common than in other published age matched Caucasian series from Sweden.

Is Automated DATA Capture As Reliable As Manual DATA Entry in Survey Based Research? Rachel A. Mikolaitis, Jessica Cornejo, Chris Alonzo, Joel A. Block and Meenakshi Jolly. Rush University Medical Center, Chicago, IL

Background/Purpose: The collection of patient reported outcomes requires accruing survey data from patients during routine medical visits. Many of these are paper-based and require manual data-entry for adequate analysis. However, entering surveys by hand is tedious, time consuming, and may result in entry-errors. Teleform data capture technology automates paper-based processes especially in high volume settings, decreases processing time and cuts personnel and material costs, but the accuracy of automated data capture has not been well documented in clinical settings.

Aims: To test the reliability of teleform captured data against traditional hand entered patient health outcomes data.

Methods: As a quality improvement initiative, we populated survey data from 50 patients using both methods in parallel. The survey had 43 multiple choice questions on health outcomes using a Likert scale. This scale was entered into the teleform program for each question. We programmed the teleform to ensure that each question had a response, and to alert the user for each missing response. We calculated internal consistency reliability by Cronbach alpha using a two-way random method to test for absolute agreement in item responses using the two methods. This analysis was repeated for each of the 43 items.

Results: The Internal consistency reliability estimates for 43 items ranged from 0.98 to 1.0. In the 7% of the items where the responses were not in 100% agreement, the discrepancy occurred by misclassification of the Likert category response by one point (0 and 1) in three different questions and subjects. This occurred due to human error in data entry by hand, or the scanner recognizing a small mark in the "0" response boxes.

Conclusion: Teleforms data-capturing for data entry is reliable and feasible for patient driven research in Rheumatology. This program has good reliability concerning correct data entry and is a faster way for data managers to capture large amounts of data in a shorter period.

Misperceptions of FMS Patients about Their Disease. Robert S. Katz[1], Hannah Bond[2], Jessica L. Polyak[2], Lauren Kwan[2] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

Background/Purpose: What do fibromyalgia patients think causes their illness. We asked fibromyalgia syndrome patients to respond to a questionnaire which asked about potential etiologic factors.

Methods: 21 FMS office patients (18 women and 3 men) completed a questionnaire about the causes and nature of their disease.

Results: The following percentages of FMS patients agreed with the following statements about FMS: my illness is caused by allergies, 4.8%; my illness is caused by a bacteria or virus, 0%; my illness is caused by antibodies in my blood that are directed against my body chemistry, 23.8%; my immune system is attacking me, 23.8%; my illness is caused by stress, 47.6%; my illness is caused by a traumatic event, 42.9%; my illness is caused by food products, 14.3%; my illness is caused by environmental toxins, 9.5%; my illness involves a strong genetic component, 9.5%; the cause of my illness is unknown, 47.6%; none of the above are causes of FMS, 14.3%; my illness is commonly progressive, 33.3%; my illness is frequently fatal, 0%; my illness occurs with flares and remissions, 81.0%; I will have to take steroids to control my illness, 23.8%; my illness is diagnosed based solely on lab test results, 4.8%; my illness is diagnosed based on lab test results and my symptoms, 76.2%; medications to treat my illness have serious side effects that include cancer, 19.0%.

Conclusion: Fibromyalgia patients commonly think their illness is related to stress, previous trauma or the cause is unknown. However, some believe fibromyalgia is an autoimmune disease. About one third of patients think that fibromyalgia is a progressive illness. Some patients have other misconceptions based on the questionnaire.Further education from practitioners needs to be given to some fibromyalgia patients to disabuse them of certain incorrect assumptions regarding the etiology and the likely course of their illness

How FMS Patients Become Workaholics. Robert S. Katz[1], Hannah Bond[2], Jessica L. Polyak[2], Lauren Kwan[2] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

Background/Purpose: Many patients with the fibromyalgia syndrome (FMS) bring in disability forms for the practitioner to fill out or have Social Security Disability applications requesting medical records mailed to the office. We asked a group of patients with fibromyalgia whether they were capable of working full-time or part-time and what strategies they use to continue working, if they are able to.

Methods: 76 office patients with FMS (68 women and 8 men; mean age 50 ± 13) completed a questionnaire about the impact of FMS on their ability to work.

Results: 48.7% were not working, 38.2% were working full-time, and 13.2% were working part-time. The reasons for not working were: FMS, 51.4%; medical problems other than FMS, 43.2%; choice, 21.6%; retired, 16.2%; childcare or other homecare responsibilities, 5.4%. The reasons for working part-time instead of full-time were: choice, 70.0%; FMS, 30.0%; medical problems other than FMS, 10.0%. Non-working respondents who were asked how FMS affected their ability to work provided the following responses: so much pain that it limited their ability to work, 54.1%; so fatigued that they couldn't work the required number of hours, 48.6%; difficulty focusing or concentrating, 45.9%; frequently late to work or miss too much work, 13.5%; employers not sensitive to FMS impairments, 13.5%. Working respondents who were asked how they were able to work with FMS provided the following responses: not giving in to FMS, 64.1%; staying busy, 53.8%; keeping a positive attitude, 48.7%; exercise, 38.5%; eating well, 38.5%; getting enough sleep, 33.3%; pacing themselves or taking breaks, 30.8%; listening to their bodies, 30.8%; medications, 28.2%; taking one thing at a time, 28.2%; relaxing, 25.6%; trying alternative therapies, 25.6%; understanding FMS, 23.1%; and setting goals, 20.5%.

Conclusion: Pain, fatigue and cognitive dysfunction seriously limited the ability of fibromyalgia patients to work. Patients who were able to continue working utilized tactics including not giving up, staying busy, maintaining a positive attitude, exercise, eating well, getting enough sleep and other strategies. Those who are disabled generally felt they were incapable of successfully using those strategies.

1566

Fibromyalgia's Impact On Relationships. Robert S. Katz[1], Alexandra Small[2], Sharon M. Ferbert[3] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois Medical School, [3]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL

Background/Purpose: The Fibromyalgia Syndrome (FMS) can place a strain on patients' personal relationships. Having a close support network is helpful in coping with illnesses, but chronic pain, fatigue, and other invisible symptoms associated with FMS can damage connections with family, friends, and co-workers. In this study, we asked FMS patients about the nature of their ties to their families, friends, and co-workers.

Methods: As a part of an Internet survey administered by the volunteer community fibromyalgia organization, AFFTER (Advocates for Fibromyalgia Funding, Treatment, Education and Research), 763 female respondents with self-described FMS responded to questions on how FMS has affected their relationships with family, friends, and co-workers. Only women's

responses were analyzed to eliminate confounding by gender. The McNemar test was done to compare percentages, using a 0.05 significance level.

Results: The mean FMS respondent age was 50.2 ± 10.8 years. Only 12.5% of the FMS group reported that co-workers were supportive, and only 18.1% reported that in-laws were supportive. Support was better among other groups: spouses/significant others (59.1%), children (41.8%), close friends (44.8%), and parents (38.0%) ($p < 0.001$). Only 9.0% of FMS patients reported that co-workers understood their limitations, and just 12.6% of patients responded that their in-laws understood the limitations imposed by the illness, compared to higher percentages in spouses/significant others (52.0%), children (36.9%), and close friends (35.1%), Only 29.7% of parents ($p < 0.001$) had an understanding of the limitations imposed by fibromyalgia. FMS patients reported that they sometimes had seriously damaged relationships with spouses/significant others (14.6%) and close friends (11.6%).

Conclusion: Except for spousal understanding (59.1%), patients perceived that less than 50% of other groups were supportive. While some FMS patients viewed spouses/significant others and close friends as strong sources of support, others reported a significant strain on those relationships. Very frequently, FMS patients reported that co-workers, in-laws, and parents were not sympathetic or kind.

These results indicate that the perceived strain on relationships as a result of having FMS can be severe, especially among coworkers, in-laws, and parents of patients. The strain on relationships could partially be due to the fact that the symptoms of FMS are invisible and therefore are often underestimated among friends and relatives of FMS patients. Better education of the public about FMS and counseling for patients may help in repairing some of these broken relationships.

1567

Sleep Study with Armband Device in Fibromyalgia Patients: Fibromyalgia Patients Don't Rest Their Weary Muscles. Robert S. Katz[1], Alexandra Small[2], Ben J. Small[3] and Jessica L. Polyak[4]. [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois Medical School, [3]Rush University Medical School, Chicago, IL, [4]Rheumatology Associates, Chicago, IL

Background/Purpose: Patients with the fibromyalgia syndrome (FMS) have frequent awakenings and poor sleep efficiency. The purpose of this study is to evaluate sleep patterns in fibromyalgia patients using an armband monitoring device, so patients could monitor sleep at home.

Methods: 16 patients with fibromyalgia and 3 normal controls were given an armband sleep device manufactured by SenseWear. Patients wore the sleep monitor for at least 4 consecutive nights. We assessed duration of sleep, sleep efficiency, and the number of awakenings reported by the device and compared those with patient self-reported sleep patterns on a VAS scale of 1–10, with 10 being sleep problems that interfere completely with daily activities.

Results: Fibromyalgia patients consisted of 10 females and 6 males.

Table 1. Summary of the sleep study changes in the patients with fibromyalgia

Controls

# of hours lying down (mean)	# of hours sleeping (mean)	# of awakenings (mean)	Sleep Efficiency (mean)
6.24	5.35	4.67	86.30%

Fibromyalgia

# of hours lying down (mean)	# of hours sleeping (mean)	# of awakenings (mean)	Sleep Efficiency (mean)
7.68	5.73	11	75.70%

Conclusion: Fibromyalgia patients wearing a sleep monitor at home exhibit many awakenings and poor sleep efficiency compared with controls. Fibromyalgia patients moved around a lot at night, possibly preventing adequate rest of their painful muscles. Ambulatory sleep monitoring to evaluate sleep efficiency, including the number of awakenings and nocturnal movement, may be helpful in understanding the pathophysiology of the myalgias of FMS. Patients can easily monitor their number of awakenings and their sleep efficiency without spending an evening in a sleep lab, and sleep evaluations might help in assessing the effectiveness of therapies for fibromyalgia.

Disclosure: **R. S. Katz**, None; **A. Small**, None; **B. J. Small**, None; **J. L. Polyak**, None.

A Survey Study of Methotrexate Use by Rheumatologists and Their Patients with Rheumatoid Arthritis. Peter Nash[1] and Dave Nicholls[2]. [1]University of Queensland, Brisbane, Australia, [2]Coast Joint Care, Maroochydore, Australia

Background/Purpose: Methotrexate (MTX) is the anchor medication for the management of rheumatoid arthritis (RA); however there is limited patient-focused data available on the use of MTX, which could be used to improve RA outcomes. The primary objective of this study, termed MATRIX (Mapping Australian Treatment Reality Involving MTX), was to assess the use and perceptions of MTX by patients with RA. Secondary objectives included the assessment of patient-reported adverse events, the use of alcohol, folic acid, and biologic agents, and the perceptions of rheumatologists. Here we highlight tolerability to MTX, the perceptions of rheumatologists, and the use of biologic agents.

Methods: Rheumatologists ($N = 46$ of 50 completed surveys) and their patients with RA ($N = 1,313$ of 1,500 completed surveys; consecutively sampled; mean age 58.5 years, 72% female) completed pre-tested, voluntary, anonymous, self-administered questionnaires about their experience with MTX.

Results: Generally, patients reported taking oral MTX regularly (78% currently taking MTX, 92% orally, 70% $\geq$ 10 mg/week) and followed prescription instructions (91% took folic acid; 46% abstained from alcohol). However, 17% of patients had discontinued from MTX (13% within 1 to 2 years), mostly because of adverse events (12%). For patients taking MTX, adverse events (including nausea, headache, mouth ulcers, light-headedness, and diarrhea) were noted by 60% of patients, but events were experienced regularly (92%) and some were continual (13%). Most patients (72%) reported never missing a dose of MTX, but 6% miss at least 1 dose every 2 months and 8% intentionally and regularly 'take a break' from MTX, despite regular attendance at the clinic. Although rheumatologists were aware of tolerability to MTX, they generally underestimated the positive attitude that patients had towards their MTX therapy; for example 35% of patients would prefer to discontinue MTX but rheumatologists estimated 47% of patients would prefer to discontinue MTX. Rheumatologists also underestimated the proportion of patients who reported taking biologic agent 'monotherapy' (ie, without MTX; $\leq$ 20%); 29% of patients were on biologic agents, and of these, 29% were taking biologic agent 'monotherapy' and 70% were taking biologic agents in combination with MTX. The most common biologic agents were adalimumab, etanercept, and tocilizumab; tocilizumab use was higher with biologic agent 'monotherapy'. Of note, compared with all patients a greater proportion of patients taking biologic agents would prefer to discontinue MTX (43%).

Conclusion: MTX was well-used and positively perceived by patients with RA. However, our study highlights the need for rheumatologists to monitor patient use of RA medication with the aim of ensuring patients continue with, and maximize, their use of MTX therapy, particularly in combination with biologic agents.

1569

Optimizing Care for Patients with Rheumatoid Arthritis Newly Treated with Biologics by Evaluating Health Status with AIMS-2. Mie Fusama[1], Hideko Nakahara[2], Keisuke Kawamoto[2], Satoko Nozato[2], Midori Taguchi[2], Kohji Nishioka[2], Shinji Higa[2], Eiji Takeuchi[2], Kayoko Higashi[2], Masao Yukioka[3], Tsuyoshi Igarashi[2], Taro Kuritani[2], Keiji Maeda[2] and Yasushi Miura[1]. [1]Kobe University, Kobe, Japan, [2]NTT West Osaka Hospital, Osaka, Japan, [3]Yukioka Hospital, Osaka, Japan

Background/Purpose: Biologics significantly improve disease activity of rheumatoid arthritis (RA), however, patient global assessment (PGA) is not always improved in parallel with disease activity scores. Though the 2011 ACR/EULAR definitions of remission criteria for RA adopt Boolean-based definition, there are few reports analyzing health status and patient satisfaction in the view of PGA for patients with RA treated with biologics.

To assess the correlation between each component of health status including patient satisfaction and Boolean-based definition of PGA remission for RA, patients newly treated with biologics were investigated for 24 weeks.

Methods: Patients with RA treated with 8 mg/kg of tocilizumab (TCZ) every 4 weeks, 3mg/kg of infliximab (IFX) at 0, 2, 6 weeks and thereafter every 8 weeks, 25mg of etanercept (ETN) twice a week were participated in this study. Health status with Arthritis Impact Measurement Scale 2 (AIMS-2), disease activity scores (tender joint count (TJC), swollen joint count (SJC),

PGA and evaluator global assessment (EGA) on visual analogue scale (VAS), DAS28-CRP, SDAI, and CDAI) were assessed at week 0 and week 24. Comparison analysis of health status was performed between the patients who achieved the remission criteria of PGA (PGA=<1cm) and those who did not. The data analysis was performed utilizing Wilcoxon rank sum test.

Results: Sixty-six patients newly treated with biologics (TCZ: 39, IFX: 16, ETN: 11) were participated. Baseline characteristics were as follows: mean±SD of age (54.6±11.7 years), duration (6.7±7.2 years), SJC (10.9±7.5), TJC (10.8±6.1), PGA (5.4±2.4cm), EGA (5.5±2.1cm), CRP (2.4±2.6mg/dl), DAS28-CRP (5.3±1.3), SDAI (35.0±15.9), and CDAI (33.0±14.7), respectively. Twenty-seven of 66 patients (40.9%) achieved PGA remission. At baseline, there were no significant differences in age, duration, SJC, TJC, PGA, EGA, CRP, DAS28, SDAI, CDAI, or components of AIMS-2 between PGA remission and non-remission groups. At week 24, SJC, TJC, EGA, DAS28-CRP, SDAI, and CDAI were significantly lower in PGA remission group. At week 24, among health status, physical function, symptom, and role of AIMS-2 were significantly improved in PGA remission group compared with non-remission group. At week 24, patient satisfactory scores were significantly improved in PGA remission group except social interaction. Only the patient satisfactory scores for household and role (work) were significantly higher in PGA remission group compared with non-remission group at baseline.

Conclusion: For the patients with lower satisfactory scores in household and role (work) of health status at baseline, it is considered difficult to achieve PGA remission even when treated with biologics. Social interaction is not improved even when PGA remission is achieved. Therefore, nurses caring patients with RA are expected to assist patients to understand the importance of early treatment, support social activity, and set proper goal of treatment by evaluating health status.

1570

Discrepancies Between Disease Activity and Disease Burden. Margot J.M. Walter[1], Adriaan van 't Spijker[1], Annelieke Pasma[2], Johanna M.W. Hazes[3] and Jolanda J. Luime[1]. [1]Erasmus MC - University Medical Center, Rotterdam, Netherlands, [2]Erasmus MC University Medical Centre, Rotterdam, Netherlands, [3]Erasmus Medical Center, Rotterdam, Netherlands

Background/Purpose: In a longitudinal study aiming to use patient self-reported disease activity measured by three domains: functional ability (HAQ), disease activity (RADAI) and fatigue (VAS) to predict change in the subsequent physician assessed DAS28 we failed to demonstrate a sufficient association between both measures. This led to the question to why there is a difference between the self-reported measures and the DAS 28.

Objectives: The aim of this study was to explore the patient's perspective on the discrepancy between patient self-reported disease activity and physician assessed disease activity.

Methods: An exploratory qualitative methodology using focus groups was applied using a semi-structured interview scheme. Patients were recruited from the RAPPORT study (RA patients from one outpatient clinic in Rotterdam). Four focus groups were convened with 29 participants.

Results: Five themes were identified: balance, mental stress, medication use, feeling of being misunderstood and lack of physical fitness. Balance (1) between activity and rest was reported to easily affect the observed discrepancy. To manage activities patients used planning, adapting, avoiding, but also ignoring of symptoms. Ignoring could results in "off days", and a number of patients accepted high levels of self-reported disease activity as they did not wish to reduce their level of activities. Mental stress (2) was regarded especially affecting levels of fatigue. Medication intake (3) was felt to have a negative influence on the self-reported measures that was not picked up by the physician measure of disease activity, although some patients mentioned that the relationship between disease and use of medication was difficult to disentangle. Feeling misunderstood (4) by others impacted on well being, maybe not directly affecting levels of self-reported disease activity, but via emotional and cognitive appreciation of the already existing symptoms. Chronicity of the disease (e.g. remarks by family and friends such as "are you still suffering from RA?"), appearing not being ill and pain and fatigue ignored by doctors were discussed. Lack of physical fitness (5) was perceived as having a negative impact on pain and fatigue both in mental and a physical way. Although patients were well aware of the potential positive impact of physical exercise, stress reducing techniques and finding the right balance in activities and rest, for many it was also hard to implement these strategies effectively into daily life.

Conclusion: Discrepancies between self-reported disease activity and physician reported disease activity in patients with low levels of DAS28 could be themed in mental stress, lack of physical fitness, difficulty in finding balance between rest and activity, feeling misunderstood by others and medication use. Patients highlighted that the reasons of the high disease burden are difficult to explain, and different combination of factors affecting self-reported disease activity hold for individual patients.

Stress management, finding the right balance and tailored physical exercise may help to improve general well being in these patients enabling them to cope better with their rheumatoid arthritis.

"Pain and Fatigue in Adult Patients with Rheumatoid Arthritis - Associations with Demographic Factors, Disease Related Factors, Body Awareness, Emotional and Psychosocial Factors". Helena Lööf[1], Fredrik Saboonchi[2], Elisabet Welin Henriksson[3], Staffan Lindblad[4] and Unn-Britt Johansson[1]. [1]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Division of Medicine, Stockholm, Sweden, [3]Karolinska Institutet, Department of Neurobiology, Care Sciences and Society., Stockholm, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: Patient's with Rheumatoid arthritis highlight fatigue as a major concern, as well as pain as a priority for improvement. Previous study has found that significant fatigue occurs in up to 70 percent of patients with Rheumatoid arthritis, and 82 percent of Rheumatoid arthritis patients (who consider their disease to be "somewhat to completely controlled") continue to report moderate to severe pain. Variables that are found to be related to fatigue are illness-related aspects, physical functioning, cognitive/emotional functioning and social environmental aspects. Pain affects quality of life, and the psychological well-being of the individual living with Rheumatoid arthritis is significantly affected by the fundamental life changes and the complexity of the disease process. Emotions have been pointed out as having a key role in the adjustment among people with Rheumatoid arthritis, and in the context of chronic pain in general. Furthermore, the tendency to focus attention on bodily sensations and internal stimuli, i.e. body awareness, has been associated with amplification of both somatic and emotional distress. Negatively toned self-focused bodily attention has been linked to less effective decision making strategies and worse adherence. The purpose of this study was to examine perceptions of fatigue and pain in adult patients with Rheumatoid arthritis and to investigate association with demographic factors, disease related factors, body awareness, emotional and psychosocial factors.

Methods: Data were collected from a convenience sample of patients with Rheumatoid arthritis recruited from a Rheumatology clinic. Eligible for inclusion were patients between 20–80 years diagnosed with Rheumatoid arthritis for at least a period of six months, according to American College of Rheumatology criteria for Rheumatoid arthritis. The patients filled out questionnaires, fatigue was measured by using the Multidimensional Assessment of Fatigue (MAF) scale, and the Visual Analogue Scale (VAS) was used to assess components of pain. To evaluate factors related to fatigue and pain, multiple stepwise linear regression analysis were performed. In the first step a univariate ANOVA was performed for all relevant independent factors. In the next step a backwards stepwise regression was performed. When the final model was found, the model assumptions was evaluated based on the residual diagnosis.

Results: 120 patients with Rheumatoid arthritis participated in the study (female 86%, $<$ 45 years 22.5%, 46–65 years 42.5%, $>$ 65 years 35 %). Fatigue in Rheumatoid arthritis associate significant with no smoking, (p=0.021), disease activity, DAS 28 (p=0.049), body awareness, BAQ (p=0.006) and PANAS, positive affect (p=0.008). The pain in Rheumatoid arthritis was significantly associated with health related quality of life, EQ-5D (p=0.008) and disease activity, DAS 28 (p=0.001). The final models for fatigue and pain were considered acceptable. Adjusted R-square were 28.6 % for fatigue and 50.0 % for pain.

Conclusion: This study identifies that in patients with Rheumatoid arthritis fatigue and pain appears to be associated with disease related factors. Furthermore, fatigue was related to body awareness and emotional factors.

Developing a Health Literacy Universal Precautions Toolkit for Rheumatology. Leigh F. Callahan[1], Victoria Hawk[2], Kimberly A. Broucksou[2], Betsy Hackney[2], Deb MacDonald[3], Lindsay Penny Prizer[1], Beth L. Jonas[2], Thomas K. Bauer[4], Rima E. Rudd[5], Cindy Brach[6] and Darren Dewalt[2]. [1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina Chapel Hill, Chapel Hill, NC, [4]Winston Salem, NC, [5]Harvard School of Public Health, Boston, MA, [6]Agency for Health Care Research and Quality, Rockville, MD

Background/Purpose: Research supports that health disparities exist between those with limited versus adequate literacy skills. Limited health literacy is associated with medication errors, increased healthcare costs, and inadequate care for chronic health conditions. In 2010, our team developed and tested a Health Literacy Universal Precautions Toolkit (HLUPTK) for use in primary care practices. Studies in rheumatology have demonstrated a significant number of patients have low literacy. The purpose of this project was to adapt the HLUPTK for use in rheumatology practices (HLUPTK-R).

Methods: We reviewed the HLUPTK and its 20 tools to determine areas for adaptation, expansion and discipline specific customization. An environmental scan was conducted to identify and assess existing health literacy tools, resources and well-designed education materials for use in the rheumatology setting. Gaps in rheumatology specific materials were also identified. A discipline specific toolkit was developed and tested in 4 rheumatology practices of various size and locations (urban vs. rural). A study team member visited all practices prior to testing. Over the 2-month testing period, practice staff reviewed the toolkit, conducted a health literacy assessment, and selected and tested a small-scale implementation of 2 or more tools. Practices completed questionnaires and participated in conference calls with the study team pre- and post- testing. They also completed Plan-Do-Study-Act (PDSA) worksheets for tested tools. Based on practice feedback and the testing results, the toolkit was revised.

Results: A new toolkit, HLUPTK-R, has been developed. Rheumatology specific resources have been added including a teachback video focusing on a patient with rheumatoid arthritis, a rheumatology-specific plain language guide, medication aides and education materials designed for rheumatic diseases. Based on feedback from the practices, the tools were shortened and reformatted. In addition, 2 new tools were developed and included: one for communicating care to other physicians and another for planning small changes in the practice setting. Furthermore based on key changes adopted by our practices, two new Quick Start guides were developed – one focused on patient encounters and the other on the practice setting. The Quick Start guides are designed to introduce the practice to the concepts of health literacy and making small changes without the need for coaching that the more comprehensive HLUPTK-R appears to require.

Conclusion: This new toolkit offers clinicians and staff in rheumatology practices a step-by-step approach to improving healthcare for patients of all literacy levels using discipline specific examples and tools. HLUPTK-R and quick start guides are now available for broader use and testing.

Baseline Screening Recommendations for Rheumatoid Arthritis Patients Treated with Disease Modifying Anti-Rheumatic Drugs: Does an Educational Intervention Change Practice in an Outpatient Clinic? Debra C. Lloyd[1], John N. Mecchella[2] and Daniel Albert[3]. [1]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [2]Dartmouth Hitchcock Medical Center, Lebanon, NH, [3]Dartmouth-Hitchcock Medical Center, Geisel School of Medicine, Lebanon, NH

Background/Purpose: In 2008, the American College of Rheumatology (ACR) developed recommendations for use of non-biologic and biologic DMARDs in the treatment of rheumatoid arthritis (RA). The purpose of this study was to assess change in baseline screening practices following completion of an educational intervention reflecting the ACR recommendations.

Methods: An educational intervention designed to update providers in and new recommendations from the ACR was completed in an outpatient rheumatology clinic in September 2009.

Staff education activities included: 1) individual review of the ACR 2008 Recommendations for the Use of Non-biologic and Biologic Disease-Modifying Antirheumatic Drugs in Rheumatoid Arthritis (DMARD); 2) development and review of "DMARD reference" sheets; 3) formal presentation of key points from the journal article to clinic staff.

Retrospective chart reviews were completed on new RA patients seen in a hospital-based outpatient clinic for a six month period immediately before and after review of the guidelines. Documentation of recommended baseline screening test results (laboratory studies, imaging and tuberculosis testing) for DMARD was assessed.

Inclusion criteria: 1) New patient to rheumatology between 04/01/2009 and 03/31/2012 (NPW); 2), rheumatoid arthritis, inflammatory arthritis (ICD 9 codes 714.0 and 714.9); 3) DMARD (methotrexate or leflunomide) therapy planned.

Exclusion criteria: 1) Alternate diagnosis after initial or subsequent evaluation; 2) no DMARD (methotrexate or leflunomide) treatment; 3) follow up appointment(s) cancelled or not attended; 4) not a new patient to rheumatology clinic; 5) current therapy with DMARD (prescribed at alternate site).

Baseline screening data for DMARDs and biologic agents was consistently identifiable in the patient record.

A file for all patients with diagnosis code of 714.0 and 714.9, seen anywhere in the hospital/clinic system between 10/2007 and 12/2010, arriving as an NPW in rheumatology was reviewed. There were 256 patients seen between 04/01/2009 and 03/31/2010. 184 records were reviewed. Data for 144 records were excluded and data from 40 records (n= 20 pre-intervention; n= 20 post-intervention) were included.

Results: Comparison of the results (CBC, LFTS, CREA, ALB, HEP B, HEP C, and CXR) for the two groups was completed using a χ^2 analysis and Fisher's exact test and there was no significant difference between pre and post scores.

Baseline screening for DMARD therapy was completed in $\geq$ 90% of the baseline for CBC, LFTs, CREA and ALB in both the pre and post intervention periods. Hepatitis B and C screening was completed in $\leq$ 25% of the pre and post intervention screenings. CXR was completed in 20% of the pre-intervention baseline screenings and 50% of the post-intervention screenings but this difference did not achieve statistical significance.

Conclusion: Completion of recommended baseline screening testing for patients receiving DMARD treatment did not increase after the educational intervention. This is constant with other failed attempts to change clinician behavior through short term educational interventions. This suggests that incorporating work flow redesign into the electronic medical record is likely to be more effective.

The Correlation of Disease Activity, Functional Status and Quality of Life with Sleep Disturbance and Balance Status in Ankylosing Spondylitis (AS). Mehmet Tuncay Duruoz, Zuhre Sari Surmeli and Esra Topcu. Celal Bayar University Medical School, Manisa, Turkey

Background/Purpose: To assess the correlation of disease activity, functional and metrological status and quality of life with sleep quality and balance status in AS.

Methods: Subjects with Ankylosing Spondylitis (AS) according to Modified New York criteria were recruited into the study. Disease activity was assessed with BASDAI. Functional status (BASFI), quality of life (ASQoL) and metrological score (BASMI) were assessed. Beck Depression Inventory (BDI), Pittsburgh Sleep Quality Index (PSQI), Leeds Assessment Scale of Handicap (Leeds Scale) were managed. Berg Balance Scale, Tinetti Balance Assessment Tool and VAS-fear of falling were used to asses patients' balance.

Results: Forty two AS patients (36 male) with mean age 38,38 (SD=11,28) years were recruited. The disease duration was 139,06 (SD=100,37) months. There were significant correlations between BASDAI and Beck Depression Inventory (p=0,01), Pittsburgh Sleep Quality Index (p=0,01). BASDAI scores were not correlated with Tinetti Balance Assessment Tool (p=0,107), VAS-Fear of Falling (p=0,111), Leeds Scale (p=0,072) and Berg Balance Scale (p=0,164). BASFI had significant correlations with Beck Depression Inventory (p=0,01), Pittsburg Sleep Quality Index (p<0,001), Tinetti Balance Assessment Tool

(p=0,028), Leeds Scale (p<0,001) and Berg Balance Scale (p=0,001). BASMI had significant correlation with Beck Depression Inventory (p=0,007), VAS-fear of falling (p=0,011), Leeds Scale (p=0,005) and Berg Balance Scale (p<0,001). BASMI was not correlated with Pittsburg Sleep Quality Index (p= 0,124) and Tinetti Balance Assessment Tool (p=0,342). ASQoL had significant correlation with Beck Depression Inventory (p<0,001), Pittsburgh Sleep Quality Index (p= 0,005), Tinetti Balance Assessment Tool (p= 0,042), Leeds Scale (p=0,001) and Berg Balance Scale (p=0,023).

Conclusion: Although disease activity had good correlation with depression and sleep disturbances it had not significant correlation with patients' balance status. The functional level which shows disease severity had significant correlation with sleep disturbances and balance status in AS. Quality of life was worse in patients with sleep disturbance and low balance status.

The Impact of Targeted Exercise Intervention On Health Outcomes in Rheumatoid Arthritis. Laura J. Durcan[1], Fiona Wilson[2], Finbar (Barry) D. O'Shea[1] and Gaye Cunnane[1]. [1]St James's Hospital, Dublin, Ireland, [2]Trinity College, Dublin, Ireland

Background/Purpose: Increased morbidity and mortality are recognized consequences of rheumatoid arthritis (RA). In addition to chronic inflammation, reduced physical activity may contribute to adverse outcomes in these patients. This study was undertaken to assess the impact of a targeted, exercise intervention on health outcomes in RA.

Methods: Patients with established, well-controlled RA were recruited. Baseline assessments relating to cardiovascular risk factors, body composition, disability, sleep quality and physical activity were ascertained using standardized measures. Exercise was then prescribed in order to a) target individual functional limitations as identified by the Health Assessment Questionnaire (HAQ) and b) increase each patients' physical activity according to the American College of Sports Medicine recommendations.

Patients were assessed every 3 weeks for 12 weeks by a rheumatologist and physical therapist. Compliance was aided by the provision of an exercise diary and a pedometer. All parameters were re-measured at the completion of the 12 week program. Ethical approval was obtained from the St James's Hospital Ethics Committee. Statistical analysis was undertaken using SPSS 18.

Results: Forty patients with RA (mean age 46 years) (SD8.0) and mean disease duration of 15.6 years (SD 10.9) were included. Thirty (75%) were seropositive and 38 (95%) had evidence of erosive disease. All fulfilled the ACR diagnostic criteria for RA. Twenty nine (72.5%) were current/ex-smokers. All (100%) were taking disease-modifying treatment; 10 (25%) were on biologic agents. Mean body mass index was 27.1 (SD 5.2). At baseline, only 2 (5%) were involved in any form of exercise.

	Pre-intervention	Post intervention	Significance
HAQ	0.81 (SD 0.38)	0.53 (SD 0.54)	0.000
Grip (lbs pressure) (R)	28.87 (SD 18.29)	33.87 (SD 18.19)	0.000
Grip (lbs pressure) (L)	25.15 (SD 15.83)	28.23 (SD 19.54)	0.000
Pain (VAS)	28.66 (SD 21.79)	20.83 (SD18.03)	0.000
Stiffness (VAS)	31.71 (SD 22.77)	23.83 (SD 23.82)	0.000
EBBS (range 43–172)	125.9 (SD 5.5)	131.5 (SD 9.4)	0.000
PSQI (range 0–21)	7.21 (SD 4.45)	6.22 (SD 3.58)	0.000
FSS (range 1–81)	37.89 (SD 25.58)	26.64 (SD 21.88)	0.000
FFM (kg)	44.76 (SD 9.38)	45.40 (SD 9.22)	0.005
BMI (kg/m^2)	27.15 (SD 5.23)	26.97 (SD 4.93)	0.316
Total cholesterol(mmol/L)	4.86(SD 0.83)	4.72 (SD 0.68)	0.018
LDL- cholesterol (mmol/L)	2.78 (SD 0.72)	2.65 (SD 0.59)	0.018
HDL- cholesterol (mmol/L)	1.44 (SD 0.33)	1.42 (SD 0.34)	0.571

EBBS: Exercise barriers and benefits scale, PSQI: Pittsburgh Sleep Quality Index, FFS: Fatigue Severity Scale, FFM: Fat Free Mass

Conclusion: A 12 week targeted exercise program yielded significant improvements in strength, pain, joint stiffness, sleep, fatigue and lipid profile, impacting on both health and quality of life in patients with RA. Although fat free mass measurements improved significantly, there was no major change in BMI suggesting that dietary adjustments may be a necessary accompaniment to a sustained exercise program in order to effect weight loss in overweight patients with RA.

Identifying Subgroups of Rheumatoid Arthritis Patients Based On Levels of Pain, Disability, and Depression. Taylor Draper[1], Sarah R. Ormseth[1], M. Custodio[2], M.H. Weisman[3], M.R. Irwin[2] and Perry M. Nicassio[2]. [1]Loma Linda University, Loma Linda, CA, [2]UCLA, Los Angeles, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA

Background/Purpose: Pain, disability, and depression are present in various degrees in patients with Rheumatoid Arthritis (RA). In spite of meeting the same diagnostic criteria, some patients with RA report much less pain, disability, and little or no psychological distress than others. The current study seeks to ascertain potential subgroups of patients in a RA sample based on levels of pain, disability, and depression and to identify factors associated with patient clustering.

Methods: The sample included 100 patients with confirmed RA participated in an assessment of their disease activity, pain, depression during an evaluation prior to participating in a randomized controlled trial. Self-report measures included the Rapid Assessment of Disease Activity in Rheumatology (RADAR), the SF-36 social functioning Scale, the Helplessness and Internality Subscales of the Arthritis Helplessness Index (AHI), the Active and Passive Pain Coping Scales of the Pain Management Inventory (PMI), the Center for Epidemiological Studies Depression Scale (CES-D), the Pittsburgh Sleep Quality Index (PSQI), Perceived Stress Scale (PSS), and the Health Assessment Questionnaire (HAQ). Cluster analysis was used in this research to ascertain the existence of subgroups of patients in a Rheumatoid Arthritis sample based on these variables.

Results: Two clusters were defined: a low-functioning group characterized by high levels of pain, disability, and depression (n = 73) and a high-functioning group characterized by low levels of pain, disability, and depression (n = 27). Analysis of Variance (ANOVA) confirmed differences between clusters on these health status factors, except disability. A second series of ANOVAs revealed that the high-functioning subgroup had greater social functioning, better sleep quality, and less passive coping and perceived stress than the low-functioning group. Hierarchical multiple regressions indicated that the best discriminators of subgroup membership were sleep quality and perceived stress.

Conclusion: These results indicate significant heterogeneity in RA patients. The data also suggest that different approaches to patient management, particularly intervention strategies aimed at reducing perceived stress and improving sleep quality, may be beneficial for patients who are functioning poorly in the face of this condition.

Barriers to Recruit Unaffected Family Members of Patients with Rheumatoid Arthritis. Axel Finckh[1], A. Debost-Legrand[2], Martin Soubrier[3], I. von Muehlenen[4], I. Creveaux[2], JJ Dubost[3], MH Papon[2], H. Ayadi[5], P. Migliorini[6], E. Petit-Teixeira[7], F. Cornélis[2] and Eprac[8]. [1]Geneva University Hospitals, Geneva 14, Switzerland, [2]GenHotel-Auvergne, Clermon-Ferrand, France, [3]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [4]Universitäts-Poliklinik, Felix-Platter Spital, Basel, Switzerland, [5]Sfax university, Sfax, Tunisia, [6]Pisa university hospital, Pisa, Italy, [7]GenHotel-Evry-EA3886, Evry, France, [8]Clermont-Ferrand, France

Background/Purpose: Prospective studies are needed to answer key questions on rheumatoid arthritis (RA) screening in at risk populations: (1) How accurately does risk factor assessment identify persons who will later develop RA? (2) Does screening and subsequent early treatment improve long-term outcomes in RA? Such studies could focus on first degree relatives of RA patients (FDR-RA), as they have up to a 10 fold increase of RA incidence compared to the general population. The number of potential FDR per RA patient has been measured to be 6.9 per RA patient (J Rheumatol 2008;35:790–6).

The aim of this report is to describe the barriers encountered recruiting healthy FDRs-RA, without clinical evidence of synovitis at inclusion, in a prospective cohort study of individuals at increased risk of developing RA.

Methods: The initial recruitment strategy for this prospective cohort of individuals at increased risk of developing RA relied on the diseased relatives with RA. Patients with RA were informed of the possibility of a free screening test of RA susceptibility for their unaffected family members. We report the rate of FDR-RA enrollment into the study resulting from direct promotional efforts targeted to RA patients.

All participants are assessed for the absence of active synovitis (physical exam and/or questionnaire), for risk factors for RA and for biomarkers of RA susceptibility at inclusion. Participants are followed prospectively until they develop (or not) RA. In case of new symptoms suggesting incident synovitis, clinical assessment is performed by a Rheumatologist.

Results: In 2010–11, the new screening study was advertised massively amongst RA patients in Switzerland and France per mail, patient conferences, health fares and articles in patient journals. The 6000 RA patients in the Swiss cohort of RA patients and 5300 RA patients of the French patient association (AFP) were directly incited to invite their FDR to participate in this screening study. After ~2 years of various promotional efforts to RA patients, we counted that less than 30 FDRs-RA enrolled via their diseased parent. Based on discussion with participants and RA patients, we hypothesize that RA patients are unwilling to promote strongly a screening study to their FDRs, which underscores the hereditary risk associated with this diagnosis and may arise to feelings of guilt related to the possibility of transmitting RA.

To date, a total of 977 RA-FDRs have been included: 560 in Switzerland and 317 in France, mainly through direct advertisement to unaffected FDRs in pharmacies. At inclusion, mean age is 45 years (SD 15), 74% are female and 95% are Caucasian. On average, these individuals have 1.2 direct relatives with RA.

Conclusion: We have observed an unexpected low inclusion rate of FDRs in response to promotional efforts targeted towards the diseased relative with RA. Informal investigation strongly suggests that the main explanation is the lack of transmission of information from the RA patients to their unaffected FDR, which appears to be linked to a feeling of guilt in relation with a hereditary disease. More investigation is needed on the transmission of information within RA affected families in order to enhance future preventive strategies.

How Disease Activity Trajectories Affect the Willingness to Change Treatment. Paul Falzer[1] and Liana Fraenkel[2]. [1]VA Connecticut Healthcare System, New Haven, CT, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT

Background/Purpose: Disease activity (DA) can change markedly over a short period, for a variety of reasons. The changes influence clinical practice and affect the willingness of patients to change their current treatment (WCT). However, impact cannot be examined in a cross-sectional study and is difficult to explore when DA is measured at only two points. This study measured DA at multiple points, distinguished observation-level DA from its patient-level trajectory, and examined the influence of both on WCT.

Methods: RA patients who were taking at least one DMARD and currently experiencing at least moderate pain were recruited from community-based rheumatology practices. They participated in four interviews over a six month period. DA was measured at each interview, using the Rapid-4. Scores were rounded up to single points. Patient-level trajectories were created, consistent with the rules described in Table 1, and each trajectory was coded as a nominal category. WCT was measured at each interview on a 10-point scale. Patient-level trajectory and observation-level Rapid-4 were examined by linear mixed models and were compared using AIC, a lower-is-better goodness of fit test.

Trajectory	Rule	N	Percent
Stable	All scores are within 1 full point on the Rapid-4	65	46
Better	>1 point difference between highest and lowest score; low score occurs later	28	20
Worse	>1 point difference between highest and lowest score; high score occurs later	24	17
Fluctuating	First and last scores are within 1 point; interim scores are >1 higher or lower	25	18

Results: N=142 patients participated. Their mean age was 59, mean duration of RA was 12.8 years; 86% were female and were 81% were Caucasian. As the table indicates, 46% of patients were stable, 20% were getting better, 17% were getting worse, and 18% were fluctuating. Observation-level Rapid-4 was significantly associated with WCT (F=5.42, df= 3/433, p=.001). Its interaction with the patient-level trajectory was also significant (F=2.55, df=15/354, p=.001) and offered the best fit (AIC is about 2% lower). Trajectory alone was non-significant and provided the worst fit of the 3 models. The figure shows estimated WCT at each Rapid-4 category for the stable and fluctuating trajectories. One exhibits a small

variation from mild to moderate; the other increases markedly at mild, then levels out.
Conclusion: Patient- and observation-level DA have a combined influence on WCT. Despite marked differences, stable and fluctuating trajectories would not be distinguished if DA were assessed at only two points.

Why Do We Need to Pilot Interventions? Essential Refinements Identified During Pilots of a Fatigue Intervention. Emma Dures[1], Nicholas Ambler[2], Debbie Fletcher[3], Denise Pope[3], Frances Robinson[4], Royston Rooke[4] and Sarah Hewlett[1]. [1]University of the West of England, Bristol, United Kingdom, [2]Frenchay Hospital, Bristol, United Kingdom, [3]University Hospitals Bristol, United Kingdom, [4]University of Bristol, Bristol, United Kingdom

Background/Purpose: An RCT showed a 6 week group cognitive-behavioural (CB) intervention for RA fatigue self-management was effective, when delivered by a clinical psychologist.[1] Few rheumatology teams have clinical psychologists; therefore the intervention was re-formatted for delivery by the rheumatology team, in preparation for a multi-centre RCT. We piloted the feasibility of the materials, training, and support for clinicians, plus the acceptability of the intervention for patients.

Methods: The clinical psychologist from the original intervention worked with researchers, patient partners and clinicians to re-format a clinician-led version. A clinician's programme manual was developed with timetables, session aims, example scripts and patient handouts. A 2-day training for the rheumatology nurse and occupational therapist was developed, focusing on CB approaches (eg Socratic questioning, goal setting), managing groups, and using the session tools (eg activity diaries). They then co-delivered the intervention to 2 patient cohorts, first supervised by the clinical psychologist, then independently with supervised debriefing. On-going refinements were made, based on a cycle of feedback, review and de-briefing during all stages of the piloting.

Results: Materials for non-CB specialists: Some material has been re-written to be more suitable for non-CB specialists to deliver (eg 'sabotage' re-written as 'self-defeating behaviours'); links between sessions, explaining how they build on each other and relate to CB theory, have been made more explicit.

Training: Clinicians expressed anxiety about using new CB skills, and the need to respond rapidly to differences in session discussions that inevitably occur between different patient groups. Thus training will be increased to 4 days, with more focus on CB theory (eg formulating helpful questions) and more practice delivering sessions (eg explaining metaphors).

Support: An increased emphasis on the use of supervised debrief/reflection emerged; thus a guide to debriefing has been added to the manual, and extra time allocated. Proposed clinical supervision/quality control has

been increased by adding supervision of any sessions that clinicians find challenging in their second pilot.

Acceptability: Feedback from the 10 patients was positive. Mean scores on rating scales (0–10, higher scores representing greater acceptability) were: satisfaction 8.8, encouragement from clinicians 9.0, sessions well-run 9.0, helpfulness of handouts 8.4, and recommendation of the intervention to other patients 8.8.

Conclusion: Piloting interventions prior to RCT is recommended but there is little evidence about how it influences development. Iterative feedback during piloting led to essential refinements, particularly in training and support, when re-formatting the CBT intervention for delivery by non-CB specialists. It is now ready for formal testing in an RCT.

The Relationship Between Perceived Cognitive Dysfunction and Objective Neuropsychological Performance in Persons with Rheumatoid Arthritis. So Young Shin, Patricia P. Katz and Laura J. Julian. University of California San Francisco, San Francisco, CA

Background/Purpose: There is an increased appreciation of the burden of cognitive impairment in persons with rheumatoid arthritis (RA). Research shows a gap between perceived cognitive dysfunction and objective neuropsychological performance in persons with chronic diseases. This study explored this relationship in persons with RA.

Methods: Individuals from a longitudinal cohort study of RA participated in a study visit that included physical, psychosocial, and biological metrics. Subjective cognitive dysfunction was assessed using the Perceived Deficits Questionnaire (PDQ; range 0–20, higher score=greater impairment). Objective cognitive impairment was assessed using a battery of 12 standardized neuropsychological measures yielding 16 indices. On each test, subjects were classified as 'impaired' if they performed 1 SD below age-based population norms. A total cognitive impairment score (range 0–16) was calculated by summing the transformed scores (higher score=worst impairment). Multiple regression analyses controlling for gender, race, marital status, income, education, disease duration, disease severity, depression, and fatigue were conducted to identify the relationship between objective and subjective cognitive measures.

Results: 120 subjects with mean ($\pm SD$) age of 58.5 (± 11.0) years were included. Sixty four percent were female, 82% were white, and 7% met criteria for major depressive disorder. Mean educational level was 15.3 (± 2.2) years and disease duration was 19.9 (± 11.1) years. Mean total cognitive impairment score was 2.5 (± 2.2, range 0–10). The proportion of persons classified as cognitively impaired on each test ranged from 8% (semantic fluency test) to 28% (design fluency test). Mean PDQ score was 5.8 (± 3.8, range 0–16). In the multivariate analysis, there was no significant relationship between PDQ score and total cognitive impairment score. However, depression and fatigue ($\beta=0.31$, $p<0.001$; $\beta=0.32$, $p=0.001$) were significantly associated with the PDQ score.

Conclusion: There was no significant relationship between perceived cognitive dysfunction and objective neuropsychological performance in this cohort. Depression and fatigue were significantly associated with perceived cognitive dysfunction. Findings emphasize the gap between subjective and objective measures of cognitive impairment and the importance of considering psychological factors in the context of cognitive complaints in clinical settings.

The Association Between Symptoms, Pain Coping Strategies, and Physical Activity Among People with Symptomatic Knee and Hip Osteoarthritis. Susan L. Murphy[1], Anna Kratz[1], David A. Williams[2] and Michael E. Geisser[1]. [1]University of Michigan, Ann Arbor, MI, [2]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: Effective use of coping strategies by people with chronic pain conditions is associated with better functioning and adjustment to chronic disease. Although the effects of coping on pain have been well studied, less is known about how specific coping strategies relate to actual physical activity patterns in daily life. The purpose of this study was to evaluate the effects of different coping strategies on symptoms and physical activity patterns in a sample of adults with knee and hip osteoarthritis (N = 44).

Methods: Physical activity was assessed by wrist-worn accelerometry; coping strategy use was assessed by the Chronic Pain Coping Inventory. We hypothesized that the use of coping strategies that reflect approach behaviors (e.g., Task Persistence), would be associated with higher average levels of physical activity, whereas avoidance coping behaviors (e.g., Resting, Asking for Assistance, Guarding) and Pacing would be associated with lower average levels of physical activity. We also evaluated whether coping strategies moderated the association between momentary symptoms (pain and fatigue) and activity. We hypothesized that higher levels of approach coping would be associated with a *weaker* association between symptoms and activity compared to lower levels of this type of coping. Multilevel modeling was used to analyze the momentary association between coping and physical activity.

Results: We found that higher body mass index, fatigue, and the use of Guarding were significantly related to lower activity levels, whereas Asking for Assistance was significantly related to higher activity levels. Only Resting moderated the association between pain and activity. Guarding, Resting, Task Persistence, and Pacing moderated the association between fatigue and activity.

Conclusion: This study provides an initial understanding of how people with osteoarthritis cope with symptoms as they engage in daily life activities using ecological momentary assessment and objective physical activity measurement.

1582

Long Term Costs and Cost-Effectiveness of an Integrated Rehabilitation Programme for Chronic Knee Pain. Mike Hurley[1] and Dr Nicola E. Walsh[2]. [1]St George's University of London, London, United Kingdom, [2]University of the West of England Bristol, Bristol, United Kingdom

Background/Purpose: Management of chronic knee pain incurs enormous direct and indirect healthcare costs. Enabling Self-management and Coping with Arthritic knee Pain through Exercise (ESCAPE-knee pain) is an integrated rehabilitation programme that, in the short term at least, is more clinically and cost-effectiveness than usual primary care. Unfortunately, the long term costs and cost-effectiveness of the programme is unknown and need to be evaluated. We continued to follow ESCAPE-knee pain participants for 2½ years after completing the programme, to establish the long term knee pain-related costs and cost-effectiveness of the programme.

Methods: 418 participants were randomised to remain on usual primary care or receive the ESCAPE-knee pain programme (individually or groups of 8 participants). Physical function (using WOMAC function sub-score) and knee pain-related health and personal costs (using Client Services Resources Inventory) were assessed at regular time points for 2½ years after completing the programme.

Missing data were imputed using multiple imputation. Mean differences in total cost (95% confidence interval) were obtained from non-parametric bootstrapped linear regression (1000 replications). Costs were estimated from a health and social care perspective in 2003/2004 prices. Costs were discounted at 3.5%.

Cost-effectiveness acceptability curves (CEAC) estimated the probability ESCAPE-knee pain had of greater net monetary benefit compared with usual care, over a range of monetary values a healthcare provider might be prepared to pay for a sustained, clinically meaningful, improvement in function (defined as ≥15% increase from baseline WOMAC-function score) after 2½ years.

Results: 250 participants (60%) were followed-up for 2½ years. Participating on ESCAPE-knee pain cost £224/person (£184-£262). Compared to those who remained on usual care, 2½ years after completing the ESCAPE-knee pain programme a significantly higher proportion (+14%) of participants maintained clinically meaningful improvement in function, and lower health and social care costs. CEAC showed there was a high probability (80–100%) ESCAPE-knee pain was more cost-effective than usual care in producing sustained clinically meaningful improvement in function.

Conclusion: ESCAPE-knee pain is a low-cost intervention with sustained clinical and economic benefits compared to than usual primary care. These conclusions need to be considered given the trial's high attrition rate and low power. Attrition rates are always high in trials with long term follow-up, and economic outcomes are rarely, if ever, used to power studies. Moreover, given

that large-scale, long-term trials are very expensive and complex, few similar studies will be performed and will suffer similar limitations. These results, therefore, are a good estimation of long term clinical and economic outcomes, and contribute to the pool of data from other trials of this chronic condition.

Therapist and Patient Perspectives On Exercise Adherence: Are We On the Same Page? Jill R. Blitz[1], Talitha Cox[2] and Amber Richards[3]. [1]Children's Hospital Los Angeles, Los Angeles, CA, [2]Children's Hospital of Los Angeles, Los Angeles, CA, [3]Children's Hospital, Los Angeles California, Los Angeles, CA

Background/Purpose: Exercise is essential to the health and function of children with chronic diseases. Patient adherence to home exercise programs has long been an obstacle for physical and occupational therapists.

Objectives: 1.To compare the perceptions of patient adherence to home exercise programs between therapists and patients. 2. To compare differences between the perceptions of rheumatology patients and patients with other diagnoses. 3. To gain a better understanding of the barriers to exercise and tools used to overcome these barriers in a pediatric physical and occupational therapy setting.

Methods: A survey was administered to physical and occupational therapists who work at a pediatric tertiary care facility. A similar survey was given to outpatients receiving physical and/or occupational therapy at the same facility, and patients seen in the Rheumatology clinic. The surveys included demographic information, frequency of exercise and a list of barriers and facilitators to choose from. Fisher's exact statistical analysis was used to compare responses of rheumatology patients versus non-rheumatology patients.

Results: 70 patients were surveyed; 36 from the outpatient physical and occupational therapy department and 34 from the Rheumatology clinic. The average age was 13.5(SD 3.8). 31 therapists completed the survey.

67% of therapists recommend that patients do their exercises every day, 20% 5x/week and 10% 3x/week. 40% of patients reported being noncompliant, 30% reported doing their exercises 5–7x/week, 20% reported 3–4x/week and 10% 1–2x/week.

The top cited barriers that therapists reported were patients' lack of interest, forgetting to do their exercises and lack of family support. Top cited barriers for patients included pain, forgetting to do their exercises and boredom. For facilitators, therapists felt that making age and developmentally appropriate exercises, a written home exercise program and family/community based activities were most helpful. Patients chose participating in sports or dance, integrating exercise into daily life and exercising with family as the most important facilitators of adherence.

There were no statistically significant differences in responses between rheumatology and non-rheumatology patients (p> 0.05).

Conclusion: Therapists and patients have different perspectives on adherence to exercise, but also agree on some aspects. The reasons for adherence or non-adherence were not dependent on diagnosis. Consideration of patients' perceived barriers and facilitators when planning home exercise programs may improve patients' adherence.

Validity of the Nurses Health Study II Physical Activity Questionnaire (NHSPAQ) in Estimating Physical Activity in Adults with Rheumatoid Arthritis (RA). Maura D. Iversen[1], Thomas Quinn[2] and Michelle A. Frits[3]. [1]Northeastern University, Department of Physical Therapy, and Brigham & Women's Hospital, Harvard Medical School, Boston, MA, [2]Northeastern University, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA

Background/Purpose: An accurate assessment of physical activity (PA) is critical to manage rheumatoid arthritis (RA). Accelerometry is an objective measure of PA but is not widely used clinically. The Nurses Health Study Physical Activity Questionnaire (NHSPAQ) is a brief, simple self-report measure used extensively to assess PA in adults with cancer and other chronic illnesses. Validity of the NHSPAQ has not been determined for estimation of PA in RA. This study examines the validity of the NHSPAQ for adults with RA when compared to accelerometry estimates and data from performance tests.

Methods: 32 adults with RA were sampled from a large tertiary care hospital-based arthritis clinic registry, consented and participated in a 1 week accelerometry trial. Medical and demographic data were collected including: age, gender, disease duration, disease activity (RADAI and DAS-CRP3), education, medications, and co-morbidities. At intake, participants completed the NHSPAQ, performed a self-paced 20-m Walk Test and Timed Step Test. Subjects were given an accelerometer to wear for 7 consecutive days and completed a second NHSPAQ at the end of the week. Descriptive statistics characterized the sample. Metabolic equivalents (METs) were derived from the NHSPAQ, accelerometers and the Timed Step Test using standardized algorithms. NHSPAQ validity was assessed by correlating NHSPAQ METs, accelerometer METs and METs derived from performance tests. Bland-Altman plots compared METs derived from the NHSPAQ and accelerometers. Posthoc power calculations were conducted

Results: 78% of subjects were female (mean age=62.1 years (SD=11.2). The mean disease duration of 21 years (SD=10). On average, RA disease was moderately active at intake (mean RADAI = 2.6 (SD=2) and 74% of subjects were taking biologics. The mean timed walk was 16.2 s (SD=3.9) and Timed Step Test METs was 4.7 (SD=0.9). Average weekly physical activity as determined by accelerometer was 33.3 METs (SD=23). A moderate correlation existed between NHSPAQ METs at one week and accelerometer METs (r =.67, p =.0001). Timed Step Test METs had a low correlation with self-reported physical activity levels (NHSPAQ METs) at one week (r =.42, p =.03). No significant correlation was found between disease activity, step test performance and NHSPAQ METs at intake. Bland-altman plots revealed METs derived from the NHSPAQ are more reliable among subjects with moderate to high physical activity levels. Posthoc power calculations suggested the study was appropriately powered

Conclusion: In this sample of adults with long standing relatively well controlled RA, the NHSPAQ appears to be a valid, simple and cost effective method of assessing PA. General fitness measures had a low correlation with weekly self-reported physical activity. Performance of the NHSPAQ appeared less stable among persons with low levels of physical activity. The NHSPAQ appears to be a valid method of assessing physical activity in adults with RA. However, the NHSPAQ may be less useful among persons engaged in low levels of physical activity

Physical Activity and Timing of Discharge From Physical Therapy Following Total Knee Replacement. Carol A. Oatis[1], Wenjun Li[2], Milagros Rosal[2], David Ayers[2] and Patricia D. Franklin[2]. [1]Arcadia University, Glenside, PA, [2]University of Massachusetts Medical School, Worcester, MA

Background/Purpose: In 2009 over 620,000 total knee replacement (TKR) surgeries were performed. That number is expected to increase to 3.5 million annually by 2030. Post-operative functional gain is variable. On average physical activity and functional ability remain diminished one year post TKR when compared to age matched controls. The purpose of this study was to examine the recovery pattern of physical activity from TKR to 6 months post surgery and its relation to the timing of physical therapy (PT) service received.

Methods: Subjects were 179 participants in an NIH funded RCT of telephone support interventions following unilateral, primary TKR. We requested the PT records from the first 102 participants who completed their TKR rehabilitation in outpatient PT and the first 40 participants who completed their PT rehabilitation in homecare and used no outpatient PT services. We received 90 outpatient and 27 homecare PT records. Participants were asked to wear an accelerometer (Step Activity Monitor™) at the ankle for four consecutive days (2 weekday and 2 weekend) before surgery and at 8 weeks and 6 months after surgery. Valid wear days required a minimum of 10 hours of wear time. Time from surgery to discharge from PT was extracted from PT records.

Results: Participants included 68% female, with a mean (SD) age of 65.1 (8.61). Mean (SD) age was 64 (8.4) and 66 (7.7) years for those completing rehabilitation in outpatient and home care respectively. All participants wore the accelerometer preoperatively with a mean of 3.3 days worn. 174, 163 and 168 participants had at least one valid wear day at baseline, 8 weeks and 6 months after surgery respectively. Mean (SD) steps/day were 7472 (3156), 6658 (3074) and 8295 (3531) at baseline, 8 weeks and 6 months respectively (Figure). Average

and median (5970) daily step counts at 8 weeks were approximately 1000 steps fewer than preoperative levels. Mean (SD) and median change in daily steps at 6 months were 738 (2591) and 354 respectively. 30% of participants had completed their rehabilitation by 8 weeks post surgery and 40% had completed it by 9 weeks. All but one participant who completed rehabilitation in home care had completed it by 8 weeks.
Conclusion: Although average physical activity at 8 weeks post TKR as measured by daily step counts was lower than pre-operative levels, almost one-third of patients had stopped receiving post TKR rehabilitation by that time. Increased functional ability and physical activity are frequent goals of TKR surgery. Our data show that many patients discontinue post TKR rehabilitation when their physical activity is still below pre-operative levels. Further research is needed to understand the association between recovery of physical activity and the timing of PT services post TKR.

Resistance Exercise Training for Fibromyalgia: A Systematic Review.
Angela J. Busch[1], Sandra Webber[1], Rachel Richards[2], Julia Bidonde[1], Candice Schachter[1], Laurel Schafer[3], Adrienne Danyliw[4], Anuradha Sawant[5], Vanina Dal Bello Haas[6] and Tamara Rader[7]. [1]University of Saskatchewan, Saskatoon, SK, [2]North Vancouver, BC, [3]Central Avenue Physiotherapy, Swift Current, SK, [4]Health Quality Council, SK, [5]London Health Sciences Center, ON, [6]McMaster University, Hamilton, ON, [7]University of Ottawa, Ottawa, ON

Background/Purpose: This systematic review investigated the effects of resistance exercise training on signs and symptoms, and physical fitness in people with fibromyalgia. Fibromyalgia, a condition of chronic pain, is frequently associated with poor physical fitness and low levels participation in physical activity.

Methods: We searched 8 electronic data bases (eg, Medline, CINAHL, EMBASE) to 01/2012. Inclusion criteria were randomized controlled trials, adults a fibromyalgia diagnosis based on published criteria, and between group data comparing resistance exercise to a control or other intervention. Study screening and data extraction were done by two independent reviewers. We extracted and analyzed data on symptoms, global rating of disease, health-related quality of life, physical function, psychological health, and adverse effects using Cochrane collaboration procedures. Studies were evaluated for risk of bias and congruence with the American College of Sports Medicine guidelines. We used the GRADE approach to evaluate the body of evidence.

Results: After removing duplicate entries, we found 1661 citations – only four studies met the selection criteria and were included in the review. The studies fell into two categories in which resistance exercise training was compared to: a) a control group (2 studies), and b) to other exercise interventions (one aerobic, one flexibility exercise). A total of 61 participants (all were women) were assigned to resistance training. The two randomized trials in the first category were 21 week moderate to high intensity progressive resistance interventions using isokinetic exercise equipment. In the second category, 8 weeks of progressive treadmill walking was compared to low to moderate intensity progressive free weight or body weight resistance exercise, and 12 weeks of flexibility exercise was compared to low intensity resistance training using light hand weights and elastic tubing. Large differences were found in pain, patient rated global, tender points, depression, fatigue, muscle strength and muscle power favoring the resistance training group when compared to the control group. Few significant differences were found when resistance exercise was compared to aerobic exercise: large effects were found in pain and sleep quality favoring the aerobics group. When compared to flexibility exercise, large differences were found in fatigue and sleep resistance training favoring the resistance training group. No injuries were observed in any of the studies.

Conclusion: There is moderate evidence that 21 weeks of medium to vigorous intensity resistance training exercise improves muscle strength, pain, and patient rated global well-being in women with fibromyalgia. There is moderate evidence that eight weeks of aerobic exercise is superior to moderate intensity resistance exercise training for reducing pain and improving sleep. There is low quality evidence that 12 weeks of low intensity resistance training is superior to flexibility exercise in women with fibromyalgia for reducing pain and fatigue and improving sleep. Furthermore, it appears that women with fibromyalgia perform resistance exercise training without adverse effects.

Despite Low Disease Activity Patients with Poly- and Dermatomyositis Perceive Activity Limitation, Reduced Grip Force and Quality of Life Longitudinally. Malin Regardt[1], Marie-Louise Schult[2], Ingrid E. Lundberg[3] and Elisabet MB Welin Henriksson[4]. [1]Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [2]Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet., Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institutet Rheum, Stockholm, Sweden

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are characterized by proximal muscle weakness. A recent study has shown that patients with PM and DM have reduced grip force compared to reference values. Although patients with PM/DM respond with clinical improvement to treatment several develop a sustained disability. Clinical data from most of the patients with PM and DM in Sweden are registered annually in the Swedish Myositis Network (SWEMYONET) registry. The aim of this study was to investigate how grip force, activity limitation and health related quality of life (HRQoL) change over time in a cohort of patients with PM/DM.

Methods: A multi-center longitudinal registry study following patients from disease onset and to 1, 2, 3, 4, 5, and 6 years follow-ups. Data were collected from the SWEMYONET registry on patients with PM/DM that had values on either grip force using Grippit, activity limitation measured by Myositis Activities Profile (MAP) or HRQoL measured with Short Form-36 (SF-36) on at least one time-point between disease onset and the 6 years follow-up during the years 2003–2012. A total of 88 patients were included (53 with PM (33 women and 20 men) and 35 with DM (19 women and 16 men)). Median age for the cohort at disease onset was 59.5 years. Disease activity was measured by Physician Global Assessment of disease activity (PGA). Patients were treated with conventional immunosuppressive treatment according to the choice of the treating physician.

Results: Both women and men had reduced grip force from disease onset and over time (compared to reference values), women up to 4 years follow-up from disease onset in right and left hand ($p < 0.02$) and men up to 4 years follow-up in the right hand and 3 years in the left hand ($p < 0.05$). At disease onset, both women and men rated their activities as moderately difficult to perform. Over time women improved at some time-points from disease onset and at the most to 3 years in all except two sub-groups of MAP (avoid overexertion and work/school). Men improved in four out of eight of MAP's sub-groups (movement, moving around, personal care and leisure) at some time-points from disease onset and at the most to 3 years The women had lower values on HRQoL in all eight dimensions of SF-36 compared to reference values from the Swedish population ($0.001 < p < 0.04$). In five of the eight dimensions of SF-36 the difference was present up to 6 years follow-up for women. Men also rated their HRQoL less than the reference values in all dimensions of SF-36 ($0.001 < p < 0.047$), but the difference was most frequent at disease onset.

Disease activity measured by PGA was lower for both women and men with PM/DM compared to disease onset and at alll time-points up to 6 years (p<0.05).

Conclusion: Even though disease activity decreases over time, patients with PM/DM still have reduced grip force and HRQoL compared to reference values. They also perceive activity limitation over time. The women with PM/DM seem to be more affected over time by the disease than men in grip force, activity limitation and HRQoL.

Relationship Over Time Between Beliefs, Motivation, and Worries about Physical Activity and Physical Activity Participation in Persons with Knee Osteoarthritis.

Linda S. Ehrlich-Jones[1], Jungwha Lee[2], Dorothy D. Dunlop[2], Pamela A. Semanik[2], Min-Woong Sohn[2], Jing Song[2] and Rowland W. Chang[2]. [1]Rehabilitation Institute Chicago, Chicago, IL, [2]Northwestern University, Chicago, IL

Background/Purpose: To determine the relationship over time between beliefs, motivation, and worries about physical activity and physical activity participation in persons with knee osteoarthritis (KOA).

Methods: Longitudinal data from 155 adults with KOA enrolled in a randomized clinical trial to assess the effectiveness of a behavioral intervention to promote physical activity were analyzed. Data included participant self-reported beliefs that physical activity can be beneficial for their disease, motivation for physical activity participation, worries about physical activity participation, and objective average daily accelerometer counts over a week's time at baseline, 3 months, 6 months, and 12 months. The relationships of physical activity with beliefs, motivation and worries about physical activity were examined by multiple regression models using general estimating equations adjusting for age, gender, body mass index, disease activity, and treatment group.

Results: Results from the adjusted analyses showed a strong significant concurrent relationship between beliefs and physical activity, as well as between motivation and physical activity (Figure 1). The predictive relationships of beliefs, motivation, and worries with subsequent physical activity were each not significant.

Figure 1. Adjusted[a] average daily activity counts for dynamic variables[b] (N=155)
[a]Modeling average daily activity counts on concurrent dynamic variables adjusted for age, gender, body mass index, disease activity, and treatment group.
[b]Belief score: not strong 0~21, strong 22~33; Motivation score: not strong 6~20, strong 21~24; Worry score: not strong −7~0, strong 1~7.
* P-value comparing not strong versus strong.

Conclusion:
• Higher levels of physical activity participation in persons with KOA were concurrently related to stronger beliefs that physical activity can be helpful for managing disease and to greater motivation for being active.
• Prior beliefs, motivation, and worries did not predict subsequent physical activity.

• These findings suggest that persistent attention to motivation and beliefs are needed to sustain higher levels of physical activity.

1589

Obesity and Rehabilitation Outcomes After Lower Extremity Arthroplasty.

Soham Al Snih, Amol Karmarkar, Timothy A. Reistetter, Jinhyung Lee, Amit Kumar, James E. Graham and Kenneth J. Ottenbacher. University of Texas Medical Branch, Galveston, TX

Background/Purpose: To examine the effect of obesity on inpatient rehabilitation outcomes after lower extremity arthroplasty procedures (hip and knee) among Medicare Beneficiaries aged 65 years and older.

Methods: We conducted a retrospective analysis in a cohort of 103,445 Medicare Part A Beneficiaries with osteoarthritis who underwent primary total hip arthroplasty (THA) (N=32,671) or total knee arthroplasty (TKA) (N=70,774) between 2007 and 2009. Patients were identified using a combination of International Classification of Diseases, Ninth Revision and diagnosis related groups codes for primary THA or TKA, osteoarthritis, overweight/obesity, and morbid obesity. Data for rehabilitation outcomes were obtained using the Inpatient Rehabilitation Facilities Patient-Assessment Instrument file. Patients were grouped in three categories (normal weight, overweight/obesity, and morbid obesity). Rehabilitation outcomes included: Functional status information (FIM scores at admission and discharge, and FIM score change) and length of stay (LOS).

Results: The prevalence of overweight/obesity and morbid obesity was 11.4% vs. 4.7% among patients with THA, and 16.8% vs. 8.1% among patients with TKA. LOS was higher among morbid obesity for both THA and TKA [4.2, (Standard Deviation=2.7) vs. 4.2 (2.7)]. Mean FIM total score change was 29.4 (1.5) vs. 29.5 (12.3) for overweight/obesity and morbid obesity among those with THA, and 30.1 (11.5) vs. 31.3 (12.2) among those with TKA. Multivariable analysis for LOS controlled for age, gender, race/ethnicity, year of discharge, and discharge destination showed that LOS in morbid obesity in both THA and TKA was higher than those with normal weight or overweight/obesity (β = 0.18, p-value 0.0037 vs. 0.20, p-value < 0.0001). Multivariable analysis for FIM total score change showed that the highest change was observed among morbid obesity with TKA (β = 2.28, p-value < 0.0001) followed by morbid obesity with THA (β = 0.91, p-value = 0.0018), overweight/obesity with TKA (β = 0.89, p-value < 0.0001), and overweight/obesity with THA (β = 0.43, p-value = 0.0236) when compared with normal weight.

Conclusion: Patients with overweight/obesity and morbid obesity experience functional gains during inpatient rehabilitation, with those in the morbid obesity group experiencing the greatest gains. LOS for those with morbid obesity was greater than the other groups, providing support to the Center for Medicare and Medicaid Services tier comorbidity system for inpatient rehabilitation following THA or TKA. Our results suggest that obesity has an impact on LOS and functional status gains during rehabilitation. Future research is needed to explore the tier-based comorbidity reimbursement system and examine the impact of obesity on other rehabilitation impairment groups.

1590

Post-Operative Rehabilitation Provides Unmet Need for Better Patient Support and Advice Following Lumbar Spinal Fusion.

Michael V. Hurley[1], James Greenwood[2] and Dr Nicola E. Walsh[3]. [1]St George's University of London, London, United Kingdom, [2]University College Hospital London, London, United Kingdom, [3]University of the West of England Bristol, Bristol, United Kingdom

Background/Purpose: In the absence of evidence-based post-operative rehabilitation, following fusion surgery for severe persistent low back pain, people receive advice to rest for 3 months then progressively resume normal function. Such unclear, generic advice is unhelpful, and post-operative recovery may be delayed or suboptimal. We introduced a structured post-operative rehabilitation program of individualised progressive exercise and self-management advice for people who had undergone

lumbar fusion. We wanted to evaluate how helpful participants found the program.

Methods: 15 patients attending follow-up appointments were asked about their concerns, experiences, perceptions and needs. 4 patients on the program (small group, once a week for 10 weeks) were asked if and how the program helped them. The main themes that emerged were documented.

Results: Patients primarily reported concerns about musculoskeletal or psychosocial issues rather than technical surgical problems, e.g. residual pain and disability, how to reduce analgesia, when to resume certain activities, etc, but complained of a *lack of advice and support*. The program enabled access to a healthcare professional who could fully address people's concerns "... my GP said to ask my consultant but I never get to see him, so it is great that I can ask you ..."

Four areas raised most concerns:

Residual symptoms: People didn't know what to expect and presence of residual symptoms concerned them "... if the operation was a success why do I still have pain ..."

Prognosis: They wanted to know what would happen "... will this metalwork wear out ... will it have to come out ...". The program allowed them to ask questions and learn from others "... I am glad to hear that exercise will not cause my spine to wear out. The others in the class have helped me see that I can get better ..."

Physical function: People were keen to return to more normal physical function but were unsure what to do, how and when "... they told me to gradually increase my activity, but which activity and when ..."

Co-morbidity: People were unclear how co-morbidity might affect outcome "... how does my diabetes affect exercise ..." "... my neck hurts as well ..." but advice was lacking, unhelpful or impractical. The program gave individuals specific advice and they experienced benefits first-hand "... the consultant just kept telling me to walk, but my knee hurt and I was scared. It is so helpful that you can help me manage all of these problems ..."

Conclusion: There is a need for better support to answer concerns that cause distress, anxiety and may impede post-operative recovery. Surgeons are primarily concerned about infection, implant failure, etc. Our post-operative rehabilitation program improved access to healthcare professionals who gave advice and support that might improve outcome. The program warrants more thorough evaluation.

Efficacy of Neoprene Wrist Supports for Patients with Rheumatoid Arthritis. Kinue Matsuo[1], Koji Tateishi[2], Natsuko Nakagawa[2] and Yasushi Miura[1]. [1]Kobe University Graduate School of Health Sciences, Kobe, Japan, [2]Konan Kakogawa Hospital, Kakogawa, Japan

Background/Purpose: Wrist joints are frequently damaged by rheumatoid arthritis (RA). Wrist supports are often used to reduce pain and strain on wrists when patients with RA engage in hand-related activities, however, evidences for the efficacy of wrist supports are quite a few. Though wrist supports are made of either elastic or hard materials, elastic materials such as neoprene are preferred by patients with RA in Japan because wrist movement is tolerated. In this study, we investigated the efficacy of neoprene wrist supports on pain, hand function, activities of daily living (ADL), and instrumental activities of daily living (IADL) for patients with RA.

Methods: Patients with consistent wrist pain for at least a week and treated without changes of biologics or disease modifying antirheumatic drugs for at least 12 weeks were participated in this study. Patients with severe deformities of the fingers affecting hand function or a history of wrist surgery were excluded. Custom wrist supports (2mm thick, 8cm width, and 75cm length) are made of neoprene rubber laminated with knit fabric on both surfaces by occupational therapists (OT) to wrap three times on midcarpal joint, radiocarpal joint, and distal radioulnar joint. The participants were instructed to wear as long as possible when engaging in hand-related activities for 12 weeks. Wrist pain by 100mm visual analog scale (VAS), active range of motion (AROM) [dorsal, volar, pronation, and supination], grip strength, pinch strength (pulp pinch and key pinch), Disabilities of the Arm Shoulder and Hand (DASH), and Assessment of Motor and Process Skills (AMPS) were assessed at baseline, 1–2, 4, 8, and 12-week of wrist supports use. AROM, grip strength, and pinch strength were measured with or without wrist supports. The same AMPS task was performed for each evaluation. Data were analyzed with Wilcoxon signed rank test.

Results: Eight wrists of six female patients (age: 64.7±16.7 (33–79) years, disease duration: 15.2±9.9 (0.5–28) years, modified health assessment questionnaire (mHAQ) score: 1.6±0.4(1.13–2.25), Steinblocker's class: II; 2 and III; 4, stage I; 1, IV; 5, Larsen's classification of wrist: grade I; 1, II; 1, III; 2, IV; 4) were participated. Neoprene wrist supports significantly reduced wrist pain and improved ADL motor ability measures during the follow-up period. Grip strength was significantly increased only when wearing wrist supports. No significant changes were observed in AROM, DASH score, and key pinch strength.

Conclusion: Neoprene wrist supports reduce wrist pain, increase grip strength immediately, and improve ADL motor ability measures without limiting range of motion of wrist joints. Thus, neoprene wrist supports may be recommended for patients with RA when carrying out daily tasks.

A Novel Approach to the Early Detection of Axial Spondyloarthritis in Patients with Inflammatory Bowel Disease: The Implementation of an Advanced Practice Physiotherapist Led Screening Program. Laura A. Passalent[1], Rebecca Morton[1], Khalid A. Alnaqbi[2], Nigil Haroon[3], Stephen Wolman[4], Mark Silverberg[5], A. Hillary Steinhart[5] and Robert D. Inman[3]. [1]Allied Health, Toronto Western Hospital, Toronto, ON, [2]Toronto Western Hospital, Toronto, ON, [3]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [4]Toronto General Hospital, Toronto, ON, [5]Zane Cohen Centre for Digestive Diseases, Mount Sinai Hospital, Toronto, ON

Background/Purpose: The prevalence of SpA in patients with inflammatory bowel disease (IBD) ranges from 3.1 – 10%, compared to <1% in the general population, defining IBD patients as high risk for developing SpA. Traditional referral pathways to rheumatologists are associated with lengthy wait times for patients with suspected inflammatory arthritis. In order to address the need to improve access to care, there has been interest in traditional role expansion using non-physician models of care. One such model has been to train advanced practice physiotherapists (APPs) in the assessment/treatment of patients with inflammatory arthritis. The purpose of this study was to implement and evaluate a unique screening program for IBD patients with suspected SpA, led by an APP. The objectives were to: measure wait times from the day of referral to the day of screening; measure a) the clinical agreement for screening results and b) agreed recommendation of MRI for further assessment between the APP and three rheumatologists with expertise in SpA, and, compare the confidence of clinical judgment between the APP and rheumatologists.

Methods: Patients attending gastroenterology clinics with a diagnosis of IBD and ≥ 3 months of back pain were referred to the program. Patients who demonstrated signs and symptoms indicative of inflammatory back pain (i.e. positive screen) were referred to the Rheumatology Clinic for diagnosis. Patients who screened negative, were provided with education on appropriate back care. Descriptive statistics described clinical characteristics and wait times. Kappa coefficient (k) measured interobserver agreement and Pearson's Correlation compared confidence of the screening results of the APP and the rheumatologists. Bivariate analyses were based on "paper patients" reviewed by the rheumatologists that included clinical and investigative results of patients previously screened by the APP.

Results: A total of 20 patients were referred to the screening program. Most patients were men (55%), and the mean age was 40.9 years ±11.8. The average duration of back pain was 9.8 years; 65% reported insidious onset. The mean Oswestry disability index was 20.3 ±13.5, indicating minimal disability resulting from back pain. The median wait time was 13 days. The APP agreed with the rheumatologists' screening results on an average of 71.4% (k=0.5; CI: 0.07–0.87) of patients. The APP agreed with the rheumatologists to recommend MRI for further assessment on an average of 66.7% (k=0.6; CI: 0.23–0.94) of patients screened. Comparison of confidence of screening results was 6.8/10 (higher values indicating higher level of confidence) for the APP versus an average confidence level of 6.4/10 for the three rheumatologists (Pearson's = 0.3).

Conclusion: The utilization of the APP to screen for inflammatory back pain in patients with IBD demonstrates clinical judgement that is aligned with that of rheumatologists with expertise in SpA. The level of

confidence of the APP was similar to the rheumatologists'. Wait times to be screened by the APP are shorter than traditional referral pathways. This screening strategy has the potential to improve access to care and act as a model of care for patients at high risk for SpA.

The Risk of Lymphoma in Patients Receiving Anti-Tumor Necrosis Factor Therapy for Rheumatoid Arthritis: Results From the British Society for Rheumatology Biologics Register - Rheumatoid Arthritis.
Louise K. Mercer[1], Mark Lunt[1], Audrey S. Low[1], James B. Galloway[1], Kath Watson[1], William G. Dixon[1], BSRBR Control Centre Consortium[2], Deborah P. Symmons[1], Kimme L. Hyrich[3] and On behalf of the BSRBR[4]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, Manchester, United Kingdom, [4]British Society for Rheumatology, London, United Kingdom

Background/Purpose: The risk of lymphoma is increased in people with RA compared to the general population and is greatest in severe RA. Anti-TNF therapy is now widely used to treat RA, especially severe RA. The aim of this study was to determine whether anti-TNF influences the risk of lymphoma when used in routine UK clinical practice.
Methods: The analysis was conducted in the BSRBR-RA, a national cohort study. Patients with RA starting treatment with the TNF inhibitors etanercept (ETA), infliximab (INF) or adalimumab (ADA) and a biologic-naïve comparison cohort exposed to non-biologic therapy (nbDMARD) were recruited between 2001–2009. Subjects were followed until 09/30/2010, first lymphoma or death, whichever came first. Subjects with a history of lymphoproliferative malignancy prior to registration were excluded. Incident cancers were identified in 3 ways; lifelong flagging with national cancer agencies; 6 monthly patient and physician questionnaires for 3 years and annual physician questionnaires thereafter. Only first lymphoma per subject, confirmed by histology or cancer agency, was analysed. The rates of lymphoma and non-Hodgkin lymphoma (NHL) in the nbDMARD cohort and in patients ever exposed to anti-TNF were compared using Cox proportional hazards models adjusted using deciles of propensity score (DP) which included baseline age, gender, DAS score, HAQ, disease duration, use of steroids, current/previous cyclophosphamide, smoking and registration date. The first 6 months of follow-up were excluded. There were too few Hodgkin lymphoma (HL) to compare rates.
Results: 84 incident lymphomas were confirmed: 20 in 3465 nbDMARD-treated subjects and 64 in 11987 anti-TNF (152 versus 96 per 100000 person-years (pyrs); Table). After adjusting using DP there was no difference in risk of lymphoma between the cohorts; hazard ratio (HR) for anti-TNF 1.13 (95% CI 0.55, 2.31). There were 5 (22%) HL in the nbDMARD cohort and 9 (13%) in anti-TNF. Among 71 NHL, the most frequent subtype was diffuse large B cell lymphoma; 8 (50% of NHL) in nbDMARD and 25 (45%) anti-TNF. There was no significant difference in risk of NHL between the cohorts (table).

	nbDMARD N=3465	Anti-TNF N=11987
Follow-up (pyrs)	13186	66353
Median follow-up (pyrs; IQR)	4.5 (2.6, 5.9)	6.4 (4.8, 7.4)
Age: (years) Mean (SD)	60 (12)	56 (12)
Gender: N(%) female	2545 (73)	9145 (76)
RA disease duration: (years) Median (IQR)	6 (1, 15)	11 (6, 19)
DAS28 score: mean (SD)	5.3 (1.1)	6.6 (1.0)
HAQ: mean (SD)	1.5 (0.7)	2.0 (0.6)
Lymphoma: N	20	64
Lymphoma: Rate per 100000 pyrs (95% CI)	152 (93, 234)	96 (74, 123)
Lymphoma: Age and gender adjusted HR (95% CI)	Referent	0.71 (0.43, 1.20)
Lymphoma: DP adjusted HR (95% CI)	Referent	1.13 (0.55, 2.31)
Hodgkin lymphoma: N	4	9
Hodgkin lymphoma: Rate per 100000 pyrs (95% CI)	30 (8, 78)	14 (6, 26)
Non-Hodgkin lymphoma: N	16	55
NHL: Rate per 100000 pyrs (95% CI)	121 (69, 197)	83 (62, 108)
NHL: Age and gender adjusted HR (95% CI)	Referent	0.79 (0.44, 1.40)
NHL: DP adjusted HR (95% CI)	Referent	1.26 (0.58, 2.72)

Conclusion: There is no evidence that anti-TNF increases the risk of lymphoma over the background risk associated with RA, but further follow up is needed to establish if the picture changes with time.

Clinical and Radiological Outcomes After One Year of Remission Steered Combination Treatment in Patients with Early Rheumatoid and Undifferentiated Arthritis.
L. Heimans[1], K.V.C. Wevers-de Boer[1], K. Visser[1], H.K. Ronday[2], M. van Oosterhout[3], J. H. L. M. Van Groenendael[4], A.J. Peeters[5], G. Steup-Beekman[6], G. Collee[7], P.B.J Sonnaville[8], B.A. Grillet[9], Tom Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]Groene Hart Hospital, Gouda, Netherlands, [4]Franciscus Hospital, Roosendaal, Netherlands, [5]Reinier de Graaf Gasthuis, Delft, Netherlands, [6]Bronovo Hospital, Netherlands, [7]MCH, The Hague, Netherlands, [8]Admiraal de Ruyter Ziekenhuis, Goes, Netherlands, [9]Zorgsaam hospital, Terneuzen, Netherlands

Background/Purpose: To evaluate the 1 year clinical and radiological outcomes of remission steered therapy in early arthritis patients treated aiming at remission (DAS<1.6).
Methods: In the IMPROVED study 610 patients were included with early rheumatoid or undifferentiated arthritis (RA or UA). All patients started with methotrexate (MTX) 25mg/wk and prednisone 60mg/day tapered to 7.5mg/day in 7 weeks. Patients in remission (DAS<1.6) after 4 months (early remission) tapered prednisone to zero and, when in remission at 8 months, tapered MTX. Patients not in early remission were randomized either to a combination of MTX 25mg/wk, hydroxychloroquine 400mg/day, sulphasalazine 2000mg/day and prednisone 7.5mg/day (arm 1) or to adalimumab (ADA) 40mg/2weeks with MTX 25mg/wk (arm 2). If not in remission after 8 months, patients in arm 1 switched to ADA+MTX and patients in arm 2 increased ADA to 40mg/week. Proportions of remission and radiological progression measured by Sharp-van der Heijde scoring method after one year follow up were compared between the different treatment strategies.
Results: After 4 months 375 patients (61%) achieved early remission and 221 (36%) did not, of which 161 patients were randomized, 83 to arm 1 and 78 to arm 2. In 62 (10%) patients the protocol was not followed, 12 were lost to follow up after 4 months and in total 34 after 1 year. Of those in early remission 361 (96%) tapered prednisone after 4 months and 200 (53%) tapered MTX after 8 months. After 1 year, remission was achieved in 257 (69%) patients and 119 (32%, 20% of all patients) were in drug free remission.
Patients in arm 1 and 2 achieved remission in similar proportions after 8 months (30 (36%) versus 27 (35%), p=1.0), but after 1 year patients in arm 2 more often achieved remission than in arm 1 (32 (41%) vs 21 (25%), p=0.01). Patients in arm 2 who at 8 months tapered ADA+MTX combination to MTX monotherapy, more often remained in remission after one year than patients tapering poly-DMARDs+prednisone to MTX monotherapy in arm 1 (17/26 (65%) vs 11/30 (37%), p=0.02). After failing to achieve remission on poly-DMARDs+prednisone, 6/24 patients (18%) who switched to ADA achieved remission after one year, compared to 8/27 (30%) who failed on ADA+MTX and increased ADA (p=0.2). Of the total study population 53% were in remission after 1 year. Median (IQR) radiological damage progression after 1 year was 0(0–0) in patients who achieved early remission, and 0(0–0) and 0(0–0) in arms 1 and 2, respectively (p=0.2).
Conclusion: After one year of remission steered combination treatment, 53% of the patients with early arthritis achieved remission. Patients in early remission after initial treatment with MTX and prednisone most often achieved remission after one year (69%) and 32% were in drug free remission. Patients who failed to achieve early remission benefited more from a treatment strategy with adalimumab than with multiple DMARDs+prednisone. In this treat-to-remission cohort, radiological damage progression after 1 year was negligible in all patients.

Genome-Wide Association Study to High-Throughput Cell-Based Phenotypic Screen Identifies Novel Chemical Inhibitors of CD40 Signaling.

Gang Li[1], Dorothee Diogo[1], Di Wu[1], Jim Spoonamore[2], Rheumatoid Arthritis Consortium International (RACI)[3], Eli Stahl[4], Nicola Tolliday[2] and Robert M. Plenge[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Broad Institute, Cambridge, MA, [3]Boston, [4]Brigham and Women's Hospital

Background/Purpose: Deriving therapeutic targets from human genetics linked with biological alterations of risk alleles may provide a more successful approach to drug development than traditional efforts that focus on biological insight alone. Here, we successfully translate a SNP association from a genome-wide association study (GWAS) in rheumatoid arthritis (RA) into a high-throughput screen (HTS) based on cellular phenotype in a human B cell line to identify inhibitors of CD40-mediated NF-κB signaling.

Methods: We fine-map the *CD40* risk locus in 7,222 seropositive RA patients and 15,870 controls genotyped on the Immunochip, together with deep sequencing of *CD40* coding exons in 500 RA cases and 650 controls. We use flow cytometry to measure CD40 protein levels on the surface of primary CD19+ from 90 healthy control individuals. We use gene expression arrays to measure CD40 RNA levels in peripheral blood mononuclear cells from 1,469 healthy control individuals. We use retroviral shRNA infection to perturb the amount of CD40 on the surface of a human B lymphocyte cell line (BL2). We develop a high-throughput NF-κB luciferase reporter assay in BL2 cells activated with trimerized CD40 ligand (tCD40L), and conduct an HTS of 1,982 chemical compounds and FDA-approved drugs. Counter-screens of the top "hit" compounds were performed in the BL2 line activated with both tCD40L and LPS, and in an additional B cell line, Ramos, activated with tCD40L and TNF. Two known and two novel compounds were tested for inhibition of tCD40-NFkB signaling in primary human CD19+ B cells by measuring CD86 expression with flow cytometry.

Results: A single common SNP at the CD40 locus explains the entire signal of association (rs4810485, $P=1.4\times10^{-9}$), without any evidence for independent rare variants contributing to RA risk. Subjects homozygous for the common RA risk allele have ~33% more CD40 on the surface of primary human CD19+ B lymphocytes than subjects homozygous for the non-risk allele ($P=10^{-9}$), a finding corroborated by expression quantitative trait loci (eQTL) analysis in PBMC's ($P<10^{-15}$). We observe a direct correlation between amount of CD40 protein and phosphorylation of RelA (p65), a subunit of the NF-κB transcription factor. Using our luciferase reporter assay, we identify 81 "hit" compounds (out of 1,982) that consistent inhibit luciferase activity following tCD40L activation. After a series of counter-screens and testing in primary human CD19+ B cells, we identify 2 "known" and 2 "novel" chemical inhibitors not previously implicated in inflammation or CD40-mediated NF-κB signaling. One known inhibitor is tranilast, a drug currently in a phase II clinical trial of RA; the other is a corticosteroid derivative. The two novel compounds represent promising tool compounds to develop new therapies to treat RA.

Conclusion: Our study demonstrates proof-of-concept that human genetics can be used to guide the development of phenotype-based, high-throughput small-molecule screens to identify potential novel therapies in complex traits such as RA.

1596

Strontium Ranelate in Knee Osteoarthritis Trial (SEKOIA): A Structural and Symptomatic Efficacy.

Jean-Yves Reginster[1], R. Chapurlat[2], Claus Christiansen[3], H. Genant[4], N. Bellamy[5], W. Bensen[6], F. Navarro[7], J. Badurski[8], E. Nasonov[9], X. Chevalier[10], PN. Sambrook[11], T. Spector[12] and Cyrus Cooper[13]. [1]University of Liège, Liège, Belgium, [2]INSERM UMR 1033 and Université de Lyon, Hôpital Edouard Herriot, Lyon, France, [3]CCBR, Ballerup, Denmark, [4]Radiology, Medicine and Orthopaedic Surgery University of California and Synarc, San Francisco, CA, [5]CONROD. The University of Queensland, Royal Brisbane and Women's Hospital, Herston, Queensland, Australia, [6]St. Joseph's Hospital and McMaster University, Hamilton, ON, [7]H. Universitario Virgen de la Macarena, Sevilla, Spain, [8]Center of Osteoporosis and Osteo-articular Diseases, Bialystock, Poland, [9]State Institute of Rheumatology, the Russian Academy of Medical Sciences, Moscow, Russia, [10]Hôpital Henri-Mondor, Creteil, France, [11]Royal North Shore Hospital, St Leonards, Australia, [12]King's College London, St. Thomas Campus, London, United Kingdom, [13]University of Oxford; Southampton General Hospital, Southampton, United Kingdom

Background/Purpose: Treatments for osteoarthritis focus on improving symptoms through non-pharmacological and pharmacological approaches. Strontium ranelate (SrRan), a treatment for osteoporosis, was shown to stimulate cartilage matrix formation in vitro, and to reduce radiographic spinal OA progression in osteoporotic women with spinal OA.

The objective of SEKOIA phase III study was to compare the efficacy of SrRan with placebo for reducing radiological progression of knee OA.

Methods: SEKOIA is a double-blind, placebo-controlled, randomized, 3-year study involving 1683 patients with symptomatic primary knee OA (Kellgren and Lawrence [KL] grade 2 or 3, joint space width [JSW] 2.5–5 mm) randomly allocated to SrRan 1 or 2g/day, or placebo. Primary endpoint was radiographic change in JSW of the medial tibiofemoral compartment from baseline to LOCF. Group comparisons were performed in the ITT using a general linear model with Dunnett's multiple comparison procedure with baseline JSW, center and sex as covariates. JSW was measured yearly using a validated computer-assisted centralised reading method. Secondary endpoints included radiological progression (JSN≥0.5mm)[1], radio-clinical progression (JSN≥0.5mm and WOMAC improvement≤20%)[2], WOMAC scores, knee pain, and adverse events.

Results: The ITT set included 1371 (82%) patients. Age was 63 ± 7 years, BMI was 30 ± 5 kg/m^2, JSW was 3.5 ± 0.8 mm. 61% were KL II. 69% were female. SrRan was associated with less progression of cartilage degradation, decrease in JSW was -0.23 ± 0.56 mm with 1g/day; -0.27 ± 0.63 mm with 2g/day and -0.37 ± 0.59 mm with placebo; estimated differences (SE) were 0.14(0.04),p<0.001 for 1g/day and 0.10(0.04),p=0.018 for 2g/day with no difference between doses. Results were confirmed in the Randomised Set and sensitivity analyses demonstrated minimal impact of missing post-baseline data.

There were less radiological and radioclinical progressors with SrRan 1 and 2 g/day:

Secondary criteria	Strontium ranelate 1 g/day (n=445)			Strontium ranelate 2 g/day (n=454)			Placebo value (n=472)
	n %	E (SE)* (95% CI)	p value	n %	E (SE)* (95% CI)	p value	
Radiological progression	99 (22%)	−10.80 (2.9) (−16.54;−5.06)	<0.001	116 (26%)	−7.50 (3.0) (−13.34;−1.66)	0.012	156 (33%)
Radioclinical progression	32 (8%)	−3.94 (1.98) (−7.83; −0.05)	0.049	28 (7%)	−5.12 (1.91) (−8.86;−1.37)	0.008	53 (12%)

*Estimated difference versus placebo

Greater reductions in total WOMAC score (p=0.045), pain (p=0.028) and physical function subscore (p=0.099), and knee pain (p=0.065) were observed with SrRan 2 g/day. SrRan was well tolerated: 86%, 88% and 87% reported an emergent adverse event (EAE) in the SrRan 1g, 2g and placebo group respectively, 17% of the patients in each group reported a serious EAE. 1 EAE in each SrRAn group, 3 in the placebo group led to death.

Conclusion: SrRan 1 and 2g/day delayed radiographic progression of knee OA, evidencing a structure-modifying effect. This structural effect is translated clinically into a lower number of patients having a radiological progression over thresholds known to be predictive of OA-related surgery suggesting that SrRan could reduce the number of patients needing knee surgery in the long-term. The structural effect was accompanied by symptom improvement at the dose of 2g/day.

Gaslini, Genoa, Italy, [8]International Investigator Consortium for MAS Diagnostic Criteria, Saint-Petersburg, Russia, [9]Centre of Pediatric Rheumatology, Sankt Augustin, Germany, [10]Necker-Enfants Malades Hospital, Paris, France, [11]Pediatric Rheumatology Collaborative Study Group [PRSCG], Cincinnati, OH, [12]Cincinnati Children's Hospital, Cincinnati, OH, [13]PRINTO and PRSCG, Genoa, Italy

Background/Purpose: Elevated IL-6 levels are associated with disease activity in patients (pts) with juvenile idiopathic arthritis (JIA).[1] Tocilizumab (TCZ), an IL-6 receptor inhibitor, was evaluated for the treatment of polyarticular-course JIA (pcJIA; RF+ and RF– poly- and extended oligoarticular JIA; systemic JIA was excluded) in the CHERISH study.

Methods: CHERISH is a 104-wk study in pts age 2–17 yrs with active pcJIA for ≥6 mo who failed MTX. In the first 16 wks, all pts received open-label (OL) TCZ every 4 wks (if body weight [BW] ≥30 kg, 8 mg/kg [n = 119]; if BW <30 kg, pts were randomly assigned to 8 mg/kg [n = 34] or 10 mg/kg [n = 35]). At wk 16, eligible pts (with ≥JIA ACR30 response) entered a 24-wk randomized (pts were assigned [1:1] to placebo [PBO] or to continue TCZ at the same dose), double-blind (DB) withdrawal period for evaluation of the primary endpoint (JIA ACR30 flare relative to wk 16). Pts who flared or completed the DB period entered an OL extension in which they received the same TCZ dose as in the lead-in period. Efficacy data (until wk 40) are presented for the ITT population; safety data are presented for the safety population to the cut date.

Results: 188 pts entered the initial lead-in period (77% girls; 79% and 46% were receiving concurrent MTX and oral corticosteroids [CS], respectively); 166 pts entered the DB period; 15 pts (8%) withdrew due to insufficient response, 3 (2%) due to adverse events (AEs), and 4 (2%) due to other reasons. The primary endpoint was met, and JIA ACR30/50/70 responses were significantly higher with TCZ compared to PBO at wk 40 (Table). Efficacy responses for the initial lead-in period at wk 16 are shown (Table). The degree of improvement was lower for these endpoints in the TCZ 8 mg/kg <30 kg BW group compared with the other 2 groups (TCZ 10 mg/kg <30 kg BW and TCZ 8 mg/kg ≥30 kg BW) (Table). At the time of the safety data cut, there were 184 pt-yrs (PY) of follow-up in the 188 pts enrolled. Rates/100PY of AEs and SAEs were 480 and 12.5; infections were the most common AEs (164/100PY) and SAEs (4.9/100PY). ALT and AST elevations ≥3× ULN were each reported in 3.7% and <1% of pts. Neutropenia (<1000 cells/mm^3) and thrombocytopenia (<50,000 cells/mm^3) occurred in 3.7% and 1.1% of pts. LDL-cholesterol ≥110 mg/dL occurred in 11.4% of pts. No grade 3/4 (>3 ULN) elevations of serum bilirubin were reported.

Table. Efficacy Endpoints

Randomized DB period (wks 16–40; ITT population: all pts who entered DB period)	All PBO n = 81	All TCZ n = 82	p^a
Primary endpoint: JIA ACR30 flare (relative to wk 16), n (%)^b	39 (48.1)	21 (25.6)	0.0024
Secondary endpoints (at wk 40 relative to day 0^c; ITT population: all pts who entered DB period), n (%)			
JIA ACR30	44 (54.3)	61 (74.4)	0.0084
JIA ACR50	42 (51.9)	60 (73.2)	0.0050
JIA ACR70	34 (42.0)	53 (64.6)	0.0032

Initial lead-in period (at wk 16: ITT population)	TCZ 10 mg/kg <30 kg BW n = 35	TCZ 8 mg/kg <30 kg BW n = 34	TCZ 8 mg/kg ≥30 kg BW n = 119	All TCZ N = 188
JIA ACR responses at wk 16,^{d} n (%)				
JIA ACR30	31 (88.6)	26 (76.5)	111 (93.3)	168 (89.4)
JIA ACR50	28 (80.0)	24 (70.6)	104 (87.4)	156 (83.0)
JIA ACR70	22 (62.9)	14 (41.2)	81 (68.1)	117 (62.2)
JIA ACR90	11 (31.4)	8 (23.5)	30 (25.2)	49 (26.1)

JIAACR core components at wk 16, mean change from baseline (% change from baseline)^e				
Active joints (0–71)	−16.8 (−63.4)	−12.5 (−55.6)	−13.0 (−73.0)	−13.6 (−68.2)
Joints with limitation in range of motion (0–67)	−13.2 (−61.8)	−8.3 (−49.9)	−9.6 (−66.0)	−10.1 (−62.4)
Parent-rated patient global assessment of well-being (VAS 0–100 mm)	−30.1 (−31.7)	−35.8 (−55.6)	−29.3 (−53.3)	−30.9 (−49.5)
Physician-rated global assessment of disease activity (VAS 0–100 mm)	−45.8 (−61.5)	−40.6 (−65.2)	−42.7 (−72.6)	−42.9 (−69.2)
Disability as measured by the CHAQ-DI (0–3)	−0.892 (−54.5)	−0.827 (−46.2)	−0.621 (−49.1)	−0.708 (−49.6)
ESR (mm/h)	−26.0 (−71.0)	−17.0 (−21.8)	−26.8 (−70.9)	−25.0 (−62.5)

^{a} Analysis adjusted for background MTX and/or CS therapy applied at wk 16.
^{b} Pts who withdrew or escaped (to OL TCZ) were classified as flared.
^{c} Pts who withdrew or escaped (to OL TCZ) or for whom endpoint could not be determined were classified as nonresponders.
^{d} Pts who withdrew or for whom the endpoint could not be determined were classified as nonresponders.
^{e} Pts who withdrew before wk 16 were excluded.

Conclusion: TCZ treatment in pcJIA was efficacious, with a sustained clinically meaningful improvement using a monthly regimen at doses of 8 mg/kg if BW ≥30 kg and 10 mg/kg if BW <30 kg. The safety profile is consistent with that in other TCZ-treated pts (eg, systemic JIA).[2]

Clinical and Serologic Predictors of Response in Rituximab-Treated Refractory Adult and Juvenile Dermatomyositis (DM) and Adult Polymyositis (PM) - the RIM Study. Rohit Aggarwal[1], Ann M. Reed[2], Dana P. Ascherman[3], Richard J. Barohn[4], Brian M. Feldman[5], Frederick W. Miller[6], Lisa G. Rider[6], Michael Harris-Love[7], Marc C. Levesque[1], Chester V. Oddis[1] and the RIM Study Group[8]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Mayo Clinic, Rochester, MN, [3]University of Miami, Miami, FL, [4]Department of Neurology, University of Kansas Medical Center, Kansas City, USA, Kansas City, MO, [5]The Hospital for Sick Children, Toronto, ON, [6]NIEHS, NIH, Bethesda, MD, [7]VA Medical Ctr, Washington, DC, [8]

Background/Purpose: The Rituximab in Myositis (RIM) Study evaluated 200 refractory myositis patients treated with rituximab, 83% of whom met the definition of improvement (DOI). The aim of this study was to identify the clinical and laboratory predictors of response in this cohort.

Methods: All patients failed corticosteroids and at least 1 other immunosuppressive (IS) agent and received rituximab at weeks 0/1 (Early) or 8/9 (Late). The 1° endpoint in this 44-week trial was time to achieve DOI [≥20% improvement in 3 of 6 core set measures (CSM) (includes manual muscle testing (MMT), muscle enzymes, HAQ, patient/parent global, physician global disease activity and extramuscular disease activity) with no >2 CSM worsening by ≥25% (excluding MMT)] at 2 consecutive visits. We analyzed the effect of the following baseline variables on the time to DOI: myositis subtype, demographics, laboratory [IgM, IgG, myositis-associated autoantibodies (MAA), CBC, creatinine], damage measures (global, muscle damage and atrophy and organ-related), disease activity and other clinical parameters (skeletal/GI/pulmonary/muscle disease activity, Raynaud, calcinosis, mechanic hands), CSM, medication (early vs. late rituximab, IS agents and corticosteroids) and MAA subset [anti-synthetase (anti-Syn), Mi-2, SRP, TIF1-γ, MJ, other autoantibodies and those without an MAA]. The Wilcoxon test was used to univariately evaluate the association of baseline variables with the time to DOI. A multivariate time-dependent proportional hazard model was built using forward selection ($\alpha=0.05$) based on univariate variables with $p<0.1$.

Results: 200 randomized patients (76 PM/76 DM/48 JDM) were analyzed (96 Early/104 Late). Table 1 lists the baseline variables which predicted time to DOI univariately. The multivariate model included autoantibodies (anti-Syn was the best DOI predictor followed by Mi-2 as compared to the 'no

MAA' subset), and global damage (lower damage had a better response). The effects of global damage diminished by week 20. Myositis subtype (JDM had a better response than adult myositis) was not statistically significant univariately, however, final model was stratified by the subtypes due to their clinical relevance and post hoc had statistical significance in multivariate models.

Table 1. Univariate predictive factors and final multivariate model

Univariate variable for predicting future DOI (0.1 level of significance)

Factor	Associated with more rapid achievement of DOI (Hazard Ratio)	p-value for Wilcoxon test for trend
Gender	males (1.28)	p=0.10
Autoantibody	Anti-Syn (2.83) Mi-2 (2.48), Other MAA (1.39) as compared with no MAA	p=0.001
White blood count	higher counts (1.44)	p=0.04
Muscle damage	lower damage (1.26)	p=0.02
Muscle atrophy	absence of atrophy (1.45)	p=0.02
Global damage	lower damage (1.30)	p=0.004
Most abnormal muscle enzyme	higher result (1.30)	p=0.09
Extramuscular disease activity	higher values (1.26)	p=0.07
Disability index	higher values (1.09)	p=0.09

Multivariate model based on the variables identified in univariate analysis

Autoantibody	Hazard ratio of DOI	P-value (comments)
no MAA	-	(Baseline)
Jo-1/other antiSyn	3.03	<0.01 (for adult PM or DM)
Mi-2	2.49	<0.01(for JDM or adult DM)
Other MAA (SRP, MJ, TIF1-γ, other)	1.38	0.140
Global Damage (dichotomized at median <23 vs. >23)	0.43	<0.01 for week 8, washes out by week 20

Conclusion: Anti-Syn and Mi-2 autoAbs strongly predicted improvement in rituximab-treated refractory myositis patients. JDM and lower disease damage predicted more rapid improvement early in course of treatment. It is unclear whether this effect is due to a delayed beneficial effect of rituximab in patients with higher damage and adult PM/DM. These results suggest that early, more aggressive therapy could be considered in some clinical and serologic myositis subsets to achieve a better therapeutic response and to avoid disease-related damage.

NF-Kb Inducing Kinase (NIK) Is a Key Regulator of Inflammation-Induced Angiogenesis. A.R. Noort[1], K.P.M. van Zoest[1], P. Koolwijk[2], D.V. Novack[3], M.J. Siemerink[1], P. P. Tak[4] and S.W. Tas[1]. [1]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Institute for Cardiovascular Research (ICaR-VU)/VU University Medical Center, Amsterdam, Netherlands, [3]Washington University School of Medicine, St. Louis, MO, [4]Academic Medical Center/ University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: In rheumatoid arthritis (RA) synovial tissue (ST) angiogenesis can be observed already in the earliest phase of disease, which may be critical in the switch from acute to chronic inflammation. The chemokine CXCL12, which is induced via the non-canonical nuclear factor-kB (NF-kB) pathway, plays an important role in angiogenesis, lymphocyte transendothelial migration, and the homing of endothelial progenitor cells. Therefore, the non-canonical pathway, with its key mediator NF-kB inducing kinase (NIK), may play an important role in pathological angiogenesis and the perpetuation of synovial inflammation in RA.

Objectives: To study the role of non-canonical NF-kB signaling in pathological angiogenesis in RA.

Methods: Expression of NIK and CXCL12 in RA ST was evaluated using immunofluorescence microscopy (IF). The angiogenic potential of endothelial cells (EC) was studied in vitro using the tube formation assay and siRNA-mediated gene silencing. Microvessel outgrowth was studied ex vivo by comparing WT and NIK$^{-/-}$ mice in the aortic ring assay. Physiological (developmental) angiogenesis was evaluated in these mice by isolectin B4 staining of the retina followed by confocal microscopy. Finally, the contribution of NIK to synovial angiogenesis was studied in vivo in antigen-induced arthritis (AIA).

Results: NIK was highly expressed in EC in RA ST and co-localized with the EC marker vWF in small (newly formed) blood vessels. NIK, p52 and CXCL12 were expressed both in EC in small blood vessels and in PNAd$^+$ high endothelial venules. In vitro, EC treated with stimuli that induce non-canonical NF-kB signaling (i.e. lymphotoxin, LIGHT, CD40L) significantly enhanced tube formation 2,5-fold (p<0.05), which could be completely blocked by siRNA targeting NIK or IKKα, but not completely by IKKβ (canonical NF-kB pathway). Aortic rings from WT and NIK$^{-/-}$ mice showed normal TNF- and VEGF-induced microvessel outgrowth. In contrast, whereas non-canonical NF-kB stimuli induced microvessel outgrowth in WT mice (unstim 29.94 ± 6.08 vs. LT 159.1 ± 50.24 vs. LIGHT 110.3 ± 17.68 (mm^2) p<0.05), no microvessel outgrowth was observed in aortic rings from NIK$^{-/-}$ mice (unstim 28.74 ± 15.89 vs. LT 45.9 ± 16.71 vs. LIGHT 43.41 ± 15.73 (mm^2)). In line with this, NIK$^{-/-}$ mice exhibited normal developmental angiogenesis in the retina, but a 50% reduction in pathological angiogenesis in synovial inflammation (blood vessels in synovial tissue WT 20 ± 5.07 vs. NIK$^{-/-}$10.2 ± 3.02).

Conclusion: NIK is preferentially expressed in EC in RA ST. Induction of non-canonical NF-kB signaling in EC resulted in enhanced angiogenesis in vitro, and siRNA-mediated selective blockade of this pathway abrogated these effects. Moreover, NIK$^{-/-}$ mice exhibited normal developmental and VEGF-induced angiogenesis, but reduced pathological angiogenesis in AIA. These findings point towards an important role of the non-canonical NF-kB pathway in pathological angiogenesis associated with chronic (synovial) inflammation. This could be exploited for the development of future new therapies for RA.

Gene Targeting of an Integrin-Mediated Signaling Adaptor Molecule, Crk-Associated Substrate Lymphocyte Type Reduced the Severity of Collagen-Induced Arthritis. Its Possible Involvement in the Pathophysiology of Rheumatoid Arthritis. Satoshi Iwata, Tomoki Katayose, Yoshiko Kichikawa, Hiromi Ichihara, Hiroshi Kawasaki, Osamu Hosono, Hirotoshi Tanaka and Chikao Morimoto. The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background/Purpose: It has been reported that the expression levels of β1 integrins and the ligands such as VCAM-1 are elevated in the affected joints of RA patients. Cas-L is a cytoplasmic docking protein downstream of β1 integrin-mediated signaling pathway and is essential for β1 integrin-mediated cell migration and costimulation in T cells. We found that the levels of Cas-L were markedly elevated in various tissues from HTLV-I tax transgenic mice, a murine model of RA. Interestingly, a large amount of Cas-L positive lymphocytes and leukocytes were shown to infiltrate into the inflamed joints, suggesting its roles for the pathophysiology of RA. To further evaluate the involvement of Cas-L in the development of RA, we analyzed collagen-induced arthritis using Cas-L knockout mice.

Methods: We immunized Cas-L knockout mice (KO) and wild-type mice (WT) on a C57BL6 background with the emulsion of chicken type II collagen (IIC) and complete Freund's adjuvant on day 0 and day 21. The animals were assessed for the severity and occurrence of arthritis. In addition, limb joints were assessed by HE staining, immunohistochemistry, and x-ray. Serum samples were collected on the day 21 and the levels

of multiple cytokines and chemokines were measured by Luminex. In vitro, IIC-specific proliferative response of lymphocytes from the draining lymph nodes (LN) was analyzed by ^{3}H-thymidine incorporation assay. CD4$^+$T cells were purified from splenocytes by MACS, and costimulatory response (CD3 plus fibronectin and CD3 plus CD28) were analyzed by the same assay. Furthermore, we made bone marrow chimera with WT (graft)/KO (host) and KO (graft)/WT (host), then challenged with collagen-induced arthritis.

Results: Although the overall incidence of arthritis was similar between KO and WT, the onset of the disease was retarded in KO, and the severity of arthritis was significantly reduced in KO compared to WT. By immunohistochemical analysis, the hindlimbs from WT showed more severe infiltration of inflammatory cells, bone destruction, inflammatory changes, and synovial thickening compared to KO. In WT, inflammatory cytokines such as TNF-α, IL- 17, IL-6 showed higher levels compared to KO. On the contrary, the level of anti-inflammatory cytokine IL-10 was lower than KO mice. Lymphocytes proliferative response against IIC was reduced in KO. Furthermore, costimulatory response of CD4+ T cells to CD3 plus fibronectin was reduced in KO, in contrast, the response to CD3 plus CD28 was higher in KO compared to WT. Finally, bone marrow chimera revealed that the severity of CIA was lower in KO (graft)/WT (host) than WT (graft)/KO (host).

Conclusion: Gene-targeting of Cas-L conferred the resistance against CIA with altered balance of the pro-inflammatory and anti-inflammatory cytokines. The costimulatory response of the T cells and IIc-specific response of lymphocytes were also altered. It seems that hematopoietic cells were more responsible for the gene-targeting effect of Cas-L based on the bone marrow chimera experiment. Taken together, Cas-L may play a pivotal role in the pathophysiology of collagen-induced arthritis. It is thus suggested that Cas-L may be a potential molecular target for the treatment of RA.

1601

Role of Focal Adhesion Kinase in Synovial Fibroblast Invasion and Arthritis. Miriam A. Shelef, David Bennin and Anna Huttenlocher. Univ of Wisconsin Schl of Med, Madison, WI

Background/Purpose: Rheumatoid arthritis is an inflammatory arthritis characterized by joint erosions and destruction. This damage is mediated in part by invasion of synovial fibroblasts into cartilage and bone. Cellular invasion has been extensively studied in cancer cells, but we are just beginning to understand the elements necessary for synovial fibroblast invasion. Focal adhesion kinase (FAK) is a protein scaffold and tyrosine kinase important for cancer cell migration and invasion. FAK may also play a role in synovial fibroblast invasion and arthritis. Phosphorylated FAK is increased in rheumatoid synovial tissue and localizes to focal adhesions in rheumatoid synovial fibroblasts. Also, FAK mediates IL-6 induction and is expressed in endothelial and immune cells. FAK inhibitors are in clinical trials for cancer, so if FAK were important for synovial fibroblast invasion and arthritis, FAK inhibitors might also be of benefit for treating rheumatoid arthritis.

Methods: Synovial fibroblasts derived from the synovial fluid of patients with rheumatoid arthritis were treated with vehicle control or two different FAK inhibitors, PF 562271 and PF 573228, and plated on Matrigel invasion chambers to assess the role of FAK in invasion. To dissect which steps of invasion require FAK activity, we assessed migration using fibronectin coated transwells and focal matrix degradation by plating synovial fibroblasts on coverslips coated with fluorescent gelatin. To determine the role of FAK in arthritis, we crossed established lines of mice to generate mice that overexpress TNFα, express tamoxifen inducible Cre recombinase, and carry FAK flanked by LoxP sites. These TNF$^+$Cre$^+$FAK$^{f/f}$mice spontaneously get arthritis due to overexpression of TNFα and can be induced to delete FAK by treatment with tamoxifen. Western blots were done to assess loss of FAK protein in splenocytes after tamoxifen treatment. Arthritis was assessed in FAK deficient and control arthritic mice by scoring paw swelling and deformity as well as testing grip strength from 2 to 5 months of age.

Results: Inhibition of FAK using either PF 562271 or PF 573228 resulted in decreased rheumatoid synovial fibroblast invasion through Matrigel and decreased migration through fibronectin coated transwells compared to vehicle control. Focal degradation of gelatin still occurs when FAK is inhibited. TNF$^+$Cre$^+$FAK$^{f/f}$mice treated with tamoxifen were found to have good deletion of FAK in splenocytes. Arthritic mice deficient in FAK did not

have significant alterations in arthritis by clinical scoring compared to arthritic mice without FAK deletion.

Conclusion: Consistent with findings in cancer cells, activated FAK is an important component of synovial fibroblast migration and the migratory component of invasion, but not focal matrix degradation. According to clinical arthritis scores, FAK does not appear to play a critical role in arthritis. Studies are ongoing to address if loss of FAK protein, as opposed to FAK inhibition, alters focal gelatin degradation and if joint erosions are altered in arthritis in the absence of FAK, which may be a more specific sign of synovial fibroblast dysfunction than clinical scores.

1602

Tie2 Signalling Induces a Pro-Inflammatory and Pro-Angiogenic Phenotype in Differentiated Macrophages, Independently of Macrophage Polarization Conditions, and Contributes to Production of Cytokines Elevated in Early Rheumatoid Arthritis. Samuel Garcia[1], Sarah Krausz[1], Carmen A. Ambarus[2], Bea Malvar Fernandez[1], Dominique L. Baeten[1], Paul P. Tak[3] and Kris A. Reedquist[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Academic Medical Center, University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: Angiopoietin (Ang) -1 and -2 signalling to the Tie2 tyrosine kinase receptor has an essential role in blood vessel remodeling and angiogenesis. Ang-1, Ang-2 and Tie2 are all expressed in rheumatoid arthritis (RA) synovial tissue. Activated Tie2 is prominently observed in RA synovial macrophages, both Ang-1 and Ang-2 can cooperate with TNF to induce macrophage IL-6 production, and Ang-1 signaling to Tie2 promotes disease persistence and progression in early RA. Here, we examined how macrophage differentiation regulates expression of Tie2 and macrophage responses to Ang-1 and Ang-2, as well as the impact of Tie2 signalling on macrophage production of secreted products elevated in the synovial fluid (SF) of early RA patients.

Methods: Human healthy donor peripheral blood mononuclear cells were isolated from buffy coats and differentiated into macrophages in the presence of Ang-1 and Ang-2, the pro-inflammatory/classically activating cyokines GM-CSF and IFN-γ, or in the presence of the anti-inflammatory/alternatively activating cytokines M-CSF or IL-10. The expression of macrophage polarization markers and Tie2 was analyzed by flow cytometry and quantitative (q)-PCR. Macrophages were stimulated with TNF in the presence or absence of Ang-1 or Ang-2 and effects on gene expression assessed using low density q-PCR arrays, ELISA and luminex. Monocyte chemotactic responses were assessed using 96-well transwell systems.

Results: Macrophage Tie2 protein and mRNA expression was observed under all conditions, but failed to correspond to pro- or anti-inflammatory phenotypes, as it was highest in macrophages differentiated in IL-10 and IFN-g. Ang-1 and Ang-2 failed to induce macrophage polarization. Each polarization condition displayed a distinct expression profile of angiogenic factors. Ang-1 and Ang-2 alone failed to influence gene expression. Ang-1, and to a lesser extent Ang-2, synergized with TNF to stimulate expression of similar gene profiles regardless of macrophage polarization conditions. Significantly enhanced TNF-induced CXCL2, CXCL-3, CXCL-9, IL-6 mRNA expression was observed. Neither Ang-1 nor Ang-2 stimulated monocyte chemotaxis. However, conditioned medium from macrophages stimulated with TNF in combination with Ang-1 or Ang-2 demonstrated significantly enhanced chemotactic activity for monocytes, compared to conditioned medium from macrophages stimulated with TNF alone. Ang-1, but not Ang-2, significantly cooperated with TNF to induce macrophage production of cytokines elevated in the SF of early RA patients, including TGFalpha, FGF2, and IL-12B.

Conclusion: Our results demonstrate that Tie2 is functionally expressed in macrophages, regardless of macrophage polarization conditions. Stimulation of macrophage Tie2 with Ang-1, and to a lesser extent Ang-2, enhances TNF induced pro-inflammatory cytokine and chemokine expression. These results suggest that Tie2 signaling, in combination with TNF, induce a pro-inflammatory and pro-angiogenic profile in differentiated macrophages, and provide a molecular basis for the role of Tie2 in promoting disease progression in both early and established RA.

1603

Inhibitor of DNA Binding 1 As a Secreted Angiogenic Transcription Factor in Rheumatoid Arthritis. Takeo Isozaki[1], M. Asif Amin[1], Alisa E. Koch[2], Ali Arbab[3], Stephanie A. Shuman[1], Christine M. Ha[1], G. Kenneth Haines III[4] and Jeffrey H. Ruth[1]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Henry Ford Hospital and Medical Centers, Detroit MI 48202, Detroit, MI, [4]Yale University, New Haven, CT

Background/Purpose: Rheumatoid arthritis (RA) is characterized by enhanced blood vessel development in joint synovium. This involves the recruitment of endothelial progenitor cells (EPCs), allowing for de novo vessel formation and pro-inflammatory cell infiltration. Inhibitor of DNA Binding 1 (Id1) is a transcription factor unique to EPCs that influences cell maturation. We hypothesized that Id1 could be secreted and expressed in RA, and influence blood vessel growth. We also wanted to define the contribution of this transcription factor in RA, and correlate it with CXCL16 expression, as EPCs also prominently express the only known CXCL16 receptor, CXCR6.

Methods: Enzyme Linked Immunosorbant Assay (ELISA) and Polymerase Chain Reaction (PCR) was used to examine Id1 levels in synovial fluids (SFs) and endothelial cells (ECs) respectively. Immunohistology and immunofluorescence (IF) histology was used to determine the expression of Id1 in RA compared to osteoarthritis (OA) and normal (NL) synovial tissues (STs). We used Matrigel angiogenesis and human dermal microvascular EC (HMVEC) migration assays to determine if recombinant human (rhuId1) and/or RA SF immunodepleted of Id1 alters angiogenic activity. Finally, CXCR6 deficient (CXCR6$^{-/-}$) and wild-type (wt) C57BL/6 mice were primed to develop K/BxN serum induced arthritis and evaluated for joint swelling. Joint tissues from these mice were examined for Id1 and correlated with CXCR6 expression and arthritis development.

Results: ST samples immunostained for Id1 showed heightened expression in RA compared to OA and NL ST. By IF staining, we found significantly more Id1 in RA compared to OA and NL vasculature, showing that Id1 expressing cells, therefore EPCs, are most active in vascular remodeling in the RA synovium. We also detected significantly more Id1 in RA compared to OA and other arthritis SFs by ELISA that highly correlated with CXCL16 levels (p<0.05, n=10, r=0.64 Pearson's Correlation). *In vitro* chemotaxis assays also showed that Id1 is highly chemotactic for HMVECs. Using *in vitro* Matrigel assays, we found that HMVECs form tubes in response to rhuId1 and sham depleted RA SF, and that Id1 immunodepleted from RA SF profoundly decreases tube formation. PCR showed that Id1 mRNA could be upregulated in both HMVECs and EPCs with tumor necrosis factor-α (TNF-α) or CXCL16, with highest amounts seen in EPCs in response to CXCL16. Finally, using the K/BxN serum induced arthritis model, we correlated EC CXCR6 with Id1 expression by immunohistochemistry. These findings were further validated by highly significant reductions in blood vessels and hemoglobin (Hb) content in joint tissues from K/BxN serum induced CXCR6$^{-/-}$ mice.

Conclusion: Our data indicates that Id1 correlates with CXCL16 in RA SF and that CXCR6$^{-/-}$ arthritic mice have notable reductions in Id1 expression and arthritis development, correlating with profound declines in vasculature and joint Hb content. We also found that Id1 is potently angiogenic, and can be upregulated in HMVECs and EPCs by TNF-α and especially CXCL16. These results indicate that CXCL16 and its receptor CXCR6 may be a central ligand-receptor pair that can be highly correlated with Id1 expression, EPC recruitment, and blood vessel formation in the RA joint.

Parity and the Risk of Developing Rheumatoid Arthritis: Results From the Swedish Epidemiological Investigation of Rheumatoid Arthritis Study. Cecilia Orellana[1], Lars Klareskog[2], Lars Alfredsson[1] and Camilla Bengtsson[1]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Rheumatoid arthritis (RA) is more common among women than among men and the gender difference in incidence seems to be most striking before menopause (1). The importance of hormonal/reproductive factors has been hypothesized to explain this difference, but the literature is scarce and contradictory. Parity has been suggested to decrease the risk of RA and postpone the disease onset but, on the contrary, a higher risk of RA in the post-partum period has been described (2). The aim of this work was to study the association between parity, post-partum period and age at first birth and the risk of developing RA in pre-menopausal women, by stratifying the cases according to presence/absence of antibodies to citrullinated peptides (ACPA).

Methods: Data from the Swedish population-based EIRA (Epidemiological Investigation of RA) case-control study comprising 603 incident cases aged 18–44 years old women and 906 controls (matched by age and residential area) was analyzed. Parity, post-partum period before the onset of symptoms and age at first birth were assessed by means of an identical questionnaire answered by the participants. In all analyses, nulliparous women were used as the reference group. Unconditional logistic regression analyses to obtain odds ratios (ORs) with 95% confidence intervals (CI) were performed.

Results: An increased risk of developing ACPA-negative RA in parous women compared with nulliparous women (OR 2.1 (95% CI 1.4–3.2)) was found. Women whose most recent delivery occurred the same year as the disease onset showed an increased risk of developing ACPA-negative RA (OR 2.6 (95% CI 1.4–4.7)). This risk decreased after 1 year (OR 1.8 (95% CI 0.9–3.6)) and reached the null value after 2 years (*p-value* for trend 0.0147). Women who delivered their first child at a younger age had an increased risk of developing ACPA-negative RA (*p-value* for trend 0.0158). No association between parity, post-partum period or age at first birth and the risk of ACPA-positive RA was observed.

Conclusion: Our results indicate that parity increases the risk of ACPA-negative RA in pre-menopausal women, but has no association with ACPA-positive RA. The increased risk seemed to be more pronounced in the post-partum period within 1 year after child delivery and among women who had their first child at young age. As previously described, a postponed onset of RA, comparable with the amelioration of the pre-established disease in pregnant women followed by a post-partum flare-up might explain these results in regards to the post-partum period. Further research is needed in order to explore the biological mechanisms behind our findings but the effect of hormonal/reproductive factors such as parity might partly explain the higher incidence of RA in pre-menopausal women.

Anti-Citrullinated Peptide Autoantibodies to Rheumatoid Synovium Epitopes in Women and Risk of Future Rheumatoid Arthritis. Elizabeth V. Arkema[1], Barbara L. Goldstein[2], William H. Robinson[3], Catriona Cramb[4], Jeremy Sokolove[5], Jing Cui[6], Susan Malspeis[6], Elizabeth W. Karlson[7] and Karen H. Costenbader[7]. [1]Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Stanford University, Palo Alto, CA, [4]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [5]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [6]Brigham and Womens Hospital, Boston, MA, [7]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Recent studies have shown that anti-citrullinated protein antibodies (ACPA) are detectable years before rheumatoid arthritis (RA) diagnosis, representing a potential early marker of RA pathogenesis. The goal of this study was to investigate the presence of several ACPAs targeted to epitopes found in the rheumatoid synovium years prior to RA diagnosis, within a nested case-control study in the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII) cohorts.

Methods: We confirmed 196 incident RA cases (NHS: 139; 1976–2008, NHSII: 57; 1989–2009) with blood collected prior to RA symptoms by medical record review. Three controls were matched to each case on year of birth, race, menopausal status and post-menopausal hormone use, time of day, fasting status

at blood draw and timing in the menstrual cycle (pre-menopausal women in NHSII only). Sixteen ACPA antigens previously identified by protein mass spectrometry were coupled to spectrally distinct beads for analysis using the BioPlex platform using a Luminex 200 instrument. These peptides included epitopes derived from clusterin, enolase, fibrinogen, histone 2A and vimentin. Cutpoints for positivity were defined by ROC analyses. Conditional logistic regression models were used to estimate risk ratios and 95% confidence intervals (RR; [95% CI]) in each cohort separately and combined using meta-analysis random effects models for 13 of the ACPAs. Multivariable-adjusted models included alcohol intake and pack-years smoking, collected by questionnaire before blood draw. We adjusted for multiple comparisons using Bonferroni adjustment. Spearman correlation was used to determine whether the number of positive ACPA reactivities was associated with the time between blood draw and diagnosis (4 mo- 14 yr) among cases only.

Results: Mean time ($\pm$SD) from blood draw to diagnosis among cases was 8.4 ($\pm$4.8) years in NHS and 5.0 years ($\pm$2.7) in NHS2. Mean age ($\pm$SD) at RA diagnosis was 64.1($\pm$8.0) and 49.2 ($\pm$5.1) years in NHS and NHSII. In NHS, 57.9% and, in NHSII, 53.0% of cases were seropositive at diagnosis. In multivariable-adjusted conditional logistic regression analyses, antibody reactivity against clusterin, enolase, 3 of the fibrinogen, both of the histone 2A epitopes and citrullinated vimentin were strongly associated with RA risk (Table). Cases with blood drawn closer in time to diagnosis had a higher number of positive ACPAs (NHS: ρ corr =0.35, p<0.0001, NHSII: ρ corr=0.25, p=0.07).

Table. Anti-Citrullinated Peptide Autoantibodies (ACPA) and Risk of Rheumatoid Arthritis in NHS and NHSII

ACPA Target	NHS (139 cases/ 416 controls) +cases/ +controls	NHS II (57 cases/ 167 controls) +cases/ +controls	Combined··· AdjustedOR* (95%CI)	p-value	p-hetμ

Enolase	6/2	4/3	9.53 (2.84, 31.99)	<0.001	1.0
Fibrinogen cit	2/0	0/2	-	-	-
Fibrinogen A 41–60 cit3 cyclic	7/2	2/2	6.52 (1.90, 22.43)	0.003	0.35
Fibrinogen A 211–230 Cit smCyclic	5/8	1/5	1.57 (0.58, 4.27)	0.38	0.45
Fibrinogen A 556–575 Cit	6/2	1/1	7.43 (1.81, 30.43)	0.005	0.76
Fibrinogen A 556–575 Cit smCyclic	14/3	7/2	14.99 (5.42, 41.41)	<0.0001	0.82
Fibrinogen A 616–635 cit3	7/1	4/2	13.85 (2.98, 64.32)	<0.001	0.64
Fibrinogen A 616–635 Cit3 smCyclic	13/0	4/2	-	-	-
Histone 2A/a-2 1–20 Cit	12/9	7/5	5.56 (2.56, 12.10)	<0.0001	0.65
Histone 2A/a 1–20 Cit sm2 Cyclic	15/10	9/3	6.72 (2.62, 17.25)	<0.0001	0.23
Vimentin	67/212	26/85	0.90 (0.64, 1.27)	0.55	0.51
Vimentin Cit	7/2	4/1	14.07 (3.77, 52.53)	<0.0001	0.83
Vimentin 58–77 Cit3 Cyclic sm1	6/0	7/2	-	-	-

*adjusted for cumulative alcohol intake and pack-years smoking
···Combined using random-effects meta-analysis models
p for heterogeneity between the two cohorts
16 separate ACPAs tested, cutoff with Bonferroni adjustment = 0.003

Conclusion: We have demonstrated that several of a panel of ACPAs targeted to the rheumatoid synovium are strongly associated with risk of future RA. The number of ACPAs recognized is associated with time to diagnosis, which suggests that epitope spreading occurs within 4 years of diagnosis and thus temporally proximal to the time of diagnosis.

Identifying a Link Between Uranium Exposure and Systemic Lupus Erythematosus in a Community Living near a Uranium Plant. Pai-Yue Lu[1], Leah C. Kottyan[1], Susan M. Pinney[2], Judith A. James[3], Changchun Xie[2], Jeanette M. Buckholz[2] and John B. Harley[4]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH, [3]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK, [4]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH

Background/Purpose: Effects of environmental exposures on the development of systemic lupus erythematosus (SLE) are potentially important and relatively unexplored in SLE pathogenesis. An excess of reported SLE cases in a community surrounding a former uranium ore processing plant provided an opportunity to evaluate the relationship between uranium exposure through downstream air or water and SLE. Our specific *a priori* objective was to explore the hypothesis that SLE patients will be found more frequently in community members exposed to high prior uranium exposure levels in the Fernald Community Cohort (FCC).

Methods: A nested case control study was performed with data from the FCC. The FCC is comprised of voluntarily enrolled individuals who lived during plant operation within 5 miles of a uranium ore processing facility in Fernald, OH and followed from 1990 to 2008, which was after the plant ceased operations. No uranium plant workers are included in this study. Potential SLE cases were identified with searches for ICD9 codes associated with lupus (710.0 and 695.4) and a medication code search for hydroxychloroquine. Sera from potential cases were screened for autoantibodies using the Bioplex 2200 multiplex assay and anti-cardiolipin antibodies using ELISA. Cases were confirmed using an operational definition that included American College of Rheumatology classification criteria and medical record documentation. Four age-, race-, and sex-matched controls were selected for every case. Cumulative uranium exposure was calculated for each individual with a dosimetry model developed by the Centers for Disease Control and Prevention. Covariates in the analysis included smoking history, alcohol intake history, and family history of SLE. Logistic regression was used to calculate odds ratios (OR) with 95% confidence intervals (CI). For comparison, preliminary analysis with rheumatoid arthritis (RA, ICD9 code 714.0) was also performed.

Results: The FCC includes 4,187 individuals with low uranium exposure, 1,273 with moderate exposure, and 2,756 with high exposure. SLE was confirmed in 20 of 26 cases with an ICD9 code of 710.0, in 2 of 5 cases with an ICD9 code of 695.4, and in 2 of 43 other cases prescribed hydroxychloroquine. The female to male ratio among cases was 5 to 1. Of the SLE cases, 5 were in the low exposure group, 7 in the moderate exposure group, and 12 in the high exposure group. Following logistic regression modeling, SLE was found to be associated with high exposure (OR 4.81, 95% CI 1.38–16.75, p = 0.043). There was no association between low or moderate uranium exposure and SLE. In the FCC overall, RA occurs at the expected prevalence, while SLE is increased by 5-fold over the expected prevalence.

Conclusion: High uranium exposure is associated with SLE relative to matched controls in this sample of uranium exposed individuals, suggesting that our hypothesis is correct. Potential explanations for this relationship include the estrogen effects of uranium, somatic mutation from ionizing radiation, or effects of some other unidentified accompanying exposure. Whatever the cause for this association, understanding the basis of this relationship is likely to provide important fundamental insight into SLE pathogenesis.

The Association Between Thyroxin Substitution and Rheumatoid Arthritis; Results From the Swedish EIRA Study. Camilla Bengtsson[1], Henrik Källberg[1], Leonid Padyukov[2] and Saedis Saevarsdottir[3]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden

Background/Purpose: Hypothyroidism is usually of autoimmune nature, in areas with sufficient iodine, and leads to chronic substitution treatment with thyroxin. The disease shares some risk factors with ACPA-positive rheumatoid arthritis (RA), i.e. smoking and the PTPN22 risk allele, while different alleles of the HLA-DRB1 locus are associated with these diseases (RA: *01, *04 and *10 (shared epitope, SE); hypothyroidism: *03)[1,2] We asked whether thyroxin substitution was associated with RA overall, the ACPA-positive or ACPA-negative subset, and whether an interaction with SE alleles was present.

Methods: Data from the Swedish population-based EIRA (Epidemiological Investigation of Rheumatoid Arthritis) case-control study was analysed. In total, 1947 incident cases and 2246 randomly selected controls (matched on age, sex, residency), aged 18–70 years, participated in the study. Those who started treatment with thyroxin before the year of onset were compared those without treatment. Participants who reported a history of thyroid cancer (1 case and 1 control) were excluded from the analyses. We calculated odds

ratios (OR) with 95% confidence intervals (CI) for RA overall and the ACPA-positive and ACPA-negative subsets, by means of unconditional logistic regression models. Adjustments for smoking and PTPN22 only marginally changed the results and were not retained in the final analyses. Interaction was evaluated by calculating the attributable proportion (AP) due to interaction and its 95% confidence interval (CI).

Results: The risk of RA among those with thyroxin substitution was doubled, compared with those without thyroxin substitution (OR=2.0, 95% CI 1.5–2.7). When divided by ACPA status, there were no major differences between these two subsets (ACPA-positive: OR=1.9, 95%CI 1.4–2.7); ACPA-negative: OR=2.2, 95%CI 1.5–3.1). The OR of ACPA-positive RA for the combination of thyroxin substitution and no SE was 1.4 (95% CI 0.7–3.0), compared with neither of these factors. The OR for the combination of no thyroxin substitution and SE was 5.7 (95% CI 4.6–6.9) and for the combination of thyroxin substitution and SE the OR was 12.0 (95% CI 7.1–20.4). Thus a strong interaction between SE and thyroxin substitution was observed (AP=0.5, 95% CI 0.2–0.8).

Conclusion: Thyroxin substitution, reflecting an underlying hypothyroidism, was associated with the risk of developing ACPA-positive and ACPA-negative RA later in life. Thyroxin substitution also interacted with the shared epitope in the development of ACPA-positive RA, indicating that in patients with hypothyroidism, the presence of the shared epitope alleles, provides an even higher risk of ACPA-positive RA. Our data suggest overlapping pathways in the development of two common autoimmune diseases.

Overweight and Obesity Increase Risk of Rheumatoid Arthritis in Women in a Large Prospective Study. Bing Lu[1], Chia-Yen Chen[2], Linda T. Hiraki[3], Karen H. Costenbader[1] and Elizabeth W. Karlson[1]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA

Background/Purpose: Several case-control studies have suggested that overweight and obesity may increase the risk of rheumatoid arthritis (RA), but the evidence is conflicting. We examined the relationship between pre-existing overweight or obesity in development of future RA in two large prospective cohorts, the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII).

Methods: The NHS is a prospective cohort study established in 1976 that enrolled 121,700 US female registered nurses, ages 30–55 years. NHSII began in 1989, enrolling 116,608 female nurses aged 25–42 years. Lifestyle and environmental exposures and anthropometric measures have been collected through biennial questionnaires. The incident RA cases were identified using the previously validated connective tissue disease screening questionnaire followed by a medical record review, according to the 1987 ACR criteria. Body Mass Index (BMI) was calculated as weight /height ^{2} (kg/m^2). Overweight and obesity were defined as 25.0'BMI<30 kg/m^2 and BMI≥30.0 kg/m^2 respectively based on World Health Organization classification. We assessed the exposure variable using a time-varying status of overweight and obesity since baseline updated every two years up to 2006/2007. Cox proportional hazards models were used to estimate hazard ratios (HR) of RA, seropositive RA, and seronegative RA phenotypes after adjusting for potential confounders.

Results: During 2,769,593 person-years of follow-up from 1976 to 2008 in NHS and 2,139,702 person-years of follow-up from 1989 to 2009 in NHSII, 1292 incident cases of RA developed (903 in NHS, 389 in NHSII). The age-adjusted incidence rates of RA ranged from 30 to 36 /100,000 person-years in NHS, and 12 to 26 /100,000 person-years in NHSII across increasing levels of BMI. Overweight and obese women have increased risk of RA compared with women with BMI<25 (Table). The multivariate hazard ratios of RA in NHS were 1.19 (95% CI, 1.03–1.38) for overweight and 1.18 (95% CI, 0.98–1.42) for obesity respectively (p trend = 0.029). Consistent with the NHS, the HRs in NHSII were 1.78 (95% CI, 1.40–2.26) for overweight, and 1.73 (95% CI, 1.34–2.23) for obesity (p trend <0.001). Further stratified analyses in NHS demonstrated that the effect of overweight and obesity on RA risk was stronger in seronegative RA than in seropositive RA. The multivariate HRs of seronegative RA were 1.30 (95% CI,

1.03–1.63) for overweight and 1.34 (95% CI, 1.01–1.77) for obese, while the HRs of seropositive RA were 1.12 (95% CI, 0.92–1.36) for overweight and 1.08 (95% CI, 0.84–1.38).

Table. Hazard ratio for incident RA according to Body Mass Index (BMI) in NHS and NHSII

BMI, kg/m^2	NHS			NHSII		
	No. Cases	Person-years	Multivariable HR (95% CI)*	No. Cases	Person-years	Multivariable HR (95% CI)*
<25.0	448	1,515,002	1.00 (Referent)	151	1,243,050	1.00 (Referent)
25.0–29.9	294	802,751	1.19 (1.03,1.38)	129	502,787	1.78 (1.40,2.26)
≥30.0	161	451,840	1.18 (0.98,1.42)	109	412,141	1.73 (1.34,2.23)
p trend			0.029			<0.001

* Adjusted for age, smoking (pack-years), alcohol use, parity/breastfeeding, oral contraceptive use, menopausal status, post-menopausal hormone use.

Conclusion: In this long-term prospective cohort study of women, we found overweight and obesity were significantly associated with increased risk of developing future RA compared to women with BMI <25kg/m^2. Future studies are needed to confirm our findings in other populations.

1609

Circulating 25-Hydroxyvitamin D Level and Risk of Developing Rheumatoid Arthritis. Linda T. Hiraki[1], Jing Cui[2], Susan Malspeis[3], Karen H. Costenbader[4] and Elizabeth W. Karlson[4]. [1]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Womens Hospital, Boston, MA, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Vitamin D has demonstrated immunomodulatory properties with potential etiologic implications for autoimmune diseases including rheumatoid arthritis (RA). However, a causal association between decreased vitamin D levels and increased RA risk has yet to be definitively demonstrated. Cross-sectional studies are not able to rule-out reverse causation. We examined the relationship between circulating 25-hydroxyvitamin D (25(OH)D) and incident RA in 2 nested case-control studies, in the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII) cohorts.

Methods: We conducted a nested case-control investigation of incident RA in prospective cohorts the NHS and NHSII. We included 170 cases with blood samples collected from at least 3 months to 14 years prior to RA diagnosis, each matched to 3 controls on age, menopausal status, postmenopausal hormone use, date, time and fasting status of blood draw. 25(OH)D levels measured by chemiluminescence immunoassay. We used conditional logistic regression to calculate the odds ratio (OR) and 95% confidence intervals for incident RA for continuous 25(OH)D, dichotomous levels categorized as insufficient(<=20ng/mL) vs. sufficient 25(OH)D and quartile cutoffs of 25(OH)D, using age-adjusted and multivariable adjusted models. We repeated the analyses stratified by categories of time between the blood draw and RA diagnosis (3 months to < 4 years, 4 years to < 8 years and >8 years). Random effects models were used to meta-analyze estimates of association from the two cohorts.

Results: Incident RA was confirmed in 123 NHS and 47 NHSII participants. Mean age at RA diagnosis was 64.3 ± 7.9 years for NHS and 49.4 ± 5.2 years for NHSII, 60% were rheumatoid factor positive. Mean time from blood draw to RA diagnosis was 8.3 ± 4.8 years for NHS and 5.0 ± 2.7 years for NHSII. Meta-analysis of crude and multivariable-adjusted conditional logistic models did not show significant associations between circulating 25(OH)D levels (continuously, dichotomously or in quartiles) and odds of RA. However, there was a 25% increased odds of developing RA with every 1ng/ml decrease in circulating 25(OH)D [OR 1.25 (95% CI 1.01, 1.54)] among those NHSII women who had blood analyzed between 3 months and <4 years prior to RA diagnosis (Table). There was no association between 25(OD)D levels and RA in longer time intervals to diagnosis.

Table. Odds ratios and 95% confidence intervals for rheumatoid arthritis associated with a 1ng/mL decrease in 25-hydroxyvitamin D

	NHS				NHSII				Pooled results		
	N cases	N controls	OR (95% CI)	p-value	N cases	N controls	OR (95% CI)	p-value	OR (95% CI)	p-value	p-heterogeneity
Total	123	368	0.99 (0.96,1.02)	0.51	47	138	1.02 (0.97,1.07)	0.42	1.00 (0.97,1.02)	0.9	0.3
Sero+ve	63	186	1.00 (0.95,1.04)	0.83	27	79	1.03 (0.95,1.12)	0.51	1.00 (0.97,1.04)	0.91	0.5
3mo-<4y	30	93	1.06 (0.97,1.03)	0.21	24	69	1.25 (1.01,1.54)	0.04	1.12 (0.96,1.03)	0.16	0.15

Conclusion: We did not find a significant overall association between circulating 25(OH)D levels and odds of developing RA among women in NHS and NHSII. However, we did detect an increased odds of RA associated with low 25(OH)D among women in the NHSII cohort only, with levels measured closest to RA diagnosis (>3months to <4 years). These results suggest that vitamin D levels fall in the time windows closest to RA diagnosis and may represent reverse causation.

The DNA Methylation Signature in Fibroblast-Like Synoviocytes (FLS) Defines Critical Pathogenic Pathways in Rheumatoid Arthritis (RA).
David L. Boyle[1], Robert Shoemaker[2], David W. Anderson[2], Wei Wang[3] and Gary S. Firestein[1]. [1]UCSD School of Medicine, La Jolla, CA, [2]NexDx, Inc., San Diego, CA, [3]UCSD, La Jolla, CA

Background/Purpose: A DNA methylation signature has been characterized that distinguishes RA FLS from osteoarthritis (OA) and normal (NL) FLS. The presence of epigenetic changes in these cells suggest that rheumatoid FLS imprinting might contribute to pathogenic behaviour. Differentially methylated loci (DML) RA FLS are located in the promoters of numerous genes implicated in RA, including validated therapeutic targets like *TNF, CXCL10,* and *IL-1Ra*. To understand how methylated genes might participate in the pathogenesis of RA, we evaluated how DML in RA FLS cluster in the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways.

Methods: Genomic DNA was isolated from fifth passage RA (n=11), OA (n=11) and normal (NL) (n=6) FLS lines obtained at the time of joint replacement (OA, RA) or from the tissue bank (NL). Methylation was evaluated using the Illumina HumanMethylation450 chip. A Welch's t-test identified RA vs. OA and RA vs. NL DML using a false discovery rate, q-value, cut off of 0.05. Genes containing DML within their promoter regions ([-2.5 kb, 500 bp] of TSS) were labeled as differentially methylated genes (DMG). The significance of DMG in KEGG human pathways was determined and resulting p-values represented the fraction of randomly selected background gene sets that were at least as enriched in genes found in the tested pathway as the DMG set. A q-value threshold of 0.01 determined significance.

Results: 2109 DMGs in RA FLS were identified for KEGG analysis. 20 out of 252 KEGG pathways were significantly altered with q <0.01 for RA compared with OA or NL FLS. The greatest differences were in the Focal Adhesion pathway (q<10e-4), with 34 DMG, including key matrix genes (*COL1A2*), signaling genes (*MAPK10, PIK3CG* and *AKT2*), and integrins (*ITGA4, ITGA7, ITGA10*). The Cell Adhesion pathway (26 DMG; q<10e-4) was also differentially methylated, suggesting that RA FLS imprinted abnormalities could affect adhesion and migration. Additional critical pro-inflammatory pathways implicated in RA were also differentially methylated, including Toll-like Receptors and Complement Cascade. The former encompassed 17 DMG, including differential methylation *of TLR1, TLR4,* and *TLR5* as well as *RIPK1* and MAP kinases (q<10e-3). The latter included *C1QB, C3, C3AR1, C4A, C4A, C4B, C4B, C4BPA,* and *C8A*(18 DMG; q=10e-4). Perhaps most intriguing, the pre-defined KEGG "Rheumatoid Arthritis" pathway was significantly different in RA FLS compared to the controls (20 DMG; q<10e-4), while the "Systemic Lupus Erythematosus" pathway was not differentially methylated.

Conclusion: KEGG pathway analysis demonstrates non-random imprinting of RA FLS. The patterns include anomalies in key cell adhesion genes (integrins, focal adhesion) and inflammation genes (signalling and innate immunity). These persistent epigenetic alterations could contribute to the aggressive phenotype of RA synoviocytes and identify potential therapeutic targets that could modulate the pathogenic behaviour.

Background/Purpose: Genome-wide association studies (GWAS) have successfully identified common variants that contribute to Behçet's disease (BD) susceptibility. However, associations due to rare and low-frequency variants have not been evaluated. It has long been debated whether the innate immune system is involved in the pathogenesis of BD. Clinical manifestations such as episodic inflammation and neutrophil recruitment to the sites of inflammation strongly suggest that the innate immune response plays an important role, although genetic evidence to support this hypothesis is sparse. Recent advances in sequencing technology allow investigators to re-sequence targeted genes to discover novel variants in large collections of cases with complex genetic traits and genetically matched controls.

Methods: We performed deep re-sequencing of two GWAS-identified genes (IL23R and IL10) and eleven genes known to have roles in innate immunity (IL1B, IL1R1, IL1RN, NLRP3, MEFV, TNFRSF1A, PSTPIP1, CASP1, PYCARD, NOD2, and TLR4) in 382 cases and 384 controls in Japanese population and 384 cases and 384 controls in Turkish population. Non-synonymous variants identified by deep exonic re-sequencing were validated by individual genotyping of 4955 samples. For statistical analyses, we performed C-alpha test, adaptive sum test and step-up methods to identify the roles of rare and low-frequency variants associated with BD.

Results: We found a non-random distribution of rare and low-frequency variants in cases and controls implicating IL23R, MEFV, TLR4, and NOD2 in BD susceptibility. Adaptive sum test and step-up methods corroborated the results for IL23R in both populations and for TLR4 in the Turkish population. Carriage of MEFV-M694V, known to cause recessively inherited familial Mediterranean fever, conferred BD risk in Turkish samples (Cochran-Mantel-Haenszel meta analysis p=1.79×10^{-12}).

Conclusion: These findings implicate innate immune and bacterial sensing mechanisms in BD pathogenesis. We are currently extending our re-sequencing efforts to CCR1, KLRK1, KLRC1–4, STAT4, and ERAP1, common variants of which we recently identified by GWAS.

Ankylosing Spondylitis Is Associated with Single Nucleotide Polymorphisms in Loci Implicating Four Aminopeptidases. Philip Robinson[1], Adrian Cortes[1], Paul Leo[1], Australian-Anglo-American Spondylitis Consortium (TASC)[2], Wellcome Trust Case Control Consortium (WTCCC).[3], International Genetics of Ankylosing Spondylosis Consortium (IGAS)[4], David Evans[5] and Matthew A. Brown[1]. [1]University of Queensland Diamantina Insititute, Brisbane, Australia, [2]Brisbane, Australia, [3]Wellcome Trust Case Control Consortium, Wellcome Trust Case Control Consortium, United Kingdom, [4]IGAS, Igas, Australia, [5]Bristol University, Bristol, United Kingdom

Background/Purpose: The aim of the study was to examine regions implicated in autoimmune diseases for association with AS. A previous association with AS has been described in the aminopetidase *ERAP1*.

Methods: 9074 European and 1550 east Asian AS cases (defined by the modified New York Criteria), and 13607 European and 1567 Asian controls were studied. Samples were genotyped on the Illumina Infinium Immunochip (196,524 SNVs), clustering performed using Opticall, and analysis performed using linear mixed modelling (FaST-LMM) to control for population stratification.

Results: 9074 European and 1550 east Asian AS cases (defined by the modified New York Criteria), and 13607 European and 1567 Asian controls were studied. Samples were genotyped on the Illumina Infinium Immunochip (196,524 SNVs), clustering performed using Opticall, and analysis performed using linear mixed modelling (FaST-LMM) to control for population stratification.

Results: After QC and removal of non-polymorphic variants, 129,030 SNPs remained. The two previously described independent associations in *ERAP1* were replicated in the European cohort (rs30187, OR=0.77, p=1.3×10^{-41}; rs10050860, OR=0.77, p=3.2×10^{-32}), and suggestive association was noted with rs30187 in the Asian cohort (OR=0.81, p=2.1×10^{-5}). rs10050860 was found to have low MAF (0.037) in the Asian cohort and therefore for this SNP in this ethnic group, the study had low power. In the European cohort, controlling for the association with *ERAP1*, SNPs in *ERAP2* and *LNPEP* were also associated with AS (lead SNP: rs2910686, OR=1.17, p=1.3×10^{-16}). We have previously demonstrated that at ERAP1, disease-protective variants are associated with reduced aminopeptidase function. At ERAP2, the AS-protective G allele of rs2248374 causes a complete loss of ERAP2 mRNA and no expression of ERAP2 protein. In HLA-B27 negative AS cases association was observed with the *ERAP2* SNP also associated with Crohn's disease (rs2549794, OR=1.2, p=8×10^{-6}). Genomewide significant association was noted at chromosome 17q21 at a locus encoding the aminopeptidase NPEPPS (rs9901869, p=3.2 $\times10^{-14}$; OR = 0.88), a further aminopeptidase involved in peptide trimming prior to HLA Class I presentation.

Conclusion: This study identifies robust association with three loci housing four aminopeptidases, *ERAP1*, *ERAP2*, *LNPEP* and *NPEPPS*. At ERAP1 and ERAP2, protective genetic associations are associated with reduced aminopeptidase function. This implicates peptide handling as a major mechanism in the aetiology of both HLA-B27 positive and negative AS.

Background/Purpose: We established an X-linked *TLR7* 3′UTR SNP (rs3853839) as a risk locus for SLE in 9,274 Eastern Asians ($P_{combined}$ = 6.5×10^{-10}). Risk-allele carriers have increased *TLR7* transcripts and more pronounced IFN signature than non risk-allele carriers. The current study sought replication of SLE-associated SNP(s) in non-Asian ancestries and explored the molecular mechanism underlying the identified genetic variant that affects TLR7 expression.

Methods: We conducted genotyping and imputation for 67–115 SNPs (varying among different ancestral backgrounds) covering ~80kb of *TLR7-TLR8* region in European Americans (EA), African Americans (AA) and Hispanics enriched for the Amerindian-European admixture (HS). Each SNP was assessed for the association with SLE. Haplotype-based conditional testing was conducted to distinguish independent signals from associated SNPs and Mantel-Haenszel testing was used in the trans-ancestral meta-analysis. Association of genotype and TLR7 expression was examined using the RT-PCR, flow cytometry and reporter assays. Pyrosequencing was used to measure allelic variations in *TLR7* transcript level.

Results: Our trans-ancestral fine-mapping confirmed the *TLR7* 3′UTR SNP rs3853839 as the only variant in *TLR7-TLR8* region exhibiting consistent and independent association with SLE (P_{meta} = 1.7×10^{-10}, OR [95%CI] =1.24 [1.18–1.34]) in 13,339 subjects of EA (3,936 cases vs. 3,491 controls), AA (1,679 vs. 1,934) and HS (1,492 vs. 807) ancestries. The risk G allele conferred elevated TLR7 expression in PBMCs from healthy individuals at both mRNA (P = 0.01 in men and 0.02 in women) and protein level (P = 0.009 in men and 0.038 in women). PBMCs from heterozygous women exhibited higher G/C allele ratios in *TLR7* transcripts 4 hours after incubation with actinomycin D (inhibitor of transcription initiation) than with vehicle control (P = 0.04), indicating a slower degradation of the G allele-containing transcripts. The non-risk allele, but not risk-allele, was predicted to match microRNA-3148 (miR-3148) at the second base in the binding site. Transcript levels of miR-3148 and TLR7 in PBMCs from 16 SLE patients and 21 normal controls were inversely correlated (R^2 = 0.255, P = 0.001), suggesting modulation of TLR7 expression by miR-3148. Overexpression of miR-3148 via transient transfection into HEK 293 cells led to more than 2-fold reduction in luciferase activity driven by the *TLR7* 3′UTR segment containing the non-risk allele compared to that containing the risk allele (P = 0.002).

Conclusion: We identified and confirmed a genome-wide significant association between the *TLR7* 3′UTR SNP and SLE susceptibility in 22,613 subjects of Eastern Asian, European American, African American and Hispanic ancestries (P_{meta} = 6.4×10^{-19}, OR [95%CI] =1.26 [1.20–1.32]). Reduced modulation by miRNA-3148 conferred a slower degradation of the risk allele containing *TLR7* transcripts, resulting in elevated levels of gene products and more robust type I IFN signature.

Analysis of the Immunochip in a Large Cohort of Juvenile Idiopathic Arthritis Cases Identifies 17 Loci At Genome-Wide Significance.

Anne Hinks[1], Joanna Cobb[1], Miranda C. Marion[2], Marc Sudman[3], John Bowes[1], Kathryn J. A. Steel[1], Mehdi Keddache[4], John F. Bohnsack[5], Stephen Guthery[5], Lucy R. Wedderburn[6], Johannes Peter Haas[7], David N. Glass[8], Sampath Prahalad[9], Carl D. Langefeld[2], Wendy Thomson[1] and Susan D. Thompson[3]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]University of Utah, Salt Lake City, UT, [6]University College London (UCL), London, United Kingdom, [7]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [8]Cincinnati Childrens Hospital Medical Center, Cincinnati, OH, [9]Emory Children's Center, Atlanta, GA

Background/Purpose: Genome-wide (GW) association studies have been hugely successful in the identification of susceptibility loci for autoimmune diseases, interestingly many of the loci are shared across these diseases. The regions identified now require more detailed fine-mapping to localize the association signal and identify putative functional variants. The Immunochip consortium was established to pool ~180 loci from 12 diseases to include on a custom

genotyping chip. Juvenile idiopathic arthritis (JIA) is the most common arthritic disease of childhood. Candidate gene studies have identified a number of common autoimmune genes that confer susceptibility to JIA. However, JIA has been less well studied using large-scale approaches. This study aimed to perform genotyping on the Immunochip to allow fine-mapping of previously associated regions and to identifying novel loci for JIA.

Methods: Genotyping was performed using the Immunochip in a large cohort from the UK, US and Germany comprising a total of 2816 JIA oligoarthritis and RF- polyarthritis cases and 13056 controls. Standard SNP and sample QC was performed, including removing samples with call rate <98%, outliers of mean heterozygosity and ancestral outliers. Each SNP was assessed for departure from an additive genetic model, and analyzed under the most appropriate model (either additive, dominant or recessive) using SNPGWA vers4.0 and adjusting for the top 5 principal components. Within regions reaching the GW significance threshold ($P<5\times10^{-8}$), conditional logistic regression was used to test for independent effects.

Results: This analysis has confirmed loci previously associated with JIA at $P<5\times10^{-8}$ (*HLA, PTPN22, PTPN2*), has strengthened the association of other previously investigated regions (*STAT4, IL2/IL21, IL2RA, SH2B3*) and has identified novel regions (*ANKRD55, TYK2, IRF1, UBE2L3, LNPEP, IL2RB, RUNX1, IL6R, ZFP36L1/RAD51B, FAS*) such that all 17 now reach GW significance. The *STAT4, PTPN2, IL2RA* regions show evidence for multiple independent effects, some of which are low-frequency variants. A further 9 novel loci have been identified at a suggestive level of significance ($P<1\times10^{-6}$). Some showed weak evidence previously (*COG6, CCR5*) and others have not been associated with JIA to date (*RUNX3, LTBR, PRM1*). The dense-mapping of some loci on the Immunochip along with bioinformatic analysis has refined the association to a single gene for 7 regions.

Conclusion: The Immunochip project enables cost-effective fine-mapping of autoimmune loci in diseases such as JIA. This analysis has confirmed and strengthened the association of previously associated genes as well as identified novel susceptibility loci for JIA. It highlights several crucial pathways, such as the IL2 pathway in JIA disease pathogenesis. Analysis of the Immunochip in this dataset, the largest cohort of JIA cases investigated to date, has greatly increased our knowledge of the genetic basis of susceptibility for JIA.

Evidence for Distinct Roles of Environmental and Genetic Factors in the Emergence of Anti Citrullinated-Protein Antibodies Positive Rheumatoid Arthritis-an Epidemiological Investigation in Twins. Aase Haj Hensvold[1], Patrik KE Magnusson[2], Monika Hansson[1], Lena Israelsson[3], Cecilia Carlens[1], Johan Askling[4], Vivianne Malmström[1], Lars Klareskog[3] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Swedish Twin Registry Karolinska Institutet, Stockholm, Sweden, [3]Karolinska Institute, Stockholm, Sweden, [4]Rheumatology Unit & Clinical Epidemiology Unit, Stockholm, Sweden

Background/Purpose: The aim of the current study was to investigate the influence of genetic and environmental factors in developing anti citrullianted-proteins antibodies (ACPA) and ACPA positive rheumatoid arthritis (RA), using a twin study approach.

Methods: We used a subset of the Swedish population based twin registry, which includes 12 590 monozygotic (MZ) and dizygotic (DZ) twins born 1958 or earlier, who had donated blood and provided information about smoking. RA was verified by data from national public care registers (1964–2009). All sera were analyzed for ACPA occurrence using a CCP2 ELISA with a cut off set to 25 U/ml. High titer of ACPA was defined as titers >75 U/ml. Twin concordance for ACPA occurrence was estimated by casewise concordance, tetrachoric correlation and odds ratios (OR). Odd ratios (OR) to develop ACPA and high titers of ACPA were calculated according to self-reported smoking status, cumulative dose of smoking and presence of any HLA_DRB1 shared epitope according to GWAS analysis. Twins were defined as smokers if they were or had been smoking regularly or occasionally. Cumulative dose of smoking was estimated by pack years.

Results: 350 out of 12590 tested individuals (2.8%) were positive for ACPA with 202 out of 12590 tested individuals (1.6%) having high titers of ACPA (>75 U/ml). 192 out of 12590 tested individuals were identified as having RA in the Swedish patient register during 1964–2009. The median age of the RA patients was 70 (range 53–94) and 73% were females. Monozygotic twins had an OR of 3.1 (95% CI 0.9–10) for developing ACPA, 7.9 (95% CI 1.7–37) for developing high titers of ACPA and 11.6 (95% CI 1.27–98.6) for developing ACPA+ RA if they had a co-twin with corresponding phenotype. Dizygotic twins had lower OR for developing ACPA (OR 1.8, 95% CI 0.5–5.8), high titers of ACPA (OR 3.6, 95% CI 0.8–16) and ACPA+ RA (OR 4.0, 95% CI 0.5–31.1) if they had a co-twin with corresponding phenotype. Smokers had an increased risk of developing ACPA (OR 1.33, 95% CI 1.08–1.63), high titer of ACPA (OR 1.63, 95% CI 1.22–2.18) and high titer ACPA+ without RA (OR 1.99, 95% CI 1.27–3.12) but not significantly increased OR for ACPA+ RA (OR 1.42, 95% CI 0.98–2.06). An increased cumulative dose of smoking was associated with ACPA, with the highest risk of developing ACPA among those smoking more than 10 pack years (OR 1.49, 95% 1.18–1.88). Presence of shared epitope conferred an increased risk of developing ACPA (OR 1.98, 95% 1.53–2.56), high titer ACPA (OR 3.12, 95% 2.15–4.54) and especially high titer ACPA+ RA (OR 7.09, 95% 3.69–13.65) with no significantly increased OR to develop high titer ACPA+ without RA (OR 1.17, 95% 0.81–1.69).

Conclusion: Results from this large population-based cohort of middle-aged twins and measurements of ACPA at one time point indicate that environment, life style and stochastic factors (such as smoking) may be more important than genetics in determining which individuals that develop ACPA, whereas genetic factors (and in particular shared epitope) may have a larger impact in determining which persisting ACPA-positive individuals that will ultimately develop arthritis.

Comparison of Conventional and Wholebody Magnetic Resonance Imaging for Assessing Inflammation and Structural Damage in Psoriatic Arthritis and Axial Spondyloarthritis. René Panduro Poggenborg[1], Susanne Juhl Pedersen[2], Iris Eshed[3], Inge Juul Sørensen[2], Ole Rintek Madsen[4], J.M. Møller[5] and Mikkel Østergaard[6]. [1]Copenhagen University Hospital in Glostrup, Copenhagen, Denmark, [2]Glostrup Hospital, Copenhagen, Denmark, [3]Sheba Medical Center, Tel Hashomer, Israel, [4]Copenhagen University Hospital in Gentofte, Copenhagen, Denmark, [5]Copenhagen University Hospital in Herlev, Copenhagen, Denmark, [6]Copenhagen University Hospital Glostrup, Glostrup, Denmark

Background/Purpose: Wholebody magnetic resonance imaging (WBMRI) is a new imaging modality where patients are scanned from "head to toe" in one single scan, but with a lower resolution than conventional MRI (cMRI). The purpose was to investigate the ability of WBMRI for detection of inflammation and structural damage in psoriatic arthritis (PsA) and spondyloarthritis (SpA), and to compare findings with dedicated cMRI.

Methods: Patients with clinically active peripheral PsA (Moll and Wright, n=19) or axial SpA (ESSG, n=19) and healthy subjects (HS, n=12) were included. WBMRI was assessed for synovitis, bone marrow oedema (BME), and bone erosions at sites included in the 78-tender joint count (TJC). Furthermore, WBMRI fat infiltration, BME and bone erosions were evaluated in 23 discovertebral units (DVUs) and in sacroiliac joints (SIJ) (8 quadrants). Wholebody imaging were performed on a 3 tesla MRI unit with built-in bodycoil (sagittal and coronal T_1-weighted pre/post-contrast and STIR sequences), and 1½ tesla cMRI (SpA and HS: of spine and SIJ; PsA and HS: unilateral hand) were performed using T_1w pre/post-contrast and STIR sequences. The PsAMRIS-hand method (1) was used for scoring synovitis in finger joints in PsA and HS.

Results: Characteristics median (range): PsA/SpA/HS age 49 (23–79)/42 (26–61)/32 (20–61) yrs. PsA/SpA disease duration: 4(0–34)/17(5–48) yrs; 78-TJC: 11 (3–65)/3 (0–17), 76-swollen joint count: 5 (0–20)/1 (0–5), and BASDAI score 45(9–85)/55(2–93) mm.

By WBMRI more than 97% of spinal DVUs and SIJ quadrants could be evaluated, whereas evaluation of peripheral joints for synovitis and BME was possible in 66 % and 55 % of joints, respectively. It was possible to evaluate 56% of the finger joints with WBMRI. BME assessed in 78 joints by WBMRI was significantly more frequent in PsA/SpA than in HS ($p < 0.05$, see table). We found no statistically significant difference between groups in WBMRI synovitis assessed in all 78 joints, or only assessed in hand joints. In contrast, PsAMRIS-hand synovitis (scored 0–36) assessed by cMRI was higher in PsA than HS ($P < 0.0005$).

The table shows median (range) scores of WBMRI and cMRI findings in joints, DVUs, and SIJ quadrants.

	PsA		SpA		HS	
	WBMRI	cMRI	WBMRI	cMRI	WBMRI	cMRI
78-joint: Synovitis (0–78)	12 (1–45)	-	10 (0–28)	-	10 (2–40)	-
78-joint: BME (0–78)	4 (0–25)*	-	2 (0–15)*	-	2 (0–5)	-
Spine: BME (0–23)	2 (0–6)*	-	1 (0–11)	1 (0–8)	0.5 (0–2)	0 (0–3)
Spine: Fat infiltration (0–23)	0 (0–7)	-	1 (0–18)	2 (0–20)*	0 (0–6)	0 (0–3)
Spine: Bone erosion (0–23)	0 (0–1)	-	0 (0–0)	0 (0–2)*	0 (0–1)	0 (0–1)
SIJ: BME (0–8)	0 (0–2)	-	0 (0–8)*	0 (0–8)*	0 (0–2)	0 (0–2)
SIJ: Fat infiltration (0–8)	0 (0–8)	-	0 (0–8)*	2 (0–8)*	0 (0–4)	0 (0–4)
SIJ: Bone erosion (0–8)	0 (0–6)	-	0 (0–8)	2 (0–8)*	0 (0–8)	0 (0–4)

Mann-Whitney test was used for comparing PsA/SpA with HS. *P<0.05.

Significant correlation was found between WBMRI and cMRI in spinal/SIJ fat infiltration (Spearman's rho: 0.52/0.52, both P<0.005), SIJ BME (0.78, P<0.0001), and SIJ bone erosion (0.72, P<0.0001). In PsA, the sensitivity, specificity and accuracy of WBMRI synovitis in the hand were 35%, 80% and 66%, when cMRI was considered the gold standard reference.

Conclusion: WBMRI showed higher scores of peripheral and axial BME in PsA and SpA, compared to HS. Highly significant correlation was found between WBMRI and conventional MRI assessments of axial BME, fat infiltration and bone erosions. WBMRI has potential value for assessing axial and peripheral disease manifestations in PsA and SpA.

1617

Whole-Body Magnetic Resonance Imaging of Disease Manifestations in Axial and Peripheral Joints and Entheses in Rheumatoid Arthritis Patients.
Mette Bjørndal Axelsen[1], Anne Duer[2], Iris Eshed[3], Jakob M. Møller[4], Susanne Juhl Pedersen[1] and Mikkel Østergaard[1]. [1]Glostrup Hospital, Copenhagen, Denmark, [2]Copenhagen University Hospital at Hvidovre, Hvidovre, Denmark, [3]Sheba Medical Center, Tel Hashomer, Israel, [4]Copenhagen University Hospital in Herlev, Copenhagen, Denmark

Background/Purpose: To investigate the ability of whole-body magnetic resonance imaging (WBMRI) to visualize synovitis, bone marrow edema and erosions in patients with rheumatoid arthritis (RA) and to examine the agreement between findings from WBMRI and clinical examination.

Methods: 3 Tesla WBMR images were acquired in a head-to-toe scan using an integrated quadrature body coil and 6 imaging stations in 20 patients with RA (14/6 women/men, aged median 54 [range 21–76] years, disease duration 6 [1–20] years) and at least 1 swollen or tender joint. Imaging time was 1 hour 25 min. STIR and pre- and post contrast T1-weighted images were evaluated for the presence/absence of disease manifestations in 76 joints, 30 entheses and in the spine by one experienced reader (IE). Each location was assessed as not imaged, imaged but not readable or readable. Clinical tender and swollen joint counts of 66 joints were performed.

Results: Signs of disease activity were more frequently found by MRI evaluation than by clinical evaluation, table 1.

Table 1. Proportions of joints with signs of synovitis, bone marrow edema, erosions and readable images, and clinical signs of joint involvement.

	Whole-body MRI Evaluation						Clinical Evaluation	
	Synovitis		Bone marrow edema		Erosions		Tender joints	Swollen joints
Joints evaluated	% with synovitis*	% Readable	% BME*	% Readable	% with erosions*	% Readable	% (N=18)	% (N=18)

*Numbers given as % of the total number of readable joints, median (range). CMC: carpometacarpal joints; MCP: metacarpophalangeal joints; PIP: proximal interphalangeal joints; DIP: distal interphalangeal joints; TMT: tarsometatarsal joints; NA: not applicable;ND: not done

Synovitis was most frequent in 1st carpometacarpal joints (CMC), wrist, the tarsometatarsal (TMT) and shoulder joints (92%, 67%, 63% and 61%, respectively). BME was most frequently present in CMC, wrist, shoulder and the acromio-clavicular joints (65%, 45%, 33% and 35%, respectively). Erosions were seen primarily in the wrist, MTP, CMC, shoulder and TMT joints (19%, 18%, 16%, 10% and 10%, respectively).

In the spine abnormal findings were less frequent. BME was seen in all cervical disco-vertebral units (DVUs) (7% of evaluated cervical DVUs), and in a few DVUs in the thoracic-lumbar spine (3% of evaluated thoracic- and lumbar DVUs). Fat infiltrations were found in the cervical and lumbar (but not thoracic) spine (3% of evaluated cervical and lumbar DVUs), and erosions were only seen in a single patient in the lumbar spine.

The most frequently involved entheses were those at greater trochanter, calcaneus, greater tuberosity of the humerus, medial condyle of the femur, and upper patella (60%, 26%, 26%, 16% and 13%, respectively, readability 75–100%). The entheses at costo-sternal joints 1 and 7, elbow, lower patella and tubers of the tibia were only readable in 40%, 10%, 25–35%, 5% and 0% of cases, respectively).

MRI findings (synovitis and BME) and clinical findings (tenderness and swelling) were not correlated, neither on the patient level (counts of involved joints) nor consistently on the level of individual joints.

Conclusion: Inflammation (synovitis and BME) in peripheral and axial joints and entheses could be identified by WBMRI, and was more frequent than detected clinically. 3T WB-MRI is a promising tool for evaluation of disease manifestations in RA patients. Optimization of positioning of the feet and hands and acquisition of images is needed.

Prevalence of Inflammatory Sacroiliitis Assessed On MR Imaging of Inflammatory Bowel Disease: A Retrospective Study Performed On 186 Patients.
Sophie Leclerc-Jacob, Guillaume Lux, Anne-Christine Rat, Valérie Laurent, Alain Blum, Isabelle Chary-Valckenaere, Laurent Peyrin-Biroulet and Damien Loeuille. Nancy Teaching Hospital, Nancy, France

Background/Purpose: Articular involvements are by far the most common extra-intestinal manifestations in inflammatory bowel disease (IBD). They include peripheral arthritis and inflammatory axial manifestation. Until now the prevalence of sacroiliitis in this same population was studied only on the structural plan. The main objective of this study was to estimate, for the first time, the prevalence of inflammatory sacroiliitis in IBD on digestive MRI defined according to ASAS (Assessment of SpondyloArthritis international Society) criteria. The secondary objective was to study the association between sacroiliitis and clinico-biological parameters in IBD.

Methods: This study was performed on 186 patients suffering from IBD followed in a gastroenterology department between 2004 and 2011: 131 with Crohn's disease (CD) (70.4%) and 55 with ulcerative colitis (UC) (29.6%). Clinico-biological and endoscopic data were collected and MR enterography or colonography was performed to assess IBD.

Two injected T1-weigthed sequences with fat saturation (FS) were used for the whole population: a coronal LAVA (liver acquisition with volume acceleration) sequence and an axial SPGR (spoiled gradient recalled) sequence. An additional injected axial LAVA sequence with FS was performed in 138 patients. On digestive MRI, sacroiliitis was scored blindly by two independent readers, a rheumatologist and a radiologist, according to ASAS criteria. The SIJ were graded bilateral, unilateral, normal and doubtful. In cases of discordance, the final diagnosis was obtained by consensus.

The association between sacroiliitis and the clinico-biological and radiological parameters of the digestive disease was analyzed by Fisher's exact test or the chi-square test (qualitative variables) and by Wilcoxon's test (quantitative variables) with a p value<0.05 as significant.

Results: The prevalence of inflammatory sacroiliitis was 16.7% (31 patients). SIJ were considered as normal in 144 cases (77.4%) and doubtful in 11 cases (5.9%). Female gender in CD (p=0.01) and advanced age in both diseases (p=0.03) were associated with sacroiliitis on MRI. Disease duration tended to be associated with sacroiliitis (p=0.06), while other parameters such as the type of IBD, localization and extension of IBD, surgical history, biological inflammation, digestive activity, and type of treatment were not associated with sacroiliitis on digestive MRI.

Conclusion: This study demonstrated for the first time the feasibility of using digestive MRI to establish the diagnosis of inflammatory sacroiliitis according to the ASAS criteria. Inflammatory sacroiliitis was evidenced by MRI in 1/6 patients suffering from IBD. This prevalence of sacroiliitis is probably underestimated due to technical and clinical factors (biologic treatment used). Added to clinico-biological data, MRI analysis should contribute to an earlier diagnosis of axial spondylarthritis in patients with IBD.

1619

Quantification of Bone Marrow Edema by Using Magnetic Resonance Imaging for the Assessment of Neck Pain Only Marginally Reflects Clinical Evaluation in Patients with Rheumatoid Arthritis and Ankylosing Spondylitis. Xenofon Baraliakos[1], Frank Heldmann[2], Ravi Suppiah[3], Fiona M. McQueen[4] and Jurgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Rheumazentrum Ruhrgebiet, Herne, Ghana, [3]Department of Rheumatology, Nuffield Orthopaedic Centre, Oxford, United Kingdom, [4]University of Auckland, Auckland, New Zealand

Background/Purpose: Despite the differences in the pathogenesis of rheumatoid arthritis (RA) and ankylosing spondylitis (AS), neck pain is a frequent clinical symptom in both diseases that was recently shown to correlate with disease activity. In this study, we evaluated the correlation between subjective reports of neck pain and objective signs of inflammation by quantification of bone marrow edema (BME) as detected by MRI in patients with RA and AS.

Methods: MR images (STIR sequence) of the cervical spine together with clinical and laboratory data of 40 patients (34 RA, 6 AS) who had participated in the recently presented CASSANDRA trial were included. MRI were assessed by two readers who were blinded for clinical data using a recently published MRI scoring system, with quantification of the extension of BME in the atlantoaxial region, corpus, facet joints and processus spinosus of all cervical vertebrae, ranging from 0–57 points. In addition, presence or absence of degenerative changes was also recorded.

Results: Baseline characteristics, neck pain and MRI scores did not differ between RA and AS patients. The mean age was 57.5 ± 11.8 years, 33/40 patients (82.5%) were female, the mean symptom duration for neck pain was 10.6 ± 8.8 years, cervical rotation 51.0 ± 17.2 degrees, CRP 0.9 ± 1.3 mg/dl, ESR 19.8 ± 26.6 mm/1h, FFbH 58.1 ± 26.3 and the Northwick Park score was 46.0 ± 17.5. BME was detected in 24/40 patients (60%), 5 of which (20.8%) had atlantoaxial involvement, 18 had BME in the vertebral body (75%), 7 in the facet joints (29.2%) and 11 in the processus spinosus (45.8%). Degenerative changes were seen in 21/40 patients (52.5%). Of those 21 patients, all (100%) had also signs of BME in the corpus, while from the 19 patients without degenerative changes, only 3 patients (15.8%) had BME in the corpus. In the more detailed analysis of the total of 240 evaluated vertebral bodies, 27 (11.3%) vertebral bodies had degeneration and in parallel inflammation in the corpus, while 24 (10%) had only degeneration, 11 (4.6%) had only inflammation in the corpus, and 178 (74.2%) had neither lesion. There was no correlation between the amount or the extension of BME and clinical or laboratory parameters for neck pain or cervical spine mobility. However, a significant difference (p=0.038) was found for BME scores of patients with a pain intensity (0–10 NRS) of ≥ 5 (5.8 ± 6.5 scoring points) vs. < 5 (1.9 ± 25 scoring points). This was partly dependent on scores for the atlantoaxial region, although the mean number of scoring points did not differ. The correlation between readers was excellent (regression coefficient. 0.942).

Conclusion: This study shows that the majority of patients with RA and AS had objective signs of BME but also degenerative changes as assessed by MRI at different locations in the cervical spine. Assessment of the the presence of BME in the atlantoaxial region is important in clinical practice, in addition to degenerative changes, since its presence seems to influence the intensity of neck pain reported by these patients.

Early Magnetic Resonance Imaging Measures Independently Predict 1- and 2-Year X-Ray Progression: Results From a Large Clinical Trial. Joshua Baker[1], Mikkel Østergaard[2], Paul Emery[3], Elizabeth C. Hsia[4], J. D. Lu[4], Daniel Baker[5] and Philip G. Conaghan[6]. [1]University of Pennsylvania, Philadelphia, PA, [2]Glostrup Hospital, Copenhagen, Denmark, [3]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [4]Janssen Research & Development, LLC/U of Penn, Spring House/Phila, PA, [5]Janssen Research and Development, LLC, Spring House, PA, [6]University of Leeds, Leeds, United Kingdom

Background/Purpose: Early predictors of progression in structural joint damage in RA are lacking. We evaluated if early MRI measures of inflammation and erosion at baseline, 12 and 24wks could predict subsequent progression in structural damage as measured by standard x-ray at 1 and 2 yrs of follow-up among 256 pts from GO-BEFORE, a large randomized trial of golimumab + MTX vs MTX alone in RA pts who were MTX-naïve.

Methods: Methods and results of the original trial have been published [1]. MRIs (contrast-enhanced; 1.5T) of the wrist and the 2nd-5th metacarpophalangeal joints of the dominant hand at baseline and wks 12, 24, 52, and 104 were obtained. MRIs were scored by 2 independent, blinded readers using the RA MRI Scoring (RAMRIS) system. X-rays (hands, wrists, forefeet at baseline, wk52, and104) were scored by 2 other, blinded readers using vdHS system. X-ray progression was defined as a change in vdHS score > 0.5 as it was in the original trial. MRI synovitis and bone edema scores were evaluated as continuous variables (per unit difference or change). Change in RAMRIS bone erosion scores was highly skewed, and was therefore dichotomized at >0.5. Multivariable logistic regression was used to determine if baseline and early measures of change in component RAMRIS scores predicted x-ray progression independent of clinical disease activity [DAS28(CRP)], change in DAS28(CRP), age, sex, baseline vdHS score, and treatment group.

Results: Higher baseline synovitis scores and *less improvement* in synovitis over the first 24 wks of follow up were both significantly and independently associated with a greater risk of x-ray progression at 1- and 2yrs (Table). Higher baseline bone edema and *less improvement* in bone edema were independently associated with a greater risk of x-ray progression at 1yr, and tended to be associated with progression at 2yrs. An increase in RAMRIS bone erosion score >0.5 at wk 24 significantly predicted x-ray progression at 1- and 2 yrs. Baseline and wk12 changes in MRI scores all significantly predicted x-ray progression at wk 52 (all p<0.05), and tended to be associated with x-ray progression at wk 104 (p=0.004–0.2).

Table. Multivariable-adjusted risk of x-ray progression at 1- and 2 years of follow-up based on early MRI measures at 24 wks (per 1 unit difference or change in respective RAMRIS score)

	vdHS Score Progression >0.5 Week 52 (N=216–234)		vdHS Score Progression >0.5 Week 104 (N=202–219)	
	OR (95% CI)	P value	OR (95% CI)	P value
Model 1*				
Baseline Synovitis	1.14 (1.04–1.24)	0.003	1.11 (1.01–1.21)	0.02
Δ Synovitis @ Wk 24	1.19 (1.06–1.33)	0.003	1.22 (1.07–1.38)	0.002
Model 2*				
Baseline Bone Edema	1.05 (1.01–1.09)	0.02	1.06 (1.02–1.11)	0.007
Δ Bone Edema @ Wk 24	1.12 (1.05–1.20)	0.001	1.06 (0.99–1.14)	0.07
Model 3*				
Baseline Bone Erosion	0.99 (0.97–1.01)	0.3	0.98 (0.95–1.01)	0.1
Δ Bone Erosion >0.5 @ Wk 24	2.85 (1.41–5.78)	0.004	4.42 (2.04–9.58)	<0.001

*adjusted for age, sex, DAS28(CRP) at baseline, change in DAS28(CRP) over the first 24wks, vdHS score at baseline, and treatment group.

1. Østergaard M, Emery P, Conaghan PG, et al. *Arthritis Rheum* 2011; 63(12): 3712–3722.

Conclusion: Early MRI measures at 12 and 24 wks independently predict x-ray changes at 1 and 2yrs of follow-up. These data support the use of MRI in clinical trials for early identification of pts with (OR who will develop) structural joint damage progression during follow up. This has implications for clinical trial design.

In Vivo Synovial Oxygen Levels Are Inversely Related to Metabolic Turnover and Disease Activity in Rheumatoid and Psoriatic Arthritis Biologic Responders. Leonard C. Harty[1], John Ryan[2], Chin Teck Ng[3], Monika Biniecka[3], Aisling Kennedy[3], Eric J. Heffernan[4], Ursula Fearon[5] and Douglas J. Veale[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Ziltron, Unit 4, Castletroy Business Park, Plassey, Limerick, Ireland, [3]Translation Rheumatology Research Group, Dublin, Ireland, [4]St. Vincent's University Hospital, Dublin, Ireland, [5]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Hypoxia, leukocyte infiltration and dysfunctional vascularity play a key role in the pathogenesis of inflammatory arthritis (IA). We examine the relationship of metabolic turnover with synovial vascularity/invasion in IA patients.

Methods: RA and PsA patients with active knee joint synovitis were recruited and assessed clinically prior to contiguous MR and PET/CT imaging followed by arthroscopy, biopsy and pO_2 measurement pre- and post-TNFi therapy. Imaging protocols were standardised for MRI, and Fluorodeoxyglucose (18FDG) PET and image-data intensity resolution was optimised for synovial tissue. Cell-specific markers (CD3, CD4, CD8, CD68), blood vessel maturity and metabolic activity (GAPDH) were quantified by immunohistologic analysis and dual-immunofluorescence. Reduction of DAS28 ≥1.2 indicated a good clinical response. Mann Whitney U and Wilcoxon test were used to compare continuous variables and Spearman's Rho was used to assess correlations. $p < 0.05$ was considered statistically significant. SPSS version 18 was employed.

Results: 21 patients, RA(n=9) and PsA(n=12), mean (age 45±16, DAS 28, 4.6±1.2 and gender 6F:15M) were recruited. At baseline *in vivo* synovial pO_2 levels inversely correlated with PET (r=-0.6, p=0.03), DAS28 (r=-0.5, p=0.05) and was inversely associated with macroscopic synovitis. Furthermore, MRI correlated with macroscopic synovitis (r=0.5, p=0.04) and sub-linining CD68 expression (r=0.7, p=0.001). Lining layer and sub-lining GAPDH expression inversely correlated with synovial pO_2(r=0.8, p=0.03) pre/post TNFi. Biologic responders showed significant reduction in PET quantification (p=0.018) which was paralleled by corresponding decreases in MRI (p=0.012), macroscopic synovitis (p=0.005), vascularity (p=0.005) and CD68sl expression (p=0.01) and an increase in pO_2 levels from 22mmHG to 37 mmHG. In contrast PET quantification in non-responders was not associated with significant reductions in MRI or macroscopic/microscopic measures of disease. Furthermore pO_2 levels in non-responders were similar pre/post therapy (22mmHG vs 25mmHG). Figure 1 shows representative PET/MRI hybrid images in a responder patient pre/post TNFi demonstrating close association between metabolic turnover and site of inflammation.
Figure 1. Hybrid PET/MRI images from the same patient before and after successful therapy demonstrating reduced inflammation and metabolism within the synovium of the knee joint.

Conclusion: This is the first study to show synovial metabolic activity and inflammation quantified by MR/PET are associated with *in vivo* hypoxia, cellular and molecular biomarkers in RA and PsA patients in response to biologic therapy. MR/PET may represent an important new imaging modality in assessing response to biologic therapy.

Characteristics of Patients with Infectious Cryoglobulinemia Vasculitis in the Absence of HCV Infection: Results From the French Nationwide Cryovas Survey. Benjamin Terrier Sr.[1], Isabelle Marie[2], Adeline Lacraz[3], Pauline Belenotti[4], Fabrice Bonnet[5], Laurent Chiche Sr.[4], Bruno Graffin Sr.[6], Arnaud Hot Sr.[7], Jean-Emmanuel Kahn[8], Thomas Quemeneur[9], Olivier Hermine Sr.[10], Jean-Marc Léger[11], Patricia Senet[12], Emmanuelle Plaisier[13], Xavier Mariette[14] and Patrice Cacoub Sr.[15]. [1]Cochin Hospital, Paris, France, [2]Service de médecine interne, CHU de Rouen, Rouen, France, Rouen, France, [3]Nephrology, CHU Bordeaux, Bordeaux, France, [4]Internal Medicine, CHU Marseille, Marseille, France, [5]Internal Medicine, CHU Bordeaux, Bordeaux, France, [6]Metz hospital, Metz, France, [7]Lyon hospital, Lyon, France, [8]Internal Medicine, Foch Hospital, Suresnes, France, [9]CHR de Valenciennes, Valenciennes, France, [10]Hôpital Necker, Paris, France, [11]Paris, France, [12]Tenon hospital, Paris, France, [13]Nephrology, Tenon Hospital, Paris, France, [14]Université Paris-Sud, Le Kremlin Bicetre, France, [15]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Hepatitis C virus infection (HCV) is the main cause of mixed cryoglobulinemia vasculitis (CryoVas). Recent data are lacking regarding demographical, clinical and biological features of patients with infectious mixed CryoVas in the absence of HCV infection.

Objectives: To analyze the features of patients with infectious mixed CryoVas in the absence of HCV infection included in the French CryoVas survey. The objective of this survey is to describe the presentation and to evaluate efficacy and tolerance of treatments in patients with CryoVas.

Methods: Eighty-one French centers of Internal Medicine, Nephrology, Rheumatology, Hematology, Dermatology and Neurology from Universitary and general hospitals have included 260 patients with non-HCV mixed CryoVas diagnosed between January, 1995 and July, 2010. Among them, 18 patients presented with infectious mixed CryoVas. Demographical, clinical and biological data, as well as therapy and outcome, were assessed.

Results: 11 women and 7 men (sex ratio F/M 1.3), mean age 57.9 ±13.5 years, were analyzed. Infectious causes were: virus infection in 8 patients [hepatitis B virus (HBV) in 4, and cytomegalovirus, Epstein Barr virus, parvovirus B19 and human immunodeficiency virus in one case each], pyogenic bacterial infection in 6 patients, parasitic infection in 2 patients (ascaridiasis and leishmaniosis in one case each), and leprosy and candidiasis in one case each. Baseline manifestations were: purpura (78%), glomerulonephritis (28%), arthralgia/arthritis (28%), peripheral neuropathy (22%), necrosis (22%), cutaneous ulcers (17%), and myalgia (11%). No gastrointestinal, central nervous system or pulmonary involvement was observed. Cryoglobulinemia was type II in 12 patients (67%) and type III in 6 (33%). Histological confirmation of vasculitis was available in 72%.

As first-line therapy, 6 patients received corticosteroids, 1 cyclophosphamide and none rituximab, but 14 patients received anti-infectious specific therapy. Among the latters, 10 were in sustained remission of the disease, 2 died of the underlying infectious disease (bacterial septicemia and Candida pneumonia), and 2 had refractory or relapsing disease related to HBV infection treated with rituximab in addition to antiviral therapy, leading to complete remission. The 4 remaining patients who did not receive specific therapy had cytomegalovirus, Epstein Barr virus, parvovirus B19 and HBV infection, and remained in remission of the CryoVas.

Conclusion: In patients with infectious mixed cryoglobulinemia vasculitis in the absence of HCV infection, virus and pyogenic bacterial infections represent the main causes. Anti-infectious specific therapy is most frequently associated with sustained remission of the disease. Thus, immunosuppressive agents should be considered only in second-line in patients with refractory and/or life-threatening vasculitis.

Serum Biomarkers Signature Identifies Patients with Overt B-Cell Non-Hodgkin Lymphoma Associated with Mixed Cryoglobulinemia in Chronic HCV Infection. Benjamin Terrier Sr.[1], Wahiba Chaara[2], Guillaume Geri[3], David Saadoun[4], Michelle Rosenzwajg Sr.[5], Damien Sene Sr.[6], Adrien Six[2], David Klatzmann Sr.[5] and Patrice Cacoub Sr.[3]. [1]Cochin Hospital, Paris, France, [2]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [5]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Paris, France, [6]Groupe Hospitalier Pitié-Salpétrière, Université Pierre et Marie Curie, Paris, France

Background/Purpose: Hepatitis C virus (HCV) is associated with B-cell disorders, including mixed cryoglobulinemia (MC) and B-cell non-Hodgkin lymphoma (B-NHL). Early diagnosis of B-NHL in HCV-infected patients, in particular those with MC vasculitis, is critical to determine the optimal therapeutic management.

Aim: We hypothesized that combination of serum biomarkers could be used to identify B-NHL associated with MC in patients with chronic HCV infection.

Methods: 155 HCV infected patients have been included [median age 62 (31–85) years, M/F 70/85], with and without MC and/or B-NHL [57 patients without MC, 17 patients with asymptomatic MC, 62 patients with MC vasculitis, and 19 patients with MC vasculitis and B-NHL]. We measured serum levels of 8 markers previously described to be increased in patients with B-NHL i.e. soluble CD22, soluble CD27, soluble IL-2Ra, soluble CD137, free-light chains of immunoglobulins, heavy chains of immunoglobulins, gammaglobulins and C4 complement fraction. We used a multiparametric analysis in order to determine a signature that identifies patients with overt B-NHL associated with MC in chronic HCV infection.

Results: Serum levels were significantly different between patients without MC, patients with asymptomatic MC, patients with MC vasculitis and those with MC vasculitis and B-NHL: soluble CD22 (6.7 vs. 11.9 vs. 20.8 vs. 36.4 ng/ml, P<0.0001), soluble CD27 (71.9 vs. 75.7 vs. 122.9 vs. 263.9 U/ml, P<0.0001), soluble IL-2Ra (877 vs. 1035 vs. 2206 vs. 4044 pg/ml, P<0.0001), soluble CD137 (296 vs. 426 vs. 539 vs. 763 pg/ml, P<0.0001), free-light chains of immunoglobulins (ratio k/l 1.13 vs. 1.08 vs. 1.79 vs. 3.01, P<0.0001), heavy chains of immunoglobulins (ratio IgMk/IgMl 1.90 vs. 1.85 vs. 4.85 vs. 31.3, P<0.0001), gammaglobulins (14.1 vs. 17.0 vs. 12.1 vs. 6.0 g/l, P<0.0001) and C4 complement fraction (0.23 vs. 0.16 vs. 0.07 vs. 0.04 g/l, P<0.0001).

Using multiparametric analysis, we identified a signature involving soluble CD27, soluble IL-2Rα, gammaglobulins and C4 levels associated with the presence of overt B-NHL in HCV-infected patients. This signature had a sensitivity of 100%, a specificity of 63%, and positive and negative predictive values of 94 and 100% for discriminating patients with overt B-NHL and those without B-NHL.

Conclusion: Overall, our data indicate that serum biomarkers signature allows identifying patients presenting with overt B-NHL associated with mixed cryoglobulinemia vasculitis in chronic HCV infection, and requiring invasive explorations in order to demonstrate the presence of malignant lymphoma.

Deletion of HLA-B27 T Cells Underlies the Immunodominant Response to Influenza Infection On Class I MHC Transgenic Mice. Ali Akram[1] and Robert D. Inman[2]. [1]University of Toronto and University Health Network (UHN), Toronto, ON, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: The role of HLA-B27 in modulating host response to infection is undefined, yet has important implications for the mechanism whereby B27 confers susceptibility to arthritis. Despite codominant expression of class I MHC (MHC-I) alleles, immune response to viral infections is characterized by a phenomenon called immunodominance (ImDc). The exact mechanisms of ImDc are not clear. Defining factors contributing to ImDc has proved difficult due to multiple MHC-I allele co-expression in humans and normal mice.

Methods: To overcome this limitation, we generated human MHC-I transgenic (Tg) mice which are deficient for endogenous mouse MHC-I molecules (i.e., H2-K$^{-/-}$/D$^{-/-}$, DKO) and express only one human MHC-I allele. To assess whether co-expression of additional MHC-I alleles influences the pattern of anti-flu CTL epitope recognition and ImDc, novel double MHC-I Tg mice were established on a DKO background.

Results: In flu-infected, double Tg HLA-A2/B7 or HLA-A2/B27 mice, IFN-γ ELISpot assays with the flu epitopes M1.58–66 (HLA-A2-specific) and NP418–426 (HLA-B7-specific) or NP383–391 (HLA-B27-specific) showed specific recognition of both peptides by both alleles respectively. In contrast, in flu-infected HLA-B7/B27 Tg mice a significantly reduced NP383-restricted CTL response was detected while there was no change in the response level of NP418-restricted CTL. Subsequent flu-specific studies revealed that co-expression of B7 and B27 is associated with i) a partial deletion of Vβ8.1$^+$ B27/NP383-restricted CD8$^+$ T cells and ii) a failure of Vβ12$^+$ CD8$^+$ T cell expansion following flu infection in B7/B27 Tg mice. Using chimeric mice, we confirmed that the lower number of naive B27-restricted CD8$^+$ T cells in B7/B27 Tg mice, compared to single Tg B27 mice, is due to negative selection of B27-restricted Vβ8.1$^+$ CD8$^+$ T cells.
Conclusion: The pattern of allele co-expression critically influences the flu CTL response. The selective deletion of B27-restricted T cells has important implications for models defining the role that HLA-B27 plays in susceptibility to reactive arthritis and ankylosing spondylitis.

With Chlamydia Infection the Macrophage Serves As Gate-Keeper for Dissemination and Induction of Host Immunity. Eric Gracey[1] and R. D. Inman[2]. [1]Toronto Western Hospital, Toronto, ON, [2]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: The obligate intracellular pathogen, Chlamydia, is the most common cause of reactive arthritis (ReA). We have demonstrated that susceptibility to experimental Chlamydia-induced ReA is determined as early as day 4 post infection implicating the innate immune response. However the cellular and molecular mechanisms during this stage have yet to be determined. Here we demonstrate the importance of the macrophage in directing both innate and adaptive immune responses to Chlamydia, and limiting dissemination of the organism.

Methods: Clodronate liposomes (CL) were used to deplete peritoneal macrophages with PBS-liposomes (PL) acting as the control. Clodronate did not affect neutrophil or lymphocyte populations. Subsequent to macrophage depletion mice were infected IP with 107 IFU Chlamydia muridarum for either 7 or 14 days. Spleens, peritoneal lavage, peritoneal membranes and blood were harvested for analysis of immune response and Chlamydia load.

Results: There was no mortality, nor signs of systemic disease associated with Chlamydia challenge in macrophage-depleted mice. Inspection of peritoneal cavity cells at day 7 demonstrated depletion of Cd11b+F4/80+ macrophages (PL; 50% of cells, CL; 5% of cells) and a significant increase in CD11b+Ly6G+ neutrophils (PL; 10% of cells, CL; 60% of cells) was seen in the mice treated with clodronate liposomes. This was coupled with a 5-fold increase in Chlamydia 16sRNA load of these cells as assessed by qPCR. 16sRNA was only detected in blood samples only in the macrophage-depleted mice, reflecting dissemination of the organism beyond the site of local challenge. At day 14 post Chlamydia infection, depletion of macrophages was associated with a significant alteration of the adaptive immune response profile, with reduced numbers of Th1 cells and activated IFNy+, CD8+ cells. This was coupled with a 20-fold increase chlamydial load compared to control mice.

Conclusion: These data indicate that macrophages are crucial in defining effective host innate immune response to Chlamydia and thereby limiting dissemination of the organism. In addition, macrophages orchestrate the development of effective adaptive host response to the organism. These studies suggest that quantitative or qualitative alteration in macrophages may play a key role in the development of post-Chlamydia sequelae such as reactive arthritis.

Frequent Conversion of Tuberculosis Screening Tests During Anti-Tumor Necrosis Factor Therapy in Patients with Rheumatic Diseases.
Chrisoula Hatzara, Emilia Hadziyannis, Anna Kandili, Stamatoula Tsikrika, Martha Minopetrou, Georgios Georgiopoulos and Dimitrios Vassilopoulos. Athens University School of Medicine, Athens, Greece

Background/Purpose: The most recent ACR Recommendations suggest annual screening for latent tuberculosis (TB) with standard tuberculin skin test (TST) or the newer interferon-gamma release assays (IGRAs), in patients with rheumatoid arthritis (RA) receiving biologics and risk factors for TB exposure. The rate and clinical significance of TB test conversion during biologic treatment, especially with anti-tumor necrosis factor (TNF) agents, has not been adequately studied so far. Our aim was to determine prospectively the rate of TB test conversion (TST, IGRAs) during anti-TNF therapy in patients with negative baseline screening.

Methods: Among a large cohort of rheumatic patients starting anti-TNF therapy, 50 consecutive patients with negative baseline TB screening (TST: < 5 mm, negative T.Spot®-TB and QuantiFERON®-TB Gold In Tube/QFT-GIT, negative CXR) were followed prospectively during anti-TNF therapy. One year later all patients underwent re-testing for TB with TST, both IGRAs and repeat CXR. Patients with a TB test conversion or changes in CXR underwent further evaluation for active TB.

Results: 50 patients (females/males=29/21, mean age=49.6±15 years) with various rheumatic diseases (RA: n=23, spondyloarthropathies/SpA: n=26, other: n=1) were enrolled in the study. Patients were treated with various anti-TNFs (adalimumab=20, etanercept=13, infliximab=13, golimumab=3, certolizumab=1) for one year. Retesting after one year, showed that 15 patients (30%) displayed conversion of at least one screening assay. Fourteen percent showed conversion of TST (n=7), 10% of T.Spot®-TB (n=5) and 6% of QFT-GIT (n=3). No patient had concomitant conversion of ≥ 2 screening tests while there was no history of remote or recent documented TB contact in the converted patients. Further work-up did not reveal any evidence of active TB in these patients. There were no significant differences in age, sex, disease diagnosis or duration, previous BCG vaccination, concomitant DMARD and/or steroid use or type of anti-TNF treatment between those who converted (n=15) vs those who did not (n=35).

Conclusion: Approximately one third of patients with negative TB screening at baseline develop conversion of at least one screening test during anti-TNF treatment. The clinical significance of these findings as well as the need for latent TB therapy in this patient group needs to be studied further.

New Insights Into the Presentation and the Management of Hepatitis B Reactivation in Patients with Autoimmune Diseases and Inflammatory Arthritis. Nina Droz[1], Laurent Gilardin[2], Patrice Cacoub Sr.[3], Francis Berenbaum[4], Daniel Wendling[5], Bertrand Godeau[6], Anne-Marie Piette[7], Emmanuelle Dernis[8], Mikael Ebbo[9], Bruno Fautrel[10], Arsène Meikinian[11], Aude Rigolet[12], Sophie Rivière[13], Stanislas Pol[1], Loic Guillevin[14], Luc Mouthon Sr.[15] and Benjamin Terrier Sr.[1]. [1]Cochin Hospital, Paris, France, [2]Saint Antoine Hospital, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]AP-HP, St Antoine Hospital, Paris, France, [5]Minjoz University Hospital, Besancon, France, [6]Service de médecine interne, Université Paris Est Créteil, AP-HP, Hôpital Mondor Créteil, France, Creteil, France, [7]Foch Hospital, Suresnes, France, [8]Centre Hospitalier, Le Mans, France, [9]Conception Hospital, Marseille, France, [10]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [11]Jean Verdier Hospital, Bondy, France, [12]Pitie-Salpetriere Hospital, APHP, UPMC Paris VI, Paris, France, [13]Lapeyronie, Montpellier, France, [14]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [15]Hopital Cochin, Paris, France

Background/Purpose: In patients with autoimmune diseases and inflammatory arthritis, immunosuppressive therapy may trigger Hepatitis B virus (HBV) reactivation, leading to significant morbidity and mortality.

Objective. To describe presentation, management and outcome of HBV reactivation occurring in patients treated for autoimmune diseases and inflammatory arthritis, and to evaluate predefined algorithm for its prevention.

Methods: French centers of Internal Medicine, Rheumatology and Hepatology have included 35 patients with HBV reactivation diagnosed between January, 2002 and March, 2012. HBV reactivation was defined as an increase >1 log IU/mL of HBV DNA levels or DNA reappearance in negative patients. Hepatitis was defined as an increase >3-fold the baseline value of alanine transaminase (ALT). We further performed an extensive literature review and provided a global analysis of 138 cases of HBV reactivations.

Results: Personal cases were treated for rheumatoid arthritis (RA, n=14), connective tissue disease (n=7), vasculitis (n=5), ankylosing spondylitis (n=4) or other diseases (n=5). At baseline, 23 (66%) patients were hepatitis B surface antigen (HBsAg) carriers, 11 had previous history of HBV infection (including 7 with HBs antibodies), and 1 patient had occult HBV infection. Reactivation occurred after a median time of 39 wk after initiation of corticosteroid (CS) and/or immunosuppressive (IS) therapy. At the time of reactivation, 30 (86%) patients were receiving CS, 11 (31%) methotrexate, 7 (20%) TNF-a blockers, 6 (17%) cyclophosphamide, 4 (11%) rituximab, 4 (11%) azathioprine, and tocilizumab and abatacept in 1 case each (3%). Median HBV DNA and ALT levels were 4.2 log IU/mL and 2-fold the baseline value, respectively, and were correlated (r=+0.49, P=0.004). Patients were clinically asymptomatic in 31 (89%) cases, while hepatitis occurred in 17 (49%), including severe hepatitis (>10-fold the baseline value) in 9 (26%). Management consisted in antiviral therapy in 32 (91%) patients, associated with discontinuation or decrease of CS/IS in 16 (46%). Neither fulminant hepatitis was noted, but one patient died of hepatocellular carcinoma.

After global analysis of HBV reactivations, reported patients were clinically asymptomatic in 102 (74%) cases, with severe hepatitis in 46 (33%) and death and/or fulminant hepatitis in 17 (12%). Reactivation kinetics differed according to the treatments used and baseline HBV status, with earlier reactivation occurring under rituximab or cyclophosphamide and in HBsAg+/HBV DNA+ patients. The use of predefined algorithm could have prevented 108 (78%) reactivations. Two reactivations occurred despite appropriate preemptive antiviral therapy. Finally, according to the algorithm, 28 patients would not have received preemptive therapy, including 2 HBcAb+/HBsAb+ Asian patients with RA receiving methotrexate or adalimumab who died of fulminant hepatitis.

Conclusion: This study provides new insights into HBV reactivations in patients with autoimmune diseases and inflammatory arthritis. Predefined algorithm seems to be effective to reduce the risk of HBV reactivation, but caution is warranted using monitoring of HBV markers.

Epistatic Interaction Between Solute Carrier 2A9 Genotype and Sugar-Sweetened Beverage Consumption in the Determination of Gout Risk.
Tony R. Merriman[1], Nicola Dalbeth[2], Peter J. Gow[3], Andrew Harrison[4], John Highton[5], Peter B. B. Jones[6], Lisa K. Stamp[7], Murray Cadzow[1], Marilyn E. Merriman[1], Ruth Topless[1], Michael A. Black[1], Amanda Phipps-Green[1] and Caitlin M. Batt[1]. [1]University of Otago, Dunedin, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Middlemore Hospital, Auckland, New Zealand, [4]Hutt Hospital, Lower Hutt, New Zealand, [5]Univ of Otago Med Sch, Dunedin, New Zealand, [6]Waikato Clinical School, Waikato Hospital, Hamilton, New Zealand, [7]University of Otago, Christchurch, Christchurch, New Zealand

Background/Purpose: Consumption of drinks sweetened with sugar or high fructose corn syrup increases both serum urate levels and the risk for gout. *SLC2A9* encodes a renal urate transporter that exchanges uric acid for glucose and fructose. Genetic variants in *SLC2A9* explain 3.5% of the variation in serum urate levels in European Caucasian (EC) populations and are strongly associated with gout in EC and New Zealand (NZ) Maori and Pacific Island (Polynesian) people. Because SLC2A9 transports both uric acid and simple hexose sugars we tested the hypothesis that *SLC2A9* genotype and sugar-sweetened beverage (SSB) consumption interact to determine the risk for gout.

Methods: NZ survey data from 1623 people with and without gout were used. Gout was determined by ARA preliminary classification criteria. SSB consumption was self-reported, including fruit juice, where one unit of drink was defined as a can or large glass. Data from the Atherosclerosis Risk in Communities (ARIC) study were also used (6003 EC controls and 153 primary gout cases determined by self-report). Two ancestral groups were studied; EC (NZ and ARIC) and NZ Polynesian. The NZ samples were genotyped for *SLC2A9* single nucleotide polymorphism (SNP) *rs11942223* using Taqman® technology. The ARIC samples had previously been genotyped for surrogate marker *rs6449173*. STATA v8.0 statistical software was used, with an interaction term included in the logistic regression analysis, derived from the ratio of the estimated odds ratio (OR) comparing exposed ($\geq$4 SSB/day) and unexposed (<4 SSB/day) *rs11942223* risk allele (T) homozygotes with the estimated OR comparing exposed and unexposed people positive for the *rs11942223* protective allele (C).

Results: The risk of gout associated with consuming $\geq$4 SSB/day without stratification by genotype was similar to the increased genetic risk observed in the T-allele homozygous groups (Table). However the normally protective C-allele conferred a considerable increase in risk for gout in individuals exposed to $\geq$4 SSB/day (for example OR increased from 0.51 to 4.93 in Polynesian. The genotype by interaction term (ORI) was significant in Polynesian (ORI=5.31, P=0.043) but not in EC (ORI =5.31, P=0.087) (all adjusted by sample set, age, sex, BMI). Combining the two groups revealed significant evidence for interaction (ORI=4.74, P=0.003).

Table. Risk of gout for $\geq$4 SSB/day stratified by genotype at SLC2A9

	European Caucasian			Polynesian (Maori/Pacific Island)		
	Obs	OR [95% CI][1]	P	Obs	OR [95% CI]	P
$\geq$4 SSB/day group unstratified	6735	1.88 [0.87–4.07]	0.11	1020	2.02 [1.37–2.98]	4.2×10^{-4}
T-allele homozygous, <4 SSB/day	6685	1.00	-	951	1.00	-
C-allele positive, <4 SSB/day		0.63 [0.47–0.84]	0.002		0.51 [0.28–0.93]	0.027
T-allele homozygous, $\geq$4 SSB/day		1.18 [0.48–2.91]	0.71		1.82 [1.19–2.77]	0.005
C-allele positive, $\geq$4 SSB/day		3.91 [0.74–20.70]	0.11		4.93 [1.14–21.33]	0.033

1. ORs were adjusted by BMI, age, sex, data set.

Conclusion: When exposed to high SSB consumption individuals with the normally gout-protective allele at *rs11942223* have a considerably elevated risk of gout. Our data suggest that SLC2A9-mediated uric acid transport is physiologically influenced by excess simple sugars derived from SSB, with excess SSB consumption negating the gout-risk discrimination normally mediated by *rs11942223*.

Microarray Analysis of Acute and Intercritical Gout.
Alicia Rodriguez-Pla[1], Lynda Bennett[1], Kathryn H. Dao[2], Edwardo Delgado[2], Typhanie Maurouard[1], M. Virginia Pascual[1] and John J. Cush[3]. [1]Baylor Institute for Immunology Research, Dallas, TX, [2]Arthritis Care and Research Center, Dallas, TX, [3]Baylor Research Institute, Dallas, TX

Background/Purpose: We aimed to identify the immune mechanism underlying gouty inflammation using microarrays analysis and modular gene expression signatures.

Methods: Whole blood along with clinical and treatment data were collected from out-patients with gout. A total of 28 samples from 20 patients (18 males and 2 females; median age 53.5 years [range 39–82]; median disease duration 2.2 years [range 0–29.11]) and from 16 matched healthy controls were obtained. Thirteen patients had active disease at their first visit, and 7 had quiescent (intercritical) disease. Whole blood RNA was extracted using standard technologies and was hybridized to Illumina HT-12 chips. Genes differentially expressed (unpaired Student's t-test) in the first visit of all gout or active gout patients (fold change $\geq$2 and a p<0.05), were selected for further consideration. Ingenuity Pathways Analysis was performed and we also adopted a module based data mining strategy, which can facilitate biomarker and biological knowledge discovery.

Results: Two hundred and four genes were found differentially expressed in gout patients at their first visit regardless of clinical activity. When active patients were selected, 184 transcripts were found dysregulated. Innate immunity genes related to the interleukin-1 (IL1) signaling pathway were up-regulated (*ORM1/ORM2*, *BNIP3L*, *EPB49*, defensins, myeloperoxidase, elastase), whereas genes involved in adaptive immunity were down-regulated (*CD79A*, *CD79B*, *CBR* complex). Modular analysis permitted us to visualize alterations in 174/260 pre-defined modules. Of those, transcripts related to innate immunity cell types, including neutrophils, were increased. Those related to B cells, T cells, NK/cytotoxic and plasma cells were decreased. Interestingly, transcripts related to an early erythrocyte cell population previously described in other IL1-mediated diseases such as systemic onset Juvenile Idiopathic Arthritis (sJIA)/Still's disease and *S. aureus* infections were upregulated. In addition, modules related to inflammation and cell death were up-regulated, while those of proliferation, cell cycle, and mitochondrial stress were down-regulated. This modular pattern might represent a biomarker of innate immunity/IL1-related diseases.

Conclusion: Patients with gout display a blood transcriptional profile similar to that seen in IL-1 dominant or autoinflammatory diseases. This fits with the current knowledge about the involvement of the inflammasome in gout and patients response to IL-1 blockade. This profile is easily interpreted using our previously described modular analysis framework. Although larger, prospective studies including newly diagnosed patients on no treatment are needed to confirm these findings, our data suggest that it is possible to use blood gene expression analysis to identify molecular and cellular pathways linked to dysregulation of innate immunity.

Genetic Variants of Serum Uric Acid and Gout: An Analysis of > 170,000 Individuals.
Hyon Choi[1], Robert M. Plenge[2], Anna Köttgen[3], Veronique Vitart[4], Murielle Bochud[5], Christian Gieger[6], Mark Caulfield[7], Marina Ciullo[8], Eva Albrecht[6], Alexander Teumer[9], Gary Curhan[10], Jan Krumsiek[11], Conall O'Seaghdha[12], Caroline Fox[13] and The Global Urate Genetics Consortium (GUGC)[14]. [1]Boston University School of Medicine, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Renal Division, Freiburg University Hospital, Freiburg, Germany, [4]Western General Hospital, Edinburgh, United Kingdom, [5]Lausanne University Hospital, Switzerland, [6]Neuherberg, Germany, [7]Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom, [8]"A. Buzzati-Traverso", Italy, [9]Ernst-Moritz-Arndt-University Greifswald, Greifswald, Germany, [10]Harvard Medical School, Boston, [11]German Research Center for Environmental Health, Neuherberg, Germany, [12]NHLBI's Framingham Heart Study and Center for Population Studies, Neuherberg, [13]NHLBI's Framingham Heart Study and Center for Population Studies, MA, [14]Boston

Background/Purpose: Gout is a common and excruciatingly painful inflammatory arthritis caused by hyperuricemia. In addition to various lifestyle risk factors, a substantial genetic predisposition to gout has long been

recognized. The Global Urate Genetics Consortium (GUGC) has aimed to comprehensively investigate the genetics of serum uric acid and gout using data from $> 140,000$ individuals of European-ancestry, 8,340 individuals of Indian ancestry, 5,820 African-Americans, and 15,286 Japanese.

Methods: We performed discovery GWAS meta-analyses of serum urate levels (n=110,347 individuals) followed by replication analyses (n=32,813 different individuals). Our gout analysis involved 3,151 cases and 68,350 controls, including 1,036 incident gout cases that met the American College of Rheumatology Criteria. We also examined the association of gout with fractional excretion of uric acid (n=6,799). A weighted genetic urate score was constructed based on the number of risk alleles across urate-associated loci, and their association with the risk of gout was evaluated. Furthermore, we examined implicated transcript expression in cis (expression quantitative trait loci databases) for potential insights into the gene underlying the association signal. Finally, in order to further identify urate-associated genomic regions, we performed functional network analyses that incorporated prior knowledge on molecular interactions in which the gene products of implicated genes operate.

Results: We identified and replicated 28 genome-wide significant loci in association with serum urate ($P \leq 5 \times 10^{-8}$), including all previously-reported loci as well as 18 novel genetic loci. Unlike the majority of previously-identified loci, none of the novel loci appeared to be obvious candidates for urate transport. Rather, they were mapped to genes that encode for purine production, transcription, or growth factors with broad downstream responses. Besides SLC2A9 and ABCG2, no additional regions contained SNPs that differed significantly ($P < 5 \times 10^{-8}$) between sexes. Urate-increasing alleles were associated with an increased risk of gout for all loci. The urate genetic risk score (ranging from 10 to 45) was significantly associated with an increased odds of prevalent gout (OR per unit increase, 1.11; 95% CI, 1.09–1.14) and incident gout (OR, 1.10; 95% CI, 1.08–1.13). Associations for many of the loci were of similar magnitude in individuals of non-European ancestry. Detailed characterization of the loci revealed associations with transcript expression and the fractional excretion of urate. Network analyses implicated the inhibins-activins signaling pathways and glucose metabolism in systemic urate control.

Conclusion: The novel genetic candidates identified in this urate/gout consortium study, the largest to date, highlight the importance of metabolic control of urate production and urate excretion. The modulation by signaling processes that influence metabolic pathways such as glycolysis and the pentose phosphate pathway appear to be central mechanisms underpinned by the novel GWAS candidates. These findings may have implications for further research into urate-lowering drugs to treat and prevent gout.

Osteoarthritis-Associated Basic Calcium Phosphate Crystals Induce IL-1β, IL-18 and S100A8 Production in a Tyrosine Kinase Dependent Manner. Geraldine M. McCarthy[1], Evanna Mills[2], Kingston Mills[2] and Aisling Dunne[2]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]Trinity College Dublin, Dublin 2, Ireland

Background/Purpose: Intraarticular basic calcium phosphate (BCP) crystals are present in the majority of osteoarthritic (OA) joints and are associated with severe degeneration. In vitro, BCP promote pro-inflammatory cytokine production and matrix metalloprotease (MMP) expression, suggesting a pathogenic role in OA. Recently it has been demonstrated that BCP crystals drive IL-1β and IL-18 production following activation of the NOD-like receptor, NLRP3. Here, we sought to determine whether uptake of BCP crystals leads to the activation of the membrane proximal kinases, Syk and PI3 kinase and to further characterise events downstream of Syk activation in order to identify novel molecular targets for the treatment of BCP related arthropathies.

Methods: Murine macrophages were stimulated with BCP crystals, with or without priming with a Toll-like receptor (TLR) agonist and IL-1β and IL-18 production was quantified by enzyme linked immunosorbent assay (ELISA). A role for Syk and PI3 kinase was determined with the use of the inhibitors, piceatannol and LY294002, respectively. Activation of the kinases was confirmed by western blotting using phospho-specific antibodies to Syk and PI3 kinase following treatment of cells with the crystals over a 30 minute time course. Finally, activation of the downstream kinase, ERK, and production of the damage associated molecule, S100A8, was assessed in the presence of piceatannol in order to determine if these events are associated with BCP dependent Syk activation.

Results: Physiological concentrations of BCP crystals (50mg/ml) induced robust IL-1β and IL-18 production in a Syk and PI3 kinase dependent manner. Treatment with the inhibitors piceatannol and Ly294002 led to a significant reduction in cytokine levels ($>80\%$) and activation of Syk and PI3 kinase was apparent after approximately 5 minutes treatment with the crystals. Phosphorylation of the downstream kinase, ERK, was prevented following treatment with the Syk inhibitor, piceatannol, thus identifying Syk kinase activation as a proximal event in BCP induced pro-inflammatory cytokine production. Finally, treatment of cells with BCP crystals led directly to the production of the danger-associated molecule, S100A8 and this was also dependent on activation of Syk.

Conclusion: Since S100A8 is considered a TLR 4 ligand, we propose a model whereby BCP crystals drive the production of S100A8 which in turn leads to the expression of pro-IL-1β and pro-IL-18 (Signal 1). In macrophages, BCP crystals can also induce the activation of the NLRP3 inflammasome (Signal 2) leading to the production of the mature forms of these cytokines. These events are dependent on tyrosine phosphorylation and we identify Syk kinase as a potential target for the treatment of BCP related pathologies.

1632

Arhalofenate Is a Novel Dual-Acting Agent with Uricosuric and Anti-Inflammatory Properties. Yun-Jung Choi, Vanina Larroca, Annette Lucman, Vic Vicena, Noe Abarca, Tim Rantz, Brian E. Lavan and Charles A. McWherter. Metabolex, Inc., Hayward, CA

Background/Purpose: In most patients with gout, elevated serum urate is linked to excess uric acid reabsoprtion in the proximal renal tubule by anion transporters/exchangers, including URAT1, OAT4 and OAT10. It is also known that initiation of serum urate lowering therapy (ULT) in gout patients significantly increases the risk of flares, a process that is believed to be mediated by mono sodium urate (MSU) crystal activation of the inflammasome with subsequent release of pro-inflammatory mediators, including IL-1β. Arhalofenate is an investigational drug which has completed phase 2 of development for the treatment of gout patients with hyperuricemia that are at risk for flares. The dual action of arhalofenate was studied for inhibition of uric acid uptake by renal urate transporters and for suppression of MSU crystal stimulated IL-1β production in isolated mouse macrophages and in a murine air pouch model.

Methods: The activities against the human urate transporters URAT1, OAT4 and OAT10 were determined using the uptake of ^{14}C-uric acid into human HEK293 cells transiently expressing the relevant transporter and compared to uptake into parental HEK293 cells. The anti-inflammatory response was evaluated following acute MSU crystal treatment of (1) mouse macrophages and (2) mouse in an air pouch model, in both cases measuring the elaboration of pro-inflammatory mediators including IL-1β.

Results: Arhalofenate inhibited uric acid uptake by all three transporters with IC$_{50s}$ of 92 μM for URAT1, 3 μM for OAT4 and 53 μM for OAT10. These results are pharmacologically relevant for inhibition of urate reabsoprtion because arhalofenate acid levels in human urine were found to be 116 $\pm$ 23 μM (Mean $\pm$ SEM) at a 600 mg dose. In thioglycolate-elicited intraperitoneal macrophages, arhalofenate acid (150 μM) suppressed IL-1β levels by 77% which was indistinguishable from dexamethasone (75%, p$<$0.05 by one-way ANOVA). In the murine air pouch model, arhalofenate treatment (250 mg/kg) for 3 days prior to MSU crystal induction resulted in 76 % reduction in the elaboration of IL-1β in response to MSU. This response was again similar to that observed for dexamethasone. The anti-inflammatory concentrations of arhalofenate acid are relevant to the human clinical exposures.

Conclusion: Arhalofenate is a novel anti-inflammatory uricosuric agent with the potential to target both serum uric acid reduction and the painful flares that accompany gout. The data from this study support that arhalofenate acts by mediating inhibition of renal transporters/exchangers of uric acid and by suppression of the production of IL-1β in response to MSU crystals in both *in vitro* and *in vivo* models of MSU crystal induced inflammation. These properties strongly support the continued clinical development of arhalofenate for treating elevated serum urate and lowering the risk of flares.

Ulodesine (BCX4208) Add-On Therapy to Allopurinol 300mg Lowers Hypoxanthine and Xanthine Plasma Levels in a Dose-Dependent Fashion: Results From a 12-Week Randomized Controlled Trial in Patients with Gout. Shanta Bantia[1], Leigh Harman[1], Cynthia Parker[1], Damon Papac[2], Andreas Maetzel[1], Brian Taubenheim[1] and Alan S. Hollister[1]. [1]BioCryst Pharmaceuticals, Inc., Durham, NC, [2]Southern Research Institute, Birmingham, AL

Background/Purpose: Ulodesine (BCX4208) is an oral, once-daily, purine nucleoside phosphorylase (PNP) inhibitor in clinical development as add-on therapy for the chronic management of hyperuricemia in patients with gout. Based on the role of PNP in purine catabolism, inhibition of PNP should reduce hypoxanthine (HX), xanthine (X) and uric acid levels. Ulodesine has demonstrated dose-dependent decreases in serum uric acid (sUA) in multiple clinical trials both as a single agent and in combination with allopurinol[1]. Plasma X and HX concentrations are significantly higher in untreated gout patients compared to hyperuricemic and normal subjects[2]. Elevated plasma X and HX concentrations are also associated with kidney stones, as seen in xanthine oxidase (XO)-deficient patients and mice[3, 4]. Moreover, HX and X are implicated in the production of reactive oxygen species leading to oxidative stress, cell damage and cardiovascular effects[5]. The objective of the study is to measure plasma X and HX concentrations in gout patients receiving 300 mg/d allopurinol plus either placebo or ulodesine.

Methods: Two hundred-seventy eight subjects with gout and sUA ≥ 6.0 mg/dL on allopurinol 300 mg/d for at least 2 weeks were randomized to receive oral ulodesine 5, 10, 20, or 40 mg/d or placebo for 12 weeks while continuing allopurinol 300 mg/d. Blood samples were collected at baseline and day 85 into heparin tubes containing BCX34 (PNP inhibitor) to prevent purine metabolism during collection and processing. Plasma concentrations of X and HX were analyzed by LC/MS/MS. [$^{15}N_2$] xanthine and [D_2] hypoxanthine were used to generate surrogate standard curves for quantification of plasma X and HX concentrations. In normal healthy subjects, the mean (+ SD) concentrations of plasma X and HX were 56 ± 13 ng/mL and < 25 ng/mL, respectively.

Results: Ulodesine combined with allopurinol produced significant reductions in plasma X and HX concentrations from baseline, compared to placebo (Table). At baseline (subjects on allopurinol 300 mg/d), the mean (+ SD) concentrations of the plasma X and HX were 500 ± 408 ng/mL and 301 ± 293 ng/mL, respectively. The reduction in mean plasma X and HX concentrations with BCX4208 treatment in gout subjects was dose-dependent.

Table. Mean Change from baseline of Day 85 Plasma Xanthine and Hypoxanthine levels BCX4208–203 Study

Metabolite	Placebo (n=40)	5 mg/day (n=39)	10 mg/day (n=38)	20 mg/day (n=41)	40 mg/day (n=36)
			Change from baseline at day 85 LSM (SEM)		
Xanthine(ng/mL)	124.9 (76.33)	-66.6 (77.46)**	-114.6(74.25)***	-138.5 (69.03)***	-183.3 (75.19)***
Hypoxanthine(ng/mL)	-22.7 (70.36)	-48.9 (71.25)	-126.8 (68.21)	-165.6 (63.05)*	-201.3 (68.97)**

*p<0.05, **p<0.005, ***p<0.001 vs. placebo

Conclusion: Using a robust LC/MS/MS method and stabilization of plasma X and HX during blood collection and processing, oral ulodesine administration demonstrated dose-dependent mean reductions in plasma X and HX concentrations in gout patients while under treatment with allopurinol. These results confirm the mechanism of action of ulodesine.

Delivering Mesenchymal Stem Cells to Arthritic Joints with Nano-Fiber Scaffold Resulted in Inhibition of Arthritis and Joint Damage in Arthritis Models. Xiangmei Zhang[1], Kunihiro Yamaoka[1], Koshiro Sonomoto[1], Masahiro Kondo[1], Shunsuke Fukuyo[1], Makoto Satake[2], Hiroaki Kaneko[2], Kazuhisa Nakano[1], Shingo Nakayamada[1], Yosuke Okada[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Integrative Technology Research Institute, Teijin Limited, Tokyo, Japan

Background/Purpose: Even though treatment of rheumatoid arthritis (RA) has emerged, aiming bone repair is still a challenge. Mesenchymal stem cells (MSCs) possess immunoregulatory function with pluripotency and efficacy on arthritis animal models has been reported by intra-venous or intra-peritoneal administration. Herein we have utilized nano-fiber poly-lactic-co-glycollic acid (PLGA) scaffold known for controlled biodegradability with less immunogenicity as an effective delivery system of MSCs to the arthritic joint.

Methods: MSCs were simply injected intra-articularly (IA) or intra-peritoneally (IP) or seeded on nano-fiber PLGA scaffold and implanted into bilateral ankles (IMP) of collagen-induced arthritis (CIA) rats at the time of immunization. Efficacy was evaluated clinically (arthritis score, body weight and hind paw thickness), radiologically (X-ray and micro-CT) and histologically (Hematoxilin-Eosin staining).

Results: Treatment of CIA with IMP significantly decreased the severity of arthritis while IA and IP showed less or no effect. Radiologic evaluation of bone destruction was also suppressed by IMP, but not by IA or IP. Histological analysis of the ankles indicated less inflammatory cell infiltration, synovial hyperplasia, pannus formation, resulting in less destruction of the cartilage and bone by IMP compared to IA and IP. Interestingly, size and weight of the spleen, draining lymph nodes in rats treated with IMP were significantly smaller than those treated with IA and IP. These phenomena were observed at both early phase (2 weeks after immunization) and late phase (6 weeks after immunization) of the disease course. Histological analysis of the draining lymph nodes revealed less or no chronic inflammation in the early phase and reduced germinal center formation at the late phase in rats treated with IMP compared to IA and IP treatment.

Conclusion: Local delivery of MSCs with nano-fiber PLGA scaffold significantly suppress arthritis and bone destruction with decreased immune response in the draining lymph node, while IA or IP had less or no effect. The amount of MSCs that we utilized in our study was far lower compared to the studies reported previously. Therefore, our results suggest the importance of MSCs to reside at the local inflammatory site for suppressing the inflammation and moreover regenerating the destructed bone sequentially.

Polyarthritis Caused by TIARP (TNFAIP9) Deficiency Critically Dependent On Dysregulated STAT3, NF-κB Signaling and Cell Death in Macrophage. Asuka Inoue[1], Isao Matsumoto[1], Naoto Umeda[1], Yuki Tanaka[1], Satoru Takahashi[2] and Takayuki Sumida[1]. [1]University of Tsukuba, Tsukuba city, Ibaraki, Japan, [2]Department of Anatomy and Embryology, Faculty of Medicine, University of Tsukuba, Tsukuba city, Ibaraki, Japan

Background/Purpose: TNFα-induced adipose-related protein (TIARP) is a six-transmembrane protein induced by TNFα and IL-6 in adipose tissue. Recently, we found that TIARP is dominantly expressed in splenic macrophages and joints of two arthritic mouse models (collagen induced arthritis;

CIA and glucose-6-phosphate isomerase (GPI) induced arthritis). In human, TIARP is also observed in human joints from patients with rheumatoid arthritis and clearly upregulated by TNFα stimulation, although the pathogenic mechanisms of arthritis remain unclear. In this study, to elucidate the role of TIARP in the development of arthritis, we have generated TIARP-deficient (TIARP$-/-$) mice.

Methods: (1) We generated TIARP$-/-$ mice in C57BL/6 (B6) background, and investigated several organs in aged (12-month-old) TIARP$-/-$ mice. The level of cytokines in the serum was measured by ELISA. (2) Peritoneal macrophages (PEM) were isolated and cultured with LPS or TNFα. Then, the production of IL-6 in culture supernatant was measured by ELISA. (3) We examined the role of TIARP in NF-κB pathway and apoptosis. PEM were cultured with TNFα, then fluctuation of NF-κB inhibitory molecule IκBα expression was detected by Western blotting. Apoptotic cells were detected by flowcytometry using anti-Annexin V antibodies. (4) We also examined the susceptibility of young (8–12-week-old) TIARP$-/-$ mice to CIA. CIA was induced by immunization with 200μg of chicken type II collagen (CII) emulsified in CFA to B6 mice, followed by boost immunization on day 21. The severity of arthritis was monitored by clinical score. (5) The level of anti-CII antibodies in the serum on day30 and 60 were measured by ELISA. (6) The level of IL-6 and TNFα in the serum on day 60 after CII immunization was measured. (7) We examined the effects of anti-IL-6 receptor mAb (MR16-1) on the development of arthritis in TIARP$-/-$ CIA mice. We injected 2mg of MR16-1 intraperitoneally on day 21 after CII immunization. (8) PEM were cultured with IL-6 for 1 h. The expression of STAT3, phosphorylated-STAT3 (p-STAT3) and SOCS3 were detected by Western blotting.

Results: (1) 80% of aged TIARP$-/-$ mice spontaneously developed arthritis. The levels of IL-6 in the serum from TIARP$-/-$ mice were significantly higher than WT mice. (2) PEM from TIARP$-/-$ produced high amount of IL-6 with LPS or TNFα stimulation. (3) PEM from TIARP$-/-$ mice showed sustained degradation of IkBα compared with WT by TNFα stimulation. TNFa-induced apoptotic cells were increased in WT but unchanged in TIARP$-/-$. (4) The severity of arthritis in TIARP$-/-$ was higher than that in WT. (5) The level of anti-CII antibodies was comparable between WT and TIARP$-/-$. (6) The serum IL-6 was significantly increased in TIARP$^{-/-}$ mice, whereas serum TNFα was not detected. (7) Administration of MR16-1 on day 21 significantly suppressed the progression of arthritis in TIARP$-/-$ CIA mice. (8) P-STAT3 expression was enhanced in TIARP$-/-$ compared with WT, whereas SOCS3 expression was comparable between WT and TIARP$-/-$.

Conclusion: These findings suggest that TIARP is a negative regulator in autoimmune arthritis through the suppression of IL-6 production, NF-κB, STAT3 signaling, and the induction of apoptosis.

Commensal Gut-Derived Bacteria As Therapy for Systemic Autoimmune Disease. David Luckey[1], Eric Marietta[1], Harvinder S. Luthra[1], Robin Patel[1], Joseph A. Murray[1], Ashutosh Mangalam[2] and Veena Taneja[1]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that leads to destruction of joints. Although etiology of RA is unknown, both genetic and environmental factors are involved in predisposition to develop RA. Genome wide association studies have shown that among the genetic factors, the strongest association of RA is with MHC region, the most significant being HLA-DRB1*0401 and DQ8. A recent study showed that patients with RA have an imbalance of gut microbiota suggesting its role in regulation of this disease. Analysis of fecal microbiota of patients with RA showed significantly less *Bifidobacteria* and bacteria of the *Bacteroides-Porphyromonas-Prevotella* group, and the *E. rectale–C. coccoides* group than the fecal microbiota of patients with non-inflammatory Fibromyalgia. Since these bacterial species are known to belong to the most common genera and groups in the human fecal microbiota, their absence in RA patients might suggest a protective role of these commensal bacteria in RA.

Methods: We have generated a mouse model of rheumatoid arthritis using HLA transgenic mice expressing RA-susceptible gene, HLA-DQ8 in the absence of their endogenous class II genes. Recently, we isolated *Prevotella histicola*, anaerobic commensal bacteria of Human gut, from bowel of a patient and have shown that it possesses anti-inflammatory activity.

Results: In this study we have tested our hypothesis if systemic disease like RA can be modulated via gut. HLA-DQ8 transgenic mice develop collagen-induced arthritis (CIA) following immunization with type II collagen (CII). We have used these transgenic mice to test if gut-derived commensal bacteria can regulate immune response and modulate arthritis. Treatment with *P. histicola* did not lead to any pathology in the gut. Transgenic mice immunized with CII and treated with *P. histicola* showed suppression of antigen-specific cellular immune response with a significant reduced production of inflammatory cytokines. Treatment with *P. histicola* led to generation of T regulatory cells in the gut and increased production of IL-10 in treated group compared to controls. Treatment of mice induced for arthritis in a therapeutic protocol led to a significant decrease in incidence (40% in treated versus 80% of control) and severity of arthritis.

Conclusion: *P. histicola* modulated immune responses in the gut thereby modulating systemic immune response and suppression of arthritis suggesting this treatment can induce tolerance in periphery leading to systemic immune suppression. Since bacteria being used for treatment is a gut-derived commensal, there are less likely to be significant side effects.

A Novel Peptide Inhibiting the Binding Between C1q and Immunoglobulin Ameliorates Joint Destruction in Rats with Collagen-Induced Arthritis. Yu Moriguchi and Tetsuya Tomita. Osaka University Graduate School of Medicine, Suita, Japan

Background/Purpose: C1q is the major subcomponent of the first component of complement protein. The activation of the complement is triggered by binding of C1q to the Fc fragment of immunoglobulin G (IgG). It has been reported that rheumatoid arthritis (RA) patients with high concentrations of C1q in their blood will suffer from joint destruction in the future. Since the activation of C1q is thought to be involved in this joint destruction, binding inhibitor between C1q and IgG will be one of the candidates of new anti-RA drug. The purpose of the present study is to identify the sequence essential for binding between C1q and IgG, to confirm the inhibitory capacity of the peptide with the same sequence, and to verify in a rat collagen-induced arthritis (CIA) model that the peptide has possibility to be a new therapeutic agent for RA.

Methods: To find the binding inhibitor, we constructed peptide array to identify amino acid sequences of C1q that is crucial for binding between C1q and IgG. Some sequences based on this peptide array analysis were subsequently confirmed to inhibit the binding between C1q and IgG, and the peptide with the most inhibitory sequence (R1 peptide) was determined. For in vivo application, rats with CIA were intraperitoneally injected with R1 peptide or methotrexate (MTX) starting after the onset of arthritis. Disease activity scores, radiographic scores, and histologic scores were evaluated on day 36. Cytokine expressions in the tissue were assessed by realtime RT-PCR. Spleen cell proliferation ex vivo in response to mitogens was examined. Osteoclast formation ex vivo induced by soluble receptor activator of nuclear factor KB ligand (sRANKL) and MCSF was examined. Immunohistochemistry was performed to verify the deposition of IgG and C1q in ankle joints.

Results: R1 peptide as well as MTX significantly decreased the disease activity scores of CIA. The mean radiographic and histologic scores were significantly lower in the R1-treated rats than in untreated rats. Steady state mRNA levels of TNF-a and IL-1b in ankle joints were decreased in R1-treated rats. There was a significant reduction in phytohemagglutinin-stimulated proliferation of spleen cells in R1-treated rats with the dose of 100 mg/kg day compared to the untreated. Furthermore the osteoclast-like cell differentiation induced by both sRANKL and MCSF was significantly inhibited in R1-treated rats compared to untreated and even MTX-treated rats. Lastly, immunohistochemistry revealed that the deposition of local C1q and was significantly suppressed in R1-treated rats.

Conclusion: The present study demonstrated that R1 peptide sequence could be essential for binding between C1q and IgG. Furthermore, R1 peptide suppresses the progression of joint destruction in a rat CIA model equivalently to MTX treatment, suggesting the peptide is a potential therapeutic agent for rheumatoid arthritis.

Synovial Fibroblast Migration Is Modulated by the Focal Contact Protein Lasp-1. Adelheid Korb-Pap[1], Jan Hillen[1], Marianne Heitzmann[1], Catherine S. Chew[2], Stefan Butz[3], Dietmar Vestweber[3], Hermann Pavenstädt[1] and Thomas Pap[1]. [1]University Hospital Muenster, Muenster, Germany, [2]Medical College of Georgia, Augusta, GA, [3]Max Planck Institute of Molecular Biomedicine, Muenster, Germany

Background/Purpose: RA synovial fibroblasts (SF) have been suggested to contribute to the spreading of disease through their ability to leave cartilage destruction sites, migrate via the bloodstream and re-initiate the destructive process at distant articular cartilage surfaces. The underlying mechanisms are unclear, but the actin-crosslinking protein Lasp-1 is of interest in this context, because it localizes to the leading edges of migrating cells and is of importance for the metastatic dissemination of different tumors. Therefore, it is particularly important to investigate the role of Lasp-1 in synovial fibroblast migration and its effects on RA.

Methods: The expression of Lasp-1 in the hind paws of wt and hTNFtg mice, an established model for human RA, was investigated by immunohistochemistry. Western-blot analyses and immunofluorescence was performed to analyze Lasp-1 expression and sub-cellular distribution in SFs from wt and hTNFtg mice. The migratory capacity of SFs derived from wild-type, Lasp-1$^{-/-}$ and hTNFtg mice was studied in a modified scratch assay as well as in a transmigration assay using murine endothelioma cells (bEnd.5) as an endothelial barrier and TNF-alpha as a stimulus. Furthermore, we used Lasp-1 knockout mice for interbreeding studies with hTNFtg mice.

Results: Immunostainings and Western Blot analyses showed a prominent expression of Lasp-1 in synovial fibroblasts obtained from hTNFtg mice with a characteristic sub-cellular distribution localizing Lasp-1 to structures of cell adhesion and invasion. In the scratch assay, Lasp-1$^{-/-}$ SFs exhibited a significantly reduced migration rate after 2 days (-30% vs. wt, p<0.05). Although the migratory capacity of unstimulated wt SFs through the endothelial monolayer was generally low (-32% vs. hTNFtg, p<0.05), this was virtually abolished by the knock out of Lasp-1 (-78% vs. wt, p<0.05). TNF-alpha enhanced the migratory potential of wild-type SFs to a significantly higher extent than of Lasp-1 null SFs (+84%, p<0.05). Interestingly, interbred Lasp1$^{-/-}$/hTNFtg mice presented milder clinical symptoms and analyses of histopathology revealed less cartilage degradation than hTNFtg mice at an age of 14 weeks.

Conclusion: Our data provide first evidence that Lasp-1 regulates the migratory capacity of synovial fibroblasts and influences the severity of arthritis in hTNFtg mice. While the mechanisms of trans-endothelial migration of SFs are largely undiscovered, our data suggest that these cells - when activated - migrate through the formation of invasive and adhesive membrane structures such as invadopodia, where Lasp-1 is prominently localized. Thus, targeting Lasp-1 may be a promising strategy modulate the invasive and migratory behavior of synovial fibroblasts in RA.

1639

FLIP in Macrophages Promotes the Progression of Serum Transfer-Induced Arthritis. Qi Quan Huang[1], Robert Birkett[2], Renee E. Koessler[1], G. Kenneth Haines III[3], Harris R. Perlman[1] and Richard M. Pope[4]. [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Yale University, New Haven, CT, [4]Northwestern Univ Med School, Chicago, IL

Background/Purpose: Flip is well known as an anti-apoptotic protein induced by chronic inflammation that protects against death receptor-mediated apoptosis. Employing a FLIP myeloid lineage knock-out mouse line ($Flip^{d/f}$, $LysM^{cre/+}$), we identified that FLIP is essential for macrophage differentiation and survival and for granulocyte homeostasis. This study was performed to define the role of FLIP in myeloid cells in K/BxN anti-GPI serum transfer-induced arthritis.

Methods: Arthritis was induced by introducing 300ml anti-GPI serum collected from K/BxN mice into $Flip^{f/f}$, $LysM^{cre/+}$ mice and the age and gender matched littermate controls. Cell types and differential in peripheral blood were determined by complete blood count. Cell types present in various organs were determined employing multi-color fluorochrome-conjugated cell marker antibodies, analyzed by flow cytometry. The mouse ankles harvested at the indicated time points were fixed in 10% formalin for H&E histological staining, or frozen in −80°c for ELISA cytokines analysis.

Results: Similar to the $Flip^{f/d}$, $LysM^{cre/+}$ mice reported earlier, $Flip^{f/f}$, $LysM^{cre/+}$ mice exhibited a significant increase of circulating neutrophils and monocytes, multi-organ neutrophil infiltration, and significantly reduced mature macrophages in multi-effector organs, such as peritoneal cavity, although it was less severe. The $Flip^{f/f}$, $LysM^{cre/+}$ developed a significantly more severe of acute phase arthritis on days 2 and 4 post-induction compared to the controls. The development of arthritis stopped after day 4 and began to improve in $Flip^{f/f}$, $LysM^{cre/+}$ mice, while the controls continued to progressive, peaking at day 9. The arthritis was significantly reduced in the $Flip^{f/f}$, $LysM^{cre/+}$ mice between days 7 to day 14 compared with the controls. Histological analysis demonstrated more articular and extra-articular inflammation and neutrophils in the $Flip^{f/f}$, $LysM^{cre/+}$ ankles collected in day 2 and 4. In contrast, inflammation, cartilage destruction, erosion and pannus were significantly reduced on day 10 and/or 14 in the $Flip^{f/f}$, $LysM^{cre/+}$ mice. Further, IL-1b in the ankle joints was significantly higher in $Flip^{f/f}$, $LysM^{cre/+}$ ankles collected in day 0, 2 and 4, but not day 10 of arthritis compared with the controls. However, IL-1b in the ankle ankles positively correlated with arthritis in the control group, but no correlation was observed in the $Flip^{f/f}$, $LysM^{cre/+}$ mice. In preliminary experiments, the infusion of wild type macrophages into the $Flip^{f/f}$, $LysM^{cre/+}$ mice just after the injection of the anti-GPI serum resulted in less severe arthritis initially but more severe arthritis later in the course.

Conclusion: These studies demonstrate that FLIP in macrophages is essential for regulating neutrophil homeostasis and acute inflammation and that it promotes the progression of the effector phase of arthritis. The lack of association between inflammation and IL-1b in the $Flip^{f/f}$, $LysM^{cre/+}$ mice is consistent with diminished IL-1b signaling. These observations suggest that FLIP in macrophages is a potential target for the therapy in patients with rheumatoid arthritis.

ACR Concurrent Abstract Session
Rheumatoid Arthritis Treatment - Small Molecules, Biologics and Gene Therapy: Safety I
Monday, November 12, 2012, 2:30 PM–4:00 PM

1640

Long-Term Safety of Tocilizumab in Patients with Rheumatoid Arthritis and a Mean Treatment Duration of 3.7 Years. Mark C. Genovese[1], Anthony Sebba[2], Andrea Rubbert-Roth[3], Juan José Scali[4], Rieke Alten[5], Joel M. Kremer[6], Laura Pitts[7], Emma Vernon[7] and Ronald F. van Vollenhoven[8]. [1]Stanford University Medical Center, Palo Alto, CA, [2]University of South Florida, Tampa, FL, [3]University of Cologne, Cologne, Germany, [4]Durand University Hospital, Buenos Aires, Argentina, [5]Schlosspark Klinik, University Medicine Berlin, Berlin, Germany, [6]Albany Medical College, Albany, NY, [7]Roche, Welwyn Garden City, United Kingdom, [8]Karolinska Institute, Stockholm, Sweden

Background/Purpose: Tocilizumab (TCZ)—an IL-6 receptor inhibitor—has demonstrated efficacy in improving signs/symptoms, reducing joint damage, and improving physical function in rheumatoid arthritis (RA) patients (pts). This analysis assessed the long-term safety of TCZ (up to 5.8 y of exposure) in adult RA pts.

Methods: Analysis was performed in all pts who received ≥1 TCZ dose in 5 placebo-controlled trials (OPTION, TOWARD, RADIATE, AMBITION, LITHE), a clinical pharmacology study, or long-term extension studies. Data were pooled and analyzed from initial TCZ exposure to April 1, 2011 (cutoff).

Results: 4009 pts were included. Mean (median [range]) duration was 3.7 (4.6 [0.0–5.8]) y; total observation time was 14,994 pt-y (PY). Rates of serious adverse events (SAEs), serious infections, myocardial infarction (MI) SAEs, stroke SAEs, hepatic SAEs, and gastrointestinal (GI) perforations were stable over time (Table). The overall rate of AEs leading to withdrawal was 5.0/100PY (95% CI: 4.7, 5.4). Infections, laboratory abnormalities, and neoplasms were the most common AEs leading to withdrawal (0.97/100PY, 0.89/100PY, and 0.80/100PY). 8 pts withdrew because of anaphylaxis events; these were previously reported.[1] Rates/100PY (95% CI) were 14.6 (14.0, 15.3) for SAEs and 0.57 (0.45, 0.70) for deaths. The most common SAEs were infections, which occurred at a rate of 4.5/100 PY (95% CI: 4.1, 4.8); the most common serious infection was pneumonia (0.95/100 PY; 95% CI: 0.80, 1.12). Overall rates/100PY (95% CI) of MI SAEs, stroke SAEs, and hepatic

SAEs were 0.25 (0.18, 0.35), 0.31 (0.23, 0.42), and 0.04 (0.01, 0.09), respectively. The GI perforation rate was 0.20/100PY (95% CI: 0.13, 0.29). There were 194 confirmed malignancies, including 65 nonmelanoma skin cancer (NMSC) cases, corresponding to an overall rate/100PY (95% CI) of 1.29 (1.12, 1.49) and, excluding NMSC, of 0.86 (0.72, 1.02). SIR for malignancies (all sites) was 1.19 (0.99, 1.42), which was not statistically different from the US general population rate (SEER database).

Table. Event Rate/100 PY (95% CI) Over 12-Month Periods

	0–12 months	13–24 months	25–36 months	>36 months
AEs leading to withdrawal	9.3 (8.3 10.4)	4.5 (3.8 5.3)	4.1 (3.4 5.0)	3.2 (2.7 3.7)
SAEs	16.1 (14.7 17.4)	14.2 (12.9 15.7)	15.7 (14.2 17.2)	13.5 (12.5 14.5)
Serious infections	4.6 (4.0 5.4)	3.9 (3.3 4.7)	5.4 (4.6 6.3)	4.2 (3.7 4.7)
MI SAEs	0.29 (0.14 0.53)	0.17 (0.05 0.39)	0.29 (0.12 0.57)	0.26 (0.15 0.43)
Stroke SAEs	0.43 (0.24 0.71)	0.26 (0.11 0.52)	0.29 (0.12 0.57)	0.28 (0.16 0.45)
Hepatic SAEs	0	0.10 (0.02 0.29)	0.04 (0.00 0.20)	0.03 (0.00 0.13)
GI perforations	0.20 (0.08 0.42)	0.13 (0.04 0.34)	0.29 (0.12 0.57)	0.19 (0.10 0.34)

Conclusion: The safety profile of TCZ in the current analysis is consistent with that in prior TCZ analyses[1,2]; it remained stable over a mean treatment duration of 3.7 y, and no new safety signals have emerged. AE rates described herein are consistent with those reported in the RA population, and the overall rate of malignancies does not exceed reported background rates (SEER database).[3–10]

When Can Biological Therapy Be Resumed in Patients with Rheumatic Conditions Who Develop Tuberculosis Infection During Tumour Necrosis Factors Antagonists Therapy? Study Based On the Biobadaser Data Registry. Maria Victoria Hernández[1], Miguel A. Descalzo[2], Juan D. Cañete[1], Raimon Sanmarti[1] and BIOBADASER Study Group[3]. [1]Hospital Clínic of Barcelona, Barcelona, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain, [3]Madrid, Spain

Background/Purpose: Tuberculosis infection (TI) is one of the most serious adverse events related to tumour necrosis factor (TNF) antagonists. According to the current treatment guidelines (1), biological therapy may be resumed after completion of the treatment of active TI. However, during TI therapy, some patients undergo a relapse of the underlying inflammatory condition due to the prolonged duration of therapy. Our objective was to analyse whether patients suffering TI during biological therapy could reinitiate the biological therapy before completion of TI therapy with no relapse of TI.

Methods: Retrospective study based on data from the Spanish Biological Therapy registry (BIOBADASER), which has included 6479 patients from the beginning of the registry (February 2000) until November 2011. During this time, 52 cases of active TI requiring the withdrawals of biologicals were reported. We selected patients on TNF blockers who reinitiated biological treatment after development of TI. We analysed: demographic characteristics; diagnosis and disease duration; type of biological agent at TI diagnosis and mean time received; type of TI; mean time from TI diagnosis until biological therapy was resumed; type of biological agent reinitiated, and outcomes. To assess differences in the outcome of TI, we divided patients into 2 groups according to reinitiation of biological treatment before (group 1) or after (group 2) TI treatment completion.

Results: Twenty-seven patients (15 female, mean age 56.7 ± 15.1 years) reinitiated biological therapy after withdrawal due to TI. Diagnoses were: 14 rheumatoid arthritis; 6 ankylosing spondylitis; 3 psoriatic arthritis; 2 juvenile idiopathic arthritis; 1 undifferentiated spondyloarthropathy and 1 Behçet's disease. Mean disease duration was 18.8 ± 9.4 years. The type of TI was: pulmonary in 14 patients; disseminated tuberculosis in 12; cutaneous in 1. The TNF blocker received at TI diagnosis was: 6 patients infliximab, 2 etanercept and 1 adalimumab in group 1; and 14 infliximab, 3 adalimumab and 1 etanercept in group 2; with a median of treatment of 13 months. Biological therapy was reinitiated while patients were receiving TI treatment in 9 out of 28 patients (group 1), with a mean TI treatment of 2.25 ± 0.9 months. Fifty-six percent of group 1 patients reinitiated with the same biological agent, whereas in group 2 only 27.7% resumed the previous treatment. The underlying inflammatory condition improved in all patients. No patient of both groups had a relapse of TI after a follow-up of 49.2 ± 28.8 months (42 ± 30.7 in group 1 and 53.2 ± 27.8 in group 2).

Conclusion: Active TI in patients receiving TNF antagonists may not be a contraindication for the reinitiation of biological therapy before completion of TI treatment, especially in patients who experience a relapse of the underlying inflammatory disease, who have a favourable outcome of TI and who have received at least 2 months of tuberculostatic therapy.

Biologics and Mortality Risk in Rheumatoid Arthritis - Results of a Population Based Study. Diane Lacaille[1], Michal Abrahamowicz[2], Eric C. Sayre[3] and John Esdaile[1]. [1]Arthritis Research Centre of Canada, University of British Columbia, Vancouver, BC, [2]McGill University, Montreal, QC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Background/Purpose: Biologic agents, due to their effect on disease activity, may reduce the risk of premature mortality in rheumatoid arthritis (RA). We evaluated the association between exposure to biologics and risk of mortality in RA, using a population-based RA cohort with administrative health data.

Methods: Using administrative billing data from the Ministry of Health, we assembled a population-based cohort including all RA cases in the province who received care for RA between 01/1996 and 03/2006, using previously published RA criteria, with follow-up until 03/2010. Administrative data was obtained on all medications since 01/1996; MD visits, hospitalizations, and tests since 01/1990. For this study we identified all RA cases who used a biologic agent (anti-TNF, rituximab, anakinra or abatacept) during follow-up. Each biologic user was matched with one RA control who never used a biologic but used at least 3 DMARDs (to mimic coverage requirements) and with a recent (within 6 mos) change in DMARD. Controls were also matched on age, sex, calendar year of inclusion and closest propensity score, using a greedy matching technique. Matched controls were given the date of initiation of first biologic of the user they were matched to. A propensity score (PS) was calculated at time of initiation using markers of RA severity, as well as co-morbidities increasing risk of death. Despite selecting controls with the closest PS, matching was imperfect; therefore PS quintiles were added to the final multivariable model. Cox proportional hazard model (PHM) was used to estimate risk of death associated with biologic exposure, evaluated as a time dependent variable representing current or recent use of anti-TNF, where cases were considered exposed for up to 3 months after discontinuation. Time analyzed was from date of initiation to death or end of follow-up. PHM analysis was also adjusted for age, sex, RA duration, Charlson co-morbidity score, PS quintiles and the variables included in the PS model that were not balanced. Sensitivity analyses were carried out to test the robustness of results.

Results: Our sample includes 2156 biologic users and 2156 matched controls (mean (SD) age: 56.3(14.6), 74.7% females). We observed 573 deaths (326 in controls; 247 in biologic users). Exposure to biologics was associated with a reduced risk of death (aHR (95%CI): 0.25 (0.18; 0.36), p < 0.0001). A sensitivity analysis not requiring matched controls to have used 3 prior DMARDs or a recent change in DMARD yielded almost identical results (aHR (95%CI): 0.26 (0.18; 0.36), p < 0.0001). Another sensitivity analysis, without use of PS, but where the PS variables were allowed to enter the PHM and controls were only required prior use of one DMARD, yielded similar results (aHR (95%CI): 0.31 (0.22; 0.45), p < 0.0001). Limitations of

our study are those inherent to observational study, including possible effect of residual or unmeasured confounding, and selection bias from non-random allocation of treatment.

Conclusion: In a population-based cohort, exposure to biologics was associated with a significant reduction in mortality. Given the increased mortality risk of RA, this has important implications for health policy makers, health care providers and people with arthritis.

Outcomes of Pregnancy in Subjects Exposed to Certolizumab Pegol.
Megan Clowse[1], Douglas C. Wolf[2], Christian Stach[3], Gordana Kosutic[4], Susan Williams[4], Ido Terpstra[5] and Uma Mahadevan[6]. [1]Duke University Medical Center, Durham, NC, [2]Atlanta Gastroenterology Associates, Atlanta, GA, [3]UCB Pharma, Monheim, Germany, [4]UCB Pharma, Raleigh, NC, [5]UCB Pharma, Brussels, Belgium, [6]University of California, San Francisco, San Francisco, CA

Background/Purpose: Certolizumab pegol (CZP) is an Fc-free, PEGylated, anti-TNF approved in the US for the treatment of Crohn's disease (CD) and rheumatoid arthritis (RA). Pre-clinical and clinical data suggest a lack of active neonatal Fc receptor-dependent placental transfer of CZP [1, 2]. There are few reports of pregnancy outcomes following exposure to CZP to date. This work provides additional information regarding the primary pregnancy outcomes in women exposed to CZP.

Methods: The global CZP safety database was searched for all medically confirmed cases of pregnancy through March 6, 2012. The proportion of live births, spontaneous miscarriages, and elective terminations for women directly exposed to CZP before or during confirmed pregnancy were compared to those expected for the general US population of pregnant women.

Results: Of 294 reported pregnancy events, 152 had known outcomes, 89 had unknown outcomes and 53 were ongoing. Of the 152 events with known outcomes, 139 were cases in which the mother had direct exposure to CZP, with 57 from the clinical trial program and 82 from post-marketing reports. The remaining 13 were cases with the father exposed to CZP resulting in 10 live births, 2 miscarriages and 1 elective termination. Of the 139 direct exposure cases with known outcomes, the underlying conditions were CD (N=107), RA (N=17) and healthy subjects (N=2) with 13 cases classified as other or having missing data. 91 of 139 cases were from the US. 103 of 139 pregnancies resulted in live births (see table) and the median gestational age was 38.3 weeks (data available for 40 births). 21 pregnancies ended in spontaneous miscarriage. 15 pregnancies resulted in elective termination. These results are similar to those reported in the general population in the US (see table). In 103 live births there were 2 reported cases of congenital disorder (Rate in the US general population is 3% [4]); 1 baby had mild, unilateral hydronephrosis on antenatal ultrasound and was described as healthy upon birth. The other baby had vesicoureteric reflux.

Population	Number of pregnancy events (N)	Live births	Miscarriages	Elective termination
Direct exposure to CZP from global safety database	139	103/139 (74.1%)	21/139 (15.1%)	15/139 (10.8%)
US General Population (National Vital Statistics Data - 1990 to 2004) [3]	6 390 000	64.3%	16.6%	19.1%

Conclusion: Currently available data from 139 pregnant women exposed to CZP, report outcomes consistent with the US National Vital Statistics data. Additional data from larger numbers of pregnant women exposed to CZP are required to validate acceptable safety and tolerability of CZP in pregnancy.

Enhanced Pharmacovigilance Reporting of Malignancies in Children and Young Adults Taking Etanercept.
Michele Hooper[1], Deborah Wenkert[1], Bojena Bitman[1], Virgil C. Dias[1], Yessinia Bartley[2], Julie Wang[3] and Julia R. Gage[4]. [1]Amgen Inc., Thousand Oaks, CA, [2]Assent Consulting, Solana Beach, CA, [3]One Amgen Center Drive, Thousand Oaks, CA, [4]Gage Medical Writing, LLC, Oak Park, CA

Background/Purpose: Recent reports suggest an increased rate of malignancy in children with juvenile idiopathic arthritis (JIA) (Simard, A&R 2010;62:3776; Beukelman A&R 2012;64:1263). In 2011, the US FDA required TNF-blocker sponsors to initiate a 10-year postmarketing reporting commitment of all malignancies in children and young adults. We present the results to date for etanercept (ETN).

Methods: We reviewed all malignancies reported in patients ≤ 30 years (yrs) of age from clinical trials (CTs) and ARGUS (postmarketing cases, observational studies). Cases were included regardless of latency period, time on ETN, lack of tumor histology, reporting source (consumer, investigator, healthcare provider, regulatory agency, literature), or confounding factors. CT malignancy rates in ETN arms were compared with placebo/comparator arms. Exposure data used to generate ARGUS reporting rates were determined from the total mg of ETN dispensed from Nov 1998 through 31 Dec 2011 and from US market research-determined age distribution (birth-30 yrs, birth-11 yrs, 12–17 yrs, 18–30 yrs) extrapolated to the global market. Confidence intervals were not calculated for ARGUS rates as the ETN exposure data are estimates. Age-specific rates were generated from the Surveillance Epidemiology and End **Results** (SEER) database v7.0.9. ARGUS reporting rates and SEER rates for all malignancies and malignancy types with ≥ 5 cases are shown.

Results: In CTs, 1 malignancy each in ETN and placebo/comparator arms has been reported. ETN exposure was 231,404 patient-years (PY) (24,820 PY in birth-11 yrs; 38,099 PY in 12–17 yrs; 168,485 PY in 18–30 yrs). Rates observed per 100,000 PY in ARGUS and SEER, respectively for all malignancies were: age birth-30 yrs: 44.5 and 26.4; birth-11 yrs: 24.2 and 15.3; 12–17 yrs: 34.1 and 17.0; and 18–30 yrs: 46.9 and 42.1. Five or more cases of leukemia, lymphoma, melanoma, thyroid, and cervical cancers were reported. Rates for melanoma, thyroid, and cervical cancers seemed similar in ARGUS and SEER. Overall ARGUS leukemia rates seemed similar to SEER except for patients birth-11 yrs (12.1 and 5.4 per 100,000 PY, respectively) based on 3 cases. There were 23 cases of lymphoma. ARGUS rates of non-Hodgkin lymphoma seemed similar to SEER. Rates per 100,000 PY for Hodgkin disease (HD) in ARGUS and SEER were: birth-30 yrs: 3.9 and 2.2; birth-11 yrs: 12.1 and 0.4; 12–17 yrs 7.9 and 2.1; 18–30 yrs: 1.8 and 4.1.

Conclusion: In the ARGUS database, overall malignancy rates seemed higher than in the general pediatric population (SEER). Stratification by age suggests higher rates for those younger than 18 years old compared to SEER rate, consistent with a report of increased malignancy in all JIA patients (standardized rate = 79.3 per 100,000 PY), and untreated JIA patients (106.5 per 100,000 PY) (Beukelman 2012). No increased malignancy rate seemed to occur in the young adult age group. The overall lymphoma reporting rate was not increased; however, there was more HD in younger patients, most with long-standing disease and multiple immunosuppressive exposures.

1645

Combination of Isoniazid for Latent Tuberculosis with Traditional and/or Biologic Disease Modifying Anti-Rheumatic Drugs Is Well Tolerated in Patients with Rheumatic Diseases.
Dilrukshie Cooray[1], Saleem A. Waraich[2], Andrew Phan[1], Rosalinda C. Moran[1] and George A. Karpouzas[1]. [1]Harbor-UCLA Medical Center, Torrance, CA, [2]Placentia, CA

Background/Purpose: Patients with rheumatic diseases (RD) are typically treated with conventional and /or biologic disease modifying anti-rheumatic drugs (DMARD's) including tumor necrosis factor inhibitors (TNFi). Prior to biologic initiation subjects are typically screened for latent tuberculous infection (LTBI) with tuberculin skin test (TST) or Quantiferon-Gold in Tube (QFN) assay (Cellestis) and chest x-ray (CXR). If positive, such patients are treated with Isoniazid (INH) for 9 months in addition to their standard therapy. Since both INH and DMARDs may be individually hepatotoxic, there is a concern for enhanced liver toxicity when those are

combined. We investigated the incidence of liver toxicity upon combination of traditional and/ or biologic DMARDs with INH in pts with RD.

Methods: One hundred and eighty patients with RD and a positive TST (≥5 mm induration) and/or QFN result, from a single institution were evaluated. Liver function tests (LFTs) including aspartate (AST), alanine aminotransferase (ALT), alkaline phosphatase (AP), and total bilirubin (TB) were tested at baseline and every 8–12 weeks while on therapy. Subjects' serial LFTs over 6 months prior to INH initiation were used as controls for incident liver toxicity while on therapy. **Results** were expressed as –fold increases from upper limit of normal (x-fold ULN).

Results: Average duration of INH therapy was 8.8 ± 3.2 months. 180 patients underwent a mean of 4.2 tests while on INH; 177 baseline samples were collected, followed by 580 additional samples during INH treatment. The latter were compared to 259 samples serially collected from the respective subjects within 6 months prior to INH therapy (table). Patients received 1.85 ± 0.83 DMARDs, 88% of which was methotrexate at a dose of 19.2 ± 2.6 mg. One hundred forty seven (82%) subjects were on concomitant TNFi. 171/177 (96.6%) baseline AST, and 164/177 (92.6%) baseline ALT tests were normal (table); Any AST or ALT elevations above the ULN occurred in 13.5% and 10.8% of tests while on INH compared to 6.5% and 3.8% respectively prior to INH (p=0.004 and p=0.001 respectively). However, AST or ALT elevations ≥2-fold ULN occurred in 2.2% and 1.5% of tests on INH compared to 0.4% and 0.4% (respective p-values of 0.2 and 0.29). In 6 out of 180 pts (3.3%) INH was thought to be responsible for elevation of LFT's therefore necessitating withdrawal of the drug. None of the pts developed significant adverse events and LFT's normalized after INH was discontinued.

AST: 180 patients/177 baseline tests/ 578 tests on INH/ 258 tests prior to INH

Baseline-n, (%)		period on INH-n, (%)		prior to INH-n (%)		p-value
Normal	171/177 (96.6)	Normal	481/556 (87)	Normal	230/246 (93)	*0.004*
		Abnormal	75/556 (13.5)	Abnormal	16/246 (6.5)	*0.004*
		≥x1.5-fold	30/556 (5.4)	≥x1.5-fold	2/246 (0.8)	*0.001*
		≥x2-fold	12/556 (2.2)	≥x2-fold	1/246 (0.4)	0.2
Abnormal	6/177 (3.4)	Abnormal	9/22 (41)	Abnormal	7/12 (58)	0.47
		≥x1.5-fold	5/22 (23)	≥x1.5-fold	1/12 (8)	0.39
		≥x2-fold	3/22 (14)	≥x2-fold	1/12 (8)	1
		Normal	13/22 (59)	Normal	5/12 (42)	0.47

ALT: 180 patients/177 baseline tests/ 580 tests on INH/ 259 tests prior to INH

Baseline-n, (%)		period on INH-n, (%)		prior to INH-n (%)		p-value
Normal	164/177 (92.6)	Normal	477/535 (89.2)	Normal	225/234 (96.2)	*0.001*
		Abnormal	58/535 (10.8)	Abnormal	9/234 (3.8)	*0.001*
		≥x1.5-fold	18/535 (3.4)	≥x1.5-fold	2/234 (0.9)	*0.048*
		≥x2-fold	8/535 (1.5)	≥x2-fold	1/234 (0.4)	0.29
Abnormal	13/177 (7.3)	Abnormal	27/45 (60)	Abnormal	12/24 (50)	0.46
		≥x1.5-fold	11/45 (24.4)	≥x1.5-fold	10/24 (42)	0.17
		≥x2-fold	5/45 (11)	≥x2-fold	4/24 (16.7)	0.7
		Normal	18/45 (40)	Normal	12/24 (50)	0.29

Conclusion: Despite the heightened concern for significant hepatotoxicity, the combination of traditional and/ or biologic DMARDs with INH is clinically well tolerated; the incidence of significant LFT elevations is uncommon in compliant and regularly monitored patients.

The Mechanism of Umbilical Cord Mesenchymal Stem Cells in the Upregulation of Regulatory T Cells by TGF-β1 in Systemic Lupus Erythematosus. Lingyun Sun, Dandan Wang, Lin Lu and Xia Li. Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background/Purpose: Umbilical cord (UC) derived mesenchymal stem cells (MSCs) have shown immunoregulation on various immune cells. The aim of this study is to investigate the mechanism of UC-MSCs in the upregulation of peripheral regulatory T cells in patients with systemic lupus erythematosus (SLE).

Methods: Peripheral blood mononuclear cells (PBMC) from 20 SLE patients and normal controls were co-cultured with UC-MSCs at the ratios of 1:1, 10:1 and 50:1 respectively for 72 hours, and the proportions of $CD4^+CD25^+Foxp3^+$ regulatory T cells were analyzed by flowcytometry. PBMC and serum from active SLE patients and normal controls were used to stimulate UC-MSCs, TGF-β1 mRNA expressions on UC-MSCs were detected by real-time PCR. Supernatant TGF-β1 levels were determined by ELISA. The TGF-β1 small interfering RNA (siRNA) was used to interfere TGF-β1 expression on UC-MSCs, then to determine its effect on the regulation of SLE Treg cells. TGF-β1 inhibitor was added in the culture system of UC-MSCs and PBMC from active SLE patients to observe its role on the upregulation of Treg cells by UC-MSCs.

Results: UC-MSCs could dose-dependently upregulate peripheral $CD4^+CD25^+Foxp3^+$ Treg proportion in SLE patients, which was not depended on cell-cell contact. UC-MSCs had no regulatory effect on Treg cells in normal controls. Compared with the non-stimulated group and normal PBMC stimulated group, PBMC from SLE patients significantly promoted TGF-β1 mRNA expression on UC-MSCs (relative gene expression was 1.00 ± 0.09, 1.95 ± 0.62, 4.20 ± 2.34, respectively, both $P<0.05$). Supernatant TGF-β1 levels were significantly elevated in the presence of SLE PBMC. Serum of SLE patients (5%) enhanced TGF-β1 mRNA expression on UC-MSCs (12.19 ± 4.49), remarkably higher than fetal bovine serum cultured group (1.33 ± 0.06, $P<0.01$) and normal control serum cultured group (2.53 ± 0.72, $P<0.01$). Additionally, TGF-β1 siRNA interfered UC-MSCs failed to upregulate Treg cells in SLE patients (SLE PBMC + TGF-β1siRNA UC-MSCs group $2.33\% \pm 0.99\%$ *vs.* SLE PBMC group $1.80\% \pm 0.65\%$, $P>0.05$). Furthermore, in the presence of TCR stimulation, TGF-β1 specific inhibitor SB431542 significantly inhibited the regulatory role of UC-MSCs on Treg cells in SLE patients (SLE PBMC+UC-MSCs+SB431542 group $4.58\% \pm 2.10\%$ *vs.* SLE PBMC+UC-MSCs group $7.85\% \pm 3.54\%$, $P<0.05$).

Conclusion: Immune microenvironment in SLE patients can significantly stimulate TGF-β1 expression on UC-MSCs, which plays an important role in the upregulation of Treg cells in patients. This study provides a new mechanism for the regulation of Treg cells by UC-MSCs in SLE.

Critical Management Decisions in Cardiac Neonatal Lupus: The Role of Fluorinated Steroids. Peter M. Izmirly[1], Sara Sahl[1], Amit Saxena[1], Nathalie Costedoat-Chalumeau[2], Jean-Charles Piette[3], Munther A. Khamashta[4], Cecilia Pisoni[5], Deborah Friedman[6] and Jill P. Buyon[1]. [1]New York University School of Medicine, New York, NY, [2]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France, [4]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [5]Médica e Investigaciones Clínicas (CEMIC), Buenos Aires, Argentina, [6]New York Medical College, Valhalla, NY

Background/Purpose: Life-threatening cardiac manifestations of neonatal lupus (cardiac-NL) include complete block, endocardial fibroelastosis (EFE) and dilated cardiomyopathy (DCM), all supportive of intense fibrosis at the AV node and beyond. The overall case fatality rate is 17.5% but ranges from 7.8% for isolated block to 46% when the block is accompanied by more extensive disease. Both prevention and treatment with fluorinated steroids (FS) have been considered but results are inconclusive and even conflicting, a disconcerting situation given the potential for maternal toxicity. Accordingly, we reviewed the records from the U.S. Research Registry for Neonatal Lupus (RRNL), and the French and U.K. Registries to ascertain whether the use of FS conferred a survival benefit for fetuses with cardiac-NL or prevented the recurrence of cardiac-NL.

Methods: Data from the RRNL were analyzed to determine whether the use of FS affected survival at six months. Isolated third degree block and risk factors associated with a poor prognosis for cardiac-NL (HR<50, DCM and EFE) were evaluated individually or in combination given the likelihood of more than one poor prognostic factor being present. The effect of FS on survival once hydrops was detected was also addressed. The efficacy of prophylactic FS was assessed in an international historical cohort.

Results: In 276 cases of cardiac-NL, sufficient data were available regarding medications used during pregnancy; 150 were treated with FS. Not unexpectedly, FS were most often used when disease extended beyond the AV node. Neither maternal race/ethnicity nor health status influenced the use

of FS. In isolated 3rddegree block, 2.6% (2/78) died by 6 months postpartum despite the use of FS compared to 0/74, in those never given FS, p=.50. In those with HR < 50 bpm, 0 of 25 exposed to FS died compared to 0 of 18 unexposed to FS. Of the 12 cases with EFE (present or absent block) 11 received FS and only 1 died (9.9%) which was an elective termination. In cases where DCM was present (with or without block) 25% (1/4) died by 6 months postpartum despite the use of FS compared to 20.0% (1/5) never given FS. In cases with ≥ 2 risk factors, 16.7% (1/6) exposed to FS died by 6 months postpartum compared to 33.3% (2/6) unexposed. In fetuses with hydrops, 55.6% (15/27) receiving FS died compared to 81.8% (9/11) who did not receive FS, p=.16. When terbutaline was added to FS for hydrops, 50.0% (5/10) died compared to 58.8% (10/17) not receiving terbutaline. With regard to prophylaxis, recurrent cardiac-NL occurred in 14.3% (2/14) of pregnancies of mothers given FS compared to 19.3% (47/257) in those not treated with FS, p=.58.

Conclusion: These data suggest that fetuses with isolated 3rd degree block, even those who develop severe bradycardia in absence of other risk factors, do well and the addition of FS does not improve the 6 month survival rate. FS may be beneficial in cardiac-NL cases which develop hydrops or have multiple poor prognostic factors. Available evidence does not support the use of FS to reduce the recurrence rate of cardiac-NL.

Lupus Anticoagulant At First Pregnancy Visit Is Predictive of Pregnancy Loss. Michelle Petri[1], Anil Mankee[1], Ehtisham Akhter[1], Hong Fang[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Multiple factors, including proteinuria, antiphospholipid syndrome, thrombocytopenia and hypertension, are predictive of pregnancy loss in SLE. In the PROMISSE study of mediators of pregnancy loss, only a battery of lupus anticoagulant tests (Dil PT, dRVVT, PTT LA, and KCT) were predictive of adverse pregnancy outcomes (including pregnancy loss, preterm birth, pre-eclampsia, and small for gestational age). We examined the predictive value of one baseline lupus anticoagulant test (dRVVT) with pregnancy loss alone in women with SLE.

Methods: This analysis is based on pregnancies that were observed from 1987 to 2011. After excluding twin pregnancies, there were 402 pregnancies from 326 different women. We determined the percentage of women who had a pregnancy loss in groups defined by potential risk factors. Generalized Estimating Equations were used to calculate p-values, accounting for repeated pregnancies of the same woman.

Results: The age at pregnancy was <20 years (3%), 20–29 (50%), 30–39 (43%), and over 40 (3%). 59% were Caucasian and 34% African-American. Predictors of pregnancy loss are shown in the table. Lupus anticoagulant at the 1stvisit was highly predictive of pregnancy loss (and ever being positive was also associated, although less so).

Table 1. Proportion with Pregnancy Loss, by characteristics of the patients.

Patient Characteristic		Proportion (%) with miscarriage	P-value[2]
	All	46/402 (11%)	
Age	<20	1/13 (8%)	0.38
	20–29	20/202 (10%)	
	30–39	19/172 (11%)	
	40+	6/12 (50%)	
Ethnicity	Caucasian	28/235 (12%)	0.77
	African American	14/135 (10%)	
	Other	4/31 (13%)	
Year of conception	1986–1994	14/115 (12%)	0.32
	1995–1999	13/83 (16%)	
	2000–2004	10/80 (13%)	
	2005+	9/122 (7%)	
RVVT measured in first trimester[1]	Normal	16/187 (9%)	0.0022
	High (>45)	6/15 (40%)	
	No first-trimester measure	24/200 (12%)	
Ever positive for high RVVT	No	26/278 (9%)	0.030
	Yes	20/117 (17%)	
	Unknown	0/7 (0%)	

		Proportion (%) with miscarriage	P-value[2]
Anticardiolipin-IGG measured in first trimester[1]	Normal	11/127 (9%)	0.96
	High	1/11 (9%)	
	No first-trimester measure	34/264 (13%)	
Anticardiolipin ever present	No	16/158 (10%)	0.41
	Yes	30/241 (12%)	
	Unknown	0/3 (0%)	
Moderately active lupus	No	27/281 (10%)	0.012
	Yes	7/27 (26%)	
	Unknown	12/94 (13%)	
Low Complement in first trimester	No	23/227 (10%)	0.37
	Yes	11/78 (14%)	
	Unknown	12/97 (12%)	
Anti-dsDNA in first trimester	No	18/198 (9%)	0.18
	Yes	15/104 (14%)	
	Unknown	13/100 (13%)	
Mean Prednisone dose in first trimester	<10 mg	23/220 (10%)	0.60
	10+	11/88 (13%)	
	Unknown	12/94 (13%)	

[1]Based on the average of the measures during the first trimester or prior to miscarriage if miscarriage occurred in first trimester.
[2]Excludes the unknowns in the calculations.

Conclusion: The strongest predictor of pregnancy loss in SLE is the lupus anticoagulant in the first trimester by dRVVT testing. In contrast to the PROMISSE study, 3 lupus anticoagulant assays were not necessary. In addition, moderate disease activity by the physician global assessment was also predictive of pregnancy loss, but not low complement, anti-dsDNA, or anticardiolipin. These data suggest that treatment of the lupus anticoagulant should be considered, even in the absence of prior history of miscarriage.

Background/Purpose: Cardiac neonatal lupus manifestations mainly include congenital heart block (CHB), endocardial fibroelastosis and dilated cardiomyopathy. We report the preliminary results of the French registry of neonatal lupus.

Methods: This French registry was established in 2000 and includes foetuses or children with neonatal lupus, born to mothers with anti-SSA or/and anti-SSB antibodies. This database has Institutional Review Board approval. Here, we report data on CHB.

Results: 141 cases of CHB born to 124 mothers were included. When the first CHB was diagnosed, 45 mothers (36 %) had an autoimmune disease: 16 had systemic lupus erythematosus (1 with an antiphospholipid syndrome), 15 had Sjögren syndrome, and 14 had another connective tissue disease (CTD). After a median follow-up period of 5.6 years, [0.03–36.5], 85 women (60%) had a diagnosis of autoimmune disease (Sjögren syndrome in 33, systemic lupus erythematosus in 32, and other CTD in 20).

At the time of the CHB diagnosis, 24 (17%) of the pregnant women were treated with corticosteroids, 13 (9.2%) with hydroxychloroquine, and 21

(14.9%) with acetylsalicylic acid. The median term at diagnosis of CHB was 22 WG [16–37 WG]. Twenty-two foetuses (15.6%) were also diagnosed with endocardial fibroelastosis. Among the 141 fetuses with CHB, there were 9 intrauterine deaths, 10 elective terminations of pregnancy, and 122 (86.5%) children born alive at a median term of 37 WG [28–40]. After a median follow-up period of 5.6 years, [0.03–36.5], 11 children (9%) had died. Three died in the neonatal period (2 from complication of CHB and one from prematurity) and 8 later on at a median age of 10 months [2–60]. Of those 8 children, 7 deaths were attributed to a cardiomyopathy associated with CHB, and one to a nosocomial infection.

Ninety five children (77.8 %) had a pacemaker, implanted at a median age of 3.7 months [0.01–14.4]. Fifteen children (12.3%) developed a cardiomyopathy requiring a medical treatment and 9 of those 15 children died from complications of this cardiomyopathy. There was no cardiac transplantation.

After a first pregnancy complicated with a CHB, 57 women had a total of 84 subsequent pregnancies. The following pregnancies were complicated by a CHB in 20.2% of cases (n=17). There were 14 cases of CHB in the 52 pregnancies non-exposed to hydroxychloroquine (26.9%) versus 3 cases in the 32 pregnancies exposed to hydroxychloroquine (9.4%; p=0.052).

Conclusion: 87% of foetuses diagnosed with CHB were alive at birth, and 9% died during a median follow up of 5.6 years. A pacemaker was inserted in 77.8% of the cases. Our data confirm that the use of hydroxychloroquine may protect against recurrence of CHB in a subsequent pregnancy (Izmirly et al, Circulation. 2012 May 24. [Epub ahead of print]*). An international prospective study is ongoing to confirm this point (PATCH study; ClinicalTrials.gov Identifier: NCT01379573).

Abnormal Serologies in the Absence of Clinical Activity Do Not Predict New or Recurrent Lupus Nephritis During Pregnancy. Jill Buyon[1], Aanam Aslam[2], Marta M. Guerra[2], Michael D. Lockshin[2], Carl A. Laskin[3], Ware Branch[4], Lisa R. Sammaritano[2], Michelle Petri[5], Joan T. Merrill[6], Allen D. Sawitzke[7] and Jane E. Salmon[2]. [1]New York University School of Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]University of Toronto and LifeQuest Centre for Reproductive Medicine, Toronto, ON, [4]Univ of Utah, Salt Lake City, UT, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]Oklahoma Medical Research Foundation, Oklahoma City, OK, [7]University of Utah Medical Ctr, Salt Lake City, UT

Background/Purpose: Renal disease is a critical concern of physicians counseling lupus patients regarding pregnancy. In patients without a history of kidney disease, does pregnancy increase the risk of first time involvement? In patients with previous renal disease, does pregnancy raise the likelihood of a renal flare? In both cases, prediction of outcome is challenging in a clinically stable patient with serologic activity (abnormal anti-dsDNA antibodies coupled with low complements). Accordingly, our objective was to assess serologic activity as a predictor of renal flares during pregnancy in patients with less than 1 gram of protein at enrollment in a large, prospective, multicenter, mutiethnic study.

Methods: The PROMISSE Study (**P**redictors of p**R**egnancy **O**utcome: Bio**M**arkers **I**n antiphospholipid antibody **S**yndrome and **S**ystemic **L**upus **E**rythematosus) prospectively evaluated 391 pregnant SLE patients. Exclusion criteria were multi-fetal pregnancy, prednisone >20mg/d, proteinuria >1gm/24hr, and creatinine >1.2mg.dL. A renal flare was defined by proteinuria increase of >500mg with or without hematuria and/or red blood cell casts. Of the 391 patients, 121 (31%) had preexisting renal disease as defined by ACR SLE criteria and/or a renal biopsy in 53 of whom 4% were Class I or II, 62% were Class III or IV, 13% were Class III/IV & V, and 21% were Class V. Overall at enrollment, 17% had only positive anti-dsDNA, 12% had only hypocomplementemia, 20% had both, and 51% were normal for both parameters.

Results: 16 renal flares occurred in 121 patients with previous renal disease. All had proteinuria, 5 (31%) had hematuria, and 1 (6%) had red blood cell casts. There were no differences between biopsy classes for patients with and without renal flares. Of the 29 patients with a history of renal disease and

both anti-dsDNA and hypocomplementemia, 5 (17%) had a renal flare. In 44 patients with either serology alone, 7(16%) had renal flares. In 48 patients with neither serology, 4 (8%) had renal flares. 5 patients were treated with increased prednisone. 3 treated patients and 2 untreated patients developed pre-eclampsia. Other adverse pregnancy outcomes included 3 (19%) fetal/neonatal deaths and 2 (13%) with SGA <5th %ile in the 16 patients with renal flares. In 270 patients with no history of kidney disease, only 3 renal flares occurred. Of the 50 patients with no history of renal disease and both anti-dsDNA and hypocomplementemia, 2 (4%) had new onset proteinuria; one was treated and developed pre-eclampsia. In 150 patients with neither serology, 1 had new onset proteinuria which was treated and had SGA <5th %ile. None of 70 with either serology alone had renal flares.

Conclusion: These data provide evidence that clinical quiescence or stability at the time of conception favors good renal outcomes during pregnancy regardless of serologic activity. Increased proteinuria (not uniformly requiring prednisone) occurred in 13% of patients with previous renal disease and 1% of those without a history of kidney disease. Thus, in counseling women with lupus who are contemplating pregnancy, abnormal serology alone should not lead to advising against pregnancy even in patients with previous renal disease.

Higher Corticosteroid Doses Early in Disease Have A Long-Term Influence On Metabolic Syndrome in Systemic Lupus Erythematosus: Data from an International Inception Cohort. Ben Parker[1], Murray B. Urowitz[2], Dafna D. Gladman Gladman[2], Mark Lunt[3], Ian N. Bruce[4] and Systemic Lupus International Collaborating Clinic (SLICC)[5]. [1]University of Manchester, Manchester, United Kingdom, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [4]Arthritis Research UK Epidemiology Unit and NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom, [5]Toronto

Background/Purpose: The Metabolic Syndrome (MetS) is a clustering of metabolic abnormalities associated with an increased risk of developing diabetes and atherosclerosis, and may add to the increased cardiovascular (CV) risk seen in SLE. We examined the potential impact of markers of inflammation and corticosteroid exposure over time on the prevalence of MetS during the first 2 years of follow-up in an international inception SLE cohort.

Methods: Recently diagnosed (<15 months) SLE patients from 30 centres across 11 countries were enrolled into The Systemic Lupus International Collaborating Clinics Registry for Atherosclerosis (SLICC-RAS) inception cohort from 2000 onwards. Baseline and annual assessments recorded clinical and laboratory data, and therapeutic exposures. MetS was defined according to the 2009 International Diabetes Federation Consensus Statement. A longitudinal analysis of the first 2 years of follow-up was performed using random effects logistic regression which was time-adjusted and took into account multiple visits. The analysis examined the association between MetS and disease activity, disease phenotype and corticosteroid exposure over the first 2 years of follow-up. Variables representing exposure at baseline and follow-up, as well as over-time, were assessed. Significant factors in regression analyses, adjusted for age, sex, ethnicity, and time, were included in the final model.

Results: We recruited 1494 patients with a mean (SD) age at enrolment and disease duration of 35.2 (13.4) years and 24.1 (18.0) weeks respectively. The prevalence of MetS was 239/1494 (16%) at enrolment, 193/1065 (12.6%) at year 1 and 207/894 (13.5%) at year 2. The highest prevalence at enrolment was in patients of Korean (30.1%) and Hispanic (31.3%) ethnicity. In multiple regression analyses current corticosteroid use (odds ratio (95% confidence interval) 1.97 (1.35, 2.87)); daily average prednisolone dose (mg) (1.03 (1.02, 1.05)); peak oral prednisolone dose (mg) (1.03(1.02, 1.04)); immunosuppressant use (1.69 (1.25, 2.28)); SLICC/ACR-DI ≥1 (3.14 (2.01, 4.89)); preceding MetS status (7.94 (5.52, 11.42)); active renal disease (2.76 (1.89, 4.03)) and higher SLEDAI-2K (1.06 (1.03, 1.09)) were associated with MetS. Anti-malarial use was protective (0.45 (0.32, 0.63)). In the final model preceding MetS status, higher peak corticosteroid dose (mg) at enrolment, elevated anti-dsDNA at enrolment, increasing age, and Hispanic ethnicity were all independently associated with MetS over time (Table 1).

Table 1. Random effects model of MetS predictors over time in SLICC-RAS

Variable	Adjusted OR (95% CI)
Preceding MetS (y/n)	4.83 (2.93,7.87)
Peak prednisolone dose at enrolment (mg)	1.02 (1.01,1.03)
Elevated anti-dsDNA at enrolment (y/n)	1.86 (1.19,2.81)
Age (years)	1.03 (1.01,1.05)
Hispanic ethnicity	3.47 (1.76,6.86)

Conclusion: The risk of developing MetS can be determined early in the SLE disease course, with subsets of patients more prone to MetS. Higher doses of steroids in very early disease influence the development of MetS over the subsequent 2 years. Therefore even from disease onset, steroid doses should be individually tailored in order to minimise longer-term CV risk.
