ACR/ARHP 2012 Annual Meeting Overall Needs Assessment/Practice Gaps

The American College of Rheumatology and the Association of Rheumatology Health Professionals are committed to providing comprehensive education to improve the knowledge and performance of physicians, health professionals and scientists. Through evidence-based educational programs, the organization strives to enhance practice performance and improve the quality of care in those with or at risk for arthritis, rheumatic and musculoskeletal diseases. The 2012 annual meeting program has been developed independent of commercial influence. The following groups were involved in the planning process: the ACR Committee on Education; the ACR Annual Meeting Planning Committee; the ARHP Education Committee and the ARHP Annual Meeting Program Planning Committee.

The program is the result of a planning process that identified educational needs to change or enhance the knowledge, competence or performance of rheumatology professionals. The program's content was derived from both needs assessment and practice gap analysis based on professional activities, practice setting, ABIM recertification requirements and physician attributes.

Program Highlights
- Educational tracks to help attendees identify content targeted to them. Tracks include: basic science, business/administration, clinical practice, clinical science, pain management and patient safety.
- Latest science and best-practices presented through peer-reviewed and selected clinical and scientific abstracts, and invited speakers providing clinical, evidence-based and quality focused content;
- Diverse formats of education delivery, including: didactic lectures, debates, and interactive sessions, such as poster tours, Meet the Professors and Workshop sessions;
- A larger forum for discussion of practical management issues such as the Curbside Consults – Ask the Professors session and Medical Aspects lectures;

- Extensive learning opportunities in the basic science of rheumatology, an area of the program developed by a subcommittee of US and internationally prominent basic scientists. Offerings include: Basic Science Symposia, State-of-the-Art Lectures, a series of Immunology Updates for the Clinicians, and a Basic Science pre-meeting course;
- Clinical management sessions, including the Thieves' Market, Curbside Consults – Ask the Professors, The Great Debate and the ACR Knowledge Bowl;
- Specific pediatric rheumatology content integrated throughout the program designed to provide a high-level educational program to pediatric rheumatologists; and relevant updates to adult rheumatologists;
- Formal presentations of new practice guidelines provided to alert the membership and explain, in an open forum, the data supporting the guidelines and propose approaches for implementation;
- Over 35 workshops designed to provide hands-on skills training.

For additional details, refer to the session level learning objectives at www.ACRannualmeeting.org.

Participation Statement

This annual meeting is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather is intended to present the opinions of the authors or presenters, which may be helpful to other healthcare professionals at arriving at their own conclusions and consequent application. Attendees participating in this medical education program do so with full knowledge that they waive any claim they may have against the College for reliance on any information presented during these educational activities. The College does not guarantee, warrant or endorse any commercial products or services.

The ACR's CME purpose is to provide comprehensive education to improve the knowledge and performance of physicians, scientists and other health professionals. The ACR will offer evidence-based educational activities designed to enhance practice performance and improve the quality of care in those with or at risk for arthritis and rheumatic and musculoskeletal diseases.

Global Learning Objectives
At the conclusion of the 2012 ACR/ARHP annual meeting, participants should be able to:
- identify recent developments in the diagnosis and management of patients with rheumatic diseases
- outline new technologies for the treatment of rheumatologic problems
- describe potential challenges in the delivery of care to patients with rheumatic diseases and to specify possible solutions
- utilize new research data to improve the quality of care of patients with rheumatic diseases
- summarize recent rheumatology research findings

Certificates of CME Credit or Participation

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of 49.75 *AMA PRA Category 1 credits™.* Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)™*, must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers, and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit ™* to *EACCME* credit should contact the *UEMS*.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)™*. For non-CME sessions, attendees may also request a certificate of participation.

Meeting Evaluations, CME Credit Certificates of Participation
Computers are available for you to complete your CME/Certificate of Participation and session evaluations online during the meeting at the CME/Internet Center located in the Concourse, near the entrance to the exhibit hall (Hall A).

International physicians, requiring a Certificate of Attendance, can find one enclosed in your meeting bag. If your country recognizes *AMA PRA Category 1 Credit(s)™* in accordance with *AMA PRA* requirements, please complete the session evaluations and CME application online using ***My Annual Meeting***.

Your evaluation of the meeting is very important. The ACR/ARHP annual meeting planning committees use feedback from attendees to assist in the development of future educational activities; therefore, we encourage you to complete your session evaluations and CME/Certificate application.

Conflict of Interest/Disclosure Statements
As an educational provider accredited by the Accreditation Council for Continuing Medical Education (ACCME), the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all speakers and moderators participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

None: Nothing to disclose
1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Speakers, moderators and abstract authors submitted their disclosure online prior to publication. Disclosures for invited speakers are listed in the indices by presenters' last name.

Abstract author disclosures are published online and in a supplement to the October issue of *Arthritis & Rheumatism*. Disclosures for the late-breaking abstracts are published online and in the December issue of *Arthritis & Rheumatism*. Any individual who refuses to disclose relevant financial relationships will be disqualified from being a planning committee member, a presenter, an author of a CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Disclosure Policy
It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias.

To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that everyone in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content.

This annual meeting is sponsored by the American College of Rheumatology for educational purposes only. The material presented is not intended to represent the only or the best methods appropriate for the medical conditions being discussed, but rather is intended to present the opinions of the authors or presenters, which may be helpful to other healthcare professionals at arriving at their own conclusions and consequent application. Attendees participating in this medical education program do so with full knowledge that they waive any claim they may have against the College for reliance on any information presented during these educational activities. The College does not guarantee, warrant or endorse any commercial products or services.

Copyright Materials Policy
The annual meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the ACR. The information and materials displayed and presented during this meeting are the property of the ACR and the presenter and cannot be photographed, copied, photocopied, transformed to electronic format, reproduced, or distributed without written permission of the ACR and the presenter. Any use of the program content for commercial purposes, which includes, but is not limited to oral presentations, audiovisual materials used by speakers, and program handouts without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

The names, insignias, logos and acronyms of the ACR, the ARHP and the RRF are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the ACR.

Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special supplement of *Arthritis & Rheumatism*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website.

However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until 4:30 PM Eastern Time on Saturday, November 10, 2012. Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy.

Evaluation of Synovial Inflammation Assessed by Macroscopic and Histological Criteria in Patients with Knee Osteoarthritis. Montserrat Romera-Baures Sr.[1], Ramon Valls-Garcia Sr.[2], Antonio Rozadilla Sr.[3], Marta Terricabras Sr.[4] and Joan Miquel Nolla Sr.[5]. [1]Hospital Universitari Bellvitge, Barcelona, Spain, [2]Hospital de Palamos, Girona, Palamos (Girona), Spain, [3]Hospital Universitari de Bellvitge, Barcelona, Spain, [4]Hospital Universitari de Bellvitge., Barcelona, Spain, [5]Hospital Universitario de Bellvitge, Barcelona, Spain

Background/Purpose: Although osteoarthritis (OA) is commonly described as a non-inflammatory joint disease, synovial inflammation is increasingly recognized as contributing to the symptoms and progression of OA. The aim of this study is the evaluation of synovial inflammation degree by macroscopic and histological findings in patients with knee OA.

Methods: Samples of synovial tissue were obtained from 22 patients with knee OA. The arthroscopy was performed under local anesthesia with sedation. During arthroscopy the joint is distended by infusion of sterile saline with a motorized suction shaver. Each patient underwent a systematic examination of the synovium from the suprapatellar poach, patellofemoral joint, lateral recesses and medial and lateral compartments of femoro-tibial joint. The arthroscopic findings were reflected in a data collection sheet. Biopsies of synovium were obtained from directly visualized areas with biopsy forceps. For macroscopic assessment of the synovial membrane we used a macroscopic semiquantitative scoring system based on the existence of vascularization and proliferation. Vascularization was assessed by the absence or presence of hyperemia and increased vascularity (score of 0 or 1). Synovial proliferation scored 0, 1 or 2 depending on the presence or absence of granularity and villous hypertrophy. The total score of the two components ranged from 0–4. The histological samples were processed with hematoxylin-eosin for histological semiquantitative scoring of synovitis. This scale was based on enlargement of the lining cell layer (0–3 points), density of the residents cells (0–3) and inflamatory infiltrate (0–3). According to the score the findings were classified in the absence of synovitis (0–1), low-grade synovitis (2–4) or high-grade synovitis (5–9 points).

Results: Samples were obtained from 20 of the 22 arthroscopies performed. Macroscopically, we observed pluricompartimental synovitis in 7 patients and localized in 6. In one patient, synovitis adjacent to chondral injury of the femoral condyle was found. Microcrystals were found in the synovium of 4 patients not previously diagnosed of microcrystalline arthropathy. Regarding the total score of macroscopic semiquantitative analysis, 10 patients (50%) scored between 2 and 4. No patient had scores of 0. Histological assessment was performed in 17 of the 20 patients, excluding those cases with presence of microcrystals or insufficient material. The microscopic semiquantitative score showed low-grade synovitis in 7 patients (41%) and high grade in 9 (53%). Only in one of the samples histological synovitis was not evidenced.

Conclusion: The frequency of synovitis in patients with osteoarthritis and synovial effusion assessed by macroscopic or histological criteria is high. Arthroscopic assessment of synovitis shows a good correlation between macroscopic dimension and microscopic histological analysis.

2

Microrna-558 Regulates the Expression of Cyclooxygenase-2 and IL-1beta Responses in Human Articular Chondrocytes. Su Jin Park, Eun-Jeong Cheon and Hyun Ah Kim. Hallym University Sacred Heart Hospital, Kyunggi, South Korea

Background/Purpose: Osteoarthritis (OA) is a chronic degenerative joint disease in which multiple factors contribute to cartilage degradation. It is widely accepted that excess production of proinflammatory cytokine, interlukin-1β (IL-1β), is associated with in the initiation and progression of cartilage destruction. In OA cartilage, IL-1β-stimulated COX-2 expresssion strongly contributes to the inflammation and cartilage destruction via upregulating PGE2 production. The objective of this study was to address whether miR-558, one of IL-1β-responsive microRNAs, can control IL-1β-mediated induction of COX-2 and catabolic effects in human articular chondrocytes.

Methods: Total RNA was extracted from the cartilage tissues of normal and OA donors or cultured human articular chondrocytes. The expression of miR-558 was quantified by TaqMan assay. To investigate the repressive effect of miR-558 on COX-2 expression, human chondrocytes and chondrogenic SW1353 cells were transfected with mature miR-558 or their antisense inhibitor (anti-miR-558). The expression of COX-2 protein was determined by western blot anaysis and the involvement of miR-558 on IL-1β-induced catabolic effects was examined by western blot anaysis and ELISA. Direct interaction between miR-558 and the putative site in the 3'-UTR of COX-2 mRNA was validated by luciferase reporter assay.

Results: Normal human articular cartilages expressed miR-558, and this expression was significantly suppressed in OA cartilages. Stimulation with IL-1β caused a significant reduction of miR-558 expression in normal and OA chondrocytes. IL-1β-induced activation of MAPK and NF-κB decreased miR-558 expression and induced COX-2 expression in chondrocytes. The overexpression of miR-558 directly suppressed the luciferase activity of a reporter construct containing the 3'-UTR of human COX-2 mRNA and significantly inhibited IL-1β-induced upregulation of COX-2, while treatment with anti-miR-558 enhanced IL-1β-induced COX-2 expression and reporter activity in chondrocytes. Interestingly, IL-1β-induced activation of NF-κB and expression of MMP-1 and MMP-13 were significantly inhibited by miR-558 overexpression.

Conclusion: These findings demonstrated that cartilage homeostasis is modulated by an elaborate network of functional microRNAs such as miR-558 that directly targets COX-2 and regulates IL-1β-stimulated catabolic effects in human chondrocytes.

3

Mesenchymal Stem Cells Differentiate Into Osteoblasts in Response to Inflammation. Koshiro Sonomoto, Kunihiro Yamaoka, Koichi Oshita, Shunsuke Fukuyo, Xiangmei Zhang, Kazuhisa Nakano, Yosuke Okada and Yoshiya Tanaka. University of Occupational and Environmental Health, Kitakyushu, Japan

Background/Purpose: Bone destruction due to enhanced osteoclast differentiation is a common observation in rheumatoid arthritis. It is well known that inflammatory cytokines cause osteoclatogenesis, however, the same cytokines also cause chronic enthesitis and excess abnormal bone formation as seen in ankylosing spondylitis. To elucidate the mechanism of this discrepancy, we herein investigated the effect of inflammation on osteoblastic differentiation property of mesenchymal stem cells (MSCs).

Methods: hMSCs were cultured in commercial osteogenic medium in the presence of inflammatory cytokines (TNF-α, IL-1β, IL-4, IL-6, IL-10 or IL-17) *in vitro*. Osteoblast differentiation was assessed by alkaline phosphates (ALP) staining and expression of osteoblastic markers and mineralization was evaluated by alizarin-red S staining.

Results: Inflammatory cytokines (TNF-α, IL-1β and IL-6) enhanced runt-related gene 2 (RUNX2) expression, ALP staining and mineralization. On the contrary, IL-4, IL-10 and IL-17 had no effect or slightly inhibited these markers. Among these cytokines, IL-1β most efficiently enhanced and promoted osteoblast differentiation, which is proved by expression of bone sialoprotein and osteocalcin. TNF-α, IL-1β and IL-6 did not alter the canonical wingless-type MMTV integration site (Wnt) signaling pathway but increase the expression of Wnt5a and its receptor, receptor tyrosine kinase-like orphan receptor 2 (Ror2), which are involved in non-canonical Wnt pathway, also known to possess important roles in osteoclastogenesis. siRNA of the Wnt5a or Ror2 completely inhibit enhanced osteoblast differentiation.

Conclusion: Inflammatory cytokines, which are well known to cause bone resorption by up-regulating osteoclast differentiation, also induced osteoblastogenesis of the hMSCs. This phenomenon indicates the involvement of MSCs in bone homeostasis under the circumstance of inflammation. Our data also indicates the quantitative or qualitative abnormality of MSCs can cause inadequate balance of bone resorption and bone formation.

4

Pro-Inflammatory Effect of Extracellular RNA On Synovial Fibroblasts From Patients with Rheumatoid Arthritis. Birgit Zimmermann[1], Silvia Fischer[2], Markus Rickert[3], Stefan Rehart[4], Angela Lehr[4], Ulf Müller-Ladner[1], Klaus T. Preissner[2] and Elena Neumann[1]. [1]Justus-Liebig-University of Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Justus-Liebig-University of Giessen, Medical School, Giessen, Germany, [3]University Hospital Giessen and Marburg, Giessen, Germany, [4]Markus-Hospital, Frankfurt, Germany

Background/Purpose: Extracellular RNA (exRNA) is present in the serum of patients suffering of different kinds of cancer. exRNA influences physiological processes like blood coagulation and endothelial cell permeability. In this study, we analyzed the presence of exRNA as well as RNase in joints and the effects of nucleic acids and nucleases on synovial fibroblasts (SF) of patients with rheumatoid arthritis (RA). RA is a chronic inflammatory disease, characterized by the destruction of cartilage as well as bone. RASF are activated cells acting as key players in cartilage destruction.

Methods: exRNA in synovium of RA (n=26), osteoarthritis (OA: n=26) and psoriatic arthritis (PsA: n=3) patients was stained in tissue sections with DAPI to locate DNA and SYTO® RNA Select™ Green Fluorescent Stain to locate RNA. RNase 1 was analysed in synovium (RA n=17; OA n=7) immunohistocally. RNase activity was measured in synovial fluid (RA n=14; OA n=5; PsA n=10) and supernatants of SF (RASF n=3; OASF n=3; PsA-SF n=4) and healthy donors (NSF) n=3) using the Quant-iT™ RNA Assay Kit. Release of exRNA by cultured SF (RASF n=3; OASF n=3; PsA-SF n=4; NSF n=3) was measured photometrically. The secretion of IL-6 was analyzed by ELISA after treating RASF (n=3) with 10 μg or 25 μg isolated autologous RNA or DNA for 15 h. Alternatively RASF (n=3) were pre-incubated for 24 h, then 5 U/ml RNase or DNase was added. In the SCID mouse model, the effect of RNase or DNase i.v. was analyzed towards migration and cartilage invasion (RNase n=10; DNase n=9; saline control n=9).

Results: Synovium of all patient showed RNA and DNA signals co-localized within the nuclei. In RA, exRNA was detectable in the lining layer. exRNA in OA lining was present only in single defined regions. PSA showed no exRNA in lining. RNase 1 was increased in lining. RNase activity (units/mg protein) in synovial fluid was significantly increased in RA (31.6±4.5 p=0.023) and OA (27.0±4.5 p=0.033) compared to PsA (18.2±2.3). RNase release (units/mg protein) by cultured cells was comparable (RASF 1.13±0.24; OASF 1.16±0.07; PsA-SF 1.05±0.18; NSF 1.01±0.15). exRNA release (ng/μg protein) was stronger in RASF (RASF 0.22±0.06; OASF 0.17±0.09; PsA-SF 0.17±0.06; NSF 0.11±0.07). RASF secretion of IL-6 was increased by RNA (10 μg 135±40%; 25 μg 118±15%) or DNA (10 μg 156±35%; 25 μg 220±59%). Only RNase reduced IL-6 release (77±14% of control, p=0.136). *In vivo*, RASF invasion was reduced at the coimplantation site by both nucleases (control 1.92±0.24; RNase 1.22±0.21 p=0.037; DNase 0.80±0.19 p=0.002). Fibroblast migration was only reduced with DNase (control 1.51±0.28; RNase 1.28±0.39 p=0.625; DNase 0.84±0.18 p=0.042).

Conclusion: Increased exRNA in the lining and the RNase activity in the synovial tissue and fluid of OA and especially in RA patients could represent a new unbalanced regulatory system in chronic inflammation including RA. The increased exRNA but unchanged RNase release by RASF *in vitro* indicates that RASF contribute to secretion of pro-inflammatory exRNA. exRNA mediates an increased cytokine release by RASF and cartilage invasion which could be inhibited by RNase application. The results illustrate the pro-inflammatory and destructive effect of exRNA in RA.

Adalimumab Inhibits TNF-Enhanced Human Osteoclast Development More Effectively Than Other Biologic Agents Under in Vitro Conditions of Chronic TNF Exposure. Bohdan P. Harvey[1] and Zehra Kaymakcalan[2]. [1]Abbott Laboratories, Worcester, MA, [2]Abbott, Worcester, MA

Background/Purpose: TNF-alpha (TNFa) has been shown to contribute to osteoclastogenesis independently and in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast development. Both TNFa and RANKL have been concomitantly detected in the synovial fluid of RA patients. However, the role of TNFa in promoting human osteoclast differ-entiation and activity in the presence of RANKL is poorly understood. In this study, we sought to determine the impact of TNFa on RANKL-induced human osteoclast development and function under chronic conditions and to assess the effectiveness of various biologic agents in blocking the effect of TNF in this system.

Methods: Primary human osteoclast precursors (OCP) were exposed to various combinations of M-CSF, RANKL and TNFa (100 ng/mL) +/− increasing concentrations of adalimumab, etanercept or abatacept for up to 7 days. Prior to adding to the cells, the biologics were pre-incubated with the cytokine cocktail for 30 min. Osteoclast differentiation was determined by the presence of large multinucleated cells positive for tartrate-resistant acid phosphatase (TRAP) and by TRAP5b activity. Resorptive activity was assessed by measuring the release of either the degradation products of plate-bound Europium-labeled collagen (Eu-col) or the cross-linked C-telopeptide of type I collagen (CTX-I) from human bone chips.

Results: In the absence of biologics, the addition of TNFa to OCP cultures with exogenous RANKL promoted earlier differentiation (increased TRAcP5b activity by day 4) and enhanced osteoclast activity (increased CTX-I levels by day 7) compared to RANKL alone. Based on early time course assessments using Eu-col, TNFa enhanced the kinetics of osteoclast maturation by 13 hrs and maintained 3-fold higher levels of osteoclast activity for up to 122 hrs. Among the biologics, adalimumab restored the rate of osteoclast differentiation and activity to levels comparable to RANKL alone at concentrations 10-fold lower than etanercept (0.74 μg/mL and 20 μg/mL, respectively). Moreover, etanercept was unable to maintain its inhibitory effect even at the highest dose tested, while abatacept was ineffective in preventing TNF-mediated augmentation of osteoclast development at all concentrations tested. Interestingly, the levels of many TNFa-responsive pro-osteoclastogenic chemokines were similarly reduced in the presence of either adalimumab or etanercept, suggesting that both agents were able to neutralize TNF during early osteoclast development.

Conclusion: These findings demonstrate that TNFa can significantly enhance the kinetics of RANKL-induced osteoclast differentiation and activity. Moreover, under chronic in vitro exposure of OCP to TNF, adalimumab is more effective than etanercept (or abatacept) in mitigating the pro-osteoclastogenic effects of TNF. Overall, our results demonstrate the central role of TNF in RA joint destruction and the sustained potency of adalimumab as compared to other biologics in preventing bone erosion due to chronic TNF exposure.

The Effect of Hydrogen Sulfide Donors On Inflammatory Mediators in Human Articular Osteoarthritic Chondrocytes. Elena F. Burguera[1], Angela Vela Anero[2], Rosa Meijide Failde[2] and Francisco J. Blanco. [1]Rheumatology Service, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Department of Medicine, University of A Coruña, A Coruña, Spain

Background/Purpose: Hydrogen sulfide (H_2S) has recently been proposed as an endogenous mediator of inflammation in several pathology models. The aim of this work was to study the possible role of H_2S as an anti-inflammatory and anti-oxidant agent in human articular chondrocytes (CHs) from osteoarthritic (OA) tissue.

Methods: We analyzed the effects of different concentrations of a fast (NaHS) or a slow (GYY4137) release H_2S donor on three key aspects of the inflammatory process in OA, namely: 1) Nitric oxide (NO) production and inducible NO synthase (iNOS) levels; 2) Production of reactive oxygen species (ROS) and antioxidant enzymes superoxide dismutase 2 (SOD2) and catalase (CAT); and 3) The production of prostaglandin E-2 (PGE-2) and cyclooxygenase (COX)-1, -2 and PGE synthase 1 (mPGES-1). NO production was quantified through the Griess reaction. Protein levels were visualized through immunocytochemistry and quantified with appropriate software; mRNA expression levels were detected with qRT-PCR. ROS levels were quantified with a fluorescence microscope after dihydrorhodamine treatment. PGE-2 levels were quantified with a specific EIA. For all studies cells were cultured in medium with 0.5% FBS and stimulated with 5 ng/ml of IL-1b and the different concentrations of NaHS and GYY4137 (ranging from 50 mM to 1000 mM) for 48h. ANOVA tests were performed and differences were considered significant when p<0.05.

Results: The concentrations of H_2S-donors used did not significantly affect cell viability (p>0.05). Concentrations higher than 100 μM of the sulfur donors were effective in reducing NO production in IL-1β stimulated OA CHs in a dose-dependent manner, probably by ameliorating the induction

of iNOS synthesis, since both iNOS mRNA and protein levels were also reduced. ROS levels were reduced when 50 and 200 μM GYY4137 were used, but not by 1000 μM, and this was accompanied, at 200 μM GYY4137, by a reduction in the expression of SOD2 and CAT. NaHS was not effective in reducing ROS directly, and no correlation was found with SOD2 and CAT expression. PGE-2 values were reduced by all concentrations of GYY4137 and NaSH (except 1000 μM) and, in the case of GYY4137, both COX-2 and mPGES-1 were also downregulated at the higher concentrations ($>$100 μM) whereas COX-1 expression was not affected. Collectively, GYY4137 was found to be more effective than NaHS to ameliorate the IL-1β-induced OA-like markers of inflammation and oxidative damage, particularly at a 200 μM.

Conclusion: Results obtained so far suggest an anti-inflammatory and antioxidant role of certain H_2S donors which might be of interest in the alleviation of OA-related inflammation processes and that should be further explored as a therapeutic approach.

Lamin A Deregulation in Human Mesenchymal Stem Cells Promotes an Impairment in Their Chondrogenic Potential and Imbalance in Their Response to Oxidative Stress. Jesus Mateos[1], Alexandre De La Fuente[2] Ivan A. Lesende-Rodriguez[2], Maria Carmen Arufe[2] and Francisco J. Blanco[1]. [1]Rheumatology Division, Proteomics Unit-ProteoRed/ISCIII, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Department of Medicine, Area of Anatomy and Human Embryology, University of A Coruña-INIBIC, A Coruña, Spain

Background/Purpose: Previous work by our group and others indicated that an accumulation of lamin A (LMNA) was associated with the osteoarthritis (OA) chondrocyte phenotype. Mutations of this protein are linked to laminopathies and specifically to Hutchinson-Guilford Progeria Syndrome (HGPS), an accelerated aging disease. Some authors have proposed that a deregulation of LMNA affects the differentiation potential of stem cells. In the present study, we examined the effect of the over-expression of LMNA, or its mutant form progerin (PG), on the mesoderm differentiation potential of MSCs.

Methods: Mesenchymal stem cells (MSCs) from human umbilical cord (UC) stroma have previously been isolated, expanded and differentiated towards mesoderm cell lineages. For efficient gene delivery of wt LMNA, PG and GFP (Green Fluorescence Protein), we used a lentiviral expression system. GFP-transduced MSCs were used as control for the differentiation study since they present a differentiation capacity similar to that of untransduced MSCs. Osteogenic potential was studied by with alizarin red staining to assess calcium deposits as well as Real-Time PCR of ALP, OC and Runx2 to assess early and late osteogenic differentiation. Adipogenic potential was studied with Oil Red staining for lipid droplets and Real-Time PCR of LPL, FABP and ADIPOQ, for early and late adipogenic differentiation. Chondrogenesis and hypertrophy were studied using immunohistochemestry and Real-Time PCR of Aggrecan, MMP-13, Type II Collagen, Type I Collagen and Type I Collagen.

Results: We found that over-expression of LMNA or PG by lentiviral gene delivery leads to defects in differentiation potential. PG-transduced MSCs present defects in adipogenic and osteogenic potential, The chondrogenic potential is defective in PG-MSCs, which present a decrease in COL2 and Aggrecan as revealed by both immunohistochemystry and Real-Time PCR. LMNA and PG-transduced MSCs have an increase in hypertrophy markers (MMP-13 and Type X Collagen) during chondrogenic differentiation, as well as a decrease in manganese superoxide dismutase (MnSODM) and an increase of mitochondrial MnSODM-dependent reactive oxygen species (ROS). ROS synthesis was partially (51%) and totally reverted by N-Acetyl Cystein, ROS scavenger, (NAC) at 20 and 40 μg/mL respectively for 1 hour in culture. In addition, defects in chondrogenesis detected by immunohistochemestry and Real Time-PCR are partially reversed by incubations with NAC at 40 μg/mL for 1 hour.

Conclusion: Our results suggest that OA process could be enhanced by defects in stem cell differentiation, partially due to imbalance in oxidative stress.

Supercharged Sox9 Protein Induces Chondrogenic Differentiation of Bone Marrow-Derived Mesenchymal Stem Cells. Yuan K. Chou[1], Shili Wu[1], Camilo Avendano[2], Tom Caldwell[2], Brian Maniaci[2], Kentaro Yomogida[1], Yong Zhu[2] and Cong-Qiu Chu[3]. [1]Oregon Health & Science University, Portland, OR, [2]VivoScript, Inc, Costa Mesa, CA, [3]Oregon Health & Science Univ and Portland VA Medical Center, Portland, OR

Background/Purpose: Osteoarthritis (OA) is characterized by progressive breakdown of articular cartilage. Regeneration of cartilage has been an attractive approach to OA therapy. Sox9 is a transcription factor belonging to the Sox (Sry-type HMG box) gene family and has been identified as a "master regulator" of the chondrocyte phenotype. We investigated whether a super positively charged cell penetrating Sox9 fusion protein can induce bone marrow-derived mesenchymal stem cells (MSC) to differentiate into chondrocytes for potential use to promote cartilage regeneration *in situ*.

Methods: A bioactive supercharged Sox9 (scSox9) was generated by fusing Sox9 with a super positively charged green fluorescence protein (GFP) using molecular engineering technology. Human bone marrow-derived MSC at passage 5 were cultured with scSox9 in monolayer or in cell aggregate for differentiation into chondrocytes. Chondrogenesis was verified by toluidine blue staining for aggrecan and by RT-PCR and immunohistochemistry for collagen type I, II and X production.

Results: scSox9 could readily enter HHF cells, a human skin fibroblasts-derived cell line and human bone marrow- derived MSC. After one hour incubation with scSox9, both HHF cells and MSC showed intracellular expression of green fluorescence indicating entry of scSox9 into these cells. scSox9 was able to induce MSC proliferation and differentiation with no requirement of additional growth factors. The number of scSox9 treated MSC was increased two folds after 72 hours in culture compared with scGFP treated MSC. As early as 48 hours, scSox9 treated MSC started changing morphology to chondrocyte-like cells and the changed morphology maintained for 21 days in culture when observation was ended. These morphologically changed cells stained positive for toluidine blue, which suggests aggrecan production. Furthermore, scSox9 induced collagen type II expression and down- regulated collagen type I and type X production. Most importantly, one time addition of scSox9 at the initiation of chondrogenesis was sufficient to induce MSC chondrogenic differentiation and maintain the chondrocyte phenotype.

Conclusion: These *in vitro* data demonstrated that scSox9 is able to enter bone marrow-derived MSC and induce chondrogenesis and maintain chondrocyte phenotype. Further investigation is warranted for the potential therapeutic use in cartilage repair by promoting regeneration of hyaline cartilage.

Function of the Chondrocyte PI-3 Kinase-Akt Signaling Pathway Is Stimulus Dependent. Richard F. Loeser and Meredith Greene. Wake Forest School of Medicine, Winston-Salem, NC

Background/Purpose: Previous studies have shown that activation of the chondrocyte PI-3K-Akt signaling pathway by IGF-1 promotes chondrocyte survival and matrix synthesis. However, other studies have shown activation of this pathway by cytokines such IL-1 plus oncostatin M (OSM) can promote chondrocyte MMP production. Based on the latter studies, some investigators have proposed targeting this pathway for treatment of OA. The purpose of the present study was to clarify the function of this important signaling pathway in chondrocytes by directly comparing the effects of anabolic and catabolic stimuli.

Methods: Human articular chondrocytes were isolated from normal adult ankle (tali) and knee articular cartilage and from knee cartilage removed at the time of joint replacement for OA (n=3 donors each for normal and OA). Primary confluent cultures were made serum-free and stimulated with IGF-1 (100ng/ml), IL-1β (0.02ng/ml), OSM (10ng/ml) or IL-1β+OSM (0.02ng/ml+10ng/ml). The doses of IL-1 and OSM were based on previous studies demonstrating increased MMP production stimulated by the combination of the two. Stimulus independent activation of Akt was achieved by lentiviral infection of constitutively active (CA) Akt. Activation of signaling proteins was measured at 30 minutes by immunoblotting of cell lysates and MMP-13 production was measured in conditioned media after overnight stimulation.

Immunoblots were quantified by densitometry and normalized to total Akt and MMP-2 respectively. Proteoglycan (PG) synthesis was measured by sulfate incorporation and collagen production by ELISA and results normalized to cell numbers.

Results: In normal chondrocytes (ankle or knee), IGF-1 stimulated strong Akt phosphorylation while IL-1β did not stimulate pAkt and the others were weak (OSM 23% and IL-1β+OSM 24% of IGF-1 stimulation). The pattern was similar in OA cells except IGF stimulated pAkt was less than in normal. Production of MMP-13 was stimulated in normal cells by OSM and IL-1β+OSM and in OA cells by IL-1β+OSM but not by either cytokine alone. Despite strong pAkt, IGF-1 did not stimulate MMP-13 production. Inhibition of PI-3 kinase by LY294002 (5μM) inhibited by 88% the OA cell production of MMP-13 by IL-1β+OSM and completely inhibited normal chondrocyte production of MMP-13. Overexpression of CA-Akt markedly stimulated PG and collagen synthesis but did not increase MMP-13 production. Inhibition of Akt1 and Akt2 using Akt inhibitor XIII (1μM) did not affect ILβ+OSM stimulated MMP-13 production.

Conclusion: The function of the PI-3 kinase-Akt pathway in articular chondrocytes is stimulus dependent. IGF-1 stimulation of this pathway is pro-anabolic and activity of Akt alone is sufficient for this effect. IL-1β+OSM weakly activate Akt phosphorylation and Akt activation alone is not sufficient to induce MMP production. The inhibition of IL-1β+OSM induced MMP-13 by the PI-3K inhibitor suggests that PI3K acts in concert with additional pathways, such as the MAP kinases, to stimulate MMP-13 production. Inhibition of these pathways, rather than PI-3K-Akt would be a better therapeutic target given the pro-anabolic and survival functions of Akt.

Fibronectin Fragment Induces Procatabolic Effects Through TLR-2 Signaling Pathway in Human Articular Chondrocytes. Su Jin Park[1], Eun-Jeong Cheon[1] and Hyun Ah Kim[2]. [1]Hallym University Sacred Heart Hospital, Kyunggi, South Korea, [2]Hallym University Sacred Heart Hospital, Kyunggi, South Korea

Background/Purpose: Fibronectin fragments (FN-fs) are increased in the synovial fluid of osteoarthritis patients and have a potent chondrolytic effect. However, little is known about the cellular receptors and signaling mechanisms that are mediated by FN-fs. Here we investigated whether the 29-kDa amino-terminal fibronectin fragment (29-kDa FN-f) regulates cartilage metabolism through Toll-like receptor-2 (TLR-2) signaling pathway in human articular chondrocytes.

Methods: Human articular chondrocytes were enzymatically isolated from articular cartilage and cultured in monolayer. In order to investigate whether 29-kDa FN-f induces MMPs production through TLR-2, human chondrocytes were transfected with TLR-2 expression plasmid or small interfering RNAs (siRNAs) targeting TLR-2 and Myeloid differentiation factor 88 (MyD88). In 29-kDa FN-f-stimulated chondrocytes, the relative levels of mRNA for matrix metalloproteinase 1 (MMP-1), MMP-3, and MMP-13 were analyzed by real-time quantitative reverse transcription-polymerase chain reaction. Protein expression levels of MMP-1 and MMP-3 and the regulatory effect of TLR-2 on 29-kDa FN-f-mediated signaling pathways were assessed by immunoblotting. MMP-13 production was measured by ELISA assay. Association of 29-kDa FN-f with human chondrocytes through TLR-2 was evaluated by fluorescence microscopic analysis.

Results: The expression levels of TLR-2, 3, 4, and 5 in TLR family were remarkably elevated in OA cartilage compared to normal cartilage. But, TLR-1 expression of normal and OA cartilages was not significantly different. When human chondrocytes were stimulated with various fibronectin fragments, TLR-2 expression was highly increased by 29-kDa FN-f stimulation. Knockdown of TLR-2 expression using siTLR-2 significantly suppressed 29-kDa FN-f-induced MMPs production in human normal and OA chondrocytes. Conversely, overexpression of TLR-2 enhanced 29-kDa FN-f-stimulated MMPs production. Moreover, we found that knockdown of MyD88, a downstream adaptor in TLR-2 signaling pathways, led to marked reduction of MMPs production induced by 29-kDa FN-f. In addition, 29-kDa FN-f-mediated phosphorylation of IkBa and p38 was apparently inhibited by transfection of siTLR-2. However siTLR-2 treatment did not affect 29-kDa FN-f-induced activation of JNK and ERK. Notably, fluorescence microscopic analysis showed direct interaction between TLR-2 and 29-kDa FN-f in human chondrocytes.

Conclusion: MyD88-dependent TLR-2 signaling pathway plays an important role in 29-kDa FN-f-stimulated procatabolic responses of human chondrocytes. Modulation of TLR-2-mediated signaling may be as a potential therapeutic strategy for the prevention of cartilage degradation in OA.

Cartilage Tissue Engineering Using Collagen Scaffolds and Human Mesenchymal Stem Cells. Clara Sanjurjo-Rodriguez[1], Adela Helvia Martinez-Sanchez[1], Silvia Diaz-Prado[2], Emma Muiños-Lopez[1], Isaac M. Fuentes-Boquete[2], Francisco J. De Toro[2] and Francisco J. Blanco[1]. [1]Osteo-articular and Aging Res. Lab. CIBER-BBN. Rheumatology Div. INIBIC-Complejo Hosp. Univ. A Coruña, A Coruña, Spain, [2]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC- University of A Coruña, A Coruña, Spain

Background/Purpose: The aim of this study was to obtain cartilage-like constructs by chondrogenic differentiation of human bone marrow mesenchymal stem cells (hBM-MSCs) grown on different collagen scaffolds.

Methods: hBM-MSCs were characterized by flow cytometry using MSC markers and analysed for their multipotential differentiation capacity. These cells were cultured at a density of 200,000 cells/cm^2 on different collagen scaffolds: Col I + Col II (C1C2); Col I + Col II + Heparan Sulfate (C1C2HS); Col I + Col II + Chondroitinsulfate (C1C2CHS); Col I + Heparin (C1OLH3). hBM-MSCs were cultured during 30 days in a chondrogenic differentiation medium supplemented with TGFβ-3. We have analysed cell growth and cell morphology by histochemical analysis and Transmission (TEM) and Scanning (SEM) Electron Microscope. Chondrogenic differentiation was confirmed by histochemical and immunohistochemical analysis. Moreover, we have tested relative gene expression of characteristic chondrocyte genes such us SOX9 and COLII. Finally, collagen concentration in the cultures supernatant was measured using a collagen Assay.

Results: hBM-MSCs were able to grow in the surface and inside of all the scaffolds and they were able to synthesize extracellular matrix (ECM) around the cells. Cellular proliferation was observed in all the scaffolds by PCNA (*Proliferating Cell Nuclear Antigen*) immunostaining, obtaining the highest values in C1C2 and in C1C2HS scaffolds. The percentage of cells, regarding the area of the analysed scaffold, was higher than 50% in C1C2 and C1OLH3 and higher than 75% in C1C2HS and C1C2CHS scaffolds. By means of immunostainings we detected Col II in the ECM of C1C2HS constructs and in the cytoplasm of the cells in C1C2 constructs. Collagen was detected in cultures supernatants of all the scaffolds obtaining the highest collagen release between 11–21 days of differentiation. These results indicated the beginning of the chondrogenic differentiation. TEM showed that cells had large number of lipid vesicles, mitochondrias and high secretory activity. SEM allowed us to study the adherence of cells, morphology and the ECM. We have detected the expression of two markers of early chondrogenesis, SOX9 and COLII, in all the constructs at 30 days.
Figure. Image obtained from the different constructs by electron microscopy analysis and immunohistochemistry. Vertically in columns going from top to bottom are shown the different types of scaffolds and ordered in rows from left to right are shown the different analysis.

Conclusion: Our data showed that the best results were obtained with C1C2HS constructs. hBM-MSCs cultured in chondrogenic medium over these scaffolds were able to differentiate better into chondrocyte-like cells and

to synthesize more ECM than over the other scaffolds. Resulting cartilage-like constructs may be suitable candidates for Tissue Engineering. *Acknowledgements*: Opocrin S.P.A.; CIBER-BBN CB0–01-0040; SAI-UDC.

Articular Cartilage Expresses the IL-15 Receptor Alpha-Chain and Responds to IL-15 with Increased Matrix Metalloproteinase Release.
Anjali Nair[1], Michael Huvard[2], Madeline Rollins[3], Arnavaz Hakimiyan[1], Lev Rappaport[1], Arkady Margulis[1], Susanna Chubinskaya[1] and Carla R. Scanzello[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]Northwestern University, Chicago, IL

Background/Purpose: IL-15, known for its effects on survival of lymphocyte subsets, plays a role in synovitis of Rheumatoid Arthritis. We reported that IL-15 is also detectable in synovial fluid (SF) of patients with knee osteoarthritis (OA), and correlates with levels of matrix metalloproteinase (MMP)-1 and MMP-3. Serum levels have been associated with development and progression of radiographic OA changes, suggesting a possible role in cartilage loss. We investigated IL-15 and IL-15 receptor staining in synovium and cartilage, and tested whether cartilage can respond directly to IL-15.

Methods: Synovial membrane (SM) and cartilage samples from five organ donors collected within 24 hours of death were formalin-fixed and paraffin embedded. Additional SM biopsies from four patients with early-stage knee OA were also collected. Six-micron sections were stained for IL-15 and IL-15Rα using immunoperoxidase technique and polyclonal antibodies directed against IL-15 (rabbit anti-human IL-15, Abcam) or the IL-15Rα chain (goat anti-human IL-15 Rα, Santa Cruz Biotechnology). Non-immune rabbit IgG and goat IgG were used as negative controls. For explants culture, 4mm cartilage punch biopsies were prepared from the tibial surfaces of an additional organ donor; 2 explants per well were placed in a 24 well plate with DMEM (+100U/ml Penicillin-Streptomycin). After 24 hours, media was replaced with 1 ml of fresh media or media+ rhuIL-15 (100ng/ml, Peprotech, NJ) or TNFα and Oncostatin M (100ng/ml each, R & D Systems, MN). Every two days for 12 days and again at 15 days, culture supernatants were collected and replaced with fresh media +/− cytokines. Consecutive supernatants were analyzed for MMP-1, -3 and -9 content using a human MMP 3-Plex Immunoassay (Meso Scale Discovery).

Results: IL-15 and IL-15Rα staining was observed in SM mononuclear infiltrates in the OA patients. Il-15 Rα staining was also identified in the synovial lining and sublining vessels in both patients and donors. Positive staining for IL-15 and IL-15Rα was observed in chondrocytes from all layers (superficial to deep). *In vitro*, IL-15 increased MMP-1 and MMP-3 release from cartilage explants compared to media controls at each time point up to 15 days. Maximum MMP-1 release reached 89.5+/− 5.1 ng/ml at day 15 (vs. media control 0.002 +/− 0.003 ng/ml, p<0.05) while MMP-3 release reached 665.7 +/−13 ng/ml by day 12 (vs. media 12.2+/− 0.2 ng/ml, p < 0.001). Lesser magnitude MMP-9 release from cartilage was observed in response to IL-15, with peak concentration of 962.7 +/− 1.8 pg/ml (p<0.05 vs.control) at day 15. TNFa and OSM induced substantial MMP-1, -3 and -9 release from explants, often >10 times higher than IL-15 induced levels.

Conclusion: Both IL-15 and IL-15Rα are expressed in SM and cartilage indicating that both tissues may respond to this cytokine *in vivo*. IL-15 induced MMP-1, -3, and -9 release from cartilage explants compared to control but of lesser magnitude than levels induced by TNFa + OSM. This is the first demonstration that cartilage is responsive to IL-15, and suggests a role for IL-15 in cartilage catabolism in various forms of arthritis including OA.

13

Visfatin/Nampt in Osteoarthritis: Sites of Production in Human Joints and Role of Its Enzymatic Activity.
Marie-Charlotte Laiguillon[1], Carole Bougault[1], Xavier Houard[1], Marjolaine Gosset[2], Geoffroy Nourissat[1], Sabrina Priam[1], Zvezdana Mladenovic[1], Claire Jacques[1], Francis Berenbaum[3] and Jeremie Sellam[4]. [1]Pierre et Marie Curie University Paris VI, Paris, France, [2]Paris Descartes University, Montrouge, France, [3]AP-HP, St Antoine Hospital, Paris, France, [4]Hopital Saint-Antoine, Pierre et Marie Curie University Paris 6, AP-HP, 75012, France

Background/Purpose: The role of cytokines produced by obese-derived adipose tissue, namely adipokines, in the pathophysiology of osteoarthritis (OA) is now well established. We recently suggested that one of them, visfatin, may play a role in OA by activating chondrocytes (1,2). Along with its cytokine effect, visfatin has an enzymatic activity called nicotinamide phosphoribosyltransferase (Nampt), which is the rate-limiting enzyme in the salvage pathway of nicotinamide adenine dinucleotide (NAD) biosynthesis from nicotinamide, an intracellular pathway involved in many biological processes including TNFα and IL-6 synthesis. Thus, we aimed to i) characterize the local site(s) of production of visfatin/Nampt by the human OA joint tissues ii) further investigate the role of its enzymatic activity in the expression of pro-inflammatory cytokines by chondrocytes and iii) determine whether visfatin/Nampt may also play a role in subchondral bone.

Methods: Human OA joint tissues (synovial membrane, cartilage, subchondral bone) from patients undergoing surgical knee replacement were incubated for 24h in serum-free media. Visfatin/Nampt release in media by the different tissues was evaluated using Western Blot and ELISA. Primary cultures of mouse chondrocytes and osteoblasts were stimulated with recombinant visfatin/Nampt (5μg/mL) for 24h. To determine the role of the enzyme activity, cells were pretreated or not 4h before visfatin/Nampt stimulation with APO866 (10nM), a pharmacologic inhibitor of Nampt activity (3). Effects of stimulation on IL-6, IL-8/Kc, IL-1β, MCP-1, VEGF and TGFβ expression, and on IL-6 and IL-8/Kc release were examined by quantitative RT-PCR and ELISA, respectively.

Results: All human OA joint tissues released visfatin/Nampt (synovium: 529 ± 356, cartilage: 237 ± 380, subchondral bone: 200 ± 104 ng/g tissue) with higher level for the synovium compared to cartilage (p<0.01). Visfatin/Nampt significantly induced IL-6, IL-8/Kc, IL-1β and MCP-1 expression by chondrocytes (n=6) and osteoblasts (n=5) (Table). Visfatin/Nampt increased the production of IL-6 and IL-8/Kc proteins by both cell types. Nampt activity inhibition by APO866 decreased pro-inflammatory cytokines expression at mRNA level (up to 97 % of inhibition) as well as at protein level (up to 63 % of inhibition) and was especially efficient in chondrocytes (Table). Effect of visfatin/Nampt was selective since VEGF and TGFβ were not modulated upon stimulation.

		Gene expression				Protein production	
		IL-6	Kc/IL-8	IL-1β	MCP-1	IL-6	Kc/IL-8
Chondrocytes (n=6)	Fold induction after visfatin/ Nampt stimulation (Mean ± SEM), p-value	10.6 ± 3 (p=0.015)	4.9 ± 1.3 (p=0.015)	878 ± 320 (p=0.015)	2.5 ± 0.4 (p=0.03)	5.8 ± 5 (p=0.016)	29.7 ± 33 (p=0.015)
	Mean % of inhibition by APO866	94%	83%	97%	62%	63%	57%
Osteoblasts (n=5)	Fold induction after visfatin/ Nampt stimulation (Mean ± SEM), p-value	296 ± 59 (p=0.03)	142 ± 64 (p=0.03)	396 ± 112 (p=0.03)	133 ± 83 (p=0.03)	51 ± 19 (p=0.05)	54 ± 23 (p=0.05)
	Mean % of inhibition by APO866	63%	79%	73%	84%	39%	49%

Conclusion: Visfatin/Nampt is produced by the cartilage, the subchondral bone and mostly by the synovial membrane. We demonstrate that Nampt activity of visfatin plays a major role in chondrocytes and osteoblasts activation, suggesting that targeting the Nampt enzymatic activity with a compound like APO866 (being tested in hematological malignancies) may be a new therapeutic approach of OA.

EPAC1 Activation Is Required for NFkB Nuclear Translocation and Osteoclast Differentiation.
Aranzazu Mediero[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Previous work demonstrated that one mechanism by which bisphosphonates inhibit osteoclast differentiation and function is via inhibition of Rap1A isoprenylation and, as a result, function. As Rap1 is the

effector of the cAMP-binding EPAC protein (exchange *protein* directly activated by cAMP), we determined the role of EPAC1 in osteoclast differentiation.

Methods: Osteoclast differentiation was studied as the M-CSF/RANKL stimulated formation of multinucleated TRAP-positive cells from primary murine (C57Bl/6) bone marrow-derived precursors or EPAC1 knockdown (lentiviral shRNA for EPAC1) RAW264.7 cells in the presence/absence of the EPAC-selective cAMP analog 8-CPT-cAMP 100nM and EPAC inhibitor BFA ($10\mu M$). Rap1 activity assay was carried out according to the manufacturers' protocol. Signaling events (EPAC, NFkB and MAPK) were studied by Western Blot in EPAC1 KO RAW264,7 cells (scrambled shRNA transfection is control for these experiments). Osteoclast marker expression was studied by RT-PCR.

Results: The EPAC-selective cAMP analogue 8-CPT-cAMP did not significantly affect osteoclast maturation ($106\pm4\%$ of control, p=NS, n=5) but the EPAC inhibitor BFA inhibited differentiation ($59\pm9\%$ inhibition, p<0.001 vs control, n=5). Activation of Rap1 was maximal 10 minutes after RANKL stimulation ($161\pm4\%$ of control, p<0.001, n=4). NFkB nuclear translocation induced by RANKL was diminished 15 minutes after stimulation in EPAC1 KO cells ($63\pm3\%$ of scrambled shRNA infected cells, p<0.001, n=4) and TRAP staining revealed no osteoclast differentiation when EPAC1 was knocked down. Moreover, pERK1/2 and pJNK are marginally activated in control cells after RANKL stimulation ($117\pm3\%$ and $107\pm2\%$ of control, respectively, p=0.5, n=4) and deletion of EPAC1 slightly decreased this activation ($93\pm2\%$ and $95\pm1\%$ of control, respectively, p=NS, n=4). Interestingly, the MEK inhibitor U0126 restores RANKL-stimulated osteoclast formation in the EPAC1 KO cells ($109\pm2\%$ of control, p=NS, n=6). Finally, in EPAC1 knockdown cells inhibition of osteoclast differentiation is correlated with decreased expression of osteoclast differentiation markers Cathepsin K, NFATc1 and Osteopontin when compared to control (4 ± 0.7, 2.3 ± 0.5 and 3 ± 0.4 fold decreased respectively, p<0.001, n=3).

Conclusion: EPAC1 is a critical intermediate in osteoclast differentiation which permits increased ERK1/2 activation and NFkB nuclear translocation. Targeting this signaling intermediate may diminish bone destruction in inflammatory arthritis.

15

Adenosine A_{2A} Receptor Stimulation Inhibits OC Formation by Suppressing NFkB Translocation to the Nucleus by A PKA-ERK1/2 Mediated Mechanism. Aranzazu Mediero[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Adenosine, a nucleoside released at sites of injury and hypoxia, mediates its effects via activation of G-protein-coupled receptors (A_1, A_{2A}, A_{2B}, A_3). Previously we reported that the $A_{2A}R$ agonist CGS21680 inhibits osteoclast (OC) differentiation in a dose-dependent manner. Here we dissected the intracellular pathways involved in $A_{2A}R$-mediated regulation of OC differentiation.

Methods: OC differentiation was studied as M-CSF/RANKL-stimulated differentiation of murine bone marrow precursors to TRAP+/multinucleated cells in the presence/absence of CGS21680 ($A_{2A}R$ agonist) and ZM241385 ($A_{2A}R$ antagonist) $1\mu M$ each, and PKA activators 8-Cl-cAMP and 6-Bnz-cAMP 100nM each and the PKA inhibitor PKI $10\mu/ml$. cAMP EIA assay and PKA activity assay were carried out according to manufacturers' directions. Signaling events (PKA, NFkB and MAPK) were studied by Western Blot in PKA knockdown (KO) (lentiviral shRNA for PKA) RAW264.7 cells (scrambled shRNA transfection is control for these experiments). OC marker expression was studied by RT-PCR.

Results: CGS21680 stimulated a maximal increase in cAMP 5–10 minutes after RANKL-CGS21680 activation (35.2 ± 3.5 fmol for CGS21680 vs. 14.4 ± 1.9 fmol for control, p<0.001, n=6) correlating with maximal PKA activity at 15 minutes (4.96 ± 0.2 units/ml vs. 3.07 ± 0.2 units/ml, CGS21680 v control, p<0.001, n=4). PKA-selective cAMP analogues 8-Cl-cAMP and 6-Bnz-cAMP inhibit OC maturation to $58\pm9\%$ and $47\pm3\%$ of control respectively (p<0.001, n=5) whereas a selective PKA inhibitor (PKI) increases OC differentiation ($126\pm6\%$ of control, p<0.001, n=5). Western Blot demonstrates that PKA activation increased over time in the presence of CGS21680, and CGS21680 inhibits NFkB nuclear translocation in control ($25\pm1\%$ inhibition, p<0.001, n=4) cells but not in PKA KO cells ($110\pm2\%$ of control, p<0.5, n=4). CGS21680 activates MAPKs (pERK1/2, p-p38 and pJNK), an effect which is blocked by ZM241385. ERK1/2 is activated by a PKA-dependent mechanism ($130\pm6\%$ of control, p<0.001, n=4), but p38 and pJNK activation is unaffected ($112\pm1\%$ and $110\pm2\%$ of control, respectively, p<0.5, n=4). $A_{2A}R$ activation inhibits the expression of OC differentiation markers (2 ± 0.05 and 1.6 ± 0.06 fold decrease for Cathepsin K and Osteopontin respectively, p<0.001, n=4) by a PKA-mediated mechanism (PKA KO cells).

Conclusion: Adenosine, acting at $A_{2A}R$, inhibits OC differentiation and regulates bone turnover via activation of PKA and inhibition of NFkB nuclear translocation. Because adenosine mediates the anti-inflammatory effects of methotrexate we speculate that the capacity of methotrexate to inhibit bone erosion in Rheumatoid Arthritis may be mediated by increases in adenosine which inhibit OC formation and function.

16

Adenosine A_{2A} Receptor Diminishes Bone Destruction At Inflamed Sites, in Part, Via Downregulating Semaphorin4D-PlexinB1 Communication Between Osteoclasts and Osteoblasts. Aranzazu Mediero[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Communication between osteoclasts and osteoblasts is essential for bone homeostasis. Semaphorin4D (Sema4D), expressed on the surface of and secreted by osteoclasts, macrophages and T cells, is a potent inhibitor of bone formation; Sema4D binds to its receptor (PlexinB1) on osteoblasts which induces RhoA activation which suppresses osteoblast differentiation by attenuating insulin-like growth factor-1 (IGF-1) signaling. Adenosine, a nucleoside released at sites of injury and hypoxia, modulates cell function by interacting with specific cell-surface receptors (A_1R, $A_{2A}R$, $A_{2B}R$, A_3R). We have recently demonstrated that $A_{2A}R$ stimulation inhibits wear particle-mediated bone destruction and sought to determine whether $A_{2A}R$-mediated regulation of Sema4D expression might play a role in preventing bone destruction.

Methods: C57Bl/6 mice mice age 6–8 weeks were anesthetized and a 1cm midline sagittal incision was made over the calvaria. 4 mice received no particles (Control), and the rest received 3mg of polyethylene particles (UHMWPE) together with $20\mu l$ of saline 0.9% or CGS21680 $1\mu M$ (n=4 each) at the surgical site every day. Animals were sacrificed after 14 days and calvaria were prepared for histology. Sema4D expression was studied by RT-PCR and Western Blot in RAW267.4 cell-derived osteoclasts in the presence/absence of CGS21680 and ZM241385 ($A_{2A}R$ antagonist) $1\mu M$ each.

Results: As previously described, exposure to UHMWPE particles induce inflammatory infiltration that is significantly decreased in the presence of CGS21680. Exposure to UHMWPE particles significantly increased expression of both Sema4D (224 ± 5cells/Ipf compare to 40 ± 2cells/Ipf in control, p<0.001, n=4) and its receptor PlexinB1 (206 ± 5cells/Ipf compare to 86 ± 4cells/Ipf in control, p<0.001, n=4) on bone surfaces close to inflammatory infiltrates and CGS21680 treatment markedly diminished overexpression of both Sema4D and PlexinB1 (34 ± 3cells/Ipf and 85 ± 3cells/Ipf respectively, p<0.001, n=4). In *in vitro* studies, RANKL induced a 2.5 ± 0.1 fold increase in Sema4D mRNA expression (p<0.001. n=4) that is completely blocked by CGS21680 in a protein kinase A-dependent fashion.

Conclusion: Inflammation promotes Sema4D secretion and PlexinB1 activation. Targeting osteoclasts via $A_{2A}R$ activation prevents wear particle-stimulated bone resorption and the inhibition of Sema4D and PlexinB1 expression likely bone resorption by permitting greater osteoblast differentiation and bone formation. Moreover, these results suggest a novel approach to prevent bone resorption in inflammatory arthritis or infectious arthritis.

Synovial Overexpression of Wnt and Wnt-1-Induced Secreted Protein 1 Induces Cartilage Damage by Skewing of TGF-Beta Signaling and Reduction of the Anti-Hypertrophy Factor Sox9. Martijn H. van den Bosch[1], Arjen B. Blom[1], Peter L. van Lent[1], Henk M. van Beuningen[1], Fons A. van de Loo[2], Esmeralda N. Blaney Davidson[1], Peter M. van der Kraan[1] and Wim B. van den Berg[2]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Although many osteoarthritis (OA) patients show significant synovial involvement, consequences are largely unknown. We found highly increased expression of canonical Wnts 2b and 16 and Wnt-1-induced secreted protein 1 (WISP1), a downstream protein, in knee joints in two experimental murine OA models. Wnt signaling has been implicated in OA incidence and modulation of the β-catenin pathway leads to OA-like changes in cartilage. In addition, TGF-β signaling is critical in cartilage maintenance. TGF-β signals via both ALK5 and ALK1, resulting in Smad 2/3 and Smad 1/5/8 phosphorylation respectively. In the present study we investigated the potency of canonical Wnts, produced by synovial cells, to induce early OA-like cartilage damage and whether canonical Wnts skew TGF-β signaling from the protective Smad 2/3 pathway to the chondrocyte hypertrophy-inducing Smad 1/5/8 pathway.

Methods: Experimental OA was induced by intra-articular injection of collagenase. Pathway analysis of microarray data was done using DAVID software. Detection of Smad 2/3 and Smad 1/5/8 phosphorylation was done by Western blot analysis. *In vivo* synovial overexpression of genes from the canonical Wnt signaling pathway was achieved by intra-articular injection of adenoviral vectors. Joint pathology was assessed by histology. Gene expression was analyzed by qPCR.

Results: Pathway analysis showed that both the Wnt and TGF-β signaling pathway were enriched in the synovium of mice with collagenase-induced OA. To determine if synovial overexpression of canonical Wnts leads to cartilage damage, adenoviral vectors for Wnts 8a and 16 were injected into murine knee joints. A significant increase in the incidence of early OA-like lesions at the medial margin of the medial tibial plateau was found 7 days after overexpression. The incidence was 92% (n=12) for Wnt8a overexpression compared to 17% (n=12) for the control virus and 80% (n=5) for Wnt16 overexpression, but only 20% (n=5) for the control virus. Because of their relatively small size, Wnts and WISP1 can enter the cartilage and possibly alter the chondrocyte phenotype. Synovial overexpression of Wnt8a and Wnt16 resulted in β-catenin accumulation in chondrocytes, a tell-tale sign of canonical Wnt signaling, indicating migration of Wnts to the cartilage. Moreover, pre-incubation with Wnt3a or WISP alone or Wnt3a + WISP1 together resulted in decreased TGF-β-induced phosphorylation of Smad 2/3, whereas phosphorylation of Smad 1/5/8 was increased *in vitro*. This implies a shift towards dominant TGF-β signaling via the hypertrophy-inducing ALK1 pathway. In addition, the expression of the anti-hypertrophic factor Sox9 was decreased after pre-incubation with Wnt3a and WISP1.

Conclusion: Canonical Wnts produced in the synovium may play an important role in OA pathology by inducing β-catenin signaling in the cartilage followed by cartilage damage. Increased expression of canonical Wnts in the synovium, as found in experimental OA, may lead to a phenotype change in articular chondrocytes, probably via modulation of the TGF-β signaling pathway, which is crucial for cartilage homeostasis. This underlines that synovial Wnt/WISP1 expression may be a potential target for OA therapy.

Identification of 14-3-3å As a New Subchondral Bone Mediator Involved in Cartilage Degradation During Osteoarthritis. Sabrina Priam Jr.[1], Carole Bougault[1], Xavier Houard[1], Marjolaine Gosset[2], Colette Salvat[3], Francis Berenbaum[4] and Claire Jacques[1]. [1]Pierre et Marie Curie University Paris VI, Paris, France, [2]Paris Descartes University, Montrouge, France, [3]University Pierre et Marie Curie, Paris, France, [4]AP-HP, St Antoine Hospital, Paris, France

Background/Purpose: OA is a complex disease not limited to cartilage degeneration. Indeed, several experiments suggest that subchondral bone remodeling could initiate and/or contribute to cartilage loss in OA through a bone/cartilage interplay. We aimed to identify soluble mediators released by loaded osteoblasts/osteocytes that could induce the release of pro-catabolic factors by chondrocytes by using a novel and unique bone/cartilage communication model.

Methods: Thanks to a three dimensional (3D) culture model, murine osteoblasts were submitted to compression in Biopress Flexercell plates (1.7 MPa, 1Htz during 24h). Then, conditioned media from compressed (CM) or uncompressed (UCM) osteoblasts/osteocytes were used to stimulate mouse articular chondrocytes. Chondrocyte expression of matrix metalloproteinase 3 (MMP-3) and MMP-13, tissue inhibitors of metalloproteinases (TIMPs), and cartilage extracellular matrix components type II collagen and aggrecan were assessed by RT-PCR, western blot analysis and ELISA. Then, soluble mediators released by compressed osteoblasts/osteocytes were identified by iTRAQ®, a differential secretomic analysis approach.

Results: Media from compressed osteoblast (CM) strongly induced MMP-3 and -13 chondrocyte mRNA expression (Table). Consistently, CM also significantly stimulated the releases of MMP-3 and -13 by chondrocytes (respectively 10.6±0.75 fold, p<0.001, and 6.5±2.1 fold, p<0.01 compared to control). In addition, CM enhances TIMP-1 expression whereas it strongly inhibited TIMP-2 and -3 expressions (Table). CM also affected cartilage matrix proteins expressions by downregulating aggrecan and type II collagen mRNA levels (Table). Effects of CM on cytosolic type II collagen protein amounts were confirmed by western blot (a decrease of 31±9%, p<0.01). In order to identify osteoblast soluble mediators responsible for this chondrocyte phenotype, osteoblast conditioned media were analyzed by iTRAQ®. This sophisticated proteomic technique allowed identification of 105 proteins secreted by osteoblasts among which only 10% were upregulated in response to compression. Among them, 14-3-3ε dose-dependently induced the release of pro-catabolic factors by chondrocytes, mimicking the effects of CM osteoblasts/osteocytes media. Furthermore, 14-3-3ε was strongly released by human OA subchondral bone and stimulated MMP-3 expression in human OA chondrocytes.

Table. Effects of media from uncompressed or compressed osteoblasts on MMPs, TIMPs and matrix proteins chondrocytes mRNA expression.

	MMP-3	MMP-13	TIMP-1	TIMP-2	TIMP-3	Collagen II	Aggrecan
UCM	5,9±3	3,4±0,4	1,5±0,4	0,7±0,2	0,6±0,1	0,7±0,3	0,7±0,3
	ns	ns	ns	p<0,01	p<0,001	ns	ns
CM	50,9±14,5	18,3±10,9	5,2±1,6	0,5±0,1	0,1±0,05	0,4±0,1	0,2±0,1
	p<0,001	p<0,001	p<0,001	p<0,001	p<0,001	p<0,01	p<0,001

Results are expressed in fold compared to control (non-stimulated chondrocytes).
Conclusion: Therefore, we identify 14-3-3ε as a novel soluble mediator critical in the communication between subchondral bone and cartilage in OA leading to MMP expression by chondrocytes. We speculate that 14-3-3ε is a potential target for a future disease-modifying OA drug.

Stress-Induced Cartilage Degradation Does Not Depend On NLRP3-Inflammasome in Osteoarthritis. Carole Bougault[1], Marjolaine Gosset[2], Xavier Houard[1], Colette Salvat[3], Lars Godmann[4], Thomas Pap[4], Claire Jacques[1] and Francis Berenbaum[5]. [1]Pierre et Marie Curie University Paris VI, Paris, France, [2]Paris Descartes University, Montrouge, France, [3]University Pierre and Marie Curie, Paris, France, [4]University Hospital Münster, Münster, Germany, [5]AP-HP, St Antoine Hospital, Paris, France

Background/Purpose: The cartilage matrix breakdown in osteoarthritis (OA) is due to both abnormal mechanical stress and activation of catabolic processes involving metalloproteinases (MMPs). Currently, IL-1beta is thought to have a major role in shifting the metabolic balance toward degradation. IL-1beta is first synthesized as an inactive precursor, which is cleaved into the secreted active form. This maturation process mainly occurs in the "inflammasome", where initiators (including NLRP3) and adaptor molecules (ASC) oligomerize to recruit and activate caspase-1, which in turn processes IL-1beta precursor. We aimed to clarify the role of both inflammasome and IL-1beta in cartilage breakdown.

Methods: First, amounts of IL-1β released from cartilage explants of 18 OA patients were assessed (ELISA). Second, in primary mouse articular chondrocytes cultures, LPS, IL-1alpha and TNF-alpha treatments were used to induce a pro-degradative phenotype, characterized by an increase in gene expression (real-time PCR) and in protein release of MMP-3, MMP-9 and MMP-13 (ELISA, zymography and Western-blot). Effects of a deficiency in NLRP3 (using NLRP3−/− mice), of an inhibition of caspase-1 (using Z-YVAD-FMK) and of a blockade of IL-1 (using IL-1RA) were investigated.

At last, excessive dynamic compression was applied on mouse cartilage explants to trigger degradation (0.5 Hz and 1 MPa for 6 h). Load-induced GAG release and increase in MMP enzymatic activity were assessed in WT, NLRP3−/− or IL-1R1−/− mice, the latter being deficient in IL-1 receptor type 1.

Results: Despite the expression of NLRP3, ASC and caspase-1 in OA chondrocytes, OA cartilage was not able to produce active IL-1beta. In mouse articular chondrocytes, LPS, IL-1alpha and TNF-alpha dose-dependently increased MMP-3, MMP-9 and MMP-13 both at gene and protein levels. This response was similar in NLRP3−/− chondrocytes and was unchanged by caspase-1 inhibition. These results demonstrate that the inflammatory stress-induced degradative phenotype was inflammasome-independent. Furthermore, the catabolic response to LPS and TNF-alpha was unchanged when IL-1 was inhibited by IL-1RA. In cartilage explants, excessive load induced an increase in GAG release (3-fold) and MMP activity (3.7-fold). This response was similar in NLRP3−/− and IL-1R1−/− -derived cartilage. Likewise, the load-induced degradative response was independent of NLRP3-inflammasome and of IL-1.

Conclusion: This study suggests that OA cartilage can be degraded independently of NLRP3- inflammasome activity. This result may explain, at least in part, why previous trials with IL-1beta inhibitors were all negative.

Osteoclastogenesis Is Inhibited by Immune Complexes Through Activating Fcγ Receptors. Lilyanne C. Grevers[1], Peter L.E.M. van Lent[1], Teun J. de Vries[2], Vincent Everts[2], J. Sjef Verbeek[3] and Wim B. van den Berg[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]ACTA, UVA, VU University Amsterdam, Amsterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Rheumatoid arthritis is characterized by chronic inflammation and osteoclast-mediated bone loss. Co-stimulatory signalling via ITAM- and ITIM-coupled receptors is essential for osteoclast formation and function. The ITAM- and ITIM-coupled Fcγ receptors (FcγR) play a crucial role in mediating inflammation and cartilage destruction in experimental arthritis, but their role in osteoclast-mediated bone loss is unknown. The aim of the present study was to investigate the role of FcγRs in osteoclastogenesis and osteoclast function.

Methods: Bone destruction was analyzed in arthritic knee joints of FcγRIIB-deficient, FcRγ-chain−/− (lacking expression of activating FcγRs), and wild type mice. Bone marrow-derived osteoclast precursors were differentiated *in vitro* towards osteoclasts in the absence or presence of immune complexes (ICs) and stimulated thereafter for 24 hrs with or without TNFα or LPS. Experiments were analyzed for the expression of FcγRs and osteoclast markers, osteoclast formation, and resorption pit formation on bone.

Results: Bone erosions and cathepsin K-positive osteoclast numbers were significantly increased (>2.6 fold) during antigen-induced arthritis in the knee joints of FcγRIIB-deficient mice. All FcγR classes were highly expressed on osteoclast precursors. Differentiation of osteoclast precursors in the presence of ICs significantly reduced osteoclast formation (37%), bone resorption (68%), and expression of the osteoclast markers cathepsin K, TRAP, CTR, DC-STAMP, and NFATc1. In the presence of ICs, osteoclastogenesis of FcγRIIB−/− precursors and bone resorption remained inhibited. In contrast, ICs could not inhibit osteoclast formation or bone resorption of FcRγ-chain−/− precursors. When IC-inhibited osteoclastogenesis was followed by stimulation with TNFα or LPS, the inhibitory effects of ICs were overruled, resulting in significantly increased osteoclast numbers and resorption levels as compared to unstimulated controls.

Conclusion: Activating FcγRs mediate IC-induced inhibition of osteoclastogenesis, which can be overruled in the presence of pro-inflammatory mediators like TNFα and LPS. This suggests that the balance of FcγR-mediated induction of inflammation, through pro-inflammatory cytokine production, as well as the direct inhibitory effect of ICs on osteoclastogenesis determines the net effect on bone loss.

IL-32 and IL-17 Interact and Aggravate Osteoclastogenesis in Rheumatoid Arthritis. Bo Young Yoon[1], Young-Mee Moon[2], Yang-Mi Her[2], Hye Jwa Oh[2], Jae-Seon Lee[2], Kyoung-Woon Kim[3], Seon-Yeong Lee[2], Yun-Ju Woo[2], Kyung-Su Park[2], Sung-Hwan Park[2], Ho-Youn Kim[2] and Mi-La Cho[2]. [1]Inje University Ilsan Paik Hospital, Goyang, South Korea,[2]Catholic University of Korea, Seoul, South Korea,[3]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea

Background/Purpose: Interleukin (IL)-32 and IL-17 play critical roles in pro-inflammatory responses and are highly expressed in the synovium of patients with rheumatoid arthritis (RA). We investigated not only the related induction of IL-17 and IL-32 in fibroblast-like synoviocytes (FLSs) from RA patients and T cells from healthy donors, but also the summative ability of the two cytokines to stimulate osteoclastogenesis.

Methods: FLSs were isolated through surgical synovectomy obtained from patients with RA or osteoarthritis (OA) and peripheral blood mononuclear cells (PBMCs) were obtained from healthy donors. Splenic CD4+ and CD4− T cells and joint specimens were obtained from autoimmune arthritis mice.Real-time polymerase chain reactions were performed to evaluate the expression of IL-32, IL-17, orphan nuclear receptor Rorγt, tartrate-resistant acid phosphatase (TRAP), cathepsin K, calcitonin receptor (CTR), matrix metalloproteinase-9 (MMP9) mRNA. IL-17 protein was measured by enzyme-linked immunosorbent assay and the T helper (Th)17-expressing T cell count was detected by fluorescence-activated cell sorting. Immunohistochemical staining and TRAP staining were performed to determine the distribution of inflammatory cytokines and the presence of osteoclastogenesis.

Results: IL-17 induced the expression of IL-32 (4.3 fold) in the FLSs from RA patients, as assessed by microarray. The IL-32 and IL-17 levels in the FLSs from the RA patients were higher than those from the OA patients, and the expressions were colocalized. IL-32 production was increased by IL-17 through the nuclear factor (NF-ⱯêB)- kB and PI3 kinase signal pathways. When FLSs from RA patients and CD4+ T cells were cocultured, the CD4+ T cells differentiated into IL-17-producing Th17 cells, which stimulated the production of IL-32 in the FLSs. Moreover, IL-32 induced the production of IL-17 in human CD4+ T cells and also induced high expression levels of IL-17 in splenic CD4+ T cells of CIA mice. IL-32 and IL-17 were colocalized near TRAP-positive areas in joint specimens of autoimmune arthritis mouse models. IL-17 and IL-32 synergistically induced the differentiation of osteoclasts, as demonstrated by the expression of osteoclast-related genes such as TRAP, cathepsin K, CTR, and MMP9.

Conclusion: IL-17 affected the expression of IL-32 in FLSs of RA patients and IL-32 induced the production of IL-17 in CD4+ T cells. Both IL-17 and IL-32 cytokines can reciprocally influence each other's production in RA and autoimmune arthritis models. Separately, IL-17 and IL-32 each stimulated osteoclastogenesis without RANKL. Together, the two cytokines synergistically amplified the differentiation of osteoclasts, independent of RANKL stimulation.

Protective Properties of Conditioned Media From Adipose Stem Cells On Osteoarthritic Chondrocytes. Maria Isabel Guillén[1], Julia Platas[1], Vicente Mirabet[2], Miguel Angel Castejón[3], Francisco Gomar[4] and Maria Jose Alcaraz[1]. [1]University of Valencia, Burjasot, Valencia, Spain, [2]Generalitat Valenciana, Valencia, Spain, [3]De la Ribera University Hospital, Alzira, Spain, [4]University of Valencia and University Hospital, Valencia, Spain

Background/Purpose: Adipose-derived mesenchymal stem cells (ASC) exhibit a high potential for cell therapy and they might also act as a cellular source for supplying soluble factors exerting anti-inflammatory or trophic effects on cells. Osteoarthritis (OA) involves the destruction of articular cartilage leading to disability. The purpose of this study was to investigate whether conditioned medium from adipose-derived mesenchymal stem cells (ASC-CM) improves the inflammatory and degradative response induced by interleukin-1β in OA chondrocytes and cartilage.

Methods: Adipose tissue from patients subjected to abdominal lipectomy surgery, was used for ASC isolation by collagenase treatment. Cells were incubated in DMEM/F12 containing 15% human serum. Cell phenotype was analyzed by flow cytometry with specific antibodies anti-CD105-PE, anti-

CD90PerCP-eFluo 710, anti-CD34APC, and anti-CD45-PE (International Society of Cellular Therapy), and cellular viability with propidium iodide. The conditioned medium (ASC-CM) was collected after 48h of culture, centrifuged and stored at -80°C in sterile conditions. Cartilage specimens were obtained from patients with diagnosis of advanced OA. Protocols were approved by the Institutional Ethical Committee. Chondrocytes were used in primary culture. Cartilage explants or isolated chondrocytes were stimulated with 10 ng/ml interleukin (IL)-1β for different times. Gene expression was analyzed by real-time PCR. Protein expression was investigated by ELISA. Nitric oxide (NO) production and matrix metalloproteinase (MMP) activity were measured as microplate fluorescence assays. Prostaglandin E$_2$ (PGE$_2$) was evaluated by RIA.

Results: IL-1β significantly increased the production of NO, PGE$_2$ and MMP activity, and the expression of IL-1β, tumor necrosis factor-α (TNFα), vascular endothelial growth factor (VEGF) and a wide range of chemokines, after 24h, with respect to basal conditions. ASC-CM treatment of OA explants or chondrocytes reduced the production of NO which was dependent on inducible NO synthase down-regulation. In addition, PGE$_2$ levels as well as MMP activity were significantly decreased. A lower expression of IL-1β, TNFα, VEGF and chemokines CCL-4, CCL-5, CCL-8, CCL-19, CCL-20, CXCL-1, CXCL-2, CXCL-3 and CXCL-8 was observed in chondrocytes treated with ASC-CM with respect to IL-1β controls. We have also evaluated the senescence marker β-galactosidase. In cells treated with IL-1β and ASC-CM for 7 days, we observed a significant reduction in senescence-associated β-galactosidase activity in comparison with chondrocytes treated with IL-1β.

Conclusion: The results of our study demonstrate the down-regulation of inflammatory and catabolic mediators by ASC-CM in OA explants and chondrocytes. Our data have revealed a protective role for ASC-CM in chondrocytes suggesting possible applications against cartilage degradation.

Differential Effects of Bone Morphogenetic Protein 2 and 9 On Chondroprotective Transforming Growth Factor β Signaling.
Arjan P. van Caam[1], Esmeralda N. Blaney Davidson[1], Elly L. Vitters[1], Laurie de Kroon[1], Ellen W. van Geffen[1], Peter ten Dijke[2], Wim B. van den Berg[1] and Peter M. van der Kraan[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Osteoarthritis (OA) is a multifactorial disease characterized by loss of articular cartilage. TGFβ is considered as a protective factor against cartilage loss in young cartilage by inducing Smad2/3 phosphorylation via the TGFβ receptor ALK5. Smad2/3 phosphorylation (Smad2/3P) lowers MMP13 expression, and prevents deleterious terminal differentiation of chondrocytes. In contrast to Smad2/3P, Smad1/5 phosphorylation (Smad1/5P), induced by BMPs but also by TGFβ, is linked to terminal differentiation and MMP13 production. Type I receptors that phosphorylate Smad1/5/8 include ALK1 and ALK3. BMP-9 signals via ALK1 and BMP-2 via ALK3, and both ligands induce enhanced glycosaminoglycan synthesis in young cartilage. BMP2 is induced in damaged cartilage while BMP9 is constitutively present in high concentrations in body fluids. If and how these factors modulate chondroprotective TGFβ signaling is still unclear. Therefore, we analyzed BMP-2 and BMP-9 induced Smad signaling and gene expression in chondrocytes, and studied their interaction with TGFβ.

Methods: Primary bovine chondrocytes, isolated from the metacarpophalangeal joint of 2 year old animals, or the human G6 chondrocyte cell line were cultured to near confluency and incubated with TGFβ1, BMP-2, BMP-9 or a combination thereof. Smad phosphorylation kinetics were analyzed by specific Smad2P and Smad1/5P staining of Western blots. Expression patterns of Smad specific response genes: PAI-1 (Smad3 signaling), and ID-1, (Smad1/5 signaling) were analyzed from 0–48h by quantitative real time PCR (qPCR). Biological activity was tested with a CAGA$_{12}$-luc transcriptional reporter construct that produces luciferase in response to Smad3 signaling. Adenovirally transduced cells (MOI = 5) were serum starved for 8h, stimulated with growth factors for 20h, and luciferase activity was measured.

Results: In primary chondrocytes, both BMP-2 and BMP-9 potently induced Smad1/5 phosphorylation, which peeked after 1 h and lasted up to 3 h. BMP-9 was more potent than BMP2. Remarkably BMP-9 (5 ng/ml or more) was also capable of inducing Smad2 phosphorylation, whereas BMP-2 (50 ng/ml) was not. BMP-9-induced Smad2 phosphorylation lasted from 1 up to 3 hours. Moreover, in contrast to BMP-2, BMP-9 was also able to rapidly (from 2 up to 24h) induce PAI-1 transcription. Both growth factors potently induced ID1 expression. Gene transcription was reflected in biological activity, as BMP-9 induced luciferase production in the CAGA$_{12}$-luc assay. Interestingly, co-stimulation of TGFβ with these BMPs revealed an even more remarkable difference between both factors. BMP-2 was able to dose dependently inhibit Smad2 phosphorylation. On the contrary, BMP-9 synergized with TGFβ on Smad2/3 phosphorylation, resulting in a 50% increase in luciferase production after co-stimulation compared to TGFβ alone (p<0.01).

Conclusion: Both BMPs show a distinct difference in Smad phosphorylation and interaction with TGFβ. Although both BMPs promote matrix synthesis (Glycosaminoglycans production), long term effects of both factors on cartilage will most likely differ due to their different effects on chondroprotective Smad2/3 signaling.

The Negative Effects of Glucocorticoids On Bone Are Primarily Mediated by Genes Involved in Osteoblast Differentiation and Bone Remodelling.
Katharina Blankenstein[1], Tara C. Brennan-Speranza[1], Karin Lyon[1], Colin R. Dunstan[1], Frank Buttgereit[2], Hong Zhou[3] and Markus J. Seibel[3]. [1]Bone Research Program, Sydney, Australia, [2]Charite University Medicine, Berlin, Germany, [3]ANZAC Research Institute, The University of Sydney, Concord, Australia

Background/Purpose: Glucocorticoids are widely used as anti-inflammatory and immunosuppressive drug for the treatment of many inflammatory and auto-immune diseases. However, long-term and high-dose glucocorticoid treatment causes bone loss and can lead to secondary osteoporosis in both human and mice. The molecular mechanisms underlying the adverse effects of glucocorticoids on bone are not well understood. We have recently demonstrated that osteoblast-targeted disruption of glucocorticoid signalling attenuates glucocorticoid-induced bone loss in mice, indicating that the detrimental skeletal effects of glucocorticoids are predominantly mediated by osteoblasts. To elucidate the role of the osteoblast in glucocorticoid-induced bone loss, in the present study we determined the effects of glucocorticoids on the gene expression profile in bone cells.

Methods: Seven-week old male CD1 outbred mice were subcutaneously implanted with slow-release pellets containing either 1.5 mg corticosterone (CS) or placebo (PLC) over 28 days. Blood was obtained weekly and osteocalcin serum levels were measured by IRMA. RNA was isolated from tibia at endpoint (day 28) and Affymetrix Gene Array analysis (GeneSpring GX) was performed to assess changes in expression of genes associated with osteoblast differentiation and the regulation of bone remodelling. Genes considered to be regulated were at least 1.5-fold differentially expressed. Quantitative RT-PCR was employed to validate the gene array results on a selection of genes.

Results: By comparing gene expression profiles in tibial RNA from mice treated with CS or PLC, we found that CS specifically regulated 391 genes. To further investigate the genes targeted by corticosterone treatment we performed gene ontology analysis with the aid of heat maps. The expression of genes implicated in osteoblast differentiation and the regulation of bone remodelling was downregulated in mice treated with CS compared to the PLC-treated control group. More precisely, we observed a downregulation of the osteoblast markers Runx2, Colα1, osteocalcin and sclerostin in CS-treated mice compared to PLC. In addition, BMP4 and BMP7 followed the same pattern. Genes that were most profoundly downregulated in the array analysis were further validated by qRT-PCR. Consistent with mRNA levels, osteocalcin serum levels were suppressed to almost undetectable levels.

Conclusion: These results confirm that glucocorticoids primarily target genes involved in osteoblast differentiation and the regulation of bone remodelling. Gene expression profile analyses may point to the pathways involved in the negative effects of glucocorticoids on bone.

Activation of the Canonical Wnt Signaling Pathway Is Tissue-Dependent in Osteoarthritic Joints: Distinct Mechanisms of Regulation by Wnt Antagonists. Thomas Funck-Brentano, Wafa Bouaziz, Hilene Lin, Valerie Geoffroy, Eric Hay and Martine Cohen-Solal. INSERM U606 Paris 7 university, Paris, France

Background/Purpose: Wnt signaling pathway is a major regulator of bone and cartilage remodeling. Modulation of this pathway has lead to controversial results on joint cartilage in murine osteoarthritis (OA) models. Therefore, this study aims to describe the in vivo activity of Wnt/βcatenin and the expression of Wnt antagonists in joint tissues during the development of OA.

Methods: Joint instability was induced by partial meniscectomy (MNX) at the right knee in TOPGAL mice, which express the lacZ gene under the control of Wnt-RE. Left knee was sham-operated. The mice were sacrificed at baseline, 2, 4, 6 and 9 weeks after surgery ($\geq$ 5 animals per time point). Analysis of the bone microarchitecture of the tibial epiphyses were assessed (Skyscan® 1172) and then the samples were prepared for quantification of OA score, X-gal staining and immunohistochemistry for the expression of Dkk-1, Sclerostin and sFRP-3.

Results: Compared to sham, the number of X-gal positive osteocytes per bone volume decreased at 4 weeks then progressively increased in the subchondral bone (ratios: 0.99 ± 0.01; 0.50 ± 0.08, p<0.05; 1.63 ± 0.43; 2.33 ± 0.81 for each time point, respectively). These changes paralleled those of bone volume/tissue volume. Xgal staining was strongly observed in growing osteophytes. The number of X-gal(+)-chondrocytes was low in articular cartilage at baseline, indicating an inhibition of Wnt pathway, but their number increased in the superficial layers with MNX until 6 weeks. The synovium showed marked staining in MNX knees compared to sham operated knees. Dkk-1 was highly expressed in normal non calcified cartilage and dramatically decreased with OA. Sclerostin and sFRP-3 were only expressed in the calcified layers and moderately increased with OA. The synovium also expressed Dkk-1 and sFRP-3 in OA knees.

Conclusion: During the course of OA, the canonical Wnt signaling pathway is mainly activated in growing osteophytes, subchondral bone and synovium while this activation was moderate in chondrocytes of articular cartilage. Distinct patterns of expression of Wnt antagonists are observed in the joint tissues that indicated multiple mechanisms of regulation of the canonical Wnt signaling pathway.

Quantitative Analysis of Bone Damage/Morphological Changes in the Citrullinated Collagen Induced Arthritis Mouse Model Using Micro-CT. Anand Dusad[1], Michael J. Duryee[1], Dong Wang[2], James R. O'Dell[3], Ted R. Mikuls[4], Geoffrey M. Thiele[3] and Lynell W. Klassen[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Medical Ctr, Omaha, NE, [3]Univ of Nebraska Med Ctr, Omaha, NE, [4]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Patients with rheumatic diseases given immunosuppressive therapy are susceptible to various types of infections, especially pulmonary infections that affect their vital prognosis. The aim of this large-scale, multi-center, prospective cohort study was to identify risk factors for development of pulmonary infection in patients receiving immunosuppressive treatment for rheumatic diseases (PREVENT study).

Methods: We enrolled those patients who were admitted to participating hospitals for treatment of rheumatic diseases and started immunosuppressive therapy with corticosteroids, conventional immunosuppressants, or biologics. Observation was stopped either 12 months after enrollment, or the day a patient developed predefined pulmonary infection or was lost-to- follow up, whichever came first. The validity of the diagnosis for pulmonary infection was assessed by an event-monitoring committee. We collected demographic data and clinical data for rheumatic diseases at baseline, data for candidate risk factors for pulmonary infection at baseline and month 6, and usage of drugs throughout the observation period. Risk factors for pulmonary infection were investigated by univariate and multivariate analyses.

Results: Of 766 patients enrolled, 668 patients (87.2%) were observed for 12 months, 32 patients (4.2%) died, and 66 (8.6%) patients were lost-to-follow up by month 12. Sixty-one patients (8.0%) developed pulmonary infection: bacterial pneumonia, 25; *Pneumocystis jirovecii* pneumonia, 20;

fungal pneumonia, 5; cytomegalovirus pneumonia, 3; tuberculosis, 3; others, 5. Kaplan-Meier curves showed a significantly lower cumulative survival rate in patients with pulmonary infection compared to those without pulmonary infection (p<0.01, log-rank test). Because treatment for RA patients without active extra-articular manifestation (articular RA patients, n=145) was significantly different from that for the rest of the patients, we performed multivariate analyses using COX hazard regression models in all patients (n=766) and in these patients excluding articular RA patients (n=621) (Table 1). Older age ($\geq$65 years-old), higher Brinkman index ($\geq$400), higher serum creatinine (sCr) level, and higher maximum prednisolone dose (mg/kg/day) during the first two weeks of treatment were significantly associated with development of pulmonary infection in all patients. Older age, higher Brinkman index, higher sCr level, and disturbed performance status were significantly associated with development of pulmonary infection in patients excluding articular RA patients.

Conclusion: This is the first large-scale, prospective study identifying risk factors for pulmonary infection in patients with rheumatic diseases in the literature. Prophylactic measures should be taken accordingly for better benefit-risk balance of treatment.

Anti-Citrullinated Protein Antibodies As an Indicator of Bone Damage in the Citrullinated Collagen Induced Arthritis Model. Anand Dusad[1], Michael J. Duryee[1], Dong Wang[2], Carlos D. Hunter[1], Bartlett C. Hamilton III[3], James R. O'Dell[4], Ted R. Mikuls[5], Lynell W. Klassen[4] and Geoffrey M. Thiele[4]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Medical Ctr, Omaha, NE, [3]University of Nebraska Medical Centre and Omaha VA Medical Center, Omaha, [4]Univ of Nebraska Med Ctr, Omaha, NE, [5]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Although the pathogenesis and cause of rheumatoid arthritis (RA) remains uncertain, various disease-driving auto-antigens and auto-antibodies with different specificities have been used as diagnostic tools. Anti-citrullinated protein antibody (ACPA) has been implicated in disease process and due to its high specificity also been used as a diagnostic tool. There have been many studies in the literature using ACPA as an indicator of radiological (X-Ray) joint damage in both RA patients and animal studies, although few have quantified bone damage using Micro-CT. This is important since this approach is increasingly considered the gold standard for analyzing and quantifying micro-structural changes in bone morphology. Therefore the purpose of this study was to correlate joint damage as quantitated by micro-CT with ACPA using our novel citrullinated collagen induced arthritis (CCIA) model.

Methods: Thirty DBA/1 mice were randomly divided into three groups. Mouse collagen (C-II) was modified [citrullinated (Cit)] using peptidyl arginine deiminase (PAD) and injected weekly for 5 weeks. As controls, mice were injected with unmodified C-II (negative control) and with Freund's complete adjuvant (FCA) as positive control. Mice were sacrificed at week 5 and micro-CT was done to quantitatively analyze bone damage. A commercially available anti-CCP antibody kit was used to measure ACPA levels in serum. Data was expressed as mean $\pm$ SD's. Pearson's 2-tailed correlation was used to correlate ACPA with measures of bone damage.

Results: Using ELISA, anti-CCP (ng/ml) was measured in serum and showed a significant increase in both Cit-C-II (29.03 ± 7.53, p = 0.03) and FCA-C-II (42.73 ± 4.56, p < 0.001) as compared to C-II (21.84 ± 5.20). Bone mineral density (BMD) showed significant loss in Cit-C-II (0.43 ± 0.04

g/cm^3, p = 0.018) and FCA-C-II (0.35 ± 0.08 g/cm^3, p = 0.001) as compared to C-II (0.49 ± 0.04 g/cm^3) group. Data was found to be consistent for several other parameters of bone quality (not shown). Significant negative correlations were observed for BMD, BV/TV, BS/TV, trabecular number, fractal dimension, connectivity density and polar moment of inertia all indicating that as ACPA increases these decrease suggesting that higher ACPA concentration is inversely associated with bone quality [Table 1].

Table 1.

	ACPA (ng/ml)
Bone mineral density [BMD (g/cm^3)]	−0.530*
Bone volume density [BV/TV (%)]	−0.654**
Bone surface density [BS/TV (mm^{-1})]	−0.662**
Trabecular number [Tb. N (mm^{-1})]	−0.628
Trabecular seperation [Tb. Sp. (mm)]	0.573**
Trabecular pattern index [Tb. Pf (mm^{-1})]	0.570**
Structural mean index [SMI]	0.510*
Fractal dimension [FD]	−0.666**
Connectivity Density [Conn. Dn (mm^{-3})]	−0.591**
Polar moment of inertia [MMI (mm^4)]	−0.647**

Pearson Correlation (2-tailed, n = 21). **Correlation is significant at 0.01 level, *Correlation is significant at 0.05 level.

Conclusion: Due to the fact that no exogenous immunogenic factor such as non-self protein or any adjuvant is used in this novel model, CCIA closely mimics the auto-immunogenic origin of RA. Using this model, we observed significant inverse associations of circulating ACPA with measures of bone quality including density, volume, surface and mechanical properties of bone. In conclusion ACPA levels in serum can successfully predict bone morphological changes in RA. Further studies focused on identifying the mechanisms underpinning these relationships are ongoing.

Role of Microrna-455 Networks in Mesenchymal Cell Differentiation and Osteoarthritis. Fumiaki Ayabe[1], Shigeru Miyaki[2], Diana Brinson[1], Satoshi Yamashita[3], Hiroyuki Nakahara[1], Koji Otabe[1], Stuart Duffy[1], Shawn Grogan[1], Shuji Takada[3], Martin K. Lotz[1] and Hiroshi Asahara[1]. [1]The Scripps Research Institute, La Jolla, CA, [2]Hiroshima University, Hiroshima, Japan, [3]National Research Institute for Child Health and Development, Tokyo, Japan

Background/Purpose: The objectives of this study were to identify cartilage specific microRNAs (miRNAs, miR-) that are regulated by SOX9 and are increased in chondrogenesis, to determine changes in osteoarthritic (OA) cartilage, and to investigate the role of miR-455-5p and miR-455-3p (miR-455s) in human chondrocytes.

Methods: To identify miRNAs specifically expressed in chondrocytes, we performed microarray and quantitative polymerase chain reaction (qPCR) on cultured mouse chondrocytes using adenovirally induced SOX9 transcription. The expression of miR-455s was analyzed by qPCR on human articular chondrocytes, human mesenchymal stem cells (MSCs). The expression of miR-455s was monitored during chondrogenic differentiation of human MSCs in pellet cultures as well as in human articular cartilage from both normal and OA knee joints. We tested the effects of interleukin-1b (IL-1b) on miR-455s expression. Double-stranded miR-455s (ds-miR-455s) was transfected into chondrocytes to identify changes in gene expression associated with OA.

Results: The expression of miR-455s mirrors SOX9 expression, with large differences between human chondrocytes and human MSCs. During chondrogenesis, miR-455s expression in MSC cultures increased in parallel with the expression of SOX9, MAF and COL10A1. Normal human articular cartilage expressed miR-455s, with significant reduction in OA tissue. In vitro treatment of chondrocytes with IL-1b suppressed miR-455s expression. Transfection of chondrocytes with ds-miR-455s down-regulated expression of inflammatory genes.

Conclusion: This study shows that miR-455s expression is altered in concert with other chondrocyte differentiation-related expression patterns. The reduction in miR-455s expression in OA cartilage and in response to IL-1b may contribute to the abnormal gene expression pattern characteristic of OA.

Level of IL-1â-Induced Epigenetic Modifications Differ in Chondrocytes From Different Histological Zones of Human Cartilage. Nahid Akhtar[1] and Tariq M. Haqqi[2]. [1]Case Western Reserve University/Metrohealth Medical Center, Cleveland, OH, [2]Metro Health Medical Center, Cleveland, OH

Background/Purpose: Osteoarthritis (OA) reduces mobility and function of the affected joint and is a leading cause of disability among the elderly. Recent evidence points to epigenetic regulation of genes in OA. Interleukin-1β (IL-1β) is the major cytokine involved in cartilage catabolism and induces the expression of pro-inflammatory genes. The aim of this study was to investigate whether IL-1β induces epigenetic changes in human chondrocytes obtained from upper, middle and deep zone cartilage.

Methods: Chondrocytes were derived by enzymatic digestion of upper, middle and deep-zone cartilage obtained from OA patients (n=10). Chondrocytes were stimulated with IL-1β (10ng/ml) *in vitro* for 24h. Global DNA methylation level was determined using MethylFlash™ Methylated DNA quantification kit (Epigentek). Total RNA was prepared and expression level of DNMT-1, DNMT-3A, DNMT-3B and HDAC-1 was quantified by TaqMan Assays. IL-1β-induced changes in the activity of total DNMT, DNMT-1, DNMT-3A, DNMT-3B, DNA demethylases and Thymine DNA glycosylase (TDG) was determined using ELISA-based assays (Epigentek). Un-stimulated and IL-1β-stimulated chondrocytes obtained from upper and deep zones were used to study the expression of 84 human epigenetic modification enzymes using mRNA array (SA Biosciences). **Results** were derived using Origin 6.1 software package and p<0.05 was considered significant.

Results: Global DNA methylation estimation showed the differential response of chondrocytes from different zones of the human cartilage to IL-1β. Total DNA methylation was significantly increased in the deep-zone chondrocytes (138%) and in upper-zone chondrocytes (18%) stimulated with IL-1β compared to controls. Expression levels of 84 key genes encoding enzymes known or predicted to modify genomic DNA and histones to regulate chromatin accessibility showed that 30 genes displayed significant differences upon IL-1β-stimulation. Among these, 29 genes were upregulated and 1 gene was downregulated. Interestingly, the mRNA array results showed a significant upregulation of DNMT-1, DNMT-3A and DNMT-3B expression in both upper and deep-zone chondrocytes stimulated with IL-1b and correlated with the increased total DNMT and DNMT-1 activity in the same chondrocytes. Activity of both DNA demethylases and TDG, enzymes essential for active DNA demethylation, was also increased in both deep and upper-zone chondrocytes by IL-1β suggesting a dynamic regulation of DNA methylation and demethylation in these chondrocytes. No significant difference in global DNA methylation, expression and activity of DNMT-1, DNMT-3A, DNMT-3B and demethylases was observed in chondrocytes from middle-zone in response to IL-1β.

Conclusion: We demonstrate a role of IL-1β-mediated epigenetic modifications in chondrocytes of the three histological zones of the human cartilage. Hypermethylation of genomic DNA in OA chondrocytes positively correlated with the expression and activity of DNA methylatranferases. This study also identify for the first time several new candidate genes that may be involved in DNA methylation, demethylation and histone modifications in response to IL-1β in human chondrocytes and thus may play a role in OA pathogenesis.

A Mouse Myeloid Precursor with Osteoclastogenic Function in Vivo. Julia F. Charles[1], Erene Niemi[2], Mary C. Nakamura[3] and Antonios O. Aliprantis[4]. [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]University of California, San Francisco; VA Medical Center, San Francisco, [3]SFVAMC/UCSF, San Francisco, CA, [4]Brigham and Women's Hsopital, Boston, MA

Background/Purpose: Osteoporosis and peri-articular erosions in patients with inflammatory arthritis are characterized by increased osteoclast resorptive activity. Although a great deal is known about how osteoclasts differentiate from precursors and resorb bone, the identity of the osteoclast precursor (OCP) in vivo remains elusive. Using ex vivo assays of osteoclast

differentiation, we previously demonstrated that the majority of bone marrow OCP activity resides in the CD11b$^{-/lo}$ Ly6C^{hi} cKit^{+} population.

Methods: Fluorescence activated cell sorting was used to examine multiple markers on OCP and to isolate OCP from mT/mG cathepsin K cre+ mice. mT/mg cathepsin K cre donor OCP are RFP+ at baseline and GFP+ in the presence of cre recombinase in mature osteoclasts. Donor OCP were transfered by intramedulary injection into NFATc1 fl/fl Mx1-Cre osteoclast deficient mice and donor derived osteoclasts were detected by IHC. Alternatively, donor OCP were injected intravenously into C57BL/6 mice 24 hrs after calvarial injection of 20mg/kg LPS. Ex vivo osteoclast, dendritic cell, and macrophage cutures and assays were performed according to standard techniques.

Results: Here we show that the CD11b$^{-/lo}$ Ly6C^{hi} cKit^{+} OCP population can be distinguished from the recently described quiescent osteoclast precursor by their proliferative capacity and absence of RANK (receptor activator of nuclear factor kappa B) expression. Similar to other myeloid precursors, OCP retain plasticity in vitro, differentiating into dendritic cells or phagocytic macrophages when stimulated with GM-CSF or MCSF, respectively. Adoptive transfer of this OCP population into osteoclast deficient hosts resulted in the formation of donor-derived mature, multinucleated TRAP^{+} osteoclasts in vivo. By combining adoptive transfer with an inflammatory stimulus (lipopolysaccharide injection into the calvaria) we further show that these OCP can be recruited to and differentiate at sites of inflammatory osteolysis. Thus, we demonstrate that bone marrow OCP can migrate to stimuli known to promote osteoclastic bone resorption.

Conclusion: We demonstrate that the CD11b$^{-/lo}$ Ly6C^{hi} cKit^{+} bone marrow population is a bona fide OCP. Furthermore, this work provides a model system to identify the chemokine and cytokine requirements for recruiting osteoclasts to sites of inflammatory bone loss in diseases such as rheumatoid and psoriatic arthritis.

Anti Citrullinated Protein Antibodies From Synovial Fluid of Rheumatoid Arthritis Patients Enhance Osteoclastogenesis. Akilan Krishnamurthy[1], Nancy Vivar Pomiano[1], Catia Cerqueira[1], Elena Ossipova[1], Karin Lundberg[1], Ulrike Harre[2], Vivianne Malmström[1], Per Johan Jakobsson[1], Lars Klareskog[3], Georg Schett[2] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Karolinska Institute, Stockholm, Sweden

Background/Purpose: Presence of anti CCP2 antibodies identifies a subgroup of RA patients that are more prone to develop bone erosions. We hypothesized that anti CCP2 IgG might have a direct effect on bone, and thus investigated the effect of anti CCP2 IgG isolated from synovial fluid (SF) of RA patients on osteoclastogenesis and bone destruction in an in vitro system.

Methods: SF (n=26) samples were collected from RA patients with anti-CCP2 IgG levels above 300AU/ml. Total IgG was isolated on Protein G columns, before applied to CCP2 affinity columns, kindly donated by EuroDiagnostica. A pool of the purified anti-CCP IgG fractions, as well as a pool of the corresponding column flow through IgG fractions were tested for the ability to influence osteoclastogenesis and bone destruction. CD14 positive cells isolated by positive selection from peripheral blood of healthy individuals were cultured in the presence of GM-CSF and IL-4 to generate immature dendritic cells. After 6 days of culture, cells were incubated in the presence of RANKL and M-CSF, with or without CCP2 IgG or flow through IgG (at a final concentration of 100ng/ml) for an additional 12 days. Osteoclasts formation was evaluated as total number of multinucleated TRAP positive cells. In parallel cultures were grown on osteologic discs and % of resorbed out of total disc areas were evaluated by computer assisted image analyses

Results: The CCP2 IgG pool significantly increased the formation of osteoclasts. In contrast the pool of the flow through IgG did not stimulate RANKL-driven osteoclastogenesis from immature dendritic cells. When assessing bone destruction CCP2 IgG but not flow through IgG was able to increase the percentage of synthetic bone resorption areas.

Conclusion: Here, we demonstrate that ACPA IgG, isolated from synovial fluid of RA patients, have the ability to enhance the RANKL-driven osteocalstogenesis from immature dendritic cells. Our findings suggest that ACPA might have a direct pathogenic effect in RA associated bone destruction.

32

Development of a Quantitative Model of Endotoxin-Induced Calvarial Bone Erosion Utilizing Micro-Computed Tomography and Pax-It Imaging Analysis Software. Diane Thome, Donald Souza, Aruna Behera, Jie Zheng, Jennifer Swantek and Gerald H. Nabozny. Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT

Background/Purpose: To facilitate an understanding of the biological factors involved in inflammation- mediated bone loss, in vitro systems and murine models of bone loss, such as endotoxin-induced calvarial erosion have been utilized. However, challenges exist with in vivo model robustness, throughput and quantitation of bone erosions. Assessment of erosion is typically determined via micro-computed tomography (MicroCT) but quantitation has been hampered by mouse to mouse variability in bone morphology and lack of consistent robust erosion obtained by endotoxin alone. We set out to develop a robust, quantitative in vivo endotoxin-induced calvarial erosion model that would be amenable for in vivo testing of potential therapeutic agents and would allow for gaining insight into processes involved in inflammatory bone loss.

Methods: Lipopolysaccharide (LPS) was injected with or without receptor activator of NF-kB ligand (RANKL), over the calvaria of mice. On day 5 or 8, mice were euthanized and processed for MicroCT analysis. Skulls were scanned at medium resolution, 70 kVp, 114 μA. Scans were rendered into 3-D. Optimal viewing angles were chosen for creation of TIFF images, which were then examined using Pax-IT imaging analysis software (MIS, Inc), using a 4-pass analysis to generate 4 areas of erosion representing each of the 4 calvarial plates. The values obtained in the 4 areas of erosion were summed to provide a measure of total area of calvarial erosion. For further validation aimed at demonstration of the quantitative nature of the model, in vivo testing of therapeutic agents known to play a role in osteoclastogenesis was implemented.

Results: Five-day dose-response studies using RANKL + LPS in B10.RIII mice resulted in severe erosive events, but dose-dependent relationships were not consistent. We compared 5-day and 8-day models. At Day 8, mice exhibited consistent and strong dose-dependent calvarial erosion with co-administration of 25 μg LPS and 10ug RANKL per mouse. We determined inclusion of RANKL was necessary for optimal erosion. Summating four 8-day studies using B10.RIII mice, co-administration of 25 μg LPS and 10 μg RANKL led to an average area of erosion of 4080 + 259 mm^2, compared to the naïve (untreated) average area of erosion of 506 + 40 mm^2. The microCT/Pax-IT analysis method facilitated reproducible, quantitative results. Importantly, therapeutic agents known to play a role in osteoclastogenesis demonstrated statistically significant reductions in bone erosion further emphasizing the quantitative nature of this model.

Conclusion: We developed a robust, quantitative endotoxin plus RANKL-induced calvarial bone erosion model through use of MicroCT and Pax-IT analysis. This model and quantitation methodology allows for testing therapeutic agents to facilitate understanding of the biological factors and processes involved in bone erosion. The ultimate goal is to impact identification of better therapeutic options for patients.

Novel Targets for Blocking Osteoclast-Mediated Resorption in Inflammatory Disorders. Kevin P. McHugh[1], Tania N. Crotti[1], Jun Li[2], Jon Hill[3], Gerald H. Nabozny[2], Steven R. Goldring[4] and P. Edward Purdue[5]. [1]Center for Advanced Orthopedic Studies, Beth Israel Deaconess Medical Center, Boston, MA, [2]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, [3]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT, [4]Hospital for Special Surgery, New York, NY, [5]Hospital for Special Surgery, Weill Cornell Medical Center, New York, NY

Background/Purpose: Osteoclasts are specialized myeloid lineage cells that mediate both pathologic and physiologic bone remodeling Fully differentiated and functional osteoclasts are found exclusively associated with the bone surface, indicating that interaction with the bone substrate plays a pivotal

role in the regulation of osteoclast biology. Most *in vitro* studies on the formation and activation of osteoclasts have been performed using cells adhered to tissue culture plastic, and there is little information regarding the specific molecular mechanisms by which adherence to the bone surface regulates the terminal stages of osteoclast differentiation. To address this discrepancy, we have compared the transcriptional profiles of osteoclasts generated on a variety of substrates, including authentic bone and have identified the unique molecular signatures that are dependent and independent of integrin beta 3, a prototypical osteoclast regulator of osteoclast function.

Methods: Bone marrow derived macrophages from wild-type and integrin beta 3 deficient mice were cultured in the presence or absence of RANKL on plastic, hydroxyapatite, or calvarial bone discs. RNA was isolated at different stages of osteoclast generation and microarray analysis and pathway mapping were utilized to identify osteoclast signaling pathways regulated by the cytokine RANKL, bone substrate, and integrin beta 3. Pathway analysis was performed using GSEA and Ingenuity pathway analysis.

Results: Microarray analysis revealed RANKL-induced molecular profiles that were uniquely and specifically regulated in osteoclasts differentiated on the authentic bone substrate compared to the other substrates. Pathway analysis revealed coordinated downregulation by bone of a cluster of genes associated with cell cycle progression. The expression level of integrin beta 3, which is induced by RANKL during osteoclast differentiation, is further modulated by culture on the bone substrate. Interestingly, bone regulated genes could be divided into those that were dependent and independent of integrin beta 3.

Conclusion: In addition to cytokines and growth factors, interaction of osteoclasts and their precursor with the bone substrate regulates pathways that are involved in osteoclast formation and activation. Although integrin beta 3 has been regarded as the essential mediator of osteoclast attachment and activation, molecular pathways independent of this integrin also modulate the genetic program during osteoclastogenesis. Analysis of these genes and their pathways provides novel targets and approaches for therapeutic targeting of osteoclast-mediated bone loss in inflammatory and related bone disorders.

Rebamipide Attenuates Pain Severity and Cartilage Degeneration in a Rat Model of Osteoarthritis by Downregulating Oxidative Damage and Catabolic Activity in Chondrocytes. Su-Jin Moon[1], Mi-La Cho[2], Yeon-Sik Hong[3], Sung-Hwan Park[2] and Jun-Ki Min[1]. [1]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]Catholic University of Korea, Seoul, South Korea, [3]Our Lady of Mercy Hospital, Inchon, South Africa

Background/Purpose: The development and progression of osteoarthritis (OA) are now believed to involve inflammation, even in the early stage of disease. Proinflammatory cytokines and chemokines are critical mediators of the disturbed homeostasis in the OA cartilage matrix. Also, OA is associated with oxidative stress. Excessive production of oxidants has been linked with apoptosis of cartilage chondrocytes both in vitro and in vivo. Rebamipide, a gastroprotective agent, exhibits an anti-inflammatory and radical-scavenging property. We investigated the effects of rebamipide on pain generation, cartilage destruction, and various indicators of local oxidative damage and inflammatory status in a monosodium iodoacetate (MIA)-induced OA rat model,

Methods: OA was induced in rats by intra-articular injection of MIA. Oral administration of rebamipide was initiated on the day of MIA injection or 3 days after. Limb nociception was assessed by measuring the paw withdrawal latency and threshold. We analyzed the samples macroscopically and histomorphologically, and used immunohistochemistry to investigate the expression of matrix metalloproteinase 13 (MMP-13), interleukin-1β (IL-1β), hypoxia-inducible factor-2α (HIF-2α), inducible nitric oxide synthase (iNOS), and nitrotyrosine in knee joints. Real-time quantitative reverse transcription-polymerase chain reaction was used to quantify the mRNA for catabolic and anticatabolic factors in human OA chondrocytes.

Results: Rebamipide showed an antinociceptive property and attenuated cartilage degeneration. Rebamipide reduced the expression of MMP-13, IL-1β, HIF-2a, iNOS, and nitrotyrosine in OA cartilage in a dose-dependent manner. Nitrotyrosine expression in the subchondral bone region was decreased in the rebamipide-treated joints. mRNA expression of MMP-1, -3, and -13, and ADAMTS5 was attenuated in IL-1β-stimulated human OA chondrocytes. By contrast, rebamipide induced the mRNA expression of tissue inhibitor of metalloproteinase -1 and -3.

Conclusion: The results show the inhibitory effects of rebamipide on pain production and cartilage degeneration in experimentally induced OA. The suppression of oxidative damage and the restoration of extracellular matrix homeostasis of articular chondrocyte suggest that rebamipide is a potential therapeutic strategy for OA.

Changes in Tibial Bone and Cartilage Structure in a Mouse Surgical Model of Osteoarthritis. Brett A. Tonkin[1], Evange Romas[2], Natalie A. Sims[1] and Nicole C. Walsh[1]. [1]St Vincent's Institute of Medical Research, Melbourne, Australia, [2]St Vincent's Hospital, Melbourne, Australia

Background/Purpose: The destabilisation of the medial meniscus (DMM) mouse osteoarthritis (OA) model is commonly used to study OA joint degeneration. In DMM-OA, the knee is destabilised by transecting the medial-meniscotibial ligament, resulting in increased loading on the medial tibial compartment. Similar to human OA, this leads to articular cartilage damage, subchondral bone accrual and osteophyte formation. We conducted a longitudinal study to define temporal changes in tibial bone structure and cartilage integrity in this model.

Methods: 12-week old male C57BL/6 mice underwent DMM or sham surgery on the right knee; left knees served as contra-lateral controls. In vivo micro-CT was performed prior to surgery, and 4, 8, 12 weeks post-surgery. NRecon and CT-Analyser (Skyscan) were used for micro-CT data reconstruction and analysis; the latter was performed using a novel approach specifically developed for assessing bone of varying mineralisation states. Histologic assessment of cartilage damage was performed using the OARSI scoring matrix for mouse models of osteoarthritis. Statistics: 2-way ANOVA, Bonferroni post-hoc tests. Baseline bone volume/tissue volumes (BV/TV) and bone mineral density were similar in all limbs.

Results: Consistent with an increase in loading, micro-CT analyses demonstrated focal increases in medial subchondral bone in DMM-OA tibiae; BV/TV and bone mineral density were significantly increased at this site compared to sham from 4 weeks post-surgery (p<0.001). In contrast, the lateral subchondral bone BV/TV did not differ between DMM-OA and sham tibiae and the tibial trabecular BV/TV was similar in all limbs, indicating no systemic effects of DMM-OA on bone remodelling. Histologic assessment demonstrated proteoglycan loss in medial articular cartilage in DMM-OA tibiae from 4 weeks post-surgery, with cartilage erosion evident by 8 weeks post-surgery. Interestingly, medial subchondral bone BV/TV was similar between DMM-OA tibiae and their contra-lateral tibiae, suggesting alterations in gait may affect the subchondral bone structure in the contra-lateral knee; an observation also made in human OA. Articular cartilage was intact in these contra-lateral tibiae.

Conclusion: In summary, focal changes in subchondral bone structure occur early in DMM-OA in response to joint destabilisation, and precede proteoglycan loss and erosion of the articular cartilage. Altered bone structure in contra-lateral tibiae of DMM-OA mice, suggests that increased subchondral bone alone, does not necessarily impact overlying articular cartilage integrity, and also serves to highlight the need to include sham-operated mice when using this model.

Role of FK506 Binding Protein 5 in Osteoclast Differentiation. Miho Kimura[1], Tatsuo Nagai[1], Reiko Matsushita[1], Atsushi Hashimoto[2], Toshiyuki Miyashita[3] and Shunsei Hirohata[1]. [1]Kitasato University School of Medicine, Sagamihara, Japan, [2]Sagamihara National Hospital, National Hospital Organization, Sagamihara, Kanagawa, Japan, [3]Kitasato University School of Medicine, Sagamihara

Background/Purpose: RA is a chronic, systemicinflammatory disease characterized by the destruction of bone in the joints. Moreover, it is well appreciatedthat systemic osteoporosis is common in RA.Previous studies have disclosed the enhanced expression of FK506binding protein 5 (FKBP5) mRNA in bone marrow CD34[+] cells in RA. Sincebone marrow CD34+ cells are precursors of osteoclast, it is possible thatoverexpression of FKBP5 might

affect osteoclastgenesis. The current studies thereforeexplore the influences of FKBP5 in osteoclast differentiation from murineRAW264.7 cells.

Methods: We generated stable transfectant clones of FKBP5 gene of murine macrophage RAW264.7 cell line, using a plasmid containing pCAGGS-FKBP5(murine)-IRES-eGFP-pA-Neo. FKBP5 expression was confirmed by Westernblotting and RT-PCR. Osteoclast differentiation was induced by stimulation withreceptor activator of nuclear factor kappa B ligand (RANKL) and was evaluatedby TRAP staining and pit formation assay.

Results: FKBP5 transfectant clones of RAW264.7cell line generated a higher number of TRAP positive multinucleated cells withhigher activity of pit formation than mock transfentants (Figure 1). Theenhancement of osteoclast differentiation of FKBP5 transfectants was only partiallyreversed by transfection of a vector bearing a mutant form of IkB (NFkB super-repressor)(Figure 2). Consistently, the results of luciferase assay and NFkB p65 ELISA revealed only very modestincrease in NFkB activity in the presence of RANKL in FKBP5 transfectants comparedwith mock transfectants. Finally, glucocorticoidenhanced not only the osteoclast differentiation from nontransfectant RAW264.7 cells, but their expression of FKBP5 mRNA in a dose-dependent manner.
Fig 1. Effect of FKBP5 on the differentiation of osteoclasts.
Fig 2. Effect of NF-kB superrepressor on osteoclast differentiation.

Conclusion: These results indicate that FKBP5promotes osteoclast differentiation by a mechanism distinct from NFkBactivation. Moreover, the data also suggest that FKBP5 might play a role in thedevelopment of osteoporosis in RA as well as in glucocorticoid-inducedosteoporosis.

Development of a Mouse Model of Natural Osteoarthritis of Knee by Induction of obesity and Bipedal Walking. Hyun Ah Kim[1], Su Jin Park[2], Eun-Jeong Cheon[2], Hyun A. Jung[1] and Kyeong Min Son[3]. [1]Hallym University Sacred Heart Hospital, Kyunggi, South Korea, [2]Hallym University Sacred Heart Hospital, Kyunggi, South Korea, [3]Hallym University Chunchun Sacred Heart Hospital, Chunchun, South Korea

Background/Purpose: Animal models of osteoarthritis(OA) are used extensively in research of its pathogenesis and in search of disease modifying anti-OA drugs. However, whether current animal models of OA properly represent human OA is a critical question. In devising an animal model which can be extrapolated into human disease, 2 factors, obesity and bipedal walking inherent in human locomotion have been under-reporesented. In this study, we sought to investigate the influence of obligatory bipedal walking on OA development in C57BL6 mice. In addition, by inducing obesity, we observed whether excess body weight acts synergistically with bipedal walking in the development of OA.

Methods: Seventy-two 31 week-old C57BL6 mice were divided into 2 groups and one group was fed with 30% fat diet and another group with control diet for 2 months. After induction of obesity, mice from each group were again divided into 2 groups and obligatory bipedal exercise was induced with specially designed treadmill for 1–4 hours daily in each group, resulting in 4 experimental groups of mice (control, control bipedal, obese, obese bipedal). After 8,10 and 12 weeks of bipedal walking, animals were sacrificed. Knee joints were obtained and graded microscopically according to scoring system recommended by OARSI histopathology initiative and modified Mankin score. Serum levels of cartilage oligomeric matrix protein-(COMP) and type II collagen degradation product were measured with ELISA. Pain behavior was assessed with von Frey fiber test and regularity index measured by catwalk test.

Results: High fat diet for 2 months induced significant weight gain in C57BL6 mice without signs of physical illness. Typical findings of human OA cartilage, including surface fibrillation, proteoglycan matrix depletion and chondrocyte loss began to appear after 8 weeks of exercise in bipedal groups and progressed as the duration of exercise increased. At 12 weeks, vertical erosion to calcifed cartilage typical of mouse OA was observed in none of control and obese groups, and in 66.6 and 100% of control bipedal and obese bipedal groups. OA grading was significantly higher in bipedal groups compared to obese and control groups, and significantly higher in obese bipedal group compared to control bipedal group. OA change in bipedal groups was accompanied by synovitis and subchondroal bone thickening while osteophyte formation was not significantly increased. OA grading was not significantly different between obese and control group. Serum levels of COMP were significantly increased in bipedal groups compared to control or obese group at 8 and 10 weeks of exercise. Threshold for von Frey fiber test decreased significantly in bipedal groups compared to control group while it significantly increased in obese group. Abnormal gait pattern measured by regularity index in catwalk test tended to increase in obese bipedal group compared to other groups.

Conclusion: By induction of obesity and bipedal exercise, natural OA mimicking human OA was induced in C57BL7 mouse. The regulation of relevant signaling mechanism during progression of OA in this model would contribute to the understanding of pathogenetic mechanism of human OA and efficient evaluation of novel therapeutic agents.

Bone Marrow Lesions On Magnetic Resonance Imaging Are Not Associated with Regions of Hypermetabolism in an Animal Model of Osteoarthritis. Arash Panahifar, Jacob Jaremko, Robert GW Lambert, Walter P. Maksymowych and Michael R. Doschak. University of Alberta, Edmonton, AB

Background/Purpose: The underlying histopathological basis for bone marrow lesions (BML) on magnetic resonance imaging (MRI) in osteoarthritis (OA) is unclear, but may be associated with pain and disease progression. BMLs are visible on fat-suppressed T2 and proton density weighted images by MRI, but not by radiography. It has been proposed that BML reflect hypermetabolic areas characterized by bone remodelling. We aimed to test this hypothesis by combining sequential *in vivo* micro-MRI with assessment of bone remodelling using a novel dynamic bone labelling methodology employing elemental strontium detection by electron probe microanalysis (EPMA).

Methods: Post-traumatic osteoarthritis (PTOA) was surgically induced in 9 rats, with an additional 3 rats included as sham-operated controls. *In vivo* micro-MRI images were obtained sequentially at baseline, 4, 8 and 12 weeks after surgery, utilizing 9.4 Tesla T2 and proton density weighted MRI to detect BML. Elemental strontium (sub-therapeutic tracer dosage) was administered daily commencing one day post-surgically until euthanasia at 12

weeks, when strontium incorporation in mineralizing tissues was assessed using EPMA.

Results: EPMA maps at all time-points demonstrated scant strontium deposition on trabecular surfaces and epiphyseal growth plates, but was most prominently incorporated at sites of developing osteophytes - indicating intensive bone turnover and new bone formation (Fig 1). Joint effusion, synovitis and occasional subchondral cysts were readily visible at 4 weeks under MRI (Fig 2), however, only tiny areas of potential BML-like signal (ill-defined increased T2 signal) were detected in this animal model starting at 4 weeks. Those foci were not located at the sites of strontium incorporation, but were seen at the margins of sub-articular cysts that developed between 4–8 weeks.
Fig 1. EPMA map of untreated rat shows hypermetabolic bone remodelling at joint margins leading to the formation of osteophytes (arrows). Growth plates are depicted with arrow heads.
Fig 2. T2-weighted/fat suppressed MRI at: A) baseline B) 8 weeks exhibiting joint effusion (arrows) and synovitis (arrow head).

Conclusion: In this animal model of PTOA, joint degeneration was associated with florid synovitis, joint effusion, minimal subchondral cyst formation, OA-associated loose body appearance and massive osteophyte formation. In humans, such dramatic arthropathy would generally be accompanied by extensive BML. Although all of the other features of severe OA were present in these animals and hypermetabolism was demonstrated at the joint margins, we detected virtually no BML at 9.4T MRI.

SDF-1 Induces Osteoclastogenesis in Rheumatoid Arthritis by Upregulating of RANKL Expression in Synovial Fibroblasts and CD4+ T Cells.

Hae-Rim Kim[1], Kyoung-Woon Kim[2], Bo-Mi Kim[1], Mi La Cho[3] and Sang-Heon Lee[4]. [1]Konkuk University School of Medicine, Seoul, South Korea, [2]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [3]Catholic University of Korea, Seoul, South Korea, [4]Konkuk University Hospital, Seoul, South Korea

Background/Purpose: Stromal cell-derived factor (SDF)-1 is involved in bone destructive process in rheumatoid arthritis (RA) and bony metastasis in malignancy, through inducing angiogenesis, producing matrix-degrading enzymes and increasing survival and migration of osteoclasts. This study aimed to determine the mechanism of SDF-1 on osteoclastogenesis in RA.

Methods: Synovial fibroblasts and CD4+ T cells were isolated from synovial tissues and peripheral blood of RA patients. The expression of SDF-1 and RANKL in the synovial tissues was evaluated using confocal microscopy. After synovial fibroblasts and CD4+ T cells were treated with rhSDF-1, the expression of RANKL mRNA was determined using real-time PCR. Osteoclastogenesis was analyzed in culture of human peripheral blood monocytes with SDF-1. Osteoclastogenesis was also determined after monocytes were co-cultured with rhSDF-1-stimulated RA synovial fibroblasts and CD4+ T cells.

Results: The expression of RANKL mRNA in RA synovial fibroblasts and CD4+ T cells was increased after SDF-1 stimulation. When RA synovial fibroblasts and CD4+ T cells were cultured with neutralizing antibody of TNF-a, the SDF-1-induced RANKL expression decreased, however, inhibition of IL-1b and IL-6 did not affect SDF-1-induced RANKL expression in both cell types. When CD14+ monocytes were cultured with SDF-1 in the absence of exogenous RANKL, the monocytes were differentiated into TRAP+ osteoclasts. Also, the monocytes were differentiated into TRAP+ osteoclasts when they were co-cultured with SDF-1-prestimulated RA synovial fibroblasts or CD4+T cells in the absence of exogenous RANKL.

Conclusion: SDF-1 induced osteoclastogenesis by up-regulating RANKL expression in RA synovial fibroblasts and CD4+T cells and this is mediated by TNF-a. The axis of SDF-1 and RANKL is a potential therapeutic target for bony destructive process in RA.

Syndecan-4 Regulates Activation of WNT Signaling in Chondrocytes.

Jessica Bertrand[1], Richard Stange[1], Giovanna Nalesso[2], Joanna Sherwood[2], Lars Godmann[1], Frank Echtermeyer[3], Francesco Dell'Accio[4] and Thomas Pap[1]. [1]University Hospital Münster, Münster, Germany, [2]Queen Mary University London, London, United Kingdom, [3]University hospital Hanover, Hanover, Germany, [4]William Harvey Research Institute, Barts and the London Queen Mary's School of Medicine and Dentistry, Centre for Experimental Medicine and Rheumatology, London, United Kingdom

Background/Purpose: Blockade of syndecan-4 (Sdc4) signaling protects mice from cartilage degradation in experimentally induced osteoarthritis (OA). Cartilage damage results in changes of chondrocyte phenotype induced by various signaling pathways including the activation of WNT signaling. Here, we hypothesized that Sdc4 modulates chondrocyte phenotype by the specific modulation of WNT signaling.

Methods: In vitro analyses were performed using neonatal wild type (wt) and Sdc4−/− chondrocytes, or a blocking Sdc4 antibody on wt chondrocytes. The influence of 100 ng/ ml WNT3a on glycosaminoglycan (GAG) production was analyzed using alcian blue staining of micromass cultures. The expression of chondrocyte marker genes (aggrecan, collagen 2, MMP13) was measured by quantitative RT-PCR. The effects of WNT3a on canonical

and noncanonical WNT signaling were analyzed using Western Blot detection of β-catenin, pLRP-6, pCamKII and pJNK and a TCF/LEF reporter assay. To investigate the in vivo relevance of the investigated pathways induction of OA in wt and Sdc4−/− mice was performed using the DMM model and stainings for β-catenin and pCamKII were performed.

Results: Micromass cultures revealed a higher basal GAG production by Sdc4−/− than wt chondrocytes. Furthermore, WNT3a stimulation led to a decrease in GAG in wt, which was not observed in Sdc4−/− chondrocytes. These findings were confirmed by a 10× higher basal production of aggrecan and collagen 2 in Sdc4−/− compared to wt chondrocytes. The expression of both genes was 10 fold increased by stimulation with WNT3a, whereas WNT3a led to a decrease in the expression of both genes in wt chondrocytes. Inverse results were found for MMP13, which was significantly less expressed in Sdc4−/− chondrocytes and was not upregulated upon WNT3a stimulation. Western blot analyses of canonical WNT signaling showed that β catenin is strongly reduced and not upregulated upon stimulation with WNT3a in Sdc4−/− chondrocytes. Confirming these findings we also found less phosphorylation of LRP6 and less activation of the TCF/Lef reporter upon WNT3a stimulation in Sdc4−/− chondrocytes. Noncanonical WNT signaling was increased in Sdc4−/− under basal conditions, but decreased upon WNT3a stimulation in Sdc4−/− and increased in wt chondrocytes. The same blockade of canonical and downregulation of noncanonical WNT signaling upon WNT stimulation were obtained by using a blocking Sdc-4 antibody. In vivo analyses of canonical WNT signaling confirmed the decreased basal activation and the missing increase after induction of OA in Sdc4−/− mice.

Conclusion: We conclude from our data that Sdc4 is a major regulator of cellular response to WNT through the prevention of the induction of canonical WNT signaling. Therefore, we suggest that the blockade of Sdc-4 protects from OA induced changes in chondrocyte phenotype by inhibiting WNT induced differentiation of chondrocytes.

Long-Distance Physical Connections Between Chondrocytes; Cell-to-Cell Communication within Articular Cartilage.
Maria Dolores Mayan[1], Raquel Gago-Fuentes[1], Paula Carpintero-Fernandez[1], Patricia Fernandez-Puente[1], Purificacion Filgueira-Fernandez[1], Virgin Valiunas[2], Peter Brink[2], Gary Goldberg[3] and Francisco J. Blanco Garcia[1]. [1]Osteoarticular and Aging Research Group. Rheumatology Division, Biomedical Research Center (INIBIC). Hospital Universitario A Coruña, As Xubias de Arriba 84, 15006, A Coruña, Spain, [2]Department of Physiology and Biophysics. State University of New York, Stony Brook, New York, SC, [3]Department of Molecular Biology. Medical Center Drive, University of Medicine and Dentistry of New Jersey, Stratford, NJ

Background/Purpose: It is believed that chondrocytes in cartilage do not connect each other, as they are isolated inside their lacunae separated from each other by a distance between 5 to 60μm. In the same lacuna can co-exit several chondocytes interacting between them. However, how the chondrocytes from different lacuna interact between each other and timely respond to physical or chemicals stimuli, are largely unknown.

Methods: Scanning Electron Microscope. Immunofluorescence and Immunohistochemistry assays. For total RNA isolation: TRIZOL® method. Electrophysiology techniques: Dual Voltage-clamp methods, whole-cell/perforated patch experiments and study of glucose and oligonucleotides transference. Transwell co-culture system and mass spectrometry (LTQ Orbitrap). SILAC® Dulbecco's Modiffied Eagle's Medium containing L-lisina [$^{13}C_6$] and/or L-arginina [$^{13}C_6$, $^{15}N_4$]. Co-immunoprecipitation experiments. In-gel digestion of immunoprecipitated proteins separated by SDS-PAGE were analysed using the nano-liquid chromatography coupled to mass spectrometry (MALDI-TOF/TOF). The identification of proteins was performed using ProteinPilot™ 3.0 Software.

Results: We have found that articular chondrocytes have long cytoplasmic arms, between 5 to 200 μm in length, that travel across the ECM and physically connect the cytoplasm of cells located in distant lacuna. Our results suggest that chondrocytes communicate through gap junctions (GJ) channels form by different types of connexins. Patch-clamp methods demonstrate that cells interchange small molecules of nucleic acids through GJ channels form by Cx43. Transwell co-culture system combine with mass spectrometry

analysis have revealed that the cytoplasmic projections and GJ play a nutritional role by exchange of glucose and amino acids. On the other hand, alteration on connexin protein levels and longer cytoplasmic arms were found in cartilage from patients with osteoarthrosis (OA).

Conclusion: The results here presented demonstrated that cells in cartilage are physically connected and cell-to-cell communication occurs through GJ channels. These results will radically change the point of view of structural organization of cartilage, mechanotransduction, chondrocytes metabolism and cell signalling. Our results suggest that altered connexin channel functions are probably involved in the physiopathology of OA. These results will likely lead to the development of new therapeutic targets for OA.

Role of Stromal Cell-Derived Factor-1 Alpha Through Smad and MAPK Pathway On Endochondral Ossification.
Gunwoo Kim[1], Seungwoo Han[1], Younkwan Jung[2], Eunju Lee[2], Hyeri Park[2], Shirine E. Usmani[3], Veronica Ulici[3] and Frank Beier[3]. [1]Daegu Fatima Hospital, Daegu, South Korea, [2]Fatima Research Institute, Daegu Fatima Hospital, Daegu, South Korea, [3]Schulich School of Medicine and Dentistry, London, ON

Background/Purpose: The main cellular events of articular chondrocytes during osteoarthritis are a loss of the traits as permanent cartilage, and a transition to hypertrophic chondrocytes responding to excessive stress. Persistant stress in an articular cartilage make the hypertrophied chondrocytes to be dead through apoptosis or form osteophytes through endochondral ossification. The research about molecular mechanisms controlling the endochondral ossification in the growth plate of bone can give us an important clue to understand the molecular mechanisms of osteoarthritis. Stromal cell-derived factor-1 alpha (SDF-1α) is elevated in joint fluid of osteoarthritis and is implicated in osteoarthritis, but it's exact function in chondrocyte biology or molecular mechanisms by which SDF-1α acts still remains unclear. In this study, we investigated the roles of SDF-1α on the endochondral ossification.

Methods: Primary chondrocytes and tibial explants from embryonic 15.5 day-old mice were cultured with PBS vehicle or recombinant mouse SDF-1α. Real-time PCR analysis was performed using Applied Biosystems 7900 HT Real-Time PCR System and TaqMan® Gene Expression Assays for *Sox9*, *Col2a1*, *Acan*, *MMP13, Col10a1*, *Runx2*. Western blot was performed with MMP13, Runx2, type 10 collagen, proliferating chondrocyte nuclear antigen (PCNA), SOX9, p-Smad1/5/8, p-ERK and p-p38. Organ culture tissues were stained with safranin O/fast green and alcian blue/alizarin red. Immunohistochemical analysis was also performed on tissue sections with Caspase3, MMP13, Runx2, type 10 collagen, PCNA and SOX9. For quantification of chondrocyte apoptosis and necrosis, cells were stained with FITC-conjugated annexin V and propidium iodide, and analyzed on a FACS Aria II.

Results: Primary chondrocyte cultures revealed that SDF-1α significantly increased the expression of *Acan*, and *Col10a1* (p$<$0.05). The master regulator gene of chondrocyte hypertrophy, *Runx2*, was also up-regulated in messenger RNA level by SDF-1α (p$<$0.05). SDF-1α increased the protein expression of Sox9, PCNA, Runx2, type 10 collagen. In addition, SDF-1α increased the phosphorylation of Smad1/5/8, Erk and p38 MAP kinase. The proportion of apoptotic cells which has Annexin V-FITC positive staining was 9.35 and 14.77% in untreated and SDF-1α treated cells, respectively. To gain further insights into the role of SDF-1α in endochondral ossification, we examined the effects of SDF-1α in tibia organ cultures. The length of tibias, compared with the controls, was significantly increased in SDF-1α treatment group (p$<$0.05). Immunohistochemical staining of organ cultures showed the expression of PCNA, the marker for chondrocyte proliferation and Sox9 markedly increased in chondrocytes of proliferating zone. In addition to proliferation marker, type 10 collagen, Runx2 and caspase3, were up-regulated in hypertrophic zone by SDF-1α.

Conclusion: Our findings reveal that SDF-1α has an effect on chondrocyte proliferation, hypertrophy and apoptosis by up-regulation of Sox9 and Runx2 through Smad and MAPK pathway during endochondral ossification.

Serum Amyloid A Level in Knee Osteoarthritis: Systemic and/or Local Production and Pro-Inflammatory Properties On Human Chondrocytes and Fibroblast-Like Synoviocytes. Dominique de Seny[1], Gaël Cobraiville[1], Sophie Neuville[1], Edith Charlier[1], Biserka Relic[1], Florence Quesada Calvo[1], Olivier Malaise[1], Denis Malaise[2], Laurence Lutteri[3], Jean-Paul Chapelle[3] and Michel G. Malaise[1]. [1]GIGA Research - University of Liège - CHU Liège, Liège, Belgium, [2]University of Liège, Liège, Belgium, [3]Medical Chemistry - CHU Liège, Liège, Belgium

Background/Purpose: Knee osteoarthritis (OA) is a disease frequently seen in obese patients, but the relationship might be more linked to fat than to weight. A-SAA is an adipokine known to be produced by adipose tissue. Fat surrounding joints, fat within the synovium, as well as mesenchymal progenitor joint cell types might contribute to the presence of A-SAA in the joint cavity. The purposes of this work are: a) to analyse spontaneous production of A-SAA by synovial adipocyte (SA), chondrocytes and fibroblast-like synoviocytes (FLS); b) to detect A-SAA in the synovial fluid (SF) and serum of osteoarthritic patients; c) to analyse the consequences of A-SAA exposure on chondrocytes and FLS on cytokines and metalloproteinase (MMPs) production.

Methods: Synovial adipocytes, primary chondrocytes and FLS were isolated respectively from cartilage and synovial membrane obtained from knee OA patients during joint replacement. A-SAA expression level was studied by ELISA test. A-SAA levels in serum and synovial fluid were measured in knee OA (n=29) compared to matched healthy volunteers (n=35). Cytokines and MMPs were studied by ELISA test.

Results: Endogenous A-SAA secretion was observed by dedifferenciated chondrocytes and fat synovial explants. In primary chondrocytes and FLS, A-SAA was highly and selectively expressed in the presence of glucocorticoïds and in a less extent in the presence of IL-1β. A-SAA SF levels of knee OA patients were each time higher than corresponding serum levels. Both serum and SF A-SAA levels were correlated with the Kellgren-Lauwrence grades. Lastly, *in vitro*, exogenous A-SAA was capable to enhance cytokines (IL-6, IL-8, GRO-a, MCP-1) and MMPs (MMP-1, MMP-3, MMP-13) expression by human chondrocytes and FLS.

Conclusion: 1. A-SAA can be secreted by mesenchymal progenitor joint cell types: synovial adypocyte, chondrocyte and FLS. 2. However, although easily detected in the synovial fuid of osteoarthritis patients, A-SAA corresponding serum levels were each time higher suggesting a predominant systemic origin. 3. Both serum and SF levels of A-SAA were related to the severity of knee OA. 4. Systemic or local A-SAA production may act locally to enhance, at least *in vitro* cytokine and MMPs production. 4. A-SAA is therefore a relevant target for a tight metabolic control.

Inhibition of WNT Signaling Pathway by Sclerostin Maintains Cartilage Homeostasis. Wafa Bouaziz, Thomas Funck-Brentano, Hilene Lin, Eric Hay and Martine Cohen-Solal. INSERM U606 Paris 7 University, Paris, France

Background/Purpose: Cartilage homeostasis is regulated by several mechanisms that influence the anabolic and catabolic tissue balance. Among them, the local activation of Wnt signaling pathway plays a major role in chondrocyte metabolism. Sclerostin, a Wnt inhibitor mainly produced by osteocytes, might regulate chondrocyte differentiation. Therefore, we aim to assess the role of Sclerostin in chondrocyte maintenance.

Methods: Primary murine chondrocytes, isolated from long bone epiphysis of 6 day-old mice, were cultured with or without Wnt3a and in the presence or absence of mouse recombinant Sclerostin (20ng/ml). Proteoglycan release induced by Wnt was quantified in the supernatant of chondrocytes by a colorimetric assay. Activation of the Wnt pathway was analyzed by the translocation of β-catenin (IF, TOP-GAL activity). Chondrocyte proliferation and apoptosis were investigated by BrdU and Tunel assays. The mRNA gene expression of anabolic and catabolic genes was quantified by RT-qPCR. We assessed the expression of Sclerostin in normal and osteoarthritic cartilage in mice with joint instability induced by partial meniscectomy (immunohistochemistry).

Results: The proteoglycan amount released in the chondrocyte culture supernatants was reduced by Wnt while it was rescued in the presence of Sclerostin. Wnt inhibited the gene expression of collagen type II (X18-fold), Sox9 (X140 fold) and Aggrecan (X90-fold) and increased the gene expression of metalloproteinases such as Adamts-4 (X5-fold), Adamts-5 (X5.5-fold), MMP3 (X7-fold) and MMP13 (X6.6-fold). In contrast, Sclerostin significantly prevented the increase of the catabolic genes induced by Wnt (X1.7-fold Adamts-4, $\times$ 1.6-fold Adamts-5, $\times$ 3.4-fold MMP3 and X4-fold MMP13) and rescued partially the expression of the anabolic genes ($\times$ 5- fold collagen type II, $\times$ 6-fold Sox-9 and X11-fold Aggrecan). Furthermore, Wnt enhanced the gene expression of collagen type X (X3-fold) which was abolished by Sclerostin (X1.6-fold). However, Sclerostin failed to exert any effect on the proliferation or the apoptosis of chondrocytes regardless of the presence of Wnt. Finally, we found that Sclerostin is expressed only in the calcified zone of the normal articular cartilage and this is increased after meniscectomy, suggesting that Sclerostin might participate to cartilage damage.

Conclusion: Herein, we showed that the inhibition of Wnt/β-catenin pathway by Sclerostin preserves chondrocyte maintenance by inhibiting chondrocyte catabolism and hypertrophy. These results further indicate the importance of Wnt antagonists in targeting cartilage degradation in OA.

The Effects of Apremilast On Osteoclasts, Osteoblasts, and Osteocytes. Mary Adams and Peter Schafer. Celgene Corporation, Summit, NJ

Background/Purpose: Apremilast (APR), a small molecule specific inhibitor of phosphodiesterase 4, works intracellularly to modulate pro- and anti-inflammatory mediator production in both immune and non-immune cells. Here, the effects of APR on osteoclasts (OCL), osteoblasts (OBL), and osteocytes (OCY) were examined in vitro.

Methods: Human bone marrow mononuclear cells were differentiated into OCL using 10nM dexamethasone and 10nM vitamin D for 7 days. APR (0.1–10 μM) was added along with fresh medium on day 0 and day 3. OCL were stained for tartrate-resistant acid phosphatase 5 (TRAP5), and OBL were stained for alkaline phosphatase. OBL were differentiated into OCY using hydroxyapatite/tricalcium phosphate biphasic calcium phosphate ceramic particles (Graftys BCP), which was placed into polycarbonate filter well inserts and cell culture media changed every 3 days for a total of 28 days. Gene expression was measured by qRT-PCR for the following: receptor activator of nuclear factor kappa-B (RANK), RANK ligand (RANKL), sclerostin (SOST) and osteoprotegerin (OPG). Protein production was measured by enzyme-linked immunosorbent assay.

Results: In OCL cultures, the number of TRAP-5+ cells was reduced by APR by 21%, 49%, and 73% at 0.1 μM, 1 μM, and 10 μM, respectively. In the OCL cultures, APR significantly reduced the levels of sRANKL protein by 25%, 21%, and 38% at 0.1 μM, 1 μM, and 10 μM, respectively. APR 1 μM and 10 μM significantly inhibited RANK gene expression by 30% and 25%, respectively. Alendronate inhibited RANK gene expression by 77%. In OBL, APR reduced sRANKL protein levels by 25% at both 1 μM and 10 μM. Rolipram, alendronate, and sulfasalazine all had no significant effect on sRANKL protein levels in the OBL supernatants. In addition, APR significantly increased OPG protein levels by 42% at 0.1 μM. Overall, APR decreased the sRANKL/OPG protein ratio by 39%, 32%, and 40% at 0.1 μM, 1 μM, and 10 μM, respectively. By comparison, rolipram, alendronate, and sulfasalazine had no effect on the sRANKL/OPG ratio. In OCY, APR significantly reduced sRANKL production by 18%, 14%, and 17% at 0.1 μM, 1 μM, and 10 μM. APR also significantly reduced SOST protein levels by 16%, 20%, and 14% at 0.1 μM, 1 μM, and 10 μM.

Conclusion: These results demonstrate that APR inhibits osteoclastogenesis in vitro at clinically relevant concentrations (0.1–1 μM). This effect was associated with a decrease in sRANKL protein expression by OBL, but also may involve decreased RANK expression on the OCL. Since the osteoclastogenesis studied in this system was driven in part by dexamethasone, these findings indicate that APR may be useful for counteracting the bone catabolic effects of corticosteroids.

Synovitis in Secondary Osteoarthritis Due to Rheumatoid Arthritis: A Proof-of-Concept Study.
Stefan Vordenbäumen[1], Tim Lögters[1], Philipp Sewerin[1], Thomas Pauly[2], Ellen Bleck[1], Paulina Philippski[1], Matthias Schneider[1], Michael Schädel-Höpfner[1] and Benedikt Ostendorf[1]. [1]Heinrich-Heine-University, Düsseldorf, Germany, [2]Rheinisches Rheumazentrum St. Elisabeth-Hospital, Meerbusch, Germany

Background/Purpose: Rheumatoid arthritis (RA) is characterized by considerable synovial inflammation which may result in secondary osteoarthritis (sOA). Primary OA (pOA) occurs in patients without predisposing disorders such as RA and displays varying degrees of synovial inflammation. Although it is conceivable that a major structural difference between sOA due to RA and pOA consists in synovial histology, direct research on such histological differences is limited. Moreover, the search for suitable biomarkers to distinguish OA subtypes is considered an important step in the search for medical treatments. We therefore investigated if synovitis in patients with sOA due to RA is different from pOA, and if it more closely resembles active RA.

Methods: Synovial tissue was collected and snap frozen at time of joint replacement in patients with (1) pOA (n = 8, hip), (2) sOA (defined as RA according to ACR/EULAR criteria plus OA in accordance with 2009 EULAR recommendations for diagnosis of knee OA (n = 4) or 1991 ACR criteria for hip OA (n = 3)), and (3) active RA without any signs of OA (n = 8 metacarpophalangeal joints; mean DAS28 5.2 ± 1.4) by arthroscopically guided biopsy or open synovectomy. Hematoxylin and eosin stained sections were used for determination of the Synovitis Score according to Krenn. Immunohistochemically stained sections were used for semiquantitative scoring or digital image analysis (% stained area) of CD68+ macrophages in a blinded fashion. Comparison of groups was by Kruskal-Wallis Test and Dunn's posthoc test. Correlations between methods of CD68 scoring were according to Spearman.

Results: High-grade synovitis was revealed by conventional histology in patients with sOA and RA (median scores: 6), but not in pOA where mild synovitis was predominant (median score 3; p = 0.012). This was largely due to the subscore on the inflammatory infiltrate with median scores of 3, 2, and 1 in sOA, RA, and pOA, respectively (p = 0.006), rather than subscores for lining layer hypertrophy (2, 2, 2.5; p = 0.013) or density of resident cells (1, 1.5, 2; p = 0.52). There was good agreement between semiquantitative scoring and digital image analysis for CD68 in all compartments (Spearman's R 0.85, 0.8, and 0.7 with p < 0.001 for lining, sublining, and total CD68 scoring, respectively). Significant differences between groups were observed in all compartments with the strongest effect in sublining CD68 staining (median stained area 35.6% vs. 15.3% and 2.9% in sOA, RA, and pOA; p = 0.0031). The difference to sOA in sublining CD68 staining was significant after posthoc analysis for pOA, but not RA. Receiver Operating Characteristic analysis confirmed sublining CD68 staining as an excellent marker to distinguish sOA due to RA from pOA (p = 0.026, AUC 0.96, LR 8).

Conclusion: Synovial tissue analysis reveals considerable inflammation in sOA due to RA. Both conventional histology and CD68 staining confirm that sOA is histologically distinct from pOA and more closely resembles active RA. Sublining CD68 is a suitable biomarker to distinguish both OA entities.

Accumulation of CD34+ Hematopoietic Stem Cells in the Initial Inflammatory Human Fracture Hematoma Is Mediated Via Chemokine Receptor Type 3 Ligands.
Paula Hoff[1], Timo Gaber[1], Martin Hahne[1], Cindy Strehl[1], Katharina Schmidt-Bleek[1], Gerd R. Burmester[2], Gerhard Schmidmaier[3], Georg Duda[1], Carsten Perka[1] and Frank Buttgereit[4]. [1]Charité University Medicine, Berlin, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]Heidelberg University Hospital, Heidelberg, Germany, [4]Charite University Medicine, Berlin, Germany

Background/Purpose: We have previously shown the early phase of human fracture healing to be characterized by hypoxia which promotes inflammation and chemoattraction. Hypoxia is also known to promote proliferation, survival and migration of different stem/progenitor cells like mesenchymal stem cells, endothelial progenitor cells or hematopoietic stem cells (HSC). However, the clinical relevance of hypoxia and inflammation in the early phase of fracture healing for HSC remains unclear.

To investigate immunological events in fracture healing, we quantified (i) CD34+ hematopoietic stem cells and (ii) inflammatory chemokines present in the early (<72h) human fracture hematoma (FH) at the fracture gap. To investigate the chronologic development, we also analyzed hematomas which resulted from the transection of the femur in patients receiving a total hip arthroplasty (THA). The THA-hematomas (THA-H) were defined as a model for fracture hematomas at time point 0h.

Methods: The proportion of HSC in the fracture hematoma from healthy patients (n=42) and patients receiving a THA (n=20) was analyzed by flow cytometry. Secreted factors were quantified by multiplex suspension array.

Results: A fracture destroys bone architecture and vascular network leading to bioenergetically restricted conditions such as hypoxia within the fracture hematoma. Although the cells present have to face those conditions, we were able to find a higher proportion of CD34+ hematopoietic stem cells in the FH as compared to THA-H (7.6±1.5 vs. 3.8±0.5 % of mononuclear cells) indicating proliferation and/or immigration of HSC in the FH. As CD34+ hematopoietic stem cells express CCR3, we investigated the concentrations of its ligands RANTES and Eotaxin. Indeed, both chemokines were present at significantly higher concentrations in the FH as compared to THA-H (RANTES: 16867±1632 vs. 9830±1397 pg/ml, p<0.01; Eotaxin: 327±76 vs. 125±15 pg/ml, p<0.001). We also identified the macrophage migration inhibitory factor (MIF) to be significantly increased in the FH (179431±28538 vs. 21751±2973 pg/ml, p<0.001).

Conclusion: Hypoxia and other bioenergetically adverse conditions in a FH contribute to the induction of inflammation, including the secretion of RANTES, Eotaxin and MIF. We suppose the high concentrations of RANTES and Eotaxin to facilitate the immigration of CD34+ HSC. The initial hypoxic conditions also mediate the secretion of the proinflammatory MIF which has been already shown to be important for successful fracture healing. Thus, the inflammatory microenvironment in the FH is among the crucial factors determining fracture healing.

Tissue Engineering for Articular Cartilage Repair, Culturing Bone Marrow Mesenchymal STEM CELLS On Collagen and Heparan Sulphate Scaffolds.
Adela Helvia Martinez-Sanchez[1], Clara Sanjurjo-Rodriguez[1], Silvia Diaz-Prado[2], Emma Muiños[1], Isaac M. Fuentes[2], Francisco J. De Toro[2], Julia Buján[3] and Francisco J. Blanco[1]. [1]Osteoarticular and Aging Res. Lab. CIBER-BBN. Rheumatology Div. INIBIC-Complejo Hosp. Univ. A Coruña, A Coruña, Spain, [2]Osteoarticular and Aging Res. Lab. CIBER-BBN. INIBIC-University of A Coruña, A Coruña, Spain, [3]Department of Medical Specialties. University of Alcala de Henares, Madrid, Spain

Background/Purpose: The aim of this study was to evaluate the chondrogenic potential of bone marrow mesenchymal stem cells (BM-MSCs) grown on type I collagen and different concentrations of heparan sulfate (HS) scaffolds and the quality of the neosynthesized cartilaginous tissue.

Methods: BM-MSCs were cultured on scaffolds for 16 and 30 days. BM-MSCs were cultured in chondrogenic differentiation medium or DMEM with 20% FBS (Fetal Bovine Serum), in both cases plus 100 nM PTHrP (Parathyroid hormone-related protein). Chondrogenic differentiation and neosythesized cartilage quality were evaluated by histochemical and immunohistochemical analysis, transmission and scanning electron microscopy and molecular biology techniques. Culture supernatants were collected every 3–4 days to determine collagen presence by Elisa assays.

Results: Isolated cells were able to proliferate on type I collagen and various concentrations of HS scaffolds, showing high percentages of positivity for PCNA proliferation marker. Hematoxylin-eosin and Massonxs trichrome stainings showed that BM-MSCs proliferated better when cultured in chondrogenic medium than in growth medium (DMEM 20%). Stimulated cells spread throughout the biomaterials in high percentage, showing a good morphology at both times as well as a wide distribution of ECM. They showed high percentages of positivity for safranin O, Toluidine Blue, aggrecan and type II collagen. Degradation of biomaterials was gradual, as fibers were replaced with ECM. Molecular analysis indicated the *expression*

of cartilage-*characteristic* genes, such as Col II and Sox9. Scanning and transmission electron microscopy confirmed cell presence and ECM synthesis after 16 and 30 days of culture. Cells showed a high number of distended rough endoplasmic reticulum cisternae, electrodense vesicles and mitochondria. Finally, culture supernatants analysis showed the release of collagen in most of the time periods studied, confirming their differentiation and cartilage ECM characteristic compounds.
Figure 1. Analysis of BM-MSCs cultured over type I collagen and HS scaffolds on chondrogenic medium: Histochemical and immunohistochemical staining after 16 days in culture (A-D); transmission electron microscopy analysis after 16 days (E, F) and 30 days (G, H) in culture; scanning electron microscopy after 30 days in culture (I-L). White arrows: cells. Black arrows: ECM.

Conclusion: Our data demonstrated that type I collagen and HS scaffolds were optimal for BM-MSCs growth and differentiation towards chondrocytes-like cells after both 16 and 30 days in chondrogenic medium. Our scaffolds favour phenotypic maintenance of the differentiated cells and synthesis of cartilage-like tissue. *Acknowledgements:* Opocrin, S.P.A; CIBER BBN CB06-01-0040; SAI-UDC; P. Esbrit (Fundación Jiménez Díaz).

The Spatial Energy Expenditure Configuration and Possible Applications in an Experimental Model of Arthritis. Susanne Klatt[1] and Rainer H. Straub[2]. [1]Laboratory of Exp. Rheumatology and Neuroendocrine Immunology, University Hospital, Regensburg, Germany, [2]University Hospital Regensburg, Regensburg, Germany

Background/Purpose: An autoimmune response with differentiation and proliferation of immune cells and the subsequent tissue-directed inflammatory process in the symptomatic phase of the disease are very energy-demanding. As recent calculations demonstrate, the activated immune system needs approximately 20% of the basal metabolic rate. Thus, energy regulation and cellular bioenergetics are of outstanding importance to serve a stimulated immune system. During inflammation, particularly during the chronic process of inflammation in long standing inflammatory diseases like rheumatoid arthritis, a reallocation of energy-rich fuels to the activated immune system is necessary in order to nourish the inflammatory process. Energy consumption and, thus, ATP generation can be measured by studying the consumption of oxygen. The energy expenditure in different organs at different time points has never been investigated during immunization (the symptomatic phase of the disease). We want to find out if, and how the energy expenditure in different organs changes during the course of experimental arthritis.

Methods: A new technique termed "spatial energy expenditure configuration (SEEC)" was developed to demonstrate bodily areas of high energy demand. SEEC is based on removal of tissue during the course of arthritis, and subsequent determination of oxygen consumption. For that purpose, small weighed pieces of the respective organ with a size of 4 mm are placed in 24-well multidishes with integrated oxygen sensors, which allows for non-invasive detection of oxygen consumption *in vitro*. SEEC was established in healthy control animals, arthritic animals and animals that underwent prior sympathectomy. The model of type II collagen arthritis in DBA/1 mice is used in order to develop an arthritic-specific SEEC. We determined the oxygen consumption in spleen, thymus, draining lymph nodes, liver, kidney, brain and knee joints during the course of experimental arthritis for 70 days. The values are given in μmol O_2/l/h and refer to 4 mm sized pieces as percentage of mouse weight.

Results: Concerning the draining lymphoid nodes, we were able to observe a marked increase in oxygen consumption (200 %) during the course of arthritis. Other investigated organs like liver or kidney decrease their oxygen consumption (control vs. arthritic animals).

Conclusion: The SEEC technique enables us to identify locations of high energy demand that are involved in the initiation and continuation of the autoimmune process in an animal model of arthritis. We identified the draining lymph nodes as target organ of the sympathetic nervous system, which will be further investigated. The technique will be applied to other chronic inflammatory disease models in order to detect further participating organs.

Human Chondrocyte Dedifferentiation Is Accompagnied by CD105 Endoglin Expression, ALK-1/Smad1/5 Phosphorylation and Leptin Production - Stimulation by Prednisolone and Aldosterone Through the Glucocorticoid Receptor. Olivier Malaise, Biserka Relic, Mustapha Zeddou, Edith Charlier, Florence Quesada Calvo, Sophie Neuville, Dominique de Seny and Michel G. Malaise. GIGA Research - University of Liège - CHU Liège, Liège, Belgium

Background/Purpose: Leptin, mainly produced by the adipose tissue including fat neighboring the joint, is considered as pro-inflammatory in osteoarthritis (OA). Normal cartilage does not express leptin, while OA cartilage is a potential producer. We recently showed that joint derived-cells such as synovial fibroblasts (SF), but also bone marrow mesenchymal stem cells, were able to spontaneously produce leptin in vitro, strongly enhanced by glucocorticoids (prednisolone and dexamethasone) involving the ALK-1/Smad1/5 pathway as inducer and the ALK-5/Smad2 pathway as inhibitor. In this work, we have tested isolated human chondrocytes (CH) for leptin, leptin receptor (Ob-R) and balance ALK-5/Smad2 - ALK-1/Smad1/5, during dedifferentiation process. Secondly, we have studied if the glucocorticoid prednisolone and the mineralocorticoid aldosterone were able to induce leptin and Ob-R expression as well as the involvement of the glucocorticoid receptor (GR) or/and mineralocorticoid receptor (MR).

Methods: Humain CH were obtained during joint replacement. To detect

surface antigens, cells were immunolabelled with the following anti-human antibodies: CD90-APC, CD105–PE, CD73-PE and analysed on a FACS-CANTO with the CellQuest software. Cells were stimulated with pred-nisolone, aldosterone, mifepristone (GR inhibitor), spironolactone and epler-onone (MR inhibitors) or TGF-β1. Leptin was determined by ELISA, while Ob-R expression, Smad1/5 phosphorylation, Smad2 phosphorylation, ALK-1 and ALK-5 were determined by Western blot.

Results: 1. Primary (PCH) and dedifferentiated (DCH) chondrocytes were similarly positive for CD90 (98.5% $\pm$ 1.5 and 99.4% $\pm$ 0.3, respectively) and CD73 (84.9% $\pm$ 24 and 98.9 $\pm$ 0.2, respectively), whereas DCH significantly increased their CD105 (endoglin) expression (33.7% $\pm$ 21 and 68.6% $\pm$ 17.8, P$=$0,004). **2.** PCH did not produce leptin nor expressed Ob-R. Opposite, DCH significantly expressed leptin and Ob-R. Both leptin and Ob-R expressions were markedly induced by prednisolone. TGF-β1 signifi-cantly downregulated prednisolone-induced leptin and Ob-R. With chondro-cyte dedifferenciation, ALK-5/Smad2 phosphorylation was progressively decreasing, while ALK-1/Smad1/5 phosphorylation was increasing. **3.** Aldo-sterone, as prednisolone, significantly induced leptin and Ob-R expression in DCH, both stimulations significantly downregulated with the GR inhibitor mifepristone, but not with MR inhibitors spironolactone and eplerenone.

Conclusion: 1. PCH expressed low levels of CD105 endoglin, exhibited an ALK-5/Smad2 phosphorylation and did not produce leptin nor Ob-R **2.** On the contrary, DCH significantly increased their capacity to express CD105 endoglin, exhibited an ALK-1/Smad1/5 phosphorylation, and spontaneously produced leptin and Ob-R. **2.** Leptin and Ob-R expressions were inhibited by TGF-β1, but markedly increased by the glucocorticoid prednisolone and the mineralocorticoid aldosterone. **4.** Prednisolone and aldosterone increased leptin and Ob-R expressions through GR but not MR stimulation.

Phosphodiesterase 4 Expression in Rheumatoid Arthritis Synovium and Anti-Inflammatory Effects of Apremilast On Synovial Fibroblasts. Lei Wu, Mary Adams, Stacey Parton and Peter Schafer. Celgene Corporation, Summit, NJ

Background/Purpose: Apremilast (APR), a small molecule specific inhibitor of phosphodiesterase 4 (PDE4), works intracellularly to modulate pro- and anti-inflammatory mediator production in both immune and non-immune cells. The expression pattern of the major PDE4 enzymes was studied in rheumatoid arthritis (RA) synovium, in normal and RA synovial fibroblasts (RASF), and the effects of APR on the production of major destructive proteases by RASF were examined.

Methods: PDE4 protein expression was measured by semiquantitative immunohistochemistry (IHC) in synovium from individuals with RA (n=3) or normal controls (n=2). Quantitative analysis of PDE4 protein expression in normal (n=3) and RASF (n=3) was conducted using an iCyte Laser Scanning Cytometer. Gene expression in normal synovial fibroblasts (n=3), RASF (n=3), peripheral blood mononuclear cells from RA (n=10) and normal controls (n=10) was measured by qRT-PCR. RASF cell cultures (n=3) were treated with 0.1–10 μM APR and then stimulated with 10 ng/mL IL-1β, TNF-α, IL-17, or IL-6 for a total of 24 hours, then supernatants were collected for analysis of matrix metalloproteinase (MMP)1, MMP13, MMP14, and cathepsin K by ELISA.

Results: IHC staining of synovial samples showed that, compared with normal samples, the superficial synoviocytes and subsynovial histiocytes in RA samples had more prevalent and more intense staining of PDE4A, PDE4B, and PDE4D. PDE4B staining was slightly higher in fibroblasts from RA patients than controls, while PDE4D staining was slightly lower. Laser scanning cytometry of normal synovial fibroblasts and RASF showed similar strong cytoplasmic staining of PDE4A in normal and RA samples. PDE4B showed abundant cytoplasmic staining, with 45% higher staining in RASF compared with controls (p<0.01). PDE4D showed moderate to strong cytoplasmic staining in normal samples, but 45% weaker expression in RASF samples (p<0.05). qRT-PCR analysis of PDE4A and PDE4B gene expres-sion was similar in RASF and controls, but PDE4D gene expression was 60% lower in RASF compared with controls (p<0.01). In RASF cell cultures stimulated with IL-1β or TNF-α, APR significantly inhibited MMP1 and MMP14 production, while in the IL-17- or IL-6-stimulated cultures, no significant inhibition of these proteases was observed.

Conclusion: Overall, PDE4 protein expression was stronger in RA vs. normal synovium, largely due to increases in superficial synoviocytes, subsynovial histiocytes, and lymphoplasmacytic cells. In RASF, there is a

shift in expression away from PDE4D toward PDE4B, and APR is capable of inhibiting MMP production in response to the JAK-independent stimuli, IL-1β and TNF-α. This study provides the preclinical rationale for using APR in RA.

The Validity of the Diagnosis Inflammatory Arthritis in Primary Care.
Markus M.J. Nielen[1], Jennie Ursum[1], François G. Schellevis[2] and Joke C. Korevaar[1]. [1]NIVEL (Netherlands Institute for Health Services Research), Utrecht, Netherlands, [2]VU University Medical Centre, Amsterdam, Nether-lands

Background/Purpose: Large population-based databases, such as elec-tronic medical records (EMRs) from patients in primary care, are useful data sources to investigate morbidity and health care utilization in patients with chronic diseases. These databases make it possible to study large groups of patients with the whole range of disease severity in a representative popula-tion, including control groups. In many countries, general practitioners (GPs) have a gatekeeper role for access to specialized care and therefore their EMRs include a complete record of all morbidity of their patients using a uniform methodology. Despite these advantages, EMRs include diagnoses which are usually not validated. In this study we investigated the validity of the diagnosis inflammatory arthritis (IA) in primary care based records.

Methods: Five general practices participating in the Netherlands Infor-mation Network of General Practice (LINH) were visited to collect diagnostic information. EMRs of 219 patients with a diagnostic code of IA (ICPC L88) in the LINH database were systematically reviewed on additional character-istics which are not routinely extracted for the LINH database: free text regarding contacts, prescriptions, medical history, referrals and correspon-dence with medical specialists. Based on coded and free text fields, all patient were categorized in one of the following groups: 1) IA, 2) osteoarthritis (OA), 3) gout, or 4) other diagnosis. These results were used to develop selection criteria to distinguish IA from non-IA in patients with all routinely available information in the LINH database.

Results: From the 219 patients diagnosed as IA in the database, the diagnosis IA was confirmed in 155 patients (70.8%), 18 patients were classified with OA (8.2%), 12 patients with gout (5.5%) and 34 patients with another diagnosis (15.5%). With these findings we developed selection criteria to include IA patients solely based on coded fields, starting with a first selection based on ICPC-code L88, followed by three sequential steps: 1) a repeat prescription for a disease-modifying antirheumatic drug (DMARD) or biological agent, 2) at least four contacts or one episode with a diagnostic code for IA, combined with at least two prescriptions (excluding DMARDs/ biological agents) with the IA diagnostic code, and 3) age at diagnosis $\leq$ 61 years. With these criteria it was not possible to distinguish between IA and OA patients with probable IA. Applying the selection criteria, resulted in a group of 139 IA patients including 77,7% IA patients and 7,9% OA patients with probable IA.

Conclusion: Based on additional diagnostic information, the diagnosis IA from EMRs of patients in primary care is sufficiently valid when using the proposed selection criteria. Since the group of IA patients still contain some patients without an IA related diagnosis, effects from studies with IA patients in primary care could be underestimated.

Comparison of Decision Rules for Identifying Patients with Rheumatoid Arthritis (RA) in Administrative Healthcare Databases. John G. Hanly, Kara Thompson and Chris Skedgel. Dalhousie University and Capital Health, Halifax, NS

Background/Purpose: Identification of RA cases in administrative healthcare databases is used to estimate disease frequency, healthcare utili-

zation and cost for RA. However, the optimal methodology for achieving this is unclear. Our aim was to examine and validate a variety of decision rules which can be applied to administrative databases to identify patients with RA.

Methods: The study was conducted at a single academic medical center and utilized administrative health care data from a geographic area of approximately 1 million people who had access to a universal healthcare system. A retrospective cohort study was performed through the Population Health Research Unit at our institution and utilized data from existing administrative databases. These included information on hospital discharges and physician billings over a 10 year period. Each RA study subject was matched by age and gender to randomly selected control subjects in the same datasets but without a diagnosis of RA or other inflammatory arthropathies. A total of 7 decision rules, some derived from previous studies, were applied to the administrative data to identify RA cases. The sensitivity, specificity, overall accuracy, positive (PPV) and negative (NPV) predictive values of these rules was compared to the diagnosis of a rheumatologist in the academic medical center as determined by chart review.

Results:

Decision Rule	Sensitivity (95% CI)	Specificity (95% CI)	Accuracy (95% CI)
#1 MacLean	87.6 (83.9, 90.7)	34.0 (27.7, 42.8)	71.9 (44.3, 64.0)
#2 MacLean/Lacaille	77.7 (73.2, 81.8)	58.3 (50.3, 66.0)	72.0 (44.9, 59.9)
#3 Shipton	89.1 (85.6, 92.0)	38.0 (30.6, 46.0)	74.0 (49.5, 69.1)
#4 Hospitalization	26.4 (22.1, 31.1)	94.5 (89.8, 97.4)	46.6 (30.7, 39.8)
#5 Rheumatologist	92.7 (89.7, 95.1)	31.9 (24.8, 39.6)	74.7 (53.5, 75.3)
#6 Combination	94.8 (92.1, 96.8)	22.7 (16.5, 29.9)	73.4 (51.1, 77.1)
#7 Single admin	96.6 (94.3, 98.2)	17.8 (12.2, 24.5)	73.2 (52.9, 82.4)

Decision Rule	PPV (95% CI)	NPV (95% CI)
#1 MacLean	76.1 (71.9, 80.0)	54.3 (44.3, 64.0)
#2 MacLean/Lacaille	81.5 (77.2, 85.4)	52.5 (44.9, 59.9)
#3 Shipton	77.3 (73.1, 81.1)	59.6 (49.5, 69.1)
#4 Hospitalization	91.9 (85.2, 96.2)	35.2 (30.7, 39.8)
#5 Rheumatologist	76.3 (72.2, 80.1)	65.0 (53.5, 75.3)
#6 Combination	74.4 (70.3, 78.2)	64.9 (51.1, 77.1)
#7 Single admin	73.6 (69.5, 77.4)	69.0 (52.9, 82.4)

Conclusion: The performance of decision rules for the identification of RA cases in administrative healthcare databases in variable and should be considered when comparing data across studies. This variability may also be used to advantage in study design when, for example, either sensitivity or specificity is the most critical issue for different population health research questions.

Use of Health Plan Data to Assess Feasibility of Large Pragmatic Clinical Trials in Rheumatoid Arthritis. Jeffrey Curtis[1], Lang Chen[1], Fenglong Xie[1], Jie Zhang[1], Kenneth G. Saag[2], Stacey Cofield[3], Kevin L. Winthrop[4], Nicole C. Wright[1] and Elizabeth S. Delzell[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Univ of Alabama at Birmingham, Birmingham, AL, [4]Oregon Health & Science University, Portland, OR

Background/Purpose: Large pragmatic clinical trials (PCTs) are increasingly used to conduct comparative effectiveness research (CER). PCTs typically have simple inclusion/exclusion criteria and hard outcomes (e.g. hospitalized infection, death) but can be challenging to conduct due to the large number of patients required. In the context of planning a safety PCT of the live zoster vaccine in older rheumatoid arthritis (RA) patients receiving anti-TNF therapy, we evaluated the use of various databases to assess the feasibility of recruiting the 4,000 patients needed for the trial (based upon sample size calculations required for 80% power) and to facilitate rheumatology site selection.

Methods: Using multiple health plan and registry databases (e.g. 100% sample of Medicare patients in 2009; younger RA patients enrolled in a commercial insurance health plan), we identified RA patients age >= 50 on the basis of physician diagnoses and receipt of received anti-TNF therapy in the last 90 days of 2009. Extrapolations were made to estimate the prevalence of anti-TNF use for patients whose pharmacy coverage data was not present in the available databases.

These eligible individuals were linked to individual rheumatologists (e.g. using National Provider Identification numbers) and cross referenced against multiple sources of information (e.g. FDA 1572 registry, known participation

in any U.S. RA registry or consortium) that) that allowed identification of rheumatologists with research experience. Rheumatologists were grouped together into practices (offices) using billing information, and offices were sorted by size based upon having the greatest to the least number of eligible patients. The number of rheumatologist offices needed to fully recruit to the needed sample size of 4,000 older RA patients on anti-TNF therapy was plotted as a function of the hypothesized patient recruitment rate (e.g. 25%, 33%, 50%).

Results: More than 150,000 RA patients receiving anti-TNF therapy at the end of 2009 were identified and grouped into the rheumatologists' offices at which they received care. The number of eligible RA patients was plotted for the largest 100 rheumatologists' offices (Figure, solid line). A majority of the largest offices had evidence that they participated in research, as evidence by the dotted line being almost superimposed with the solid line for the first 6000+ patients). Even with a participation rate that was < 30%, fewer than 40 rheumatologist offices with a prior history of clinical research would be required in order to successfully recruit the proposed PCT.
Conclusion: Large health plan and registry databases appear useful to assess feasibility of large pragmatic trials and to assist in selection of rheumatology sites with the greatest number of eligible patients. This novel approach is applicable to trials with simple inclusion/exclusion criteria that can be readily assessed in these data sources.

Accuracy of Canadian Health Administrative Databases in Identifying Patients with Rheumatoid Arthritis Seen by Rheumatologists. Jessica Widdifield[1], Sasha Bernatsky[2], J. Michael Paterson[3], Karen Tu[5], Ryan Ng[3], J. Carter Thorne[4], Janet E. Pope[5] and Claire Bombardier[1]. [1]University of Toronto, Toronto, ON, [2]Research Institute of the McGill University Health Ctre, Montreal, QC, [3]Institute for Clinical Evaluative Sciences, Toronto, ON, [4]Southlake Regional Health Centre, Newmarket, ON, [5]Western University of Canada, St. Joseph's Health Care, London, ON

Background/Purpose: In a predominantly universal single-payer health system, Canadian health administrative data are a valuable tool and increasingly used for research. Few studies have rigorously evaluated the accuracy of administrative data for identifying patients with rheumatoid arthritis (RA). The aim of this study was to validate administrative data algorithms to identify RA in the Canadian province of Ontario.

Methods: We performed a retrospective chart abstraction study among a random sample of 450 patients (unselected by diagnoses), from 18 rheumatologists. Using rheumatologist-reported diagnosis as the reference standard, the RA and non-RA patients were then linked to administrative data to validate different combinations of physician billing diagnoses (P), hospitalization diagnoses (H) and pharmacy (drugs dispensed) data (Rx) to estimate sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) in differentiating RA from non-RA patients.

Results: 149 rheumatology patients were classified as RA and 301 as

non-RA based on our reference standard definition. Most patients were female (77% RA cases; 65% non-RA cases) and the mean (SD) age for RA cases and non-cases was 62 (14) and 58 (17) years, respectively. Among non-RA cases, the most prevalent diagnoses were osteoarthritis (45%), seronegative spondyloarthropathies (19%) and connective tissue diseases (19%). Test characteristics of selected algorithms tested are reported in Table 1. Overall, using any physician-billing algorithms, sensitivity was very high (94–100%). Specificity and PPV were modest to excellent and increased when algorithms required multiple RA claims or claims by a specialist. There was a slight increase in sensitivity and decrease in specificity and PPV as the observation window for multiple billing diagnoses increased from 1 to 2 years. The addition of RA drugs (disease-modifying agents, biologics, or systemic steroids) in our algorithm had little impact on sensitivity but decreased both specificity and PPV.

Table 1. Test characteristics of selected algorithms

Algorithm	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
1 H ever	22	96	75	72
1 P ever	100	60	55	100
2 P in 1 year, any physician	98	77	68	99
2 P in 2 years, any physician	99	76	67	99
2 P in 3 years, any physician	99	75	66	99
3 P in 1 year, any physician	95	86	77	97
3 P in 2 years, any physician	97	82	73	98
3 P in 3 years, any physician	97	81	72	98
1 P ever by a specialist	99	77	68	100
2 P in 1 year at least 1 P by a specialist	98	83	74	99
2 P in 2 years at least 1 P by a specialist	99	82	73	99
2 P in 3 years at least 1 P by a specialist	99	81	72	99
3 P in 1 year at least 1 P by a specialist	95	88	80	97
3 P in 2 years at least 1 P by a specialist	97	86	77	98
3 P in 3 years at least 1 P by a specialist	97	85	77	98
1 H or 3 P in 1 year at least 1 P by a specialist	95	87	78	97
1 H or 3 P in 2 years at least 1 P by a specialist	97	85	76	98
1 H or 3 P in 3 years at least 1 P by a specialist	97	84	75	98
1 P AND 1 Rx	97	68	63	97
2 P AND 1 Rx	97	77	70	98

H: Hospitalization code; P=physician diagnostic code; Specialist = rheumatologist, internal medicine, orthopedic surgeon; Rx: oral corticosteroid, disease-modifying anti-rheumatic drug (DMARD) or biologic.

Conclusion: This study has demonstrated the accuracy of administrative data algorithms for identifying RA. We found that for RA patients that have seen a rheumatologist, physician-billing algorithms are highly sensitive in identifying these patients. Our findings suggest that pharmacy data do not improve the accuracy in identifying RA. One potential limitation is that our sample was drawn from rheumatology clinics, and thus our estimates may not be generalizeable on the population level. However, ongoing work to validate these algorithms in a random sample of 7500 patients from the general population is being done to further support our findings.

A Validated Mathematical Model Using Electronic Health Records to Identify Rheumatoid Arthritis Patients for Observational Studies. Aarat M. Patel[1], Ilinca D. Metes[2], Larry W. Moreland[3], Melissa Saul[3], Stephen R. Wisniewski[4] and Marc C. Levesque[3]. [1]Univ of Pittsburgh Med Ctr/Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA

Background/Purpose: To develop and validate a search algorithm with a high specificity and sensitivity to identify rheumatoid arthritis (RA) patients in a large health care system linked by an electronic health record (EHR) system.

Methods: Records from the Medical Archival Retrieval System (MARS) at the University of Pittsburgh Medical Center (UPMC) were used to identify potential RA patients. We searched the UPMC MARS system for subjects with a 714.0 International Classification of Diseases, 9th revision (ICD-9) code and used a recursive partitioning method to develop a search algorithm for the identification of RA patients; the recursive partitioning method used the 714.0 ICD-9 code and tested 35 additional variables (serology, inflammatory markers, medications and specific words in physician notes). At each step during the development and validation of the algorithm, patients were classified by the algorithm into those likely or unlikely to have RA and representative sets of these patient records were reviewed to determine whether subjects met ACR/EULAR RA classification criteria.

Results: We initially analyzed the effect of the clinical setting (inpatient vs. outpatient rheumatology clinic) on the identification of RA patients. For inpatient subjects, there was a low PPV of a 714.0 ICD-9 code for the identification of RA patients (39.0%) whereas for outpatient-rheumatology subjects there was a high PPV of a 714.0 ICD-9 code for the identification of RA patients (87.3%), (n=95, p<0.0001; Fisher's exact test). When the records of outpatient-rheumatology patients with and without a 714.0 ICD-9 code were analyzed (N=400), the sensitivity, specificity, PPV and NPV of a 714.0 ICD-9 code was 98%, 88%, 87% and 98%, respectively. Using recursive partitioning a 3 variable algorithm was identified 1.) 714.0 ICD-9 code, 2.) ratio of the words "rheumatoid arthritis" per rheumatology visit and 3.) ratio of "RA" per rheumatology visit improved the specificity for identifying RA patients. The sensitivity, specificity, PPV and NPV of the algorithm was 93%, 95%, 94% and 95%, respectively (n=400). Validation of this algorithm with analysis of an additional 400 subjects produced similar results (95%, 96%, 96%, 95%, respectively). Using this algorithm to analyze all unique outpatient-rheumatology patients in the 2009 calendar year (n=5,859) resulted in the identification of 1,495 RA patients. The final validation step with a sample of these subjects (n=400) resulted in a sensitivity, specificity, PPV and NPV of 93%, 96%, 93% and 96%, respectively.

Conclusion: The ICD-9 code for RA (714.0) alone was not reliable for identifying RA patients in the inpatient setting and had suboptimal specificity in the outpatient rheumatology setting. We developed and validated a simple algorithm using recursive partitioning that used 3 variables to identify RA patients. This simple algorithm, which is now validated for an entire calendar year, represents a substantial improvement in terms of sensitivity and specificity over existing published algorithms. Using an EHR and this electronic search algorithm will enable large-scale comparative effectiveness studies on the treatment and management of RA in "real-world" clinical settings.

A British Survey of Time to Presentation and Treatment of Rheumatoid Arthritis in Subjects of Black and Minority Ethnic Origin. Sonia Panchal[1], Ash Samanta[1], Arumugam Moorthy[1], Sawson Hayat[2], Ira Pande[2], Adewale O. Adebajo[3] and Kuntal Chakravarty[4]. [1]University Hospitals of Leicester, Leicester, United Kingdom, [2]Nottingham University Hospitals, Nottingham, United Kingdom, [3]Academic Rheumatology Group, D, Sheffield, United Kingdom, [4]University of Bedfordshire Post Graduate Medical School, Romford, United Kingdom

Background/Purpose: National guidelines mandate urgent referral of rheumatoid arthritis (RA) for specialist treatment if more than three months from symptom onset; initial combination therapy with disease modifying anti-rheumatic drugs (DMARDs) and only if not appropriate, monotherapy with rapid escalation[1]. A national audit of patients with RA conducted by The British Society for Rheumatology (BSR) showed that there were considerable delays from symptom onset to referral, from referral to specialist review, and initiation of DMARD therapy[2]. There were also wide variations regionally and a perception that there may be a differential between black and minority ethnic (BME) groups in terms of time of onset of symptoms to referral to a specialist centre and starting DMARDs. This study aimed to investigate the above features in centres that are geographically located within areas containing a high BME population and to compare this with the white Caucasian population.

Methods: Four centres were identified based on a high local BME population. Data were collected prospectively for potential time delays in the following areas: symptom onset to GP (general practice) consultation; GP to specialist referral; referral to specialist review; diagnosis to DMARD treatment, combination therapy, and biologic therapy. All consecutive BME and Caucasian RA patients on DMARDS attending outpatient clinics were included over an 8 week period.

Results: In total 189 patients were analysed. 111 (59%) were Caucasian vs. 78 (41%) BME (60 (77%) Asian, 2 (3%) Afro-Caribbean). 146 (77%) were female with an average age between 50–59 years, and average disease duration of 6–10 years. 30 (38%) of the BME group compared with 40 (36%) of the Caucasian group had more than six-months time delay from symptom onset to specialist referral. Time from referral to specialist review greater than three months was 10 (13%) BME group vs. 21 (19%) Caucasian group. 16 (21%) BME group vs. 18 (16%) Caucasian group had a delay of more than three months from diagnosis to initiation of DMARD therapy. Interestingly, 58 (74%) of the BME group had monotherapy in comparison to 79 (71%) of the Caucasian group. 17 (22%) of the BME group had biologic therapy with an average of 2–5 years post diagnosis, whilst 20 (18%) of Caucasians had biologic therapy.

Conclusion: Our results importantly highlight a significant delay in time from presentation and initiation of treatment for RA patients of BME origin. There may be a range of ethnically specific culturally centred reasons for such delay[3]. Culturally different migrant and non-migrant internal or national minorities may inadvertently be subjected to indirect discrimination and exclusion. It is paramount to gain a deeper understanding of potential underlying cultural differences in order to educate and facilitate appropriate healthcare and support within minority populations. The empowerment of patients of minority communities through culturally appropriate health education initiatives can encourage such persons to seek early medical advice and treatment thereby promoting equity amongst diverse populations.

5 Million Patients and Not 0.34% Is Worrisome: Burden of Rheumatoid Arthritis in India Based On a Bone and Joint Decade India Community Oriented Program for Control of Rheumatic Disease. Arvind Chopra[1], R. Ghorpade[1], S. Sarmukkadam[2], VL Joshi[1], AJ. Mathews[3], L. Gauri[4], A. Rahim[5], K. Datta[6], S. Chaturvedi[7], B. Thakuria[8], A. Mahajan[9], R. Singh[10], A. Ghosh[11], R. Handa[12], M. Saluja[1], A. Venugopalan[1], V. Kunjeer[1], B. Paul[5], S. Pal[6], K. Wangjam[10], T. Kumar[11] and K. Mahendranath[13]. [1]Center for Rheumatic Diseases, Pune, India, [2]BJMC, Pune, India, [3]Government Medical College Hospital, Trivandrum, India, [4]SP Medical College, Bikaner, India, [5]Calicut Medical College, Calicut, India, [6]Advance Rheumatology Clinic, Hyderabad, India, [7]FRCH, Pune, India, [8]Guwahati Medical College & Hospital, Guwahati, India, [9]Government Medical College, Jammu, India, [10]Regional Institute of Medical Sciences, Imphal, Manipur, India, [11]Institute of Post Graduate Medical Education and Research, Kolkata, India, [12]AIIMS, New Delhi, India, [13]Rheumatology Clinic, Bangalore, India

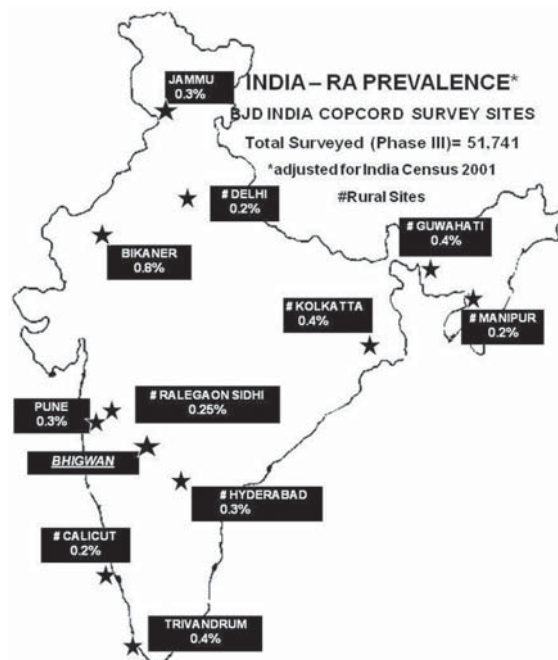
Background/Purpose: The 1 % prevalence of RA Worldwide is a deep rooted ancient dogma. None of the recent WHO ILAR COPCORD (Community Oriented Program for Control of Rheumatic Diseases) surveys Worldwide support this contention (Best Pract Res Clin Rheumatol 2008; 22:583–604); Cuba & Mexico being exception (J Clin Rheumatol 2012;18: 167-69). COPCORD Bhigwan (India) reported (J Rheumatol 2002; 29: 614-21) an unusually high rural prevalence of RA 0.55% (ACR 1987) and encouraged a country wide exploration. We now present the results of RA prevalence in India.

Methods: We adopted the COPCORD Bhigwan model to complete non random population surveys (Stage I) at 12 sites (Fig)as per standard COPCORD methods (http://www.copcord.org); a cross sectional house to house population screen to identify cases with current/past pain (phase I) and evaluate (phase II) respondents for pain, impact, quality of life and rheumatology evaluation (phase III). All patients were examined by rheumatologists. 51,741 populations qualified for the current analysis. The classification/diagnosis was essentially clinical with minimal supporting investigations. Indigenously designed Windows based program was used for a central data entry and analysis using standard stat software.Data was further adjusted for age-sex standardization to India census population 2001; 95% confidence intervals shown in parenthesis. Site sample sizes, pain rates and prevalence of several rheumatic disorders are submitted in another abstract.

Results: 198 patients (83% women) were classified as clinical RA. The crude point prevalence was 0.38 (0.30, 0.44) and the adjusted rate was 0.34 (0.08, 0.79). The overall female to male ratio was 5:1. Patients were distributed in various age groups (years); 2% in 15–24, 42% in 25–44, 40% in 45–64, and 16% in 65+ age group. The adjusted prevalence rate of RA for each of the survey sites is shown in the figure. Except for the prevalence of 0.8% in a site in the state of Rajasthan (West India), a large number of sites in the rest of the country seem to be in the range 0.2 to 0.3%. However, even

a low prevalence of 0.34% would mean that India (1.2 billion populations) has probably 5 million patients.

COPCORD surveys are limited by lack of investigations and follow up. In India, RA may be overestimated clinically because of a large pool of seronegative inflammatory arthritis (RA mimics). COPCORD Pune (India) reported a crude point prevalence of 0.45% RA which when reclassified as per ACR 1987 criteria and further standardized was reduced to 0.19% (J Rheumatol 2009; 36: 614-22).

We believe that the true prevalence of RA in India is likely to be even less than 0.34% and that may bring some solace.


Conclusion: Though the prevalence of RA 0.34% in India is several folds less than the elusive 1% that has been taught for years, the burden of RA nonetheless is extremely high and needs to be seriously addressed at a national level.

[1]Center for Rheumatic Diseases, Pune, India, [2]B J Medical College, Pune, India, [3]Government Medical College Hospital, Trivandrum, India, [4]SP Medical College, Bikaner, India, [5]Calicut Medical College, Calicut, India, [6]Advance Rheumatology Clinic, Hyderabad, India, [7]FRCH, Pune, India, [8]Guwahati Medical College & Hospital, Guwahati, India, [9]Government Medical College, Jammu, India, [10]Regional Institute of Medical Sciences, Imphal, Manipur, India, [11]Institute of Post Graduate Medical Education and Research, Kolkata, India, [12]AIIMS, New Delhi, India, [13]Madras Medical College, Chennai, India, [14]ERC Unit, Chennai, India, [15]Rheumatology clinic, Bangalore, India

Background/Purpose: The maiden COPCORD (Community Oriented Program for Control of Rheumatic Diseases) population survey in village Bhigwan (Pune) findings proposed a high burden of pain and arthritis in India (J Rheumatol 2002; 29: 614-21). We carried out a national survey using COPCORD Bhigwan fast track model.

Methods: COPCORD population survey (Stage I) was completed in 3 parallel phases: 1(cross sectional house to house survey for demographics and screening), 2 [record pain (human mannequin) and disability (validated Indian HAQ), 3 (standard of care rheumatology evaluation). 12 volunteer rheumatologists chose non-random sites (Fig) and survey sample as per COPCORD diktat (http://www.copcord.org). Population was essentially screened for current (last 7 days) and/or past pain in joints or musculoskeletal (MSK) soft tissues. Trained volunteers from the community completed phases 1 & 2. The classification/ diagnosis were essentially clinical with minimal supporting investigations. Indigenously designed Windows based program was used for a central data entry and analysis using std stat software (SPSS & Epi Info v6). Prevalence rates were age-sex standardized to India census population 2001; 95% confidence intervals shown in parenthesis. Response rate at all sites > 80%.

Results: 56,541 populations surveyed.16% (14.2, 18.3) self reported MSK pain(current &/or past, any site); frequent sites-knee 8.5%, back 6.2%, ankle/feet 3.8%,shoulder 3.2%, elbow 2.9%, hand/wrist 2.9%, neck 1.5%. The frequency of pain at several sites and overall in rural was nearly twice urban. Self reported MSK pain was the predominant ailment in the community.

**Table shows the point prevalence of selected clinical disorders.**

Disorder	Prevalence
Rheumatoid arthritis	0.34 (0.08, 0.79)
Undifferentiated inflammatory arthritis	0.22 (0.05,0.68)
Seronegative Spondyloarthritis	0.23 (0.05,0.68)
Ankylosing Spondylitis	0.03 (0.02, 0.05)
Osteoarthritis, any form	4.39 (3.30,5.61)
Osteoarthritis knee	3.34 (2.43, 4.47)
Gout	0.04 (0.03, 0.05)
Soft tissue rheumatism, any form	1.31 (0.77, 2.11)
Ill defined symptoms, non specific arthralgias	4.25 (3.23, 5.53)
Lupus & other connective tissue disorders	0.02 (0.01, 0.03)

Background/Purpose: Rheumatoid arthritis (RA) is estimated to be one of the leading causes of non-fatal burden in the world. However, data from developing countries including Latin America are limited, and the real burden of inflammatory arthritis in this population is unknown. The aim of our study was to evaluate the impact of disease activity on health-related quality of life (HRQOL) using a large cohort of Argentinian patients with early inflammatory arthritis.

Methods: We included patients with diagnosis of early RA (American College of Rheumatology 1987' criteria) or undifferentiated arthritis (UA) belonging to CONAART (Consorcio Argentino de Artritis Temprana - Argentine Consortium for Early Arthritis). CONAART is a prospective cohort of Argentinian patients with diagnosis of early arthritis (<2 years of disease duration). Data are collected every 3 months, including Health Assessment Questionnaire (HAQ), Clinical Disease Activity Index (CDAI) and pharmaco-economic data. The generic EuroQoL (EQ-5D) was derived from HAQ and patient's visual analogue scale of pain using previously validated regression models. Patients were stratified and compared according to diagnosis and disease activity levels (CDAI). All comparisons were adjusted for sex, age and comorbidities.

Results: We included 777 patients (RA=628; UA=149). Mean follow-up 14.5 ± 10.1 months (990 patients-year). Mean age was 48 ± 14 years, 82% were female and disease duration was 8.6 ± 6.3 months. On baseline visit CDAI and HAQ were 24.6 ± 14.4 and 1.2 ± 0.9, respectively. Mean EQ-5D score during follow-up was 0.74 ± 0.13. No difference regarding HRQL was observed between RA and UA (0.73 ± 0.12 and 0.75 ± 0.13, respectively). EQ-5D showed a negative correlation with disease activity (rho spearman=-0.74, p<0.0001). Mean EQ-5D in patients in remission was 0.91 ± 0.04, low disease activity=0.82 ± 0.81, moderate disease activity=0.72 ± 0.09 and high disease activity=0.61 ± 0.11 (Graph 1). Considering remission as the ideal situation, patients with early RA or UA in low disease activity entail a disease burden of 0.07 (95%CI= 0.06 – 0.08) quality-adjusted life-years (QALYs) after one year of follow-up. In similar conditions, patients with moderate disease activity lose 0.17 (95%CI= 0.16–0.18) QALYs, and those with high disease activity lose 0.28 (95%CI = 0.27–0.30) QALYs.

Graph 1. Health-related quality of life stratified by disease activity and diagnosis

Health-related quality of life stratified by disease activity and diagnosis
Conclusion: Regardless of the diagnosis of UA or RA, patients with early inflammatory arthritis and active disease inflict a substantial disease burden. The impact of arthritis in HRQL showed a linear relationship with disease activity level. This remarks the importance of an early and aggressive treatment in patient with this condition.

61

Role of Health Literacy in Population Estimates of Musculoskeletal Disorders. Catherine L. Hill[1], Sarah L. Appleton[2], Tiffany K. Gill[3], Julie Black[4], Rima E. Rudd[5] and Robert J. Adams[2]. [1]The Queen Elizabeth Hospital, Woodville, Australia, [2]University of Adelaide, Woodville South, South Australia, Australia, [3]University of Adelaide, Adelaide, South Australia, Australia, [4]Arthritis SA, Marleston, Australia, [5]Harvard School of Public Health, Boston, MA

Background/Purpose: Disease diagnosis carries with it implications for self care and for healthful action. Public health campaigns, for example, are regularly launched to raise awareness of disease symptoms and new developments in medication and self management. In addition, self-report of musculoskeletal conditions is often used to provide population prevalence estimates and to determine disease burden and influence policy. However, self-report of certain conditions such as rheumatoid arthritis (RA) and osteoporosis are frequently inaccurate, suggesting that there is inadequate communication to the patient of their diagnosis. Such errors have consequences for treatment of those with musculoskeletal conditions, public health planning, and public policy.

Purpose: To examine the association between functional health literacy (FHL) and three commonly self-reported musculoskeletal conditions in a South Australian representative population survey

Methods: A cross-sectional random population survey was conducted in 2008 of 2824 participants aged 15 years and over, using an interviewer-administered questionnaire. Functional health literacy was measured using the Newest Vital Sign (scored as inadequate FHL (score 0–1), at risk of inadequate FHL (2–3) and adequate FHL (4–6)). Participants were also asked about self-reported medically diagnosed arthritis (including subtype; rheumatoid arthritis, osteoarthritis, 'other', 'don't know'), gout, and osteoporosis. Multiple logistic regression was performed using adjustment for age and sex.

Results: Of the 2824 participants, the prevalence of self-reported medically-diagnosed arthritis, gout and osteoporosis were 25.2%, 4.9% and 5.6%, respectively. The prevalence of those at-risk for inadequate FHL was 24.0% and of a high likelihood of inadequate FHL was 21.0%. However, over 50% of respondents with arthritis or gout had at risk or inadequate FHL, increasing to 70% of those self-reporting osteoporosis. After adjustment for age and sex, respondents in the arthritis subgroup of 'don't know', and

self-reported osteoporosis were significantly more likely to have inadequate FHL than the general population (Table 1).

Table 1. Associations of musculoskeletal conditions with limitations in functional health literacy.

	At risk or inadequate FHL		Inadequate FHL	
	% (n)	Adjusted*	% (n)	Adjusted*
All arthritis				
No	41.0%	1.00	18.1%	1.00
Yes	56.9%	1.14 (0.93-1.38)	29.4%	1.01 (0.81-1.27)
Arthritis type				
No arthritis	41.0%	1.00	18.1%	1.00
OA	51.0%	0.77 (0.58-1.02)	26.9%	0.81 (0.59-1.13)
RA	58.2%	1.46 (1.01-2.14)	22.4%	0.82 (0.52-1.29)
"don't know" type	65.0%	1.58 (1.18-2.13)	37.5%	1.47 (1.08-2.00)
other	40.6%	0.71 (0.34-1.50)	18.2%	0.63 (0.24-1.65)
Gout				
No	44.3%	1.00	20.3%	1.00
Yes	59.1%	0.96 (0.66-1.41)	35.5%	1.09 (0.74-1.62)
Osteoporosis				
No	43.5%	1.00	19.5%	1.00
Yes	70.3%	1.67 (1.15-2.44)	42.1%	1.62 (1.13-2.33)

*Adjusted for age and sex

Conclusion: This cross sectional population survey indicates a substantial burden of low health literacy amongst people with musculoskeletal disease in the general population. Those participants who 'don't know' the type of arthritis or who self-report osteoporosis are more likely to have poor FHL, suggesting that inadequate health literacy may influence communication and understanding of musculoskeletal diagnoses. This has implications for provider patient communication, individual health care, population estimates of musculoskeletal disease, and for the potential impact of public health messages.

62

Clinical Implication of Rheumatoid Factor Formation According to Various Hepatitis B Virus Infection Status and Vaccination. Sang Tae Choi[1], Hyun Woong Lee[1], Jung-Soo Song[2], Soo Kon Lee[3] and Yong-Beom Park[3]. [1]Chung-Ang University School of Medicine, Seoul, South Korea, [2]Chung-Ang University College of Medicine, Seoul, South Korea, [3]Yonse University College of Medicine, Seoul, South Korea

Background/Purpose: Rheumatoid factor (RF) is produced as a result of polyclonal B cell activation, but the reasons for its production are still unknown. RF positivity can be seen in several diseases other than rheumatoid arthritis (RA), such as other rheumatic diseases and viral infection as well as in normal individuals. It was reported that RF was present in hepatitis B virus (HBV) infection. However, the types of antigens or antibodies of HBV and the hepatitis B viral load that play an important role in the development of RF remain obscure. In this study, we investigated the RF positive rates and titers of RF according to various HBV infection status and vaccination, and the relationship between the titers of RF and serum HBV DNA levels in HBV endemic areas.

Methods: The subjects were 13,670 individuals who visited the Severance Hospital Health Promotion Center in Seoul, Korea, for routine health check-up from January 2004 to December 2004. The samples were tested for RF (IgM type) and HBV infection by screening for the presence of HBsAg, anti-HBs (IgG type), and anti-HBc (IgG type). The HBeAg, anti-HBe (IgG type), and HBV DNA were analyzed in subjects positive for HBsAg. The RF positive rates and the titers of RF were evaluated based on the presence of each HBV viral marker, and correlation between the titers of RF and the serum HBV DNA levels was assessed.

Results: RF was positive in 3.5% of all subjects, and HBsAg was positive in 4.3%. HBsAg was positive in 21.7% of RF positive subjects. The HBsAg positive group had higher RF positive rate than negative group (17.5% vs 2.9%, $p < 0.001$). The RF positive rate was lower in those who had anti-HBs

after HBV vaccination than in HBsAg positive subjects (2.7% vs 17.5%, $p <$ 0.001). Among HBsAg positive subjects, the RF positive rate in the anti-HBs positive group was higher than that in the anti-HBs negative group (30.3% vs 16.8%, $p = 0.047$). However, there was no significant difference in the RF positive rate between the anti-HBc positive and negative groups, and HBeAg positive and negative groups. In multiple logistic regression analysis, the RF positive rate was increased in positive HBsAg (PR = 7.82, 95% CI 5.74 to 10.67, $p < 0.001$), female sex (PR = 1.21, 95% CI 1.01 to 1.46, $p = 0.042$) and older age (PR = 1.01, 95% CI 1.001 to 1.019, $p = 0.027$). Among the RF positive patients, the titer of RF in HBsAg positive patients were higher than those in HBsAg negative patients (159.7 ± 217.1 IU/mL vs 83.0 ± 179.2 IU/mL, $p = 0.001$). However, there were no significant differences in the titer of RF between anti-HBc positive and negative groups, and between HBeAg positive and negative groups. The load of HBV DNA may be closely correlated with the titer of RF in patients with chronic hepatitis B ($r = 0.508$, $p = 0.005$).

Conclusion: HBV infection is an important cause of the false positive RF in HBV endemic area. Especially hepatitis B viral load may be associated with the titer of RF. Therefore, HBV vaccination may decrease the risk of RF formation.

The Association Between Silica and the Risk of Anti-Citrullinated Protein Antibody Positive RA in the Malaysian and Swedish Epidemiological Investigation of Rheumatoid Arthritis Studies. Abqariyah Yahya[1], Camilla Bengtsson[1], Lars Klareskog[2], Chun Lai Too[3], Shahnaz Murad[4] and Lars Alfredsson[1]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden, [4]Institute for Medical Research, Kuala Lumpur, Kuala Lumpur, Malaysia

Background/Purpose: Silica exposure has been associated with an increased risk of developing ACPA+ (anti-citrullinated protein antibody) RA, especially among smokers (1). These findings were based on a Caucasian population. In this study we aimed at examining the association between silica exposure (and its interaction with smoking) and the risk of ACPA+ RA in an Asian population. In addition, we examined possible interaction between silica exposure and the major genetic risk factor for ACPA+ RA, i.e. the HLA-DRB1 shared epitope (SE) alleles, in both a Caucasian and an Asian population.

Methods: Data from the Malaysian EIRA (MyEIRA) and its sister study, the Swedish EIRA study were used. In total, 149 incident cases and 213 controls from MyEIRA and 823 incident cases and 1161 controls from EIRA, all men, were included. Self-reported silica exposure, defined as exposure to stone dust, rock drilling or stone crushing were taken into consideration. Smoking was defined as ever/never cigarette smokers. We examined the association between exposure to silica with the risk of ACPA+ RA, by calculating odds ratios (OR) with 95% confidence intervals (CI), using logistic regression. All analyses were adjusted for age and residential place. Interaction was evaluated by calculating the attributable proportion (AP) due to interaction and its 95% confidence interval (CI).

Results: In MyEIRA, an increased risk of ACPA+ RA (OR=2.88, 95%CI 1.02–8.14) was observed among those exposed to silica. Ever smokers exposed to silica had a particularly high risk of ACPA+ RA (OR= 8.27, 95%CI 1.64–41.44), compared with never smokers not exposed to silica. No association was found regarding ACPA- RA. When data from both studies were combined, we found that silica-exposed individuals with SE alleles had almost eleven times higher risk of ACPA+RA however the interaction was insignificant (AP=0.27, 95%CI -0.09–0.64).

Conclusion: Silica exposure in combination with smoking among men increased the risk of ACPA+ RA in an Asian population. These data extend previous results based on a Caucasian population reported from the Swedish EIRA study (1). In the combined analyses of these studies, there was an indication of interaction between silica and SE, though it was insignificant. We believe that this finding strengthen the hypothesis of modifiable lung exposure and risk for ACPA+ RA.

Use of Moist Snuff and the Risk of Developing Rheumatoid Arthritis; Results From the Swedish Epidemiological Investigation of Rheumatoid Arthritis Study. Lars Alfredsson[1], Lars Klareskog[2] and Camilla Bengtsson[1]. [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden

Background/Purpose: Smoking is the major known environmental risk factor for RA, and notably this risk factor is exclusively seen in ACPA-positive RA. Whether this increased risk is due to nicotine or other substances of inhaled tobacco smoke is unclear. Smokeless tobacco contains nicotine and is often used as an alternative to smoking. The role of smokeless tobacco in the etiology of RA has to date only been reported from a Swedish study based on male construction workers, where no association was observed between the use of moist snuff and the risk of RA[1]. However, whether smokeless tobacco is related to the ACPA-positive or ACPA-negative RA remains to be elucidated. In this report we aimed at investigating the association between the use of moist snuff and the risk of RA, and if this exposure has different impact on ACPA-positive and ACPA-negative disease.

Methods: Data from EIRA (Epidemiological Investigation of Rheumatoid Arthritis), a population-based case-control study from Sweden, was used. In total, information from1962 incident cases and 2247 randomly selected controls (matched on age, sex and residency), aged 18–70 years, was analysed. Ever, current and past moist snuff users were compared with never users. We calculated odds ratios (OR) with 95% confidence intervals (CI) for RA overall and the ACPA-positive and ACPA-negative subsets, by means of unconditional logistic regression models. All analyses were adjusted for age, sex, residency, pack-years of cigarette smoking and alcohol consumption.

Results: In total, 254 (13%) cases were ever moist snuff users compared with 290 (13%) controls, resulting in an odds ratio of 1.0 (95% CI 0.8–1.2). When exposure to moist snuff was analysed in relation to the incidence of ACPA-positive and ACPA-negative disease, no associations were observed. Furthermore, neither current nor past moist snuff use was related to the risk of RA, or the two sub-groups of the disease.

Conclusion: The use of moist snuff was not associated with RA risk, neither with regard to ACPA-positive nor ACPA-negative RA. The increased risk of RA associated with smoking may thus not be due to nicotine.

Serum Inflammatory Biomarkers Correlated Stronger with a Panel of Serum Steroid and Pituitary Hormones in a Cohort of Pre-Rheumatoid Arthritis (pre-RA) Than in Non-RA Control (CN) Subjects. Alfonse T. Masi[1], Kevin B. Elmore[1], Azeem A. Rehman[1], Jean C. Aldag[1] and Robert T. Chatterton[2]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL, [2]Northwestern University, Chicago, IL

Background/Purpose: Inflammatory cytokines influence steroid hormone production in tissue culture and affect serum levels and synovial fluid of active RA patients. Inflammatory biomarker and hormonal network correlations were compared in this nested prospective study of pre-RA and CN subjects, to identify differences in their associations prior to clinical RA onset.

Methods: Residents of Washington County, MD (21,061: 12,381 F, 8,680 M) enrolled in the Project CLUE cohort in 1974 and donated serum samples. After 3 to 20 (median 11) years, 54 cohorts were diagnosed ACR-definite RA (36 F, 18 M). Each pre-RA was matched on entry features with 4 non-RA (216 total: 144 F, 72 M) cohort members. Stored (−70 °C) sera were available on most subjects for assays of a comprehensive panel of 8 inflammatory markers, 15 steroids in women, and 8 in men. CRP and ASAA were assayed (mg/L) by high sensitivity ELISA at Boston University using reagents provided by Hemagen. A subset of female CRP assays was done by a modified-membrane ELISA method (mg/L) at Northwestern University (NWU). Quantikine cytokine assays (pg/mL) were done at

Specialty Laboratories, Inc., Santa Monica, CA, using reagents from R & D Systems, Inc. Cytokine assays included: IL-1β; IL-6 (F only); TNF-α; IL-1rα; sTNF-R1 and IL-2sRα. A panel of 15 steroids in women and 8 in men were tested by immunoassay methods in a hormone research laboratory at NWU. First, histograms of pre-RA vs CN immunomarkers and hormonal values, stratified by entry pre- vs post-menopausal and sex status, were compared to identify range differences (p<0.050). Next, matrix correlation tables of 8 inflammatory biomarkers and 18 hormones, and their P-P ratios (18 F, 8 M) were constructed using log-transformation and analyzed by age- and sex-adjusted partial Pearson (r_p) and unadjusted rank order Spearman (rho) methods to identify subject group differences (p<0.050). Principal component analysis (PCA) was performed on 148 subjects having values on 8 hormones, 6 immunologic markers, sex, entry age, and the study group variable (CN vs pre-RA).

Results: Among 225 total subjects with at least one paired immunologic and hormonal (I-H) test (46 pre-RA, 179 CN), 6 significant differences in correlations (deltas) were found, all stronger in the pre-RA vs CN (Table). PCA on 148 total subjects yielded 6 components, explaining 71.7% variance, which may be labeled as: (1) male sex-related hormones and sTNF-R1 (22.9%); (2) precursor hormones and estradiol (18.0%); (3) IL-1β and IL-1rα (10.2%); (4) cortisol, TNF-α, and entry age (7.7%); (5) CN vs pre-RA (6.9%), and (6) IL-2sRα (6.1%).

Differences Found in Correlations	Pre-RA Correlations			CN Correlations			Delta p values
	r_p	p	n	r_p	p	n	
CRP x Prolactin	0.413	0.005	46	0.047	0.539	179	0.021
ASAA x 17-OH Preg	0.303	0.091	34	−0.097	0.295	120	0.042
ASAA x Estradiol	0.631	<0.001	31	0.086	0.370	114	0.001
IL-1β x Testosterone	0.410	0.010	41	−0.041	0.630	143	0.009
IL-1βx Cortisol	0.295	0.068	41	−0.065	0.438	146	0.043
IL-2sRα x LH	−0.339	0.043	38	0.103	0.234	137	0.016

Conclusion: Stronger correlations of inflammatory biomarker and hormonal panels were found in pre-RA than in CN, and PCA indicated CN vs pre-RA as an independent component. These new data may lend support to a concept of neuroendocrine-immune dysregulation preceding clinical onset of RA, which deserves further investigation.

66

Pre-Rheumatoid Arthritis (pre-RA) Subjects Had a Minority Excess with Clearly Low Serum Cortisol Levels and Females Had Lower Mean Androstenedione Levels Than Control (CN) Cohorts in Analysis of a Large Panel of Serum Steroids and Pituitary Hormones. Alfonse T. Masi[1], Kevin B. Elmore[1], Azeem A. Rehman[1], Jean C. Aldag[1] and Robert T. Chatterton[2]. [1]University of Illinois College of Medicine at Peoria, Peoria, IL, [2]Northwestern University, Chicago, IL

Background/Purpose: Low serum DHEAS may predispose a minority of premenopausal women to RA. A comprehensive panel of serum steroids, their related product-to-precursor (P-P) ratios and pituitary hormones has not been reported in pre-RA vs non-RA control (CN) subjects. This nested case-control prospective study permitted such comparison to assess adrenal and gonadal hormone alterations prior to clinical onset of RA.

Methods: Residents of Washington County, MD (21,061: 12,381 F, 8,680 M) enrolled in the Project CLUE cohort in 1974 and donated serum samples. After 3 to 20 (median 11) years, 54 cohorts were diagnosed ACR-definite RA (36 F, 18 M). Each pre-RA was matched on entry features with 4 non-RA (216 total: 144 F, 72 M) cohort members. Stored (−70 °C) sera were available on most subjects for assays of a comprehensive panel of hormones (15 F, 8 M) by immunoassay methods in a Northwestern University research laboratory. Histograms were compared of pre-RA vs CN hormonal levels and P-P ratios, stratified by entry pre- vs post-menopausal and sex status, to identify range differences (p<0.050). Hormonal correlations were also compared on age-adjusted, log-transformed values by partial Pearson and by Spearman methods. Principal component analysis (PCA) included 8 hormonal values, entry age, sex, and the study group variable (CN vs pre-RA).

Results: In 54 total pre-RA, 6 (11%) had abnormally low cortisol (< 120 nmol/L) levels vs 2 (0.93%) of 215 CN (p = 0.001). The respective P-P ratio of cortisol product to deoxycortisol precursor did not differ between study groups, or the preceding hydroxylated steroid P-P ratios. In females, mean (SEM) androstenedione ($\Delta 4A$) level (nmol/L) was 2.01 (0.44) in 28 pre-RA vs 3.52 (0.30) in 108 CN (p = 0.017). The lower $\Delta 4A$ level in pre-RA was consistent with a lower ratio of < 0.700 for the $\Delta 4A$ product to 17-OH progesterone precursor, found in 61% of pre-RA vs 34% of CN (p = 0.031). PCA of 11 variables yielded 4 components, explaining 75.2% of total variance: (1) sex and male-related hormones (30.2%); (2) precursor hormones, entry age, and estradiol (25.0%); (3) cortisol (10.5%), and (4) CN vs pre-RA (9.5%).

Principal Component Analysis: Factors and Loadings of 182 Subjects

Component # 1		Component # 2		Component # 3		Component # 4	
Factors	Loading	Factors	Loading	Factor	Loading	Factor	Loading
Sex	0.950	$\Delta 4A$	0.816	Cortisol	0.876	CN_RA	0.911
Testosterone	0.919	DHEA	0.715				
DHEAS	0.846	17-OH Prog.	0.711				
		17-OH Preg.	0.632				
		Entry Age	-0.586				
		Estradiol	0.537				

Conclusion: An excess minority of pre-RA had deficient cortisol levels, females had lower mean androstenedione than CN, and PCA identified cortisol and the CN vs pre-RA variable as independent components, findings which deserve further investigation.

67

Increased Prevalence of Hypothyroidism Preceding Rheumatoid Arthritis - an Epidemiological Study. Anne M. Kerola[1], Tuomo Nieminen[2], Markku J. Kauppi[3], Hannu Kautiainen[4], Kari Puolakka[5], Lauri J. Virta[6] and Tuomas Kerola[3]. [1]Medical School, University of Helsinki, Helsinki, Finland, [2]Division of Cardiology, Helsinki University Central Hospital, Helsinki, Finland, [3]Department of Internal Medicine, Päijät-Häme Central Hospital, Lahti, Finland, [4]Unit of Primary Health Care, Kuopio University Hospital, Kuopio, Finland, [5]Department of Medicine, South Karelia Central Hospital, Lappeenranta, Finland, [6]Research Department, the Social Insurance Institution, Turku, Finland

Background/Purpose: Rheumatoid arthritis (RA) is associated with a wide set of comorbidities, including several autoimmune diseases such as autoimmune thyroiditis, which is a common cause of hypothyroidism. Whether the prevalence of hypothyroidism is elevated during the preclinical phase of RA when several autoimmune processes are already activated is not yet known. The aim of the study was to compare the prevalence of hypothyroidism among RA patients and non-RA-subjects at the time of RA diagnosis, and to determine whether the risk of hypothyroidism varies by age at the onset of RA, or by sex or rheumatoid factor (RF) status.

Methods: We identified 7,209 incident RA patients diagnosed between January 2004 and December 2007 from a Finnish nationwide register of special reimbursements for medication costs. The presence of hypothyroidism was identified from the same register based on special reimbursement decisions for thyroxine substitution. The prevalence of hypothyroidism at the onset of RA was compared to that of an age- and sex-matched Finnish population, and a standardized rate ratio (SRR) for hypothyroidism was calculated.

Results: The SRR for hypothyroidism preceding RA was 1.51; 95% confidence interval (CI): 1.35-1.67. The SRR was highest among younger RA patients, the excess prevalence of hypothyroidism decreasing steadily and wearing off among patients who were older at the time of diagnosis (Figure). The SRR for hypothyroidism was almost 2.5 among women between 20 and 49 years of age at RA diagnosis. The absolute prevalence of hypothyroidism, however, increased with age as it does in the general population. The SRR was similar between RF-positive and RF-negative patients: 1.46 (95% CI: 1.27-1.66) and 1.61 (95% CI: 1.34-1.91), respectively. Sex also did not modify the SRR point estimates, although the results did not reach statistical significance among men.
Figure. The standardized rate ratios (SRR) of hypothyroidism according to sex and age among 7,209 RA patients at disease onset compared with their age- and sex-matched non-RA equivalents. 95% confidence intervals are shown with whiskers.

Conclusion: The prevalence of hypothyroidism is already increased among RA patients at the disease onset, especially among young women. This calls for attention to screening for hypothyroidism in younger RA patients. Furthermore, the clinician should be mindful of the possibility of RA as the underlying cause of joint symptoms in young female patients with hypothyroidism.

68

Cardiovascular Comorbidities Antedating the Diagnosis of Rheumatoid Arthritis. Anne M. Kerola[1], Tuomas Kerola[2], Markku J. Kauppi[2], Hannu Kautiainen[3], Lauri J. Virta[4], Kari Puolakka[5] and Tuomo Nieminen[6]. [1]Medical School, University of Helsinki, Helsinki, Finland, [2]Department of Internal Medicine, Päijät-Häme Central Hospital, Lahti, Finland, [3]Unit of Primary Health Care, Kuopio University Hospital, Kuopio, Finland, [4]Research Department, the Social Insurance Institution, Turku, Finland, [5]Department of Medicine, South Karelia Central Hospital, Lappeenranta, Finland, [6]Division of Cardiology, Helsinki University Central Hospital, Helsinki, Finland

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with increased cardiovascular morbidity. Evidence suggests that RA patients are at an increased risk of coronary heart disease (CHD) early in the disease process. Whether the risk of CHD is elevated before the onset of RA symptoms remains to be ascertained. The aim of the study was to assess the prevalence of CHD, chronic hypertension and chronic congestive heart failure among incident RA patients at the time of diagnosis in comparison to age- and sex-matched non-RA-subjects. Furthermore, the impact of age at the onset of RA as well as sex and the presence of rheumatoid factor (RF) on the risk of cardiovascular diseases was evaluated.

Methods: A cohort of 7,209 incident RA patients diagnosed between January 2004 and December 2007 was identified from a Finnish nationwide register of special reimbursements for medication costs. The presence of cardiovascular diseases antedating the reimbursement decision for RA was identified from the same register. The prevalence of cardiovascular comorbidities at RA diagnosis was compared to the general Finnish population, and a standardized rate ratio (SRR) for each cardiovascular disease was calculated.

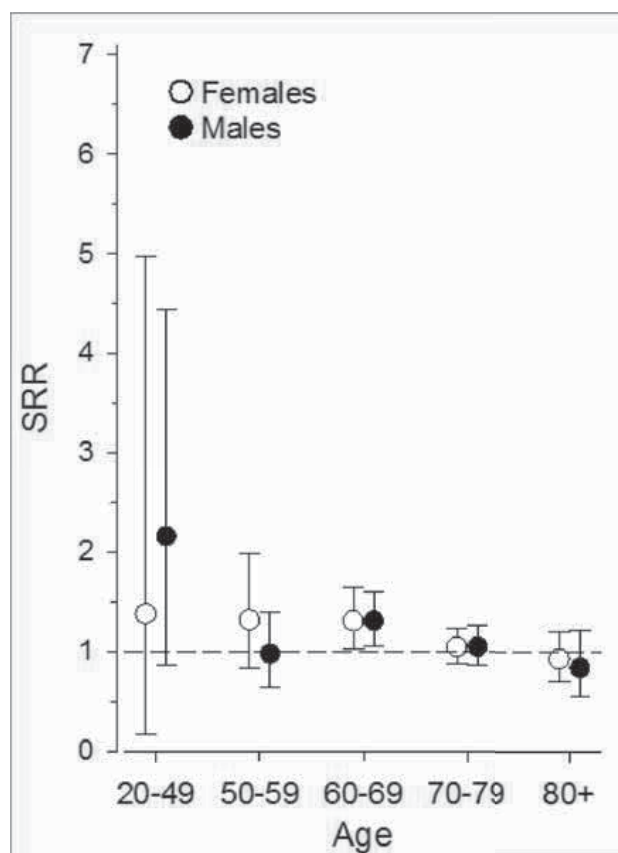
Results: The risk of having CHD at RA diagnosis was slightly elevated, the SRR being 1.10 (95% confidence interval [CI]: 1.01-1.20). Patients who were younger at the onset of RA had a trend towards a higher CHD rate ratio than older patients, although the risk was not significantly elevated in most age subgroups (Figure). The CHD rate ratio was essentially similar irrespective of RF status - 1.15 (95% CI: 1.00-1.32) among RF-negative and 1.08 (95% CI: 0.97-1.19) among RF-positive patients. The SRR of chronic hypertension was significantly increased only among the RF-negative RA cases (1.19, 95% [95% CI: 1.10-1.30]). The prevalence of chronic congestive heart failure did not differ between the incident RA patients and the general population.


Figure. The standardized rate ratios (SRR) of CHD among 7,209 patients at the onset of RA according to sex and age (with 95% confidence intervals).

Conclusion: The CHD rate ratio is already augmented in RA patients at disease onset; the increase is more pronounced among younger patients and similar between RF-positive and RF-negative patients. The findings highlight the importance of early prevention of atherosclerosis regardless of RF status.

69

The Presence of Asymptomatic Carotid Plaques in Patients with Inflammatory Joint Disease Results in Inadequate Treatment to Lipid Targets in Cardiovascular Disease Prevention. Anne G. Semb[1], Silvia Rollefstad[2], Inge C. Olsen[2], Desiree van der Heijde[3] and Tore K. Kvien[2]. [1]Diakonhjemmet Hospital, Olso, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The prevalence of asymptomatic carotid plaque (a-CP) is high in patients with inflammatory joint disease (IJD). Patients with a-CP should receive intensive lipid lowering (LL) treatment in cardiovascular prevention. Our aim was to evaluate presence of a-CP, if CV risk calculators predict presence of a-CP in patients with IJD and if optimizing cut off points in various risk calculators will improve this prediction.

Methods: We performed CV risk stratification in patients with IJD (n= 345), [rheumatoid arthritis (RA) (n=210), ankylosing spondylitis (AS) (n=87) and psoriatic arthritis (PsA) (n=49)] by using SCORE, Framingham and Reynolds CV risk algorithms with recommended cut off points at 5%, 10% and 10% respectively. Ultrasound of the carotid arteries was performed. Cross-tabulations, Chi^2 and ROC curves were used to calculate sensitivity/specificity, odds- and likelihood ratio (LR) for identifying a-CP. The ROC closest point (0.1) and 80% sensitivity was used for optimizing the identification of a-CP.

Results: A-CP was present with similar frequency in RA, AS and PsA (48.3%, 41.4% and 41.7% (p=0.46). Two hundred and eleven patients had SCORE<5% indicating no need for LL prevention (Table 1). However, 72 (34.1%) of these patients had a-CP and should receive intensive LL treatment. In patients with SCORE ≥5% (n=124), indicating a need for moderate LL prevention, 81 (65.3%) had a-CP and should therefore be categorized to intensive LL treatment. The sensitivity for identifying a-CP was 0.53, the specificity: 0.76 and LR+: 2.24. Optimizing the cut off value by using closest point (0, 1) (SCORE: 4%: specificity: 0.65, specificity: 0.72, LR+:2.33) or 80% specificity (SCORE: 2.65: sensitivity: 0.80 specificity: 0.56 LR+:1.83) did not improve the ability of SCORE to identify a-CP. According to the new guidelines for prevention of CV disease (2011)[1], the sensitivity, specificity and LR+ for identifying a-CP was 0.47, 0.77 and 2.05 respectively. The associations between a-CP and cut off values for other risk calculators are shown in Table 2.

Table 1. European heart SCORE according to presence of symptomatic carotid plaque

| | Carotid plaque n (%) | | | | | | | |
	SCORE ≥ 5%	SCORE < 5%	OR (95% CI)	p-value	Sensitivity	Specificity	LR+	LR−
IJD	81 (65.3)	72 (34.1)	3.64 (2.28, 5.80)	<0.0001	0.53	0.76	2.24	0.62
Closest point to (0,1)	**SCORE ≥ 4%**	**SCORE < 4%**						
IJD	100 (66.2)	53 (28.8)	4.85 (3.05, 7.71)	<0.0001	0.65	0.72	2.33	0.48
80% sensitivity	**SCORE ≥ 2.66%**	**SCORE < 2.65%**						
IJD	123 (60.6)	30 (22.7)	5.23 (3.19, 8.58)	<0.0001	0.80	0.56	1.83	0.35
	New SCORE classification: >5%, <10% & LDL >2.5 or ≥10%&LDL≥1.8	**New SCORE classification: otherwise**						
IJD	72 (63.2)	80 (36.4)	3.000 (1.88, 4.80)	<0.0001	0.47	0.77	2.05	0.68

Table 2. Framingham and Reynolds cardiovascular risk scores

| | Carotid plaque n (%) | | | | | | | |
	Framingham ≥ 10%	Framingham < 10%	OR (95% CI)	p-value	Sensitivity	Specificity	LR+	LR−
IJD	128 (61.2)	25 (19.8)	6.38 (3.80, 10.73)	<0.0001	0.84	0.56	1.88	0.29
Closest point to (0,1)	**Framingham ≥ 12.2%**	**Framingham < 12.2%**						
IJD	113 (64.6)	40 (25.0)	5.47 (3.41, 8.78)	<0.0001	0.74	0.66	2.17	0.40
80% sensitivity	**Framingham ≥ 11%**	**Framingham < 11%**						
IJD	122 (63.5)	31 (21.7)	6.30 (3.84, 10.33)	<0.0001	0.80	0.62	2.07	0.33
	Reynolds ≥ 10%	**Reynolds < 10.0%**						
IJD	63 (67.0)	84 (36.7)	3.51 (2.11, 5.83)	<0.0001	0.43	0.82	2.43	0.69
Closest point to (0,1)	**Reynolds ≥ 5.7%**	**Reynolds < 5.7%**						
IJD	102 (64.6)	43 (27.3)	4.86 (3.03, 7.79)	<0.0001	0.69	0.68	2.11	0.45
80% sensitivity	**Reynolds ≥ 4.5%**	**Reynolds < 4.5%**						
IJD	118 (61.8)	29 (22.0)	5.74 (3.47, 9.51)	<0.0001	0.80	0.59	1.94	0.34

Conclusion: Carotid ultrasound will assist in the correct classification of patients with IJD into intensive LL in about 1/3 of patients with SCORE<5% and 2/3 of patients with SCORE≥5%. The CV risk calculators are poor predictors of a-CP in patients with IJD.

The Impact of Systemic Autoimmune Rheumatic Disease On One-Year Mortality in Congestive Heart Failure Patients: A Population-Level Analysis. Stephanie O. Keeling, Asvina Bissonauth, Becky Leung and Padmaja Kaul. University of Alberta, Edmonton, AB

Background/Purpose: Little is known about the prevalence of systemic autoimmune rheumatic diseases (SARDs) in patients with congestive heart failure (CHF) and its contribution to long-term adverse events. Therefore, we documented the prevalence of SARDs in an incident cohort of patients hospitalized with CHF in the province of Alberta, Canada and examined the association between SARDs and 1-year mortality after adjusting for traditional cardiovascular risk factors.

Methods: This retrospective cohort study examined all Alberta residents, aged 20 years and older, hospitalized with incident CHF between April 1, 1999 and December 31, 2008. Definitions of CHF, SARDs and other comorbidities were based on established ICD-9 &-10 codes. SARDs included rheumatoid arthritis, systemic lupus erythematosus, inflammatory myositis, systemic sclerosis, Sjogren's syndrome, overlap syndrome and other connective tissue diseases. Hospitalization records in the five years prior to the incident CHF hospitalization were examined to identify the presence of SARDs and other comorbidities. Baseline characteristics and comorbidity rates of SARDs/non-SARDs patients were described. The independent association of SARDs and mortality after adjusting for demographic and traditional cardiovascular risk factors was calculated with logistic regression. Kaplan-Meier analysis and the log-rank statistic examined the unadjusted one-year mortality between SARDs/non-SARDS patients.

Results: SARDs prevalence was 3.1% (1208 patients) out of 38,668 patients hospitalized with CHF. Patients with SARDs were younger, more likely female, and had lower rates of diabetes, hypertension, COPD, anemia and renal disease (Table 1). After multivariate adjustment, SARDs was associated with higher odds of 1-year mortality (adjusted Odds Ratio 1.3 (95% Confidence Interval 1.2–1.5) (Table 2). Kaplan-Meier analysis showed greater 1-year mortality in SARDs versus non-SARDs hospitalized CHF patients (not shown in abstract).

Table 1. Baseline characteristics of SARDs versus non-SARDs CHF patients

CHARACTERISTIC	SARDS	Non-SARDs	p-value
Age (mean (STD))	74.8 (13.2)	72.9 (12.7)	<0.01**
Male sex	18,842 (50.3%)	347 (28.7%)	<0.01
Diabetes	12624 (33.7%)	331 (27.4%)	<0.01
Hypertension	28432 (75.9%)	885 (73.3%)	0.04
Dementia	4832 (12.9%)	108 (8.9%0	<0.01
COPD	17756 (47.4%)	628 (52.0%)	<0.01
Anemia	14560 (38.9%)	724 (59.9%)	<0.01
Cerebrovascular disease	8016 (21.4%)	259 (21.4%)	0.95
Renal disease	6181 (16.5%)	248 (20.5%)	<0.01
Cancer	7042 (18.8%)	216 (17.9%)	0.40
PVD	6780 (18.1%)	236 (19.5%)	0.22
Atrial fibrillation	12549 (33.5%)	393 (32.5%)	0.46
1-year mortality	11238 (30.0%)	422 (34.9%)	<0.01

**p-value was based on Kruskal-Wallis one-way analysis of variance.
P-values of categorical variables are based on Chi-square test.

Table 2. Logistic regression of 1-year mortality in incident CHF

Effect	OR (95% Confidence Interval)
Male	1.2 (1.1–1.2)
Age	1.0
SARDs	1.3 (1.2–1.5)
Hypertension	0.7 (0.6–0.7)
Dementia	1.8 (1.7–2.0)
COPD	1.1 (1.0–1.1)
Anemia	1.3 (1.2–1.3)
Cerebrovascular disease	1.3 (1.2–1.4)
Renal disease	1.7 (1.6–1.8)
Cancer	2.5 (2.4–2.6)
PVD	1.2 (1.1–1.2)

Conclusion: Significant mortality risk exists among SARDs patients hospitalized with CHF despite lower rates of factors such as diabetes and hypertension. Agressive recognition and management of CHF in SARDs patients may improve survival rates. Further work is needed to examine the outpatient prevalence of SARDs in this population.

The Association Between Preclinical Markers for Cardiovascular Disease and Rheumatoid Arthritis-Related Autoantibodies in First-Degree Relatives without Rheumatoid Arthritis. Ryan W. Gan[1], Jan M. Hughes-Austin[2], Kevin D. Deane[3], Elaine M. Urbina[4], Peter K. Gregersen[5], Michael H. Weisman[6], V. Michael Holers[3] and Jill M. Norris[1]. [1]Colorado School of Public Health, Aurora, CO, [2]Colorado School of Public Health/University of Colorado Anschutz Medical Campus, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [6]Cedars-Sinai Medical Center, Los Angeles, CA

Background/Purpose: Rheumatoid arthritis (RA) is characterized by systemic inflammation and immune dysregulation, including the presence of autoantibodies and elevated inflammatory markers in subjects with classifiable RA as well as in those who have yet to progress to clinically-apparent RA. In addition, the risk for cardiovascular disease (CVD) is greatly increased in patients with RA, with autoantibodies and systemic inflammation believed to be major contributors to the pathogenesis of CVD in patients with RA. Furthermore, Maradit-Kremers and colleagues have shown that the increased risk for CVD may precede the development of classifiable RA, leading to the hypothesis that autoantibodies and systemic inflammation are influencing the development of CVD in subjects even prior to the onset of joint symptoms in RA. The Studies of the Etiology of RA (SERA) demonstrated previously an association between autoantibody positivity and increased levels of circulating cytokines in subjects without RA but at elevated risk for future RA, as they are first-degree relatives (FDRs) of probands with RA. We utilized these SERA FDRs to test the hypothesis that CVD may be apparent in FDRs at-risk for future RA, and may also be related to systemic RA-related autoantibodies.

Methods: RA-related autoantibody (Ab) positivity is defined as positivity for one of the following autoantibodies: rheumatoid factor by nephelometry (RF), RF isotype-IgM, IgA, IgG, or anti-cyclic citrullinated peptide (anti-CCP2). Ab positive and negative FDRs from the SERA parent cohort were evaluated after a 10-hour fast for the following outcome measures related to CVD: carotid intima media thickness (cIMT), carotid stiffness, flow-mediated dilation (FMD) of the brachial artery, abdominal adipose tissue using computed tomography (CT), blood pressure, lipids, lipoproteins and adipokines. Levels of these pre-clinical CVD phenotypes were log-transformed and compared by current autoantibody positivity status using linear regression.

Results: The Table presents data from the first 30 FDRs undergoing the CVD evaluation (planned enrollment n=100). Overall, Ab positive FDRs had *lower* (ie, better) intima media thickness of the internal carotid artery (both max and average measures) than Ab negative FDRs; there were no other significant differences between CVD-related measures and Ab status.

Table. CVD-related measures by RA-related autoantibody positivity. CVD variables are back-transformed after adjusting for age and gender using linear regression.

	Ab Positive n=16 Mean	Ab Negative n=14 Mean	p-value
Age (years)*	48.0	54.3	0.27
Gender (% Female)*†	81.3	57.1	0.24
Current Smoker (% Yes)*†	0%	14.3%	0.21
Blood Pressure			
Systolic (mm/Hg)	118.79	118.16	0.92
Diastolic (mm/Hg)	72.99	72.91	0.98
Lipids, lipoproteins and adipokines			
LDL (mg/dL)	98.39	114.92	0.27
HDL (mg/dL)	52.24	51.14	0.87

Triglycerides (mg/dL)	117.96	115.85	0.98
ApoB (mg/dL)	83.03	94.26	0.11
ApoA (mg/dL)	155.12	151.15	0.70
ApoB/ApoA	0.54	0.62	0.13
Adiponectin (ug/mL)	9.08	9.82	0.74
Leptin (ug/mL)	13.49	12.82	0.91
C-reactive protein (mg/L)	1.56	2.83	0.18
Adiposity			
BMI (kg/m^2)	28.70	27.47	0.63
Subcutaneous Fat Area (cm^2) at L4/5	271.54	317.52	0.48
Visceral Fat (cm^2) at L4/5	82.73	102.78	0.54
Carotid Intima Media Thickness (averaged over left and right cIMT)			
cIMT, carotid bulb (max mm)	0.86	0.98	0.19
cIMT, carotid bulb (avg mm)	0.70	0.78	0.26
cIMT, common carotid artery (max mm)	0.72	0.75	0.50
cIMT, common carotid artery (avg mm)	0.59	0.63	0.34
cIMT, internal carotid artery (max mm)	**0.65**	0.81	0.02
cIMT, internal carotid artery (avg mm)	**0.52**	0.64	0.03
Measures of Carotid Stiffness			
Peterson's Elastic Model (mmHg)	525.39	524.63	0.99
Circumferential Arterial Strain (no units)	0.093	0.094	0.91
Beta Stiffness Index (no units)	5.59	5.60	0.99
Elastic Modulus, Incremental (mmHg)	2493.73	2381.08	0.88
Young's Elastic Pressure Modulus (mmHg/mm)	466.90	455.57	0.94
Arterial Compliance (mm2/mmHg)	0.103	0.103	0.99
Flow Mediated Dilatation (Δ%)	5.01	3.92	0.21

*Variables are unadjusted.
†Variables are dichotomous and not log transformed.

Conclusion: This preliminary analysis suggests that the autoantibody-positive FDRs did not have worse indicators of vascular health compared to autoantibody-negative FDRs, which is contrary to our *a priori* hypothesis. These results tentatively indicate that the increased risk for CVD that is seen in RA is not detectable in the preclinical autoantibody phase of the disease, using the structural or functional vascular changes measured herein. Analysis of the larger cohort is warranted to confirm these results.

Relationships Between Air Pollution and Presence of Rheumatoid Arthritis-Related Autoantibodies in Individuals without Rheumatoid Arthritis: Studies of the Etiology of Rheumatoid Arthritis. Ryan W. Gan[1], Kevin D. Deane[2], Gary O. Zerbe[3], Michael H. Weisman[4], Jane H. Buckner[5], P. K. Gregersen[6], Ted R. Mikuls[7], James R. O'Dell[8], Richard M. Keating[9], V. Michael Holers[2] and Jill M. Norris[1]. [1]Colorado School of Public Health, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]Colorado School of Public Health / University of Colorado Anschutz Medical Campus, Aurora, CO, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Benaroya Research Institute at Virginia Mason, Seattle, WA, [6]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [7]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [8]Univ of Nebraska Med Ctr, Omaha, NE, [9]University of Chicago, Chicago, IL

Background/Purpose: Rheumatoid arthritis (RA) is characterized by the presence of circulating autoantibodies, which can be predictive of

future RA development in currently unaffected individuals. The specific etiology of RA is unknown; however, studies have suggested that respiratory exposures such as smoking and proximity to road traffic may be associated with development of RA. To elucidate the relationship between respiratory exposures and explore the potential that inhaled exposures may act early in the pathogenesis of RA, leading to early generation of RA-related autoimmunity, we evaluated the association between exposure to air pollution, measured by yearly average particulate matter (PM) 2.5 and 10, and presence of RA-related autoantibodies.

Methods: The Studies of the Etiology of Rheumatoid Arthritis (SERA) is a multicenter study evaluating first-degree relatives (FDRs) of a proband with RA. FDRs lack classifiable RA at enrollment and are serially assessed for the presence of RA-related autoimmunity and potential risk factors for RA development. Outcomes assessed were presence of rheumatoid factor (RF), and the High Risk profile (positive for anti-CCP autoantibody and/or ≥2 RF isotypes), demonstrated to be >96% specific for future RA. Exposure to PM was assigned using the Environmental Protection Agency Air Quality System and interpolated with inverse distance weighted spatial analyses using Geographic Information Systems. PM exposures were linked to resident zip codes of FDRs living within 50 km of an air monitoring station in five states. PM exposures were categorized by tertiles (low, moderate, high levels) due to evidence of nonlinear associations with autoantibodies. RA-related autoantibody status and PM tertiles were analyzed using nonlinear mixed models to account for repeated measures.

Results: Our study population had a mean age of 45 years, was 70% female, 72% non-Hispanic White, and mostly non-smokers (88%). A majority of our study population lived in Colorado (39.1%) followed by California (29.4%), Nebraska (12.6%), Washington (10.6%), and New York (8.3%). No significant associations were observed between RA-related autoantibody outcomes and PM 2.5 or PM10 tertiles (Table).

Table. Odds ratios (OR) for rheumatoid factor and high risk profile in relation to tertiles of PM 2.5 microns in diameter and PM 10 microns in diameter.

	Outcome			
	Rheumatoid Factor n=110 cases		High Risk Profile n=105 cases	
PM 2.5 (n=860 FDRs, 1743 visits)	OR	95% CI	OR	95% CI
Low (< 8.2 µg/m³)	1.00	ref	1.00	ref
Moderate (8.2 to 9.9 µg/m³)	0.74	0.34-1.63	0.41	0.16-1.07
High (> 9.9 µg/m³)	1.26	0.40-3.94	0.50	0.15-1.68
PM 10 (n= 728 FDRs, 1473 visits)	n= 93 cases		n= 96 cases	
Low (< 23.8 µg/m³)	1.00	Ref	1.00	Ref
Moderate (23.8 to 26.7 µg/m³)	0.95	0.44-2.05	0.59	0.25-1.40
High (> 26.7 µg/m³)	0.98	0.44-2.19	0.48	0.20-1.15

Adjusted for age, ethnicity, gender, current smoking status, education, and recruitment site. The reduced sample size for the PM10 analysis is due to a smaller number of air monitoring stations measuring PM10.

Conclusion: These results suggest that exposure to PM is not significantly associated with autoantibody positivity in individuals without RA, although there is a trend towards an inverse association between PM and the High Risk Profile, which is contrary to our *a priori* hypothesis that PM is associated with increased risk of RA-related autoimmunity. The observed results could be due to the aggregate nature of our exposure variable. Alternatively, exposure to PM may not be an initial trigger of autoimmunity but may act later to facilitate the development of clinically-apparent RA. Continued observation of this cohort is important to investigate the exact role of air pollution in the etiology of RA.

73

Trends in 21st century Health Care Utilization in a Rheumatoid Arthritis Cohort Compared to the General Population.

Sofia Hagel[1], Ingemar F. Petersson[2], Ann B. I. Bremander[3], Elisabet Lindqvist[1], Charlotte Bergknut[4] and Martin Englund[2]. [1]Department of Clinical Sciences, Lund, Section for Rheumatology, Lund University and Skåne University Hospital, Lund, Lund, Sweden, [2]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [3]Halmstad University School of Business and Engineering, Halmstad, Sweden, [4]Lund University, Lund, Sweden

Background/Purpose: To study twenty-first century trends in health care utilization by rheumatoid arthritis (RA) patients compared to the general population.

Methods: Observational cohort study; using Swedish health care register data, we identified 3977 Region Skåne residents (mean age year 2001, 62.7 years and 73% women) consulting for RA (ICD-10 codes M05 or M06) in 1998–2001.We randomly sampled two referents from the general population per RA patient matched for age, sex, and area of residence. We calculated the year 2001–2010 trends for the annual ratio (RA cohort/referents) of the mean number of hospitalizations and outpatient clinic visits.

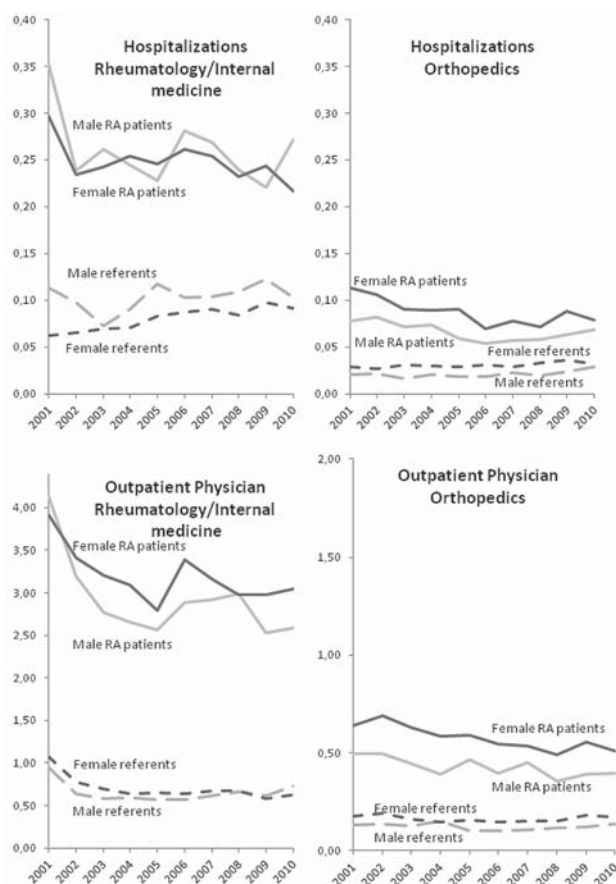
Results: By the end of the 10-year period 62% of RA patients and 74% of referents were still alive and resident in the region. From 2001 to 2010 the ratio (RA cohort/referents) of the mean number of hospitalizations for men and women decreased by 27% (p=0.01) and 28% (p=0.004), respectively. The corresponding decrease was 29% (p=0.005), and 16% (p=0.004) for outpatient physician care, 34% (p=0.009) and18% (p=0.01) for nurse visits, and 34% (p=0.01) and 28% (p=0.004) for physiotherapy (Figure 1 and 2).
Figure 1. Health care utilization during the first decade of the twenty-first century by patients in a closed rheumatoid arthritis cohort and their matched referents from the general population. The y-axes show the mean number of visits per subject per calendar year.


Figure 2. Health care utilization during the first decade of the twenty-first century by patients in a closed rheumatoid arthritis cohort and their matched referents from the general population. The y-axes show the mean number of visits per subject per calendar year.

Conclusion: During the twenty-first century, coinciding with increasing use of earlier and more active RA treatment including biological treatment, the overall inpatient and outpatient health care utilization by a cohort of RA patients decreased relative to the general population.

Length of Stay for Rheumatoid Arthritis Related Orthopedic Surgery Has Improved Over the Past 3 Decades and Is Related to Disease Markers. Results From Two UK Multicentre Inception Cohorts (1986–2011) Compared with National Data. Elena Nikiphorou[1], Stephen Morris[2], David James[3], Patrick D. Kiely[4], David Walsh[5] and Adam Young[6]. [1]ERAS, St Albans City Hospital and University College London (UCL), St Albans, United Kingdom, [2]Research Department of Epidemiology and Public Health, 1–19 Torrington Place, United Kingdom, [3]Diana Princess of Wales Hospital, Grimsby, United Kingdom, [4]St. Georges Hospital, London, United Kingdom, [5]City Hospital, Nottingham, United Kingdom, [6]St Albans City Hospital, St Albans, United Kingdom

Background/Purpose: Length of Stay (LoS) is one of the main drivers of costs for orthopedic surgery in RA. Better medical and surgical treatments in recent years should result in shorter LoS. Studies have reported LoS trends in RA-related orthopedic interventions, but less is known about clinical factors affecting it. In the current economic climate, with over-pressurized health services, identifying and targeting such factors could result in reduced LoS, and improved health care utilization planning.

Methods: LoS has been examined in two very similar multi centre inception cohorts, the Early RA Study (ERAS) (n=1465, 1986–1999) and the Early RA Network (ERAN) (n=1236, 2002–2010). Details of orthopedic interventions included date, type of procedure and LoS. The results were validated against the National Joint Registry and Hospital Episode Statistics, and follow up based on the National Death Register. Standard clinical, laboratory and x-ray measures recorded at baseline and annually were used to investigate factors affecting LoS with univariate and multivariate regression analysis.

Results: There were 770 (29%) out of 2701 patients in ERAS & ERAN who had a total of 1602 procedures: 40% major, of which 88% were total joint replacements (mainly knee followed by hip); 24% were intermediate (mainly hand/foot surgery) & 16% were minor (soft tissue surgery surgery/tendon transfers). A gradual reduction in the median LoS was noted over 25 years for major, intermediate and minor procedures: 10, 4 & 2 days respectively (IQRs 7–15, 3–7, 1–4) in ERAS & 7, 3 & 1 days (IQRs 5–8, 1–7, 1–2) in ERAN. Figure 1 shows the changing median LOS for the commonest types of surgery: Total Knee & Hip Replacements (TKRs & THRs) over 25 years. Figure 2 shows TKR median LoS compared with national data. Extrapolation of national data suggests that in the 1990s TKRs resulted in longer LoS than in the 2000s. The cost of a TKR based on 5 days LoS currently in the UK is ≤5576. The decline in LoS across various procedures has resulted in reduced costs. In multivariate analyses LoS varied significantly by type of procedure, DAS, hemoglobin (HB) levels and HAQ scores. Normal baseline HB significantly reduced LoS by 1.8 days (p=0.001), baseline HAQ<1 by 1.8 days (p=0.002) & low 1year DAS (<3.2) by 1.1 days (p=0.051).

Figure 1.
Figure 2.
Conclusion: LoS in RA-related orthopedic surgery has declined over the last 25 years, which could be a reflection of improved management of RA, and medical and surgical in patient treatments. Normal baseline HB, low baseline HAQ and low DAS at 1 year were found to be significant predictors for LoS.

Patient-Reported Outcomes Associated with Achieving and Maintaining Low Disease Activity in Rheumatoid Arthritis. Martin J. Bergman[1], James W. Shaw[2], Mary Cifaldi[2], Gourab De[3], Tony He[4], Rajeev Ayyagari[4] and James Signorovitch[4]. [1]Taylor Hospital, Ridley Park, PA, [2]Abbott Laboratories, Abbott Park, IL, [3]Analysis Group, Inc., New York, NY, [4]Analysis Group, Inc., Boston, MA

Background/Purpose: Treat-to-target (T2T) guidelines for rheumatoid arthritis (RA) recognize low disease activity (LDA) as an acceptable therapeutic goal, particularly in patients with longstanding disease. The guidelines advocate that treatment targets be maintained throughout the course of the disease. A study was conducted to assess associations of patient-reported outcomes (PROs) with achievement and maintenance of LDA.

Methods: Data were taken from four phase II/III randomized trials of adalimumab (ADA), alone or in combination with methotrexate (MTX), vs. MTX monotherapy for the treatment of RA in patients with early or late stage disease. Changes in scores for the Health Assessment Questionnaire Disability Index (HAQ-DI), the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) subscale, the four domains of the Work Productivity and Activity Impairment (WPAI) questionnaire, a visual analog scale measuring pain (VAS-P), and other PRO measures were compared between patient groups defined according to achievement of LDA after 12 weeks of treatment. Among those patients who achieved LDA, changes in PROs were compared between subgroups defined according to maintenance of LDA following an additional 12 or 14 weeks of treatment (based on the timing of study follow up). LDA was defined as having a composite disease activity score based on 28 joints and C-reactive protein (DAS28-CRP-4) <3.2 at a given assessment. The principle analyses were conducted using pooled data from the four trials with additional analyses being stratified by disease duration (i.e., early or late) or treatment received (i.e., ADA or MTX).

Results: A total of 2,533 patients with DAS28-CRP-4 assessments at baseline and after 12 weeks of treatment were included in the study. Compared with patients who did not achieve LDA after 12 weeks of treatment (N=1,820), those achieving LDA (N=713) had significantly greater improvements in scores for the HAQ-DI, FACIT-F, and VAS-P as well as the presenteeism, overall work impairment, and activity impairment domains of the WPAI. Among the 684 patients achieving LDA at week 12 with follow-up at week 24/26, those who maintained LDA (N=557) had significantly greater improvements in scores for the HAQ-DI, FACIT-F, VAS-P, and activity impairment domain of the WPAI than those who failed to sustain LDA (N=127). Similar results were obtained when performing analyses in disease duration and treatment subgroups.

Mean ± SD Changes in (A) Week 12 Outcomes for Patients with and Without LDA at Week 12 and (B) Week 24/26 Outcomes for Patients Who Maintained or Lost LDA after an Additional 12/14 Weeks of Treatment

Outcome	Change from Week 12 - Baseline (A)			Change from Week 24/26 - Baseline (B)		
	Did Not Achieve LDA	Achieved LDA	P-value	Did Not Maintain LDA	Maintained LDA	P-value
HAQ-DI [range: 0–3]	−0.51 ± 0.57	−0.90 ± 0.64	<0.0001	−0.67 ± 0.75	−1.01 ± 0.65	<0.0001
FACIT-F [range 0–52]	7.19 ± 10.73	11.33 ± 10.63	<0.0001	9.00 ± 11.45	12.16 ± 10.63	<0.0001
WPAI [range: 0–100]						
Absenteeism	−6.54 ± 30.62	−13.40 ± 33.25	0.0511	−13.57 ± 39.41	−9.54 ± 27.66	0.5907
Presenteeism	−13.71 ± 26.55	−24.66 ± 27.29	0.0004	−14.00 ± 27.98	29.25 ± 25.40	0.0917
Overall work impairment	−12.64 ± 29.42	−29.81 ± 33.25	<0.0001	−22.49 ± 41.05	31.55 ± 29.22	0.3495
Activity impairment	−19.65 ± 25.66	−33.78 ± 26.38	<0.0001	−12.94 ± 28.66	38.74 ± 26.22	<0.0001
VAS-P [range: 0–100]	−24.03 ± 27.89	−41.98 ± 24.78	<0.0001	−27.87 ± 30.38	44.44 ± 23.80	<0.0001

Notes: With the exception of the WPAI, which was administered in only one of the four trials, results are presented for analyses of the pooled trial data. Wilcoxon tests were performed to facilitate group comparisons. The FACIT-F was scored so that higher values indicated less fatigue. All other outcomes were scored so that higher values indicated worse functioning, work productivity, or pain.

Conclusion: RA patients achieving LDA after 12 weeks of treatment have significantly reduced disability, pain, work impairment, and fatigue compared to those who do not achieve LDA. A similar pattern of differences is observed between patients who maintain LDA and those who fail to do so after 24/26 weeks of treatment. The results of this investigation support the value of achieving and maintaining LDA, as recommended by the T2T guidelines.

The Difference in Performance of DAS28 and RADAI During Pregnancy Might Explain Discrepancies Between Older and More Recent Studies On the Impact of Pregnancy On Rheumatoid Arthritis. Jan Naterop[1], Johanna M.W. Hazes[2] and Radboud J.E.M. Dolhain[2]. [1]Erasmus Medical Center, University Medical Center Rotterdam, Rotterdam, The Netherlands, Rotterdam, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands

Background/Purpose: Pregnancy is the only condition in which Rheumatoid Arthritis (RA) shows spontaneous remission. Both older and more recent studies showed improvement of disease activity, which was more pronounced and occurred earlier in pregnancy in the older studies. An explanation for the difference in improvement could be that the older studies measured RA disease activity retrospectively using self-assessed questionnaires, whereas the more recent studies measured disease activity prospectively using a joint score. The Disease Activity Score in 28 joints (DAS28) and the self-assessed Rheumatoid Arthritis Disease Activity Index (RADAI) are both valid tools to determine the disease activity in RA. However the influence of pregnancy on the RADAI score has not been determined. Insight into this may contribute to a better understanding of the difference in outcome between older and more recent studies. Should the RADAI prove to be a valid instrument during pregnancy, it could be used for studies on RA and pregnancy. The aim of this study is to determine the validity of the RADAI during pregnancy in patients with RA by determining the correlation and agreement of the RADAI to the DAS28.

Methods: Pregnant RA patients were visited at their home-address (once before conception, during every trimester and three times post partum). During these visits the disease activity was measured by the RADAI and the DAS28. Correlation coefficients were determined for each time point. Furthermore, patients were stratified according to three disease states (high, intermediate, low and remission combined) based upon DAS28 and RADAI, with cut off points for the RADAI that are thought to be equivalent to those used for the DAS28.

Results: Disease activity determined by RADAI as well as by DAS28 showed a decrease during pregnancy and a flare after delivery (p< 0.01) (fig. 1). The correlations between DAS28 and RADAI were good (pre conception rho = 0.49, all other time points 0.61 < rho < 0.71 (p<0.01). When patients were stratified according to disease states, it was shown that according to the RADAI more patients showed remission or low disease activity during first trimester. (1st trim. RADAI 42,1%;DAS28 26.3%), whereas during the 3rd trimester these percentages were comparable (RADAI 43.3%; DAS 41.3%). After delivery, for both the RADAI and the DAS28, highest disease activity was observed at 12 weeks after delivery. Despite this the agreement on the disease activity states between RADAI and DAS28 was low (0.28 < kappa < 0.51).

Fig 1.

Conclusion: The RADAI and DAS28 show moderate to good correlations. The RADAI might be a useful questionnaire to determine the disease activity for pregnant patients with RA. The study also shows that the RADAI

score drops earlier than the DAS28. This might explain why earlier studies that used self-assessed questionnaires show earlier improvements as compared to recent studies.

77

Comorbid Conditions Do Not Explain Divergent Patient Assessments of Disease Activity and Global Health in Patients with Rheumatoid Arthritis. Dörte Huscher[1], Katja Thiele[2], Sascha Bischoff[2], Ulrich von Hinüber[3], Guido Hoese[4], Kirsten Karberg[5], Wolfgang Ochs[6] and Angela Zink[1]. [1]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Rheumatologist in Private Practice, Hildesheim, Germany, [4]Rheumatologist in Private Practice, Stadthagen, Germany, [5]Rheumatologist in Private Practice, Berlin, Germany, [6]Rheumatologist in Private Practice, Bayreuth, Germany

Background/Purpose: In the discussion of the 2010 ACR/EULAR remission criteria the issue has been raised to what extent patients are able to distinguish rheumatoid arthritis (RA) related disease activity from global health assessment. It was proposed that co-morbidity is a major driver of poor self-assessed global health when exceeding disease activity.

Methods: We used cross-sectional data of 2,242 RA patients, enrolled in the National Database of the German Collaborative Arthritis Centres between 2005 and 2010, for whom both self-assessed disease activity [VAS 0–100] and global health [NRS 0–10] were documented. Patients who were seen in more than one year were included only once. For comparison, the disease activity scale was transformed to NRS 0–10.

Results: 75% of the patients were female, their mean age was 62.3 years, the median disease duration 7.9 years. For 1,673 patients (75%) the ratings of disease activity and of global health were equal, 213 (10%) rated global health better and 356 (16%) worse. While mean global health scores in these three groups were rather similar, disease activity ratings revealed remarkable differences. Patients who rated their global health worse than their current disease activity were more frequently male, had low mean self-assessed disease activity, and a low DAS28 score. Their pain scores were, however, above their self-assessed disease activity. The proportions of patients with co-morbid conditions were comparable between the groups that rated "better" and "worse", but higher for those patients who gave the same scores for global health and disease activity. For patients with comorbid conditions, the average number of comorbid conditions was higher in patients who rated their global health better than those who rated worse.

Table 1. Characteristics of patients with better, the same or worse global health rating when compared to self-assessed disease activity. Displayed are mean (and median) if not indicated otherwise.

	Patient's assessment: global health compared to disease activity		
	better	the same	worse
N [% of all 2,242 patients]	213 [9.5%]	1,673 [74.5%]	356 [15.9%]
Male	25%	24%	31%
Age, years	61.1	62.7	60.9
Disease duration, years	8.6 (5.6)	10.9 (8.8)	9.3 (6.0)
Patient ass. disease activity [NRS 0-10]	5.1 (5.0)	4.5 (5.0)	2.2 (2.0)
Patient ass. global health [NRS 0-10]	3.3 (3.0)	4.5 (5.0)	4.1 (3.5)
Pain [NRS 0-10]	4.1 (4.0)	4.5 (5.0)	3.6 (3.0)
Number of tender joints	2.0 (0.0)	1.7 (0.0)	1.0 (0.0)
Number of swollen joints	1.3 (0.0)	1.2 (0.0)	0.9 (0.0)
ESR	26.1 (18.0)	22.9 (17.0)	22.9 (16.0)
CRP	1.4 (0.6)	1.0 (0.4)	1.0 (0.4)
DAS28(ESR, global health)	3.2 (3.0)	3.2 (3.0)	3.0 (2.8)
Physician ass. disease activity [NRS 0-10]	2.0 (1.0)	1.5 (1.0)	1.4 (1.0)
With comorbidity	66%	81%	68%
Number of comorbidities if any	2.5 (2.0)	2.6 (2.0)	2.1 (2.0)

Conclusion: The majority of patients with RA gave concordant ratings for disease activity and global health. Differences in ratings were mainly driven by higher disease activity, while global health scores were similar between the groups with concordant and discordant ratings. Comorbidity played no recognizable role for differences between both scores.

78

Factors Influencing On the Discordance Between 2011 ACR/EULAR Criteria and Physician's Clinical Judgment for Remission in Rheumatoid Arthritis Patients. Yoon-Kyoung Sung[1], Bo Young Yoon[2], Soo-Kyung Cho[1], Chan-Bum Choi[1], Dae-Hyun Yoo[1], Jae-Bum Jun[1], Tae-Hwan Kim[1], Shin-Seok Lee[3], Tae-Jong Kim[3], Jisoo Lee[4], Jung-Yoon Choe[5], Sung-Hoon Park[5], Seung-Jae Hong[6], Yeon-Ah Lee[6], Jinseok Kim[7], Eun-Mi Koh[8], Hoon-Suk Cha[8], Jaejoon Lee[8], Won-Tae Chung[9], Sung Won Lee[9], Choong-Ki Lee[10], Hye-Soon Lee[11], Wan-Hee Yoo[12], Young Mo Kang[13] and Sang-Cheol Bae[14]. Background/Purpose: Remission is a primary end point in the treatment of rheumatoid arthritis (RA). To ensure more uniform reporting of outcome measures, American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) recently developed new definitions of RA remission. The 2011 ACR/EULAR remission criteria provide the stringent definition of remission, but do not always concordant with the state of remission defined by physicians. The purpose of this study was to compare the concordance between new remission criteria and physician's clinical judgment of remission and to identify influencing factors on discordance between them.

Methods: Total of 1,140 patients with RA were recruited from KORean Observational study Network for Arthritis (KORONA), a database generated by rheumatologist investigators across the South Korea. The frequency of remission was evaluated based on various definitions including the Boolean based ACR/EULAR criteria and physician's clinical judgment. The agreement between them was estimated by Cohen's kappa (κ). For the patients in remission according to Boolean based ACR/EULAR criteria and/or physician's judgment (n=279), we divided them into three groups; Group 1(remission according to both criteria and physician's judgment), Group 2 (remission only by criteria), and Group 3 (remission only by physician's judgment). On multinomial logistic regression analysis, we identified influencing factors for both discordant groups compared to concordance group in remission

Results: Remission rates with the Boolean based ACR/EULAR remission criteriam CDAI, and SDAI were 10.5%, 16.4% and 17.2%, respectively. Remission rate according to physician's clinical judgment was 18.4%, while DAS28 remission rate was 27.4%. The agreement between new criteria and physician's clinical judgment for remission was low (κ =0.202) and the concordant remission rate was only 4.1% (n=51, group 1), while the prevalence of remissions by only criteria and physician's judgment were 6.1% (n=69, group 2) and 13.9% (n=159, group 3), respectively. Multinomial logistic regression analysis shows that the pain affected on both discordant groups and sleep disturbance and fatigue were associated with remission only by physician's clinical judgment. These indicated that patient's subjective symptoms such as pain, fatigue, and sleep disturbance may influence on the discordance between 2011 ACR/EULAR criteria and physicians' clinical judgment for remission (Table).

Table. Multinomial logistic results for discordant remissions as compared to concordant remission between Boolean based ACR/EULAR criteria and physician's clinical judgment (N=279)

Variable	Remission according to Boolean based ACR/EULAR criteria only				Remission according to physician's clinical judgment only			
	Coefficient	SE	Significance	Odds ratio (95% CI)	Coefficient	SE	Significance	Odds ratio (95% CI)
Disease duration	−2.823	1.697	.096	.059 (.002-1.652)	−.002	1.618	.999	.998 (.042-23.806)
Age	−.026	.017	.124	.974 (.942-1.007)	−.009	.017	.592	.991 (.959-1.024)
Male	.181	.452	.689	1.198 (.494-2.903)	.119	.449	.791	1.126 (.468-2.713)
Normal ESR	−.034	.429	.937	.967 (.417-2.240)	−.175	.424	.680	.840 (.366-1.927)
Normal CRP	−.716	.401	.075	.489 (.223-1.074)	.089	.392	.821	1.093 (.507-2.354)
HAQ-DI	2.018	1.113	.070	7.527 (.850-66.645)	1.557	1.088	.152	4.744 (.563-39.982)
Fatigue	−.008	.010	.428	.992 (.974-1.011)	.023	.008	**.003**	**1.024 (1.008-1.040)**
Sleep disturbance	−.007	.017	.675	.993 (.961-1.026)	.025	.013	**.050**	**1.026 (1.000-1.052)**
Pain	.060	.030	**.043**	**1.062 (1.002-1.125)**	.105	.029	**<.001**	**1.110 (1.050-1.174)**

Conclusion: Although the 2011 ACR/EULAR remission criteria are stringent than physician's clinical judgment, their agreement was low and patients' subjective symptoms such as pain, fatigue, and sleep disturbance were associated with discordance between them.

79

Physician's Global Assessment Is Affected by Physician's Age and Gender, but Not by Patient Age and Gender in Rheumatoid Arthritis Patients Treated in Routine Care. Data From the Danish Nationwide Danbio Registry. Cecilie Lindstrom Egholm[1], Theodore Pincus[2], Lene Dreyer[3], Torkell Ellingsen[4], Bente Glintborg[3], Marcin Kowalski[5], Tove Lorenzen[4], Ole Rintek Madsen[3], Henrik Nordin[6], Claus Rasmussen[7] and Merete L. Hetland[8]. [1]Copenhagen University Hospital/DANBIO at Glostrup, Copenhagen, Denmark, [2]NYU Hospital for Joint Diseases, New York, NY, [3]Copenhagen University Hospital at Gentofte, Gentofte, Denmark, [4]Region Hospital Silkeborg, Silkeborg, Denmark, [5]Aalborg Hospital, Aalborg, Denmark, [6]Rigshospitalet, Copenhagen, Denmark, [7]Vendsyssel Hospital, Hjoerring, Denmark, [8]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Several studies have shown that significant discordance exists between patient (PATGL) and physician (DOCGL) global measures of rheumatoid arthritis (RA) disease activity. These studies have focused on patient-related factors associated with discrepancy. However, relatively little is known about possible physician-related factors that might explain the DOCGL. The aim of the present study was to determine potential physician-related factors associated with the DOCGL score.

Methods: Physician data (e.g. age, sex, title and experience) were requested by questionnaire from physicians who use the Danish nationwide rheumatological DANBIO-registry in their clinical work. DANBIO data based on first encounters between patients and physicians in the registry were analysed. Patient data included: sex, age, duration of disease, Health Assessment Questionnaire (HAQ) score, C-reactive protein (CRP), swollen (SJC28) and tender joint counts (TJC28), treatment (biologic/non bio), and 100 mm visual analogue scales (VAS) for PATGL, pain and fatigue. Multivariate linear regression analysis was performed to determine physician- and patient-related factors that affected DOCGL.

Results: 90 physicians returned the questionnaire (34%). The physicians were matched with 8,970 patient encounters, for which physicians were 55% females, age 52 (47– 56) years (median, Interquartile Range (IQR)), 78% were consultants in rheumatology, no. of patients seen per month per physician was 80 (50–120). Patients were 74% females, age 61 (51–70) years, disease duration 7 years (2–15), CRP 6 (3–12) mg/L, HAQ 0.75 (0.25–1.375), SJC 1 (0–3), TJC 2 (0–6), pain 32 (14–57) mm and fatigue 42 (19–67) mm. 34% were treated with biologics. The median DOCGL was 12 (5–27) mm and PATGL 39 (17–64) mm - a difference of 27 mm.

Table 1 shows patient and physician factors associated with the DOCGL. DOCGL was higher in male physicians, in the younger half of physicians

and in physicians who were not consultants. Patient gender did not affect DOCGL, whereas SJC and TJC did. Patient age was statistically but not clinically significant for DOCGL. Thus, on average, the DOCGL in a male non-consultant less than 52 years old was 9.8 mm higher than that of a female consultant above 52 years of age.

Table 1. Results of multivariate linear regression analysis of physician and patients factors as predictors of DOCGL, only statistically significant variables included.

Variable	Estimate	95 % CI	p
Intercept	−0.577		
Physician			
Sex female	1		
male	3.345	2.672–4.018	<0.001
Age > 52 years	1		
≤ 52 years	3.461	2.754–4.168	<0.001
Consultant in rheumatology, yes	1		
No	3.126	1.747–4.505	<0.001
Patient			
Age (10 years' increase)	−0.0018	−0.0024−−0.0014	<0.001
Patient VAS-global	0.147	0.135–0.159	<0.001
CRP	0.116	0.100–0.133	<0.001
SJC28 (range 0-28)	2.775	2.672–2.878	<0.001
TJC28 (range 0-28)	0.745	0.680–0.809	<0.001

Referent group for continuous variables is represented by each 1-unit increase in that variable when not otherwise stated. Results adjusted for patient gender, clinic site, country for medical exam, research experience, experience with joint scoring, number of patients seen monthly, and assessed level of importance of inflammation, fibromyalgia, comorbidity and patient social factors. VAS = Visual Analogue Scale, measured on a 0-100 mm scale; CRP= C-reactive protein, measured in mg/L; SJC28 = swollen joint count on 28-joint assessment; TJC28 = tender joint count on 28-joint assessment. Adjusted R^2 = 0.69.

Conclusion: This study of 90 physicians matched with >8,000 RA patients treated in routine care showed clinically significant inter-physician variations in the physicians′ global score. Male physicians scored on average 3.1 mm higher than female, physicians that were < 52 years old scored 3.7 mm higher than their older counterparts, and consultants scored 3.1 mm lower than non-consultants. SJC and TJC, but not patient age and gender, also affected the physicians′ global score. The significant contribution of physician-associated factors may have implications for research involving measures of physicians′ global score and for clinical care.

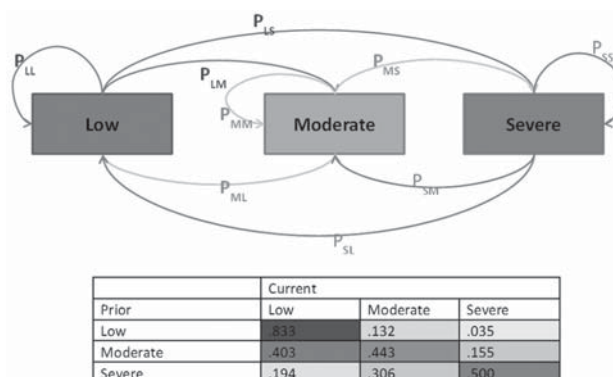
Validation of Remission of Rheumatoid Arthritis by Traditional Disease Activity Score and Provisional Criteria by American College of Rheumatology and European League Against Rheumatism: Patient Reported Outcomes Analyzed From 3 Phase III Golimumab Trials. Chenglong Han[1], E. Keystone[2], Roy Fleischmann[3], Josef S. Smolen[4], Paul Emery[5], Mark C. Genovese[6], Mittie K. Doyle[7] and Elizabeth C. Hsia[7]. [1]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [2]University of Toronto, Toronto, ON, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [5]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [6]Stanford University Medical Center, Palo Alto, CA, [7]Janssen Research and Development, LLC, Spring House, PA

Background/Purpose: Remission by Boolean-based definition (all scores on the tender joint and swollen joint count, CRP (mg/dL), and patient global assessment ≤1) and by Simplified Disease Activity Index-based definition (SDAI, <3.3) were proposed by ACR/EULAR. Using patient reported outcomes as anchors, this analysis validated these remission criteria against traditional Disease Activity Score (DAS28) using CRP remissions (<2.6) in 3 RA patient populations.

Methods: The efficacy of golimumab (GLM) was assessed in methotrexate (MTX)-naïve RA patients (GO-BEFORE, N=637), RA patients with inadequate response to MTX (GO-FORWARD, N=444) and RA patients previously treated with biologic anti-TNFα agent(s) with baseline MTX use (GO-AFTER, N=305). Pooled data from patients who received placebo

(PBO) + MTX, or GLM (50 or 100mg) + MTX, q4 weeks were used for this analysis.Patient reported outcomes were measured with the following: Health Assessment Questionnaire (HAQ), Physical and Mental Component Summary Scores of 36-item short-form health survey (SF36 PCS and MCS), Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue), and a Visual Analogue Scale (VAS, 0–10) of impact of RA on daily work productivity. Descriptive statistics were provided forpatient reported outcomes among patients in remission as defined by the 3 remission definitions.

Results: Greater proportions of patients treated with GLM + MTX vs patients treated with PBO + MTX achieved remission in the 3 studies by each remission definition.In the pooled analysis, the remission rate at wk 24 was the highest (20.2%) by DAS28, compared to remission by SDAI (10.6%, $p<0.001$) and remission by Boolean-based definition (8.6%. $p<0.001$). Patients with remission by DAS28 achieved normal physical function (HAQ≤0.5), normal SF-36 PCS, and MCS (≥50) by 67.8%, 38.4%, 62.2%, respectively; these parameters were numerically lower when compared to patients with remission by SDAI (81.3%, 62.8%, 72.1%, respectively) or by Boolean-based definition (82.0%, 63.5%, 74.3%, respectively). Patients in remission by DAS28 had higher HAQ scores (0.43 ±0.49) compared to patients in remission by SDAI (0.26±0.41) or Boolean-based criteria (0.28±0.44).Similar results were observed in measures of FACIT-fatigue and productivity VAS scores. Among MTX-naive patients in the GO-BEFORE study who achieved remission by DAS28, 71.3% achieved normal physical function compared to 86.9% of those in remission by SDAI and 86.5% of patients in remission by Boolean-based definition. Among anti-TNFα experienced patients in the GO-AFTER study, 62.1% of those in remission by DAS28 achieved normal physical function compared to 65.0% of those in remission by SDAI, and 66.7% of patients in remission by Boolean-based definition.

Conclusion: While disease remission has been adapted as a target in the management of RA, more stringent remission criteria proposed by ACR/EULAR can provide optimal patient-reported outcomes.


81

Transitions Among Disease Activity States: Estimates and Models of Covariate Associations. George W. Reed[1], David H. Collier[2], Andrew S. Koenig[3],Katherine C. Saunders[4], Joel M. Kremer[5] and Sameer Kotak[6]. [1]University of Massachusetts Medical School, Worcester, MA, [2]Amgen Inc., Thousand Oaks, CA, [3]Pfizer Inc., Collegeville, PA, [4]CORRONA, Inc., Southborough, MA, [5]Albany Medical College and The Center for Rheumatology, Albany, NY, [6]Pfizer Inc., New York, NY

Background/Purpose: Many RA patients have variable disease activity over time due to disease variability, reduction in efficacy of current medications, environmental factors and other co-morbid disease changes. Prior methodologies have been developed but in the absence of application with real data the models have not been validated. The model applied to patient clinical data may potentially provide insights into clinically relevant associations to disease state transitions and enhance treatment methods.

Methods: Disease activity states of low, moderate and severe were defined using CDAI (Low:CDAI≤10; Moderate 10<CDAI≤22; and Severe 22<CDAI).A Markov Model for repeated measures allowing for covariate dependence was used to model transitions among three states (Figure 1a) - from a prior disease state to a current disease state.Population transition probabilities were estimated and a multinomial logistic regression model used to examine the impact of covariates on disease states and if the impact of covariates depended upon the prior disease state.Initiation of DMARDS, duration of RA, age and insurance were used as covariates of interest. Disease activity measures at repeated visits of RA patients were used from the CORRONA RA registry (Oct, 2001 to Feb, 2012).There were 160,262 visits from 24,136 RA patients with CDAI measured at the visit and at the prior visit.

Results: Estimated transition probabilities in the population are in Figure 1b, showing that if the disease state at the prior visit was low then the probability of remaining low (P_{LL}) is 0.833 and the probability of transitioning to moderate disease (P_{LM}) at the next visit is.132, and to severe (P_{LS}) is.035.Transition from any state to low disease was seen to improve from 2001-05 to 2009-12 with P_{LL} going from 0.79 to 0.84 ($p<0.001$). Logit models estimated the effect of covariates adjusted for time between visits. A patient in a prior state of moderate disease had a relative risk ratio of 7.6 (95%CI: 7.08–8.21) to be in moderate disease at the current visit (vs a patient in a prior state of low disease) if no DMARD was initiated on the prior visit.If a DMARD was initiated the risk was reduced to 4.08 (3.59–4.63). Longer duration of RA increased the risk of transition in a moderate or severe state. Age and insurance did not interact with prior disease states but showed an association with current disease state - with private insurance associated with lower levels of disease and age 50–64 with a larger risk for moderate and severe disease vs age <50.

	Current		
Prior	Low	Moderate	Severe
Low	.833	.132	.035
Moderate	.403	.443	.155
Severe	.194	.306	.500

Conclusion: Estimation of transition probabilities among disease states provides a snapshot of RA population risks dependent upon prior states and a methodology for examining factors associated with those risks. Current models estimate the impact of initiating DMARDS and the duration of RA and provide a proof of concept of the modeling framework that can be mined for examining further associations.

82

Variability of the SF-6D Determinants Over Time in Early Arthritis: Results From the Espoir Cohort. Cécile Gaujoux-Viala[1], Bruno Fautrel[2], Kossar Hosseini[3], Francis Guillemin[3], René-Marc Flipo[4] and Anne-Christine Rat[5]. [1]Lorraine University, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy; Paris 6 - Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Paris 6 - Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [3]Lorraine University, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy, France, [4]Rheumatology Department, Lille University Hospital, Lille, France, [5]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy, France

Background/Purpose: There is growing emphasis on the cost-effectiveness of treating rheumatoid arthritis. The SF-6D, derived from the SF36, is an indirect utility measure widely used to calculate quality-adjusted life-years in order to assess health benefits. Few trials directly record the health utility measures (or the SF36), needed for economic analyses. Consequently linear regression methods have been used to transform Health Assessment Questionnaire (HAQ) scores into utility measures.

Objective: 1) To assess which variables are associated with the SF-6D in early arthritis over 3 years

2) To check if these associations are stable over 3 years

Methods: – *Patients*: Between 2002 and 2005, the ESPOIR cohort enrolled 813 patients with recent arthritis in at least 2 joints with 6 weeks to 6 months disease duration.

– *Data available*: SF-6D utility measures were longitudinally assessed in 813 patients with EA (at baseline, 6 months, 1, 2 and 3 years). Clinical and biological variables and X-rays were also recorded.

– *Analysis*: The determinants of SF-6D-derived utility values at each time-point over 3 years were assessed by multivariate linear regressions to analyze which specific aspects of early arthritis were independently associated with the SF-6D.

Results: At baseline, higher HAQ, patient global evaluation, pain, fatigue, and lower mental status were significantly associated with lower SF-6D. HAQ and AIMS2-SF-mental scores explained 49 and 14% of the variance respectively. At 6 months, 1, 2 and 3 years, higher HAQ, patient global evaluation, fatigue, age and lower mental status were significantly associated with lower SF-6D. HAQ and AIMS2-SF-mental scores explained 7 to 13% and 55 to 57% of the variance respectively (figure).

% variance of the SF-6D explained

■HAQ ■Mental score ■Patient Global Assessment
Conclusion: The determinants of the SF-6D varied over 3 years in EA patients. At baseline, the SF-6D was essentially determined by function whereas after 6 months, the SF-6D was essentially determined by mental status. Cost-effectiveness models should not use utility values derived from HAQ.

83

Substantial Functional Disability Is the Key Determinant of Discrepancies Between EQ-5D and SF-6D Utility Measures in Early Arthritis: Results From the Espoir Cohort. Cécile Gaujoux-Viala[1], Bruno Fautrel[2], Kossar Hosseini[3], Francis Guillemin[4], René-Marc Flipo[5] and Anne-Christine Rat[4]. [1]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy; Paris 6 - Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [2]Paris VI University, Paris, France, [3]Lorraine University, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy, France, [4]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F- 54 000, Nancy, France, [5]Rheumatology Department, Lille University Hospital, Lille, France

Background/Purpose: The EQ-5D, a 5-dimensional multi-attribute questionnaire, and the SF-6D, derived from the SF36, are 2 indirect utility measures widely used to calculate quality-adjusted life-years in order to assess health benefits.

Objective: 1) To assess which variables at baseline are associated with EQ-5D and SF-6D in early arthritis 2) To assess which variables at baseline are associated with substantial utility differences between EQ-5D and SF-6D.

Methods: –*Patients*: EQ-5D and SF-6D utility measures were assessed in 813 patients included in the French nationwide ESPOIR cohort, which enrolled early arthritis (EA) patients with ≥2 swollen joints for less than 6 months and suspicion of RA.

– *Analysis*: Determinants of EQ-5D and SF-6D at baseline were assessed by multivariate linear regression. Multivariate linear regression was used to determine which aspects of EA were independently associated with the difference between the two utility measures in patients with substantial utility difference, i.e. l SF-6D – EQ5D l >0.074 (highest minimal important difference, MID).To assess the determinants of having substantial utility difference, patients were divided into 3 categories at baseline:l SF-6D-EQ-5D l >0.074 and SF-6D>EQ-5D, l SF-6D – EQ-5D l >0.074 and EQ-5D>SF-6D and the others corresponding to no substantial difference (reference category). Variables collected at baseline were analyzed by polytomous logistic regression, with the 3 categories as dependent variables.

Results: At baseline, mean values were 0.52±0.31 (range -0.59 to 1) for EQ-5D and 0.58±0.11 (range 0.30 to 0.92) for SF-6D. In the multivariate linear regression model, higher HAQ, pain and lower mental status (AIMS2-SF) were significant determinants of a lower EQ-5D. HAQ and AIMS2-SF-mental scores explained 41.4 and 7.9% of the variance respectively. Higher HAQ, patient global evaluation, pain, fatigue, and lower mental status were significantly associated with lower SF-6D. HAQ and AIMS2-SF-mental scores explained 49.3 and 14.5% of the variance respectively.

The majority of patients presented a substantial difference between the 2 utility values>0.074 (66.5%) (mean difference 0.064 [range -0.421;0.941]). In these patients, higher disability, lower mental status and higher CRP were associated with substantial difference between EQ-5D and SF-6D. HAQ and AIMS2-SF-mental scores explained 43.3 and 2% of the variance respectively.

In the polytomous logistic regression model, HAQ, lower mental status and higher pain were associated with substantial difference between EQ-5D and SF-6D. Lower disability was associated with the probability that EQ-5D was substantially superior than SF-6D in comparison with no substantial difference. Higher disability was associated with the probability that SF-6D was substantially superior to the EQ-5D.

Conclusion: Higher functional disability is the key element leading to substantial difference between the two utility measures in EA patients. EQ-5D and SF-6D are not interchangeable especially in patients with worse functional ability and the results of cost-utility studies using different utility instruments must not be compared.

84

Benefits of Treat-to-Target Guideline Compliance in Patients with Rheumatoid Arthritis: A Retrospective Claims Analysis. Martin J. Bergman[1], James W. Shaw[2], Mary A. Cifaldi[2], Annie Guerin[3], Pooja Chopra[3] and James Signorovitch[4]. [1]Taylor Hospital, Ridley Park, PA, [2]Abbott Laboratories, Abbott Park, IL, [3]Analysis Group, Inc., Montreal, QC, [4]Analysis Group, Inc., Boston, MA

Background/Purpose: To achieve clinical remission/low disease activity in patients with rheumatoid arthritis (RA), the treat-to-target (T2T) guidelines recommend frequent disease monitoring through patient-rheumatologist interactions. The economic implications of treating to target have not been fully quantified.This study aimed to estimate the effects of compliance with T2T recommendations regarding patient follow-up on health care resource utilization (HRU) and medical service costs in RA patients newly initiated on a disease-modifying anti-rheumatic drug (DMARD).

Methods: Patients ≥18 years old with ≥2 RA diagnoses and ≥1 prescription fill for a DMARD that was preceded by a rheumatologist encounter (within 7 days) were identified from the MarketScan® Commercial Claims and Encounters database (1/2000 to 9/2011).A patient's index date was randomly selected among all new DMARD initiation dates with ≥3 months of continuous enrollment before and ≥15 months after that date. Patients with a follow-up rheumatologist visit within 90 days of the index date were defined as compliant, while all others were classified as noncompliant.HRU and costs (measured from a payer's perspective in 2010 US dollars) were measured over a 1-year period starting 90 days after the index date.Adjusted all-cause HRU and medical service costs were compared between compliant and noncompliant patients using multivariable regression.

Results: A total of 15,103 RA patients were selected with 10,739 (71.1%) being designated as compliant.The average age was 49.9 years, and 23.2% were male.After adjusting for potential confounding, compliant patients exhibited significantly fewer inpatient admissions and inpatient days, fewer emergency room (ER) visits, and less use of other medical services but significantly more outpatient visits than noncompliant patients.Consequently, compliant patients had significantly lower adjusted inpatient costs but significantly higher adjusted outpatient costs than noncompliant patients.The inpatient cost reduction offset the increase in outpatient costs such that there was no significant difference between the two cohorts with respect to aggregate adjusted medical service costs.

Comparison of all-cause HRU and medical costs between compliant and noncompliant RA patients

	Unadjusted Incidence Rate				Unadjusted Mean Medical Cost			
	Compliant [A]	Not Compliant [B]	Adjusted IRR (95% CI) [A]/[B]	P-value	Compliant [A]	Not Compliant [B]	Adjusted Cost Diff. (95% CI) [A]-[B]	P-value
All medical services					13,662	11,596	321 (−825, 1,487)	0.624
INPT visits					3,620	3,715	−933 (−1,721, −290)	0.020
No. INPT admissions	0.17	0.17	0.86 (0.77, 0.97)	0.010				
No. INPT days	0.97	1.04	0.78 (0.66, 0.94)	0.007				
Outpatient visits	20.35	17.75	1.05 (1.02, 1.07)	<0.001	8,793	6,515	1,665 (888, 2,843)	<0.001
ER visits	0.36	0.36	0.90 (0.83, 0.99)	0.023	305	303	−20 (−70, 20)	0.340
Other	3.38	3.25	0.93 (0.88, 0.98)	0.004	943	1,063	−135 (−294, 29)	0.124

Abbreviations: HRU, health resource utilization; RA, rheumatoid arthritis; IRR, Incidence Rate Ratio; CI, Confidence Interval; INPT, inpatient; ER, emergency room.
Notes: The other medical service category included laboratory, radiology, and other ancillary services. Given that the unadjusted incidence rates and means could have been biased due to confounding, comparative estimates were adjusted for age, region, insurance, comorbidities, index year, and HRU and costs at baseline (chosen based on P < 0.05).

Conclusion: RA patients benefit from being followed in a manner consistent with T2T guidelines.Notably, they exhibit fewer inpatient visits with lower length of stay and lower ER utilization without incurring an increase in medical service costs due to more frequent follow-up with a rheumatologist.However, more research is needed to assess the impact of rigorous follow-up on patient quality of life.

An Innovative Strategy to Implement Clinical Practice Guidelines for Rheumatoid Arthritis and Osteoarthritis Patients Through Facebook.
Lucie Brosseau[1], George Wells[2], Sydney Brooks[3], Gino De Angelis[4], Mary J. Bell[5], Mary Egan[1], Stéphane Poitras[1], Judy King[1], Lynne Casimiro[6], Laurianne Loew[1] and Michael Novikov[1]. [1]University of Ottawa, Ottawa, ON, [2]University of Ottawa Heart Institute, Ottawa, ON, [3]The Arthritis Society, Ontario Division, Toronto, [4]Univeristy of Ottawa, Ottawa, ON, Ottawa, ON, [5]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, [6]Montfort Hospital, Ottawa, ON

Background/Purpose: A major issue in health research today is finding effective and efficient ways to exchange knowledge between researchers, clinicians and the general public. Evidence Based Clinical Practice Guidelines (EBCPGs) are systematically developed statements that help practitioners decide on appropriate health care in specific clinical circumstances. The purpose of the study is to determine if an updated online evidence-based educational program delivered through *Facebook* is effective in improving the knowledge, skills, and self-efficacy of patients with arthritis in relation to evidence-based self-management rehabilitation interventions (updated Ottawa Panel EBCPGs) for OA and RA.

Methods: Adult patients (>18 years old) with self-reported OA or RA were eligible for the study. A total of 110 participants were recruited from the general public and different arthritis patient organizations throughout Canada. Eleven participants were selected to participate in a focus group using the Delphi process to rank and select effective self-management strategies for OA and RA according to level of implementation burden. Ninety-nine participants were then selected to participate in the online *Facebook* intervention which included a "group" web-page providing case-based video clips on how to apply the selected self-management interventions. Over a 3-month period, participants were asked to complete 3 online questionnaires regarding their previous knowledge, intention to use/actual use of the self-management strategies, self-efficacy and confidence in managing their condition.

Results: Knowledge acquisition scores improved among OA and RA participants with a mean difference of 1.8 (p<0.01) when compared from baseline to immediate post-intervention. At 3 months post-intervention, almost all self-management strategies were successful with participants following through on their intention to use the self-management strategies, however, statistically significant results were only demonstrated for "aquatic jogging" (p < 0.05) and"yoga" (p < 0.05) among OA participants, and "aquatic therapy" (p<0.01) among RA participants. Statistically significant knowledge acquisition scores improved by 31% for ice massage (p<0.01),

22% for transcutaneous electrical nerve stimulation (p<0.05), 21% for bed rest (p<0.05), 19% for balneotherapy (p<0.01), 14% for yoga (p<0.05), 12% for low level laser therapy (p<0.05), and 11% for semi-rigid inserts in extra depth shoes (p<0.05). Self-efficacy was maintained from immediate post-intervention to 3 months follow-up, and confidence improved as the study progressed.

Conclusion: Patients were able to perform the interventions in the privacy and comfort of their own home, discuss and learn from experience of other individuals afflicted with the same disease using this popular social networking site. This online program can provide patient organization representatives with the opportunity to learn about evidence-based self-management strategies for OA and RA, to increase their awareness of useful community resources, and support their efforts to disseminate the information to others with arthritis.

86

Longitudinal Hypertension Diagnosis and Control Among a Primary Care Medically Homed Population with Rheumatoid Arthritis.
Katya Voelker[1] and Christie M. Bartels[2]. [1]Univ of Wisconsin School of Medicine and Public Health, Madison, [2]Univ of Wisconsin School of Medicine and Public Health, Madison, WI

Background/Purpose: Hypertension is a key risk factor for cardiovascular disease (CVD) in patients both with and without rheumatoid arthritis (RA). In their review on hypertension in RA, Panoulas et al (2008) cited relative risks of hypertension for CVD events ranging from 1.5 to 4.3.Reports vary further regarding hypertension prevalence in RA largely due to varying case definitions and timing of observations. Herein we examined hypertension prevalence, diagnosis and control using standard Joint National Committee-7 (JNC-7) hypertension diagnostic criteria applied to a medically homed RA population.

Methods: Using a cohort design we studied all adult patients with rheumatoid arthritis who were medically homed receiving primary care and rheumatologic care within a large multispecialty practice. Patients were considered "medically homed" for each consecutive year (2005–2011) that they met definitions requiring ≥2 visits over a 24 month baseline (including at least 1 primary care visit and 1 rheumatology visit). RA was determined using algorithms requiring two ICD-9 claims of 714.0–714.4 in 24 months (modified Katz 1997, MacLean 2000). Hypertension diagnosis eligibility was defined by applying Joint National Committee-7 (JNC-7) hypertension diagnostic criteria: 3 or more blood pressures >140/90 or 2 or more pressures >160/100 on >2 separate visits. An algorithm was used to search for >1 ICD-9 hypertension code (Tu 2007) or any antihypertensive medication to indicate hypertension diagnosis. Total hypertension prevalence counted diagnosed and undiagnosed cases meeting JNC definitions. Control was also based on JNC-7 criteria requiring 3 normal blood pressures <140/90. Descriptive statistics were used to report hypertension prevalence, diagnosis and control during the baseline and subsequent medically homed period.

Results: In our population of 1,099 medically homed RA patients (mean age 56; 76% female) the prevalence of hypertension was 30% at baseline and 56% during follow up.Hypertension generally increased with age (Fig. 1). Compared to older patients, a higher proportion of younger patients remained undiagnosed. Although older patients were more often diagnosed, three quarters remained uncontrolled.

Figure 1. Hypertension diagnosis and control in medically homed RA patients at (A) baseline and (B) longitudinal follow up.

Conclusion: Our examination of medically homed RA patients receiving both primary care and rheumatology care highlights the importance of examining longitudinal data for assessing diagnosis and control of hypertension among patients with RA. These data illustrate that point prevalence

estimates may under report hypertension rates relative to standard JNC definitions using multiple observations. Overall, young hypertensive RA patients were proportionally less likely to be diagnosed and control remained poor across all age groups.

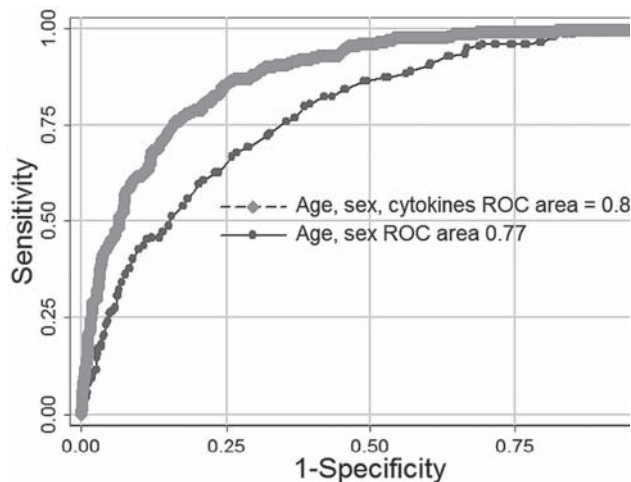
Prediction of Mortality in Rheumatoid Arthritis Using a Serum Cytokine Profile. Agustin Escalante[1], Roy W. Haas[1], Daniel F. Battafarano[2] and Inmaculada Del Rincon[1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Brooke Army Medical Ctr, San Antonio, TX

Background/Purpose: Cytokines are important in the pathogenesis of RA. Their concentration in the serum rises immediately prior to RA onset, and may be associated with disease outcome. We are not aware of any studies of serum cytokines in relation to mortality in RA. In the present study we examined the accuracy of a profile of 38 cytokines in the prediction of mortality in an RA cohort.

Methods: We studied RA patient participants in a longitudinal study of RA outcomes who were recruited at a routine visit to a rheumatologist.After a baseline assessment that included a collection of a serum specimen, which was stored for future study, patients were tracked yearly for follow-up.We identified deaths thorough next of kin, physician or public database reports, confirmed by death certificate.We used stepwise logistic regression to examine the association between serum cytokine levels and mortality, adjusting for the confounding influence of age and sex. We used receiver operator characteristic(ROC) curves to measure accuracy of mortality prediction.

Results: We studied 1,328 RA patients.A serum sample for cytokine measurement was available in 1,217 patients, who accrued 5,965 person-years of observation, or an average of 4.9 years per patient (range 1 day to 15 years).During this time, 204 deaths occurred for a mortality rate of 3.4 per 100 patient-years, 95% CI 3.0 to 3.9.Using age- and sex-adjusted stepwise logistic regression to identify cytokines associated with mortality, we found that the serum concentrations of the following 8 cytokines were independently associated with increased mortality: IP-10, 1.48 (1.03, 2.11); EGF, 1.27 (1.05, 1.54); TNF-a, 1.47 (1.12, 1.91); MCP-1, 1.60 (1.14, 2.24); IL-8, 1.75 (1.36, 2.23); IL-3, 1.67 (1.05, 2.67); IFN-g, 1.4 (1.08, 1.80); and GRO, 2.08 (1.40, 3.09). In the same model, the following 5 cytokines were independently associated with reduced mortality:MDC, 0.36 (0.26, 0.51); GCSF, 0.54 (0.39, 0.74); MIP-1a, 0.75 (0.62, 0.90); and IL-17, 0.71 (0.57, 0.89).Values shown are odds ratios (95% CI). The area under the mortality prediction ROC curve for a model including age and sex plus the above 13 cytokines was significantly higher than a model that included age and sex alone (0.876 vs. 0.776, P < 0.001) (see figure).


Conclusion: A serum cytokine profile is significantly associated with mortality in RA, and its accuracy in predicting mortality within 5 years is superior to that of age and sex alone. We are not aware of any previous reports of mortality prediction in RA using serum cytokine profiles.

The Effect of Weather On Patient Symptoms in Rheumatoid Arthritis: A Systematic Review of the Literature and Exploration of "weather sensitivity". Annika Cutinha[1], Frederick Wolfe[2] and Kaleb Michaud[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Patients with rheumatoid arthritis (RA) often attribute an exacerbation of their symptoms to changes in the weather. There are several studies examining this relationship. We conducted a systematic review of the existing literature on the effect of weather on symptoms in RA, and a follow up study that characterized patients with RA that reported being "weather sensitive".

Methods: A systematic review of Medline and Embase from inception until November 2011 looked for articles that report the effect of any aspect of weather on any symptom or outcome of patients with arthritis and 765 articles qualified. Then only included were non-duplicative articles in English with RA patients. We identified a subset of patients as "weather sensitive"(WS) based on patients reporting worse symptoms with increased weather. We observed that the percentage of WS patients in the studies reviewed, along with the difference in study methods, played a role in determining the final results. In order to identify WS patients and determine if they differ from other patients, we queried a cohort of 6901 US rheumatic disease patients (including 4655 RA, 1206 osteoarthritis (OA), and 374 fibromyalgia (FMS)) participating in an observational study and compared their demographic and clinical characteristics.

Results: Only 19 articles (N=3357 RA patients) qualified for our review. These studies did not find a consistent association between weather and RA symptoms. For example, 4 studies found a positive correlation between temperature and symptoms like pain and stiffness, 4 others found a negative correlation, and 4 more found no correlation. We had similar results for 11 articles studying humidity and RA outcomes: 6 positive, 1 negative, and 4 had no correlation. For atmospheric pressure, 3 were positive, 1 was negative, and 6 had no correlation. Of the 4655 RA patients we surveyed, 63% reported being WS (compared to 71% of OA and 78% of FMS), 20% were not, and the remaining 17% did not know. Columns 2–3 of Table 1 list their characteristics. Patients in the WS group were younger, less male, less educated, and had shorter RA duration. They also had worse RA symptoms as measured by HAQ, pain VAS, and SF36. The logistic multivariable regression for WS odds ratios are provided in column 4. We accounted for possible over reporting of symptoms by including a patient symptom count and polysymptomatic distress scale.

Table. Characteristics of RA patients by weather sensitivity and multivariable logistic regression.

	Not weather sensitive (N=926) (SD)	Weather sensitive (N=2926)	Odds ratio (95%CI)
Age (years)	64.8 (12.0)	62.1 (12.3)	0.98 (0.97, 0.99)
Male (%)	25.6	15.0	0.71 (0.58, 0.88)
Education (0-17 years)	14.7 (2.2)	14.1 (2.3)	0.91 (0.88, 0.95)
RA duration (years)	19.7 (12.1)	18.6 (SD 12.3)	0.99 (0.99, 1.00)
HAQ (0-3)	0.61 (0.7)	1.10 (SD 0.7)	1.26 (1.02, 1.55)
Pain VAS (0-10)	2.16 (2.4)	3.97 (SD 2.7)	1.09 (1.04, 1.15)
SF36 Physical CS Score	44.3 (11.4)	36.0 (SD 10.8)	0.97 (0.96, 0.99)
Symptom count (0-37)	4.9 (4.6)	8.4 (6.0)	1.05 (1.03, 1.08)
Polysymptomatic distress scale (0-31)	6.2 (6.5)	11.5 (7.9)	1.02 (1.00, 1.04)

Conclusion: Although widely believed, no consistent association in the literature between weather and RA symptoms was seen.Patients with worse function and pain are more likely to report being WS even after controlling for sociodemographic status and general symptoms. Future studies aimed at objectively measuring WS are needed to further evaluate whether subjective symptoms are more correlated with weather possibly through increased pain sensitization.

Poor to Moderate Performance of Patient Self-Report in Indentifying Periodontitis in Patients with Rheumatoid Arthritis. Ted R. Mikuls[1], Jeffrey Payne[2], Harlan Sayles[3], Shawneen Gonzalez[2], Jeffrey Markt[4], Mark Beatty[2], Grant W. Cannon[5], David McGowan[5], Gail S. Kerr[6], Robert Redman[7], Andreas M. Reimold[8] and Garth Griffiths[8]. [1]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Lincoln, NE, [3]University of Nebraska Medical Center, Omaha, NE, [4]Omaha, NE, [5]George E. Wahlen VA Medical Center, Salt Lake City, UT, [6]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [7]Washington DC VA, Georgetown and Howard University, Washington, DC, [8]Dallas VA and University of Texas Southwestern, Dallas, TX

Background/Purpose: Periodontitis (PD) is a putative risk factor for rheumatoid arthritis (RA) risk and progression.PD is defined as inflammation of the supporting tissues of the teeth, progressive attachment and bone loss and is characterized by pocket formation and/or gingival recession. No single definition of PD has been well established and consistently applied in research. Although results from standardized periodontal examinations are considered the 'gold-standard' for PD classification, studies examining the relationship of PD with RA have also relied on patient self-report for case ascertainment. The goal of this study was to examine the performance of patient self-reporting in identifying PD based on results from a standardized periodontal exam in patients with established RA.

Methods: In a multicenter study, RA patients satisfying ACR classification criteria underwent a standardized, calibrated, periodontal evaluation. PD was defined as the presence of clinical attachment loss 6 mm for 2 or more teeth and one or more sites with a probing depth $\geq$ 5 mm (consistent with severe PD). Characteristics of patients with and without PD were compared using the Student's t-test or Chi-square test. Patients responded to 6 questions previously used in research studies to assess for a history of PD, treatment, and/or related signs and symptoms (Table); the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the questions were calculated.

Results: Of the RA patients examined (n = 245), 82 (33.5%) had PD based on examination.Factors associated with an increased PD frequency included age (mean 62 vs. 57 yrs for PD vs. no PD, p = 0.014), male gender (82% vs. 53%, p < 0.001), ever smoking (78% vs. 55%, p < 0.001), and seropositivity for RF (92% vs. 81%, p = 0.025) or anti-CCP antibody (93% vs. 77%, p = 0.004). There were no associations of race, education, alcohol use, select comorbidity (diabetes, hypertension, heart disease), or medication use (prednisone, methotrexate, or biologic therapy) with the presence of PD. The metric properties of PD-related questions are shown:

	RA/+PD	RA/No PD	Sens.	Spec.	PPV	NPV
Do your gums bleed after you brush your teeth?	32%	14%	0.317	0.858	0.531	0.713
Have you ever been told that you have periodontal or gum disease involving bone loss or deep pockets?	37%	16%	0.366	0.839	0.536	0.722
Have you ever been told that you need periodontal or gum treatment (e.g. scaling and root planning or a "deep cleaning")?	39%	20%	0.390	0.804	0.500	0.724
Do you see a periodontist for treatment or cleanings?	28%	25%	0.284	0.748	0.365	0.672
Do you have "loose" teeth?	21%	4%	0.207	0.957	0.708	0.706
Have you ever had periodontal surgery?	16%	13%	0.159	0.875	0.394	0.670
Positive response to $\geq$ 1 PD screening question	70%	50%	0.707	0.497	0.414	0.771

Affirmative responses to the PD-questions were all more common (p $\leq$ 0.002) in RA patients with PD vs. No-PD, with differences in all but questions 4 and 6 being statistically significant.

Conclusion: In studies examining the relationship of PD with RA, patient self-report does not represent an adequate surrogate of clinically defined PD.In this study severe PD is very common in patients with established RA, affecting 1 in 3 patients. Although demonstrating moderate to good specificity in some cases, questions commonly used to assess for the presence of PD yield insufficient sensitivity (< 40%) in this population. Both PPV and NPV of these questions were consistently below 80% in this population, suggesting that misclassification and study bias are likely to occur in RA studies using patient self-report for PD case ascertainment.

90

Physical Function, Pain and Fatigue Are Related to Sleep Disturbance in Females with Rheumatoid Arthritis. Cathrine Austad[1], Tore K. Kvien[2] and Till Uhlig[2]. [1]Diakonhjemmet Hospital, Norway, Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: Sleep quality is an important aspect of health and well-being and the Outcome Measures in Rheumatology Clinical Trials group has identified sleep quality as a key concern for rheumatoid arthritis (RA) patients[1]. Patient reported sleep-disturbance is included in the RAID (RA Impact of Disease) score, but not in many other core patient reported outcomes (PROs) and is rarely reported in clinical trials.The aim of this study was to assess self-reported sleep disturbance in a large sample of patients from a population based RA registry and identify factors associated with self-reported sleep disturbance.

Methods: In a population based RA registry in Oslo, Norway, 868 patients aged 20–79 years (mean (SD) age 59.9 (12.3) years, disease duration 13.0 (10.8) years, 77.1% females) responded to a mailed questionnaire in 2009 (response rate 60.6%). 844 patients answered the numeric rating scale (NRS) on sleep disturbance due to RA (part of the RAID questionnaire) within the last week, and reported use of benzodiazepine like sleeping drugs (zopiclone/zolpidem = z-hypnotics) and other medications used in the treatment of RA. Other PROs included 100mm visual analogue scales (VAS) for pain, fatigue and patient global disease activity, HAQ (0–3, 3 worst), SF-36 with physical (PCS) and mental (MCS) component scores (0–100, 0=worst), RA Disease Activity Index (RADAI, 0–10, 10 worst) and RAID score (0–10, 10=extreme/very poor). Multivariate linear regression analyses were used to identify factors independently associated with sleep disturbance (0–10 NRS, 10=extreme sleep disturbance) and adjusted for age and disease duration.

Results:

Table 1. Clinical findings in females and males

	Female Mean (SD)	Male Mean (SD)	p-value
Significant gender differences			
· Disease duration (years)	13.5 (11.1)	11.5 (9.7)	0.02
· VAS fatigue (0-100)	45.9 (28.8)	40.5 (28.7)	0.02
· HAQ (0-3)	0.97 (0.73)	0.64 (0.62)	<0.001
· PCS (0-100)	36.0 (11.6)	37.9 (11.6)	0.05
· RAID (0-10)	3.46 (2.14)	2.96 (2.14)	0.004
· Sleep disturbance (0-10)	3.19 (2.79)	2.41 (2.71)	0.001
· Use Z-hypnotics	20.8%	12.6%	0.004
No significant gender differences			
· Age (years)	59.9 (12.6)	59.7 (11.4)	0.83
· VAS pain (0-100)	34.9 (24.3)	31.6 (25.1)	0.11
· VAS patient global (0-100)	37.8 (24.9)	34.5 (24.6)	0.10
· MCS (0-100)	46.8 (11.6)	47.3 (11.8)	0.61
· RADAI (0-10)	3.25 (1.70)	3,00 (1,72)	0.07
· Use sDMARD	60.5%	60.6%	0.99
· Use biologics	20.3%	18.7%	0.61
· Use prednisolone	35.4%	35.9%	0.91

Multivariate linear regression analyses, adjusted for age and disease duration, with sleep disturbance assessed by NRS(0–10) as dependent variable, identified significant independent associations with female gender (B=0.40, 95% CI 0.06, 0.74), HAQ (B=0.40, 95% CI 0.13, 0.67), RADAI (B=0.42, 95% CI 0.27, 0.57), VAS pain* (B=0.15, 95% CI 0.041, 0.27), VAS fatigue* (B=0.18, 95% CI 0.11, 0.25) and MCS* (B= -0.52, 95% CI -0.65, -0.38). *per 10 unit change.
Use of z-hypnotics was significantly associated with MCS, PCS, HAQ, RADAI, RAID, NRS sleep disturbance, VAS pain/fatigue/patglob (all p<0.001), and disease duration (p=0.03).

Conclusion: Sleep disturbance in RA is to a higher degree reported by females, and is independently associated with pain, fatigue and worse mental and physical function. Sleep is independently associated with RA disease impact and therefore merits attention in clinical care.

Correlations of Single Item Health Literacy Screening Questions with Established Measures of Health Literacy in Subjects with Rheumatoid Arthritis. Itziar Quinzanos[1], Joel M. Hirsh[1] and Liron Caplan[2]. [1]Denver Health Med Ctr, Denver, CO, [2]Denver VAMC and Univ of Colorado School of Medicine, Aurora, CO

Background/Purpose: Preliminary research suggests that Health Literacy (HL) is associated with the functional status of rheumatoid arthritis (RA) patients.Single Item Health Literacy Screening (SILS) questionnaires are a convenient method of establishing the health literacy of patients. However, the wording of SILS, version 2 (SILS2, "How comfortable are you filling out medical forms by yourself?" Wallace LS, et al. J Gen Intern Med. 2006;21:874-7.)) may be misinterpreted by RA patients as an query regarding their physical limitations.We assessed the construct validity of the SILS2 by correlating scores with standardized HL measures.

Methods: English-speaking adult RA patients at Denver Health enrolled in a cross-sectional study. Subjects were asked to complete the SILS2, an older version of the SILS (SILS1, "How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy?" Chew, et al. Fam Med 2004;36:588–594), as well as two longer HL measurement tools (Short Test of Functional Health Literacy in Adults [STOFHLA] and the Rapid Estimate of Adult Literacy in Medicine [REALM-]).Pearson correlation was used to assess the construct validity of the various tools.

Results: 110 subjects participated in the study. There was a strong correlation between the two SILS versions (Table 1). The correlation of SILS2 and REALM or STOFHLA was less robust (Table 1), but still moderately well correlated, though the distribution of scores within each SILS2 category demonstrated substantial scatter (Figures 1 and 2).

Table 1. Correlations of various measures of health literacy in subjects with RA

	SILS1	SILS2	REALM
SILS2	0.693	–	–
REALM	0.385	0.411	–
STOFHLA	0.416	0.439	0.554

STOFHLA = Short Test of Functional Health Literacy in Adults;
REALM = Rapid Estimate of Adult Literacy in Medicine;
SILS = Single-Item Literacy Screener
Conclusion: The SILS2 has construct validity in the assessment of HL in patients with RA. The SILS instruments are moderately good reflections of HL for groups of RA patients, however the substantial scatter of scores within each SILS category likely limits the clinical utility of the SILS in determining the HL on any one subject.

92

Combined Response Index in Diffuse Systemic Sclerosis (CRISS)–Which External Anchors to Use When Developing the Index? Baseline Analysis. Dinesh Khanna[1], Veronica Berrocal[1], James R. Seibold[2], Peter A. Merkel[3], Maureen D. Mayes[4], Kristine Phillips[1], Robert W. Simms[5], Shervin Assassi[4], Philip J. Clements[6] and Daniel E. Furst[6]. [1]University of Michigan, Ann Arbor, MI, [2]Scleroderma Research Consultants LLC, Avon, CT, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Texas Health Science Center at Houston, Houston, TX, [5]Boston University School of Medicine, Boston, MA, [6]UCLA School of Medicine, Los Angeles, CA

Background/Purpose: As part of an NIH sponsored effort to develop a data-driven CRISS, we evaluated the face, content, and construct validity (convergent and discriminant) of patient (Pt) and physician (MD) assessments for use as the "external gold standards" or "anchors" to compare against individual core set items developed as part of a consensus meeting conducted by the Scleroderma Clinical Trial Consortium (Khanna D, Ann Rheum Dis 2008). This methodology has been used for developing other response criteria.

Methods: We recruited patients with early diffuse SSc (< 5 years) at four scleroderma centers in the United States. Pre-defined outcome measures were collected. These included demographics (e.g., age, disease duration), patient-reported outcomes (e.g., HAQ-DI, SF-36), physical examination (e.g., skin score, joint count), and physiological/ radiological tests (e.g. echocardiogram, pulmonary function tests).We assessed the test characteristics of 8 potential Likert anchors (3 MD-derived: global assessment; activity of skin involvement; severity of skin involvement and 5 Pt. derived: patient global assessment; activity of skin involvement; limitations due to skin involvement; overall pain; transition question regarding overall health)against the above measures. The associations between anchors and outcome measures were assessed using Spearman correlation. The discrimination between the anchors (trichotomized) and outcome measures was assessed using parametric or non-parametric tests. Each anchor was ranked (1[weakest]-8 [best]) based on the strength of the correlation (convergent validity) and significance of p value for trichotomized variables (discriminant validity) vs. each outcome measure. Due to skewness in the distributions, the median of the rankings for each anchor was used to identify anchors with the best convergent and discriminant validity.

Results: 200 patients completed the baseline visit. The mean (SD) age was 50 (11.9) yrs, disease duration was 2.4 (1.6) yrs, modified Rodnan skin score was 20.6 (10.1), and HAQ-DI was 0.96 (0.79). All 8 anchors have face validity. MD global, Pt. global, and Pt-activity skin have content validity as they assess overall SSc/ skin involvement [major feature of the SSc]. There were high correlations between the 3 MD anchors (r= 0.57–0.69) but wide variation forpt. anchors (r=0.17–0.58). The pt. anchors complemented MD anchors (r=0.18–0.47).Among the MD-administered anchors, global assess-

S41

ment had the best convergent and discriminant validity (Table). Of the patient-administered anchors, patient global assessment and pain had the best convergent and discriminant validity (Table).

Anchors	Median Ranking* (Convergent)	Median Ranking* (Discriminant)
MD global assessment	5	6
MD activity-skin	3	4
MD severity-skin	6	5
Pt global assessment	5	5
Pt activity-skin	5	4
Pt limitations due to skin	5	5.5
Pt overall pain	6	5.5
Pt Transition question	1	2

* Higher number denotes higher median ranking

Conclusion: All anchors (except transition anchor) have high convergent and discriminant validity. These measures will serve as key anchors in the analysis of the CRISS longitudinal database and the development of a composite index.

93

Health State Utilities in Systemic Sclerosis: Results From the UCLA Scleroderma Quality of Life Study.

Mohsen Sadatsafavi[1], Dinesh Khanna[2], Paul Maranian[3], D. Furst[4], Amir Khakban[1] and Carlo A. Marra[1]. [1]Univ of British Columbia, Vancouver, BC, [2]University of Michigan, Ann Arbor, MI, [3]UCLA Medical School, Los Angeles, CA, [4]University of California at Los Angeles, Los Angeles, CA

Background/Purpose: Health state utility values (HSUVs) are used as weightings for quality-adjusted life years (QALYs) in economic analyses. It is not clear whether available instruments yield similar results or what domains of health are contributing to the overall score in a sample of patients with systemic sclerosis (SSc).

Methods: Our study included 223 individuals with rheumatologist-confirmed SSc from one academic center. An interviewer administered direct heath state utilities including the Time Trade Off (TTO), Visual Analogue Scale (VAS), and Standard Gamble (SG). We calculated the Short Form 6D from SF-36. Other clinical and health services variables were also collected.

Results: The mean age of the SSc sample was 51 years (SD 15) with the majority being female (84%).Mean (SD) health state utility values were 0.65 (0.13) for the SF-6D, 0.76 (0.28) for the TTO, 0.84 (0.22) for the SG, and 0.67 (0.19) for the VAS (P = 0.02).These measures are moderately correlated and appear to discriminate across measures of disease severity and function such as the physician's global assessment, digital tip ulcer count, swollen joint count, and tender joint count. Most HSUV measures show a monotonic descending relationship with measures of increased severity.

Table 1. Discriminant ability of health state utility value measures.

Disease Severity Measure	Category	SG	TTO	VAS	SF6D
			Mean	(SD)	
Physician's Global Assessment (0-10)	<2	.90(.16)	.85(.22)	.75(.15)	.72(.13)
	2-6	.82(.25)	.74(.30)	.63(.20)	.63(.12)
	>6	.80(.24)	.67(.31)	.63(.20)	.59(.10)
Digital Tip Ulcers	<0	.84(.22)	.76(.29)	.67(.19)	.65(.13)
	0-1	.85(.26)	.82(.30)	.63(.21)	.64(.14)
	>1	.88(.21)	.85(.22)	.84(.12)	.75(.19)
Rodnan score	<2	.83(.25)	.77(.28)	.69(.20)	.66(.13)
	2-13	.89(.16)	.81(.25)	.68(.19)	.66(.13)
	>13	.78(.27)	.66(.33)	.63(.19)	.63(.11)
Tender joint count	<0	.86(.21)	.79(.26)	.68(.19)	.67(.13)
	0-1	.68(.37)	.55(.38)	.61(.27)	.62(.07)
	>1	.83(.24)	.72(.32)	.63(.19)	.62(.13)
Swollen joint count	<0	.85(.22)	.77(.28)	.67(.19)	.65(.13)
	0-1	.62(.44)	.54(.45)	.59(.26)	.55(.17)
	>1	.88(.17)	.80(.26)	.72(.17)	.72(.14)

Conclusion: Different methods to generate HSUVs appear to provide different estimates, which have important implications for economic analysis. However, all of the methods appear to display construct validity with respect to clinical and health services variables.

94

Medical Costs and Health Care Resource Use in Patients with Systemic Sclerosis in an Insured Population.

Daniel E. Furst[1], Ancilla W. Fernandes[2], Serban R. Iorga[3], Warren Greth[4] and Tim Bancroft[3]. [1]UCLA Medical School, Los Angeles, CA, [2]MedImmune LLC, Gaithersburg, MD, [3]OptumInsight, Eden Prairie, MN, [4]MedImmune, LLC, Gaithersburg, MD

Background/Purpose: Systemic sclerosis (SSc) is a chronic connective tissue disease affecting the skin and/or internal organs. Data on US economic burden of SSc is scant or old. The objective of this study was to estimate the medical costs and health care resource utilization of subjects with newly diagnosed and existing SSc in a large national US insurer.

Methods: Subjects at least 18 years of age and with claims-based evidence of SSc (ICD-9-CM 710.1x) were identified from a health plan database during 2003–2008. Subjects were divided into two cohorts; newly diagnosed and existing based on claims history of SSc. Subjects were matched using a ratio of 1:3 to unaffected controls, based on demographic and clinical characteristics. Healthcare costs and resource use were captured during a 12 month post-index period. A generalized linear model (GLM) was used to predict costs, controlling for demographic and clinical characteristics.

Results: 1,103 subjects with newly diagnosed SSc were matched to 3,309 controls, and 1,648 existing SSc subjects were matched to 4,944 controls. Mean overall annual healthcare costs were substantively higher among newly diagnosed subjects than matched controls ($18,934 vs. $5,302, p<0.001) and among existing disease subjects than matched controls ($17,365 vs. $5,508, p<0.001). Ambulatory costs were the largest driver of overall costs among both newly diagnosed and existing SSc subjects (mean annual ambulatory costs = $7,455 newly diagnosed; $6,713 existing). When adjusting for clinical and demographic characteristics (including comorbid conditions) with a GLM, the cost ratio of newly diagnosed SSc subjects to controls was 2.132 (95%CI: 1.84–2.47), and the cost ratio of subjects with existing SSc to controls was 1.988 (95%CI: 1.77–2.23). Predictors for higher costs after controlling for other variables were: evidence of lung disease, GI bleeding, renal disease, useof systemic corticosteroids, or drugs used to treat pulmonary hypertension (PAH)(all p<0.001). Significantly higher proportions of newly diagnosed and existing SSc subjects had post-index ambulatory visits, primary care physician visits, specialist visits, emergency department visits, and inpatient hospital stays (all p<0.001) than matched controls. Of the selected medications studied, a greater proportion of SSc subjects (both newly diagnosed and existing) than controls had claims for systemic corticosteroids, methotrexate, mycophenolate mofetil, cyclophosphamide, bosentan, and sildenafil (all p<0.001).

Conclusion: Medical costs and resource use associated with treating either new or existing SSc are high (compared to unaffected controls), and subjects with serious disease complications experience the highest costs. These findings emphasize the need to develop more effective therapeutic management strategies for multi-system diseases like SSc.

Smoking Is Associated with Worse and More Widespread Pain, Worse Disease Activity, Function, Fatigue and Health Related Quality of Life in Patients with Axial Spondyloarthritis–Results From a Population Based Cohort. Ann B. I. Bremander[1], Ingemar F. Petersson[2], Emma Haglund[3], Stefan Bergman[4] and Lennart TH Jacobsson[5]. [1]Halmstad University School of Business and Engineering, Halmstad, Sweden, [2]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, [3]Spenshult Hospital for Rheumatic Diseases, Halmstad, Sweden, [4]R&D Center Spenshult, Oskarström, Sweden, [5]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Background/Purpose: In subjects with early axial Spondyloarthritis (SpA) smoking has recently been associated with earlier onset of disease, worse lesions of the sacroiliac joints and in later stages syndesmophyte progression. The aim was to study associations of smoking habits with self-reported information in a large population based cohort of patients with axial SpA.

Methods: A cross-sectional questionnaire survey performed in 2009 included all health care seeking subjects aged >18 years with a diagnosis of SpA according to ICD 10 codes identified by a regional health care register (n=3711). Smoking habits were studied in patients with ankylosing spondylitis (AS, ICD M45) and in patients who fulfilled criteria for "non AS axial SpA" (*without* having one of AS). Criteria for non AS axial SpA were based on data from the questionnaire: pain for 3 months or more during the last 12 months together with 2 or more features out of 5 (inflammatory back pain, history of psoriasis, uveitis/tendinitis, inflammatory bowel disease or heredity). The questionnaire included data on smoking (never smokers vs. ever smokers), disease activity (BASDAI) physical function (BASFI), general health (BAS-G) all measured with numerical rating scales 0–10 (best to worst), health related quality of life (EQ-5D, 0–1 worst to best), pain, fatigue (numerical rating scales 0–10 best to worst) and number of painful regions noted on a pain mannequin (0–16 best to worst). Linear regression analysis was performed and all data were controlled for sex and age.

Results: Response rate was 76% whereof 2167 (58%) returned the questionnaire and 18% declined participation in the study. 598 subjects had an AS diagnose and 572 fulfilled the criteria for non AS axial SpA.

The AS group had a mean age of 54 (SD14) years and 35% were women. Never smokers constituted 48% of the AS group. Ever smokers had worse scores in all studied variables compared with never smokers.

The linear regression analysis showed that ever smokers in the AS group had worse self-reported scores in BASDAI with age-sex adjusted parameter estimate (B) = 0.60 (95% CI 0.21; 1.00), BASFI B = 0.51 (95% CI 0.11; 0.91) and fatigue B = 0.51 (95% CI0.06; 1.00). There was a tendency to worse scores for ever smokers also in EQ-5D B = -0.04 (95% CI -0.09; 0.001).

Mean age in the non AS axial SpA group was 55 (SD 14) years and 68% were women. Never smokers constituted 38% of this group. Also in the non AS axial SpA group the linear regression analysis showed that ever smokers had worse self-reported scores in BASDAI with age-sex adjusted parameter estimate (B) = 0.59 (95% CI 0.23; 0.94), BASFI B = 0.59 (95% CI 0.17; 1.00), pain B = 0.45 (95% CI 0.08; 0.82) and fatigue B = 0.43 (95% CI0.03; 0.83), no of painful areas B = 0.73 (95% CI0.06; 1.46) and also in EQ-5D B = -0.06 (95% CI -0.11; -0.002).

Conclusion: In a large population based axial SpA cohort, both patients with AS and non AS axial SpA who were ever smokers reported worse clinical features compared with never smokers. Further longitudinal studies are needed to better understand cause and effect. However, smoking cessation should be recommended not only due to general health perspectives but also due to disease specific issues.

Quality of Care: Reference and Counter Reference From Family Physicians and Rheumatologists' perspectives- A Pilot Study. Thiago D. Baumgratz[1], Raphael Battisti[1], Mirella Cuziol[1], Ana Carolina Reiff Janini[1], R.A. Levy[2] and Mirhelen M. Abreu[3]. [1]Medical Student at Universidade Federal de São Carlos, São Carlos, Brazil, [2]Hospital Universitário Pedro Ernesto, Rio de Janeiro, Brazil, [3]Universidade Federal de São Carlos, São Carlos, Brazil

Background/Purpose: We delineated family physicians' and rheumatologists' point of view when primary care is facing cases of rheumatic diseases. We also tried to identify barriers in the reference and counter reference.

Methods: This is a pilot study, transversally designed, with family physicians and rheumatologists in a single city. The methodological steps were: (1) Development and preparation of three clinical scenarios that simulate and address different levels of clinical severity; (2) application of these scenarios in the population of family physicians and rheumatologists; (3) validation of the study scenarios. The final scenarios constructed were: (a) *Scenario one:* a patient with an autoimmune disease diagnosis presenting fever and fatigue; (b) *Scenario two*: a patient with fibromyalgia and with poor adherence to the healthcare plan, requiring a medication to relief the symptoms; (c) *Scenario three:* patient with septic arthritis, prostration, and in poor clinical conditions. The scenarios were presented to two groups of physicians, which should choose regarding three decisions: (Decision 1) To apply a healthcare plan (investigation and/or treatment) and refer to a rheumatologist; (Decision 2) to prescribe medication and do not reference to rheumatologist; and (Decision 3) to refer to a rheumatologist with no primary care intervention. Finally, a multiple-choice questionnaire addressing potential factors that lead to barriers in the reference process of and counter reference was applied. Descriptive analysis was performed to map the results. As this was a pilot study, we used bootstrap method for constructing hypothesis tests.

Results: Twenty-two family physicians and rheumatologists were involved. Family physician's initiative to refer to specialized care was similar to the rheumatologist' expectation (median: 1.5 [minimum 1.5 to maximum 1.7], for family physicians and 1.6 [1.3 to 2] for rheumatologists). For *Scenario one*, the majority of interviewee chose Decision 1 [1.27 (1 –3), SD 0.59)]. For the *Scenario two*, respondents chose the decision 2 [2 (1 – 3), SD 0.76)]. For the *Scenario three, Decision three* was the preferred [1.47 (1–3), SD 0.83)]. For the reference and counter-reference system evaluation, family physicians tend to refer any clinical case that could be a rheumatic disease. They consider that there is a poor communication between family physician and rheumatologist [4.2 (2–5), SD 1.01)].

Conclusion: There is a tendency for referral to rheumatologists and a poor perception of risk. This posture can contribute to the quality of care impairment. Proper communication seems to be a hurdle for the reference and counter reference system.

Systematic Review of Explanatory and Predictive Models in Rheumatology: Lack of Adhearance to Methodologic Standards. Daniel A. Albert. Dartmouth-Hitchcock Med Ctr, Lebanon, NH

Background/Purpose: Prognostic and explanatory models are frequently utilized in clinical medicine to assist in judgments about diagnosis, prognosis, and treatment options. I surveyed predictive and explanatory models in rheumatology by conducting a systematic review using a PubMed (Medicine) search of a two year period, starting January 1, 2010, and ending December 31, 2011. This identified 564 articles using the key words: "Rheumatology," and "prediction," "models," "stepwise," "regression," "multivariate," "survival," "prognosis," "propensity scores," "cost-effectiveness," "decision analysis," and "diagnosis."

Methods: Out of the 564, I identified 76 articles, which I reviewed by abstract, and of these 42 articles were selected for review of their full text for adherence to methodologic standards.

Results: Studies addressed a variety of issues including diagnosis, prognosis, identification of risk factors, biomarker studies, and disease activity. Data sets included institutional, multi-institutional, and national registries. Prospectively acquired, retrospectively acquired, and cross-sectional data was used. Regression techniques included logistic, linear, generalized estimating equation (GEE) and generalized linear model (GLM). Two studies used classification and regression trees (CART) analysis, 2 used a Bayesian approach, and one used neural network. Only one study explicitly described a power calculation. Internal validation by bootstrapping, split sample, or similar techniques was used in 13 of 42 studies, but only 4 used an external validation step. Discrimination (ROC Curves) or clinical utility (sensitivity and specificity) was described in 12 studies, but only 3 were subjected to calibration.

Sunday, November 11

Conclusion: A minority of published prognostic and explanatory models adhered to established methodologic standards. Very few studies contained a validation study and those that did were small and thus subject to over fitting. Several studies provided information on discrimination; however, few of these were calibrated using data from the validation study. A consensus scoring system of prognostic and explanatory models similar to that which has been utilized for systemic reviews needs to be constructed and adopted by the rheumatologic clinical epidemiology and clinical trial community.

How to Assess Risks for Pulmonary Infection in Patients Receiving Immunosuppressive Treatment for Rheumatic Diseases? A Report From a Large-Scale Prospective Cohort Study. Hayato Yamazaki[1], Ryoko Sakai[1], Ryuji Koike[1], Yasunari Miyazaki[1], Michi Tanaka[1], Toshi-hiro Nanki[1], Kaori Watanabe[1], Shinsuke Yasuda[2], Takashi Kurita[2], Yuko Kaneko[3], Yoshiya Tanaka[4], Yasuhiko Nishioka[5], Yoshinari Takasaki[6], Kenji Nagasaka[7], Koichi Amano[8], Shigeto Tohma[9], Makoto Dohi[10], Takahiko Sugihara[11], Haruhito Sugiyama[12], Yasushi Kawaguchi[13], Nao-hiko Inase[1], Sae Ochi[14], Hiroyuki Hagiyama[15], Nobuyuki Miyasaka[1] and Masayoshi Harigai[1]. [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Hokkaido University, Sapporo, Japan, [3]Keio Univ School of Medicine, Tokyo, Japan, [4]University of Occupational and Environmental Health, Kitakyushu, Japan, [5]The Univeristy of Tokushima Graduate School, Tokushima, Japan, [6]Juntendo University School of Medicine, Tokyo, Japan, [7]Ome Municipal General Hospital, Ome, Japan, [8]Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan, [9]Sagamihara National Hospital, Sagamihara, Japan, [10]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [11]Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan, [12]National Center for Global Health and Medicine, Tokyo, Japan, [13]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [14]Tokyo Metropolitan Bokutoh Hospital, Tokyo, Japan, [15]Yokohama-city Bay Red Cross Hospital, Yokohama, Japan

Background/Purpose: Patients with rheumatic diseases given immunosuppressive therapy are susceptible to various types of infections, especially pulmonary infections that affect their vital prognosis. The aim of this large-scale, multi-center, prospective cohort study was to identify risk factors for development of pulmonary infection in patients receiving immunosuppressive treatment for rheumatic diseases (PREVENT study).

Methods: We enrolled those patients who were admitted to participating hospitals for treatment of rheumatic diseases and started immunosuppressive therapy with corticosteroids, conventional immunosuppressants, or biologics. Observation was stopped either 12 months after enrollment, or the day a patient developed predefined pulmonary infection or was lost-to- follow up, whichever came first. The validity of the diagnosis for pulmonary infection was assessed by an event-monitoring committee. We collected demographic data and clinical data for rheumatic diseases at baseline, data for candidate risk factors for pulmonary infection at baseline and month 6, and usage of drugs throughout the observation period. Risk factors for pulmonary infection were investigated by univariate and multivariate analyses.

Results: Of 766 patients enrolled, 668 patients (87.2%) were observed for 12 months, 32 patients (4.2%) died, and 66 (8.6%) patients were lost-to-follow up by month 12. Sixty-one patients (8.0%) developed pulmonary infection: bacterial pneumonia, 25; *Pneumocystis jirovecii* pneumonia, 20; fungal pneumonia, 5; cytomegalovirus pneumonia, 3; tuberculosis, 3; others, 5. Kaplan-Meier curves showed a significantly lower cumulative survival rate in patients with pulmonary infection compared to those without pulmonary infection (p<0.01, log-rank test). Because treatment for RA patients without active extra-articular manifestation (articular RA patients, n=145) was significantly different from that for the rest of the patients, we performed multivariate analyses using COX hazard regression models in all patients (n=766) and in these patients excluding articular RA patients (n=621) (Table 1). Older age (≥65 years-old), higher Brinkman index (≥400), higher serum creatinine (sCr) level, and higher maximum prednisolone dose (mg/kg/day) during the first two weeks of treatment were significantly associated with development of pulmonary infection in all patients. Older age, higher Brinkman index, higher sCr level, and disturbed performance status were significantly associated with development of pulmonary infection in patients excluding articular RA patients.

Table 1. Multivariate analysis using COX hazard regression models in all patients with rheumatic diseases and in these patients excluding articular RA patients

Characteristics	All patients (n = 766)		Patients excluding articular RA patients (n = 621)	
	HR (95% CI)	p value	HR (95% CI)	p value
Age (≥65 years)	4.00 (2.27–6.98)	<0.01	4.20 (2.35–7.50)	<0.01
Female	1.07 (0.55–2.09)	0.84	1.12 (0.56–2.23)	0.75
Brinkman index ≥400	2.56 (1.33–4.94)	0.01	2.65 (1.34–5.22)	0.01
Serum Cr (mg/dl)	1.21 (1.04–1.41)	0.01	1.23 (1.06–1.43)	0.01
Performance status (III or IV)	1.71 (0.93–3.17)	0.09	1.89 (1.01–3.52)	0.04
Maximum dose of PSL, 0–2W (mg/kg/day)	3.57 (1.44–8.81)	0.01	2.12 (0.82–5.48)	0.12
Number of mPSL pulse therapy, 0–2W	0.97 (0.62–1.54)	0.91	0.99 (0.62–1.57)	0.96
Use of immunosuppressants, 0–2W	0.82 (0.46–1.45)	0.49	0.81 (0.44–1.48)	0.49
Use of biologics, 0–2W	1.40 (0.52–3.77)	0.51		

RA, rheumatoid arthritis; HR, hazard ratio; 95% CI, 95% confidence interval
Cr, creatinine; PSL, prednisolone; mPSL, methylprednisolone
Performance status was graded by the Eastern Cooperative Oncology Group scale.
0–2W, duration during first two weeks from the enrollment of the study.
Immunosuppressants include azathioprine, methotrexate, cyclophosphamide, tacrolimus, cyclosporin, mizoribine, mycophenolate mofetile and leflunomide.
Biologics include infliximab, etanercept, adalimumab, tocilizumab, rituximab and abatacept.

Conclusion: This is the first large-scale, prospective study identifying risk factors for pulmonary infection in patients with rheumatic diseases in the literature. Prophylactic measures should be taken accordingly for better benefit-risk balance of treatment.

Cancer Iincidence and Type of Malignancy in Rrheumatologic Ddiseases in Korea: Head-to-Head Comparison. Sung Hae Chang, Jin Kyun Park and Eun Bong Lee. Seoul National University Hospital, Seoul, South Korea

Background/Purpose: Rheumatic diseases (RD) are associated with increased risk of developing cancer. However, it remains to define, if particular cancers are more frequent in certain rheumatic diseases. To address this, the incidence and site of cancer were analyzed in a large cohort of patients with rheumatoid arthritis (RA), dermatomyositis/polymyositis (DM/PM), systemic sclerosis (SSc), systemic lupus erythematosus (SLE) and ankylosing spondylitis (AS).

Methods: All patients with a confirmed diagnosis of a RA, AS, SLE, DM/PM, and SSc who underwent clinical care in our institution between January 2000 and April 2012 were enrolled in this retrospective study. Data on site, staging, treatment, and outcome of cancer were ascertained per chart review. The cancer incidence rates in RDs were compared with those of the National Cancer Registry and standardized incidence ratios (SIR) were calculated.

Results: A total of 4,726 patients with RD (female, 71.0 %) were analyzed. During the follow-up duration of 34,447 person-years (PY), 244 (female, 71.7 %) patients developed cancer with an overall incidence rate of 5.2%. The SIR of cancer was significantly higher at 1.7 in patients with RD (95 % confidence interval (CI), 1.51–1.90) than the general population. In a subgroup analysis, RA (SIR 1.81, 95 % CI, 1.52–2.14), DM/PM (SIR 3.11, 95 % CI, 2.21–4.16), and SLE (SIR 1.65, 95 % CI, 1.29–2.04) were associated with a higher cancer incidence, whereas SSc (SIR 1.43, 95 % CI, 0.94–2.01) and AS (SIR 1.11, 95 % CI, 0.512–1.39) were not (**Table 1**). In RA, breast cancer was most common with 29 (22.0 %) cases, followed by 26 (19.7%) gastric, 24 (18.2%) lung, and 14 (10.6%) colon cancer. In DM/PM, lung cancer was most common with 7 (17.9 %) cases, followed by 5 (12.8 %) colon, 4 (10.3 %) gastric and 3(7.7 %) breast cancer. In SSc, lung cancer was most common with 10 (35.7%) cases, followed by 3 (10.7%) gastric, 2 7.1%)

cervix, and 2 (7.1%) colon cancer. In SLE, thyroid cancer was most common with 12 (16.2%) cases, followed by 7 (9.5%) breast, 7 (9.5%) cervix, and 7 (9.5%) liver and intrahepatic bile ducts cancer. In AS, liver cancer was common with 3 (17.9%) cases, followed by 2 (12.5%) lymphoid leukemia, and 2 (12.5%) thyroid cancer.

Table 1. Standardized incidence ratios (SIRs) and 95 % confidence interval (CIs) of cancer in rheumatic diseases.

Rheumatologic disease	Person-year (PY)	Observed cases	Expected cases	SIR	95% CI
All rheumatic diseases	34,447	244	169.7	1.7	1.51-1.90
Rheumatoid arthritis	8,230	132	72.8	1.81	1.52-2.14
Dermatomyositis/Polymyositis	1,988	39	12.5	3.11	2.21-4.16
Systemic Sclerosis	3,094	28	19.6	1.43	0.94-2.01
Systemic Erythematosus Lupus	12,118	74	44.9	1.65	1.29-2.04
Ankylosing Spondylitis	7,709	16	17.8	1.11	0.512-1.39

Conclusion: To the best of our knowledge, this is the first study to show different malignancy risks among rheumatologic diseases in a head-to-head comparison. As particular cancer types are more frequent in certain rheumatic diseases, patients might benefit from cancer surveillance tailored to their RD.

Further Evidence On Biased Cancer Risk Estimation in Studies Comparing A Subpopulation to the General Population. Koray Tascilar[1] and Hasan Yazici[2]. [1]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical School, Rheumatology, Istanbul, Turkey

Background/Purpose: We had previously proposed a selection bias in studies estimating cancer risk in patients with rheumatoid arthritis (RA) stemming from the comparison of a selected subpopulation to the general population (Arthritis Rheum. 2011;63;2543-4). Biased estimates would be the result of a) death of a part of the subpopulation due to cancer before being selected, b) prevention of an autoimmune/inflammatory condition by cancer treatment and c) a lower probability of being selected/detected merely because of having cancer. These would cause the rate of accumulation of cancer cases in the selected subpopulation to be lower than that in the general population and hence a decrease in the comparative incidence if tracked over time. We had also demonstrated such a decrease in the comparative incidence over time in studies reporting cancer risk in RA patients (Ann Rheum Dis 2012;71(Suppl3):456). We conducted a systematic literature search to see whether such a bias exists in studies reporting the cancer risk in other autoimmune/inflammatory disorders.

Methods: We conducted multiple PubMed searches using the search terms "polymyositis", "dermatomyositis", "sarcoidosis", "psoriasis", "Crohn's", "ulcerative", "lupus", "SLE", "Sjogren", "ANCA", "polyarteritis", "Wegener", "polyangiitis", "vasculitis", and "scleroderma" between June 2001 and February 2012. We combined these terms with "cancer" and "standardized" to capture studies that reported standardized incidence ratios or standardized morbidity ratios. We retrieved full-text manuscripts of studies that reported comparative incidence. Studies that reported multiple incidence ratios with respect to follow-up time were included.

Results: Our search identified 192 articles and we retrieved 36 articles of relevance in full-text. Among the 36 articles retrieved, 10 reported incidence comparison of overall cancer at multiple timepoints. There were 3 studies on inflammatory myopathies, 1 study each with scleroderma, Wegener's granulomatosis, ulcerative colitis, Crohn's disease, polymyalgia rheumatica, SLE and sarcoidosis. Number of timepoints ranged from 2 to 10, sampling period ranged from 10 to 48 years. The comparative incidence at the latest timepoint was lower in 9 of the 10 articles by 56 to 98% as compared to the earliest.

Conclusion: We provide further evidence that current methods of comparision of cancer incidence in a selected subpopulation to the general population results in biased estimates.

Disclosure: K. Tascilar, None; **H. Yazici**, None.

Kidney Function and the Risk of Incident Gout in A Population-Based Cohort of Adults: Atherosclerosis Risk in Communities Study. Mara McAdams DeMarco[1], Anna Kottgen[2], Andrew Law[3], Janet W. Maynard[4], Josef Coresh[1] and Alan N. Baer[4]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University Hospital Freiburg, Freiburg, Germany, [3]Johns Hopkins, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD

Background/Purpose: The 1-year cumulative incidence of gout in patients with new onset end stage renal disease is 5% and rises to 15% by 5 years, far exceeding the risk in the general population. This higher prevalence of gout could be explained by hyperuricemia as a consequence of reduced renal function and subsequent development of gout or due to common risk factors. Although the risk of developing gout is high among those with end stage renal disease, the risk of gout for those with moderate kidney dysfunction is unclear. We estimated the risk of developing gout over a range of estimated glomerular filtration rate (eGFR) values in participants enrolled in the Atherosclerosis Risk in Communities (ARIC) cohort study.

Methods: ARIC is a prospective population-based cohort recruited in 1987–1989 from 4 US communities, consisting of 4 visits over 9 years. Participants were included in this analysis if they answered the gout query and were free of gout at baseline. Incident gout was defined as self-reported onset after baseline. Serum creatinine was estimated using a modified kinetic Jaffé reaction. Glomerular filtration rate (eGFR) was estimated using the CKD-Epi equation and categorized as $\geq$90, 60–90, or <60 ml/min/1.73 m^2. Using a Cox Proportional Hazards model (age as time scale), we estimated the hazard ratio (HR) and 95% confidence intervals (CI) of incident gout by baseline eGFR, adjusted for confounders (sex, race, and center) and clinical factors (diuretic use, diabetes, hypertension, obesity, and alcohol intake). Additionally, we adjusted for visit 2 serum urate level (measured with the uricase method) to test for mediation.

Results: A total of 10,871 ARIC participants met the study criteria. The study population was 43% male, 21% African American and the mean age at cohort entry was 54 years (SD=5.7). The mean eGFR was 92 (SD=14.9) ml/min/1.73 m^2. At baseline, 217 (2%) participants were classified as having eGFR<60 ml/min/1.73 m^2; 4,502 (41%) with an eGFR between 60 and 90 ml/min/1.73 m^2; and 6,152 with an eGFR >90 ml/min/1.73 m^2 (57%). There were 274 incident gout cases. The results are presented in the table. After accounting for confounders and clinical factors, a 10 ml/min/1.73 m^2 decrease in eGFR was associated with increased risk of gout (HR=1.15, 95% CI: 1.10–1.25). Compared to those with an eGFR $\geq$90, the adjusted HR of incident gout was 1.13 (95% CI: 0.88–1.46) for those with an eGFR between 60 and 90 ml/min/1.73 m^2 and 2.57 (95% CI: 1.58–4.17) for those with an eGFR< 60 ml/min/1.73 m^2. eGFR was not associated with incident gout after accounting for V2 serum urate level, suggesting full mediation. There was no evidence of effect measure modification by race (p=0.46) or sex (p=0.39).

Table. Risk of Gout by eGFR

	HR of Gout (95% CI)	P-value
Model 1: Unadjusted		
eGFR for each 10 unit decrease	1.12 (1.03, 1.22)	0.004
eGFR≥90	Ref	0.01
60≤eGFR<90	1.08 (0.84, 1.38)	
eGFR <60	2.80 (1.74, 4.50)	
Model 2: Adjusted sex, race, and center		
eGFR for each 10 unit decrease	1.18 (1.09, 1.27)	<0.0001
eGFR≥90	Ref	0.002
60≤eGFR<90	1.17 (0.91, 1.51)	
eGFR <60	2.93 (1.82, 4.73)	
Model 3: Adjusted sex, race, center, diuretic use, hypertension, diabetes, obesity, continuous alcohol intake		
eGFR for each 10 unit decrease	1.15 (1.10, 1.25)	0.0003
eGFR≥90	Ref	0.009
60≤eGFR<90	1.13 (0.88, 1.46)	
eGFR <60	2.57 (1.58, 4.17)	
Model 4: Adjusted sex, race, center, diuretic use, hypertension, diabetes, obesity, continuous alcohol intake, serum urate level at visit 2.		
eGFR for each 10 unit decrease	0.97 (0.90, 1.05)	0.47
eGFR≥90	Ref	0.20
60≤eGFR<90	0.82 (0.63, 1.06)	
eGFR <60	0.88 (0.52, 1.48)	

Conclusion: Moderately reduced kidney function was associated with a 2.6-fold increased risk of gout independent of comorbid conditions. These findings suggest that kidney function may be a risk factor for gout that is partially mediated by increased serum urate levels.

Sonographic Assessment of Normal Peripheral Joints: Evaluation According to Demographics Parameters. Flavia S. Machado, Rita N.V. Furtado, Rogerio D. Takahashi, Ana Leticia P. de Buosi and Jamil Natour. Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: to describe quantitative and semiquantitative joint ultrasound measurements in healthy people and compare them among different demographic parameters.

Methods: Bilateral ultrasound measurement of small, medium and large joints were performed in 130 healthy volunteers, stratified into five age groups (A: 18–29, B: 30–39, C: 40–49, D: 50–59, E: 60–80 years). Forty six joint recesses per patient were studied: radiocarpal, distal radioulnar, ulnocarpal, 2nd metacarpophalangeal (MCP) (dorsal, palmar, radial), 3rd MCP (dorsal, palmar), 2nd and 3rd proximal interphalangeal joint of the hand (dorsal, palmar), coronoid fossa; olecranean fossa, glenohumeral (GU) axillary recess, posterior GU recess, hip, knee, talocrural, talonavicular, subtalar, dorsal 1st metatarsophalangeal joint (MTP), dorsal 2nd MTP and 5th MTP (dorsal, lateral). Quantitative measurements of synovial recess (QSR) and semiquantitative measures of synovial hypertrophy (SSH), Power Doppler (SPD), bone erosion (SBE) (score 0–3) and articular cartilage (AC) (score 0–4) were performed by a blinded radiologist using a linear probe (6–18 MHz; Esaote, Genoa, Italy). Sonographic measurements were correlated with age group and other demographic parameters.

Results: Five thousand nine hundred and eighty joint recesses were studied in 130 healthy adults; mean age 44.84, 76,9% women, 62,3% white. The highest values of QSR were found in the hip (6.35mm), axillary GU recess (2.46mm) and posterior GU recess (2.45mm). The joint recess with greater frequency of supposed pathological scores were: 2nd MTP (78.8%) and 1st MTP (69.3%) for SSH; radiocarpal (17.7%) and 1st MTP (15.8%) for SPD; posterior GU recess (23.1%) and ulnocarpal (4.2%) for SBE. The highest QSR and the worst SSH measurement (p<0.02) were observed in age groups D and E and the worst SPD and SBE (p<0.041) were observed in age group E. Minor AC changes (score 1) (p <0.001) were observed in age groups D and E. There were positive correlations among ultrasound measurements with height, age, weight and body mass index (BMI) in 26,1%, 34,8%, 43,5% and 43,5%, respectively, of all the articular recesses studied.

Conclusion: Articular sonographic measurements were performed in several types of joints in healthy adults at different age groups. Mainly synovial hypertrophy, but also Power Doppler, bone erosions and articular cartilage were associated with the worst measurements scores at oldest age groups.

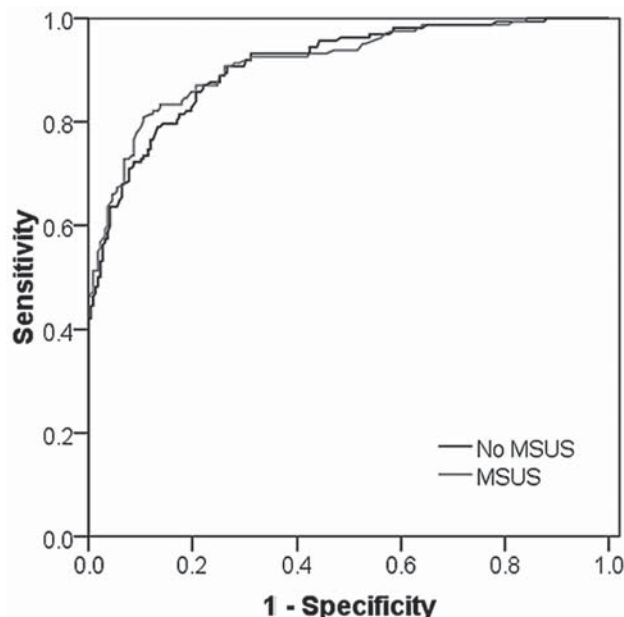
A Pragmatic Musculoskeletal Ultrasound Screening Protocol Does Not Add to a Predictive Algorithm for Persistent Inflammatory Arthritis in a UK Early Arthritis Clinic. Arthur G. Pratt[1], Alice R. Lorenzi[2], Gillian Wilson[2], Philip N. Platt[2] and John D. Isaacs[3]. [1]Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Freeman Hospital, Newcastle upon Tyne, United Kingdom, [3]Musculoskeletal Research Group, Institute of Cellular Medicine, Newcastle University and Newcastle upon Tyne NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom

Background/Purpose: Analyses of large clinical datasets from early arthritis cohorts permit the development of algorithms that may be used for outcome prediction in individual patients. The value added by routine use of musculoskeletal ultrasound (MSUS) in an early arthritis setting, as a component of such predictive algorithms, remains to be determined.

Methods: A retrospective analysis of a large, true-to-life, observational inception cohort of early arthritis patients in Newcastle, UK, which included patients with inflammatory arthralgia but no clinically swollen joints, was undertaken. All patients underwent a pragmatic, 10 minute MSUS assessment protocol during their first visit. Logistic regression was used to develop two "risk metrics" that predicted the development of a persistent inflammatory arthritis (PIA), their derivation differing only according to whether or not MSUS parameters were allowed to be incorporated into the final prediction model.

Results: 379 included patients were assigned definitive outcome diagnoses after ≥12 months follow-up (median 28 months), of whom 162 (42%) developed a persistent inflammatory arthritis. A simple risk metric, derived purely from 12 readily obtainable baseline clinical and serological parameters, had an excellent discriminatory utility with respect to an outome of PIA (area under ROC curve 0.91; 95% CI 0.88–0.94). A similar metric, derived from the same 12 parameters in addition to 5 MSUS parameters, had an almost identical, and not significantly superior, discriminatory utility (area under ROC curve 0.91; 95% CI 0.89–0.94)


Conclusion: MSUS use as a routine component of assessment in an early arthritis clinic does not add substantial discriminatory value to a risk metric for predicting PIA. More work is needed to refine a precise role of this imaging modality as a diagnostic tool in this clinical setting.

The Usefulness of A NEW Musculoskeletal ULTRASOUND Scoring System of the Hands and Wrist Joints (US10) for Evaluation of EARLY Rheumatoid Arthritis Patients. Karine R. Luz, Rita N.V. Furtado, Marcelo M. Pinheiro, Giovanna S. Petterle and Jamil Natour. Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Ultrasound (US) can be a useful tool for monitoring rheumatoid arthritis (RA). However, it can be time consuming when applied to too many joints as there is lack of uniformly standardised scoring system. Thus the aim of the present study was to propose a new US score of the hands and wrist joints (US10) and to evaluate its correlation with clinical, laboratory and functional status during a 48-weeks follow-up.

Methods: Forty-eight early RA patients with less-than-1 year symptom with no previous use of disease-modifying antirheumatic drugs (DMARD) were enrolled on the study. The patients underwent clinical, laboratory assessment and blinded US examination at baseline, 3, 6, 9 and 12 months. The US10 included the following joints: wrist, second and third metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. This score was

composed by the following 10 parameters, according to inflammation: qualitative (0–1; range of 0–16) and semi-quantitative (0–3; range of 0–48) scoring to synovial proliferation (SPQ10, SPSQ10) and to power Doppler (PD) (PDQ10, PDSQ10), and qualitative (0–1) gray scale and PD scores for tenosynovitis/paratendinosis (GSTN10, PDTN, range of 0–10). A second US finding was categorised according to joint damage: a qualitative (0–1) and semi-quantitative (0–3) scoring to bone erosions (ERQ10, range of 0–12; ERSQ10, range of 0–36) and to cartilage damage (CAQ10, range of 0–4; CASQ10, range of 0–12). The following were clinical and laboratory assessments: C-reactive protein level (CRP), 28-joint Disease Activity Score (DAS 28) and Health Assessment Questionnaire (HAQ). All patients were treated with the same protocol of treatment and by just one rheumatologist.

Results: The mean ± duration of the symptoms was 7,58 (± 3,59) months. All patients had high activity disease with mean ± DAS 28 of 6,50 (± 1,29). At baseline, there was significant correlation between all US parameters for inflammation (p<0,05) and the US parameters for joint damage (ERQ10, ERSQ10 and CASQ10) also had a good significant correlation (p<0,05) with synovial proliferation parameters. Besides, significant correlation (p<0,05) between all the US10 parameters for inflammation and CRP was observed. In addition, the PD and tenosynovitis scores showed a significant correlation (p<0,05) with DAS28. Longitudinal changes through out 12 months for the inflammation parameters (SPQ10, SPSQ10, GSTN and PDTN) and for bone erosions scores showed a highly significant correlation (p<0,05). There was a significant correlation between changes in the US parameters for synovial proliferation for tenosynovitis and the DAS28 changes (SPQ10/DAS28: r=0,33, p<0,05; SPSQ10/DAS28: r=0,30, p<0,05; TNQ10/DAS28: r=0,48, p<0,05; TNQPD10: r=0,48, p<0,48) in a 12-month period. After one year, there was also a significant correlation between changes in the inflammation scores, in the CRP and in HAQ.

Conclusion: A new US scoring system of hand and wrist joints (US10) seemed to be a useful tool to monitor inflammation and joint damage in early RA patients with a significant correlation to longitudinal changes of disease activity criteria.

Combined Synovial and Structural Ultrasound Score for the Diagnosis of RA. Gary A. Kunkel, Grant W. Cannon and Daniel O. Clegg. George E. Wahlen VA Medical Center, Salt Lake City, UT

Background/Purpose: Current ultrasonographic scoring systems used to assess the degree of finger joint synovitis in rheumatoid arthritis (RA) are not designed for distinguishing healthy or osteoarthritis (OA) patients from those with RA in clinical settings. In this pilot study we explore a novel scoring approach using structural as well as quantitative synovial ultrasonographic features to distinguish between healthy and OA finger joints and those with RA.

Methods: 22 patients with RA, 16 healthy controls, and 14 OA controls received a comprehensive ultrasound of one hand's metacarpophalangeal and proximal interphalangeal joints, with scores assigned using a modification of a previously reported RA scoring system called the Semiquantitative Synovial Score (SSS), and using the novel approach called the Combined Structural/ Synovial Score (CSSS). The SSS relied on the presence or absence of hypoechoic synovial tissue/fluid bulging over the lines between the joint-forming bones or extending to the diaphysis. If either condition was met the joint was classified as supporting the diagnosis of RA ("RA-supported"). The CSSS utilized structural features of osteophyte and erosion, as well as measured thickness of the synovial cavity over the bony diaphysis and Doppler signal. If >1+ Doppler signal, >2mm of synovial thickness, or an erosion >1mm in two orthogonal planes was imaged the joint was classified as "RA-supported." The number of joints classified as "RA-supported" was tallied for each of the two scoring methods. Sensitivity and specificity for each method were calculated with respect to the clinical diagnosis of RA, and receiver operating characteristic (ROC) curves plotted across the range of possible scoring cutoffs.

Results: The SSS was highly sensitive (100%), but without specificity (0%) for the diagnosis of RA, when RA was defined as having more than 1 joint classified as "RA-supported." The CSSS had high sensitivity (95%) and moderate specificity (77%) when RA was defined as having any joint classified as "RA-supported". Moderate sensitivity (73%) and high specificity (97%) were found when having more than 1 joint classified as "RA-supported" was required to diagnose RA. Results of a sensitivity analysis of

several different variations of the CSSS show some differences in the sensitivity and specificity of this system when different parameters are used such as volar or dorsal-only scans.

"RA-supported" >0	Semiquantitative Synovial Score	Combined Structural/ Synovial Score
Sensitivity-RA	1	0.95
Specificity-O	0	0.57
Specificity-H	0	0.94
Specificity-All	0	0.77

"RA-supported" >1	Semiquantitative Synovial Score	Combined Structural/ Synovial Score
Sensitivity-RA	1	0.73
Specificity-O	0	0.93
Specificity-H	0	1
Specificity-All	0	0.97
Conclusion: A novel combined structural and quantitative synovial hand joint scoring system was capable of distinguishing OA and healthy controls from RA subjects in this pilot evaluation.

Development of a 6 Joint Simplified Ultrasonographic Score to Assess Disease Activity in Patients with Rheumatoid Arthritis. Tomas Cazenave[1], Christian A. Waimann[2], Gustavo Citera[3] and Marcos G. Rosemffet[1]. [1]Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofisica, Buenos Aires, Argentina, [3]Instituto de Rehabilitación Psicofísica., Buenos Aires, Argentina

Background/Purpose: Ultrasound has become a routinely available bedside method for the evaluation of patients with Rheumatoid Arthritis (RA). However, it is time consuming, making it difficult to use in daily clinical practice. The aim of our study was to develop a new standardized ultrasound score including only 6 joints that could be applied to daily monitoring disease activity in patients with RA.

Methods: We included RA patients (American College of Rheumatology 1987 criteria). Each patient underwent clinical, radiological and ultrasonographic (US) evaluation. Clinical data included 28-joints count and disease activity index 28 (DAS28). Ultrasound evaluation was performed by two rheumatologists who were blind to clinical examination. Six joints were evaluated: bilateral wrist (dorsal view of radio and intracarpal joint), second metacarpophalangeal (2MCP; dorsal and palmar view), and fifth metatarsophalangeal (5MTP; dorsal view). US synovitis was defined as a gray scale (GS) score ≥1. Synovial vascularity was assessed by power Doppler (PD) and graded from 0 to 3, according to OMERACT standards. The US score comes from the addition of the presence of synovitis (one point) and the degree PD, with a total score ranged from 0 to 40 (synovitis subscale = 0–10; PD subscale = 0–30). Final score was correlated with clinical variables (Spearman's rho) and stratified according to patients' disease activity (Kruskal Wallis and post-hoc tests).

Results: 124 patients were included. Mean age was 53 ± 13 years, 86% were female, and disease duration was 9.4 ± 8.5 years. Tender and swollen joints count were 3.3 ± 4 and 3.5 ± 4.5, respectively. DAS28 score was 3.8 ± 1.4. A total of 744 joints were evaluated. 548 (74%) exhibited

ultrasonographic changes (PD ≥ 1 = 35%; synovitis = 69%). 2MCP and 5MTP showed erosions in 70% and 83%, respectively. Mean ultrasonographic score was 11.4 $\pm$ 6.5 (Doppler subscale 4.8 $\pm$ 6.5; Synovitis subscale 6.6 $\pm$ 2.2). The score had a moderate correlation with swollen joint count and DAS28 (Spearman's rho 0.60 and 0.54, respectively; p<0.001). The score was able to discriminate patients with high disease activity from those with moderate, low activity and remission (Remission= 8 $\pm$ 4, low activity= 9 $\pm$ 5, Moderate activity= 11 $\pm$ 5, High activity= 19 $\pm$ 8; p<0.01). Excluding the 5MTP and synovitis subscale did not affect the results, showing an excellent correlation with primary score (Spearman's rho 0.98 and 0.96, respectively; p<0.001). US examination was fast, taking 8 minutes per patient, including documentation.

Conclusion: A reduced US score of 6 joints showed to be fast and a valid tool to detect and monitor disease activity in patients with RA. Ultrasonographic assessment of bilateral wrist, second MCP and fifth MTF could be enough for evaluating overall inflammatory activity, reducing the examination time, thereby making it possible to integrate the ultrasound to the daily rheumatologic practice.

Sensitivity to Change of the Ultrasound synovitis SONAR Score in RA Patients: Results of the Scqm Cohort. Pascal Zufferey[1], Almut Scherer[2], Hans Rudolf Ziswiler[3], Giorgio Tamborrini[4], Laure Brulhart[5] and Burkhard Moeller[6]. [1]Lausanne University Hospital, Lausanne, Switzerland, [2]SCQM Foundation, Zurich, Switzerland, [3]Inselspital, University of Bern, Bern, Switzerland, [4]University Hospital, Zurich, Switzerland, [5]Geneva, Switzerland, [6]Inselspital Bern, Bern, Switzerland

Background/Purpose: Since the end of 2009, an ultrasound scoring call SONAR has been implemented for RA patients as a routine tool in the SCQM registry (Swiss Clinical Quality Management registry for rheumatic diseases). A cross-sectional evaluation of patients with active disease and clinical remission according to the DAS28$_{ESR}$ and the novel ACR/EULAR remission criteria from 2010 clearly indicated a good correlational external validity of synovial pathologies with clinical disease activity in RA (2012 EULAR meeting

Objective: of this study was to evaluate the sensitivity to change of B-mode and Power-Doppler scores in a longitudinal perspective along with the changes in DAS28$_{ESR}$ in two consecutive visits among the patients included in the SCQM registry

Methods: All patients who had at least two SONAR scores and simultaneous DAS28$_{ESR}$ evaluations between December 2009 and June 2012 were included in this study. The data came from 20 different operators working mostly in hospitals but also in private practices, who had received a previous teaching over 3 days in a reference center. The SONAR score includes a semi-quantitative B mode and Power-Doppler evaluation of 22 joints from 0 to 3, maximum 66 points for each score. The selection of these 22 joints was done in analogy to a 28 joint count and further restricted to joint regions with published standard ultrasound images. Both elbows and wrist joints were dynamically scanned from the dorsal and the knee joints from a longitudinal suprapatellar view in flexion and in joint extension. The bilateral evaluation of the second to fifth metacarpophalangeal and proximal interphalangeal joints was done from a palmar view in full extension, and the Power-Doppler scoring from a dorsal view with hand and finger position in best relaxation

Results: From the 657 RA patients with at least one score performed, 128 RA patients with 2 or more consultations of DAS28$_{ESR}$, and a complete SONAR data set could be included. The mean (SD) time between the two evaluations was 9.6 months (54). The mean (SD) DAS28$_{ESR}$ was: 3.5 (1.3) at the first visit and was significantly lower (mean 3.0, SD.2.0, p:<0.0001) at the second visit. The mean (SD) of the total B mode was 12 (9.5) at baseline and 9.6 (7.6) at follow-up (p=0.0004). The Power-Doppler score at entry was 2.9 (5.7) and 1.9 (3.6), at the second visit, p <0.0001.

The Pearson r correlation between change in DAS28$_{ESR}$ and the B mode was 0.44 (95% CI: 0.29, 0.57, p < 0.0001),and 0.35 (95% CI: 0.16, 0.50, p = 0.0002) for the Power-Doppler score,. Clinical relevant change in DAS (>1.1) was associated with a change of total B mode score >3 in 23/32 patients and a change a Doppler score >0.5 in 19/26.

Conclusion: This study confirms that the SONAR score is sensitive to change and provides a complementary method of assessing RA disease activity to the DAS that could be very useful in daily practice.

108

Disparity Between Sonographic and Clinical Criteria of Remission in Psoriasis Arthritis. Christian Dejaco[1], Rusmir Husic[1], Judith Gretler[2], Winfried B. Graninger[1] and Josef Hermann[1]. [1]Medical University Graz, Graz, Austria, [2]Auenbruggerplatz 15, Graz, Austria

Background/Purpose: To compare ultrasound and clinical definitions of remission in psoriasis arthritis (PsA).

Methods: Prospective study of 70 consecutive PsA patients [mean age 51.1 ($\pm$SD 11.6) years, 30% female, median disease duration 7.0 (range 0–44.7) years]. Clinical and ultrasound examination was performed at 68 joints and 14 entheses (lateral epicondyle, triceps insertion, quadrizeps insertion, proximal and distal insertion of patellar ligament, Achilles tendon, plantar fascia), and Disease Activity index for PSoriatic Arthritis (DAPSA), composite psoriatic disease activity index (CPDAI), HAQ and PASI were calculated. The following clinical definitions of remission were applied: DAPSA ≤ 3.3, CPDAI (joint, entheses and dactilytis domains) =0 or a Boolean definition with a score ≤ 1 in all of the following categories: tender joints (TJ), swollen joints (SJ), CRP, patient's (PGA) and evaluator's global assessment (EGA), enthesitis and dactylitis. Sonography was performed by two rheumatologists blinded to clinical data using an ESAOTE Twice ultrasound device. Power Doppler (PD) signals were graded from 0 to 3. The presence of perisynovitis and tenosynovitis was also recorded. Ultrasound remission was defined by a PD-score of 0 at joints, entheses and tendons.

Results: Fifteen (21.4%), 12 (17.1%) and 11 (15.7%) PsA patients were in remission according to the CPDAI, DAPSA and the Boolean definitions. A lower prevalence of PD signals in at least one joint or tendon was found in patients in remission according to DAPSA (58.3% vs. 84.5%, p=0.039 and 8.3% vs. 38.6%,p=0.043, respectively) and the Boolean definition (54.5% vs. 84.7%, p=0.022 and 9.1% vs. 37.9%, p=0.06, respectively) whereas the prevalence of active synovitis was similar in inactive and active disease groups according to CPDAI (66.7% vs. 83.6%, n.s.). Tenosynovitis tended to be more prevalent in cases with active disease according to CPDAI compared to patients in remission (38.9% vs. 13.3%, p=0.06). Frequencies of active enthesitis and perisynovitis were similar in groups with active and inactive disease according to CPDAI, DAPSA and the Boolean definitions.

Three (4.3%) patients had no PD-signal in joints, entheses and tendons. Comparing patients with PD-score=0 [n=14 (20%)] and PD-score≥ 1 at joints we found a lower number of SJ [0 (0–4) vs. 1 (0–15), p=0.007] and lower ESR [6.5 (1.0–17.0) vs 10.0 (1.0–74.0), p=0.049] among patients with inactive disease. CPDAI, DAPSA, TJ, CRP, PGA; EGA and HAQ were similar in both groups.

Patients without PD-signals at tendons [n=46 (65.7%)] had lower DAPSA [9.9 (0.1 –70.2) vs. 17.4 (0.2 –60.8), p=0.012], lower PGA [30 (0–80) vs. 40 (0–80), p=0.024], lower CRP [2.0 (0–20.3) vs. 4.8 (0.6–49.5), p=0.013] and lower ESR [6.0 (1.0–47.0) vs. 18.0 (5.0–74.0), p<0.001] compared to patients with active tenosynovitis.

Patients without PD signals at entheses [n=27 (38.6%)] did not differ from patients with active disease regarding clinical scores and laboratory measures.

Conclusion: Our data demonstrate a disparity between ultrasound and clinical definitions of remission in PsA. DAPSA and Boolean based definitions of remission are closer to ultrasound defined remission than a CPDAI based definition.

Does Joint Sonography Really Add Clinically Important Information Beyond Clinical Joint Examination? Miriam Gärtner[1], Helga Radner[1], Gabriela Supp[1], Peter Mandl[1], Daniel Aletaha[1], Klaus P. Machold[1] and Josef S. Smolen[2]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Sonographic assessment of joint activity in patients with rheumatoid arthritis (RA) is considered to be more sensitive than

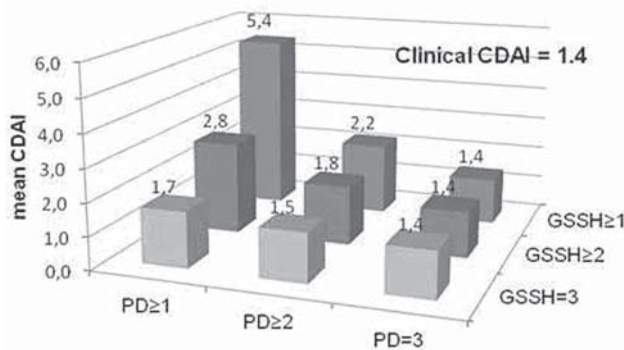
the respective clinical assessment. However, this difference may be less dependent on the physical technique used (i.e. palpation vs. ultrasound), but rather related to differences in arbitrary definitions of the presence or absence of "joint activity". We aimed to evaluate the differences in numbers of clinically and sonographically active joints in RA, with special regard to the impact of sonographic definitions of activity.

Methods: We performed sonographic imaging of 22 joints of the hands of RA patients in clinical remission (n=60; defined as Clinical Disease Activity Index=CDAI $\leq$ 2.8). Each joint was assessed for grey scale synovial hypertrophy (GSSH) and power Doppler (PD) signal on a four point scale (0=no, 1=mild, 2=moderate and 3=marked). We investigated the sensitivity and specificity of clinically swollen joints for presence of sonographic activity, when using different cut points and combinations of sonographic definitions of activity. For the clinical assessment we used the strict conventional approach of not calling a joint swollen in case of any doubt. We then assessed changes of CDAI if the clinical swollen joint count (SJC) was replaced by sonographically active joints.

Results: Among the 1320 joints of patients in remission a total of 887 (67.2%) were GSSH positive and 269 (20.4%) were PD positive.

Clinical joint swelling was 100% specific for sonographic activity, even when stringent sonographic criteria (score=3) were applied. The maximum sensitivity was 25% using the most stringent sonographic criteria (GSSH=3 and PD=3).

Calculating CDAI by replacing the number of clinically swollen by the number of sonographically active joints (sCDAI) according to the various definitions above, resulted in high values using GSSH$\geq$1 or PD$\geq$1 (mean sCDAI=15.5) compared to the clinical CDAI of 1.4. However, sCDAI values approached the clinical CDAI with increasing stringency of the sonographic definition used, and were even numerically identical when accepting only grade 3 PD signals (Figure).

CDAI values calculated using diffent sonographic definitons


Conclusion: Sonography revealed residual signals of joint activity in patients in CDAI remission. Changing the stringency of the sonographic criteria toward higher signals for determination of joint activity led to similar results when considered in the context of overall disease activity, such as in the CDAI.

Comparing Palmar and Dorsal Ultrasound Assessment of Small Joint Synovitis in Rheumatoid Arthritis: Dorsal Greyscale Mode Yields Significantly Better Concordance with Power Doppler. Matthias Witt[1], Felix Mueller[1], Hendrik Schulze-Koops[2] and Mathias Grunke[1]. [1]Division of Rheumatology, Medizinische Klinik und Poliklinik IV, University of Munich, Munich, Germany, [2]Division of Rheumatology, Medizinische Klinik and Poliklinik IV, University of Munich, Munich, Germany

Background/Purpose: MCP and PIP joints are frequently involved in rheumatoid arthritis. Complete ultrasound assessment of these joints requires the palmar and the dorsal approach for both the grey scale (GSUS) and the power Doppler (PDUS) modality. However, depending on the approach used, the frequency of findings consistent with synovitis seems to differ considerably. As ultrasound assessment increasingly influences our understanding of disease

remission, this study was undertaken to investigate the role of palmar versus dorsal GSUS and PDUS in therapy-naive patients with rheumatoid arthritis.

Methods: Patients with newly diagnosed and therapy-naive RA were included. Patients were assessed by clinical examination and ultrasound. Ultrasound was performed with grey scale (GSUS) and power Doppler (PDUS) of the metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints, using the dorsal and palmar approach. Synovitic findings in GSUS and PDUS were graded semiquantitatively from 0 to 3 as specified before. After the initial assessment, patients were treated with anti-rheumatic drugs according to national guidelines and were seen on a regular outpatient basis. Clinical and sonographic reevaluation together with assessment of EULAR responses was performed at month 6.

Results: Sofar, 40 patients with RA were included into this ongoing study. Palmar and dorsal GSUS identified 44.4% and 27.3% synovitic findings, respectively (p < 0.05). MCP joints with GSUS synovitis were tender and/or swollen in 53.4% and 62.6% in the palmar and volar approach, respectively (differences not significant). MCP joints with GSUS findings were PDUS positive in 17.8% using the volar approach compared to 71.7% using the dorsal approach (p < 0.001). Similar results were seen in the PIP joints with no significant differences concerning clinical concordance, while ultrasound concordance with PDUS was statistically significant between the palmar and dorsal approach.

Conclusion: In therapy naïve RA patients, marked discrepancies between palmar and dorsal GSUS can be observed. While palmar GSUS detects significantly more synovitic findings than dorsal GSUS, both the clinical and PDUS concordances are low. The dorsal approach, on the other hand, shows significantly better concordance between GSUS and PDUS. The reasons are manifold and include anatomical differences between the palmar and the dorsal aspect of the joints resulting in different sensitivities for GSUS and PDUS. In order to optimize ultrasonographic evaluation of small joints in RA, these findings require further clarification. Further analysis is underway to reassess GSUS and PDUS in these patients at month 6 of treatment.

Ultrasound Measurement of Metacarpal Cartilage Thickness Correlates with Joint Space Narrowing in the Metacarphalangeal Joints of Patients with Rheumatoid Arthritis. Peter Mandl[1], Helga Radner[1], Gabriela Supp[1], Peter V. Balint[2], Daniel Aletaha[1] and Josef S. Smolen[3]. [1]Medical University of Vienna, Vienna, Austria, [2]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: To correlate cartilage thickness as measured by ultrasound (US) with joint space narrowing as measured by conventional radiography in the metacarpophalangeal (MCP) joints of patients with rheumatoid arthritis.

Methods: In this pilot study we examined 120 MCP joints of 15 patients with rheumatoid arthritis (RA). The cartilage layer of the metacarpal heads and proximal phalangeal bases of digits 2–5 were assessed bilaterally using a 15 Mhz linear transducer (GE Logic E9) from a dorsal longitudinal view in midline, with joints in 90° flexion. Cartilage thickness was measured in mm with an integrated caliper on static images. Joint space narrowing (JSN) was evaluated using the van der Heijde modified Sharp scoring method (vdHS) performed on conventional posterior-anterior radiographs of both hands. Cartilage thickness was correlated with x-ray findings using Spearman correlation, while differences of JSN within groups of different cartilage thickness (using tertiles) were evaluated by Kruskal-Wallis test.

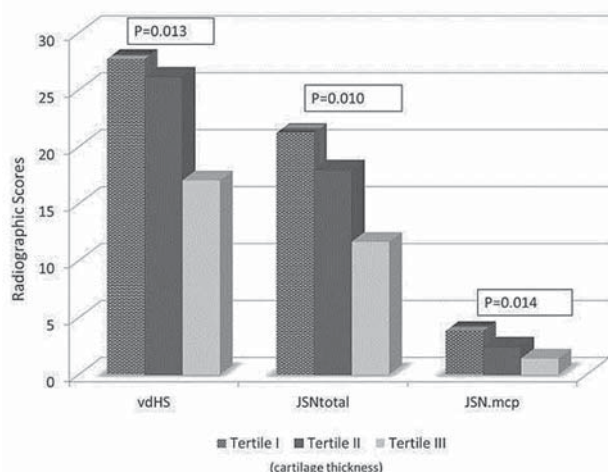
Results: Mean disease duration was 9.3+6.2 years, mean CDAI 8.3+7.4; 63% of the patients were rheumatoid factor positive. US measurement of metacarpal cartilage thickness was 0,38+/−0,17 mm and correlated with total JSN of MCP 2–5 (r=0.54, p<0.001) as well as with the total vdHS (r=0.53, p<0.001). No correlation was found between phalangeal cartilage thickness and JSN. Metacarpal cartilage thickness correlated better with JSN than the sum score of metacarpal and phalangeal cartilage thickness (r=0.54 p<0.01 vs. 0.47 p<0.05). Moderate correlation was found between the left and right hand with regard to metacarpal cartilage thickness (r=0.56, p<0.05). Correlation was slightly higher between metacarpal cartilage thickness of the left hand and JSN (r=0.57 vs. 0.53; p<0.05). Significant differences of total vdHS, total JSN and JSN sum score for the MCP joints (JSN.mcp) were found between tertiles of metacarpal cartilage thickness using Kruskal-Wallis Test (Figure 1). No correlation between cartilage thickness and disease activity, functional disability, or disease duration was seen.


Figure 1. Differences of JSN between groups of different cartilage thickness using tertiles. Tertile I: mean cartilage size 0.0189 (±0.003) mm; Tertile II: mean cartilage size: 0.035 (±0.005) mm; Tertile III: mean cartilage size: 0.058 (±0.009) mm

Conclusion: JSN by radiography indeed represents cartilage thickness at least in MCP joints. When radiographic scoring is not available, US measurement of cartilage thickness of the metacarpal head might be a feasible alternative to depict cartilage damage in patients with rheumatoid arthritis. Phalangeal cartilage thickness has no added value beyond the measurement of metacarpal cartilage thickness.

112

Time-Integrated Synovitis Activity Assessed by Power Doppler Ultrasound Significantly Correlates with Radiographic Progression in Rheumatoid Arthritis Patients Treated with Methotrexate Alone but Not in Those Treated with TNF Antagonists, Kei Ikeda, Daiki Nakagomi, Yoshie Sanayama, Mieko Yamagata, Ayako Okubo, Taro Iwamoto, Hirotoshi Kawashima, Kentaro Takahashi and Hiroshi Nakajima. Chiba University Hospital, Chiba, Japan

Background/Purpose: Although a number of studies have shown a higher sensitivity of ultrasound than clinical joint examination in detecting synovitis in patients with rheumatoid arthritis (RA), only a few studies have actually demonstrated the superiority of ultrasound to conventional measures in evaluating synovitis that causes structural damage. In this study, we aimed to demonstrate that structural damage progression is associated with time-integrated power Doppler (PD) signals more significantly than with time-integrated DAS28 in RA patients receiving methotrexate or biological agents.

Methods: Patients with an established diagnosis of RA who required new or additional treatment with either methotrexate (MTX), TNF antagonists, or tocilizumab (TCZ) were consecutively enrolled in this study. Patients underwent clinical, laboratory, and ultrasonographic assessment at baseline and at 12 and 24 weeks of follow-up. Patients also underwent radiographic assessment at baseline and at 24 weeks. A systematic multiplanar ultrasound examination of 28 joint regions was performed and gray-scale (GS) synovitis and PD signals were recorded with semi-quantitative scores (0–3).

Results: Forty-eight RA patients were enrolled. All 17 patients in MTX group were treated with MTX alone, whereas 20 out of 23 patients in TNF group and all eight patients in TCZ group received combination therapy with MTX. Changes in DAS28 and CDAI significantly correlated with those in total GS and PD scores between baseline and 12 weeks. The absolute values of standardized response means (SRM) for total PD scores between baseline and 12 weeks tended to be larger (TNF antagonists, 1.43; TCZ, 1.93) than those for DAS28 (TNF antagonists, 1.39; TCZ, 1.71), CDAI (TNF antagonists, 1.07; TCZ, 1.03), or total GS scores (TNF antagonists, 1.40; TCZ, 0.86) in patients treated with biological agents. When time-integrated disease activity was calculated by summing scores at three visits, the correlation between time-integrated total PD scores and changes in total Sharp scores during 24 weeks was statistically significant, whereas the correlations between time-integrated DAS28 or total GS scores and changes in total Sharp

scores were not statistically significant. In sub-group analyses for each treatment regimen, time-integrated total PD scores significantly correlated with changes in total Sharp scores in patients treated with MTX alone, but not in those treated with TNF antagonists (Figure).
Conclusion: PD ultrasound represents synovitis activity that causes joint damage progression more directly than DAS28 or GS synovitis does. The lack of correlation between time-integrated total PD scores and changes in total Sharp scores in patients treated with TNF antagonists may reflect the protective effect of TNF antagonists against joint damage that is independent of synovitis activity.

113

Power Doppler Signal Is Frequently Positive Among Patients with Rheumatoid Arthritis in Clinical Remission and Normal Serum Matrix Metalloproteinase-3 (MMP-3) Levels. Tadashi Okano, Tatsuya Koike, Masahiro Tada, Kenji Mamoto, Yuko Sugioka, Atsuko Kamiyama and Hiroaki Nakamura. Osaka City University Medical School, Osaka, Japan

Background/Purpose: Serum matrix metalloproteinase-3 (MMP-3) is useful bio markers of synovitis associated with rheumatoid arthritis (RA). Ultrasonography (US) has recently become more popular as a method of evaluating joint synovitis. The purpose of this study is to determine the significance of grey scale ultrasonography (GSUS) and power Doppler ultrasonography (PDUS) scores by comparison with serum biomarkers and clinical disease activity assessment.

Methods: We selected 151 consecutive patients with RA at our hospital outpatient clinic. The patients underwent musculoskeletal ultrasonography at 26 synovial sites in the following joints: bilateral first to fifth MCP (dorsal recess), first IP and second to fifth PIP (dorsal recess) joints and the wrists (dorsal radial, dorsal median and dorsal ulnar). The GS and power PD signals were scored in each joint using a scale from 0 to 3. The GSUS and PDUS scores are the sums of the scores obtained for the 26 synovial sites. Correlations among serum CRP, ESR and MMP-3 values and disease activity evaluated using the DAS28-ESR, DAS28-CRP, SDAI, CDAI were analyzed along with the PDUS positive ratio in patients in remission and in patients with normal MMP-3 values.

Results: The clinical characteristics of the 151 patients (128 females and 23 males; mean age, 60.5 ± 13.1 years) with RA were as follows. They received only DMARDs (n = 80), and biological DMARDs (n = 71). The GSUS and PDUS scores were significantly and positively correlated with ESR, CRP, MMP-3, DAS28-ESR, DAS28-CRP, SDAI and CDAI. The PDUS score >1 was positive in 28 of 34 patients (82.3%) in remission with DAS28-CRP (< 2.6) and in 52 of 61 (85.2%) with normal serum MMP-3 levels. The PDUS score >2 was positive in 10 of 34 (29.4%) patients in remission with DAS28-CRP and in 30 of 61 (49.2%) with normal serum MMP-3 levels. The levels of PDUS score in the remission patients using biological DMARDs was less than the remission patients using only DMARDs.

Conclusion: Both GSUS and PDUS scores were closely correlated with clinical disease activity and serum biomarkers. These results indicate that US findings accurately reflect the pathogenesis of RA. However, patients in remission and normal serum MMP-3 levels also had a high rate of positive PD scores. We considered that US is more accurate for clinically evaluating patients with RA.

114

US Examination of Wrists and Hands: A Comparison Between Rheumatoid Arthritis and Psoriatic Arthritis. Andrea Delle Sedie[1], Elisa Cioffi[1], Linda Carli[1], Elena Sardano[2], Stefano Bombardieri[1] and Lucrezia Riente[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Immunology Unit, University of Pisa, Italy

Background/Purpose: very little is known about the differences in joint and periarticular structure involvement in rheumatoid or psoriatic arthritis (PsA). The main pathological features detected by US in rheumatoid arthritis (RA) are synovitis and bone erosion while, in spondyloarthropathies, entheseal inflammation is the common feature. Tendon involvement is particularly frequent and dactylitis is a typical PsA manifestation. Aim of the study was to find possible differences in ultrasound (US) involvement of wrist and hand in PsA and RA.

Methods: bilateral US examination of the wrist and hand was performed, by the same physician blinded to the diagnosis, in a consecutive, unselected, group of subjects affected by RA and PsA, using a Logiq 9 (General Electrics Medical Systems, Milwaukee, WI) with a linear probe (14 MHz). Radiocarpal, intercarpal, metacarpophalangeal, proximal interphalangeal and distal interphalangeal joints and flexor and extensor tendons (in wrist and hand) were examined bilaterally. Bone erosion and tenosynovitis were diagnosed according to the OMERACT definitions [1], while synovitis was considered when a synovial hypertrophy (with or without power Doppler signal) was present. The patients were recruited on a time-criteria (the last who came for an outpatient visit). The RA and PsA diagnosis was given by other rheumatologists, according to the 1987 ACR and Caspar criteria, respectively.

Results: mean age and disease duration were comparable for both groups, while male/female ratio was different (as expected) (Table 1). US findings are reported in Table 1. The number of hand joints involved was higher in RA than in PsA (182 vs 150). Given the results, it is interesting that the total number of proliferative tenosynovitis was significantly greater in RA (49/68 vs 7/34 in PsA at the wrist level and 58/98 vs 13/63 in PsA at the hand level).

Table 1.

	RA (N=55)	PsA (N=55)
F/M	48/7	28/27
Mean age (yrs)	60.7±12.7	57.4 ± 12.5
Disease duration (months)	113.3 ± 97.7	100.6 ± 95.6
Wrist synovitis (N of pts; %)	38;69	24;44
Hand synovitis (N of pts; %)	28;51	37;67
Wrist tenosynovitis (N of pts; %)	23;43	16;29
Hand tenosynovitis (N of pts; %)	22;40	25;45
Hand erosions	30;54	26;47

Conclusion: Wrist synovitis occurred significantly more frequently in RA patients than in PsA subjects, while no significant differences were observed in hand synovitis between the groups. There was no difference in tendon involvement for frequency between RA and PsA groups considering the number of patients with tenosynovitis but it became significantly different when considering the total amount of tenosynovitis (as well as the number of proliferative tenosynovitis). The latter aspect could be determined by a more aggressive inflammation of the tendons in those patients that present tendon involvement and are affected by RA (only 10 RA patients had hand proliferative tenosynovitis, compared to 7 in the PsA group, indicating a lower frequency of synovial proliferation in the second group). There were no other significant differences in the results of the two groups.

Composite Ultrasound Score in Spondyloarthropathies. Maria L. Acosta Felquer[1], Cristian Quiroz[1], Santiago Ruta[2], Javier Rosa[1], Marina Scolnik[2], Leandro Ferreyra Garrott[1], Ricardo Garcia-Monaco[3] and Enrique R. Soriano[4]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, [4]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina

Background/Purpose: A comprehensive ultrasound (US) scoring system which includes enthesitis tenosynovitis and synovitis for use in patients with spondyloarthropathies (SpA) is not yet available. The objective of the study was to develop an US composite scoring system, including both enthesitis tenosynovitis and synovitis, suitable for the evaluation of patients with SpA.

Methods: Consecutive patients with SpA according to the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for axial, and/or peripheral spondyloarthritis and Rheumatoid arthritis (RA) patients fulfilling ACR/EULAR criteria (control group) in whom an US was performed were included. US examination was done by an experienced rheumatologist using both grey scale US and power Doppler (PD). The following articular areas were assessed: 2–3 MCP joints, 2–3 proximal PIP joints, wrist, knee and second and fifth MTP joints. Knee and ankle entheses were examined. Both second and third flexor and fourth and sixth extensor tendons of the hands were examined for tenosynovitis. Synovitis, tenosynovitis and enthesitis were defined according to OMERACT preliminary definitions. Both GS and PD synovitis were graded on a semiquantitative scale from 0 to 3. For each one of the structures examined (enthesis, tendons and synovial) an initial US score was obtained by multiplying the semiquantitative scale by the number of sites involved. Using that score patients were classified into a new US structure specific (enthesis, tendons and synovial) activity score ranging from 0 (no activity) to 3 (severe activity) for that structure. Finally adding the US structure specific activity scores a composite US activity score was constructed ranging from 0 (no activity) to 3 (severe activity).

Results: 33 patients with SpA (70% males, mean (SD) age: 51 (14.6) and 35 with RA (97% females, mean (SD) age: 55.7 (16) were included.

Table. Comparison of different variables related to disease activity in the different US composite activity score classification groups in patients with SpA and RA.

					SpA	
US composite activity score classification	N patients (%)	Mean DAS28 (SD)	Mean ESR (SD)	Mean HAQ (SD)	Mean VAS Physician (SD)	Mean CPDAI (SD)
0 (none involvement)	1 (3)	2.3 (0)	18 (0)	0.25 (0)	20 (0)	0 (0)
1 (mild)	26 (79)	3.99 (0.9)	21 (15.8)	0.63 (0.54)	46.5 (20)	3.3 (1.9)
2 (moderate)	6 (18)	5.15 (1.3)	36 (31)	1.33 (0.8)	46.7 (27)	4.2 (3.9)
3 (severe)	0 (0)	-	-	-	-	-
P value (1-mild vs 2-moderate) Mann Whitney		0.1366	0.2107	0.0477	0.9197	0.9363

					RA	
US global severity classification	N patients (%)	Mean DAS28 (SD)	Mean ESR (SD)	Mean HAQ (SD)	Mean VAS Physician (SD)	Mean CDAI (SD)
0 (none involvement)	0 (0)	-	-	-	-	-
1 (mild)	24 (69)	4.6 (1)	21 (15.8)	0.94 (0.83)	40.6 (22)	17.9 (8.6)
2 (moderate)	11 (3)	5.7 (0.7)	36 (31)	1.22 (0.9)	63 (20)	29.2 (9.2)
3 (severe)	0 (0)	-	-	-	-	-
P value (1-mild vs 2-moderate) Mann Whitney		0.0067	0.2551	0.386	0.008	0.0051

Most patients were classified as with mild disease activity by the US composite activity classification score in both diseases SpA and RA. In both diseases patients with higher US cmposite score had higher indices of disease activity although the differences were not always significant.

Conclusion: An US composite activity classification score taking into account synovial, enthesis and tendons involvement proved to correctly discriminate patients with SpA and RA in different activity status according to classical activity indices.

116

Correlation Between Clinical and Ultrasonographic Examination of the Calcaneal Enthesis in Patients with Ankylosing Spondylitis: A Controlled Study. Suellen Narimatsu[1], Rita N.V. Furtado[1], Andre Rosenfeld[2], Germana. B. Q. Estrela[1], Jorge E. P. Proglhof[3] and Jamil Natour[4]. [1]Universidade Federal de São Paulo - UNIFESP, São Paulo, Brazil, [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo - UNIFESP, Sao Paulo, Brazil, [4]Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: 1 – To compare US findings of calcaneal entheses between AS patients and healthy subjects; 2 – To assess the calcaneal entheses by US and correlate with clinical, functional and inflammatory aspects in patients with AS.

Methods: We conducted a cross sectional study of 50 patients with AS and 30 healthy volunteer subjects matched for age and sex. The clinical evaluation of patients included a global health scale, visual analogue scale (VAS) for pain and edema, calculation of BASDAI, BASFI, BASMI, HAQ-S, ASDAS-VHS and enthesitis index SPARCC (Spondyloarthritis Research Consortium of Canada Enthesitis Index). The US exam was performed at right and left entheses of samples by a radiologist expert in musculoskeletal "blind" to clinical findings. The analysis of the US was based on MASEI index (Madrid Sonographic Enthesis Index) and the total analysis of its subitems. For evaluation was used the Esaote MyLab60 machine equipped with a linear transducer with a frequency of 6–18 MHz.

Results: Were evaluated by the US 160 calcaneal entheses in the whole sample. The patients had ages between 18–65 years (43.44 + 9.91) and healthy subjects 18–65 years (38.7 +8.52). The mean disease duration was 11.11 (+ 6.77) years. The comparison of average Masei between patient and control groups (16.32 + 11.11 / 10.70 + 5.27) was not significantly different (p = 0.519). The comparison of each find in the US between groups showed statistical significance for the detection of erosion (17 patients / healthy 0) with p = 0.00 and power Doppler (PD) (6/0) with p = 0.053. There was no correlation between the presence of bursitis, calcification, erosion, thickening, structural change in the US evaluation of calcaneal tendon with clinical, functional, inflammatory activity in patients. However, the PD of the entheses was correlated with VAS pain (0.344, p= 0.00) and VAS edema (0.486, p = 0.00). The VAS pain and VAS for edema of the calcaneal entheses correlated statistically (0.653, p = 0.00).

Conclusion: The US of the calcaneal entheses of individuals with AS had more erosion and capture the PD when compared with control subjects. The PD on these entheses was the only parameter on US that correlates with clinical variables.

Ultrasound for Diagnosis of Carpal Tunnel Syndrome – Comparison of Different Methods to Determine Median Nerve Volume and Value of Power Doppler Sonography. Christian Dejaco, Martin Stradner, Dorothea Zauner, Werner Seel, Nicole E. Simmet, Alexander Klammer, Kerstin Brickmann, Judith Gretler, Florentine Moazedi-Fürst, Rene Thonhofer, Rusmir Husic, Josef Hermann and Stefan Quasthoff. Medical University Graz, Graz, Austria

Background/Purpose: Routine use of sonography for the diagnosis of carpal tunnel syndrome (CTS) is hampered by the lack of consensus regarding anatomical landmarks for the measurement of median nerve volume and difficulty of determining thresholds for abnormal median nerve swelling. This study was conduced to compare ultrasound measurement of median nerve cross-sectional area (CSA) at different anatomical landmarks and to analyze the value of Power Doppler (PD) signals within the median nerve.

Methods: We prospectively studied 135 consecutive patients with suspected CTS undergoing clinical and electrophysiological evaluation at two subsequent visits within three months. Final diagnosis of CTS was established by the evaluating neurologist based on findings from these conventional methods at both visits. Median nerve sonography was performed by two rheumatologists using a GE Logiq E9. CSA was

measured at 5 different levels at forearm and wrist; and CSA wrist to forearm ratios or differences were calculated. Intra-neural PD-signals were semiquantitatively graded (scale 0–3). Diagnostic values of different ultrasound methods were compared by receiving operating characteristic (ROC) curves using SPSS (v19.0).

Results: CTS was diagnosed in 111 (45.5%) wrists; 84 (34.4%) had no CTS and 49 (20.1%) were possible CTS cases. Diagnostic values were comparable for all sonographic methods to determine median nerve swelling with AUCs ranging from 0.75 to 0.84. Thresholds of 9.8 and 13.8 mm2 for the largest CSA of the median nerve yielded a sensitivity of 91% and a specificity of 92%, respectively. In cases of mild median nerve swelling the relative increase in CSA between the entrapment area and forearm provided additional diagnostic certainty (AUCs from 0.60 to 0.67). Increased vascularity as indicated by a PD-score ≥2 had a specificity of 90% for the diagnosis of CTS. Reliability of sonographic median nerve volumetry was good as indicated by an intra-class correlation coefficient of 0.90 (95% CI: 0.79–0.95).

Conclusion: Sonographic assessment of median nerve swelling and tissue vascularity at different anatomical landmarks allows for a reliable confirmation of the diagnosis in patients with clinically suspected CTS

Colour Doppler Sonography of the Knee Joint: A Useful Tool to Discriminate Arthritis From Osteoarthritis? Wolfgang Hartung[1], Nelly Beitinger[1], Boris P. Ehrenstein[1], Christian Lüring[2], Joachim Grifka[3], Benno Schreiner[3], Martina Müller[4] and Martin Fleck[1]. [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [2]Universitiy Clinic Aachen, Aachen, Germany, [3]University of Regensburg, Bad Abbach, Germany, [4]University Clinic Regensburg, Regensburg

Background/Purpose: To determine the diagnostic value of Colour Doppler ultrasound (CDUS) in patients with inflammatory arthritis (IA) versus osteoarthritis (OA) of the knee joint.

Methods: Standardized CDUS examinations have been performed in 111 knee joints of 106 patients (70 female, 36 male) presenting with severe OA (n=72) or confirmed IA (n=39) of one or both knee joints, to determine the degree of synovial inflammation in a semiquantitative fashion. To definitely distinguish inflammatory from non-inflammatory disease, synovial fluid has been obtained from every patient within 24 hours after sonography and analyzed synovial fluids containing up to 1000 white blood cells (wbc)/ul were considered non-inflammatory, whereas 5000 or more wbc/ul have been classified as inflammatory, respectively.

Results: The CDUS sum score of OA patients was determined at 3.3 (range 0–8). In contrast, IA patients exhibited significantly elevated synovitis scores at 5.3 (range 3–9) (p < 0.001). However, high synovial CDUS activity could be observed in OA patients sporadically. Therefore, there is no definitive CDUS threshold that clearly separates OA from IA patients.

Table 1. Mean CDUS scores of the patients with osteoarthritis vs. arthritis of the knee.

Scan	OA patients (n = 73)	IA patients (n = 39)
suprapatellar	0.14 (0–2)	0.64 (0–2)
infrapatellar	0.14 (0–2)	0.44 (0–2)
medial longitudinal	1.2 (0–3)	2.0 (1–3)
lateral longitudinal	2.0 (0–3)	2.3 (1–3)
Total score	3.3 (0–8)	5.3 (3–9)**

OA = Osteoarthritis, IA = inflammatory arthritis of the knee, ** (Chi square test: p value < 0.001).

Conclusion: CDUS is a valuable instrument to assist clinicians in distinguishing OA from IA of the knee, but nevertheless should always interpreted within the clinical context.

Ultrasound (US) Findings in Patients with Knee Pain: Sensitivity and Specificity for the Diagnosis of Knee Osteoarthritis and Development of an US Prediction Score. Erika Catay[1], Santiago Ruta[2], Javier Rosa[1], David A. Navarta[1], Ricardo Garcia-Monaco[3] and Enrique R. Soriano[4]. [1]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, [4]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires and Fundacion PM Catoggio, Buenos Aires, Argentina

Background/Purpose: The diagnosis of knee osteoarthritis (OA) is based mainly on clinical examination and radiological features. The objectives were to evaluate the sensitivity and specificity of different ultrasound (US) findings and to develop an US score for the diagnosis of knee OA.

Methods: Consecutive patients complaining of knee pain with and without previous diagnosis of knee OA (ACR criteria) and no other known rheumatologic condition were included. US examinations were performed by an experienced rheumatologist, blinded to clinical data, using a My Lab 70 machine (Esaote) provided with a multi-frequency linear transducer (4–13 MHz).The following US abnormal findings were investigated (presence/absence): joint effusion (increased hypoechoic or anechoic intraarticular material, within synovial recesses greater than 4 mm), osteophytes (cortical protrusions at the joint margin), menisci protrusion (a distance between the peripheral border of the meniscus and the outline of the tibial plateau greater than 2 mm), degenerative femoral hyaline cartilage involvement (loss of sharpness of the cartilage margins and/or loss of homogeneity of the cartilage layer and/or focal or extended cartilage thinning) and Baker's cyst (abnormal hypo-anechoic, displaceable and compressible material within the gastrocnemius-semimembranosus, with a transverse diameter greater than 4 mm). We developed a US score using logistic regression analysis (OA as dependant variable) with US features included in the model. Weighting of each of these variables was obtained using the regression OR

Results: 75 knees were examined in 52 patients without knee OA (mean age 59.5 ± 16 years, 34 female/18 male) and 127 knees were examined in 87 patients with knee OA (mean age 72.6 ± 8.3 years, 70 female/17 male).

Table 1. Diagnostic characteristics of different US abnormal findings for the diagnosis of knee OA.

	Sensitivity %, (95% CI)	Specificity %, (95% CI)	PPV %	NPV %
Joint effusion	89.8 (83–94)	32 (22–44)	69	64.8
Osteophytes	85.8 (78–91)	77.3 (66–86)	86.5	76.3
Menisci protrusion	48 (39–57)	93.3 (85–98)	92.4	51.4
Degenerative femoral hyaline cartilage involvement	92.9 (87–97)	84 (74–91)	90.7	87.5
Baker's cyst	16.5 (10–24)	82.7 (72–90)	61.7	36.9

Table 2. US score.

Variables		OR	Points
Joint effusion	Ifpresent	1	1
Degenerative femoral hialine cartilage involvement	Ifpresent	44	4
Osteophytes	Ifpresent	5.8	3
Menisci protrusion	Ifpresent	1.5	2
Maximum Total score			10

Knees with OA had significantly higher scores than knees without OA (mean (SD): 8.1 (2.3) vs 2.1 (2.7); p<0.001, respectively. The area under the Receiver operative curve (ROC) was 0.93 (95% CI: 0.89–0.97). A value ≥ than 5 had a sensitivity of 92 % and specificity of 81 % for the diagnosis of knee OA (LR + 4.9).

Conclusion: The identification of both osteophytes and degenerative femoral hyaline cartilage involvement by US showed the best diagnostic performance among all the US features investigated for the diagnosis of knee OA. A combined US score showed very good discriminative value for the diagnosis of knee OA in our population. A prospective cohort study would be needed to confirm these results.

120

Evaluation of Joint Involvement in Patients Suffering From Early Polymyalgia Rheumatica Using High Resolution Ultrasound. Sandra Balser[1], Emmanuelle LeBras[1], Boris P. Ehrenstein[1], Martina Müller[2], Martin Fleck[1] and Wolfgang Hartung[1]. [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [2]University Clinic Regensburg, Regensburg

Background/Purpose: The new EULAR/ACR 2012 classification criteria for polymyalgia rheumatica (PMR) are the first classification criteria that contain musculoskeletal ultrasound (MUS) in an additional algorithm resulting in an increased specificity. Therefore, the joint involvement has been investigated by MUS in a cohort of recent onset PMR patients analyzing the distribution of the novel ultrasound criteria.

Methods: All patients of our tertiary rheumatology center with newly diagnosed PMR between 01/2011 and 06/2012 were included in this retrospective study. MUS has been performed in all patients with suspected PMR. The final diagnosis of PMR was established by a rheumatologist according to physical examination, laboratory analysis, MUS, and after excluding other conditions mimicking PMR.

Results: In 35 patients the diagnosis of PMR was established. Pathological MUS findings of shoulder or hip joints were present in 80.0 % of these patients. Biceps tenosynovitis, subdeltoid bursitis or glenohumeral synovitis of at least one shoulder were observed in 74.3% patients. Of those patients with pathological MUS findings of the shoulder, 92.3 % had a biceps tenosynovitis of at least one shoulder, 80.8 % presented with bilateral biceps tenosynovitis, whereas only 46.2 % had a subdeltoid bursitis and 34.6 % a glenohumeral synovitis of at least one shoulder. Synovitis or trochanteric bursitis of at least 1 hip could be detected in 25.7 % of all PMR patients. 66.7 % of the patients with hip affection in MUS presented with pathological MUS findings of both hips and both shoulders (Tab. 1).

Table 1: MUS findings in PMR patients.

	PMR-Patients (n = 35)
At least 1 shoulder with biceps tenosynovitis, subdeltoid bursitis or glenohumeral synovitis	26 (74.3%)
Both shoulders with biceps tenosynovitis, subdeltoid bursitis or glenohumeral synovitis	24 (68.6%)
At least 1 shoulder with biceps tenosynovitis or subdeltoid bursitis	26 (74.3%)
Both shoulders with biceps tenosynovitis or subdeltoid bursitis	22 (62.9%)
At least 1 shoulder with biceps tenosynovitis	24 (68.6%)
Both shoulders with biceps tenosynovitis	21 (60.0%)
At least 1 hip with synovitis or trochanteric bursitis	9 (25.7%)
Both hips with synovitis or trochanteric bursitis	7 (20.0%)
Patients with no pathological finding as above	7 (20.0%)
At least 1 shoulder and 1 hip with findings as above	7 (20.0%)
Both shoulders and both hips with findings as above	6 (17.1%)

Conclusion: The most common pathological ultrasound finding in patients with PMR was a (bilateral) biceps tenosynovitis. Pathological ultrasound findings of the hips were less frequent, but in two thirds of these patients combined with pathological findings of both hips and both shoulders.

121

The Diagnostic Value of Color Doppler Ultrasonography in Giant Cell Arteritis. Merete L. Hetland[1], Geirmund Myklebust[2], Glenn Haugeberg[2] and Andreas P. Diamantopoulos[2]. [1]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [2]Hospital of Southern Norway HF, Kristiansand, Norway

Background/Purpose: Color Doppler Ultrasonography (CDUS) has been shown to be a non-invasive promising tool to diagnose Giant Cell Arteritis (GCA). The aim of our study was to evaluate the diagnostic value of CDUS in patients suspected to have GCA in clinical care.

Methods: Patients referred to our outpatient clinic between January 2010 and April 2012 with a tentative diagnosis of GCA were consecutively examined. A clinical evaluation was performed and the temporal arteries and the large vessels (carotid and axillary arteries) were assessed using a Siemens

Acuson Antares ultrasound system (high frequency transducer 7–14 MHz). CDUS was considered positive when the typical sign of halo (arterial wall swelling in transverse and longitudinal view) was observed in the temporal arteries. The patients were diagnosed with large vessels vasculitis (LVV) when intima-media complex thickness was homogenous and more than 1.5 mm in the carotid artery and more than 1 mm in the axillary artery. After the CDUS examination, unilateral biopsies of the temporal artery were carried out in the majority of the patients. The diagnostic value of CDUS, temporal artery biopsy and the American College of Rheumatology classification criteria for the GCA (ACR-GCA) were tested against the gold standard, for this study defined as final clinical GCA diagnosis established by an experienced rheumatologist.

Results: Seventy-eight patients (48 females, 30 males) were successively referred to our outpatient clinic. Thirty-six were diagnosed with GCA (27 females, 9 males) and all of them had a positive CDUS of the temporal artery. In addition, we found 4 patients with positive CDUS of the temporal artery but with other diagnoses (1 polyarteritis nodosa, 1 granulomatosis with polyangiitis and 2 with infections). Among the 36 patients with GCA, 32 fulfilled the ACR-GCA classification criteria. Temporal artery biopsy was positive in 20 of the 28 GCA patients who had a biopsy performed. Large vessel involvement was observed in 13 patients (36%). The mean time between the first presentation of symptoms and the diagnosis was 2.3 months (3.0 months in GCA patients with LVV and 1.7 months in classic GCA). In our series, sensitivity and specificity was 100% and 91% for CDUS, 64% and 95% for the temporal artery biopsy and 94% and 90% for the ACR-GCA classification criteria, respectively.

Conclusion: We conclude that CDUS has an excellent sensitivity and a high specificity to diagnose GCA in daily clinical care. CDUS do also have the advantage to identify large vessel involvement in GCA patients. We recommend the use of CDUS as a first line assessment tool in diagnosing GCA.

Grey-Scale Ultrasonography with Power Doppler Technique: An Available Tool for the Assessment of Subclinical Joint Inflammatory Activity in Juvenile Idiopathic Arthritis. Paz Collado[1], Rosa Merino[2], J. Graña Sr.[3], Sagrario Bustabad-Reyes[4], MariLuz Gamir[5], Mari Luz García[6] and Inmaculada Calvo[7]. [1]Severo Ochoa University Hospital, Madrid, Spain, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Hospital Juan Canalejo, Spain, [4]Hospital Universitario de Canarias, La Laguna. Tenerife, Spain, [5]Ramon y Cajal University Hospital, Madrid, Spain, [6]Hospital de Basurto, Bilbao, Spain, [7]Hospital de La Fe, Valencia, Spain

Background/Purpose: To investigate the usefulness of ultrasonography with power Doppler (PDUS) in detecting synovitis compared with clinical examination on large number of joints in JIA.

Methods: This multicenter study included 42 children with active JIA. Clinical and PDUS assessments were performed blindly on 44 joints. Active disease was defined by high acute phase reactants with clinically active arthritis. Active arthritis on US was defined as synovial hypertrophy, effusion, or increased vascularity on power Doppler (PD) scan. McNemar test was used to compare the percentage of joints showing synovitis detected by clinical examination and by PDUS.

Results: In total, 1848 joints were examined both clinically and by PDUS. Physical examination showed 277 joints (15.0%) having clinically active synovitis, and of these, 184 (10%) had synovitis confirmed by US. Furthermore, up to 177 joints (9.6%) were shown to have synovitis on US examination alone. The percentage of joints with synovitis confirmed by PDUS (19.5%, n=361 joints) was statistically higher than the percentage of joints having clinically active synovitis, 15.0% ($p < 0.0005$). Of the 361 joints with GS synovitis detected by US examination, 116 (32.1%) joints were shown to have inflammatory activity by PD signal detected in SH. Subclinical active synovitis was confirmed by PDUS in 51/177 joints (28.8%) that only seemed to have synovitis on US examination.

Conclusion: The study shows that the PD-technique along with GS examination increases the sensitivity of US in detecting subclinical synovitis in JIA. However, longitudinal studies in children are required to know subsequent structural damage.

123

Detection of Synovitis in Clinically Inactive Juvenile Idiopathic Arthritis Patients by Ultrasonography with POWER Doppler. Paz Collado[1], Mari-Luz Gamir[2], Rosa Merino[3], Consuelo Modesto[4], Indalecio Monteagudo[5] and Juan Carlos Lopez-Robledillo[6]. [1]Severo Ochoa University Hospital, Madrid, Spain, [2]Ramon y Cajal University Hospital, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Hospital Valle de Hebron, Barcelona, Spain, [5]Gregorio Marañón Hospital, Madrid, Spain, [6]Hospital Niño Jesus, Madrid, Spain

Background/Purpose: The advances in therapeutic effectiveness have created a need for looking for imaging tools that describe more precisely the clinical state of disease inactivity. The well-known advantages of ultrasonography with power Doppler (PDUS) makes that this technique is ideal for evaluation of the pediatric population in the clinical setting and lets clinicians choose an appropriate treatment to induce remission. The purpose of this study was to determine the prevalence of abnormalities detected by ultrasonography (US) in JIA patients presenting clinically inactive disease (ID) –on medication and off medication – and to compare between two groups.

Methods: Study design: Cross-sectional, multicenter study. Patients: Inclusion criteria: 1) JIA patients, age from 4 to 16 years old, 2) remission according to clinical assessment by their consultant doctor for a minimum of 6 months prior to the screening, 3) taking stable disease modified antirheumatic drugs (DMARDs) therapy or have discontinued medications for JIA for a minimum of 6 months, 4) biologics naïve patients. Exclusion criteria: Intra-articular steroid injection in the last 6 months. Data collected: Clinical and PDUS assessments were performed blindly on 44 joints. Other clinical and laboratory markers of activity disease were collected. For the analysis the Outcome Measure in Rheumatology in Clinical Trials (OMERACT) definitions for rheumatoid arthritis of synovitis and tenosynovitis were applied in our patients. The presence of Doppler signal inside the intraarticular synovium or in the synovial sheath was considered as inflammatory activity.

Results: 34 patients, of whom 23 patients have attained clinical remission on medication (CRM) with DMARD therapy and 11 patients have attained inactivity disease off medication (CR) (3). The mean (SD) disease duration was 48.10 (35) months. Half of the study patients have attained one or more previous inactivity disease state, but there was no significant difference between the 2 groups. Thirteen (38.2%) patients had evidence of ≥1 US findings, although the number of US abnormalities detected in CRM patients was higher than CR group, there were no significant differences between the 2 groups in detecting GS synovitis (p=0.86) and PD signal (p=0.38). US examination showed 37 joints presented GS synovial hypertrophy and 18 (48 %) of 37 joints with GS synovitis presented increased PD signal.

Conclusion: Our study shows that a proportion of patients presenting clinically inactive disease presented GS synovitis and some of them seem to present inflammatory activity detected by PDUS. The significance of these findings has importance in order to obtain an accurate definition of disease status in the growing skeleton of JIA patients.

Reliability of an Ultrasound Scoring Measure for Juvenile Localized Scleroderma (jLS). Suzanne C. Li[1], Melissa S. Liebling[2], Andrea S. Doria[3], Molly Dempsey-Robertson[4], Carsten Hamer[5], Sven Opitz[5], Faridali Ramji[6], Stephanie Edgerton[6], Jose Jarrin[3], Tanicka Kornyat[2], Michael Malone[6], Arun Mohanta[3], Shuzhen Zhang[4] and Knut M. Wittkowski[7]. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Hackensack University Medical Center, Hackensack, NJ, [3]Hospital for Sick Children, Toronto, ON, [4]Texas Scottish Rite Hospital, Dallas, TX, [5]Schon Klinik Hamburg Eilbek, Hamburg, Germany, [6]University of OK Health Science Center, Okc, OK, [7]Rockefeller University, New York, NY

Background/Purpose: Although ultrasound (US) shows great potential for aiding assessment of LS disease activity, its use has been limited because both image acquisition and interpretation are operator dependent. Our multidisciplinary group (LOCUS, LOcalized scleroderma Clinical and Ultrasound

Study group) has worked to develop an US scoring measure (U-DA) to help standardize sonographic interpretation of jLS patients (Pediatr Rheumatol 2010;8:14). The U-DA evaluates echogenicity and vascularity (color Doppler signal) differences in each tissue layer of the lesion compared with the corresponding normal tissue layer. A score of 0 represents no difference n the lesion compared with the normal site.

Objective: To assess the reliability of an ultrasound scoring measure (U-DA) for jLS.

Methods: LOCUS conducted a 3-day workshop meeting in 2009 on acquiring and interpreting US scans from jLS patients, which was attended by 12 radiologists and sonographers from 5 pediatric rheumatology centers. The group had developed a preliminary ultrasound scoring measure in 2007, and this preliminary measure was reviewed in conjunction with jLS US images showing the range of sonographic differences that had been observed up to the time of the meeting. This review led to modification of U-DA; definitions for scoring levels were then finalized. A tutorial on U-DA scoring was conducted, followed by individual scoring of two jLS US scans and collective review of scoring of these scans. Eleven attendees then scored a randomly-ordered set of 16 jLS scans, with 10 attendees rescoring the same set in a different random order on a second day. Kendall coefficients of concordance were calculated to determine intra-and inter-rater reliability, and scoring of each U-DA was separately analyzed to evaluate for potential issues.

Results: Raters showed moderate to high intra-rater reliability for scoring total echogenicity (Kendall's coefficient 0.77 to 0.92) and vascularity (Kendall's coefficient 0.64–0.92), where total refers to sum of scores from each identifiable tissue layer (dermis, hypodermis, deep tissue). A moderate level of inter-rater reliability was found for scoring total echogenicity (Kendall's coefficient 0.64, 0.56) and vascularity (0.58, 0.57). A high level of agreement was observed for dermis scoring (for example, majority of raters agreed on dermis vascularity score for 15/16 scans), with a much lower level of agreement observed for deep tissue scoring (majority agreement for 10/16 scans on deep tissue vascularity score).

Table 1. Intra- and Inter-rater reliability of U-DA Total Echogenicity, Total Vascularity

U-DA Scoring Parameter	Kendall's Coefficient	P value
Total Echo: Inter-rater, 1st reading	0.64	<0.0001
Total Echo: Inter-rater, 2nd reading	0.56	<0.0001
Total Echo: Intra-rater reliability range	0.77–0.92	0.118 to <0.0001
Total Vasc: Inter-rater, 1st reading	0.58	<0.0001
Total Vasc: Inter-rater, 2nd reading	0.57	<0.0001
Total Vasc: Intra-rater reliability range	0.64–0.92	0.1374 to <0.0001

Conclusion: The U-DA was found to have a moderate level of intra- and inter-rater reliability for total echogenicity and vascularity. Among the different tissue layers, deep tissue layer showed the lowest concordance. More training in deep tissue layer evaluation may further improve the reliability of scoring the U-DA.

Borderline Right Ventricular Involvement in Patients with Systemic Sclerosis without Pulmonary Hypertension. Luna Gargani[1], Piotr Gosciniak[2], Cosimo Bruni[3], Serena Guiducci[3], Silvia Bellando Randone[3], Lorenza Pratali[1], Gergely Agoston[4], Alberto Moggi Pignone[5], Albert Varga[4], Rosa Sicari[1], Eugenio Picano[1] and Marco Matucci Cerinic[3]. [1]Institute of Clinical Physiology, National Research Council, Pisa, Italy, [2]WSZ, Department of Cardiology, Szczecin, Poland, [3]Department of Biomedicine, Division of Rheumatology AOUC, Excellence Centre for Research, Florence, Italy, [4]University of Szeged, Faculty of Medicine, 2nd Dept of Internal Medicine & Cardiology Center, Szeged, Hungary, [5]University of Florence, Department of Medicine, Division of Rheumatology, Florence, Italy

Background/Purpose: Cardiac dysfunction in systemic sclerosis (SSc) is associated with poor prognosis. Right ventricular involvement is tipically associated to pulmonary hypertension (PH) in these patients. However, primary myocardial involvement, independently of pulmonary hypertension and without significant renal or pulmonary involvement, may also be present. The aim of the present study was to evaluate left and right ventricular function by transthoracic Doppler echocardiography in SSc patients without PH.

Methods: Sixty-five SSc patients without Doppler-derived signs of PH (49 women, mean age, $46+12$ years) and 29 healthy age-matched controls (18 women, mean age $49+15$ years, p=ns) prospectively underwent a comprehensive transthoracic 2D and Doppler echocardiography, including tissue Doppler imaging analysis (TDI) of both right and left ventricle.

Results: SSc patients showed similar left ventricular systolic and diastolic function parameters compared to controls, but significantly worse values in systolic and diastolic right ventricular function (see table below), although still within normal limits.

Echo variables	SSc 65 pts	Controls 29 pts	p
EF (%)	63.0 ± 5.1	65.6 ± 6.4	.07
MAPSE (mm)	15.9 ± 2.5	15.8 ± 3.1	.86
LV S′ TDI (cm/sec)	9.5 ± 1.9	9.0 ± 1.8	.31
LA area (cm^2)	16.6 ± 3.8	16.4 ± 4.6	.93
E/E′	7.8 ± 2.1	7.0 ± 2.1	.12
TAPSE (mm)	22.5 ± 4.3	26.7 ± 4.6	<.0001
RV S′ TDI (cm/sec)	13.5 ± 2.8	15.7 ± 2.0	<.0001
RV E′ TDI (cm/sec)	12.7 ± 3.9	14.7 ± 3.7	<.05
PASP (mmHg)	24.7 ± 5.5	24.8 ± 5.5	.95

Conclusion: In SSc patients without overt cardiac dysfunction and no PH, borderline right ventricular primary involvement can be detected by transthoracic Doppler echocardiography. The clinical implications of these very early alterations are still to be determined.

Ultrasonography of Salivary Glands: Diagnostic and Prognostic Value in Primary Sjögren's Syndrome. Nicoletta Luciano[1], Chiara Baldini[1], Rachele Pascale[2], Francesco Ferro[1], Alessandro Paolicchi[2], Davide Caramella[2] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy

Background/Purpose: To assess the accuracy of ultrasonography of the salivary glands (US) in the diagnosis of primary Sjögren's syndrome (pSS) and to verify whether US abnormalities can be correlated to patients' clinical features, to the histopathological score of minor salivary gland biopsies and to the patients' unstimulated sialometry of whole saliva.

Methods: Consecutive patients with a diagnosis of pSS made according to the AECG criteria were enrolled in the cross sectional prospective study. The control group consisted of subjects with suspected SS who did not fulfill the AECG criteria for pSS. US examination of the parotid and submandibular salivary glands was performed by a real-time US (Esaote Technos MPX) equipped with a 7.5/10 MHz linear transducer. The size, parenchymal echogenicity and fibrosis of major salivary glands were evaluated by the same observer who was not aware of the patients' clinical diagnosis. Parenchymal inhomogeneity was assessed scoring as 0 = completely normal, 1 = slight abnormalities/few hypoechogenic areas, 2 = multiple hypoechogenic areas or 3 = many or confluent hypoechogenic lesions. US abnormalities were compared with patients' clinico-serological data, sialometric findings and minor salivary gland focus score. For statistical comparisons, the t-test, the chi square test and logistic regression analysis were employed. P-values <0.05 were considered significant.

Results: Out of the 122 consecutive patients included in the study, 74/122 (71 F:3M, age 54.7±11.8 yrs) met the AECG criteria for pSS while the other 48/122 (45 F:3M, age 54.8±14.9 yrs) represented the control group. US abnormalities were found in 53/74 pSS patients vs 10/48 control group (p<0.0001); the grading values 2 and 3 resulted more frequent in the pSS group (36/74 vs 2/48; p<0.0001). Overall, the sensitivity of US was 71%, specificity 79% (96%, if we considered only parotid inhomogeneity), positive predictive value 84% and negative predictive value 64%. Parenchymal inhomogeneity of both parotid and submandibular glands correlated with antinuclear antibodies (ANA), anti-Ro/SSA, hypergammaglobulinemia and Rheumatoid Factor positivities. Patients with score 3 had significantly higher ESSDAI score (grade 3 vs 1, p=0.004; grade 3 vs 2, p=0.037) and showed trends towards lower salivary flow in comparison to other subgroups (grade 3 vs 1, p = 0.01; grade 3 vs grade 2, p= ns). When pSS patients where

stratified according to parenchymal inhomogeneity, no difference was found in the presence of focal sialadenitis.

Conclusion: Major salivary glands US may be a specific tool in the diagnosis of pSS. US abnormalities should be investigated particularly in pSS patients with positive serological markers.

Ultrasonographic Evaluation of the Hands of Patients with Primary and Secondary Sjögren's Syndrome. Cristina Hernández-Díaz[1], Luis M. Amezcua-Guerra[2], Angélica Vargas[2], Alberto Lopez-Reyes[3] and Carlos Pineda[1]. [1]Instituto Nacional de Rehabilitación, Mexico City, Mexico, [2]Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico, [3]Instituto Nacional de Rehabilitacion, Mexico City, Mexico

Background/Purpose: Primary Sjögren's syndrome (pSS) is an auto-immune disease characterized by lymphocyte infiltration of various exocrine glands, often associated with joint involvement traditionally described as non-erosive. On the other hand, patients with secondary Sjogren's syndrome (sSS) to rheumatoid arthritis (RA) can show a pattern of arthritis indistinguishable from that observed in patients with RA without SS associated. The description of these differential patterns of disease activity was described by plain X-ray films. The advent of new imaging techniques such as magnetic resonance imaging (MRI) and musculoskeletal ultrasound (MSUS) have changed paradigms of subclinical structural damage in various rheumatic diseases. Objective: To characterize by MSUS the morphologic and structural changes in the joints of the hands of patients with SS.

Methods: Patients with the diagnosis of pSS according to the European-American criteria for the classification of Sjögren's syndrome and sSS patients with associated AR as a control group. A Siemens Acuson Antares ® MSUS equipment was used, using a hockey stick type probe (7–12 MHz) images were obtained from the carpal recess, metacarpal and interphalangeal joints of both hands. The presence of synovitis (synovial hypertrophy or joint effusion), erosions and Doppler signal were intentionally sought. MSUS pathology definitions were used as described by the OMERACT group study.

Results: Seventeen patients with pSS and 18 sSS were evaluated, mean age of 60.2 ± 11.91 years. Time evolution of the disease in pSS group was 3 years and 9 years for sSS. Fourteen patients (82%) of the pSS group were positive for rheumatoid factor compared with one hundred percent of individuals with sSS *(p= ns)*. Anti-Ro/SSA antibody was positive in 59% (10) of patients with the primary presentation of the syndrome, unlike the secondary form which was only found in 2% (11) *(p = 0.004)*. Anti-La/SSB antibody was positive in 6 patients with pSS (35%) compare to 0% (0) from the sSS group *(p = 0,007)*. Anti-cyclic citrullinated protein antibodies were positive in most patients with the secondary form of SS (72%), while only 1 out of 17 patients with pSS were positive (6%) *(p = <0.001)*. None of the patients evaluated in this study were positive for anti-Sm antibody. Synovitis of the radiocarpal and midcarpal recesses were found in 62% (21) of the 34 wrists evaluated in pSS group and 81% (29/36) of sSS,; erosions were found in 3 (9%) wrists of patients with pSS and in 14 (39%) of sSS *(p = 0.004)*. Synovitis was present in several joints (wrists, MCP and PIP) in both groups of patients evaluated (Fig.1), predominantly the 2nd and 4th MCP joints of patients with sSS *(p < 0.05)*.

Conclusion: High resolution MSUS confirms that pSS arthropathy is as inflammatory as sSS associated with RA, however is clearly not as erosive.

Quantitative Assessment of Synovitis in Patients with Rheumatoid Arthritis Using Fluorescence Optical Imaging. Valentin S. Schäfer[1], Wolfgang Hartung[1], Patrick Hoffstetter[1], Jörn Berger[2], Martina Müller[3], Martin Fleck[1] and Boris P. Ehrenstein[1]. [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [2]mivenion GmbH, Berlin, Germany, [3]University Clinic Regensburg, Regensburg

Background/Purpose: To prospectively evaluate quantitative assessment of indocyanine green (ICG)-enhanced fluorescence optical imaging (FOI) for differentiation of synovitic from non-synovitic joints in patients suffering from rheumatoid arthritis (RA).

Methods: FOI of the hands was performed in patients with active RA as

recommended by the manufacturer (Xiralite system, Mivenion GmbH, Berlin, Germany; ICG bolus of 0.1 mg/kg/ body weight, sequence of 360 images, one image per second, stratified fluorescence readout (FLRO) of 3 phases (I: 1 – 120 s; II: 121 – 240 s; III: 241 to 360 s)). To dissect the effect of the overall perfusion of the hand from the perfusion due to active synovitis, a fluorescence ratio (FLRA) was calculated for each individual joint dividing the readout of the joint by the readout of the eponychium of the index finger. For comparison, absence or presence of synovitis in 5 joints of the clinical predominant hand (carpal joint, metacarpophalangeal and proximal interphalangeal joints of digits II & III) were analyzed using grayscale (GSUS) and power Doppler (PDUS) ultrasonography, or magnetic resonance imaging (MRI). The mean FLRO and FLRA were compared between joints with absent vs. present synovitis determined by GSUS, PDUS and MRI using student's t-test.

Results: Ninety joints of 18 patients (8 female (44%), mean (± SD) age 63±10 years) with RA were included. The quantitative analysis for individual joints yielded values for the FLRO ranging from 4.4 to 49.0 × 10³, and the FLRA ranging from 0.37 to 2.27. A comparison of mean (±SD) of FLRO and FLRA is depicted in table 1. Overall, the analyses based on the FLRA revealed a higher discrimination than the analyses related to the FLRO. The most significant differences were observed for mean values of phases II & III. A sensitivity of 26/39 (67%) and a specificity of 31/40 (77%) were calculated for the FLRA of phase III using a cut-off value of more than 1.2 to detect MRI-diagnosed synovitis with FOI.

Table 1. Mean fluorescence readout and fluorescence ratios for joints with vs. without evidence of synovitis determined by established imaging techniques.

Synovitis	n	phase I 1–120 s mean ± SD FOI readout	p	phase II 121–240 s mean ± SD FOI readout	p	phase III 241–360 s mean ± SD FOI readout	p
GSUS yes	39	21.0 ± 11.4	ns	23.5 ± 10.4	<.01	15.8 ± 7.9	<.01
GSUS no	51	17.7 ± 7.5		16.6 ± 6.8		10.5 ± 4.8	
PDUS yes	23	24.1 ± 12.3	<.05	23.8 ± 9.3	<.05	15.0 ± 5.9	ns
PDUS no	67	17.5 ± 7.7		18.2 ± 8.7		12.0 ± 7.0	
MRI yes	39§	20.9 ± 10.1	ns	22.3 ± 9.5	<.05	14.8 ± 7.3	<.05
MRI no	40§	17.8 ± 9.6		17.2 ± 9.2		10.9 ± 6.5	
		FOI ratio		**FOI ratio**		**FOI ratio**	
GSUS yes	39	1.06 ± 0.47	ns	1.33 ± 0.48	<.05	1.37 ± 0.48	<.01
GSUS no	51	0.91 ± 0.32		1.10 ± 0.26		1.12 ± 0.26	
PDUS yes	23	1.22 ± 0.46	<.01	1.52 ± 0.52	<.01	1.53 ± 0.53	<.01
PDUS no	67	0.89 ± 0.33		1.09 ± 0.26		1.12 ± 0.26	
MRI yes	39§	1.11 ± 0.46	<.01	1.38 ± 0.47	<.001	1.41 ± 0.46	<.001
MRI no	40§	0.86 ± 0.33		1.06 ± 0.26		1.08 ± 0.26	

Fluorescence readout results are displayed for better readability divided by 10³, FOI= fluorescence optical imaging, GSUS=grey scale ultrasonography, PDUS=power Doppler ultrasonography, MRI=magnetic resonance imaging; §11 joints could not be evaluated with MRI; ns comparison was not significant (p≥.05) with student's t-test.

Conclusion: ICG enhanced FOI has a potential for visualizing synovitis in subjects with RA. For adequate FOI interpretation, phases II & III appear to be most relevant. Utilizing the presented quantitative approach, significant differences of the mean FLRO and particularly of the FLRA could be demonstrated comparing synovitic to non-synovitic joints in patients with active RA. However, a definitive cut-off value for either analytic method could not be established.

Comparison of Automated, Computer-Based Assessment and Visually Assessed Disease Activity Scores in ICG-Enhanced Fluorescence Optical Imaging in Patients with Rheumatic Disorders: A Feasibility Study. Stephanie G. Werner[1], Michael Schirner[2], Hans-Eckhard Langer[3], Mathias Cziumplik[2], Jörn Berger[2], Marina Backhaus[4] and Malte Bahner[2]. [1]RHIO (Rheumatology, Immunology, Osteology) Duesseldorf, Duesseldorf, Germany, [2]mivenion GmbH, Berlin, Germany, [3]Duesseldorf, Germany, [4]Charite University Hospital, Berlin, Germany

Background/Purpose: Modern diagnostic imaging technologies including US and MRI become increasingly important in the management of rheumatic joint disorders. Semiquantitative scores, like the RAMRIS or the

US7 – score aim at measuring disease activity especially for clinical trials. Most recently, fluorescence optical imaging (FOI) became clinically available for diagnostic imaging. Most recently, it has been shown that automatic, computer-based image analysis of FOI using dedicated software is technically feasible and offers high reproducibility. Measurement of areas of high signal intensity expressed as DACT value may provide a reliable quantitative readout for inflammatory activity. In this feasibility study we compared the results of visual reading of FOI using the semiquantitative scoring system FOIAS (fluorescence optical imaging activity score) for visually assessment with this automatic, computer-based algorithm for quantitative analysis.

Methods: 45 patients (34 f, mean age 55y, mean DAS28 4.2) were selected. First 4 readers analyzed all 45 image data sets individually, and then 2 of the four readers performed a consensus reading. For articular location of increased signal intensities (ISI) the FOIAS was used. For extraarticular location the signals were graded semiquantitatively on a scale of 0 to 2. These values were added to a single number representing the overall fluorescence signal intensity of the hands (cFOIAS, complete FOIAS). For DACT the automatically generated composite images were generated. Using dedicated parameters of the histograms, automatic extraction of the hands from the image background was performed by the computer. The algorithm separated the hands from the forearm in a standardized manner by using a multiple of the length of the middle finger. A threshold in the fluorescence intensity curve was set to discriminate high and low intensity areas. The area of high intensity was calculated and the values of each patient were divided by the 90th percentile of normal individuals which was defined as reference value. DACT was expressed as high signal intensity area $_{patient}$ / healthy reference. DACT in healthy individual equaled 1. Then cFOIAS and DACT value were compared.

Results: Correlation of the cFOIAS and the DACT value was high, while all 4 readers and the consensus readings showed good interreader reliability. Two sample scatter plots are shown in the figure.
Conclusion: Assessment of disease activity in FOI using automated, computer-based algorithms correlated well with visual assessment with a scoring system. While the semiquantitative assessement is time consuming and can be biased by the reader, the automatic calculation may be an objective and fast tool for assessment of disease activity. Following work should concern to proof this and the potential value of DACT for monitoring of treatment response in longitudinal, interventional studies.

Is Bone Scintigraphy Still Useful to Diagnose Rheumatoid Arthritis After the Appearance of 2010 ACR/EULAR Classification Criteria? Ji Young Kim[1], Soo-Kyung Cho[2], Min-Kyung Han[2], Yun Young Choi[1] and Yoon-Kyoung Sung[2]. [1]Hanyang University College of Medicine, Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: For many years, the importance of bone scintigraphy to measure inflammation in the joints of patients with RA has been emphasized. Moreover, increased blood pool activity of involved joints in bone scintigraphy corresponds to inflammatory synovitis which is characteristic feature in early RA. Therefore, bone scintigraphy especially with blood pool phase, might be useful in suggesting early joint involvement in RA. The aim of this study was to investigate the usefulness of bone scintigraphy in the diagnosis of rheumatoid arthritis (RA) with assisting the 2010 ACR/EULAR classification criteria.

Methods: A total of 156 patients who firstly visited the rheumatology department and had taken bone scintigraphy and blood pool image with screening laboratory and radiologic tests to confirm RA diagnosis were retrospectively enrolled. Gold standard RA patients were defined as the patients who started disease modifying anti-rheumatic drugs within 3 months

of their first visit. After dividing patients into two groups according to the presence or absence of arthritis on their first presentation, we evaluated the diagnostic validity of bone scintigraphy as an independent diagnostic tool (BS only) and as an assistant tool for physicians' application of 1987 and 2010 criteria (BS assisted diagnosis) to detect RA. In BS assisted diagnosis, the number, symmetricity, and distribution of involved joints were evaluated with BS results instead of physician's assessment.

Results: Seventy-five (48.1%) of the 156 patients had active arthritis on physical examination (Group I) and the others of 81 patients did not have arthritis at first visit (Group II). Among them, 56 (74.7%) in group I and 5 (6.2%) in group II were RA patients, respectively. For group I patients (n=75), who were eligible to 2010 criteria, the sensitivity of the bone scintigraphy alone was extremely low (42.9%) with elevated specificity (100%), though those of 2010 criteria assessed by only physician (82.1% and 94.7%, respectively). For this group, the sensitivity of BS assisted diagnosis (75.0%) was slightly lower than that of the diagnosis by physician. For group II patients (n=81) who are not eligible for 2010 criteria, only BS or BS assisted diagnosis identified 2 more RA patients among 5 gold standard RA patients who did not satisfy either 1987 or 2010 criteria (Table).

Table. Comparison of the diagnostic validities of the bone scintigraphy (BS) and BS assisted diagnosis

	Subjects	Sensitivity, %	Specificity, %	PPV, %	NPV, %	AUC (95% CI)
Group I. Patients with Arthritis at presentation (who eligible for 2010 criteria, n=75)						
	BS only	42.9	100	100	37.3	-
1987 criteria	Physician only	66.0	99.2	97.4	86.1	0.864 (0.770–0.958)
	Physician with BS	58.9	100	100	45.2	0.911 (0.844–0.977)
2010 criteria	Physician only	82.1	94.7	97.9	64.3	0.923 (0.803–1.0)
	Physician with BS	75.0	94.7	97.7	56.2	0.943 (0.883–1.0)
Group II. Patients without Arthritis at presentation (who are not eligible for 2010 criteria, n=81)						
	BS only	40.0	98.7	66.7	96.2	-
1987 criteria	Physician only	0	100	-	93.8	0.636 (0.362–0.909)
	Physician with BS	20.0	100	100	95.0	0.696 (0.355–1.0)
2010 criteria	Physician only	0	100	-	93.8	0.861 (0–1.0)
	Physician with BS	40.0	100	100	96.2	0.862 (0–1.0)

Conclusion: In usual practice, BS assisted diagnosis is not superior to physician's assessment, especially after appearance of 2010 ACR/EULAR classification criteria. However, bone scintigraphy is still helpful to rule out non RA patients in patients with arthritis and to find out RA patients among patients without arthritis on physical examination.

Subclinical Arthritis Visualised by Positron Emission Tomography and Macrophage Targeting Precedes Clinical Flare in Rheumatoid Arthritis Patients in DAS28 Remission. Y.Y.J. Gent, A.E. Voskuyl, N. Ahmadi, N. Hoetjes and C.J. van der Laken. VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: Macrophages play an important role in the pathophysiology of Rheumatoid Arthritis (RA). Targeting of macrophages by (R)-[^{11}C]PK11195 positron emission tomography (PET) has previously been successfully used for imaging of (subclinical) synovitis in preclinical and established RA patients. It is known that a considerable number of RA patients with minimal disease activity or remission may have subclinical disease activity as well. Therefore, we have performed a prospective pilot study in which (R)-[^{11}C]PK11195 PET was used to visualise subclinical inflammation in hand and/or wrist joints of RA patients that are in DAS28 clinical remission, in relation to magnetic resonance imaging (MRI) at baseline and clinical outcome within 3 years.

Methods: High spatial resolution (R)-[^{11}C]PK11195 PET scans and contrast-enhanced MRI scans of both hands and wrists were performed in twenty-nine RA patients without any signs of arthritis according to a 28-joint count and fulfilling DAS28 clinical remission. PET tracer uptake was scored semiquantitatively according a 0–3 scale and MRI scans were scored for presence of synovitis and bone marrow edema (BME) according to the OMERACT RAMRIS score. Cumulative scores were calculated by adding

up joint scores of all metacarpophalangeal, proximal interphalangeal and wrist joints (range PET 0–66; range MRI 0–222).

Results: *(R)*-[^{11}C]PK11195 PET scans showed evidence of subclinical arthritis in at least one hand and/or wrist joint in 16/29 (55%) of patients. Flare of clinical arthritis was found in 17/29 (59%) of patients within 3 years of clinical follow-up. Patients with cumulative PET scores >6 (n=3) and scores of 4–5 (n=2) developed arthritis in hands/wrists within respectively 26 weeks and 52 weeks. Patients with high cumulative PET scores of >6 also depicted high cumulative MRI scores of >37. In patients without flare of clinical arthritis within 3 years (n=12), PET scores were always low or negative (≤1), but MRI scores varied between 0 and 27.

Conclusion: This prospective pilot study shows that macrophage targeting by *(R)*-[^{11}C]PK11195 PET visualises subclinical synovitis in hand/ wrist joints of RA patients in DAS28 remission. At patient level, high cumulative PET scores may predict a short-term flare of arthritis activity. *(R)*-[^{11}C]PK11195 PET may be of additive value to MRI for detection of subclinical synovitis in DAS28 remission patients, in particular with regard to specificity, but this needs to be confirmed in larger patient cohorts.

132

FDG-PET Evaluation of Axillary Lymph Nodes and Large Joints of Patients with Rheumatoid Arthritis Treated with Anti-TNF Drugs.
Koichi Okamura[1], Yukio Yonemoto[1], Tetsuya Kaneko[1], Kimihiko Takeuchi[2], Tsutomu Kobayashi[1] and Kenji Takagishi[1]. [1]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Isesaki Fukushima Hospital, Isesaki, Gunma, Japan

Background/Purpose: F-18 fluorodeoxyglucose (FDG) positron emission tomography (PET) can be used to image synovial inflammation in patients with rheumatoid arthritis (RA). The development of molecular imaging methods would be beneficial, especially in RA patients. In the present study, we evaluated whether the FDG uptake of the affected joints and the axillary lymph nodes (AxLN) represented by the standardized uptake value (SUV) correlated with the clinical assessment of patients with RA. In addition, we evaluated if there was a correlation between the differences in the SUV and the improvement of the clinical findings in RA patients receiving anti-TNF therapies.

Methods: Forty-two patients (10 male, 32 female; average age: 55.67 (18–74) years) who underwent anti-TNF therapies (infliximab (IFX) for 17 patients, etanercept (ETN) for 14 patients and adalimumab (ADA) for 11 patients), were enrolled in this study. The average disease duration of these patients was 11.7 (0.6–49) years. Clinical disease activity was assessed by using disease activity scoring (DAS) 28, DAS28-CRP, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI) and numbers of 28 tender and swollen joints count (TJC, SJC) and measuring erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), serum matrix metalloproteinase-3 (MMP-3) and rheumatoid factor (RF) at baseline (0M) and after 6 month (6M) of the therapies. FDG-PET/CT was performed 0M and 6M. The PET images were interpreted by two experienced nuclear physicians and increased FDG uptake in bilateral shoulder, elbow, wrist, hip, knee, and ankle joints and bilateral AxLN were recorded. Therapeutic response was evaluated by the changes in the sum of the maximal SUV (total SUVmax) of all 12 measured joints and the clinical findings.

Results: Before treatment, the total SUVmax was correlated with the DAS28 (r=0.532,p=0.001), DAS28-CRP (r=0.529,p<0.001), SDAI (r=0.491, p=0.001), CDAI (r=0.457, p=0.002), ESR (r=0.506, p=0.001), CRP (r=0.385, p=0.012), TJC (r=0.416, p=0.007) and SJC (r=0.467, p=0.002), respectively. The SUVs of AxLN were correlated with the SUV of the ipsilateral wrist joints. The ΔSUV, the difference in the total SUVmax before and after treatment, significantly correlated with the ΔDAS28 (r=0.498, p=0.001), ΔDAS28-CRP (r=0.517, p<0.001), ΔSDAI (r=0.550, r<0.001), ΔCDAI (r=0.534, p<0.001), ΔESR (r=0.485, p=0.001), ΔCRP (r=0.437, p=0.003), ΔTJC (r=0.447, p=0.003) and ΔSJC (r=0.525, p<0.001), respectively. ΔSUV of AxLN did not correlate with ΔCRP, ΔESR and ΔMMP-3, however, correlated with the Δ SUV of the same or other side of the wrist joint.

Conclusion: FDG-PET can image the extent of inflammation in patients with RA. In addition, the FDG uptake of the axillary lymph nodes might reflect the disease activity especially in the wrist joints. FDG-PET can be used to evaluate the response of RA patients to biological treatment.

Utility of PET-CT Imaging in IgG4-Related Disease.
Arezou Khosroshahi, Leslie Lee, Mollie Carruthers, Rusen Acu, Pietro Bonaffini, Vikram Deshpande, Dushyant Sahani and John H. Stone. Massachusetts General Hospital, Boston, MA

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibro-inflammatory condition characterized by unique pathological features that affect a wide variety of organs. The disease process may be active long before patients present with symptoms from the mass effect of the IgG4-related lesions or the organ damage. Morphologic and functional imaging studies are increasingly used in the diagnosis and monitoring of response to therapy in inflammatory diseases. Positron-emission tomography/computed tomography (PET/CT) enables the acquisition of whole-body images and provides functional information about disease activity. The purpose of our study was to describe the PET/CT findings in patients with histologically-proven IgG4-RD and to evaluate their correlation with disease activity.

Materials/Methods: We searched the IgG4-RD Registry at Massachusetts General Hospital. Between March 2007 and May 2012, 20 patients (7 female and 13 male; median age 57 years, range 27–81), underwent whole body ^{18}F-fluoro-2-deoxy-D-glucose positron-emission tomography/computed tomography (FDG PET-CT) imaging. All 20 patients had diagnoses of IgG4-RD based on the characteristic histology and immunostaining findings for this condition. We compared the sites of disease activity identified by PET/CT to the sites identified by their clinicians through symptoms, signs, laboratory findings, and other imaging studies.

Results: Patients presented with various symptoms including: flank/back pain (7 patients), face swelling (3), neck swelling (3), proptosis (2), cough (2), weight loss (2), sinus congestion (2), and dry mouth/eyes (1). Thirteen of 20 patients (65%) had multi-organ disease at presentation, affecting some combination of the pancreas, bile ducts, liver, gallbladder, lung, salivary glands, orbitals, aorta, thyroid, kidney, retroperitoneum, and lymph nodes. The mean number of organs involved among patients with multi-organ disease was 4.1 (ranging 2–7 organs). Seven patients (35%) had localized disease at presentation (5 RPF, 1 lymphadenitis, 1 orbital pseudotumor).

The serum IgG4 was elevated in 8 patients at the time of PET-CT imaging (mean 635.6 mg/dL). FDG PET was positive in all 20 patients (mild to intense uptake in 19 and low in 1 subject). In 17/20 patients (85%), FDG uptake was concordant with clinical manifestations of active inflammation. In addition 7/20 patients (35%) had FDG uptake in organs not suspected of involvement on a clinical basis alone (RPF, lymph nodes, thoracic aorta, lung, lacrimal glands and nasopharynx).

Conclusion: In IgG4-RD, FDG PET-CT is a sensitive imaging tool for the detection of subclinical disease. This modality can demonstrate additional sites of disease not obvious by clinical presentation or on conventional CT imaging, therefore providing a more complete assessment of the extent of organ disease. It's utility as a tool for monitoring treatment response and guiding therapy requires prospective studies.

Co-Existence of Gout in Rheumatoid Arthritis: It Does Happen! A Population Based Study.
Adlene Jebakumar, Cynthia S. Crowson, P. Deepak Udayakumar and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Even though there are a few cases in the literature reporting co-existence of gout and rheumatoid arthritis (RA), it has been a long time popular belief that gout does not occur in patients with RA. We aimed to assess the occurrence, clinical presentation, and possible risk factors for gout in patients with RA.

Methods: We retrospectively reviewed a population-based incidence cohort of patients who fulfilled 1987 ACR criteria for RA in 1980–2007. All subjects were longitudinally followed through their complete community medical records until death, migration, or April 2012. Gout was defined using the physician diagnosis, along with typical monosodium urate crystal positivity in synovial fluid or the 1977 ARA clinical criteria for gout. We

excluded the patients with pseudogout, hyperuricemia without gout, septic arthritis, traumatic arthritis, and RA initially misdiagnosed as having gout. Cumulative incidence of gout in RA adjusted for the competing risk of death was estimated. Cox models were used to assess risk factors for gout in RA.

Results: The study population included 813 patients, 537 (66%) were rheumatoid factor positive; 33% had rheumatoid nodules, and 53% had erosive joint disease. During 9771 total person-years of follow-up (mean 12.0 years per RA patient), 22 patients developed gout by clinical criteria. The great toe was the most common site of gout (12 of 22 patients). The 25 year cumulative incidence of gout diagnosed by clinical criteria was 5.3%. Typical intracellular monosodium urate crystals were present in 9 of 22 patients with acute gout; all had developed gout after the RA incidence date. The 25 year cumulative incidence of gout diagnosed by clinical criteria including presence of urate crystals is 1.3%. The prevalence of gout in RA on Jan 1, 2008 was 1.9% (11 of 582 patients) as opposed to expected prevalence of 5.2% (or 30 patients) based on National Health and Nutrition Examination Survey (NHANES) data using age and sex specific prevalence rates.

Risk factors for gout in RA were: older age (hazard ratio [HR] 1.5 per 10 year increase; p = 0.04), male sex (HR 3.18; p = 0.03) and obesity (HR 3.5; p = 0.03). The presence of erosive RA joint disease reduced the risk of gout (HR 0.24; p = 0.03). Gout has become more common in patients diagnosed with RA in recent years (1995–2007) than in previous years (1980–1994; HR 5.6; p = 0.007).

Conclusion: Gout does occur in patients with RA though at a lower rate than in the general population, with a minimum/maximum cumulative incidence of 1.3/5.3%. Risk factors for gout in RA generally mirror those in the general population.

135

A Pilot Study of the Efficacy of IL1 Blockade by Anakinra in Acute Calcific Periarthritis of the Rotator Cuff. Pascal Zufferey, Melanie Faucherre, Pierre A. Varisco, Berengere Aubry Sr., Isabelle Fabreguet and Alexander K. So Sr.. CHUV, Lausanne, Switzerland

Background/Purpose: Calcific periarthritis of rotator cuff can induce acute and severe shoulder pain and is accompnied by signs of acute inflammation. The calcific deposits are composed of calcium phosphate crystals such as hydroxyapatite or basic calcium phosphate. These crystals stimulate the production and release of IL1b from macrophages, in an analogous manner to MSU and CPPD crystals. As IL1 blockade is effective in reducing signs and symptoms of inflammation in acute gout, we performed a pilot study to study if it is also effective in calcific periarthritis

Methods: 5 consecutive patients were included (mean age: 62, 3 females, 2 males) between March 2011 and March 2012. Symptoms of acute shoulder pain at rest had to be present for <7 days before inclusion, associated with limitation of shoulder mobility and the presence on calcification in the rotator cuff by conventional radiography. None of the patients had responded to at least 48 hours of high doses of NSAIDs. Exclusion criteria included no corticosteroid therapy in the last 2 weeks and the exclusion of other rheumatologic or infectious diseases-.Clinical evaluation consisted of patient assessment of pain (total, rest and activity) by VAS (100mm scale) at days 0, 1, 3, 15, 42 and clinical examination of shoulder mobility at days 0, 3, 15. ESR and CRP were measured at days 0, 3. Plain radiographs were performed at days 0 and 15 and an ultrasound examination (including Doppler) was performed at days 0, 3, 15. Anakinra 100mg daily was administered for 3 consecutive days after the first evaluation (day 0). Rescue analgesics were allowed and recorded.

Results: At inclusion, all patients had severe shoulder pain: mean (SD) VAS day pain of 72mm (±25mm), mean VAS night pain of 96 (± 5) and impaired shoulder mobility. CRP was elevated in all of them (mean of 3X). Treatment with anakinra lead to rapid relief of pain in all patients, starting already on the first night following the first injection. The reduction of VAS pain was particularly striking for rest pain: mean (SD) VAS of 4mm (± 5) at day 1 and this response was maintained for the 5 patients at the end of the three injections without any need of rescue medication. Mean rest VAS was 6 (±8) at day 3. The effect on day pain was less spectacular: mean (SD) VAS at D1 of 30 (± 18), at D3 of 27 (± 11). Shoulder mobility also improved and the CRP normalized in 4 of 5 patients at day 3. At day 42, 4 of 5 the patients were still totally asymptomatic. On X rays and US, the calcifications were reduced in size: mean maximal diameter of 21 mm at day 0 to 12 mm at day 15, but did not disappear in any patient. The main change

on US was a significant and rapid (at day 3) reduction of Doppler activity around the calcification.

Conclusion: This pilot open study suggests that IL-1β inhibition may be an interesting therapeutic approach in acute calcific periarthritis, especially in patients who have not responded adequately to NSAIDs. The effect on pain seems to be more rapid (within a few hours) than steroid injection although a randomized controlled study needs to be performed to confirm this observation.

136

A Delphi Exercise to Identify Characteristic Features of Gout—a Study of Opinions From Patients and Physicians to Inform New Classification Criteria. Rebecca Prowse[1], Nicola Dalbeth[2], H. R. Schumacher[3], Tuhina Neogi[4], Tim L. Jansen[5], Jaap Fransen[6] and William Taylor[1]. [1]University of Otago, Wellington, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA, [4]Boston Univ School of Medicine, Boston, MA, [5]St Radboud University Nijmegen Medical Centre, Netherlands, [6]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Updated classification criteria for gout are required. The aim of this study was to identify a comprehensive list of features that might discriminate between gout and similar conditions, for use in a subsequent case-control study for developing and testing new classification criteria.

Methods: Two Delphi exercises were conducted using web-based questionnaires; one with physicians who have an interest in gout and one with patients who have gout. Physicians rated a list of potentially discriminating features that were identified via literature review and expert opinion and patients rated a list of features that they generated themselves. Agreement was defined by the RAND/UCLA disagreement index. Multiple iterations were conducted until consensus was reached or no changes in participant ratings were observed.

Results: Forty-four highly experienced physicians (62% response rate) and nine patients (11% response rate) responded to all iterations. For physicians, 71 items were identified by literature review and 15 more were suggested by physicians. The physician survey showed agreement for 26 discriminatory features and 15 that were not discriminatory. The patients identified 46 features of gout for which there was agreement on 25 items as being discriminatory and seven items being not discriminatory. The results of highly rated features for both physician and patient surveys are summarised in the Table (showing areas of agreement and disagreement). Patients and physicians agreed upon several key features of gout: suddenness of onset, redness, marked tenderness and swelling of the affected joint, elevated serum urate levels, presence of tophi, presence of urate crystals in synovial fluid and involvement of the first metatarsophalangeal joint. Physicians emphasized imaging and patterns of symptoms, whereas patients emphasized functional impact, dietary triggers and idiographic perception of symptoms.

Table. The overlap and differences between features highly rated (median 7 to 9) by physicians and patients. US: ultrasonography, CT: computed tomography, DECT: dual energy CT, MRI: magnetic resonance imaging

Highly rated by physicians	Highly rated by physicians and patients	Highly rated by patients
Typical X-ray erosion	Hyperuricaemia	Difficulty walking
Snowstorm joint effusion appearance on US	MSU crystals in joint/tissue aspirate	Can't use affected joint
Tophi on US, DECT, CT or MRI	Tophi	Interrupts sleep
Double-contour sign on US	Podagra ever	Medication helps
Monoarthritic attacks in first few years, becoming oligo-, then polyarthritic over time	Abrupt and severe pain	Throbbing/severe, sharp annoying pain
Podagra at first attack	Redness around the affected joint	Gout attack often occurs after eating seafood/shellfish/alcohol
Complete resolution of attacks	Marked joint tenderness	The affected joint is hot or burning
Resolution of an attack within 7-14 days	Monoarticular joint involvement	The affected joint enlarged/swollen
Mid-foot joint involvement		If you injure an area that has been affected by gout, it takes longer to heal than one that has not been affected by gout
Uric acid nephrolithiasis		Only one foot is usually affected at a time
		The pain is less present even when the affected joint is not being moved/used

Conclusion: Physicians' and patients' perceptions of the key features of gout have some similarities but many differences. The list of features with a

median rating of 7 to 9, generated by both patients and physicians, will be examined in a case-control study to identify the most sensitive and specific combination for the classification of crystal-proven gout.

137

Monosodium Urate Crystals Inhibit Tenocyte Viability and Function: Implications for Periarticular Involvement in Chronic Gout. Ashika Chhana[1], Karen E. Callon[1], Bregina Pool[1], Dorit Naot[1], Gregory Gamble[1], Brendan Coleman[2], Fiona M. McQueen[1], Jillian Cornish[1] and Nicola Dalbeth[1]. [1]University of Auckland, Auckland, New Zealand, [2]Middlemore Hospital, Auckland, New Zealand

Background/Purpose: Recent advanced imaging studies have demonstrated that urate deposition in periarticular structures is common in gout. Urate deposition has been observed both adjacent to and within tendons, suggesting that monosodium urate monohydrate (MSU) crystals are likely to be in direct contact with tenocytes, the stromal cells of tendons. The aim of this study was to determine the effects of MSU crystals on tenocyte viability and function.

Methods: Cultures of primary rat tenocytes were prepared from Wistar rat tails. Primary human tenocytes were prepared from patients undergoing orthopedic surgery. MTT assays were used to assess tenocyte viability following culture with MSU crystals. Cells cultured with MSU crystals for various times were stained with Annexin V and propidium iodide, and flow cytometry was used to determine changes in the levels of apoptosis. Real-time PCR was used to determine changes in gene expression and Sirius red staining to detect changes in collagen deposition in tenocytes cultured with MSU crystals.

Results: MSU crystals reduced viability in a dose-dependent manner in both primary rat and human tenocytes (Figure). Differing MSU crystal lengths and increased serum levels in cultures did not alter this effect. The reduction in tenocyte viability was specific to MSU crystals, as soluble uric acid did not reduce cell viability. Flow cytometry showed that MSU crystals rapidly induced cell death, but apoptosis levels remained unchanged. Culture with MSU crystals reduced mRNA expression of collagen types 1 and 3; and tenocytic markers, including tenomodulin, scleraxis and tenascin-C. Collagen deposition was inhibited in tenocytes cultured with MSU crystals in a dose dependent manner.
Figure. Effects of MSU crystals on primary rat and human tenocyte viability. Cell viability was assessed using the MTT assay following 24 hours of culture with MSU crystals. Data shown are mean (SEM); one-way ANOVA (P<0.0001) with *post hoc* Dunnett's test *p<0.0001 versus control (no MSU crystals).

Conclusion: These data indicate that MSU crystals directly interact with tenocytes to reduce cell viability and function. These interactions may contribute to tendon damage in patients with chronic gout.

138

Evaluating Appropriate Use of Prophylactic Colchicine and Urate Lowering Therapy in Gout. Michael George[1], Sally W. Pullman-Mooar[2] and H. Ralph Schumacher[3]. [1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania and Philadelphia Veterans Hospital, Philadelphia, PA, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA

Background/Purpose: Colchicine is recommended to prevent gout flares in patients initiating and increasing uric acid lowering therapy until serum uric acid is ≤ 6 mg/dL. Many patients, however, are prescribed colchicine without adequate urate lowering therapy or remain on colchicine after uric acid targets have been met. The recent dramatic increase in colchicine cost in the United States has made it even more important to examine current prescribing practices, identify variables that influence these practices, and promote appropriate colchicine use.

Methods: Pharmacy identified 193 patients at a VA medical center with active outpatient colchicine prescriptions on 11/4/2011. Electronic medical record review revealed 126 patients prescribed colchicine for ≥ 30 days for prophylaxis of gout flares. Colchicine prescribing was defined as inappropriate if 1) no concurrent urate lowering therapy was prescribed, 2) uric acid was not at goal and urate lowering therapy had not been initiated or increased in the past 3 months, or 3) uric acid goals were met for > 1 year and flares had resolved in the absence of tophi. Demographic and clinical variables in appropriate and inappropriate groups were compared.

Results: Of 126 patients prescribed prophylactic colchicine, 34 (27.0%) were prescribed no urate lowering therapy, 50 (39.7%) were not at uric acid goal and had not had urate lowering therapy increased in the prior 3 months, and 9 (7.1%) were at uric acid goal for more than one year with no flares or tophi. Colchicine use was considered appropriate in 33 patients (26.2%) – 20 (15.9%) with urate lowering therapy initiated or increased in the past 3 months, 12 (9.5%) at uric acid target for < 1 year, and 1 (0.8%) at uric acid target for > 1 year but with continued flares. Patients appropriately prescribed colchicine were younger, had shorter time on colchicine, and were more likely to have been seen by Rheumatology as opposed to being managed solely by primary care. Allopurinol dose and allergy, uric acid level, and renal function were similar in the two groups (see table).

Comparison of Patients Appropriately and Inappropriately Prescribed Prophylactic Colchicine

	Appropriate (N=33)	Inappropriate (N=93)	P Value
Age, yrs	65 [33–89]	70 [37–89]	0.01
Male, no. (%)	33 (100.0)	92 (98.9)	1.0
Colchicine daily dose, mg	0.6 [0.3–1.2]	0.6 [0.3–1.2]	0.57
Time on colchicine, yrs	1.12 [0.07–17.4]	3.26 [0.05–14.1]	0.0002
Allopurinol dose, mg	200 [100–400]	200 [100–400]	0.34
Allopurinol allergy, no. (%)	1 (3.0)	7 (7.5)	0.36
Crystal confirmed, no. (%)	33 (42.4)	37 (39.8)	0.79
Uric acid level, mg/dL	6.7 [4.2–14.2]	7.4 [3.6–13.2]	0.36

GFR, mL/min/1.73m^2	64 [37–126]	67 [27–144]	0.87
Rheumatology visit ≤ 1 yr, no. (%)	19 (57.6)	20 (21.5)	<0.0001
Rheumatology visit ever, no. (%)	25 (75.8)	51 (54.8)	0.04

Skewed data expressed as median [range]. Percentages may not add up to 100 because of rounding.

Conclusion: Our results demonstrate a high incidence of what we considered inappropriate prophylactic colchicine use, driven largely by failure to prescribe concurrent urate lowering therapy or adequately increase these medications. Rheumatology consultation was associated with improved colchicine prescribing. Increased education of primary care physicians about current standards of care is needed to avoid unnecessary colchicine exposure and excessive health care system costs.

139

Lack of Effect of Supplemental Vitamin C On Serum Urate in Patients with Gout. Lisa K. Stamp[1], Christopher Frampton[1], John L. O'Donnell[2], Jill Drake[3] and Peter T. Chapman[3]. [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]Canterbury Health Laboratories, Christchurch, New Zealand, [3]Christchurch Hospital, Christchurch, New Zealand

Background/Purpose: The key to effective long-term management of gout is sustained reduction of serum urate (SU) <0.36mmol/L. It has been suggested that supplemental vitamin C reduces SU in healthy controls via its uricosuric effect. However, it is unclear whether the reduction in SU is of a similar magnitude in patients with gout (who have reduced urate excretion) or whether co-administration of allopurinol lessens the magnitude of SU reduction from vitamin C. The aims of this study were to determine effects of modest dose supplemental vitamin C on SU in patients with gout both as monotherapy and in combination with allopurinol.

Methods: Patients with gout and a SU >0.36mmol/L were recruited. 20

patients already receiving allopurinol were randomised to either increase the dose of allopurinol or commence vitamin C 500mg/d. 20 patients not receiving urate lowering therapy were randomised to either start allopurinol or vitamin C 500mg/d. Plasma ascorbate, creatinine, SU, urine urate and creatinine were measured at days 0 and week 8.

Results: 18/20 patients who received Vitamin C were male with a mean age of 61.2 years (39–86). 18/20 patients who did not receive vitamin C were male with mean age of 55.0 years (27–78). There was no significant difference in baseline SU or eGFR between those who received vitamin C and those who did not (SU 0.50 ±0.11mmol/l vs. 0.50 ± 0.09mmol/l p=0.89; eGFR 65.5 ± 15.7 vs. 67.9 ± 20.7 p=0.67). 30% in the vitamin C group were receiving diuretics compared to 25% in the no vitamin C group (p=0.72).

In the 20 patients receiving supplemental vitamin C there was a significant increase between week 0 and week 8 in plasma ascorbate (34.2μmol/l; p<0.001). There was no significant change in plasma ascorbate in those who did not receive vitamin C. The reduction in SU was significantly less in those 20 patients receiving vitamin C compared to those who started or increased the dose of allopurinol (0.014mmol/l vs. 0.118mmol/l p<0.001) (Figure). Allowing for eGFR did not affect these results.

Since Vitamin C is uricosuric we assessed change in urinary urate excretion using the Simkin index. In those patients already receiving allopurinol, addition of Vitamin C or an increase in allopurinol dose had no effect. In contrast, in those patients starting allopurinol there was a significant reduction in the Simkin index compared to those starting vitamin C (−0.13 vs. 0.002 p<0.011).
Figure. Effect of vitamin C and allopurinol on serum urate.

Conclusion: In this study supplemental vitamin C at modest dose (500mg/d) for 8 weeks had no significant urate lowering effect in patients with gout despite increasing plasma ascorbate concentrations. These results differ from findings in hyperuricaemic healthy controls. The uricosuric effect of modest dose vitamin C appears less in patients with gout both as monotherapy and in combination with allopurinol. Whether larger doses will be effective remains to be determined.

Patients That Continue to Flare Despite Apparent Optimal Urate Lowering Therapy. Dinesh Khanna[1], Puja Khanna[1], David Hagerty[2], Chris Storgard[2], Robert Mischler[2] and Robert Morlock[2]. [1]University of Michigan, Ann Arbor, MI, [2]Ardea Bioscience, San Diego, CA

Background/Purpose: Gout is a common inflammatory arthritis and its worldwide prevalence is increasing. The purpose of this study is to describe physician, patient and treatment characteristics in those patients who are considered "controlled" by their physician with xanthine oxidase (XO) inhibitor therapy, despite having 2 or more flares per year and assess sUA levels by XO inhibitor and XO inhibitor dose.

Methods: Data were assessed from a survey of US physicians about gout disease management. Patient results were confirmed through in-depth chart audits assessing diagnosis, comorbid conditions, and laboratory assessments. Disease severity was measured using a physician global assessment (mild, moderate or severe), flare counts, joint damage and presence of tophi. Type and dose of XO inhibitor, length of current treatment, physician type and patient socio-demographics factors were identified. XO inhibitor control was defined using a 10-point physician assigned score with higher scores indicating more control ("Do you consider this patient to be well controlled on their current urate lowering therapy (ULT) therapy, where control means there is no desire to increase the dose to achieve better control?"). Patients with a

score of >=7/10 were classified as "controlled". Multivariate and descriptive statistics were used to describe patients having more than 2 flares per year (excluding treatment initiation flares) where physicians reported "no desire to increase dose" of the current ULT.

Results: Physicians interviewed included 125 rheumatologists and 124 primary care physicians. Of the 1245 patients with gout, 81% were male and the average age was 57 (sd=13). 858 (69%) patients were treated with a XO inhibitor of which 278 (32%) patients classified as controlled but experienced 2 or more flares in the last year. 101 (36%) achieved sUA <= 6mg/dL. Patients defined as controlled and reporting 2 or more flares a year were more likely to have tophi (30% vs. 18%; p<0.01) compared to patients classified as controlled and having 1 or less flares a year. Likewise patients defined as controlled and reporting 2 or more flares a year had higher sUA (7.0 vs. 6.4 mg/dL; p<.01), whereas patients classified as uncontrolled had an average sUA > 8.0mg/dL across XO inhibitors and there was no difference by dose. A backward stepwise multivariate model predicting patients classified as controlled and continuing to flare (2+ flares in the last year) found chart documented co-existing kidney disease (OR 2.4; p<0.01), alcoholism (OR 2.4; p<0.01) and depression (OR 1.8; p<0.05) to be associated with higher flares. Additionally, treatment with anti-hyperglycemic agents (OR 1.6; p<0.05) and physician identified tophi (OR 1.6; p<0.05) also predicted perceived control in patients with 2 or more flares in the last year.

Conclusion: Only 26% of the 621 patients receiving allopurinol were flare free in the 12-month period. Less than 50% of patients obtain sUA < 6mg/dL regardless of treatment. Despite patients being considered controlled, 38% continued to have > 2 flares per year. These patients are more likely to have kidney disease and other comorbid conditions. Current treatment options for these patients may not be sufficient to adequately control gout flares.

Effectiveness of Prophylaxis with Anti-Gout Medications On Risk of Gout Attacks. Tuhina Neogi[1], Clara Chen[2], Jingbo Niu[1], Christine E. Chaisson[2], David J. Hunter[3], Hyon K. Choi[1] and Yuqing Zhang[4]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University School of Public Health, Boston, MA, [3]University of Sydney, Sydney, Australia, [4]Boston University, Boston, MA

Background/Purpose: While a few studies have examined colchicine's ability to prevent gout attacks, NSAIDs have not been formally studied in this regard, despite use of naproxen and its apparent efficacy in the febuxostat trials. Little data are available on effectiveness of prophylaxis with anti-gout medications on risk of gout attacks as used in the community. Further, dosing and choice of NSAID type for prophylactic purposes may vary widely in the community. We evaluated the association of colchicine and NSAID use with risk of recurrent gout attacks in an internet-based cohort of persons with gout.

Methods: We conducted an internet-based case-crossover study (each person acts as his/her own control, eliminating the effect of time-invariant confounders) to assess risk factors for gout attacks among persons with pre-existing gout. Subjects with gout who had ≥1 attack in the prior year were recruited online from across the US, with their gout diagnosis verified through medical records review. Participants logged onto the study website when they had a gout attack and provided exposure information (including medication use) over the 14-day period prior to the gout attack (case-period) using an online questionnaire. The same questionnaire was collected for a 14-d period during an intercritical period (control-period). Medication use between 3–14 days was not collected in an earlier study period ('03-'07) and was imputed assuming the data was missing at random. We examined the relation of colchicine and NSAID use, respectively, over specific time spans (prior 1–2 days, 1–7 days, and 1–14 days) to the risk of gout attacks using conditional logistic regression.

Results: Of the 724 participants (from 49 US states and D.C.) who experienced ≥1 gout attack during the study period, 78.5% were male, 89% were White, and 58% had a college education. 38.4% were on some form of ULT on study entry (majority on allopurinol 300mg/d). Colchicine was taken primarily as 0.6mg/d and the most common NSAID used was ibuprofen. Colchicine protected against gout attacks when taken consistently over a 14 day period, but not over shorter periods (Table). The increased risk of gout attacks when colchicine was used only in the prior 2 days (i.e., without having taken it in the prior 3–14 days) likely indicates its use in anticipation of an

impending gout attack (confounding by indication). However, very few only took colchicine in the prior 1 or 2 days only, limiting its interpretability. NSAID use did not appear to protect against gout attacks, regardless of consistent use (Table).

Table. Effect of consistent use of anti-gout prophylactic medication over a 2-week period

Time-Period over which medication was taken**	Adjusted* ORs (95% CI)	
	Colchicine	NSAIDs
Taken daily in prior 14 days	0.46 (0.30–0.69)	1.05 (0.75–1.46)
Taken daily in prior 7 days only	0.62 (0.17–2.24)	1.17 (0.53–2.58)
Taken in prior 1 or 2 days only	2.16 (1.28–3.65)†	1.11 (0.84–1.46)
Not taken at all in prior 14 days	1.0 (ref)	1.0 (ref)

*adjusted for diuretic and aspirin use, purine, alcohol, water and caffeine intake, use of the other prophylactic medication (NSAIDs or colchicine, as appropriate) and urate-lowering medications; Results were similar when limited to those who met ACR criteria for gout.
** Note: the majority of persons who used these medications in the prior 1-2 days also used the medication daily in the prior 3-14 days
†These results may reflect confounding by indication – those who are taking these medications only recently (i.e., without longer-term use) may be doing so because of concern regarding risk of impending gout attack, or because they only recently started ULT; very few took the medication only in the prior 1 or 2 days only.

Conclusion: Colchicine was effective in protecting against gout attacks when taken consistently; intermittent or short-term use did not confer protection. We cannot exclude the possibility that particular formulations and/or doses of NSAIDs are effective; nonetheless, as used in the community, NSAIDs were not associated with lower risk of gout attacks.

Efficacy of Canakinumab Versus Triamcinolone Acetonide According to Multiple Gouty Arthritis-Related Health Outcomes Measures. Ari Gnanasakthy[1], Andrew Sarkin[2], Rachel Lale[2], Kyle Choi[2] and Jan D. Hirsch[3]. [1]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [2]Health Services Research Center, University of California, San Diego, CA, [3]Skaggs School of Pharmacy & Pharmaceutical Sciences, University of California, San Diego, CA

Background/Purpose: Canakinumab (CAN), a selective, fully human, anti-IL-1β monoclonal antibody, may be a potential therapeutic option for treating acute gout attacks and delaying new attacks in these patients (pts). Efficacy and safety of canakinumab was previously demonstrated in two 12-week, multicenter, double-blind, double dummy, active controlled trials (β-RELIEVED [N=228]; β-RELIEVED II [N=226]).[1] Health-related quality of life was also measured in these studies, but not all patients completed each questionnaire. Therefore, a composite health outcomes response endpoint was developed to better interpret each patient's overall response to treatment.

Methods: This analysis used pooled data from the β-RELIEVED program, which included pts meeting ACR 1977 preliminary criteria for acute GA and contraindicated, intolerant or unresponsive to NSAIDs and/or colchicine.[1] A composite response endpoint representing overall change in gout-related health outcomes, from baseline to 12 weeks, included clinical markers (serum urate and flare activity); patient-reported data from the Gout Impact Scale (GIS) of the Gout Assessment Questionnaire[2] 2.0 (comprising 6 items related to pain and quality of life); and the SF-36 (Table). Variables represented outcome domains comprising a composite response to GA treatment as recommended by expert rheumatologists.[3] Patients were categorized as responders for each variable if they had greater than a minimally important change (per published literature) from baseline. Variable values [1 (responder) or 0 (nonresponder)] were added to create a composite responder endpoint for each patient (Cronbach's α = 0.76).

Results: For 8 out of 12 variables measured, the percentage of CAN responders was significantly greater than that for TA (Table, $P<0.05$). Mean composite response scores were significantly higher for CAN pts vs TA pts (mean [SD]; 4.7 [2.7] vs 3.7 [2.4], $P<0.001$). Overall, pts receiving CAN also met a higher percentage of response criteria (65%) than pts given TA (49%), $P<0.001$. Treatment differences remained even after serially removing individual responder variables and domains from the composite endpoint, indicating that the differences between CAN and TA were robust.

Table 1. Responders (%) for Gouty Arthritis-Related Health Outcomes Measures at 12 weeks

Outcome Domain	Variable	Responder Definition	CAN		TA	
			n	%	n	%
Urate	Serum urate	>25% reduction[3]	199	6.5	204	8.8
Flare frequency	Flare past 4 weeks	No	115	90.2***	113	68.1
	New flare during trial	No	225	71.6***	229	51.1
	Use of rescue medications	No	225	58.7***	229	38.4
Pain	Gout pain severity past 4 weeks (GIS, 1-10 scale)	>2 point reduction[4]	113	85*	116	74.3
	Bodily pain (SF-36, 0-100 scale)	>10 point reduction[5]	192	66.1	181	58.6
Patient global response	How well doing past 4 weeks (GIS, 1-10 scale)	>2 point reduction[4]	113	69.0	113	58.8
	Global treatment response	Acceptable, good or excellent	211	94.3**	213	85.4
	GIS Global Scale (GIS, 0-100)	>8 points[4]	114	81.4*	115	70.2
Health related quality of life (Disease specific) (GIS, very poor – excellent)	Gout related quality of life	>1 point improvement[4]	65	41.5**	85	18.8
	Gout related physical health	>1 point improvement[4]	62	30.6**	77	10.4
	Gout related mental health	>1 point improvement[4]	61	31.1	82	19.5
OVERALL	Average percentage responder criteria met	-		65.0%***		49.0%

* $P<0.05$; ** $P<0.01$; *** $P<0.001$.

Conclusion: These results demonstrate superior efficacy, across multiple health-outcomes variables comprising clinical markers and patient reported outcomes, of CAN versus TA over 12 weeks in patients contraindicated, intolerant or unresponsive to NSAIDS and/or colchicine.

Proposed Gout Treatment Guidelines and Meeting Serum Urate and Flare Goals. Jasvinder A. Singh[1], David Hagerty[2], Chris Storgard[2], Robert Mischler[2] and Robert Morlock[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Ardea Bioscience, San Diego, CA

Background/Purpose: Although gout is a relatively common condition, treatment is often not ideal with many patients continuing to experience multiple flares and some developing complications associated with the disease. To improve patient care the American College of Rheumatology (ACR) recently proposed a draft set of recommendations for treating patients with gout. The purpose of this study is to assess the percentage of patients that meet the recently proposed treatment guidelines and the impact of following guideline recommendations on reaching serum uric acid (sUA) and flare targets.

Methods: Data were assessed from a quantitative survey of US physicians about gout disease management. Laboratory and clinical data were confirmed through chart audits using a structured case report form. The sample was restricted to patients treated with allopurinol or febuxostat. Xanthine oxidase (XO) inhibitor and initial dose, use of prophylactic medication, sUA level, physician type (rheumatologist vs. primary care physician [PCP]), patient socio-demographics factors, and flare rates (treatment and non-treatment related) were recorded/abstracted. Descriptive statistics were used to describe quality indicators consisting of the number of patients initiating XO inhibitor therapy with anti-inflammatory prophylaxis medication, titration of allopurinol and having multiple sUA assessments. A multivariate model was used to assess the impact of patient, clinician, and quality indicators on achieving sUA < 6 and < 1 flare over a 12-month period.

Results: The sample included 125 rheumatologists and 124 PCPs. Of the 1,245 patients with gout, 858 (69%) were treated with a XO inhibitor: 621 (72.4%) were treated with allopurinol and 237 (27.6%) were treated with febuxostat. Rheumatologists managed the care for 500 (58.3%) patients and

PCPs managed the care for 358 (41.7%) patients. Anti-inflammatory prophylaxis treatment was used in 67% of cases treated by rheumatologists and only 37% of cases treated by PCPs. Multiple sUA assessments over a 12-month period were done in 68% and 53% of patients managed by rheumatologists and PCPs, respectively. Allopurinol dose was titrated above 300mg in 8% of patients treated by a PCP and 29% of patients treated by rheumatologists (p<0.01). Only 25% of patients obtained sUA < 6 and reported < 1 flare per year. Controlling for confounding factors, a multivariate model found quality indicators for the use of prophylaxis flare prevention at treatment initiation, multiple sUA assessments and physician type as predictive of achieving sUA and flare goals.

Conclusion: Only 25% of patients reach sUA < 6 and < 1 flare over a 12-month period. Adherence to draft ACR guidelines vary by physician type. Patients receiving guideline recommended care are more likely to achieve treatment goals, yet, significant opportunities exist to improve care for the majority patients regardless of physician specialty, including use of prophylactic treatment, dose titration of urate-lowering therapy and/or effective treatment strategies to bring patients to sUA goal and eliminating flares.

144

Long-Term Safety of Canakinumab in Patients with Gouty Arthritis.
Alexander So[1], Reike Alten[2], H. Ralph Schumacher[3], Mark Bloch[4], Thomas Bardin[5], Markus R. John[6], Gerhard Krammer[6], Jan Michael Nebesky[6], Aiyang Tao[7] and Naomi Schlesinger[8]. [1]CHUV, Univ of Lausanne, Lausanne, Switzerland, [2]Charité Univ Medicine, Berlin, Germany, [3]Department of Medicine, University of Pennsylvania and VA Medical Center, Philadelphia, PA, [4]Holdsworth House Medical Practice, Sydney, Australia, [5]Hôpital Lariboisière, Paris, France, [6]Novartis Pharma AG, Basel, Switzerland, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [8]UMDNJ-RWJMS, New Brunswick, NJ

Background/Purpose: Gouty arthritis (GA) is a chronic inflammatory disease. Targeting the inflammatory pathway through IL-1β inhibition with canakinumab (CAN) may provide significant long-term benefits. CAN safety versus triamcinolone acetonide (TA) over initial 24 weeks (blinded study) for patients (pts) with history of frequent attacks ($\geq$3 in year before baseline) was reported earlier from core (β-RELIEVED [β-REL] and β-REL-II) and first extension (E1) studies[1]. Herein we present full 18-month long-term CAN safety data, including open-label second extension (E2) studies.

Methods: GA pts completing β-REL E1 and β-REL-II E1 studies[1] were enrolled in these 1-year, open-label, E2 studies. All pts entering E2, whether randomized to CAN or TA, received CAN 150 mg sc on demand upon new attack. Data are presented only for pts randomized to CAN, and are reported cumulatively, i.e. including corresponding data from previously reported core and E1 studies. Long-term safety outcomes and safety upon re-treatment are presented as incidence rate per 100 patient-years (pyr) of study participation for AEs and SAEs. Deaths are reported for all pts (randomized to CAN or TA). Selected predefined notable laboratory abnormalities are shown (neutrophils, platelets, liver and renal function tests). Long-term attack rate per year is also provided.

Results: In total, 69/115 (60%) and 72/112 (64.3%) of the pts randomized to CAN in the two core studies entered the two E2 studies, of which 68 and 64 pts, respectively completed the E2 studies. The 2 study populations had differing baseline comorbidity and geographic origin. Lab data (not time adjusted) for neutropenia appears worse after retreatment in β-REL E2, and deterioration of creatinine clearance appears worse after retreatment (Table 1). The time-adjusted incidence rates for AEs were 302.4/100 pyr and 360/100 pyr, and for SAEs were 27.9/100 pyr and 13.9/100 pyr in β-REL E2 and β-REL-II E2 respectively (Table 1). The time-adjusted incidence rates of any AEs, infection AEs, any SAEs, and selected SAEs before and after re-treatment are presented in Table 1. Incidence rates for AEs and SAEs declined after re-treatment, with the exception of SAEs in β-REL-II E2, which increased from 2.9/100 pyr to 10.9/100 pyr (no infection SAEs after retreatment in β-REL-II E2, and other SAEs fit no special pattern). In the total safety population (N=454, core and all extensions), there were 4 deaths, 2 in the core studies previously reported[1] and 2 during the β-REL E2 study (one patient in the CAN group died from pneumonia; one patient in the TA group who never received CAN died of pneumococcal sepsis). None of the deaths was suspected by investigators to be study drug related. The mean rates of new attacks per year on CAN were 1.21 and 1.18 in β-REL E2 and in β-REL-II E2.

Table 1.

Time-adjusted AEs*/ SAEs*	β-RELIEVED E2 Randomized to CAN* 150 mg sc (N=113)**			β-RELIEVED-II E2 Randomized to CAN* 150 mg sc (N=112)

Prevalence of Non-Gout Arthritis in Patients with Gout: Not As Sparing As Previously Thought.
Fernando Perez-Ruiz[1] and Ana M. Herrero-Beites[2]. [1]Hospital Universitario Cruces, Baracaldo, Spain, [2]Hospital de Gorliz, Gorliz, Spain

Background/Purpose: the presence of other chronic inflammatory disease has been historically and academically thought to be "protective" conditions for the development of gout.

Objective: to evaluate the presence of concomitant chronic arthritis in patients with gout.

Methods: analysis of a dataset from a 20-year cohort of patients with gout prospectively included for follow-up. Diagnosis of associated rheumatic diseases at baseline or during follow-up were included if present. Classification criteria for such concomitant diseases varied depending on the classification criteria at the moment diagnosis was made.

Results: from 904 patients with 3,315 patient-year observation. Diagnosis of gout was based on crystal observation in 731 (80.8%). The number of patients and cumulated prevalence (n/%) of pyrophosphate arthritis (PPA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) were 46/5.09, 5/0.55, 4/0.44, 3/0.33 respectively, very close to that

expected in the general population. All patients with a diagnosis of both disease had crystal-proven gout (MSU crystals) or crystal (CPP)+X-ray proven PPA. Previous PPA was present in 3/46 patients, and both CPP and MSU crystals were observed in the same synovial fluid sample in 13/46, in the 23 left PPA appearing after properly controlled gout, no MSU crystals being observed in synovial fluid. Previous RA was present in 4/5 patients, previous PsA in 3/3, and previous SpA in 3/3. Only a patient developed RA 2-year after being satisfactorily treated for crystal proven gout, and showing high titers of RF and anti-CCP antibodies.Patients with PPA and RA showed higher age and more frequent chronic kidney disease than patients with PsA or SpA. Diuretic use, a risk factor for gout, was frequent in all groups (Table 1).

	Age	Serum urate (mg/dl)	CKD (% 3–5)	BMI (kg/sqm)	DIURETICS (%)
PPA	73 ± 10	8.75 ± 1.31	52	27.8 ± 4.1	48
RA	67 ± 11	9.06 ± 1.17	40	27.9 ± 2.9	20
PsA	56 ± 9	9.80 ± 2.04	0	29.2 ± 4.5	25
SpA	58 ± 6	8.73 ± 1.72	33	27.7 ± 0.1	33

Conclusion: the cumulated prevalence of other arthritis is as much in patients with gout as expected in the general population. Systematic analysis of synovial fluid samples, despite a previous and well established previous diagnosis allows to identify MSU and CPP crystals in patients suffering from other joint diseases but also to identify CPP crystals in patients with gout.

146

The Treatment of Acute Gouty Arthritis in Complex Hospitalized Patients with Anakinra. Mary Bach, Jane Park, Pradipta Ghosh, Peter A. Simkin and Gregory C. Gardner. University of Washington, Seattle, WA

Background/Purpose: The management of acute crystal-induced arthritis in the hospital setting may be a difficult clinical problem due to co-morbidities that limit the use of traditional treatment options. Anakinra, an anti-IL1 receptor antagonist, has been successful in the treatment of acute/ chronic gout in 3 published series and 4 case reports totaling 27 patients and 2 case reports of calcium pyrophosphate dihydrate (CPPD) disease. We have previously reported our experience with 17 medically complex patients (16 gout, 1 CPPD) who had received 24 courses of anakinra which successfully treated their acute arthritis. The purpose of this study is to add additional case experience in the use of anakinra in this same population.

Methods: We reviewed our consult records over the past 5 years to identify inpatients with acute crystal-induced arthropathy treated with anakinra. Data extracted from the charts included age, gender, BMI, co-morbidities, uric acid level, joint(s) and soft-tissue sites involved, anakinra dosing, time to initial improvement, time to complete resolution of signs and symptoms of inflammation, and any possible side effects (i.e. infection or leukopenia).

Results: Twenty-six patients who had received 40 courses of anakinra were identified. Eighteen patients had failed colchicine and/or steroids, and an additional 8 patients were felt not to be candidates for traditional therapy due to co-morbid disease. None of the patients were candidates for NSAID therapy. In 29 of the 40 episodes, the arthritis was polyarticular. Foot and ankle joints were most commonly affected (44.5%) followed by hand and wrist (25%), knees (18.5%), shoulders, elbows and tendons (12%). Following first dose of anakinra, 67.5% of patients demonstrated significant pain improvement within 24 hours and 85% had significant relief by 48 hours. Complete resolution of signs and symptoms of gout occurred by day 5 in 72.5%. Seven patients received up to 5 courses with no apparent decrement in response. Anakinra was well-tolerated and no adverse outcomes were attributed to the drug. Only one patient appeared to be refractory to this form of IL-1 inhibition.

Conclusion: Anakinra is an effective and safe alternative treatment for acute gouty arthritis in medically complex patients who fail or cannot undergo more conventional therapy

147

Improvements in Long-Term Health-Related Quality of Life in Chronic Gout Patients Refractory to Conventional Therapies Treated with Pegloticase: Results From Responder Cohort. Dinesh Khanna[1], Puja Khanna[2] and Faith D. Ottery[3]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Savient Pharmaceuticals, Inc., East Brunswick, NJ

Background/Purpose: In replicate, 6-month, randomized, placebo-controlled Phase 3 clinical trials a subgroup of patients with treatment-refractory chronic gout (RCG) who received pegloticase infusions (8 mg) every 2 weeks (q2wk) demonstrated statistically significant improvements in multiple patient-reported outcome (PRO) measures derived from the HAQ and SF-36. Patients who showed sustained urate-lowering (defined as responders in the blinded trials) could continue treatment for up to an additional 2.5 years in an open-label extension (OLE) study, thus providing data on health-related quality of life (HRQoL) with long-term pegloticase administration in a responder cohort.

Methods: The OLE enrolled patients at 46 centers in the US, Mexico and Canada. Patients enrolled in the blinded trials were >18 years of age, with baseline uric acid (UA) ≥8 mg/dL and at least one of the following: 3 or more self-reported gout flares during the prior 18 months, 1 or more tophi, or gouty arthropathy (defined clinically or radiographically) and contraindication to allopurinol or failure to normalize UA during 3 or more months of treatment at the maximum medically appropriate dose. Pegloticase dosing regimen (8mg q2wks or q4wks) was determined at study entry and could be adjusted twice during the trial. All patients received prophylaxis for infusion reactions (IRs) and flares. A responder was defined as uric acid levels <6 mg/dL for at least 80% of the time during months 3 and 6. Data from the final visit of the blinded trials was used as the baseline value for the OLE study. Subjects completed the SF-36 and HAQ-DI at 3, 6, 12, 18, 24 and 30 months.

Results: 57 patients receiving q2wk pegloticase completed the blinded trials (36 responders, 29 non-responders). 35 of the 36 responders entered the OLE study; 21 continued with q2wk dosing and 14 elected once monthly dosing at study entry. The table presents mean change from baseline for multiple HRQoL measures.

Study	Visit	HAQ-DI change from baseline		Physician's GA change from baseline		HAQ Pain change from baseline		SF-36 PCS change from baseline	
		N	Mean	N	Mean	N	Mean	N	Mean
RCT (months)	3	36	−0.13*	36	−7.45*	36	−8.78*	36	3.48*
	6	35	−0.21	33	−19.94	36	−19.89	36	6.48*
OLE (months)	3	32	−0.29	30	−16.97	33	−20.91	33	6.04
	6	31	−0.33	28	−21.21	31	−20.03	32	6.98
	12	30	−0.31	28	−19.86	31	−21.81	31	6.97
	18	27	−0.30	25	−18.20	27	−18.56	29	5.99
	24	2	−0.44	1	−46.00	2	−27.00	2	10.42
	Final	32	−0.27	30	−19.63	33	−21.58	33	5.36

GA: global assessment, PCS: Physical Component Summary.

Conclusion: Pegloticase treatment during the OLE was associated with improvements in PROs for an additional 2.5 years among patients identified as urate responders during the first 6 months of blinded treatment.

148

Towards a Preliminary Definition of Remission From Gout. William Taylor[1], Nicola Dalbeth[2], Jasvinder A. Singh[3], Kenneth G. Saag[4] and H. R. Schumacher[5]. [1]University of Otago, Wellington, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Univ of Alabama-Birmingham, Birmingham, AL, [5]University of Pennsylvania and VA Medical Center, Philadelphia, PA

Background/Purpose: There is currently no agreed criterion for remission in chronic gout. The aim of this study was to develop a preliminary definition for remission in chronic gout.

Methods: Eighty unique paper patient profiles were generated by creating plausible baseline and 12-month values of measures for each core domain recommended by OMERACT for chronic gout trials. Rheumatologists

interested in gout were invited by email to evaluate each profile within an online survey and to decide whether the 12-month values indicated that the paper patient had attained a state of remission or not and the confidence in that decision (scale of 0 to 10). The exercise also asked respondents to consider whether the change in measures from baseline to 12-months represented a response to treatment or not, but those results have been reported separately. The distribution of the confidence ratings (-10 meaning high confidence of not in remission to $+10$ meaning high confidence of being in remission) for each patient profile were examined by a panel of 5 very experienced rheumatologists, who made a judgement that the distribution of confidence ratings indicated remission, not remission or uncertainty. An agreement of at least 80% was required amongst the 5 experts, to classify the remission status of the profile otherwise it was classified as 'uncertain'.

Results: There were 35 respondents. The median number of respondents per rated profile was 22.5 (range 22 to 33). This represents a median of 64% profiles that were rated by every respondent (range 63% to 94%). Two respondents did not rate any profiles and 63% (n=22) rated all 80 profiles. Of the 80 paper profiles, there was agreement by the panel of 5 experts that only 3 were in remission, 18 were uncertain and 59 were not in remission.

The mean, minimal value and maximal value for each measure, by remission status are shown in the Table. The p-value refers to ANOVA, comparing values across the 3 groups.

Table. Mean (range) of core domain measures for different categories of remission status

	Judgement of remission status			
	Not remission (n=59)	Remission (n=3)	Uncertain (n=18)	p-value
SUA (mmol/L)	0.45 (0.20 to 0.80)	0.23 (0.20 to 0.30)	0.31 (0.20 to 0.40)	<0.001
Attack frequency (over previous 3 months)	3.53 (0 to 7.00)	0 (0 to 0)	1.06 (0 to 4.00)	<0.001
Tophus size (mm^2)	823.94 (0 to 1800)	0 (0 to 0)	380.56 (0 to 1350)	<0.001
Tophus number	2.75 (0 to 6)	0 (0 to 0)	1.50 (0 to 7)	0.004
Mental health component of SF-36	70.73 (50 to 86)	78.67 (72 to 85)	76.78 (66 to 93)	0.021
Physical health component of SF-36	74.46 (50 to 91)	84.67 (80 to 88)	80.44 (58 to 90)	0.025
Pain VAS (0 to 100)	27.17 (14 to 83)	20.00 (16 to 26)	21.89 (10 to 35)	0.267
HAQ-DI	0.87 (0 to 2.20)	0 (0 to 0)	0.53 (0 to 2.10)	0.001
Patient Global VAS (0 to 100)	53.02 (26 to 85)	33.00 (28 to 36)	41.22 (26 to 62)	0.001

Conclusion: The domains that showed the greatest discrimination between remission and non-remission were SUA, tophi and flares. Pain between flares did not appear to discriminate between remission and non-remission status. The following definition of remission is proposed, based approximately on the maximal values observed in those who attained remission:

SUA no more than 0.36 mmol/l AND no gout attacks in prior 3 months AND no tophi AND patient global assessment no more than 3 (0 to 10 scale).

149

Natural Language Processing in the Evaluation of Gout Quality Indicators.
Gail S. Kerr[1], J. Steuart Richards[2], Carl A. Nunziato[3], Olga V. Patterson, Scott L. DuVall[5], David D. Maron[3] and Richard L. Amdur[6]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]Washington DC VA and Georgetown University, Washington, DC, [3]Washington, DC, [4]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [5]Washington DC VA and Georgetown Unviversity, Washington, DC

Background/Purpose: Gout is a common inflammatory arthritis with significant impact on both patients and health care systems. Despite ACR/EULAR management guidelines and gout quality indicators (QI) developed to improve outcomes, standard of care is often suboptimal and infrequently measured. We evaluated the standard of care of in a cohort of Veterans Affairs (VA) gout patients, using QI that include medication, laboratory and counseling criteria.

Methods: During a 4 year period, VA administrative data was used to identify gout outpatients (ICD 9 codes: 274.xx and at least 2 related visits). QIs assessed were QI 1: patients with creatinine clearance < 60 ml/min, initial allopurinol dose to be < 300 mg/day; QI 2: uric acid (UA) within 6 months of allopurinol start; QI 3: if on colchicine CBC, CPK done within 6 months; QI 4: counseling on gout specific diet, weight loss and alcohol consumption. For QI 4, natural language processing (NLP), a technique that analyzes large amounts of text to identify key words and/or phrases, was used to extract dietary, alcohol and weight loss counseling data from electronic medical records. Data collected were socio- demographics, comorbidities [HTN, DM, CVD, hyperlipidemia, obesity and chronic kidney disease (CKD)] and number of rheumatology outpatient visits for gout. QI compliance versus non-compliance was compared using chi-square analyses.

Results: Of 2,280 gout patients, 2,260 (99.1%) were male, with mean age of 66.8 years. Comorbidities were common: HTN in 2,102 (92.2%); Obesity in 1,578 (69.2%); CVD in 1,384 (60.7%); hyperlipidemia in 1,170 (51.3%); DM in 1,075 (47.1%); and CKD in 748 (33.8%). Most 1,587 (69.6%) had at least one rheumatology outpatient visit, and more than half received specific gout therapy: colchicine was dispensed to 1424 (62.5%) and allopurinol to 1,336 (58.6%) patients. Compliance with each QI was as follows: QI 1: 92.1%; QI 2: 44.8%; QI 3: CBC monitoring 70%; but only 6.3% for both CBC and CPK (only 1 patient had CPK without CBC). For QI 4, there was counseling for weight loss in 1008 (44.2%), diet in 390 (17.1%), alcohol in 137 (6.0%) and 51 (2.2%) had counseling on all 3 elements. Of those on new allopurinol prescriptions, target serum uric acid (< 6 mg/dl) was achieved in 64 (30.1%) patients within one year. Compared with non-compliant patients, patients compliant with QI 2 had more rheumatology visits (3.5 vs. 2.6; p< 0.001), while those compliant with QI 3 (CBC) were older (67.3 vs 64.9 years p<0.001) and had more CKD (p<0.001), DM (p<0.001) and CVD (p<0.001). Patients with DM, obesity, and hyperlipidemia were more often counseled on diet compared to those without comorbidities. Alcohol counseling was less frequent in gout patients with hyperlipidemia (p= 0.024) and DM (p=0.012) compared to patients without comorbidities.

Conclusion: In our study cohort, compliance with QI for uric acid and CPK monitoring were subpar. In gout patients, specific dietary counseling appeared to be directed by other comorbidities. NLP proved a valuable tool for evaluating dietary QI in patients with gout.

150

Ulodesine (BCX4208) Long-Term Safety When Added to Allopurinol in the Chronic Management of Gout: A Phase 2 24-Week Blinded Safety Extension and Vaccine Challenge Study.
Alan S. Hollister[1], Andreas Maetzel[1], Michael A. Becker[2], Robert Terkeltaub[3], David Fitz-Patrick[4], Valerie Smith[5] and William P. Sheridan[1]. [1]BioCryst Pharmaceuticals, Inc., Durham, NC, [2]University of Chicago, Chicago, IL, [3]VA Medical Ctr, San Diego, CA, [4]East-West Medical Research Institute, Honolulu, HI, [5]Pharpoint Research, Inc., Durham, NC

Background/Purpose: A majority of gout patients treated with 300 mg/d allopurinol do not reach the therapeutic goal range serum uric acid concentration (sUA) of <6.0 mg/dL. Added to allopurinol, ulodesine (BCX4208), a purine nucleoside phosphorylase inhibitor, synergistically reduces sUA and allows a greater proportion of gout patients to reach sUA <6.0 mg/dL. The objectives of this study were (1) to extend the safety assessment of a 12 week efficacy study through 24 weeks of drug administration, (2) to evaluate immune responses to vaccine challenge, and (3) to confirm continued efficacy of ulodesine.

Methods: 278 gout patients (M:F=266:12) with sUA >6.0 mg/dL despite allopurinol 300 mg/d received placebo or ulodesine at 5, 10, 20, or 40 mg/d for 12 wks. 160 subjects entered the combination treatment extension to 24 wks on their blinded treatment assignment; 27 on placebo, and 39, 32, 33, and 29 on BCX4208 5, 10, 20, and 40 mg/d. All subjects received gout flare prophylaxis with colchicine or naproxen. At 16 or 20 wks, subjects were vaccinated with tetanus toxoid (TT) and/or multivalent pneumococcal polysaccharide vaccine (PPSV), and antibody levels were measured before and 4 wks after vaccination in 84 subjects.

Results: Subject mean (range) age was 49 y (19–69), BMI was 35.9 (22.8–62.2), 45% had mild or moderate renal impairment, and 14% had diabetes in a mostly white population (79%). Total adverse event (AE) rates by 24 weeks were 45.3 per 100 patient-months (pt-mo) for placebo and 33.8, 41.0, 41.3, and 58.2 in the ulodesine 5, 10, 20, and 40 mg/d treatment arms. Infectious AE rates were 8.3 for placebo and 6.3, 6.5, 7.3, and 5.1 per 100 pt-mo, for the respective ulodesine arms. Infection severity, type, location,

and causative agent were similar among study arms. There were no opportunistic infections. The ulodesine dose-related reduction of total lymphocyte count and lymphocyte subsets remained at a plateau reached between week 8 and 12. There were 4 and 11 protocol-specified withdrawals for CD4+ cell count <350 cells/mL in the ulodesine 20 and 40 mg/d arms by 24 weeks. The proportion of antibody responses to vaccination with TT (≥4-fold increase in antibody titers) and PPSV (>2-fold increase in antibody titers to >4 of 6 antigens) was similar or greater in ulodesine- than in placebo-treated subjects. The proportion of subjects with sUA levels <6.0 mg/dL among those completing week 24 was 25% (6 of 24) in the placebo group, and 40% (14 of 35), 50% (13 of 26), 46% (12 of 26), and 55% (12 of 22) in the 5, 10, 20, and 40 mg/d ulodesine arms.

Conclusion: Ulodesine was safe and generally well tolerated when added to allopurinol for up to 24 wks. Patients generated a healthy immune response to vaccination. Adverse event frequency and severity was similar among all groups and no differences were seen in the rate or severity of infections. There were no protocol-driven study drug withdrawals due to low lymphocyte counts in the placebo, 5 mg/d, and 10 mg/d groups. The efficacy of ulodesine in reducing sUA at 12 wks was sustained at 24 weeks.

151

Management of Gout Attacks in the Community. Tuhina Neogi[1], Clara Chen[2], Christine E. Chaisson[2], David J. Hunter[3], Hyon Choi[1] and Yuqing Zhang[4]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University School of Public Health, Boston, MA, [3]University of Sydney, Sydney, Australia, [4]Boston University, Boston, MA

Background/Purpose: We previously examined management of gout attacks in the community in 2003-4. Since then, new agents have become available and gout publications have increased, potentially raising awareness about appropriate gout attack management. We therefore re-evaluated these patterns in a large community sample.

Methods: We conducted an internet-based prospective cohort study of gout (2003–2012). Subjects with gout who had ≥1 attack in the prior year were recruited online from 49 states and D.C., with their gout diagnosis verified through medical records review. Subjects provided information about comorbidities, baseline medications, treatment of their gout attacks and whether they consulted a healthcare professional (HCP) for attacks that occurred during one year of follow-up. We estimated the risk of having '1 and ≥2 attacks in one year using life table methods. We determined the frequency and predictors of definitely inappropriate (use of urate-lowering therapy (ULT) acutely in absence of prophylactic use) and potentially inappropriate (use of analgesics alone, alternative remedies alone, or no medications) management of gout attacks.

Results: 1015 subjects with gout were followed for one year (78% male, mean age 53.6, mean BMI 31.9). Since 2005 (N=783), 63.5% had ≥1 self-reported comorbidity (hypertension 56%, kidney disease 19%, kidney stones 14%, diabetes 14%, CHF 7%, peptic ulcer disease 4%). ULT was used by 45%: allopurinol 42%, probenecid 2%, febuxostat 0.9%, sulfinpyrazone 0.1%. Colchicine was used for prophylaxis by 23%; 5% used it without ULT. Similarly, 23% used NSAIDs for prophylaxis; 8% used it without ULT.

The risk of having ≥1 attack and of ≥2 attacks in 1 year was 74.4% and 50.6%, respectively. Medications used to manage gout attacks, either alone or in combination were NSAIDs (52%), colchicine (34%), analgesics (27%), oral glucocorticoids (13%), alternative remedies (0.4%), and ULT acutely (without prior prophylactic use) (0.7%). No medications were used in 12%. Potentially and definitely inappropriate attack treatment occurred in 17.7% and 0.7%, respectively, an improvement from 2003-4 (Table 1). 53% never consulted a HCP for any attack, 25% only did so sometimes, and 22% did so for each attack, a substantial change from 2003-4. The most common HCP consulted for an attack were primary care (51%), ER (10%), rheumatologist (8%), podiatry (5%), and nurse practitioner (5%). In contrast to our previous study, consulting a HCP resulted in lower chance of inappropriate attack management. Age, gender, and disease durationwere also associated with inappropriate management (Table 2).

Table 1. Management of acute gout attacks in 2003–2004 and 2005–2012

NSAIDs	2003–2004 (N=232) 67%	2005–2012 (N=783) 52%
Colchicine	35%	34%
Analgesics +/− other meds	23%	27%
Analgesics alone	22%	6%
Oral glucocorticoids	9%	13%
Alternative remedies	2%	0.4%
No medications	9%	12%
Any ULT acutely in absence of prior use	5%	0.7%
Allopurinol acutely in absence of prior use	3.4%	0.4%
Inappropriate management of acute gout attack:	26%	18.4%
Definitely inappropriate	5%	0.7%
Potentially inappropriate	21%	17.7%
Consulted a HCP for acute gout attack:		
Always	54%	22%
Sometimes	24%	25%
Never	21%	53%

Table 2. Factors related to use of any inappropriate therapy for acute gout attack management

	Adjusted* OR (95% CI)
Consulted HCP for the attack	0.49(0.35–0.68)
Age (for every 10-year increase)	1.13(1.01–1.28)
Female sex	1.46(1.01–2.10)
Disease duration ≤1 year	1.36(1.00–1.88)

*Adjusted for age, sex, BMI, race, education, total # of attacks in one year, consulted HCP for the attack, comorbidities (HTN, renal disease, CHF, diabetes, peptic ulcer disease), disease duration.
HCP=healthcare professional.

Conclusion: In this large cohort of gout patients recruited from across the US, overall management of gout attacks appears to have improved over the past 8 years. Gout management education efforts still need to be focused on primary care, ER and particularly patients themselves as they are the most likely to manage gout attacks.

152

Rilonacept for Gout Flare Reduction: Estimation of Number Needed to Treat to Benefit (NNTB). Robert R. Evans[1], Steven P. Weinstein[1], George D. Yancopoulos[2] and Yuhwen Soo[2]. [1]Regeneron Pharmaceuticals Inc, Tarrytown, NY, [2]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

Background/Purpose: Two similarly designed phase 3 randomized clinical trials (PRESURGE-1 and PRESURGE-2) in gout patients initiating urate-lowering therapy (ULT) showed that subcutaneous treatment with the IL-1 antagonist rilonacept 80 or 160 mg weekly resulted in a significant reduction in the mean number of gout flares (GFs) per patient by 71%-80% relative to placebo over 16 weeks. Analyses were performed to estimate the number needed to treat to benefit (NNTB).

Methods: Using pooled data for the placebo and rilonacept treatment groups (n~160 per pooled group), NNTB was estimated using 1) classical calculations based on binary outcomes, 2) graphical analyses based on the distributions within each treatment group of the number of flares experienced by each patient, and 3) the estimated distributions of flares per patient in the placebo and rilonacept group using negative binomial and Poisson distributions, and the distribution of the difference between groups.

Results: Approximately half the placebo patients (48.4%) did not have a GF, but the other half averaged 2.2 GFs/patient. Approximately 30% more patients on rilonacept vs placebo had less than 1 GF, and approximately 25% more patients on rilonacept vs placebo had less than 2 GFs. NNTBs are ~4 based on either one of these individual binary outcomes. However, considering NNTB based on these binary outcomes individually does not account for the partial overlap of subgroups that benefit, nor for uncaptured flare reduction among patients with multiple GFs. Graphical analysis suggests that almost all of the patients destined to flare would likely have benefited from rilonacept treatment. A patient who would have had one GF would likely have none, and those destined to have multiple GFs would have fewer. With an estimated mean reduction in GFs of 74% with rilonacept, patients destined

to flare would average about 1.6 fewer GFs. Combining these benefits shows that of 2 patients initiating ULT, 1 would not be expected to flare, even without prophylaxis, but the other patient would be expected to flare and would benefit from rilonacept, resulting in an NNTB of ~2. The difference in the negative binomial distributions and the difference in the Poisson distributions (Skellam distribution) independently confirm an NNTB of ~2; conditional on benefit with rilonacept, the mean benefit is about 1.65 fewer GFs. The most common category of adverse event (AE), infections, was balanced among treatment groups; the most frequent treatment-related AE, injection site reaction, was greatest with rilonacept 160 mg. The incidence of SAEs was low and similar across treatment groups.

Conclusion: This analysis shows that approximately 50% of patients with gout who are initiating ULT would benefit from treatment with rilonacept, resulting in an NNTB of ~2. Conditional on benefit with rilonacept, patients would experience about 1.6 fewer GFs with treatment.

153

Prevention of Recurrent Calcium Stones in Subjects with Hyperuricosuria: A Randomized Controlled Trial of Febuxostat Vs Allopurinol. David S. Goldfarb[1], Patricia A. MacDonald[2], Lhanoo Gunawardhana[3], Solomon Chefo[3] and Lachy McLean[4]. [1]New York Universtiy Langone Medical Center, New York, NY, [2]Takeda Pharmaceuticals USA, Inc., Deerfield, IL, [3]Takeda Global Research & Development Center, Inc., Deerfield, IL, [4]Takeda Global Research & Development Center, Inc, Deerfield, IL

Background/Purpose: About one-third of patients with recurrent calcium oxalate (CaOx) stones have hyperuricosuria as a urinary risk factor. Febuxostat (FEB), a newer xanthine oxidase inhibitor (XOI), may be superior to allopurinol (ALLO) in stone prevention. ALLO treatment has been shown to reduce the incidence of recurrent CaOx stones in hyperuricosuric stone formers (SF). We studied whether FEB would reduce 24h urinary uric acid (uUA) excretion and prevent stone formation and pre-existing stone growth.

Methods: In this 6-month, double-blind, multicenter, randomized, controlled trial, hyperuricosuric (>700 mg/d) adult subjects with a history of CaOx stones and ≥1 3-mm stone in its longest in-plane diameter as seen by multidetector computed tomography (MDCT) were randomized to receive daily FEB 80 mg, ALLO 200 or 300 mg (based on baseline Ccr), or PBO. Patients were excluded if they had a history of gout or secondary hyperuricemia, if they had received ALLO within the past 2 years or ever received FEB. Primary end-point was percent change from baseline (CFB) to month 6 in 24h uUA; secondary end-points were percent CFB in size of index stone, CFB in number of stones and in 24h creatinine clearance (Ccr).

Results: Of 99 subjects enrolled, 86 completed the study. Key baseline characteristics were balanced. Most subjects were men (86%), had a mean lifetime history of 10.9 stone episodes, mean largest stone diameter of 9.9 mm and a mean number of stones 5.7 on MDCT. Normal renal function was present in 97% of patients (mean baseline Ccr was 147 mL/min/1.73m^2). Mean baseline serum urate (sUA) was 6.3 mg/dL, 24h urine calcium excretion was 272.2 mg/d, and 24h uUA was 952.7 mg/d. FEB led to significantly greater reduction from baseline in 24h uUA than either PBO or ALLO. Reductions in stone size and number with FEB were not statistically greater than with ALLO or PBO. In all groups, there were no statistically significant changes in 24h Ccr and serum creatinine did not change. Rates of adverse events (AE) were similar across the treatments groups. One patient in the placebo group experienced a serious AE of nephrolithiasis, but remained in the study.

	PBO (n=33)	FEB 80 mg (n=33)	ALLO 300 mg (n=33)
Baseline uUA (mg/d)	909.4 ± 166.4	1000.6 ± 224.0	948.1 ± 231.2
Treated 6-month uUA (mg/d)	783.5 ± 288.0	411.4 ± 288.4	580.0 ± 301.8
CFB in uUA (%)	−12.7 ± 28.8	−58.6 ± 28.6[a,b]	−36.4 ± 37.0
Baseline sUA (mg/dL)	6.3 ± 1.24	6.2 ± 1.63	6.3 ± 1.49
Treated 6-month sUA (mg/dL)	6.2 ± 1.28	3.3 ± 1.11	4.6 ± 1.26
CFB in sUA (%)	−1.04 ± 13.5	−47.3 ± 16.7[b,c]	−26.2 ± 12.6
CFB in stone size (%)	3.2 ± 23.70	−6.5 ± 28.36	0.6 ± 12.61
CFB in stone number	0.1 ± 1.82	−0.1 ± 1.61	0.3 ± 1.95

mean±SD; [a]P=0.003 vs ALLO; [b,c] P<0.001 vs PBO and ALLO, respectively.

Conclusion: FEB 80 mg lowered 24h uUA significantly more than ALLO 300 mg in SF with hyperuricosuria. Neither XOI was associated with

significantly reduced stone number or size compared with PBO after 6 months of treatment. Extended duration of FEB treatment leading to greater 24h uUA reductions may demonstrate improved prevention of CaOx stone recurrence.

Dual-Energy Computed Tomography As a Diagnostic Tool for Gout During Intercritical Periods. Gabriel S. Breuer[1], Naama Bogot[2] and Gideon Nesher[1]. [1]Shaare Zedek Medical Center, Jerusalem, Israel, [2]Shaare Zedek Medical Center p o box 3235 Jerusalem, Israel, Israel

Background/Purpose: Dual-energy computed tomography (DECT) is a sensitive method for identifying uric acid deposits in joints and periarticular soft tissues in patients suspected of having gout. Diagnosis of gout cannot be confirmed by polarized microscopy during asymptomatic (intercritical) periods as joint aspiration is not feasible in most cases. We estimated the yield of dual-energy computed tomography (CT) in detection of uric acid tissue deposits during intercritical periods in patients suspected of having gout.

Methods: Patients aged at least 18 years with a history of recurrent, short-lived mono- or oligo-arthralgia or arthritis, referred to the rheumatology clinic for diagnosis of their condition, were included. All had uric acid levels >6 mg/dl and were completely asymptomatic at the time of clinical and radiological evaluations. Patients with a confirmed diagnosis of gout and patients on urate-lowering medicationswere excluded. DECT screened the specific joints and periarticular soft tissues that were previously involved in each case.

Results: 22 patients (18 men, 4 women) were included. Their mean age was 57+17 years. Articular or soft-tissue urate deposits were identified by DECT in 11 cases (50%). Uric acid level did not differ significantly between the groups with or without deposits (8.5+2 and 8.7+1.2 mg/dl, respectively). The table shows the yield of DECT in various anatomic locations:

Area screened	feet	knees	elbows	hand
Number of cases	18	8	1	4
Cases with urate deposits	7	2	0	3
% with urate deposits	39%	25%	0	75%

Conclusion: In asymptomatic hyperuricemic patients with a history of recurrent short-lived mono- or oligo-arthralgia or arthritis, DECT identified urate crystals in 50%, confirming a diagnosis of gout. DECT is a valuable tool in diagnosing gout during intercritical periods.

Accuracy of International Classification of Disease Codes for Calcium Pyrophosphate Disease in the Veterans Adminstration Healthcare System. Karri A. Huber[1], Lawrence M. Ryan[2] and Ann K. Rosenthal[2]. [1]MCW Froedtert Hospital, Milwaukee, WI, [2]Medical College of Wisconsin, Milwaukee, WI

Background/Purpose: Calcium pyrophosphate disease (CPPD) commonly affects elderly patients, but few advances in our management of this disease have occurred in the 50 years since it was first described. Progress has been hampered by the absence of large population-based studies of CPPD. The National Veterans Administration (VA) system would be an ideal location to perform such studies. However, the accuracy of the diagnostic codes for CPPD in this database have not been confirmed. We set out to determine the accuracy of International Classification of Disease (ICD) codes for pseudogout/other disorders of calcium metabolism (275.49) and chondrocalcinosis (712.1–712.39) for the diagnosis of CPPD in a single VA hospital database and to describe the clinical picture of this disease in the VA population.

Methods: After approval by the IRB, 256 patients identified as having CPPD by ICD-9 codes for chondrocalcinosis (712.1–712.39) and pseudogout/other disorders of calcium metabolism (275.49) were identified at the Clement J. Zablocki VA Medical Center in Milwaukee, WI for the years 2009–2011. A chart review was performed by a second year rheumatology fellow for each patient and patients were categorized as having definite, probable, possible CPPD or no evidence of CPPD based on the diagnostic criteria proposed by

McCarty and Ryan. Other data collected included patient demographics, the number and type of joints involved, whether the patients had been seen by the VA rheumatology service, and co-morbidities including renal disease and diabetes.

Results: Based on the medical records review, 227/256 (88.6%) patients met criteria for CPPD. Of these, 46 patients met definite criteria, 163 met probable criteria, and 18 met possible criteria for CPPD. Of these 227 patients, 107 (47.1%) patients had ICD-9 code 275. Seventy three (32.1%) had ICD-9 code 712, and 47 (20.7%) had both codes documented. The average age was 73.28 years (range 32–94 years), and, consistent with VA demographics in this age cohort, 98.2 % were men. Sixty-one (26.8%) had stage III or greater chronic kidney disease and 79 (34.8%) had diabetes. Many patients had both acute and chronic arthritis, as 166 (73.1%) had at least one documented episode of acute arthritis, while 208 (91.6%) had chronic articular symptoms. Knee involvement occurred in 86 patients, followed in frequency by involvement of the hand (68), wrist (64), foot (35), ankle (34), elbow (20), and olecranon bursa (10). The average number of joints involved for patients with chronic arthritis was 2.35 (range 1–6) and for acute was 2.012 (range 1–6). Rheumatology had evaluated 51.5% of these patients, including 83% with definite CPPD, 43.6% with probable CPPD, and 44.4% with possible CPPD.

Conclusion: We found a high correlation between evidence of CPPD documented in medical records and the ICD codes 275.49 and 712 in the medical records database at a single VA medical center. The demographics of this population and pattern of joint involvement confirm prior studies of the epidemiology of this disease and further support the accuracy of these codes. These findings suggest that the national VA healthcare database may be useful for future clinical studies of CPPD.

156

Menopause and the Prevalence of Gout and Hyperuricemia: An Age-Matched Case Control Study. Eswar Krishnan[1] and Mihoko Bennett[2]. [1]Stanford University, Stanford, CA, [2]Stanford University, Palo Alto, CA

Background/Purpose: Among women, the prevalence of gouty arthritis (gout) and hyperuricemia (serum urate>6.0 mg/dL) increases steeply after the age 60. This increase has been attributed to menopause, and its attendant declines in circulating concentrations of reproductive hormones. However it is not clear whether the 'effect' of menopause is merely a reflection of increasing age as these two factors are tightly correlated.

Methods: We performed multiple unmatched and age matched case-control analyses using data on women aged 20–60 years from the NHANES1999–2010 cycles. For the latter, each case of gout, defined as self-reported physician diagnosis, 3 age-matched controls were chosen at random. Menopause was defined as absence of menstrual bleeding in the preceding 12 months, excluding those caused by pregnancy, medications, hormones, medical conditions or surgical procedures. Unmatched and matched multivariable analyses were performed by Survey weighted logistic regressions that adjusted for age, body mass index, ethnicity, hypertension and serum creatinine. Models were repeated with hyperuricemia as the outcome variable.

Results: A) Gout: In unmatched analyses, the bivariate and multivariable odds ratio for menopause were 3.0(1.4,6.5) and 1.3(0.6,2.7) respectively. In the age-matched analyses, bivariate odds ratio was 0.9 (0.4,1.8) and multivariate odds ratio was not significant. B) Hyperuricemia: In unmatched analyses the odds ratio for menopause in bivariate and multivariable models were 2.3 (2.0–2.8) and 1.25(1.01–1.54) respectively. In age-matched logistic regression models, the bivariate and multivariable odds ratios were 1.3(1.1,1.4) and 0.98(0.86–1.11) respectively

Conclusion: After offsetting the effect of age by matching, menopausal status was not associated with increased prevalence of gout or hyperuricemia.

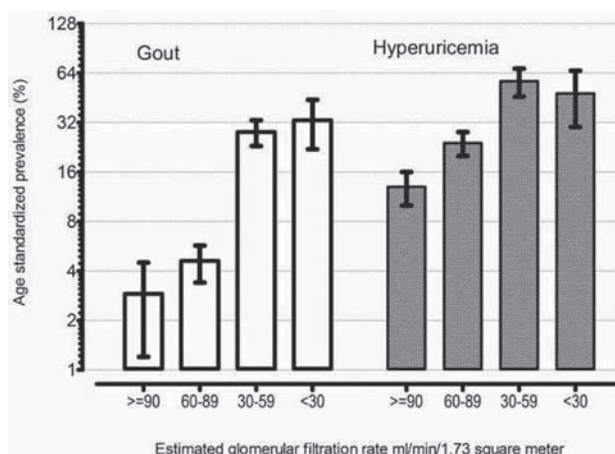
157

Prevalence of Gout Among Adults with Chronic Kidney Disease in the United States, 2009–10. Eswar Krishnan. Stanford University, Stanford, CA

Background/Purpose: The kidney is a major route of clearance of uric acid, a product of purine metabolism. The links between kidney disease, hyperuricemia, and gout in the general population are not well understood.

Our objective was to estimate prevalence of gout and hyperuricemia among people with chronic kidney disease (CKD) in the US general population.

Methods: The study was designed as a cross-sectional analysis of the most recent National Health and Nutrition Examination Surveys (NHANES 2009–2010), a nationally representative sample of civilian men and women aged 20 years or older (n=5,589). Gout was defined per self-reported physician or health professional diagnosis. Hyperuricemia was defined as serum urate > 7.0 mg/dL for men and > 6 mg/dL for women. Estimated glomerular filtration rate (eGFR) calculated using the Chronic Kidney Disease-EPI equation was used to classify CKD as mild, moderate or severe.

Results: In 2009–2010, there were 5.2 million men and 2.3 million women with gout in the US. Of these, 1.25 million men and 0.78 million women had moderate or severe CKD. The prevalence of gout and hyperuricemia was 5-fold higher among those with moderate or severe CKD compared to those with no CKD. In multivariable logistic regression analyses that adjusted for age, gender, body mass index, hypertension, diabetes, hypertension medications including diuretics, blood lead levels, and hyperlipidemia the odds ratios of gout and hyperuricemia were 5.8 (1.2, 26.5) and 19.5 (3.8, 99.2) among those with severe CKD compared to those with no CKD.


Conclusion: Gout is a major comorbidity of CKD with about 2 million Americans suffering from gout and moderate to severe CKD. The prevalence for gout and hyperuricemia increases as the severity of CKD worsens.

158

Focus Groups Reveal Knowledge Gaps in Patients with Gout-A Qualitative Study. Puja Khanna[1], Veronica Berrocal[1], Tonya Hays[2], Daniel J. Clauw[1] and David A. Williams[3]. [1]University of Michigan, Ann Arbor, MI, [2]UCLA, Los Angeles, CA, [3]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: Gout is the most treatable arthritis in the Western World and there are effective medications available to treat both acute episodes and chronic gout. Prior studies have shown that treatment of chronic gout leads to improvement in patient-reported outcomes, and inadequate control has a substantial economic impact on the patient, employer, and society. Despite this, gout has the lowest adherence to medications (38%) across common chronic conditions such as hypertension, osteoporosis and diabetes mellitus. Currently, demographics, comorbidities, and poor adherence to chronic therapy are considered important attributes in developing poorly controlled gout. There is limited qualitative research assessing barriers to treatment and management among patients and health care providers. Therefore, we performed focus groups in patients with gout to identify conceptual gaps from patients' perspective.

Methods: A trained moderator conducted formal in-depth focus groups in gout patients, who were enrolled using an online screening survey where they provided details of their gout management including medications. The script for the focus group included questions to test their knowledge about the natural history of gout, understanding about different aspects of treatment of gout (acute treatment vs. prophylaxis vs. chronic urate-lowering therapy), beliefs about how long the treatment should be taken, discussion on adherence

to their medications, perceptions about the association between diet and alcohol and gout flares, and coping with an acute attack of gout. Adherence to medications was measured using a validated eight-question adherence instrument, Morisky Medication Adherence Scale, which is scored as low, medium, and high adherence.

Results: Twenty-four patients participated in 4 focus groups that lasted 90 minutes each. Baseline demographics showed predominantly white males (75%), 18% Hispanic, mean age 47.8 (15.4) years, 33% had tophaceous gout as diagnosed by their physician, and 62% were on ULT. Majority were receiving care from their primary care physicians (PCP, n=13), 4 from a rheumatologist, and remaining from PCP/ other subspecialties (n=5), or self-treated (n=2). The following themes emerged upon transcription of the scripts from these sessions: 1) Patients did not have a clear understanding of the natural history of gout; 2) patients did not realize that recurrent acute flares resulted in chronic joint damage; 3) there was lack of knowledge regarding treatment options and duration of therapy for acute and chronic gout; 4) patients felt that physicians did not spend enough time explaining the progression, i.e. natural history of the disease and its long-term effects; 5) patients did not grasp the need for chronic ULT to avoid complications and disability; and 6) patients were not aware of treatment goals for hyperuricemia, as evident by adherence to their gout medications. In these groups, 38% had low and 42% had medium adherence to their gout medications, respectively (per MMAS).

Conclusion: This qualitative study provides important insight into key modifiable variables that can be targeted to develop educational materials for patients.

159

Clinical Efficacy Outcomes with up to 3 Years of Pegloticase Treatment for Refractory Chronic Gout. Michael A. Becker[1], Herbert S. B. Baraf[2], Robert A. Yood[3], Aileen M. Dillon[4], Janitzia Vazquez-Mellado[5], Faith D. Ottery[6], Dinesh Khanna[7] and John S. Sundy[8]. [1]University of Chicago, Chicago, IL, [2]Arthritis & Rheumatism Associates, Wheaton, MD, [3]Reliant Medical Group, Worcester, MA, [4]Kaiser Foundation Hospital, San Francisco, CA, [5]Hospital General de Mexico, Mexico city, Mexico, [6]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [7]University of Michigan, Ann Arbor, MI, [8]Duke University Medical Center, Durham, NC

Background/Purpose: Pegloticase, a recombinant modified mammalian uricase conjugated to mPEG, was approved for use in refractory chronic gout in the US in 2010. The Phase 3 clinical program comprised replicate, randomized, placebo-controlled trials (RCTs) followed by an open-label extension (OLE) study for a total treatment duration of up to 3 years. Here we focus on tophus resolution, flares, and tender/swollen joint counts with long-term pegloticase administration.

Methods: Patients entering the RCTs were >18 years of age, had baseline uric acid (UA) ≥8 mg/dL and at least one of the following: 3 or more self-reported gout flares during the prior 18 months, 1 or more tophi, or gouty arthropathy and contraindication to allopurinol or failure to normalize UA during 3 or more months of treatment at the maximum medically appropriate dose. The OLE enrolled patients at 46 centers in the US, Mexico and Canada who completed a RCT. Pegloticase dosing regimen (8 mg q2wks or q4wks) was determined at entry to the OLE and could be adjusted twice during the trial. All patients received prophylaxis for infusion reactions and flares. A tophus complete response was defined as 100% reduction in the measured area of at least 1 tophus of baseline diameter ≥5 mm without growth of any other baseline tophus or appearance of any new tophi. 547 evaluable tophi were present in 113 patients at baseline. Serial physician's global assessments (GA) were scored on a visual analogue scale from 0 (very good) to 100 (very bad) as a measure of patient well-being resulting from disease activity and assessments of 54 joints for swelling or tenderness were also performed.

Results: Most subjects completing blinded treatment (151/157) entered the OLE study. Among the 149 patients treated with pegloticase in the OLE study (2 elected observation only), 110 had received pegloticase during randomized testing and 39 had received placebo. Mean UA was 10 mg/dL at the OLE baseline (see baseline definition below). After 1 year of OLE treatment (week 52 visit), 59% of patients remaining in the study (62/105) had UA levels below 6 mg/dL. Secondary endpoints over time are presented in the Table below at study baseline, Week 13 (first measurement), one year, and final visit.

Efficacy variable	OLE Baseline*	Week 13	Week 52	Final Visit (LOCF)
Patients with SUA less than 6 mg/dL (%)	0.7%* (1/147)	48% (59/122)	59% (62/105)	45% (63/141)
Patients with tophus CR	RCTs baseline used	45% (36/80)	74% (50/68)	60% (56/94)
Mean tender joint counts (0-54 joints)	12*	5	3	4
Mean swollen joint counts (0-54 joints)	9*	4	2	3
Physician GA score (0-100)	48*	20	13	17

	Flare Data per 3 Month Period			
	Months 1-3	Months 4-6	Months 10-12	Months 22-24
Subjects with flares (%)	52%* (78/149)	38% (51/136)	26% (30/114)	17% (14/83)

*OLE baseline was defined as baseline data from the RCTs in patients treated with pegloticase and with a gap in therapy of <4 weeks between studies; for all other patients OLE baseline data was collected prior to the first OLE infusion. LOCF includes the data for all evaluable patients "carried forward" from the time of their final visit in the study.

Conclusion: Treatment with pegloticase for up to an additional 2.5 years beyond the 6 months of blinded trial participation was associated with ongoing benefits for patients. The OLE population data shown provides a conservative estimate of benefit as data are pooled for responders and non-responders. Patients undergoing sustained treatment with pegloticase can be expected to show meaningful clinical improvements with up to 3 years of therapy.

160

Pegloticase Long-Term Safety: Data From the Open-Label Extension Trial. Michael A. Becker[1], Herbert S. B. Baraf[2], Robert A. Yood[3], Aileen M. Dillon[4], Janitzia Vazquez-Mellado[5], Faith D. Ottery[6], Dinesh Khanna[7] and John S. Sundy[8]. [1]University of Chicago, Chicago, IL, [2]Arthritis & Rheumatism Associates, Wheaton, MD, [3]Reliant Medical Group, Worcester, MA, [4]Kaiser Foundation Hospital, San Francisco, CA, [5]Hospital General de Mexico, Mexico city, Mexico, [6]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [7]University of Michigan, Ann Arbor, MI, [8]Duke University Medical Center, Durham, NC

Background/Purpose: Pegloticase is a recombinant modified mammalian uricase conjugated to mPEG and approved for treatment of refractory chronic gout. Pegloticase safety was evaluated during 2 replicate, 6-month randomized, placebo-controlled trials (RCTs).[1] An open-label extension (OLE) of these trials for up to 2.5 additional years of therapy evaluated long-term safety.

Methods: Patients completing one of the RCTs (n=157) could enroll in the OLE study conducted at 46 sites in the US, Canada, and Mexico. Patients (n=149) received pegloticase 8 mg infusions Q2 weeks or Q4 weeks. Patients received prophylaxis for infusion-related reactions (IRs) and gout flares (flare prophylaxis could be discontinued after 3 months in the OLE). Safety was evaluated with special interest in gout flares and IRs (defined as any adverse event occurring during or within 2 hours after infusion and not reasonably attributable to another cause).

Results: Of 157 RCT completers, 151 (96%) entered the OLE study and 149 received pegloticase (2 patients chose observation only). Patients received a mean of 28 ± 18 (SD) pegloticase infusions (range= 1–59) and were followed for a mean of 25 ± 11 months in the OLE study. The most common reasons for study withdrawal were AEs in 18% (27/149) of patients and loss of urate-lowering response in 11% (16/149). Nearly all patients (98%) had at least one AE during the OLE study. Gout flares and IRs were the most frequently reported adverse events (see table below); these were less common in patients sustaining urate-lowering response to treatment and those receiving the q2wk dosing regimen. Most AEs were investigator-rated (worst category per patient) as moderate (53%) in intensity. Overall, 54 patients (36%) had AEs rated as severe; these were deemed treatment-related in 25 (17%) patients. The most common treatment-related severe AEs were IRs and flares in 11 (7.4%) and 10 (6.7%) subjects, respectively. No patients with sustained urate-lowering response to treatment had a severe treatment-related IR or a severe gout flare.

Among the 13 serious AEs considered possibly related to pegloticase, there were 11 IRs, 1 skin necrosis, and 1 nephrolithiasis. Among the 11 serious IRs, all but one (91%) occurred when serum UA exceeded 6 mg/dL. A total of 4 deaths occurred during the OLE study; all were judged as unlikely related to study drug by the investigator. Laboratory assessments (CBC, CMP and U/A) identified no significant treatment-related change from baseline (except in UA).

Adverse Events in the OLE study	All treated patients (N=149) N (%)
Subjects with any AE	146 (98)
Subjects with serious AEs	51 (34)
Subjects with serious AEs related to study drug	13 (9)
Discontinuations due to AE	11 (7)
Most common AEs (incidence >10%)	
Gout flare	106 (71)
Infusion-related reaction	65 (44)
Arthralgia	29 (20)
Upper respiratory tract infection	27 (18)
Pain in extremity	26 (17)
Back pain	25 (17)
Diarrhea	22 (15)
Peripheral edema	21 (14)
Urinary tract infection	20 (13)
Nausea	17 (11)
Headache	16 (11)
Fatigue	15 (10)
Sinusitis	15 (10)
Nasopharyngitis	15 (10)

Conclusion: The safety profile of long-term pegloticase treatment was consistent with that observed during the 6-month RCTs with no new safety signals identified. As all but one of the 11 serious IRs reported during this study occurred when the UA level was >6 mg/dL, UA should be measured prior to infusions and pegloticase should be discontinued when UA levels rise >6 mg/dL after an initial response.

Increased Serum Uric Acid: Consequence or Cause of Increased Cardiovascular Risk.
Inger L. Meek[1], Harald E. Vonkeman[1] and Mart A.F.J. van de Laar[2]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]Medisch Spectrum Twente & University of Twente, Enschede, Netherlands

Background/Purpose: Reports on cardiovascular (CV) disease in hyperuricemia and gout show conflicting results. Some studies show hyperuricemia to be an independent risk factor for CV events and death, others find no such associations or only with gouty arthritis. Gout and hyperuricemia have also been associated with individual CV risk factors such as increasing age, male sex, overweight, hypertension, dyslipidemia, diabetes and inflammation. Studies evaluating the complex associations between serum uric acid, inflammation, gouty arthritis and CV risk are lacking. This study was done to investigate the associations between serum uric acid and cardiometabolic risk factors and estimated CV risk in patients with gouty arthritis, non-gouty arthritis, and degenerative joint disease. To explore the effect of uric acid lowering therapy (ULT) on CV risk.

Methods: Analysis of the relation between serum uric acid and estimated 10-year risk of CV death (SCORE risk calculation, low risk version corrected for diabetes by increasing age with 15 years) and individual CV risk factors, i.e. systolic blood pressure (SBP), TC/HDL ratio (TC/HDL), diabetes and smoking in patients with osteoarthritis (OA, n=197), rheumatoid arthritis (RA, n=675) and gouty arthritis (GA, n=201) in a cohort of consecutive patients attending the Arthritis Center Twente in 2009. Subanalysis of the effect of uric acid lowering therapy (ULT; allopurinol or benzbromarone, target serum uric acid 0.36 mmol/L) on estimated 10-year CV risk in GA patients. Differences between groups and associations between CV risk variables and tertiles of serum uric acid were tested with ANOVA (for continuous cardiovascular risk factors) or Chi squared statistics (for nominal cardiovascular risk factors), adjusted for differences by age and sex.

Results: mean estimated 10-year CV risk was significantly higher in GA (GA 9.5% vs 5.7% in OA and RA, p<0.05). In RA and OA mean estimated 10-year cardiovascular risk as well as individual cardiometabolic parameters (OA: mean SBP, mean TC/HDL; RA: mean SBP, mean TC/HDL, prevalence diabetes. p<0.05) correlated with serum uric acid values. None of these correlations were present in GA. In GA plasma uric acid was lower in patients on ULT (0.32 mmol/l ULT vs 0.47 mmol/l non-ULT, p<0.05), age and frequency of CV events did not differ from non-ULT users. ULT did not affect mean estimated 10-year CV risk (9.7% ULT vs 8.9% non-ULT, p<0.05).

Conclusion: Gouty arthritis is a red flag for increased CV risk, as shown by higher prevalence of previous CV events and increased metabolic parameters of CV risk. Serum uric acid is associated with metabolic parameters of CV risk and 10-year risk of CV death. Effective ULT does not affect 10-year CV risk. Increased serum uric acid is therefore probably secondary to a high cardiometabolic risk profile.

162

Metabolic Syndrome: The Genesis of Nephrolithiasis in Gout Patients?
Filipi M. Mello[1], Rafael B. Tomita[2], Ricardo Fuller[2], Marco Antonio G. P. Filho[2], Thiago B. M. Barros[2], Leandro L. do Prado[2], Kristopherson L. Augusto[2] and Claudia Goldenstein-Schainberg[2]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Rheumatology Division - University of São Paulo, São Paulo, Brazil

Background/Purpose: Gout patients have a high frequency of metabolic syndrome (MS), a disorder known to be associated with hyperinsulinemia. The latter condition augments proximal tubular sodium reabsorption and leads to reduced renal urate excretion and hyperuricemia. There are no data, however, evaluating whether MS can influence gout-associated clinical characteristics. Thus, we aimed to determine the prevalence of MS in our population and to investigate if the presence of MS would characterize a particular clinical and laboratorial gout profile.

Methods: This was a cross-sectional study of 158 gout patients (ACR criteria). MS was defined in accordance to the National Cholesterol Education Program ATP III (NCEP-ATP III) and the International Diabetes Federation (IDF) criteria. Demographic, anthropometric (body mass index - BMI) and clinical data were evaluated. Fasting serum levels of UA, glucose, triglycerides and cholesterol fractions were analyzed by routine laboratory tests.

Nephrolithiasis was demonstrated by usual ultrasonography and urate under-excretion defined as UA clearance lower than 7.5 ml/min. Statistical comparisons were performed using *Fisher's exact*, chi-square, student's T and Spearman's tests and P<0.05 was considered significant.

Results: The frequency of MS in gout patients was 73% and 71% according to NCEP ATPIII and IDF criteria respectively. Further comparison of 125 patients with MS and those 33 without this condition revealed similar mean ages (63.0 ± 11.5 vs 62.5 ± 12.9; p>0,05) and male predominance (94% and 75%). As expected, those with MS had higher BMI (30.2 + 5.5kg/m2 vs 27.0 ± 5.8kg/m2; p= 0.005) and higher prevalences of systemic arterial hypertension (93.3% vs 75% p= 0.012) and diabetes (25.8% vs 0, p= 0.001), though comparable frequency of coronary artery disease (22.5% vs 16.7%; p = 0.469). With regard to gout clinical/laboratorial characteristic, patients with MS had more nephrolitiasis (37.1% vs 16.7%, p= 0.026), but they did not differ from patients without MS concerning the presence of tophi (52.8% vs. 55.6%; p= 0.780) or uric acid underexcretion (83.1% vs 94.4%; p= 0.148). Current alcohol consumption, mean estimated creatinine clearance and mean serum levels of uric acid, were alike in both groups (p>0.05).

Conclusion: The novel demonstration that MS in gout is associated to nephrolithiasis suggests that this condition may underlie the genesis of uric acid stones. Whether insulin resistance may account for a renal alteration that may ultimately impair buffering and amplification of acidic urine remains to be determined. Moreover, the elevated prevalence of MS in gout patients from our country (almost ¾) is higher than overall rates of 63% MS in gout worldwide, indicating possible influence of dietary, geographical and/or genetic background.

Evaluating Allopurinol Therapy and Serum Uric Acid Levels in Medicare Beneficiaries with Gout.
Melea Ward[1], Anthony M. Louder[2], Keith A. Szymanski[3] and Leonardo Tamariz[4]. [1]Competitive Health Analytics, Louisville, KY, [2]Competitive Health Analytics, Inc., Louisville, KY, [3]Takeda Pharmaceuticals America, Inc., Deerfield, IL, [4]University of Miami, Miami, FL

Background/Purpose: Higher serum uric acid levels in gout patients have been associated with an increased frequency and risk of gout flares and greater subsequent healthcare costs. Despite the wide availability of allopurinol, achieving a therapeutic serum uric acid (sUA) level remains problematic for clinicians and patients. The objectives of this study included identifying predictors of an sUA response to allopurinol and investigating the associated healthcare costs.

Methods: A retrospective cohort study of a large health benefits company was conducted among Medicare Advantage Prescription Drug (MAPD) plan patients with gout newly initiated on allopurinol between 1/1/08 and 12/31/10. Patients were separated into two cohorts defined by their sUA response to allopurinol (sUA < 6 mg/dL or sUA > 6 mg/dL). Mean allopurinol adherence, as measured by proportion of days covered (PDC), was reported at 12 months follow-up. Multivariate logistic regression was used to determine factors associated with allopurinol response. A generalized linear model was developed to assess the association between allopurinol response and total healthcare costs.

Results: Of the 2,703 patients initiated on allopurinol, 57% had a baseline sUA and 33% had sUA ≤ 6 mg/dL in the follow-up period. Higher adherence was associated with achieving an sUA < 6 mg/dL compared to > 6 mg/dL (PDC=0.74 and 0.59, respectively, p<.0001). Predictors of sUA < 6 mg/dL included female sex, higher allopurinol PDC, and allopurinol dose >100 mg/day (OR:1.74, CI:1.41–2.13; OR:12.28, CI:8.25–18.28; OR:5.84, CI: 4.73–7.20, respectively). Hispanic ethnicity, higher baseline sUA, renal impairment (Stage 3 vs. Stage 1), colchicine use, and NSAID use were associated with lower odds of responding to allopurinol therapy (OR:0.32, CI:0.14–0.76; OR:0.60, CI:0.56–0.66; OR:0.41, CI:0.30–0.55; OR:0.79, CI:0.65–0.97; OR:0.68, CI:0.55–0.85, respectively). There were no significant differences in total healthcare costs between the two cohorts.

Conclusion: A large percentage of patients initiated on allopurinol did not have adequate sUA monitoring, and did not achieve an sUA < 6 mg/dL. Drivers of a therapeutic response included increased adherence and dose escalation. This study demonstrates that ample opportunity exists for clinicians and patients to improve sUA monitoring and treatment adherence when initiating urate lowering therapy.

The Prevalence of Gout in a Large Tertiary Hospital and the Impact of in-Hospital Attacks of Acute Gout On Patient Outcomes and Health Resource Utilisation – a Nested Case-Control Study.
John HY Moi[1], Mark Tacey[1], Carol Roberts[2], Caroline Brand[1], Alexandra Gorelik[2] and Sharon Van Doornum[1]. [1]The Royal Melbourne Hospital, The University of Melbourne, Melbourne, Australia, [2]The Royal Melbourne Hospital, Melbourne, Australia

Background/Purpose: Acute gout can develop in hospitalised patients either as a new event or as a recurrence of established disease. To date there have been no studies examining the effect of in-hospital acute gout on hospital length of stay (LOS) or health resource utilisation. This study was performed to investigate the burden of gout in a hospitalised population and to assess the impact of acute gout on patient outcomes and health resource utilisation.

Methods: The study utilised hospital administrative data from The Royal Melbourne Hospital, Victoria over a ten year period (1 January 2001 to 31 December 2010). Gout was defined according to The International Statistical Classification of Diseases and Related Health Problems, 10th Revision, Australian Modification (ICD-10-AM) codes and subdivided into three categories: 'P-gout' (gout was the primary reason for admission or was a pre-existing condition requiring treatment initiation/adjustment during admission), 'C-gout' (gout occurred as a complication during hospitalisation and was not a pre-existing condition), or 'A-gout' (gout was an associated diagnosis and did not require specific treatment during admission). The overall burden of gout was measured by determining the prevalence of gout diagnoses affecting all hospital admissions (excluding day case admissions) over the study period. The effect of acute gout on patient outcomes and health resource utilisation was measured in a nested case control study with matching of 'C-gout' patients to controls (ratio of 1:5) by age, gender, and principal diagnosis. Outcome measures included LOS, 28-day hospital readmission rates, and total number of hospital days in the 12 months post hospital discharge. For comparisons between 'C-gout' and matched control cases, the student T-test or Wilcoxon ranksum test for continuous data and Chi[2]test for categorical data were used. A p-value of <0.05 was considered significant.

Results: There were 278,491 multi-day hospital admission episodes during the 10 year study period. Of these, 1,400 (0.5%) had an ICD-10-AM code for gout ('P-gout'=1,058, 'C-gout'=307 and 'A-gout'=35). A steady increase in the annual burden of gout of 0.22% over 10 years was noted. Patients who experienced an in-hospital attack of acute gout had a substantially longer LOS than the controls (median 13 days (IQR 7–25) vs. 5 days (IQR 2–11), p<0.001) and also had higher readmission rates in the first 28-days (p=0.002) and during the first 12 months (p<0.001) of hospital discharge.

Conclusion: Our study demonstrates a growing burden of in-hospital gout attacks and increased utilisation of health resources in patients who experience acute gout as a complication of their hospital stay. It was not possible from the design of our study to exclude other potential confounding factors which may have contributed to the observed increased hospital LOS.

Colchicine Is Associated with a Decreased Rate of Myocardial Infarction in Gout Patients: Interim Results From a Retrospective Cohort Study.
Daria B. Crittenden[1], Cilian J. White[1], Michael DeBerardine[1], Grace Kim[1], Binita Shah[2], Jessica C. Kimmel[1], Rima D. Patel[1], Steven P. Sedlis[2], Jeffrey D. Greenberg[1], Craig T. Tenner[3], Bruce N. Cronstein[1] and Michael H. Pillinger[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]NYU School of Medicine, Division of Cardiology, New York, NY, [3]NYU School of Medicine, Department of Internal Medicine, New York, NY

Background/Purpose: Atherosclerosis is an inflammatory process, but to date no anti-inflammatory agent has definitively been shown to alter cardiovascular (CV) risk. Colchicine is an anti-inflammatory agent that

inhibits macrophages, endothelial cells, and neutrophils, all implicated in atherosclerosis. In a cross-sectional study, we found that colchicine use was associated with reduced prevalence of myocardial infarction (MI) in gout patients [1]. To further evaluate the relationship between colchicine and CV risk, we initiated a retrospective cohort study. Here we present an interim analysis.

Methods: We identified all active New York Harbor VA patients with an assigned ICD-9 code for gout or hyperuricemia between 2000-09. Charts were manually screened to confirm a diagnosis of gout utilizing ACR criteria, and pharmacy records were used to identify subjects on daily colchicine for $\geq$ 30 days (colchicine group). Subjects receiving no colchicine prescriptions formed the control group. Baseline characteristics including CV risk factors and medication use were ascertained. We excluded patients who did not meet our diagnostic criteria for gout, who received as-needed colchicine only, or with $\leq$ 3 months of follow-up time available for evaluation. We defined colchicine lapse as any period of non-colchicine use beginning 2 weeks after medication cessation (to account for the elimination time of the drug). The primary outcome was MI during the study period.

Results: 7819 subjects had requisite ICD-9 codes. Among 1031 charts reviewed to date, 214 patients met gout criteria and 183 were enrolled. Of these, 121 subjects (66%) used colchicine (totaling 363.8 patient-years of exposure) and 62 subjects (34%) used no colchicine (totaling 249.8 patient-years of follow-up). Colchicine and control groups had similar rates of hypertension (0.85 vs 0.92, p=0.2), diabetes (0.37 vs 0.3, p=0.4), hyperlipidemia (0.66 vs 0.56, p=0.3), coronary artery disease (0.29 vs 0.37, p= 0.3), and allopurinol use (0.22 vs 0.21, p= 1.0), as well as similar BMI (30.6 vs 29.8, p=0.3), serum urate (8.4 vs 8.2 mg/dL, p=0.6), and creatinine (1.3 vs 1.4 mg/dL, p=0.7). Colchicine users experienced no MIs while on their medication. In contrast, control patients had 4 MIs (0 vs 6.4%; p=0.01), and 3 MIs occurred during colchicine lapses (3%; lapse vs colchicine p=0.09; lapse vs control p=0.43; mean time from last colchicine use to MI 5.9 months). We also compared rates of MI per patient-year between colchicine exposure (0.0), control follow-up (0.016), and colchicine lapse follow-up (0.018) periods, and observed significant differences between colchicine vs control (p=0.036) and colchicine vs lapse (p=0.035), but not between control vs lapse group MI rates (p=0.26).

Conclusion: In this interim analysis, gout patients taking colchicine had a significantly reduced rate of MI vs non-users, and vs themselves during periods when not taking colchicine. These data suggest that colchicine is protective against MI, though probably only during active use. Evaluation of the remaining 6,788 patients is ongoing.

Low-Dose Allopurinol Promotes Greater Serum Urate Lowering in Gout Patients with Chronic Kidney Disease Vs Normal Renal Function.

Michael DeBerardine[1], Mark C. Fisher[2], Robert T. Keenan[3], Michael H. Pillinger[1] and Daria B. Crittenden[1]. [1]NYU School of Medicine, Division of Rheumatology, New York, NY, [2]Massachusetts General Hospital, Boston, MA, [3]Duke University, Durham, NC

Background/Purpose: Patients with chronic kidney disease (CKD) may be at increased risk for allopurinol (ALLO) hypersensitivity, possibly because impaired renal excretion causes accumulation of the active ALLO metabolite oxypurinol (OXY). For this reason, lower doses of ALLO are recommended when initiating urate lowering in CKD patients. OXY accumulation suggests that ALLO should also be more efficacious in CKD patients, a hypothesis not previously tested. We therefore assessed whether ALLO is more effective at lowering serum urate (sUA) in patients with CKD vs those with normal renal function.

Methods: Using the electronic medical record of the NY Harbor VA Health Care System, we identified all gout patients taking 100 mg or 300 mg of ALLO daily between August 2007 and August 2008 for whom both pre- and post-treatment sUAs were available. ALLO use was identified using pharmacy records and confirmed by individual chart review. Baseline characteristics were obtained. Patients in each ALLO dose group were categorized by National Kidney Foundation stages, and mean change in sUA for each ALLO dose according to CKD stage was determined.
Results: Among 1288 charts reviewed, 199 patients met entry criteria and had sufficient data to permit evaluation. 95 patients were taking 100 mg and 104 were taking 300 mg ALLO daily. 100 mg vs 300 mg groups were similar in age (71.4±1.2 vs 68.7±1.1 years) and BMI (29.1±0.6 vs 30.9±0.6). Overall, patients taking 300 mg experienced a trend toward greater sUA decrease vs those taking 100 mg (2.9±0.2 vs 2.5±0.2 mg/dL, p=0.13), resulting in a lower post-treatment mean sUA in the 300 mg group (7.0±0.2 mg/dL for 100 mg dose, 6.1±0.2 mg/dL for 300 mg dose, p=0.001). Across increasing degrees of renal insufficiency, mean decreases of sUA in patients taking 300 mg did not change significantly. In contrast, in patients taking 100 mg, decreases in sUA (in mg/dL) increased progressively from stage I to V CKD: stage I (n=10) sUA decrease = 1.7±0.6, stage II (n=25) = 2.4±0.4, stage III (n=46) = 2.7±0.4, stage IV (n=8) = 2.5±0.9, stage V (n=6) = 3.1±0.6. Whereas patients with normal renal function (stage I) experienced greater sUA lowering with 300 mg vs 100 mg (3.4±0.7 vs 1.7±0.6 mg/dL, p=0.04), 100 mg ALLO was as efficacious as the 300 mg dose in patients with stage V CKD (sUA decrease 3.1±0.6 vs 3.1±0.2 mg/dL, p=0.5).

Conclusion: In patients with gout, low-dose ALLO is progressively more effective for sUA lowering in proportion to increasing degrees of renal insufficiency, presumably owing to OXY accumulation. No such effect was seen at the 300 mg dose, suggesting that sUA-lowering effects may reach a ceiling in CKD patients. These data support the strategy of starting gout patients with CKD on low-dose ALLO and titrating upwards only as needed, not only to minimize toxicity, but also because lower doses may be more effective in CKD patients, and higher doses may confer little or no additional benefit.

167

Serum Uric Acid Control and Risk of Flare According to Different Cut-Offs in Patients with Gout: Longitudinal Analysis From the King Study of the Italian Society for Rheumatology. Maria Manara[1], Carlo Alberto Scirè[2], Marco A. Cimmino[3], Marcello Govoni[4], Fausto Salaffi[5], Greta Carrara[1], Carlomaurizio Montecucco[6], Marco Matucci-Cerinic[7], Giovanni Minisola[8] and Kick-off of the Italina Network for Gout (KING) Study Group[9]. [1]Epidemiology Unit -Italian Society for Rheumatology, Milano, Italy, [2]Epidemiology Unit -Italian Society for Rheumatology, Milan, Italy, [3]Rheumatology - Department of Internal Medicine - University of Genoa, Genova, Italy, [4]Section of Rheumatology - Department of Clinical and Experimental Medicine - University of Ferrara, Ferrara, Italy, [5]Rheumatology Unit - Polytechnic University of the Marche, Jesi, Italy, [6]Division of Rheumatology - University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [7]Department of Biomedicine & Division of Rheumatology AOUC - University of Florence, Florence, Italy, [8]Rheumatology Unit - San Camillo Forlanini Hospital, Rome, Italy, [9]SIR, Italy

Background/Purpose: The therapeutic goal of the management of gout is to promote crystal dissolution and prevent crystal formation. For this reason national and international guidelines recommend to maintain the serum uric acid (sUA) below the saturation point for monosodium urate (from 5 to 6.38 mg/dl). In this analysis we evaluated the influence of different sUA levels on the risk of acute attack in an observational setting.

Methods: This is a longitudinal analysis of an ongoing multicentre cohort study including 450 patients with prevalent clinically diagnosed gout from 30 rheumatology centers across Italy (Kick-off of the Italian Network for Gout, KING, promoted by the Italian Society for Rheumatology - SIR; NCT01549210) recruited from June 2011 and January 2012. Participants were centrally selected from clinical registers by random sampling. All patients underwent full clinical evaluation at baseline, including general and disease-specific characteristics. During the first 6 months of follow-up the number of flares, sUA and concurrent treatment were collected.

The relationship between sUA and risk of flare was analyzed using logistic models on complete data, and estimation of the risk of flare is presented as odds ratios (OR) and 95% confidence intervals (CI). The optimal cut-off of sUA was explored by identifying the minimum cut-off associated with a significant increase of risk of flare.

Results: A total of 178 patients were included in the analyses: 92.7% were male with a mean (SD) age of 64.5 (10.9) years, 22.9% had tophaceous and 18.7% polyarticular disease. Mean (SD) sUA was 6.1 (1.6) mg/dl, of which 26.9% $<$5mg/dl, 26.4% from 5–6mg/dl, 16.8% from 6–7mg/dl and 29.8 above 7mg/dl. During the follow-up of 6 months 60 patients (33.7%) presented at least one flare with a total of 140 flares.

SUA levels were linearly associated with an increased risk of flare: OR[95%CI] of 1.39 [1.13,1.71] per each mg/dl increase. The adjusted analyses confirmed a similar increase of risk of flare regardless of changes in urate-lowering therapy or prophylactic treatment: OR 1.38 [1.12,1.71]. The minimum cut-off associated with a significant increase of risk of flare was 5.9 mg/dl with an OR of 1.90 [1.01,3.59]. Consistently, using sUA$<$5mg/dl as reference category, 5–6mg/dl was not associated with a significant increase of risk of flare (OR 1.54 [0.60, 4.15]) while 6–7mg/dl and $>$7mg/dl were associated with significant ORs: 2.90 [1.03,8.16] and 3.52 [1.43,8.62], respectively.
Conclusion: The optimal management of gouty patients requires strict control of serum uric acid levels. A virtual absence of risk of flare is associated with levels of uric acid levels below 4mg/dl, but the operative cut-off of 6mg/dl is a robust limit to discriminate patients with increased risk of relapse.

Allopurinol Use Is Associated with a Decreased Risk of Myocardial Infarction. Lamiae Grimaldi-Bensouda[1], Annick Alpérovitch[2], Elodie Aubrun[1], Nicolas Danchin[3], Michel Rossignol[4], Lucien Abenhaim[5], Pascal Richette[6] and PGRx MI Group[7]. [1]LA-SER, Paris, France, [2]Inserm U708-Neuroepidemiology, La Pitié-Salpêtrière Hospital, Paris, France, [3]Coronary disease unit, Georges Pompidou European Hospital, Assistance Publique-Hôpitaux de Paris and Paris-Descartes University, Paris, France, [4]LA-SER, Centre for Risk Research, Montreal, [5]LA-SER Europe Ltd, London, United Kingdom, [6]Lariboisière Hospital, Paris, France, [7]Paris, France

Background/Purpose: Xanthine oxidase inhibitors (XOI) reduce both urate levels and the oxidative stress in the vasculature, which are known cardiovascular risk factors. However, the effects of XOI on major cardiac events such as myocardial infarction (MI) are unknown. The objective was to investigate whether XOI use is associated with a modified risk of myocardial infarction.

Methods: We used a matched case-control study comparing patients with first ever MI with controls. Cases were retrieved from a myocardial infarction registry consisting of 63 cardiology centers, whereas controls were selected from general practice settings. The association between XOI or colchicine use and MI was assessed by adjusted OR from conditional logistic regression.

Results: Data are from 2277 MI patients matched to 4849 controls. Allopurinol was by far the most frequent XOI taken by participants of this study. The adjusted OR (95% CI) for MI in allopurinol users was 0.75 (0.56–1.01), and it was 0.66 (0.49–0.89) using the whole pool of referents (n=8444). The effect of allopurinol persisted across subgroups by sex, presence of hypertension, and in ST-segment elevation MI patients. In contrast, colchicine use was not associated with a modified risk of MI: aOR= 1.17 (0.70–1.93).

Conclusion: Allopurinol, but not colchicine use, is associated with around a 30% reduction in the risk of myocardial infarction. Besides its urate lowering property, allopurinol might have a cardio protective effect.

Disclosure: L. Grimaldi-Bensouda, None; **A. Alpérovitch**, None; **E. Aubrun**, None; **N. Danchin**, None; **M. Rossignol**, None; **L. Abenhaim**, None; **P. Richette**, None;

Post-Marketing Safety Surveillance Data Reveals Patterns of Use for Pegloticase in Refractory Chronic Gout. Kenneth M. Bahrt, Anthony E. Yeo, Tina L. Howson and Faith D. Ottery. Savient Pharmaceuticals, Inc., East Brunswick, NJ

Background/Purpose: Pegloticase is a recombinant modified mammalian uricase conjugated to mPEG which was approved in the US in 2010 for treating hyperuricemia in patients with refractory chronic gout. The pegloticase development program comprised 2 randomized, placebo-controlled trials (6 months; N=212) followed by an open-label extension study for a total treatment duration of up to 3 years. Trial entry was preceded by a 1 week washout period for urate-lowering therapies. Patients were considered "responders" if they met the primary efficacy endpoint of uric acid (UA) $<$6 mg/dL for 80% of time during months 3 and 6. 42% of patients met this definition (vs. 0% with placebo; p$<$0.001) in the randomized trials[1].

Post-hoc analyses revealed a significant relationship between a loss of urate-lowering response to therapy and the presence of high titer anti-pegloticase antibodies. Loss of response was also associated with increased risk of infusion reactions (IRs). Further analyses confirmed that the great majority of IRs occurred in patients who had already lost their urate-lowering response to therapy (20/22 or 91% for patients receiving pegloticase 8 mg q2wks and 24/34 or 71% for patients treated q4wks). These two findings led to clear guidance that patients treated with pegloticase should discontinue treatment if UA levels rose above 6 mg/dL (particularly with 2 consecutive levels $>$6 mg/dL). New information provided by post-marketing pharmaco-

vigilance suggests a relationship between serum UA levels <6 mg/dL, IRs and concomitant use of xanthine oxidase inhibitors (XOIs).

Methods: Post-marketing AE data were collected as standard, unsolicited reporting and summarized from September 14, 2010 to November 30, 2011 to evaluate concomitant XOI use.

Results: During approximately one year of commercial pegloticase use in the US, IRs were reported in 20 patients and anaphylaxis in 8 patients. Among the reports of IRs, 8 patients had UA >6, 7 had UA <6 and UA was unknown at the time of the IR in 5. Among the reports of anaphylaxis, 4 patients had UA levels >6, 2 had UA levels <6 and 2 had unknown UA. Importantly, AE reporting revealed that 40% of patients (8/20 IRs and 3/8 cases recorded as anaphylaxis) were receiving one or both XOIs in addition to pegloticase. Details of these 11 patients are provided in the table.

Patients with infusion reactions receiving concomitant XOIs

ID	SUA on XOI	Infusion #	Previous SUA	Demographic
Patient A	8.2 mg/dL on febuxostat	3rd	Previous infusion 5-6 mg/dL range	Caucasian male, unspecified age
Patient B	3.4 mg/dL on febuxostat	2nd	4.1 mg/dL at baseline on febuxostat	87 year old (yo) white male
Patient C	9.5 mg/dL on febuxostat	3rd	Previous 4.5 mg/dL prior to 2nd infusion	49 yo Caucasian male
Patient D	undetectable on febuxostat	3rd	Previous very low (unspecified)	57 yo Caucasian male
Patient E	8.6 mg/dL on allopurinol	4th	Previous 5.2 mg/dL prior to 3rd infusion	55 yo Caucasian male
Patient F	6.8 mg/dL on allopurinol	3rd	Previous 1.3 prior to 2nd infusion	31 yo male, of unknown origin
Patient G	5.5 mg/dL on both XOIs	3rd or 4th	Previous 5.3 mg/dL	38 yo Caucasian male
Patient H	7.4 mg/dL on both XOIs	3rd	Previous 4.6 mg/dL prior to 2nd infusion	42 yo African-American male

Patients with anaphylaxis receiving concomitant XOIs

ID	SUA on XOI	Infusion #	Previous SUA	Demographic
Patient I	6.7 mg/dL on allopurinol	3rd	Previous 7.6 mg/dL but had missed appt	58 yo white male
Patient J	4.3 mg/dL on allopurinol	2nd	Previous 4.3 mg/dL prior to 2nd	60 yo white male
Patient K	7.1 mg/dL on febuxostat	3rd	Previous <0.5 prior to ??2nd infusion	47 yo white male

Conclusion: Post-marketing adverse event reporting provided valuable information regarding pegloticase administration in the real world setting. Importantly, the use of concomitant urate-lowering therapies has the potential to mask the rise of UA levels in patients treated with pegloticase and confound the use of UA as a biomarker of response. XOIs should be discontinued prior to initiation of pegloticase and not restarted while on treatment. Further, UA monitoring and discontinuation of pegloticase upon loss of efficacy are critical to safe and effective care.

Relative Risk of Infusion Reactions with KRYSTEXXA® (pegloticase) From Post-Approval Safety Data: Results From Sept 2010 to June 2012. Raymond L. Malamet, Tina L. Howson, Anthony E. Yeo, Kenneth M. Bahrt and Marsha Wolfson. Savient Pharmaceuticals, Inc., East Brunswick, NJ

Background/Purpose: During randomized clinical trials (RCTs) with pegloticase, the incidence of infusion-related reactions (IRs) was 26% including 5 cases of anaphylaxis (determined post-hoc using published criteria).[1,2] Post-hoc analyses revealed a relationship between loss of urate-lowering response and IRs. This relationship could not have been detected during the trials as investigators were blinded to pre-infusion uric acid (UA) values. These analyses led to guidance on measuring UA levels as a biomarker of therapeutic response and IR risk, and included the recommendation that patients discontinue pegloticase if serum uric acid (UA) was >6 mg/dL, particularly at 2 consecutive q2wk infusions.[3] In order to determine whether this guidance was effective in reducing the incidence of IRs, the company reviewed IRs from post-approval safety data.

Methods: We estimated the incidence of IRs by comparing usage information from the RCTs and the post-approval period (Sept 14, 2010 to June 1, 2012). An estimate of the total number of infusions given in the post-approval period was derived from the number of vials sold during that period compared to the number administered to a defined number of patients in the 6-month RCTs.

Results: 852 individual vials for infusion were administered to the 85 patients receiving the approved dose of pegloticase during the RCTs (8 mg every 2 weeks) and there were 22 reports of IRs (see Table). During the post-approval period, 5727 vials were sold and the company received 58 reports of IRs and anaphylaxis (43 reports of IRs, 15 reports of anaphylaxis). The above information was used to estimate the relative risk reduction for IRs during the post-approval period compared with the RCTs period. When determined this way, there was a 61% reduction (95% CI: 36.3 to 75.9) in the risk of IR during the post-approval period vs. the RCTs.

While providing evidence for relatively low rates of IRs, these estimates have substantial limitations. The actual number of patients receiving infusions is difficult to estimate from vials sold. In addition, the number of IRs depends on voluntary reporting and some adverse events are reported to the FDA and not to the company. Finally, these estimates are valid only for the time period of collection as practice patterns may change with accrued clinical experience.

	IR present	IR absent	Total
Post-approval safety surveillance	58	5669	5727
Pooled RCTs	22	830	852
Totals	80	6499	6579

Conclusion: The risk of IRs estimated for pegloticase during a defined post-approval period was reduced by 61% relative to rates of IRs seen in the RCTs. Post-approval surveillance will continue to assess whether IR risk is adequately mitigated by adherence to the recommended stopping rules based on elevated serum UA. Additional real world data with pegloticase, collected over a longer time period, should provide more robust estimates of IRs that can be compared to the clinical trials experience.

Disease Modifying Agents Combined with Isoniazid for Latent Tuberculosis in Patients with Rheumatic Diseases. Josiane Bourré-Tessier[1], Mireia Ariño i Torregrosa[2] and Denis Choquette[3]. [1]Institut de Rhumatologie de Montréal, Université de Montréal, Montréal, QC, [2]Universitat de Valencia, Massanassa, Spain, [3]University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC

Background/Purpose: Reactivation of latent tuberculosis (LTB) has been described with the use of anti-TNF for the treatment of rheumatic diseases. Combined treatment of isoniazid (INH) and DMARDs such as methotrexate (MTX) and sulfasalazine (SSZ) can potentially increase the risk of liver toxicity. The goal of this study was to investigate the risk of liver toxicity in rheumatic patients taking isoniazid (INH) and disease modifying agents (DMARDs) or biologics.

Methods: We reviewed the Institut de Rhumatologie de Montréal database (RhumaData®) for rheumatic patients with positive tuberculin skin test who took INH and at least one concomitant DMARD or biologic between August 2001 and April 2011. Liver function tests (LFT) were tested at baseline and during therapy.

Results: Of 922 patients screened with tuberculin skin test, 87 patients tested positive and received INH. During INH treatment, 75.9% were taking concomitant DMARDs (71.3% MTX, 19.5% hydroxychloroquine (HCQ), 5.7% SSZ, 3.4% leflunomide), 82.0% were taking concomitant biologics, and 46.0% were using NSAIDs on a regular basis. Twenty-four percent had

abnormal liver enzymes during INH therapy. Most of them were mild or transient, but 8% (7 patients) had significant abnormalities leading to INH discontinuation. Among these patients, mean (min, max) was 241 (52, 617) for AST and 262 (92, 669) for ALT. Concomitant medications taken by patients who stopped INH were: biologics (4 patients), MTX (1), biologic and MTX (1), biologic, leflunomide and HCQ (1).

Conclusion: The use of INH for LTB was generally well tolerated in patients with rheumatic diseases on a background regimen of DMARDs or biologics. However, the rate of significant abnormalities is our study is higher than the reported rates for INH hepatitis in the literature. There is no evident association between liver anomalies and specific combination with DMARDs. Therefore, it is prudent to follow LFT closely on patients taking combination therapy.

A Systematic Review and Meta-Analysis of Antibiotic Treatment for Reactive Arthritis. Claire E. Barber[1], Joseph Kim[2], R. D. Inman[3], John Esdaile[4] and Matthew T. James[5]. [1]University of Calgary, Calgary, AB, [2]University of Calgary, Calgary, [3]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [4]University of British Columbia, Vancouver, BC, [5]Univeristy of Calgary, Calgary

Background/Purpose: Although bacterial infections are a common precipitant, it is unclear whether antibiotic treatment is effective for reactive arthritis. The purpose of this study was to conduct a systematic review and meta-analysis of randomized controlled trials to examine the efficacy and safety of antibiotic treatments for reactive arthritis.

Methods: Medline, Embase, Pubmed, Cochrane CENTRAL Register of Controlled trials were searched up to November 2011 using MeSH terms and keywords pertaining to two major themes: *reactive arthritis* and *antibiotic therapy.*Randomized controlled trials of antibiotic use for reactive arthritis reporting on: remission, joint counts, pain or patient global scores were included. Two reviewers independently extracted information on the definition of reactive arthritis, features of study quality, type of treatment and outcomes. Pooled relative risks for binary outcomes (failure to achieve remission and adverse events) and pooled mean differences for continuous variables (joint counts, pain and patient global scores) were computed. Potential sources of heterogeneity were investigated using stratified analyses and meta-regression.

Results: Twelve trials were eligible for inclusion and 10 provided adequate data for meta-analysis. The pooled relative risk of failure to achieve remission from a random effects model showed no significant benefit of antibiotic treatment (seven trials, 375 participants RR 0.74, 95% CI 0.49–1.10); however, substantial heterogeneity was observed ($I^2=76.3\%$, $p<0.0001$). The treatment effect did not significantly differ by the type of organism triggering the reactive arthritis (*Chlamydia* versus other), use of combination versus mono-therapy, or risk of bias. However, when only blinded trials were pooled, the treatment effect was attenuated and heterogeneity decreased significantly (RR 0.87, 95% CI 0.70–1.10, $I^2=32.8\%$, $p=0.19$). No significant effects of antibiotic treatment were observed on swollen joint counts (six trials, 375 participants weighted mean difference 0.21, 95% CI 1.16, 0.75, $I^2=82.9\%$, $p<0.0001$) tender joint counts (five trials, 326 participants, standardized mean difference 0.10, 95% CI -0.58, 0.78, I^2 86.9%, $p<0.0001$), pain (three trials, 220 participants, standardized mean difference 0.16, 95% CI -0.15, 0.46, I^2 12.6%, $p= 0.381$), or patient global scores (four trials, 284 participants, standardized mean difference 0.15, 95% CI -0.08, 0.39, I^2 0.0%, $p= 0.499$); however, antibiotics were associated with a 97% increase in gastrointestinal adverse events.

Conclusion: Trials of antibiotic treatment for reactive arthritis have produced heterogeneous results which may be related to differences in study quality. The current evidence base does not support the use of antibiotics in routine clinical practice for the management of reactive arthritis.

173

Latent Tuberculosis Screening and Treatment in Rheumatoid Arthritis Patients Eligible for Anti-TNF Therapy in Endemic Areas: Does It Work? Ieda Laurindo, Ana C. M. Ribeiro, Julio C. B. Moraes, Carla G.S. Saad, Karina Rossi Bonfiglioli, Fernando H.C. Souza, Ana L. G. Calich, Mariana G. Waisberg, Lissiane K. N. Guedes and Eloisa Bonfa. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: Background: Current recommendations for latent tuberculosis infection (LTB) screening and treatment in patients eligible for anti-TNF agents are not well established in endemic regions. Thus, the aim of this study is to evaluate the long-term efficacy of LTB screening and treatment in RA patients under TNF blockers tight control therapeutic strategy.

Methods: Two hundred and two RA patients (1987 criteria) eligible for anti-TNF agents were initially screened for LTB by PPD test, chest X-ray and history of contact. Two hundred and nine patients receiving traditional DMARDs comprised the control group. Patients and controls were regularly followed at 1–3 months interval, from January 2007 to December 2011. During the study period, PPD was repeated in patients with TB clinical suspicion or due to extended (>12 months) interruption/re-start of biologic treatment.

Results: 202 patients were treated with anti-TNF blockers, 85(42%) with one agent and 117(58%) with two or more: 181 received infliximab, 93 adalimumab and 75 etanercept. LTB screening (PPD and/or history of contact and/or X-ray) was positive in 69(34%) patients. In 65%(45 patients) PPD was positive, 36%(n=25) had history of contact and 21%(n=15) with X-ray alterations. Of note, in the 24 LTB patients with negative PPD, contact history accounted for 75% and X-ray for 37% of the positive screened cases. LTB treatment with isoniazid during 6 months was administered to all positive screened patients and none developed TB during follow-up. Regarding the 133 remaining screening negative patients none had TB during the first twelve months of anti-TNF therapy. PPD test was repeated in only 53 patients (26%) due to interruption/re-start of biologic treatment (51cases) or clinical TB suspicion (2 cases). PPD turned out to be positive in five patients: three that received LTB treatment and the two patients with clinical TB suspicion, both diagnosed as active TB (after 14 and 36 months of anti-TNF treatment) and properly treated with standard TB treatment. In those RA patients under traditional DMARDs, three cases (1.5%) of active TB were observed. Thus, the frequency of TB in RA patients during five years of observation was similar in patients under biological and traditional DMARDs (1% vs. 1.5%, p=0.68), although higher than the expected for the area (60/100,000/ per year).

Conclusion: The present study provided evidence that the recommended screening and treatment protocol for LTB in patients under anti-TNF treatment was also efficient in endemic areas, with a special attention to contact history in those with negative PPD. Active TB diagnosis during anti-TNF treatment seems not to be related to screening failure, reinforcing the importance of constant clinical surveillance.

Prevalence, Risk Factors, and Functional Impact of Arthralgias Among Patients with Chronic Hepatitis C Virus Infection. Samir Bhangle[1], Vincent Lo Re[1], W. Gina Pang[1], Kyong-Mi Chang[2], Valerianna Amorosa[2], Jay Kostman[1], H. Ralph Schumacher[3] and Alexis Ogdie[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]Philadelphia VA Medical Center, Philadelphia, PA, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA

Background/Purpose: The prevalence, risk factors and functional impact of joint pain are not well described in chronic hepatitis C virus (HCV)-infected patients, particularly in the setting of human immunodeficiency virus (HIV) coinfection. Our objectives were to determine if the prevalence of arthralgias was higher among chronic HCV-infected patients compared to HIV/HCV-coinfected persons and those with HIV alone, and to evaluate the risk factors and functional impact of joint pain in chronic HCV patients.

Methods: A cross-sectional study was performed among patients with chronic HCV infection aged 18–80 years followed at the infectious disease and hepatology clinics. Patients with HIV infection seen in the same clinics were enrolled as a comparison group. HIV was chosen as a comparison given that it is a chronic infection with similar risk factors. Joint pain was defined by patient self-report. Standardized interviews by trained personnel were conducted and the Multidimensional Health Assessment Questionnaire (MD-HAQ) was administered to assess the impact of joint pain on physical function and emotional well-being. The electronic medical records of all participants were reviewed up to the date of study visit to abstract relevant clinical data for hypothesized risk factors.

Results: Of the 210 patients enrolled, 178 had HCV infection (90 mono, 88 co-infected with HIV) and 32 had HIV only. Joint pain was reported by 63/90 (70%) of the HCV-mono-infected, 48/88 (54%) of the HCV-co-

infected, and 17/32 (53%) of the HIV-mono-infected patients. The MD-HAQ results in the 178 HCV-infected patients demonstrated a mean pain score of 5.9/10, mean physical function score 2.5/10, mean global assessment of function 4.2/10, and mean RAPID3 12.7. No differences were observed between subjects with and without joint pain with regards to age (p=0.62), sex (p=0.53), race (p=0.32), and clinical site (p=0.32). Differences in clinical characteristics among those with and without joint pain among patients with chronic HCV infection are displayed in the table below.

Analysis of Potential Risk Factors Among Patients with Chronic HCV

	HCV (mono and co-infected) N= 178 (%)	Joint pain N= 111 (%)	No Joint pain N= 67 (%)	P value
Current HCV treatment	23 (13)	15 (14)	8 (12)	NS*
HIV	88 (49)	48 (43)	40 (60)	0.03
Genotype 1	135 (76)	86 (77)	49 (73)	NS
2	6 (12)	2 (2)	4 (6)	
3	6 (12)	2 (2)	4 (6)	
Smoking	65 (37)	52 (47)	13 (19)	<0.001
Alcohol	5 (3)	5 (5)	0	0.07
Sleep Disturbance	85 (48)	74 (67)	11 (16)	<0.001
Dry eyes	25 (14)	24 (22)	1 (2)	<0.001
Dry mouth	55 (31)	50 (45)	5 (8)	<0.001
Peripheral neuropathy	37 (21)	37 (33)	0 (0)	<0.001
Myalgia	36 (20)	36 (32)	0 (0)	<0.001
Depression	70 (39)	60 (54)	10 (15)	<0.001
Anxiety	79 (44)	70 (63)	9 (13)	<0.001
AST†, Mean (SD)	63.8 (50.5)	67.9 (5.5)	57 (4.9)	NS
ALT†, Mean (SD)	58.8 (48.7)	59.8 (5.0)	57.2 (5.6)	NS
HCV viral load, Mean (SD)	3.1 million (6.8)	3.3 million (7.9)	2.8 million (4.2)	NS

*NS: p-value>0.05, †AST= alanine amino transferase and ALT= alanine amino transferase.

Conclusion: Joint pain was common (62%) among patients with chronic HCV and was associated with diminished functional status and emotional well-being. HCV/HIV co-infected and HIV mono-infected have significantly lower rates of joint pain compared with HCV mono-infected patients, possibly due to T-cell moderation by HIV resulting in decreased effects of the hepatitis C virus or the intensive outpatient follow-up many HIV patients receive.

The Impact of Hepatitis Screening On Diagnosis and Treatment in Rheumatoid Arthritis. Richard Conway, Michele Doran, Finbar (Barry) D. O'Shea and Gaye Cunnane. St James's Hospital, Dublin, Ireland

Background/Purpose: Hepatitis testing is an important pre-requisite to the diagnosis and treatment of patients with rheumatic disease. Joint symptoms may be a manifestation of acute or chronic hepatitis B or C. Immunosuppressive treatment may increase viral load in patients with undiagnosed viral hepatitis. The prevalence of hepatitis varies amongst populations, but even in areas with low endemic levels, it is imperative to identify those in whom current or past infection may influence clinical outcome. The CDC recommends testing for 4 components: hepatitis B surface antigen, hepatitis B surface antibody, hepatitis B core antibody and hepatitis C antibody. Although ACR recommendations do not specifically recommend hepatitis screening, they do advocate vaccination against hepatitis B in all patients. This study was conducted in order to identify new cases of hepatitis in a cohort of patients with RA attending a large university teaching hospital and to evaluate the extent of the hepatitis screen undertaken.

Methods: One hundred consecutive patients, with a diagnosis of RA, were retrospectively assessed for completeness of hepatitis screening by reviewing their hospital records. A dedicated teaching session for all members of the rheumatology team was then conducted, highlighting the results of the survey and explaining the rationale for complete hepatitis screening in all patients with RA. Paper reminders were placed on all desks to alert staff to screen patients at clinic review. A prospective study of hepatitis screening of a separate cohort 100 consecutive out-patients with RA was then performed.

Results: In the initial 100 patients, 21% were male, mean age was 65 years. 85% were taking methotrexate and 22% were on biologic treatments (18% anti-TNF agent, 4% Rituximab). Liver profile was abnormal in 20%. A complete hepatitis screen was present in only 8%, while 12% had a hepatitis B core antibody checked and 53% had a test for hepatitis C.

In the 100 patients assessed after staff education, 26% were male, mean age was 63 years. 86% were taking methotrexate and 27% were on biologic treatments (23% anti-TNF agent, 4% Rituximab). Liver profile was abnormal in 30%. A full hepatitis screen was available in 63%, while 65% had a hepatitis B core antibody checked and 81% had a test for hepatitis C.

In the total 200 patients, we identified 3 cases of positive hep B core antibody, 11 cases of positive hep B surface antibody and 1 case of positive hep C antibody. On retrospective analysis, 2 had identifiable risk factors for blood-borne infections (both healthcare workers).

Table 1. Completeness of Hepatitis Screening

	Pre education, n=100	Post education, n=100
Any hepatitis screen	54%	81%
Full hepatitis screen	8%	63%
Hep B surface antigen	40%	77%
Hep B surface antibody	46%	77%
Hep B core antibody	12%	65%
Hep C antibody	53%	81%

Conclusion: Even in populations where hepatitis B or C is not endemic, laboratory screening will reveal new cases of hepatitis that should be identified prior to immunosuppressive treatment. Educational initiatives are helpful in teaching staff working in busy clinical environments to screen patients, but ongoing reminders are likely to be essential.

176

Prevalence and Associations of Hepatitis C Arthritis in Chronic Hepatitis C Virus Infection. Elizabeth D. Ferucci[1], Holly S. Ryan[1], Tammy L. Choromanski[1], Lisa J. Townshend-Bulson[1], Stephen E. Livingston[1], Brian J. McMahon[1] and Mark H. Wener[2]. [1]Alaska Native Tribal Health Consortium, Anchorage, AK, [2]University of Washington, Seattle, WA

Background/Purpose: Chronic infection with hepatitis C virus (HCV) has been reported to cause inflammatory arthritis and/or fibromyalgia. Case series of patients with HCV-associated arthritis have been described, but population-based studies of individuals with chronic HCV including systematic interview and evaluation by a rheumatologist have been limited.

Methods: Study participants were recruited from a population-based cohort with chronic HCV. Any individual in the cohort who had not been treated with anti-viral therapy was invited to participate. The study visit included an interview for joint symptoms and fatigue, including the London Fibromyalgia Epidemiology Study Screening Questionnaire; assessment of functional status with the Health Assessment Questionnaire disability index (HAQ-DI); examination by a rheumatologist including joint count and tender point count; and a blood draw. Sera were tested for the following autoantibodies: cyclic citrullinated peptide (CCP), rheumatoid factor (RF) by nephelometry, RF isotypes (IgG, IgM, and IgA) by ELISA, and ANA by immunofluorescence. After the study visit and medical record review, participants were categorized as follows: 1) HCV-associated arthritis; 2) RA; and 3) no inflammatory arthritis.

Results: To date, 71 study participants have been recruited, of whom 6 (8.5%) were classified as HCV-associated arthritis, 4 (5.6%) as RA, and 61 (85.9%) as no inflammatory arthritis. CCP and RF were more common in those with RA, when compared to HCV arthritis and no inflammatory arthritis groups (CCP 67%, 0%, and 2%, respectively, p =0.006; RF 100%, 20%, and 40%, p=0.03). Of the RF isotypes, only RF IgG prevalence differed by group (75%, 0%, and 27%, p=0.04). ANA prevalence did not differ by group (50%, 80%, and 35%, p=0.09). The mean HAQ-DI was similar across groups (0.41, 0.52, and 0.29, p=0.29), and the prevalence of fatigue interfering with activities was also similar (50%, 83%, 48%, p=0.29). There was a difference between groups in screening positive for fibromyalgia on the questionnaire (25%, 67%, and 15%, p=0.01), but no difference in mean number of tender points on examination (10.5, 8.2, 4.6, p=0.06) or in the proportion with 11 or more tender points present (50%, 33%, and 16%, p=0.09).

Conclusion: In chronic HCV infection, CCP, RF, and RF IgG differ in the groups with HCV arthritis, RA, and no inflammatory arthritis. Positive fibromyalgia screen by questionnaire is more common among those with HCV arthritis, but disability, fatigue, and the number of tender points on exam are similar. Future studies are ongoing with a goal to expand our ability to characterize HCV associated arthritis.

Antibodies to Citrullinated Peptides in Tuberculosis. Isabella Lima[1], Rodrigo Oliveira[2], Ajax Atta[2], Samyra Marchi[3], Lúcio Barbosa[3], Eliana Reis[3], Mitermayer G. Reis[3] and Mittermayer Santiago[1]. [1]Escola Bahiana de Medicina e Saúde Pública, Salvador, Brazil, [2]Universidade Federal da Bahia, Salvador, Brazil, [3]Fundação Oswaldo Cruz, Salvador, Brazil

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by symmetric polyarthritis, rheumatoid factor positivity (RF) in the majority of patients, and bone erosions shown in radiographs. More recently, research has been conducted into anti-citrullinated peptides antibodies (ACPAs) to which greater sensitivity and specificity have been attributed than RF for diagnosis of RA. However, these antibodies have also been described in infectious diseases, particularly tuberculosis, placing the high specificity of the test in doubt. The aim of the present research was to study the presence of ACPAs in patients with tuberculosis (TB).

Methods: Patients with bacteriologically confirmed pulmonary tuberculosis, RA according to the American College of Rheumatology criteria, in addition to healthy controls (C) were included in the study. ACPAs were researched by two methods: anti-CCP (INOVA) and anti-MCV (Orgentec), in addition to RF by ELISA, in accordance with the protocol recommended by the manufacturers.

Results: The study was conducted in 50 patients with TB, 50 with RA and 20 healthy controls. Anti-CCP antibodies were found in 39 (78%) of the patients with RA, median titer: 128 U (interquartile interval: 24 to 233) whereas anti-MCV antibodies were found in (50%) of the patients with RA, median titer of 21U (interquartile interval: 10 – 218). Of the patients with TB two (4%) had positivity for anti-CCP and anti-MCV and no patient in the control group tested positive for these antibodies. Sensitivity of anti-CCP for diagnosis of RA was 78% (CI: 63 to 88%) and specificity of 97% (CI: 89 to 99%) while the sensitivity of anti-MCV was 50% (CI: 35 – 64%) and specificity of 97% (CI: 89 to 99 %). RF was positive in 40 (80%) of the patients with RA, in 30 (60%) of those with TB and in 1 (5%) of the controls. Thus, sensitivity of RF was 80% (CI: 65 to 89%) and specificity of 55% (CI: 43 to 67%) for diagnosis of RA.

Conclusion: Our findings showed high sensitivity of anti-CCP and high specificity of both anti-CCP and anti-MCV antibodies for diagnosis of RA, even in a population with high incidence of tuberculosis. The higher frequency of positivity of ACPA in TB observed in previous studies may be attributed to methodological factors.

Intravenous Immunoglobulin in Parvovirus B19 Mediated Pure Red Cell Aplasia: A Retrospective Study in 10 Patients and a Review of 123 Cases. Yoann Crabol Hôpital Cochin, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France

Background/Purpose: The efficacy of intravenous immunoglobulin (IVIg) therapy in patients with pure red cell aplasia (PRCA) related to human parvovirus B19 (HPV-B19) infection is mainly supported by cases reports and few small retrospective studies.

Methods: We conducted a retrospective study and reviewed all cases of HPV-B19 PRCA treated with IVIg in the Assistance Publique-Hôpitaux de Paris hospitals between January 2000 and December 2005. In addition all published HPV-B19 PRCA cases treated with IVIg were reviewed from 1980 to 2012.

Results: Among the 36 cases collected, PRCA was confirmed in 22, and among these 22, only 10 had proven HPV-B19 infection. 9 patients were immunocompromised including 4 who had undergone transplantation. All patients had severe anemia (hemoglobin 5.0 ± 1.9 g/dL (mean$\pm$standard deviation (SD)). Three presented severe clinical symptoms related to anemia, and six had symptoms consistent with HPV-B19 infection. HPV-B19 PCR was positive at diagnosis on bone marrow aspiration in 7/7 patients. Patients received 2.7 ± 2.1 IVIg courses at a dose of 1.3 ± 0.54 g/kg/course. Hemoglobin correction was achieved in 9/10 cases within 80 ± 54 days. The only non responsive patient had underlying myelodysplasia. Negativation of blood HPV-B19 PCR was achieved in 35 to 159 days. Side effects of IVIg were noted in 4 patients: acute reversible renal failure and pulmonary edema, 2 cases each.

Including our series, we reviewed in literature 133 patients with HPV-B19 PRCA treated with IVIg. All except 2 of them were immunocompromised, including 39 HIV infected patients and 63 solid organ transplanted. After first IVIg course, hemoglobin correction was observed in 124 cases but 42 patients relapsed, in a mean time of 4,3 months. Among the 96 patients in whom the 12 months response to IVIg treatment was available, hemoglobin correction was achieved in 45 patients while persistant anemia was noticed in 51. In univariate analysis, HIV infection and absence of anti HPV-B19 IgM at diagnosis were associated with 12 months anemia persistence. Mean first IVIg dose (2,2g/Kg) didn't differ significantly between responders and non responders. Overall survival was significantly better in responders patients. Side effects were noticed in 18 cases, including 9 cases of acute renal failure.

Conclusion: IVIg therapy is efficient and relatively safe in immunocompromised patients with HPV-B19 PRCA. Deepness of immunosuppression seems to be an important determinant of persistence response to treatment.

Evaluation of Anakinra Therapy in Seven Adults After Suboptimal Response to Etanercept Therapy for Tumor Necrosis Factor Receptor-Associated Periodic Fever Syndrome. Amanda K. Ombrello[1], Patrycja M. Hoffmann[1], Anne Jones[1], Karyl S. Barron[2] and Daniel L. Kastner[1]. [1]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [2]NIAID-NIH, Bethesda, MD

Background/Purpose: Tumor Necrosis Factor Receptor-Associated Periodic Fever Syndrome (TRAPS) is an autoinflammatory disease inherited in an autosomal dominant fashion. TRAPS develops secondary to mutations in *TNFRSF1A*. Associated symptoms include periodic attacks of peritonitis, constipation, arthritis in large joints, arthralgia, migratory rash with underlying myalgia, periorbital edema, conjunctivitis, splenomegaly, and increased risk for AA amyloid deposition. Typically, attacks last from days to weeks. The common treatment modalities are corticosteroids, the p75:Fc fusion protein, etanercept, and IL-1 antagonists. Recent studies suggest that multiple cytokines are involved in the pathogenesis of TRAPS. To date, there are limited data comparing the efficacy of etanercept and IL-1 inhibitors in TRAPS. To explore this, we have analyzed the response of seven patients with TRAPS who were transitioned from etanercept to anakinra due to modest response while on etanercept.

Methods: CRP and ESR were measured serially in seven patients with TRAPS who had been initially treated with etanercept and were subsequently switched to anakinra. Patient records were evaluated for clinical and laboratory associations. Patients with the R92Q and P46L variants were excluded from our analysis.

Results: Seven adult patients with TRAPS were switched from etanercept to anakinra therapy due to poor symptom control and persistent elevation in inflammatory markers. Among all seven patients, the range of ESR before starting anakinra (no patients were actively flaring at the time labs were drawn) was 37–91 mm/hr and after was 5–18 mm/hr. The range of CRP before starting anakinra was 18.10–186 mg/L and after was <0.5–8.85 mg/L. The etanercept doses ranged from 50mg weekly to 75mg weekly. The anakinra doses ranged from 100mg daily to 300mg daily. One patient with AA amyloidosis had normalization of proteinuria and stabilization of creatinine within 16 months of starting anakinra. Patients reported fewer flares, shorter duration of flares, and decreased necessity for additional medications during flares (corticosteroids and narcotics).

Conclusion: Our findings indicate that in some patients, anakinra therapy is superior to etanercept therapy for TRAPS. Of the seven patients, all of them experienced clinically significant decreases in inflammatory markers including CRP and ESR as well as clinical improvement in symptoms related to TRAPS upon the initiation of anakinra.

Safety of Canakinumab in a Large Cohort of Patients with Cryopyrin-Associated Periodic Syndrome: Results From the β-Confident Registry.
H. Hoffman[1], J. B. Kuemmerle-Deschner[2], P. Hawkins[3], T. van der Poll[4], Ulrich A. Walker[5], B. Rauer[6], J. M. Nebesky[6] and H. Tilson[7]. [1]University of California at San Diego, San Diego, CA, [2]University Hospital Tuebingen, Tuebingen, Germany, [3]University College London Medical School, London, United Kingdom, [4]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]Universitäts-Poliklinik, Felix-Platter Spital, Basel, Switzerland, [6]Novartis Pharma AG, Basel, Switzerland, [7]The University of North Carolina Gillings School of Global Public Health, Chapel Hill, North Carolina

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) is an extremely rare autoinflammatory disorder associated with over-production of interleukin-1β (IL-1β). Canakinumab, a fully human, selective, anti-IL-1β monoclonal antibody, is approved for the treatment of CAPS (including familial cold autoinflammatory syndrome [FCAS] and Muckle-Wells syndrome [MWS]). In order to enhance long term data, the β-Confident Registry, a global, prospective, observational study, is monitoring safety and disease progression in patients treated with canakinumab over a 5-year period.

Methods: CAPS patients receiving canakinumab as part of their routine medical care are included in the registry. Data are collected during routine clinical assessments (no mandatory visits), and the registry is updated every 6 months. Assessments include adverse events (AEs); physician's global assessment of autoinflammatory disease activity; and C-reactive protein (CRP) and serum amyloid A (SAA) levels. Data reported here are adverse events through 18 months of follow-up (cut-off date, March 2012). Additional safety data will be updated with the presentation, as available.

Results: Since December 2009, 229 patients with CAPS and other autoinflammatory diseases have enrolled. Selected baseline characteristics are shown in the Table. Overall, 59 AEs (25.8%) were reported in 29 patients (12.7%). Infections were the most common AE, with 12 AEs (5.2%) reported in 8 patients (3.5%), and upper respiratory type infections accounted for most. CNS disorders were the second most common AE, with 7 AEs (3.1%) reported in 5 patients (2.2%), and headache accounted for most. 11 Serious AEs (4.8%) were reported in 8 patients (3.5%), including 1 malignancy (rectal adenocarcinoma in a 76 yo MWS patient) and 2 infections (pneumonia in a 40 yo female CAPS patient with later hospital discharge; aseptic meningitis in a 25 yo female CINCA patient with recovery). There was only 1 permanent canakinumab discontinuation, due to patient preference.

Table. Baseline characteristics of enrolled patients

	Overall (N=229)	FCAS (n=35)	MWS (n=135)	NOMID (n=18)	Others (n=29)
Age groups:					
< 18y	74	7	33	11	18
≥ 18y	155	28	102	7	11
Sex:					
Male	107	12	68	10	15
Female	122	23	67	8	14
NLRP3 mutation, n(%)					
Yes	183 (79.9)	35 (100.0)	126 (93.3)	15 (83.3)	7 (24.1)
No	16 (7.0)	0	3 (2.2)	1 (5.6)	12 (41.4)
Unknown/missing	30 (13.1)	0	6 (4.4)	2 (11.1)	10 (34.5)

Thiopurine S-Methyltransferase Levels in Patients with Behçet's Disease.
Hakan Emmungil[1], Melike Kalfa[1], Raika Durusoy[2], Figen Yargucu Zihni[1], Gokhan Keser[1] and Kenan Aksu[1]. [1]Dept. of Internal Medicine, Division of Rheumatology, Ege University, Izmir, Turkey, [2]Department of Public Health, Ege University, Izmir, Turkey

Background/Purpose: Azathioprine (AZA) is an immunosuppressive agent which is widely used not only for the treatment of Behcet's disease (BD), but also for the treatment of many systemic inflammatory diseases including systemic lupus erythematosus (SLE) and various systemic vasculitis. Thiopurine S-methyltransferase (TPMT) is a genetically moderated key enzyme involved in the metabolism of AZA. Low TPMT levels may cause a tendency for AZA-related adverse effects. In the present study, TPMT levels in patients with BD were compared with healthy controls, as well as with patients with SLE or with systemic vasculitis, as disease control groups. We investigated the relationship between TPMT levels and AZA-related adverse effects, and also whether TPMT levels were affected by AZA treatment.

Methods: In the present cross-sectional study, 101 patients with BD (M/F: 61/40; mean age 42.15±10.33 years), 74 patients with SLE (M/F: 11/63; mean age: 39.86±11.69 years), 44 patients with systemic vasculitis (M/F: 21/23; mean age 47.09±13.36 years) and 101 healthy controls, age and sex matched with BD were included. Detailed past medical data were available for all patients. The TPMT activity in red blood cells was measured using ELISA. AZA was stopped three days before measurements in patients already receiving this drug. Data were presented as mean ± SD. Mean TPMT levels (mIU/ml) were compared with Student's t, Mann Whitney U and Kruskal Wallis tests, and Receiver Operating Characteristic (ROC) analysis was used to determine whether TPMT could be used to predict toxicity.

Results: Mean TPMT levels in BD (22.80±13.81) were comparable with healthy controls (22.71±13.49), but significantly lower than in patients with SLE (29.37±11.39) (p<0.001). There were 130 patients, 77 with BD, 35 with SLE, and 18 with systemic vasculitis who had used or have been currently using AZA treatment. TPMT levels were not significantly different between patients with and without AZA treatment. AZA-related adverse effects involving gastrointestinal tract, liver and bone marrow were identified in 8 out of 130 patients (5 with BD and 3 with SLE). Although the mean TPMT levels were significantly lower in patients suffering from AZA-related adverse effects (14.08±9.49) than in patients without adverse effects (25.62±12.68) (p=0.013), a cut-off value for predicting AZA-related adverse effects could not be determined with ROC analysis (Area under the curve: 0.249).

Conclusion: This was the first study evaluating TPMT activity in Turkish adult population. Despite more frequent AZA-related adverse effects in the presence of low TPMT levels, absence of a certain cut-off value for TPMT levels implicate that variation in the level of this enzyme may not be the only factor determining AZA-related adverse events. Clinical relevance of TPMT testing should further be determined with larger prospective studies.

Comprehensive Analysis of Protein Expression in Peripheral Blood Mononuclear Cells From Patients with Behçet's Disease.
Takuya Yoshioka[1], Manae Kurokawa[1], Yukiko Takakuwa[1], Hiromasa Nakano[2], Seido Ooka[2], Nobuko Iizuka[1], Toshiyuki Sato[1], Mitsumi Arito[1], Kouhei Nagai[3], Kazuki Okamoto[1], Naoya Suematsu[1], Noboru Suzuki[1], Shoichi Ozaki[2] and Tomohiro Kato[1]. [1]St. Marianna Univ School Med, Kawasaki, Japan, [2]St. Marianna University School of Medicine, Kawasaki, Japan, [3]Kinki Univ., Kinokawa, Japan

Background/Purpose: To elucidate the pathophysiology of Behcet's disease (BD) and to establish biomarkers for the disease, we comprehensively analyzed protein expression of peripheral blood mononuclear cells (PBMCs).

Methods: PBMCs were obtained from 16 patients with BD, 16 patients with rheumatoid arthritis (RA), and 16 healthy control (HC) subjects. Proteins, extracted from the PBMCs, were separated by 2-dimensional differential gel electrophoresis. Proteins were identified by mass spectrometry.

Results: As a result, a total of 563 protein spots were detected. Compared to HC, 14 spots showed significantly higher intensity with more than 1.2 folds, and 9 spots showed significantly lower intensity with less than 1/1.2 folds in BD. The spots with higher intensity included proteins involved in T cell activation, metabolism of pre-mRNAs, and protein trafficking. The spots with lower intensity included cytoskeltal proteins. Similarly, compared to RA, 98 spots showed significantly higher intensity with more than 1.2 folds, and 17 spots showed significantly lower intensity with less than 1/1.2 folds in BD. The spots with higher intensity in BD than in RA included proteins associated with bacteriolysis, oxidation/reduction, activation of transcription, regulation of kinases, and modulation of glycosylation. We completely discriminated the BD patients from the HC subjects and from the RA patients by multivariate analyses of 23 and 35 protein spots, respectively. The analyses using only 1–3 protein spots provided areas under the receiver operating characteristic curves of 0.797–0.898 in the discrimination of the BD patients from the HC subjects, from the RA patients, and from the both HC subjects and RA patients.

Conclusion: Taken together, the protein spots which contributed to the discrimination could be biomarker candidates for BD. In addition PBMC-derived proteins, expression of which was significantly altered in BD, may be involved in the pathophysiology of BD.

A Strong Association Between HLA-A*26 and Behçet's Syndrome in Japanese Patients: From Two-Center Cohort Study of Behçet's Syndrome. Tatsuo Kobayashi[1], Mitsumasa Kishimoto[2], Kazuki Yoshida[1], Yuri Ohara[2], Hiroto Nakano[1], Masahiro Minoda[1], Hideto Oshikawa[1] and Kazuo Matsui[1]. [1]Kameda Medical Center, Kamogawa City, Chiba, Japan, [2]St. Luke's International Hospital, Chuo-ku, Tokyo, Japan

Background/Purpose: An association between Behçet's Syndrome (BS) and HLA-B*51 is widely reported among many different ethnic groups. Recently, a few reports from Taiwan, Greece and Japan were published that indicated HLA-A*26 is also associated with BS independently from HLA-B*51, but these studies may have some limitations. These limitations include small numbers, were not written in English, only analyzed BS with ocular lesions, or were mainly led by ophthalmologists. Therefore, the association between HLA-A*26 and BS still remains unclear. For this report we studied phenotype frequencies (PF) of HLA-A and HLA-B in Japanese BS patients seen by not only ophthalmologists but also experts in different specialties, mainly rheumatologists.

Methods: All BS patients seen at tertiary care centers of Kameda Medical Center and St. Luke's International Hospital in Japan between 2003–2012 were included in the analysis. Patients were mainly seen by rheumatologists, followed by neurologists, dermatologists, ophthalmologists, and gastroenterologists. The diagnosis of BS was made on clinical manifestation and expert opinions. Charts were reviewed for DNA typing of HLA alleles and disease manifestations. To compare PF, we adopted data from the central bone marrow data center registry of Japanese Red Cross Society (n=263016) as a control for the general population in Japan. The significance of the distribution of phenotypes was analyzed by one-sample proportions test and the primary P-values were corrected by using the Bonferroni correction (Pc). We analyzed manifestations by Fisher's exact probability test or t-test.

Results: As for HLA-A and HLA-B, 80 and 81 patients were tested respectively (88 patients were eligible for HLA-B*51 analysis) and 6 HLA-A and 19 HLA-B alleles were detected. Of all, PF of HLA-A*26 was significantly higher than the general Japanese population (42.5% vs. 22.6%, Pc=8.0 × 10^{-4}). The same is true for HLA-B*51 (44.3% vs. 17.1%, Pc=7.1×10^{-10}). No significant differences were seen in other HLA alleles. Secondly, we analyzed the difference in manifestations of BS patients stratified by HLA-A*26 or HLA-B*51. No significant difference was seen except for age of onset, which was younger in patients with HLA-B*51 than without it (mean±SD (years): 34.1±13.6 vs. 41.3±17.9, P=0.041). There is also a tendency that gastrointestinal (GI) lesions are less likely for patients with HLA-B*51 (28.2% vs. 46.9%, P=0.082). We detected no significant

difference of manifestations between HLA-A*26 positive patients and negative patients.

Table 1. Phenotype frequency of HLA-A and HLA-B in BS patients compared with the general population in Japan (extracted data were shown)

	PF of BS patients (%)	PF of the general Japanese (%)	P-value	Pc-value
HLA-A*02	46.3	42.9	0.62	
-A*24	58.8	60.1	0.83	
-A*26	42.5	22.6	3.6 × 10^{-5}	8.0 × 10^{-4}
-A*33	58.8	60.1	0.06	
HLA-B*51	44.3	17.1	3.2 × 10^{-11}	7.1 × 10^{-10}
-B*52	16.1	21.0	0.34	
-B*54	16.1	14.6	0.83	

Conclusion: HLA-A*26 is found to be alleles for BS susceptibility among BS patients not only with ocular lesions but also various manifestations in Japan. Moreover, our study also showed that patients with HLA-B*51 have younger onset and a lower tendency of GI lesions.

The Retrospective Review of 39 Intestinal Behçet's Disease Focusing On the Requirement for the Immunosuppresive Drugs Other Than Corticosteroid. Yoshitaka Kimura[1], Kurumi Asako[1], Hirotoshi Kikuchi[2], Akiteru Takeuchi[3] and Hajime Kono[4]. [1]Department of Internal Medicine, Teikyo University school of medecine, Tokyo, Japan, [2]Teikyo University, Tokyo, Japan, [3]6-7-8 Arakawa, Tokyo, Japan, [4]Teikyo University School of Medicine, Tokyo, Japan

Background/Purpose: To examine the demography, clinical characteristics, features of intestinal lesions, treatment, and prognosis in patients with the intestinal Behçet's disease currently followed at a university hospital in Tokyo especially focusing on the factors that correlated with additional immunosuppresive therapies to corticosteroid.

Methods: The records of 39 patients with intestinal Behçet's disease were retrospectively reviewed who were treated at the Teikyo University Hospital between August 1st, 2011 and March 31th, 2012. We compared the well-controlled patients treated only with steroid or 5-ASA/SASP, with the poorly-controlled patients who required additional immunosuppressive drugs or anti-TNFa antibodies.

Results: The patients were consisted of 26 male and 13 female with the average age of 56.8 ± 13.1 years old. The mean age at onset of Behçet's disease was 35.5 ± 11.2 years. They developed the intestinal lesions at mean age 41.3 ± 13.0 years. HLA-B51 or HLA-A26 were positive in 35.4% or 32.3%, respectively. Seventeen cases were complete Behchet's and 22 were incomplete type. Almost all patients had oral ulcerations and skin lesions. Twenty five cases had arthritis, 7 had epididymitis. Vascular and central nervous system involvements were seen in 8 and 2 patients, respectively. The most frequent initial symptom for intestinal Behcet's was abdominal pain (22 cases). Other initial symptoms were melena/bloody stool (16 cases) and diarrhea (9 cases), fever (5 cases), dysphagia (2 cases). The intestinal lesions existed in various lesions of the gastrointestinal tract including esophagus (3 cases) and small intestine (4 cases), ileo-cecal area (31 cases), ascending colon (7 cases), transverse colon (3 cases), descending colon (3 cases), sigmoid colon (2 cases), rectum (5 cases). They (28 cases) were treated with predonisolone of the average 32.5mg daily as the initial dosage. Thirty two patients were treated 5-ASA or SASP. Fourteen cases were added with methotrexate, and 3 cases with cyclosporine. Infliximab was administrated in 6 cases. In the patients who needed immunosuppressive drugs or anti-TNFa antibodies other than steroids, we found the significantly higher HLA-B51 positivity (42%) and higher CRP at the beginning of treatment (10.5±8.5 mg/dL). In addition, the poorly responded patients with corticosteroid and sulfasalazopyridine showed more frequent atypical intestinal lesions.

Conclusion: The restrospective review revealed that the requirement for the additional immunosuppresive therapies could have a linkage to the HLA-B51 in patietnts with intestinal Bachet's disease.

Long-Term Efficacy and Safety of Tumour Necrosis Factor Antagonists for Patients with Behçet's Disease with Uveitis As Main Involvement. M. Victoria Hernández, Marina Mesquida, Gerard Espinosa, Victor Llorens, Laura Pelegrin, Juan D. Cañete, Ricard Cervera, Alfredo M. Adan and Raimon Sanmarti. Hospital Clínic of Barcelona, Barcelona, Spain

Background/Purpose: To assess the long-term efficacy and safety of tumour necrosis factor (TNF) antagonists (infliximab [IFX], adalimumab [ADA] and golimumab) for the treatment of patients with Behçet's disease (BD) with uveitis who failed to respond or did not tolerate conventional treatment.

Methods: Retrospective study of patients with BD and uveitis treated with anti-TNF therapy in a tertiary reference hospital. Data analyzed were: demographic characteristics; disease duration and type of uveitis; visual acuity; previous treatments; dosage, type and duration of biological agent used; outcome (remission, loss of efficacy, adverse events). The characteristics of uveitis, including the degree of inflammation and disease course, were analyzed according to the definitions of the Standardization of Uveitis Nomenclature (SUN) criteria.

Results: We included 15 patients (8 male, mean age 36.9 ± 8.3 years) with BD and severe intraocular inflammation. Mean disease duration was 9.6 ± 5.7 years; 66.6% had panuveitis and 26.6% posterior uveitis. All patients had previously received oral glucocorticoids (GC) and 60% had received > 2 immunosuppressive (IMS) drugs. Thirteen patients were treated with IFX and 2 with ADA as initial anti-TNF therapy. Six of 13 patients treated with IFX were switched to another anti-TNF agent due to adverse events or loss of efficacy: 5/13 were switched to ADA and 1/13 was switched to golimumab. Globally, 7/15 patients were treated with ADA. IFX was infused at a dose of 5 mg/kg for a mean of 10.4 months (range: 2–24). ADA 40 mg was administered subcutaneously every 2 weeks for a mean of 29 months (range: 9–44). The mean follow-up was 37 months (range: 10–72). Twelve (80%) patients achieved remission. Three patients were able to discontinue all systemic IMS and GC drugs. Best corrected visual acuity remained stable or improved in 27/29 eyes. Three serious adverse events requiring IFX withdrawal were reported: 1 severe infusion reaction, 1 disseminated tuberculosis, and 1 prostatitis.

Conclusion: Infliximab and adalimumab are effective biologic agents for the treatment of uveitis in patients with Behçet's disease, achieving remission in 80% of patients. The treatments were, generally, well tolerated and only three patients required withdrawal.

186

Long-Term Infliximab Therapy in Patients with Behcet's Disease Is Well Tolerated without Increasing Risk of Serious Infections. Sho Ueda[1], Hiroshi Tsukamoto[1], Yasushi Inoue[1], Masahiro Ayano[1], Satomi Hisamoto[1], Naoko Ueki[1], Atsushi Tanaka[1], Shun-ichiro Ohta[1], Naoyasu Ueda[1], Yojiro Arinobu[1], Hiroaki Niiro[1], Takahiko Horiuchi[1] and Koichi Akashi[1]. [1]Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan

Background/Purpose: Infliximab (IFX) is a monoclonal antibody against tumor necrosis factor-a (TNF-a) and is increasingly used in various immune-related diseases including rheumatoid arthritis (RA), ankylosing spondylitis, inflammatory bowel diseases and Behcet's disease (BD). Among patients with RA, serious hospitalized infection rates were previously reported as 8.16 (IFX) and 7.78 (nonbiological regimens) per 100 person-years and 2-year continuation rates of IFX were previously reported as around 40%. On the other hand, there are few reports regarding the long-term safety and persistent response of IFX therapy in BD patients. It is of importance to assess the safety and the efficacy of IFX for BD, since the backgrounds of these diseases are different.

Methods: We retrospectively studied consecutive 109 patients who met the established criteria by the Behcet's Disease Research Committee of Japan for the diagnosis of BD, and were continuously followed up between January 2007 and December 2011 in a single center (Department of Clinical Immunology and Rheumatology/Infectious Disease of Kyushu University Hospital). During this period, 39 patients with BD received IFX therapy and 70 did not. Among the 39 patients, 36 were treated with IFX for uveitis. Serious hospitalized infections and the discontinuations of IFX were investigated based on medical records. The frequency data were compared using Chi-square test. The continuous data were compared using Wilcoxon non-parametric tests. The time-course data were analyzed by Kaplan-Meier method.

Results: Between patients with and without IFX, there were no significant differences in median [IQR] age (37 [26–42] vs 43 [32–54] years), median duration of disease (4.1 [0.7–7.8] vs 4.2 [1.0–11.0] years), median follow-up period (2.4 [1.4–3.9] vs 2.4 [0.9–5.0] years), and percentage of concomitant prednisolone (>10mg/day) user (10.3% vs 14.3%). On the other hand, significant ($p<0.01$) differences were observed in the proportion of males (76.9% vs 41.4%), manifestation of uveitis (92.3% vs 37.1%) and genital ulcers (48.7% vs 78.6%), and concomitant use of immunosuppressive drugs (41.0% vs 17.1%). Serious infection rates were comparable between two group; 2.01 with IFX and 1.54 without IFX per 100 person-years. Among BD patients with IFX therapy, bacterial colitis and pelvic inflammatory disease occurred in 2 patients and both occurred within 1 year from initiation of IFX therapy. IFX infusion was interrupted in 5 of the 39 patients due to adverse events (n=3) and removals (n=2). Two-year continuation rate was estimated as 85.3%.

Conclusion: In the treatment of BD, IFX therapy was not associated with an increased risk of hospitalizations for serious infections. In addition, 2-year continuation rate of IFX was considerably higher than that previously reported in RA patients.

Effect of Colchicine On Cholesterol Levels in Patients with Familial Mediterranean Fever and Behçet's Syndrome. Serda L Ugurlu[1], Emire Seyahi[2], Idil Hanci[1], Huri Ozdogan[3], Seval Masatlioglu-Pehlivan[4] and Hasan Yazici[5]. [1]MD, Istanbul, Turkey, [2]Cerrahpasa Faculty of Medicine, Istanbul University, Istanbul, Turkey, [3]MD, Division of Rheumatology, Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [4]MD, Rheumatology, Istanbul, Turkey, [5]Istanbul University, Cerrahpasa Medical School, Rheumatology, Istanbul, Turkey

Background/Purpose: We and others have previously shown that patients with Familial Mediterranean Fever (FMF) had low cholesterol levels when compared to healthy controls (1–2). The causes of this abnormality are not understood. It could be due to an inherent effect of FMF or due to a lipid lowering effect of colchicine. We conducted a 12 week study to determine whether colchicine would decrease serum lipid levels in patients with FMF and Behcet syndrome (BS).

Methods: Blood cholesterol and triglycerides levels were measured in 24 patients with FMF (11 M, 13 F) and 16 (8 M, 8 F) patients with BS who were registered at the outpatient clinic of Cerrahpasa Medical Faculty. All patients were naive to colchicine or immunosuppressive treatment or any other lipid lowering drugs at study entry. Blood cholesterol and triglycerides levels were measured again after 12 weeks of colchicine 1.5 mg daily.

Results: There were 19 (8 M, 11 F) patients with FMF and 15 (7 M, 8 F) patients with BS who completed 12 weeks period. Patients with FMF were (mean age: 33.8 ± 14.1 years) significantly younger than BS patients (mean age: 36.5 ± 9.5) (P = 0.001). Colchicine did not change significantly cholesterol and triglycerides levels in patients with FMF (Table). This was also true for patients with BS (Table). Mild diarrhea was observed in 2 patients with FMF and in 1 with BS.

Table. Lipid levels before and after colchicine treatment

	FMF (n = 19)			BS (n = 15)		
	Before colchicine	After colchicine	P	Before colchicine	After colchicine	P
T. cholesterol	168.95 ± 77.1	181.26 ± 48.3	0.58	181.43 ± 50.9	172.3 ± 44.4	0.53
Triglycerides	122.2 ± 82.26	128.21 ± 69.56	0.75	111.7 ± 62.9	106.5 ± 52.1	0.18
LDL cholesterol	120.37 ± 44.3	112.16 ± 39.9	0.35	115.14 ± 38.43	106.1 ± 39.7	0.85
HDL cholesterol	42.11 ± 13.4	47.11 ± 10.9	0.1	47.93 ± 9.205	48.3 ± 9.9	0.3

Conclusion: This study provided no evidence that colchicine changes lipid levels in patients with FMF and BS.

Etiology of Uveitis: A Hospital-Based Study in a Referral Centre. Claudia Ferrari[1], Rosaria Talarico[1], Michele Figus[2], Chiara Stagnaro[1], Anna d'Ascanio[1] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Ophthalmology Unit, University of Pisa, Pisa, Italy

Background/Purpose: Defined as an intraocular inflammation, uveitis may be associated to a systemic disease or represent an isolated entity. It affects people from all parts of the world, and it is a significant cause of severe visual impairment, accounting for 10% of blindness in the Western world. Screening for associated extra-ocular manifestations is mandatory in uveitis patients. The aim of the study was to analyse the etiology and the pattern of uveitis in a cohort of patients followed in the context of a *uveitis clinic* of a rheumatologic referral centre

Methods: The study included 120 patients (M/F: 86/34; mean age at disease onset 35 years) with uveitis examined from January 2009 to May 2012. All patients had a comprehensive rheumatologic and ophtalmological evaluation, including: clinical history, Snellen visual acuity, slit-lamp examination, applanation tonometry, dilated fundus examination and/or visual field and/or fluorescein-angiography and/or optical coherence tomography. Moreover, all patients underwent the standard protocol of serological examinations for uveitis, including routine examination, acute phase reactants, HLA typing, serum fluorescent treponemal antibody absorption detection, main viral and bacterial screening, serum angiotensin-converting enzyme, serum lysozyme, tuberculin reaction tests, non-organ specific auto antibodies profile and, when required, chest X-Ray.

Results: Seventy percent of patients referred by ophthalmologists, 27% patients directly attending our department and 3% referred by general practitioners. Posterior uveitis was the most common feature (46%), followed by anterior uveitis (28%), panuveitis (16%), and intermediate uveitis (10%). For 57 of 120 (47%) patients with uveitis, a specific aetiologic diagnosis was established, while 53% of patients were found to have idiopathic uveitis. In the posterior uveitis group (n=55), a specific diagnosis was made for 21 patients (38%); the most frequent forms were represented by toxoplasmosis (48%) and Behçet's disease (25%). In the anterior uveitis group (n=34), a specific diagnosis was made in 19 patients (56%). The most common diagnoses included herpetic infection (53%), Fuchs' heterochromic iridocyclitis (22%), HLA-B27-positive anterior uveitis ± associated to a spondylarthropathy (20%). Among patients with panuveitis (n=19), 15 (79%) had a specific aetiologic diagnosis, in the majority of cases linked to Behçet's disease (88%). In the intermediate uveitis group (n=12) only two etiologies were identified: sarcoidosis and multiple sclerosis.

Conclusion: In this hospital-based study, the most common cause of uveitis is idiopathic. However, a multi-disciplinary approach may surely improve the diagnosis of uveitis secondary to autoimmune diseases.

Pedal Swelling As a Characteristic Phenotype of the New Category of Autoinflammatory Disease Associated with NOD2 Gene Mutations. Qingping Yao. Cleveland Clinic, Cleveland, OH

Background/Purpose: Autoinflammatory diseases are characterized by seemingly unprovoked episodes of inflammation, without high titer autoantibodies or antigen specific T cells, and derive from genetic variants of the innate immune system. We previously reported a case series of a new autoinflammatory disease associated with nucleotide oligomerization domain (NOD2) gene mutations. Herein, I report a characteristic phenotype as an addition to further define this disease entity.

Methods: Six patients with pedal swelling and other autoinflammatory phenotypes were enrolled between January 2009 and April 2012. These patients were tested for NOD2 gene mutations.

Results: All 6 patients were non-Jewish Caucasians, with 5 female, 1 male. The mean age at disease diagnosis was 49 years (range 29–63) and disease duration was 3.9 years (range 0.4–10) (Table 1). These patients usually presented with weight loss, self limiting fever, dermatitis, and inflammatory polyarthritis/polyarthralgia. Apart from previously reported characteristic spongiotic dermatitis, all patients also shared a prominent clinical feature: ankle/foot swelling/pain (Figure 1) which was primarily unilateral. There was no convincing evidence of inflammatory bowel disease, sarcoidosis, or Blau's syndrome. All patients carried the NOD2 gene mutations, with R702W/IVS8^{+158} in 4 and 2 having rare variants R703C and T189/wild type.

Conclusion: The current cohort has affirmed and extended that dermatitis, pedal swelling and positive NOD2 mutations may characterize this entity.

NLRP3 Gene Analysis for Patients with Schnitzler's Syndrome. Cong-Qiu Chu[1], Carrie R. Austin[2], Trudy M. Doyle[2], Kelley A. Goodwin[2], Noha El Torgomen[2], Regina Treudler[3] and Tammy M. Martin[4]. [1]Oregon Health & Science Univ and Portland VA Medical Center, Portland, OR, [2]Oregon Health & Science University, Portland, OR, [3]Universitätsklinikum Leipzig AöR, Leipzig, Germany, [4]Oregon Health & Science Univ, Portland, OR

Background/Purpose: Schnitzler's syndrome is characterized by chronic urticaria, intermittent fever, arthralgia, bone pain, gammopathy and marked systemic inflammation. The striking response to IL-1 blockade suggests that Schnitzler's syndrome is an IL-1 mediated condition of the expanding spectrum of systemic autoinflammatory disorders. However, the mechanism leading to the increased IL-1 activity has remained elusive. We aim to identify genetic predisposition in patients with Schnitzler's syndrome.

Methods: Genomic DNA was extracted from peripheral blood mononuclear cells from 4 patients with a clinical diagnosis of Schnitzler's syndrome. DNA sequencing was performed in both directions of NLRP3 gene regions, including exon 3 which contains the majority of mutations associated with the cryopyrinopathies. Genetic data of patients was compared with the reference sequence for mutations.

Results: Of the 4 patients with Schnitzler's syndrome, 2 had classical findings of monoclonal IgM, kappa; one with polyclonal IgA; and one with polyclonal IgG and IgA. All of the 4 patients were refractory to non-biologic immunosuppressive treatment but achieved sustained clinical remission with daily use of anakinra. DNA sequence analysis of NLRP3 revealed a disease-associated mutation encoding the V198M substitution in the patient with polyclonal IgG and IgA. However, this mutation was not found in the other 3 patients. No other disease-associated mutations were identified in NLRP3 for this patient or in the other 3 patients.

Conclusion: Genetic studies of Schnitzler's syndrome have been scanty primarily due to the rarity of the condition and the results have been mixed. Our 4 patients consist of classical (2 cases) and atypical (2 cases) Schnitzler's syndrome. The V198M mutation was found in one with atypical Schnitzler's syndrome (polyclonal IgG and IgA). Interestingly, this mutation was previously reported in one patient with classical Schnitzler's syndrome with monoclonal IgM, kappa (1). However, another genetic study on a patient with classical Schnitzler's syndrome found no mutations in NLRP3 (2). The distinct feature of Schnitzler's syndrome is its gammopathy which is poorly responsive to IL-1 blockade suggesting that IL-1 may not mediate the gammopathy. Complete analysis of NLRP3 exons and their flanking regions in this cohort is underway as disease-associated mutations outside of exon 3 have been reported and there may be as yet unknown mutations involved in this phenotype. The presence of an NLRP3 mutation in another patient with Schnitzler's syndrome confirms the finding that this disorder is inflammasome-mediated.

Analysis of Genes Involved in Autoinflammatory Diseases in Adult Onset Still's Disease.

Emma Garcia-Melchor[1], Dolors Grados[2], Eva Gonzalez-Roca[1], Elena Riera[3], Manel Juan[1], Jordi Yagüe[1], Juan Ignacio Aróstegui[1], Javier Narváez[4] and Alejandro Olivé[2]. [1]Hospital Clinic Barcelona, Barcelona, Spain, [2]Hospital Universitario Germans Trias i Pujol, Badalona, Spain, [3]Hospital Mutua de Terrassa, Terrassa, Spain, [4]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain

Background/Purpose: Adult Onset Still's Disease (AOSD) is a systemic inflammatory disease characterized by fever, skin rash, articular involvement, lymphadenopathy, hepatosplenomegaly and serositis. Due to the absence of autoantibodies and autoantigen-specific T cells and the efficacy of treatment with IL-1β blocking agents, AOSD has been considered an autoinflammatory disease. Some entities of this group are inherited diseases caused by mutations in genes related with the processing of IL-1β. The cryopyrinopathies are caused by heterozygous gain-of-function mutations in NLRP3 gene (Nucleotide-binding domain Leucine Rich repeat family Pyrin domain containing 3) and share some clinical features with AOSD like fever, cutaneous and musculoskeletal involvement and serositis. Heterozygous gain-of-function NOD2 (Nucleotide Oligomerization Domain 2) mutations are associated with Blau syndrome, which is characterized by uveitis and, like AOSD, fever and chronic arthritis. The aim of this study is to analyze the potential involvement of mutations in the NALP3 and NOD2 genes in AOSD patients.

Methods: Eighteen patients with AOSD from two hospitals in Spain were enrolled. All the patients fulfilled the Yamaguchi criteria and informed consent was obtained from each participant. The study protocol was approved by the ethics committee from the Hospital Universitari Germans Trias i Pujol. Genomic DNA was extracted from whole blood using the Roche MagNAPure Compact (Roche Diagnostics, Indianapolis, IN). Exon 4 of NOD2 gene (GeneBank NM 022162.1) and exon 3 of NLRP3 gene (GeneBank NM 001243133.1) were amplified by polymerase chain reaction. Bidirectional fluorescence sequencing was performed using an ABI BigDye Terminator version 3.1 Cycle Sequencing kit and run on a 3730XL DNA Analyzer. As control population, the European Caucasic samples from 1000 Genome Project (n=379) were used. Differences in frequencies of alleles and genotypes between AOSD patients and controls were examined using the Chi-squared method, Fisher's exact test and logistic regression with Statistical Analysis Software (SAS).

Results: Most AOSD patients showed no pathogenic variants in NALP3 or NOD2 gene. Of interest, two patients were carriers of a NOD2 polymorphism associated with Crohn disease (p.R702W, rs206684) without having any symptom suggestive of inflammatory bowel disease, and another one was carrier of a rare NOD2 variant of uncertain significance that was previously reported in a patient with spondyloarthritis (p.R791Q, rs104895464). In the NALP3 analysis, one patient was carrier of the variant of uncertain significance p.V198M (rs121908147).

Conclusion: AOSD has some similarities with inherited autoinflammatory syndromes like the clinical presentation and the efficacy of treatment with IL-1β blocking agents. Although in our series none of the AOSD patients carried a true disease-associated mutation, the possibility of an inherited autoinflammatory disease should be considered in the differential diagnosis and ruled out by means of genetic analysis.

Clinical and Laboratory Findings in A Cohort of Italian Patients with Adult Onset Still'S Disease: The Role of IL-18 As A Disease Biomarker.

Roberta Priori[1], Serena Colafrancesco[1], Carlo Perricone[1], Antonina Minniti[1], Cristiano Alessandri[2], Giancarlo Iaiani[3] and Guido Valesini[1]. [1]Rheumatology Unit, Sapienza University of Rome, Rome, Italy, [2]Sapienza University of Rome, Rome, Italy, [3]Department of Infectious Diseases and Tropical Medicine, Sapienza University of Rome, Rome, Italy

Background/Purpose: Adult Onset Still's Disease (AOSD) is a systemic inflammatory syndrome driven by interleukin (IL)-18. Since differential diagnosis between AOSD, sepsis and other inflammatory conditions can be difficult, we aimed to investigate IL-18 serum levels in AOSD and to assess whether this cytokine could be used as disease biomarker.

Methods: Patients with AOSD (Yamaguchy criteria) were evaluated. Disease activity was assessed with Pouchot's and Rau's criteria and patients were defined active if they had ≥4 criteria. Serum IL-18 levels were detected by ELISA (Immuno-Pharmacology Research, Italy) in patients with AOSD and sepsis (according to ACCP/SCCM Consensus Conference). Furthermore, patients with Rheumatoid Arthritis (RA), Sjögren Syndrome (SS), Systemic Lupus Erythematosus (SLE) and healthy subjects (NHS) served as controls. Area under the receiver operating curve (ROC-AUC) analysis was used to evaluate the diagnostic utility of the IL-18.

Results: Clinical and laboratory features of 50 AOSD patients are described in table.

AOSD patients		N=50
Male/Female		23/27
Age at onset [mean (range), years]		34 (17–64)
Symptoms	**N**	**%**
Fever	50	100.0
Arthralgia	39	78.0
Rash	38	76.0
Sore Throat	30	60.0
Lymphadenopathy	29	58.0
Arthritis	24	48.0
Hepatomegaly	19	38.0
Splenomegaly	19	38.0
Myalgia	15	30.0
Pleuritis	3	6.0
Pericarditis	2	4.0
Abdominal Pain	1	2.0
Laboratory features	**mean**	**range**
ESR (mm/h)	74.8	20–124
CRP (mg/dl)	84.8	3–354
WBC (cells/μl)	19004.7	8600–35900
Ferritin (ng/ml)	5582	69–32800
AST (UI/l)	67.4	8–404
ALT (UI/l)	91.6	4–535

Two patients experienced DIC, one with fatal outcome. Considering Pouchot's and Rau's criteria, active patients were 18/50 (36%) and 21/50 (42%), respectively. Mean ferritin was higher in active than non active patients (p=0.001). IL-18 was detected in 30 patients with AOSD, 7 with sepsis, 21 with RA, 21 with SS, 20 with SLE and 21 NHS. IL-18 significantly correlates with AOSD activity score (p<0.0001) and ferritin level (p=0.0127). Mean IL-18 was significantly higher in AOSD than in sepsis [1298.7 pg/ml (range 0–6015) vs 113.5 pg/ml (range 52–328), p=0.008]. The ROC-AUC analysis for IL-18 serum levels between AOSD and sepsis was 0.712 [cut-off=179 pg/ml, specificity (sp)=69.7%, sensitivity (se)=87.5%, likelihood (LR)=2.89]. IL-18 serum levels were significantly higher in active than non active patients and sepsis (p=0.0039 and p=0.007, respectively). The ROC-AUC analysis for IL-18 between active AOSD and sepsis was 0.845 (cut-off=223 pg/ml, sp=87.5%, se=80.9%, LR=6.48). The ROC-AUC analyses for IL-18 between AOSD patients and other groups (NHS, RA, SS, SLE) were respectively 0.853 / 0.720 / 0.750 / 0.791 (NHS: cut-off=293.7 pg/ml, sp=85.19%, se=85.71%, LR=5.79; RA: cut-off=335.5 pg/ml, sp=81.48%, se=52.38%, LR=2.83; SS: cut-off=424.3 pg/ml, sp=74.07%, se=66.67%, LR=2.57; SLE: cut-off =268.2 pg/ml, sp=85.19%, se=60%, LR=4.05).

Conclusion: The clinical and laboratory findings of our cohort overlap with the literature. Ferritin parallels disease activity, suggesting that the Rau's criteria could be more accurate. AOSD prognosis is usually favourable but severe complications may occur. Finally, a significant difference in IL-18 serum levels between patients with AOSD and sepsis was observed, and IL-18 can represent a useful biomarker in the differential diagnosis between AOSD and other inflammatory conditions. Moreover, IL-18 serum levels reflects disease activity.

193

Tocilizumab in Adult Still's Disease: The Israeli Experience. Ori El-kayam[1], Nizar Jiries[2], Zvi Dranitzki[3], Shaye Kivity[4], Merav Lidar[5], Ofer Levy[6], Mahmoud Abu-Shakra[7], Hagit Sarvagil-Maman[1], Hagit Padova[1], Dan Caspi[8] and Itzhak Rosner[9]. [1]Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Bnai Zion Medical Center, Israel, [3]Hadassah hebrew university, Jerusalem, Israel, [4]Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, Tel-Hashomer, Israel, [5]Sheba Medical Center, Ramat Gan, Israel, [6]Asaf Harofe Medical Center, [7]Soroka Medical Centre and Ben Gurion University, Beer-Sheva, Israel, [8]Tel Aviv, Israel, [9]Bnai Zion Medical Center / Technion Faculty of Medicine, Haifa, Israel

Background/Purpose: The objective of this study was to review the clinical and laboratory characteristics of patients with adult's Still disease treated with tocilizumab (TCZ) in Israel.

Methods: Israeli rheumatologists who have ever treated a patient suffering from adult Still's disease with TCZ were asked to review their files with special emphasis on the symptoms of the disease (arthralgias/arthritis, fever, sore throat, pleura-pericarditis, hepatitis), number of tender and swollen joints, ESR, CRP and dosage of prednisone at the initiation of TCZ, after 6 months and at the end of follow-up.

Results:: 11 cases were ascertained. All the patients fullfilled the Yamagushi classification criteria for adult Still's disease: 7 men, aged 33 ± 12, mean duration of disease of 7 years (range 1–25 years). Until treatment with TCZ, the mean number of disease modifying drugs, including $TNF\alpha$ blockers was 4; 7 out of 11 have previously failed $TNF\alpha$ blockers. TCZ was administered at a dosage of 8 mg/kg every 4 weeks in 8 patients and every 2 weeks in 3 patients. The mean follow- up was 15 months. All the patients, except 2, completed at least 6 months of treatment. At the start of TCZ treatment, despite a mean prednisone of $31mg \pm 28$ mg/d, all the patients reported joint pain; the mean tender and swollen joints count was 12 and 8, respectively. In addition, fever was reported in 7 patients, rash in 5, pleuritis in 3 and hepatitis in 2.The mean ESR and CRP were 65 and 13, respectively. After 6 months of treatment and at the end of follow-up, the number of swollen and tender joints, the ESR and CRP and the dosage of prednisone decreased significantly (Table 1). At the end of follow up, only 2 patients still complained of mild arthralgias and none reported systemic symptoms.

	Start of TCZ	After 6 months	End of follow-up
Swollen joints count	8 ± 6	1.25 ± 1.7*	0.7 ± 1.2*
Tender joints count	11.9 ± 7.7	2.25 ± 2*	1.2 ± 0,7*
ESR	65 ± 32	3.4 ± 1.5*	4.3 ± 2.26*
CRP (mg/dl)	13 ± 17	0.47 ± 0.17*	0.46 ± 0.6*
Prednisone dosage (mg/d)	31 ± 28	4.8 ± 3.5*	3.5 ± 5*

* Mean±SD; p<0.05
Mean; SD

Conclusion: TCZ is extremely efficacious in adult Still's disease. Although randomized controlled studies are needed to confirm this observation, TCZ should be strongly considered in the treatment of patient with adult Still's disease.

194

Long-term Efficacy of Tocilizumab in A Patient with Amyloidosis and Interstitial Pneumonia Secondary to Multicentric Castleman's Disease (MCD). Michihito Katayama[1], Soichiro Tsuji[1], Satoshi Teshigawara[1], Eriko Kudo-Tanaka[1], Maiko Yoshimura[1], Akane Watanabe[1], Akiko Yura[2], Yoshinori Harada[2], Yoshinori Katada[2], Jun Hashimoto[1], Masato Matsushita[3], Yukihiko Saeki[1] and Shiro Ohshima[1]. [1]Osaka-Minami Medical Center, Kawachinagano City, Japan, [2]Kawachinagano City, Japan, [3]Osaka Minami Medical Center, Osaka, Japan

Background/Purpose: Castleman's disease is a benign lymphoproliferative disorder characterized histologically by follicular hyperplasia and capillary proliferation with endothelial hyperplasia. In addition, overproduction of Interleukin-6 (IL-6) was shown in the germinal centers of hyperplastic lymph node of patients with multicentric Castleman's disease (MCD), and is implicated in the pathogenesis of MCD. We evaluated long-term efficacy of IL-6 blockade therapy in a patient with both amyloidosis and interstitial pneumonia secondary to MCD.

Methods: A 61-year-old male had abnormal shadows on his chest radiography pointed out by medical checkup in June 1999. Based on the results of a lymph node biopsy in April 2004, he was diagnosed with plasma cell-type MCD. Abnormal shadow on chest radiography indicating interstitial pneumonia, marked anemia, hypoalbuminemia, hypergammaglobulinemia and proteinuria were observed, and got worse gradually. In November 2007, the patient was admitted to our hospital. He showed marked lymphadeno-pathy at multiple sites, general malaise, low grade fever, loose stool, edema, coughing and dispnea on exercise were observed. The administration of Tocilizumab (TCZ) (8 mg/kg, every 2 weeks) was initiated in December 2007. As his disease activity was extremely high, it is necessary to use concomitant administration of low dose prednisolone to maintain the inflammation low. We monitored clinical findings, laboratory findings, functional test, imaging, and quality of life (QOL) evaluated by SF36 in the patient for four years after initiation of the IL-6 blockade therapy. Moreover, we examined the efficacy of TCZ for the treatment of amyloidosis by intestinal biopsies both at the baseline and one year after first administration of TCZ.

Results: At the baseline, abnormal laboratory findings were as follows; severe anemia, hypoalbuminemia, hypergammaglobulinemia, an elevated CRP level, an elevated serum amyloid A protein (SAA) level, an elevated IL-6 level and proteinuria (2.39 g/day). The results of the respiratory function test indicated obstructive dysfunction of the lung, and blood gases on room air showed hypoxia. Chest CT scan revealed interstitial pneumonia with multiple cysts distributed throughout the lung fields and generalized lymph node enlargement. Endoscopic biopsy of the stomach and duodenum revealed heavy deposition of AA amyloid at the baseline indicating amyloidosis secondary to MCD. TCZ reduced the levels of both CRP and SAA, and improved anemia and hypoalbuminemia. Disappearance of urinary protein was achieved within a year. Lymph nodes throughout the body decreased in size. The results of the images and functional test demonstrated improvement in the patient's interstitial pneumonia. One year after initiation of treatment with TCZ, endoscopic biopsy of former sampling site of the stomach and duodenum revealed disappearance of AA amyloid. The result of SF36 indicated the improvement both in physical and mental QOL. No severe side effect were observed during the treatment period.

Conclusion: This case report indicates the long-term efficacy of TCZ for the treatment of MCD. Moreover, TCZ is effective for the treatment of amyloidosis, interstitial pneumonia secondary to MCD.

Background/Purpose: To describe the characteristics and the outcome of inflammatory arthritis in patients with myelodysplastic syndrome (MDS).

Methods: French multicenter retrospective study which included patients with MDS and inflammatory arthritis. Patient's clinical, biological and radiological data at the diagnosis, during the follow-up were recorded, as well as treatment regimen. Patients with isolated arthritis were compared to MDS-associated vasculitis (n=22).

Results: Twenty-two patients with myelodysplastic syndrome (77.5 years [69–81]; 10 women) were included. IPSS score of the myelodysplastic syndrome was 0.75 [0–1.4]. Inflammatory arthritis was present in all patients, with polyarthritis in 14 (64%) and symmetric involvement in 15 cases (68%).

At the diagnosis of the arthritis, median DAS28-CRP was 4.5 [2–6.5], with the presence of anti-CCP antibodies in 2 cases (9%) and radiological erosions in 1 case. The median time between the diagnosis arthritis and MDS was of 9 [2–30] months, with median articular symptoms duration of 3 months [2–8]. The appearance of these 2 diseases was concomitant in 6 (27%) cases; arthritis preceded MDS in 12 (55%) and occurred after MDS in 4 (18%) cases. Characteristics of arthritis and of MDS, as well as treatments at the different points are in table 1. Whereas the number of swollen and tender joints significantly diminished during follow-up, as was the median DAS28-CRP (from 4.3 [3.8–4.6] at baseline to 2.9 [1.75–3.3]; p<0.05, C-reactive protein remained elevated (CRP>20 mg/l in 14 (64%) at baseline versus 8 (42%)). Nevertheless, no patients show any radiographic progression and new anti-CCP positivity during the follow-up of 29 [9–76] months. No correlation was found in concern the evolution of MDS and inflammatory arthritis. In concern the treatments, whereas almost all patients have corticosteroids, the associated treatment was present in only 4 cases (hydroxychloroquine in 2 cases, salazopyrine and etanercept, n=1; each). Eleven patients died during the follow-up from complications of MDS treatment or acutisation. In patients with MDS-associated vasculitis (n=22), death occurred in 17 cases (77%), but survival was not different from patients with only inflammatory arthritis.

Table 1.

Number of evaluable patients	Baseline assessment N=22	First visit N=19	Second visit N=11	Third visit N=9	Last visit N=19

* p<0.05 versus baseline
* p<0.005 versus baseline

Conclusion: This study describes the characteristics of associated inflammatory arthritis in MDS. At the difference of other inflammatory arthritis, the use of other than steroids immunosuppressors is very poor, probably in relation with the underlying hemopathy. The use of biologics in this condition could be preferred to methotrexate, but need prospective studies.

Sarcoidosis in Northern New England. Clinical Characteristics and Predictive Factors for More Aggressive Therapy. Alireza Meysami[1], Kevin F. Spratt[2] and Christopher M. Burns[3]. [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Geisel School of Medicine at Dartmouth, Lebanon, NH, [3]Dartmouth Medical School, Lebanon, NH

Background/Purpose: Sarcoidosis is characterized by a variable clinical presentation. DMARDs and biologics have been used for resistant and/or organ-threatening disease. We analyzed the cases of sarcoidosis in a tertiary medical center in northern New England.

Methods: This was a retrospective review of the medical charts of patients who presented to Dartmouth-Hitchcock Medical Center from 2005–2010. Data were extracted from the electronic medical records using ICD-9 code. Patients with biopsy-proven non-caseating granuloma or Lofgren's syndrome were included. Patients were divided into those requiring either no treatment or steroids alone (non-immunosuppression (Non-IMS) group) and those requiring immunosuppressive medication beyond steroid (IMS group).

Results: 402 charts were reviewed and 120 patients met the inclusion criteria. Comparison was made with data from the ACCESS study (736 patients, Baughman et al., 2001). See table1. In addition, Comparison was made between IMS and Non-IMS group in the study. Of 29 patients in the IMS group, 82.7% had 2 or more organs involved (P<0.0005). 68.9% were followed by Rheumatology service in IMS group (P<0.0001). Eye (P<0.003), Musculoskeletal (P<0.0004) and nervous system (P<0.030) involvement often required IMS. The average ACE level (Unit/L) was 66.8 in IMS and 48.3 in Non IMS group (P<0.0339). See Table 2.

Presence of other	P < 0.16	3	3
Autoimmune disease			
ACE level at diagnosis (unit/L)	P < 0.033*	48.3	66.8

Conclusion: We have characterized a unique sarcoidosis population in rural northern New England, mainly Caucasian with more musculoskeletal, skin and kidney involvement and less lung involvement compared to existing data. 24% of our patients required treatment beyond steroid (IMS group). The use of IMS was associated with the number of organs involved ($>=2$), and the specific organ involvement (eye, musculoskeletal, nervous system) at the time of diagnosis. We also observed a trend toward higher ACE levels in patients requiring the use of IMS. Rheumatologists followed most patients on IMS treatment, perhaps due to familiarity with these agents and/or seeing more complicated cases in their clinic.

Collapsing Glomerulopathy in Collagen Vascular-Like Disease. Rawad Nasr[1], Christine Johns[2] and Elie Gertner[3]. [1]University of Minnesota, Minneapolis, MN, [2]Regions Hospital, St Paul, MN, [3]Regions Hospital and University of Minnesota Medical School, St. Paul, MN

Background/Purpose: Collapsing Glomerulopathy (CG) is an uncommon podocytopathy with distinct clinical and pathological characteristics. It is usually associated with HIV disease or parvovirus B19 infection. There are a few case reports of CG in association with well defined connective tissue diseases mainly SLE. The rheumatological literature does not describe patients with CG and marked serological abnormalities who do not have sufficient clinical findings to diagnose definite collagen vascular disease.

Objective: Our objective is to expand the spectrum of rheumatological disease that may accompany CG to include patients with marked serological abnormalities, but minimal clinical findings that do not meet criteria for definite collagen vascular disease. These patients all appear to have a very similar mode of presentation and course. Rheumatologists should be aware of this condition and its association with marked serological abnormalities.

Methods: A review of all kidney biopsies performed at Regions Hospital from 2004 till 2012 revealed four cases of CG not associated with other diseases. We conducted a chart review of these patients. These four cases were then compared with the sixteen cases of collagen vascular-like disease in the renal literature to construct a profile of patients with collagen vascular-like disease and CG.

Results: Four patients (all non-Caucasian) were identified. Ages ranged from 29 to 51 years. All patients presented with massive proteinuria (approximately 20 grams / 24 hours) and renal insufficiency. None of the renal biopsies showed evidence of lupus nephritis, immune complex deposition or vasculitis. All had evidence of CG. All testing for HIV, parvovirus B19, and other known causes of CG were negative.

Age	Sex	Ethnicity	Clinical	Cr (mg/dl)	Proteinuria (gr/24 hr)	ANA	Other	Rx	Outcome
38	M	AA*	Arthralgias Dry mouth	3.7	21	1:160	High titer Anti-RNP, IgG ACLA*	Prednisone, MMF*	Improved at 6 mo f/u
51	M	Cambodian	None	3.4	20	1:80	Low titer ds-DNA	Prednisone	On PD* after 3 mo
25	F	African	Alopecia	2.4	12	1:1280	High titer Anti-RNP, IgA/ IgM ACLA*, ds-DNA	Prednisone, Cyclosporine, and Hydroxychloroquine	On HD* after 3 years
29	F	Hispanic	Headaches	7.6	Notdone	1:640	High titer Anti MPO, low C3	Prednisone	On HD* at onset

* ACLA=Anti-cardiolipin Antibodies, PD= Peritoneal Dialysis, HD= Hemodialysis, AA= African American, MMF=Mycophenolate Mofetil

In comparison, the few cases of collagen vascular-like disease and CG in the renal literature also had marked proteinuria, renal insufficiency, and were treated with prednisone $+/-$ immunomodulatory therapy like MMF. Most patients became dialysis dependent within two years of diagnosis (some sooner) despite initial response to steroids.

Conclusion: Rheumatologists may be asked to see patients with collagen vascular-like disease (minimal symptoms and marked serological abnormalities) with severe proteinuria and renal insufficiency due to CG. The presence of high titer antibodies suggests that immune activation may play a role in the podocytopathy of some patients with CG. Treatment with steroids and the agents described to date does not seem to be effective in the long term. Further definition of these patients and treatment trials are necessary.

Diagnostic Predictors and Clinical Outcomes in Patients Presenting Solely with Lymphadenopathy. Huifang Lu, Xerxes Pundole and Khanh Vu. UT MD Anderson Cancer Center, Houston, TX

Background/Purpose: Patients presenting solely with radiologic evidence of lymphadenopathy (LAD) to tertiary cancer centers are often diagnosed with malignancy or autoimmune diseases such as sarcoidosis. However, the baseline characteristics predictive of a cancer or sarcoidosis diagnosis, clinical outcomes and follow-up time are unknown.

Methods: Retrospective chart review of adult patients (age $>$ 18) presenting with LAD and without an apparent mass at other sites, such as the breast or prostate; seen at Mary Ann Weiser Suspicion of Cancer Clinic and rheumatology clinics at The University of Texas MD Anderson Cancer Center, new consultation from January 1, 2003, to June 30, 2007, and followed to December 31, 2011. Data collected and analyzed included age, sex, follow-up time, comorbidities, B symptoms, laboratory test results, imaging studies, histopathology analyses, and final diagnosis. Multiple logistic regression was used to asses baseline characteristics predictive of a cancer diagnosis.

Results: Of the 66 patients studied, 36 (55%) were diagnosed with cancer; the most common type was lymphoma. Sarcoidosis (17%) and reactive hyperplasia (23%) were the most commonly seen benign causes of LAD. Malignancy was diagnosed in 94%, 79%, and 70% of patients with supraclavicular, retroperitoneal, and abdominal LAD, respectively, suggesting an association between these locations and a cancer diagnosis. A benign diagnosis was more common with localized LAD than with generalized LAD (63% vs 37%). The final multiple logistic regression models showed age (used as a continuous variable) (p=0.0342) and hypertension (p=0.0399) to be associated with a cancer diagnosis. Another model using age as a dichotomized variable ($<$50, $\geq$50) (p=0.0447) and hypertension (p=0.0245) showed both to be associated with a cancer diagnosis, suggesting hypertension and age as independent factors in predicting a cancer diagnosis. Other comorbidities like history of smoking, history of alcohol, history of prior cancer and rheumatologic disease did not have a significant association with a cancer diagnosis. Mean serum levels of angiotensin-converting enzyme (ACE) checked in 24 of the 66 patients, were higher in patients without cancer than in patients with cancer. No significant statistical correlation was observed between B symptoms and a cancer diagnosis. On histopathology varying proportions of cell types were found in the lymph node specimens and a conclusive relationship with a particular diagnosis was not evident overall. The average follow-up time was 7 months, although in 1 of the patients a conclusive diagnosis was arrived at after 1 year. None of the patient's with sarcoidosis progressed to a cancer diagnosis.

Conclusion: Older patients with hypertension presenting to a cancer center with abdominal, retroperitoneal, or in particular supraclavicular LAD are at risk for the diagnosis of hematologic malignancy. We recommend that they should be followed for at least 1 year for a definitive diagnosis. A larger prospective study should be conducted to analyze other factors such as localized vs. generalized LAD or ACE levels (or other laboratory values) and their correlation with a cancer diagnosis.

Joint, Hand and Feet Swelling As a Presenting Symptom of Hereditary Angioedema. Maria J. Gutierrez[1] and Timothy J. Craig[2]. [1]Penn State College of Medicine Milton S. Hershey Medical Center, Hershey, PA, [2]Penn State College of Medicine Milton S. Hershey Medical Cente, Hershey, PA

Background/Purpose: Hereditary Angioedema (HAE) is a rare disorder caused by deficiency or impaired function of C1 esterase inhibitor. Early and accurate diagnosis of HAE is important to initiate appropriate therapy and avoid potentially fatal outcomes. However, HAE symptoms can mimic other conditions potentially leading to incorrect diagnosis and delay in treatment. Our purpose was to investigate the proportion of hand, feet and joint swelling as presenting signs of hereditary angioedema across different countries.

Methods: A web-based survey was conducted among physicians who treated HAE patients within their practice in over 30 countries in North and Latin America, Europe, Asia, Africa and Oceania. Physicians voluntarily accessed and completed the internet-based survey between November 2010 and February 2011.

Results: A total of 201 international physicians who treated HAE patients completed the survey. Most patients treated by surveyed physicians were under 35 years-old (67%) and symptoms had first presented during childhood or adolescence in 77% of all cases. Among respondents there was widespread consensus about delay between the first HAE attack and diagnosis. Overall, only 14% of treated patients had been diagnosed within the first year and in 48% of cases there was a reported delay of 4 or more years. The patient's most common complaint that prompted evaluation for HAE was facial swelling. Nonetheless, hand, feet or joint swelling were listed as one of the two most common symptoms at onset by 40% of physicians. Interestingly, hand, foot and joint swelling were also ranked among the three most problematic symptoms during attacks by 35% of physicians surveyed.

Conclusion: HAE is a rare condition that usually presents during the first two decades of life and may present with hand, feet and joint swelling as main symptom. In addition, an important proportion of surveyed physicians thought that this is one of the most problematic symptoms of patients with HAE. Accordingly, HAE should be included in the differential diagnosis of certain types of joint and extremity edema, and thus, increased awareness of the pediatric rheumatology community could lead to a decrease in the morbidity and mortality of this condition.

Rheumatic Manifestations and Connective Tissue Diseases in Autoimmune Hepatitis of the Child and the Adult. Federico Zazzetti[1], Nora C. Fernandez[1], Javier Benavidez[1], Luis A. Colombato[1], Graciela R. Rodriguez[2], Graciela Nardi[2], Carolina Bru Morón[3], Oscar L. Rillo[4], Nelo A. Quadrini[3], Stella M. Garay[5], Mariana Fabi[5], Teresita Gonzalez[5] and Juan C. Barreira[1]. [1]Buenos Aires British Hospital, Buenos Aires, Argentina, [2]Hospital Dr. Ignacio Pirovano, Buenos Aires, Argentina, [3]Hospital Dr. Enrique Tornú, Buenos Aires, Argentina, [4]Hospital Tornú, Buenos Aires, Argentina, [5]Hospital IAEP Sor María Ludovica, La Plata, Argentina

Background/Purpose: Autoimmune hepatitis (AIH) is a progressive fibrosing inflammatory disease of the liver of unknown etiology, leading to cirrhosis. Its course is usually fluctuating and its clinical manifestations protean. Forty % of type I AIH and 80% of type II is diagnosed in childhood. Up to 30% of patients with AIH will develop rheumatic manifestations. Moreover, AIH can be associated with various connective tissue diseases (CTD), although there is a lack of studies comparing pediatric and adult populations in this regard. The aim was to analyze the frequency of rheumatic manifestations and CTD in patients with AIH in a pediatric population (≤ 16 years old) compared with adults.

Methods: Patients of any age who fulfilled the 1998 modified diagnostic criteria for AIH of the Autoimmune Hepatitis International Group assisted in Hepatology services of the intervening centers. They were clinically evaluated by a hepatologist and referred to a rheumatologist. Demographic, clinical and serological variables, as well as additional studies and biopsies were recorded. Rheumatic manifestations and CTD were registered and defined according to ACR criteria. Means were reported for numeric variables and percentages for categorical. To compare two groups Mann Whitney and X^2 tests were applied. A 0.05 α-error was chosen.

Results: Forty-eight patients with AIH were analyzed: 28 adults, 89% female, mean age at inclusion 50 ± 17 years (range=19–75) and age at diagnosis of AIH 41 ± 18 years (range=18.6–70), and 20 pediatric, 75% female, mean age at inclusion 13.8 ± 4 years (range=5–16) and age at diagnosis of AIH 9.7 ± 4 years (range=1.5–16). Sixty-four % (18/28) of adults and 55% (11/20) of pediatric had at least one rheumatic manifestation (p=n/s). There were no differences in the type and frequency of rheumatic manifestations analized in the two age groups, including malar rash, oral ulcers, parotitis, photosensitivity, xerophthalmia, xerostomia, telangiectasias, Raynaud's, vasculitis, xeroderma, subcutaneous nodules, arthralgia, arthritis, myositis, interstitial lung disease, serositis, citopenias, glomerulonephritis, proteinuria and nervous system involvement. Nine CTD were found, 5 in adults (17.8%, SLE=4, Sjögren=1) and 4 in pediatric patients (20%, SLE=3, JIA = 1). Comparing both groups, the pediatric group had more jaundice (p=0.03), hepatomegaly (p=0.0001), cirrhosis (p=0.03), splenomegaly (p=0.003), anemia (p=0.003), ESR (p=0.04), AST (p=0.0006), ALT (p=0.006), FAL (p=0.01), total bilirubin (p=0.003), ANA (p=0.04), ASMA (p=0.0001) and LKM (p=0.03). There were no differences regarding histological findings of liver biopsies. Autoimmune thyroiditis was more frequent in adults 4/28 vs 1/20 (p=0.001).

Conclusion: The frequency of rheumatic manifestations and CTD was similar in both groups, but pediatric patients had a more severe hepatic involvement and higher levels of autoantibodies. Regardless of age, 2 of 10 patients with AIH presented an associated CTD, and at least half of them developed rheumatic manifestations. Systemic lupus was the most frequent CTD associated to both groups. The systematic search for defined CTD and/or rheumatic manifestations should be an essential part of the clinical evaluation of AIH.

High Rate of Autoimmune Manifestations During Idiopathic CD4 Lymphocytopenia. Alexis Régent[1], Brigitte Autran[2], Guislaine Carcelain[2], Benjamin Terrier[3], Alain Krivitzky[4], Eric Oksenhendler[5], Nathalie Costedoat-Chalumeau[6], Pascale Hubert[2], Olivier Lortholary[7], Nicolas Dupin[8], Patrice Debré[2], Loic Guillevin[9] and Luc Mouthon[1]. [1]Hopital Cochin, Paris, France, [2]Laboratoire d'Immunologie Cellulaire Et Tissulaire, Paris, France, [3]Cochin Hospital, Paris, France, [4]Département de médecine interne, Hôpital Avicenne, AP-HP, Bobigny, France, [5]Département d'Immunologie Clinique, Hôpital Saint-Louis, AP-HP, Paris, France, [6]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [7]Service de maladies infectieuses, Hôpital Necker-Enfants malades, AP-HP, Paris, France, [8]Service de Dermatologie, Hôpital Cochin, AP-HP, Paris, France, [9]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France

Background/Purpose: When first described by the Center for Disease Control, idiopathic CD4 lymphocytopenia (ICL) was characterized by opportunistic infections in patients with a CD4 count≤300/mm3 or ≤20% lymphocytes. It is now well established that auto-immune manifestations occur during primary or secondary immunodeficiencies.

Methods: We prospectively included 36 patients (21 females) with ICL between January 1991 and June 2011. T lymphocyte phenotyping and lymphocyte proliferation assay were realized at diagnosis. Infectious, auto-immune manifestations and malignancies during a mean follow-up of 7.6±6.7 years were recorded and correlated with data at inclusion.

Results: Twenty four patients showed infections (11 with human papillomavirus infection), 11 autoimmune symptoms, 5 malignancies and 7 mild or no symptoms. Autoimmune and/or inflammatory manifestations include immune thrombocytopenic purpura (n=5), autoimmune hemolytic anemia (n=3), central nervous system vasculitis (n=1), Goodpasture syndrome (n=1), grade II duodenal villous atrophy (n=1), Crohn disease (n=1), antiphospholipid syndrome (n=1) and Hashimoto's thyroiditis (n=1). At the time of diagnosis, mean $CD4^+$, $CD8^+$, $CD19^+$ and natural killer (NK) cell counts were 126/mm3 (range 4–294), 238/mm3 (1–1293), 107/mm3 (3–547) and 115/mm3 (5–416), respectively. Most patients exhibited deficiency in $CD8^+$, $CD19^+$, and/or NK cells. Patients with infections had a significantly lower NK cell count (p=0.03) and those with autoimmune manifestations higher $CD45RO^+CD8^+$ count (p=0.02). T-cell proliferation induced by mitogens and antigens revealed great discrepancies. Six patients died (16.6%) during follow-up. $CD4^+$ T-cell count < 150/mm3 and NK cell count <100/mm3 were predictors of death.

Conclusion: 30.5 % patients with ICL show auto-immune manifestations during clinical course. These patients had higher $CD45RO^+CD8^+$ count at diagnosis. In addition to CD4 lymphocytopenia, patients often have CD8, CD19 and NK cell defects. Mortality is related to an initial $CD4^+$ count≤ 150/mm3 and NK cells≤100/mm3.

202

Diseases Associated with Markedly Elevated Ferritin Levels. Reshma Marri, Payal J. Patel, Amita Thakkar, Rochella A. Ostrowski, Eric McBride and Rodney Tehrani. Loyola Univ Medical Ctr, Maywood, IL

Background/Purpose: Adult onset Still's disease (AOSD) is a rare form of inflammatory arthritis with inflammatory systemic disease of unknown

etiology. It is a diagnosis of exclusion and can be a diagnostic challenge. A patient with suspected AOSD at our institution prompted a retrospective chart review of all patients with markedly elevated ferritin levels.

The patient, a 59 year old male with fever of at least one month who underwent an extensive negative evaluation for infection, malignancy, and other autoimmune etiologies was treated with high dose corticosteroids. A ferritin level at admission was 2200 ng/mL and rapidly rose to almost 50,000 ng/mL. Treatment for AOSD with IL-1 and IL-6 inhibition was unsuccessful and he died within one month from multi-organ failure. A bladder wall biopsy obtained just prior to death revealed an anaplastic large cell lymphoma.

Methods: In order to determine the association of autoimmune disease, including AOSD, with markedly elevated ferritin levels, in comparison to non-autoimmune diagnoses, we conducted a retrospective chart review of patients with elevated ferritins > 10,000 ng/mL seen at our institution from January 2000 to July 2011. Cases were divided into two subgroups, those with values between 10,000–15,000 and >15,000 ng/ml for analysis. The highest ferritin value was used when an individual subject had multiple values. There were 108 charts identified and reviewed for diagnoses at the time of the elevated ferritin level. Patients with either autoimmune disease, malignancies, liver disease, and/or infection were included in the analysis. Patients with hemoglobinopathies were excluded to avoid confounding of the ferritin levels by frequent blood transfusions. The remaining 88 cases were included for analysis.

Results: Twenty six patients with ferritin levels between 10,000–15,000 ng/ml were identified. The mean age of patients in this subgroup was 46.6 years. Of these patients, 10/26 (38%) had elevated ferritin levels secondary to liver disease, 7/26 (27%) malignancy/infection, 6/26 (23%) malignancy alone, 1/26 (4%) autoimmune disease, and 1/26 (4%) infection and liver disease/infection respectively. There were 62 patients with ferritins greater than 15,000 with a mean age of 44.3 years. Of these patients, 29/62 (47%) had liver disease, 9/62 (14%) malignancy, 7/62 (11%) autoimmune, 7/62 (11%) infection, 4/62 (6%) liver disease/infection, 4/62 (6%) malignancy/infection and 2/62 (3%) autoimmune/infection.

Conclusion: The observation that both ferritin groups include higher percentages of patients with liver disease and malignancy compared to autoimmune disease. Although not a part of the diagnostic criteria for AOSD, the presence of hyperferritinemia is commonly used to assist with diagnosis. These findings suggest that other diagnoses such as malignancies or liver disease should be considered in the differential diagnoses of markedly elevated ferritin levels. The diagnosis of AOSD is a diagnosis of exclusion and other underlying causes need to be ruled out.

Clinical Course Factors Associated with Outcome of Monoarthritis: A Retrospective Study of 173 Cases. Hyemin Jeong[1], Eun-Jung Park[2], Jiwon Hwang[2], Ji Young Chai[3], Joong Kyong Ahn[4], Eun-Mi Koh[5] and Hoon-Suk Cha[6]. [1]Samsung Medical Center, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Jesang Hospital, Seongnam-si Gyeonggi-do, South Korea, [4]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Seoul, South Korea, [6]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South Korea

Background/Purpose: To evaluate the clinical features and outcomes in patients with monoarthritis and to investigate predictive factors associated with the clinical course in terms of a definite diagnosis and polyarticular involvement.

Methods: A retrospective analysis of 173 patients who had undiagnosed monoarthritis (UMA) at least six weeks' duration at a single tertiary hospital between January 2001 and January 2011. Baseline characteristics, laboratory data, radiographic findings and clinical course were reviewed.

Results: Of 173 patients (80 males and 93 females), the mean age was 43.1 ± 15.1 years. The median follow-up duration was 21 months (range, 1.5 to 120). Most commonly involved joints were the knee (23.7%) and wrist (23.7%), followed by the ankle (18.5%). A definite diagnosis was made in 71 patients (40.5%); 27 patients with rheumatoid arthritis (RA) based on the 2010 ACR/EULAR classification criteria, 18 patients with Behcet's disease (BD) according to the diagnostic criteria of the BD research committee of Japan, 23 patients with peripheral arthritis of spondyloarthropathy (SpA) based on the ASAS criteria, 2 patients

confirmed with infectious arthritis (one with *Nontuberculous mycobacterium* and one with methicilline-resistant *Staphylococcus aureus*), and one patient as SAPHO syndrome. The other 102 patients (59.5%) remained unclassified because of lacking in requirements and seemed to have shorter follow-up duration (23.0 versus (vs) 16.5 months, p = 0.08). Of total 173 patients, 24 patients (13.9%) were progressed to oligo- or polyarthritis and 92 patients (53.2%) remained UMA. The rate of patients treated with non-steroidal anti-inflammatory drugs without disease modifying antirheumatic drugs is higher in UMA group than diagnosed group (53.3% vs 22.2%, p < 0.001). The UMA patients were related to lower baseline C- reactive protein (CRP) (OR 0.67, 95% CI 0.53 to 0.85, p = 0.001), and the negativity of anti-cyclic citrullinated protein antibody (ACPA) (OR 0.34, 95% CI 0.13 to 0.89, p = 0.027). Rheumatoid factor did not show significant association (OR 0.75, 95% CI 0.37 to 1.51, p = 0.418). HLA-B27 was checked in 27 patients only who were suspicious of SpA and the positivity was 44.4%. The initial site of joint involvement was predictive for later diagnosis; the wrist joint for RA (odds ratio (OR) 9.09, 95% confidence interval (CI) 3.70 to 22.34, p < 0.001), the knee joint for BD (OR 3.43, 95% CI 1.29 to 9.15, p = 0.01) and the ankle joint for peripheral SpA (OR 6.19, 95% CI 2.38 to 16.08, p < 0.001). The presence of bony erosion at initial visit was associated with the progression to oligo-or polyarthritis (OR 2.88, 95% CI 1.09 to 7.59, p=0.03).

Conclusion: Our data showed clinical course of monoarthritis. A definite diagnosis was made in less than half of the patients and remaining UMA patients seemed to have favorable prognosis. Initial site of joint involvement, the bony erosion on initial radiograph, baseline CRP and the ACPA status can help to predict the course of monoarthritis.

Characterization of Joint Disease in Mucopolysaccharidosis Type I Mice and the Effects of Enzyme Replacement Therapy. Patricia Oliveira[1], Guilherme Baldo[2], Fabiana Mayer[2], Barbara Martinelli[2], Luise Meurer[2], Roberto Giugliani[2], Ursula Matte[2] and Ricardo M. Xavier[3]. [1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil, [2]Hospital de Clinicas de Porto Alegre, [3]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Background/Purpose: Mucopolysaccharidosis type I (MPS I) is a lysosomal disorder caused by deficiency of alpha-L-iduronidase, which leads to storage of glycosaminoglycans. Patients with MPS I present destructive changes in their joints in a process not well understood. The MPS I animal model is a useful tool to study the disease pathogenesis; however the changes in the MPS I joints were never investigated. This work aimed to describe the joint disease progression in the murine model of MPS I, and the effect of treatment with enzyme replacement therapy (ERT).

Methods: Normal (wild type) and untreated MPS I mice were sacrificed at different time points (from 2 to 12 months). In addition, some MPS I mice were treated with ERT and sacrificed at 6 months. The knee joints were collected and hematoxylin and eosin staining was used to evaluate the articular architecture. Safranin-O and Sirius-Red staining was used to analyze proteoglycans (PGs) and collagen content. In addition we analyzed the expression of matrix-degrading metalloproteinases (MMPs), MMP-2 and -9, by immunohistochemistry.

Results: We observed progressive joint alterations from 6 months, including presence of synovial inflammatory infiltrate, destruction and thickening of the cartilage extracellular matrix and PGs and collagen depletion. Also, we observed an increase in the expression of MMP-2 and -9, which could explain the degenerative changes. We also investigated the effect of ERT when started at 2 months, which showed no benefits, suggesting that the poorly vascularized cartilage is difficult to reach, and an ancillary therapy might be needed for patients.

Conclusion: Our results suggest that the degenerative joint and bone disease in MPS I animals presents some similarities to osteoarthritis. More important, our results evidence the need for and an ancillary therapy for patients.

Idiopathic Inflammatory Myositis Is Associated with an Increased Incidence of Systemic Sclerosis. Shreyas H. Chaudhary[1], Susanna Proudman[2] and Vidya S. Limaye[2]. [1]Medical Student University of Adelaide, Adelaide, Australia, [2]Royal Adelaide Hospital, Adelaide, Australia

Background/Purpose: Systemic sclerosis (SSc) and idiopathic inflammatory myositis (IIM) are two systemic autoimmune connective tissue diseases with predominant effects on skin and muscle respectively. Although they generally occur as distinct disease entities, some features of SSc and IIM may be seen together in "overlap syndromes" or in mixed connective tissue disease (MCTD). The aim of this study was to determine the occurrence of SSc in IIM, and vice versa, in patients without features of MCTD or overlap syndromes. We also sought to compare the incidence of SSc in IIM, with that of rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and primary Sjogrens syndrome (pSS).

Methods: The South Australian (SA) Myositis Database has registered all patients with biopsy-proven IIM in SA subsequent to 1980. All adult muscle biopsies performed in SA are reported in a central diagnostic laboratory and are subjected to peer review. The criteria used to diagnose IIM are those based on current published literature. Myositis-associated antibodies (MAA) and myositis-specific antibodies (MSA) have been measured on 138 patients with myositis. The South Australian Scleroderma Register similarly registers all patients in SA diagnosed with limited or diffuse SSc. Fisher's exact T-test was used for statistical comparisons.

Results: The incidence of SSc in IIM was 18/426 (4.2%). A greater proportion of IIM patients had SSc (18/426) than RA (2/426, p=0.003) or MCTD (4/426, p=0.004).There was a trend towards a greater proportion of IIM patients having SSc than SLE or pSS (each 8/426, p=0.07). There was no difference in the proportion of females amongst patients with IIM alone (231/426) compared with IIM and SSc (13/18, Fishers exact T test p =0.15. Of the 18 patients with SSc and IIM, 14 had polymyositis, 3 dermatomyositis, 2 inclusion body myositis and one had necrotizing myopathy. Four patients had antibodies to PM-Scl (3 of these had polymyositis, one had dermatomyositis). Antibodies to other MSA or MAA were detected as follows: Ku (n=2), MI-2 (n=1), PL12 (n=1), Jo-1 (n=1) and Ro52 (n=2). Of the 177 patients on the SA Scleroderma Register, 22 had suspected IIM (incidence of IIM in SSc =12.4%). Of these 22 patients, 18 had elevations in creatinine kinase levels, and ten had biopsy confirmation of IIM.

Conclusion: Although the population incidence of RA, SLE and pSS is greater than SSc, in IIM, there is a greater incidence of SSc and SSc is the commonest autoimmune connective tissue disease in IIM. The co-occurrence of these two conditions raises the possibility of shared disease susceptibility.

Clinical, Laboratory, and Cellular Responses in the Rituximab in Myositis Trial in Patients Enrolled At the National Institutes of Health. Lisa G. Rider[1], Adrienne L. Yip[1], Iren Horkayne-Szakaly[2], Rita Volochayev[1], Joseph A. Shrader[3], Maria L. Turner[4], Heidi H. Kong[4], Minal S. Jain[3], Anna V. Jansen[1], Chester V. Oddis[5], Thomas A. Fleisher[6] and Frederick W. Miller[1]. [1]National Institute of Environmental Health Sciences, National Institutes of Health, Bethesda, MD, [2]Joint Pathology Center, Silver Spring, MD, [3]Rehab Medicine, NIH Clinical Center, Bethesda, MD, [4]NCI, NIH, Bethesda, MD, [5]University of Pittsburgh, Pittsburgh, PA, [6]Laboratory Medicine, NIH Clinical Center, Bethesda, MD

Background/Purpose: To assess changes in myositis core set measures, clinical and laboratory data, and paired muscle biopsies from NIH patients enrolled in the Rituximab in Myositis (RIM) trial.

Methods: Eighteen patients (5 dermatomyositis [DM], 8 polymyositis [PM], 5 juvenile DM) completed muscle and skin assessments, patient-reported outcome measures (PROs), and laboratory tests following administration of rituximab. Adult patients had muscle biopsies at weeks 0 and 16. Percent change and

standardized response means (SRM) were examined over 44 weeks, and the percent change in the definitions of improvement (DOI) was compared.

Results: Core set activity measures improved by 18–70% from weeks 0–44, although creatine kinase was the least sensitive to change (SRM 0.6 for CK vs. 1.2–2.0 for other core set measures). Response rates at week 44 ranged from 72–94% by various DOIs for myositis. For DM patients, strength and functional measures improved by 17–64%, and skin measures by 0–43% (Table). Muscle strength measures (SRM 1.3–2.2) were more sensitive to change than skin assessments (SRM 0.6–1.1). Constitutional, gastrointestinal, and pulmonary systems improved 44–70% (SRM 0.9–2.7). PROs, including SF-36 and PedsQL Fatigue scale, improved 25–28% (SRM 1.0–1.2), but the Fatigue Severity Scale and a dyspnea score did not change.

CD20 B cells were generally depleted in the peripheral blood and frequently depleted in muscle. No effects were observed on blood or muscle T cells or on other muscle biopsy parameters (inflammation, regeneration, vascular abnormalities, and fibrosis). Seven of 10 patients with CD20 in the muscle at baseline depleted CD20 in the muscle and peripheral blood at week 16. Of these, only one achieved the DOI at week 16, and 6 patients achieved the DOI at week 44. One patient who responded clinically at weeks 16 and 44 depleted CD20 in the periphery and had reduced, but did not deplete, CD20 in the muscle. Three patients had reduced or depleted CD20 in the periphery but increased CD20 in the muscle, and all 3 met the DOI at weeks 16 and 44. In terms of memory B cells in the peripheral blood, 1 adult DM patient did not deplete CD20+CD27+ cells but met the DOI, and 2 juvenile DM patients depleted CD20+CD27+ cells but did not meet the DOI. The other 11 patients with CD20+CD27+ cells depleted these cells and met improvement criteria.

Measure [potential range]	Median Baseline value	Median % change Week 0–44	Standardized Response Mean Week 0–44
Muscle			
MMT-8 Score [0–80]	54.5	28c	2.2
Total MMT Score [0–260]	188.0	24c	2.1
QMT-8 [0–250 lb.]	61.8	64b	1.3
MDAAT Muscular VAS [0–10 cm]	4.8	48c	1.5
DAS Muscle [0–11]	8.0	17a	1.4
CMAS [0–52]	34.0	26a	1.2
HAQ/CHAQ [0–3]	1.4	50a	1.2
Skin			
CDASI [0–168]	17.5	17	0.9
DLQI [0–30]	4.5	43a	0.6
MDAAT Cutaneous VAS [0–10 cm]	3.4	28	1.1
DAS Skin [0–9]	6.0	0	1.0

a $P < 0.05$,
b $P < 0.01$,
c $P < 0.005$.

Conclusion: Myositis patients enrolled at the NIH had similar high rates of clinical response to rituximab compared with patients in the overall RIM trial. Most measures were very responsive, but muscle measures had a greater degree of change than skin. Depletion of CD20+ cells in the periphery and target tissue did not always correlate with clinical response.

Interferon-Driven Chemokines Are Associated with Changes in Disease Activity Among Rituximab-Treated Refractory Myositis Patients with Pulmonary Involvement—the RIM Study. Cynthia S. Crowson[1], Ann M. Reed[1], Molly Hein[1], Abigail B. Green[1], Consuelo Lopez de Padilla[1], Rohit Aggarwal[2], Dana P. Ascherman[3], Marc C. Levesque[4] and Chester V. Oddis[4]. [1]Mayo Clinic, Rochester, MN, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]University of Miami, Miami, FL, [4]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: The Rituximab in Myositis (RIM) Study provides a unique resource for biomarker investigation of homogeneously treated refractory adult and juvenile myositis patients. Building on prior cross-sectional findings, we examined the longitudinal utility of Type 1 interferon (IFN)-driven chemokines as clinical biomarkers of disease activity in myositis patients treated with B cell depletion.

Methods: All 200 enrolled refractory myositis patients (failed steroids and ≥1 other immunosuppressive agent) received 1 gram of rituximab on 2 consecutive weeks–weeks 0/1 (Early) or weeks 8/9 (Late). Using serum samples

collected at weeks 0 and 16, multiplexed sandwich immunoassays (Meso Scale Discovery) quantified IFN-regulated chemokines and other pro-inflammatory cytokines. An IFN chemokine score combining IFN-inducible T-cell chemoattractant (I-TAC), IFN-inducible 10-kd protein (IP-10), and monocyte chemotactic protein 1 (MCP-1) was computed. Data collected at each visit included: muscle enzymes, physician global, muscle and extramuscular visual analog scale (VAS) scores (0–10 cm) and Myositis Disease Activity Assessment Tool variables (i.e., VAS score for organ involvement). Pulmonary involvement was defined as VAS>1 cm and included active interstitial lung disease (ILD) and respiratory muscle weakness (i.e., dysphonia and dyspnea). Changes in IFN chemokine and VAS scores were calculated as week 16–week 0, and correlations were assessed using Spearman methods.

Results: In 181 patients (87 Early, 94 Late) with available serum samples, changes in IFN chemokine score correlated with changes in physician global (r=0.19 p=0.017), muscle (r=0.19 p=0.019) and extramuscular VAS (r=0.24 p=0.002). These associations persisted after adjusting for muscle enzymes (global r=0.15 p=0.056; muscle r=0.16 p=0.046 and extramuscular r=0.25 p=0.002), suggesting that the IFN chemokine score is complementary to muscle enzymes. The IFN chemokine score at week 0 correlated with change in extramuscular VAS (r=−0.18 p=0.027), but not with change in global or muscle VAS (r<0.1).

In patients with pulmonary involvement (n=70), IFN chemokine score at week 0 was more strongly correlated with changes in disease activity (global r=−0.37 p=0.004; muscle r=−0.36 p=0.005; extramuscular r=−0.41 p=0.001) than in patients without pulmonary involvement (n=111; r=0 to 0.14). The change in IFN chemokine score was also more strongly correlated with the change in disease activity by VAS among patients with pulmonary involvement (global r=0.27 p=0.04; muscle r=0.45 p<0.001; extramuscular r=0.41 p=0.001) compared to patients without pulmonary involvement (r=0.06 to 0.15). Results for patients with active ILD (n=32) were similar to those for non-parenchymal pulmonary involvement.

Conclusion: Changes in IFN chemokine score correlated with changes in disease activity, particularly among myositis patients with pulmonary involvement (with or without active ILD). The IFN chemokine score may be a useful clinical biomarker for patients with myositis, especially in patients with lung involvement. In addition, these chemokines may provide useful insights into the pathogenesis of myositis or specific manifestations.

Outcome of Muscle Function and Disease Activity in Patients Recently Diagnosed with Polymyositis and Dermatomyositis–Preliminary Results of a 1-Year Follow-up Registry Study.

Helene Alexanderson[1], Jenny Bergegård[2], Christina Ottosson[3], Maryam Dastmalchi[4] and Ingrid E. Lundberg[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Solna, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden, [4]Rheumatology Unit, Karolinska University Hospital in Solna, Karolinska Institutet., Stockholm, Sweden

Background/Purpose: Most patients with polymyositis (PM) and dermatomyositis (DM) develop sustained muscle impairment. The aim of this study was to evaluate the muscle endurance (Functional Index 2, FI-2), muscle strength (MMT-8) and disease activity (selected 6-item core set measures) at 6 and 12 months after PM/DM diagnosis onset (baseline).

Methods: 72 patients, 40 with PM and 32 with DM, diagnosed 2003–2010 who performed the FI-2 and the MMT at baseline were included. They had median age md (Q1-Q3) 55 (41–70) years and md diagnosis duration 0 (0–1) months. 44 were women and 28 were men, 34 patients had md 50 (30–60) mg of prednisone/day, 38 were without medication. Mixed Linear Model with time as fixed variable was used with the Bonferroni after test to compare genders and diagnosis at different time points. Individually patients were identified as responders improving > 20% or worsening > 20% in the FI-2/MMT at follow-ups compared to baseline. Significance level was set to 0.05.

Results: The group had md 27 (8–60) % of FI-2 maximal score and md 94 (83–99) % of MMT maximal score at baseline (p<0.000) with no significant change at 6 or 12 months compared to baseline. Men had higher FI-2 scores md 50% (22–84) of maximal score at baseline, 84% (17–88) at 6 months, 61% (27–90) than women md 13% (5–42) at baseline, 19% (6–47) at 6 months and 18% (10–46) at 12 months (p<0.000) and men improved more over time in FI-2 than women (p<0.000). 44% of 41 patients were responders and 22% worsened in FI-2 score at 6 months and 49% of 45 patients were responders and 29% worsened at 12 months. 19 % of 37 patients were responders in MMT score at 6

months and 15% of 33 patients were responders at 12 months, no patient worsened. PM and DM patients improved in VAS physician global disease activity at 6 and 12 months compared to baseline (p<0.034, p<0.002) but patients with PM had significantly higher scores 10 (5–30) mm at 12 months compared to DM md 6 (4–15) mm (p<0.043). The men had significantly reduced global extra-muscular VAS scores at 6 and 12 months compared to baseline (p<0.011, 0.021) and women remained unchanged. Patients with DM had reduced extra-muscular disease activity at 6 and 12 months (p<0.022, p<0.021) while there was no change in PM.

Conclusion: Male patients seem to improve more over time than women in muscle endurance and improve in extra-muscular disease activity while women do not. Patients with DM seem to have lower disease activity compared to PM and DM patients improve in extra-muscular disease activity while patients with PM do not. Between 44–49 % were responders and 22–29 % worsened in muscle endurance while 15–19% were responders and none worsened in muscle strength.

209

Clinical Study of Determination of Myositis-Associated Autoantibodies in Japanese Patients with Connective Tissue Diseases except Autoimmune Myositis.

Toshio Kawamoto[1], Masakazu Matsushita[1], Ken Yamaji[1], Naoto Tamura[1] and Yoshinari Takasaki[2]. [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Juntendo University, Tokyo, Japan

Background/Purpose: Anti-Jo-1 antibody is detected in the sera of patients with polymyositis/dermatomyositis (PM/DM). The antigen to which this antibody is directed is histidyl-tRNA synthase, an aminoacyl-tRNA synthase (ARS) which occurs in the cytoplasm of eukaryotes, and various anti-ARSs have been identified depending on differences of corresponding amino acids. In addition, other autoantibodies detected in patients with myositis include anti-Ku antibody, anti-Mi-2 antibody, anti-SRP antibody, and anti-PM-Scl antibody. This study was performed to evaluate the clinical characteristics and usefulness of determining the serum levels of these antibodies in patients with connective tissue diseases (CTD) other than PM/DM.

Methods: The study included 337 patients with CTD who had been followed up at the outpatient service of this hospital. Of them, 63 had PM/DM, 86 had systemic lupus erythematosus (SLE), 86 had rheumatoid arthritis (RA), 29 had Sjögren's syndrome (SjS), 11 had mixed connective tissue disease (MCTD), 14 had progressive systemic sclerosis (SSc), 12 had ANCA-associated vasculitis, 5 had Behçet's disease, 6 had aortitis syndrome, 7 had adult-onset Still's disease, and 18 had other diseases. Serum levels of antibodies were determined using Myositis Profile 3 Euroline Blot Test Kit commercially available from EURO-IMMUN (Lubeck, Germany).Clinical features were assessed for cases found to be positive for these autoantibodies.

Results: The analysis revealed that 12 patients were positive for anti-PL7 antibody, among other anti-ARS antibodies, and 6 of these patients had CTD other than PM/DM. Similarly, anti-PL12 antibody was detected in 4 patients including those with SLE, RA or MCTD. Anti-EJ antibody and anti-Jo-1 antibody were also detected frequently in RA and other non-myositis CTD. As for other myositis-associated autoantibodies, anti-PM-Scl75 antibody was detected in 7 patients with SLE and 2 patients with RA, while anti-Ku antibody was demonstrated in 3 patients with PM/DM, 4 patients with SLE and 3 patients with MCTD.

Regarding the relationship between the autoantibodies detected and clinical manifestations, concurrent interstitial pneumonia (IP) was high in incidence irrespective of underlying disorders among anti-ARS antibody-positive patients with CTD other than PM/DM. Anti-Ku antibody, anti-SRP antibody and anti-Mi-2 antibody, on the other hand, were detected also in non-myositis connective tissue diseases; however, there was no definite correlation between these antibodies and clinical manifestations including IP. The data obtained were reviewed also with respect to arthritis and Raynaud's phenomenon.

Conclusion: Serum levels of antibodies associated with myositis were determined in 337 patients, and anti-ARS antibodies were detected in a number of patients with CTD other than PM/DM. These autoantibodies detected were strongly correlated with IP, which tended to be intractable. The present results indicate that it is clinically useful to determine the serum levels of anti-ARS antibodies and other myositis-associated autoantibodies in patients with CTD complicated by IP even when their underlying diseases are not myositis.

An Analysis of Metabolic Syndrome in Adult Dermatomyositis with a Focus On Cardiovascular Disease. Mariana T. Moraes, Fernando H.C. Souza, Thiago B. M. Barros and Samuel K. Shinjo. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: Metabolic syndrome (MetS) is a cluster of metabolic abnormalities associated with increased cardiovascular risk. MetS has been systematically evaluated in all systemic autoimmune rheumatic diseases except for dermatomyositis (DM). Hence, we evaluated the frequency of MetS in DM patients and analyzed the possible association of MetS with traditional cardiovascular disease (CVD) risk factors and DM-related clinical and laboratorial features.

Methods: The present cross-sectional single center study included 84 consecutive DM patients (Bohan & Peter, 1975) and 105 healthy control individuals. MetS was diagnosed according to the National Cholesterol Education Program Adult Treatment Panel III.

Results: The median age was similar in both the DM and control groups (aged 41.5 *vs.* aged 42.0, respectively; $p=0.378$) with a comparable predominance of the female gender ($p=0.904$) and white race ($p=0.654$) in both groups. The median disease duration was 4 years (range: 1–7). The DM patients had a higher prevalence of MetS (41.7 *vs.* 7.0%, $p<0.001$), diabetes mellitus (17.9 *vs.* 1.0%, $p<0.001$), ischemic stroke (4.8 *vs.* 0%, $p=0.024$), and a family history of premature CVD (32.8 *vs.* 8.6%, $p=0.004$). However, the frequency of sedentarism, hypothyroidism, smoking habit and alcohol intake were similar in both groups ($p>0.05$). Further analysis of the DM patients with ($n=35$) and without MetS ($n=49$) revealed that the patients with this complication were older (50.0±14.5 vs. 40.9±14.6, $p=0.006$) and had a similar disease duration ($p=0.925$) and a higher incidence of systemic arterial hypertension prior to the disease (54.3 *vs.* 10.2%, $p=0.001$). The frequency of other comorbidities, previously mentioned lifestyle contributing factors, clinical and laboratory disease features, and therapy schemes were similar in both groups ($p>0.05$). In a multivariate analysis, only hypertension diagnosed prior to the disease was associated with MetS (odds ratio 10.47, 95% confidence interval 2.62–44.81).

Conclusion: MetS is highly prevalent in DM and prior hypertension seems to be a major determinant of its development while disease and therapy related factors do not appear to play a relevant role.

Efficacy and Safety of Disease Modifying Drugs, Biologic Therapies and Immunoglobulin in Patients with Polymyositis and Dermatomyositis: A Systematic Literature Review. JA Martinez-Lopez Sr.[1], J. Graña Sr.[2], Santiago Muñoz-Fernandez[3], I. Rua-Figueroa[4], José M. Pego-Reigosa[5], Estíbaliz Loza Sr.[6] and SER group for the study of systemic autoimmune diseases[7]. [1]Fundacion Jimenez Diaz, Madrid, Spain, [2]Hospital Juan Canalejo, Spain, [3]Hospital Infanta Sofía, Madrid, Spain, [4]Hospital de GC Dr Negrin, Las Palmas GC, Spain, [5]Hospital do Meixoeiro, Vigo, Spain, [6]Research Unit. Sociedad Española de Reumatología, Madrid, Spain, [7]Madrid

Background/Purpose: The aim of this study was to systematically review the efficacy and safety of available drugs in patients with polymyositis (PM) or dermatomyositis (DM)

Methods: We systematically searched MEDLINE, EMBASE and the Cochrane Central Register of Controlled Trials up to October 2011 using a comprehensive search strategy for disease modifying drugs (DMARD), biologic therapies, intravenous immunoglobulins (IVIG), primary PMS and DPM, efficacy and safety (mesh terms and text words). Selection criteria were predefined by protocol. We selected meta-analysis, systematic literature reviews, clinical trials (CT), that included >18 year-old patients primary PMS and DM on the selected drugs, English, Spanish and French languages. Studies including patients with secondary PMS or DM, and basic science studies were excluded. Title and abstract selection and subsequent detailed review of selected articles were independently performed by two reviewers. A hand search of the selected articles was performed. The included studies quality was graded using the Oxford Levels of Evidence Scale, and results expressed as level of evidence (LE), recommendation grade (RG).

Results: The search strategy identified 2,442 potentially relevant articles, of which 114 were selected for full paper review. Twenty articles were eventually included in the analysis. The selection included 7 randomized CT, 13 open trials, which analyzed 334 patients. Main characteristics and results are shown in the table.

Table 1. Main results of the systematic literature review

Study	Efficacy
Amato (2011), RCT (n=16 DM), 52 w, Oxford 1c ETA vs PCB	-Improvement on IMACS: ETA/PCB 55%/60% -Prednisone stop: ETN/PCB 73%/20%, p<0,001 -Median time to treatment failure: ETA/PCB 358 d/148 d, p<0,001
Bunch (1978), RCT (n=14 PM), 12 w, Oxford 2b AZA vs PCB	-Muscle biopsy: AZA/PCB improvement, p>0,050 -MMT: improvement, AZA/PCB improvement, p>0,050
Bunch (1980), RCT (n=16 PM), 12 w, Oxford 2b AZA vs PCB	-CPK levels: AZA/PCB improvement, p>0,050 -Muscular strength AZA/PCB improvement, p=0,580 -Muscle biopsy: AZA/PCB improvement, p>0,050
Dalakas (1993) RCT (n=15 DM), 24 w, Oxford 1c IVIG (1 infusion) vs PCB	-Neuromuscular symptoms and scores of muscular strength: IG more improvement than PCB, p<0,018 p<0,035 -Muscle biopsy of IG patients: clear improvement
Fries (1973) RCT (n=8 PM), 16 w, Oxford 2b CYC vs PDN	-Disease activity: CYC 5/5 worsened; PDN 3/3 improvement
Miyasaka (2011) RCT (n=26 PM/DM), 26 w, Oxford 1b IVIG vs PCB	-MMT: IG/PCB improvement 92%/57%, p>0,050 -Dysphagia: IVIG ceased 5/7 (71%), PCB no improvement 2/2 (100%), p=0.167 -ADL score: IG/PCB improvement p>0,050 -CPK levels: IG/PCB improvement p>0,050
Vencovsky (2000) RCT (n=36 PM/DM), 24 w, Oxford 1c MTX vs CyA	-Muscle endurance and functional test: MTX/CyA improvement 29%/47%, p>0,050 -Clinical assessment: MTX/CyA improvement 65%/58%, p>0,050 -Global patient assessment: MTX/CyA improvement 59%/68%, p>0,050 -Muscle MRI: MTX/CyA improvement, p>0,050 -CPK levels: MTX normal levels, CyA elevated -ANA +: MTX/CyA 76%/68%, p>0,050
Cherin (2002) OT (n=35 PM), 3 yr, Oxford 2b IVIG	-Muscle power: improvement 25/35 (71%) -Muscle disability scale score: improvement 28/35 (80%) -Esophageal disorders: ceased 8/11 (27%) -Relapses: 7/25 (28%) -Steroids reduction: 22/35 (63%) -CPK levels: normal 19/33 (58%), improvement 14/33 (42%)
Cherin (1994) OT (n=11), 16 w, Oxford 2b IVIG	-British Medical Council Research grading system: improvement 3/11 (27%) -CPK levels: reduction 8/11 (73%)
Chung (2007) OT (n=8 DM), 24 w, Oxford 2b RTX	-Partial remission: 3/8 (38%) -Muscle enzyme levels and skin scores: not significantly changed from those at baseline
Dastmalchi (2008) OT (n=13 PM/DM), 16 w, Oxford 2b IFX	-IMACS: improvement 3/9 (33%), worsened 3/9 (33%) -MMT: no improvements -Muscle MRI: worsened 5 patients -Muscle biopsy: no changes from baseline
García Hernán. (2010), OT (n=14 PM/DM), 1 yr, Oxford 2b RTX + CYC	-Comlete or partial remission 1 m/6 m/1yr: 65%/100%/64% -British Medical Research Council grading system: improvement 100% -5 relapses, median of time to relapse: 11 m -Significant decreased: EGS, CPK, Mb, LDH -Pulmonary function: improvement 75%
Hara (2003) OT (n=11), 12 w, Oxford 2b IVIG	-MMT: improvement 7/8 (88%) -ADL score: improvement 7/8 (88%) -CPK levels: improvement 7/8 (88%)
Hengstman (2008) OT (n=6 PM/DM), 26 w, Oxford 2b IFX + MTX	-Patient and physician disease activity assessment, MMT, handheld dynamometry: improved -CPK levels: improved 2/6 (33%)
Kameda (2005) OT (n=10 DM + interstitial pneumonia), Oxford 2b Prednisolone + CYC + CyA	-5 survived for > 2 yr well
Levine (2005) OT (n=7 DM), 52 w, Oxford 2b RTX	-MMT: improvement 6/7 (86%) -Rash, alopecia, and reduced forced vital capacity, improved markedly -4 relapses
Mastaglia (1998) OT (n=7 PM/DM), Oxford 2b IVIG	-Complete or partial remission: 5/7 (71%) -Fuerza muscular: improvement 5/7 (71%) -CPK levels: normalization 5/7 (71%)
Mok (2007) OT (n=4 PM), 28 w, Oxford 2b RTX	-Promimal muscle power scores: improved 100% -CPK levels: improvement 100%, 2 normalization -HAQ: improvement 100% -Disability scores, SF-36: trend to improvement
Saito (2008) OT (n=15 PM/DM), 12 w, Oxford IGIV	-MMT: improvement 14/15 (93%) -ADL score: improvement 12/15 (80%) -CPK levels: improvement 15/15 (100%)
Tokano (2002) OT (n=11 DM/PM), 24 w, Oxford 2b CyA	-Respiratory symphoms improveement, ↑ PaO$_2$>10 mmHg, ↑ %DLCO, improvement chest radiology/TACAR, ↓ steroids doses >10%, ↓ LDH>25%: 7/11 (64%) maintained improvement

Abbreviations: PM=polymyositis; DM=dermtomyositis; w=week; m=month; yr=year; ETA=etanercept; PCB=placebo; AZA= azathioprine; CPK=creatine phosphokinase; CYC=cyclophosphamide; PDN=prednisone; CyA= cyclosporine A; MTX= methotrexate; IVIG=intravenous immunoglobulins; RTX=rituximab; IFX=infliximab; MMT=Manual muscle tests; ADL= activities of daily living; EGS= erythrocyte globular sedimentation; LDH= L-lactate dehydrogenase; IMACS=International Myositis Assessmenet Clinical Studies; HAQ=health assessment questionnaire.

Conclusion: Rituximab is effective to achieve remission in patients with PM/DM refractory to standard therapy (high dose prednisone and DMARD), (LE 2b; GR B-C). There is no current evidence on the efficacy of infliximab in patients with PM/DM (LE 2b; GR B-C). The addition of etanercept to steroids does not increase response rate or decreased adverse events (LE 1c, GR B), but could be useful as steroids sparring in DM patients (LE 1c, GR B). The addition of azathioprine to steroids does not increase response rate or decreased adverse events in DM patients (LE 2b; GR B-C). IVIG are effective to achieve remission in patients with PM/DM refractory to DMARD (LE 2b, GR B-C).

Distinctive Characteristics of Anti-Mi-2 and –p155/140 Autoantibody Production in Two Cohorts of Mexican Patients with Dermatomyositis.

Monica Vazquez-Del Mercado[1], Marcelo Petri[2], Luis J. Jara-Quezada[3], Miguel A. Saavedra-Salinas[4], Claudia Cruz-Reyes[5], Olga-Lidia Vera-Lastra[6], Lilia Andrade[7], Mario Salazar-Paramo[8], Laura Gonzalez-Lopez[9], Jorge Gamez-Nava[10], Rosa E. Prieto-Parra[8], Teresita Martin Marquez[1], Jason Y.F. Chan[11], Edward K.L. Chan[11] and Minoru Satoh[11]. [1]Universidad de Guadalajara, Guadalajara, Mexico, [2]Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, Mexico, [3]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, [4]Centro Médico Nacional, México, Mexico, [5]Centro Medico La Raza Instituto Mexicano del Seguro Social Mexico D.F., Mexico D. F., Mexico, [6]Inst Mexicano Seguro Social, Mexico City, Mexico, [7]CMN 20 Noviembre ISS STE, Mexico, Mexico, [8]Instituto Mexicano Del SS, Guadalajara, Mexico, [9]Hospital Regional de Zona 110, Instituto Mexicano del Seguro Social (IMSS), Guadalajara, Jalisco, Mexico, Guadalajara, Jalisco, Mexico, Mexico, [10]Centro Medico de Occidente, Guadalajara Jal, Mexico, [11]University of Florida, Gainesville, FL

Background/Purpose: Various autoantibodies associated with a unique subset of polymyositis/dermatomyositis (PM/DM), including antibodies to Jo-1 and other synthetases, SRP, Mi-2, PM-Scl and others, have been described. Specificities of autoantibodies and associated clinical manifestations in PM/DM are known to be affected by both genetic and environmental factors. In particular high prevalence of DM and anti-Mi-2 in Central America is thought to be associated with high UV index of the area. Prevalence of autoantibodies and clinical manifestation in PM/DM patients were evaluated comparing two cohorts in Mexico

Methods: Ninety-five Mexican patients with PM/DM (66 DM, 29 PM; 67 Mexico City, 28 Guadalajara) were studied. Autoantibodies recognized by sera were characterized based on protein analysis by immunoprecipitation using ^{35}S-methionine labeled K562 cell extract and RNA analysis in immunoprecipitates by urea-PAGE and silver staining. Clinical information was from database and chart review.

Results:

DM was 69% in Mexican PM/DM and anti-Mi-2 was the most common autoantibody specificity (35%), followed by anti-p155/140 (11%); however, anti-Jo-1 that is the most common in most PM/DM studies was only 4%. DM was more common and comparable in both Mexico City and Guadalajara (69% and 71%, respectively). However, autoantibody profile in DM of Mexico City vs Guadalajara showed striking difference; anti-Mi-2 was 59% vs 15% (P = 0.001) whereas anti-p155/140 was 9% vs 30% (P = 0.05), respectively. Thus, despite comparable DM dominance and similar UV index in two areas, prevalence of anti-Mi-2 was very high (59%) in Mexico City but not in Guadalajara (15%), suggesting a role of factors other than UV. Reported differences in genetic background of Mexican-Mestizo in these two areas (higher percentage of Amerindian derived genes in Mexico City vs European derived gene dominance in Guadalajara area) may be related to the difference in prevalence of autoantibodies. Clinical feature of anti-Mi-2(+) DM (n = 30) vs anti-Mi-2(−) DM (n = 36) was compared. Male was more common in anti-Mi-2(+) vs (−) (37% vs 22%,P=0.27). Shawl sign (86% vs 62%, p=0.0002) and weight loss (59% vs 45%, p=0.30) were more common in anti-Mi-2(+) DM than anti-Mi-2(−) DM. High CPK (> 2000) (88% vs 35%, p= 0.0001) was more common in anti-Mi-2(+) and levels of muscle enzymes were higher in anti-Mi-2(+) group than anti-Mi-2(−) group (CPK p = 0.0001, LDH p = 0.001).

N=	PM/DM 95	DM 66	DM Mexico City 46	DM Guadalajara 20	PM 29
Autoantibodies					
Mi-2	35%	45%	59%[1]	15%[1]	10%
p155/140	11%	15%	9%[2]	30%[2]	0%
Jo-1	4%	3%	4%	0%	7%
Myositis specific antibodies negative	36%	21%	15%	35%	69%

1, p=0.001; 2, p=0.056 by Fisher exact test

Conclusion: Anti-Mi-2 is at high prevalence in Mexican DM and associated with male, shawl sign, and high CPK. Prevalence of anti-Mi-2 and anti-p155/140 was significantly different in Mexico City vs Guadalajara, suggesting roles of factors other than UV in DM autoantibody production. Significant difference in clinical features of DM within a same country need to be carefully evaluated and the role of environmental and genetic factors will need further studies.

Nsaids Suppress the Inflammatory Reaction Related to Muscle Soreness but May Delay Recovery.

Matthias Rother[1], Egbert J. Seidel[2], Alexander Fischer[2] and Ilka Rother[1]. [1]IMR Partner GmbH, Graefelfing, Germany, [2]Sophien- and Hufeland Clinic, Weimar, Germany

Background/Purpose: Eccentric muscle contraction causes an inflammatory reaction with pain peaking 24 to 48 hours after exercise–delayed onset of muscle soreness (DOMS). NSAIDs are used frequently for treatment or even prevention of DOMS. But evidence for treatment effects of NSAIDs is controversial. Timing of intervention and pharmacological properties of the specific NSAID tested might explain the controversial results. In two previous studies using a daily life oriented model of DOMS induced by walking down stairs we found for 200 mg celecoxib when given about 16 h after exercise a modest, insignificant reduction in pain [Phys Med Rehab Kuror 2012; 22: 57–63]. Ketoprofen (100 mg bid), a higher potent anti-inflammatory drug, caused a delay in recovery from DOMS when given immediately after exercise [Phys Med Rehab Kuror 2012; accepted for publication].This study investigated the effects of a Cox-2 inhibitor (90 mg qd etoricoxib) on markers of inflammation, pain and muscle force after eccentric exercise.

Methods: Randomized, double-blind, placebo-controlled, cross over study in 50 healthy subjects exposed to equipment based, eccentric exercise of the lower limb ("extrafit Beinstrecker", extrafit INVESTMENT GmbH, Germany). Subjects with pain during muscle contraction of at least 5 on an 0–10 point categorical scale at 16±2 h after exercise were eligible for randomization. Pain at rest and during contraction, muscle force, pain threshold at tender point and markers of inflammation (high sensitive C-reactive Protein (hsCrP), sedimentation rate, leucocyte number) were evaluated at various time points during the treatment period of 7 days.

Results: There is a non significant trend for reduction of pain at rest with etoricoxib treatment for the first 24 h of treatment (etoricoxib: 10.4±9.7, placebo: 11.5±9.9). For peak torque and pain threshold at the tender point, there is a trend of delayed recovery with etoricoxib treatment. HsCrP is increased due to DOMS and showed significant cross-over effects (p=0.0089). The carry-over effect might be due to anti-inflammatory effects of etoricoxib in period I (p=0.0341) carried over into period II. This is in line with the overall result indicating a significant long term anti-inflammatory effect evident through a reduction in hsCrP as compared to placebo (p=0.0203). Overall, also a trend of reduction in model induced increase of leucocytes (p=0.0981) was shown. Sedimentation rate was insensitive to the model and treatment effects.

Conclusion: Equipment based eccentric exercise of the lower limbs appears to be a robust model of muscle pain. This approach allows the design of cross-over studies since the exercise load can be individualized and adapted to differences in muscle force of the dominant vs. non-dominant limb. Treatment related effects are in line with previous studies indicating a modest analgesic effect but evidence for delayed recovery. This supports the concept that the inflammatory reaction is an essential part of the recovery process.

Anti-inflammatory treatment might cause a delay in recovery. Caution should be used when using NSAIDs for the treatment of exercise induced muscle pain.

Inflammatory Muscle Disease Associated Pulmonary Hypertension - Clinical Features and Survival At a National Referral Centre. Matthew Webber[1], D. Dobarro[1], Clive Handler[2], Christopher P. Denton[3], Benjamin E. Schreiber[2] and John G. Coghlan[2]. [1]Royal Free Hospital, London, United Kingdom, [2]Royal Free Hospital, London, London, United Kingdom, [3]UCL, London, United Kingdom

Background/Purpose: The association between connective tissue disease (CTD) and pulmonary hypertension (PH) is well known, especially in the scleroderma population. However, the association between inflammatory muscle disease (IMD) and PH has not been described in detail.

Methods: We searched our prospectively collected database of patients undergoing diagnostic right heart catheterization (RHC) from January 2000 to December 2011 for patients with a diagnosis of IMD who had been investigated at the Pulmonary Hypertension Unit, Royal Free Hospital, London (a national tertiary centre). Patient data was sourced from written notes and electronic medical records.

Results: Of the twenty patients with IMD who underwent RHC at the unit, 17 were diagnosed with PH. Mean age was 61 years and 76% were female with 11 patients diagnosed as dermatomyositis (DM) and 6 as polymyositis (PM). Mean pulmonary artery pressure (mPAP) was 41.2 mmHg with a pulmonary vascular resistance (PVR) of 730.7 (dynes.s.cm^{-5}). Mean 6 minute walk test (6MWT) result was 215 meters and mean NTproBNP values were 176.5 pmol/l. On HRCT scan 70% of patients had evidence of extensive interstitial lung disease (ILD), 24% had limited fibrosis and 1 patient showed no prior evidence of ILD.

Eleven patients went on to receive vasodilator therapies. Of these, 9 underwent repeat RHC at 3–6 months. There was a trend towards improvement: mPAP fell from 40 to 34.2 mmHg (p=0.20) and PVR fell from 704 to 375 dynes.s.cm-5 (p=0.10).

In the 6MWT there was a mean increase of 65.9 meters from baseline to 3–6 months post therapy start date and this improvement was maintained with a mean final result of 380 meters. NTproBNP values showed a weak trend towards reduction, with a fall from 189 to 143 pmol/l (p=0.29) 3–6 months post treatment.

Amongst all 17 patients diagnosed with PH the overall median survival was 41.6 months. In the 12 patients with extensive ILD associated DM/PM the 1, 3 and 5 year survival rates were 75%, 42% and 28% respectively compared to 100%, 75% and 37% for the 5 patients with limited/no ILD (p=0.19 for difference).

Conclusion: This analysis is the largest of its kind to assess hemodynamic characteristics and functional response to treatment in this rare group of patients. Patients with IMD who develop PH have shown an improvement in mPAP, PVR, 6MWT and NTproBNP although statistical significance was not reached.

There was no significant difference between outcomes in patients with or without extensive ILD and the survival rates in patients with extensive ILD were higher when compared to a similar group of patients in a regional scleroderma population. Given the young age of some of these patients and the poor prognosis it may be beneficial to consider them for lung transplantation at an early stage in their diagnosis. Despite the poor prognosis however, this observed response to treatment may buy time for pulmonary rehabilitation and the use of combination therapies in patients who are either not eligible or waiting for transplant.

215

Abnormal Videofluoroscopy Swallow Study Finding in Inflammatory Myopathy Patient with Dysphagia As Predictor of Prognosis. Hye Won Kim, Hwang Kim, Sung Hae Chang, Hye Jin Oh, Myeong Jae Yoon, Bong Seung Ku, Byeong Mo Oh and Eun Young Lee. Seoul National University College of Medicine, Seoul, South Korea

Background/Purpose: Previous reports of dysphagia in patients with inflammatory myopathy (IM) have been focused on detection, intervention and rehabilitation. However, whether dysphagia with abnormal videofluoroscopy swallow study (VFSS) findings is in relation to clinical manifestations and treatment response is not known. We hypothesized that clinical entities in IM patients with dysphagia would be distinct from non-dysphagia patients and abnormal VFSS finding could be a predictor of prognosis.

Methods: Total 236 patients with IM were reviewed in this study. Of them, the patients with dysphagia were evaluated with clinical functional scale, VFS scale, new VFSS scale, and American Speech-Language-Hearing Association National Outcome Measurement System swallowing scale. VFSS score was categorized into oral, pharyngeal and esophageal phase based on modified Logemann's methods. Association between VFSS scale and serum creatinine kinase (CK), clinical findings, or treatment response were analyzed.

Results: Among 236 IM patients, 28 patients had IM related dysphagia (26 with dermatomyositis, 1 polymyositis and 1 inclusion body myositis). Ten male and 18 female with mean age of 42.7 were included. Dysphagia was a presenting symptom in 5 patients (17.9%) and rest of patients developed dysphagia in average 221 days later. The VFSS results showed more prevalent abnormalities in pharyngeal phase than oral phase (n=26 vs. n=9). Baseline CK level was higher in delayed laryngeal elevation and epiglottic closure (LEEC) patients than in normal LEEC patients (473.8 ± 415.6 mg/dl vs 3931.7 ± 5532.3 mg/dl, p=0.008) (Figure). There was no correlation in total VFSS score with baseline CK level. Intravenous immunoglobulin were significantly more prescribed in delayed LEEC patients than in normal LEEC patients (OR=10.7, p=0.047). Frequency of pulmonary involvement and malignancy were significantly different between patients with dysphagia and patients without dysphagia (7.1% vs 40.4%, p<0.001, 35.7% vs 9.6%, p=0001, respectively) (Table 1).

Table 1. Comparison of clinical characteristics between IM patients with dysphagia versus without dysphagia

Baseline characteristics	Dysphagia (n=28)	Nondysphagia (n=208)	p-value
Male/female (n, %)	10/18 (35.7/64.3)	47/161 (22.6/77.4)	0.157
Age (mean ± SD)	42.7 ± 21.6	46.3 ± 14.5	0.244
DM/PM/IBM (n, %)	26/1/1 (92.9/3.6/3.6)	156/51/1 (75.0/24.5/0.5)	0.013
Creatinine kinase	**3869.8 ± 5916.3**	**1546.3 ± 3529.9**	**0.004**
Interstitial lung disease (n, %)	**2 (7.1)**	**84 (40.4)**	**<0.001**
Malignancy (n, %)	**10 (35.7)**	**20 (9.6)**	**0.001**
Conclusion: Abnormal VFSS findings in IM Patients with dysphagia were more prominent in pharyngeal phases than oral phases. Delayed LEEC was associated with higher baseline CK level and use of intravenous immunoglobulin. IM patients with dysphagia showed lower pulmonary involvement and higher malignancy. These results indicate that dysphagia in IM is not only a localized symptom or disabling condition, but also a predictor of prognosis.

216

Clinical and Serological Associations of Malignancy in Adult Patients with Polymyositis and Dermatomyositis. Yuji Hosono, Ran Nakashima, Yoshitaka Imura, Naoichiro Yukawa, Hajime Yoshifuji, Motomu Hashimoto, Koichiro Ohmura, Takao Fujii and Tsuneyo Mimori. Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are systemic connective tissue disorders, which are often associated with internal malignancy. Several studies have reported the association between

autoantibodies (Abs) and clinical manifestations of the disease. In adult PM/DM, the association of malignancy with anti-p155/140 Ab is reported. However, background of association of malignancy in whole IIM patients is currently unclear. Here, we intended to analyze the clinical and serological associations of malignancy in adult IIM patients.

Methods: Clinical data and serum samples were collected from 207 adult Japanese patients with PM/DM (119 with DM and 88 with PM). Myositis-specific Abs were screened using the RNA immunoprecipitation assay (anti-ARS and anti-SRP) and immunoprecipitation with [^{35}S] methionine-labelled HeLa cells (anti-p155/140 and anti-CADM-140).

Results: 30 patients (14.5%,15 females and 15 males) had history of malignancies.20 patients (66.7%) were DM and 10 patients were PM (33.3%).No certain common cancer types were not recognized.In comparison with malignancy-negative patients, the average age at IIM onset was higher in malignancy-positive IIM patients (52.3 vs 59.6 years). Among malignancy-positive IIM patients, anti-p155/140 (N = 10,33.3%) and anti-ARS (N = 13,43.3%) predominated.2 (6.7%) were anti-SRP positive,1 (3.3%) was anti-CADM140 positive, and other 3 (10%) patients were positive for unknown Ab that immunoprecipitated a 120kDa protein.Anti-p155/140 showed the strong association with the onset of myositis and malignancy.All anti-p155/140-positive patients were diagnosised progressive malignancies at the same time of DM onset, while the onset of myositis proceeded 6.1 years at average before malignancy in 9 (69%) anti-ARS-positive patients. In addition, all anti-p155/140-positive patients were DM,whereas 46.2% (N=6) of anti-ARS-positive patients were PM. Onset age of patients with anti-p155/140 Ab were higher than that of patients with other Abs (65.7 vs 56.6).

Conclusion: Anti-p155/140 Ab and anti-ARS Abs were predominantly found among PM/DM patients associated with malignancy.Malignancies in PM/DM patients with anti-p155/140 were all diagnosed at the onset of DM,whereas the onset of malignancies in patients with anti-ARS did not coincide with myositis.These results suggest that different mechanisms maybe present in the association with malignancy and myositis between the two antoantibody-positive patient groups. Screening of autoantibodies and work up of malignancy are recommended in advanced age patients with a new diagnosis of DM.

217

Myositis-Associated Usual Interstitial Pneumonia Has Better Survival Than Idiopathic Pulmonary Fibrosis.

Christine McBurney[1], Rohit Aggarwal[2], Kevin Gibson[3], Kathleen Lindell[4], Carl Fuhrman[1], Diane Koontz[1], Frank Schneider[4], Naftali Kaminski[4] and Chester V. Oddis[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]Pittsburgh, PA

Background/Purpose: Usual interstitial pneumonia associated with idiopathic pulmonary fibrosis (IPF-UIP) has a poor prognosis with a median survival of 3 years. It is unknown whether myositis-associated UIP (MA-UIP) has an improved survival compared to IPF-UIP patients (pts). Our objective was to compare the cumulative and pulmonary event-free survival between MA-UIP and IPF-UIP.

Methods: Adult MA-UIP and IPF-UIP pts were identified using prospective registries. Pts with myositis (PM/DM/overlap) or the antisynthetase syndrome and radiographic UIP on HRCT scan (verified by a thoracic radiologist) or a lung biopsy revealing UIP histology were included. IPF pts met ATS criteria and had UIP pathology. Death status and date were verified with the Social Security Death Index. Kaplan-Meier survival curves and the log rank test compared cumulative and pulmonary event free survival (event = transplant or death) between a) all MA-UIP and IPF-UIP pts, b) MA-UIP pts with biopsy proven UIP (n=25) vs. IPF-UIP pts matched for age, gender and baseline FVC (±10%). Cox proportional hazards ratios compared overall and event free survival controlling for co-variates.

Results: IPF-UIP pts (n=81) had a mean age of 63 (±8.4), 73% male, 98% Caucasian, baseline FVC% 65 (±15.3) and DLCO% 47 (±17.3). The MA-UIP patients (n=43) had a mean age of 46 (±11.0), 35% male, 83% Caucasian, baseline FVC% 60 (±19.6) and DLCO% 47 (±18.3).

Median cumulative and event free survival time from diagnosis in IPF vs. MA-UIP was 5.2/1.8 years vs. 16.1/10.8 years, respectively. The 5 and 10 year % unadjusted event-free (graph 1) and cumulative survival was significantly worse in IPF-UIP vs. MA-UIP (25/0 vs. 80/50 and 59/32 vs. 80/65)

($p < 0.001$). The hazard ratio (HR) of IPF-UIP vs. MA-UIP pts was 2.86 (95% CI 1.45–5.61) for cumulative and 5.0 (95% CI 2.8–8.7) ($p<0.001$) for event-free survival. IPF-UIP event-free survival (but NOT cumulative survival) remained significantly worse than MA-UIP with a HR of 6.4 (95% CI 3.0–13.8) after controlling for age at ILD diagnosis, gender and baseline FVC%.

Out of 81 IPF-UIP, 36 died (mean age 68) and 45 had transplant (mean age 65) compared to 16 deaths (mean age 54) and 10 transplants (mean age of 54) in 43 MA-UIP. Respiratory failure was the most common cause of death in both groups, followed by infection.

25 biopsy-proven MA-UIP pts showed significantly better event free survival compared to matched IPF-UIP pts.

Graph 1. Kaplan-Meier curve for event free survival of MA-UIP and IPF-UIP
Conclusion: MA-UIP pts demonstrated a significant survival advantage over a matched IPF cohort, suggesting that despite similar histologic and radiographic findings at presentation, the prognosis of MA-UIP is superior to that of IPF-UIP. Thus, in pts with a radiographic or pathologic UIP picture, it is critical to distinguish those with an underlying autoimmune etiology as their course and response to therapies may differ from pts with true IPF.

Proteomics Study of a Phase 1b Trial with an Anti-IFN-α Monoclonal Antibody Indicates Association of Soluble Interleukin 2 Receptor with Type I Interferon Activity in Patients with Dermatomyositis or Polymyositis.

Xiang Guo, Brandon W. Higgs, Wei Zhu, Yihong Yao and Wendy White. MedImmune, LLC, Gaithersburg, MD

Background/Purpose: To evaluate downstream effects of an anti-IFN-α monoclonal antibody (mAb) in adult dermatomyositis (DM) and polymyositis (PM) patients using serum proteomics and gene expression profiling from patient blood and muscle samples.

Methods: A phase 1b randomized, double-blinded, placebo-controlled, multicenter clinical trial was conducted in adult patients with DM or PM. Whole blood, serum, and muscle specimens were procured both pre and 98 days post administration with an anti-IFN-α mAb, sifalimumab. Affymetrix whole genome arrays were used to measure transcript expression in whole blood and muscle, while a multiplex luminex immunoassay was used to measure serum levels of more than 130 proteins. Target modulation of type I IFN activity was measured using a 13 gene type I IFN gene signature in patients following administration with either sifalimumab or placebo.

Results: Serum levels of soluble interleukin-2 receptor (sIL-2R) were significantly higher at baseline in 19 DM and 18 PM patients showing an elevated blood type I IFN signature than in 6 DM and 5 PM patients without an elevated signature and 20 normal controls. Among patients with high baseline type I IFN gene signature, those expressing high levels of sIL-2R had lower manual muscle testing (MMT8) scores at baseline, compared to patients with only an elevated baseline type I IFN gene signature. Following administration with sifalimumab, whole genome transcript profiling identified

the IL2 signaling pathway as among the top ten most suppressed pathway, along with several T cell-related signaling pathways. This result was not identified in placebo-dosed patients. Sifalimumab also down-regulated sIL-2R levels by more than 30% in 3 DM and 4 PM patients, with no significant change in 11 placebo dosed patients. Further, patients showing strong sIL-2R down-regulation post dosing of sifalimumab, also exhibited suppression of the type I IFN gene signature (target suppression > 80% in the blood).

Conclusion: Our results demonstrate that sIL-2R levels in the serum of myositis patients, in combination with a blood type I IFN gene signature, may correlate with disease activity in a patient subset better than a type I IFN gene signature alone. Sifalimumab down-regulated serum sIL-2R levels in a subset of myositis patients that also showed strong suppression of the type I IFN gene signature in blood. These results suggest the possibility to combine sIL-2R and type I IFN gene signature as a prognostic marker for myositis patients.

Significant Functional Improvement Using Aggressive Immunomodulatory Therapy in Patients with Inflammatory Myopathy and Interstitial Lung Disease. Ramona Mihu[1], Roger D. Rossen[1], Jovan Popovich[2] and Sandra L. Sessoms[1]. [1]Baylor College of Medicine, Houston, TX, [2]The Methodist Hospital, Houston, TX

Background/Purpose: Pulmonary disease in patients with idiopathic inflammatory myopathies, polymyositis (PM), dermatomyositis (DM), and clinically amyopathic dermatomyositis (CADM) is a major cause of morbidity. Approximately 35–40% of patients with PM/DM/CADM develop interstitial lung disease (ILD) during the course of their illness. Mortality ranges from 45–71% in those with ILD. Treatment of ILD in patients with inflammatory myopathies remains a challenge. In the absence of evidence-based data from randomized control trials, corticosteroids are regarded as the mainstay of therapy, although their effect is variable.

Methods: We retrospectively evaluated 62 patients with idiopathic inflammatory myopathies treated during the past ten years.

Results: Of the 62 patients reviewed, 22 developed ILD with varying degrees of functional impairment; 11 of the 22 had PM, 8 had DM and 3 had CADM. Three eventually died of causes unrelated to their lung disease. Pulmonary disease severity was judged by measuring blood oxygen saturation, dyspnea and tachypnea at rest, and following exercise, radiographic evidence of pulmonary infiltration and signs of pulmonary restriction and impaired diffusion capacity by pulmonary function testing. Patients were followed for at least 24 months, with an average length of follow up of 121 months. All ILD patients received combination therapy with an average number of 3 immune modulating agents plus corticosteroids. Four out of the 7 patients with severe ILD received concomitant combination therapy with IVIG, cyclophosphamide and cyclosporine for up to 6 months; 7 other moderate to severely affected patients received IVIG plus cyclosporine in addition to corticosteroids. Patients' functional capacity before and after treatment was evaluated according to the NYHA criteria developed for the assessment of patients with heart failure. The table (below) demonstrates that immunomodulatory therapy resulted in a statistically significant improvement, (Chi Square = 10.3, Df = 3 p < 0.02). One patient developed *Candida* pneumonia and 3 who were treated with cyclosporine and other agents had reversible declines in renal function during therapy. Four patients developed Herpes Zoster during the follow up period, but long after the aggressive immunomodulatory therapy was finished. Treatment was otherwise well tolerated.

Change in function

Functional class	1	2	3	4
before treatment	3*	8	5	6
after treatment	10	9	3	0

Worse

Better

*No. patients in each functional class

Conclusion: Our results support the early use of aggressive immunomodulatory therapy with a combination of agents designed to interfere with T cell recruitment, activation and replication in patients with idiopathic inflammatory myopathies and ILD.

220

Efficacy of Rituximab for the Treatment of Refractory Inflammatory Myopathies Associated with Anti-Histidyl-tRNA Synthetase Antibodies (the FORCE Jo1 Study). Yves Allenbach[1], Aude Rigolet[1], Marguerite Guiguet[2], Isabelle Marie[3], Eric Hachulla[4], Dominique Farge[5], Kuberaka Mariampillai[1], Serge Jacquot[6], Fabienne Jouen[7], Olivier Boyer[8], Lucile Musset[9], Serge Herson[1] and Olivier Benveniste[1]. [1]Pitie-Salpetriere Hospital, Paris, France, [2]Paris, France, [3]Service de médecine interne, CHU de Rouen, Rouen, France., Rouen, France, [4]Department of Internal Medicine, Claude Huriez Hospital, University of Lille, Lille CEDEX, France, [5]EBMT, Paris, France, [6]INSERM U905, Université de Rouen, Rouen, France, [7]Rouen University Hospital, Rouen Cedex, France, [8]INSERM U905, University of Rouen, Rouen, France, [9]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: anti-histidyl-tRNA synthetase (anti-Jo1) antibodies are found in approximately 25–30% of patients with idiopathic inflammatory myopathies, frequently in the frame of an anti-synthetase syndrome characterized (in addition to the myositis) by the association of interstitial lung disease (ILD, one of the main prognostic factor), arthritis, Raynaud's phenomenon and mechanic's hands. The recommended treatment is high dose corticosteroids in association with an immunosuppressant. Nevertheless, some patients remain refractory. We tested the efficacy of rituximab in this situation.

Methods: we conducted a prospective, multicenter, open, phase II study (ClinicalTrials.gov: NCT00774462) of rituximab (1g at day 0 (D0), 15 and month 6). Inclusion criteria were myositis as defined by the 119th ENMC workshop (Hoogendijk JE, et al. Neuromuscul Disord 2004;14:337–45) with anti-Jo1 antibodies, refractory to conventional treatments (i.e. failure, lack of efficacy or major side effects of prednisone and at least two immunosuppressants, leading the physician to a DMARD decision). Endpoints were evaluated at month 12 (M12).

Results: 12 patients were enrolled (8 men, median (IQR) age 50 (32 to 59)). The delay between diagnosis/first treatment and inclusion was 23 months (12 to 45). Patients already received in average 3 lines of treatments (2 to 4). Associated treatments with rituximab were prednisone (n=12), methotrexate (n=1), azathioprine (n=6), intravenous immunoglobulins (n=4), mycophenolate mofetil (n=2) and cyclophosphamide (n=1). Eleven patients completed the study and one was lost of follow-up after 3 weeks. No particular side effects due to rituximab were observed.

Muscle weakness evaluated by the manual testing (Kendall's test on 10 muscles,) was 94.5 (range 75 to 100) at D0. Only 1 patient had normal strength (=100) at DO, and 6 patients at M12. Median creatine kinase (CK) was 1331 U/l (range 32 to 11718) at D0. Only 1 patient had normal CK level (< 190 U/l) at D0, and 9 patients at M12. Effort dyspnea was noticed in 7/12 patients at D0 and 4/11 at M12. At DO, pulmonary tests showed, median FVC: 72% (46 to 117), FEV1: 69% (46 to 104) and DLCO/VA ratio: 73 (43 to 127). At M12, on the 6 patients who completed functional respiratory tests, 3 presented an increase by more than 10% of their FVC, FEV1 or DLCO/VA. Arthritis were observed in 9/12 patients at D0 vs. 4/11 at M12. Anti-Jo1 antibody titers remained stable over time, with no seronegativation. Finally, at M12 on 11 patients, the burden of associated treatments was unchanged (n=1) or even increased (n=4) in 5 patients but was slimmed-down for 6 patients.

Conclusion: in the difficult situation of long past history of refractory anti-synthetase syndrome with anti-Jo1 antibodies, rituximab seems effective in 50% of the cases permitting a reduction of immunosuppressants. This effect is observed on muscle strength, ILD and arthritis. Rituximab should now be evaluated in a phase III trials in this homogenous group of patients.

Expanding the Clinical and Serological Spectrum of MDA5-Associated Dermatomyositis. John C. Hall[1], Livia Casciola Rosen[1], Sonye K. Danoff[2], Lesly-Anne Samedy[1] and Lisa Christopher-Stine[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins School of Medicine, Baltimore, MD

Background/Purpose: Dermatomyositis (DM) is a heterogeneous systemic disease with specific autoantibodies (Abs) which correlate with unique clinical phenotypes. Melanoma differentiation-associated gene 5 (MDA5) Abs have been described (in several Japanese DM patient cohorts and one US DM cohort) in conjunction with amyopathic DM and rapidly progressive interstitial lung disease (ILD). Given the widening spectrum of associated clinical findings, we sought to determine prevalence of Abs to MDA5, associated clinical findings and whether Ab titers correlated with clinical course in a longitudinal cohort of myositis patients.

Methods: This is a retrospective case series review of clinical and serologic features of eleven DM patients with MDA5 Abs who were evaluated at the JHU Myositis Center. In addition, six MDA5 + patients with longitudinal data and banked serologic samples were evaluated for clinical correlations (MRC scale strength, cutaneous features, arthritis, ILD) with Ab titers.

All patients were evaluated as part of routine clinical care between 2006 and 2012. Informed consent was obtained, and 165 consecutive DM patients (for whom banked serum samples were available) were tested for the presence of MDA5 Abs. Patient sera were screened for autoantibodies by immunoprecipitation (IP) of *in vitro* transcribed/translated (IVTT), radiolabeled MDA5. When multiple serum samples were available from the same patient, IPs were performed simultaneously and run on the same gel for comparison. Patient sera were further screened for antibodies against Jo-1 and Ro52 by ELISA, and Mi-2 and NXP2 by IP of IVTT generated protein.

Results: MDA5 was targeted in 11/165 (6.7%) patients with DM. In our cohort of 11 MDA5+ patients, 82% (9/11) presented with a symmetric polyarthropathy; 5% (5/11) demonstrated overt clinical myopathy; and only 64% (7/11) had ILD. The majority of ILD stabilized with immunosuppression. Only two patients had progressive ILD, and both were anti-Ro 52 positive. All MDA5+ positive patients remained Ab positive over the entire course of follow-up. Longitudinal MDA5 antibody titers were assessed in 6 patients; with the exception of one patient, titers did not vary significantly over time, nor did they track with clinical course. Jo-1 was negative in all MDA5+ patients, while anti-Ro52, frequently found in Jo-1 positive patients, was seen in 3 of 11 patients.

Conclusion: This report adds to our growing understanding of the expanding phenotype of MDA5+ DM. The MDA 5 phenotype can overlap with the antisynthetase syndrome (e.g. mechanics hands, arthritis, myositis, fever and ILD),; however autoantibodies to Jo-1 were not found concomitantly. Many patients presented initially with an inflammatory arthritis that looked clinically similar to RA, and many patients had an overt myopathy. While MDA5 autoantibodies remained positive throughout disease course and relative titer did not correlated with clinical course, even patients with a relatively fulminant clinical course of disease with regard to ILD, myositis, cutaneous disease, and arthritis were often able to attain sustained clinical remission, in some cases even after discontinuation of immunosuppression.

Lung Nodules in Patients with Idiopathic Inflammatory Myopathies. Laura C. Cappelli[1], Andrew L. Mammen[2], Sonye K. Danoff[3], Grant H. Louie[1], Thomas E. Lloyd[2] and Lisa Christopher-Stine[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD

Background/Purpose: The idiopathic inflammatory myopathies are associated with an increased incidence of malignancy, and interstitial lung disease (ILD) has been reported in as many as 20–78% of patients with polymyositis and dermatomyositis when followed from diagnosis. As a result of these associations, patients often receive CT scans of the chest where lung nodules are incidentally discovered. The radiographic nature of these lung nodules and whether they tend to increase in size, regress, or remain stable in size has not been described. The aim of this study was to define the prevalence of lung nodules in patients with inflammatory myopathies in a large clinical cohort evaluated at a Myositis Center, the clinical features associated with the presence of lung nodules, and whether the nodules changed in size over time.

Methods: Data was obtained from the cohort of 976 patients referred to the Myositis Center at Johns Hopkins. Only patients with confirmed inflammatory myopathies and at least one chest CT scan performed at our Center for clinical purposes were included in the study. For patients with more than one CT, all CTs were reviewed. The presence of interstitial lung disease was defined by decreased total lung capacity (TLC) or diffusion capacity (DLCO) on pulmonary function testing and/or presence of ground glass opacities on chest CT.

Results: 298 of the 976 patients had at least one chest CT performed at our Center. The prevalence of lung nodules in these patients was 25.5% (76/298). Only 5 patients had a nodule > 10 mm, and in those patients with follow up CTs, none of these nodules increased in size. Interstitial lung disease was present in 34.9% of the total cohort. The prevalence of nodules was not significantly different in those who had interstitial lung disease and those who did not (26.9% and 24.7% respectively, p=0.68). Of the 76 patients with lung nodules, 39.4 % (30/76) had a follow-up chest CT. The interval for follow-up was variable and ranged from 3 to 19 months. On subsequent CTs, none of the nodules had progressed in size by more than.2 cm and 51.6% (16/31) had regressed entirely.

Conclusion: Lung nodules are frequently observed in patients with inflammatory myopathies, but not greatly increased in prevalence over healthy adults where they are reported in 18% of patients. Lung nodules were no more common in patients with ILD than those patients without ILD. The lung nodules do not likely represent malignancy as they do not progress when followed over time. In fact, about half of patients had regression of the nodules,

High Prevalence and Clustering Over Time of Anti-PL-7 Autoantibody-Positive Idiopathic Inflammatory Myopathies. Yoshioki Yamasaki[1], Minoru Satoh[2], Hidehiro Yamada[1], Machiko Mizushima[1], Takahiro Okazaki[1], Hiroko Nagafuchi[1], Seido Ooka[1], Tomohiko Shibata[1], Hiromasa Nakano[1], Hitoshi Ogawa[1], Kohei Azuma[1], Akihiko Maeda[1], Hirofumi Mitomi[1], Tomofumi Kiyokawa[1], Kosei Tsuchida[1], Hidenori Mikage[1], Jason Y.F. Chan[2] and Shoichi Ozaki[1]. [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]University of Florida, Gainesville, FL

Background/Purpose: Unusually high prevalence of autoantibodies to threonyl tRNA (PL-7) [17% in polymyositis/dermatomyositis (PM/DM) associated with lower levels of serum creatine kinase (CK) and milder muscle weakness (vs. anti-Jo-1 positive patients)] was found in our study 8 years ago. We extended and analyzed a larger population of patients with PM/DM to further clarify the clinical characteristics of patients with anti-PL-7 antibodies.

Methods: The diagnosis of PM/DM and clinically amyopathic DM (cADM) was based on the Bohan and Peter criteria and modified Sontheimer's criteria, respectively. Autoantibodies in sera from 97 Japanese patients with PM/DM (36PM/57DM/4cADM) were characterized by immunoprecipitation of K562 cell extract. Antibodies to Jo-1, melanoma differentiation-associated gene (MDA) 5, and Mi-2 also were tested by ELISA. Clinical and laboratory data were retrospectively collected.

Results: The prevalence of autoantibodies to aminoacyl tRNA synthetases (ARS) such as histidyl (Jo-1) (22%), glycyl (EJ) (4%), isoleucyl (OJ) (1%), and alanyl tRNA synthetase (PL-12) (1%), and autoantibodies to Ku (7%), p155/140 (5%), SRP (4%), and Mi-2 (3%) was similar to other studies. However, prevalence of anti-PL-7 was unusually high (12%, 12/97) in contrast to other studies showing a prevalence of up to 4% ($p < 0.05$ by Fisher exact test) consistent with our previous report. Notably, disease onset of patients with anti-PL-7 was either before 1993 or after 2002 and none between 1994–2001 whereas onset years of patients with anti-Jo-1 was distributed throughout (Table 1).

Table 1. Prevalence of autoantibodies to PL-7 and Jo-1 according to year of onset.

Year	90–93	94–97	98–01	02–05	06–09	10–12
n	6	5	13	19	39	15
Anti-PL-7 (%)	50	0	0	16	10	13
Anti-Jo-1 (%)	17	60	23	11	23	20

Interstitial lung disease (ILD) was common in all anti-ARS-positive patients. Manual muscle testing (MMT) (total score of 90) <80 was only in

10% of anti-PL-7 group vs. 35% in anti-Jo-1 group, CK >3000 IU/l was 17% in anti-PL-7 vs. 57% in anti-Jo-1 (*p* <0.05 by Fisher exact test) (Table 2).

Table 2. Frequency of ILD and severity of muscle involvement in patients with anti-ARS antibodies (vs. patients with no anti-ARS antibodies).

Autoantibodies (n)	PL-7 (12)	EJ (4)	Jo-1 (21)	ARS (−) (57)	P
ILD (%)	92[a]	100[a]	100[a]	49	[a]<0.05 vs. ARS (−)
MMT (max 90) (SD) <80 (%)	85 (5) 10[b]	90 (0) 0	81 (10) 35	81 (10) 40	[b]<0.1 vs. ARS (−)
Serum CK IU/l (IQR) <200 IU/l (%) >3000 IU/l (%)	942 (360–2679) 8 16	715 (246–1308) 25 0	3726[c] (756–5534) 5[d] 57[e]	606 (181–1807) 25 14	[c]<0.1 vs. PL-7[c] <0.05 vs. ARS (−)[d] <0.1 vs. ARS (−)[e] <0.05 vs. PL-7[e] <0.1 vs. EJ

Conclusion: Persistently high prevalence of anti-PL-7 antibodies was observed in this cohort, however, there was a 10 year period when anti-PL-7 was not observed, suggesting roles of environmental factors. Muscle involvement was milder in patients with anti-PL-7 and EJ vs. anti-Jo-1.

Standardized Incidence Ratios and Predictors of Malignancies in 215 Southern Chinese Patients with Inflammatory Myopathies. Chi Chiu Mok[1], Chi Hung To[1], ML Yip[2] and King Yee Ying[3]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Kwong Wah Hospital, Kowloon, Hong Kong, [3]Princess Margaret Hospital, Hong Kong, Hong Kong

Background/Purpose: To examine the standardized incidence ratios (SIRs) and predictive factors for malignancy in a cohort of southern Chinese patients with inflammatory myopathies (IM).

Methods: Patients with polymyositis (PM), dermatomyositis (DM) or amyotrophic dermatomyositis (ADM) diagnosed between 2000 and 2010 in the three regional hospitals were studied. Diagnosis was made according to the Peter and Bohan criteria. Demographic data, clinical presentation, time of diagnosis of malignancies since diagnosis and the nature of malignancies were retrieved. Patients with malignancies diagnosed more than 1 year before the onset of IM were excluded. The age- and sex-adjusted standardized incidence ratios (SIRs) of malignancies in comparison to those of the general population obtained from the cancer registry of Hong Kong within the same study period were calculated. Demographic data, types of IM (DM vs ADM vs PM), creatine kinase (CK), presence of concomitant rheumatic diseases, extra-muscular manifestations were analyzed as predictors for malignancy in Cox regression models.

Results: 215 patients (65% women) with IM were studied (125 DM, 75 PM, 15 ADM) with a mean follow-up of 4.7±4.6 years. The mean age of disease onset was 51.5±16.3 years. Concomitant rheumatic diseases were diagnosed in 39 (18.1%) patients. 52 patients (24.2%) (44 DM, 6 PM, 1 ADM) were diagnosed to have malignancies. 13 (25%) and 14 (26.9%) malignancies, respectively, were identified within the preceding 1 year and at the same time of IM diagnosis. The mean time interval between the diagnoses of IM and malignancies was 1.29±1.56 years. The age- and sex-adjusted SIRs for malignancies for DM and PM were 3.9 [2.8–5.5] and 1.1 [0.5–2.6], respectively. The most frequently associated malignancies were: nasopharyngeal cancer 21 (40%), gastrointestinal cancer 10 (19%), lung cancer 10 (19%), breast cancer 4 (7.6%), cervical cancer 3 (5.7%), and the corresponding age- and sex-adjusted SIRs were 26.8 [16.5–41.5], 1.3[0.7–2.5], 1.8[0.9–3.5], 1.9[0.7–5.2], 8.4[2.6–26.5], respectively. On univariate analysis, the age at IM diagnosis (HR 1.03[1.02–1.05]), male gender (HR 3.88[1.95–7.74]), history of smoking (HR 3.86[1.95–7.65]), the diagnosis of DM (HR 3.37[1.39–8.14]), oropharyngeal muscle involvement (HR 2.55[1.28–5.07]) were associated with malignancies whereas the presence of concomitant rheumatic diseases (HR 0.23[0.05–0.95]), presence of interstitial lung disease (HR 0.37[0.16–0.85]) and use of azathioprine (HR 0.35[0.18–0.68]) were protective. Cox regression analysis revealed that a history of smoking (HR 2.7[1.12–6.56]), and oropharyngeal muscle involvement (HR 2.65[1.22–5.75]) were independently associated with malignancies.

Conclusion: DM, but not PM, was associated with an increased risk of malignancies compared to general population. DM patients in southern Chinese were particularly at risk of carcinoma of nasopharynx, lung and cervix.

Polymyositis in HIV+ Patients Is Associated to Uncontrolled Viral Load. Yves Allenbach[1], Odile Dubourg[1], Thierry Maisonobe[1], Anthony Behin[2], Charles Duyckaerts[1], Guillaume Breton[1], Olivier Fain[3], Marie-Caroline Meyhoas[4], Catherine Leport[5], Marc-Antoine Valentin[6], Daniel Vittecoq[7], Jean-François Bergmann[8], Thomas Anslik[9], Marie-Paule Chauveheid[10], Zahir Amoura[11], Thomas de Broucker[12], Pierre Bourgeois[1], Bruno Eymard[2], Serge Herson[1] and Olivier Benveniste[1]. [1]Pitie-Salpetriere Hospital, Paris, France, [2]Institute of Myology, Pitie-Salpetriere Hospital, Paris, France, [3]Service de médecine interne, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France., Bondy, France, [4]Department of Infectious Diseases, Saint Antoine Hospital, Paris, France, [5]Paris, France, [6]Department of Infectious Diseases, Pitié-Salpetriere Hospital, Paris, France, [7]Department of Infectious Diseases, K Bicetre Hospital, Kremlin-Bicetre, France, [8]Internal Medicine, Lariboisiere Hospital, Paris, France, [9]Internal Medicine, Ambroise Pare Hospital, Boulogne Billancourt, France, [10]Internal Medicine, Bichat Hospital, Paris, France, [11]CHU Pitié-Salpêtrière, Paris, France, [12]Department of Neurology, Delafontaine Hospital, Saint Denis, France

Background/Purpose: Different myopathies can be observed in HIV-infected patients, such as idiopathic inflammatory myopathies (inclusion-body myositis or polymyositis) or toxic mitochondrial myopathies secondary to antiretroviral therapy. The frequency and the evolution of those different myopathies is not precisely known, thus we aimed to describe all HIV patients from our center who presented a myopathy.

Methods: We conducted a systematic review of computerised database of the department of pathology to select HIV infected patients who underwent a muscle biopsy during the 2005–2011 periods. For each biopsies, morphological (hematein eosin staining), mitochondrial (Gomori trichrome, succinic dehydrogenase and cytochrome oxidase staining) and immunological (HLA1, lymphocytes subclasses staining) analyses were performed.

Results: During the studied period, 2880 muscle biopsies were performed. Fifty biopsies (1.7%) were realised in 45 HIV+ patients (mean age: 50.1 years [39–61,2]).

Among the 50 biopsies, 43 were abnormal. The most frequently observed myopathy was polymyositis (60%). Among pathologically diagnosed polymyositis during this period of time (n=161), 23 (14%) were diagnosed in HIV+ patients. After polymyositis, mitochondrial abnormalities were the most frequently observed lesions (54%, myositis and mitochondrial abnormalities beeing observed concomitantly in some patients). Five cases (13%) of inclusion body myositis were also pathologically diagnosed.

Compared to a cohort of 50 anti-synthetase syndrome patients (with anti-Jo1 Abs), HIV polymyositis patients had a less severe weakness (MRC manual testing ≥ 4/5 83% in HIV+ vs. 54% for Jo1+ patients p<0.05) and lower CK levels (1677 vs. 4975 IU/L, p<0.05). Muscle weakness disappeared within six months after steroid treatments and/or highly active antiretroviral therapy introduction or modification. HIV viral load was detectable (125.186±21.295 copies/ml) for 80% of polymyositis patients whereas it was undetectable for all patients with isolated mitochondrial abnormalities (p<0.01). For the 7 patients with isolated mitochondrial abnormalities (suggesting mitochondrial toxicity), nucleoside-analogue reverse-transcriptase inhibitors were stopped for another highly active antiretroviral therapy combination, in the frame of an interventional study (the Myotox trial). Two years latter, no significant change concerning either muscular symptoms, CK level or pathological features of mitochondrial abnormalities were observed after this intervention.

Conclusion: This retrospective study showed that polymyositis is the most frequent HIV associated myopathy, and suggested that a HIV test must be proposed to every patient presenting a polymyositis. Polymyositis in HIV patients seemed not severe, and is associated with uncontrolled HIV replication. HIV patients with isolated mitochondriopathy did not improve after nucleoside-analogue reverse-transcriptase inhibitors withdrawal.

Autoantibodies to Small Ubiquitin-Like Modifier Activating Enzymes in Japanese Patients with Dermatomyositis. Manabu Fujimoto, Takashi Matsushita, Yasuhito Hamaguchi, Kenzo Kaji, Minoru Hasegawa and Kazuhiko Takehara. Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan

Background/Purpose: Myositis-specific autoantibodies (MSAs) are closely associated with distinct clinical subsets within idiopathic inflammatory myopaties, and thus serve as useful diagnostic tools. Recently, anti-small ubiquitin-like modifier activating enzyme (SAE) autoantibody has been reported as a novel MSA in dermatomyositis (DM) patients. In this study, we detected this autoantibody in a Japanese DM cohort and assessed its clinical correlations.

Methods: In this study, 456 consecutive Japanese patients with DM (11 children, 455 adults) including 373 with classic DM and 83 with clinically amyopathic DM (CADM) were examined. Controls included 62 patients with polymyositis, 108 with systemic lupus erythematosus, 433 with systemic sclerosis, and 124 with interstitial lung disease (ILD) alone. Autoantibodies were detected by immunoprecipitation assays using ^{35}S-methionine-labeled or unlabeled K562 cell extracts and western blotting using anti-SAE1/2 antibodies.

Results: Sera from 7 (1.5%) DM patients immunoprecipitated 90 and 40 kDa proteins, and were confirmed to react with SAE by western blotting. One patient had juvenile DM, while the other 6 had adult DM (median age of onset, 67 years). None of the control sera had this antibody. Heliotrope rash, Gottrons papules, periungual lesions, V signs, and Shawl signs were observed in 57%, 86%, 100%, 57%, and 86%, respectively. Consistent with a UK cohort study[1], skin manifestations preceded muscle involvement in 86% patients with anti-SAE antibodies. Systemic features were present in 57% of patients inbcluding 2 patients with severe dysphagia. In addition, chronic ILD was substantially higher in anti-SAE-positive DM patients (71%) than those negative (34%).

Conclusion: Consisitent with the UK cohort study, this study confirmed that anti-SAE antibody is specific for DM and that anti-SAE antibody characteristically occur in patients who present with CADM first and then progress to develop myositis with a high frequency of systemic features, including dysphagia. Our study also revealed a high frequency of ILD in Japanese DM patients with anti-SAE antibody.

Long Term Outcome of Interstitial Lung Disease in Idiopathic Inflammatory Myopathies and Amyopathic Dermatomyositis. Machiko Mizushima[1], Hidehiro Yamada[2], Yoshioki Yamasaki[1], Masaomi Yamasaki[3], Minoru Satoh[4] and Shoichi Ozaki[5]. [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]St. Marianna University, Kawasaki, Japan, [3]St Marianna University, Yokohama City Seibu Hospital, Yokohama, Japan, [4]University of Florida, Gainesville, FL, [5]St. Marianna University School of Medicine., Kawasaki, Japan

Background/Purpose: The aim of this study was to assess the long term clinical course and outcome of interstitial lung disease (ILD) in polymyositis/dermatomyositis (PM/DM) and to determine predictive factors for the outcome of PM/DM-associated ILD.

Methods: Among 228 patients with IIM and clinically amyopathic dermatomyositis (cADM), 140 patients with ILD were identified by medical records search at our hospital. Pulmonary high-resolution computed tomography (HRCT) scan was available in 93 patients and their clinical features were analyzed.

Results: Mean follow up period (SD) of the 93 patients was 68 (55) months. Clinical course of ILD was monophasic resolution in 24 patients (25.8%), chronic stable in 30 (32.3%), relapsing in 32 (34.4%) and fatal progressive within one year in 7 (7.5%) (Table 1). Univariate analysis indicated older age (p =0.444), dermatomyositis (p =0.0393), cough (p =0.0167), periungual erythema (p =0.0123), lower values of aldolase

(p =0.047) and AST (p =0.031) were associated with the fatal ILD. Female (p =0.0045), concurrent malignancy (p =0.0037), and the absence of anti-aminoacyl-tRNA synthetase (ARS) antibodies (p =0.0292) were associated with the monophasic resolving ILD. Overall 5-years survival rate of PM/DM-associated ILD was 84%. anti-ARS antibodies positivity was associated with chronic & relapsing course of ILD. HRCT findings and its extension were not associated with the clinical course.

Table 1. Clinical characteristics in cADM/PM/DM patients according to clinical course of ILD.

	resolved (n=24)	chronic stable (n=30)	chronic relpsing (n=32)	fatal (n=7)
Female (%)	91.7	63.3	50.0	85.7
age at onsea of ILD (SD)	54 (12)	51 (15)	49 (10)	60 (7)
cADM/DM/PM (%)	12.5/62.5/25	10/50/40	6.3/59.4/34.4	0/100/0
periungual erythema (%)	58.3	46.7	37.5	100
malignancy (%)	33.3	6.7	6.3	14.3
anti-ARS antibody positive (%)	20.8	50	56.3	0
CK (SD)	891.7 (1233)	2063.6 (3779)	2314 (2129)	552.6 (414)
aldolase (SD)	17.6 (22)	48.3 (78)	50.2 (49)	7 (1)
KL-6 (SD)	1152.5 (1819)	1956.7 (794)	1133.5 (976)	907.4 (526)
%VC (SD)	77.1 (15)	86.1 (21)	73.2 (15)	79.1 (20)
alveolar to arterial PO2 difference (SD)	18 (13)	30.1 (41.5)	29.4 (31.2)	50.8 (27.1)
Groud-glass opacities (%)	50	63.3	53.1	71.4
consolidation (%)	66.7	26.7	53.1	71.4
traction bronchiectasis (%)	95.8	93.3	62.5	71.4
linear opacity (%)	87.5	80	87.5	85.7
honeycombing (%)	0	3.3	93.8	0
follow up period months (SD)	94.3 (52.9)	46.4 (36.7)	90.5 (56.1)	1.9 (1.6)

Conclusion: Patients with IIM-associated ILD presenting with predictive factors for poor outcome may require more aggressive therap.

Simultaneous Initiating of Glucocorticoids and disease-Modifying Antirheumatic Drug Therapy in Polymyositis and Dermatomyositis Patients Results in the Opportunity to Taper Dosage of Glucocorticoids Early. Kavish J. Bhansing[1], Piet LCM Van Riel[1], Sigrid Pillen[2], Baziel G.M. van Engelen[1] and Madelon C. Vonk[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Catharina Wilhemina Hospital, Nijmegen, Netherlands

Background/Purpose: Glucocorticoids are the cornerstone of therapy in patients with polymyositis (PM) and dermatomyositis (DM). However, side effects are common. Furthermore, glucocorticoids exhibits an potential inhibitory effects on skeletal muscle regeneration. Therefore disease-modifying antirheumatic drugs (DMARDs) are used as glucocorticoids sparing agents. To date limited studies are available in which the glucocorticoids sparing effects of DMARDs are evaluated. The aim of this study is to analyze whether an early start of DMARDs in patients with PM or DM leads to the opportunity to taper dosage of glucocorticoids early.

Methods: All available patients with PM and DM of the Nijmegen Myositis inception cohort which was started in 2009 were included. The data available of this cohort consist of clinical features at diagnosis combined with follow up information on treatment and complications. All patient fulfilled the Bohan and Peter diagnostic criteria.

Early start of DMARD was defined as start of methotrexate, azathioprine, hydrochloroquine, mycophenolate, tacrolimus or sulfasalazine within 3 months after diagnosis. Dosage of less than 15 mg of prednisone was regarded as clinical relevant tapering. Two subgroups (early DMARD and non-early DMARD) were compared to analyze for time to reach the dosage of 15 mg prednisone with a follow-up of 1 year using a multivariate cox proportional hazards model.

Results: In the early DMARD starters group 36 patients were included and 25 patients as non-early DMARD starters. The mean age in early DMARD starters was 46 (SD 17) and 37 years (SD 17) in the non-early DMARD starters group. Clinical features and serology revealed no significant differences (Table 1).

Table 1. Study population characteristics

Characteristics	Early DMARD starters (n = 36)	Non-early DMARD starters (n = 25)	Significance (p-value)
Age, mean±SD (years)	46 ± 17	38 ± 17	NS
Gender (male/female)	15/21	7/18	NS
Type of myositis (PM/DM)	23/13	15/10	NS
Serum CK at diagnosis, median (Units/liter)	2467 (386–7370)	1523 (400–7275)	NS
ANA	21/32 (66%)	19/24 (79.2%)	NS
Anti-SSA	10/33 (30%)	8/24 (33%)	NS
Anti-SSB	1/33 (3%)	1/24 (4%)	NS
Anti-Jo1	9/33 (27%)	9/24 (38%)	NS
Interstitial lung disease*	8/36 (22%)	4/25 (16%)	NS

Interstitial lung disease, defined as fibrosis on HRCT-scan or < 70 % vital capacity on pulmonary function within 1 year after diagnosis; NS: not significant

In a Cox regression analysis, early start of DMARD therapy was found to be an independent predictor of tapering dosage of prednisone to less than 15mg (hazard ratio, 2.3; 95% CI, 1.1–4.8; p = 0.03) (fig.1).
Figure 1. Survival curve of early and non-early DMARD starters for time to reach < 15 mg of prednisone use.

Conclusion: Simultaneous start of DMARD therapy with glucocorticoids leads to the opportunity to taper glucocorticoids to clinical significant lower dosages within 1 year after diagnosis in patients with PM and DM compared to adding DMARDs later or glucocorticoids alone in the course of the disease.

Clinical Differences Between Adult and Juvenile Dermatomyositis Associated with Anti-NXP2 Autoantibodies.
Sarah Tansley[1], Zoe Betteridge[1], Harsha Gunawardena[2], Lucy R. Wedderburn[3], Hector Chinoy[4], Robert G. Cooper[5], Jiri Vencovsky[6], Lenka Plestilova[7], Ingrid E. Lundberg[8], Katalin Danko[9], Melinda Vincze[9], Neil McHugh[1], UK JDRG[10] and EuMyoNet[11]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]North Bristol NHS Trust, Bristol, United Kingdom, [3]University College London (UCL), London, United Kingdom, [4]The University of Manchester, Manchester, United Kingdom, [5]Hope Hospital, Salford, United Kingdom, [6]Institute of Rheumatology, Prague, Czech Republic, [7]Institute of Rheumatology, Prague 2, Czech Republic, [8]Karolinska Institutet, Stockholm, Sweden, [9]University of Debrecen, Debrecen, Hungary, Debrecan, Hungary, [10]London, United Kingdom, [11]Stockholm, Sweden

Background/Purpose: Myositis specific antibodies (MSA) can divide dermatomyositis patients into distinct clinical subsets and help predict the risk of disease complications such as interstitial lung disease and malignancy. Anti-NXP2 antibodies are one of the commonest MSA found in juvenile dermatomyositis (JDM) and can be identified in 18–25% cases. They have been associated with calcinosis and a severe disease course with more persistent disease activity. Anti-NXP2 antibodies have been found in adult myositis cohorts at a much lower frequency of 1.6%. A possible association with malignancy has been described in adults.

In this study we identified anti-NXP2 antibodies in a cohort of 172 juvenile and 1331 adult patients with idiopathic inflammatory myopathy and compared the clinical disease characteristics of both groups.

Methods: Serum samples were obtained from EuMyoNet and UK JDRG repositories. Immunoprecipitation of radio-labelled K562 cells was performed on all samples. Those with a band in the 140kDa region were further assessed by western blot using an NXP2 overexpression cell lysate (Abnova).

Results: Anti-NXP2 antibodies were identified in 20 children (11.6%) and 10 adults (0.8%). All children with anti-NXP2 antibodies had dermatomyositis. There was a strong association with calcinosis in children which was seen in 55% (p<0.0009). Of the adults nine had dermatomyositis and one polymyositis. One adult patient had calcinosis. An additional diagnosis of malignancy was present in three adults (breast, uterine, pancreatic) (p=0.051). When patients with anti-TIF1γ antibodies, (which are already known to be strongly associated with malignancy) were excluded this association became statistically significant (p=0.027).

Conclusion: Anti-NXP2 antibodies are associated with an increased frequency of calcinosis in JDM. Calcinosis is a common cause of morbidity in JDM but is rarely seen in adult disease. It is interesting therefore that one adult patient with anti-NXP2 antibodies also had calcinosis. In JDM calcinosis is associated with delayed diagnosis, a chronic disease course and inadequately treated disease. Anti-NXP2 in JDM have previously been shown to be associated with a more severe disease course with worse functional status and persistent disease activity. The increased risk of calcinosis may therefore reflect more aggressive disease in anti-NXP2 positive children.

Consistent with previous findings there is an association with malignancy in our anti-NXP2 positive adult population. Whilst malignancy in JDM is rarely seen it is an important disease association in adults and associated with a poorer prognosis. Identification of anti-NXP2 in adult myositis patients may have important prognostic implications, particularly in older adults and should warrant a high level of suspicion for additional malignant disease. Whilst the same MSA are found in adult and juvenile dermatomyositis and define clinical subsets, important clinical differences are seen depending on patient age. Whether this reflects differences in aetiology, pathogenesis or age-specific disease modifiers is yet to be established.

Hydroxy-3-Methylglutaryl-Coenzyme A Reductase (HMGCoR) Antibody in Necrotizing Myopathy and the Role of Statins.
Ashima Malik[1], Rohit Aggarwal[1], Zengbiao Qi[1], Noreen Fertig[1], Diane Koontz[1], Rufus W. Burlingame[2], David Lacomis[3] and Chester V. Oddis[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]INOVA Diagnostics, Inc., San Diego, CA, [3]University of Pittsburgh Medical Ctr, Pittsburgh, PA

Background/Purpose: Statin use is associated with myalgias, muscle weakness and elevated muscle enzymes, but recent reports of a statin-induced immune-mediated necrotizing myopathy (IMNM) have been intriguing. Of particular interest is the recently reported hydroxy-3-methylglutaryl-coenzyme A reductase antibody (anti-HMGCoR). Our Aim is to evaluate anti-HMGCoR antibody positivity and statin exposure in antibody negative necrotizing myopathy patients.

Methods: Using a large prospective computerized database we identified 48 patients with antibody negative Necrotizing Myopathy from 1980–2011, confirmed by a pathologist- review of all biopsies. As a comparison cohort we had SRP positive myositis patients (32), a subset known to have necrotizing myopathy with poor prognosis. Other controls were Non-SRP non-necrotizing myositis patients (73), non-myositis controls (21), antibody positive necrotizing myopathy controls (13). A validated anti-HMGCoR ELISA assay was done on all cases and controls with values (units/ml) as negative < 20, low positive 20–39, medium positive 40–59, high positive at ≥ 60. Computerized database and clinical chart review was done for history of statin use and other clinical parameters. Chi square test was used to compare between cases and various controls for statin use and anti-HMGCoR positivity. All myositis specific autoantibody testing was done in a research lab using ELISA and immunoprecipitation.

Results: 256 biopsies were reviewed and 48 identified as antibody negative necrotizing myositis. Anti-HMGCoR positivity was significantly (p<0.001) associated with antibody negative necrotizing myopathy 47.9% (23/48) as compared to a) all myositis and non-myositis controls 7.2% (10/139), b) SRP control alone 0% (0/32), c) Non-SRP non-necrotizing myositis controls 5.5% (4/73), but not when compared alone to antibody positive necrotizing myopathy (4/13) (with 2 on statin), P =0.54).

Higher titer anti-HMGCoR levels were seen in antibody negative (17/48) and antibody positive necrotizing myopathy (4/13) but not in other controls (2/126). Statin use was more common (p<0.001) in antibody negative necrotizing myopathy (23/48) as compared to all myositis and non-myositis control (17/127), b) SRP control alone (2/26), c) Non-SRP non-necrotizing myositis control (11/70) but only trend compared alone to antibody positive necrotizing myopathy (3/13 (with 2 anti-HMGCoR +) P =0.06).

Within patients with necrotizing myopathy: anti-HMGCoR was associated with patients on statin (19/24) as compared to patients without statin (7/27), p <0.01). Anti-HMGCoR antibodies were more common in any patients on statin (20/34) as compared to patients without statin (20/138), p < 0.001).

Conclusion: Anti-HMGCoR is strongly associated with antibody (−) necrotizing myopathy vs. anti-SRP (+) myositis. Moreover, anti-HMGCoR is more common in necrotizing myopathy pts with history of statin use vs. no statin use.

231

Pulmonary Hypertension in the Antisynthetase Syndrome. Helena Andersson[1]. T. Mogens Aalokken[2], Torhild Garen[3], Oyvind Molberg[4] and Jan Tore Gran[1], [1]Oslo University Hospital, Oslo, Norway, [2]Oslo, Norway, [3]Oslo University Hospital Rikshospitalet, Oslo, Norway, [4]Department of Rhematology, Oslo University hospital, Rikshospitalet, Oslo, Norway

Background/Purpose: To describe the frequency and clinical characteristics of pulmonary hypertension (PH) in a cohort of Antisynthetase Syndrome (ASS) patients.

Methods: Patients from a single referral center diagnosed between 1994–2010 with a positive serologic test (immuno-blot) of antisynthetase antibodies, interstitial lung disease (ILD) and/or myositis were defined as ASS (N=90). All data were retrospectively collected from medical reports. A diameter of the Pulmonal artery >29 mm, measured by CT-scans, was defined as pathological. PH was suspected with an estimated pulmonary arterial pressure (PAP) of >45mmHg at transthoracal eccocardiography (TTE), and defined as a mean PAP >25 mmHg measured by right heart catheterization (RHC). The ratio between forced vital capacity and diffusion capacity of the lungs (FVC/DLCO) was considered pathological, indicating PH, at values > 1.6. All examinations were done within 3 months for each patient.

Fisher's exact test was used to evaluate statistical significance (p<0.05)

Results: The cohort consisted of 75 anti-Jo1 positive, seven PL-7 positive and eight PL-12 positive patients with mean age at ASS diagnosis of 48 years (range 12–82 yrs) and median disease duration of seven years (range 0.25–34 yrs). Fourteen patients were referred to RHC due to clinical suspicion of PH. Ten out of 14 were diagnosed with PH, with a median PAP of 38 mmHg (range 26–55). Eight out of 10 patients had a pre-capillary type of PH, defined as pulmonal capillary wedge pressure (PCWP) < 15mmHg. Over all frequency of PH was 11 % (10/90). Twelve of 14 patients had available TTE-exams, all but one indicating PH with estimated PAP of >45mmHg. The Pulmonal artery was pathological enlarged in 9/10 patients with PH, median diameter 40 mm (range 33–45). Although not statistic significant (p<0.07), the result indicates a correlation between enlarged pulmonary artery and PH. Seven of nine patients with PH had pathological FVC/DLCO ratios. All 10 PH patients had manifest ILD at time of PH diagnosis. 2/10 patients with PH had co-existing rheumatic disease, both systemic sclerosis. The diagnosis of PH was made 36–336 months after ASS onset. Five of 10 patients with PH died during the observation-period.

Clinical characteristics of ASS patients with performed RHC

PATIENT	SEX/ AGE	ANTIBODY	SS-A	FVC/ DLCO	DLCO	DIA A PULM	ECCO mmHg	RHC mmHg	PCWP/ mmHg	DEATH
PH										
1	M 61	Jo-1	+	2,12	17	45	60	33	2	+
2	F 63	Jo-1		NA	NA	36	55	35	14	
3	M 44	Jo-1	+	1,52	38	42	40	26	9	
4	F 43	Jo-1	+	1,91	45	42	70	44	7	
5	F 54	Jo-1	+	3	15	33	70	38	10	+
6	F 18	Jo-1	+	2,5	12	40	NA	50	8	+
7	M 33	Jo-1	+	2,23	26	38	60	38	16	
8	F 21	Jo-1		1,62	17	NA	76	55	18	+
9	M 43	Jo-1	+	1,8	41	41	60	26	7	
10	F 55	Jo-1	+	0,82	56	33	98	50	15	+
No PH										
11	M 60	Jo-1	+	1,87	56	28	60	23	11	
12	F 12	PL-12	+	1,17	47	33	45	18	2	
13	F 19	Jo-1		1,45	33	27	NA	15	4	
14	F 31	PL-12	+	2,09	31	33	70	24	6	

Conclusion: In this cohort of 90 ASS patients and with a median disease duration of seven years, a PH frequency of 11 % diagnosed by RHC was observed. The study indicated a correlation between enlarged Pulmonal artery and PH. In spite of small series, the results indicate PH as an important complication of ASS and should be given further notice.

232

The Natural History of Sporadic Inclusion Body Myositis–an Observational Longitudinal Study. Pedro Machado[1], Andrea Cortese[1], Jasper Morrow[1], Liz Dewar[1], Andy Hiscock[1], Adrian Miller[1], Stefen Brady[2], David Hilton-Jones[2], Matt Parton[1] and Michael G. Hanna[1]. [1]MRC Centre for Neuromuscular Diseases, UCL Institute of Neurology, London, United Kingdom, [2]Oxford Muscle and Nerve Centre, John Radcliffe Hospital, Oxford, United Kingdom

Background/Purpose: Our aim was to assess prospectively the clinical features and functional impact of inclusion body myositis (IBM), to identify reliable outcome measures for future trials and to identify prognostic factors of this condition.

Methods: Patients were classified with either probable or definite IBM, according to the Griggs' criteria (Griggs RC, et al. Ann Neurol 1995;38:705–713) or with clinically defined IBM, according to the Medical Research Council criteria (Hilton-Jones D, et al. Neuromuscul Disord 2010;20:142–147). Clinical data, manual muscle testing (MMT), quantitative muscle testing (QMT) of quadriceps extensors with HUMAC Norm CSMi™ dynamometer and IBM functional rating scale (IBM-FRS) were collected according to a standardised protocol (IBM-Net) at baseline (n=51) and one-year follow-up (n=23, QMT performed in a subgroup of 13 patients). The responsiveness to change of MMT, QMT and IBM-FRS was assessed by calculating the standardized response mean (SRM). Cox-regression analysis was performed to estimate the effect of sex, age at disease onset and previous or current treatment with steroids or immunosuppressants on the time to using a walking stick. Time to using a walking stick was modelled using a Kaplan-Meier curve.

Results: Mean age at disease onset was 58 years (16% before the age of 50). Weakness of quadriceps and finger flexors with sparing of proximal upper limb muscles was the most common presentation. After a median time of 7 years of disease, 63% of patients had lost independent walking ability and needed assistive devices. Twenty-seven patients (53%) reported difficulties with swallowing. IBM was initially misdiagnosed in 50% of cases, the commonest misdiagnosis being polymyositis. MMT, IBM-FRS and quadriceps QMT significantly declined after one year (by 5.2%, 13.8% and 27.9% respectively). QMT of the quadriceps muscle (SRM=1.8) and IBM-FRS (SRM=1.3) were the most sensitive measures of disease progression. Disease onset after 55 years of age (HR=4.1; 95% CI=1.7, 9.8; p=0.001), but not sex or treatment, was predictive of a shorter time to requirement of a walking stick (figure). We detected no differences in disease presentation and progression between clinically and pathologically defined IBM patients.
Conclusion: IBM is a disabling myopathy with prominent involvement of specific muscle groups, particularly quadriceps femoris and finger flexors, which are essential for activities of daily living. IBM is still probably an underrecognised and misdiagnosed disease. During one year follow-up, the responsiveness of QMT of quadriceps femoris and of IBM-FRS were greater than MMT, which makes the former two measures more sensitive markers of disease progression. Onset of the disease after 55 years of age was predictive of a shorter time to using a walking stick.

IFN Signature Is Associated with Autoantibody Profiles in Patients with Idiopathic Inflammatory Myopathies. Saskia Vosslamber[1], Louise Ekholm[2], Anna Tjarnlund[3], Clio P. Mavragani[4], Lenka Plestilova[5], Martin Klein[5], Mary K. Crow[6], Peter J. Charles[7], Leonid Padyukov[8], Jiri Vencovsky[5], Ingrid E. Lundberg[3] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]1Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Solna, Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [3]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Solna, Karolinska Institutet, Sweden, Stockholm, Sweden, [4]School of Medicine, University of Athens, Athens, Greece, Athens, Greece, [5]Institute of Rheumatology, Prague, Czech Republic, [6]Hospital for Special Surgery, New York, NY, [7]Oxford University, London, United Kingdom, [8]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare autoimmune diseases characterized by the presence of autoantibodies, proximal muscle weakness and muscle inflammation. Recent studies showed an activated type I IFN activity (IFN signature) in a subset of patients and suggest a pathogenic role for type I interferon (IFN) in IIM patients. The extent of this signature appears to be related to disease activity, however, the relevance to disease or the underlying mechanism resulting in such a signature has not been revealed yet.

The aim of this study was to examine if the type I IFN activity in whole blood and sera from IIM patients correlates to disease activity, clinical manifestations or autoantibody profile.

Methods: Clinical data were collected from 94 polymyositis, dermatomyositis and inclusion body myositis patients recruited from the Karolinska University Hospital and Prague University. Serological data was obtained using lineblot assay. RNA samples, obtained from whole blood were assessed for expression levels of 9 IFN related genes using BioMark™Dynamic Arrays. IFN score was determined as the average gene expression level of these genes. Median IFN score was used to define the presence of an IFN signature.

Sera were assessed for IFN activity using a bioassay where expression of 3 type I IFN-inducible genes were quantified using real-time PCR. Two groups of patients, IFN+; IFN-, were categorized based on the sum of individual gene expression scores. Differences between these groups were assessed for clinical and serological data, as well as correlation between IFN signature and variables.

Results: The IFN signature in peripheral blood was present in a subgroup of patients with myositis. No significant difference in the presence and extent of the IFN signature was observed between ANA negative and ANA positive patients. Comparison of the IFN signature in patients positive for myositis associated or specific autoantibodies revealed that the highest IFN score was found in U1RNP positive patients (mean IFN score = 23.66), followed by La positive patients (mean IFN score = 11.94) and Ro60 positive patients (..). Comparable results were found in patients with multiple autoantibody specificity and those only positive for one of these antibodies. In addition, a majority of Jo-1 and Ro-52 positive patients were characterized by the presence of an IFN signature, although most of these patients appear to be positive for multiple autoantibody specificities. Detailed analysis revealed that presence of an IFN signature was related to multi-autoantibody specificity, i.e. 17 out of 23 patients positive for 2 or more autoantibodies (70%) versus 30 out of 71 of the patients positive for 1 or none of the specific autoantibodies (45%) displayed an IFN signature (Pearson Chi square p=0.008).

Significantly more IFN+ patients were positive for ANA compared to IFN- patients (p=0.001). No correlation between IFN activity in sera and disease activity was found.

Conclusion: These data reveal a preferential presence of the IFN signature in IIM patients that are characterized by multiple autoantibody specificities. These findings suggest a role for autoantibodies in the induction of type I IFN activity in IIM.

Central Sensitization Is Associated with Spontaneous Pain in Knee Osteoarthritis. Anisha B. Dua[1], Tuhina Neogi[2], Rachel A. Mikolaitis[3], Joel A. Block[3] and Najia Shakoor[3]. [1]Rush Universtiy Medical Center, Chicago, IL, [2]Boston Univ School of Medicine, Boston, MA, [3]Rush University Medical Center, Chicago, IL

Background/Purpose: Osteoarthritis (OA) is a chronic, prevalent disease that is a major cause of pain and disability. Pain is the primary symptom of OA, however its characteristics and pathophysiology remain poorly understood. Studies suggest that patients with knee OA have increased central sensitization, measured by pressure pain thresholds (PPTs) and temporal summation (TS) to repeated non-nociceptive stimulation. Here we evaluated the relationship between central sensitization (TS and PPTs) and pain magnitude in symptomatic knee OA.

Methods: Persons with moderate to severe radiographic (Kellgren-Lawrence (KL) grade $\geq$2) and symptomatic (at least 30mm on WOMAC visual analog scale) knee OA were compared with age matched controls without knee pain or OA (radiographic KL grade of 0–1, pain <20 on WOMAC VAS), and no history of diabetes, arthroplasty, or chronic widespread pain. In subjects with bilateral knee OA, the most symptomatic side was considered the "affected" side. Participants answered questionnaires regarding knee pain and function including the question "do you feel spontaneous pain in your knee?" Temporal summation (TS) was measured by application of a 60g Von Frey monofilament repeatedly (30 times) to pre-determined anatomic sites. Participants answered the question "do you consider this painful?" (yes/no) and rated their pain on a scale of 1–10. Pain pressure thresholds (PPT) were measured using a pressure algometer applied to pre-determined anatomic sites with steadily increasing pressure and recordings were taken at the first sensation of pain.

Results: 42 OA participants (mean age 54.1 ± 8.1 years) and 12 controls (mean age 52.9 ± 11.1 years) were evaluated. Significantly more OA subjects demonstrated TS compared with controls at the ipsilateral (54.8% vs 16.6%, p=0.02) and contralateral knee (49% vs 0%, p=0.005). PPTs were lower in the OA group but did not reach significance. KOOS and WOMAC pain scores did not correlate with PPT or TS at any of the several sites evaluated (rho= −0.115 to −0.139 and 0.150 to 0.286 respectively, p >0.05).

Spontaneous pain in the knee was reported by those with knee OA more frequently than controls (74.3% vs 0%, p=0.001) and those with spontaneous knee pain had lower PPTs than those without spontaneous knee pain (Table 1). In patients with OA, spontaneous knee pain was also associated with the presence and pain rating of TS at the ipsilateral and contralateral tibial tuberosities (Table 1).

Table 1. Relationship Between Spontaneous pain, Pain Pressure Thresholds and Temporal Summation

Spontaneous Pain	Yes	No	P value
Pain Pressure Threshold Radial Styloid (kgf)*, (Mean ± SD)	2.42 ± 1.07	4.39 ± 1.25	0.001
Pain Pressure Threshold Medial Joint Line (kgf), (Mean ± SD)	2.05 ± 1.08	3.98 ± 1.61	0.001
Pain Pressure Threshold Tibial Tuberosity (kgf), (Mean ± SD)	3.52 ± 1.44	5.01 ± 1.11	0.005
Presence of Temporal Summation Ipsilateral Tibial Tuberosity	69.20%	30.70%	0.012
Pain rating post-stimulus for eliciting Temporal Summation Ipsilateral Tibial Tuberosity Scale (Mean ± SD)	4.3 ± 2.6	1.6 ± 1.7	0.003
Presence of Temporal Summation Contralateral Tibial Tuberosity	65.40%	11.10%	0.007
Pain rating post-stimulus for eliciting Temporal Summation Contralateral Tibial Tuberosity Scale (Mean ± SD)	3.7 ± 2.3	1.4 ± 1.3	0.001

*kgf = kilograms of force

Conclusion: Conventional pain scales do not correlate well with measures of central sensitization. However, the presence of spontaneous pain is more frequent in OA patients than controls, and those who have spontaneous pain have generalized decreases in thresholds to pain sensation (lower PPTs) and also are more likely to demonstrate temporal summation.

235

Peripheral and Central Sensitization in Patients with Different Degree of Knee Osteoarthritis. Lars Arendt-Nielsen[1], Thomas Navndrup Eskehave[2], Morten Asser Karsdal[3], Anne C. Bay-Jensen[3], Hans Christian Hoeck[4] and Ole Simonsen[5]. [1]Aalborg University, Aalborg, Denmark, [2]Ålborg University, Ålborg, Denmark, [3]Nordic Bioscience A/S, Herlev, Denmark, [4]C4Pain, Ålborg, Denmark, [5]Frederikshavn Hospital, Frederikshavn, Denmark

Background/Purpose: Though pain is the cardinal symptom of osteoarthritis (OA) the underlying causes are not fully understood. However, peripheral and central sensitization has been suggested to play an important role in OA pain. The aim of this study was to investigate associations between mechanism based pain assessment parameters associated with peripheral and central sensitisation in painful knee OA and clinical manifestations (K&L, Pain intensity, WOMAC).

Methods: 217 patients with different degrees of OA pain (rated on a visual analog scale (VAS) from 0 to 100) and 36 healthy controls participated in the study. Patients were allocated into: controls (VAS 0–9), Group A (VAS 10–39), Group B (VAS 40–69) and Group C (VAS 70–100). Pressure pain thresholds (PPT′s) were measured in the peripatellar region, tibialis anterior and extensor carpi radialis muscle before, during and after conditioning pain modulation (CPM). Temporal summation to repeated mechanical stimulation was measured at all sites. A sensitization index was constructed based on PPT′s, temporal summation and CPM. Pain and soreness areas were obtained. The radiologic assessment of OA was made by specialists using Kellgren & Lawrence grading scale (0–4).

Results: All patient groups had significantly lower PPT′s compared to controls. Patients showed facilitated temporal summation and reduced CPM function compared to controls. Significant correlations were found between CPM effect (r=0.23, p<0.01), degree of temporal summation (r=−0.36, p<0.01) and PPT (r=0.22, p<0.01) and clinical Vas ratings. The index of pain sensitization revealed that 37.3 % of the patients were twice as pain sensitive as controls. The pain sensitization score was significantly was correlated with VAS ratings (0.36, p<0.01) and pain/soreness areas (r=0.14, p<0.05 and r=0.15, p<0.05)

Conclusion: Patients with mild, moderate and severe pain had significantly lower PPT′s compared to controls. Furthermore, patients with OA had significantly more central sensitization (decreased CPM effect and increased temporal summation) compared to controls. This study is the first to demonstrate a tool for OA patient stratification into sensitized and non-sensitized based on relevant pain assessment parameters. This stratification can be useful for diagnosis and future treatment of OA patients and for monitoring the effects of new drugs under the development for OA pain.

The Relationship Between Vibratory Sense and Somatosensory Pain Measures in Knee Osteoarthritis. Anisha B. Dua[1], Rachel A. Mikolaitis[2], Tuhina Neogi[3], Joel A. Block[2] and Najia Shakoor[2]. [1]Rush Universtiy Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Boston Univ School of Medicine, Boston, MA

Background/Purpose: Osteoarthritis is the most common form of arthritis, and is a major cause of pain and disability. Continuous nociceptive input can influence somatosensory processing, and studies suggest that patients with knee OA have altered somatosensory findings, demonstrated by decreased vibration perception threshold (VPT), pressure pain thresholds (PPTs), and temporal summation (TS) elicited by repeated non-nociceptive stimulation. Here, we further characterize the relationship between these somatosensory measures in knee OA.

Methods: Persons with moderate to severe radiographic (Kellgren-Lawrence (KL) grade ≥2) and symptomatic (at least 20mm on WOMAC visual analog scale) knee OA were evaluated. In subjects with bilateral OA, the most symptomatic side was considered the "affected" side. VPT was measured using a biothesiometer (Bio-Medical Instrument Co., Newberry, Ohio) that provided vibratory stimulation at multiple predetermined anatomic sites. VPT was recorded as the first sensation of vibration (volts). TS was assessed by application of a 60g Von Frey monofilament repeatedly (30 times) to various sites. Participants answered the question "do you consider this painful?" (yes/no) and rated the extent of their pain on a scale of 0–10, immediately and after 10 seconds. PPT's were measured using a pressure algometer applied to pre-defined sites with steadily increasing pressure. Recordings were taken at the first sensation of pain.

Results: 42 OA participants (mean age 54.1 ± 8.1 years) were evaluated. Subjects who demonstrated TS at the ipsilateral tibial tuberosity had significantly lower PPTs at multiple sites compared to those without TS (Table 1). VPT and PPTs were directly correlated at several anatomic sites (Table 2). VPT was lower at the first metatarsophalangeal joint (MTP) in those that demonstrated TS at the ipsilateral tibial tuberosity vs those that did not (8.2±3.3 vs 12.1±4.8 volts, p=0.005). VPT was also lower at the first MTP in those that sensed/rated pain at the ipsilateral tibial tuberosity 10 seconds post-stimulation (for TS) vs those that did not (7.6±4.2 vs 11.3±4.2 volts, p=0.011).

Table 1. Relationship between Temporal Summation and Pain Pressure Threshold

Pain Pressure Threshold (kilograms of force), (Mean ± SD)	Presence of Temporal Summation at Ipsilateral tibial tuberosity		P-value
	Yes	No	
Ipsilateral radial styloid	2.56 ± 1.19	3.71 ± 1.53	0.01
Contralateral radial styloid	2.51 ± 1.26	3.75 ± 1.50	0.007
Ipsilateral tibial tuberosity	3.16 ± 1.56	4.59 ± 1.39	0.003
Contralateral tibial tuberosity	3.57 ± 1.61	4.48 ± 1.32	0.052
Ipsilateral medial joint line	2.16 ± 1.23	3.44 ± 1.64	0.008
Contralateral medial joint line	2.54 ± 1.46	3.77 ± 11.81	0.02

Table 2. Correlation between VPT at Multiple Sites with PPT at the Ispilateral Tibial Tuberosity and Medial Joint Line

	PPT Ipsilateral tibial tuberosity Spearman's rho (p value)	PPT Ipsilateral medial joint line Spearman's rho (p value)
VPT Ipsilateral medial ankle	0.416 (0.006)	0.476 (0.001)
VPT Ipsilateral lateral knee	0.432 (0.004)	0.405 (0.008)
VPT Ipsilateral tibial tuberosity	0.350 (0.02)	0.268 (0.09)
VPT Ipsilateral medial knee	0.338 (0.03)	0.389 (0.01)

Conclusion: Key measures of central sensitization appear to be well correlated in this group, with lower pain thresholds (PPT) in those that demonstrate TS. Higher pain thresholds and the absence of TS were both associated with decreased vibratory sense acuity (higher VPT). Thus, the well documented loss of vibratory acuity in patients with knee OA may also be part of an inhibitory pathway reflected in higher pain thresholds and lack of temporal summation.

Association Between Pain Threshold, Symptoms and Radiographic Knee and Hip Osteoarthritis: The Johnston County Osteoarthritis Project. Adam P. Goode[1], Xiaoyan A. Shi[2], Jordan Renner[3], Richard Gracely[4], Mehrnaz Maleki-Fischbach[5] and Joanne M. Jordan[6]. [1]Duke University, Durham, NC, [2]SAS Institute, Inc, Cary, NC, [3]University of North Carolina, Chapel Hill, NC, [4]Chapel Hill, NC, [5]National Jewish Health, Denver, CO, [6]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

Background/Purpose: Little is known of the association between pain threshold and knee/hip symptoms as well as radiographic knee/hip osteoarthritis (rOA). These analyses: 1) determined the association between pain threshold and presence of knee/hip symptoms or knee/hip rOA, 2) determined the association between pain threshold and the number of joints with knee/hip symptoms or rOA and 3) determined if associations differed by demographic or clinical characteristics.

Methods: Dolorimeter measurements for pain threshold were available for 1,602 participants returning for second follow-up (2008–11) in the Johnston County Osteoarthritis Project. Participants mean age was 67.9 (SD 9.0), 67.2% female, 31.0% African American, mean body mass index (BMI) 31.5 (SD 7.1) and a mean Center for Epidemiologic Studies Depression (CES-D) Scale score of 31.5 (SD 7.1). Pain threshold measurements were averaged (mean of 3.6kg ((SD 0.7)) over three trials from left and right trapezius muscles. Knee and hip OA were both defined by a Kellgren-Lawrence score of 2–4. Knee and hip symptoms were obtained at clinical interview with "on most days do you have pain, aching or stiffness in at least one knee/hip?". Associations were determined with logistic regression while adjusting for age, race, BMI, CES-D scores and presence of hip or knee rOA. Interactions between pain threshold and clinical and demographic characteristics were tested at p<0.05.

Results: Knee and hip rOA were present in 45.7% and 40.3% of participants, respectfully. Knee and hip symptoms were present in 38.4% and 29.3% of participants, respectfully. A 1-unit increase in pain threshold was significantly associated with symptoms in the knee (adjusted odds ratio [aOR] 0.64 ((95% CI 0.54, 0.76)) and hip (aOR 0.67 ((95% CI 0.57, 0.79)). The figure illustrates the associations between pain threshold and number of knees and hips with symptoms. Compared to those without knee or hip symptoms, those with higher pain threshold were 20% less likely to have 1 joint with symptoms and 50% less likely to have 4 joints with symptoms. No significant associations were found with increased pain threshold and presence of knee or hip rOA or number of joints with knee and hip rOA. No significant interactions were found between pain threshold and demographic or clinical characteristics.
Figure. Associations between pain threshold and number of knees and hips with symptoms*.

* referent = those with no knees or hips with symptoms

Conclusion: Participants with higher pain threshold were less likely to report knee and hip symptoms, an association that strengthened with the number of symptomatic joints. In contrast, no association was found with increased pain threshold and knee or hip rOA. These findings suggest the presence of knee or hip rOA may not be informative in understanding an individual's knee or hip symptoms or useful for evaluating the efficacy of treatments targeting symptoms.

238

Inevitable Deterioration? Trajectories and Risk Profiles of Pain in Patients with Radiographic, Symptomatic Knee Osteoarthritis. Jamie E. Collins[1], William M. Reichmann[2], Jeffrey N. Katz[1] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Womens Hospital, Boston, MA

Background/Purpose: Knee pain is the primary reason that patients with OA seek medical care. The goal of this study is to describe pain trajectory over three years in a cohort of patients with radiographic, symptomatic knee OA.

Methods: We used data from the Osteoarthritis Initiative (OAI), a multi-center, longitudinal, prospective observational study of knee OA. Pain assessments were done at baseline and at yearly visits for 4 years. We defined patients with symptomatic knee OA as those with central reader Kellgren/Lawrence (KL) score >2 and a WOMAC pain score >0. We used group-based trajectory modeling to identify distinct patterns of pain progression. To minimize the impact of baseline flare effect we restricted our analysis to visits occurring in months 12 through 48. We also built multivariable generalized linear models to determine factors affecting change in pain severity over time. Factors examined included sex, race, education, baseline comorbidities, 12-month age, BMI, alignment, KL grade, and depression.

Results: We used the data from 1,447 OAI study participants with radiographic, symptomatic knee OA at month 12. The average WOMAC pain at month 12 was 24 (0–100 scale with 100 = worst) with standard deviation 17.6. Individual pain reports varied markedly over time. For example, at 48 months, 51% reported a *lower* pain score than at 12 months and 36% reported a *highe*r score. Also, 32% of all patients reported having no pain at one or more subsequent follow-up visits. Group based trajectory modeling identified 4 distinct pain trajectories [Figure]. Two-thirds of patients (groups 2 and 3 in Figure) started with moderate pain and showed little change on average over three years. The 12.6% in the highest pain trajectory tended to increase in pain by an average of 6 points over 3 years of follow-up, while patients in the first category (lowest pain at 12 months) decreased by an average of 9 points. Higher BMI, depression, and KL grade at the beginning of observation were associated with pain worsening over time in multivariable models.

Figure: WOMAC Pain Trajectories
Conclusion: We found that knee pain is highly variable over time and that pain neither worsens nor improves, on average, over three years in a majority of patients. Just 12.6% of patients demonstrate progressive worsening. These observations of highly variable pain reports with relatively little change on average over time contrast with the frequent clinical teaching that osteoarthritis symptoms progressively worsen over time.

Knee Osteoarthritis Symptom Assessments That Combine Pain and Physical Activity Are Superior to Pain Alone. Grace H. Lo[1], Timothy E. McAlindon[2], Gillian A. Hawker[3], Jeffrey B. Driban[2], Lori Lyn Price[2], Jing Song[4], Charles Eaton[5], Marc C. Hochberg[6], Rebecca D. Jackson[7], C. Kent Kwoh[8], Michael C. Nevitt[9] and Dorothy D. Dunlop[4]. [1]Michael E. DeBakey Veterans Affairs Medical Center/Baylor College of Medicine, Houston, TX, [2]Tufts Medical Center, Boston, MA, [3]Women's College Research Institute, University of Toronto, Toronto, ON, [4]Northwestern University, Chicago, IL, [5]Warren Alpert Medical School at Brown University, RI, [6]University of Maryland, Baltimore, MD, [7]Ohio State University, Columbus, OH, [8]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [9]University of California-San Francisco, San Francisco, CA

Background/Purpose: Symptom assessment in knee osteoarthritis (OA) is challenging. Knee pain does not always correlate well with radiographic severity, perhaps because people modify/avoid activities to reduce symptoms. Accelerometers/pedometers can inexpensively and easily quantify physical activity. We hypothesize that symptom assessment accounting for pain intensity in the context of physical activity will improve discrimination across OA radiographic severity levels.

Methods: We studied Osteoarthritis Initiative (OAI) participants with ≥ 4 days accelerometer monitoring, knee-specific WOMAC pain data, *and* knee x-rays from the 48-month visit. Accelerometer data included average daily step count and average daily activity counts (i.e., weighted sum of activity frequency and intensity). Four composite knee pain and activity scores (KPAS) were calculated:

KPAS1 = daily step count/(Total WOMAC Pain Score + **1**)
KPAS2 = daily activity count/(Total WOMAC Pain Score + **1**)
KPAS3 = daily step count/(WOMAC Walking Pain Score + **1**)
KPAS4 = daily activity count/(WOMAC Walking Pain Score + **1**)
Figure 1. Histograms stratified by K-L Grade of the Total WOMAC Pain Score and KPAS1.

Lower KPAS values reflect greater symptoms, consistent with less activity and/or greater pain. X-rays were read for Kellgren and Lawrence (K-L) grade

(0–4). For each participant, only right knee data were evaluated. Total WOMAC pain score, WOMAC walking pain score, accelerometer data, and KPAS scores were tested for normality, and score discrimination by K-L grades using stratified histograms, Kruskal–Wallis testing, and quantile regression analyses (excluding WOMAC walking pain) unadjusted and adjusted for age, sex and BMI.

Results: 1472 participants, mean age 64.9 ($\pm$ 9.1), mean BMI 28.1 ($\pm$ 4.8), 43% male, were included. No symptom score was normally distributed, with pain assessments being the most skewed.

Table 1. Kruskal–Wallis testing of symptom assessments across adjacent K-L grades.

	Symptom Assessments							
K-L Grade Comparisons	WOMAC	WOMAC Walk	Step Count	Activity Count	KPAS1	KPAS2	KPAS3	KPAS4
0 v. 1			X	X			X	
1 v. 2	X	X			X	X	X	X
2 v. 3				X				
3 v. 4	X	X			X	X	X	X

"X" denotes statistically significant differences.

Table 2. Quantile regression: Differences in <u>median</u> symptom scores across K-L grade groups.

Outcome	Adjustment Factors	Median Scores KL 0 (Referent)	Differences in Median Scores from Referent Group				P for trend
			KL 1	KL 2	KL 3	KL 4	
WOMAC Total Pain	Unadjusted	0	0	1	1	4	*p=.006*
	Adjusted[a]	0	0	1	1	4	*p<.001*
Step count	Unadjusted	6253	−763*	−774*	−930*	−1957*	*p<.001*
	Adjusted[a]	18436	−286*	−242	−222	−299	p=0.20
Activity count	Unadjusted	211358	−13429	−20681*	−30746*	−51700*	*p<.001*
	Adjusted[a]	647624	−1920	732	7038	−3197	p=0.79
KPAS1	Unadjusted	4367	−627*	−1338*	−1674*	−3499*	*p<.001*
	Adjusted[a]	11709	−387	−1116*	−1245*	−2912*	*p<.001*
KPAS2	Unadjusted	146556	−14023	−40866*	−46057*	−110077*	*p<.001*
	Adjusted[a]	448042	−6880	−28642*	−29064*	−88068*	*p<.001*
KPAS3	Unadjusted	5560	−500*	−1088*	−1024*	−2842*	*p<.001*
	Adjusted[a]	16208	−179	−334	−271	−2226*	*p<.001*
KPAS4	Unadjusted	183218	−5603	−25181*	−23770*	−85471*	*p<.001*
	Adjusted[a]	614784	−892	−7509	−5994	−56155*	*p=.003*

[a] Adjusted for age, sex, and BMI
* Statistical difference of group median compared to the referent (KL score of 0) median; p<0.05.
Referent group is K-L grade 0. For WOMAC score, higher score = greater symptoms. For all other scores, lower score = greater symptoms.

Conclusion: Symptom assessments incorporating pain intensity and physical activity improved discrimination across radiographic OA severity. Pain better discriminates high disease severity while physical activity better distinguishes low severity. Relationships of KPAS measures with x-ray severity were robust to adjustment for traditional OA risk factors. To improve sensitivity, physical activity should be routinely assessed in studies of knee OA symptoms.

Degenerative Changes in Patients with Knee Pain: A Comparative Study Between Ultrasound and Conventional Radiology. Santiago Ruta[1], Erika Catay[2], Javier Rosa[2], David A. Navarta[2], Ricardo Garcia-Monaco[3] and Enrique R. Soriano[4]. [1]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [2]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [3]Radiology and Imagenology Department, Hospital italiano de Buenos Aires, Buenos Aires, [4]Rheumatology Unit, Internal Medical Services, Hospital Italiano de Buenos Aires, Instituto Universitario Hospital Italiano de Buenos Aires, and Fundacion PM Catoggio, Buenos Aires, Argentina

Background/Purpose: Knee osteoarthritis (OA) is one of the most common rheumatologic joint diseases and causes an important disability in the elderly population. To date the gold standard for the diagnosis of knee OA is radiographic. However, these findings might not be useful in early stages.

Objectives: to investigate the ability of ultrasound (US) to detect abnormal findings related to OA in patients complaining of knee pain in comparison with conventional radiology (CR).

Methods: Consecutive patients over 50 years of age complaining of knee pain without a previous diagnosis of knee OA (ACR criteria) and no other known rheumatologic disease were included. US examination was performed by an experienced rheumatologist, blinded to clinical data, using a My Lab 70 machine (Esaote) provided with a multi-frequency linear transducer (4–13 MHz). A standardized scanning method was adopted in order to investigate the following US abnormal findings (presence/absence):

- osteophytes: defined as cortical protrusions at the joint margin seen in two planes and visualized as either proximal or distal to the joint
- degenerative femoral hyaline cartilage involvement: defined as loss of sharpness of the cartilage margins, loss of homogeneity of the cartilage layer and/or cartilage thinning (focal or extend to the entire cartilaginous layer)

Weight-bearing anteroposterior (AP) and lateral knee radiographs were read by an experienced rheumatologist, blinded to the clinical date and US findings, who assessed the presence or absence of osteophytes and degenerative femoral hyaline cartilage involvement, defined as the presence of femorotibial (FT) joint space narrowing. The FT space width was measured at the most peripheral site and at the mid-point of the medial compartment and lateral compartment. Frequency of each feature was calculated and compared between groups by chi2 test. A p value < 0.05 was considered significant.

Results: 84 patients (mean age 69 ± 10 years, 66 female/18 male) were included for a total of 116 knees evaluated (32 patients complained of bilateral knee pain). Both the presence of osteophytes and degenerative femoral hyaline cartilage involvement were significantly more frequently detected by US than CR (Table). The presence of at least one of these degenerative changes was found in 81/116 knees in 56 patients by US and in 64/116 knees in 42 patients by CR ($p < 0.05$ for both comparisons) (Table).

Table. US and CR features among patients with knee pain

		Ultrasound	Conventional radiology	p
Degenerative femoral hyaline cartilage involvement	Patients, n° (%)	41/84 (48.8)	26/84 (30.9)	0.0181
	Knees, n° (%)	70/116 (60.3)	46/116 (39.6)	0.0016
Osteophytes	Patients, n° (%)	52/84 (61.9)	26/84 (30.9)	0.0001
	Knees, n° (%)	77/116 (66.4)	41/116 (35.3)	<0.0001
Degenerative changes¶	Patients, n° (%)	56/84 (66.6)	42/84 (50)	0.0285
	Knees, n° (%)	81/116 (69.9)	64/116 (55.2)	0.0211

¶defined as the presence of at least one of the other findings: degenerative femoral hyaline cartilage involvement and/or osteophytes

Conclusion: US had the ability to detect more degenerative changes compared with CR in patients > 50 years old complaining of knee pain and without a previous diagnosis of knee OA. The use of US in patients with knee pain and normal CR might be useful in the diagnosis of early stage OA.

241

Excess Body Weight and 4-Year Function Outcomes: Comparison of African-Americans and Caucasians in the Osteoarthritis Initiative. Carmelita J. Colbert, Orit Almagor, Joan S. Chmiel, Jing Song, Dorothy D. Dunlop, Karen W. Hayes and Leena Sharma. Northwestern University, Chicago, IL

Background/Purpose: Given the heterogeneity of knee OA impact, it is important to identify persons at risk for poor outcome. A better understanding of differences between risk groups may lead to development of more effective prevention strategies. Losina et al recently demonstrated losses in quality-adjusted life years due to knee OA and obesity, disproportionately high in black and Hispanic women (Ann Intern Med 2011). The impact within racial groups of greater than healthy body weight on more proximal outcomes is not well understood. We tested the hypothesis that African-Americans have a greater risk (vs. Caucasians) of poor baseline-to-4-year function outcome within each strata: women with high BMI, women with large waist circumference, men with high BMI, and men with large waist circumference. The OAI cohort study, enriched with individuals above a healthy body weight, provided an ideal setting.

Methods: Using WOMAC function, 20 meter walk, and chair stand performance, poor outcome was defined as moving into a worse function group or remaining in the 2 worst groups over 4 years. Logistic regression was used to evaluate the hypothesized relationships between racial groups and outcomes within each stratum, adjusting for age, education, and income, and then further adjusting for BMI, comorbidity, depressive symptoms, physical activity, knee pain, and OA severity.

Results: In 3,695 persons with or at higher risk for knee OA, high BMI and large waist circumference were each associated with poor outcome. As shown in the table, among women with high BMI and among women with large waist circumference, African-Americans were at greater risk for poor outcome by every measure, adjusting for age, education, and income. From fully adjusted models (not shown), potential explanatory factors included income, comorbidity, depressive symptoms, pain, and disease severity. Findings were less consistent for men (see table), emerging for the 20 meter walk or chair stand outcomes, and potentially explained by age and knee pain.

Table. Odds of poor 4-year outcome associated with race by gender, BMI and waist circumference groups, adjusting for age, education, and income (AA = African-American, C = Caucasian, significant results bolded)

	Poor WOMAC outcome adjusted OR (95% CI)	Poor 20 meter walk outcome adjusted OR (95% CI)	Poor chair stand outcome adjusted OR (95% CI)
AA vs. C women (in women with high BMI, ≥ 25 kg/m²)	*1.54 (1.19, 1.98)*	*1.43 (1.07, 1.91)*	*1.81 (1.37, 2.39)*
AA vs. C women (in women with large waist circumference, > 88 cm)	*1.55 (1.21, 1.99)*	*1.57 (1.18, 2.07)*	*2.02 (1.54, 2.65)*
AA vs. C men (in men with high BMI, ≥ 25 kg/m²)	1.26 (0.87, 1.81)	*1.94 (1.31, 2.87)*	*1.56 (1.07, 2.28)*
AA vs. C men (in men with large waist circumference, > 102 cm)	1.53 (0.93, 2.52)	*2.24 (1.30, 3.85)*	1.34 (0.80, 2.23)

Conclusion: Among women with high BMI and among women with large waist circumference, African-Americans were at greater risk than Caucasians for poor 4-year outcome by each measure evaluated, adjusting for age, education, and income. Modifiable factors that may in part explain these findings in women in the OAI include comorbidity, depressive symptoms, and knee pain. Targeting such factors, while supporting weight loss, may help to lessen the outcome disparity between African-American and Caucasian women.

242

Relationship of Objective to Self-Reported Physical Activity Measures Among Adults in the Osteoarthritis Initiative. Grace E. Ahn[1], Jing Song[1], Jungwha Lee[1], Pamela A. Semanik[1], Rowland W. Chang[1], Leena Sharma[1], Charles Eaton[2], Rebecca Jackson[3], Alex Mysiw[4] and Dorothy D. Dunlop[1]. [1]Northwestern University, Chicago, IL, [2]Warren Alpert Medical School at Brown University, RI, [3]Ohio State University, Columbus, OH, [4]Denison University, Granville

Background/Purpose: Physical activity conveys health benefits for people with osteoarthritis (OA). Public health activity guidelines are tied to time spent in bouts of moderate/vigorous physical activity (MVPA) lasting 10 minutes or more. This study compares objective accelerometer measures of MVPA with self-reported Physical Activity Scale in the Elderly (PASE) scores and their association with function in adults with and without radiographic knee OA.

Methods: The Osteoarthritis Initiative accelerometer ancillary study includes 586 adults without and 969 with radiographic knee OA (Kellgren-Lawrence score ≥2 in one or both knees), aged 55 and above. Participants' response to the PASE questionnaire was followed by 7 days of accelerometer monitoring. Accelerometer measures included average daily MVPA minutes and MVPA minutes acquired in bouts. Function measures included gait speed averaged from two 20 meter walks, WOMAC (Western Ontario MacMaster) function, and SF12 (12-Item Short Form Health Survey) physical function. Nonparametric Spearman correlations were used to assess associations.

Results: Adults with and without knee OA had mean (SD) PASE scores: 149.82 (78.5), 154.5 (79.0); mean accelerometer MVPA minutes/day: 15.6 (17.2), 19.2 (20.5) and mean MVPA bouted minutes/day: 7.2 (12.4), 9.3

(15.8), respectively. PASE score correlations with accelerometer measures are shown below. In this sample, PASE was correlated most strongly with total activity counts followed by MVPA minutes and had weakest association with MVPA minutes accumulated in bouts. Further analysis shows all objective accelerometer measures had stronger associations with function than PASE (e.g., correlations from overall sample of gait speed function with self-reported PASE: r=0.16, accelerometer counts: r=0.29, MVPA: r=0.34, MVPA bouts: r=0.28). These findings were true of both adults with and without radiographic OA.

Table. Spearman Correlation Coefficients (r) between Self-Reported PASE Scores and Objective Physical Activity Accelerometer Measures

	Accelerometer Physical Activity Measures		
OAI Radiographic Subgroups	**Average Daily Counts of Total Activity**	**Average Daily Moderate/Vigorous Activity Minutes**	**Average Daily Moderate/Vigorous Activity Minutes in Sessions of 10 Minutes or More**
All n = 1555	0.38 (0.34, 0.42)	0.33 (0.28, 0.37)	0.20 (0.15, 0.24)
With Radiographic OA (n = 969) r (95% CI)	0.35 (0.30, 0.41)	0.31 (0.25, 0.37)	0.21 (0.15, 0.27)
Without Radiographic OA (n = 586) r (95% CI)	0.42 (0.36, 0.49)	0.35 (0.28, 0.42)	0.18 (0.10, 0.26)

Conclusion: In this sample with and without radiographic knee OA, the self-reported PASE score had stronger although modest correlations with objective measures of total activity than with MVPA minutes or MVPA bouted minutes. Objective physical activity measures compared to self report had stronger relationships with function. The choice of PASE, a recall measure of various activity types, and/or objective measurement for future epidemiologic studies must take into account the purpose for which physical activity is being measured.

243

Relationship of Physical Activity with Health Utility in the Osteoarthritis Initiative. Dorothy D. Dunlop[1], Jing Song[1], Rowland W. Chang[1], Jungwha Lee[1], Pamela A. Semanik[2], Linda S. Ehrlich-Jones[3], Kai Sun[1], Leena Sharma[1], C. Kent Kwoh[4], Charles Eaton[5] and Larry Manheim[1]. [1]Northwestern University, Chicago, IL, [2]Rehabilitation Institute Chicago, Oak Park, IL, [3]Rehabilitation Institute Chicago, Chicago, IL, [4]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [5]Warren Alpert Medical School at Brown University, RI

Background/Purpose: Cost effectiveness analyses of arthritis interventions require utility measurements to evaluate their relative effectiveness. Clinical guidelines for knee osteoarthritis (KOA) treatment include a substantial role for physical activity. Recognizing the importance of physical activity, there are federal recommendations for US adults that now include persons with arthritis. To investigate if attainment of these guidelines translates into better health-related utility in adults with KOA, we analyzed data from the Osteoarthritis Initiative (OAI).

Methods: Physical activity was measured by accelerometers on 1154 OAI participants aged 49 to 84 years with radiographic KOA (KL grade ≥2 from central lab) in at least one knee at the 48 month follow-up visit. Activity intensity was determined from established accelerometer cutpoints for moderate-to-vigorous [MV] intensity (counts ≥ 2020/minute). Physical activity was classified as 1) inactive (no bouts of MV activity lasting 10 minutes over the week); 2) insufficient activity (bouts of MV activity/week < 150 minutes), or 3) met the 2008 Physical Activity Guidelines aerobic component (≥150 MV minutes/week acquired in bouts ≥10 minutes). An SF6-D utility score (0=worst to 1=best possibility utility) was derived from participant responses to the SF-12 questionnaire collected at the 48 month visit. The relationship of physical activity levels to average health utility controlled for demographics (age, gender, race, education, income), knee factors (KL grade, knee symptoms, WOMAC knee pain, knee injury history) and general health (BMI, comorbidity, depression, smoking, hip pain, ankle pain, foot pain) using multiple linear regression.

Results: Almost half (48%) of adults with KOA were inactive; another 40% failed to meet recommended Guidelines. Average utility scores consistently increased with better levels of physical activity: 0.772 for inactive,

0.797 for insufficient and 0.835 for meeting guidelines groups (p trend<.0001). To determine if higher physical activity levels consistently correspond to better health utility among people with similar demographics and measured health we examined utility differences controlling for these factors. These results (Table) showed a strong cross-sectional relationship and a statistically significant linear trend.

	Differences in mean utility between physical activity levels adjusted for demographic, knee health and general health factors		
Adjustment Factors n=1154	**Insufficient vs Inactive(95% CI)**	**Meet Guideline vs Inactive (95% CI)**	**Trend Test**
Unadjusted	0.025 (0.010, 0.040)	0.063 (0.039, 0.086)	p<.001
Demographic	0.020 (0.005, 0.036)	0.053 (0.029, 0.077)	p<.001
Demographic+ Knee+ General Health Factors	0.011 (−0.002, 0.024)	0.023 (0.003, 0.044)	p=.018

Conclusion: Despite known benefits of physical activity, most adults with KOA were inactive. Inactive adults with KOA had significantly lower health-related utility levels than persons who were insufficiently active as well as those who met Guidelines. These findings show a strong relationship between greater physical levels and better health utility. These findings support interventions to improve health-related utility for adults with KA by increasing physical activity, even if recommended levels are not attained

244

Minimal Clinically Important Difference and Patient Acceptable Symptom State for the Oarsi -Omeract Intermittent and Constant OA Pain (ICOAP) Measure. Z. Anna Liu, Tetyana Kendzerska, Joy Elkayam, Shefali Ram and Gillian A. Hawker, Women's College Research Institute, University of Toronto, Toronto, ON

Background/Purpose: The Intermittent and Constant Osteoarthritis Pain (ICOAP) measure was developed to evaluate the OA pain experience, independent of the effect of pain on physical activity. ICOAP has been shown to be reliable, valid and responsive to treatment in knee OA. This study sought to establish for ICOAP the Minimal Clinically Important Difference (MCID) for improvement and worsening, and the Patient Acceptable Symptom State (PASS).

Methods: In subjects with painful knee OA, the ICOAP was administered twice by telephone, two-weeks apart. The ICOAP is comprised of two subscales (constant and intermittent pain); the total score (range 0–100) is the sum of subscale scores, with higher scores indicating worse pain. At both time points, participants were asked to report their knee pain in the past 48 hours and the acceptability of their current knee pain state (acceptable or unacceptable). At second interview, participants were asked to report the degree to which their knee pain had changed (5-point scale from much worse to much better). MCID was calculated as the mean absolute change in ICOAP scores (Time 2−Time 1) for those who reported 'slightly better' or 'slightly worse' versus 'no change'. PASS was defined as the threshold ICOAP score at or above which participants considered their pain as 'unacceptable'. Logistic regression was used to assess the ability of ICOAP change scores to predict reported improvement or worsening, and the relationship between scores and pain state acceptability.

Results: 136 participants completed the study; 66 (54%) were female with a mean age of 73.9 years (SD 9.5). Median ICOAP constant, intermittent and total scores were 0/100 (range 0–90), 37.5 (0–87.5) and 25 (4.6–88.6), respectively, at Time 1 and 0 (0–95), 37.5 (0–95.8), and 23.9 (4.6–95.5) at Time 2. 'Slight improvement' was associated with a mean decrease of 2 and 7 points for the ICOAP constant and intermittent scales, respectively, while 'slight worsening' was associated with a mean increase of 4 points for both scales. The threshold ICOAP subscale scores associated with an unacceptable symptom state were: 20/100 (constant pain); 40/100 (intermittent pain); and 30/100 (total score). Changes in ICOAP subscale and total scores had good discriminative validity for self-reported improvement versus no change/worsening (Figure 1; AUC = 0.60–0.75) and for reported worsening (AUC 0.73–0.82). Absolute ICOAP scores were highly predictive of the acceptability of symptom state (AUC 0.71–0.84).

ROC Curves for Comparisons

ROC Curve (Area)
— Change in ICOAP, intermittent subscale, AUC (0.7482)
– – Change in ICOAP, constant subscale, AUC (0.6001)
– · – Change in ICOAP, total score, AUC (0.7484)
Conclusion: In an observational cohort, we determined the MCID and PASS for ICOAP total and subscale scores. These findings will assist clinicians and researchers in interpreting the clinical meaning of ICOAP scores for pain in knee OA. Future work will determine whether ICOAP MCID values differ across settings, including with clinical interventions.

Similarities of Patient Self-Report Scores From a Multidimensional Health Assessment Questionnaire (MDHAQ), Laboratory Tests, Physician Global Assessment, and Polyarticular Involvement in Patients with Osteoarthritis and Rheumatoid Arthritis. Isabel Castrejón, Yusuf Yazici and Theodore Pincus. NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Rheumatoid arthritis (RA) and osteoarthritis (OA) are distinct diagnoses, based on widely differing pathogenetic mechanisms and treatments. However, OA patients may experience functional disability, pain and global distress at levels similar to RA patients. Furthermore, although differences may have been more pronounced in the past, at this time many OA patients have polyarthritis and levels of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) similar to RA patients. A systematic comparison of patients with RA vs OA, including patient self-report scores, involvement of specific joints, laboratory tests, and physician global assessment, appeared of value.

Methods: All patients seen at an academic rheumatology center complete a multidimensional health assessment questionnaire (MDHAQ) at each visit to assess physical function, pain, patient global estimate (all 0–10), routine assessment of patient index data (RAPID3)–a composite of these 3 measures (0–30), and a rheumatoid arthritis disease activity index (RADAI) self-report of painful joints. RADAI is scored 0–3 for 16 joint groups (8 right, 8 left): fingers, wrist, elbow, shoulder, hip, knee, ankle, toes (total 0–48). A binary scoring of 0 or 1 (to mimic a physician joint count) was also computed. All patients are assigned a physician global estimate. ESR and CRP are assessed in many patients. Measures were compared in 174 RA vs 113 OA consecutive patients: normally distributed variables by means and *t* tests, non-normally distributed variables by medians and Mann-Whitney tests, and categorical variables by chi-square tests; *p* values were adjusted for 23 comparisons.

Results: Mean age was 49.3 in RA patients vs 62.8 years in OA patients ($p < 0.0002$, adjusted for 23 comparisons). Median values for physical function, pain, patient global estimate, RAPID3, ESR, CRP, and mean physician global estimate did not differ in RA vs OA. Median total RADAI and binary scores were slightly higher in RA than OA (not statistically significant). More than 4 involved joint groups were self-reported by 64% of RA and 58% of OA patients. Involvement of wrists was higher in RA vs OA

(51% vs 32%, adjusted $p = 0.023$); no other differences in specific joint group involvement were statistically significant, adjusted for 23 comparisons.

	RA patients N = 174	OA patients N = 113	P	Adj. P*
DEMOGRAPHIC VARIABLES				
Age, years: mean (SD)	49.3 (15.1)	62.8 (12.5)	<0.00001	<0.002
Gender, % female	80%	73%	0.18	NA
Ethnicity, %			0.10	NA
● White	49%	65%		
● African American	14%	8%		
● Hispanic	27%	21%		
● Asian	8%	3%		
● Other	2%	3%

CLINICAL AND LABORATORY VARIABLES				
Disease duration, years: mean (SD)	7.5 (6.2)	6.6 (5.2)	0.34	NA
ESR, mm/h, median (IQR)	14 (9–28)	12 (8–24)	0.87	NA
CRP, median (IQR)	1.6 (0.4–5)	5 (0.3–6)	0.36	NA
Physician global estimate (0–10): mean (SD)	2.9 (1.8)	2.9 (1.5)	0.97	NA
PATIENT SELF-REPORT MEASURES				
Physical function (0–10): median (IQR)	2.3 (0.6–4.3)	1.7 (0.7–3.3)	0.24	NA
Pain (0–10): median (IQR)	5 (2–8)	5 (3.5–7.5)	0.26	NA
Patient global estimate (0–10): median (IQR)	4 (1.5–7.5)	5 (2.5–6.5)	0.85	NA
RAPID3 (0–30): median (IQR)	11.7 (4.9–19.2)	11.8 (6.8–16.7)	0.80	NA
RADAI SELF-REPORT JOINT COUNT DATA				
Total RADAI (0–48): median (IQR)	9 (2–20)	7 (4–13)	0.75	NA
Binary RADAI (0–16): median (IQR)	6 (2–12)	4 (3–8)	0.33	NA
Number (%) scoring ≥4 joint groups	111 (64%)	66 (58%)	0.36	NA
INVOLVEMENT OF SPECIFIC JOINT GROUPS				
Fingers	98 (56%)	47 (42%)	0.01	0.23
Wrist	89 (51%)	36 (32%)	0.001	0.023
Elbow	53 (30%)	27 (24%)	0.22	NA
Shoulder	75 (43%)	46 (41%)	0.68	NA
Hip	62 (36%)	43 (38%)	0.67	NA
Knee	88 (51%)	77 (69%)	0.003	0.069
Ankle	70 (40%)	31 (28%)	0.02	0.46
Toes	71 (41%)	30 (27%)	0.01	0.23

*Adjusted for 23 comparisons. NA = not applicable (unadjusted $P > 0.05$).

Conclusion: OA and RA result in similar patient self-report MDHAQ scores. Further, physician global estimate, ESR, CRP and polyarticular involvement are similar in OA and RA at this time. RA and OA may have been more distinct in the past, when RA patients were younger, had much more severe clinical status, and less effective treatments. The data emphasize the need for careful evaluation by a knowledgeable physician to distinguish OA from RA, and may improve understanding of the concerns of OA patients, most of whom have polyarticular disease, functional disability and pain scores similar to patients with RA.

Routine Assessment of Patient Index Data 3 (RAPID3) Is a Valid Index for Routine Care in Patients with Osteoarthritis. Alfredomaria Lurati[1], Luca Bertani[1], Daniela Bompane[1], Mariagrazia Marrazza[1], Katia Angela Re[1] and Magda Scarpellini[2]. [1]Rheumatology Unit, Magenta, Italy, [2]Ospedale Fornaroli, Magenta, Italy

Background/Purpose: RAPID3 (routine assessment of patient index data) is an arithmetic composite index of three Core Data Set, patient self-report, measures: physical function (0–3 converted to 0–10), pain (0–10), and patient global estimate (0–10) for a total of 0–30. It can be completed in the waiting room and can be calculated in only few seconds. Aim of this study was to compare RAPID3 with the Western Ontario and Mc-Master Universities Osteoarthritis Index (WOMAC) in patients with knee or hip osteoarthritis (OA)

Methods: patients with symptomatic knee or hip osteoarthritis as main rheumatologic diagnosis (VAS pain > 50 on a visual scale 0–100mm) according to the ACR (American College of Rheumatology) criteria and with stage 2 or 3 according to the Kellgren-Lawrence radiographic criteria were eligible. All subjects were clinically evaluated individually by an experienced rheumatologist and were asked to complete the self-report questionnaires (the original version of the WOMAC for hip or knee osteoarthritis and the RAPID3). There was no specific order in which the tests were completed; rather, each participant selected the order. Agreement between WOMAC and RAPID3 scores was estimated with rho Spearman correlation statistic and Cohen's kappa.

Results: 478 patients (155 males, 323 females) with hip (n=38) or knee (n=70) osteoarthritis were enrolled in daily practice clinical care during

2010–2012. Mean age ($\pm$SD) was 63 ± 14.4 years old. Mean score was 67 ± 9.1 for WOMAC and 6.5 ± 2.1 for RAPID3. RAPID3 and WOMAC have shown a global correlation rho index of 0.72 (p<0.01) and a Cohen's kappa of 0.7. Computing analysis for diagnosis, the means of WOMAC and RAPID3 weren't significantly different between patients with hip or knee osteoarthritis ($67\pm$ 9.9 vs 68 ± 6.8 and 6.4 ± 2.1 vs 6.6 ± 2.1, respectively. p>0.05). The Spearman's rho was 0.63 for hip osteoarthritis (p<0.01) and 0.78 for knee osteoarthritis. Cohen's kappa was 0.68 for hip osteoarthritis (p<0.01) and 0.78 for knee osteoarthritis, respectively.

Conclusion: Up to date there's not literature about the use of RAPID3 in patients with OA. In our study we found a strong correlation between RAPID3 and WOMAC in patients with either hip and knee OA, confirmed by a linear regression model developed using all variables collected. RAPID3 provide informative quantitative data for patient status from one visit to the next comparable to other self-reported questionnaire as WOMAC in a time sparing manner.

Meager Depression Screening and Mental Health Referral Rates for Patients with Arthritis in a National Sample. Mary Margaretten, Patricia P. Katz, Laura Trupin, Gabriela Schmajuk, Jennifer Barton, Jinoos Yazdany and Edward Yelin. UCSF, San Francisco, CA

Background/Purpose: Depression in patients with arthritis is common and leads to poor health outcomes. While it has been shown that rheumatologists rarely communicate about depression to their patients with arthritis, there are no data about screening practices for depression in this population. Our objectives were to describe national rates of depression screening in patients with arthritis and real-world practices for mental health referrals for patients with arthritis and prevalent depression.

Methods: In 2005 the National Ambulatory Medical Care Survey, an annual visit-based cross-sectional survey conducted in physicians' offices, began collecting data about depression screening practices. Using 2005–2009 data, we compared office visits coded for current arthritis with other office visits to assess the rate of pre-existing depression, depression screening, and mental health referrals. Of 102,050 adult visits, we identified 14,611 coded for current arthritis (osteoarthritis and/or inflammatory arthritis) over the five-year study period. Multivariate logistic regression adjusted for age, race, and gender determined the independent association of depression and arthritis. Patients with a current diagnosis of depression were excluded from analyses of depression screening practices leaving 12,457 patient visits without depression. The chi-square test of association was used to compare depression screening practices, provider characteristics, and referral rates for mental health services between patients with and without arthritis. Patients with and without arthritis who had a current diagnosis of depression (n=11,664) were included in analyses for mental health referrals.

Results: The odds ratio for comorbid depression in patients with arthritis was 1.5 (95% CI 1.4, 1.6) controlling for age, race, and gender. Depression screening occurred in 77 (0.6%) of the eligible 12,457 visits associated with arthritis. Patients with arthritis were less likely to have depression screening services at their office visit compared to patients without arthritis (OR.69; 95% CI.54,.87). No rheumatologists screened their patients with arthritis for depression. Patients with arthritis and depression were less likely to receive referrals for psychotherapy (OR.43; 95% CI.38,.51), mental health providers (OR.25; 95% CI.15,.42), or other mental health services (OR.41; 95% CI.33,.51) compared to patients without arthritis.

Conclusion: Ambulatory physicians in the United States, whether they are rheumatologists or primary care providers, rarely screen for depression in patients with arthritis. Furthermore, identified depressed patients with arthritis are less likely to receive referrals for mental health services. Both recognition and treatment practices need to be improved for patients with arthritis and depression in order to improve health outcomes.

Synovial Fluid Leptin Level Is Associated with Residual Pain and Functional Disability One Year After Total Joint Arthroplasty. Anne Lübbeke[1], Gabor J. Puskas[1], Axel Finckh[2], Domizio Suva[1], Sylvette Bas[3], Cem Gabay[1], Daniel Fritschy[1] and Pierre Hoffmeyer[1]. [1]Geneva University Hospitals, Geneva, Switzerland, [2]Geneva University Hospitals, Geneva 14, Switzerland, [3]Geneva University Hospitals, Switzerland

Background/Purpose: A sizeable number of patients continue to suffer from pain, functional disability and reduced quality of life after total joint arthroplasty (TJA). The etiology of post-TJA pain is not well established and the presence of chronic pain of neuropathic origin has been suggested. Leptin has been identified as a mediator of the immuno-inflammatory response in osteoarthritis (OA), and its pro-inflammatory functions could explain its role in peripheral pain sensitization. We previously demonstrated that high synovial fluid (SF) leptin concentrations correlate with increased preoperative pain in hip and knee OA patients. In addition, animal models have suggested the involvement of leptin in the pathogenesis of pain at the spinal level and in the development of neuropathic pain. Our objective was to assess pain, function, patient satisfaction and general health in patients undergoing TJA according to SF leptin concentration.

Methods: Prospective cohort study of patients with primary OA undergoing total hip or knee arthroplasty between January and December 2010. On the day of intervention, SF was sampled and leptin concentrations were assessed using an ELISA kit. Exposure was SF leptin concentration ($\leq$19.6 ng/ml vs. >19.6 ng/ml= highest quartile). Outcomes were: joint pain, function and general health measured pre- and at 1 year postoperative with WOMAC, VAS for pain, and SF-12, and patient satisfaction at 1 year measured on 5-item Likert scale.

Results: 167 TJAs were included, 88 total hip and 79 total knee arthroplasties. Mean age was 72 years, mean BMI 28 kg/m^2, 58% were women. High intra-operative SF leptin concentrations (>19.6 ng/ml) were found in 39 (23.4%) joints. Compared to leptin levels <19.6 ng/ml their presence was associated with significantly higher pain levels on both WOMAC and VAS pain scales, with lower function and worse physical and mental health scores both pre- and 1 year postoperative (effect sizes ranging from 0.4 to 0.7) and with lower satisfaction (see Table). Residual pain of $\geq$5 on the VAS was present in 33% of TJAs with high leptin concentration compared to 13% in the other group (RR 2.5, 95% CI 1.3; 4.7). The degree of improvement in all domains (difference pre- to postoperative) was not significantly modified by SF leptin levels.

Table 1. Preoperative and 1-year postoperative assessment of pain, function and general health according to leptin concentration

	Leptin 1–3rd quartile $\leq$ 19.6 ng/ml	n	Leptin 4th quartile > 19.6 ng/ml	n	4th vs. 1–3rd quartile Unadjusted mean difference (95% CI)	4th vs. 1–3rd quartile Adjusted mean difference (95% CI)*

*Adjusted for age, ASA score, OA site (hip vs. knee) and Charnley disability grade with use of multivariable linear regression

Conclusion: High intra-articular leptin were strongly associated with more residual pain and functional disability 1 year after arthroplasty. However, the degree of improvement was independent of leptin concentration. With respect to pain these results lend support to the hypothesis that high intra-articular leptin levels could favor spinal pain sensitization and the development of neuropathic pain earlier in the disease process.

Medial Subchondral Bone Marrow Lesions Increase the Odds of Knee Joint Replacement–Data From the Osteoarthritis Initative. Frank Roemer[1], C. Kent Kwoh[2], David Hunter[3], Michael J. Hannon[4], Robert M. Boudreau[5], Felix Eckstein[6], Zhijie Wang[4], Markus R. John[7] and Ali Guermazi[8]. [1]Klinikum Augsburg, Augsburg, Germany, [2]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [3]University of Sydney, Sydney, Australia, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA, [5]University of Pittsburgh, Pittsburgh, PA, [6]Paracelsus Medical University, Salzburg, Austria, [7]Novartis Pharma AG, Basel, Switzerland, [8]Boston University School of Medicine, Boston, MA

Background/Purpose: Knee joint replacement (KR) is a cost-effective procedure with good long-term outcomes. However, there is no clear consensus on indications for KR. Subchondral bone marrow lesions (BMLs) have been identified as important structural features relevant to clinical manifestation (e.g.pain) as well as structural progression (e.g. cartilage loss). Thus, BMLs are promising biomarkers for structural progression to important clinical outcomes such as KR. The aims of this study were therefore to test whether presence and size of BMLs increased odds of KR, and whether worsening of BMLs over time increased odds of KR.

Methods: We studied 121 knees from OAI participants that underwent KR before the 48 month visit at two time points (T0 and T-1) prior to KR, (i.e. for a KR reported at the 48 month (M) visit, T0 = 36M and T-1 = 24M). These were matched with 121 control knees that did not undergo KR based on radiographic disease stage, sex, and age ($+/-$ 5y). 3Tesla MRIs were read for subchondral BMLs in 14 articular subregions using the semiquantitative MOAKS system. Only BML size, which is scored from 0–3, was considered in this study. Analyses were performed on a plate (medial tibia, medial femur, lateral tibia, lateral femur, trochlea, patella) and compartmental level (medial tibio-femoral joint [TFJ], lateral TFJ and patello-femoral joint–[PFJ]). Conditional logistic regression was applied to assess the risk of KR relative to the maximum BML size per plate at T0. In addition, the number of subregions per compartment showing BML worsening from the time point prior T0 (=T-1) to T0 was analyzed relative to the odds of KR following T0.

Results: Subjects were on average 65.3 years old (SD $\pm$ 8.6), predominantly female (58.1%) and overweight (mean BMI 29.6 SD $\pm$ 4.9). The odds of KR were significantly greater for knees exhibiting large (i.e. grade 3) BMLs in the medial compartment when compared to the knees without BMLs at T0 (Table 1). Further, the odds for KR were significantly greater for knees with '3 subregions exhibiting increase in BML size in the medial TF compartment from T-1 to T0 compared to knees with no subregions showing worsening (OR 3.35, 95%CI 1.14–9.82). No significant associations were found for smaller lesions, the lateral TFJ and PFJ and respective plates cross-sectionally or longitudinally.

Conclusion: On a plate-level analysis, presence of large BMLs in the medial femur and/or tibia at the time point prior to KR was associated with increased odds of KR, while presence of large BMLs in the lateral TFJ or in the PFJ was not. Worsening of BML size in ≥3 subregions in the medial TF compartment from T-1 to T0 was associated with increased odds of KR when compared to knees without worsening in any subregion in the same compartment.

Incident and Worsening Cartilage Damage in the Lateral Compartment and Multiple Subregions Worsening in the Medial Compartment Increase the Risk for Knee Replacement - Data From the Osteoarthritis Initiative. Frank Roemer[1], C. Kent Kwoh[2], Michael J. Hannon[3], Robert M. Boudreau[4], Felix Eckstein[5], David J. Hunter[6], Zhijie Wang[3], Markus R. John[7] and Ali Guermazi[8]. [1]Klinikum Augsburg, Augsburg, Germany, [2]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]Paracelsus Medical University, Salzburg, Austria, [6]University of Sydney, Sydney, Australia, [7]Novartis Pharma AG, Basel, Switzerland, [8]Boston University School of Medicine, Boston, MA

Background/Purpose: Knee joint replacement (KR) is a cost-effective procedure with good long-term outcomes. However, at present there is no clear consensus on indications for KR. Imaging biomarkers capable of predicting KR therefore are urgently needed and may be helpful in clinical studies and trials that utilize KR as an outcome. Specific MRI-based quantitative measures of cartilage morphology have recently been described to be associated with an increased risk of KR. The aim of the present study was to determine whether longitudinal changes in semi-quantitative MRI-based measures of cartilage differ between knees undergoing KR and control knees not undergoing KR. We used a compartment-based analysis (i.e., medial tibio-femoral (MTF), lateral tibio-femora (LTF) or patello-femoral (PF)0.

Methods: We studied 127 knees from OAI participants (age 46–81 years) that underwent KR before the 60 month visit at two time points prior to KR, (e.g. for a KR reported at the 48 month (M) visit, T0 = 36M and T-1 = 24M).127 control knees that did not undergo KR were matched for KL grade (0/1, 2, 3, 4), gender, and age ($+/-$ 5y) and were assessed at the same T0 and T-1 visits. 3 T MRIs were read for cartilage morphology using the semiquantitative MOAKS system in 14 articular subregions, which scores cartilage from 0 to 3 in regard to proportion of the area of the subregion involved and from 0 to 3 in regard to percentage of subregion involved by full thickness loss. Within-grade coding was used to score definite visual changes that do not fulfill criteria of a full grade change. Conditional logistic regression was applied to assess compartmental changes in cartilage morphology from T-1 to T0 with respect to risk for KR following T0.

Results: Subjects were on average 65.7 years old (SD $\pm$ 8.8), predominantly female (59.8%) and overweight (mean BMI 29.7 SD $\pm$ 4.82). The K/L distribution was: KL0: 8 (3.15%) KL1: 8 (3.15%), KL2: 57(22.44%), KL3:146 87(34.25%) and KL4: 94 (37.01%).

Development of full thickness cartilage damage and full grade worsening in the LTF, but not MTF compartment from T-1 to T0 was associated with greater odds for KR (OR 2.8, 95% CI 1.01–7.78 and 4.5 95% CI 1.52–13.30, respectively). More than 3 subregions exhibiting worsening in the MTF compartment was associated with increased odds for KR (OR 14.5, 95% CI 1.90–110.93), while this was not observed for the LTF or PF compartments.

Conclusion: Development of full thickness cartilage damage and worsening in the LTF compartment as well as multiple subregions showing worsening cartilage damage in the MTF compartment increase odds for TKR. Presence and change of these imaging biomarkers may be important prognostic markers when KR is used as a long-term outcome.

Smaller Baseline and Follow-up Quadriceps Muscle Cross-Sectional Area Increases the Odds of Knee Replacement in Knee Osteoarthritis. Serter Gumus[1], Michael J. Hannon[2], Diana Kaya[1], C. Kent Kwoh[3] and Kyongtae Ty Bae[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA

Background/Purpose: Knee osteoarthritis (OA) is one of the major causes of disability among elderly. Knee replacement (KR) is the final effective treatment of OA after other treatment attempts fails to provide pain relief. Quadriceps muscle is the major stabilizer of knee joint. Our purpose was to evaluate the relationship between quadriceps muscle quality and total knee replacement incidence in patients having OA.

Methods: Cases were defined as the participants who had a KR between 36 to 60 months visit. Controls were matched by age (within 5 years), sex and baseline central Kellgren-Lawrence grade (0/1, 2, 3 and 4). Participants who had available mid-thigh MR imaging scans (15 contiguous slices, 5mm slice thickness) at baseline and 24 month follow-up were evaluated. Femoral insertion point of oblique tendon of adductor magnus muscle was determined as a landmark for each thigh for matching purposes to account for differences thigh length and body surface area (BSA). This slice was chosen for segmentation and cross-sectional area (CSA) measurements of quadriceps, hamstring muscles and intramuscular, subcutaneous fat (QM, HM, IMF, SCF). Segmentation was done by a radiologist who was blinded to TKR status. A second radiologist segmented 20 legs for reliability measurements.

Muscle quality (MQ) was defined as the peak muscle strength divided by muscle CSA. Four pairs were excluded for baseline and four additional pairs were excluded for follow-up MQ measurements because the peak strength values were not available. Conditional logistic regression analysis was used for statistical evaluation.

Results: There were 46 case-control pairs of thighs and knees (54 right, 38 left) from Osteoarthritis Initiative (OAI) database that were included in this case-control study. The mean ± SD age and BSA were 63.3 ± 8.9, 1.99 ± 0.23 respectively. Fifty percent of the participants were female and 7.6% were African American. Inter and intraobserver ICC was 0.997 and 0.999 respectively. In adjusted models, QMCSA was smaller in case group both in baseline and follow-up images (p=0.17, p=0.24 respectively). Baseline and follow up QM quality (QMQ) was not significantly different between cases and controls. HMCSA, HMQ, SCFCSA and IMFCSA measurements did not show any significant differences between case and controls.

Descriptive information of quadriceps muscle in participants with and without KR

	Knee Replacement(−)		Knee Replacement(+)		
	Number of patients	Mean ± Std. Deviation	Number of patients	Mean±Std. Deviation	p value
Baseline Quadriceps Muscle Cross-sectional Area, cm²	46	48 ± 13.9	46	44 ± 13.3	0.017
Follow-up Quadriceps Muscle Cross-sectional Area, cm²	46	47.3 ± 14.1	46	43.9 ± 13.1	0.024
Baseline Quadriceps Muscle Quality	42	7.4 ± 1.9	42	7.5 ± 2.1	0.66
Follow-up Quadriceps Muscle Quality	38	7.1 ± 2	38	7 ± 2	0.8

Conclusion: QMCSA seems to be significantly smaller in case group even the QMQ is not significantly different. We think that QMCSA has a potential of being one of the biomarkers for predicting future TKR candidates. Future studies may address the importance of increasing QMCSA by life style modifications and its effects on progression of disease.

Presence of Severe Medial Mensical Pathology Increases the Odds for Knee Replacement: Data From the Osteoarthritis Initiative. Frank Roemer[1], C. Kent Kwoh[2], David J. Hunter[3], Robert M. Boudreau[4], Michael J. Hannon[5], Markus R. John[6], Felix Eckstein[7], Michel Crema[8], Zhijie Wang[5] and Ali Guermazi[9]. [1]Klinikum Augsburg, Augsburg, Germany, [2]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [3]University of Sydney, Sydney, Australia, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Pittsburgh School of Medicine, Pittsburgh, PA, [6]Novartis Pharma AG, Basel, Switzerland, [7]Paracelsus Medical University, Salzburg, Austria, [8]Boston University, Boston, MA, [9]Boston University School of Medicine, Boston, MA

Background/Purpose: Knee joint replacement (KR) is a cost-effective procedure with good long-term outcome. However, at present there is no clear consensus on indications for KR. Imaging biomarkers capable of predicting KR therefore are urgently needed and will aid in the decision making process on a patient level as well as in clinical studies and trials. The aim of the study was to assess if presence and severity of meniscal damage and extrusion at the time point prior to KR increases for the odds of KR, using a matched case-control study design.

Methods: Participants were drawn from the Osteoarthritis Initiative (OAI), a multicenter observational study, including 4796 participants with, or at risk of knee osteoarthritis. 120 knees from 113 OAI participants that received KR before the 48 month visit were studied at the time point prior to KR ((e.g. for a KR reported at the 48 month (M) visit, T0 = 36M). These were matched with the same number of control knees for radiographic disease stage, gender, and age (+/− 5 y). 3Tesla MRIs were read for medial and lateral meniscal morphology and extrusion using the semiquantitative MOAKS system, which scores meniscal morphology from 0 to 8 and for the following locations: anterior horn, body, posterior horn, medial and lateral. Grades 0 and 1 are considered the reference as a grade 1 lesion depicts intrameniscal signal changes of unknown relevance. Grades 2–5 code different types of meniscal tears while grades 6–8 code different grades of

meniscal maceration. Extrusion was graded from 0–3 at the medial and lateral joint lines on the coronal images.

Conditional logistic regression was applied to assess the odds of KR at T0 considering different measures of meniscal morphology.

Results: 240 knees;one knee per subject from 120 cases of KR and 120 matched controls that had available T0 data were included. Subjects were on average 65.5 ears old (SD ± 8.6), predominantly female (58.1%) and overweight (mean BMI 29.5 SD ± 4.88). Odds of KR was significantly greater for the subgroup exhibiting any type of maceration of the medial meniscal body and the medial posterior horn at T0 compared to knees without any meniscal pathology in these locations as the reference. Knees with a maximum grade of any meniscal maceration (i.e., grades 6–8) in any of the 3 medial compartment locations had an greater odds for KR when compared to knees with a maximum of zero or one (Figure 1).No significant associations were observed for the lateral compartment or for mensical extrusion

Conclusion: Presence of any medial meniscal pathology of the body and any type of maceration of the medial posterior horn at T0 increases the odds for KR compared to knees without relevant meniscal alterations. Further, the odds of KR is greater when a maximum grade of mensical maceration is present in any of the medial meniscal locations. Meniscal extrusion or pathology in the lateral compartment did not increase the odds of KR.

253

Incidence of Osteoarthritis-Related Knee and Hip Joint Surgery in Southern Sweden. Aleksandra Turkiewicz, Ingemar F. Petersson, Leif E. Dahlberg and Martin Englund. Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden

Background/Purpose: To estimate the incidence and age and sex patterns of subjects having had osteoarthritis (OA)-related surgical treatment.

Methods: The Skåne Health Care Register (SHCR) is a legislative, mandatory register based on physicians' International Classification of Diseases (ICD) 10 diagnostic codes and the classification of health care procedures and surgical codes according to KKÅ97. The register covers all in- and outpatient health care in southern Sweden (total population 1.3 million). For the year 2011 we identified patients ≥35 years of age having had the hip replacement and a main diagnosis of hip OA (M16) or having the knee replacement or other knee surgery (arthroscopic or endoscopic exploration of the joint, synovectomy, excision of meniscus or articular cartilage or other surgery of synovial membrane of the knee) in conjunction with the main diagnosis of knee OA (M17) or derangement of meniscus due to old tear or injury (M23.2), which we consider probable OA. We obtained annual cumulative incidence of OA-related surgery in 2011 by cross referencing with the population register to include all residents (aged ≥35) of Skåne by the 31st Dec 2010. To obtain estimates of the annual cumulative incidence of OA-related knee or hip surgery among all known knee or hip OA patients we used the point prevalence of knee and hip OA by the 31st Dec 2011 based on the SHCR register data from years 1999–2011.

Results: The annual incidence of OA-related knee replacement in the population aged ≥35 was 18.6 per 10,000 persons (95%CI: 17.6; 19.6), 16.1 for men and 21.0 for women. The annual incidence of other OA-related knee surgery in the population was 11.8 per 10,000 persons (95%CI: 11.0; 12.6), 14.6 for men and 9.2 for women. The 2011 incidence of OA-related hip replacement in the population was 19.3 per 10,000 persons (95%CI 18.3; 20.3), 11.7 for men and 16.1 for women. The annual incidence of OA-related knee and hip replacement in the population ≥65 years of age was 35 and 37 per 10,000 persons respectively.

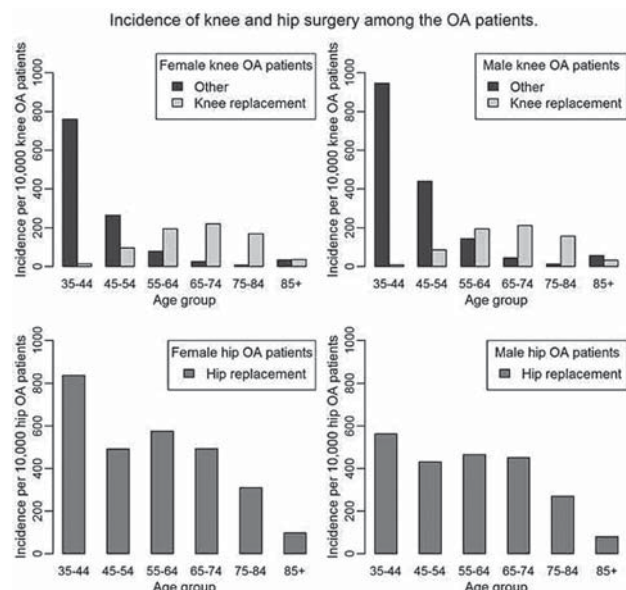
The incidence of OA-related knee replacement surgery among known prevalent knee OA patients aged ≥35 was 156 per 10,000 cases and peaked at age 65–74 years. The incidence of OA-related hip replacement among known prevalent hip OA patients was 359 per 10,000 cases and peaked at age 35–44 years (Figure).


Figure. The annual incidence of osteoarthritis-related knee and hip joint surgery among the OA-cases.

Conclusion: The present high incidence of OA-related surgeries in those aged ≥65 together with the estimated increased prevalence of hip and knee OA in next decades warrants great concerns for the future burden on the health care system. Efficient conservative treatment options should be sought.

Effects of Strontium Ranelate On Knee Osteoarthritis Pain: A Responder Analysis. JY. Reginster[1], Roland Chapurlat[2], N. Bellamy[3], E. Czerwinski[4], JP Devogelaer[5], L. March[6], K. Pavelka[7] and Cyrus Cooper[8]. [1]University of Liège, Liège, Belgium, [2]Hôpital Edouard Herriot, Lyon, France, [3]CONROD. The University of Queensland, Royal Brisbane and Women's Hospital, Herston, Queensland, Australia, [4]Krakow Medical Centre, Kraków, Poland, [5]Cliniques Universitaires St. Luc, Brussels, Belgium, [6]University of Sydney, Insitute of Bone and Joint Research, Royal North Shore Hospital, St Leonards - Sydney, Australia, [7]Institute of Rheumatology, Prague 2, Czech Republic, [8]University of Oxford; Southampton General Hospital, Southampton, United Kingdom

Background/Purpose: In a large, randomised, placebo-controlled, double-blind phase-III 3-year study (SEKOIA), strontium ranelate 2g/day (SrRan) has demonstrated structure-modifying activity associated with statistically significant symptomatic improvement in patients with knee OA. In clinical trials, results for symptom improvement are usually reported as mean change in score which may not be directly clinically meaningful. The objective of this analysis was to describe, at an individual level, the effects of strontium ranelate on pain in patients with knee OA compared to placebo.

Methods: The main objective of the SEKOIA study was to demonstrate the effects of strontium ranelate on radiographic progression of knee osteoarthritis. Included patients were men and women over 50 years old, with symptomatic primary knee OA (at least 40 on a 100 mm visual analog scale (VAS) on most days of the previous month i.e. 1/2 days, Kellgren and Lawrence [KL] grade 2 or 3, and joint space width [JSW] 2.5–5 mm). Symptoms were assessed every 6 months over 3 years using the WOMAC questionnaire and a 100 mm VAS ("How would you rate the pain you have felt in the studied knee within the last 48 hours?"). Proportions of patients with an improvement of at least 20% or 50% from baseline of their WOMAC pain subscore[1] or pain VAS and proportion of OMERACT-OARSI-like responders[2] (calculated using improvement in pain and function but not

patient's global assessment as it was not assessed in this study) were compared using a chi^2 test.

Results: The ITT population included 1371 (82%) patients. At baseline, the mean, age was 63±7 years, BMI was 30±5 kg/m^2, VAS was 54±22 mm, and WOMAC was 132±62 mm. 61% were KL grade II and 69% were female. There were no differences between groups at baseline. Over 3 years, a significantly greater percentage of strontium ranelate 2g-treated patients had 20% improvement in WOMAC pain compared with placebo (72% vs 64%, p= 0.010) and a trend was seen with 50% improvement (51% vs 45%, p = 0.078). Similar results were confirmed on the VAS, with a greater number of patients having an improvement in global knee pain of at least 20% (76% vs 70%, p = 0.034) or at least 50% (60% vs 53%, p = 0.065) compared to placebo. When combining improvement in pain with improvement in function (OMERACT-OARSI-like responders) the percentage of responders was significantly greater in the strontium ranelate 2g group (54% vs 47%, p = 0.035) than in the placebo group.

Conclusion: Strontium ranelate 2g/day is associated with a greater number of patients having a clinically relevant decrease in their pain level over 3 years compared to placebo-treated patients. Strontium ranelate treated patients were also more likely to be OMERACT-OARSI-like responders.

Clinically Meaningful Effect of Strontium Ranelate On Knee Osteoarthritis Symptoms. O. Bruyere[1], N. Bellamy[2], J. Brown[3], P. Richette[4], L. Punzi[5], X. Chevalier[6], Cyrus Cooper[7] and Jean-Yves Reginster[1]. [1]University of Liège, Liège, Belgium, [2]CONROD. The University of Queensland, Royal Brisbane and Women's Hospital, Herston, Queensland, Australia, [3]Rheumatology Centre, Quebec City, QC, [4]Hôpital Lariboisière, Paris, France, [5]Azienda Ospedaliera di Padova, Padova, Italy, [6]Hôpital Henri-Mondor, Creteil, France, [7]University of Oxford; Southampton General Hospital, Southampton, United Kingdom

Background/Purpose: In the SEKOIA study, strontium ranelate 2g/day has been demonstrated to reduce total WOMAC score, pain subscore and global knee pain assessed using a visual analog scale (VAS) in comparison to placebo in patients with symptomatic primary knee osteoarthritis. The aim of these complementary analyses was to determine the number of patients considered as responders in terms of MPCI (Minimal Perceptible Clinical Improvement) and MCII (Minimal Clinical Important Improvement).

Methods: SEKOIA is a double-blind, placebo-controlled, randomized, international 3-year study aiming to demonstrate the effects of strontium ranelate on the radiographic progression of knee osteoarthritis. Clinical symptoms were assessed every 6 months over 3 years by the WOMAC questionnaire and a VAS. Percentages of patients reaching MPCI or MCII published values (1,2) were compared using a chi^2 test.

Results: ITT set included 1371 (82%) patients. In mean, age was 63±7 years, BMI was 30±5 kg/m^2, VAS was 54±22 mm, and WOMAC was 132±62 mm. 61% were KL II and 69% were female. Over 3 years, SrRan was associated with a greater number of MPCI and MCII responders as described in the table hereafter. This suggests that a greater number of patients reaches a threshold of improvement of their knee OA symptoms considered as clinically relevant with strontium ranelate treatment over 3 years compared to placebo.

	Placebo (N = 472) n (%)	Strontium ranelate 2 g (N = 454) n (%)	Difference relative to placebo [95% CI]	p-value
WOMAC Pain subscore				
Patients above MPCI threshold (9.7mm)	255 (55)	289 (65.5)	10.6 [4.2;16.9]	**0.001**
WOMAC Stiffness subscore				
Patients above MPCI threshold (10mm)	247 (52.8)	270 (60.1)	7.4 [0.9;13.8]	**0.025**
WOMAC Physical function subscore				
Patients above MPCI threshold (9.3mm)	229 (49.1)	257 (57.9)	8.7 [2.3;15.2]	**0.008**
Patients above MCII threshold (−9.1mm)	231 (49.6)	257 (57.9)	8.3 [1.9;14.8]	**0.012**
Knee pain by VAS				
Patients above MCII threshold (−19.9mm)	277 (59.4)	302 (67.7)	8.27 [2.05;14.49]	**0.010**

MPCI responders were statistically significantly greater from M18 (pain and function WOMAC subscores, p = 0.003 and p = 0.013, respectively) compared to the placebo group. Interestingly, after 2 years of treatment a significantly greater number of MPCI responders were observed for the WOMAC stiffness subscore (p = 0.008) in the strontium ranelate group. An earlier effect, close to statistical significance (p = 0.051) was also detectable for physical function MPCI responders.

Conclusion: This study demonstrates that positive effects of Strontium Ranelate on pain and physical function in patients with knee OA are clinically meaningful. Effect is early with a greater number of MPCI responders observed as soon as 18 months of treatment.

Strontium Ranelate Decreases the Level of Urinary CTX-II in Patients with Knee Osteoarthritis. Julien Collette[1], Olivier Bruyere[2] and Jean-Yves Reginster[3]. [1]Labo Ria Chu Sart Tilman, Liege, Belgium, [2]Universite De Liege, Liege, Belgium, [3]University of Liège, Liège, Belgium

Background/Purpose: Knee osteoarthritis is a chronic disease affecting the global joint and characterized by cartilage degradation as well as subchondral bone remodelling. Effects of strontium ranelate (SrRan) on urinary CTX-II, an osteoarthritis-related biomarker, and on serum CTX-I and b-ALP, two markers of bone metabolism, were investigated.

Methods: The urinary level of collagen type II C-telopeptide fragments (uCTX-II), the serum levels of collagen type I C-telopeptide fragments (sCTX-I) and bone phosphatase alkaline (sb-ALP) were assessed in all patients included in the SEKOIA study at baseline and after 3, 6, 12, 24 and 36 months of treatment. 1683 patients have been included in this double-blind, placebo-controlled, randomized, international 3-year phase III study aiming to demonstrate the effects of SrRan on the radiographic progression of knee osteoarthritis and have been allocated to SrRan 1g or 2g per day or placebo. Analyses were performed by SUPREME (Liège) using ELISA (uCTX-II and sCTX-I) or a chemiluminescent immunoenzymatic assay (sb-ALP). CTX-II was corrected for urinary creatinine level. Group comparisons were assessed in the ITT (1371 patients) using a Mann-Whitney-Wilcoxon test for uCTX-II or a general linear model with sex, baseline and centre as covariates for sb-ALP and sCTX-I.

Results: At baseline, no significant difference was observed between the groups on uCTX-II, sCTX-I and sb-ALP levels. At the last visit, uCTX-II was significantly lower in the SrRan 1g and 2g groups than in the placebo group with an estimated mean difference of −0.04 and −0.03 μg/mmol respectively (p=0.003 for SrRan 1g group and p=0.021 for SrRan 2g group). Early differences between the treatment groups were demonstrated at 3 months, uCTX-II was significantly lower in the SrRan 1g and 2g groups than in the placebo group with an estimated mean difference of −0.04 and −0.07 μg/mmol creatinine (p<0.0001) respectively.

The results on bone markers sb-ALP and sCTX-I are those expected with SrRan, the level of sb-ALP was higher in SrRan 2g group compared to placebo and the level of sCTX I was lower in both SrRan groups compared to placebo at all visits from 3 months.

Conclusion: Treatment with strontium ranelate significantly decreases the level of urinary CTX-II compared to placebo in patients suffering from knee osteoarthritis, suggesting that strontium ranelate slows the evolution of knee osteoarthritis.

Meta-Analysis of Four 12-Week Phase III Clinical Trials Investigating the Effect of TDT 064, a Transdermal Gel, in Osteoarthritis of the Knee. Matthias Rother[1], Johannes C. Vester[2], Wolfgang W. Bolten[3] and Philip G. Conaghan[4]. [1]IMR Partner GmbH, Graefelfing, Germany, [2]IDV Data Analysis and Study Planning, Krailling, Germany, [3]Klaus-Miehlke-Klink, Wiesbaden, Germany, [4]University of Leeds, Leeds, United Kingdom

Background/Purpose: A transfersome is an ultradeformable lipid vesicle originally developed to deliver high concentrations of drug (eg NSAIDs) transdermally. Large interventional trials in osteoarthritis (OA) of the knee comparing ketoprofen-containing vesicles (IDEA-033) to vesicles without active drug (called Sequessome, TDT 064) showed conflicting results for IDEA-033[1–3] but all demonstrated pronounced treatment effects of the vehicle itself (TDT 064) that, in one study,[4] were comparable to 100 mg b.i.d. celecoxib and statistically significantly superior to oral placebo.[4] Objectives were to investigate how the treatment effects seen with TDT 064 compare with the results reported for the placebo arm of other OA interventional studies using a meta-analytic approach.

Methods: The efficacy of TDT 064 gel has been evaluated in four randomized, double-blind, parallel-group multicenter, 12-week Phase III studies of IDEA-033 in knee OA that included TDT 064 as a drug-free vesicle control group. The meta-analysis combines the results of the WOMAC pain subscales from the studies which were standardized to a 0–100 scale. The resulting pre-post effect size (ES) is the standardized difference (Cohen)[5] of the changes from baseline of the WOMAC pain subscale score at Week 12 (based on the standard deviation of the changes of the corresponding TDT 064 group). Effect sizes of 0.2, 0.5, and 0.8 are used to represent small, medium, and large effect sizes, respectively.[5] The results of the meta-analysis are presented as two-sided tests with two-sided 95.0% confidence intervals (CIs; Hedges'g). The results of this analysis are compared with those of a meta-analysis of placebo responses from other conventional trials as published by Zhang et al.[6]

Results: The ES calculated for a total of 1061 patients with OA of the knee treated with TDT 064 gel was 1.15 (CI: 1.09–1.21). The respective values for the individual 4 studies were 1.33 (CI: 1.18–1.47)[1], 1.12 (CI: 1.03–1.21)[2], 1.05 (CI: 0.87–1.24)[3], and 1.12 (CI: 1.00–1.24)[4]. The results were comparable irrespective of whether 2.2 g or 4.4 g of TDT 064 gel was used (ES 2.2 g: 1.17 [CI: 1.07–1.28]; ES 4.4 g: 1.12 [CI: 1.04–1.20]). This compares to an ES of 0.51 (CI: 0.46–0.55) reported for all placebo applications and an ES of 0.63 (CI: 0.47–0.80) for the topical placebo arm investigated with topical formulations in the meta-analysis of Zhang et al.[6]

Conclusion: Pain reduction reported in 4 comparative, double-blind studies in knee OA using TDT 064 is substantially higher than the reduction reported for the topical placebo arm of other interventional trials. The magnitude of the difference indicates that this effect is unlikely to be due to a placebo response alone.

Efficacy and Safety of the Chinese Herbal Compound Hou-Lou-Xiao-Ling Dan in Patients with Osteoarthritis of the Knee: Results of a Phase II International Study. Marc C. Hochberg[1], Lixing Lao[1], Patricia Langenberg[1], Harry H. S. Fong[2], David Y-W. Lee[3] and Brian Berman[1]. [1]University of Maryland, Baltimore, MD, [2]University of Illinois at Chicago, Chicago, IL, [3]Harvard Medical School, Boston, MA

Background/Purpose: Traditional Chinese Medicine (TCM), which includes the use of herbal medicines, is widely used to treat osteoarthritis (OA) of the knee in Asian societies; furthermore, many persons with OA in the United States use TCM therapies. The scientific basis for the use of TCM in the treatment of OA, however, is relatively sparse. Huo-Luo-Xiao-Ling (HLXL) Dan is a Chinese herbal compound that is used for the treatment of arthritis and Bi syndrome in Asia and has been shown to have anti-inflammatory and immunomodulatory properties in preclinical models of rheumatoid arthritis. The primary objective of this study was to examine the efficacy and safety of a proprietary formulation of HLXL Dan in patients with osteoarthritis (OA) of the knee who continued to have symptoms despite receiving standard analgesic and/or anti-inflammatory treatment.

Methods: A randomized, double-blind, placebo-controlled phase II clinical trial was conducted at two sites: the University of Maryland Center for Integrative Medicine and the Chinese University of Hong Kong. Patients with symptomatic radiographic knee OA who fulfilled ACR classification criteria and had moderate or greater frequent knee pain in one or both knees despite receiving background analgesic and/or anti-inflammatory medicines were randomized to receive either HLXL Dan at a dose of 5,180 mg/day (15 capsules in 3 divided doses) or matching placebo for 8 weeks. Clinical assessments were performed at baseline and weeks 2 and 8 including measurement of knee pain and function with the WOMAC OA Index, patient global assessment (PGA) and PGA of response to therapy (PGART) at end of study. Safety assessments were performed at each visit. Data were analyzed using an intent-to-treat protocol; statistical significance was inferred if $P <= 0.05$.

Results: A total of 92 patients were enrolled: 53 in the U.S. and 39 in Hong Kong. Overall, the mean age was 60 years, 65 (71%) were women and 64 (70%) were of Asian ethnicity. Mean (SD) baseline WOMAC pain and function score was 4.3 (1.5) and 4.2 (1.6), respectively, and PGA was 2.2 (0.8). There were no significant differences between HLXL- and placebo-treated groups in baseline variables. While both groups had significant improvement in all outcome measures after 8 weeks, there were no significant differences between the HLXL- and placebo-treated groups. At 8 weeks, about two-thirds of subjects noted that they were better based on PGART responses; there was no difference between treatment groups. In mixed models repeated measures analysis, there were no significant differences in WOMAC pain or function scores or PGA between groups; furthermore, there was no interaction between clinical site and degree of improvement. Average adherence exceeded 80 percent and was similar between clinical sites. Finally, there was a significantly greater rise in mean ALT levels in the HLXL-treated group compared with the placebo-treated group (3.8 [10.4] vs 0.1 [5.8] U/l) but no significant difference in either AST or γGT levels.

Conclusion: These data fail to demonstrate that a proprietary form of the Chinese herbal compound HLXL Dan is efficacious for treating the symptoms of knee OA.

Long-Term Tanezumab Treatment for Osteoarthritis: Efficacy and Safety Results. Alfonso E. Bello[1], Evan F. Ekman[2], David Radin[3], Isabelle Davignon[4], Michael D. Smith[4], Mark T. Brown[4], Christine R. West[5] and Kenneth M. Verburg[4]. [1]Illinois Bone & Joint Institute, Glenview, IL, [2]Southern Orthopaedic Sports Medicine, Columbia, SC, [3]Stamford Therapeutics Consortium, Stamford, CT, [4]Pfizer, Groton, CT, [5]Pfizer, Williamston, MI

Background/Purpose: Nerve growth factor (NGF) levels are associated with increased pain perception and are elevated in joints of arthritis patients. Tanezumab, a humanized monoclonal antibody, inhibits NGF with high specificity and affinity. A non-controlled, randomized, dose-blinded extension study (NCT00809783) following placebo-controlled and active comparator, multiple-dose, Phase III parent studies was conducted to evaluate long-term efficacy and safety of tanezumab in patients with osteoarthritis (OA) of the knee or hip.

Methods: Patients were eligible to enroll up to 12 weeks after their last dose of study medication in the parent study. Patients (N=2142) received tanezumab 2.5 mg (n=522), 5 mg (n=832), or 10 mg (n=788) IV every 8 weeks up to 80 weeks. Safety assessments included adverse event documentation, physical and neurological examinations and laboratory tests. Efficacy analyses included change from baseline in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain and Physical Function subscales and Patient's Global Assessment of OA.

Results: Demographic characteristics were similar across treatments. Mean duration of combined parent and extension study treatment for tanezumab 2.5, 5, and 10 mg was 353, 345, and 335 days, respectively. The most frequently reported treatment-related adverse events were paresthesia, arthralgia and hypoesthesia. Osteonecrosis was reported for 28 (1.3%) patients, only one event subsequently was adjudicated as osteonecrosis. Concomitant non-steroidal anti-inflammatory drugs (NSAIDs) use was associated with increased incidence of rapidly progressive osteoarthritis. A total of 187 patients (8.7%) underwent total joint replacements (TJR). All-cause TJR frequency was 5.2% in those not taking NSAIDs (n=1173) vs.13.0% in the concomitant NSAID cohort (n=969). Patients from tanezumab groups in the parent studies reported sustained improvement in WOMAC pain in the extension study (Figure). Few patients (7.2%) discontinued due to lack of efficacy indicating that treatment had a persistent beneficial effect. Similar results were observed for other efficacy endpoints.

Note: Figure represents the subset of patients who received tanezumab in the parent study
* Gap between last parent study dose and BL ≥8 weeks
Abbreviations: WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index; BL, baseline
Conclusion: Repeated doses of tanezumab 2.5 mg, 5 mg, and 10 mg every 8 weeks were efficacious and generally safe with no new safety signals identified. Persistent beneficial efficacy similar to that observed in the parent studies was demonstrated and maintained in OA patients over the long term.

Adjudication of Reported Serious Adverse Joint Events in the Tanezumab Clinical Development Program. Marc C. Hochberg[1], Steven B. Abramson[2], David S. Hungerford[3], Edward McCarthy[4], Eric P. Vignon[5], Michael D. Smith[6], Leslie Tive[7], Kenneth M. Verburg[6] and Christine R. West[8]. [1]University of Maryland, Baltimore, MD, [2]NYU Hospital for Joint Diseases, New York, NY, [3]Johns Hopkins University, Baltimore, MD, [4]The Johns Hopkins University School of Medicine, Baltimore, MD, [5]Centre Hospitalier, Pierre Benite, France, [6]Pfizer, Groton, CT, [7]Pfizer Inc, New York, NY, [8]Pfizer, Williamston, MI

Background/Purpose: Tanezumab (TNZ) has been shown to be efficacious for pain and function in patients with hip and knee osteoarthritis (OA). Unexpected reports of adverse events described as osteonecrosis (ON) developed in patients enrolled in clinical trials in the TNZ development program. These reports led the FDA to impose a temporary clinical hold on the program.

Methods: Patients with reported adverse events of ON (N = 87) and reported total joint replacement (TJR) unrelated to ON (N = 299) were identified. Source documents were requested from site investigators; documents from 87 (100%) and 162 (54.2%) of patients with ON or TJR unrelated to ON, respectively, were obtained. All available source documents were reviewed by an independent adjudication committee (IAC) comprised of 3 rheumatologists, 1 orthopedic surgeon and 1 bone pathologist who were blinded to treatment assignment. Consensus was reached on all but 7 cases.

Results: The IAC classified the 249 cases into four categories: Primary ON; Rapidly progressive OA (RPOA; type 1 = loss of joint space width ≥ 1 mm over approx. 1 year, or type 2 = abnormal loss/destruction of bone uncommon for end-stage OA); Normal progression of OA (NPOA); Not enough information to distinguish between RPOA and NPOA; Other joint condition/diagnosis; or Not enough information to distinguish between primary ON, worsening OA or another diagnosis. Results of the adjudication are shown in Table 1. Of the 87 patients with an adverse event reported as ON, only 2 were adjudicated with primary ON; 34 (39.1%) were adjudicated with RPOA while the majority of others were adjudicated with NPOA or subchondral insufficiency fracture. The remaining 34 patients adjudicated with RPOA had a TJR unrelated to an adverse event of ON.

There was a significant dose-response relationship between incidence of RPOA and increasing dose of TNZ when given as monotherapy (0, 6 and 11 per 1000 person-years at doses of 2.5, 5 and 10 mg, respectively [P = 0.0124]) (see Figure 1). There was also an increased incidence of RPOA when TNZ was given in combination with NSAIDs as compared to montherapy (P < 0.001). Incidence was increased in all combination treatments compared to placebo, TZB monotherapy, and active comparator treatments. The highest rate of RPOA occurred in the TNZ 10 mg in combination with NSAIDs group (30 per 1000 person-years).

Table 1. Adjudication Results

Final diagnosis, n(%)	Total patients (N = 249)	Total joints (N = 282)
Primary osteonecrosis	2 (0.8)	2 (0.7)
Rapidly progressive OA	68 (27.3)	71 (25.2)
Normal progression OA	119 (47.8)	142 (50.4)
Other condition	29 (11.6)	33 (11.7)
Insufficient information	31 (12.5)	34 (12.1)

Rapidly Progressive OA
Phase 3 OA Studies, Event Rate by Dose
Conclusion: The rate of RPOA was greatest in patients who received TNZ with NSAIDs or TNZ alone at doses >= 10 mg. The mechanism for this association remains unclear. These results support the continued study of TNZ alone at doses below 10 mg for treatment of OA.

Effect of Advancing Age On the Gastrointestinal Safety of Celecoxib Versus Nonselective Nonsteroidal Anti-Inflammatory Drugs: A Post Hoc Analysis of GI-Reasons. Lee S. Simon[1], Byron Cryer[2], Gurkirpal Singh[3], Chunming Li[4] and Margaret Noyes Essex[5]. [1]SDG LLC Consulting, West Newton, MA, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]Stanford University School of Medicine, Palo Alto, CA, [4]Pfizer Inc, New York, NY, [5]Pfizer, Inc, New York, NY

Background/Purpose: Celecoxib use was associated with a lower risk of clinically relevant upper and lower GI events than nonselective (ns)NSAIDs in patients (≥ 55 years) with osteoarthritis (OA) at moderate GI risk, in standard US clinical practice, in the GI Randomized Event and Safety Open-Label NSAID Study (GI-REASONS).[1]Age has been identified as a factor for increasing patient risk for a GI adverse event when using NSAIDs. The objective was to assess whether the observed decreased GI risk with celecoxib compared to nsNSAIDs varies with advancing age in 8067 patients from the GI-REASONS trial.

Methods: A post hoc analysis of a prospective, randomized, open-label, blinded end point study[1] where patients were randomized (1:1) and stratified by *H pylori* status to receive celecoxib or any nsNSAID for 6 months. Patients randomized to the nsNSAID arm could switch between nsNSAIDS; crossover between treatment arms was not allowed. The primary end point, a composite of investigator and blinded adjudicated clinically significant upper and lower GI events, was assessed according to age (< 60 years, 60–69 years, and ≥ 70 years). Analyses were performed on the intention-to-treat (ITT) population controlling for *H pylori*status.

Results: 4035 celecoxib and 4032 nsNSAID patients with OA were included in the ITT population. 1344 (33.3%) and 1363 (33.8%) were aged < 60 years, 1997 (49.5%) and 1949 (48.3%) were aged 60–69 years, and 688 (17.1%) and 714 (17.7%) were aged ≥ 70 years in the celecoxib and nsNSAID groups, respectively. Age was not specified in 6 patients in both treatment groups. Significantly more patients aged < 60 years and ≥ 70 years in the nsNSAIDs group than in the celecoxib group met the primary end point at 6 months (Table 1). Consistent with the primary results, the most commonly used nsNSAID in each age group was meloxicam. The number of patients using gastric protective agents in the

celecoxib and nsNSAID groups were 310 (25.5%) and 335 (27.4%) aged < 60 years, 525 (28.4%) and 517 (28.5%) aged 60–69 years, and 169 (25.8%) and 223 (32.7%) aged ≥ 70 years, respectively. The number of patients who experienced moderate to severe abdominal symptoms in the celecoxib and nsNSAID groups were 37 (2.8%) and 49 (3.6%) aged < 60 years, 40 (2%) and 72 (3.7%) aged 60–69 years, and 17 (2.5%) and 17 (2.4%) aged ≥ 70 years, respectively.

Table 1. Clinically Significant Upper and Lower GI Events

| | Celecoxib | | nsNSAID | | OR (95% CI) | P Value |
	N	Patients With Event n (%)	N	Patients With Event n (%)		
< 60 years	1344	13 (1.0)	1363	30 (2.2)	2.3 (1.2–4.3)	0.0120
60–69 years	1997	35 (1.8)	1949	47 (2.4)	1.4 (0.9–2.1)	0.1570
≥ 70 years	688	6 (0.9)	714	21 (2.9)	3.7 (1.5–9.2)	0.0035

Conclusion: Celecoxib use had a lower risk of clinically significant upper and lower GI events than nsNSAIDs in patients < 60 and ≥ 70 years in the GI-REASONS trial. These data should be considered when prescribing NSAIDs for patients with OA.

Flexible Footwear Reduces Dynamic Joint Loads in Knee Osteoarthritis: Results of a 6 Month Randomized Controlled Trial. Najia Shakoor[1], Roy H. Lidtke[1], Louis F. Fogg[2], Rachel A. Mikolaitis[1], Markus A. Wimmer[1], Kharma C. Foucher[1], Laura E. Thorp[1] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center

Background/Purpose: Dynamic joint loads are important in the pathophysiology of knee OA and biomechanical interventions aim to reduce these loads in hopes of improving symptoms and delaying disease progression. Recent evidence suggests that footwear can influence dynamic knee loading and that flat, flexible shoes may result in lower knee loads compared to more supportive, stiff-soled shoes. Here, we evaluate the longitudinal effects of flexible footwear ("mobility" shoe) compared to a control shoe on knee loading over 6 months.

Methods: Subjects with radiographic (KL grades ≥ 2) and symptomatic (at least 30mm pain of 100mm scale while walking) medial compartment knee OA were recruited and randomized to receive a flexible soled shoe (mobility shoe) or identical appearing "control" shoe with stiffer sole. The stiffness of the soles was evaluated using a biomaterial testing system and was substantially different between the shoes. Investigators and participants were blinded to shoe assignment. Baseline gait analyses were performed using an optoelectronic camera system and multi-component force plate in subjects' "own shoes", study shoes, and barefoot. Subjects were instructed to wear the study shoes at least 6 hours/day for 6 days/week. Gait analysis was repeated at 6, 12 and 24 weeks. The peak knee adduction moment (KAM), a validated marker of medial compartment loading, was evaluated. An intent-to-treat analysis was performed with imputation of missing data using a hot deck method. Repeated measures analysis of variance compared the two arms and planned contrasts were used to further analyze the data and load reductions at various time points.

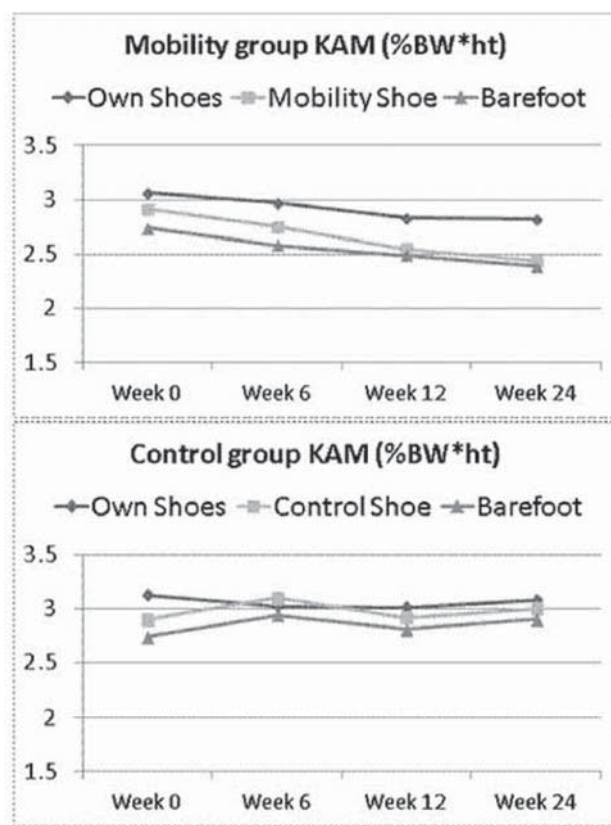
Results: 22 participants (13 women, mean age 55±7 years) were assigned to the mobility shoe and 28 (21 women, mean age 55±8 years) to the control shoe. When evaluating the different walking conditions (study shoe, barefoot, own shoes), there were differences over time in the mobility group vs control. Compared to their own shoes at baseline, the mobility group experienced a 20% reduction in the KAM by 24 weeks (3.06±1.22 to 2.44±0.72 %BW*ht, p=0.002) while the control group experienced no significant reduction (3.13±0.81 to 3.00±0.66 %BW*ht, p=0.361). Furthermore, as previously described with use of the mobility shoe, there was a trend for a gait adaptation with reduction in loading during the own shoe condition (7.5%, p=0.154) and barefoot gait (13%, p=0.111) in the mobility shoe group from baseline to 24 weeks (Figure).


Figure. KAM over 24 weeks in Mobility and Control groups.

Conclusion: This double-blind randomized controlled trial suggests that use of flat, flexible footwear, in this case the mobility shoe, over 6 months results in significant reductions in medial knee loading compared to a stiff-soled control shoe. Thus, the use of flexible footwear may be an effective biomechanical intervention for the management of knee OA.

Efficacy of Ketoprofen Vs Ibuprofen and Diclofenac: A Systematic Review of the Literature and Meta-Analysis. Fabiola Atzeni[1], Pier Carlo Sarzi-Puttini[1], Luigi Lanata[2] and Michela Bagnasco[2]. [1]University Hospital L Sacco, Milan, Italy, [2]Dompé SpA, Milan, Italy

Background/Purpose: The management of mild-to-moderate pain has traditionally been based on the use of non-steroidal anti-inflammatory drugs (NSAIDs) and the synthetic non-opioid analgesic paracetamol (acetaminophen), both of which are effective, widely recommended, and extensively used. Among the NSAIDs, ketoprofen, ibuprofen and diclofenac have been used for the last 30 years. The published placebo-controlled randomised clinical trials (RCTs) do not allow direct comparisons of the various NSAIDs, but meta-analyses can be used to make indirect comparisons that can demonstrate similar (but not identical) drug efficacy.

The aim of this systematic review of the literature and meta-analysis of randomised controlled trials (RCTs) was to compare the efficacy of orally administered ketoprofen vs ibuprofen and/or diclofenac.

Methods: The literature was systematically reviewed and search was restricted to randomised clinical trials comparing the efficacy of oral ketoprofen (50–200 mg/day) vs ibuprofen (600–1800 mg/day) or diclofenac (75–150 mg/day) published until June 2011 in the Medline, Cochrane Central and Embase databases. The study selection was made independently by two rheumatologists in accordance with the Cochrane Collaboration guidelines.

Results: A total of 13 RCTs involving 898 patients met the inclusion criteria: eight ketoprofen vs ibuprofen and five comparing ketoprofen vs diclofenac. Nine of the 13 RCTs included 544 patients with systemic

rheumatic diseases such as RA, OA, ankylosing spondylitis (AS), low back pain or painful shoulder. The difference in efficacy between ketoprofen and ibuprofen/diclofenac was statistically significant (0.459, 95% CI 0.33–0.58; P=0.00) at all point-estimates of the mean weighted size effect (Fig 1). The test of heterogeneity for the efficacy outcome was not statistically significant ($c^2 = 18.07 - df= 12 - P = 0.1136$). Concerning the estimated efficacy outcomes, ketoprofen was superior to ibuprofen/diclofenac in all of the 13 RCTs, reaching a statistically significant difference ($P < 0.05$) in nine studies. The heterogeneity for the efficacy outcome was not different across the studies and this guaratees that the compared trials are homogeneous and the meta-analysis results reliable and valid. The meta-analysis showed that the effect of therapeutic doses of ketoprofen was strongly greater than the effect of therapeutic doses of ibuprofen or diclofenac.
Figure 1. The size effect of ketoprofen and ibuprofen/diclofenac.

Conclusion: Findings of this meta-analysis support strong recommendation that the efficacy of orally administered ketoprofen in relieving moderate-severe rheumatic pain and in improving functional status and general conditions is significantly better than that of diclofenac/ibuprofen.

Specialized Footwear Decreases Medial Tibial Bone Mineral Density Over 48 Weeks in Knee Osteoarthritis. Justin B. Gan, Laura E. Thorp, Roy H. Lidtke, Rachel A. Mikolaitis, Louis F. Fogg, Joel A. Block and Najia Shakoor. Rush University Medical Center, Chicago, IL

Background/Purpose: Osteoarthritis (OA) is characterized by increased subchondral bone mineral density at affected joints. In the knee, proximal tibial bone mineral density (BMD) is associated with dynamic joint loading (Thorp et al, *Bone*, 2006), and thereby serves as a marker for structural consequences of sustained altered joint loading. Biomechanical interventions such as specialized footwear (the mobility shoe) have been shown to reduce joint load in knee OA. We hypothesized that load reduction with use of the mobility shoe would yield appreciable reductions in proximal tibial BMD over 48 weeks.

Methods: Subjects with mild to moderate medial compartment radiographic knee OA were randomized to wear either the mobility shoe or "non-flexible" control shoe. All participants and investigators were blind to treatment group allocation. Participants were asked to wear the shoes 6 hours per day at least 6 days per week. Subjects underwent DXA scanning of bilateral knees at baseline and at 24 and 48 weeks after starting the intervention. These scans were evaluated in a blinded manner by a trained investigator using a previously validated method. The BMD of the medial and lateral regions of the tibial plateau were measured in each knee. Repeated measures ANOVA (rm-ANOVA) was used to evaluate changes in BMD over time in each group.

Results: Nine subjects in the mobility shoe group and 13 subjects in the control group had BMD data available at all three time points (0, 24, and 48 weeks). The mobility shoe group demonstrated a significant reduction in the medial proximal tibial BMD of the affected knee from 0 to 24 to 48 weeks (p=0.01, see Table). The control shoe group did not demonstrate a statistically significant reduction in medial proximal tibial BMD over this time (see Table). There were no significant changes in lateral tibial BMD in either group from 0 to 24 to 48 weeks (see Table).

	Control Shoe (n=13)	Mobility Shoe (n=9)
Medial Tibial BMD (g/cm^2)*		
Week 0	0.850 ± 0.138	0.836 ± 0.116
Week 24	0.848 ± 0.183	0.818 ± 0.121
Week 48	0.851 ± 0.137	0.790 ± 0.092
rm-ANOVA, p-value	p=0.979	p=0.01
Lateral Tibial BMD (g/cm^2)*		
Week 0	0.669 ± 0.119	0.681 ± 0.132
Week 24	0.688 ± 0.091	0.690 ± 0.133
Week 48	0.699 ± 0.116	0.691 ± 0.145
rm-ANOVA, p-value	p=0.267	p=0.466

*Values are the mean ± SD unless otherwise indicated; BMD, bone mineral density; rm-ANOVA, repeated measures ANOVA.

Conclusion: The mobility shoe yielded a significant reduction in medial tibial BMD over 48 weeks of use. A control walking shoe did not yield similar BMD changes. These results suggest that use of the mobility shoe can lead to potentially beneficial structural changes in subchondral bone as the result of a dynamic load reducing intervention.

265

Reducing Loads in the Contralateral Side in Medial Knee Osteoarthritis; A 3-Year Follow-up Study. Roy H. Lidtke and Joel A. Block. Rush University Medical Center, Chicago, IL

Background/Purpose: No strategies have been shown to prevent Medial knee osteoarthritis (MKOA). For those with symptomatic unilateral MKOA, the contralateral knee may be at risk for developing MKOA. Early adaptation of load reducing strategies may reduce the development of the disease in the contralateral knee.

Methods: 90 subjects (69F 21M, Age 60±8, BMI 28.3±4.0) with radiographic and symptomatic medial knee OA (K-L grade 2–3, ambulatory pain >30 mm on a 100 mm VAS) were randomized into a control group fitted with bilateral neutral foot orthosis or a treatment group fitted with 7 degree valgus posted foot orthosis. The knee joint with greater pain was labeled as the index side. Subjects underwent gait analyses using an optoelectronic camera system and multi-component force plate. Subjects walked at their normal speed, and comparisons were performed after matching for speed. The peak external knee Adduction Moment (KAddM) (%body weight * height, %BW*Ht) was calculated and used as the primary endpoint. Subjects were evaluated at baseline and again at 36 months with and without the orthosis. Changes in the peak KAddM between conditions and time variable were calculated and expressed as a percentage change in the control condition. Nonparametric confidence intervals were calculated with the binomial method around the percentage of change to assess statistical significance with significance set at p<0.05.

Results: After 3 years the contralateral knee showed a 5.01±0.09% (Median±IQR) increase in medial knee load when the control orthosis was added while there was a (−)5.29±0.72% (Median±IQR) decrease in the medial knee load with the addition of the wedge orthosis in the treatment group. In the wedge treatment group the median drop in knee adduction moments between baseline and 36 months was (−)7.61±0.84% in the contralateral knee and (−)6.49±0.13% on the index side (Median±IQR). Interestingly After 3 years in the control treatment group there was a 10.66±0.52% increase in the medial knee loads on the index side while there was a (−)11.29±0.74% decrease in the medial knee loads on the contralateral side (Median±IQR).

Conclusion: The contralateral knee may be at risk in subjects with MKOA. These data suggest that the contralateral knee may get better benefit using load reducing strategies such as valgus wedge foot orthosis. The greatest sustained reduction of knee loads was seen in the contralateral knee of the control group. Since the control group was wearing custom foot orthosis posted to perpendicular to the ground it may be that a non-valgus posted custom foot orthosis on the contralateral side may be of benefit for reducing the progression of knee osteoarthritis.

Knee Joint Stabilization Therapy in Patients with Osteoarthritis of the Knee: A Randomized, Controlled Trial. Jesper Knoop[1], Joost Dekker[2], Marike van der Leeden[3], Martin van der Esch[1], Carina A. Thorstensson[4], Martijn Gerritsen[1], Ramon E. Voorneman[1], Wilfred FH Peter[1], Mariette de Rooij[1], Suzanne Romviel[1], Willem F. Lems[5], Leo D. Roorda[3] and Martijn P.M. Steultjens[6]. [1]Reade, centre for rehabilitation and rheumatology, Amsterdam, Netherlands, [2]VU University Medical Centre, Department of Rehabilitation Medicine, EMGO Institute and Department of Psychiatry, Amsterdam, Netherlands, [3]Reade, Amsterdam, Netherlands, [4]University of Gothenburg, Institute of Neuroscience and Physiology, Gothenburg, Sweden, [5]VU University Medical Center, Amsterdam, Netherlands, [6]Glasgow Caledonian University, Glasgow, Scotland

Background/Purpose: Patients with knee osteoarthritis (OA) and instability of the knee joint may not benefit optimally from regular strengthening training. Therefore, we evaluated the effectiveness of a newly developed exercise program which initially focused on knee joint stabilization, before starting with muscle strengthening exercises and training of daily activities in knee OA patients and instability of the knee joint, compared to muscle strengthening exercises and training of daily activities only.

Methods: A single-blind, randomized, controlled trial involving 159 patients with knee OA and knee joint instability, randomly assigned to two treatment groups. Both groups received a supervised exercise program for 12 weeks, consisting of muscle strengthening exercises and training of daily activities, but only in the experimental group exercises initially focused on knee joint stabilization. Outcome measures included activity limitations (WOMAC physical function, primary outcome), pain and knee stability.

Results: Both treatment groups demonstrated large (20–40%) and clinically relevant reductions in activity limitations, pain and knee instability, which were sustained six months post treatment. No differences in effectiveness between experimental and control treatment were found on WOMAC physical function (B (95% CI) = −0.36 (−2.85–2.12)) or any secondary outcome measure.

Conclusion: Both exercise programs were effective in reducing activity limitations and pain and restoring knee stability in knee OA patients with instability of the knee. Against this background, no additional effect of initial knee joint stabilization training, before starting muscle strengthening exercises and training of daily activities could be demonstrated, emphasizing a dominant role of muscle function in stabilizing the knee joint.

Osteopontin in Patients with Primary Knee Osteoarthritis: Relation to Disease Severity. Ramy Abdelnaby. Ain Shams University, Cairo, Egypt

Background/Purpose: To investigate the role of plasma and synovial fluid Osteopontin in primary knee osteoarthritis in relation to disease severity grading.

Methods: Forty patients aged 52–85 years with knee osteoarthritis and 15 healthy controls were enrolled in this study. The radiographic grading of knee osteoarthritis was performed by using the Kellgren-Lawrence-criteria to determine the disease severity. Osteopontin levels were measured using enzyme-linked immunosorbent assay.

Results: Osteoarthritis patients had higher plasma Osteopontin concentrations compared to healthy controls (171.37±15.96 vs 15.6±3.41ng/mL, P<0.0001). There was a highly significant positive correlation between plasma levels of Osteopontin and severity of the disease (r=0.923, p=<.0001) and a positive correlation between synovial levels of Osteopontin and severity of the disease (r=0.627, p=<0.05). Through ROC curve, results showed that to determine Osteoarthritis cases through measuring plasma Osteopontin levels it should be equal to or higher than the cut-off value, 83±4.25 ng/ml. To identify K-L grade 2 osteoarthritis from plasma Osteopontin levels must be equal to or more than, 132.25±3.1 ng/ml, to identify K-L grade 3 osteoarthritis it must be equal to or more than, 159.25±1.5 ng/ml, to identify K-L grade 4 osteoarthritis it must be equal to or more than, 183±0.9 ng/ml, with sensitivity 100% at these values.

Conclusion: Measurements of plasma and/or synovial levels of Osteopontin could possibly serve as a biochemical parameter for determining grades of different disease severity and may be predictive of prognosis with respect to the progression of osteoarthritic disease process.

Knee Osteoarthritis and Serum Uric Acid Concentration: The Third National Health and Examination Survey. Tony Ning, Carl Pieper, Virginia B. Kraus, William E. Kraus and Kim M. Huffman. Duke University Medical Center, Durham, NC

Background/Purpose: Osteoarthritis (OA) is a disease that is thought to be the result of many factors, which includes inflammatory causes. A recent study examined the relation of knee OA, synovial uric acid levels, and how it relates to NLRP3 inflammasome activity. It was demonstrated that synovial uric acid concentration is strongly correlated with markers of inflammasome activity and knee osteoarthritis. In addition, baseline synovial TNF alpha and synovial IL-18 was associated with changes in the osteophyte scores in 3 year longitudinal models of knee. This main focus of our research project is to examine the relation of serum uric acid concentration (SUA) and the severity of radiographic knee osteoarthritis. We hypothesized that higher concentrations of SUA is positively associated with the severity of radiographic knee OA as measured by Kellgren/Lawrence grades.

Methods: We used the National Health and Nutrition Examination Survey (NHANES III) database to carry out our research. Patients over the age of 60 had bilateral, non weight bearing knee films done. Our database was created by merging variable datasets provided by the NHANES III, which included lab values, knee imaging, demographics, as well as physical exam findings. A total of 2188 survey participants were in our database after excluding patients who either had gout or were on allopurinol. We performed correlative analyses between serum uric acid concentrations and different measurements of knee osteoarthritis using SAS Enterprise Guide version 2.3. The correlation between serum uric acid concentration and knee osteoarthritis was examined with Pearson's score of correlation. Co-variates were taken into account using generalized linear modeling. The NHANEs survey design was taken into account by applying sampling weights to our variables.

Results: A statistically significant correlation was seen in univariate analyses between serum uric acid concentration and measurements of radiographic knee OA, which included the combined total KL score (R=0.086, p<0.001), the combined total medial tibial sclerosis score (R=0.053, p=.01), and the combined total osteophyte score (R=0.069, p=0.001). Linear regression modeling was then preformed between the measurements of knee osteoarthritis and serum uric acid concentration to account for age, gender, body mass index (BMI), serum creatinine (Cr). Statistical significance was lost when accounting for these covariates.

Conclusion: In conclusion, our study showed a statistically significant correlation between serum uric acid concentration and radiographic measurements of knee osteoarthritis. This relationship was lost while accounting for age, gender, BMI, and serum creatinine. It is likely that soluble uric acid acts locally in increasing risk for OA.

Differences Between Patients with Hip and Knee Osteoarthritis. Kim F. Le Marshall[1], Bradley Yee[2], Paul A. Dieppe[2], Albert Leung[1], Carolyn Page[3], Peter F. Choong[3], Michelle Dowsey[3] and Keith K. Lim[1]. [1]Western Hospital, Melbourne, Australia, [2]University of Plymouth Campus, Plymouth, United Kingdom, [3]St Vincent's Hospital, Melbourne, Australia

Background/Purpose: This observational study was designed to examine the hypothesis that patients with hip osteoarthritis (OA) have a shorter duration of symptoms but more advanced radiological changes and more severe symptoms at first presentation to our clinic than similar patients with knee OA.

Methods: This pilot case-comparison study compared 35 consecutive hip OA patients and 70 (age and sex matched) knee OA patients from a single tertiary osteoarthritis clinic from 2008 to 2011. BMI, total symptom duration, duration of presenting complaint, Multi-attribute Arthritis Prioritisation Tool (MAPT) scores and Modified Kellgren-Lawrence (MKL) scores were recorded for each patient's first presentation to the clinic, where available. The MAPT score, designed to prioritise and monitor patients who may require joint surgery, is a severity score (out of a total of 100) derived from a standardised patient questionnaire. Data for the two groups was compared by non-parametric Mann-Whitney U testing, performed by a statistician who was blinded to the study hypothesis.

Results: Both groups had similar age, sex and BMI. The hip MAPT score (median = 71.3, interquartile range 37.9–89.6) was significantly higher than the knee MAPT score (median = 36.9, IQR 11.4–74.8); mean rank for hip group was 64.8 and mean rank for knee group was 47.1 ($U = 1638$, p = 0.005). The hip MKL scores (median = 4, IQR 4–5) were significantly higher than the knee MKL scores (median 4, IQR 3–4); mean rank for hip group was 65.7 and mean rank for knee group was 46.7 ($U = 1669.5$, p = 0.002). The total duration of symptoms for the hip group (median = 30, IQR 12–54 months) was significantly less than the duration of symptom for the knee group (median = 48, IQR 24–108 months); mean rank for hip group was 33.6 and mean rank for knee group was 44.1 ($U = 545.5$, p = 0.045). The duration of presenting complaint for the hip group (median = 6, IQR 3.0–6.5 months) was significantly less than the duration of presenting complaint for the knee group (median = 9.5, IQR 5.5–12.0 months); mean rank for hip group was 32.1 and mean rank for knee group was 45.1 ($U = 500$, p = 0.012).

Conclusion: In this pilot case-comparison study, patients with hip OA presented after a shorter duration of symptoms with higher MAPT and MKL scores than their knee OA counterparts. In other words, hip OA patients were more likely to present earlier to our clinic but were conversely more likely to have more advanced radiological changes and worse symptoms (by MAPT score) than knee OA patients. These findings support our hypothesis and warrant a larger observational study.

270

Use of Drug Combinations in Patients with Osteoarthritis: A Population-Based Cohort Study. Daniel Prieto-Alhambra[1] and Rosa Morros[2]. [1]URFOA-IMIM, Parc de Salut Mar; Idiap Jordi Gol; University of Oxford; University of Southampton, Barcelona, Spain, [2]IDIAP Jordi Gol; Institut Català de la Salut, Spain

Background/Purpose: Patients affected with osteoarthritis (OA) use different drugs in search for relief. We used a large database including medical records and pharmacy invoice data to explore use of drugs in OA patients in the period 2006–2010: non-steroidal anti-inflammatory drugs (NSAIDs), Symptomatic Slow Acting Drugs for OA (SYSADOA), COX-2 inhibitors (COX2i), opioids, and analgesics (paracetamol and metamizol).

Methods: We screened the SIDIAP Database (www.sidiap.org) to identify those aged 40 years or older with a new diagnosis of OA, and ascertained use of NSAIDs, COX2i, SYSADOA, opioids, and analgesics in the period 2006–2010. SIDIAP contains anonymised medical records and pharmacy invoice data of a representative >4.9 million people in Catalonia (North-East Spain). We estimated prevalence (and 99% Confidence Intervals) of use of these drugs and their combinations, and the incidence (and 99%CI) of new users among newly diagnosed OA patients in the study period assuming a Poisson distribution.

Results: We identified 238,536 patients with an incident clinical diagnosis of OA. Among these, 128,655(53.9%) were treated with 3 or more drugs, and 60,740(25.5%) with 2 drugs. The most common combinations among the latter were:1.oral NSAID+analgesic, 2.topical NSAID+analgesic, and 3.oral NSAID+SYSADOA. Besides, 34,802(14.6%) patients received only 1 drug (the 3 most common being, in descending order: oral NSAID, analgesic and SYSADOA), and 14,339(6.0%) were not on pharmacologic treatment. Incidence of use of oral and topical NSAIDs, SYSADOA and analgesics decreased slowly from 2006 to 2010, while opioids increased continuously in the same period [Figure]. Incidence of use of COX2i rose steeply in the period 2006–2008, and continued increasing slowly from then onwards [Figure].
Figure. Incidence rates (and 99%CI) of newly indicated drugs for OA in the period 2006–2010: a) The most commonly used analgesic (Paracetamol), SYSADOAs and the most commonly prescribed opioid (tramadol) [top]; b) Topical and oral NSAIDs, Paracetamol (alone and combined with other drugs), and Opioids; c) Cox 2 inhibitors.

Conclusion: About 75% of OA patients are treated with at least 2 drugs, and more than half receive 3 or more. Incidence of use of commonly used drugs (such as analgesics and topical NSAIDs) is decreasing, whilst prescriptions of opioids increase. In addition, use of COX2i continues to grow, yet

more slowly after 2008, when warnings on the detrimental effects of COX2i on cardiovascular health were published. These data suggest that patients with OA are often polymedicated, and that current guidelines are poorly implemented in general practice. This has potential implications not only in terms of health care costs but also for patient safety.

Bone Marrow Lesions in Knees with Osteoarthritis: Can Parameters From Dynamic Contrast Enhancement Predict Change in Bone Marrow Lesion Volume or Knee Pain Change? Andrew D. Gait[1], Timothy F. Cootes[1], Elizabeth J. Marjanovic[1], Matthew J. Parkes[1], Charles E. Hutchinson[2] and David T. Felson[1]. [1]University of Manchester, Manchester, United Kingdom, [2]University of Warwick, Coventry, United Kingdom

Background/Purpose: Dynamic contrast enhancement is a powerful tool for highlighting features of a medical image which may not otherwise be seen on "static" scans. While used extensively in other settings, it has not been used until now to study bone marrow lesions (BMLs) in osteoarthritis (OA), lesions which vary over time in volume and change with knee pain.

Methods: We studied 23 patients who had patellofemoral (PF) OA. All met ACR criteria for knee OA and were participating in a trial of PF knee braces. All patients had no treatment at baseline, were on brace at 12 weeks and acquired MRI's with a gadolinium(Gd)-enhanced dynamic image sequence at both times.

Within these knees, 40 PF or femoral BMLs were manually segmented at baseline and 12 weeks on sagittal Gd-enhanced images (TR 500ms, TE 17ms, FoV 16cm, 384×384). Knee osteoarthritis outcome score (KOOS) pain data was collected at each time.

We assessed dynamic parameters within BMLs in two steps: (1) transforming the segmented BML from the sagittal sequence to the axial dynamic sequence (TR 5.4ms, TE 1.9ms, FoV 14cm, 256×256); (2) using the extended Kety model (Tofts 1997) to calculate the parameters v_e (fractional extracellular volume), v_p (fractional blood plasma volume) and K^{trans} (transfer coefficient from v_p to v_e:a direct measure of perfusion) at each voxel. The mean of each parameter was calculated for each BML (one to three per patient), taking care to ensure that this was done consistently between the baseline and 12 week images. The distribution of K^{trans} within the BMLs was heterogeneous and limited to small volumes, so to avoid averaging of diverse values, we examined peak K^{trans} value in the BML also. To compare with KOOS, mean parameters and peak K^{trans} value were examined across all BMLs within a knee.

To evaluate the relation of the parameters to BML volumes and KOOS, we calculated Spearman rank correlation coefficients.

Results: After 12 weeks, change in mean values of the parameters K^{trans}, v_e and v_p did not correlate either with change in volume of the BML (K^{trans}: r=0.02; v_e: r=−0.07; v_p: r=0.02) or change in KOOS (K^{trans}: r=0.18; v_e: r=0.03; v_p: r=0.09). Change in the peak value of K^{trans} correlated better with change in volume of the BML (r=0.43: p=0.0056, see figure) but not with KOOS (r=−0.11).

Change in Ktrans max vs Change in BML volume
Conclusion: There are no clear correlations between the means of the parameters K^{trans}, v_e and v_p and change in BML volume or KOOS. The peak K^{trans} value of a BML may be related to its likelihood of undergoing change.

Interim Safety Analysis of a Phase 2, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group, Efficacy Study of Apremilast (CC10004) in Subjects with Erosive Hand Osteoarthritis. Juergen Rech[1], Wolfgang Ochs[2], Wolfgang Spieler[3], Herbert Kellner[4], Ulf Müller-Ladner[5], Mathias Grunke[6], Matthias Schneider[7] and Georg Schett[8]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Rheumatology Practice, Bayreuth, Bayreuth, Germany, [3]Rheumatology Specialty Practice, Zerbst, Germany, [4]Centre for Inflammatory Joint Diseases, Munich, Germany, [5]Kerckhoff-Klinik GmbH, Bad Nauheim, Germany, [6]Medizinische Klinik und Poliklinik IV, University of Munich, Munich, Germany, [7]Heinrich-Heine-University, Duesseldorf, Germany, [8]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Apremilast is a small molecule, specific phospodiesterase4 inhibitor under investigation for a number of inflammatory conditions, including psoriasis and psoriatic arthritis. We report results of an interim safety analysis of a phase 2, multicenter, randomized, double-blind, placebo-controlled, parallel-group study in 18 patients with erosive hand osteoarthritis (EHOA).

Methods: Subjects with a diagnosis of EHOA, fulfilling the classification criteria of the American College of Rheumatology with a disease duration of ≥6 months, were randomized to oral apremilast 20 mg BID or matching placebo. All subjects with at least the baseline visit reported were included in the analysis. Adverse events (AEs) were graded according to the Common Terminology Criteria for Adverse Events (CTCAE) v3.0.

Results: A total of 76 AEs were reported since the study started in 2010 (FPFV 29-Nov-2010, data lock for interim analysis 30-May-2012). Most AEs were mild to moderate in severity (93.5%); only 5 (6.6%) were grade 3 (severe). No grade 4 or 5 AEs were reported. The most commonly reported AEs were related to "Pain " 38% (Pain-Head/headache in 6/11 patients (55%) and Pain-Joint in 3/11 patients (27%) or "Gastrointestinal" (18%), with the most frequent AEs being headache (16%), fatigue (8%), diarrhea (7%), and joint pain (7%). Thirty-five AEs (46%) were considered possibly treatment related. Of these, 97% were mild to moderate and only 1 (3%) was grade 3 (hypotension). The most frequent treatment-related AEs were headache (9/35 [26%]), fatigue (3/35 [9%]), and diarrhea (3/35 [9%]). No serious AEs or deaths were reported during the study.

Conclusion: Given the lack of treatment options for patients with EHOA, there is an unmet need for an effective treatment to reduce the burden of this disease. Considering the pathophysiology of EHOA, mechanism of action of phosphodiesterase 4 inhibitors, and the reported AEs in earlier trials, we conclude that apremilast may also be well tolerated in patients with EHOA. Apremilast, if proven to be efficacious in ongoing investigations, will be an interesting treatment option for patients with EHOA.

The Prevalence of Periarticular Lesions On Magnetic Resonance Imaging and Its Relation to Knee Pain in the Community Residents in Korea. In Je Kim[1], Kyeong Min Son[2], DH Kim[3], Yeong Wook Song[4], Ali Guermazi[5] and Hyun Ah Kim[6]. [1]Hallym University Kangdong Sacred Heart hospital, Seoul, South Korea, [2]Hallym university Chunchun sacred heart hospital, Chunchun, South Korea, [3]Chunchon, South Korea, [4]Seoul National University Hospital, Seoul, South Korea, [5]Boston University School of Medicine, Boston, MA, [6]Hallym University Sacred Heart Hospital, Kyunggi, South Korea

Background/Purpose: The purpose of this study was to investigate the prevalence of periarticular lesions detected by magnetic resonance imaging (MRI) and its association with knee pain and radiographic knee osteoarthritis (OA) in community residents in Korea.

Methods: Participants (n=357) were randomly chosen regardless of knee OA or knee pain from the population-based Hallym Aging Study. Demographic data and knee pain data including the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index were obtained by questionnaire.

We assessed periarticular lesions on 1.5-tesla MRI in the more symptomatic knee. Periarticular lesions included prepatellar or infrapatellar bursitis, anserine bursitis, Baker's cyst, and tibiofibular cyst. The association between each lesion and knee pain was examined by logistic regression analysis after adjustment of age, gender, body mass index, radiographic knee OA and other periarticular lesions.

Results: Radiographic knee OA was present in 34.5% of subjects. The most prevalent lesion was Baker's cyst (27.5%), followed by tibiofibular cyst (9.5%). Anserine bursitis was significantly associated with the presence of knee OA (OR 4.45, 95% CI [1.45–13.61]). Anserine bursitis among the subjects with OA was more common in the subjects with knee pain (21.8%) than in those without pain (7.1%). Anserine bursitis and Baker's cyst were significantly associated with knee pain (OR 3.47, 95% CI [1.18–10.21] and OR 2.03, 95% CI [1.19–3.45], respectively). Other periarticular lesions were not associated with knee pain or the presence of knee OA.

Conclusion: Incidental periarticular lesions on MRI of the knee are common in the middle- aged and elderly community residents in Korea. Anserine bursitis is related with knee pain and knee OA. Baker's cyst is associated with knee pain.

ACR Poster Session A
Pediatric Rheumatology - Clinical and Therapeutic Aspects: Pediatric Systemic Lupus Erythematosus, Pediatric Vasculitis and Pediatric Myositis
Sunday, November 11, 2012, 9:00 AM–6:00 PM

274

Childhood Onset Angiitis of the Central Nervous System: What Outcomes Can We Expect? Lena Das, Sook Fun Hoh, Terrence Thomas and Thaschawee Arkachaisri. KK Women's and Children's Hospital, Singapore, Singapore

Background/Purpose: Imaging findings in large-medium vessel Childhood Onset Primary and Secondary Angiitis of the Central Nervous System (cPACNS & cSACNS) are well described, however, structural changes of individual cerebral vessels after treatment has not been described. Our aim was to describe clinical outcomes and vessel progression using structural magnetic resonance angiography (MRA).

Methods: Children before age 16 with acute onset neuro-deficit and MRA findings suggestive of vasculitis-irregularity and/or narrowing of medium to large-sized cerebral vessels with repeated MRA studies, evaluated by pediatric rheumatologists and neurologists at KK Women's and Children's Hospital from January 2011–December 2012, were included. Patient demographic and clinical data were analysed. Median and interquartile range (IQR) were used for descriptive data.

Results: 7 patients were identified, 4 - cPACNS and 3–cSACNS (2–Takayasu Arteritis (TA), 1 - post-varicella CNS vasculitis). Median onset age was 9.0 years (IQR 6.4–14.0) with 5 males. Median follow-up duration was 21 months (IQR 7.0–31.0) with 3–6 months duration for repeated MRI/MRA (median numbers of MRI/MRA of 4 (IQR 2.0–6.0)). Motor deficits (hemiparesis) were present in 6/7, status epilepticus in 2/7 and aphasia and/or dysarthria in 4/7. Patient characteristics and distribution/sizes of cerebral vessels involved, along with the clinical outcomes and vessel progression after therapy is depicted in Table 1.

Upon a median follow-up of 21 months, all patients improved or had resolution of their initial motor deficits. They had also returned to school although 3/7 had continued cognitive impairment. None had clinical relapse despite further reduction of affected vessels (patient 3 at month 3, patient 1 at month 6 and patient 2 at month 9). All main arteries (MCA-M1, ACA-A1, ICA) were not recanalized at the end of the follow-up.

Table 1. Demographic, Clinical and Vessel Progression in Children with Angiitis of the CNS

Patient	Age (years)	Gender	Type*	Presentation	Treatment	Follow-up Time (months)	Initial MRA	MRA Outcome	Clinical Outcome**
1	6.4	M	P	R hemiparesis, GCS 15.	Aspirin, TCM	25	L MCA (M1)	L MCA (M1), ICA	No MD. No CI.
2	14	M	P	L hemiparesis, dysarthria, GCS 14.	Steroid pulses, CTX, MMF	17	R MCA (M1, M2)	R MCA (M1, M2), ICA	Improved MD. No CI.
3	9	M	P	R hemiparesis, aphasia, GCS 15.	Steroid pulses, CTX, MMF	21	L MCA, ACA (A1), ICA	No change	Improved MD. Improved CI. Mild aphasia.
4	8	F	S	R hemiparesis, aphasia, GCS 11.	Steroid pulses, CTX	7	L MCA (M1, M3, M4)	L MCA (M1)	No MD. No CI.
5	12	M	S	L hemiparesis, dysarthria, GCS 15.	Steroid pulses, CTX	3	R ICA, L ACA (A1)	Improved R ICA, L ACA	No MD. No CI.
6	1.75	M	S	Status epilepticus, GCS 12.	Acyclovir	54	L MCA (M1), ICA	L MCA (M1), ICA	Improved MD. Improved CI. Ongoing seizures.
7	14	F	P	L hemiparesis, status epilepticus, GCS 6.	Steroid pulses, CTX, MMF	31	L MCA (M1)	L MCA (M1)	No MD. Improved CI.

*Type: P Primary, S Secondary; GCS Glasgow Coma Scale; MCA Middle cerebral artery; ACA anterior cerebral artery; ICA internal carotid artery; TCM Traditional Chinese Medicine; CTX Cyclophosphamide; *Clinical Outcome: MD Motor Deficit; CI Cognitive Impairment

Conclusion: Despite our small cohort and regardless of the cause, after almost 2 years of follow-up, main arteries including MCA-M1 and ACA-A1, did not seem to recanalize. Interval improvements on MRA seemed to be limited to smaller M2 and M3 branches. Clinical outcomes, especially motor deficits may not follow the cerebral vessel course over time, however. Due to the rarity of diseases, multicenter with larger cohort studies are needed to confirm our initial observations and this is ongoing in our region.

Pediatric Rheumatology Practitioners Experience with Biologics in Juvenile Dermatomyositis: Survey Results. Anjali Patwardhan[1], Kelly Rouster-Stevens[2], Harry L. Gewanter[3], Grant D. Syverson[4], Renee F. Modica[5], Kara M. Schmidt[6] and Charles H. Spencer[1]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Emory-Children's Center, Atlanta, GA, [3]Pediatric & Adolescent HP, Midlothian, VA, [4]Medical College of Wisconsin, Wauwatosa, WI, [5]University of Florida, Gainesville, FL, [6]Univ of Louisville, Louisville, KY

Background/Purpose: Biologic therapy is increasingly prescribed in rheumatologic disorders. Juvenile dermatomyositis (JDM), the most common inflammatory myopathy in children, can be challenging to manage in a subset of patients. There are multiple reports of cytokine involvement in JDM. There is a paucity of information regarding the use of biologics for JDM among pediatric rheumatology practitioners, and only one clinical trial investigating a biologic in JDM. The purpose of the study is to examine pediatric rheumatology (PR) experience in North America with biologic therapy in children with JDM

Methods: The Childhood Arthritis and Rheumatology Research Alliance JDM Subcommittee on Biologics developed a 15-question on-line survey. Of the 231 pediatric rheumatology practitioners contacted, 105 (45%) participated between 2/17-3/20/2012

Results: Over half (57%) of the respondents currently managed 1–10 patients with JDM; 10% of respondents reported ≥20 patients with JDM in their practice. Sixty-one percent of respondents had used biologics in patients with JDM, with 32%, 5%, and 4% prescribing rituximab, etanercept and infliximab, respectively; 17% had prescribed more than one biologic. The majority of respondents (89%) had used biologics in combination with other therapies, while 11% had used biologics as monotherapy in JDM. The biologics used by the respondants were, rituximab, infliximab, etanercept and anakinra and abatacept. Among the respondents that used biologics, uncontrolled disease was the primary rationale for prescribing this medication. Over half of respondents used biologics after the patients failed other therapies; 11% of respondents used biologics for systemic (internal organ) involvement and 15% had used biologics for severe ulcerative disease. Seventy-three percent of respondents that used biologics noted improvement, while 10% reported worsening disease. Over half (53%) of respondents that used biologics noted improvement in calcinosis, while 64% reported side effects (common and uncommon). Among the respondents that had not used biologics (39%) in JDM, 88% would use this therapy if the opportunity arose; nearly half (47%) of these respondents had not used biologics because of

uncertainty regarding effectiveness in JDM. Seventy percent of practitioners recommended that biologics be formally studied in patients with JDM; 24% of respondents were unsure and 6% felt biologics should not be studied in patients with JDM

Conclusion: Several PR have used biologics in the management of pediatric patients with JDM. Among respondents that have not used biologics in this patient population, most would be interested in prescribing biologics. This survey supports the rationale for considering clinical trials and consensus protocols to elucidate the safety and effectiveness of biologics in children with JDM. Further information will be gathered by the CARRA JDM Subcommittee on Biologics through second survey to prioritize specific medications for investigation

Development of a Longitudinal, Propective Cohort of Young Adults with Childhood-Onset Systemic Lupus Erythematosus. Aimee O. Hersh[1], Erica F. Lawson[2], Emily von Scheven[2], Edward Yelin[3] and John F. Bohnsack[1]. [1]University of Utah, Salt Lake City, UT, [2]UC San Francisco, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA

Background/Purpose: Data on the adult outcomes of childhood-onset systemic lupus erythematosus (cSLE) are lacking, and a feasible methodology is needed to obtain long-term follow-up on these patients after transition from pediatric to adult rheumatology care. The purpose of this study was to use established methodology to develop a prospective longitudinal cohort study of young adults with cSLE, in order to assess long-term clinical, socioeconomic and behavioral health outcomes.

Methods: Based on prior methodology utilized in the University of California San Francisco Lupus Outcomes Study (Yelin, 2007), a 45 minute baseline in-depth telephone interview survey was developed which includes patient-reported validated items pertaining to multiple domains including demographic and socioeconomic characteristics, cumulative disease manifestations, recent SLE activity and assessment of the transition from pediatric to adult rheumatology care. The survey was pilot tested and revised based on responses from the pilot testing. The initial cohort was developed by querying the clinical database from the University of Utah pediatric rheumatology clinic to identify patients diagnosed with cSLE (age <18 years at diagnosis) who are currently 18–30 years of age and met ACR criteria for SLE at diagnosis. Potential subjects were contacted by mail using their last known address in their medical record; interested subjects who received mailings returned a response card indicating their interest in study participation. These subjects were contacted by phone and completed the baseline interviews, and will be interviewed annually.

Results: 109 potential subjects were identified and contacted by mail, 50 subjects indicated an interest in participating; no response forms were returned which declined participation in the study. Twenty-six potential subjects were not reachable due to out of date contact information and 8 subjects were deceased. To date, 41 subjects have completed the baseline interview. Median age is 24 years (range 18–30), median disease duration is 11 years (range 4–20). The cohort is 95% female, ethnicities include Caucasian (78%), Hispanic (15%) and other (7%). Sixty-eight percent of subjects reported a history of renal disease; 51% had a history of renal biopsy and 2 subjects had a renal transplant. Nine subjects (22%) reported a lupus flare in the 3 months prior to the baseline interview. Eleven (26%) of subjects reported an emergency room visit for their SLE within the past year, nine (22%) subjects were hospitalized. Eight-five percent of subjects rated their health as "excellent/very good/good" and 15% rated their health as "fair/poor." Thirteen (32%) of subjects reported a lapse in insurance since turning 18, seven (17%) of subjects reported that this had a direct, negative impact on their health.

Conclusion: This abstract describes the successful establishment of a prospective longitudinal cohort of patients with cSLE as they enter adulthood. Such an inception cohort will permit the accurate estimation of the impact of biologic, socioeconomic, behavioral and access-to-care factors on disease outcomes over time.

Dyslipidemia in Juvenile Dermatomyositis: The Role of Disease Activity. Katia T. Kozu[1], Clovis Artur Silva[2], Eloisa Bonfa[1], Adriana M. Sallum[3], Rosa M.R. Pereira[4], Vilma S. Viana[1], Eduardo F. Borba[5] and Lucia M. A. Campos[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo-SP, Brazil, [4]University of São Paulo, São Paulo, Brazil, [5]University of Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Dyslipidemia has been infrequently investigated in pediatric population with autoimmune rheumatic diseases. However, lipid abnormalities in these diseases may occur due to multiple risk factors such as body composition, chronic inflammation, autoantibodies, lipodystrophy, sedentarism and therapy, especially glucocorticoid. The objectives of this study was to evaluate the presence of dyslipidemia in Juvenile Dermatomyositis (JDM) and its possible risk factors.

Methods: 25 JDM patients were compared to 25 healthy controls according to demographic data, body composition, fasting lipoproteins, glycemia, insulin, antibodies and muscle enzymes. The following JDM scores were assessed: Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing (MMT), Disease Activity Score (DAS), Myositis Disease Activity Assessment Analogue Scale (MYOACT) and Myositis Intention to Treat Activity Index (MYTAX).

Results: Abnormal lipid profile was found in nine patients and four controls (36% vs. 16%, p=0.196). JDM patients demonstrated significant higher levels of triglycerides (TG) [80 (31–340) vs. 61 (19–182) mg/dL, p=0.011] and higher frequency of abnormal levels of high density lipoproteins (HDL) (28% vs. 4%, p=0.04) when compared to controls. JDM patients with dyslipidemia demonstrated significant lower median of HDL levels compared to those without this condition [29 (0–49) vs. 50 (39–72) mg/dL, p=0.0005] and also had significant higher TG levels [128 (31–340) vs. 69 (46–138) mg/dL, p=0.011]. JDM with dyslipidemia demonstrated a higher frequency of low HDL levels (77% vs. 0%, p=0.0001), and also a higher frequency of increased levels of TG (44% vs. 0%, p=0.01), and TC (33% vs. 0%, p=0.03). Positive anti-LPL antibody was detected in just one JDM patient with abnormal lipid profile. JDM with dyslipidemia had higher ESR (26 vs. 14.5mm/1[st]hour, p=0.006), CRP (2.1 vs. 0.4mg/dL, p=0.01), DAS (6 vs. 2, p=0.008), MYOACT (0.13 vs. 0.01, p=0.012), MYTAX (0.06 vs. 0, p=0.018), and lower scores of CMAS (47 vs. 52, p=0.024) and MMT (78 vs. 80, p=0.001) compared to JDM without dyslipidemia. Positive correlations were detected between TG levels and CRP(r=0.697, p=0.001), DAS (r=0.610, p=0.001), MYOACT (r=0.661, p=0.001), MYTAX (r=0.511, p=0.008), and negative correlations with CMAS (r=−0.506, p=0.009) and MMT (r=−0.535, p=0.005). No differences were found between these groups regarding body composition, lipodystrophy, anti-LPL antibodies, and treatment (current and cumulative doses of prednisone, methotrexate and hydroxichloroquine) (p>0.05), except by higher frequency of cyclosporine current use in patients with dyslipidemia (33% vs. 0%, p=0.03).

Conclusion: Dyslipidemia in JDM patients was characterized by increased levels of TG and low levels of HDL, and disease activity and cyclosporine use were the mainly factors associated to these metabolic abnormalities.

Evaluating Cardiovascular Risk Factors of Impaired Glucose Tolerance, Diabetes Mellitus, and Metabolic Syndrome in a Primarily Latino Population with Pediatric Rheumatic Diseases Associated with Vasculitis. Sara M. Stern, Jamie Wood, Katherine AB Marzan, Andreas Reiff, Bracha Shaham and Diane Brown. Children's Hospital Los Angeles, Los Angeles, CA

Background/Purpose: Pediatric (PED) systemic rheumatic diseases associated with vasculitis (DAV) such as Systemic Lupus Erythematosus (SLE), Mixed Connective Tissue Disease (MCTD) and the various systemic vasculitides (SV) were previously largely fatal but are now chronic diseases (DZ). However, as adults these patients (pts) appear to have advanced cardiovascular disease (CV) with atherosclerosis that begins in childhood and is impacted by risk factors. The objective of this study was to evaluate PED

pts with DAV for risk factors of CV: diabetes mellitus (DM), impaired glucose tolerance (IGT), and metabolic syndrome (MS).

Methods: A prospective study of 14 PED pts with DAV at a tertiary care children's hospital. Each pt had 3 manual blood pressures (BP), a waist circumference, and a physical exam. After an overnight fast, a 2 hour oral glucose tolerance test (OGTT), fasting insulin level, fasting lipid panel, c-peptide, and hemoglobin A1c (HbA1c) were completed. Outcome measures included the OGTT, HDL and triglyceride (TG) levels, homeostatic model insulin resistance index (HOMA-IRI) and a diagnosis of MS. MS was established when 3 of 5 criteria (CR) were met: waist circumference ≥ 90% for age and gender (A&G), high TG (≥ 90% A&G), low HDL (≤10% A&G), high BP (systolic or diastolic BP > 90% for height, A&G or taking BP medication), and IGT (OGTT 2-h glucose ≥ 140 mg/dl). Insulin resistance (IR) was defined as a HOMA-IRI > 3.0.

Results: 14 pts (12F:2M) 11.5 to 16.9 yrs old were included; 10 pts with SLE, 2 with MCTD, 1 with granulomatosis with polyangiitis (GPA/WG), and 1 with microscopic polyangiitis (MPA). Mean age of DZ onset was 12 yrs with mean DZ duration of 2.6 years. 12/14pts were Latino. The majority of pts were Tanner (T) 3–5 (T3 29%, T4 29%, T5 21%) for pubic hair and T4–5 (T4 42%, T5 25%) for breast development. 10 pts had normal BMIs, 1 was < 5%ile, 2 were between 85th and 95th %ile, and 1 was > 95th %ile. All SLE pts had mild DZ activity by SLE Disease Activity Index (SLEDAI) and both pts with SV had a Birmingham Vasculitis Activity Scale of 1. All pts had a history of steroid use with 10 pts currently using steroids: 4 (1–5 mg), 2 (6–15 mg), 4 (16–30 mg) daily.

1 pt met 3 CR for MS (SLE), 2 pts met 2 CR (1 SLE, 1 MCTD), 7 pts met 1 CR (5 SLE, 1 MCTD, 1 SV). 5 (3SLE, 2MCTD) met criteria for HDL, 2 (2SLE) for TG, 5 for BP (3SLE, 1MCTD, 1SV), 1 (SLE) for waist circumference, and 1 (SLE) for IGT. Pts had a mean HbA1c of 5.3 ±0.25% and none met criteria for DM. 1 pt had a HOMA-IRI >3.0. 5 pts (SLE) had acanthosis nigracans, and 5 (3SLE, 1MCTD, 1SV) had high c-peptide levels (> 3.1 ng/mL). Of the 5 pts with elevated c-peptide, 3 (2SLE, 1 MCTD) had high fasting insulin (> 10 ulU/mL).

Conclusion: High rates of elevated c-peptide levels and low HDL levels were seen in PED pts with DAV. No pts met criteria for DM. While only 1 pt met formal criteria for MS, IGT, and IR, a majority of pts had components of MS and/or IR. Higher rates (71.4% vs 40.7%) of pts had ≥1 criteria of MS compared to the general adolescent Mexican-American population in the NHANES III study where a less stringent definition was used for MS (S. Cook et al). These findings illustrate that CV risk factors are prevalent in PED pts with DAV and screening should be routinely completed.

279

Distribution of Vasculitides in Childhood Arthritis and Rheumatology Research Alliance-Affiliated Pediatric Rheumatology Centers in the United States. Melissa A. Lerman[1], Peter A. Merkel[2] and for the CARRA Registry Investigators[3]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Stanford

Background/Purpose: The epidemiology of pediatric vasculitis is poorly described. Two studies in the 1990s described the frequency in pediatric rheumatology centers in the United States and Canada (1.2–2.4% of rheumatologic diagnoses). Subsequently, consensus classification criteria for pediatric vasculitis were developed, yet disease patterns have not been reassessed. Although many immunomodulatory regimens are used, practice patterns for treatment of pediatric vasculitis are not known. Recently, the Childhood Arthritis and Rheumatology Research Alliance developed a registry of children treated at pediatric rheumatology centers in the United States (CARRAnet). The purpose of this study was to delineate the distribution and treatment of vasculitides within the first 24 months of CARRAnet.

Methods: This is a retrospective observational cohort study using CARRAnet. 55 centers submitted data on patients with defined rheumatologic disease (vasculitis, 35 centers) (May 2010-May, 2012). Not all patients with these diagnoses at each study site were included. Demographic, diagnostic evaluation, disease manifestation, and treatment data were collected using standardized forms and entered into an electronic database. This cohort includes children with vasculitis: granulomatosis with polyangiitis (GPA); Beh et's disease (BD); Takayasu arteritis (TAK); microscopic polyangiitis (MPA); central nervous system vasculitis (CNSV); systemic polyarteritis nodosa (PAN); cutaneous PAN; Churg-Strauss syndrome (CSS).

Results: 129 children, 1.8% of the registry, had vasculitis (Table 1). The median age of onset was 12.1 years; the median time to diagnosis was 2.8 years. There was a significant difference in the distribution of the age at onset (p<0.01), but not in the distribution of sex, race, or ethnicity (p=0.14, p=0.28, p=0.68), between vasculitides. Most children were treated with glucocorticoids (96%) and a non-biologic disease modifying anti-rheumatic drug (DMARD) (91%); 60% were treated with cyclophosphamide. 33% were treated with a biologic DMARD: tumor-necrosis factor inhibition (14%); CD20-depletion (15%).

Table 1.   Demographics and Treatment of Vasculitis in CARRAnet*

Disease	Number	% of CARRAnet**	
Vasculitis	129	1.8 (1.5, 2.1)	
	Number	**% of Vasculitis****	
Granulomatosis with Polyangiitis	64	49.6 (40.7–58.5)	
Behcet's Disease	18	14.0 (0.1–21.2)	
Takayasu Arteritis	16	12.4 (7.3–19.4)	
Microscopic Polyangiitis	11	8.5 (4.3–14.8)	
CNS Vasculitis	7	5.4 (2.2–10.9)	
Systemic PAN	7	5.4 (2.2–10.9)	
Cutaneous PAN	4	3.1 (0.9–7.7)	
Churg Strauss Syndrome	2	1.6 (0.2–5.5)	
Demographics	**Number**	**% of Vasculitis****	**p value†**
Sex (% Female)	77	59.7 (50.7–88.2)	0.14
Race (% Caucasian)	98	76.0 (67.7–83.1)	0.28
Ethnicity (% Hispanic)‡	14	10.9 (6.1–17.7)	0.69
		Median**	
Age Onset‡		12.1 (0.2–17.6)	<0.01
Time to Diagnosis§‡		2.8 (0.1–13.5)	0.03
Treatment	**Number**	**% of Vasculitis****	**p value†**
% Non-biologic DMARD	117	90.7 (84.3–95.1)	0.15
% Cyclophosphamide‡	77	59.7 (50.7–68.2)	<0.01
% Biologic DMARD	43	33.3 (25.3–42.2)	0.60
% TNF Inhibition	18	14.0 (8.5–21.2)	<0.01
% CD20 Depletion‡	19	14.7 (9.1–22.0)	—

*Abbreviations: CNS, central nervous system; PAN, polyarteritis nodosa; DMARD, disease modifying anti-rheumatic drug. TNF, Tumor Necrosis Factor.
**Percent (95% Confidence Interval); median in years (range), †Difference in distribution between vasculitides, significant p value ≤0.05. ‡Data not available on all 129 subjects. §Years from symptom onset to diagnosis.

Conclusion: While the frequency of vasculitis in CARRAnet is similar to that in earlier clinic-based registries, the distribution of diagnoses differs in that a greater percentage of children had GPA and TAK and a smaller percentage MPA. Compared to a recent pediatric GPA cohort, despite the increased use of CD20 depletion (15 vs. 1.5%), children were not spared exposure to cyclophosphamide (75 vs. 83%). Among pediatric rheumatology centers, treatment regimens for vasculitis vary considerably. This study demonstrates the usefulness of CARRAnet to study pediatric rheumatic conditions, especially rare vasculitides. Expanded enrollment of the cohort, and follow-up of cases, will provide important observational data not obtainable by single-center studies.

Pediatric automated Neuropsychological Assessment Metrics As a Screening Tool for Neuropsychiatric Childhood-Onset Systemic Lupus Erythematosus. Patricia Vega-Fernandez[1], Eyal Muscal[2], Natasha M. Ruth[3], Frank Zelko[4], Andrea Vincent[5], Erin C. Thomas[6], Marisa S. Klein-Gitelman[7], Debra Canter[8], Alison Tian[9], Lisa Ravindra[10], HaiMei Liu[11], Jessica Hummel[12], Deborah M. Levy[9], Hermine Brunner[13] and Tresa Roebuck-Spencer[5]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Baylor College of Medicine, Houston, TX, [3]Medical University of South Carolina, Charleston, SC, [4]Children's Memorial Hospital, Chicago, IL, [5]University of Oklahoma, Norman, OK, [6]Anne and Robert C Lurie Hospital, Feinstein School of Medicine, Northwestern University, Chicago, IL, [7]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [8]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [9]The Hospital for Sick Children, Toronto, ON, [10]University Hospital, Cincinnati, Cincinnati, OH, [11]Children's Hospital of Fundan University, Shanghai, China, [12]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [13]Cincinnati Children's Hospital Medical Center and PRSCG, Cincinnati, OH

Background/Purpose: Neuropsychiatric involvement appears to be common in childhood-onset systemic lupus erythematosus (cSLE), with

neurocognitive dysfunction (NCD) identified in as many as 59%. NCD is typically detected via formal neuropsychological testing but it is costly, time intensive, not readily available, and requires specialized advanced training. Recently, computerized tests have been explored as more feasible screening tools of NCD such as the Pediatric Automated Neuropsychological Assessment Metrics (PedANAM), a library of automated tasks assessing various aspects of cognitive status. The *objective* of this ongoing study is to determine the feasibility of the PedANAM to monitor cognitive status in cSLE in a clinical setting.

Methods: cSLE patients (pts) were recruited from 5 pediatric rheumatology centers. Demographic and disease relevant information was recorded. The 10 subtests of the PedANAM were administered to each patient. Pts were observed for at least part of the testing to document effort (motivation) and technical difficulties.

Results: Initial baseline data for 34 of an expected 200 pts were analyzed (94% females; mean age of 15.8 yrs; White 41%, Black 35%, Hispanic 18%, Asian 6%). Pts were mostly in high school; 2 pts repeated a grade, and 5 received special school services. PedANAM completion required 35–55 minutes. Mean reaction time for correct responses (MNc; in msec) and accuracy (AC; % of correct responses) were measured for each subtest. All pts completed testing. Six pts responded randomly and unusually quickly, which may indicate reduced motivation. Overall, pts had the greatest difficulty comprehending requirements on the continuous performance subtest (CPT) that measures working memory based on observation, self-report and poor performance patterns (e.g. low AC and high MNc scores). Pts were grouped by presence vs. absence of neuropsychiatric SLE (NPSLE) symptoms. Those with at least one symptom were significantly slower on a test of recognition memory (Code Substitution Delayed subtest or CDD) and less accurate on the CPT subtest (p's <.05). Using Pearson correlations, slower MNc and lower AC scores on the CDD were associated with disease activity measured by the SLEDAI (r= −.384; p =.036) (see Figure) and greater reported problems on the PCF-43 (r= −.463; p =.023).
Conclusion: This study demonstrated acceptable feasibility of the PedANAM to monitor cognitive status in a clinical setting. A few pts had difficulty with comprehension of test directions, particularly on the CPT, which may warrant re-evaluation of current test directions. These data demonstrate that slower performance on the CDD and less accurate performance on the CPT are related to greater disease symptomatology. Further research is needed to explore the relationship between cognition and cSLE activity.

281

The Pediatric Automated Neuropsychological Assessment Metrics - Reproducibility and Responsive to Change in Cognition in Childhood-Onset Lupus. Patricia Vega-Fernandez[1], Marisa S. Klein-Gitelman[2], Jessica Hummel[3], Erin C. Thomas[4], Jennifer L. Huggins[3], Frank Zelko[5], Tresa Roebuck-Spencer[6], Jun Ying[7] and Hermine Brunner[8]. [1]Cincinanti Children's Hospital Medical Center, Cincinnati, OH, [2]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Anne and Robert C Lurie Hospital, Feinstein School of Medicine, Northwestern University, Chicago, IL, [5]Children's Memorial Hospital, Chicago, IL, [6]University of Oklahoma, Norman, OK, [7]University of Cincinnati, Cincinnati, OH, [8]Cincinnati Children's Hospital Medical Center and PRSCG, Cincinnati, OH

Background/Purpose: The Childhood-onset Systemic Lupus Erythematosus (cSLE) *Neuropsychological Battery* (AC&R 2010; 62: 1029–33) was introduced to standardize neuropsychological testing (NPT), specifically probing the domains *Attention, Working Memory, Psychomotor Speed, Visuoconstructural Ability (VCA).* The Pediatric Automated Neuropsychological Assessment Metrics (PedANAM) software was developed to measure cognition in children ≥ 10 years. Performance on the PedANAM subtests is assessed by accuracy (AC = % of correct answers), mean reaction time for correct responses (MNc), & throughput (TP), the number of correct responses per minute. The *purpose of this study* was to (1) assess the reproducibility & (2) investigate the criterion validity of the PedANAM, using the *cSLE Neuropsychological Battery* as external standard.

Methods: cSLE patients and best-friend controls completed the PedANAM twice at baseline and then every 6 months. NPT was done at baseline and repeated after 18 month; Performance on Formal Neurocognitive Testing was standardized to age/gender/race-specific z-scores (mean 0, standard deviation 1) and then used to measure overall and domain-specific cognition (attention, processing-speed, working memory, VCA). Neurocognitive dysfunction (NCD) was graded as: no-NCD: all z-scores > −1; mild/moderate NCD: at most two z-scores < −1 but > −2 or one z-score < −2; moderate/severe: at least three z-scores < −1 or two z-scores < −2]. Intraclass and Spearman correlation coefficients were done to assess reproducibility and responsiveness to change.

Results: Among 40 cSLE & 40 controls (85% females), 13 (16.25%) had NCD at baseline and 18-month follow-up data were available for 24 cSLE and 16 control patients. Most subtests had good reproducibility in mean reaction time (MNc) and fair-good reproducibility in accuracy (AC) and consistency (CVc) (Table 1). Changes of AC scores were found positively related to changes of NCD domain scores. In particular, improved (worsening) NCD attention was found positively related to improved (or worsening) AC scores in Matching to Sample, Procedural Reaction Time, and Spatial Processing (r's >0.3, p's<0.05) over 18 months. Positive and negative relationships were also found between NCD domain scores and PedANAM MNc and CVc scores respectively (Table 2).

Table 1. Test-Retest reliability of the PedANAM of the PedANAM Scores

PedANAM Subtests	Mean reaction time for correct response (MNc)	Percentage of correct responses (AC)	Consistency (CVc = SD of MNc/MNc)
Code Substitution Delayed	0.58 (0.44, 0.71)	0.38 (0.21, 0.55)	0.21 (0.02, 0.40)
Code Substitution	0.80 (0.73, 0.88)	0.44 (0.27, 0.61)	0.43 (0.27, 0.60)
Continuous Performance Test	0.71 (0.61, 0.81)	0.78 (0.70, 0.86)	0.68 (0.57, 0.79)
Logical Relations	0.77 (0.69, 0.86)	0.23 (0.03, 0.43)	0.15 (0.00, 0.35)
Matching to Sample	0.64 (0.52, 0.76)	0.52 (0.37, 0.67)	0.57 (0.42, 0.72)
Matching Grids	0.77 (0.68, 0.85)	0.43 (0.25, 0.60)	0.38 (0.21, 0.56)
Mathematical Processing	0.91 (0.87, 0.95)	0.25 (0.05, 0.45)	0.62 (0.49, 0.75)
Procedural Reaction Time	0.47 (0.32, 0.62)	0.10 (0.00, 0.31)	0.16 (0.00, 0.38)
Spatial Processing	0.71 (0.61, 0.82)	0.26 (0.03, 0.49)	0.34 (0.17, 0.51)
Sternberg Memory Search	0.52 (0.38, 0.67)	0.55 (0.41, 0.69)	0.27 (0.10, 0.45)
Simple Reaction Time	0.68 (0.57, 0.79)	not estimable	not estimable

Values are intraclass correlation coefficients and 95% confidence intervals (in brackets).

Table 2. Relationship between changes of PedANAM score & changes of NCD domain scores*

PedANAM parameter	PedANAM Subtest*	ALL study participants (N=40)				
		Working Memory	Psychomotor Speed	Attention	Visuoconstructional Ability	All Domains
Percentage of correct responses (AC)	Code Substitution Delayed					
	Code Substitution					
	Continuous Performance Test					
	Logical Relations					
	Matching to Sample			0.35		0.30
	Matching Grids					
	Mathematical Processing					
	Procedural Reaction Time		0.36	0.34		0.39
	Spatial Processing			0.33	0.33	0.52
	Sternberg Memory Search					
Consistency (CVc = SD of MNc/MNc)	Code Substitution Delayed					
	Code Substitution					
	Continuous Performance Test			−0.32		
	Logical Relations					
	Matching to Sample		−0.35		−0.33	−0.41
	Matching Grids					
	Mathematical Processing					
	Procedural Reaction Time			−0.44		−0.38
	Spatial Processing					
	Sternberg Memory Search					
Mean reaction time for correct response (MNc)	Code Substitution Delayed				0.31	
	Code Substitution				0.40	
	Continuous Performance Test	0.31				
	Logical Relations					
	Matching to Sample		−0.36			
	Matching Grids					
	Mathematical Processing				0.39	
	Procedural Reaction Time				0.37	
	Spatial Processing				0.33	
	Sternberg Memory Search					

Conclusion: The PedANAM has good reproducibility especially for MNc measures. Changes cognitive domain scores were found significantly related to changes of performance scores of several PedANAM subtests over 18 months of follow up. These results are in line with our earlier research.

282

Clinical and Laboratory Features Distinguishing Juvenile Polymyositis and Muscular Dystrophy in Children.

Gulnara Mamyrova[1], James D. Katz[1], Robert V. Jones[1], Peter A. Lachenbruch[2], Mona Shah[2], Olcay Y. Jones[1], Anupam Chahal[1], Seema Agrawal[1], Frederick W. Miller[2], Lisa G. Rider[2] and the Childhood Myositis Heterogeneity Group[3]. [1]George Washington University, Washington, DC, [2]NIEHS, NIH, Bethesda, MD, [3]Bethesda, MD

Background/Purpose: We examined demographic, clinical and laboratory features of juvenile polymyositis (JPM) and muscular dystrophy in children to improve classification of these two conditions.

Methods: Thirty-nine patients with probable or definite JPM (31 JPM and 8 JPM overlapping with another connective tissue disease) by Bohan and Peter criteria and 9 patients with various muscular dystrophies (1 Duchenne's carrier, 8 limb girdle dystrophies) were examined. Differences in demographic and clinical features (including musculoskeletal, cutaneous, gastrointestinal, pulmonary, cardiac, constitutional signs and symptoms), muscle enzyme levels, Magnetic Resonance Imaging (MRI), electromyography (EMG), and muscle biopsy features between patients with JPM and dystrophies were evaluated by Fisher's exact and Rank sum tests. Backwards step-wise logistic regression modeling, followed by exact logistic regression, was performed to examine significant univariable differences between JPM and dystrophies in a multivariable model.

Results: Delay to diagnosis was longer in patients with dystrophies (median 12.0 months) compared with JPM (median 4.0 months, respectively, p=0.03). In addition, the following demographic, clinical and laboratory features distinguished JPM and dystrophies:

Features	JPM n/N (%)	Muscular dystrophies n/N (%)	P value
African-American Race	17/39 (43.6)	0/9 (0.0)	0.018
Insidious illness onset (○ 6 mo from first symptom to diagnosis)	11/31 (35.5)	7/9 (77.8)	0.05
Muscle atrophy on exam	17/37 (45.9)	8/9 (88.9)	0.027
Muscle atrophy on MRI	4/21 (19.0)	5/6 (83.3)	0.008
Increased insertional and spontaneous activity/fibrillation potentials on EMG	17/18 (94.4)	5/9 (55.6)	0.03
Complex repetitive discharge on EMG	16/23 (69.6)	2/9 (22.2)	0.02
Diffuse variation of myofiber size on muscle biopsy	20/38 (52.6)	9/9 (100.0)	0.008
Fiber hypertrophy on muscle biopsy	3/38 (7.9)	4/9 (44.4)	0.018
Myofiber fibrosis on muscle biopsy	4/38 (10.5)	5/9 (55.6)	0.007
Absence of response to treatment with prednisone	2/39 (5.1)	3/9 (33.3)	0.039
Absence of response to treatment with other immunosuppressive agents	2/39 (5.1)	4/9 (44.4)	0.008

Other features did not differ between JPM and dystrophies, including frequency of abnormal values and levels of serum muscle enzymes (CK, LDH, Aldolase, AST, and ALT); muscle edema and fatty replacement of muscle on MRI; inflammatory features on muscle biopsy; presence of short duration, small amplitude polyphasic motor units action potentials (MUAPS) and positive sharp waves on EMG; and demographic features (age at diagnosis, family history of autoimmune disease). Examining the 8 variables that were significant on univariate analysis in backwards selection stepwise logistic regression, followed by exact logistic regression, revealed less frequent myofiber fibrosis on muscle biopsy (OR = 0.1) and onset speed (OR = 0.16) to be significant predictors of JPM vs. muscular dystrophy. Because there were no African-American patients with dystrophies, a point estimate for race could not be obtained. The final multivariable model, including myofiber fibrosis, onset speed and race, provided a sensitivity of 55.6%, specificity of 97.2%, positive predictive value of 83.3%, and negative predictive value of 89.7%.

Conclusion: Muscular dystrophy can present similarly to patients with idiopathic inflammatory myopathy, particularly polymyositis. Selected demographic, clinical, and laboratory features may be helpful in distinguishing these patients, particularly the presence of myofiber fibrosis on muscle biopsy and a slower illness onset.

283

Hospitalizations for Patients with Chilhood-Onset Systemic Lupus Erythematosus in the Pediatric Health Information System Databse.

Aimee O. Hersh, Charlie Casper, Tellen D. Bennett, Susan L. Bratton, John F. Bohnsack and Rajendu Srivastava. University of Utah, Salt Lake City, UT

Background/Purpose: To describe patient demographics, admission characteristics and clinical care for hospitalized patients with childhood-onset systemic lupus erythematous (SLE).

Methods: Retrospective cohort study of the Pediatric Health Information System (PHIS) database, January 1, 2004 to December 31, 2010. The PHIS database was developed by the Children's Hospital Association and contains comprehensive administrative inpatient data from 43 independent, freestanding, pediatric hospitals in the United States. A total of 42 hospitals and 279.6 hospital-years of data were included in this analysis. The study cohort includes subjects with an International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) discharge diagnosis code for SLE (710.0) who had their first admission during the study period and were between 5–17 years old. Routine hospitalizations for intravenous (IV) cyclophosphamide were defined as hospitalizations with IV cyclophosphamide administration and a length of stay (LOS) of ≤ 2 days. ICD-9-CM and clinical transaction codes were used to identify commonly performed procedures and medications administered.

Results: We identified 11,647 admissions by 3,085 patients for childhood-onset SLE during the seven-year study period. Subjects had a median age (interquartile range (IQR)) of 14 (12–16) years, 81.7% were female, 36.3% African-American, 25.3% Hispanic, 21.8% White and 5.8% Asian. The median (IQR) and mean (SD) number of admissions per patient were 2 (1–4) and 3.8 (5.1) respectively. Fifty-one percent had a LOS of ≤ 2 days. Short-stay admissions associated with cyclophosphamide administration accounted for 2,108 (or 18.1%) of the total hospital admissions. Over the study period 25.5% of subjects had at least one admission to the intensive care unit. Table 1 summarizes the frequency of commonly performed procedures and administration of relevant medications. Fifty-nine (1.9%) subjects died during the study period resulting in an inpatient mortality per admission of 0.5%.

Table 1. Clinical care for childhood-onset SLE subjects in the PHIS database

	By Admission n= 11647	By Subject n=3085
Imaging, No. (%)		
Abdominal CT	607 (5.2)	475 (15.4)
Brain CT	714 (6.1)	529 (17.4)
Brain MRI	896 (7.7)	679 (22.0)
Brain MRA	515 (4.4)	418 (13.5)
Procedures, No. (%)		
Renal Biopsy	1080 (9.3)	932 (30.2)
Dialysis±	963 (8.3)	261 (8.5)
Electroencephalogram (EEG)	514 (4.4)	401 (13.0)
Ventilation Assistance	218 (1.9)	196 (6.4)
Immunosuppressive medications, No. (%)		
Any oral steroid	7206 (61.9)	2235 (72.4)
Methylprednisolone	5318 (45.7)	1992 (64.6)
Hydroxycholoroquine	5902 (50.7)	1767 (57.2)
Cyclophosphamide	3189 (27.4)	973 (31.5)
Mycophenolate Mofetil	2359 (20.3)	905 (29.3)
Azathioprine	613 (5.3)	298 (9.7)
Rituximab	580 (5.0)	288 (9.3)
Tacrolimus	285 (2.4)	127 (4.1)
Methotrexate	163 (1.4)	117 (3.8)
Immune Globulin (IVIG)	527 (4.5)	311 (10.1)

- CT = Computed Tomography
- MRI= Magnetic Resonance Imaging
- MRA= Magnetic Resonance Angiogram
- ± Includes hemodialysis and peritoneal dialysis

Conclusion: Utilizing the PHIS database, we identified a large cohort of hospitalized patients with childhood-onset SLE. Based on subject demographics and the expected frequency of commonly performed procedures and treatment, this cohort appears to be representative of the childhood-onset SLE population in the United States. Further work is needed to determine cause for admissions, subsequent treatment, and longitudinal outcomes for this cohort.

Treatment and Outcome of ANCA-Associated Vasculitis in Children: A Pilot Study. Marinka Twilt[1], Audrey Bell-Peter[1], Ronald M. Laxer[1], Christian Pagnoux[2], Diane Hebert[3], Elizabeth Harvey[3], Shehla Sheikh[1] and Susanne M. Benseler[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]Hospital for Sick Children, Toronto, ON

Background/Purpose: Childhood ANCA vasculitides are rare, yet organ- or even life-threatening systemic vasculitides. Children most frequently present with rapidly evolving, severe disease such as pulmonary-renal syndrome. In 2009, evidence-based EULAR treatment recommendations were published. Treatment efficacy and safety data are largely derived from adult studies. The aim of this study was to report treatment efficacy and safety of the 2009 EULAR recommendations for severe-moderate disease onset in consecutive pediatric patients with newly diagnosed ANCA vasculitides.

Methods: A single-center cohort study of consecutive children newly diagnosed with ANCA vasculitis since July 2010 was performed. All children were treated according to the implemented EULAR recommendations. Baseline clinical and laboratory characteristics, treatment regimens and their efficacy and safety were analyzed. Disease activity was documented using the Pediatric Vasculitis Activity Score (PVAS). Adverse and serious adverse events and disease damage were captured.

Results: A total of 8 children (4 female, 4 male) were included, median age at diagnosis was 13.8 years (range 10.9–17.4 years); presenting clinical features were nephritis in 7 (including renal failure in 2) and lung disease in 4 (including pulmonary hemorrhage in 3), ENT involvement in 3 (including subglottic stenoses in 2), and eye disease in 3 (1 episcleritis). Laboratory investigation: median ESR was 72mm/h, CRP 99mg/dl. ANCA testing was positive in 7 children (6 c-ANCA, +PR3, 1 p-anca, +MPO). All patients were treated with high dose prednisone, with a tapering scheme, and iv cyclophosphamide pulses, 4/8 received additional plasmapheresis (PLEX) (3 for pulmonary renal syndrome - 1 for renal failure). Seven children completed the induction therapy and were commenced on Azathioprine, with low-dose prednisone for maintenance. Disease activity at diagnosis: median PVAS was 19 (14–29); Follow-up PVAS: 3 (1–5) at 3 month and 3 (1–3) at 6 months. One child remained in renal failure and remains on dialysis. Safety: 50% of the PLEX treated children developed a central line clot and subsequent pulmonary embolism requiring long-term anticoagulation. No clots were seen in patients not treated with PLEX. Clots are a known complication of central lines though. Pulmonary blastomycosis was confirmed in one child receiving PLEX and cyclophosphamide, who presented with a single lung nodule at 3 months of treatment. She responded rapidly to anti-fungal therapy. No early disease flares were noticed during the follow-up.

Conclusion: A significant decrease in disease activity was seen in all children with newly diagnosed, severe ANCA vasculitis treated according to the EULAR recommendations (PVAS 19 to 3). An increased risk of clots was seen in children treated with adjunctive plasmapheresis.

Disclosure: M. Twilt, None; **A. Bell-Peter**, None; **R. M. Laxer**, None; **C. Pagnoux**, None; **D. Hebert**, None; **E. Harvey**, None; **S. Sheikh**, None; **S. M. Benseler**, None.

285

Rituximab for Severe Disease Flares in Childhood ANCA Vasculitides. Marinka Twilt[1], Rayfel Schneider[1], Audrey Bell-Peter[1], Sharon Dell[2] and Susanne M. Benseler[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]the Hospital for Sick Children, Toronto, ON

Background/Purpose: Children with ANCA vasculitides frequently present with life-threatening organ manifestations including alveolar hemorrhage, critical subglottic stenosis and renal failure due to rapidly progressive glomerulonephritis (GN). The current initial management for adults includes high-dose steroids and cyclophosphamide. The majority of patients experience a serious disease flare. In adult studies, Rituximab is highly effective in the treatment of severe vasculitis flares. The aim of this study was to evaluate efficacy and safety of Rituximab for treatment of severe disease flare in children with ANCA vasculitides.

Methods: A single-center cohort study of consecutive children with ANCA vasculitis treated with Rituximab for severe disease flares was performed between January 2009 until July 2011. Children were managed according to a previously implemented protocol. Clinical, laboratory and imaging features, previous therapies, including efficacy and safety were documented in serial assessments. Disease activity was captured by Pediatric Vasculitis Activity Score (PVAS). Safety evaluation included adverse events and disease-related damage domains by Vasculitis Damage index (VDI).

Results: Six children (5 females, 1 male) were included, median age at diagnosis 7.8 years. Diagnosis: All children had lung involvement including 4 presenting with hemorrhage, 3 with renal disease and 3 with ENT involvement, including subglottic stenosis in 2. ANCAs: +c-ANCA +PR3 in 4 patients, + p-ANCA +MPO in 1 and -ANCA + MPO in 1. All children previously received high dose steroids and cyclophosphamide; previous maintenance treatment included: azathioprine in 1, MMF in 2 and MTX in 4 children. Two patients were still on MTX maintenance at time of flare. Disease flare: median disease duration until time to flare was 16 months (12–62 months); 5/6 had lung flares (hemorrhage, new nodules) and 1 child developed new GN. Treatment: All 6 children received Rituximab (500 mg/m2, 2 doses q2weeks) plus high dose prednisone (2 mg/kg/day, max 60 mg/day) and one patients continued on MTX maintenance. Plasmapheresis just prior to Rituximab was used in 2 children. Efficacy: The median PVAS at time of flare was 6; 4 children had no evidence of active disease at 3 months (PVAS=0), and 5 at 12 months. All patients completely depleted their B-cells. After Rituximab therapy, ANCAs were positive in 4 patients at 3 months and 2 patients after 12 months. Safety: Infusion reactions were uncommon. One child experienced itchiness, fever and myalgias during the 2nd cycle of infusions. One patient developed Pneumocystis Jiroveci pneumonia. Five children received a second course of Rituximab at 6–13 months postinitial course upon return of their B-cells.

Conclusion: A complete response (PVAS=0) was seen in 67% of

children with severe disease flares of ANCA vasculitis following treatment with Rituximab and high dose prednisone. This is a significantly higher response rate than with the current induction treatment for childhood ANCA vasculitides. Retreatment with Rituximab was required in the majority of children. Rituximab therapy was effective and safe; however long-term observations will determine the safety of repeated Rituximab treatment.

286

The Association of *N*-Methyl-D-Aspartate Receptor Antibodies and Neurocognitive Dysfunction in Pediatric Lupus Patients and in the Offspring of Adult Patients with Lupus. Natasha M. Ruth[1], Mary C. Kral[2], Stephanie Slan[3], Tamara K. Nowling[1], Murray H. Passo[1] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC, [3]Medical University of South Carolina, Charlestons, SC

Background/Purpose: Approximately 1/5 of all systemic lupus erythematosus (SLE) starts in childhood and central nervous system (CNS) dysfunction is more common in childhood-onset SLE. CNS disease is second only to nephritis as a cause of morbidity and mortality in patients with SLE. Despite these findings, the diagnosis of CNS disease in SLE remains difficult. Anti-NMDA receptor antibodies are anti-double stranded DNA antibodies that cross react with the NMDA receptors NR2a and NR2b. The activation of the NMDA receptor is critical in learning and memory and is expressed on neurons throughout the hippocampus and cortex. The purpose of this study is to measure the prevalence of anti-NR2 glutamate receptor antibodies in patients with childhood onset SLE and JIA and to assess the association between elevated anti-NMDA-NR2 subunit receptor antibodies and neurocognitive dysfunction in pediatric patients with SLE and patients with JIA.

Methods: Patients diagnosed with SLE prior to age 18 were recruited along with a JIA control patient. Each patient underwent formal neurocognitive testing, assessing a range of cognitive domains. Serum NMDA receptor-NR-2 subunit antibody levels were measured in all subjects by ELISA.

Results: 17 lupus patients (16 female, 1 male, 9 African American, 5 Caucasian, 3 others), ages 10–20 and 7 JIA patients (5 female, 2 male, all Caucasian), ages 10–21 completed NMDA receptor antibody testing and of those all but one SLE patient completed formal neurocognitive testing. T-test comparison of the lupus cohort to the JIA cohort revealed that there were group differences for Full Scale IQ (p=.007), single word reading skills (p=.013), and math calculation skills (p=.039). The JIA patients performed better in these areas than did the SLE patients. The SLE patients also had higher NMDA receptor antibody levels and NMDA receptor antibodies correlated significantly (p=.005) with reaction time.
Conclusion: These findings suggest that pediatric patients with lupus have greater cognitive dysfunction than do patients with JIA. Patients with lupus also had higher NMDA receptor antibody levels than did the JIA controls. The higher antibody levels correlated with reaction time which has been a sensitive index of CNS injury in other diseases such as TBI. These preliminary results suggest that checking NMDA receptor antibody levels may be helpful in patients where there is concern for CNS lupus. Further research is necessary to study these antibody levels over time. We are also currently studying these antibody levels in children of mothers with SLE which will provide insight into the effects of fetal exposure during pregnancy.

287

Variation in Healthcare Utilization by Region and Number of Rheumatologists Per State Among Pediatric Medicaid Patients with Lupus Nephritis Prior to End-Stage Renal Disease in the United States, 2000–2004. Linda T. Hiraki[1], Candace H. Feldman[2], Graciela S. Alarcon[3], Jun Liu[4], Michael A. Fischer[2], Wolfgang C. Winkelmayer[5] and Karen H. Costenbader[6]. [1]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [5]Stanford University School of Medicine, Stanford, CA, [6]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Unequal healthcare access and utilization may contribute to the striking sociodemographic disparities seen in outcomes for children with lupus nephritis. Medicaid is the U.S. federal-state program providing health insurance to low-income children and parents. We investigated variation in US nationwide frequencies of emergency department (ED), outpatient and inpatient visits among children with lupus nephritis enrolled in Medicaid, 2000–2004, in the months preceding the development of end-stage renal disease (ESRD).

Methods: We identified all children aged 3 to <18 years with SLE (≥3 ICD-9 codes of 710.0, each >30 days apart) in the Medicaid Analytic eXtract (MAX) from 2000–2004. This dataset contains all outpatient and inpatient Medicaid claims for enrollees in 47 U. S. states and the District of Columbia. These data were linked to those from the U.S. Renal Data System, which includes information on essentially all ESRD patients in the U.S., for the same years. We compared utilization of ED, outpatient and inpatient visits per year in the Medicaid enrolled time prior to development of ESRD for those in different categories according to: region of residence in the US, residence in a US designated Health Professional Shortage Area (HPSA), and quartiles of rheumatologist number in state of residence. Multivariable generalized linear models were adjusted for each of these variables along with enrollee age, race, sex, months of Medicaid enrollment and a validated measure of socioeconomic status combining seven US Census zip code level variables.

Results: Of the 254 pediatric lupus nephritis patients identified, the mean age was 14.2 (± 2.4) years; 72% were female, 61% were African American and 19% were Hispanic. Mean duration of Medicaid enrollment prior to the onset of ESRD was 28.5 (±16.4) months. Among all patients there was an average of 2.0 (± 2.4) ED visits per year, 10.8 (± 9.4) outpatient visits and 2.4 (± 2.6) inpatient visits. In multivariable adjusted models, children residing in areas with the lowest quartile of rheumatologists per state had on average 4.2 more ED visits per year (p=0.001) compared with those in the highest quartile of rheumatologists per state. Children residing in the West had on average 5.4 more outpatient visits per year (p= 0.03), and those in the South had 1.2 fewer inpatient visit per year (p= 0.03) than those in the Northeast. We did not observe statistically significant variation in utilization by HPSA.

Conclusion: We observed significant differences in health care utilization among children enrolled in Medicaid with lupus nephritis prior to the onset of ESRD. Low number of rheumatologists per state was the most important factor associated with more annual ED visits. This finding in addition to regional variation in annual inpatient and outpatient visits within this medically complex and low-income Medicaid population deserves further investigation.

288

Validation of Promis Modules for Use in Childhood-Onset Lupus. Alexandria J. Greenler[1], Laura E. Schanberg[2], Michael P. Flannery[1], Shannen Nelson[1], Janet Wootton[2], Esi M. Morgan DeWitt[1] and Hermine I. Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Duke University Medical Center, Durham, NC

Background/Purpose: The impact of childhood-onset lupus (cSLE) and its treatment on quality of life (QoL) has not been systematically established. The *Patient Reported Outcomes Measurement Information System* (PROMIS™, http://nihpromis.org) is a publicly available system to measure patient reported outcomes that features electronic data collection. Although several legacy QoL measures have been validated for cSLE, each is longer than the *PROMIS™ Pediatric Short Forms* (Short Forms) which are ≤ 10 items each. The objective of this study was to investigate the feasibility and construct validity of the *Short Forms* in cSLE in a clinical setting.

Methods: As part of an ongoing project at two sites, 30 of 100 projected patients completed the *Pediatric PROMIS™ Short Forms* (Anger, Anxiety, Depression, Fatigue, Mobility, Upper Extremity, Pain Interference, Peer Relationships) and legacy QoL measures (Pediatric Quality of Life Inventory™ Generic Core [GC] & Rheumatology Modules [RM], Simple Measure of Impact of Lupus Erythematosus in Youngsters [SMILEY], Childhood Health Assessment Questionnaire [CHAQ], Child Health Questionnaire [CHQ], pain and well-being visual analog scales [VAS]). Questionnaire scores were compared and Pearson correlation analysis was performed in support of the construct validity of the Short Forms when used in cSLE.

Results: Participants (80% female; 48% White, 52% Black or Asian) had a mean age of 15.8 yrs (SD 2.1) and mean SLEDAI score of 5.8 (SD 4.57). No problems were encountered with completion of all PROMIS™ Short Forms (mean score = 50, clinically relevant score difference = 10) which required 5–10 minutes in total (legacy QoL tools >15 min each). On average, cSLE patients showed clinically relevant decrease in the Short Form assessing upper extremity function compared to healthy children, while the other QoL domains were less affected (Table 1). This is also supported by the scores of the CHQ-PHS and GC. Concurrent validity of the Short Forms is supported by moderate correlations with the scores of various legacy measures. Comparison to cohorts of healthy children and those with juvenile arthritis will be provided.

Table 1. Comparative scores of QoL Scores in cSLE*

PROMIS Short forms		CHAQ		PedsQL-GC		PedsQL-RM		SMILEY		CHQ-P5O	
Anger	49.5 (10.3)									Behavior (BE)	74.9 (11.3)
Anxiety	45.8 (11.6)					Worry	69.0 (22.7)				
				Emotional	74.6 (21.6)			Effect	67.3 (16.6)		
Depression	45.3 (10.1)									Mental Health (MH)	74.4 (10.8)
						Treatment	79.9 (16.2)	Burden	61.9 (15.8)	Self-esteem (SE)	18.1 (16.8)
Fatigue	49.9 (13.7)									Role/Social Limits-Physical (RP)	84.7 (26.0)
		Walk	0.3 (0.6)								
Mobility	47.5 (10.9)	Arise	0.5 (0.7)							Physical function (PF)	82.4 (21.2)
		Hygiene	0.2 (0.6)								
		Play	0.9 (0.8)								
		Dress & Grooming	0.3 (0.7)	Physical	68.2 (25.4)	Activity	86.9 (17.9)	Limitations	61.2 (21.4)

Completed by: Child										Completed by: Parent	

‡Values are means (standard deviations). ‡The PROMIS™ short form T score distributions are standardized such that a 50 represents the average for the US general population, and the standard deviation around that mean is 10 points. A high score always represents more of the concept being measured (for symptoms and other negatively-worded concepts like pain, fatigue, and anxiety, a 60 is one standard deviation worse than averages for functional scores and other positively-worded concepts like physical or peer relationships, a 60 is one standard deviation better than average).

Table 2. Construct validity of the PROMIS Short Forms

PROMIS SHORT FORMS	Anger	Anxiety	Depression	Fatigue	Mobility	Upper extremity function	Pain Interference	Peer relationships

Values are correlation coefficients
*denotes moderately significant (p < 0.050)
**denotes strongly significant (p < 0.001)

Conclusion: Preliminary analysis supports QoL measurement using the PROMIS™ Short Forms as feasible and concurrently valid. If confirmed in the larger sample, clinicians treating cSLE will be able to utilize PROMIS™ measures for a more efficient patient self-report of health outcomes, taking advantage of easy interpretation of scores and changes in scores, thereby, reducing respondent burden and making QoL assessment feasible in both research and clinical care settings.

Mycophenolate Mofetil and Abatacept Combination Therapy in Refractory Pediatric Systemic Lupus Erythematosus Nephritis. Rhina Castillo[1], Suhas M. Radhakrishna[2], Andreas O. Reiff[1] and Katherine AB Marzan[1]. [1]Children's Hospital Los Angeles, Los Angeles, CA, [2]Kaiser Permananete Medical Group, Oakland, CA

Background/Purpose: Nephritis (LN) in pediatric systemic lupus erythematosus (pSLE) requires treatment (tx) with corticosteroids (CS) and other agents such as mycophenolate mofetil (MMF) or cyclophosphamide (CYC). However, some patients (pts) fail standard therapy leaving physicians with few options. Although a recent phase II randomized controlled combination trial of abatacept and MMF (ABA+MMF) in adult SLE did not meet its endpoints, we examined if this combination therapy may have a therapeutic benefit in pSLE pts with refractory LN.

Methods: We performed a retrospective observational study in 5 pSLE pts with class IV and V lupus nephritis. All pts were treated with ABA+MMF after previous treatment and failure or intolerance to CYC and MMF with concomitant CS. Data collected included demographics, disease duration, renal histology and medications used. SLE Disease Activity score (SLEDAI) including parameters of systemic and renal disease activity were assessed at baseline and after 12 weeks of each tx.

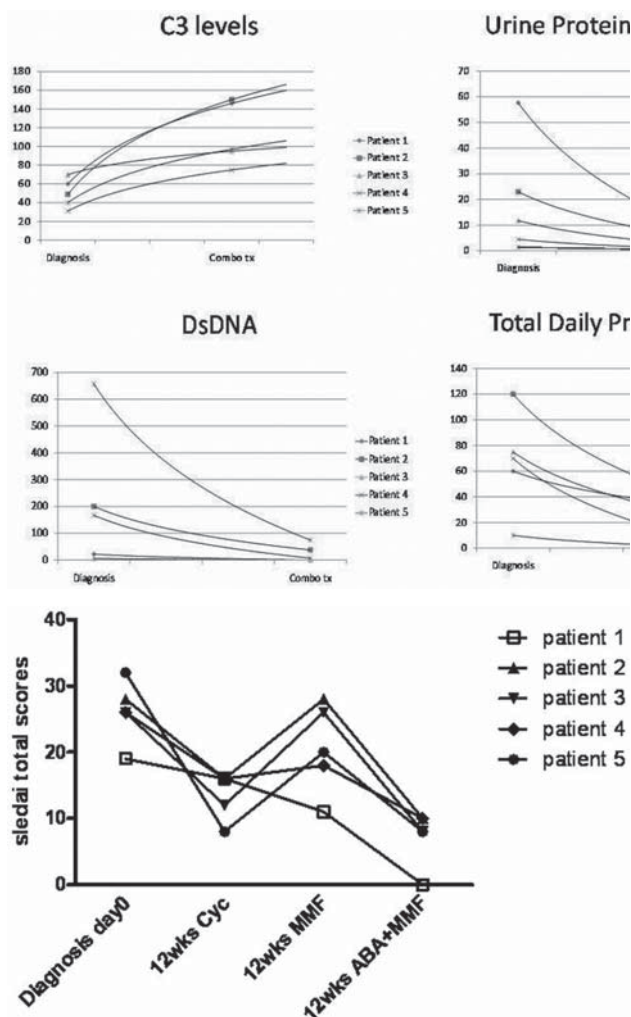
Results: Pt age at diagnosis was 9–15years (mean 12.6 ± 2.3). Average disease duration was 22–97 months (mo) (mean 52.8 ± 30.8), before ABA+MMF therapy was started. Two pts had class IV, 1 pt had class V and 2 pts had class IV/V LN.

All 5 pts had a statistically significant decrease in their SLEDAI scores and successfully had their steroid dose reduced while on ABA+MMF. One pt achieved complete remission and 3 pts were completely weaned off steroids after an average of 9 mo (3–16mo). Repeated ANOVA analyses comparing SLEDAI scores at baseline and after 12 weeks of CYC, MMF and ABA+MMF respectively, showed a statistically significant pattern of change from the baseline score with each change in therapy (P<0.0001). Paired comparison of SLEDAI scores on each drug to baseline scores showed the most significant improvement with combination therapy (MMF+ABA p=0.0001, CYC p=0.0199, MMF p=0.0520).

C3 levels

Urine Protein

DsDNA

Total Daily Pr


Conclusion: The above data suggests that combination therapy with ABA+ MMF can be superior to MMF alone and may be an effective option in refractory pSLE nephritis, raising the possibility of a synergistic effect between the two drugs. Additional studies are needed in pSLE to further assess the efficacy of this combo tx.

Long-Term Outcomes in Neonatal Lupus. Amit Saxena[1], Peter M. Izmirly[2], Deborah Friedman[3] and Jill P. Buyon[2]. [1]New York University School of Medicine, New York, NY, [2]NYU School of Medicine, New York, NY, [3]New York Medical College, Valhalla, NY

Background/Purpose: Several studies have evaluated mortality and short-term morbidity in neonatal lupus (NL), however there have been no substantive descriptions of the long term cardiac, rheumatologic, or neurodevelopmental outcomes in children exposed to maternal anti-Ro antibodies. This study was initiated to ascertain the prevalence of these outcomes in NL children and their unaffected siblings, and to evaluate whether certain fetal echocardiographic risk factors or pacemaker placement associates with long term morbidity.

Methods: The study utilizes a retrospective cohort of family members from the Research Registry for Neonatal Lupus (RRNL). Follow-up questionnaires were completed for 75 cardiac NL children, 35 cutaneous NL children, and 74 unaffected siblings. The questionnaires focus on symptoms associated with rheumatic and cardiac diseases, and information on pacemakers, developmental milestones, medical diagnoses and medications. Records from the RRNL were reviewed for fetal echocardiographic data.

Results: Of 184 total respondents, 52 children (28%) were age 0–5, 45 (24%) were 5–10, 30 (16%) were 10–15, 32 (17%) were 15–20, and 25 (14%) were > 20 years old. Among the 75 cardiac NL cases, 64 (85%) had 3rd degree heart block, 3 (4%) 2nd degree, 5 (7%) 1st degree, and 3 (4%) isolated cardiomyopathy. 53 (79%) of the 67 with advanced block were paced, 43% of whom had at least one replacement. 15 (20%) cardiac NL cases were reported as ever having "heart failure" and 31 (41%) "an enlarged heart." Median age was significantly higher in those reporting an enlarged heart (p=0.016), and those needing a pacemaker and replacement (p=.001 and 0.003, respectively). Of 37 cardiac NL children > 10 yrs, 19% required cardiac medications (digoxin, ACE inhibitor, or beta blocker), vs. 5% < 10 yrs (p=0.086). Fetal echocardiographic dilated cardiomyopathy and valvular disease were positively associated with number of pacemaker replacements (p=0.044 and 0.008). Of the total 110 NL patients, 1 developed JIA, 1 psoriasis/iritis, 1 IBD, and 3 thyroid disease. Of the 74 unaffected siblings, 1 developed 1 RA, and 1 sarcoidosis. Autism was diagnosed in 3 (3%) NL children and 2 (3%) healthy siblings. 5 (5%) and 6 (8%) NL and unaffected children respectively were taking medications for ADHD. Hydrocephalus was diagnosed after birth in 6 (5%) NL children, 3 requiring shunts. In 13 (12%) and 2 (3%) NL and unaffected children, delays in motor milestones were reported (p=0.027). 41 (37%) NL children had ever been considered small in height or weight for age vs. 14 (19%) healthy siblings (p=0.005). However, only 12 (11%) NL children were still considered small at the time of the questionnaire vs. 9 (12%) of the unaffected siblings.

Conclusion: Older age is associated with a reported history of heart enlargement, greater need for pacing, and cardiac medications. This supports the requirement for continued intensive long term cardiac evaluation in affected children. Risks exist in NL for delayed motor milestones, and transient failure to thrive. This further suggests the need for comprehensive surveillance, perhaps with a multidisciplinary protocol at a center familiar with these children.

Illness Features Associated with an Increased Risk of Mortality in Children with Juvenile Idiopathic Inflammatory Myopathies. Adam M. Huber[1], Gulnara Mamyrova[2], Julia A. Lee[3], Peter A. Lachenbruch[4], Ira N. Targoff[5], Frederick W. Miller[4], Lisa G. Rider[4] and Childhood Myositis Heterogeneity Study Group[6]. [1]Dalhousie University, Halifax, NS, [2]George Washington University, Washington, DC, [3]NIEHS, Bethesda, MD, [4]NIEHS, NIH, Bethesda, MD, [5]Oklahoma Medical Research Foun, Oklahoma City, OK, [6]Bethesda

Background/Purpose: Juvenile idiopathic inflammatory myopathies (JIIM) are potentially life-threatening systemic autoimmune diseases but little in known regarding factors associated with mortality.

Methods: Patients enrolled in a nationwide registry which included demographics, clinical and laboratory features, and outcomes. Timing of features (at diagnosis, after diagnosis or ever) was recorded. Mortality status was available for 419/441 (95%) patients (342 juvenile dermatomyositis (JDM), 30 juvenile polymyositis (JPM) and 47 juvenile connective tissue disease associated myositis (JCTM)), based on the Social Security Death Index or physician report. Poisson regression was used to assess univariable associations with mortality. Random survival forest classification followed by Poisson regression was used to assess multivariable associations.

Results: The cohort was 74% female, 69% white, median diagnosis age 7.6 years and median follow-up 4.3 years. There were 17 deaths (4%): 7 pulmonary (interstitial lung disease [ILD]), 3 gastrointestinal (perforation or hemorrhage), 3 multisystem (sepsis, multi-organ failure) and 4 unknown.

For univariable analysis, features present at diagnosis associated with an increased risk of death (P<0.05) were disease subgroup (mortality 2.3% JDM, 6.7% JPM, 14.9% JCTM), hospitalization, onset severity, younger age at diagnosis, anti-synthetase, anti-Ku or -La autoantibodies, dysphagia, abdominal perforation, Raynaud's phenomenon, ILD, shawl sign rash, gastroesophageal reflux and dysphonia. Features present after diagnosis associated with an increased risk of death were wheelchair use at last assessment, ILD, fever, pneumothorax or pneumomediastinum, abdominal perforation and number of hospitalizations. For features present at any time, including unknown timing, additional features associated with increased risk of death included syncope, dyspnea, sclerodactyly, weight loss, and decreased risk: fatigue, Gottron's papules and linear extensor erythema. Multivariable analyses revealed the following:

MULTIVARIABLE ANALYSIS		Incidence Rate Ratio	P-value
Features present at time of diagnosis			
	Raynaud's phenomenon	10.2	0.000
	Onset severity	3.8	0.01
Features present after diagnosis			
	Wheelchair use at last assessment	11.3	0.000
	ILD	5.1	0.004
	Any anti-synthetase autoantibody	4.4	0.02
Features present at any time			
	Fatigue	0.02	0.000
	ILD	12.8	0.001
	Weight loss	5.9	0.04

Conclusion: We have identified illness features associated with an increased risk of death in a large JIIM cohort. Some, such as ILD, anti-synthetase autoantibodies and Raynaud's, extend to JIIM the factors that have been associated with mortality in adult disease. Others, such weight loss, severity at onset, and fatigue (protective) are novel to this JIIM cohort. These results warrant further study in additional cohorts to confirm their predictive value.

Clinical Utility of Anti-CADM-140/Melanoma Differentiation-Associated Gene 5 Autoantibody Titers in Patients with Juvenile Dermatomyositis and Rapidly Progressive Interstitial Lung Disease. Shinji Sato[1], Norimoto Kobayashi[2], Kazuko Yamazaki[3] and Yasuo Suzuki[1]. [1]Tokai University School of Medicine, Isehara, Japan, [2]Shinshu University School of Medicine, Matsumoto, Japan, [3]Yokohama City University Hospital, Yokohama, Japan

Background/Purpose: The presence of anti-CADM-140/(Melanoma Differentiation-Associated Gene 5: MDA5) autoantibody is specific for adult dermatomyositis (DM), especially in patients with little or no muscle manifestations (clinically amyopathic dermatomyositis: CADM). Its presence is known to have a strong association with rapidly progressive interstitial lung disease (RP-ILD). Recently, it was reported that anti-CADM-140/MDA5 antibody titers measured by an enzyme-linked immunosorbent assay (ELISA) were useful for predicting outcomes of RP-ILD as well as for monitoring disease activity in patients with adult DM and RP-ILD. However, despite its diagnostic utility in adult DM, its clinical significance in juvenile DM (JDM) is still unclear. Here, we have examined this issue using anti-CADM-140/MDA5 ELISA.

Methods: Serum samples from 35 patients diagnosed with JDM (26 with classical JDM and 9 with juvenile CADM) were screened for autoantibody using a previously established anti-CADM-140/MDA5 ELISA. Associations between anti-CADM-140/MDA5 titer and clinical course and outcome were analyzed.

Results: Sera from 11 of 35 patients (31%) with JDM were found to contain anti-CADM-140/MDA5 antibody (6 with classical JDM and 5 with juvenile CADM). All 11 patients who possessed anti-CADM-140/MDA5 antibody had ILD, of whom 6 developed RP-ILD. JDM patients with anti-CADM-140/MDA5 antibody were significantly more likely to have RP-ILD compared with those without this antibody (P=0.0017). In anti-CADM-140/MDA5-positive patients, the mean antibody titer before treatment was significantly higher in those with RP-ILD than in those without (166.7 units vs. 57.4 units, P= 0.048). Four of 6 patients with RP-ILD died despite intensive therapy. In a patient who responded to therapy and survived, the titer of anti-CADM-140/MDA5 antibody decreased to the cut-off level, in parallel with improved respiratory symptoms. In contrast, the mean anti-CADM-140/MDA5 titer in patients who failed to respond to therapy and died did not decrease significantly, being maintained at a high level over the disease course as also observed in patients with adult DM (197.2 units vs. 76.2 units, P=0.17, n=3).

Conclusion: These results illustrate the clinical utility of establishing anti-CADM-140/MDA5 antibody titers in patients with JDM and RP-ILD as well as in patients with adult DM and RP-ILD.

Usefulness of Cardiac Magnetic Resonance in the Assessment of Myocardial Inflammation and Fibrosis in Children Born to Mothers with Anti-SSA/Ro Antibodies: A Prospective Study of 23 Cases and 6 Controls. Nathalie Costedoat-Chalumeau[1], Alice Maltret[2], Kateri Levesque[1], Shelby Kutty[3], Elisabeth Villain[2], Phalla Ou[2] and Gaëlle Guettrot-Imbert[4]. [1]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [2]Groupe Hospitalier Necker - Enfants Malades, Paris, France, [3]Division of Pediatric Cardiology, university of Nebraska Medical Center and Children's Hospital ans Medical Center, Omaha, NE, USA, Omaha, [4]Hopital Gabriel Montpied, Clermont-Ferrand, France

Background/Purpose: Besides congenital heart blocks (CHB), others manifestations of cardiac neonatal lupus erythematosus syndrome (NLES) include endocardial fibroelastosis (EFE), and dilated cardiomyopathy. Recently, autopsy of fetuses and children with cardiac NLES showed that EFE was under-diagnosed by echocardiography. We investigated the utility of cardiac magnetic resonance (CMR) for myocardial characterization, in children exposed *in utero* to anti-SSA/Ro antibodies (Ab), with focus on inflammation and fibrosis.

Methods: Children born to mothers with anti-SSA/Ro Ab were enrolled in a prospective study performed from December 2011 to June 2012. The control group consisted of 6 healthy children born to mothers without anti-SSA Ab. All the children had a complete cardiac testing with electrocardiogram, echocardiography and a CMR assessments (T2-weighted sequence for myocardial edema, T1-weighted sequence before and after intravenous administration of gadolinium for hyperemia, and late gadolinium enhancement). Positive findings in 2 of 3 sequences were considered diagnostic of myocarditis, and positive late gadolinium enhancement indicative of fibrosis.

Results: 23 children with (n=15, group 1) and without (n=8, group 2) cardiac NLES were included. Cardiac manifestations in group 1 were complete CHB (n=10), 2nd degree CHB (n=2), 1st degree CHB (n=1), supraventricular tachycardia (n=2). EFE was present on the *in utero* echocardiography in 7.

Group 2 included 3 children with cutaneous manifestations of NLES, and 5 symptom free children (2 had siblings with NLES manifestations).

11 children (10 in group 1 and 1 in group 2) had abnormal CMR whereas only 3 (all in group 1) had abnormal postnatal echocardiography (table1). Interestingly, no myocardial inflammation was observed after 3 months of life. The 6 children of the control group (anti-SSA-) had normal CMR.

CMR was performed twice in 3 children (2 with CHB and 1 with supraventricular tachycardia and EFE). In 2 children, the second MRI showed stability or an improvement of inflammation after 5 and 11 days respectively. In the third child (with CHB), an extension of fibrosis was observed after 9 months. This child died of heart failure at 2.8 years old despite cardiac pacing.

	Normal CMR	Normal but incomplete CMR (without injection)	Inflammation	Inflammation and fibrosis	Fibrosis
Children	11	2	2	2	6
Median age of children at CMR (years)	1.75 [0.01–8.54]	0.93	0.17	0.14	2.14 [0.01–7.6]
Number of children					
- group 1 (SSA+, cardiac NLES)	4	2	2	1	6
- group 2 (SSA+, no cardiac NLES)	7			1	
In utero echocardiography					
- normal	11	1		1	2
- EFE		1	2	1	3
- Not available					1
Post natal echocardiography					
- normal	11	2	1	1	5
- EFE			1	1	1

Conclusion: CMR is more sensitive than echocardiography to show myocarditis and/or fibrosis associated to anti-SSA antibodies. Further studies are needed to correlate CMR characteristics with late onset dilated cardiomyopathy.

Effects of Obesity On Health-Related Quality of Life in Childhood-Onset Systemic Lupus Erythematosus. Rina Mina[1], Marisa S. Klein-Gitelman[2], Shannen Nelson[3], Lori B. Tucker[4], B. Anne Eberhard[5], Nora G. Singer[6], Deborah M. Levy[7], Kathleen A. Haines[8], Karen Onel[9], Marilynn G. Punaro[10], Kathleen M. O'Neil[11], Michael Henrickson[12], Jun Ying[13] and Hermine I. Brunner[3]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati, Cincinnati, OH, [2]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]BC Childrens Hospital, Vancouver, BC, [5]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [6]Director, Division of Rheumatology, Metro-Health Medical Center, Case Western Reserve University, Cleveland, OH, [7]The Hospital for Sick Children, Toronto, ON, [8]Hackensack Univ Med Ctr, Hackensack, NJ, [9]University of Chicago, Chicago, IL, [10]Texas Scottish Rite Hospital, Dallas, TX, [11]Riley Hospital for Children, Indianapolis, IN, [12]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [13]University of Cincinnati, Cincinnati, OH

Background/Purpose: Obesity in adults with Systemic Lupus Erythematosus (SLE) is associated with an added risk of cardiovascular disease, decreased health-related quality of life (HRQOL), and increased disability. While cross-sectional studies report the prevalence of obesity in adult SLE cohorts at 27–29%, there are no studies that address the frequency of obesity in childhood-onset SLE (cSLE) or its impact on patient well-being. Patients with cSLE are more often treated with corticosteroids than adults with SLE, putting them likely at a higher risk for obesity. The purpose of this study is to estimate the frequency of obesity in our cSLE cohort and evaluate the effect of obesity on HRQOL measures in cSLE.

Methods: Obesity was defined as a body mass index $\geq 95^{th\%}$ of the sex-specific CDC 2000 BMI-for-age growth charts. In a prospective cSLE cohort (n=202), we compared the domain and summary scores of the generic and rheumatology modules of the Pediatric Quality of Life Questionnaire Inventory (PedsQL) and Child Health Questionnaire (CHQ) between obese cSLE patients and three comparison groups: 1) non-obese cSLE; 2) non-obese healthy children; and 3) obese controls without cSLE. Using mixed-effects models that adjusted for important predictors, we evaluated the independent contribution of obesity on HRQOL measures.

Results: Twenty five percent (n=51) of the cSLE patients in the cohort were classified as obese. We found a significant negative impact of obesity on overall HRQOL which persists even after adjustment for corticosteroid use, disease activity, disease damage, gender, and race of the patients *(Table 1)*. Obese cSLE patients had significantly lower physical and school functioning, and more pain compared to all three comparator groups (p-values<0.0001–0.05). There was also poorer emotional functioning in obese cSLE patients compared to their non-obese counterparts and healthy children (p-values <0.0001–0.04). Parents of obese cSLE patient worry more and perceive more physical limitations and limited family activities (p-values <0.0001–0.01).

Table 1. Difference in scores of health related quality of life (HRQOL) measures in cSLE according to presence of obesity*

*Values are mean ± standard error of the mean (SEM). For details, please refer to Table 1. NS-not significant; ND-not calculated (no comparison data).
** P-value from adjusted mixed effects models with summary and domain scores of HRQOL measures as dependent variable and presence of obesity (yes/no) as independent variable. Models adjusted for disease activity (SLEDAI scores ≤ 4 or not), daily prednisone dose (<0.2 mg/kg/day or not), race (African American or not), gender, and disease damage (total SLICC-DI scores ≤ 1 or not).
† P-value from 2-sided t-test comparing HRQOL scores from A (obese cSLE) vs. C (healthy controls).
†† P-value from 2-sided t-test comparing HRQOL scores from A (obese cSLE) vs. D (obese non-cSLE).
¶ Historical controls. For PedsQL-Generic Module: healthy pediatric patients with no chronic illness (N=9565) (1). For PedsQL-Rheumatology Module: healthy pediatric patients and JIA controls (N=141) (1). For CHQ: healthy pediatric controls (N=391).
¶¶ Historical controls. Obese pediatric patients without rheumatologic disease (N=63) *(Varni JW, et al. Impaired health-related quality of life in children and adolescents with chronic conditions: a comparative analysis of 10 disease clusters and 33 disease categories/severities utilizing the PedsQL 4.0 Generic Core Scales. Health Qual Life Outcomes. 2007; 5:43).*

Conclusion: Our study demonstrates that about 25% of cSLE patients evaluated were obese. Obesity negatively impacts many aspects of HRQOL particularly physical functioning and pain/hurt domains. Given the adverse effects on HRQOL, there appears to be an urgent need to include weight management in the day-to-day management of children with cSLE.

Brain Biopsy Diagnosis in Magnetic Resonance Imaging Negative Childhood Primary Angiitis of the Central Nervous System. Senq-J Lee, Cynthia Hawkins, Suzanne Laughlin, Shehla Sheikh and Susanne M. Benseler. The Hospital for Sick Children, Toronto, ON

Background/Purpose: Primary CNS vasculitis in childhood (cP-ACNS) is a devastating inflammatory brain disease mandating rapid and accurate diagnostic evaluation, in order to optimize neurologic outcomes. Traditional investigations including inflammatory markers are often abnormal, but not specific. Neuroimaging using MRI is considered the gold standard for detecting parenchymal inflammatory lesions, but is also not specific for cPACNS. We hypothesize that patients can still be diagnosed with cPACNS even if they have normal initial MRI studies, hence consideration of brain biopsy is vital. The aims of our study are: (1) To determine the proportion of children with confirmed cPACNS with normal initial MRI studies, and secondly, to calculate MRI sensitivity; (2) To report their presenting clinical, laboratory and brain histopathology findings, treatment response and long-term outcome.

Methods: We conducted a single centre cohort study of children diagnosed with cPACNS satisfying modified Calabrese criteria between 1990 and 2010. The study included all patients with normal MRI studies (defined as no evidence of an inflammatory or ischemic lesion at diagnosis) with subsequent confirmatory brain biopsy. Clinical, laboratory, histopathologic, treatment and patient outcome data was collected for these patients. MRI-studies were evaluated by a neuroradiologist, and histopathology by a neuropathologist.

Results: Out of 107 children diagnosed with cPACNS, 80 children were diagnosed with angiography-positive cPACNS; all had abnormal MRIs. 27 patients were diagnosed with angiography-negative cPACNS; 25 (93%) had abnormal MRIs. MRI sensitivity for the overall cohort was 98%, 100% for angiography-positive and 93% for angiography-negative cPACNS. Two children fulfilled inclusion criteria: previously healthy 11 and 13 year old males, both presenting with acute onset seizures progressing to refractory status epilepticus. Both patients had elevated serum inflammatory markers. One had a slightly raised WBC in CSF, the other had two normal CSF studies. Both patients had extensive workup for infection and rheumatologic disease, returning negative. Extensive imaging including CT, conventional angiogram, MRA, MRI, and MR spec-

troscopy returned normal. Treatment was with a standardized protocol of small vessel cPACNS, including corticosteroids, pulse IV cyclophosphamide for 6 months, followed by maintenance Mycophenolate Mofetil for 18 months. On last follow-up, one patient had mild residual neurologic deficits and intermittent seizures on anti-epileptics; the second had an excellent outcome with no neurologic deficit and seizure-free on Topiramate monotherapy.

Conclusion: Neuroimaging is a corner stone in the diagnostic evaluation of childhood CNS vasculitis. In our cohort, MRI was highly sensitive, however, a negative MRI does not rule out the diagnosis of cPACNS. In children presenting with refractory seizures, and/or if there is a high clinical suspicion, a brain biopsy should be considered despite repeatedly negative or non-diagnostic MRI studies.

A Brazilian Multicenter Study of 71 Children and Adolescents with Takayasu's Arteritis.

Maria Teresa Terreri[1], Gleice Clemente[2], Clovis Silva[3], Silvana Sacchetti[4], Adriana M. Sallum[5], Lucia M. A. Campos[6], Maria Carolina Santos[4], Flavio Sztajnbok[7], Rozana Gasparello de Almeida[7], Virginia P. Ferriani[8], Blanca E. Bica[9], Teresa Robazzi[10], Marcia Bandeira[11], Andre Cavalcanti[12], Marise Lessa[13], Sheila K. Feitosa de Oliveira[13] and Maria Odete Hilario[14]. [1]Universidade Federal de São Paulo/UNIFESP, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo - Unifesp, São Paulo, Brazil, [3]MD; PhD; São Paulo-SP, Brazil, [4]Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil, [5]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo-SP, Brazil, [6]University of São Paulo Medical School, São Paulo, Brazil, [7]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [8]FMUSP-Ribeirao Preto, Ribeirao Preto, Brazil, [9]International Investigator Consortium for MAS Diagnostic Criteria, Rio de Janeiro, Brazil, [10]Universidade Federal da Bahia, [11]Hospital Infantil Pequeno Príncipe, Curitiba, Brazil, [12]Universidade Federal de Pernambuco, Recife, Brazil, [13]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [14]Universidade Federal de Sao Paulo/UNIFESP, Sao Paulo, Brazil

Background/Purpose: Takayasu's arteritis is a chronic granulomatous disease that affects the vascular wall of the large arteries and can result in end organ damage. It is more prevalent in young women, but can also occur in the childhood. The disease is rare and there are few reports about the clinical features at this age. Our aim was to describe the clinical features of Takayasu's arteritis in children and adolescents in our population.

Methods: In this Brazilian multicenter retrospective study including 10 pediatric rheumatology centers we identified 71 children and adolescents with Takayasu's arteritis. Patients' demographic, clinical, laboratory, angiographic, therapeutic data and disease outcome were recorded.

Results: Of the 71 patients, 51 (72%) were girls, with a mean age at onset of 9.2 years (range 4 months to 17.2 years); the average time to diagnosis was 1.2 years; and the mean follow-up time was 5.4 years. The most frequent angiographic type was type IV (41%) followed by type V (27%) and the abdominal aorta was the most affected vessel (63.4%). The main lesion was arterial stenosis (84.5% of patients). At initial presentation 80.6% of patients had increased acute phase reactants and 41% of patients had a positive Mantoux test. The predominant clinical symptoms at onset were constitutional (77.5%), followed by neurological (70.4%) and musculoskeletal symptoms (64.8%). The main cardiovascular manifestation was arterial hypertension (84.5%). At the final evaluation, neurological symptoms were predominant (22.7%) and decrease of peripheral pulses (66.7%) was the main cardiovascular manifestation. Sixty four (90.1%) patients were treated with corticosteroids, 30 patients (42.3%) with methotrexate as the first immunosuppressive treatment and 18 (25.4%) were treated with cyclophosphamide as initial therapy. Infliximab was used in only 4 patients throughout the follow-up. At the final evaluation, 55% of patients were in disease remission, 28% had active disease, 7% died and in 10% the outcome was unknown.

Conclusion: Takayasu's arteritis is a rare childhood disease. In this multicenter study we observed a high rate of disease remission, however prospective studies are needed in order to better define overall disease outcome.

Effectiveness of Intravenous Cyclophosphamide in Severe or Refractory Juvenile Dermatomyositis - a National Cohort Study UK and Ireland.

Elena Moraitis[1], Katie Arnold[2], Clarissa Pilkington[1] and Juvenile Dermatomyositis Research Group[3]. [1]Great Ormond Street Hospital, London, United Kingdom, [2]UCL Institute of Child Health, London, United Kingdom, [3]London, United Kingdom

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare autoimmune vasculopathy affecting primarily the muscle and skin, but can also involve other organs.

Early and aggressive treatment improves outcome and prevents complications. Cyclophosphamide has been used as a second-line agent in the treatment of severe or refractory JDM. The published literature on the effectiveness of cyclophosphamide in JDM is limited to a small case series and case reports.

The objective of the study is to describe the response to cyclophosphamide in the patients with severe or refractory JDM.

Methods: 56 patients treated with cyclophosphamide between years 2000–2011 were identified in the JDM National (UK and Ireland) Cohort Biomarker Study and Repository for Idiopathic Inflammatory Myopathies. 8 patients were excluded due to incomplete data or too short follow up. For the 48 patients included, demographics, myositis core outcome variables, skin measures, laboratory measures, steroid dose and other treatments were recorded at baseline, time 6, 12, 18, 24 months and last follow up post commencement of the drug.

Results: Indications for starting cyclophosphamide were ulcerative or severe skin disease, profound muscle weakness, lung disease, gastro-intestinal vasculopathy or refractory disease. Previous medications were steroids and Methotrexate for 47 patients and steroids and Cyclosporin for 1 patient.

All patients starting with muscle weakness (n=44) significantly improved at time12, and the gains were maintained at follow up (see table1). Physician VAS was available for 32 patients and these all improved by 12 and 24 months, and for 31 remained stable at follow up.

At last follow up 26/46(56%) had no rash, 32/46(69%) had normal nailfolds, 37/45(82%) had no Gottron's, and calcinosis improved in 9/14 (64%).

Table 1.
Table 2.
Conclusion: This study, the largest to date, demonstrated significant improvement in both muscle and skin domains in patients with JDM treated with intravenous cyclophosphamide.

Cyclophosphamide appears effective in the treatment of severe or refractory JDM.

Childhood-Onset Predicts Increased Disease Damage and Steroid Toxicity in a Cohort of Adults with Systemic Lupus Erythematosus. Erica F. Lawson[1], Laura Trupin[1], Jinoos Yazdany[1], Aimee O. Hersh[2], Emily von Scheven[1] and Edward H. Yelin[1]. [1]University of California San Francisco, San Francisco, CA, [2]University of Utah, Salt Lake City, UT

Background/Purpose: While previous work has shown that adults with childhood-onset systemic lupus erythematosus (cSLE) have increased risk of mortality, renal disease and myocardial infarction as compared to individuals with adult-onset SLE (aSLE), little is known about differences in cumulative disease damage or steroid toxicity between adults with cSLE and aSLE. The goal of this study was to determine whether adults with cSLE are at increased risk for disease damage and steroid toxicity as compared to those with aSLE.

Methods: Data derive from the 2007–2011 cycles of the Lupus Outcomes Study (LOS), an annual longitudinal telephone survey of diverse English-speaking subjects with confirmed SLE. The Brief Index of Lupus Damage (BILD), a validated, patient-reported measure, was used to assess SLE-associated damage (Yazdany, 2011). Subjects age 18–63 were included in the analysis (N=823). Subjects were classified as childhood-onset if age at diagnosis was < 18 years (N=105). Outcome variables included BILD score and the presence of steroid-related damage. Steroid-related damage was defined as a self-reported history of cataracts, diabetes mellitus (DM), osteoporosis or avascular necrosis (AVN). We used negative binomial regression and logistic regression to compare cSLE and aSLE with and without adjustment for current age, gender and ethnicity. Disease duration was not included in the model due to colinearity with current age and category of age at onset.

Results: Mean age ($\pm$SD) was 46 years ($\pm$11), and 93% were female. Ethnicities included Caucasian (60%), Hispanic (10%), African American (12%), Asian (12%) and other (7%). Subjects with cSLE were more likely to be ethnic minorities (p<0.001). Mean age at diagnosis was 14 ($\pm$3) for subjects with cSLE and 33 ($\pm$10) for subjects with aSLE. Mean disease duration was 18 years ($\pm$8) for subjects with cSLE and 14 years ($\pm$10) for subjects with aSLE. Unadjusted mean BILD score was 1.8 (median 1, range 0–11) among subjects with cSLE and 2.0 (median 1, range 0–12) among subjects with aSLE. In adjusted analysis, there was greater SLE damage among subjects with cSLE (Table 1). There was no difference in unadjusted

frequency of steroid-related damage (cataracts, DM, osteoporosis or AVN) between cSLE and aSLE groups (30% vs. 33%). However, in adjusted analysis, subjects with cSLE were twice as likely to report steroid toxicity as compared to subjects with aSLE (odds ratio 1.9, 95% CI 1.1–3.3).

Table 1. Disease-related damage and steroid-related damage (osteoporosis, AVN, cataracts or DM) according to the BILD among subjects age 18–63 with SLE*

Variable	Mean BILD score (95% CI)†	Percent of subjects with steroid toxicity (95% CI)#
Childhood-onset SLE	2.63 (2.06–3.19)	46% (35–57%)
Adult-onset SLE	1.91 (1.77–2.04)	32% (28–35%)

*AVN = avascular necrosis; DM = diabetes mellitus, BILD = Brief Index of Lupus Damage; 95% CI = 95% confidence interval.
†Mean BILD score calculated from negative binomial regression results, adjusted for age, gender and ethnicity; P = 0.005
#Percent of subjects with steroid toxicity calculated from logistic regression results, adjusted for age, gender and ethnicity; P = 0.013

Conclusion: In this large cohort of adults with SLE, onset of lupus in childhood predicts increased disease damage. Childhood-onset SLE also predicts increased risk of steroid-related damage, which may be due to greater cumulative steroid exposure. Tight disease control and minimization of steroid use in childhood may be important to decrease long-term morbidity in cSLE.

Reduction of Cerebral and Corpus Callosum Volumes in Childhood-Onset Systemic Lupus Erythematosus. A Volumetric Magnetic Resonance Imaging Analysis. Aline T. Lapa[1], Wesley G. Ferreira[1], Mariana Postal[1], Nailu A. Sinicato[1], Roberto Marini[2], Fernando Cendes[1] and Simone Appenzeller[3]. [1]State University of Campinas, Campinas, Brazil, [2]Universidade Estadual de Campinas, Sao Paulo, Brazil, [3]State University of Campinas, São Paulo, Brazil

Background/Purpose: Cerebral atrophy has been described to occur in SLE with variable frequency. Aging, systemic diseases, corticosteroid use and central nervous system (CNS) involvement may lead to cerebral atrophy. However, studies evaluating the prevalence of cerebral atrophy in childhood-onset systemic lupus erythematosus (cSLE) using magnetic resonance imaging (MRI) volumetric measurements are rare. Objectives: To determine the frequency of cerebral and corpus callosum atrophy in cSLE and to determine the possible relationships between atrophy and clinical, laboratory and treatment features of the disease.

Methods: A total of 51cSLE patients (48 female; mean age=17.0; SD=3.9) and 50 healthy age and sex matched volunteers (37 women; mean age=18.4; SD=5.7) followed at the pediatric rheumatology unit of the State University of Campinas were enrolled in this study. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age. Mood disorders were determined through Becks Depression and Becks Anxiety Inventory in all participants. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity (SLEDAI), damage (SDI) and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated. MRI scans were performed in a 3T Phillips®scanner using a standardized protocol. Sagittal T1 weighted images were used for semiautomatic volumetric measurements. Volumes smaller 2 standard deviation from the means of controls were considered abnormal. Non-parametric tests and correlation were used for statistical analysis.

Results: In cSLE, cerebral (mean volume=1077.1 cm^3; SD=94.5) and corpus callosum (mean volume=11.8 cm^3; SD=1.8) volumes were significantly smaller when compared to cerebral (mean volume=1191.7; SD=122.1; p<0.001) and corpus callosum (mean volumes=10.8; SD=1.6; p<0.005) volumes of healthy volunteers. Corpus callosum atrophy were identified in 4 (7.8%; p=0.005) and cerebral atrophy 7 (14%; p=0.003) cSLE and in none of the controls. The presence of corpus callosum atrophy was associated with positive anti-dsDNA antibodies (p=0.018). An indirect

correlation between age and corpus callosum volume (r=−0.88; p<0.001) was observed. The presence of cerebral atrophy was associated with the presence of depression (p=0.007), vasculitis (p<0.001) and disease activity (p=0.04). No relationships between cerebral and corpus callosum volume and disease duration, the presence of CNS manifestations, total corticosteroid dose, and the presence of antiphospholipid antibodies were observed.

Conclusion: Cerebral and corpus callosum atrophy is observed more frequently in cSLE when compared to controls. The presence of immunological and clinical features are associated with the presence of atrophy. Depression was the only neuropsiquiatric manifestation associated with cerebral atrophy.

300

Prevalence and Clinical Significance of Hippocampal Atrophy in Childhood-Onset Systemic Lupus Erythematosus. Aline T. Lapa[1], Renata Brabosa[2], Mariana Postal[1], Nailu A. Sinicato[1], Roberto Marini[3], Fernando Cendes[1] and Simone Appenzeller[4]. [1]State University of Campinas, Campinas, Brazil, [2]Faculdade de Ciencias Medicas, Universidade Estadual de Campinas, Campinas, Germany, [3]Universidade Estadual de Campinas, Sao Paulo, Brazil, [4]State University of Campinas, São Paulo, Brazil

Background/Purpose: Hippocampal atrophy is associated with corticosteroid use and may be related to cognitive impairment in systemic lupus erythematosus (SLE).Objectives: To determine the prevalence of hippocampal atrophy in childhood-onset SLE (cSLE) using manual magnetic resonance imaging (MRI) volumetric measurements. To determine the possible relationship between hippocampal atrophy and disease duration, corticosteroid therapy, central nervous system (CNS) manifestations and the presence of antiphospholipid antibodies.

Methods: A total of 21 cSLE patients (21 female; mean age 17.28; SD=3.63) and 21 healthy age and sex matched volunteers (21 female; 20.57; SD=5.39) were enrolled in this study. A complete clinical, laboratory and neurological evaluation was performed. Neurological manifestations were analyzed according to the ACR classification criteria. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale for children (WISC-III) and Wechsler Intelligence Scale for adults (WAIS), according to age and validated in Portuguese. Mood disorders were determined through Becks Depression and Becks Anxiety Inventory in all participants. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current drug exposures. Total dose of corticosteroids and other immunosuppressant medications used since the onset of disease were calculated by data obtained by careful review of the medical charts. The cumulative dose of corticosteroids used was calculated by the sum of daily dosages versus time (days) of treatment. MRI scans were performed in a 3T Phillips scanner using a standardized protocol. Volumetric 1mm T1 weighted images were used for manual volumetric measurements. Volumes smaller 2 standard deviation from the means of controls were considered abnormal. Non-parametric tests and correlation were used for statistical analysis.

Results: Right (mean volume=3.65cm^3; SD=0.49) and left (mean volume=3.64cm^3; SD=0.41) hippocampal volumes were significantly smaller in cSLE compared to healthy volunteers (right mean hippocampal volume=4.59cm^3; SD=0.44; p<0.001; and left mean hippocampal volume=3.94cm^3; SD=1.5; p<0.001). Hippocampal atrophy was observed in 13 (62%) cSLE patients and none of the controls. Hippocampal atrophy was associated with the presence of positive ANA (p=0.048), anticardiolipine antibodies (p=0.02), total corticosteroid dose (p=0.029), low complement (p=0.029) and vasculitis (p=0.03). Cognitive impairment was more frequently observed in patients with hippocampal atrophy (p=0.002). No relationships between hippocampal atrophy and age, disease duration, SLEDAI and SDI was observed.

Conclusion: Hippocampal atrophy is frequently observed in cSLE and associated with the presence of cognitive impairment. Immunological and clinical features and total dose of corticosteroids are associated with hippocampal atrophy.

301

Decreased Frequency of Dystrophic Calcifications in Children with Juvenile Dermatomyositis: A 10-Year Study. Lauren M. Pachman[1], Gabrielle A. Morgan[2], Megan L. Curran[1], Lori J. Ferguson[2] and Chiang-Ching Huang[3]. [1]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Children's Hospital of Chicago Research Center, Cure JM Myositis Center, Chicago, IL, [3]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: In Juvenile Dermatomyositis (JDM), dystrophic calcifications, associated with increased morbidity and mortality, have been reported for 20–30% of patients. There are few laboratory indicators of disease activity, and a duration of untreated disease (DUD) greater than 4.5 months is associated with normalization of muscle enzymes (CK, Aldolase, LDH, SGOT), commonly used to guide response to therapy.

Objective: To determine the current frequency of dystrophic calcifications in children with JDM.

Methods: Patients with definite/probable JDM (overlap syndromes excluded) seen between 2000 and 2010 at the Ann and Robert H. Lurie Children's Hospital enrolled (IRB #2012–12858). At the first visit of 90 children, 52 were untreated and 38 were previously treated. Demographic data were obtained (Table), and their clinical inflammation assessed by disease activity scores (DAS) for skin and muscle. Diagnosis was confirmed by laboratory testing, and MRI directed muscle biopsy.

	Untreated (N=52)	Treated (N=38)	*P*-value
White/Hispanic (N, %)	46 (88%)	36 (95%)	0.51
Female (N, %)	40 (77%)	28 (74%)	0.91
Age at onset (year, mean±SD)	5.8±3.17	6.2±3.4	0.52
Disease duration (month, mean±SD)	10.4±16.2	9.6±13.4	0.79
DAS skin (mean±SD)	5.8±1.3	4.9±2.3	0.055
DAS muscle (mean±SD)	4.0±2.6	4.1±2.8	0.91

Results: Of the 52 untreated patients, 5 (9.6%) had calcinosis at presentation. The 52 children were initially treated with oral prednisone (47), IV prednisone (45), methotrexate (48), hydroxychloroquine (11), cyclosporin (1), mycophenolate (2), IVIG (0), and alendronate (0). During their disease course, the following medications were used: oral prednisone (50), IV methlyprednisone (45), methotrexate (48), hydroxychloroquine (21), cyclosporin (10), mycophenolate (29), IVIG (6), and alendronate (0). At follow-up 4/5 of the children's calcifications had resolved and the fifth one had diminished in size. None of the children with initially untreated JDM developed new calcifications. Of the 38 children previously treated, 7 (18%) had calcifications. Medications taken: oral prednisone (25), IV methylprednisone (5), methotrexate (25), hydroxychloroquine (20), cyclosporin (3), mycophenolate (2), IVIG (5), and alendronate (2). At follow-up, of the 7 children with calcifications: 2 improved in size (1 totally resolved), 3 remained the same, one developed more advanced calcification (from moderate to severe), and one developed 36 deposits months later.

Conclusion: In untreated JDM without calcifications, no deposits developed during a mean follow-up period of <4 years. Of the 5 untreated JDM with calcifications, 4/5 resolved and the one diminished. Of the seven treated JDM referred with calcifications, only one totally resolved, and one developed new calcifications after 36 months of therapy. These data suggest that early immunosuppressive therapy may impair the development of dystrophic calcifications in JDM, for only 7.0% of this total group had calcifications. None of the 52 initially untreated children without calcifications developed them at a later time. We speculate that dystrophic calcifications in JDM are preventable.

Accuracy of Systemic Lupus International Collaborating Clinics Classification Criteria Applied to Juvenile Systemic Lupus Erythematosus Patients. Marìa M. Katsicas[1], Ezequiel Borgia[2], Ileana Villarroel[2] and Ricardo Russo[3]. [1]MD, Buenos Aires, Argentina, [2]MD, Caba, Argentina, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Systemic lupus erythematosus (SLE) is a prototype autoimmune disease. The most widely used classification criteria for SLE were those developed by the American College of Rheumatology (ACR) in 1982 and revised by a committee in 1997, but not validated in that revision. The Systemic Lupus Collaborating Clinics (SLICC) revised the ACR SLE classification criteria and validated new criteria in order to improve clinical relevance and incorporate new knowledge in SLE immunology.

To assess sensitivity and specificity of revised and validated new SLICC SLE classification criteria in a cohort of Juvenile SLE patients.

Methods: The SLICC criteria rule for SLE classification requires: 1) four criteria, with at least one clinical criterion and one immunologic criterion or 2) lupus nephritis alone in the presence of ANA or anti-DNA antibodies. Seventeen criteria were identified. Cases were JSLE patients who were attending a single tertiary center in the past 10 years. JSLE had been diagnosed on clinical and immunological grounds by experienced pediatric rheumatologist. Controls were patients with rheumatic diseases other than SLE: Juvenile Idiopathic Arthritis (JIA); Juvenile Dermatomyositis (JDM), Autoimmune Hepatitis (AH) and Juvenile Systemic Sclerosis (JSS). Criteria were reviewed from prospectively developed databases and medical records by pediatric rheumatologists in order to establish the number and frequency of new criteria fulfilled by each patient. Descriptive statistics were used to characterize both patients groups. Summary statistics included overall sensitivity and specificity. McNemar's test was used to assess differences between ACR 1997 criteria and SLICC criteria with respect to accuracy.

Results: Cases: 107 patients with JSLE were included (F: 89 M: 18), age at onset: 12 (3–16) yo. Controls: 102 patients with JIA (36 patients, systemic 20, polyarticular 16); JDM (28), AH (28) and JSS (10), F:76 M: 26, age at onset: 11 (2–16) yo. SLICC SLE criteria sensitivity was 100 % vs 86% ACR 1997 criteria, while specificity was 98% vs 96% (p=0.009). Six patients with a clinical diagnosis of JSLE were correctly classified by SLICC but not by ACR criteria.

Table. lists the sensitivity and specificity of each criterion in SLICC SLE criteria

SLICC SLE criteria	Sensitivity %	Specificity %
Acute cutaneous lupus	61	100
Chronic cutaneous lupus	2	100
Oral ulcers	11	100
Nonscarring alopecia	14	98
Synovitis	65	68
Serositis	13	98
Renal	56	99
Neurologic	11	100
Hemolytic anemia	21	98
Leukopenia or Lymphopenia	34	95
Thrombocytopenia	31	92
ANA	100	60
Anti-DNA	63	100
Anti-Sm	30	100
Antiphospholipid antibodies	33	100
Low complement	91	90
Direct Coombs test	29	98

Conclusion: The SLICC new criteria performed better than the ACR 1997 criteria in a cohort of patients with JSLE. These new criteria allowed better accuracy than previous criteria in some variables such as low complement, anti-DNA, acute cutaneous lupus, ANA, and renal involvement.

Ancestral Group Differences in Pediatric SLE Early Disease Severity: An Analysis of the Carranet Registry. Jennifer M.P. Woo[1], Alice DC Hoftman[1], Emily von Scheven[2], Deborah K. McCurdy[1], Ornella J. Rullo[1] and CARRA Registry Investigators[3]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]UC San Francisco, San Francisco, CA, [3]Durham

Background/Purpose: Ancestral background may contribute to increased disease morbidity in patients with pediatric lupus systemic erythematosus (pSLE) of non-European descent; however, there exists a paucity of information describing the effects of ancestry on the early disease processes of pSLE. We recently identified that pSLE patients of not uniquely European ancestry (nonEA) at a tertiary care center in Los Angeles, California, were more likely to present with more active disease during the first 12 months of diagnosis. We aim to assess whether children and adolescents with pSLE of nonEA ancestry have a more severe early disease course than their European American counterparts.

Methods: CARRAnet Registry data was obtained for 665 subjects with pSLE (diagnosis <18 years); 130 were further identified as diagnosed within 12 months prior to their baseline visit between 2010 and 2012. Demographic and socioeconomic data, ACR SLE criteria, and SLE Disease Activity Index (SLEDAI) were evaluated at baseline, and any renal biopsy results were recorded. Cumulative steroid exposure and use of additional immunosuppressive agents was also documented. Impact of disease was assessed, using ACR functional class, health-related quality of life, Childhood Health Assessment Questionnaire (CHAQ), and physician global assessment (PGA). Comparison of these data between self-reported Hispanic- (HA), Asian- (A), African- (AA), non-European (nonEA; including all subjects of mixed ancestry or or of not uniquely European ancestry), and European- (EA) American patients with pSLE was conducted.

Results: Age at onset was slightly higher among HA, A, and nonEA patients when compared with EA pSLE (Table 1). All Non-EA pSLE groups were more likely to have renal involvement during year 1 than EA; similarly, HA, A, and nonEA were more likely to present with proteinuria than EA (22%, 30%, 17% vs. 12.5%). However, total ACR criteria and SLEDAI scores near diagnosis did not differ among all non-EA groups compared to EA (Table 1). HA, AA, and nonEA pSLE received more immunosuppressive agents in addition to steroids, and more A pSLE had >1 month of cumulative steroids compared to EA pSLE (Table 1). Furthermore, A pSLE patients had more active PGA scores than EA. Overall, the EA and all non-EA groups had comparable duration of symptoms prior to diagnosis despite lower rates of insurance coverage in HA and nonEA and more HA, AA, and nonEA subjects reporting poverty-level household incomes than EA (Table 1).

Table 1. Clinical and socio-economic characteristics of EA, nonEA, HA, AA, and A pSLE patients.

EA-European American; HA-Hispanic American; AA-African American; A-Asian American; nonEA-of mixed ancestry or not uniquely of EA descent, including HA, AA, and A groups; SLEDAI-SLE Disease Activity Index; PGA-physician Global Assessment; CHAQ-Childhood Health Assessment Questionnaire
*p-values taken in comparison to EA values and considered significant at $p< 0.05$
‡Values assessed at time of enrollment/baseline visit, which occurred within 12 months of symptom onset and 12 months of diagnosis
† % of patients requiring cumulative prednisone >1 month
††Number of immunosuppressive agents required in addition to steroids and/or hydroxychloroquine

Conclusion: CARRAnet Registry pSLE patients of not uniquely European ancestry present at a slightly older age and potentially reflect a more active and refractory disease during the initial 12 months compared to EA counterparts. As the CARRAnet Registry continues to grow and additional follow-up data is collected, trends may emerge to further support ancestry-related differences in disease severity in the early stages of pSLE.

Burden of Childhood Central Nervous System Vasculitis: Identifying High Risk Factors for Poor Cognitive Outcome. Peter J. Gowdie, Marinka Twilt, Pascal N. Tyrrell, Robyn Westmacott, Tania Cellucci, Shehla Sheikh, Nick Blancette and Susanne M. Benseler. The Hospital for Sick Children, Toronto, ON

Background/Purpose: Childhood primary angiitis of the CNS (cPACNS) is an increasingly recognized, reversible cause of severe neurological and psychiatric deficit such as stroke, refractory seizures and hallucination in previously healthy children. Aggressive immunosuppression has significantly decreased the mortality, however little is known about the long-term neurocognitive burden of cPACNS. Objectives: To describe the neuropsychological outcome of children with cPACNS, compare the cognitive burden between distinct disease subtypes and identify risk factors for poor neurocognitive outcome.

Methods: A single-centre cohort study of children with cPACNS based on Calabrese criteria was performed. Children had to have completed a standard neurocognitive evaluation. Demographic characteristics, disease subtypes, clinical features, laboratory markers, neuroimaging studies, brain biopsy findings and treatment regimens were captured. Neurocognitive function was evaluated with a standardized battery of neuropsychological tests including domains of cognitive, social, emotional and adaptive function. The primary study outcome was the Full Scale IQ (FSIQ). Secondary outcomes included neurological function as defined by the Paediatric Stroke Outcome Measure PSOM, Health-related Quality of Life (PedsQL), disease activity and disease damage (VAS). Analysis: Univariate analysis compared variables between distinct disease subtypes; a multivariate prediction model for adverse cognitive outcome was used

Results: A total of 104 children were diagnosed with primary CNS vasculitis in the study interval, of whom 63 (61%) completed the neuropsychological assessment. Of these 19 had small vessel CNS vasculitis (SVcPACNS) and 44 angiography-positive CNS vasculitis (APcPACNS). The cohort included 28 girls (16 SVcPACNS, 12 APcPACNS) and 35 boys (3 SVcPACNS, 32 APcPACNS), median age at diagnosis was 8.1 years; SVcPACNS patients were older at diagnosis (9.8 vs. 7.5 years). At diagnosis, SVcPACNS patients present significantly more commonly with seizures(79%, p<0.05) and acute behaviour change (47% p<0.05), while hemiparesis was more frequently seen in APcPACNS (91%,p<0.05). Outcome: Overall, the mean FSIQ was 93 (52–132). The mean FSIQ in SVcPACNS was 82 (54–119) and was significantly lower than in APcPACNS, 97 (52–132) (p<0.05). Abnormal FSIQ scores (<85) were seen in 53% of the SVcPACNS and 27% of APcPACNS patients. Children with SVcPACNS had lower scores than APcPACNS in the subdomains of verbal comprehension, working memory and processing speed (p<0.05). Prediction model: Children with SVcPACNS and with seizures were at the highest risk of cognitive deficits.

Conclusion: Children with cPACNS carry significant disease burden. The inflammation causes drastically impaired cognitive functioning including comprehension, processing speed and memory deficits. Children with SVcPACNS and in particular those presenting with seizures are at the highest risk for adverse cognitive outcome. Early rehabilitation interventions have to be tailored to this high risk group.

Clinicopathologic Correlates for Activity and Damage of Lupus Nephritis in Childhood-Onset Systemic Lupus Erythematosus. Ravi Nunna[1], Rina Mina[1], Michael Bennett[2], Shannen Nelson[3], Jessica Hummel[4], Prasad Devarajan[2], David Witte[3] and Hermine I. Brunner[3]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Med Ctr, Cincinnati, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: High AI activity (AI), tubulointerstitial (TI), and chronicity index (CI) scores from renal biopsy may predict poor renal outcomes in lupus nephritis (LN) in childhood-onset systemic lupus erythematosus (cSLE). Our aim is to evaluate the relationship between histologic evidence of renal disease activity and damage of LN with conventionally used biomarkers in cSLE.

Methods: Biopsy specimens of 18 cSLE patients were rated by a single nephropathologist for the AI, TI, and CI. Using logistic regression, the relationships between the biomarkers and high scores for AI (≥ 7), high CI (≥ 3), and high TI (≥ 4) were evaluated. Biomarkers evaluated include serum creatinine, creatinine clearance, urine sediment, proteinuria, albumin, blood pressure, anti-ds DNA antibody, C3, C4, sedimentation rate, and blood urea nitrogen (BUN); these were obtained on the day of renal biopsy to 30 days after.

Results: Patient's mean age $\pm$ SD was 14.1 $\pm$ 2.7 years. LN class distribution was as follows: II (28%), III (17%), IV (50%), and III plus IV (6%). All were positive for anti-ds DNA antibody. Only elevated BUN (odds ratio=14, 95% CI=1.2–156, p-value=0.05) was significantly associated with high TI score. None of the biomarkers were significantly associated with high AI and high CI scores using cut-offs as specified above (see Table).

Table. Relationship of high AI, high CI, and high TI scores with conventional biomarkers*

Biomarker	High AI Score N=12 Odds ratio	P-value	High CI Score N=4 Odds ratio	P-value	High TIAI Score N=10 Odds ratio	P-value
Systolic blood pressure	1.10 (0.98–1.17)	NS	1.03 (0.96–1.10)	NS	1.04 (0.97–1.12)	NS
Diastolic blood pressure	1.16 (0.99–1.36)	NS	1.02 (0.91–1.14)	NS	1.02 (0.92–1.13)	NS
Hematuria (> 5 RBC/ hpf)	0.67 (0.08–5.68)	NS	2.22 (0.25–20.17)	NS	1.29 (0.16–10.45)	NS
Pyuria (> 5 WBC/hpf)	1.00 (0.13–7.99)	NS	0.67 (0.08–5.68)	NS	1.40 (0.20–10.03)	NS
Urine protein to creatinine ratio	2.02 (0.88–4.78)	NS	27.03 (0.22–990)	NS	1.60 (0.87–2.95)	NS
Albumin	0.08 (0.01–1.07)	NS	0.85 (0.09–7.98)	NS	0.38 (0.07–2.11)	NS
C3	0.90 (0.12–6.78)	NS	0.55 (0.07–4.56)	NS	0.50 (0.07–3.68)	NS
C4	2.00 (0.11–37.83)	NS	0.29 (0.01–5.66)	NS	1.25 (0.07–23.26)	NS
Sedimentation rate	1.00 (0.97–1.03)	NS	1.00 (0.97–1.03)	NS	0.98 (0.94–1.01)	NS
Serum creatinine	1.09 (0.08–14.66)	NS	9.33 (0.62–139.51)	NS	1.78 (0.13–23.52)	NS
Creatinine clearance	0.99 (0.97–1.02)	NS	1.00 (0.98–1.02)	NS	0.99 (0.96–1.01)	NS
BUN	7.00 (0.65–75.74)	NS	3.00 (0.37–24.17)	NS	14.00 (1.25–156.61)	0.05

*High AI ($\geq 7/24$), high CI ($\geq 3/12$), and high TI ($\geq 4/21$) N-number of patients, Total N=18

Conclusion: Commonly used biomarkers are poorly associated with histological features for activity and damage of LN in cSLE highlighting the need for better biomarkers that can be used in clinical care.

Children with Probable SLE by ACR Criteria May Need More Aggressive Lupus Treatment Early in the Disease Course. Anjali Patwardhan[1], Igor Dvorchik[2] and Charles H. Spencer[1]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH

Background/Purpose: This research explores whether delay of the childhood-onset SLE (cSLE) diagnosis until 4/11 ACR criteria are met affects patient outcome negatively

Methods: Institutional Review Board approval was obtained to retrospectively review the charts of 98 SLE patients seen in the rheumatology clinic at Nationwide Children's Hospital over the past 24 years. All the patients were divided in to two groups, 'definitive cSLE' - who met the minimum 4/11 or more ACR criteria at presentation in rheumatology clinic and the 'probable cSLE' who did not meet the minimum criteria. Both the groups were assessed for disease severity, damage and gradient of damage. Appropriate statistical tests were used, i.e. Chi-Square test, Fisher's Exact test, Univariate logistic regression and Wilcoxon two-sample test were utilized. All tests were conducted in SAS 9.2

Results: Out of 98 cSLE patients, 71 % were included in definitive cSLE (DcSLE) group while 29 % were included in probable cSLE (PcSLE) group. The mean time for PcSLE group to reach DcSLE status was 20.3 months There was no difference in the ethnic distribution (p=0.7370). PcSLE were more likely to have a higher male: female ratio (p=0.032), and were older at presentation that DcSLE (p=0.045). PcSLE patients were less likely to have internal organ involvement (7.1% vs. 25.7%), were less likely to be hospitalized and receive pulse steroids (P=0.0142) or oral steroids (0.0172) at presentation. PcSLE patients were less likely to be hospitalized to receive pulse steroids ever (p=0.0628), were less likely to have renal disease ever (p=0.0653) and nervous system disease ever (p=0.0182). PcSLE was more likely to receive hydroxychloroquine (p=0.050). The organ damage was assessed using SLICC/ACR damage index at 1, 5 and 10 years post diagnosis. The maximum damage was recorded within first 5 years of the diagnosis. Initial damage was predictive of later damage. D pSLE had higher disease damage scores at 5 and 10 years. We compared the gradient between the onsets of symptoms and the development of organ damage in the two groups. The PcSLE patients had significantly higher internal organ damage gradient as compared to DcSLE (p value=0.0169)

Conclusion: In our population, PcSLE patients had a significantly high gradient of damage than the DcSLE group. In spite of D pSLE being more severe diseases ever and more diseases damage, the disease damage progression was steeper and faster in PpSLE. This may be explained by the fact that PpSLE patients received a less intense treatment regimen at presentation than DcSLE group. It may be that PcSLE patients need just as early vigorous treatment as the children with DcSLE

Risk Factors for Poor Outcomes in Hospitalized Patients with Pediatric Systemic Lupus Erythematosus. Mary Beth F. Son[1], Victor M. Johnson[2], Mindy S. Lo[2] and Karen H. Costenbader[3]. [1]Children Hospital Boston, Boston, MA, [2]Children's Hospital Boston, Boston, MA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Disparities in care among adults with SLE are well documented. We investigated associations of demographic factors and volume of annual inpatient hospital admissions with poor outcomes, including intensive care unit admission, renal failure and in-hospital mortality, among hospitalized patients with pediatric SLE.

Methods: The Pediatric Health Information System (PHIS) is an administrative database contributed to by >40 freestanding U.S. pediatric hospitals. We queried PHIS regarding all discharges for patients aged 3–21 years with at least one ICD-9 code for SLE from Jan 2006-Sept 2011. Patient demographics, medical insurance, hospital and ICU admissions, lengths of stay, renal failure (based on ICD-9 coding), and deaths were recorded. We classified hospitals according to the volume of inpatient admissions per year, in quartiles. We used summary statistics and univariable analyses to examine demographics of hospital admissions, readmissions, and lengths of stay. We employed multivariable logistic regression analyses, controlling for patient age, sex, race, ethnicity, insurance type (private, governmental, self-pay, or none), U.S. region (Northeast, South, Midwest and West), and hospital volume to examine risk factors for adverse outcomes, including ICU admission, renal failure and in-hospital mortality.

Results: A total of 3,389 patients with 14,631 admissions were identified in the study period. 2,781 patients (82%) were female and the median age at the time of the index admission was 16 years (IQR=14–18). White and African American race each comprised nearly 37% of the patients (n=1,250 and 1,252), while 5% (n=172) were Asian. Over a quarter of patients (n=888, 26%) were Hispanic or Latino. 87% of patients (n=2,953) had insurance, with over half supported by governmental insurance (n=1876, 55%). More than a third of patients had renal disease (n=1273, 38%); however, only 0.7% (n=24) had renal failure and 0.2% (n=8) required dialysis therapy. The high volume hospitals had shorter length of stay as compared to low volume hospitals (median 2 days, IQR=1–5, vs. 3 days, IQR=1–6, p<0.001), although readmissions per patient were more frequent in the higher volume hospitals (median 2, IQR= 1–6, vs. 2, IQR=1–3, p<0.001). Ten percent of admissions included an ICU stay. Overall in-hospital mortality was low at 0.4% (n=57). In multivariable models, ICU stays were associated with age <10 years at first admission (OR=1.61 [1.16 to 2.25], p<0.05). Poor outcome, defined as renal failure and death, was strongly associated with governmental insurance (OR=2.51 [1.47 to 4.29], p<0.05).

Conclusion: In our cohort of hospitalized children with SLE, hospital volume affected length of stay and number of readmissions, but not in-hospital mortality. Governmental insurance in this group of patients was associated with renal failure and in-hospital mortality. Further studies are needed to understand the relationships of medical insurance type and hospital volume with poor outcomes, in order to address modifiable barriers to care in pediatric SLE.

Next-Generation Sequencing of Urinary Microrna in Human Lupus Nephritis. Beatrice Goilav[1], Iddo Z. Ben-Dov[2], Irene Blanco[3], Olivier Loudig[3], Dawn M. Wahezi[4] and Chaim Putterman[3]. [1]Children's Hospital at Montefiore, Bronx, NY, [2]The Rockefeller University, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Children's Hospital Montefiore, Bronx, NY

Background/Purpose: Lupus nephritis (LN) is a common manifestation of SLE associated with significant morbidity and mortality. microRNAs (miRs) are small non-coding RNAs that regulate translation and mRNA stability. Preliminary studies have reported changes in miR expression in kidney tissue, urine, and PBMC that correlated with disease activity in LN. However, use of RNA deep-sequencing methods has not been previously described. We aimed at identifying miR expression patterns in LN by RNA sequencing.

Methods: Cell-free urine supernatants from adult (n=9) and pediatric (n=4) female patients with LN were obtained at the time of active disease and during remission. Total RNA was used to prepare small RNA cDNA libraries for Illumina sequencing. Multiplexing through sample-specific 3' adapters ("bar coding") was applied to limit batch effects, labor and cost. Sequenced reads were mapped to the human genome and small RNA databases, and miRs were quantified by relative read abundance. qRT-PCR was used for quantitative validation of sequencing results.

Results: We were able to obtain reproducible profiles of miRNA from the small RNA fraction. In a paired-sample analysis comparing the number of miR sequence reads in urine of active versus inactive LN, we found significant upregulation of multiple miRNAs, including −185, −328, −378, −874, and −423. In total, we found differential expression of 19 miRs during active nephritis. A subset analysis revealed 13 miRs that were upregulated by a 400-1,000 fold change during active disease in pediatric, but not in adult samples. Differential expression of several miRs was confirmed by miRNA qRT-PCR.

Conclusion: In summary, we detected a group of miRs (most of which have not been previously described in lupus) with significantly higher presence in the urine during active LN, particularly, in pediatric patients. These miRs may represent biomarkers for disease activity or indicators of specific histologic features. Several urine miRs were previously found to be differentially expressed in immune cells, which may imply that their presence in urine originates from infiltrating rather than kidney resident cells. Finally, upregulated miRs during active LN could imply that their "protective" target genes are repressed in relapse, and that identifying the latter may reveal novel therapeutic pathways in this challenging disease.

Cell Type Specific Transcriptome Analysis in Patients with Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis (JIA-ERA). Amita Aggarwal, Arpita Myles and Priyanka Gaur. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background/Purpose: Enthesitis Related Arthritis Category of Juvenile Idiopathic Arthritis (JIA-ERA) is the most common category of JIA seen in Asian Indians. Transcriptome analysis is a useful tool to analyse pathways involved in disease pathogenesis. Peripheral blood and synovial fluid mononuclear cells (PBMC and SFMC) analysis showed involvement of innate immune cells in

JIA-ERA.However PBMC/SFMC have variable number of different cells and that can affect interpretation. No data is available on cell type specific transcriptome analysis of blood and synovial fluid in children with JIA-ERA.

Methods: Six samples each of peripheral blood and synovial fluid were collected from patients with JIA-ERA. Blood from 6 healthy controls was also collected. Mononuclear cells were separated by density gradient centrifugation. B cells, T cells and monocytes were separated using MACS columns and purity assessed by flow cytometry. After RNA extraction and checking the quality of RNA (RIN>8) microarray was done using Illumina chips WG 12 for whole PBMC/SFMC population, T cells, B cells and monocytes. Some of the significant genes were validated by qRT-PCR.

Results: Unsupervised hierarchical clustering revealed that cell subsets could be distinguished based on their gene expression profile.No significant differences were observed between PBMC of patients and healthy controls. Comparison of SFMC and PBMC reconfirmed the results seen earlier. Results obtained with monocytes, T cells and B cells are summarized below:

Groups compared	Genes up regulated	Genes down regulated	Number of dysregulated pathways [total (significant)]	Pathways of immunological relevance
EB vs EF	776	189	19 (12)	Cell adhesion, IgA production, antigen processing, lysosomal processing
CBMO vs EBMO	821	1251	21 (12)	Cytokine signaling, TLR signaling, antigen presentation, chemokinessignaling
EBMO vs EFMO	595	512	17 (9)	Complement cascade, cytokine signaling, antigen presentation
CBTC vs EBTC	497	477	20 (6)	Cell adhesion, cytokine signaling
EBTC vs EFTC	513	342	20 (13)	Cell adhesion, antigen processing, cytokine and chemokinessignaling
CBBC vs EBBC	648	900	26 (16)	Cell adhesion, BCR signaling, leukocyte migration, antigen processing, chemokinessignalling
EBBC vs EFBC	740	915	8 (0)	

EB: ERA blood mononuclear cells, CB: control blood mononuclear cells, EF: ERA Synovial fluid mononuclear cells, Mo: CD14+ monocytes, TC: CD3+ T cells, BC: CD3-CD14-CD19+B cells

The most prominent differences were found in monocyte subset. TLR pathway was one of the major pathway identified besides antigen presentation, cytokine and chemokine signalling

Conclusion: Monocyte probably play a major role in pathogenesis of JIA-ERA and TLR signalling may be the pathway involved.

STAT3 Plays a Central Role in NLRP3 Inflammasome-Mediated IL-1β Production and Pyronecrosis. Jehad H. Edwan[1], Tri M. Tran[1], Mones Abu-Asab[2], Raphaela T. Goldbach-Mansky[3] and Robert A. Colbert[1]. [1]NIAMS NIH, Bethesda, MD, [2]NEI NIH, Bethesda, [3]Translational Autoinflammatory Diseases Section NIAMS NIH, Bethesda, MD

Background/Purpose: Gain of function mutations in *NLRP3* cause cryopyrin-associated periodic fever syndromes (CAPS), the most severe form of which is neonatal-onset multisystem inflammatory disease (NOMID), which is characterized by recurrent episodes of systemic and organ-specific inflammation. Mutations in *NLRP3* result in self-activation, promoting inflammasome-mediated IL-1beta processing and release, and can induce cell death through a process known as pyronecrosis. Many inflammatory disease manifestations are responsive to IL-1beta inhibitors, although patients often continue to have minor disease flares in the context of infections or other stressors. The hematopoietic cells that are the major producers of IL-1beta in NOMID and mechanisms mediating IL-1beta release and pyronecrosis have not been well elucidated.

Methods: Whole blood cells from NOMID patients and controls, THP-1 monocytic cells, and stably STAT3 knock down THP-1 cells were stimulated with LPS in the presence of cathepsin B and STAT3 inhibitors, followed by ATP treatment. Supernatants were collected and incubated with IL-1beta capturing beads. Cells were fixed and permeabilized and stained with IL-1beta, CD14, CD16 and CD83 antibodies, and cells and beads were evaluated by flowcytometry. LPS stimulated cells were also evaluated using immunofluorescent and electron microscopy and western blot assays.

Results: A sub-population of monocytes characterized by CD14hi/CD16low expression, produce the majority of IL-1beta in peripheral blood in response to LPS stimulation in NOMID and control PBMCs. In NOMID patients this subpopulation of monocytes also undergoes rapid cell death following LPS stimulation alone. The cell death is temporally associated with IL-1beta release, and is consistent with pyronecrosis. In contrast, CD14hi/CD16low cells from

healthy subjects only release IL-1beta after both LPS and ATP stimulation and are relatively resistant to cell death. IL-1beta release is partially inhibited in NOMID cells by caspase-1 inhibitors, and is blocked completely by inhibitors of cathepsin B. Cathepsin B inhibitors also prevent pyronecrosis. Similar to cathepsin, STAT3 inhibitors significantly abrogated cell death and IL-1beta release in NOMID cells. STAT3 inhibition also abolished all ATP-dependent IL-1beta release and cell death in monocytes from healthy subjects. Moreover, shRNA-mediated knockdown of STAT3 in THP-1 cells completely prevented ATP dependent IL-1b release and cell death. We confirm that STAT3 associates with mitochondria, and that inhibition of STAT3 but not cathepsin B, prevents mitochondrial damage suggesting that mitochondrial STAT3 activation may be upstream of cathepsin B activation.

Conclusion: These results identify the predominant IL-1beta-producing cell population in the peripheral blood of NOMID patients and healthy contorls, and identify a novel role for STAT3 in mediating *NLRP3* effects on pyronecrosis and IL-1beta release. We suggest that cell death may contribute to IL-1beta release.

The DEK Autoantigen Regulates Formation of Neutrophil Extracellular Traps and Zymosan Induced Arthritis in Mice. Nirit Mor-Vaknin[1], Anjan K. Saha[1], Maureen Legendre[1], Marta J. Gonzalez-Hernandez[1], M. Asif Amin[2], Bradley J. Rabquer[2], Julie M. Jorns[3], Mariana J. Kaplan[1], Barbara S. Adams[4], David A. Fox[5], Alisa E. Koch[2] and David Markovitz[1]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Ann Arbor, MI, [4]Univ of Michigan Health System, Ann Arbor, MI, [5]Univ of Michigan Med Ctr, Ann Arbor, MI

Background/Purpose: The nuclear oncoprotein DEK is a known autoantigen associated with juvenile idiopathic arthritis (JIA) and other autoimmune diseases. DEK is actively secreted by human macrophages and serves as chemoattractant for leukocytes, including neutrophils and T cells. We have previously demonstrated that DEK and anti-DEK autoantibodies are abundant in the inflamed synovia of JIA patients. Postranslational modification, particularly acetylation, of DEK markedly increases its autoantigenicity, suggesting an active role for DEK and DEK autoantibodies in the inflamed joint. Using zymosan induced arthritis (ZIA) mouse model, we demonstrate that DEK contributes to the development of inflammatory arthritis by recruiting neutrophils to the joint. Remarkably, DEK also appeared to be required for the formation of neutrophil extracellular traps (NETs) and is detected in association with known NET markers in human neutrophils from synovial fluids of JIA patients.

Methods: We investigated the role of DEK using the ZIA mouse model, comparing 129/B6 wild type (WT) to DEK knockout (DEK KO) mice. Zymosan A from *Saccharomyces cerevisiae*, or an equal amount of sterile saline, was injected through the suprapatellar ligament into the joint cavity of WT and DEK KO mice. Inflammatory cytokines in the joint tissue homogenates were detected by ELISA. Neutrophils from healthy volunteers were purified by centrifugation over a discontinuous Histopaque gradient. Synovial fluid neutrophils from JIA patients and mouse bone marrow neutrophils were isolated in a similar manner. The Transwell system was used for chemotaxis assays. The neutrophil markers Ly6G, elastase and DEK and were detected by immunoflorescence and confocal microscopy.

Results: Significant levels of DEK were found in NETs from JIA synovial neutrophils. In the ZIA mouse model, DEK KO mice displayed significantly less inflammation in the joints compare to WT. Substantially reduced levels of pro-inflammatory cytokines were detected in zymosan injected joints from DEK KO vs. WT mice. Neutrophil migration into the injected joints was markedly lower in DEK KO vs. WT mice and DEK KO neutrophils demonstrated defects in NETs formation in response to lipopolysaccharide (LPS) and *Escherichia coli.*

Conclusion: Extracellular DEK found in the supernatant of activated primary human neutrophils serves as a chemoattractant and is important for NET formation. DEK is also detected in NETs produced by synovial fluid neutrophils of JIA patients. These results demonstrate that the nuclear autoantigen DEK plays a major role in the development of inflammation in the joints, suggesting an active role for DEK in the development of JIA as well as other autoimmune diseases.

Blood-Based Biomarkers of Neurocognitive Dysfunction in Childhood-Onset Systemic Lupus Erythematosus. Hermine I. Brunner[1], Jessica Hummel[1], Shannen Nelson[2], Erin C. Thomas[3], Jennifer L. Huggins[1], Megan L. Curran[4], Jun Ying[5] and Marisa S. Klein-Gitelman[6]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital, Cincinnati, OH, [3]Anne and Robert C Lurie Hospital, Feinstein School of Medicine, Northwestern University, Chicago, IL, [4]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [5]University of Cincinnati, Cincinnati, OH, [6]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL

Background/Purpose: Several brain-reactive autoantibodies in the blood have been inconsistently associated with Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) in adults but very little is known whether such findings are relevant to neurocognitive dysfunction (NCD) with childhood-onset systemic lupus erythematosus (cSLE). NCD with cSLE often impairs working memory, visuoconstructional (VC) ability, attention and working speed. The objective of this research was to examine the relationship between select candidate biomarkers in the serum for their usefulness in the identification of cSLE-associated NCD.

Methods: As part of a larger study, the cognitive ability of 38 patients with cSLE was studied using the *cSLE Battery of Neuropsychological Tests* (Ross et al; 2008) that probes cognitive domains typically impaired with cSLE, with overall cognitive performance expressed as the average z-scores of the standardized tests (mean in healthy reference population= 0; standard deviation= 1). Serum levels of neutrophil gelatinase associated lipocalin (NGAL; involved in blood-brain barrier integrity), as well as auto- antibodies to NR2 (involved in neuronal plasticity and apoptosis); phospholipids (aPL) (associated among others with white matter hyperdensities on magnetic resonance imaging and thrombosis), and ribosomal-P (associated with depression and seizure; proposed involvement in neuronal apoptosis) were measured using commercially available standard assays.

Results: The overall level of cognitive function was significantly worse in those with cSLE who tested positive for aPL-antibodies as compared to aPL-antibody negative cSLE patients [mean+SE; -2.44 ± 1.13 vs. -0.38 ± 0.61; p= 0.041]. We found aPL antibodies to be associated with a 5-fold increased risk of NCD (40% vs. 12%; p =0.08). We also found anti-ribosomal P antibodies present in 67% (24/38) of the cSLE patients. As shown in **Figure 1,** those who tested positive for anti-ribosomal P antibodies had a significantly lower overall cognitive functioning vs. cSLE patients without anti-ribosomal P antibodies (p= 0.0006). Conversely, we found serum levels of anti-NR2 antibodies to be unrelated to cognitive ability. The same was true for serum levels of NGAL.

Cognitive Ability with cSLE

y=sum of z-score with tests probing attention, working meory, processing speed and VC ability
Conclusion: Presence of aPL and anti-ribosomal P antibodies in the serum is associated with the level of cognitive ability of children with cSLE, providing proof-of principle that discovery of biomarkers for NPSLE in the blood is feasible. Additional research is necessary to assess whether the duration of antibody exposure and/or the combination of antibodies are suited to reliably identify patients who suffer from cSLE-associated NCD or are at risk of developing it.

Epigenetic Changes in Fibrosis and Myocyte Repair Genes May Contribute to Pathogenesis in Monozygotic Twins Discordant for Cardiac Manifestations of Neonatal Lupus. Paula S. Ramos[1], Timothy D. Howard[2], Miranda C. Marion[2], Satria Sajuthi[2], Robert M. Clancy[3], Jill P. Buyon[3] and Carl D. Langefeld[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]New York University School of Medicine, New York, NY

Background/Purpose: Cardiac manifestations of neonatal lupus (cardiac-NL) which comprise conduction defects and cardiomyopathy, occur in fetuses exposed to maternal anti-Ro antibodies and carry a case fatality rate of nearly 18%. The discordance rate for monozygotic (MZ) twins suggests a role for epigenetic factors in addition to maternal autoantibodies, genetic and environmental influences. Analysis of MZ twins represents the ideal design to dissect the role of epigenetic factors. Notably, the onset of cardiac-NL can occur within one week of a normal ultrasound and is most often detected between 18–24 wks gestation, and hence, there is very limited confounding due to environmental cues that might occur over decades, as for discordant MZ twins with other autoimmune diseases. As such, the analysis of these twins early in life has unprecedented value to test for disease-associated epigenomic variation and reveal potential metastable epialleles. This study examines an axis of heritable genetic information in human genomic DNA involving cytosine methylation and addresses the hypothesis that susceptibility to cardiac-NL is influenced by epigenetic variability.

Methods: Genomic DNA was extracted from two Caucasian monochorionic MZ male twin pairs who were discordant for cardiac-NL (advanced block). The source of one pair was umbilical cord blood and the other was saliva from 18-month-olds. DNA methylation profiling was performed using the Illumina Infinium HumanMethylation450 BeadChip. Probes with a detection P-value<1.0E-05 were excluded. A paired *t*-test on the probe-specific β-values was computed and significance was assessed as the intersection of meeting an FDR threshold and mean DNA methylation difference $(\Delta\beta)>|0.10|$.

Results: Significant hypomethylation in both affected twins was observed in genes with fibrosis and myocyte repair functions. With regard to fibrosis, these include protein phosphatase 1A (PPM1A; $\Delta\beta=-0.11$, P<1.E-15) a SMAD phosphatase, and a disintegrin and metalloproteinase domain 12 (ADAM12; $\Delta\beta=-0.13$, P<1.E-15), an enhancer of TGFb1 transcription. For myocyte repair, included are the LIM-protein 1 gene (FHL1; $\Delta\beta=-0.14$, P=1.2E-30) implicated in cardiomyopathy, the myocardin-like 2 gene (MKL2; $\Delta\beta=-0.13$, P<E-100) involved in cardiovascular morphogenesis, and the mitoferrin-2 gene (SLC25A28; $\Delta\beta=-0.33$, P=1.2E-78), implicated in hemoglobin biosynthesis. The most significant hypermethylated site is located in the membrane associated guanylate kinase gene MAGI2 $(\Delta\beta=0.40$, P=1.2E-39).

Conclusion: To our knowledge, this is the first study analyzing global disease-associated methylation patterns in early-life tissue of MZ discordant twins. The data support an epigenetic mechanism underpinning cardiac-NL discordance in MZ twins despite identical DNA sequence and exposure to maternal autoantibody via a shared placenta.

Transcriptome and Surface Phenotype Analyses Suggest an Alternatively Activated (M2) Function for Hemophagocytes. Scott W. Canna[1], Ana Patrícia Costa Reis[2], William E. Bernal[3], Kathleen E. Sullivan[3], Michele E. Paessler[1] and Edward M. Behrens[1]. [1]Childrens Hospital of Philadelphia, Philadelphia, PA, [2]Childrenxs Hospital of Philadelphia, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: Hemophagocytes (HPCs) are activated macrophages identified in situ by having engulfed other hematopoietic cells. HPCs are rarely seen in normal bone marrow, but are abundant in a variety of cytokine storm syndromes. HPCs are the pathologic hallmarks of two related

diseases: Macrophage Activation Syndrome (MAS) and Hemophagocytic Lymphohistiocytosis (HLH). The function of the HPC is controversial. Some evidence suggests HPCs are inflammatory and pathogenic, while other evidence supports a housekeeping or anti-inflammatory role for these cells by pointing out their absence in some patients with overt MAS or HLH and their high expression of scavenger receptors like CD163. However, no study has yet attempted to directly phenotype these cells. Using two distinct approaches, we now show that HPCs display an M2, or anti-inflammatory phenotype.

Methods: Splenic HPCs induced in an animal model of MAS utilizing repeated Toll-like Receptor 9 (TLR9) stimulation in the context of IL-10 receptor blockade were isolated by single cell laser capture microdissection with the assistance of a board certified hematopathologist (MP). Gene expression levels of these cells were measured using microarray and compared to those of laser-captured resting splenic macrophages. Highly differentially expressed genes were verified using quantitative RT-PCR. Differential regulation of pre-determined gene sets was analyzed using a Gene Set Enrichment Analysis (GSEA). Additionally, bone marrow biopsies from patients with MAS or HLH noted to have excessive hemophagocytosis as part of their clinical evaluation were subjected to immunohistochemistry for markers of classical (M1) or alternative (M2) activation and scored by a blinded hematopathologist (MP).

Results: Of 6 treatment and 6 control samples, the RNA of 4 samples in each group were of sufficient quality for analysis. The gene sets meeting statistical significance for upregulation in HPCs were those related to the proteasome, M2 gene regulation, cytoskeleton regulation, and Nod-like receptor signaling. The gene set for M1 gene regulation was not found to be different between HPCs and resting macrophages. Human bone marrow biopsies stained for the mannose receptor and M2 marker CD206 showed HPCs with a membrane-bound staining pattern. HPCs with such staining for the M1 differentiation marker CD64 were very rarely identified.

Conclusion: For the first time, we have described the functional program of *in situ* HPCs as alternatively activated (M2) and potentially anti-inflammatory. This raises questions about elimination of HPCs as a therapeutic rationale, and supports future investigations into optimal treatment strategies for hemophagocytic diseases.

Pediatric Lupus Nephritis: Micrornas–Macro Inflammation. Patrícia Costa Reis, Pierre Russo and Kathleen E. Sullivan. Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: New biomarkers to guide clinical management of lupus nephritis (LN) patients are highly desirable, since the histopathologic classification currently in use is an unreliable predictor of treatment response and disease outcome. MicroRNAs have emerged as a new class of biomarkers in several rheumatic diseases, but their role in LN is still unclear. These noncoding RNAs have a post-transcriptional regulatory effect, playing a key role in fundamental cellular processes and influencing immunologic function, especially in the maintenance of immunological tolerance. Perturbations in the microRNA expression patterns can, therefore, lead to pathological conditions, including autoimmune diseases, like systemic lupus erythematosus (SLE).

MicroRNA studies performed on serum, urine and peripheral blood mononuclear cells have revealed distinct profiles in SLE patients. Further studies are thus necessary to identify a specific LN microRNA signature, which will illuminate SLE pathogenesis and may lead to novel LN biomarkers.

The main aim of this study is to identify the microRNA signature in kidneys of children with LN. The ultimate goal is to find microRNAs associated with disease activity and prognosis that may guide clinical practice.

Methods: Paraffin-embedded tissue samples from children with LN, kidney biopsies performed on kidney donors, and post-streptococcal glomerulonephritis were used for microRNA extraction with Quiagen™ miRNeasy kit. Direct digital detection of microRNAs, through molecular barcodes, was performed with the nCounter® human miRNA assay kit.

Results: The microRNA signature can clearly differentiate samples from normal kidneys of those affected with LN. From over 700 human microRNAs analyzed, miR-26a and miR-30b were identified as being associated with pediatric LN. A significant decrease in the expression of these microRNAs

was found in LN class IV, when compared to normal tissue, post-streptococcal glomerulonephritis, LN class III or LN class V.

Conclusion: An altered microRNA signature can lead to the dysregulation of gene expression and broadly alter cell behavior. The study of microRNAs can, therefore, improve our understanding of the pathogenesis of several diseases. With this project, miR-26a and miR-30b were identified for the first time as components of the microRNA signature in kidneys of children with LN. These microRNAs are predicted to regulate the expression of genes that interfere with cell cycle, apoptosis and immune regulation, including IL18R1, which has been implicated in the pathogenesis of nephritis and tissue inflammation and HDAC9, which acts as an epigenetic switch in effector T cell-mediated systemic autoimmunity. This study has provided new insights for LN pathogenesis and for the development of new biomarkers.

The Interleukin-10 (IL-10) Producing Regulatory B Cell ("B10 cell") Compartment Expands with Disease Activity in Juvenile Dermatomyositis (JDM) and Pediatric-Onset Systemic Lupus Erythematosus (pSLE). Ioannis Kalampokis, Jeffrey A. Dvergsten and Thomas Tedder. Duke University Medical Center, Durham, NC

Background/Purpose: pSLE and JDM are multisystem inflammatory diseases, whereas juvenile idiopathic arthritis (JIA) is typically an organ-limited disease. "B10 cells", a rare subset of human B cells with anti-inflammatory properties characterized by their functional capacity to produce IL-10, originate from a progenitor pool ("B10pro cells") and expand in response to inflammation. We conducted the first pediatric study of B10/B10pro cells with the primary objective of evaluating whether peripheral blood B10/B10pro cell frequencies expand and correlate with disease activity in the 3 most common pediatric autoimmune diseases.

Methods: Following institutional review board approval, pediatric (1–16 years old) subjects with JIA, JDM or pSLE were recruited from the outpatient pediatric rheumatology clinic and the inpatient unit at Duke Children's Hospital. Subjects with systemic-onset JIA, rituximab therapy within 1 year, current intercurrent illness, or major surgical procedure within 3 months were excluded. For analysis, two groups were defined (JDM/pSLE vs. JIA) and assessed for disease activity (inactive vs. active). After obtaining informed consent, a single blood sample from each subject was analyzed by flow cytometry. B10 and B10+B10pro cell numbers were determined by surface CD19 and intracellular IL-10 staining following *ex vivo* incubation with lipopolysaccharide (LPS) or CpG oligonucleotides in the absence (5 hour assay measuring B10 cells) or presence (48 hour assay measuring B10+B10pro cells) of recombinant CD40L. A visual analog scale (VAS) score was used to estimate disease activity. Non-parametric tests were used for statistical analysis due to small sample size. B10 and B10+B10pro frequencies were compared using the Mann-Whitney U test. VAS score correlations were performed by Spearman's rho. Due to multiple comparisons, significance was defined as $p<0.01$.

Results: 33 patients were recruited, 17 with JIA (8 inactive, 9 active) and 16 with JDM/pSLE (8 inactive, 8 active). No significant differences in the frequencies of B10 or B10+B10pro cells were observed in JIA between active and inactive subjects. Significant differences were observed during disease remission between JIA and JDM/pSLE, with the later group having lower frequencies of B10 ($p=0.0003$) and B10+B10pro ($p=0.0006$) cells in response to CpG. Within the JDM/pSLE group, there were significant differences in the frequencies of B10 cells in response to LPS ($p=0.0030$) and CpG ($p=0.0019$), and B10+B10pro cells in response to CpG ($p=0.0006$) between active and inactive subjects. Significant positive correlations with disease activity were observed in the JDM/pSLE group in the B10 responses to LPS ($p=0.0034$, rho=0.685) and CpG ($p=0.0036$, rho=0.682), and the B10+B10pro responses to CpG ($p=0.000001$, rho=0.915).

Conclusion: During disease remission, patients with JDM/pSLE have lower frequencies of B10 and B10+B10pro cells compared to patients with JIA. B10 and B10+B10pro cell frequencies increase with active disease in JDM/pSLE (but not in JIA); the magnitude of this expansion highly correlates with disease activity. Thereby, peripheral blood B10+B10pro cell expansion may represent a novel disease activity marker in patients with JDM/pSLE.

Fatty Acid Profiling: Potential New Biomarkers in Juvenile Idiopathic Arthritis (pilot study). Weng Tarng Cham[1], Enzo Ranieri[2], Janice Fletcher[2] and Christina A. Boros[3]. [1]Women's and Children's Hospital, North Adelaide, SA 5006, Australia, [2]SA Pathology, North Adelaide, SA 5006, Australia, [3]University of Adelaide/Women's and Children's Hospital, Adelaide, Australia

Background/Purpose: The prostanoids are a family of biologically active lipids derived from the 20-carbon essential fatty acids (LCPUFA) all of which are involved in the inflammatory response. ω3-fatty acids, Eicosapentaenoic acid (EPA) and Docosapentaenoic acid (DPA), are anti-inflammatory, whilst the ω6-fatty acid, Arachidonic acid (AA), metabolites: 15-S-Hydroxyeicosatetraenoic acid [15(S)-HETE], Thromboxane B2 (TXB2), Prostaglandin F2α (PGF2α) and 6-Keto-Prostaglandin F1α (6-k-PGF1α) are pro-inflammatory. Liquid Chromatography Tandem Mass Spectrometry (LC-MSMS) allows contemporaneous analyses of multiple prostanoids with high accuracy using small blood samples. This method has never been used previously to measure these analytes in JIA and may find biomarkers which can help us predict disease activity and treatment response.

We aim to measure prostanoid profiles in patients with JIA using LC-MSMS.

Methods: Samples from 55 JIA patients (26 polyarthritis, 29 oligoarthritis) and 6 healthy siblings of JIA patients were collected onto specially prepared filter papers and analysed using LC-MSMS.

Results: The M:Fratio was 1:3, the average age at study entry (9.4 ± 5.0 y), average disease duration (44.7 ± 41.5 m), with 83.6% receiving treatment with NSAID, and 38.2% with Methotrexate (MTX).

15(S)-HETE levels were significantly higher in oligoarthritis than polyarthritis patients (Mann-Whitney U, p=0.046). Spearman rank correlations showed that MTX treatment correlated positively with 15(S)-HETE (p=0.01, R=0.493) but correlated negatively with TXB2 (p=0.004, R=−0.514), Leflunomide treatment correlated negatively with PGF2α (p=0.022, R=−0.448), Etanercept treatment correlated negatively with PGF2α, (p=0.013, R=−0.481) and correlated positively with 6-k-PGF1α (p=0.0216, R=0.451).

Stepwise linear regression showed TXB2 levels to be significantly higher in healthy controls compared to JIA patients (p=0.011) and JIA patients on MTX had significantly higher EPA levels (p=0.017) and lower AA:EPA ratios (p=0.011). 6-k-PGF1α level increased by 0.37nM in JIA patients with every extra month of disease (p=0.022) and DPA level reduced by 0.09nM with every point rise in Juvenile Arthritis Disease Activity Score (p=0.032).

Conclusion: We have been able to determine prostanoid profiles from whole blood using LC-MSMS in patients with JIA. Treatment with MTX increases the levels of anti-inflammatory prostanoids. This relationship has not been demonstrated previously.

NSAIDs are the mainstay of treatment in patients with JIA and resulted in lower TXB2 levels compared to healthy controls.

15(S)-HETE has been identified as a potential biomarker of disease activity in JIA

However, disease progression appears to continue in JIA despite treatment as shown by the elevation in 6-k-PGF1α levels. We are currently performing longitudinal analyses to elucidate the relationships between prostanoid profiles and disease subtype, activity and medication response.

Replication Analysis of Non-HLA Gene Variants with Prior Evidence of Association with Juvenile Idiopathic Arthritis. Justine Ellis[1], Raul Chavez[1], Anne-Louise Ponsonby[1], Angela Pezic[1], Roger Allen[2], Jonathan Akikusa[2] and Jane Munro[2]. [1]Murdoch Childrens Research Institute, Parkville, Australia, [2]Royal Childrens Hospital, Parkville, Australia

Background/Purpose: Over the last few years, there have been numerous reports of associations of single nucleotide polymorphisms (SNPs) at various genetic loci with juvenile idiopathic arthritis (JIA). However, apart from a select few variants, the majority of these association findings would benefit from further replication in independent populations to confirm their involvement in disease risk. We examined a total of 60 SNPs in or around 44 genes previously examined by others for association with (total) JIA in the ChiLdhood Arthritis Risk factor Identification sTudY (CLARITY), a new Australian collection of cases and healthy child controls.

Methods: DNA from a total of 324 JIA cases (mean age 9.7 years, 67.3% female) and 568 controls (mean age 7.8 years, 40.7% female) was available for genotyping. Genes and SNPs were chosen based on reports by others over the last five years, and included *PTPN22* (rs 2476601), *IL2RA* (rs706778), *ATXN2* (rs653178), *C12orf30* (rs17696736), *C3orf1* (rs4688011), *JMJDC1* (rs12411988), *PTPN2* (rs7234029), *STAT4* (rs7574865), *TRAF1/C5* (rs2900180), and *VTCN1* (rs12046117). SNPs were genotyped using the Sequenom MassARRAY system. Allelic and genotypic association analyses were performed using PLINK. A p < 0.05, along with an odds ratio (OR) in the same direction as the original association report(s) was taken as evidence of replication of the prior findings.

Results: Following data QC, 292 cases and 497 controls were analysed. Evidence of replication was generated for *PTPN22* (Allelic OR = 1.67; 95% CI 1.16, 2.40; p (best test) = 0.006), *ATXN2* (OR = 1.54; 95% CI 1.25, 1.89; p = 3.8×10^{-5}), *C12orf30* (OR = 1.47; 95% CI 1.20, 1.81, p = 0.0002), *C3orf1* (OR = 1.32; 95% CI 1.03, 1.69; p = 0.030), *STAT4* (OR = 1.38; 95% CI 1.10, 1.74; p = 0.003), and *TRAF1/C5* (OR = 1.24; 95% CI 1.00, 1.53; p = 0.021). We were unable to confirm association with *IL2RA*, *PTPN2*, and *VTCN1*; however, this may reflect a lack of statistical power since ORs were directionally consistent with previous reports. Results for *JMJDC1* were neither statistically significant, nor were the ORs directionally consistent. Restriction of the dataset to 204 cases and 248 controls in whom Caucasian ancestry of all four grandparents could be confirmed did not materially alter these findings.

Conclusion: We have provided further confirmation of association of (total) JIA with a number of genes, adding to the growing international data that is clarifying the underlying genetic risk component of this serious childhood disease. Pooling of currently available candidate gene data for meta-analyses, and pooling of samples for large genome-wide association study efforts will likely provide further clarity. Future work to better define the overall JIA risk profile should also include an examination of gene-gene and gene-environment interactions.

Gamma Interferon-Induced Protein-10 (IP-10) As a Potential Biomarker for Disease Activity in Pediatric Localized Scleroderma. Katherine Kurzinski[1], Carol A. Feghali-Bostwick[2], Christina Kelsey[1], Kelsey Magee[2] and Kathryn S. Torok[1]. [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Pediatric localized scleroderma (LS) is an autoimmune disease affecting the skin and underlying tissue. Cutaneous findings assist in categorizing the patients into active or inactive (predominately damage) disease states. The biopsies of those with active disease features demonstrate a lymphocytic infiltrate. T helper (Th) lymphocytes and their associated cytokines have been identified in the tissue and in the peripheral circulation of patients with scleroderma. This study was designed to evaluate the levels of Th-associated cytokines and chemokines at various stages of LS, with a particular focus on active disease and its clinical parameters.

Methods: Plasma samples were obtained from 69 pediatric LS patients and 71 healthy pediatric controls. Several cytokines and chemokines were evaluated using a Millipore luminex panel comparing LS to healthy controls, with additional analysis predetermined to be dedicated to LS patients with active disease. LS patient samples were categorized as either clinically "active" or "inactive" at the time of collection. Active disease was defined by the presence of new, enlarging, erythematous lesions and a Physician Global Assessment of Disease Activity (PGA-A) score greater than zero. Nonparametric statistics were employed comparing cytokine levels between LS and healthy groups and between active and inactive LS patients ($\alpha = 0.05$).

Results: IP-10 levels were significantly elevated in LS patients compared to healthy controls, $u = 4.785$, $p <.001$, as well as in LS patients with active disease compared to inactive disease, $u = 3.305$, $p =.001$ (Figure). Also, IP-10 levels were elevated in patients with new lesions, a variable strongly reflecting disease activity (trending toward significance, $p =.057$). IP-10 levels were also significantly correlated to two well accepted disease activity outcome measures, the modified Localized Scleroderma Skin Severity Index (mLoSSI) ($\rho = 0.343$, $p = 0.004$), a quantitative assessment of disease activity, and the PGA-A ($\rho = 0.450$, $p < 0.001$).

	Healthy	LS (overall)	Active LS	Inactive LS
	n = 71	n = 69	n = 30	n = 39
Median (pg/mL)	445.8	1140.34	2087.25	880.5
IQR (pg/mL)	246.0–833.5	497.9–2495.7	956.6–3099.0	447.8–1289.8
Conclusion: Our previous serologic analyses as well as studies in systemic sclerosis have identified gamma interferon-induced protein-10 (IP-10) as a potential molecule of interest in the pathogenesis of scleroderma. An elevation of plasma IP-10 levels in pediatric localized scleroderma (LS) when compared to those of healthy controls further supports these findings. Analyses demonstrating IP-10 elevation in patients with active disease and correlations with valid activity measures suggest that IP-10 may be a biomarker for disease activity in LS.

Evaluation of Anti-Citrullinated Type II Collagen and Anti-Citrullinated Vimentin Antibodies in Patients with Juvenile Idiopathic Arthritis. Brooke Gilliam, Anil K. Chauhan and Terry L. Moore. Saint Louis University, St. Louis, MO

Background/Purpose: Several studies have identified anti-cyclic citrullinated peptide (CCP) antibodies as an important indicator for destructive disease in patients with juvenile idiopathic arthritis (JIA). This is of particular significance in patients with IgM rheumatoid factor (RF)-positive polyarticular JIA, which closely resembles rheumatoid arthritis (RA). While the role of anti-CCP antibodies in RA and JIA is better understood, the identity of the target proteins of this modification remains undefined. We evaluated serum from patients with JIA to investigate the presence of anti-citrullinated type II collagen (CII) and anti-citrullinated vimentin antibodies, and their association with RF and anti-CCP antibody isotypes and previously measured anti-citrullinated fibrinogen and α-enolase antibodies. Our aim was to determine the prevalence and significance of previously identified target proteins for citrullination and elucidate their role in the disease process of JIA.

Methods: Sera were obtained from 96 patients with various JIA subtypes, 19 systemic lupus erythematous (SLE) patients, and 10 healthy children. All sera were measured for antibodies against citrullinated and native CII and vimentin (vim1–16, vim59–74) by ELISA. Results were compared to anti-CCP antibody and RF isotypes, and our previously measured anti-citrullinated fibrinogen antibodies and anti-citrullinated α-enolase antibodies, in addition to erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP).

Results: Mean levels of all anti-citrullinated antibodies were significantly higher in JIA patients than in healthy children ($p<0.05$). The most commonly detected citrullinated autoantibodies were anti-citrullinated CII (33.3%) and anti-citrullinated fibrinogen antibodies (32.3%), with the least commonly detected being anti-citrullinated α-enolase antibodies (9.4%). One IgM RF-positive polyarthritis patient was positive for all tested anti-citrullinated autoantibodies. The most common combination of positivity was anti-citrullinated CII and anti-citrullinated fibrinogen antibodies in 7 patients. Twenty-two subsets of patients were identified based on their anti-citrullinated autoantibody profile, not including anti-CCP antibody isotypes. Anti-citrullinated CII antibodies correlated significantly with all other citrullinated autoantibodies ($p<0.05$). Anti-citrullinated vimentin 1–16 and 59–74 demonstrated strong correlation with each other, and both correlated significantly with anti-citrullinated fibrinogen and alpha-enolase antibodies ($p<0.05$). Anti-citrullinated vimentin 1–16 antibodies also correlated with ESR ($p<0.05$). When including the group of citrullinated autoantibodies in

logistic regression analysis, anti-citrullinated fibrinogen remained as the only autoantibody significantly correlated with joint damage ($p<0.05$).

Conclusion: This study demonstrates that multiple citrullinated epitopes can be detected in JIA patients, especially those patients with polyarticular disease. Anti-citrullinated fibrinogen antibodies remained as the single citrullinated autoantibody to correlate significantly with joint damage.

Glycosylation of Vitamin D Binding Protein Reduced in Juvenile Idiopathic Arthritis Patients At Risk of Disease Extension. David S. Gibson[1], Sorcha Finnegan[2], Gwen Manning[3], Mark Duncan[4], Stephen R. Pennington[5], Terry L. Moore[6] and Madeleine Rooney[7]. [1]Arthritis Research Group, Queens University Belfast, Belfast, United Kingdom, [2]Queen's University, Belfast, Belfast, United Kingdom, [3]Proteome Research Centre, University College Dublin, Dublin, Ireland, [4]Division of Endocrinology, University of Colorado, Denver, [5]UCD Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin 4, Ireland, [6]Saint Louis University, St. Louis, MO, [7]Queens University Belfast, Belfast, United Kingdom

Background/Purpose: Juvenile idiopathic arthritis (JIA) comprises a poorly understood group of chronic, childhood onset, autoimmune diseases with variable clinical outcomes.We investigated whether profiling of the synovial fluid (SF) proteome by a fluorescent dye based, two-dimensional gel (DIGE) approach could distinguish the subset of patients in whom inflammation extends to affect a large number of joints, early in the disease process. The post-translational modifications to candidate protein markers were verified by a novel deglycosylation strategy.

Methods: SF samples from 57 patients were obtained around time of initial diagnosis of JIA. At 1 year from inclusion patients were categorized according to ILAR criteria as oligoarticular arthritis (n=26), extended oligoarticular (n=8) and polyarticular disease (n=18). SF samples were labeled with Cy dyes and separated by two-dimensional electrophoresis. Multivariate analyses were used to isolate a panel of proteins which distinguish patient subgroups. Proteins were identified using MALDI-TOF mass spectrometry with vitamin D binding protein (VDBP) expression and siaylation further verified by immunohistochemistry, ELISA test and immunoprecipitation. Candidate biomarkers were compared to conventional inflammation measure C-reactive protein (CRP). Sialic acid residues were enzymatically cleaved from immunopurified SF VDBP, enriched by hydrophilic interaction liquid chromatography (HILIC) and analysed by mass spectrometry.

Results: Hierarchical clustering based on the expression levels of a set of 23 proteins segregated the extended-to-be oligoarticular from the oligoarticular patients. A cleaved isoform of VDBP, spot 873, is present at significantly reduced levels in the SF of oligoarticular patients at risk of disease extension, relative to other subgroups ($p<0.05$). Conversely total levels of vitamin D binding protein are elevated in plasma and ROC curves indicate an improved diagnostic sensitivity to detect patients at risk of disease extension, over both spot 873 and CRP levels. Sialysed forms of intact immunopurified VDBP were more prevalent in persistent oligoarticular patient synovial fluids.

Conclusion: The data indicate that a subset of the synovial fluid proteome may be used to stratify patients to determine risk of disease extension. Reduced conversion of VDBP to a macrophage activation factor may represent a novel pathway contributing to increased risk of disease extension in JIA patients.

Immune Response to Porphyromonas Gingivalis Citrullinated α-Enolase Cross-Reacts with Human α-Enolase in Polyarticular JIA Patients. Peggy Lee[1], Rebecca Howsmon[2], Claire Murphy[2], Sarah Ringold[1] and Anne M. Stevens[1]. [1]University of Washington, Seattle, WA, [2]Seattle Children's Research Institute, Seattle, WA

Background/Purpose: Antibodies recognizing cyclic citrullinated peptides (CCP) are highly specific for rheumatoid arthritis (RA) and polyarticular juvenile idiopathic arthritis (poly JIA), and may both predict and contribute to early onset and an aggressive disease course. Risk factors for RA, including the HLA-DRB1 shared epitope (SE) and smoking, are associated with higher levels of anti-CCP antibodies. It is unknown what the natural targets of

anti-CCP are, or how they are generated. P. gingivalis, associated with gingivitis and periodontitis, expresses a citrullinated protein, α-enolase, with homology to human α-enolase, and thus is a strong candidate for the autoantigen bound by anti-CCP antibodies. The P. gingivalis α-enolase may serve as a link between oral inflammation induced by P. gingivalis and arthritis. The pathogenesis of JIA may thus involve molecular mimicry between epitopes from citrullinated bacterial and human, triggering autoimmunity in genetically susceptible individuals.

Methods: Anti-citrullinated enolase peptide antibodies (anti-CEP) were quantified by ELISA in plasma from 20 RF+ poly JIA patients ages 7.1–18.5 years and 20 age- and sex-matched controls. Target peptides were selected based on previously identified immunodominant epitopes in adult RA patients, and included *P. gingivalis* CEP citrulline- versus arginine-containing sequences and the human CEP peptide homologs. Citrullinated vimentin and citrullinated non-immunogenic CEP were negative controls. Antibodies to CCP were assayed by QUANTA Lite CCP3.1 IgG/IgA ELISA.

Results: Antibodies to CCP were detected in all 20 RF+ JIA patients and in one of 20 controls, though at low titer. Antibodies to Hu-CEP were detected in 9 JIA patients (45%). All patients with anti-Hu-CEP antibodies also carried Abs to PG-CEP. A tight correlation was found between anti-PG CEP and anti-Hu CEP ($R^2=0.70$), suggesting cross-reactivity between antibodies. Patients with the DRB1 shared epitope (n=12) were no more likely to carry anti-Hu-CEP (50%) or anti-PG-CEP (58%) than those without the shared epitope (n=8, 38%, 50%). No differences were found between patients and controls in control peptide responses, which were all low. Only weak correlations were detected between anti-CEP and age of onset or disease activity as assessed by ESR, CRP, active joint count, loss of range of motion, MD assessment or CHAQ.

Conclusion: A high proportion of patients with RF+ poly JIA develop Abs to citrillinated proteins, which were not detected in healthy children. The coincidental occurrence of anti-Hu-CEP and anti-PG CEP suggest an etiologic role for P. gingivalis infection in poly JIA.

Immunoprecipitation and Advanced Proteomics for the Discovery of Novel Antigenic Targets in Juvenile Idiopathic Arthritis.
Ginger L. Janow[1], Cristina Clement[2], Norman T. Ilowite[3], Laura Santambrogio[2] and Steven A. Porcelli[4]. [1]Children's Hospital at Montefiore, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Children's Hospital Montefiore, Bronx, NY, [4]Albert Eistein College of Medicine, Bronx, NY

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic condition seen by pediatric rheumatologists. The pathogenesis of disease is poorly understood, but is believed to be mediated by an adaptive immune response involving auto-reactive B-cells and T-cells. There are high concentrations of immune complexes in the joint but specificities of these immune complexes are unknown. We hypothesize that joint destruction is partly the result of an adaptive immune response mediated by antibodies, and that examination of peptides and proteins in the synovial fluid (SF) of children with JIA combined with the identification of antigens targeted by antibodies found in arthritic SF will help clarify the pathogenesis of JIA.

Methods: Subjects with JIA with active arthritis of the knee requiring intra-articular corticosteroid injection were recruited from our pediatric rheumatology clinic. Subjects seen by pediatric orthopedics requiring arthroscopic knee surgery for traumatic injuries were recruited as controls. SF was collected from the knee of 4 children with JIA and 2 orthopedic controls. Specimens were diluted, centrifuged, and filtered. Peptidome and proteome were separated with ultrafiltration spin columns and advanced MS/MS was carried out. Protein A&G was used to isolate IgG inclusive immune-complexes. Antigens were eluted with glycine and analyzed using trypsin restriction with MS/MS. Ingenuity pathway analysis was used to analyze the proteome.

Results: High concentrations of immune complexes were found in the joints of JIA patients, nearing 50% of the total sample. Pathway analysis of the proteomes revealed statistically significant overlap with 5 relevant canonical pathways in all patients: acute phase response signaling, complement activation, coagulation system, intrinsic prothrombin activation, and extrinsic prothrombin activation. Peptidome analysis revealed the breakdown products of structural components including multiple collagen subtypes. Antibody-targeted antigens present in three out of the 4 patients but absent in controls were alpha-1-antitrypsin precursor, hyaluronan binding protein, haptoglobin, and protein S100-A9.

Conclusion: Proteome analysis confirmed the validity of our methods, revealing significant overlap with 5 pathways already known to be important in the pathogenesis of JIA. Given the role of short peptides as antigenic targets of T cell responses, the composition of the peptidome in the synovial tissues and fluids of JIA patients is likely to contribute to disease associated adaptive immune responses. The preliminary finding of the breakdown products of structural components suggests a mechanism for amplification of the auto-immune process during inflammation. While the role of the identified antibody-targeted antigens in pathogenesis remains unclear, it is of interest that some of these proteins, including alpha-1-antitrypsin and protein S100-A9 have been implicated as biological markers in both adult RA and JIA. Future research will validate the presence of these antibodies in a larger sample. These antibodies could have potential roles as biomarkers for disease and as targets for treatment.

Measurement and Evaluation of Isotypes of Anti-Citrullinated Fibrinogen and Anti-Citrullinated Alpha-Enolase Antibodies in Juvenile Idiopathic Arthritis Patients.
Brooke Gilliam, Sandra Crespo-Pagnussat, Anil K. Chauhan and Terry L. Moore. Saint Louis University, St. Louis, MO

Background/Purpose: Anti-cyclic citrullinated peptide (CCP) antibodies in juvenile idiopathic arthritis (JIA) have been identified as an important indicator for destructive disease, as is the case with rheumatoid arthritis (RA). Recently, studies have focused on identifying the target proteins of the citrulline modification in both RA and JIA. We found that both IgG anti-citrullinated fibrinogen and α-enolase antibodies were present in our JIA population. In this study, we evaluated serum from patients with various subtypes of JIA to further investigate the presence of isotypes (IgA, IgM) of anti-citrullinated fibrinogen and anti-citrullinated α-enolase, and their association with rheumatoid factor (RF) and anti-CCP antibody isotypes (IgA, IgM, IgG) and other clinical parameters.

Methods: Sera were obtained from 93 JIA patients, 17 systemic lupus erythematosus (SLE) patients, and 10 healthy children. All sera were measured for antibodies against citrullinated and native fibrinogen and α-enolase IgA and IgM by ELISA. Results were compared to anti-CCP antibody isotypes and RF isotypes, in addition to previously measured IgG anti-citrullinated fibrinogen and α-enolase antibodies. All results were also correlated with various clinical parameters.

Results: IgA anti-citrullinated α-enolase antibodies were positive in 14, IgG in 9, and IgM in 11 JIA patients. IgA anti-citrullinated fibrinogen antibodies were positive in 16, IgG in 31, and IgM in 17 JIA patients. Overall, the isotypes of anti-citrullinated fibrinogen and α-enolase appeared more frequently in the polyarticular subset of JIA. One IgM RF-positive polyarticular JIA patient was positive for all 3 isotypes of anti-citrullinated fibrinogen antibodies. IgM anti-citrullinated α-enolase antibodies correlated significantly with IgM anti-citrullinated fibrinogen antibodies (r=0.479, p<0.001), and IgM anti-citrullinated α-enolase antibodies correlated significantly with IgM anti-CCP antibodies (p<0.005). IgM anti-citrullinated fibrinogen antibodies correlated significantly with erythrocyte sedimentation rate (p<0.05). IgA anti-citrullinated α-enolase antibodies correlated significantly with IgA anti-citrullinated fibrinogen antibodies (p<0.05). IgA anti-citrullinated α-enolase antibodies also correlated significantly with IgA RF and IgM RF (p<0.05), and IgA anti-citrullinated fibrinogen antibodies correlated significantly with IgA anti-CCP antibodies and IgM RF (p<0.05). No significant differences were noted the levels of citrullinated autoantibody isotypes when comparing patients with and without joint damage.

Conclusion: Studies have suggested measuring anti-CCP antibody isotypes in both RA and JIA patients, and recent studies have identified target proteins of the citrulline modification. We found that isotypes of both anti-citrullinated fibrinogen and α-enolase antibodies are present in the serum of JIA patients. JIA patients with elevated isotypes of anti-citrullinated fibrinogen and α-enolase antibodies should be evaluated prospectively in comparison with JIA patients who exhibit a less diverse isotype pattern to further determine their role in the pathogenesis of JIA.

Disclosure: **B. Gilliam**, None; **S. Crespo-Pagnussat**, None; **A. K. Chauhan**, None; **T. L. Moore**, None.

325

Anti-Cyclic Citrullinated Peptide Antibody Isotyping and Identification of Citrullinated Proteins in the Synovial Fluid of Juvenile Idiopathic Arthritis Patients. Brooke Gilliam, Sandra Crespo-Pagnussat, Anil K. Chauhan, Reema H. Syed and Terry L. Moore. Saint Louis University, St. Louis, MO

Background/Purpose: Several citrullinated proteins have been detected in the serum and synovial fluid (SF) of rheumatoid arthritis (RA) patients. However, few studies have evaluated citrullination of proteins in juvenile idiopathic arthritis (JIA). It has been proposed that anti-cyclic citrullinated peptide (anti-CCP) antibodies play a pathogenic role in the development of anti-CCP antibody positive arthritis, and it is expected that these antibodies would be present at higher concentrations at the site of inflammation. We evaluated SF from JIA patients to investigate the presence of anti-CCP antibody isotypes and identified specific citrullinated autoantibodies in JIA SF.

Methods: Anti-CCP antibody isotypes (IgA, IgG, IgM, IgA/IgG) were measured by ELISA in the SF of 47 JIA patients. As non-inflammatory controls, SF from 10 osteoarthritis (OA) patients was used. Twenty-four SF samples from patients with various diagnoses were treated and transferred to PVDF membranes and probed with antibodies to native-α enolase, native fibrinogen, and anti-modified citrulline (AMC). SF samples were immuno-precipitated with antibodies to fibrinogen and α-enolase, and citrullinated antibodies were then detected with AMC assay.

Results: Eleven of 47 (23%) JIA SF samples were positive for at least one anti-CCP antibody isotype. IgM anti-CCP antibodies were positive in 9 JIA patients, IgG anti-CCP antibodies were positive in 8 patients, and 2 were positive for IgA anti-CCP antibodies. Three JIA patients were positive for the combined IgA/IgG anti-CCP antibodies. Polyarthritis patients demonstrated significantly higher levels of all anti-CCP antibody isotypes compared to other JIA subtypes (p<0.05), and even higher levels when only evaluating IgM rheumatoid factor (RF)-positive polyarthritis patients. Serum-matched anti-CCP antibody data was available on 27 JIA patients and 5 controls. All IgM RF-positive polyarthritis patients were positive for IgG anti-CCP antibodies in both serum and SF. Two JIA patients positive for IgG anti-CCP antibodies in SF were negative in serum. More JIA patients were positive for IgA anti-CCP antibodies in serum than in SF, while SF showed increased positivity for IgM anti-CCP antibodies compared to serum.

Western blot analysis revealed multiple citrullinated proteins in JIA that were not detected in OA. Immunoprecipitation with α-enolase and fibrinogen, followed by AMC detection showed presence of these specific citrullinated proteins in JIA and no detection in OA

Conclusion: All anti-CCP antibodies were detected in the SF of JIA patients. The most commonly found anti-CCP antibody isotype in JIA SF was IgM, which may be partly indicative of defective B cell class switching in these patients. Measurement of only IgG anti-CCP antibodies would have overlooked 4 JIA patients with elevated levels of IgA and/or IgM anti-CCP antibodies, indicating the importance of measuring all 3 isotypes. The abundance of citrullinated proteins in JIA SF may be characteristic of inflammation, as seen in RA and spodyloarthritis. We have shown the detection of citrullinated proteins at the site of inflammation, specifically identifying citrullinated fibrinogen and α-enolase in SF.

Silencing Intraarticular Snail Expression Ameliorates Rat Collagen-Induced Arthritis Through Induction of Mesenchymal-Epithelial Transition in Synovial Fibroblasts. Chrong-Reen Wang, Shih-Yao Chen, Ai-Li Shiau, Yuan-Tsung Li, Ming-Fei Liu and Chao-Liang Wu. College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background/Purpose: Morphological characteristics of rheumatoid arthritis (RA) synovial fibroblasts (SF) are similar to transformed cells. We hypothesized that epithelial-mesenchymal transition (EMT) of SF regulated by snail contributes to the progression of RA. The pathogenic role of EMT was studied, and the therapeutic effect on arthritis was evaluated by silencing intraarticular snail expression.

Methods: Expression of snail, mesenchymal markers including cadherin-11, epitheral markers and/or phospho-AKT was detected by RT-PCR, immunoblot and/or immunohistochemical analyses on RA synovium, and synovial tissues and SF from normal or collagen-induced arthritis (CIA) rats. Modulation of in vitro expression in SF and in vivo effect on normal or CIA joints was performed by lentivirus-mediated transfer of cDNA or shRNA specific to snail. In vivo responses were evaluated by clinical and histopathological assessments, and immunohistochemical staining on joints. In vitro cell viability and invasion were determined by colorimeric method and modified Boyden chamber, respectively. IL-6 concentrations in culture supernatants were quantified by enzyme-linked immunosorbent assay.

Results: Snail was expressed at high levels in synovial tissues of RA and CIA. Overexpression of snail in SF and joints of normal rats promoted EMT by down-regulation of epithelial markers, gain of mesenchymal markers and enhancement of invasive capacity. Moreover, silencing snail expression ameliorated CIA through the induction of mesenchymal-epithelial transition.

Conclusion: These data demonstrate that regulation of snail in SF alters cell morphology and gene expression between epithelial and mesenchymal phenotypes. These findings implicate that EMT regulated by snail might be explored as a novel therapeutic strategy targeting SF in RA.

Tolerogenic Dendritic Cells Ameliorates the Disease Severity of Murine Collagen-Induced Arthritis. Bin Ning[1], Shang-You Yang[2], Jianlu Wei[1], Weiming Gong[1] and Paul H. Wooley[2]. [1]Shandong University Jinan Central Hospital, Jinan, China, [2]Via Christi Wichita Hospitals, Wichita, KS

Background/Purpose: Rheumatoid arthritis (RA) is a common auto-immune disease characterized by synovial inflammation, cartilage breakdown and bone destruction with the involvement of various types of cells including dendritic cells (DCs). A subset of dendritic cells that induce tolerance is called tolerogenic DCs (tolDCs). They may represent a promising immunosuppressive therapeutic tool for the attenuation of pathogenic T cell responses in autoimmune arthritis. In this study, we examine a series of stable antigen-specific tolDCs with tracking green fluorescent protein (GFP) to investigate their influence in the murine collagen induced arthritis (CIA) model.

Methods: The DCs were isolated from bone marrow of DBA/1Lac/J mice, and stimulated with IL-10 (10ng/ml), TGF-β (10ng/ml), and type II Collagen (CII) to induce CII-specific tolerogenic dendritic cells (tolDCs). The cells were then infected with Lenti-GFP viral vectors for GFP transduction. The GFP-tolDCs were injected ip into CIA mice at the time of arthritis onset. Arthritic animals were clinically assessed 3 times a week. The arthritic paws and blood specimens were harvested at 8 weeks after onset for histological, immunological and molecular analyses.

Results: The phenotype of tolDCs was confirmed by flow cytometry and ELISA. Lymphocyte proliferation assays resulted in semi-matured, high IL-10 and TGF-β production, and low lymphocyte stimulatory capacity with low IFN-γ secretion. Both clinical and histological assessment on the animal studies indicated that the mice receiving tolDCs transfusion had a rapid and significant reduction in severity of arthritis compared to the controls (P<0.01). Fluorescent microscope observation showed aggregated green fluorescent cells in the inflamed synovial membrane where only sporadic presence in liver, spleen or lungs. Data also indicated the extended high expression levels of IL-10 and TGF-β at 4 weeks after the treatment, whereas the IL-17 expression was lower than controls (P < 0.01).

Conclusion: This study reports the successful establishment of a stable phenotype of CII-specific tolDCs and its potential therapeutic influence on collagen-induced arthritis in mice. Introduction of GFP-tolDCs significantly ameliorates the clinical and pathological progress of the experimental arthritis. TolDCs were cumulative at the inflammatory joints and the treatment diminished Th17 response (IL-17 expression). Further investigation is due to reveal the mechanism of tolDCs in regulation of the progression of rheumatoid arthritis.

IL-7; An Important Pro-Inflammatory Factor That Affects Myeloid Cell Function in RA and CIA. Nathan D. Chamberlain[1], Seung-jae Kim[1], Michael Volin[2], Anjali Mehta[1], Nadera J. Sweiss[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL

Background/Purpose: The aim of the study was to examine the role of IL-7 in the pathogenesis of rheumatoid arthritis (RA) as well as in collagen induced arthritis (CIA).

Methods: Linear regression analysis was employed to correlate expression of IL-7 and IL-7R with levels of DAS28 score in RA monocytes. Next, the contribution of IL-7/IL-7R to RA synovial fluid induced monocyte migration was examined by in vitro chemotaxis. Finally, CIA mice were treated therapeutically with IgG or anti-IL-7 antibodies and clinical parameters, joint proinflammatory factors, % spleen TH-1 and TH-17 cells as well as markers of bone destruction were quantified employing ELISA, FACS analysis or real-time RT-PCR.

Results: We show that patients with higher disease activity express elevated levels of IL-7 ($R^2=0.54$, $p=2.10\times10^{-14}$) and IL-7R ($R^2=0.56$, $p=6.59\times10^{-15}$) in 76 RA monocytes suggesting that ligation of IL-7 to IL-7R may be associated with disease progression. Next, experiments were performed to determine whether IL-7 and its receptor play a role in RA synovial fluid mediated monocyte migration. We found that neutralization of IL-7 in RA synovial fluid or blockade of IL-7R on monocytes greatly suppressed RA synovial fluid-mediated monocyte migration further documenting the importance of IL-7 and IL-7R function in myeloid cells. In order to evaluate whether IL-7 is a potential target in RA pathogenesis, CIA, a chronic murine model of RA was employed. We show that like in RA, IL-7R is significantly elevated in the lining and sublining macrophages as well as in sublining endothelial cells in CIA compared to PBS treated ankles. Additionally CIA mice produce 3 fold higher joint IL-7 levels compared to the control group. Hence to examine the role of IL-7/IL-7R in CIA pathology, CIA mice were therapeutically treated with anti-IL-7 antibody or IgG control starting on day 26 post CIA induction. These studies demonstrate that anti-IL-7 antibody treatment significantly reduced joint inflammation on days 33, 37, 40, 41 and 42 post CIA induction compared to the control group however there were no differences detected between the two treatment groups on days 28 and 30. We next found that joint TNF-a as well as ankle and serum levels of CCL2/MCP-1 were 2 fold higher in the IgG group compared to anti-IL-7 antibody treated CIA mice. We also demonstrate that anti-IL-7 treatment was capable of markedly reducing expression of markers for CIA bone erosion including RANKL (3 fold) and Cathepsin K (10 fold). In contrast the percentage of CD3, CD4, TH-1 and TH-17 positive cells was similar in anti-IL-7 and IgG treatment groups. Consistent with these findings joint IL-6 levels were unaffected by anti-IL-7 therapy while there was a trend towards lower levels of joint IL-1b and IL-17 however these values were not significantly different among the two treatment groups.

Conclusion: These novel results suggest for the first time that ligation of IL-7 to IL-7R can affect cell migration, production of proinflammatory factors and osteoclast differentiation from myeloid cells in RA as well as in experimental arthritis models.

The SYK Inhibitor, Fostamatinib, Administered Alone or in Combination with Methotrexate in Rat Collagen-Induced Arthritis, Reduces Bone Erosions, Biomarkers of Cartilage/Bone Destruction, and Synovial Osteoclastogenic Cytokines. Polly Pine[1], Ayodele Apatira[1], Betty Y. Chang[1], Nathan Schoettler[2], Elliott B. Grossbard[1] and Ernest Brahn[2]. [1]Rigel Pharmaceuticals, So San Francisco, CA, [2]UCLA School of Medicine, Los Angeles, CA

Background/Purpose: Spleen tyrosine kinase (SYK) is expressed in hematopoietic cells and is a major downstream regulator of signaling through Fcγ and immunoglobulin receptors as well as non-immunoglobulin receptors associated with adaptor proteins DAP12 and FcRg in osteoclasts. Inhibition of SYK has been shown to reduce the severity of collagen-induced arthritis (CIA). This provided the rationale for the development of the SYK inhibitor, fostamatinib (R788), as a potential treatment for rheumatoid arthritis (RA). In the present rat CIA study, we characterize the activity of fostamatinib alone or with co-administered methotrexate (MTX), on paw inflammation, bone erosion, serum biomarkers of bone destruction, and synovial proinflammatory cytokine expression.

Methods: Syngeneic LOU rats were immunized on day 0 with native type II collagen. At the onset of arthritis (day 10), a total of 59 rats were treated with either a vehicle control, fostamatinib at one of two dose levels (15 or 30 mg/kg q.d. by p.o. gavage), MTX alone (0.4 mg/kg s.c., q.w. for 3 weeks), or fostamatinib (15 or 30 mg/kg) in combination with s.c. MTX q.w. Hind limbs were scored daily for clinical arthritis severity using a standardized method based on the degree of joint inflammation. Serum and synovial tissue were harvested at sacrifice, and biomarker expression was assessed by ELISA. Blinded high resolution digital radiographs and micro3D-CT of hind limbs were obtained at the end of the study (day 28).

Results: Arthritis severity was significantly reduced within 7 days after initiation of fostamatinib therapy and continued to improve throughout the study. By day 28, the mean clinical score in the vehicle group was 7.4 compared with 4.1 and 2.4 in the fostamatinib groups (15 and 30 mg/kg, p< 0.0003 and 0.0001, respectively). Co-administration of MTX with fostamatinib further reduced the clinical scores to 3.6 and 2.1 (15 and 30 mg/kg, respectively, p< 0.0001 vs vehicle, p< 0.0001 vs MTX alone, p> 0.05 vs fostamatinib alone). Radiographs (day 28) demonstrated a significant reduction in joint damage: 5.1 (vehicle) vs. 0.6, 0.0, 0.5, and 0.08 (15 mg/kg and 30 mg/kg fostamatinib alone, 15 mg/kg and 30 mg/kg fostamatinib with MTX, respectively, p< 0.0001 for all groups vs vehicle). Treatment with MTX alone significantly reduced joint damage, although the response was not as robust as that seen with fostamatinib (mean radiographic score = 2.8, p< 0.02 vs vehicle). These findings were confirmed with micro3D-CT analysis. Serum RANKL and COMP were reduced in fostamatinib-treated rats, and combination treatment did not further reduce the level of bone biomarkers. Synovial IL-18, IL-6, and IL-1b were reduced (30 mg/kg fostamatinib with or without MTX vs vehicle). Fostamatinib and MTX treatment were well tolerated and had no overt adverse effects.

Conclusion: Fostamatinib significantly reduced the severity of established rat CIA, had modest additional improvement with co-administered MTX, and was superior to MTX alone. These results indicate that fostamatinib may have potential therapeutic benefits for both the inflammatory synovitis and bone erosions of CIA. Fostamatinib is currently in Phase III trials for RA.

Fut1 Plays A Unique Role in K/BxN Serum Transfer Arthritis by Regulating Angiogenesis and Adhesion Molecule Expression. M. Asif Amin, Phillip L. Campbell, Takeo Isozaki, Jeffrey H. Ruth, Jonathan Vargo, Steven E. Domino and Alisa E. Koch. University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: Angiogenesis is important in rheumatoid arthritis (RA) synovial tissue proliferation and leukocyte ingress into the inflamed joints. Fucosyltransferases (Futs) are involved in the synthesis of glycoconjugates and blood group antigens and other Futs have been shown to be important in inflammatory pathways such as leukocyte homing. Hence, we examined the role of another Fut, Fut1, in angiogenesis and leukocyte recruitment in inflammatory arthritis.

Methods: Mouse lung endothelial cells (ECs) from Fut1 null and wild type (wt) mice were used to perform Matrigel tube formation assays in vitro. We performed Matrigel plug in vivo angiogenesis assays using Fut1 null and wt mice. Some of the plugs were homogenized for hemoglobin determination while others were sectioned to perform immunofluorescence to count the number of blood vessels. To determine the contribution of Fut1-mediated angiogenesis and leukocyte recruitment in an animal model of arthritis, we performed the serum transfer K/BxN arthritis model employing Fut1 null and wt mice. Mouse ankles were measured before induction of arthritis and then on alternate days. Ankles were harvested on day 9, the day of maximum arthritis. Some of the arthritic ankles were homogenized to determine hemoglobin (Hb) while others were sectioned for blood vessel counts. To determine the mechanism of decreased leukocyte recruitment, we performed immunofluorescence for adhesion molecule expression in wt and Fut1 null mouse ankle sections. We stimulated Fut1 null and wt ECs and performed quantitative PCR and enzyme linked immunosorbent assays for adhesion molecule expression.

Results: Fut1 null ECs formed significantly less tubes compared to wt ECs on Matrigel. In the Matrigel plug in vivo angiogenesis assays, we found

that Fut1 null mice had less Hb, an indirect measure of angiogenesis (four fold decrease) compared to wt mice. By immunofluorescence, wt mouse plugs formed significantly greater number of blood vessels. Fut 1 null mice were resistant to K/BxN arthritis showing a significant decrease in ankle circumference in comparison with wt mice. Fut1 null mouse arthritic ankle homogenates had less Hb, when compared to wt mice. Blood vessels formed in Fut1 null mouse ankle sections were four fold decreased compared to wt mouse ankle sections. This suggests that Fut1 plays a critical role in K/BxN arthritis development by modulating angiogenesis. Adhesion molecules are important in leukocyte recruitment into inflammatory sites. After finding decreased leukocytes in Fut1 null mouse sections, we examined the expression of adhesion molecules in arthritic mouse sections. By dual immunofluorescence, we found a marked decrease in intercellular adhesion molecule-1 (ICAM-1) in Fut1 null arthritic ankle sections. ICAM-1 expression was significantly decreased at both mRNA and protein levels in Fut1 null compared to wt mouse ECs, suggesting the mechanism of decreased leukocyte recruitment into the inflamed joint when Fut1 is absent.

Conclusion: These data suggest that Fut1 mediates inflammatory arthritis by modulating angiogenesis and may be a novel approach to treat angiogenesis-dependent diseases such as RA.

PDL241, a Novel Humanized Monoclonal Antibody, Reveals CD319 As a Therapeutic Target for Rheumatoid Arthritis. Michel P.M. Vierboom[1], Jacky Woo[2], Hakju Kwon[2], Debra Chao[2], Shiming Ye[2], Jianmin Li[2], Karen Lin[2], Irene Tang[2], Nicole Belmar[2], Taymar Hartman[2], Elia Breedveld[1], Bert A. 't Hart[1] and Gary C. Starling[2]. [1]Biomedical Primate Research Centre, Rijswijk, Netherlands, [2]Abbott Biotherapeutics, Redwood City, CA

Background/Purpose: Current therapies have shown tremendous progress in the treatment of rheumatoïd arthritis (RA). However, a substantial group of RA patients are still refractory to these therapies or develop resistance. RA patients that are resistant to anti-CD20 therapy illustrate the need for therapies targeted against cells of the late B cell lineage. We identified CD319, a marker of differentiated B cells as a potential target for therapy of RA.

Methods: A humanized antibody PDL241 directed against CD319 was generated. The binding of PDL241 to human tissues was analyzed by immunohistochemistry and FACS analysis of PBMC. Functional activity of PDL241 on PBMC was demonstrated in vitro and in a HuSCID mouse model. PDL241 is a primate specific antibody and safety and efficacy was tested in a collagen-induced arthritis (CIA) model in the rhesus monkey. The rhesus CIA model is an autoimmune-mediated model of polyarthritis with inflammation and erosion of joints that shares several important cellular and histopathological features with RA.

Results: We found that CD319 was expressed on plasma cells, but not CD20 positive B cells, in rheumatoid arthritis synovial tissues. In cultures of PBMC, PDL241 bound plasmablasts and plasma cells but not naïve and memory B cells, and inhibited the production of immunoglobulins in an Fc-dependent manner in vitro by reducing the numbers of late stage B cell lineage cells. High levels of CD319 on plasmablasts and plasma cells rendered them susceptible to ADCC mediated by NK cells. PDL241 also was able to reduce production of human IgM in a PBMC-transfer HuSCID model. Finally, PDL241 showed a beneficial activity in a rhesus macaque model of collagen-induced arthritis (CIA). Treatment with PDL241 resulted in a reduction of collagen-specific IgG and IgM production in the early phase of the disease leading to a reduction in joint swelling and the subsequent destruction of cartilage and bone.

Conclusion: CD319 was identified as a potential therapeutic target in RA following analysis of expression and in functional assays of IgM production from PBMC. The functional activity of PDL241 in the rhesus CIA model further supported the promise of targeting CD319 in RA. Development of PDL241 was halted due to immunogenicity observed in non-human primate models; however, the current study demonstrated the strong potential of CD319 as a therapeutic target in a range of autoimmune diseases, including RA, where CD319-expressing cells have a role in the pathology.

Blockade of CTGF Restores Aberrant Ostoclastgenesis in Collagen Induced Arthritis (CIA) Mice Through Inhibition of Th-17 Differentiation. Kazuhisa Nozawa[1], Maki Fujishiro[2], Ayako Yamaguchi[3], Mikiko Kawasaki[2], Shouzou Ichinose[2], Mitsuaki Yanagida[2], Kazuhisa Iwabuchi[2], Keigo Ikeda[4], Shinji Morimoto[5], Megumi Morioka[6], Yoshinari Takasaki[1] and Iwao Sekigawa[4]. [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Juntendo University Graduate School of Medicine, Chiba, Japan, [3]Juntendo University Graduate School of Medicine, Tokyo, Japan, [4]Juntendo University Urayasu Hospital, Tomioka, Urayasu, Chiba, Japan, [5]Juntendo University Urayasu Hospital, Tokyo kyo, Japan, [6]Nihon Nosan Corporation, Kanagawa, Japan

Background/Purpose: Our previous study demonstrated changes in the profiles of serum protein biomarkers in infliximab-treated rheumatoid arthritis (RA) patients using a novel approach to proteomic research. Several proteins exhibited vast changes in expression after infliximab treatment, and we have reported connective tissue growth factor (CTGF) appeared to be a potent strong biomarker in infliximab-treated RA patients. Furthermore, we also found that CTGF was upregulated in both serum level and tissue expression of patients with RA, and that CTGF was related to disease progression of RA through abnormal activation of osteoclasts in vitro. To extend our research project, this study was conducted to clarify roles of CTGF for RA pathogenesis. To investigate more precise roles of CTGF for RA pathogenesis, we analyzed effects of blockade against CTGF pathway on the progression of arthritis in collagen induced arthritis (CIA) mouse.

Methods: CIA was introduced in DBA/1J mice by immunization in combination with typeIIcollagen and complete Freund's adjuvant (CFA). The efficacy and mechanisms for prevention of the arthritis were evaluated in the mice treated with or without neutralizing anti-CTGF monoclonal antibody (mAb).

Results: The blockade of CTGF by anti-CTGF mAb treatment significantly ameliorated the arthritis compared to the non-treated controls. Moreover, serum levels of C reactive protein (CRP) and matrix metalloproteinase (MMP)-3 reduced in the CTGF-treated mice. The blockade of CTGF decreased interleukin (IL)-17 and IL-21 production from purified CD4+ T lymphocytes. Although gene expression of retinoic-acid-receptor-related orphan receptors gamma t (RORgt) was not suppressed by anti-CTGF mAb treatment, those of interferon regulatory factor-4 (IRF-4) and IkappaBzeta, which are other important molecules for Th-17 differentiation, were suppressed. In addition, the blockade of CTGF inhibited pathological T lymphocytes proliferation against typeIIcollagen restimulation extra vivo. Moreover, aberrant sRANKL/MCSF-induced osteoclastgenesis of CD14+ progenitor cells in CIA was restored by anti-CTGF mAb treatment.

Conclusion: The present study demonstrated that the blockade of CTGF significantly prevented a progression of arthritis in CIA mice. The administration of anti-CTGF mAb had suppressive effects on aberrant pathological T cells proliferation and Th17 differentiation in CIA mice. In addition, the blockade of CTGF pathway might restore aberrant ostoclastgenesis of CIA through direct effect to CD14+ osteoclastic progenitor cells and indirect effects for Th-17 differentiation. CTGF may become a new target molecule for treatment of RA.

Pressure and Blood Flow Measurements in Efferent Lymphatics As Biomarkers of Arthritic Flare. Echoe M. Bouta[1], Ronald Wood[2], Christopher T. Ritchlin[3], Lianping Xing[1] and Edward M. Schwarz[1]. [1]University of Rochester, Rochester, NY, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]University of Rochester Medical Center, Rochester, NY

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease with episodic flares in affected joints. These flares are associated with decreased lymphatic drainage. In TNF-Tg mice, a model of inflammatory-erosive arthritis, the popliteal lymph node (PLN) expands in volume during the pre-arthritic "expanding" phase and then "collapses" during flare. Currently, the factors that cause PLN collapse are unknown. Local changes in physiology are reasonable explanations given the finding that PLN and iliac lymph node collapse occurs in series along the ipsilateral axis in the setting of unaltered chronic inflammation and systemic autoimmunity. Thus, we tested the hypothesis that PLN collapse and arthritic flare are associated with increased pressure and decreased blood flow within the efferent lymph node (PLN) of inflamed joints.

Methods: The PLNs of TNF-Tg mice (C57B6) were phenotyped as expanding or collapse with contrast-enhanced MRI. Pressure measurements

were performed by inserting a glass micropipette connected to a pressure transducer into the PLN of anesthetized WT and TNF-Tg mice. Blood flow within the lymph node and lymph node volume were measured by 3D power Doppler ultrasound and volumetric rendering in Amira.

Results: Lymph node pressure was significantly decreased in expanding PLN of TNF-Tg mice vs. that of WT mice (3.4 ± 0.4 vs 6.7 ± 0.6 cmH$_2$O; p<0.01). The pressure in collapsed PLN of TNF-Tg mice was significantly greater vs. expanding node in the same mice (8.6 ± 1.7 vs. 3.4 ± 0.4 cmH$_2$O; p<0.05), but similar to WT node. We also found that the volume of blood vessels positive for Doppler flow was significantly 6-fold less in collapsed vs. expanding PLN of TNF-Tg mice (0.050 ± 0.036 mm^3 vs. 0.3042 ± 0.08192 mm^3; p<0.05) (Figure).
Conclusion: Here we describe a novel approach to quantify lymph node pressure and blood flow within PLNs of WT and TNF-Tg mice. Our finding of significantly decreased lymphatic pressure during the pre-arthritic stage is consistent with the theory that lymphangiogenesis is a compensatory mechanism to prevent synovitis and joint damage during RA pathogenesis. Furthermore, increased pressure and decreased vascular flow observed in collapsed PLN is also consistent with this theory, and suggest that lymphatic pressure and blood flow within the efferent lymph nodes are potential biomarkers to assess RA progression and response to therapy, with the later achieved using clinically relevant non-invasive ultrasound.

Selective iNOS Inhibition Increases the Lymphatic Pulse and Drainage From Arthritic Joints in TNF-Tg Mice. Yawen Ju, Ronald Wood, Lianping Xing, Christopher T. Ritchlin and Edward M. Schwarz. University of Rochester Medical Center, Rochester, NY

Background/Purpose: Sufficient lymphatic drainage, which is partially controlled by an intrinsic lymphatic pulse, is an important mechanism to limit joint inflammation and destruction from arthritis. We reported recently that arthritic flare in TNF transgenic (TNF-Tg), a mouse model of inflammatory-erosive arthritis, coincides with the loss of the lymphatic pulse afferent to expanding draining lymph nodes, causing their collapse. From other models, the lymphatic pulse is known to be controlled by endothelia nitric oxide synthase (eNOS), and inhibited by inducible NOS (iNOS) expresses in Gr-1+ cells. To determine if this mechanism controls the lymphatic pulse and lymphatic drainage in inflammatory-erosive arthritis, we tested the hypotheses that: 1) Gr-1+/iNOS+ cells are present in the draining lymph nodes of flaring TNF-Tg mice; and 2) selective iNOS inhibition increases the lymphatic pulse and drainage from joints to draining lymph nodes.

Methods: Immunohistochemistry for Gr-1 and iNOS was performed on popliteal lymph node (PLN) frozen sections from WT and TNF-Tg mice. The lymphatic pulse and flow afferent to the PLN were quantified in TNF-Tg mice with collapsed PLN (>8-month-old) and WT controls (n=4 legs) via *in vivo* near infrared indocyanine green (NIR-ICG) imaging before and after saline (placebo), iNOS specific inhibitor L-NIL (4mg/kg), or general NOS inhibitor L-NAME (5mg/kg) was injected S.C. in footpad.

Results: Immunohistochemistry showed more iNOS expressing Gr-1+ cells in collapsed vs. expanding PLN (127 vs. 3 cells/mm^2), and undetectable numbers in WT PLN. Saline did not change the lymphatic pulse in either WT or TNF-Tg mice. However, L-NIL significantly increased the pulse in TNF-Tg mice (from $0.42 +/-0.84$ to $2.19 +/-0.77$ pulse/min; p<0.05), but not in age-matched WT mice ($0.96 +/-1.42$ to $3.13 +/-2.36$ pulse/min; p=0.08). Moreover, L-NIL significantly increase lymphatic flow in TNF-Tg vs. saline ($73.48 +/-8.9$ vs, $53.25 +/-12.72$ % ICG clearance; p<0.05). In contrast, L-NAME decreased the clearance rate in both WT ($27.77 +/-13.78\%$) and TNF-Tg ($9.07 +/-33.65\%$), but did not significantly change the pulse rate.

Conclusion: We demonstrated that large numbers of iNOS expressing Gr-1+ cells exist in collapsed PLN of TNF-Tg mice with flaring inflammatory-erosive arthritis, and that the specific iNOS inhibitor L-NIL increased the lymphatic pulse and afferent lymphatic drainage. These results suggest that selective iNOS inhibition may be effective in ameliorating arthritic flare by improving lymphatic drainage, which is currently being tested in a prospective study of flaring TNF-Tg mice treated for 6-weeks with L-NIL, L-NAME, or placebo. The effects of these treatments on knee and ankle synovitis and focal joint bone erosion determined by CE-MRI, micro-CT and histology will be presented.

Treatment with Bgp-15, a Novel Insulin Sensitizer Attenuates Collagen-Induced Arthritis in DBA/1 Mice. Peter Mandl[1], Silvia Hayer[1], Stephan Blüml[1], Victoria Saferding[1], Despoina Sykoutri[1], Kurt Redlich[1] and Josef S. Smolen[2]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: BGP-15, a small synthetic hydroxylamine derivative is a member of a new class of insulin-sensitizing medications also known as chaperone-inducers. Beside its beneficial effects on glycemic control and insulin sensitivity in patients with Type 2 diabetes, BGP-15 is known to induce heat shock protein Hsp72 and heat shock transcription factor HSF1, which in turn are involved in joint inflammation. Moreover, BGP-15 also inhibits poly-ADP-ribose polymerase (PARP) and the phosphorylation of c-JUN N-terminal kinase via Hsp72 overexpression. Therefore it might also play a role in the regulation of inflammatory joint disease. Our objective was to evaluate the *in vivo* effects of BGP-15 on collagen-induced arthritis (CIA) in DBA/1 mice.

Methods: Arthritis was induced by intradermal injection of bovine type II collagen (bCII) and incomplete Freund's adjuvant (CFA) in male DBA/1 mice. BGP-15 was administered either one week prior to the first immunization (prophylactic experiment, n:14 in both groups) or upon the appearance of symptoms (therapeutic experiment, n:12 in both groups) in drinking water. Arthritis incidence and severity was assessed for 28 days following the second immunization (boost) with bCII and CFA on day 21. Histological evaluation was carried out on hind paws using Osteomeasure® software. Anticollagen antibodies were measured by enzyme-linked immunosorbent assay. The cellular composition of the draining lymph nodes was measured by flow cytometry. *In vitro* cytokine measurements were carried out on dendritic cells and macrophages differentiated from murine bone marrow macrophages.

Results: BGP-15 significantly reduced the incidence of CIA by 28% and also reduced both paw swelling (p≤0.01) and grip strength (p≤0.05) in the prophy-

lactic experiment. In the therapeutic experiment BGP-15 significantly attenuated both paw swelling (p≤0.01) and grip strength (p≤0.05). Histological evaluation of the hind paws demonstrated reduced area of inflammation (p≤0.05), area of erosion (p≤0.01) and number of osteoclasts (p≤0.05) in the BGP-15 treated group when compared to the control group. No significant differences were revealed between anticollagen antibody levels or in the distribution of T-cells, B-cells, dendritic cells and monocytes/macrophages harvested from draining lymph nodes, suggesting an effect predominantly involving the innate immune system. In line with these findings BGP-15 (1mM) inhibited the LPS-induced production of IL-12, IL-6 and TNF in both dendritic cells and macrophages.

Conclusion: Our results demonstrate that the novel chaperone-inducer BGP-15 has a profound prophylactic and therapeutic effect on autoimmune arthritis, mainly due to an effect on the effector phase.

Preclinical Development of ALX-0061, an Anti-IL-6R Nanobody® for therapeutic Use in Rheumatoid Arthritis with a High in Vitro Affinity and Potency and a Competitive in Vivo Pharmacological Profile. Maarten Van Roy[1], Hans Ulrichts[1], Stefaan Rossenu[1], Sandy Jacobs[1], Sofie Poelmans[1], Gert Verheyden[1], Michel Vierboom[2], Bert 't Hart[2], Judith Baumeister[1] and Josefin-Beate Holz[1]. [1]Ablynx N.V., Zwijnaarde, Belgium, [2]Biomedical Primate Research Centre, Rijswijk, Netherlands

Background/Purpose: Interleukin-6 (IL-6) is a pleiotropic cytokine inducing a wide range of biological activities via its receptor IL-6R. IL-6 plays an important role in the pathogenesis of a variety of diseases, including rheumatoid arthritis (RA), and blocking of IL-6R results in clinical benefit as shown with tocilizumab (TCZ), a monoclonal antibody targeting IL-6R.

Nanobodies are therapeutic proteins based on the smallest functional fragments of heavy chain-only antibodies, naturally occurring in the *Camelidae* family. ALX-0061 is a bispecific anti-IL-6R Nanobody engineered to obtain an extended half-life *in vivo* by targeting human serum albumin, in combination with a high *in vitro* affinity and potency for the anti-IL-6R building block.

The presented work was aimed at determining the ALX-0061 *in vitro* and *in vivo* profile and at translating these results to a first-in-man (FIM) dose.

Methods: ALX-0061 was characterized extensively using *in vitro* systems: biological activity, specificity and affinity was assessed and compared to TCZ. Due to very tight target binding, the affinity of ALX-0061 for IL-6R could not be accurately determined via surface plasmon resonance and the new and more sensitive Gyrolab™ platform was used.

The PK/PD properties of ALX-0061 were examined in naive cynomolgus monkeys and in an human (h)IL-6-induced acute phase response model in the same species in which platelet numbers and plasma concentrations of CRP and fibrinogen were monitored as disease parameters.

In vivo efficacy of ALX-0061 was assessed in a collagen-induced arthritis (CIA) rhesus monkey model. In this model, inflammation of the joints was induced via sensitization with collagen type II, after which clinical endpoints were assessed in correlation to biomarker deregulation.

Results: ALX-0061 neutralized specifically both soluble and membrane IL-6R with a comparable *in vitro* potency to TCZ. However, affinity of ALX-0061 for IL-6R (0.19 pM ± 0.08 pM) was 2000-fold superior compared to TCZ (462 pM ± 138 pM).

In the cynomolgus monkey, ALX-0061 showed a dose-dependent and complete inhibition of three hIL-6-induced inflammation parameters. PK analysis in the same species demonstrated a half-life (5.7 to 7.4 days) similar to that reported for serum albumin which was predicted to translate into a convenient *iv* dosing regimen in humans. Measurement of total sIL-6R levels in these studies supported the calculation of the FIM dose.

Although emergence of neutralising anti-drug antibodies was observed in most of the ALX-0061- or TCZ-treated animals in the CIA disease study, both drugs demonstrated a clear biological effect as shown on CRP levels. A clinical effect was obvious in animals with active drug exposure throughout the course of the study.

Conclusion: ALX-0061 combines high *in vitro* affinity and potency with favorable PK/PD properties in non-human primates and has the potential to be an effective treatment for RA in humans. A Phase I/II clinical trial is ongoing. Interim analysis of the single ascending dose part were encouraging, results from the multiple dose part are expected in H2 2012.

In Vivo Quantification of Joint Inflammation in a Murine Arthritis Model by Anato-Molecular Imaging. Smriti K. Raychaudhuri[1], Anupam Mitra[1], Kuang Gong[2], Jian Zhou[2], Jinyi Qi[2], Siba P. Raychaudhuri[1] and Abhijit J. Chaudhari[3]. [1]UC Davis School of Medicine/VA Sacramento Medical Center, Mather, CA, [2]University of California, Davis, Davis, CA, [3]UC Davis School of Medicine, Sacramento, CA

Background/Purpose: Positron Emission Tomography (PET) using the radiotracer 18F-fluorodeoxyglucose (FDG) with X-ray Computed Tomography (CT) has the ability of producing an in vivo, three-dimensional quantitative map of joint metabolism (hence inflammation) with co-registered anatomy. We report our experience on using 18F-FDG-microPET/CT as a quantitative marker for monitoring the pathogenesis of inflammatory arthritis in the collagen induced arthritis (CIA) mouse model.

Methods: CIA was induced in 8–12 weeks old male DBA/1 mice (n=10) by injecting 100mg bovine collagen type II in 100ml of complete Freund's adjuvant intradermally into the proximal tail followed by a second intradermal injection of collagen II with incomplete Freund's adjuvant on day 21. At baseline (1 day before the first injection), 5 randomly chosen animals underwent microPET/CT scan for assessment of baseline status. At days 28 and 56, 5 animals respectively were scanned using microPET/CT, clinical scoring was performed, and joint tissue was derived for histopathological analysis. Quantitative metrics derived from microPET/CT were correlated against clinical score and histopathology outcomes on a per joint and whole limb basis.

Results: Images from microPET showed a marked increase in metabolic activity at affected joints of the upper and/or lower extremity at follow-up compared to baseline values. microCT images provided detailed assessment of bone destruction. At the early time point (day 28), increase in metabolic activity by an average of 20% was observed in the limbs. This further increased to an average of 50% at day 56 as the disease progressed. Focal activity was visualized at individual affected joints by utilizing advanced resolution-recovery methods. microPET/CT metrics at the early and late time points seemed to broadly correlate with clinical and histopathology scores at the arthritic sites.
Figure 1. An 18F-FDG-microPET scan of the limb of an animal with collagen induced arthritis. Resolution recovery methods allow unparalleled visualization of the details of inflammatory activity.

Conclusion: Our study shows that quantitative metrics associated with disease pathogenesis can be derived from 18F-FDG-microPET/CT. Changes in clinical score and histopathology outcomes seem to correlate with microPET/CT metrics on both a per joint and whole limb basis. microPET/CT may provide a promising tool for understanding the pathogenesis of arthritis and for monitoring response to new treatments in experimental arthritic models.

The Potent Phosphoinositide-3-Kinase-(δ,γ) Inhibitor IPI-145 Is Active in Preclinical Models of Arthritis and Well Tolerated in Healthy Adult Subjects. James R. Porter, Janid Ali, Jonathan P. DiNitto, Joi Dunbar, Kerrie Faia, Jennifer Hoyt, Brianne Leary, Alice R. Lim, Christian Martin, Charlotte McKee, Patrick O'Hearn, Melissa Pink, Jennifer Proctor, John Soglia, Bonnie Tillotson, Kerry White, David G. Winkler and Vito J. Palombella. Infinity Pharmaceuticals, Inc., Cambridge, MA

Background/Purpose: Phosphoinositide-3-kinases (PI3K) play pivotal roles in cell signaling and regulate a variety of cellular functions. PI3K-δ and PI3K-γ isoforms are necessary for adaptive and innate immunity and are important mediators in inflammatory and autoimmune diseases. IPI-145 is a potent PI3K-δ,γ inhibitor in clinical development for patients with advanced hematologic malignancies and inflammatory/autoimmune disorders. The isoform selectivity and activity of IPI-145 were evaluated using *in vitro* and *in vivo* models, and a Phase 1 study was conducted in healthy adult subjects.

Methods: *In vitro* isoform selectivity and activity of IPI-145 was determined by measuring direct binding to PI3K isoforms, and via isoform-specific cell-based assays. Cell proliferation assays were performed by stimulating human peripheral blood CD19$^+$ B cells or CD3$^+$ T cells in the presence or absence of IPI-145. The PI3K-δ inhibitory activity of IPI-145 in human whole blood was measured in a basophil activation assay. The *in vivo* anti-inflammatory activity of IPI-145 was assessed in a rat collagen-induced arthritis model. Female Lewis rats with established type II collagen-induced arthritis were treated with IPI-145 (0.1 to 10 mg/kg) or vehicle once daily via oral gavage and paw swelling was assessed by plethysmometry.

The safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of single and multiple ascending doses of IPI-145 was evaluated in a Phase 1 double-blind, placebo controlled, randomized clinical trial in healthy adult subjects. The *ex vivo* effect of IPI-145 on basophil activation in whole blood was assessed in both the single and multiple ascending dose portions of the study.

Results: IPI-145 potently inhibits PI3K-δ and PI3K-γ, with K_i values of 23 pM and 243 pM, respectively. IPI-145 is significantly less active against the PI3K-α isoform, with a K_i value of 25.9 nM, and inhibits PI3K-β with a K_i value of 1.6 nM. The IC_{50} of IPI-145 in a PI3K-δ-selective assay is 1 nM, and the IC_{50} in a PI3K-γ-selective assay is 32 nM. The IC_{50} values of IPI-145 in human B-cell and T-cell proliferation assays are 0.5 nM and 9.5 nM, respectively. In human whole blood, IPI-145 potently inhibits PI3K-δ specific basophil activation with an IC_{50} of 78 nM. In the rat collagen-induced arthritis model, the area under the ankle diameter versus time curve was reduced 25% to 89% relative to vehicle controls across the 0.1 to 10 mg/kg dose range evaluated.

In the Phase 1 clinical study there was a proportional increase in IPI-145 exposure following single ascending and repeat dose administration. A rapid onset and durable effect of IPI-145 in the *ex vivo* basophil assay was observed at all dose levels. In addition, IPI-145 is clinically well tolerated following single and repeat daily doses of IPI-145.

Conclusion: IPI-145 is a potent inhibitor of PI3K-δ,γ in biochemical and cellular assays and is active in B-cell and T-cell proliferation assays and the rat collagen-induced arthritis model. The preclinical activity and the favorable tolerability, PK, and PD profiles of IPI-145 in healthy human subjects support ongoing Phase 2 clinical trial plans in subjects with autoimmune and inflammatory disorders.

Differences Between Juvenile and Adult Rodents with Collagen Induced Arthritis. Tracy D. Wilson-Gerwing[1], Isaac V. Pratt[1], David M.L. Cooper[1], Tawni I. Silver[1] and Alan M. Rosenberg[2]. [1]University of Saskatchewan, Saskatoon, SK, [2]Royal University Hospital, Saskatoon, SK

Background/Purpose: Juvenile idiopathic arthritis (JIA) is among the most common chronic diseases of childhood. Arthritis is a potentially disabling disease that can result in ongoing pain and inflammation. Although chronic intra-articular inflammation is common to both children and adults with chronic arthritis there are, apart from onset age, clinical characteristics that further distinguish chronic arthritis in pediatric and adult populations. Collagen induced arthritis (CIA) is a model of inflammatory joint disease. For the first time, this project demonstrates that juvenile and adult rats respond differently to the inflammation and pain resulting from CIA.

Methods: Juvenile (5 wks old) and adult (13 wks old) male Wistar rats were immunized with an emulsion of bovine type II collagen and incomplete Freund's adjuvant. Naive juvenile and adult rats were included as controls. Paws were scored on a scale of 0 (normal paw) to 4 (disuse of paw). Animals were monitored for weight changes. Two weeks following development of arthritis, animals were euthanized and hindpaws were collected and imaged with micro-computed tomography (micro-CT), magnetic resonance imaging (MRI) and ultrasonography. Images were evaluated qualitatively for the degree of soft tissue swelling, joint changes and bone destruction.

Results: Juvenile rats developed arthritis significantly earlier than their adult counterparts (p=0.0126) and experienced less erythema and edema of the affected paws (p<0.0001). Micro-CT of affected hindpaws demonstrated that adult CIA rats exhibited widespread boney changes over the phalanges, metatarsals and tarsus while juveniles had more localized damage of phalanges and metatarsals. MRI of hindpaws confirmed extensive edema and inflammatory insult in the adult CIA rats compared to their juvenile counterparts. Ultrasound of distal phalanges of the juvenile CIA animals showed tissue edema not evident on inspection.
Conclusion: This research is the first to identify differences between juvenile and adult rats with CIA and provides evidence that the disease process may differ between the two age groups. This model will allow for studying arthritis pathogenesis and treatment interventions in juvenile versus adult populations.

Myeloid Deletion of SIRT1 Aggravates Inflammatory Arthritis Via Nuclear Factor-Kappab Activation in Animal Model of Rheumatoid Arthritis. Sang-il Lee and Yun-Hong Cheon. Gyeongsang National University School of Medicine, Jinju, South Korea

Background/Purpose: The nuclear factor-kappaB (NF-kB) activation plays a pivotal role and macrophages are of central importance in the pathogenesis of rheumatoid arthritis (RA). The SirT1, which is a class III histone deacetylase, deacetylates acetyl group of various transcription factors including NF-kB and modulates their functions, suggesting that myeloid deletion of SirT1 may affect inflammatory arthritis such as RA. The study was performed to assess the function of SirT1 in inflammation and joint destruction in *in vivo* model of RA.

Methods: The mice with myeloid cells-specific deletion of SirT1 (M-SirT1 KO) were generated by using the loxP/Cre recombinase system. K/BxN serum transfer arthritis was induced in M-SirT1 KO mice and their age-matched littermate loxP controls (Sirt1$^{loxP/loxP}$LysM-Cre$^{-/-}$) by injection of K/BxN serum. Arthritis severity was assessed by clinical and histopathologic scoring. The levels of inflammatory cytokines in the joints and serum were measured by ELISA. The NF-kB acetylation, activation, and cytokine/chemokine expression were assessed by Western, EMSA, and ELISA, respectively, using bone marrow-derived macrophages (BMMs).

Results: M-SirT1 KO showed severe form of inflammatory arthritis accompanied by aggravated histopathologic findings including synovial inflammation, bone erosion, and cartilage damage. These effects were paralleled by increased F4/80+ macrophage infiltration into synovium and increased levels of IL-1, IL-6, and RANKL. TNF-α stimulated M-SirT1 KO BMMs displayed hyperacetylated p65 and increased NF-kB binding activity than controls, resulting in increased transcriptional activation of proinflammatory target genes.

Conclusion: This study demonstrates that SIRT1, in macrophages, functions to inhibit NF-kB-mediated transcription, implying that myeloid cell-specific modulation of SirT1 may be beneficial in the treatment of inflammation arthritis such as RA.

Oral Administration of a Novel Small Molecule BET Bromodomain Inhibitor, RVX-297, Reduces Disease Severity in a Rat Collagen-Induced Arthritis Model. R. Jahagirdar[1], S. Attwell[1], E.M. Gesner[1], K.G. McLure[1], H.C. Hansen[1], J. Chen[2], J. Wu[1], K. Norek[1], N. Shenoy[2], G.S. Wagner[1] and P. R. Young[1]. [1]Resverlogix Corporation, Calgary, AB, [2]Aravasc Inc., Sunnyvale, CA

Background/Purpose: BET (Bromodomain and Extra-Terminal) proteins have recently emerged as a key epigenetic regulator of genes at the transcriptional level and inhibition of their binding to select histone peptide sequences bearing acetylated lysines can suppress the production of some inflammatory cytokines. Here we determine the activity of a novel, orally bioavailable BET inhibitor, RVX-297, in an animal model of rheumatoid arthritis.

Methods: Binding of RVX-297 to purified bromodomains (BDs) was measured by competition with a tetra-acetylated peptide derived from the amino terminus of histone 4 using fluorescence resonance energy transfer (FRET) and by thermal denaturation of BDs. The effect of RVX-297 on inflammatory mediators in cellular assays was measured by quantitative RT-PCR. RVX-297 was dosed by oral gavage in the rat collagen-induced arthritis (CIA) model, an experimental model of polyarthritis that has been widely used for preclinical evaluation of anti-arthritic agents.

Results: RVX-297 selectively binds to BET bromodomains (e.g. IC$_{50}$s = 0.82 and 0.012mM for BRD4 BD1 and BD2, respectively), but not to other BDs tested. *In vitro*, RVX-297 dose dependently inhibited LPS-induced IL-6 in mouse bone marrow-derived macrophages, (IC50 = 0.3 mM) and T-cell receptor-induced IL-17 mRNA expression in human PBMCs (IC50 of 3.7 mM). Furthermore, in human primary synovial fibroblasts taken from patients with rheumatoid arthritis, RVX-297 inhibited TNFa-induced MMP1, MMP3, RANKL, VCAM-1 and IL-6 expression, all of which have been associated with diseased tissue. These observations suggested that RVX-297 might also show activity in an autoimmune disease model for rheumatoid arthritis.

Following administration of collagen, the rat collagen-induced arthritis model develops a measurable polyarticular inflammation, progressive destruction of cartilage and bone destruction in association with pannus formation. Therapeutic oral administration of RVX-297 from the onset of established arthritis significantly reduced the progression of disease severity in a dose-dependent manner (25 to 75 mg/kg b.i.d.). On day 7 of arthritis, RVX-297 (75 mg/kg b.i.d.) inhibited the increase in ankle diameter by 92% relative to disease controls. To further characterize the pharmacodynamic effects, histopathology of the ankle and knee joints was evaluated. At 50 mg/kg and 75 mg/kg, b.i.d., RVX-297 reduced the histopathology parameters in the in the ankle by 64% and in the knee by 86–94%.The expression of the inflammatory mediators IL-1b, MMP3, MMP13, RANKL, VCAM-1 and IL-6 were all reduced in the ankle joint at the mRNA or protein level.

Conclusion: These results demonstrate that the BET inhibitor RVX-297 significantly decreases clinical signs of disease in a rat model of rheumatoid arthritis, reflecting a decrease in production of a number of cytokine and inflammatory mediators. Therefore, BET inhibitors offer promise for the treatment of rheumatoid arthritis and other autoimmune diseases.

Novel Combination Therapy of Existing Repurposed Therapies, Designed by Predictive Software Modeling, Shows Profound Impact On Disease Progression in a Murine Collagen-Induced Arthritis Model. Shireen Vali[1], Canio Refino[2], Jay Dela Cruz[2], Robinson Vidva[1], Prashant Nair[1], Saumya Radhakrishnan[1], Pradeep Fernandes[1], Taher Abbasi[1] and Gurkirpal Singh[3]. [1]CellWorks Group, Saratoga, CA, [2]InTouch Bio, Alameda, CA, [3]Stanford University School of Medicine, Palo Alto, CA

Background/Purpose: Rheumatoid Arthritis (RA) involves a complex interaction of multiple cell systems, cytokines and mediators. We recently developed a predictive software-based mathematical model that emulates RA pathophysiology at cellular level by incorporating the interaction of known cell systems and associated signaling and metabolic pathways. For this study, this model was used to design a novel therapy for RA by screening more than one million in-vivo equivalent studies. CWG952 is an oral small molecule novel multi-targeted therapy, rationally designed to reduce signs, symptoms and radiologic progression of RA. It combines 3 FDA-approved drugs, repurposed from different indications, in a computer-generated specific ratio of individually sub-therapeutic dosages. We present results of this therapy on the murine collagen-induced arthritis (mCIA) model in an early therapeutic RA setting.

Methods: mCIA was induced in male DBA-1 mice by subcutaneously injecting 0.05 ml/mouse of Bovine Collagen in complete Freund's adjuvant (CFA) emulsion on day 0. A booster dose of collagen in incomplete Freund's adjuvant (IFA) emulsion was given via the same route three weeks later (day 21). On day 21, mice without clinical signs of RA were randomly assigned to 2 groups of 9 and subsequently orally gavaged with CWG952 or vehicle. Front and hind paws were evaluated every other day for clinical disease using a 0–4 scale with a maximum score of 16 per animal. After obtaining a terminal serum sample, mice were sacrificed on day 42. Hind paws were collected, processed and evaluated by a histopathologist blinded to group assignments. Scores (0 to 5), for synovitis, panus formation, cartilage destruction and bone erosion were assigned to each hind paw and mean scores for each mouse were calculated.

Results: Compared to the vehicle control, CWG952 treatment regimen significantly slowed disease progression and decreased the median total clinical disease by 72% and histological disease by 43% respectively. Liver enzyme and lipid assays conducted on the terminal serum samples showed no difference between the Vehicle and CWG952 treatment arms. Key efficacy results are summarized below.

	Vehicle control (n=9), Mean ± SEM	CWG952 (n=9), Mean ± SEM	P values (2-tailed t-test)
Day 39 Paw Scores	10.89±1.01	6.89±1.42	0.044
Paw Scores (mean day 25–41)	7.57±1.07	4.14±1.20	0.060
Synovitis Score	4.22±0.35	3.06±0.39	0.041
Cartilage Destruction	3.72±0.51	2.22±0.46	0.043
Bone Erosion	3.83±0.49	2.28±0.48	0.038

Conclusion: CWG952, an oral combination of 3 FDA-approved drugs, repurposed from other indications, and combined at sub-therapeutic dosages, shows profound impact on disease progression. These results suggest that CWG952 can be an effective therapeutic agent for treating RA.

Functional Impairment in an Animal Model for Rheumatoid Arthritis Assessed As Changes in Gait Is Due to Joint Destruction but Not Synovial Inflammation *Per Se.* Gregor Bauer[1], Constantin Aschauer[1], Birgit Niederreiter[1], Josef S. Smolen[2], Kurt Redlich[1] and Silvia Hayer[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: To investigate the individual impact of synovial inflammation, subchondral bone erosion or cartilage damage on functional impairment in an animal model of Rheumatoid Arthritis (RA).

Methods: We analysed gait profiles in human tumor necrosis factor transgene (hTNFtg) animals, using the video-based Catwalk gait analysis system (from Noldus, Netherlands). In this system, mice run along an illuminated glass plate. A digital camera measures light emissions resulting from the contact of paws on the glass plate. We evaluated gait profiles at different time points of disease (6, 10, 15 week of age) in hTNFtg animals. Wildtype littermates served as controls. Bodyweight and clinical signs of arthritis including paw swelling and grip strength were also evaluated. To investigate whether gait changes are pain related, we treated hTNFtg animals with diclofenac (50 mg/kg, i.p.) at week 10 and week 15 after birth and analysed gait profiles before, as well as 1h and 3h after treatment. To analyse inflammatory joint destruction, we quantitatively assessed the extend of synovial inflammation, subchondral bone erosion and cartilage damage on hematoxylin & eosine (H&E), tartrate-resistant acid phosphatase (TRAP) and toluidine-blue stained paw sections. We performed correlation studies between gait parameters and the histopathological components.

Results: We identified several gait parameters among them weight bearing, stride length and contact area of the paw to be significantly decreased in hTNFtg animals compared to sex- and age-matched wildtype animals. Moreover, we found a marked reduction in maximum intensity, an indicator for weight bearing, in week 10 and 15 compared to week 6 old hTNFtg mice. Similar effects were seen in print width, print area, print length, max contact max intensity and max contact area at different stages of disease. Interestingly, analgesic treatment with diclofenac (50 mg/kg, i.p.), resulted in a better improvement of weight-bearing parameters in 10 week old hTNFtg mice than in 15 week old hTNFtg animals indicating an pain independent, irreversible functional impairment in progressed disease. To further investigate to which extend synovial inflammation, subchondral bone erosion or cartilage damage are responsible for the functional impairment of joints, we correlated these components with changes in different gait parameters. We observed strong correlations of various gait parameters with the amount of cartilage damage, whereas subchondral bone erosions correlated to a lesser extend and synovial inflammation did not correlate at all.

Conclusion: Video-based Catwalk gait analysis is a useful tool for quantitative assessment of functional impairment in inflammatory, destructive arthritis. Joint destruction due to cartilage damage but not synovial inflammation *per se* is the most important component leading to functional impairment of hTNFtg mice.

Non Classical Monocytes Are Required for Initiation Phase While Macrophages Are Necessary for the Resolution Phase in the K/BxN Murine of Inflammatory Arthritis. Alexander V. Misharin[1], G. Kenneth Haines III[2] and Harris R. Perlman[1]. [1]Northwestern University, Chicago, IL, [2]Yale University, New Haven, CT

Background/Purpose: Monocytes and macrophages play an essential function in the pathogenesis of rheumatoid arthritis. However, monocytes and macrophages are a heterogenous population and thus the role that the individual subsets play in the initiation, perpetuation and/or resolution phases of inflammatory arthritis is unknown. Here we utilized strategies to deplete selective populations of monocyte and macrophage subsets but not neutrophils, to uncover the role of these cells in the development and resolution phases of arthritis.

Methods: C57BL/6 and CD11b-DTR transgenic mice were used in the study. Conditional monocyte/macrophage ablation was induced by repetitive administration of diphtheria toxin (DT) into CD11b-DTR transgenic mice during initiation and resolution phases of inflammatory arthritis. Selective depletion of classic Ly6C+CCR2+ monocyte subset was achieved via administration of anti-CCR2 antibody during initiation and resolution phases

of inflammatory arthritis. Arthritis was induced using K/BxN serum transfer model and its severity was assessed using the clinical and histological scoring systems.

Results: Mice pretreated with DT and every three days for 14 days exhibited reduced numbers of peripheral blood monocytes but had no change in neutrophils. Subsequently, these mice initially developed K/BxN serum transfer induced arthritis but the arthritis was short lived and reached only a very moderate severity. An additional study was also performed, which entailed the administration of DT at day 7 and every 3 days until days 14–17 following the initial injection of K/BxN serum. Surprisingly, deletion of monocytes and synovial macrophages markedly delayed the resolution phase of the K/BxN serum transfer induced arthritis. In contrast, depletion of classic monocytes during both progressive phase and resolution of arthritis did not affect development or resolution of arthritis.

Conclusion: These data suggest a dual role for monocytes/macrophages in inflammatory arthritis that may be mediated by the local milieu. Thus, macrophages in the joint may initially function as one of central inflammatory mediators of the destructive arthritis, while their phenotype may be polarized to a wound healing or regulatory type macrophage during the resolution of arthritis. The fact that classic monocytes were dispensable for both initiation and resolution of arthritis is of special interest, since most of the macrophages in the arthritis joint are monocyte derived. Taken together, these data indicate that targeting monocytes and macrophages as single type of monocyte/ macrophage may not be therapeutically beneficial. Future therapies that identify the crucial type of macrophage at each stage of disease will lead to the development of novel therapeutics for RA.

Predictive Software-Based Mathematical Modeling: A Novel Approach to Development of Oral Therapies for Rheumatoid Arthritis–Validation in a Murine Collagen Induced Arthritis Model. Gurkirpal Singh[1], Robinson Vidva[2], Prashant Nair[2], Saumya Radhakrishnan[2], Pradeep Fernandes[2], Taher Abbasi[2], Canio Refino[3], Jay Dela Cruz[3] and Shireen Vali[2]. [1]Stanford University School of Medicine, Palo Alto, CA, [2]CellWorks Group, Saratoga, CA, [3]InTouch Bio, Alameda, CA

Background/Purpose: Rheumatoid Arthritis (RA) involves complex interactions of multiple cell systems, cytokines and mediators, and interlinked signaling. While molecularly-targeted therapies manipulate specific interactions, it is possible that other, previously redundant, paths are subsequently activated, thus causing drug resistance. Ideal therapy design requires simultaneous modulation of multiple targets to achieve eventual convergence and synergy. A predictive software algorithm would tremendously increase the ability to identify such therapies.

Methods: A predictive in-vivo equivalent simulation technology emulating RA pathophysiology at cellular and molecular level was designed by assimilating information from 8928 publications over the past 8 years. The simulation platform is a co-culture of 8 cell systems representing RA phenotypes, associated signaling and metabolic networks and includes nearly 100000 cross-talks and interactions among approximately 31366 molecules. The platform was extensively validated using more than 4000 studies and correlated with retrospective human clinical drug data and animal experiments. A digital library representing 100 targeted drugs from different indications was screened in combinations of two's and three's translating to more than one million in-vivo studies. Automated analytics engine using the assay data from the studies generated a therapy candidate which is a combination of 3 oral FDA-approved drugs (CWG952), based on criteria of efficacy, synergy and PK/PD compatibility. For in-vivo validations, mCIA was induced in male DBA/1 mice and those with paw scores between 1 and 5 on day 19 were randomly assigned to treatment arms (9/group): CWG952 and anti-TNF with treatment started at 12hrs of enrollment.

Results: The RA predictive model was dynamically simulated to disease condition followed by application of CWG952 therapy. The simulations predicted a percentage reduction in TNF, IL6, IL1B, IL17a, RANKL and CRP by 81.8, 90.5, 85.9, 86.5, 85.1 and 95.5 respectively from disease condition with respect to control state. The model also predicted a 83.1 % reduction in bone and cartilage degradation and 85.1% inhibition of osteoclast activity. Anticipated effect on phenotypic disease markers were close to those seen in clinical trials of TNF-alfa inhibitors. The figure shows results from animal experiments (mCIA model) demonstrating a comparable efficacy to etanercept.
Conclusion: In-vivo validations of mathematically-designed CWG952 show results comparable to etanercept. These results, along with other previously published validations [1], suggest a robust validation of a software-based mathematical modeling approach that incorporates the complex interaction of immunomodulating molecules, and can potentially lead to the development of innovative therapies for immunological diseases.

Sclerostin Protects Against Inflammatory Bone Loss by Regulating Tnfalpha Mediated p38-Mapkinase Activation. Corinna Wehmeyer[1], Christina Wunrau[1], Athanasios Stratis[1], Ina Kramer[2], Michaela Kneissel[2], Thomas Pap[1] and Berno Dankbar[1]. [1]University Hospital Muenster, Muenster, Germany, [2]CH-4056 Basel, Switzerland

Background/Purpose: Progressive loss of joint structure is a hallmark of rheumatoid arthritis (RA). TNFα has been shown to promote the destruction of bone by increasing the number of bone-resorbing osteoclasts and decreasing the number of bone-forming osteoblasts. The Wnt-Inhibitor sclerostin negatively regulates osteoblast differentiation and the disruption of this endogenous inhibitor increases the ability of Wnts to stabilize β-catenin and stimulate osteogenesis. Since it has been shown that sclerostin is upregulated in response to TNFα, we studied its role in inflammatory arthritis using the hTNF transgenic (hTNFtg) mice model of RA.

Methods: Sclerostin expression was assessed by immunohistochemistry, Western-blot-analysis, and RT-PCR. The localisation of β-catenin was determined by immunfluorescence staining. Western-blot-analysis was used to evaluate p38-MAPK phosphorylation. Sclerostin knockout (SOST$^{-/-}$) mice were crossed with hTNFtg mice to generate TNFα overexpressing mice that lack sclerostin (SOST$^{-/-}$hTNFtg). Clinical disease severity, bone erosion, cartilage destruction and synovial inflammation in SOST$^{-/-}$hTNFtg and hTNFtg mice were evaluated by histomorphometric, x-ray and micro-CT analysis. hTNFtg mice were treated with blocking antibodies against murine sclerostin or control-vehicle.

Results: Immunohistological staining revealed high expression of sclerostin in synovial tissue of hTNFtg ankle joints, especially in infiltrating synovial-like fibroblasts (SF). Only negligible staining was observed in wildtype animals. *In vitro,* hTNFtg SF expressed sclerostin whereas wildtype did not. Unexpectedly, radiographic, microCT and histopatological examination of hind paw joints of SOST$^{-/-}$hTNFtg mice demonstrated that the loss of sclerostin dramatically accelerated joint damage in this mouse model of RA. SOST$^{-/-}$hTNFtg mice displayed significantly more synovial hyperplasia, proteoglycan loss and bone erosion compared to hTNFtg mice. Moreover, injection of a neutralizing antibody to murine sclerostin in hTNFtg mice did not improve clinical signs of arthritis and but led to elevated inflammation as well as bone erosion. *In vitro,* upon stimulation of hTNFtg and SOST$^{-/-}$hTNFtg SF with recombinant Wnt3a, β-catenin translocated to the nucleus, but this was not affected by loss of sclerostin. Of note, recombinant sclerostin was able to inhibit the TNFα induced p38-MAPK activation of wildtype SF.

Conclusion: Since p38-MAPK signalling specifically regulates inflammation induced bone loss, our data strongly suggest a protective function of sclerostin against TNFα-mediated joint destruction by inhibition of TNFα induced p38-activation in synovial fibroblasts. The blockade of inflammatory cytokine action proposes a complete novel function of sclerostin.

The Loss of S100A4 Prevents Induction of Experimental Arthritis in Human Tumour Necrosis Factor Transgenic Mouse Model. Michal Tomcik[1], Christine Boehm[2], Carina Scholtysek[3], Lucie Andres Cerezo[1], Wolfgang Baum[3], Clara Dees[3], Christian Beyer[3], Jerome Avouac[4], Pawel Zerr[3], Katrin Palumbo-Zerr[3], Alfiya Akhmetshina[3], Radim Becvar[1], Oliver Distler[5], Mariam Grigorian[6], Gerhard Kroenke[3], Georg A. Schett[3], Joerg HW Distler[3] and Ladislav Senolt[1]. [1]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Medical University of Vienna, Vienna, Austria, [3]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [4]Paris Descartes University, Rheumatology A department, Cochin Hospital, Paris, France, [5]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [6]Institute of Cancer Biology, Danish Cancer Society, Copenhagen, Denmark

Background/Purpose: Our previous study demonstrated increased levels of S100A4 protein in sera, synovial fluid and synovial membrane of patients with rheumatoid arthritis (RA) compared to osteoarthritis. S100A4 regulates apoptosis and induces production of matrix metalloproteinases by synovial fibroblasts. Furthermore, S100A4 stimulates synthesis of tumour necrosis factor (TNF)-α by mononuclear cells and CD3 lymphocytes. The aim of this study was to investigate the effect of loss of S1004 in the induction of experimental arthritis in the human TNF transgenic (hTNFtg) mouse model.

Methods: We crossed the heterozygous hTNFtg mice with S100A4 knockout (S100A4$-/-$) mice. Following genotype determination, mice were clinically assessed for paw swelling, grip strength, leg movement and body weight every week from 6th to 14th week of age in a blinded manner. Sections of hind paws and tibias were histologically analyzed for synovial inflammation, cartilage loss, bone erosions, osteoclast numbers and bone formation parameters with the OsteoMeasure image analysis system.

Results: In the group of hTNFtg;S100A4$-/-$ mice, paw swelling and grip strength were significantly improved compared to hTNFtg;S100A4+/+ (p<0.05 for both parameters). Although not significant, body weight of hTNFtg;S100A4$-/-$ mice was slightly increased. Consistent with the clinical observations, histological analysis of the tarsal joints of hTNFtg; S100A4$-/-$ mice showed reduced pannus formation (area of inflammation decreased by 66±3%, p<0.01) and cartilage destruction (cartilage loss decreased by 63±6%, p<0.01) compared to hTNFtg;S100A4+/+ mice. Similarly, osteoclast numbers were decreased by 84±3%, (p<0.01) and bone erosions were less severe (area of bone erosion decreased by 81±4%, p<0.01) in hTNFtg;S100A4$-/-$ mice. Furthermore, hTNFtg;S100A4$-/-$ mice were protected from systemic bone loss. Absence of S100A4 completely reversed increased osteoclast formation and bone resorption in hTNFtg mice. hTNFtg; S100A4$-/-$ mice had an increased bone volume per total volume (BV/TV) by 78±20% (p<0.05), as well as a decrease in trabecular separation by 39±4% (p<0.05) compared to hTNFtg;S100A4+/+. The protection from systemic bone loss observed in hTNFtg;S100A4$-/-$ mice was further supported by decreased numbers of osteoclasts per bone perimeter (N.Oc/B.Pm decreased by 43±2%, p<0.01), decreased bone surface covered by osteoclasts (Oc.S/BS decreased by 52±3%, p<0.01), increased numbers of osteoblasts per bone perimeter (N.Ob/B.Pm increased by 129±20%, p<0.05) and increased bone formation rate per bone surface (BFR/BS increased by 112±18%, p<0.05).

Conclusion: These results suggest that the loss of S100A4 effectively prevented the induction of experimental arthritis via protecting against TNF-induced synovial inflammation, cartilage and bone destruction, and systemic bone loss. Thus, S100A4 might represent a novel therapeutic target in RA.

Liver Fibrosis Evaluated by Shearwave Elastograpy Is Associated with Body Mass Index and Serum AST, but Not Methotrexate Cumulative Dose and Duration in Patients with Rheumatoid Arthritis. Tae Yeob Kim, So-Young Bang, Joo Hyun Sohn and Hye-Soon Lee. Hanyang University Guri Hospital, Guri, South Korea

Background/Purpose: Methotrexate (MTX) is a widely used drug for treatment of rheumatoid arthritis (RA), and a concern with drug-related liver fibrosis is an unsolved problem. ShearWave elastography (SWE) is a newly developed, repeatable and reproducible real-time elastography technique for the evaluation of liver fibrosis. This study aimed to detect the associated factors with liver stiffness (LS) in patients taking MTX with RA.

Methods: We prospectively analyzed a total of 171 patients (female 135, mean age 54.3 ± 9.4 years) with RA who underwent SWE, serum sample and arthropometric measurement on the same day (August 2011-February 2012). Also, we calculated MTX cumulative dose and duration. LS measured by SWE is expressed in kilo-Pascal (kPa) with mean value. Based on the previous our study, significant fibrosis defines as liver stiffness above 7.0 kPa. The factors associated with liver fibrosis were evaluated by univariate and multivariate analysis using SPSS 19.0 Statistical Software.

Results: Among 171 patients, 37 paients (21.6%) had SWE results suggesting significant fibrosis. In univariate analysis, body weight, body mass index (BMI), waist circumference, serum AST, ALT, HDL, glucose, and metabolic component were associated with liver fibrosis (p<0.05). Neither MTX cumulative dose (4768 ± 3145 mg vs. 4870 ± 3436 mg, p=0.87) nor MTX duration (330 ± 203 weeks vs. 338 ± 196 weeks, p=0.84) was associated with elevated liver stiffness. In multivariate analysis, only BMI $\geq 25 \text{kg/m}^2$ (odds ratio 18.9, 95% confidence interval 4.0–91.2, p<0.001) and serum AST levels (expB=1.198, 95%CI 1.008–1.251, p=0.036) were associated with significant fibrosis.

Conclusion: Significant fibrosis by SWE was detected in about 20% of patients taking MTX with RA, and was associated with only high BMI and serum AST levels, but not MTX cumulative dose and duration.

Preliminary Results From a Controlled Study Assessing the Humoral Immune Response to Vaccines in Rheumatoid Arthritis Patients Treated with Tocilizumab. CO Bingham III[1], Warren C. Rizzo[2], Micki Klearman[3], Azra Hassanali[4], Ruchi Upmanyu[5] and Alan J. Kivitz[6]. [1]Johns Hopkins University, Baltimore, MD, [2]Advanced Arthritis Care & Research, Scottsdale, AZ, [3]Genentech Inc, South San Francisco, CA, [4]Genentech Inc, San Francisco, CA, [5]Roche, Welwyn Garden City, United Kingdom, [6]Altoona Center for Clinical Research, Duncansville, PA

Background/Purpose: Tocilizumab (TCZ) is an IL-6–receptor inhibitor for treatment of rheumatoid arthritis (RA) patients (pts). Because TCZ may impact how IL-6 modulates T-cell activation and regulates B-cell differentiation, response to vaccination in TCZ-treated pts is of interest. VISARA is the first randomized controlled study of the effects of TCZ on response to 23-valent pneumococcal polysaccharide vaccine (23VPPV) and tetanus toxoid vaccine (TTV) in RA pts on stable MTX. Preliminary analysis of study endpoints and post hoc analyses assessing impact of concomitant oral corticosteroids (OCS) are presented.

Methods: RA pts with inadequate response/intolerance to ≥ 1 anti-TNF agent were stratified by age and randomly assigned (2:1) to TCZ 8 mg/kg IV every 4 wks + MTX (TCZ) or MTX only (MTX). Baseline (BL) serology samples were collected 3 wks after the first infusion, just before 23VPPV and TTV vaccination. Anti-pneumococcal and anti-tetanus antibody titers were evaluated at wk 8, after which all pts received TCZ+MTX for 12 more wks. Endpoints were proportion of pts with positive response (2-fold or >1 mg/L increase in serum antibody titers) to ≥ 6 of 12 23VPPV serotypes (primary) and proportion with positive response (4-fold or ≥ 0.2 mg/L increase in serum antibody titers) to TTV (secondary) at wk 8 (5 wks postvaccination).

Results: Data are available for 74/91 enrolled pts and presented for 61 pts who met per-protocol criteria (ie, received ≥ 1 dose of study medication and both vaccines, had available BL and 8-wk titer samples and no protocol violations). At wk 8, 53.7% of TCZ+MTX and 65% of MTX pts responded to ≥ 6 of 12 23VPPV serotypes, a difference of 11.3% (not statistically significant at 95% CI level [CI: –37.3, 14.6]). When evaluated by age, the proportion of responders >50 y was lower by 10% in both arms. More MTX than TCZ+MTX pts responded to serotype combinations (from ≥ 1 to 12). However, the 95% CIs for the proportions of responders were wide and overlapping in both arms (Figure). A higher proportion of TCZ+MTX (43.9%) vs MTX pts (36.8%) responded to TTV, but the difference (7.1%) was not significant ([95% CI: –19.5%, 33.6%]). Two TCZ pts had nonprotective BL antibody titers (ie, <0.1 IU/mL); both achieved protective levels by wk 8. In pts taking OCS, the mean BL OCS dose was slightly higher in the responder than in the nonresponder MTX group, whereas the doses were similar in both TCZ+MTX groups (data not shown). Safety of TCZ was consistent with previous reports in RA pts.

Percentages of Pts Responding to Combinations of 12 23VPPV Serotypes (mean values and 95% CIs)
Conclusion: Based on the 95% CI for the difference in proportions of responders, TCZ does not appear to significantly attenuate responsiveness to 23VPPV or TTV compared with MTX. However, given the small study sample size and the short duration of TCZ treatment before vaccination, in line with current recommendations, pts should, if possible, be up to date with required immunizations before initiating TCZ to maximize the vaccine response.

Reduction of Inflammation with Abatacept and Tocilizumab Results in Lower N-Terminal Pro Brain Natriuretic Peptide Levels in Patients with Rheumatoid Arthritis: Results From Prospective Cohort Studies. Inge A.M. van den Oever and Mike T. Nurmohamed. Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of heart failure (HF). The chronic inflammatory state in RA is associated with increased levels of N-terminal pro-brain natriuretic peptide (NT-proBNP), a biomarker for HF. Recently, a study demonstrated that NT-proBNP levels in RA patients decreased under TNF-blocking therapy. It is unknown whether this is also observed in biologics with other mode of actions. We evaluated the effects of abatacept and tocilizumab therapy on NT-proBNP levels.

Methods: In 34 RA consecutive patients starting with abatacept (10 mg/kg every 4 weeks) and 14 RA consecutive patients starting with tocilizumab (8 mg/kg every 4 weeks), disease activity parameters and serum samples were collected at baseline and after 12 weeks of therapy. Clinical response was assessed using EULAR response criteria. Responding patients comprised both good and moderate EULAR responders. NT-proBNP levels were measured by the Elecsys 2010 electrochemiluminescence method (Roche diagnostics). For statistical analyses t-tests, Mann-Whitney U tests and linear regression were used.

Results: NT-proBNP levels did not change significantly after 12 weeks (p=0.6) and there were no significant differences in NT-proBNP levels at baseline or after 12 weeks of treatment between the tocilizumab and abatacept group (p=0.16 and p=0.3, respectively). 34 patients (71%) were EULAR responders, (6=12% good, 28=88% moderate) and 14 patients (29%) were non-responders. Baseline DAS28, CRP and BSE were higher, though not significantly, in responders compared to non-responders (table). Baseline NT-proBNP levels were higher in responders versus non-responders (p=0.044). Change in NT-proBNP levels after 12 weeks of treatment was significantly different between responders and non-responders (p=0.002), with decreasing NT-proBNP levels in responders and increasing levels in non-responders.

Table 1. RA-related factors and NT-proBNP levels at baseline and after 12 weeks of treatment

	Baseline	12 weeks	p value
NT-proBNP (pg/ml)	7.5 (3.8–19.2)	7.8 (4.5–16.9)	0.599
Responders	8.1 (4.0–23.4)	6.7 (4.1–14.6)	0.013
non-responders	6.2 (2.9–8.5)	13.43 (4.9–17.3)	0.068
CRP (mg/l)	16.5 (2.8–42.5)	7.5 (1.0–13.5)	0.008
Responders	23.0 (4.3–44.8)	7.5 (1.0–12.8)	0.001
non-responders	7.5 (1.3–19.5)	7.5 (3.0–16.5)	0.760
ESR (mm/h)	37 (21–60)	17 (7–30)	<0.001
Responders	39 (27–63)	16 (6–24)	<0.001
non-responders	29 (10–50)	27 (16–46)	0.958
DAS28	5.72 (1.44)	4.34 (1.37)	<0.001
Responders	5.96 (1.15)	3.90 (1.07)	<0.001
non-responders	5.12 (1.88)	5.40 (1.47)	0.390

mean (SD) or median (IQR)

difference between EULAR responders versus non-responders in delta NT-proBNP after 12 weeks
Conclusion: There was a remarkable difference in the course of NT-proBNP levels between EULAR responders and non-responders, as responders started with higher baseline levels which decreased significantly under both abatacept and tocilizumab treatment, while in contrast the NT-proBNP levels of non-responding patients increased. These findings indicate favourable effects of abatacept and tocilizumab on cardiac function in RA patients responding to treatment and underscore the importance of tight control of systemic inflammation in order to decrease CV risk.

Prospective Follow-up of Tocilizumab Treatment in 764 Patients with Refractory Rheumatoid Arthritis: Tolerance and Efficacy Data From the French Registry Regate (REGistry –RoAcTEmra). Jacques Morel[1], Marie-Odile Duzanski[2], Thomas Bardin[3], Alain G. Cantagrel[4], Bernard Combe[1], Maxime Dougados[5], Rene-Marc Flipo[6], Jacques-Eric Gottenberg[7], Xavier Mariette[8], Martin Soubrier[9], Olivier Vittecoq[10], Alain Saraux[11], Thierry Schaeverbeke[12] and Jean Sibilia[13]. [1]Hopital Lapeyronie, Montpellier, France, [2]Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [3]Hôpital Lariboisière, Paris, France, [4]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [5]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [6]Hopital R Salengro CHRU, Lille CEDEX, France, [7]Strasbourg University Hospital, Strasbourg, France, [8]Université Paris-Sud, Le Kremlin Bicetre, France, [9]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [10]Rouen University Hospital & Inserm905, University of Rouen, Rouen Cedex, France, [11]CHU de la Cavale Blanche, Brest Cedex, France, [12]Groupe Hospitalier Pellegrin, Bordeaux, France, [13]CHU Hautepierre, Strasbourg, France

Background/Purpose: To assess tolerance and safety of rheumatoid arthritis (RA) treatment by tocilizumab (TCZ) in real life

Methods: The French Society of Rheumatology and the Club Rheumatism and Inflammation set up the REGATE registry to prospectively collect, every 6 months for 5 years, data from 1500 patients treated with TCZ for refractory rheumatoid arthritis.

Results: From January 13th 2011 to April 2nd 2012, RA patients treated by TCZ initiated after January 1st 2010 have been prospectively included from 76 French centres in the REGATE registry. Among the 764 included patients (women: 80.1%, mean age 57.2±13.4 years, mean disease duration: 14.1 years (9.57), mean number of prior DMARD: 2.6 (±1.6), 76.3% RF-positive, 77.9% ACPA positive), 5.4% of patients had a history of cancer and 6.15% of severe infection, 19.1% of cardiovascular events and 24.2% of dyslipidemia before TCZ. 16.2% had not received any anti-TNF prior to TCZ and the mean number of biologics before TCZ was 2.1±1.5. The last biologic prescribed before initiation of TCZ was an anti-TNF for 59.1% of patients, rituximab for 17.7%, abatacept for 22.2% and others (kineret, ocrelizumab) for 1%. The median time between the last dose of the previous biologic and the first infusion of TCZ was 1.83 months (0–120).

Before TCZ, mean DAS28 was 5.18±1.3. 68.7% of the patients received corticosteroids with a mean dose of 12.93 ± 41.4 mg/day. 38.3% of patients were treated with TCZ as monotherapy, and 61.7% with a concomitant DMARD mainly methotrexate (83%). After 1.3 years, the drug was stopped for 79 patients: 39 of them (51.9%) for non response and in 33 of them (44%) for safety reasons. 440 patients have already had at least 1 follow-up visit with mean current follow-up duration of 7.5 (±4.6) months corresponding to an exposure of 274 patients/year (PY). Ten patients discontinued TCZ for infusion-reactions (2.3%). Twenty two severe infections (11 soft tissues, 4 gastrointestinal, 3 articular, 3 respiratory tract and 1 genital) were reported in 20 patients corresponding to a rate of severe infections of 8.0/100 PY. The other SAE were 3 gut perforations (1/100 PY), 2 lymphoma (0.7/100 PY), 1 skin cancer (0.36 /100 PY), but no cardiovascular event and death were recorded.

Conclusion: These first and preliminary results of the REGATE registry show that a high proportion of patients treated with TCZ was previously treated by anti-TNF (87%) even though it can be prescribed as a first line biologic. In addition, TCZ is not infrequently prescribed in monotherapy in clinical practice (38%). Severe infections are in the higher range observed with biologics but deserve to be confirmed after longer exposure duration.

352

Meta-Analysis: Influence of Methotrexate, Anti-TNF and Rituximab On the Immune Response to Influenza and Pneumococcal Vaccines in Patients with Rheumatoïd Arthritis. Charlotte Hua[1], Thomas Barnetche[2], Bernard Combe[3] and Jacques Morel[3]. [1]Hôpital Lapeyronie, Montpellier, France, [2]CHU Bordeaux Pellegrin, Bordeaux, France, [3]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Vaccines against influenza and streptococcus pneumonia are currently recommended for patients with rheumatoid arthritis (RA). This meta-analysis assesses current literature data on the impact of methotrexate (MTX), anti-TNF or rituximab (RTX) on the humoral response to pneumococcal and influenza vaccines in RA patients.

Methods: Data sources were Medline, Embase and Cochrane databases and ACR 2011 abstracts. To be included, studies had to contain a group of RA patients treated with MTX, anti-TNF or RTX and a control group of RA patients without the treatment of interest. Both groups had to receive either pneumococcal or influenza vaccine. **Results** had to show rates of responders based on the antibody response ratio, corresponding to the level of antibodies measured at 1 month following vaccination as numerator and the level of antibodies at vaccination as denominator, for pneumococcal serotypes 6B and 23F or one of the 3 strains of influenza virus: H1N1, H3N2 and B. Out of 59 potentially relevant studies, 11 met inclusion criteria. Odds-ratios and their 95% confidence intervals were pooled using the generic inverse variance method. The heterogeneity between studies was assessed using the Cochran's Q-test and the I^2 value, and a random effect model was performed if necessary. All the analyses were realized with the RevMan software 5.1 version. A significant statistical threshold of 0.05 was used.

Results:

Following pneumococcal vaccination: response was reduced in patients treated with anti-TNF + MTX compared to those treated with anti-TNF not combined with MTX (pooled odds-ratio (OR) = 0.58; 95% confidence interval (CI) 0.36–0.94; p=0.03 for 23F and 0.33; 95% CI 0.20–0.54; p<0.0001 for 6B). Rates of responders were similar in patients under MTX alone and those treated with MTX +anti-TNF (OR = 1.21; 95% CI 0.83–1.75 for 23F and 0.96; 95% CI 0.57–1.59 for 6B). The immune response was lower in patients treated with RTX, combined in most cases with MTX, than in patients under MTX as monotherapy (OR = 0.22; 95% CI 0.11–0.47; p<0.0001 for 23F and 0.25; 95% CI 0.11–0.58; p=0,001 for 6B).

Following influenza vaccination: proportion of responders was not different between patients treated with MTX and those not treated with MTX (OR= 1.36; 95%CI 0.69–2.68 for H1N1, 1.33; 95%CI 0.70–2.53 for H3N2, 1.28; 95%CI 0.64–2.56 for B). Response was decreased in patients under PBO+MTX versus patients under PBO not combined with MTX (OR for responders to at least 2 strains = 0.35; 95% CI 0.18–0.66; p=0.001). Patients treated with anti-TNF with or without MTX had same responders rates than patients whose treatment did not include anti-TNF (OR for responders to at least 2 strains = 0.42; 95% CI 0.17–1.09). Patients under RTX in monotherapy or in combination with DMARDs had a diminished humoral response compared to patients treated with DMARDs without RTX, significance being reached for H3N2 and B (OR = 0.11; 95% CI 0.04–0.31; p<0.0001 and 0.29; 95% CI 0.10–0.81; p=0.02).

Conclusion: Immune response to both vaccines is reduced with RTX but not with anti-TNF. MTX decreased immunogenicity of pneumococcal vaccine whereas results about influenza vaccine are less homogeneous but suggest an impairment of the response due to MTX therapy.

The Effect of Combination Therapy and Prednisolone On Haemostatic Markers in Rheumatoid Arthritis. Inge A.M. van den Oever[1], Danka J.F. Stuijver[2], Debby den Uyl[3], Bregje van Zaane[4], Marieke M. ter Wee[5], Willem F. Lems[5], D. van Schaardenburg[1], Joost C.M. Meijers[4], Victor E.A. Gerdes[4] and M. T. Nurmohamed[6]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands, [3]VU University medical centre, Amsterdam, Netherlands, [4]Slotervaart Hospital, Amsterdam, Netherlands, [5]VU University Medical Center, Amsterdam, Netherlands, [6]VU University Medical Center/Jan van Bremen Research Institute, Amsterdam, Netherlands

Background/Purpose: There is accumulating evidence that rheumatoid arthritis (RA) should be considered as prothrombotic state, explaining the increased risk of thromboembolic events. Suppressing inflammation could reduce this hypercoagulability. COBRA, the combination of step-down prednisolone, methotrexate and sulfasalazine (SSZ) is an effective antirheumatic therapy. However, glucocorticoids have been identified as risk factor for the development of thromboembolism. In this study we evaluated the course of haemostatic markers in RA patients during strong anti-inflammatory therapy and the dose-dependent effect of prednisolone on coagulation and fibrinolysis.

Methods: 22 patients diagnosed with early RA, were randomised to either COBRA therapy or an attenuated form (COBRA-light) with halved initial prednisolone dose and no SSZ. At baseline and after 1, 4 and 26 weeks of treatment, 10 ml of citrated blood was collected for measurement of prothrombin time (PT), activated partial thromboplastin time (aPTT) and five haemostatic markers: prothrombin fragment 1+2 (F1+2), factor VIII (FVIII), von Willebrand factor (vWF), plasminogen activator inhibitor (PAI-1) and D-dimer. For statistical analyses t-tests and linear regression were used.

Results: Baseline characteristics were not significantly different between the 2 groups (each 11 patients). DAS44, CRP and ESR decreased significantly after 26 weeks (p<0.001). aPTT, D-dimer and F1+2 decreased during treatment in all patients (table). There was a significant positive association between decrease in CRP and BSE with D-dimer and decrease in CRP, BSE and DAS44 with F1+2 at all time points. There was no difference in the markers between the two groups, except for a stronger decrease in aPTT after 2 weeks (p=0.03) in the COBRA group. This difference was no longer seen at 4 weeks.

Table. Change in haemostatic factors in all 22 RA patients

	baseline	2 weeks	4 weeks	26 weeks
DAS44	3.9 (0.6)			1.6 (0.9)**
ESR (mm/h)	25 (12–43)			4 (3–7)**
CRP (mg/L)	13.0 (5.5–29.5)	2.5 (2.5–2.7)**	2.5 (2.5–4.5)**	2.5 (2.5–2.7)**
aPTT (sec)	29.9 (28.5–34.9)	26.2 (25.1–31.4)**	26.8 (25.5–29.9)**	27.9 (26.6–30.4)*
PT (sec)	11.2 (0.4)	11.3 (0.5)	11.1 (0.5)	11.2 (0.5)
FVIII (%)	142 (105–179)	151 (112–196)*	152 (123–193)	127 (111–170)
D-dimer (FEU/L)	1.18 (0.63–3.34)	0.55 (0.29–1.26)**	0.49 (0.26–0.84)**	0.25 (0.21–0.78)**
F1+2 (pmol/L)	342 (253–496)	192 (146–305)*	212 (160–285)**	213 (153–319)*
PAI-1 (ng/ml)	35 (25–49)	40 (19–63)	24 (16–53)	42 (17–73)
vWF (%)	115 (87–149)	121 (86–157)	138 (94–189)*	101 (86–143)

Values are mean (SD) or median (IQR) *p <0,05 and **p<0.001 change compared to baseline

Conclusion: Overall, both COBRA and COBRA-light therapy induced an improvement of inflammatory and procoagulant factors in RA. Prednisolone could have attenuated this effect, since the coagulation factors FVIII, vWF increased during the first weeks, when doses of prednisolone were highest. However, there were no remarkable differences in the haemostatic markers between the two groups, indicating that doses higher than 30 mg of prednisolone have no attributable effect on the procoagulant state in RA.

354

Delayed Onset of Hepatitis and/or Neutropenia in Patients with Rheumatoid Arthritis Treated with Combination Therapy of Methotrexate and Leflunomide. Seung Won Choi[1], Ji Seon Oh[1], You Jae Kim[2], Bon San Koo[3], Min Wook So[3], Yong-Gil Kim[3], Chang-Keun Lee[3] and Bin Yoo[3]. [1]University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, South Korea, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea, [3]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea

Background/Purpose: The adverse effects of combination therapy of methotrexate (MTX) and leflunomide (LEF) have been reported in many studies. Because combination of various doses of each drug is used in clinical practice, the reported incidence of hepatitis and neutropenia is variable. Currently, the incidence of such adverse events according to the duration of combination therapy has not been established. The purpose of this study is to evaluate the incidence of delayed onset of hepatitis or neutropenia in patients with rheumatoid arthritis (RA) treated with combination therapy of MTX and LEF.

Methods: We retrospectively reviewed medical records of 144 RA patients who had been treated with combination of fixed dose of MTX and 20mg of LEF, and who had been followed up with regular laboratory evaluation for longer than 6 months. We evaluated the incidence of hepatitis (serum aminotransferases greater than two times the upper limit of normal) and/or neutropenia (absolute neutrophil count < 1500/uL) according to the treatment duration.

Results: Mean age of patients was 55.3 ± 9.6 (range, 34–77; male: female, 27:117). Mean duration of combination therapy of MTX and LEF was 17.8 ± 13 months (range, 1.6–59.5 months; median 14 months). Mean doses of MTX was 9.8 ± 1.5 mg per week (range, 7.5–15 mg/week). The overall incidence of hepatitis was 19% (20/144). Of 144 patients, 14 (10%), 8 (6%), and 2 (1%) had delayed onset of hepatitis after 6, 12, and 24 months, respectively. Among patients with delayed onset of hepatitis after 6 months, mean duration of combination treatment was 14.5 ± 6.3 months (range, 8.3–26.0 months), and calculated cumulative doses of MTX and LEF, 628.7 ± 307.1 mg and 8.7 ± 6.0 g, respectively. The overall incidence of neutropenia was 6% (8/144). Of 144 patients, 7 (5%), 4 (3%), and 1 (1%) had delayed onset of neutropenia after 6, 12, and 24 months, respectively. Among patients with delayed onset of neutropenia after 6 months, mean duration of combination treatment was 18.0 ± 16.0 months (range, 6–52 months), and calculated cumulative doses of MTX and LEF, 774.0 ± 691.3 mg and 14.0 ± 10.9 g, respectively.

Conclusion: This study suggested that delayed onset of hepatitis and/or neutropenia in patients with combination treatment of MTX and LEF was relatively common during 6–12 months of treatment. In addition, regular monitoring for such adverse events should be required for cumulative toxicity of long-term combination therapy.

Metaanalysis of 5-Aminoimidazole-4-Carboxamide Ribonucleotide Transformylase (ATIC) 347C>G Polymorphism Affecting Methotrexate Efficacy and Toxicity in Rheumatoid Arthritis Patients. Fardina Malik[1] and Prabha Ranganathan[2]. [1]Alton Memorial Hospital, Alton, IL, [2]Washington Univ School of Med, St. Louis, MO

Background/Purpose: Methotrexate (MTX) exerts its effect in part by inhibiting 5-aminoimidazole-4-carboxamide ribonucleotide transformylase (ATIC), a key enzyme in the purine biosynthetic pathway. Published data suggests an association between a non-synonymous single nucleotide polymorphism (SNP) in the ATIC gene (347C>G, Thr116Ser) with MTX efficacy and toxicity in patients with rheumatoid arthritis (RA); however this association has been inconsistent. The aim of this study was to investigate the effects of the ATIC 347C>G SNP on MTX efficacy and toxicity in patients with RA by performing a meta-analysis.

Methods: Studies examining the association of the ATIC 347C>G polymorphism with MTX efficacy and toxicity in RA patients were systematically identified from the Pubmed and Ovid Medline databases (from 1999 to May 31st 2012). Studies reporting genotypic or allelic distribution of ATIC 347C>G polymorphism in relation to MTX efficacy and/or toxicity were deemed eligible for the current analysis. Meta-analyses for both MTX efficacy and toxicity were separately performed to explore the composite effect of the ATIC 347C>G SNP on these outcomes. Fixed (Mantel-Haenszel) and random effects (DerSimonian and Laird) models were utillized based on the presence or absence of between-study heterogeneity. OpenMeta-Analyst software (beta version) was used for data entry and analysis.

Results: Five studies with sufficient data were included in the meta-analysis of the ATIC 347C>G SNP's association with MTX efficacy which represented 1100 RA patients. The meta-analysis did not demonstrate a significant association between the ATIC 347C>G polymorphism and MTX efficacy (Figure 1A). The pooled odds ratio (OR) using the fixed effects model was 1.194 (95% CI 0.915, 1.559; p = 0.193) with a trend towards between-study heterogeneity (p=0.091) and using the random effects model was 1.168 (95% CI 0.786, 1.736; p = 0.441). For the meta-analysis of the ATIC 347C>G SNP's association with MTX toxicity, five studies with sufficient data were included which represented 1055 patients. Meta-analysis using the fixed effects model demonstrated a significant association of the ATIC 347C>G SNP with MTX toxicity with an OR of 0.686 (95% CI 0.515, 0.915; p = 0.010) with no evidence of between-study heterogeneity (p=0.245) (Figure 1B).

A				
Studies	Estimate (95% C.I.)	CC	CG or GG	
Wessels et al. 2006	2.217 (1.261, 3.900)	51/97	36/108	
Takatori et al. 2006	0.679 (0.291, 1.582)	19/67	14/38	
Sharma et al. 2009	1.377 (0.729, 2.599)	61/77	144/196	
Grabar et al. 2010	0.842 (0.399, 1.774)	14/93	20/115	
Owen et al. 2012	0.993 (0.634, 1.556)	66/139	81/170	
Overall (I^2=50% , P=0.091)	1.168 (0.786, 1.736)	211/473	295/627	

B				
Studies	Estimate (95% C.I.)	CC	CG or GG	
Wessels et al. 2006	0.494 (0.264, 0.924)	21/94	39/106	
Takatori et al. 2006	0.708 (0.338, 1.483)	27/76	21/48	
Weisman et al. 2006	0.365 (0.165, 0.809)	52/185	15/29	
Grabar et al. 2010	0.881 (0.488, 1.592)	63/93	81/115	
Owen et al. 2012	0.949 (0.540, 1.667)	27/140	34/169	
Overall (I^2=27% , P=0.245)	0.686 (0.515, 0.915)	190/588	190/467	

Conclusion: Our meta-analysis suggests that the ATIC 347C>G polymorphism may be a predictor of MTX toxicity in patients with RA, with the C allele being protective and the G allele conferring a higher risk for toxicity.

Safety of Abatacept in Rheumatoid Arthritis with Chronic Hepatitis B VIRUS Infection. Melissa Padovan[1], Elisabetta Lanciano[2], Oscar Epis[3], Alessandro Mathieu[4], Giulia Erba[5], Leopoldo Ciani[6], Sarah Giacuzzo[1] and Marcello Govoni[1]. [1]Section of Rheumatology, Ferrara, Italy, [2]Rheumatology Unit, Bari, Italy, [3]Rheumatology Unit, Milano, Italy, [4]Rheumatology Unit, Cagliari, Italy, [5]Medical Clinics, Monza, Italy, [6]Unit of Internal Medicine, Legnano, Italy

Background/Purpose: In patients with rheumatoid arthritis (RA) concomitant hepatitis B (HBV) represents a therapeutic challenge limiting, DMARD treatment options (conventional and biologics, especially anti-TNFa and rituximab) are limited. About abatacept there are unclear and scant data confined to isolated medical records review and anecdotal case reports. This observational multicenter retrospective study was planned to verify safety of abatacept in this particular setting in a group of italian patients.

Methods: Six rheumatologic centres in different geographical areas of Italy were invited to participate in the study and provided data from patients with RA and positive HBV serology treated with abatacept in recent years. HBV serological markers, RA clinical and laboratory data were assessed by retrieving information from clinical documentation (hospital records, patient folders and clinical charts) provided by each participating centre and stored in a dedicated database. Follow-up data at 3 months intervals, up to 24 months, were analysed. The dose of Abatacept was given according to the standard guidelines, every two weeks for the first month and then monthly.

Results: 33 patients were included, 5 male and 28 female, mean disease duration 12 ± 5 ys and baseline active disease (average DAS28 = 5.56 ± 1.5). 22 patients (66.6%) were RF positive and 19 (57%) ACPA positive. Prior biologics were tried unsuccessfully in 15 (2 biologics) and 5 patients (3 biologics) before starting abatacept. In combination with abatacept patients received methotrexate (18), leflunomide (4), sulphasalazine or hydroxicloroquine (1), corticosteroid alone (8). At baseline 27 patients were categorized as inactive carrier (one of these was also anti-HCV positive) and 4 patients as occult carries (anti-core positive) for HBV. Liver function tests were normal and HBV-DNA titer was low or undectable in all patients. Seven patients received antiviral prophylaxis, 5 with lamivudina e 1 with adefovir first and then tenofovir. In the follow-up assessment data were available in 14 patients ongoing at 12 months (DAS28 = 3.99±1.2) and in 5 patients ongoing at 24 months (DAS28 = 2.10 ±1.6) break point of follow-up. No patients experienced reactivation of hepatitis B; liver function tests remained normal and serologic HBV status remained the same as at baseline. Discontinuation of therapy was due to inefficacy (13 primary, 12 secondary), patient's decision (2), low compliance (1), lost to follow-up (1) and adverse events (4) none of them HBV related. The high rate of withdrawal can be justified by the particular characteristics of the included patients, being long-standing refractory RA with an high rate of previous treatment failure.

Conclusion: Our study–not designed to test efficacy - shows encouraging data about safety of abatacept in patients with concomitant HBV positive serology also in patients without any antiviral prophilaxys. More prospective data are needed to confirm these preliminary results.

Is the Impact of Methotrexate On Mortality in Rheumatoid Arthritis Independent of Its Effect On Disease Activity? Dietmar MJ Krause[1], Bernadette Gabriel[2], Gertraud Herborn[3] and Rolf Rau[3]. [1]Internistische und rheumatologische Gemeinschaftspraxis, Gladbeck, Germany, [2]Private Practice, Gladbeck, Germany, [3]Evangelisches Fachkrankenhaus, Ratingen, Germany

Background/Purpose: Methotrexate (MTX) is the anchor drug in the treatment of rheumatoid arthritis (RA). MTX shows effects on disease activity, radiologic progression and mortality. These three effects are thought to be associated with each other. Therefore, MTX-treatment is often stopped in case of insufficient improvement of disease activity. However, this association is incompletely understood.

Methods: We analysed data of one of the earliest MTX-cohorts in Europe (Evangelisches Fachkrankenhaus Ratingen). From 1980 to 1987 all patients starting treatment with MTX (n=271) were enroled in a prospective observational study. One year after baseline, response to MTX-treatment was determined (improvement or no improvement of at least 20%). Nearly all patients continued MTX-treatment independent of this response (due to lack of alternative treatments). In 1995 and 2003, the follow-up of 250 patients could be determined. Cox regression was applied to estimate risks for increased mortality.

Results: Ten years after baseline, 88 patients were deceased, 64% of the patients alive were still on MTX-treatment. 59 patients died in the following eight years. A Cox model with age, gender, response to MTX-treatment after one year, number of swollen joints ten years after baseline and continuation of MTX-treatment as covariates showed independent positive effects of continued MTX-treatment on mortality (hazard ratio (HR): 0,63; 95%-confidence interval (CI): 0,44–0,89, p = 0,009). In the group of non-responders the HR was 0,41 (95% CI 0,14–1,16), significance was missed due to the small number of patients in this group (n=23)

Conclusion: In this cohort, there are hints of a mortality lowering effect of MTX that is independent of its effect on disease activity. This might have consequences for treatment decisions in RA patients with insufficient MTX-efficacy on disease activity.

Six Months of an Attenuated Cobra Regimen ('COBRA-light') Is Clinically Noninferior to the Original Cobra Regimen: An Open-Label Randomized Trial in Early Rheumatoid Arthritis. Debby den Uyl[1], Marieke M. ter Wee[1], Maarten Boers[1], Alexandre Voskuyl[1], P.J.S.M. Kerstens[2], Mike T. Nurmohamed[3], Hennie G. Raterman[1], D. van Schaardenburg[3], N. van Dillen[2], B.A.C Dijkmans[1] and W.F. Lems[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Reade | Jan van Breemen Research Institute, Amsterdam, Netherlands, [3]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: Early, intensive treatment of rheumatoid arthritis (RA) with combination therapy (COBRA therapy) considerably lowers disease activity and suppresses radiological progression. Although proven to be very effective, uptake of COBRA therapy among rheumatologists has been suboptimal, for reasons including fear of possible side-effects. A modified schedule of the COBRA therapy with a lower dose of prednisone ('COBRA-light'), might be equally effective and lessen concerns about side-effects. The purpose of this study was **to** investigate whether **COBRA-light therapy is non-inferior to** COBRA-therapy in patients with early, active RA. Trial duration: one year.

Methods: 164 patients with early, active RA were randomised to either COBRA therapy (MTX 7.5 mg/week, SSZ 2 g/day and prednisone 60 mg/d, tapered to 7.5 mg/day) (n=81) or COBRA-light therapy (MTX 25 mg/week and 30 mg prednisone, tapered to 7.5 mg/day) (n=83). Primary treatment goal was minimal disease activity, defined as DAS44 < 1.6. After 3 months

treatment, MTX dose could be **increased** up to 25mg/week, when DAS44 remained above 1.6. **A difference in change of** DAS44 **>** 0.5 between the groups after 6 months was considered clinically relevant, and set as the boundary of non-inferiority. Patients, physicians and assessors were aware of treatment allocation as this trial is an open label trial.

Results: At baseline, patients had moderately active disease: COBRA, mean (SD) DAS44 4.13 (0.81); COBRA-light, 3.95 (0.90). Two patients *(COBRA-light arm)* did not *initiate treatment and t*wo patients dropped-out of the study due *to adverse events (myocardial infarction in COBRA-arm and manic episode in COBRA-light arm). At 6 months DAS44* had significantly decreased in both groups: COBRA, –2.50 (1.21); COBRA-light, –2.18 (1.10) (Table). The difference between the groups in DAS44 change was 0.32 (95% CI: –0.03;0.68; p=0.08), i.e. within the noninferiority boundary. Minimal disease activity (DAS$_{44}$<1.6) was reached in almost half of patients in both groups (49% and 41% in COBRA and COBRA-light respectively). There were no significant differences between the treatment groups with respect to other measurements of disease activity including the EULAR and ACR response criteria and the HAQ-score.

Table 1. Outcome week 26

	COBRA (n=81)	COBRA-light (n=81)	P
Δ DAS44*	−2.50 (1.21)	−2.18 (1.10)	0.08
Absolute DAS44	1.63 (0.96)	1.77 (1.14)	NS
Minimal disease activity (DAS44<1.6)	49%	41%	NS
Δ HAQ	−0.8 (0.6)	−0.8 (0.7)	NS
Δ Tender joints	−14 (11)	−13 (11)	NS
Δ Swollen joints	−11 (6)	−10 (6)	NS
Δ ESR, mm/h	−21.5 (−37;−8)	−13.5 (−34;−4)	0.09
Δ CRP mg/L	−9.5 (−25;−1)	−8.5 (−29;−1)	NS
Δ Patient's global assessment disease activity, (0–100)	−34 (−59;−7)	−41 (−65;−17)	NS
Δ Physician's global assessment disease activity, (0–100)	−36 (−59;−9)	−31 (−54;−10)	NS
ACR 20 response	72%	72%	NS
ACR 50 response	56%	62%	NS
ACR 70 response	37%	49%	NS
EULAR good response	75%	65%	NS
EULAR non-response	6%	11%	NS
ACR/EULAR remission (Boolean)	15%	24%	NS
Intra-articular injections, n (%)	0%	4%	NS

* Δ: delta, difference between 0 and 26 weeks
Data are presented as mean (±SD) or median (interquartile range). Differences between groups were tested with independent T-test, Mann-Whitney U test or Chi square test. A p<0.05 was considered statistically significant.

Conclusion: Results at 6 months suggest that COBRA-light therapy is non-inferior to standard COBRA therapy: both strategies effectively lower disease activity in early, active RA patients. The clinical and radiological effects at one year are pending.

Improved Radiological Outcome of Rheumatoid Arthritis: Early Treatment with methotrexate might be a key Prognostic Factor. Christoph Fiehn[1], Elisabeth Belke-Voss[1], Dietmar Krause[2], Siegfried Wassenberg[3] and Rolf Rau[4]. [1]ACURA Centre for Rheumatic Diseases, Baden-Baden, Germany, [2]Dept. for Medical Informatics, Biometry and Epidemiology, Ruhr University, Bochum, Germany, [3]Evangelisches Fachkrankenhaus Ratingen, Rheumazentrum, Ratingen, Germany, [4]Düsseldorf, Germany

Background/Purpose: To compare the rate of radiological progression in patients with rheumatoid arthritis (RA) diagnosed in the 1980s with those of the late 1990s until 2005 and to evaluate key factors for differences in prognosis.

Methods: 92 RA patients which were firstly seen in our clinic from 1997 to 2005 and in which baseline and at least one follow up radiograph of hands and feet were available were retrospectively identified. As a control group, 89 RA patients from 1986 to 1990 were matched for the criteria disease duration, age and number of x-ray controls. In both groups patients had a disease

duration of less than 5 years at first consultation (mean: 22 ±17 months). Radiologic damage was measured by the Ratingen score (RS).

Results: The baseline RS was significantly lower in the 1997–2005 group compared to the 1986–1990 group (mean 3.8 ±8.7 vs. 7.7 ±13.0 respectively, p<0.0001). This was also the case in the patients firstly seen before the approval of TNF-Inhibitors in 2000 (n=29, mean baseline RS 1997–2000: 2.7 ±4.9; p<0.001 in comparison to 1986–1990). Moreover, the 1997–2005 group showed significantly less radiologic progression than the 1986–1990 group during follow-up (ΔRS/year of 0.95 ±2.19 vs. 5.69 ±8.43; p<0.0001). In the later group more patients (73% vs. 28%; p=0.0001) received methotrexate (MTX), mainly early in the course of the disease. In contrast, the overall rate of DMARD treatment was not significantly different in both groups. Twenty one (23%) of the patients in the later group received biologic drugs, in the majority TNF-Inhibitors. Multivariate analysis showed that early start of MTX (before or directly after first consultation) was a significant predictor of low radiographic progression (p<0.005), as were low ESR at baseline and belonging to the later group. In contrast, neither treatment with glucocorticoids or biologic drugs nor the overall rate of MTX-use were predictive for a better outcome.
Fig. Mean Ratingen scores and radiologic progression in the different groups 1986–90 and 1997–2005 (grey and black). The results of the x-ray analysis were separated in dependence from the time after the first consultation (columns). The differences were statistically significant (p<0.0001) between the two groups at each time point.

Conclusion: Radiologic damage is markedly diminished in RA patients seen since the late 1990s. Early treatment with MTX may be the key factor for this improved prognosis. However, due to the retrospective design of the study, a bias cannot be completely excluded.

Initial Introduction of Treat-to-Target Strategy in Patients with Recent Onset Rheumatoid Arthritis Is More Effective Than Delayed Introduction of Strategy with More Clinical and Functional Remission Achieved for 2-Years: Results of the Treating to Twine Targets (T-4) Study.
Yukitomo Urata[1], Yoshihide Nakamura[2] and Ken-ichi Furukawa[3]. [1]Seihoku Central Hospital, Gosyogawara, Japan, [2]Hirosaki University Graduate School of Medicine, Hirosaki, Japan, [3]Hirosaki, Japan

Background/Purpose: To compare the clinical, radiological and functional efficacy of initial versus delayed introduction of strategy which is treat-to-target to patients with recent onset rheumatoid arthritis (RA) after 2-years follow up.

Methods: A post hoc analysis of the T-4 (treating to twine targets) study which is a multicenter, randomized and open trial in newly diagnosed RA patients (mean duration 1.4±1.1 yrs) who has not previously received disease-modifying anti-rheumatic drugs (DMARDs) was performed. In the T-4 study, a total of 243 RA patients were randomly allocated to one of four strategy groups: routine care (R group, n=62); disease activity score in 28 joints (DAS28)-driven therapy (D group, n=60); matrix metalloproteinase (MMP)-3-driven therapy (M group, n=60); or both DAS28- and MMP-3-driven therapy group (Twin; T group, n=61). Specifically, medication was started with sulfasalazine (1 g/day) in all intervention groups. Targets were DAS28 <2.6 for D group, MMP-3 normalisation for M group, and both DAS28 <2.6 and MMP-3 normalisation for T group. If the value in question did not fall below the previously measured level, we intensified medication

including methotrexate, other DMARDs and biologic agents. From 56 weeks all patients were allocated to T group, treatment was adjusted every three months if the value in question did not fall below the previously measured level. 61patinets in initial treat-to-target introduced group (T→Tgroup) were compared with 62 patients in delayed treat-to-target introduced group (R→Tgroup) for 2 years. Functional ability was measured by the Health Assessment Questionnaire (HAQ), radiological progression was measured by Sharp/van der Heijde scoring (SHS).

Results: Baseline differences between the two groups were not significant. Clinical (simplified disease activity index≤3.3) and functional (HAQ=0) remission at 2 years was achieved by more patients in initial treat-to-target introduced group (T→Tgroup) (51% and 74%) than in delayed group (R→T group) (18%; p<0.0001 and 50%; p=0.0063). There are no significant difference between initial and delayed group (52% versus 47%; p=0.5283) for radiographic remission (DSHS<0.5).

Conclusion: The results of post hoc analysis in T-4 study suggest that initial introduction of treat-to-target strategy in patients with recent onset RA is more effective than delayed introduction of strategy with more clinical and functional remission achieved for 2-years.

Impact of Tumour Necrosis Factor Inhibitor Treatment On Hand Bone Loss in Rheumatoid Arthritis Patients Treated in Clinical Practice. Results From the Nationwide Danish Danbio Registry.
Lykke Midtbøll Ørnbjerg[1], Mikkel Østergaard[1], Pernille Bøyesen[2], Trine David Jensen[3], Anja Thormann[1], Ulrik Tarp[1], Wolfgang Bøhme[1], Ditte Dencker[1], Hanne M. Lindegaard[1], Uta Engling Poulsen[1], Annette Hansen[1], Vibeke Stevenius Ringsdal[1], Annette Schlemmer[1], Niels Graudal[1], Anne Rødgaard Andersen[1], Jakob Espesen[1], Gina Kollerup[1], Torben Grube Christensen[1], Randi Pelck[1], Bente Glintborg[1], Ole Rintek Madsen[1], Dorte Vendelbo Jensen[1], Ole Majgaard[1] and Merete L. Hetland[4]. [1]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Copenhagen, Denmark, [2]Diakonhjemmet Hospital, Olso, Norway, [3]Dept. of Endocrinology, Hvidovre Hospital, Copenhagen, Denmark, [4]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Rheumatoid arthritis (RA) is characterised by progressive joint destruction and periarticular bone loss. In RA patients with insufficient response to Disease-Modifying Anti-rheumatic drugs (DMARDs) treated in clinical practice tumour necrosis factor inhibitors(TNFi) retard the joint damage(1), but their impact on hand bone loss and predictors thereof are not known. The aim of this study was to compare hand bone changes during treatment with Disease-Modifying Anti-rheumatic drugs (DMARDs) and subsequent treatment with TNFi in RA patients in clinical practice, and investigate the association between radiographic progression and hand bone loss. Furthermore, to identify predictors of hand bone loss during TNFi treatment in clinical practice.

Methods: X-rays of hands were obtained 2 yrs before start of TNFi(pre-baseline), at the start of TNFi(baseline) and 2 yrs after(follow-up). Clinical data from the DANBIO registry and patient files were collected. Hand x-rays were scored blinded to chronology according to the Sharp/van der Heijde method. Hand bone mineral density (BMD) was estimated with Digital X-ray Radiogrammetry(DXR), a computerised method to measure cortical bone thickness of the 2nd–4th metacarpal. Annual (absolute and relative) hand BMD loss and radiographic progression rates during DMARD and TNFi treatment were calculated. Potential predictive baseline variables were investigated with univariate regression and significant variables included in a multiple linear regression analysis with annual BMD loss during TNFi treatment as the dependent variable.

Results: 136 RA patients (85% women, 71% rheumatoid factor positive, age 55(23–84) years(median (range)); disease duration 5(1–53) years) had three x-rays suitable for DXR. Pre-baseline 28 joint disease activity score-(DAS28) was 4.3(1.6–6.9). At baseline DAS28 was 5.3(1.4–8.2) and inflximab(74%), etanercept(13%), or adalimumab(13%) was started. At follow-up, 59% were on initial TNFi, 27% had switched to another TNFi and 14% had withdrawn. DAS28 was 3.1(1.4–7.7). Data on BMD loss and radiographic progression are shown in Table 1. Patients with radiographic progression (change in Total Sharp Score >0) had higher BMD loss than patients without radiographic progression in both the DMARD (−0.94 mg/cm^2 (median) vs. −0.54, p = 0.03, Wilcoxon) and TNFi period (−0.74 vs. 0.34, p = 0.004, Wilcoxon). Independent predictors of BMD loss during the TNFi period were: higher age (−0.2mg/cm^2/10 year increase) and 28 swollen joint count (SJC) (−0.4mg/cm^2/joint increase).

	BMD and radiographic status			Annual change in BMD and TSS		P-value (1)
	Prebaseline X-ray	Baseline X-ray	Follow-up X-ray	DMARD period	TNFi period	
TSS median (IQR), units	6 (0–21)	10 (1–29)	12 (2–31)	0.6 (0.0–2.5)	0.0 (0.0–0.8)	<0.0001
BMD median (IQR), g/cm²	0.55 (0.48–0.61)	0.53 (0.45–0.59)	0.52 (0.44–0.57)	−0.0079 (−0.017–002)	−0.0047 (−0.012 − −0.001)	0.001
BMD median (IQR), %				−1.55 (−3.45–0.44)	−1.11 (−2.52–0.15)	0.02
Correlation TSS vs. BMD (2)	−0.45	−0.45	−0.43	−0.23	−0.27	
P-value (2)	<0.0001	<0.0001	<0.0001	0.0007	0.001	

[1]Wilcoxon Signed Rank [2]Spearman. The DMARD period is the period between pre-baseline and baseline X-rays, while the TNFi period is the period between baseline and follow-up X-rays. TSS, Total Shap Score (of hands); BMD, Bone Mineral Density

Conclusion: In 136 established RA patients TNFi treatment reduced BMD loss and radiographic progression. High age and SJC predicted BMD loss during TNFi treatment. During DMARD- and TNFi treatment radiographic progression and BMD loss were moderately correlated.

Response to Etanercept, but Not Infliximab or Adalimumab, Is Inversely Associated with Body Mass Index. James R. Maxwell[1], Darren Plant[2], Anne Barton[3], Kimme L. Hyrich[3], Ann W. Morgan[4], John Isaacs[5] and Anthony G. Wilson[6]. [1]University of Sheffield, Sheffield, United Kingdom, [2]University of Manchester, Manchester, United Kingdom, [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester Academy of Health Sciences, Manchester, United Kingdom, [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [5]Newcastle University, Newcastle upon Tyne, United Kingdom, [6]Section of Musculoskeletal Sciences, University of Sheffield, Sheffield, United Kingdom

Background/Purpose: Recent studies have demonstrated inverse association between BMI and radiographic severity in patients with Rheumatoid Arthritis (RA). There is also preliminary evidence that body mass index (BMI) may influence response to anti-TNF treatment. We hypothesized that BMI may affect response to the three most commonly used anti-TNF agents. The aim of this study was to determine if BMI is associated with response to individual anti-TNF agents in RA patients.

Methods: 2,160 patients were included, of whom 726 were treated with Infliximab, 737 Etanercept and 697 Adalimumab. Linear regression was used to investigate the influence of BMI, recorded at baseline on the change in DAS28 between baseline and 6 months of treatment, adjusted for gender, DMARD treatment, smoking, baseline DAS28 and HAQ score. Similar models were constructed to examine change in ESR and CRP. The proportion of patients achieving EULAR improvement criteria according to stratified BMI was compared using the Chi squared test. Analyses were performed separately according to individual anti-TNF agents.

Results: Mean disease duration was 13.7 years. BMI was not associated with change in DAS between baseline and 6 months and there was no statistical difference in the proportion of patients achieving EULAR response criteria according to BMI for any of the medications. For patients treated with Etanercept, but not Adalimumab or Infliximab, BMI was inversely associated with change in both ESR and CRP (p=0.003, and p<0.0001 respectively).

Conclusion: Change in inflammatory activity in response to Etanercept, but not Infliximab or Adalimumab, is inversely associated with BMI. Response to Infliximab has been reported to be reported to be inversely related to higher BMI in a study of 89 patients however our much larger study did not replicate this finding. Our data suggest that higher doses of Etanercept may be required in RA patient with high BMI. Studies are required to determine if lower doses of this agent could be used in patients with lower BMI.

Risk Factors for Radiographic Progression During TNF-Inhibitor Treatment in 932 Rheumatoid Arthritis Patients Treated in Clinical Practice: Results From the Nationwide Danish Danbio Registry. Lykke Midtbøll Ørnbjerg[1], Mikkel Østergaard[1], Pernille Bøyesen[2], Anja Thormann[1], Ulrik Tarp[1], Wolfgang Bøhme[1], Ditte Dencker[1], Hanne M. Lindegaard[1], Uta Engling Poulsen[1], Annette Hansen[1], Vibeke Stevenius Ringsdal[1], Annette Schlemmer[1], Niels Graudal[1], Anne Rødgaard Andersen[1], Jakob Espesen[1], Gina Kollerup[1], Torben Grube Christensen[1], Randi Pelck[1], Bente Glintborg[1], Ole Rintek Madsen[1], Dorte Vendelbo Jensen[1], Ole Majgaard[1] and Merete L. Hetland[3]. [1]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Copenhagen, Denmark, [2]Diakonhjemmet Hospital, Olso, Norway, [3]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Despite treatment with tumour necrosis factor inhibitors (TNFi) some rheumatoid arthritis (RA) patients progress radiographically in randomised controlled trials and observational cohorts (1). Risk factors for radiographic progression during TNFi treatment in clinical practice have not been investigated. The aim of this study was to identify baseline risk factors for radiographic progression during 2 years follow-up of TNF-inhibitor treated RA patients in clinical practice.

Methods: X-rays of hands and wrists obtained at the start of TNFi (baseline) and approximately 2 years after (follow-up) were collected from 16 Danish departments, and linked with clinical data from the DANBIO registry. X-rays were blinded to chronology and scored according to the Sharp/van der Heijde method. Potential predictive baseline variables (28-joint Disease Activity Score(DAS28), C-reactive protein(CRP), 28 Swollen Joint Count(SJC), 28 Tender Joint Count(TJC), Health Assessment Questionnaire-(HAQ), Total Sharp Score (TSS), age, gender, IgM Rheumatoid Factor (IgM-RF), disease duration, number of previous Disease-Modifying Anti-Rheumatic Drugs (DMARDs), concomitant methotrexate (MTX), concomitant prednisolone, type of TNFi drug) were investigated with univariate regression and significant variables (p < 0.05) included in a logistic regression analysis with +/− radiographic progression (change in TSS> 0) as dependent variable.

Results: 932 patients (75% women, 79% IgM-RF positive, age 57(19–88) years (median(range)); disease duration 6(1–70) years), DAS28 5.4(4.6–6.1) (median(inter-quartile range(IQR)), TSS 30(38) (mean(SD)) 14(2–44)(median(IQR)) had available X-rays. At baseline 59% of patients started treatment with infliximab, 18% with etanercept and 23% with adalimumab. 15% of patients received TNFi monotherapy, 76% combination therapy with MTX and 9% with other DMARDs. At follow-up (median 526, IQR 392–735days), 59% were treated with the initial TNFi, 29% had switched to another TNFi and 12% had withdrawn from TNFi.

Yearly change in TSS was 0.6(2.4) units (mean(SD)), 0.0(0.0–0.5)(median(IQR)). 27% of patients progressed radiographically (change in TSS >0) during TNFi treatment. Independent risk factors for progression were baseline TSS, age, IgM-RF and concomitant treatment with prednisolone (Table).

Table. Final model of logistic regression analysis (n = 932)

Predictors of X-ray progression	Odds Ratio	P value
TSS (pr. unit increase)	1.004	0.049
Age (pr. year increase)	1.03	0.0002
IgM RF (if positive)	1.75	0.006
Concomitant prednisolone (if treated)	1.39	0.03

Conclusion: In this nationwide observational study of 932 RA patients, baseline TSS, age, IgM-RF and concomitant prednisolone were risk factors for radiographic progression during 2 years follow-up.

Moderate Rheumatoid Arthritis Despite Methotrexate Treatment: Risk of Radiographic Progression. Bruno Fautrel[1], Gaia Gallo[2], Yves Brault[3] and Henk Nab[4]. [1]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [2]Pfizer, Rome, Italy, [3]Pfizer, Paris, France, [4]Pfizer Europe, Rome, Italy

Background/Purpose: Clinical remission or low disease activity are the main goals of rheumatoid arthritis (RA) treatment and European League Against Rheumatism guidelines recommend switching treatment after 3–6 months in patients who do not achieve these targets.[1] Despite this, in Europe the majority of patients have moderate disease activity and many of them remain on methotrexate (MTX) which may lead to disease progression and functional deterioration. Several risk matrix models have been already developed but always include a patient population with mostly severe RA and never in subjects with a stable moderate disease state. The objective of this study was to identify (a combination of) factors contributing to the risk of radiographic progression (RP) among moderate RA subjects despite MTX treatment.

Methods: Subjects from the MTX arm of the TEMPO trial[2] with sustained moderate RA (defined as $3.2 \leq$ mean disease activity score in 28 joints ≤ 5.1 during the last 6 months of the first year) were analyzed for radiographic progression after 2 and 3 years. Univariate logistic regression was performed to identify baseline predictors of RP. Predictor variables with $p < 0.10$ were selected for stepwise multivariate analysis. Receiver-Operating Characteristic (ROC) analysis was used to evaluate the performance of the final model to predict disease progression; the area under the ROC curve (AUC) was calculated as a measure of accuracy.

Results: During the last 6 months of the first year, 96 subjects had moderate RA, out of 187 patients that started MTX. Of these subjects, RP (change from baseline in modified Total Sharp Score [mTSS] ≥ 0.5) occurred in 48 (50%) and 54 (56%) at 2 and 3 years, respectively, with a subgroup of 25 (26%) and 33 (34%) subjects who experienced a higher degree of RP (change from baseline in mTSS >3.0) at 2 and 3 years, respectively. Univariate analysis showed erythrocyte sedimentation rate (ESR), rheumatoid factor (RF) positivity, and C-reactive protein (CRP) levels were significantly predictive of mTSS change >3.0 at both 2 and 3 years ($p < 0.05$ for all; **Table**). Multivariate analysis of these variables showed ESR and RF positivity were predictive of mTSS change >3.0 after 2 and 3 years ($p < 0.05$ for all). ROC analysis found the AUC = 0.73 for both models, indicating a fair test of prediction.

Conclusion: Subjects with sustained moderate RA despite treatment with MTX are at risk of disease progression. Both ESR and RF positivity at baseline were strongly predictive of radiographic progression in these subjects.

Improvement of Health-Related Quality of Life in RA Patients Treated with Biologics - One-Year Follow-up Data of the German Biologics Register Rabbit. Kerstin Gerhold[1], Adrian Richter[1], Matthias Schneider[2], Hans Joachim Bergerhausen[3], Winfried Demary[4], Anke Liebhaber[5], Joachim Listing[1], Angela Zink[1] and Anja Strangfeld[1]. [1]German Rheumatism Research Center, a Leipniz Institute, Berlin, Germany, [2]Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany, [3]Wedau Kliniken - Klinikum Duisburg, Duisburg, Germany, [4]Private Practice, Hildesheim, Germany, [5]Private Practice, Halle, Germany

Background/Purpose: Health related quality of life (HRQoL) has been increasingly recognized as a crucial indicator of disease burden in chronic diseases such as rheumatoid arthritis (RA). To measure the effectiveness of biologic disease modifying anti-rheumatic drugs (bDMARDs) on patient-assessed disease burden, we investigated the one-year course of HRQoL in a cohort of RA patients treated with bDMARDs or synthetic DMARDs (sDMARDs) after failure of at least one DMARD.

Methods: Patients enrolled in the German biologics register RABBIT from 2006 up to 2010 with a minimal observation period of one year were included. SF-36 questionnaire was used to capture patient-assessed mental and physical health at baseline and after one year of follow-up. Disease activity was measured by means of DAS28, patient-assessed functional capability by means of the FFbH (Funktionsfragebogen Hannover) score. We applied last-observation-carried-forward (LOCF) method for patients discontinuing initial therapy and patients who were lost to follow-up from the ITT-population. Level of statistical significance for differences between baseline and one-year follow-up values of physical and mental health subscales was set at a=0.00625 using Bonferroni correction for multiple testing of the 8 subscales (paired t-test for pre-treatment versus post-treatment comparisons, two-sided).

Results: Data of 804 patients treated with TNF inhibitors (anti-TNF), 234 patients treated with tocilizumab (TOC), 450 patients treated with rituximab (RTX), 124 patients treated with abatacept (ABA), and of 816 patients treated with sDMARDs were included in the analysis. LOCF was used in 226 anti-TNF patients, 58 TOC, 57 RTX, 43 ABA and 158 sDMARD patients. Mean disease duration at baseline was between 10.1 and 13.9 years in the bDMARD groups, and 6.0 years in the sDMARD group. At baseline all bDMARD groups showed higher disease activity, lower functional capacity and poorer values for all subscales of physical and mental health than the sDMARD group. At one-year follow-up, disease activity, functional capacity as well as all SF-36 scales had improved in all treatment groups. However, bDMARD patients developed greater improvement, especially in the mental health subscales, compared to sDMARD patients.

Table 1. Mean values of SF36 scales and improvement after one year (D=mean$_{(1-year)}$-mean$_{(baseline)}$)

SF36 scales		Anti-TNF	TOC	RTX	ABA	s-DMARD	Anti-TNF	TOC	RTX	ABA	s-DMARD
		Mean values at baseline					Improvement [D]				
Physical Health Scales	Physical Function	45.1	39.7	37.5	37.5	55.0	5.9*	7.0*	4.6*	4.5	1.7
	Physical Role	24.4	19.6	18.1	17.9	33.7	11.8*	17.9*	10.9*	4.8	9.1*
	Body Pain	31.2	29.8	30.0	26.1	39.1	12.3*	13.9*	9.8*	8.8*	7.7*
	General Health	40.8	40.0	39.3	35.0	46.9	5.1*	7.6*	4.6*	3.4	2.3*
Mental Health Scales	Vitality	37.2	37.1	32.5	32.5	44.2	5.7*	7.0*	4.5*	4.3*	3.3*
	Social Function	61.9	56.9	56.9	55.5	68.3	6.1*	7.8*	6.1*	6.6*	2.8*
	Role Emotional	50.3	48.2	44.4	41.7	54.1	7.8*	9.2*	7.8*	9.4	4.0
	Mental Health	57.2	59.9	56.5	54.3	59.9	4.9*	4.4*	3.1*	5.2*	1.9*
Disease activity	DAS28 (ESR)	5.2	5.6	5.5	5.6	4.6	−1.4*	−2.1*	−1.2*	−1.2*	−1.0*
Functional capability	FFbH	65.1	60.0	53.5	53.8	72.1	4.4*	3.9*	7.1*	4.8*	2.8*

Conclusion: Patients treated with bDMARDs had a worse disease state due to disease activity and functional capacity at enrollment, compared to patients on sDMARDs, which reflects treatment choices in daily care. All bDMARDs improved patientsx HRQoL beyond control of disease activity and physical function. Benefit of treatment with bDMARDs was particularly noticeable in the mental health subscales of the SF-36.

Efficacy of Methotrexate (MTX) According to Anti-Citrullinated Protein Antibody (ACPA) Status in an Early Inflammatory Arthritis Cohort.
Sarah C. Horton, David Pickles, Paul Emery, Maya H. Buch and Jane E. Freeston. University of Leeds, Leeds, United Kingdom

Background/Purpose: Data suggests patients with early, ACPA negative, rheumatoid (RA) and undifferentiated arthritis (UA) are less likely to achieve remission with MTX at 4 months in comparison to ACPA positive patients [1]. In patients with probable RA, MTX only delayed progression to RA in ACPA positive patients [2]. The objective was to determine whether response to MTX differs according to ACPA status in an early inflammatory arthritis cohort.

Methods: Patients with UA or RA (2010 ACR/EULAR criteria) initiated on MTX as first-line DMARD up to December 2011 were identified from the Inflammatory Arthritis disease CONtinuum (IACON) registry in Leeds. Outcome measures at 6 months were remission (DAS28-CRP<2.6) and EULAR response. Outcomes were analysed where complete response datasets were available using with last observations carried forward for patients who stopped MTX or escalated to combination DMARD therapy prior to 6 months. Logistic regression was used to compare the rate of DAS28 remission and EULAR good response at 6 months, adjusting for DAS28 at baseline.

Results: Of 78 patients commencing MTX monotherapy, 51 of 53 ACPA positive and 14 of 25 ACPA negative patients fulfilled 2010 RA criteria. Radiographic erosions were present in 6/35 (24%) ACPA negative and 11/53 (21%) ACPA positive patients. Table 1 displays baseline characteristics according to 2010 RA criteria and ACPA status. Over 6 months methotrexate was continued as monotherapy in 49 patients: alternative DMARD(s) were added (n=25), cessation (n=1), enrolment in clinical trial (n=1), death (n=1) and loss to follow-up (n=2). Patients escalating to combination DMARD therapy did so at a median time of 3 months on a median (IQR) weekly dose of MTX of 20 mg (20 to 25mg). This was similar to the weekly dose of MTX at 6 months in patients continuing monotherapy (median 20; IQR 15 to 25). Datasets were complete for analysis of response in 60 patients (Table 2). Rate of remission was higher in ACPA positive patients; odds ratio(OR) 8.9, 95% confidence interval (CI) 2.0 to 40. There was a trend towards a superior rate of EULAR good response in ACPA positive patients at 6 months (OR 2.1, 95% CI 0.6 to 7.7).

Table 1. Baseline Characteristics

	RA (2010 criteria)		UA	
	ACPA+ n= 51	ACPA− n= 14	ACPA+ n= 2	ACPA− n= 11
Age, mean (SEM)	53 (2)	60 (4)	58 (15)	44 (5)
Female, n (%)	36 (71)	8 (57)	1 (50)	9 (82)
Shared epitope, n positive/n tested (%)	20/22 (91)	4/6 (67)	Not recorded	8/9 (89)
RF positive, n (%)	44(86)	5 (36)	1 (50)	1 (9)
Symptom duration, median (IQR), wks	33 (17–77)	32 (11–62)	6, 77	28 (25–91)
Erosions, n (%)	11(22)	6(43)	0	0
Joint involvement (M=medium, L=large, S=small joints):	.	.	.	.
	0	0	1 (50)	0
1 M/L	0	0	0	0
2–10 M/L	11 (22)	3 (21)	1 (50)	3 (27)
1–3 S	14 (28)	1 (7)	0	8 (73)
4–10 S	26 (51)	10 (71)	0	0
>10 (at least 1 S)				

Table 2. Response at 6 months

ACPA Status	Escalation to combination DMARD therapy, n (%)	Weekly MTX dose in mg (IQR)	Baseline DAS28, median (IQR)	6 month DAS28, median (IQR)	Reduction in DAS28, median (IQR)	DAS28 Remission Baseline, n(%)	DAS28 Remission 6 months, n(%)	EULAR Response, n (%)		
								Good	Moderate	None
Positive (n=38)	13 (34)	20 (20 to 25)	3.9 (2.9 to 5.3)	2.5 (2.0 to 3.7)	1.1 (0.4 to 2.1)	8 (21)	20 (53)	13 (34)	12 (32)	13 (34)
Negative (n=22)	8 (36)	20 (15 to 25)	3.5 (3.0 to 4.6)	3.5 (2.5 to 4.2)	0.0 (−0.5 to 1.3)	5 (23)	5 (23)	4 (18)	4 (18)	14 (64)

Conclusion: Rate of remission was higher in ACPA positive vs ACPA negative patients, and there was a trend towards superior rate of eular response. Escalation of therapy was comparable between the groups. This data suggests that seronegative patients may be less responsive to MTX and may require a different treatment regimen.

Improved Fatigue-Related Quality of Life in CAPRA-2, a 12 Week Study of 5-Mg Modified (Delayed) Release Prednisone in Rheumatoid Arthritis.
Rieke Alten[1], Amy Grahn[2], Patricia Rice[3] and Frank Buttgereit[4]. [1]Schlosspark-Klinik, University Medicine, Berlin, Germany, [2]Horizon Pharma, Deerfield, IL, [3]CliniRx Research, Naperville, IL, [4]Charite University Medicine, Berlin, Germany

Background/Purpose: Quality of life in rheumatoid arthritis (RA) patients can be improved by reducing the common symptom of fatigue caused by disease related factors such as pain and inflammation. Recent studies indicate that glucocorticoid treatment improves patient reported fatigue (Westoff et al, 2011). Chronotherapy with a modified (delayed) release (MR) prednisone tablet may also improve these symptoms. NP01 (Horizon Pharma, Deerfield IL) is a proprietary MR formulation of prednisone that results in a 4 hour delay in traditional pharmacokinetic parameters of prednisone. This formulation capitalizes on known cytokine and endogenous biologic rhythms. Here we report fatigue scores from the Circadian Administration of Prednisone in Rheumatoid Arthritis-2 (CAPRA-2) study which evaluated patients with active RA on stable disease-modifying antirheumatic drugs (DMARDs) given MR prednisone or placebo.

Methods: The study was a 12-week, double-blind, placebo-controlled study that randomized 350 RA patients to either 5 mg MR prednisone (n=231) or placebo (n=119) taken once daily at bedtime (eg, 10pm) in addition to their standard DMARD treatment (Buttgereit et al, 2012). The primary endpoint was the proportion of patients achieving ACR20 response after 12 weeks. A secondary objective was to compare treatment with 5 mg MR prednisone and placebo in the change from baseline on the Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) questionnaire. This 13 item questionnaire assesses the effect of fatigue on daily activity and function on a 5-point scale (0=not at all, 1=a little bit, 2=somewhat, 3=quite a bit, 4=very much), with a score range of 0 to 52.

Results: The mean baseline FACIT-F fatigue score was comparable in the 5 mg MR prednisone group and the placebo group (28.81 vs 28.73, Table 1). The least square mean (LSM) absolute increase from baseline to Week 12 was greater in the 5 mg MR prednisone group than in the placebo group (3.83 vs 1.59), indicating a reduction of fatigue (Table 1). The difference in FACIT-F score between baseline and Week 12 was clinically relevant for 5 mg MR prednisone but not for placebo (minimal clinically important difference [MCID]: 3–4; Cella et al, 2005). At Week 12, the LSM change from baseline was statistically significantly greater for 5 mg MR prednisone than for placebo, (LSM difference=2.24 [95% CI: 0.76, 3.72], p-value=0.0032) (Table 1). Similar results occurred for observed case data. These findings were consistent with improvement in ACR20 score.

Table 1. FACIT-F Fatigue Score at Each Visit (mITT Population, BOCF)

Visit		FACIT-F Fatigue Score		
		5 mg MR-Prednisone	Placebo	5 mg MR-Prednisone vs. Placebo
Baseline	n	231	119	–
	Mean (SD)	28.81 (10.443)	28.73 (10.725)	–
Week 12	n	231	119	–
	Mean (SD)	32.54 (10.893)	30.25 (10.465)	–
Absolute Change from Baseline to Week 12	LSM	3.83	1.59	–
	LSM Difference (SE)	–	–	2.24 (0.754)
	95% CI for LSM Difference	–	–	0.76, 3.72
	p-value	–	–	0.0032

Abbreviations: FACIT-F = Functional Assessment of Chronic Illness Therapy – Fatigue; mITT = modified intention-to-treat; BOCF = baseline observation carried forward; MR = modified-release; SD = standard deviation; LSM = least square mean; SE = standard error; CI = confidence interval.
Note: LSMs are from an analysis of covariance (ANCOVA) model with baseline results, treatment, and geographic region as factors. Model effects were from the Type III estimates.

Conclusion: Patients treated with 5 mg MR prednisone had significant improvement in FACIT-F scores compared with placebo, indicating a reduction in fatigue and improvement in an important aspect of quality of life. Chronotherapy with a MR prednisone formulation improves ACR scores and provides a potential new treatment option for patients with RA that can also improve symptoms of fatigue.

368

Impact of Etanercept-Methotrexate Therapy On Patient-Reported Outcomes in Rheumatoid Arthritis Patients with up to 12 Months of Symptoms.

Paul Emery[1], Piotr Wiland[2], Wolfgang Spieler[3], Jean Dudler[4], Stefanie Gaylord[5], Theresa Williams[5], Ronald Pedersen[5], Andrew S. Koenig[5], Bonnie Vlahos[5] and Sameer Kotak[6]. [1]Leeds General Infirmary, Leeds, United Kingdom, [2]Wroclaw Medical University, Wroclaw, Poland, [3]Rheumatology Specialty Practice, Zerbst, Germany, [4]University Hospital of Lausanne, Lausanne, Switzerland, [5]Pfizer Inc., Collegeville, PA, [6]Pfizer Inc., New York, NY

Background/Purpose: Patient-reported outcomes (PROs) in patients with rheumatoid arthritis (RA) are critical in evaluating RA treatment effects on function and health-related quality of life (HR-QoL). Significant improvement in PROs has been reported in RA studies of biologic agents, including etanercept (ETN), but most studies have been conducted in patients with established disease. In addition to assessing treatment effects in early RA, there is interest in therapeutic strategies that allow dose reduction or withdrawal of biologic therapy (biologic-free) after induction of response. The PRIZE trial is an ongoing, 3-period study to evaluate the efficacy of combined ETN and methotrexate (MTX) therapy in patients with early, moderate-to-severe RA and to assess whether efficacy (remission) can be maintained with ETN dose reduction or biologic-free (Period 2) or drug-free (Period 3). Herein we report PROs associated with ETN 50 mg QW plus MTX (ETN50/MTX) therapy administered for 52 wks in Period 1 (induction) of the PRIZE trial.

Methods: In Period 1, MTX- and biologic-naïve patients with early, active RA (symptom onset ≤12 mo from enrollment; DAS28 >3.2) received open-label ETN50/MTX for 52 wks. The starting dose of MTX was 10 mg QW; at the discretion of the investigator, titration was permitted up to a maximum of 25 mg QW to achieve remission. Corticosteroid boosts were administered to patients not achieving low disease state at wks 13 and 26, unless contraindicated or not tolerated. PROs were assessed using the Health Assessment Questionnaire (HAQ) total score; Patient Acceptable Symptom State (PASS); EuroQol-5 Dimensions (EQ-5D) total index; Short Form Health Survey (SF-36); Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue; Work Instability Scale for Rheumatoid Arthritis (RA-WIS); and Work Productivity and Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA).

Results: A total of 306 patients received treatment in Period 1 (mITT population); 222 (73%) patients completed the period. The majority of patients were female (70%), with a mean age of 50 y, mean DAS28 of 6.0 (median, 6.0), and duration of disease symptoms from onset of 6.5 months (median, 6.3 mo). Significant and clinically meaningful improvements in

PROs, including in HAQ, EQ-5D, SF-36, and FACIT-Fatigue, were demonstrated with ETN50/MTX therapy from baseline to the final on therapy visit (Table; $P<0.0001$). Similar improvements were observed in all dimensions of RA-WIS and WPAI:RA (Table; $P<0.0001$).

Table. Effects of ETN50/MTX on PROs in Early RA Patients in Period 1 of the PRIZE Study (N = 306)

Parameter	Baseline Mean (SD)	Final on Therapy Visit Mean (SD)	Δ from Baseline Mean (SD)
HAQ Disability Index	1.3 (0.7)	0.5 (0.6)	−0.8* (0.7)
EQ-5D Utility Score	0.5 (0.3)	0.8 (0.3)	0.3* (0.3)
EQ-5D VAS	50.9 (22.6)	77.2 (24.1)	27.4* (28.1)
SF-36 Physical Component Score	33.6 (8.0)	45.5 (9.7)	11.9* (9.6)
SF-36 Mental Component Score	42.9 (10.9)	50.6 (9.3)	7.5* (10.6)
FACIT-Fatigue	29.1 (12.6)	39.9 (11.4)	10.9* (12.2)
RA-WIS	13.5 (6.1)	4.8 (6.5)	−8.9* (6.6)
WPAI:RA, % activity impairment due to RA	57.2 (24.3)	21.5 (25.5)	−36.4* (29.4)

Endpoint	% Patients (95% CI), Final on Therapy Visit
Normal HAQ score (≤0.5)	66.6† (60.9, 71.9)
Clinically meaningful improvement in HAQ Disability Index (Δ ≥0.22)	80.2‡ (75.2, 84.6)
PASS	82.0† (77.2, 86.1)
RA-WIS High (>17)	7.7† (4.6, 11.9)
RA-WIS Low (0–9)	79.9† (74.2, 84.9)
RA-WIS Low/Medium (0–17)	92.3‡ (88.1, 95.4)

Note: Final on therapy visit and Δ values are for observed cases.
*$P < 0.0001$ vs baseline, paired t-test; †$P < 0.0001$ vs baseline, McNemar's test; ‡$P < 0.0001$ vs baseline, Binomial test; mITT population.
HAQ score: range, 0–3, 20 items; lower score = less functional disability; ≤0.5 = normal; Δ ≥0.22 = clinically meaningful.
EQ-5D: range, 0–1; higher scores = better QoL; Δ ≥0.05 = clinically meaningful.
FACIT-Fatigue: range, 0–52; higher scores = less fatigue; Δ ≥3.0 = clinically meaningful.
WPAI:RA: 0–100% work impairment; lower % = less work impairment.
RA-WIS >17 = high risk of work disability; RA-WIS 0–9 = low risk of work disability; and RA-WIS 0–17 = low or medium risk of work disability.

Conclusion: Combination therapy with ETN50/MTX for 52 wks in patients with <12 mo of symptomatic, active RA resulted in significant, clinically important improvements in measures of physical function, including normal HAQ (66.6% of patients), HR-QoL, fatigue, and work productivity. These outcomes are consistent with those reported in prior studies in patients with more established disease.

369

Differences in Short-Term Radiographic Progression Following Early Response to Adalimumab Plus Methotrexate Vs. Methotrexate Alone.

Ronald F. van Vollenhoven[1], James W. Shaw[2], Mary A. Cifaldi[2], James Signorovitch[3], Eric Q. Wu[3], Thomas Samuelson[3], Elizabeth Faust[3] and Paul Emery[4]. [1]Karolinska Institute, Stockholm, Sweden, [2]Abbott Laboratories, Abbott Park, IL, [3]Analysis Group, Inc., Boston, MA, [4]University of Leeds, Leeds, United Kingdom

Background/Purpose: To prevent disease progression, treat-to-target recommendations for rheumatoid arthritis (RA) include the evaluation and adjustment of drug therapy at least every 3 months until a target level of remission or low disease activity is achieved. It is well established that anti-tumor necrosis factor (TNF) treatment modifies associations between disease activity and radiographic progression over periods of 1–2 years.[1] We aimed to assess whether TNF inhibition modifies this association over the initial 3–6 months of treatment for early RA.

Methods: Methotrexate (MTX)-naïve early RA patients randomized to double-blind treatment with adalimumab (ADA)+MTX combination therapy vs. MTX monotherapy were drawn from the Phase III PREMIER clinical trial. Associations between week 12 disease activity, assessed using DAS28-CRP(4), and changes in modified total sharp score (mTSS) from baseline to week 26 were compared between the ADA+MTX and MTX arms using generalized additive regression. mTSS progression was modeled as an absolute score change and as a worsening of ≥5 units.[2] Models were fit with and without adjustment for baseline mTSS, DAS28, numbers of tender and swollen joints, and RA duration.

Results: A total of 219 MTX-treated patients and 241 ADA+MTX-treated patients were included in the investigation. The mean age was 52 years, 73% were female, and the average RA duration was 9 months. In the

adjusted analyses, patients treated with ADA+MTX experienced limited mean increases in mTSS from baseline to week 26 that were numerically similar across all levels of week 12 DAS28, whereas patients treated with MTX showed a sharp increase in mTSS progression with increasing week 12 DAS28 (Figure). Compared to patients who were treated with MTX alone, those treated with ADA+MTX achieving a DAS28 ≤2.6 at week 12 had a significantly smaller change in mTSS (difference: −1.59; 95% CI: −2.74, −0.44) and a significantly lower risk of mTSS progression of ≥5 units (odds ratio [OR]: 0.19; 95% CI: 0.06, 0.61) at week 26. Results were similar for unadjusted analyses.

DAS-28 vs. Constant mTSS Change Adjusted
Conclusion: Early RA patients achieving a given disease activity level by week 12 with ADA+MTX experience less radiographic progression by week 26 than those achieving the same disease activity level with MTX alone. This could reflect the slower onset of response to MTX and/or a separate structure-protective effect for anti-TNF treatment. These aspects should be considered when setting disease activity targets with the goal of limiting radiographic progression.

Characteristic of the Japanese Patients with Rheumatoid Arthritis (RA) of Rapid Radiographic Progression (RRP) Treated with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) in Daily Practice: A Large-Scale Prospective Longitudinal Cohort Study (the 1st report of Apple Survey). Akitomo Okada[1], Atsushi Kawakami[1], Takaaki Fukuda[2], Toshihiko Hidaka[3], Tomonori Ishii[4], Yukitaka Ueki[5], Takao Kodera[6], Munetoshi Nakashima[7], Yuichi Takahashi[8], Seiyo Honda[9], Yoshiro Horai[1], Tomohiro Koga[1], Ryu Watanabe[10], Hiroshi Okuno[10] and Katsumi Eguchi[11]. [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Kurume University Medical Center, Kurume, Japan, [3]Zenjinkai Shimin-No-Mori-Hospital, Miyazaki, Japan, [4]Tohoku University, Sendai, Japan, [5]Sasebo, Japan, [6]Tohoku Kosei Nenkin Hospital, Sendai, Japan, [7]Japanese Red Cross Nagasaki Genbaku Hospital, Nagasahi, Japan, [8]Yu Family Clinic, Sendai, Japan, [9]Kurume University School of Medicene, Kurume, Japan, [10]Tohoku University Hospital, Sendai, Japan, [11]Sasebo City General Hospital, Sasebo, Nagasaki, Japan

Background/Purpose: There has been few epidemiological report of longitudinal radiographic progression in rheumatoid arthritis (RA) patients captured in daily practice. In 20 related-centers of the Nagasaki University and Tohoku University in Japan we are conducting a large-scale prospective study (Apple Survey) to investigate extent of radiographic progression. We have tried to assess the extent of rapid radiographic progression (RRP) in synthetic disease modifying anti-rheumatic drugs (DMARDs)-treated RA patients.

Methods: We have selected the RA patients treated not by biologic DMARDs but by synthetic DMARDs for 1 year. One hundred fifty-three out of the 964 patients registered between May 09 and March 12 had evaluable data at present. Patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University, Tohoku University and related centers. DAS28-ESR was assessed every 3 months. Radiographs of the hands and feet were taken every 6 months. The images were scored by trained readers through modified total Sharp score (mTSS). RRP was defined as yearly progression of mTSS >3.0. We have examined what variables are associated with the development of RRP at 1 year.

Results: Ten variables including gender, disease duration at baseline, age, CRP at baseline (mg/dl), presence of autoantibodies (RF or anti-CCP Abs), DAS28-ESR at baseline, time-integrated DAS28-ESR during 1 year, mTSS at baseline, HAQ at baseline and the use of MTX or non-MTX DMARDs were evaluated through univariate and logistic regression analysis to explore the development of RRP at 1 year. RRP was found in 17 out of 153 patients (11.1%). Logistic regression analysis has found that short disease duration (p = 0.0061), younger age (p = 0.038), high time-integrated DAS28-ESR (p = 0.015) and high mTSS at baseline (p = 0.035) are independent variables to predict the development of RRP. There were the trend of presence of autoantibodies (p = 0.074) and non-MTX DMARDs use (p = 0.054) toward RRP at 1 year.

Conclusion: Our results have revealed the characteristic of synthetic DMARDs-treated Japanese RA patients who develop RRP. The treat-to-target strategy is particularly recommended in these patients.

371

Treat-to-Target Strategy Aiming At Achievement of Structural and Functional Remission in Patients with Active Elderly-Onset Rheumatoid Arthritis. Takahiko Sugihara[1], Tatsuro Ishizaki[2], Tadashi Hosoya[1], Shoko Iga[1], Waka Yokoyama[1], Fumio Hirano[1], Nobuyuki Miyasaka[3] and Masayoshi Harigai[3]. [1]Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan, [2]Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, [3]Tokyo Medical and Dental University, Tokyo, Japan

Background/Purpose: Treat-to-target is the consensus treatment strategy for patients with rheumatoid arthritis (RA), but supporting evidence for treat-to-target strategy in elderly RA patients in clinical practice is insufficient. The objective of this study was to evaluate structural damage and physical disability of patients who developed RA at ≥60 y/o (elderly onset RA, EORA) and were treated aiming at low disease activity (LDA) in Choju registry of rheumatoid arthritis on non-biologic and biologic disease-modifying antirheumatic drugs (DMARDs) for elderly patients in Japan (CRANE), a prospective, mono-centric registry.

Methods: Of 150 Japanese elderly (≥60 years) patients with RA enrolled in the CRANE, we identified 106 methotrexate-naïve EORA patients with moderate to severe disease activity (disease activity score 28 joints (DAS28)≥ 3.2) and disease duration ≤ 3 years at the enrollment. We analyzed data from 84 patients who completed 12-month follow-up in this study. The treatment was adjusted every 3 months aiming at LDA (DAS28< 3.2). We started treatment with non-biologic DMARD monotherapy (methotrexate (MTX), tacrolimus, salazosulfapyridine, or bucillamine), followed by TNF inhibitors, then tocilizumab or abatacept. The co-primary outcomes were DAS28, Δtotal sharp score (TSS) and Health Assessment Questionnaire-Disability Index (HAQ-DI) at week52.

Results: Baseline characteristics of the 84 patients were as follows: mean age, 75.3 y/o; mean disease duration, 0.92 years; mean DAS 28, 6.33; mean HAQ, 1.23; anti-CCP antibody positive, 66.3%. Rates for comorbidity of the patients were 33.8% for chronic lung diseases, 12.8% for cardiovascular diseases and16.3% for diabetes mellitus. At week 12, 77.6% and 14.1% of the patients were receiving MTX at 7.3±1.8 mg/week and tacrolimus, respectively. At weeks 24 and 52, 16.9% and 33.3 % of the patients were treated with TNF inhibitors. LDA and functional remission (HAQ-DI≤0.5) were

achieved in 29.1% and 42.6% of the patients at week 24, respectively, and in 45.9% and 58.1% at week 52, respectively. Structural remission (ΔTSS/ year$\leq$ 0.5) were observed in 39.3 % and rapid radiographic progression (RRP,ΔTSS/year$>$3) in 32.6% of the patients. Triple (clinical, structural and functional) remission at week 52 was observed in 8.3% of the patients. Mean DAS28 at weeks 0, 12 and 24 and mean HAQ-DI at week 52 was significantly higher in the patients with RRP compared to those without RRP. The multiple logistic regression model involving the area under the curve (AUC) of DAS28 (accumulated DAS28) between week 0 and week 12, as well as age, sex, anti-CCP antibody status, HAQ-DI, and presence of bony erosions at week 0, predicted RRP at week 52 well with the C statistic of 0.897, and the AUC of DAS28 during the first 3 months predicted RRP better than those during the first 6 or 12 months (the C-statistic, 0.879 for 0–6 months, and 0.834 for 0–12 months).

Conclusion: Achieving LDA, structural remission and functional remission in daily clinical practice using non-biologic and biologic DMARDs in EORA patients were realistic goals. Rapid achievement and sustainment of clinical remission is indispensable to prevent RRP in the patients with EORA.

372

TRAF1/C5 Locus Is Associated with Response to Anti-Tumor Necrosis Factor Therapy in Patients with Rheumatoid Arthritis. Helena Canhao[1], Ana M. Rodrigues[2], Maria José Santos[3], Diana Carmona-Fernandes[4], Bruno Bettencourt[5], Jing Cui[6], Fabiana Rocha[5], Jose canas Silva[3], Joaquim Polido Pereira[4], Jose Alberto Pereira Silva[7], José Antonio Costa[8], Domingos Araujo[9], Candida Silva[10], Helena Santos[11], Catia Duarte[12], Fernando Pimentel-Santos[13], Jaime C. Branco[13], Robert M. Plenge[6], Daniel H. Solomon[14], Jacome Bruges Armas[5], José A. P. Da Silva[15], João E. Fonseca[16] and Elizabeth W. Karlson[17]. Background/Purpose: Some of the allelic variants associated with rheumatoid arthritis (RA) susceptibility are related to tumor necrosis factor (TNF) signaling pathways. We hypothesized that they might influence the response to anti-TNF drugs. The primary aim of our work was to investigate potential associations between RA risk alleles specifically selected for their relevance on RA biologic pathways and the response to anti-TNF treatment in a Southern European population using a nationwide register.

Methods: We evaluated 383 RA patients for associations between anti-TNF treatment response, assessed by an absolute change in DAS28 at six months as the primary outcome, and single nucleotide polymorphisms (SNP) from _TRAF1/C5, TNFAIP3, REL, PADI4, PTPN22 and PTPRC_ loci and _HLA-DRB1*04_ high-resolution genotyping. We also studied the same association taking the proportion of EULAR good responders and non responders at six months as the outcome. Univariate and multivariate linear and logistic regression analyses were performed, adjusting for clinical variables known to influence treatment response.

Results: Our study sample included 383 Caucasian individuals with RA, 89.5% were women. 72.6% were seropositive. At six months, 119 (31.1%) patients were classified as good responders, 175 (45.7%) as moderate responders and 89 (23.2%) as non-responders according to the EULAR response criteria.

The minor allele (G), which is the risk allele for RA susceptibility, rs3761847 SNP in the _TRAF1/C5_ region was associated with a poor anti-TNF treatment response either in linear (coefficient −0.24; 95% confidence interval (CI) −0.43, −0.06; p-value 0.009) and in logistic univariate (odds ratio (OR) 0.61; CI 0.41, 0.92; p-value 0.018) and multivariate regression analyses. P-value of 0.009 for linear models either univariate and multivariate was very close to the level of significance set to 0.0083 after Bonferroni correction to multiple comparisons (Table 1).

Table 1. Association of the rs3761847 single nucleotide polymorphism of _TRAF1/C5_ locus with the response to anti-TNF treatment

Change in DAS	Absolute change in DAS n=383		EULAR good response vs non-response n=208 (good=119, non=89)	
	Linear regression models	Logistic regression models		
1.95 (1.26) 1.82 (1.31) 1.38 (1.19)	Univariate Coef. −0.24 CI −0.43,−0.06 P 0.009	Multivariate Coef. −0.23 CI −0.40,−0.06 P 0.009	Univariate OR 0.61 CI 0.41,0.92 P 0.018	Multivariate OR 0.58 CI 0.37,0.91 P 0.019

No significant associations were observed between _HLA-DRB1_ or the other allele variants with the response to anti-TNF treatment.

Conclusion: The rs3761847 _TRAF1/C5_ RA risk locus influenced the anti-TNF treatment response in the Southern European population assessed in this study. Additional studies in other populations are necessary to confirm the relevance of this finding.

373

Patient-Reported Outcomes in Early Rheumatoid Arthritis Patients Failing to Achieve Stable Low Disease Activity: Comparing Addition of Adalimumab to Methotrexate Monotherapy with Maintenance On Adalimumab Plus Methotrexate. Arthur Kavanaugh[1], Ronald F. van Vollenhoven[2], Paul Emery[3], James W. Shaw[4], Mary A. Cifaldi[4], Stefan Florentinus[5] and Josef S. Smolen[6]. [1]UCSD School of Medicine, La Jolla, CA, [2]Karolinska Institute, Stockholm, Sweden, [3]University of Leeds, Leeds, United Kingdom, [4]Abbott Laboratories, Abbott Park, IL, [5]Abbott, Rungis, France, [6]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Treat-to-target guidelines for rheumatoid arthritis (RA) suggest adjusting therapy every 3–6 months for pts who fail to achieve a disease activity target. However, pts treated with adalimumab (ADA) plus methotrexate (MTX) can exhibit a delayed clinical response without radiographic damage.[1] Data from the Optimal Protocol for Treatment Initiation with MTX and ADA (OPTIMA) trial were used to evaluate differences in patient-reported outcomes (PROs) between pts maintained on ADA+MTX after failing to achieve a stable treatment target on that regimen compared to those treated with ADA+MTX after failing to respond to MTX monotherapy.

Methods: MTX-naïve pts ≥18 years of age with RA <1 year and active disease were randomized to ADA+MTX (N=515) or placebo (PBO) plus MTX (N=517) for 26 wks (Period 1). Those who failed to achieve stable low disease activity (LDA) (DAS28$_{CRP}$ <3.2 at wks 22 and 26) were offered open-label (OL) ADA+MTX for an additional 52 wks (Period 2). Pts completed the Work Productivity and Activity Impairment (WPAI) questionnaire, Health Assessment Questionnaire Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) subscale, Patient Acceptable Symptom State (PASS) classifier, and other PRO measures at wk 0 (baseline) and subsequent time points.

Results: At the end of Period 1, 259/466 (56%) ADA+MTX pts failed to achieve stable LDA (OL ADA carry-on arm) compared with 348/460 (76%) PBO+MTX pts (rescue ADA arm). Baseline characteristics for the OL ADA carry-on arm and rescue ADA arm were comparable, though pts in the former were less likely to be employed (46.8% vs. 55.7%, P=0.029) and were more fatigued (mean FACIT-F score: 23.6 vs. 25.8, P=0.022) than pts in the latter. Between wks 0 and 26, pts in the OL ADA carry-on arm had significantly greater improvements in physical functioning (mean HAQ-DI score change: −0.7 vs. −0.6, P=0.001), activity impairment (mean WPAI activity impairment score change: −24.6% vs. −18.3%, P=0.002), and health satisfaction (change in percent in PASS: 39.6% vs. 27.2%, P<0.001) than pts in the rescue ADA arm. Compared with pts in the OL ADA carry-on arm, pts in the

rescue ADA arm experienced significantly greater improvements in most PROs throughout Period 2. However, differences between the groups in improvements at wk 78 relative to wk 0 were statistically non-significant.

Mean Changes in PROs Relative to Wk 0 (Differences in Mean Changes Relative to Wk 26)

PRO	MCID	Treatment Arm	Wk 26	Wk 52	Wk 78
WPAI [range: 0–100]					
Absenteeism	7	OL ADA carry on	−11.9	−16.7	−18.4
		Rescue ADA	−11.9	−19.2 (−2.5)	−20.0 (−1.6)
Presenteeism	7	OL ADA carry on	−17.9	−24.0	−28.3
		Rescue ADA	−15.6	−29.8 (−8.0**)	−33.7 (−7.7**)
Overall work impairment	7	OL ADA carry on	−18.3	−26.7	−30.9
		Rescue ADA	−17.5	−33.4 (−7.5**)	−36.7 (−6.5)
Activity impairment	7	OL ADA carry on	−24.6	−31.2	−32.5
		Rescue ADA	−18.3*	−32.3 (−7.4**)	−32.9 (−6.7**)
WIS [range: 0–23]	NE	OL ADA carry on	−4.1	−5.3	−5.3
		Rescue ADA	−3.8	−7.6* (−2.6**)	−6.8 (−1.8**)
HAQ-DI [range: 0–3]	0.22	OL ADA carry on	−0.7	−0.8	−0.9
		Rescue ADA	−0.6*	−0.9 (−0.2**)	−0.9 (−0.2**)
FACIT-F [range: 0–52]	3–4	OL ADA carry on	8.7	10.7	11.1
		Rescue ADA	7.5	10.9 (1.3)	11.6 (1.6)
PASS [range: 0–100]	NA	OL ADA carry on	39.6	48.5	53.9
		Rescue ADA	27.2*	48.2 (12.2**)	60.1 (18.6**)

Notes: The FACIT-F and PASS were scored so that higher values indicated less fatigue and more satisfaction, respectively. Other outcomes were scored so that higher values indicated worse functioning or work productivity. Differences between groups in outcome trajectories were modeled using generalized estimating equations. Missing data were accounted for using multiple imputation. The MCID is the smallest change in measurement that signifies an important improvement or worsening.
Abbreviations: PRO, patient-reported outcome; MCID, minimum clinically important difference; OL, open label; ADA, adalimumab; WPAI, Work Productivity and Activity Impairment questionnaire; WIS, Work Instability Scale; HAQ-DI, Health Assessment Questionnaire Disability Index; FACIT-F, Functional Assessment of Chronic Illness Therapy Fatigue subscale; PASS, Patient Acceptable Symptom State; NE, not established; NA, not applicable.
*P < 0.05, mean change relative to wk 0 different from OL ADA carry-on arm
**P < 0.05, mean change relative to wk 26 different between arms

Conclusion: The results of this study suggest that sustained treatment with ADA+MTX in the absence of an initial clinical response can yield substantial benefits beyond the inhibition of radiographic progression. In addition, for patients not achieving stable LDA with MTX alone, the introduction of ADA after six months of treatment allows for significant improvements in work productivity and other PROs.

Prevalence of Biologic Utilization Over Calendar Time Among Medicare Beneficiaries with Rheumatoid Arthritis. Jie Zhang[1], Fenglong Xie[1], Elizabeth S. Delzell[1], Lang Chen[1], James Lewis[2], Kevin Haynes[3], Kenneth G. Saag[4] and Jeffrey Curtis[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Pennsylvania, [3]University of Pennsylvania., Philadelphia, PA, [4]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: The establishment of Medicare prescription drug coverage in 2006 and FDA approval of abatacept and rituximab for treatment of rheumatoid arthritis (RA) provided alternative biologics covered under Medicare for RA patients with fee for service coverage. Our objective was to examine the prevalence of biologic use among Medicare beneficiaries with RA from 2006 to 2009.

Methods: Using data from the 100% sample of U.S. Medicare beneficiaries with RA (>= 2 RA diagnoses from rheumatologist visit occurring between 7 and 365 days apart), we identified eligible RA patients with continuous Part A, B, and D coverage for each 3 months interval from July 1st, 2006 to December 31st, 2009; those who had at least one filled prescription or infusion during the 3 months were categorized as users. Among beneficiaries who initiated a biologic after at least 12 months without exposure to any biologic, we performed logistic regression to examine factors associated with the choice of an injection versus an infusion biologic, including demographics, concomitant glucocorticoids and non-biologic DMARDs, calendar year, physician preference, and receiving subsidy for Medicare part B premium from state of residence. Physician preference was measured by the percentage of patients treated with infusion biologics out of all patients treated with biologics in the preceding 6 months by each physician, grouped into quartiles.

Results: From 2006 to 2009, approximately 27% of all U.S. Medicare beneficiaries with RA treated by rheumatologists received biologics. The prevalence of infliximab use declined from 14.9% in the 3rd quarter of 2006 to 12.2% in the 4th quarter of 2009. In contrast, the prevalence of abatacept increased from 1.1% to 4.0% during this time. We did not observe an increase in the use of self-injectable biologics (Figure 1). After adjusting for covariates, we found that stronger physician preference for infusion biologic was associated with increased odds of infusion biologic use (odds ratio comparing highest quartile to the lowest quartile, 8.9; 95% CI, 8.0–10.0) and receiving subsidized Medicare coverage was associated with increased injection biologic use (odds ratio, 2.8; 95% CI, 2.6–3.0).
Figure 1. Prevalence of Biologics among Medicare Beneficiaries with Rheumatoid Arthritis

Conclusion: The prevalence of injection and infusion biologics remained stable from 2006 to 2009. The choice of infusion versus injection biologics appeared to be strongly driven by patients' financial considerations and physicians' preferences.

Cell Phone Based Automated Monitoring of Patients with Early Rheumatoid Arthritis. Kari Puolakka[1], Tuulikki Sokka[2] and Hannu Kautiainen[3]. [1]Department of Medicine, South Karelia Central Hospital, Lappeenranta, Finland, [2]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [3]Orton Rehabilitation, Helsinki, Finland

Background/Purpose: Frequent monitoring improves patient compliance and outcomes of RA. Limited resources may hinder adherence to recommendations to frequent assessment. A remote assessment could be a solution with patient's global assessment (PtGA) as a measure.

Methods: A novel, cell-phone based monitoring system has been invented (SandRA).

Each incident patient with early RA is being registered in SandRA monitoring–with his or her informed consent. Baseline PtGA is recorded. Every 2 weeks during the following 6 months, SandRA sends automatically an SMS to the patient's cell phone, and patient answers by one push on keyboard. The first 2 SMSs concern medications ("Have you used the prescribed drug treatments?" Y/N) and adverse events ("Have you experienced any problems with the drug?" Y/N). From 6 weeks onwards, PtGAs is inquired: ("What is the severity of RA on scale 0 to 10, when 0 corresponds absence of RA symptoms and 10 as severe RA symptoms as you can imagine?"). Based on data from our previous early RA cohorts, a treatment target was set at 5-3/10 (figure 1).
The patients' answers are recorded in SandRA database and automatically analyzed. If an answer does not indicate problems, patient receives an automatic SMS response of the answer being recorded. If an answer indicates problems, i.e., patient has not used the treatment, has experienced adverse events, or RA has not improved at the pace defined, the patient receives an SMS: "Your nurse will call you within 2 working days". At the same time, the nurse receives an e-mail about the patient's problem. If the problem cannot be solved on the phone, the patient is called for a visit for treatment adjustment.

Results: We analyzed 137 consecutive patients registered in SandRA. The patients' regular doctor appointments were scheduled at 3 and 6 months. Most patients achieved the treatment target, i.e., their PtGAs were under the alarm line (panel A). SandRA picked out 34%, 31%, 29%, and 31% of the patients at 6, 10, 18, and 22 weeks for assessment before regular appointments (panel B).

Conclusion: A novel automated cell phone based monitoring system may provide a feasible method to achieve treatment target in patients with early RA.

Strategies for Use of Prednisolone in Rheumatoid Arthritis Have Changed Over the Past Decade: Data From the NOR-DMARD Register. Anna-Birgitte Aga, Elisabeth Lie, Till Uhlig, Tore K. Kvien and Espen A. Haavardsholm. Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: Focus on early aggressive treatment in patients with rheumatoid arthritis (RA) has increased during the past decade. There is evidence for the efficacy of prednisolone as bridging therapy awaiting the therapeutic effect of DMARDs as well as evidence for a disease-modifying effect of glucocorticoids. Our objective was to investigate pattern in prednisolone use in RA patients in the past decade.

Methods: Data for this study were provided by the NOR-DMARD register, including adult patients with inflammatory arthropathies starting a new DMARD regimen at 5 Norwegian centers. These analyses included Methotrexate (MTX) naïve RA patients starting MTX mono and biologics naïve RA patients starting TNF inhibitor (TNFi) + MTX between 2000 and 2010. Each group was divided into 2-year intervals according to date of treatment start. The proportion using prednisolone, and mean prednisolone doses at baseline and at 6 months were assessed. Comparisons between first vs. last time period were made by Chi^2-test and two-sample t-test. Possible linear effects of time were assessed by logistic and linear regression with year of treatment start as a continuous variable. 6-month DAS28 remission rates were calculated.

Results: 2573 pts were included–MTX mono n=1866 [70% female, 62% RF+, mean (SD) age 56.0 (13.7) years, time from diagnosis 3.6 (7.7) years] and TNFi+MTX n=707 [70% female, 75% RF+, age 52.1 (13.2) years, time from diagnosis 9.1 (9.3) years]. In patients starting MTX mono the proportion of patients using prednisolone at baseline increased over the years, while the proportion still using prednisolone at 6 months decreased (table). The differences between the first and the last period were statistically significant, but the effect of time was not linear. In the TNFi+MTX group the proportion of patients using prednisolone at baseline was stable during the decade, but the proportion at 6 months was significantly lower in the last vs. the first time period. The mean doses of prednisolone were stable throughout the decade in both groups. Proportions of patients reaching 6-month DAS28 remission increased gradually over the years in both groups (table).

Proportion of patients on prednisolone [%(n)]	2000–2002	2003–2004	2005–2006	2007–2008	2009–2010	p-value*
MTX mono (n=1866) Baseline [%(n)]	49.0 (172)	44.7 (207)	45.9 (181)	62.3 (223)	60.7 (182)	0.003
6 month [%(n)]	32.5 (114)	29.4 (136)	30.2 (119)	35.2 (126)	21.7 (65)	0.002
TNFi+MTX (n=707) Baseline [%(n)]	56.5 (48)	51.1 (94)	48.3 (69)	49.4 (79)	49.6 (67)	0.32
6 month [%(n)]	35.3 (30)	26.1 (48)	28.0 (40)	28.8 (46)	14.8 (20)	<0.001
Prednisolone dose mg/day [mean(SD)]						p-value**
MTX mono (n=1866) Baseline [mean(SD)]	8.9 (3.6)	9.1 (4.5)	8.9 (4.0)	8.9 (3.7)	9.2 (4.1)	0.37
6 month [mean(SD)]	6.0 (2.8)	5.6 (2.5)	5.7 (3.2)	5.4 (2.5)	5.6 (2.7)	0.44
TNFi+MTX (n=707) Baseline [mean(SD)]	8.0 (3.4)	7.2 (3.0)	7.5 (3.3)	7.9 (4.9)	7.1 (3.6)	0.17
6 month [mean(SD)]	5.8 (2.9)	5.5 (2.5)	5.3 (2.4)	5.7 (3.0)	7.6 (12.4)	0.45
DAS28 remission 6 month [%(n)]						p-value*
MTX mono (n=1866) 6 month [%(n)]	17.8 (43)	29.2 (95)	33.7 (89)	38.1 (80)	37.6 (44)	<0.001
TNFi+MTX (n=707) 6 month [%(n)]	16.9 (10)	29.3 (36)	34.5 (38)	31.4 (27)	46.3 (25)	0.003

* chi^2 –test first vs. last period, ** two sample t-test first vs. last period.

Conclusion: A higher proportion of RA patients used prednisolone when starting MTX in the recent years, and an increasing proportion of patients tapered and discontinued prednisolone. The observed increases in DAS28 remission rates likely reflects the implementation of modern DMARD treatment strategies including treatment earlier in the disease course and at lower levels of disease activity, but the changes in the use of prednisolone may be a contributing factor.

Use and Long Term Use of Complementary and Alternative Medicine in Rheumatoid Arthritis Patients. Peri H. Pepmueller[1], Ramzy Jandali[1], Anu Sharma[2], Shannon Grant[3] and Katherine C. Saunders[4]. [1]Saint Louis University, St. Louis, MO, [2]Center for Rheumatic Diseases, Bethesda, MD, [3]Axio Research LLC, Seattle, WA, [4]CORRONA, Inc., Southborough, MA

Background/Purpose: Studies have identified widespread use of complementary and alternative medicine (CAM), particularly in patients with rheumatic disease. Most have reported results over short time frames, i.e. "used in last year" or "ever use"; few have evaluated long-term (LT) use of CAM. In addition, studies have often looked at all patients in a rheumatology practice rather than those with rheumatoid arthritis (RA) only. The purpose of this study was to quantify the frequency of ever and LT use of CAM in patients with RA and to identify characteristics associated with ever and LT CAM use.

Methods: Data from RA patients participating in the Consortium of Rheumatology Researchers of North America (CORRONA) registry, an independent prospective observational cohort with >30,000 RA patients enrolled from over 100 academic and private practices across the US, were examined. Patients provided data regarding the use of glucosamine/chondroitin, fish oil, borage seed oil, evening primrose oil, and flax seed oil at clinic visits. Other CAM use such as acupuncture, massage, or yoga was not collected. Patients with at least two years of follow-up and at least three visits were included in the analysis. Primary outcome was any CAM use within 2 years of first visit. LT use was defined as use of the same CAM at 3 consecutive visits or all visits in one year. Logistic regression was used to calculate odds ratios (ORs) of CAM use (ever or LT) by patient demographics, disease characteristics, and medication history.

Results: 11,970 patients were included in the analysis; 35.2% reported any CAM use, but only 10.8% reported LT use (p<0.0001). Fish oil was the most common CAM reported (27.3%). Without adjusting for other factors, patient demographics, medication history, and lower disease activity [Disease Activity Score (DAS28), tender/swollen joint count, modified Health Assessment Questionnaire (mHAQ), Clinical Disease Activity Index (CDAI), physician/patient assessments] were associated with ever and LT CAM use (Table 1). Separate multivariate models for ever and LT CAM use had the listed predictors in common (Table 1).

Table 1. Patient characteristics at first visit associated CAM use

Demographics	OR No Adjustment Ever CAM	LT CAM	OR (95% CI) With Adjustment[1] Ever CAM	LT CAM
Older age	1.005#	1.006#	N	N

Medical History				
NSAID use	1.274*	1.418*	1.31 (1.20 – 1.43)*	1.49 (1.29 – 1.72)*
Exposure to 3+ DMARDs vs 0	1.293#	1.131	1.30 (1.13 – 1.49)#	N
Patient report anxiety/ depression	1.188*	1.011	1.19 (1.09 – 1.31)#	N

[1]Multivariate models built separately for ever and LT CAM using stepwise logistic regression.
* p<0.0001, #p<0.05
N = not included in model

Conclusion: The results show significant differences in patient characteristics between CAM users and non-users, but clinical characteristics are similar suggesting that patient characteristics rather than disease severity are the driving force behind CAM use. CAM use with first visits after 2006 suggests that CAM use is increasing. Although "ever use" of CAM was 35.2%, the LT use was significantly lower, 10.8%, implying that patients may try complementary therapy, but few continue.

378

Use of Anti-Tumor Necrosis Factor Monotherapy and Adherence with Non-Biologic Disease-Modifying Anti-Rheumatic Drugs in Combination with Anti-Tumor Necrosis Factor Therapy Among Rheumatoid Arthritis Patients in a Real-World Setting. Nicole M. Engel-Nitz[1], Sarika Ogale[2] and Mahesh Kulakodlu[1]. [1]OptumInsight, Eden Prairie, MN, [2]Genentech, South San Francisco, CA

Background/Purpose: Studies have shown better response for anti-TNFs (aTNF) when they are used in combination with non-biologic DMARDs (nbDMARD), than when used as monotherapies.[1] Therefore, non-adherence to nbDMARDs prescribed in combination with aTNFs may reduce the benefit obtained with these agents. This study examined the use of aTNF monotherapy in the real world, and adherence with nbDMARDs in patients receiving combination aTNF+nbDMARDs.

Methods: We conducted a claims analysis of adult RA patients in a US managed care plan, initiating an aTNF (etanercept; adalimumab; infliximab; golimumab; or certolizumab pegol) between Jan 2006 and Dec 2010. aTNF initiators were classified as 'biologic-naïve' or 'previously-exposed', based on prior biologic use. Patients were followed from aTNF initiation until discontinuation of that aTNF or plan disenrollment. The proportion of patients receiving aTNF as monotherapy (i.e. never received nbDMARD during aTNF follow-up) was determined; nbDMARDs included methotrexate (MTX), leflunomide, sulfasalazine, hydroxychloroquine, cyclophosphamide, gold salts, azathioprine, cyclosporine, and d-penicillamine. In patients receiving combination therapy (i.e. received nbDMARD at any time during aTNF follow-up), adherence to nbDMARDs was defined as the percent of days that patients received any nbDMARD while they were receiving the aTNF agent. Thus, 100% adherence indicates that the patient was on some nbDMARD 100% of the time during their aTNF follow-up based on filled prescriptions. Adherence with MTX was also assessed separately.

Results: Of 7,074 biologic-naive RA patients initiating an aTNF, 27% received it as monotherapy and 73% in combination with nbDMARDs. Of 2,690 aTNF patients previously exposed to biologics, 31% received monotherapy and 69% in combination with nbDMARDs. Only 42% of patients receiving aTNF monotherapy vs. 89% of combination therapy patients had filled a nbDMARD prescription during the 6 months prior to initiating the aTNF agent. Among biologic-naïve combination therapy patients, 52% of patients adhered with nbDMARD therapy less than 80% of the time while receiving aTNFs; 32% of the patients had less than 60% adherence. Of biologic-naïve patients who received aTNF combination therapy with methotrexate, 56% had less than 80% adherence with MTX and 35% had less than 60% adherence with MTX while receiving the aTNF. Results were similar for aTNF patients previously exposed to biologics. Adherence calculated here based on claims data may be an overestimate because we do not know if patients consumed the filled prescriptions.

Conclusion: This study found that up to 31% of patients receiving an aTNF agent for RA in the real-world received it as monotherapy, and a substantial proportion of those receiving combination therapy had less than 60% adherence with nbDMARDs. Some of these patients may have suboptimal outcomes, as suggested by evidence that RA patients receiving aTNFs in combination with nbDMARDs have better response.

379

Persistency and Predictors of Persistency of Adalimumab Among Rheumatoid Arthritis (RA) Patients in a US Registry. Allan Gibofsky[1], Katherine C. Saunders[2], Arijit Ganguli[3], Mary Cifaldi[3], Shannon Grant[4], Jerry Clewell[3], Neelufar Mozaffarian[3], James Shaw[5], Reva McCaskill[3], George W. Reed[6] and Jeffrey D. Greenberg[7]. [1]Hospital for Special Surgery, New York, NY, [2]CORRONA, Inc., Southborough, MA, [3]Abbott Laboratories, Abbott Park, IL, [4]Axio Research LLC, Seattle, WA, [5]Abbott, Abbott Park, IL, [6]University of Massachusetts Medical School, Worcester, MA, [7]NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: There are limited observational data to guide physician decision-making when choosing to begin a patient on a new biologic treatment. Understanding real-world trends in persistency on therapy and factors related to persistency would aid in this process. We sought to identify predictors of persistence on adalimumab (time to discontinuation and change in treatment) in a large US registry of RA patients.

Methods: The CORRONA registry is a large, multicenter, longitudinal database of RA patients enrolled from > 90 academic and private practices across the USA. RA patients enrolled in CORRONA between March 2002 and September 2011 who initiated adalimumab and had at least one follow up visit post-initiation were included in this analysis. Discontinuation of adalimumab and treatment change were modeled separately. Discontinuation was defined as stoppage of adalimumab for any duration, while treatment change included discontinuation of adalimumab, change in adalimumab dose/ frequency, or adding /discontinuing a DMARD. Kaplan-Meier curves were used to estimate persistence quartiles. Associations between patient characteristics and persistence were estimated using univariate and multivariate proportional hazards (PH) regression models.

Results: 1639 patients initiated adalimumab and had at least one follow-up visit, 1003/1639 patients discontinued adalimumab, with a Kaplan-Meier estimate of median days to discontinuation: 632 (95% CI: 564.5–717). A multivariable model showed risk of discontinuation was associated with prior use of another biologic, number of swollen joints, duration of RA and prednisone use at initiation (Table 1). 1358/1639 patients experienced some form of treatment change. Median days to treatment change: 276 (95% CI: 258–298). Likelihood of treatment change increased with prior use of biologics, number of swollen joints and prednisone use at initiation; it decreased with concomitant use of MTX at initiation (Table 1). Hazard Ratios represent the baseline risk association.

Table 1.

	Hazard Ratio	(95% Confidence Interval)	P-value
Predictors of Discontinuation			
Use of previous biologic	1.532*	(1.259–1.864)	<0.0001
SJC at initiation	1.010+	(1.001–1.018)	0.0301
RA duration at initiation	1.005	(1.002–1.007)	0.0002
Prednisone use at initiation	1.279	(1.180–1.386)	<0.0001
Predictors of Change in Treatment			
Use of previous biologic	1.613*	(1.438–1.809)	<0.0001
SJC at initiation	1.015	(1.007–1.023)	0.0001
Prednisone use at initiation	1.116	(1.069–1.166)	<0.0001
MTX use at initiation	0.876	(0.835–0.919)	<0.0001

SJC, swollen joint count
*time varying association. HR estimates initial risk association; association decreases over time
+time varying association. HR estimates initial risk association; association increases over time

Conclusion: In the CORRONA registry, persistence on adalimumab was inversely correlated with factors suggestive of high disease severity. Patients using concurrent MTX with adalimumab at initiation were less likely to experience a change in their treatment compared to non-MTX users.

DMARD and Biologic Use During Pregnancy Among Rheumatoid and Psoriatic Arthritis Patients in the Corrona Registry. John J. Cush[1], George Reed[2], Katherine C. Saunders[3], Joel M. Kremer[4], Jeffrey D. Greenberg[5] and Arthur Kavanaugh[6]. [1]Baylor Research Institute, Dallas, TX, [2]UMass Medical School, Worcester, MA, [3]CORRONA, Inc., Southborough, MA, [4]Albany Medical College, Albany, NY, [5]NYU Hospital for Joint Diseases, New York, NY, [6]UCSD School of Medicine, La Jolla, CA

Background/Purpose: CORRONA is a nationwide longitudinal disease-based registry that includes 32875 rheumatoid (RA) and 5462 psoriatic arthritis (PsA) patients. We sought to ascertain the frequency of pregnancy among 5377 women of childbearing age within the CORRONA registry and assess the impact of pregnancy on disease activity and medication use.

Methods: Females aged 18–45 yrs, diagnosed as RA or PsA with >12 mos follow-up were included. A preconception (PRE) visit < 12 mos of a self-reported pregnancy (PREG) was required. Disease activity and therapy were assessed at PRE and PREG visits and included CDAI, GAS, mHAQ, TJC, SJC and the % off all DMARDs or biologics (DMARD-free). We tallied those who flared or improved (defined: 20% change in TJC+SJC) and the percent moving to or from low activity (CDAI remission or LDAS) and high activity (CDAI moderate or severe). Therapies were classified as MTX, non-biologic DMARDs (NB-DMARD), TNF inhibitors (TNFi), other biologics (oBiologic) or all DMARDs (NB-DMARD or TNFi or oBiologic). The outcome of pregnancy was not the object of these analyses. While 251 total pregnancies (221 pts) were identified, 147 pregnancies (126 pts) met inclusion criteria. No differences were observed between included and excluded patients.

Results: 147 pregnancies (130 RA, 17 PsA) were found for a frequency of 2.3%. Mean age was 32.4 yrs and disease duration 7.3 yrs. Time span from PRE to PREG was 4.9 mos (RA) and 6.3 mos (PsA). Overall drug use and disease activity was less than that seen in nonpregnant CORRONA patients (data not shown). At the PRE visit TNFi were most often used (54%) with surprisingly less MTX (16%), oBiologic (4%), Pred (23%), NSAIDs (34%) use (Table). At PRE 69% were in CDAI remission or LDAS. PREG impact was modest with median change from PRE-PREG being zero for 8/10 activity measures. Joint counts improved in 31% and flared in 27% during PREG, with 36% having a 1–2 increase in joint count. From the PRE to PREG, only 13% of 101 low activity pts worsened to high activity. Conversely, 43% of those with high activity improved to low activity during

PREG. MTX and NB-DMARD decreased with PREG, yet some continued MTX (4%) or NB-DMARD (21%) at PREG. Biologic use was halved from 59% (PRE) to 29% (PREG) and DMARD-free rose from 28% to 61% during PREG. 61 patients were biologic free at PRE and only 2 (3.3%) started biologics during PREG. Conversely of 80 PRE patients who took TNFi, 42 (53%) stopped TNFi during PREG.

Comparison of Therapies and Activity Pre- and during Pregnancy

(n=147)	PRE	PREG
TJC	2.0	2.2
SJC	2.0	1.9
CDAI	7.8	7.7
GAS	5.9	6.0
Low Activity %	68.9	59.9
High Activity %	31.3	17.8
mHAQ	0.22	0.22
ESR mm/hr	20.5	22.4
MTX %	15.7	4.1
NB DMARD%	40.1	21.1
TNFi %	54.4	27.2
Other Biologics	4.1	2.0
DMARD Free %	27.9	61.2
Prednisone %	23.1	12.2
NSAID %	34.0	12.2

Conclusion: TNFi were most frequently used in those apparently planning to become pregnant and also during PREG. RA and PsA patients who become pregnant are likely to have low level disease activity and less commonly used MTX, NB-DMARD, Pred or NSAIDs. While the literature suggests up to 80% of RA patients improve during PREG, this large CORRONA cohort showed less disease activity change with 12% moving from low to high activity and only 43% moving from high to low activity during PREG.

381

DAS Does Not Predict Increasing Treatment in Early Rheumatoid Arthritis: Results From the CATCH Study. Lonnie Pyne[1], Vivian P. Bykerk[2], Carol A. Hitchon[3], Edward Keystone[4], J. Carter Thorne[5], Boulos Haraoui[6], Ashley Bonner[7], Janet E. Pope[8] and CATCH Investigators[9]. [1]Western University, London, ON, [2]Hospital for Special Surgery, New York, NY, [3]University of Manitoba, Winnipeg, MB, [4]University of Toronto, Toronto, ON, [5]Southlake Regional Health Centre, Newmarket, ON, [6]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [7]McMaster University, Hamilton, ON, [8]Western University of Canada, St. Joseph's Health Care, London, ON, [9]Toronto, ON

Background/Purpose: The disease activity score (DAS) was developed in RA to guide therapy. Its utility in practice for early rheumatoid arthritis (ERA) has not been fully studied. The aim was to determine factors most strongly associated with an increase in therapy in ERA at 3 and 6 months.

Methods: Data were collected from Canadian Early Arthritis Cohort (CATCH) patients who were included if they had >2 visits and baseline and 6 months data. A regression analysis determined factors associated with treatment intensification.

Results: Of the 1,145 ERA patients, 790 met inclusion criteria. Mean age was 53.4 (SD 14.7), disease duration 6.1 months (SD 2.8), 75% were female, baseline DAS28 was 4.7 (SD 1.8) and 2.9 (SD 1.8) at 6 months. Factors most strongly associated with intensifying treatment in univariate analyses were MD global (assessment) (OR= 7.8 at 3 months and OR=7.4 at 6 months, P<0.0005) and SJC (OR= 4.7 and OR=7.3 at 3 and 6 months, P<0.0005). DAS did not affect treatment intensification as strongly in univariate analyses (OR= 3.0 at 3 months and OR=4.6 at 6 months, P<0.0005). In the logistic regression model only MD global was consistently associated with treatment intensification (OR= 1.5 and OR=1.2 at 3 and 6 months respectively, P<0.0005). DAS28 was not a consistent predictor of treatment intensification (OR= 1.0, P= 0.987 at 3 months and OR=1.2 P=0.023 at 6 months). If adjusting for multiple comparisons, only MD global was significant at both 3

and 6 months. When treatment was intensified; only 2% of physicians listed DAS28 as a reason for the treatment change, compared to 52%, 50% and 24% for SJC, TJC and MD global respectively. For the same SJC, larger joint involvement was more likely to influence treatment than small joint involvement at 3 months (OR=1.4, P=0.027). At 3 (but not 6) months for the same joint count, larger joint involvement was more associated with increasing therapy (P=0.027).

Table 1. Summary of variables in logistic regression model of increase therapy (strict definition) at 3 and 6 months. Model had a percent correct classification of 76.2% and P-value <0.0005 at 3 months and 79.3% and P-value <0.0005 at 6 months

	Age	TJC	SJC	ESR	CRP	Patient Global Assessment	HAQ-DI	Pain Today	MD Global Assessment	DAS28
Exp(B) (95% C.I.) 3 months	0.989 (0.975, 1.002)	1.019 (0.985, 1.055)	1.050 (0.998, 1.105)	1.008 (0.991, 1.024)	1.005 (0.984, 1.026)	1.007 (0.996, 1.017)	0.541 (0.357, 0.820)	1.116 (0.995, 1.251)	1.460 (1.316, 1.620)	0.999 (0.855, 1.167)
P-Value	0.089	0.273	0.061	0.372	0.638	0229	0.004	0.060	<0.0005	0.987
Exp(B) (95% C.I.)6 months	*	0.997 (0.962, 1.033)	1.098 (1.040, 1.160)	0.985 (0.968, 1.002)	**	1.015 (1.004, 1.027)	0.872 (0.569, 1.336)	0.996 (0.885, 1.122)	1.249 (1.106, 1.412)	1.235 (1.029, 1.481)
P-Value	—	0.868	0.001	0.083	—	0.007	0.529	0.952	<0.0005	0.023

Conclusion: Physician global assessment was independently associated with an increase in treatment at 3 and 6 months in ERA, whereas DAS28 was only significant at 6 months. SJC was also strongly related to treatment intensification at 6 months. Physicians rarely stated that DAS28 was the reason for increasing treatment and the data demonstrate that MD global assessment (which is not part of the DAS) is the main reason for treatment intensification in ERA.

Does Biased Risk Perception Explain the Underuse of Disease Modifying Anti-Rheumatic Drugs?
Richard W. Martin[1], Andrew J. Head[2], James D. Birmingham[1] and Aaron T. Eggebeen[1]. [1]Michigan State University College of Human Medicine, Grand Rapids, MI, [2]College of Human Medicine, Michigan State University, Grand Rapids, MI

Background/Purpose: The prescription of a Disease Modifying Anti-rheumatic Drugs (DMARD) for patients with rheumatoid arthritis (RA) is considered a standard of effective care. However a recent study of Medicare managed care enrollees, only 63% received a DMARD. The explanation for underutilization is not fully known. In a sample of 144 patients, Constantinescu et al found compared to white adults with RA, African American patients assigned greater importance to the risks of treatment over the likelihood for benefit. The purpose of our study was to evaluate the determinants of risk perception (RP) in a large cohort of community RA patients and predictors of their willingness to take a proposed DMARD (DMARD willingness).

Methods: A single center, cross-sectional mail survey of RA patients in a community rheumatology practice. Patient characteristics including heath literacy screening index (HL), depression, RA duration, DMARD experience including bother from current DMARD side effects, satisfaction with RA control, Decision Regret Scale,TNFi knowledge, happiness, HAQ2, and CDAI were collected. Patients were presented a hypothetical decision scenario where they were asked to consider switching DMARDs. They evaluated how risky the proposed medication was and how likely they would be to take it. Predictors of RP and DMARD willingness were identified with hierarchical linear regression modeling.

Results: The completed sample included 1009 RA patients. The overall survey response rate was 71%. Patient characteristics: age 61.6 years (range 18–93), 75% female, minority 6.5%, low or marginal health literacy 8.8%, depression 15.0%, duration RA 13.1 years (range 0.5–68). A regression model evaluating predictors of RP demonstrated a $R^2 = 13.5$. The standardized regression coefficients show the strongest predictor of RP was HAQ2 disability (B=.152), followed by HL (B= −.149), and current or past experience of DMARD related bother(B=.146). Age, TNFi knowledge, happiness and depression, and other demographics did not significantly add to the predictive power of the model. A second model of predictors of DMARD willingness had a $R^2 = 12.7\%$. The standardized regression coefficients show the strongest predictors of DMARD willingness were satisfaction with control of RA (B=−1.67) and regret related to their previous DMARD choice (B=−1.60), and HL (B= 1.49). Age and other demographic characteristics, extent of past RA and general DMARD related experience, happiness and depression did not significantly add to the predictive power of the model.

Conclusion: RP was influenced by negative RA disease and treatment experience, while DMARD willingness was affected by perceived disease control. Health literacy, independent of low educational achievement or other demographic, was a predictor of both RP and DMARD willingness. When proposing to initiate a new DMARD, clinicians must be alert for cognitive impairment whether derived from educational, language, age related decline in information processing that could affect patient decision making. Time pressures increase cognitive load, which might justify extending the time of deliberation beyond the constraints of the office visit by using decision aids.

383

2002-04 Vs. 2007-09: Initiation of Combination, and Tapering/ Discontinuation (DC) Patterns of TNFi and MTX in a US (RA) Patient Registry: Analysis with CDAI Scores.
Deborah Wenkert[1], Shannon Grant[2], David H. Collier[1], Andrew S. Koenig[3] and Joel M. Kremer[4]. [1]Amgen Inc., Thousand Oaks, CA, [2]Axio Research LLC, Seattle, WA, [3]Pfizer Inc., Collegeville, PA, [4]Albany Medical College, Albany, NY

Background/Purpose: We compared patient (pt) characteristics, for initiating, tapering and DC of TNFi/MTX combination therapy (CT), among RA pts seen during 02–04 vs. 07–09 to detect changes in practice.

Methods: In the Consortium of Rheumatology Researchers of North America (CORRONA), a rheumatoid arthritis (RA) registry, the relationship between maximum CDAI(Clinical Disease Activity Index) and the use of CT during the 2 time intervals was compared using all RA pts in CORRONA and those with >=2 yrs of follow-up (f/u) (N=4955; N= 6847). DC'ing/tapering MTX, TNFi, or both and reasons for DC'ing were compared among the subset who initiated CT (n=315; n=697 respectively).

Results: Among pts receiving CT, age, gender and patterns of adding TNFi to MTX vs. MTX to TNFi were similar in the 2 time periods; The mean CDAI at CT initiation (for all pts and pts with >=2 yr f/u) was lower in 07–09 (18.6 and 18.3 vs. 14.6 and 14.0, p<0.001). 35% of all pts starting CT were on prednisone at initiation during the 02–04 interval vs. 30.4% during 07–09, p=0.084. Among all RA pts with 2 yrs of f/u a higher percentage of patients initiated CT in 07–09 than 02–04 in each maximum CDAI category. Although MTX DCing rates were similar between the 2 time periods, tapering was more frequent in the 07–09 (51%) vs 02–04 cohort (38.8%), p = 0.029. DCing (or switching) the TNFi occurred among 37% of pts initiating CT during 07–09 vs. 31.7% (02–04) p=0.105. Baseline CDAI did not predict DC patterns. The mean CDAI at time of DC was higher in the 02–04 cohort for MTX, TNFi or both with overall mean CDAIs (02–04 vs. 07–09) at the time of DC of CT of 19.4 vs. 13.2 p<0.001. The mean CDAI at time of DC of prednisone, was similar between the two time periods (15.2 vs. 15.0) p=NS.

Physician-recorded reasons for DC'ing MTX or TNFi were consistent across time intervals.

RA pts with 2 yr F/U after a visit in	2002–2004	2007–2009	Total
N	4955	6847	11,802
% of pts with a max CDAI during the 2 yr F/U who DID NOT receive CT anytime during the 2yr	p-value		
Max CDAI 10–22	80.8 %	74.3 %	<0.001
Max CDAI >22	74.2 %	71.1%	0.038
RA pts with 2 yr F/U after initiating CT	2002–2004	2007–2009	Total
N	315	697	1012
% of RA pts DCing CT during 2 yrs F/U	p-value		
DC only MTX (continuing TNFi)	15.2 %	13.1 %	0.350
DC only TNFi (continuing MTX)	31.7 %	37.0 %	0.105
DC both MTX + TNFi	7.9 %	6.5 %	0.390
DC Prednisone	33.6 %	43.5 %	0.085
CDAI (SD) at time of DC of RA pts who DC	p-value		
MTX only	14.2 (11.0)	10.6 (12.2)	0.088
TNFi only	20.5 (14.0)	14.5 (13.0)	<0.001
both MTX + TNFi	25.1 (17.2)	10.9 (10.1)	<0.001
DC Prednisone	15.2 (12.7)	15.0 (15.0)	0.951

Conclusion: We found lower CDAIs among those initiating CT between 07–09 and lower CDAIs among those weaning or stopping CT in 2 yrs of f/u, perhaps reflecting stricter definition and implementation of aggressive treatment goals in the later time periods.

Treating Rheumatoid Arthritis to Target: A Canadian Patient Survey.
Boulos Haraoui[1], William G. Bensen[2], J. Carter Thorne[3], John P. Wade[4], Melissa Deamude[5], Jane M. Prince[6] and Jean Legare[7]. [1]Institut de Rhumatologie de Montréal, Montreal, QC, [2]St. Joseph's Hospital and McMaster University, Hamilton, ON, Hamilton, ON, [3]Southlake Regional Health Centre, Newmarket, ON, [4]University of British Columbia, Vancouver, BC, [5]Dr. William G. Bensen Medicine Professional Corporation, Hamilton, ON, [6]Vancouver Coastal Health, Vancouver, BC, [7]Arthritis Alliance of Canada, Montreal, QC

Background/Purpose: Recently, many countries, including Canada, evaluated rheumatologists' acceptance and agreement with a set of 10 Treat to Target (T2T) recommendations for rheumatoid arthritis (RA), developed by an international task force.[1–3]In this study, the Canadian T2T steering committee evaluated how Canadian patients with RA perceive these recommendations. To assess the current state of RA management in Canada from a patient perspective and to assess whether, and to what extent, Canadians with RA agree with the 10 T2T recommendations.

Methods: Participating rheumatologists were asked to invite consecutive RA patients to complete a 20-question survey. The survey was designed to assess relevant socio-demographic variables, disease duration, current approach to RA management as seen from the patient perspective, and agreement with the T2T recommendations. Each T2T recommendation was re-phrased and/or re-worded in order to be easily understood by all RA patients, regardless of their level of education.[4]

Results: A total of 959 patients (77% females) were recruited by 22 participating rheumatologists from 6 Canadian provinces. Patients had a mean age of 59.1 yrs and a mean disease duration of 12.9 yrs. Approximately 72% of patients were on methotrexate (23.9% monotherapy, 76.1% combination therapy), 22.5% were treated with biologics (13.4% monotherapy, 86.6% combination therapy), and 17.5% were receiving corticosteroids. The patients' mean pain intensity over the week preceding the survey was 3.4 on a 10-point scale. The majority (88%) of patients was seen by their rheumatologist every 2–6 months; approximately 92% indicated having their joints examined and being asked about their daily activities at every visit. Over 89% of the patients rated ≥8 on a 10-point scale on the clarity of their rheumatologist's explanation. In Canada, agreement with the T2T recommendations was higher among patients than rheumatologists: For patients, the results ranged from 8.6 for recommendation #4 (frequency of adjustment of drug therapy) to 9.5 for recommendation #7 (consideration for making clinical decisions). The average rheumatologists' agreement scores ranged from 6.9 for recommendation #5 (the frequency of measures of disease activity) to 9.1 for recommendation #10 (the patient needs to be involved in

the decision-making process).[3]Among patients, agreement with recommendation #4 decreased with increasing age of the patient (from 9.1 for patients <43 yrs to 7.9 for patients >74 yrs). The agreement with recommendation #5 was significantly higher for patients in Quebec (9.4) and New Brunswick (9.3) compared to British Columbia (8.6)

Conclusion: The results of this survey shed some light on the management of RA in Canada and demonstrated a significant level of agreement with the T2T recommendations among Canadian patients. Additional efforts may be required to identify the reasons behind differences in agreement levels between patients and physicians in order to narrow certain gaps and improve RA management.

The Wide Variation in Corticosteroid Use in Early Rheumatoid Arthritis - There Is Need for Guidelines.
A. Bharadwaj and Carol Alves. Basildon & Thurrock University Hospital NHS Trust, Basildon, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune inflammatory disease which causes significant pain and swelling in the joints. The early treatment of the disease mainly rests on two groups of agents; Disease modifying drugs and Corticosteroids. Steroids are very effective for the treatment of early disease, acutely controlling the disease activity and reducing the long-term damage They are used both as systemically (Oral or Intramuscular) or locally, however there is no consensus on the required dose, route of administration or duration of use in this condition.

The published data about adverse events of steroid usage in this situation is not clear and there is suggestion that quick aggressive control of inflammatory disease may actually outweigh the risk of damage.

Methods: A questionnaire was sent by post to all consultant Rheumatologists in England under 'Freedom of Information act (FOI)' to 131 NHS trusts. Questions were aimed to enquire about the initial steroid regime used by consultant rheumatologists in adult cases (≥ 18 yrs) of confirmed RA. The responses were received back by post and analysed.

Results: Total response received were 130 (92 % response rate), with 82.4 % agreeing on the early routine use of steroids in their practice. 53.6% used the Oral route, 48% used the intramuscular (IM) route and 45.6% of Consultants used the intra-articular route (either alone or in combination with other routes).

For those who used oral Prednisolone, the initial starting dose varied from 60mg (6.3%) to 7.5 mg (11.1% responses) per day with the majority using an initial dose of 15 mg (25.3%) or 20mg (23.8%) daily.

The duration of oral steroid use varied from 1 month (4.2%) to 2 yrs (4.2%) with the majority being for 4–6 months (72.3%).

The dose of IM Depomedrone varied from 40mg - 160 mg, with majority using 120 mg (86.2%), for a total duration that again varied from 2 months to 2 years, with the majority being 6 months (52.2%).

The dose of intraarticular injection for large joint also varied from 20 mg to 60 mg of Depomedrone with 40 mg used by majority (92%) of rheumatologist.

Conclusion: Majority of Rheumatologist use steroids for initial treatment of early Rheumatoid Arthritis. There is a wide variability in the use of steroids including its route, dose and duration of use. There is therefore an urgent need of scientifically proved guidelines on their initial use.

Costs of Tumor Necrosis Factor Blockers Per Treated Rheumatoid Arthritis Patient Using Real-World Drug Data in a US Managed Care Population.
Vernon F. Schabert[1], Crystal Watson[2], George Joseph[2], Paige Iversen[1], Chakkarin Burudpakdee[1] and David J. Harrison[2]. [1]IMS Health, Alexandria, VA, [2]Amgen Inc., Thousand Oaks, CA

Background/Purpose: Etanercept (ETN), adalimumab (ADA), and infliximab (INF) are FDA-approved tumor necrosis factor (TNF)-blocker treatments for moderate to severe rheumatoid arthritis (RA) and are commonly used first-line biologics. These agents have differing modes of

administration and dose ranges. It is important to understand the true cost of treatment with these agents including the effects of real-world dosing data, gaps in therapy, varying persistence, and switching. This study describes the annual TNF-blocker costs for patients treated with ETN, ADA, and INF, using data from a US managed care population.

Methods: The IMS LifeLink™ Health Plan Claims database was used to identify RA patients (18–64 years) with ≥ 1 claim for ETN, ADA, or INF between February 1, 2008 and July 5, 2010. Their first TNF-blocker claim after ≥ 6 months of continuous enrollment defined their index claim and medication. Patients were classified as "new" if they did not have a claim for the same agent in the previous 6 months (pre-index period) or "continuing" if they did. Patients were followed for 1 year after their index claim. Patients were excluded if they had a diagnosis in their pre-index period of psoriasis, psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis, or juvenile idiopathic arthritis. Total annual TNF-blocker dose was computed and costs were calculated using the March 2012 wholesale acquisition costs and Medicare Physician Fee Schedule for TNF-blocker related administrations. For patients who switched agents in the first year, costs of other TNF blockers used were attributed to the patients' index medication.

Results: Overall, 16,280 patients with RA (7,754 [47.6%] ETN, 4,834 [29.7%] ADA, 3,692 [22.7%] INF) were identified. Mean age was 50.3 years and 76.5% were female. Overall, patient characteristics were similar. INF was more commonly given by a rheumatologist (63.3% vs 57.3% ADA and 53.5% ETN) and less likely to be a new agent (28.4% vs 39.1% ADA and 33.7% ETN). The majority of patients had commercial insurance (83.0%-86.0%) and the majority of plans were preferred provider organizations (65.0%-70.0%). The overall 1-year TNF-blocker cost per RA patient was lowest for patients on ETN ($16,787), followed by ADA ($19,308) then INF ($22,939). For patients new to TNF-blockers, 1-year cost per treated patient was $15,828 for ETN, $17,250 for ADA, and $19,397 for INF; 1-year cost per continuing patient was $17,275 for ETN, $20,626 for ADA, and $24,345 for INF.

Conclusion: Across new and continuing RA patients, ETN was the most frequently prescribed TNF-blocker and had the lowest cost per treated patient as observed in real-world drug utilization data.

387

Medication Choices and Medication Survival in a National Multicentre Community Based Rheumatoid Arthritis Cohort. Lynden Roberts[1], Kathleen Tymms[2], Julien P. de Jager[3], Geoffrey O. Littlejohn[4], Hedley Griffiths[5], Dave Nicholls[6], Paul Bird[7], Julie Hill[8], Philip McCloud[8], James C. Scott[9], Jane Zochling[10] and OPAL Consortium[11]. [1]James Cook University, Townsville, Australia, [2]Canberra Rheumatology, Canberra, Australia, [3]Suite 2, Osler House, Southport, Australia, [4]Monash Medical Center, Melbourne, Australia, [5]Barwon Rheumatology Service, Geelong, Australia, [6]Coast Joint Care, Maroochydore, Australia, [7]Combined Rheumatology Practice, Sydney, Australia, [8]McCloud Consulting Group, Sydney, Australia, [9]Roche Products Pty Limited, Sydney, Australia, [10]Menzies Research Institute Tasmania, Hobart, Australia, [11]Melbourne, Australia

Background/Purpose: A sizeable body of high-quality research underpins our knowledge of the efficacy of various RA therapies. Outside the controlled environment of these clinical trials, however, in real world practice many additional factors may influence the use of DMARD/bDMARDs. There is little knowledge of whether the trial evidence is being implemented in real world settings, or whether the trial efficacy and safety translates into clinical effectiveness.

Methods: Point of care clinical software has been used to collect data since 2009 from 20 participating Australian rheumatology treatment centres. Patients with a rheumatologist diagnosis of RA were identified. Medication changes were analysed in 9 prespecified categories to permit the construction of population treatment algorithms. Medication survival was assessed using Kaplan Meier plots. The change in disease activity following a medication change was also assessed.

Results: RA patients numbered 9570, with 73% female, mean age 62, and median disease duration 7 years. Any DMARD was used in 87% overall, and 30% had used a biologic DMARD. The DMARD/bDMARD usage above 1% in the cohort included methotrexate 71%, Hydroxychloroquine 25%, Leflunomide 24%, Sulfasalazine 17%, Etanercept 12%, Adalimumab 11%, Tocilizumab 5%, Abatacept 3%, Golimumab 3%, Rituximab 2.5%, and Certolizumab 2%. Median DMARD survival ranged from 49 to 231 months for the

most common DMARDs and from 9 to 49 months for the most common biologic DMARDs. A tree diagram representing the observed treatment changes was constructed. Of the 2256 patients whose first RA medication was monotherapy Methotrexate and who required a change, 31% changed to greater than 1 conventional DMARD, 29% added Leflunomide, 17% added a bDMARD, and 16% ceased therapy. Of the 466 patients whose first change in RA medication was to Methotrexate plus Leflunomide and required a second change, 31% returned to monotherapy Methotrexate, 18% changed or added another conventional DMARD, 20% changed to monotherapy DMARD other than methotrexate, and 28% added a bDMARD.

Conclusion: Australian rheumatologists are making frequent changes in medications in their RA patients and appear to be implementing best evidence guidelines. Australian regulatory requirements for utilizing subsidised biologic therapy may also be affecting choices. The most commonly observed treatment algorithm in patients who required therapeutic escalation had patients starting with DMARD monotherapy followed by DMARD combination therapy followed by bDMARD combined with DMARD combination therapy. Shorter median survival of biologic therapies than traditional therapies may reflect the more refractory nature of the patients who are selected for these therapies. Analysis of the effect of a medication switch on disease activity will be of interest in this cohort.

388

Retention Rate of the Anti-TNF Biologics in the Treatment of Rheumatic Diseases and Predictive Factors for Drug Withdrawal: Data From the Hong Kong Biologics Registry. Chi Chiu Mok[1], Cherry Kwan[1], Helen Chan[2], Ka Lai Lee[3] and Lai-Shan Tam[4]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Kowloon Hospital, Hong Kong, Hong Kong, Hong Kong, [3]Pamela Youde Eastern Hospital, Hong Kong, Hong Kong, [4]The Chinese University of Hong Kong, Hong Kong, China

Background/Purpose: To study the retention rate of the anti-TNF biologics in the treatment of rheumatic diseases and the associated factors for drug withdrawal

Methods: Data on the use of biological agents for the treatment of various rheumatological disorders in 14 public hospitals were collected prospectively. Efficacy data, serious adverse events, withdrawal of biologics and reasons for withdrawal were collected at regular time intervals. The cumulative retention rate of individual agent was studied by the Kaplan-Meier method and factors associated with drug withdrawal were studied by Cox regression.

Results: From 2005 to 2012, 1335 courses of anti-TNF biological agents in 991 patients with rheumatic diseases were used. There were 553 women and 438 men (mean age 44.9±13.9 years and duration of underlying disease 7.4±6.6 years). Underlying rheumatic diseases were: rheumatoid arthritis(RA) (50%), spondyloarthropathy (SpA)(37%), psoriatic arthritis(PSA) (11%) and others (2%). The initial choice of the anti-TNF biologics was: infliximab (IFX) (N=618, 46%), etanercept (ETN) (N=468, 35%), adalimumab (ADA) (N=208, 16%) and golimumab (GLM) (N=41, 3%). The dosages of the biologics used were: IFX (intravenous; 3–5mg/kg for RA, 5mg/kg for SpA and PSA), ETN (subcutaneous; 50mg/week or 25mg 2x/week), ADA (subcutaneous; 40mg every 2 weeks) and GLM (subcutaneous; 50mg every 4 weeks). The mean duration of administration per course of biologic was 20.1±19.7 months. 692 (52%) courses of anti-TNF agents were abbreviated because of the following reasons: 238 (34%) lack /loss of efficacy (primary or secondary failure); 185 (27%) serious adverse events; 123 (18%) financial reasons; and 146 (21%) other or unspecified reasons. The overall cumulative drug withdrawal rate (due to either lack /loss of efficacy or adverse events) at 12, 24 and 36 months was 28%, 39% and 46% for IFX, and 22%, 27% and 32% for ETN, and 23%, 27% and 34% for ADA, respectively (log rank test; p<0.005 between IFX and either ETN or ADA). When drug withdrawal was broken down into that due to loss of efficacy and adverse events, data remained significant in favor of ETN to IFX. The follow-up time of ADA users was significantly shorter than those of ETN, and there was no significantly difference in the withdrawal rates between ETN and ADA. The commonest reasons for drug withdrawal because of serious adverse events were: allergic skin reaction (3.6%), infusion/injection site reactions (2.1%) and tuberculous infection (1.9%). Among 26 patients who developed tuberculosis, 21 patients were IFX users, 4 were ETN users and 1 was GLM user. Patients with RA had significantly lower drug retention rate than SpA or PSA patients (log rank test; p<0.05). Cox regression analysis revealed that the anti-TNF agent used (IFX versus ETN/ADA/GLM; HR 1.46 [1.17–1.81];

p=0.001) and rheumatoid arthritis (vs other diagnoses; HR 1.47 [1.13–1.93]; p=0.005) was independent predictors for drug withdrawal due to inefficacy or serious adverse events after adjustment for age, sex and disease duration.

Conclusion: Our Registry data reveals that IFX is associated with a significantly higher withdrawal rate for both loss of efficacy over time and the development of serious adverse events, in particular tuberculosis.

389

Oral Glucocorticoid Sparing Effects of Rituximab in Rheumatoid Arthritis Patients Who Have Switched from an Anti-TNF Therapy - an Administrative Claims Database Analysis. Stephen Johnston[1], Tripthi Kamath[2], Nianwen Shi[1], Robert Fowler[1], Bong-Chul Chu[1] and William Reiss[3]. [1]Truven Health Analytics, Washington, DC, [2]Genentech, Inc., South San Francisco, CA, [3]Genentech Inc., South San Francisco, CA

Background/Purpose: The current treatment paradigm in RA is to attempt to decrease concomitant use of oral glucocorticoids (OGC). This study examined the OGC-sparing effects of Rituximab in U.S. RA patients who had switched from an anti-TNF therapy.

Methods: Retrospective cohort study using a large U.S. administrative claims database. Patients selected for study were adults aged ≥18 years who had had been diagnosed with RA between 1/1/2004-3/31/2011 had initiated Rituximab treatment after treatment with anti-TNF therapy between 3/1/2006-3/31/2011, and had OGC use within 30 days prior to Rituximab initiation. Rituximab 'exposure periods' were constructed using Rituximab infusion dates and the recommended administration frequency schedule, equaling the duration of time from initiating Rituximab until the first occurrence of 1) switch to a different biologic disease modifying antirheumatic drug (BDMARD), 2) 90-day gap in treatment with Rituximab, 3) disenrollment from health insurance, 4) reaching 3/31/2011, or 5) reaching a maximum study follow-up of 36 months. Patients were excluded if within the 12-month period prior to Rituximab initiation they had been diagnosed with a non-RA indication for any BDMARD.

During the Rituximab exposure periods the study outcomes, proportion of patients using OGCs and average OGC dose expressed in prednisone equivalent, were measured in sequential 90-day intervals, the first of which commenced as of Rituximab initiation. A multilevel random coefficient model was used to test for statistically significant OGC-sparing effects over time.

Results: A total of 952 Rituximab exposure periods from 938 unique patients were included for study; average age 54.7 years, 79.2% female. Table displays the study results. The proportion of patients using OGCs decreased over time, with slight non-monotonic fluctuations, from 80.6% of patients in months 1–3 to 54.1% of patients remaining on therapy in months 34–36. The mean OGC dose also decreased over time, again with slight non-monotonic fluctuations, from 5.7 mg among patients in months 1–3 to 3.2 mg among patients remaining on therapy in months 34–36. The decreases in the proportion of patients using OGCs ($P<0.0001$) and the average OGC dose ($P<0.0001$) were both statistically significant. In sensitivity analysis subset to only patients remaining on therapy through months 34–36, the OGC use patterns were similar to those from among overall sample.

Table. OGC use over time since Rituximab initiation

Month range	Sample N	% using OGCs	OGC dose*	
			Mean	SD
1–3	952	80.6%	5.7	7.4
4–6	864	79.3%	5.5	6.1
7–9	715	73.6%	5.0	5.9
10–12	594	67.7%	5.0	6.3
13–15	381	69.0%	4.5	5.4
16–18	313	64.2%	4.4	5.8
19–21	242	59.1%	4.3	7.1
22–24	191	58.1%	3.4	4.6
25–27	162	56.2%	3.5	5.8
28–30	129	55.8%	4.0	9.2
31–33	98	57.1%	3.1	3.5
34–36	74	54.1%	3.2	4.1

*Average daily dose, expressed in prednisone equivalent (mg), calculated among all patients

Conclusion: In this study, statistically significant OGC-sparing effects were observed in RA patients who had switched to Rituximab after treatment with anti-TNF therapy. The clinical implications of such OGC-sparing effects warrant further investigation.

390

Performance of Criteria for Remission in a Long-Term Observational Study of Patients with Early Rheumatoid Arthritis. Bjorn Svensson[1], Maria LE Andersson[2], Sidona-Valentina Bala[1], Kristina Forslind[3] and Ingiäld Hafström[4]. [1]Lund University, Lund, Sweden, [2]R&D Center, Spenshult Hospital, Oskarström, Sweden, [3]Helsingborgs Lasarett and Lund University Hospital, Helsingborg, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: Remission is widely accepted as the goal of treatment in RA and has to be sustained to keep joint damage at a minimum (Smolen et al 2010). The DAS28<2.6 remission criterion is widely used but criticized for allowing remission to be present in spite of several swollen or tender joints. The recently proposed Boolean ACR/EULAR remission criteria are more stringent and do not have this bias but their utility in long-term observational studies needs to be evaluated. The present study addresses the performance of these criteria over 8 years in an observational study of patients with early RA.

Methods: 839 patients, included in 1992–1999, within one year from disease onset in the BARFOT observational study were followed for 8 years. The following remission criteria (RCr) were applied: The DAS28 RCr (DAS28<2.6) and the ACR/EULAR RCr (≤1 swollen joint, ≤1 tender joint, CRP ≤1 mg/dl and patient global assessment ≤1 (0–10 scale). Sustained remission was defined as remission at all four visits at 1, 2, 5 and 8 years. Radiographic joint damage was assessed by the Sharp van der Heijde method (SHS).

Results: Sustained remission was present in 79 patients (14%) by the DAS28 RCr and 16 (3%) by the ACR/EU RCr. In patients in sustained remission by the DAS28 RCr, radiological progression (RP) with SHS of >0 occurred in 31, 45, 57 and 65% and by the ACR/EU RCr in 21, 46, 46 and 62% at 1, 2, 5 and 8 years, respectively. The likelihood ratios for the ability of sustained remission by the the DAS28 criteria and the ACR/EU criteria, respectively, to identify patients with favorable radiographic outcome from baseline to 8 years was 2.2 vs 1.9 for a change in SHS of ≤0 (minimal RP), 1.5 vs 1.4 for a change of <5 (clinically relevant change) and 1.4 vs 1.3 for a change of <8 (<1 point per year). A small number of patients in sustained remission by DAS28 RCr had at some point in time more than one swollen or tender joint. More than one joint was found in 11 of 315 assessments (3.5%) of tender joint count (max 5 in one case) and in 28 of 315 assessments (9%) of swollen joint count (max. 6 in one case).

Conclusion: The new ACR/EU criteria appear too stringent to be feasible in long-term observational studies. Only a very small number of patients were identified and the ability to predict favorable radiographic outcome was not significantly superior. Sustained remission by the DAS28 criteria was more than four times as frequent and the frequency of possible false remissions was very low. Therefore, awaiting further development, the DAS28 remission criterion could be preferred in long-term observational studies.

391

DAS28 Is Not a Sufficient Disease Activity Measure for Obese Rheumatoid Arthritis Patients - Don't Leave the Feet Behind. Vikram Garg[1], Paul Maranian[2], Mihaela B. Taylor[3], Harold E. Paulus[4], David Elashoff[4] and Veena K. Ranganath[5]. [1]UCLA David Geffen School of Medicine, VA Greater Los Angeles Healthcare System, Los Angeles, CA, [2]UCLA Medical School, Los Angeles, CA, [3]University of California Los Angeles, Los Angeles, CA, [4]University of California, Los Angeles, Los Angeles, CA, [5]University of California, Los Angeles, Western Consortium of Practicing Rheumatologists, Los Angeles, CA

Background/Purpose: Current literature suggests that obesity impacts disease activity in rheumatoid arthritis (RA) and the incidence of obesity is on

the rise. The objective of this study was to evaluate how obesity (BMI≥30) affects different composite disease activity measures in RA, specifically evaluating differences between 28 vs 44 joint counts measures.

Methods: We examined a long-term prospective observational cohort of early poor prognosis seropositive RA patients (within 15 months of symptom onset) from the Western Consortium of Practicing Rheumatologists. Patients included had a diagnosis of RA according to the ACR 1987 criteria, DMARD-naive, positive rheumatoid factor, ≥6 SJC, and ≥9 TJC. BMI was categorized above and below 30. The following baseline characteristics were collected: age, gender, BMI, disease duration, CCP status, prednisone use, sharp scores, and radiographic evidence of osteoarthritis (OA). Components needed to calculate DAS44/ESR-4 item, DAS28/ESR-4 item, and CDAI were also collected at baseline. Patients completed a comprehensive questionnaire at study entry including: demographics, health, medication, pain visual analog scale (VAS), patient global VAS, and the Health Assessment Questionnaire-Disability Index (HAQ-DI).

Results: Significant difference between obese and non-obese patients were observed for baseline swelling of MCP, knees, ankles, and MTP joints, tender ankle joints, HAQ-DI and MD global. Consequently, DAS44/ESR-4item was significantly higher in the obese early RA patients, but DAS28/ESR4 item and CDAI were not significantly different. Other baseline measures were not different.

Table 1. Baseline Values

	BMI 20–30 (N=184)	BMI >30 (N=64)	
	mean (SD)	Mean (SD)	P-VALUE
Age	51.4 (13.1)	51.6 (11.4)	NS
Female	75.5%	78.1%	NS
Duration	8.16 (8.8)	6.57 (5.6)	NS
On MTX	54.4%	59%	NS
Nodules	0.18 (0.5)	0.08 (0.3)	NS
OA present	36.6%	37.7%	NS
ESR	40 (24.7)	42.7 (25.3)	NS
CRP	2.9 (6.9)	3.5 (4.1)	NS
On Pred	46.2%	45.9%	NS
CDAI	36.1 (14.4)	40.8 (16.3)	NS
HAQ-DI	1.1 (0.7)	1.4 (0.7)	0.005
das44esr4	4.6 (1.2)	5.1 (1.3)	0.01
das28esr4	6.1 (1.1)	6.4 (1.1)	NS
Pt global	54.5 (27.7)	57.9 (25.7)	NS
MD global	48.1 (21)	55.1 (20.3)	0.03
Tender28	13.5 (7.1)	14.5 (8.1)	NS
Tender44	20 (9.5)	21.7 (11.52)	NS
LE tender	6.9 (4.3)	7.2 (4.6)	NS
UE tender	13.2 (6.9)	14.4 (7.9)	NS
Ankle tender	0.9 (0.9)	1.3 (0.9)	0.004
Swell28	12.5 (6.6)	14.9 (7.3)	0.04
Swell44	17.4 (8.6)	22.2 (10.6)	0.003
LE swollen	5.5 (4.2)	8 (4.9)	<.001
UE swollen	11.6 (6.2)	14.4 (7)	0.008
MCP swollen	4.8 (3.2)	6.2 (3.3)	0.004
Knee swollen	0.8 (0.9)	1.2 (0.9)	0.001
Ankle swollen	0.8 (0.9)	1.4 (0.8)	<.001
MTP swollen	4 (3.7)	5.5 (4.1)	0.01

LE- lower extremity, UE- upper extremity

Conclusion: Our results suggest that in obese RA patients, swelling of the LE weight bearing joints may impact composite disease activity measures. DAS44/ESR-4 item (considered a gold standard measure) was significantly different between obese and non-obese RA patients, while the DAS28/ESR-4 item and CDAI were not. Several studies that examined the relationship between BMI and disease activity (Sahebari et al 2011, Klaasen et al 2011, Baker et al 2011), used DAS28 as their measure of disease activity. Our findings suggest that weight bearing joints should be included when assessing RA disease activity in obese patients, and future studies are needed to validate these results.

392

Analysis of Factors Impact On Patient Global Assessment in Daily Practice Based On Observational Cohort IORRA (Institute of Rheumatology, Rheumatoid Arthritis).

Yasushi Inoue, Eiichi Tanaka, Ayako Nakajima, Eisuke Inoue, Akiko Kobayashi, Daisuke Hoshi, Naoki Sugimoto, Kumi Shidara, Yohei Seto, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Patient global assessment (PtGA) is an element of the new ACR/EULAR remission criteria for rheumatoid arthritis (RA). This definition has been reported to better predict structural or functional outcomes than DAS28, and we have also reported the importance of maintaining stringent remission to avoid progressive functional damage (ACR 2011 #332). Boolean-based remission for clinical trials (Boolean trials) consists of 4 components: (tender [TJC28] and swollen joint counts [SJC28] as assessed by 28 joints, C-reactive protein [mg/dL], and PtGA (0–10 scale) values being ≤1). In most patients, whether Boolean trials remission is achieved or not depends on PtGA. It is therefore necessary to reveal what factors are significantly associated with PtGA.

Methods: The Institute of Rheumatology, Rheumatoid Arthritis (IORRA), is a hospital-based large observational cohort of RA patients. Clinical information and laboratory data have been collected biannually since 2000. Pain, PtGA, and physician global assessment (PhGA) scores were rated using a Visual Analogue Scale (0–10 cm). The validated Japanese versions of Health Assessment Questionnaire (J-HAQ) scores and European Quality of life 5 Dimensions (EQ-5D) ratings were used to evaluate physical function and quality of life (QOL), respectively. The subjects in this study were RA patients who participated in the IORRA survey during April 2011. Correlations between PtGA score and clinical parameters, including medications and pain VAS, J-HAQ, PhGA, and EQ-5D were examined by Spearman's correlation. Univariate and multivariate logistic regression models were used to evaluate the effect of clinical parameters on PtGA scores of >1 compared to PtGA scores of '1. Odds ratios (OR) with 95% confidence intervals (CI) were calculated using the JMP 9.0. software package.

Results: We analyzed 5,276 Japanese RA patients from whom all 4 components of Boolean trials remission were available. TJC28, SJC28, and CRP were satisfied in 78.3%, 72.8% and 84.4% of them, respectively. By contrast, only 31.3% of the patients fulfilled PtGA scores of ≤1, but among them, Boolean trials remission was achieved in 76.9%. PtGA was closely correlated with J-HAQ (r = 0.54), EQ-5D (r = 0.66) and pain VAS (r = 0.86). In multivariate analyses, significant factors associated with a PtGA score >1 were J-HAQ (OR = 1.96; 95% CI, 1.61–2.40; p<0.001), non-steroidal anti-inflammatory drug (NSAID) use (OR = 1.40; 95% CI, 1.20–1.64; p<0.001), TJC28 (OR = 1.26; 95% CI, 1.17–1.36; p<0.001), SJC28 (OR = 1.11; 95% CI, 1.05–1.16; p<0.001), CRP (OR = 1.18; 95% CI, 1.06–1.33; p = 0.003), age (OR = 0.99; 95% CI, 0.98–0.99; p<0.001), and EQ-5D (OR = 0.001; 95% CI, 0.000–0.001; p<0.001).

Conclusion: In RA patients, a PtGA score of ≤1 was associated with not only joint involvements (TJC, SJC), inflammation (CRP), and physical dysfunction, but also impaired QOL, younger age, and NSAID use.

393

Defining Criteria for Rheumatoid Arthritis Patient-Derived Disease Activity Score That Corrresponds to Disease Activity Score 28 and Clnical Disease Activity Index Based Statuses and Response Criteria.

Alexander MH Leung[1], Daniel Farewell[2], Chak S. Lau[3] and Ernest Choy[4]. [1]Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom, [2]Cardiff, ENGLAND, United Kingdom, [3]Queen Mary Hospital, Hong Kong, Hong Kong, [4]Cardiff University School of Medicine, Cardiff, United Kingdom

Background/Purpose: Patient-based disease activity score (PDAS1 [with ESR] & PDAS2 [without ESR]) in rheumatoid arthritis (RA) are

transformed for the linear regression analyses. EULAR good response and DAS28 remission were similarly assessed by logistic regression analysis.

Results: A total of 2573 patients were included: MTX mono n=1866 [69.9 % female, 62 % RF+, mean (SD) age 56.0 (13.7) years (yrs), time from diagnosis 3.6 (7.7) yrs] and TNFi + MTX n=707 [70.3 % female, 75 % RF+, mean (SD) age 52.1 (13.2) yrs, time from diagnosis 9.1 (9.3) yrs]. Significant time trends were found in both groups for baseline values of DAS28, 28-SJC and CRP (table). Significant time trends were also found for baseline disease duration, SDAI, MHAQ, 28-TJC, ESR, physician global, patient global and joint pain VAS (data not shown). Further, there was a trend towards increasing 6-month DAS28 remission rates over the years in both groups, whereas a gradual increase in the EULAR good response rate was only observed in patients starting MTX mono (table).

	2001–2002	2003–2004	2005–2006	2007–2008	2009–2010	p value
Baseline DAS28 [mean(SD)]						
MTX mono	5.17 (1.26)	5.06 (1.33)	4.85 (1.29)	4.62 (1.39)	4.75 (1.30)	<0.001
TNFi+MTX	5.88 (1.23)	5.25 (1.23)	5.21 (1.25)	4.87 (1.46)	4.64 (1.41)	<0.001
Baseline 28-SJC [mean(SD)]						
MTX mono	9 (6)	8 (6)	7 (6)	6 (5)	6 (5)	<0.001
TNFi+MTX	10 (5)	9 (6)	8 (5)	6 (5)	6 (4)	<0.001
Baseline CRP, mg/l [median(IQR)]						
MTX mono	22 (7–35)	13 (5–31)	10 (5–25)	8 (3–20)	7 (3–21)	<0.001
TNFi+MTX	27 (12–54)	19 (8–37)	12 (5–30)	9 (5–22)	7 (3–20)	<0.001
EULAR good response 6 months [%(n)]						
MTX mono	25.7 (59)	35.5 (105)	37.8 (90)	33.5 (65)	39.2 (40)	0.03
TNFi+MTX	29.3 (17)	44.6 (50)	46.5 (46)	43.6 (34)	38.0 (19)	0.47
DAS28 remission 6 months [%(n)]						
MTX mono	17.8 (43)	29.2 (95)	33.7 (89)	38.1 (80)	37.6 (44)	<0.001
TNFi+MTX	16.9 (10)	29.3 (36)	34.5 (38)	31.4 (27)	46.3 (25)	0.003

Conclusion: Mean baseline disease activity level for patients starting MTX treatment and for patients starting the first TNFi has decreased from high to moderate during the last decade. Mean disease duration also decreased significantly. These findings indicate that clinicians have implemented modern, more aggressive RA treatment strategies which will hopefully result in better long-term patient outcomes.

396

Prevalence, Concordance and Predictors of Early and Sustained Remission Assessed by Various Indices in the French Early Arthritis Espoir Cohort. Cédric Lukas[1], Ihsane Hmamouchi[2], Xavier Le Loet[3], Bruno Fautrel[4] and Bernard Combe[5]. [1]Montpellier 1 University, Lapeyronie Hospital, Montpellier, France, [2]El Ayachi Hospital, Rabat, Morocco, [3]CHU de ROUEN, Rouen, France, [4]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [5]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Clinical remission is the best achievable state in patients with rheumatoid arthritis (RA). The definition of remission, however, is still under debate. The aim of this study was to assess the prevalence of remission during the initial follow-up of a cohort of patients with early inflammatory arthritis, to evaluate the concordance across different criteria sets in defining this state, and to look for predictive factors for early- and sustained remission.

Methods: Patients from the French ESPOIR cohort, who had arthritis involving at least 2 joints for between 6 weeks and 6 months, and had not received any specific therapy before their inclusion, were followed-up every 6 months.Treatment was collected, but no specific strategy was imposed. We analyzed early remission (at 6 months follow-up) and sustained remission (remission state in both 6 months- and 1 year visits) in 3 different groups of patients: Patients who were diagnosed as having RA according to 2010 ACR/EULAR criteria (RA), undifferentiated arthritis (UA) after 1 year of follow-up, and the entire cohort (ESPOIR). Remission was defined according to 2011 ACR/EULAR criteria, 28 Joint Disease Activity Score (DAS28<2.6), and Simplified Disease Activity Index (SDAI<3.3). Agreement across available criteria sets was evaluated by k-coefficient. Predictive factors for sustained remission at 1 year in RA patients were analyzed by

logistic regression, with potential predictive factors tested from available clinical, biological and demographic data.

Results: 813 patients were included, mean age (SD) 48.1(12.6) years, 45.8% positive for rheumatoid factor (RF), 38.8% for anti-CCP test. Early remission rates in the RA/UA/ESPOIR groups were observed in respectively 29.2% (181/682), 51.4% (55/123) and 32.7% (239/813) of patients by DAS28; 15.7%, 29.1% and 18% by SDAI; and 11.2%, 29.1% and 12.8% by ACR/EULAR criteria. Agreement between classifications of remission by k-statistics was low for DAS28 vs ACR/EULAR (r=0.44 [0.38–0.51]), high for SDAI vs ACR/EULAR (r=0.78 [0.72-0-84]), and moderate for SDAI vs DAS28 (r=0.54 [0.48–0.61]). Lower baseline disease activity scores (DAS28<5.1), non-menopausal status and younger age (<50 years) were the best predictive factors for sustained remission at 1 year, with consistent results across the 3 definitions of remission.

Remission rates at 6 months
Conclusion: Our study showed that the rate of early (6 months) and sustained remission at 1 year in a cohort of early inflammatory arthritis is dependent on the definition used, with a variable degree of agreement across criteria sets, but with consistent predictive factors of favourable outcome at 1 year in patients finally diagnosed with RA: Younger age, lower baseline DAS28 and non-menopausal status.

397

Assessment of Global Disease Activity in Rheumatoid Arthritis Patients Monitored in the Measurement of Efficacy of Treatment in the Era of Rheumatology Database: The patient's Versus the rheumatologist's Opinion. E. Gvozdenovic[1], R. Koevoets[1], R. Wolterbeek[1], Désirée van der Heijde[1], T.W.J. Huizinga[1], C.F. Allaart[1] and Robert B. M. Landewé[2]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center/University of Amsterdam & Atrium Medical Center, Amsterdam, Netherlands

Background/Purpose: Disagreement on disease activity between rheumatoid arthritis (RA) patients and rheumatologists may influence treatment decisions and compliance.

The aim is to compare the physician's (PhGDA) and patient's (PtGDA) assessment of global disease activity and to identify factors that might influence these differences over time, as well as factors that may influence the patients and the physicians score separately.

Methods: Anonymous data were used from 2118 Dutch patients included in the Measurement of efficacy of Treatment in the Era of Rheumatology (METEOR) database, a worldwide online tool for disease monitoring in RA. PhGDA and PtGDA were scored independently on a 100 mm visual analogue scale (VAS) with 0 and 100 as extremes. Intra-class correlation coefficients (ICC) were calculated as a measure of agreement and a Bland Altman plot was created to visualize the differences between PhGDA and PtGDA. Linear Mixed Model analysis was used to model PtGDA and PhGDA over time. Logistic repeated measurements were used to model the difference in PtGDA and PhGDA (PtGDA≥PhGDA vs. PtGDA<PhGDA) over time. Gender, age, swollen joint count, tender joint count, VAS pain, disease duration and ESR were considered as possible determinants in both models.

Results: Mean (SD) age was 57 (15) years and 67% of the patients were female. Agreement between PtGDA and PhGDA was moderate (ICC: 0.57). Patients scored on average 11 units higher (worse) than rheumatologists, 95% limits of agreement: −25.2 to 47.6. Patient's perception of pain (VAS) was positively associated with a PtGDA being

higher than PhGDA. Similarly, ESR and swollen joint counts were positively associated with a PhGDA being higher than a PtGDA (Table 1). Both PtGDA and PhGDA were independently associated with tender joint count, swollen joint count, disease duration, and pain (VAS) for pain.

Table 1. Clinical parameters associated to the difference between PtGDA and PhGDA as a binary dependent variable.*

Variable	PtGDA versus PhGDA* Estimate β, 95% CI	p-value
Male	0.16 −0.15, 0.47	0.30
Age	−0.00 −0.01, 0.01	0.46
Disease duration	0.01 −0.01, 0.02	0.23
ESR	−0.01 −0.02 −0.00	<0.01
SJC28	−0.29 −0.36, −0.21	<0.01
TJC28	−0.04 −0.10, 0.02	0.22
VAS pain patient	0.05 0.04, 0.06	<0.01

*1= patient scores equal or higher than the physician; 0= physician scores higher than the patient. (Reference category=0)

Conclusion: Patients rate global disease activity consistently higher than their rheumatologists. Patients base their judgment primarily on the level of pain; while physicians use SJC and ESR to rate global disease activity.

398

Basal Metabolic Rate As an Indicator of Rheumatoid Arthritis Disease Activity and Predictor of Remission. Heather Jones[1], Annette Szumski[2] and Andrew S. Koenig[2]. [1]Pfizer Inc, Collegeville, PA, [2]Pfizer Inc., Collegeville, PA

Background/Purpose: The role of body mass index (BMI) in rheumatoid arthritis (RA) disease activity and response to treatment has been difficult to determine.[1] As a measure of physiologic function, basal metabolic rate (BMR) may be a better indicator than BMI for clinical assessment and treatment response in RA patients. In this posthoc analysis, the relationship between BMR, BMI, disease activity and responses to etanercept (ETN)-methotrexate (MTX) treatment were assessed in subjects with moderately active RA in the PRESERVE trial.[2]

Methods: Subjects with DAS28 >3.2 and ≤5.1 despite stable doses of oral MTX received open-label ETN 50 mg once weekly (QW) plus MTX (titration to ≤25 mg/week through week 28) for 36 weeks (Period 1). Posthoc analyses of disease activity and treatment response by BMR and BMI categories at baseline and Week 36 of treatment were conducted in subjects who received ≥1 treatment dose and had Week-36 assessments. The Mifflin-St Jeor[3] and revised Harris-Benedict[4] formulas were used to calculate BMR. Adjusted mean DAS28 scores were calculated using ANCOVA with BMR categories and weight as predictors at baseline and using weight and baseline scores as predictors at Week 36. Similar analysis performed on BMI categories but weight was excluded because it was not significant. Pearson correlations were used to determine overall associations between BMR/BMI and DAS28.

Results: Of 829 subjects analyzed, the proportions of patients with each category of BMR (Mifflin-St Jeor) were evenly distributed and half had a BMI in the low to normal range (table). At baseline, higher BMR was significantly associated with lower DAS28 scores after adjusting for weight (r=−0.127, p=0.008), and lower BMI was associated with lower DAS28 scores (r=0.124, p<0.001). At week 36, higher BMR was significantly associated with lower DAS28 scores (r=−0.233, p<0.001) and were also associated with a greater likelihood of remission (DAS28<2.6, p<0.001). Similar results were seen using the revised Harris-Benedict[6] formula. Higher BMI was significantly associated with higher week 36 DAS28 scores (p=0.002) and with decreased likelihood of remission (p=0.047).

Adjusted Mean DAS28 scores by Baseline BMR and BMI Category at Baseline and Week 36 of Treatment with ETN-MTX in Subjects With Moderate RA

		n (%)	Baseline Mean (95% CI)	Week 36 Mean (95% CI)
BMR	Very low (≤1188)	208 (25)	4.47 (4.40, 4.50)	2.90 (2.72, 3.07)
	Low (>1188 and ≤1305)	207 (25)	4.40 (4.34, 4.46)	2.65 (2.50, 2.80)
	High (>1305 and ≤1461)	209 (25)	4.38 (4.32, 4.44)	2.32 (2.17, 2.46)
	Very high (>1461)	205 (25)	4.25 (4.16, 4.33)	2.08 (1.88, 2.28)
BMI	Low to Normal (≤25)	418 (50)	4.33 (4.29, 4.38)*	2.42 (2.32, 2.52)
	Overweight (>25 and ≤30)	268 (32)	4.39 (4.34, 4.44)*	2.44 (2.32, 2.57)
	Obese (>30)	143 (17)	4.46 (4.39, 4.54)*	2.77 (2.59, 2.95)

*Means were calculated by 1-way ANOVA with BMI category as a predictor. DAS28 = Disease Activity Score based on a 28-joint count. Last observation carried forward imputation for missing data.

Conclusion: Subjects with moderate RA and higher BMRs demonstrated a better clinical response after 36 weeks of etanercept-MTX treatment compared to their counterparts with lower BMRs after adjusting for weight. Our data confirm previous research that BMI is suggestive of treatment outcomes in RA, but may not be clinically meaningful. In addition, the data suggest that BMR may be a more sensitive predictor than BMI. Further research is needed to evaluate the relationships between BMR, BMI, disease activity and treatment outcomes in RA.

Can Sustained Remission of Rheumatoid Arthritis Be Predicted? an Analysis From the Japanese National Database of Rheumatic Disease (NinJa). Yoichiro Haji[1], Mitsumasa Kishimoto[1], Ryo Rokutanda[1], Sachiko Ohde[2], Gautam A. Deshpande[2], Yuri Ohara[1], Chisun Min[1], Yasuhiro Suyama[1], Hisanori Shimizu[1], Ken-ichi Yamaguchi[1], Akira Takeda[1], Yukio Matsui[1], Masato Okada[1] and Shigeto Tohma[3]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]St.Luke's Life of Science Institute, Tokyo, Japan, [3]Sagamihara National Hospital, Sagamihara City, Japan

Background/Purpose: Achievement of clinical remission in rheumatoid arthritis (RA) is now the goal of therapy to reduce joint damage and disability, and maintain or improve quality of life. Sustained remission is critical to attain these outcomes. Predictive factors for sustained remission of RA are not known. The purpose of this study is to identify prognostic factors of sustained remission and build a predictive model.

Methods: Data from RA patients registered in a nationwide Japanese cohort database (*NinJa:* National Database of Rheumatic Diseases by iR-net in Japan) in 2009 and 2010 were used to evaluate baseline characteristics, treatment profiles, and the following clinical outcomes: tender joint count (TJC), swollen joint count (SJC), C-reactive protein (CRP), ESR, patient Visual analog scale (VAS), physician VAS, and Modified Health Assessment Questionnaire (MHAQ). All patients with SDAI remission in 2009 were divided based on whether remission was maintained in 2010. A multivariate Cox regression model was constructed for predictive factors and a prognostic prediction model was constructed. Bootstrapping was used for internal model validation.

Results: Out of 4215 patients with RA in the 2009 cohort, 930 patients had SDAI remission, and 623 patients (67.0%) had sustained remission after 1 year. Compared to non-sustained remission group, duration of disease, SJC, CRP, ESR, patient VAS, physician VAS, and MHAQ were significantly lower in the sustained remission group (p<0.05). Mean SDAI score in the sustained remission group was 1.45 ± 0.92 versus 2.08 ± 0.86 in the non-sustained remission group (p<0.05). A prognostic prediction model with a total score of 6 points was constructed as follows: 2 points for MHAQ >1; 1 point each for SJC >1, ESR >20, patient VAS >0.5, and physician VAS >0.5. Area under the receiver operating characteristic (ROC) curve for this model was 68.8% (95% CI: 65.0–73.0%). Bootstrapped validation beta coefficients of predictors were identical to the original cohort data.

Conclusion: We found that duration of disease, SJC, CRP, ESR, patient VAS, physician VAS, and MHAQ are significantly lower in those with sustained remission after 1 year. A prediction model was successfully built and validated using clinically relevant parameters.

High Patient Global Assessment Scores Associate with the Residual Disease Activity Unidentified by a 28-Joint Examination in Rheumatoid Arthritis Patients Approaching Clinical Remission.
Yasushi Inoue, Eiichi Tanaka, Ayako Nakajima, Eisuke Inoue, Akiko Kobayashi, Daisuke Hoshi, Naoki Sugimoto, Kumi Shidara, Yohei Seto, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Patient global assessment (PtGA) is a component of the new ACR/EULAR remission criteria for rheumatoid arthritis (RA). It has been reported that >50% of patients who satisfied the other 3 components failed to achieve remission due to their higher PtGA score. Certain problems related to the higher PtGA among such patients may have been hidden. However, it remains to be clarified whether RA patients with a PtGA score ≤1 would essentially differ from those with a score >1, and whether significant differences would be found when comparing patients with a PtGA score ≤1 to those with a slightly higher score.

Methods: The Institute of Rheumatology, Rheumatoid Arthritis (IORRA), is a hospital-based large observational cohort of RA patients. Clinical information and laboratory data have been collected biannually. PtGA scores were rated using a Visual Analogue Scale (0–10 cm). Swollen and tender joint counts were recorded by examination of 45 joints. Components of DAS28 were documented as TJC28 and SJC28, and the other joint involvements in this study were described as "TJC45-28" and "SJC45-28." The validated Japanese versions of Health Assessment Questionnaire (J-HAQ) scores and European Quality of life 5 Dimensions (EQ-5D) ratings were used to evaluate physical function and quality of life (QOL), respectively. The subjects were 2,973 RA patients who participated in the IORRA survey in April 2011, and "fulfilled 3 other components" defined as TJC, SJC, and CRP being ≤1. Multivariate logistic regression analyses were performed to evaluate factors associated with PtGA in 2 models; model 1, patients with a PtGA >1 compared to those with a PtGA ≤1, and model 2, patients with a 1<PtGA ≤2 compared to those with a PtGA ≤1. Odds ratios (OR) with 95% confidence intervals (CI) were calculated using the JMP 9.0 software package.

Results: Among patients fulfilling the other 3 components, only 42.8% achieved Boolean trials remission. Multivariate analysis showed that, whether Boolean trials remission was achieved or not was independently associated with age (OR = 0.99; 95% CI, 0.98–0.99; p<0.001), SJC28 (OR = 1.10; 95% CI, 1.04–1.16; p<0.001), TJC28 (OR = 1.26; 95% CI, 1.17–1.37; p<0.001), J-HAQ (OR = 1.97; 95% CI, 1.62–2.41; p<0.001), EQ-5D (OR 0.001; 95% CI, 0.000–0.001; p<0.001), and NSAID use (OR = 1.41; 95% CI, 1.20–1.65; p<0.001). Notably, "SJC45-28" was also strongly associated (OR = 1.18; 95% CI, 1.02–1.38; p<0.001) with achieving Boolean trials remission. When factors were analyzed in patients with a 1<PtGA ≤2 (n = 538) compared to those with a PtGA ≤1, significant associations were similarly found in age, SJC28, TJC28, J-HAQ, EQ-5D, NSAID use, and "SJC45-28", indicating that a slight increase of PtGA would reflect the hidden problems and residual disease activity.

Conclusion: Among patients fulfilling 3 other components, high PtGA scores (>1), even if only slightly higher, were closely related to impaired QOL, physical dysfunction, joints involvement, and NSAID use. Furthermore, any joint involvement unidentified by a 28-joint examination significantly influenced PtGA in the IORRA cohort. In clinical practice, a rheumatologist must pay attention to the other joints when the PtGA score is >1.

Can We Improve Outcomes in Early Rheumatoid Arthritis by Determining Best Practices? an Analysis of the Canadian Early Rheumatoid Arthritis Cohort (CATCH).
Jamie Harris[1], Vivian P. Bykerk[2], Carol A. Hitchon[3], Edward Keystone[4], J. Carter Thorne[5], Gilles Boire[6], Boulos Haraoui[7], Glen S. Hazlewood[4], Ashley Bonner[8], Janet E. Pope[9] and CATCH Investigators[10]. [1]Western University, London, ON, [2]Hospital for Special Surgery, New York, NY, [3]University of Manitoba, Winnipeg, MB, [4]University of Toronto, Toronto, ON, [5]Southlake Regional Health Centre, Newmarket, ON, [6]CHUS - Sherbrooke University, Sherbrooke, QC, [7]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [8]McMaster University, Hamilton, ON, [9]Western University of Canada, St. Joseph's Health Care, London, ON, [10]Toronto, ON

Background/Purpose: The goal of ERA treatment is remission but many patients do not achieve this state due to patient factors and perhaps differences in treating physicians. Studying treatment variation can lead to adopting best practices. Our objective was to investigate whether site differences occur and have an effect on outcome in ERA, and if so, to determine whether site size and/or differences in treatment explain the variability.

Methods: Sites from the CATCH database that had >40 patients at 6 months after enrolment were studied. Included sites were randomly renumbered and assigned a letter with investigators blinded. Patient data was used to calculate remission by several definitions (DAS28 < 2.6, SDAI ≤ 3.3, CDAI ≤ 2.8) and to determine treatment and treatment changes. Regression models included site as a variable and confounding baseline characteristics (HAQ, DAS28, serology, presence of erosions, cigarette smoking, age, gender, symptom duration, and SES) that had a p-value < 0.10 in univariate analyses.

Results: Of the 1138 baseline patients, 798 and 640 patients had data at 6 and 12 months respectively. Baseline descriptive statistics revealed that (mean (SD) or %): age 52(17) years; 72% female; 23% had erosions; 54% either were current or ever smokers; 37% anti-CCP positive; 51% RF positive; disease duration 187(203) days; HAQ 0.9(0.7); DAS28 4.5(1.4). Regression analyses showed that site is an important predictor for mean changes in DAS28 (p ≤ 0.000), increase in DAS28 (p ≤ 0.004), DAS28 remission (p ≤ 0.000), CDAI remission (p ≤ 0.000), and SDAI remission (p ' 0.022). Regression analyses including treatment showed that increases in medication was the strongest predictor of bad outcome (p < 0.05) and caused site to lessen some of its predictive ability.

Mean change in DAS28 from baseline to 6 months and baseline to 12 months by site arranged from smallest to largest
Proportion of patients ever on parenteral methotrexate by site arranged from smallest to largest, p-value = 0.000
Conclusion: The two largest sites had the biggest mean changes in DAS at 6 and 12 months. Site is a predictor for ERA outcome. The fastest and best indicator for low DAS/remission was initial treatment with combination

DMARDs and for 12 months the latter approach or initial treatment with parenteral methotrexate at 20–25mg per week. We cannot say if an unmeasured factor accounted for better changes in DAS at the largest sites.

Discordant Inflammatory Markers in Veterans with Rheumatoid Arthritis: Baseline Characteristics and Relationship with Disease Activity.
Rebecca Belsom[1], Archana Jain[1], Jeffrey Curtis[2], Shuo Yang[2], Ted R. Mikuls[3], Lang Chen[2] and Angelo L. Gaffo[4]. [1]University of Alabama, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [4]Birmingham VA Medical Center and University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Discrepancies between erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) elevations with clinical disease activity frequently occur in rheumatoid arthritis (RA) patients and may be due to comorbid factors other than RA disease activity. We hypothesize that common comorbidities such as current or prior tobacco use, congestive heart failure (CHF), coronary artery disease (CAD), and diabetes mellitus (DM) are associated with discrepancies in inflammatory marker elevations in RA patients.

Methods: We performed a cross-sectional analysis using data collected at the baseline visit in the Veterans Affairs Rheumatoid Arthritis (VARA) cohort. We obtained demographics and comorbidities (tobacco use, CHF, DM, CAD, sleep apnea, chronic obstructive pulmonary disease, malignancy, osteoarthritis, obesity) from linked Decision Support Services (DSS)-derived medical data. We used the following cutpoints to define normal laboratory values for ESR and CRP: 1)ESR for age over 50, 20mm/hr for men and 30 mm/hr for women; age under 50, 15mm/hr for both sexes 2) CRP of 0.8 mg/dL for both sexes. Concordant values were defined as both tests either being above or below these cutpoints. We analyzed the frequencies of comorbidities in patients with low disease activity by the clinical disease activity index (CDAI $\leq$ 10) in relation to: 1) concordant vs. discordant elevations in inflammatory markers and 2) low or moderate/high disease activity by DAS28-ESR ($<$3.2 or $\geq$3.2) and DAS28-CRP ($<$2.67 or $\geq$2.67). Finally, we documented the frequencies of comorbidities in patients who met all the current ACR/EULAR Boolean-based definition requirements and in those who met only the 3 clinical criteria but failed the CRP $\leq$ 1 criterion.

Results: We identified 1158 RA patients with baseline ESR and CRP values. There were 392 with concordantly normal, 368 with concordantly elevated, 205 with elevated ESR/normal CRP and 193 with elevated CRP/ normal ESR at baseline. Patients in low disease activity by the CDAI were equally likely to have an elevated CRP and normal ESR as they were to have a normal CRP and elevated ESR, irrespective of comorbidities. Fewer than 10% of patients with a low CDAI had moderate-high disease activity by DAS28-ESR and DAS28-CRP. There were 157 patients who met all ACR/EULAR Boolean remission criteria and 35 who met all criteria except for CRP $\leq$1. Among tobacco users, 20% who otherwise would have met ACR/EULAR remission criteria did not due to a CRP $>$ 1.

Conclusion: Common medical comorbidities are frequently associated with elevated ESR and/or CRP in patients with RA. ESR by itself or as part of the DAS28-ESR was as likely to be elevated and categorize patients in low disease activity as CRP by itself or as part of the DAS28-CRP. Despite potential concern that the presence of various comorbidities might significantly influence ESR and CRP and decrease the likelihood that patients meet current ACR/EULAR remission criteria, we did not observe strong evidence for this problem in veterans with RA.

403

The Impact of Reaching Low Disease Activity in the First Year On Future Disability and Damage in Patients with Early Rheumatoid Arthritis.
Pooneh Akhavan[1], George A. Tomlinson[2], Paul R. Fortin[3] and Claire Bombardier[1]. [1]University of Toronto, Toronto, ON, [2]Toronto General Hospital, Toronto, ON, [3]Division of Rheumatology, Centre de recherche du centre hospitalier universitaire de Québec, Faculté de médecine de L'université Laval, Quebec City, QC

Background/Purpose: Remission has been proposed as the goal of treatment in patients with early rheumatoid arthritis (RA) by current clinical practice guidelines. Remission is ideal but rare and achieving a low disease activity state (LDA) may be a more realistic goal.The objective of this study was to assess the impact of LDAS at one year on patient function and x-ray progression.

Methods: We used data from The Study Of New Onset Rheumatoid Arthritis (SONORA), a North American prospective cohort of patients with early RA. Our analysis is based on 3 years of follow-up. The Simplified Disease Activity Index (SDAI) and patients' function (HAQ-DI) were measured at baseline, years 1, 2 and 3. Hand x-ray was performed yearly up to year 2; a modified sharp score of $\geq$3.5 indicated important x-ray progression[1].

Multivariate linear regression analysis was performed to assess the impact of reaching LDA (yes/no) at year 1 on future HAQ. Logistic regression was used to assess the impact of reaching LDA at year 1 on x-ray progression (yes/no) at year 2. Both analyses were adjusted for potential clinical confounders. Missing data were imputed using Multiple Imputation.

Results: Baseline characteristics of 984 eligible patients included: mean (sd) age 53 (14.8), disease duration 5.3 (3.1) months, swollen joint count (SJC) 9.4(7.1), tender joint count (TJC) 10.1 (8.0), CRP 1.4 (1.5), SDAI 30.5 (16.6) and median (IQR) HAQ 1.0 (0.37–1.63) and modified Sharp score 3.0 (0.0–7.0). Year 1 LDA was achieved in 37% of patients and x-ray progressed in 17%.Year 1 LDA was strongly associated with lower HAQ at 3 years (p=0.0003). Other predictors included higher baseline HAQ (p$<$.0001), older age (p=0.002), higher Joint space narrowing (JSN) score (p=0.03) and gender (female) (p=0.007) which were associated with higher HAQ. Complete case and imputed analyses showed similar results. Year 1 LDA was significantly *a*ssociated with less X-Ray progression at year 2 (OR 0.68, 95% CI 0.47–0.98; p=0.04) in the imputed case analysis (was not significant in complete case analysis). Baseline Sharp score (1.06, 1.01–1.12; 0.03), positive rheumatoid factor (1.98, 1.2–3.2; 0.01), positive anti-CCP (1.95, 1.1–3.4; 0.03), higher CRP 1.15 (1.01–1.30; 0.03) were also predictors of x-ray progression.

Conclusion: Reaching low disease activity is associated with improved long term outcomes in early RA. This provides strong supports for the current treat to target recommendations. An assessment of prognostic factors at baseline is essential and can help clinicians stratify patients and individualize RA treatment.

Remission is a Difficult Target in Clinical Practice When RA Disease Is Established.
Till Uhlig[1], Elisabeth Lie[1], Cecillie Kaufmann[2], Erik Rødevand[3], Knut Mikkelsen[4], Synnøve Kalstad[5] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Vestre Viken, Drammen, Norway, [3]St. Olavs Hospital, Trondheim, Norway, [4]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [5]Tromsø, Norway

Background/Purpose: Clinical remission is the treatment target in rheumatoid arthritis (RA) and several composite indices are available for evaluation of remission and low disease activity (LDA) states. We currently have little information on how disease duration impacts remission and LDA

rates in daily clinical practice. We examined how often clinical remission and LDA is achieved in clinical practice using existing definitions in RA patients with variable disease duration.

Methods: Data were retrieved from the NOR-DMARD register. For the present analyses we used data from all 4568 patients starting with a synthetic (n=3095) or biological (n=1473) DMARD with available a 3-month follow-up data, and also from 3262 patients with available 6 months follow-up data. Mean (SD) age was 54.7 (13.7) yrs, disease duration was 8.5 (7.9) yrs, 72.7% of patients were females.

Applied definitions for clinical remission included the Disease Activity Score based on 28 joint counts (DAS28) <2.6, the Simplified Disease Activity Index (SDAI) <3.3, the Clinical Disease Activity Index (CDAI) <2.8, Routine Assessment of Patient Index Data (RAPID3, range 0–10) <1, and the ACR/EULAR remission definition (A/E) with tender joint count, swollen joint count, patient global assessment (scale 0–10), and CRP (mg/dL) all <1. We also explored a practical remission definition of A/E without CRP (A/E PRAC), and low disease activity for DAS28 (<3.2), SDAI (<11), CDAI (<10) and RAPID3 (<2). The four investigated categories for disease duration were: <1 year, 1<6 years, 6–10 years, and >10 years.

Results: The table shows percentages for patients according to disease duration periods who met different remission and LDA definitions after 3 months and 6 months of DMARD treatment.

While the new A/E remission criteria were most stringent, for all remission indices the likelihood of remission after 3 and 6 months of DMARD treatment decreased with increasing RA disease duration (Chi square test p<0.01 for all comparisons for 3 and 6 months follow-up). Remission and low disease activity rates after 3 and 6 months were clearly best in patients with up to one year disease duration. Only 6–9 percent of patients with disease duration over 1 year achieved after 3–6 months DMARD treatment a state of remission according to the A/E criteria.

Disease duration (yrs)	All	<1	1-<6	6-<10	>10	All	<1	1-<6	6-<10	>10
	Remission 3 months (%)					Remission 6 months (%)				
DAS28	21.2	26.3	19.9	16.9	18.1	24.7	31.7	20.8	23.5	19.6
SDAI	8.9	12.6	7.6	7.7	6.0	10.8	14.4	10.2	8.8	8.0
CDAI	9.5	12.9	8.2	8.4	6.8	11.4	15.4	10.3	9.7	8.4
RAPID3	19.4	25.5	17.0	19.2	14.0	20.1	26.0	20.0	18.0	14.2
A/E	8.0	11.0	6.8	6.5	5.7	9.4	11.6	9.0	8.0	7.7
A/E PRACT	9.5	12.9	8.6	7.9	6.9	11.3	14.3	10.1	9.8	9.1
	LDA 3 months (%)					LDA 6 months (%)				
DAS28	34.0	39.9	32.2	30.5	30.3	39.7	47.5	38.0	35.0	34.3
SDAI	40.5	46.9	38.3	37.2	36.4	46.7	55.1	45.1	42.7	40.3
CDAI	41.0	47.0	38.5	37.4	37.9	47.3	55.0	45.8	43.2	41.6
RAPID3	38.7	46.8	36.6	36.3	32.4	40.7	48.5	40.2	37.7	33.6

Conclusion: The target of remission varies in difficulty across different remission criteria and is less often achieved with increasing disease duration. These observations have implication for how treat-to-target can be managed in a realistic way in patients with established disease and may indicate that many patients with established disease will need an individualized target due to joint destruction, co-morbidities and other factors.

Frequencies of Boolean and Index Based ACR-EULAR Remissions Differ Slightly Depending On the Method of Patient Global Assessment. Paul Studenic, Josef S. Smolen and Daniel Aletaha. Medical University Vienna, Vienna, Austria

Background/Purpose: Two definitions of remission have been put forward by the ACR and EULAR: a Boolean based, requiring swollen and tender joint counts (SJC, TJC), C-reactive protein (CRP in mg/dl) and patient global assessment (PGA on a 0–10cm scale, VAS) to be ≤1; and an index based definition, requiring the simplified disease activity index (SDAI) to be ≤3.3. The patient global has been shown to be crucial in fulfilling the criteria (1). In many settings a numerical rating scale (NRS) is preferred instead of a VAS. Here, we investigated whether the use of a NRS-like assessment would lead to different remission frequencies compared to a VAS.

Methods: We obtained data of a random cross-sectional visit of RA outpatients from a longitudinal observational database. We used simulated (s)-NRS values, in which VAS values were rounded to the closest integer, for calculation of the SDAI. We compared proportions of patients in Boolean and/or SDAI remission between PGA by VAS and sNRS, evaluating their difference or agreement descriptively by Kappa and receiver operating curve analyses (ROC).

Results: We identified 922 RA patients (80% female, 56% rheumatoid factor (RF) positive, mean disease duration 8 years). In the main analysis, 12.8% of patients were in Boolean remission using sNRS versus 11.3% using VAS (see table).

All patients in Boolean remission using VAS also were in remission by sNRS. Boolean remission using VAS and sNRS had a high agreement (κ of 0.93). SDAI remission frequencies were higher than Boolean remission frequencies with a good agreement (table), and showed a κ of 0.94 for the comparison of VAS and sNRS. In sensitivity analyses, in which we rounded all VAS values either up to the next higher integer, or down to the next lower integer to obtain the sNRS, confirmed the main analysis (table).

When using SDAI to test for Boolean remission in a ROC analysis, SDAI evaluated by VAS and by sNRS showed similar characteristics (AUC=0.99 for both), and sensitivity and specificity for the SDAI remission cutoff of 3.3 were 0.96 and 0.94 for VAS and 0.90 and 0.95 for sNRS.

. Frequencies of remission using different types of PGA

	VAS	sNRS – rounded arithmetically	sNRS – rounded up	sNRS – rounded down
% SDAI Remission	17.5	16.6	13.5	21.0
% Boolean Remission	11.3	12.8	11.3	15.2
% Boolean remitters within SDAI remitters	64.7	72.3	71.7	71.7
% SDAI remitters within Boolean remitters	97.1	90.7	82.7	95.7
Agreement SDAI/Boolean Remission (κ)	0.74	0.77	0.74	0.78

Conclusion: As expected SDAI remission rates were somewhat higher than Boolean remission rates. This was consistent regardless of the method used to assess the patient global. While Boolean remission was about 15% more frequent using sNRS than VAS, SDAI remission was numerically lower with sNRS than VAS. Thus, using a sNRS instead of a VAS for PGA assessment seems to have little impact regarding the achievement of both SDAI and Boolean remission so that sNRS may be a valid tool for PGA assessment in the new remission criteria. However, this assumption will have to be tested using true rather than simulated NRS.

βig-h3 Regulates the Inflammatory Arthritis by Mediating Selective Recruitment of Effector/Memory T Cells. Keum Hee Sa, Jin Hee Kang, Mahmudul Md Alam, Kyung Hwa Lee, Churl Hyun Im, Eon Jeong Nam, In San Kim and Young Mo Kang. Kyungpook National University School of Medicine, Daegu, South Korea

Background/Purpose: Transforming growth factor-beta inducible gene-h3 (βig-h3) is abundantly expressed in synovial tissues of rheumatoid arthritis (RA) and has a regulatory role in growth, differentiation, adhesion, migration, and survival of cells. Previously, we found that βig-h3 regulates the adhesion and migration of T cells expressing a high level of $\alpha5\beta1$ integrin. Therefore, we sought to investigate whether βig-h3 regulates the adhesion of specific T cell subsets selectively and whether it recruits T cells into arthritic tissues differentially according to expression of βig-h3 in a soluble form or *in situ* within synovial tissues.

Methods: T cells were isolated using negative selection kit with MACS. T cell subsets were isolated with antibodies against CD4, CD45RO, and a5 integrin using FACS Aria™. Adhesion of T cell subsets was investigated on βig-h3-coated microtitre plates. βig-h3 overexpressing mice were generated

by the insertion of hβig-h3 transgene downstream of albumin promotor. βig-h3 deficient mice were also prepared by deleting βig-h3 gene using homologous recombination. Collagen antibody induced arthritis (CAIA) model was prepared. Recruitment of effector T cells was evaluated using in vivo homing assay.

Results: T cells isolated from SF of RA were mostly $\alpha5\beta1^{Hi}$, while most of those from PB of controls were $\alpha5\beta1^{Lo}$. Adhesion of SF T cells on the coated βig-h3 was enhanced compared with normal or RA PB T cells, which was inhibited by the function blocking antibody against $\alpha5\beta1$ integrin. RGD peptide, which also binds to $\alpha v\beta3$ integrin, did not block βig-h3-mediated adhesion of T cells, while dhfas-1, a fragment of the 4th fas-1 domain of βig-h3, blocked the adhesion in a dose-dependent manner. The proportion of CD45RO$^+$ cells among T cells was increased in the PB and SF of RA compared to PB of controls. Most of the CD45RO$^+$ T cells were $\alpha5\beta1^{Hi}$ population, while almost all the CD45RO$^-$ T cells were $\alpha5\beta1^{Lo}$ population. βig-h3-mediated adhesion were higher in the CD4$^+$CD45RO$^+\alpha5^{Hi}$ T cells compared with CD4$^+$CD45RO$^+\alpha5^{Lo}$ and CD4$^+$CD45RO$^-\alpha5^{Lo}$ T cells (0.40 ± 0.03 vs 0.19 ± 0.03 and 0.22 ± 0.02, respectively, $P < 0.01$). In βig-h3-trasgenic CAIA mice, arthritis severity was efficiently ameliorated compared with control ($P < 0.05$) and tissue sections revealed a decreased number of infiltrating T cells. In βig-h3 deficient mice, the severity of CAIA was significantly less severe compared to wild type C57BL6/J mice ($P < 0.05$), which was consistent with reduced histologic scores. To evaluate the role of βig-h3 in T cell recruitment into synovial tissues, in vivo homing of T cells was assessed after adoptive transfer of CSFE-labeled effector T cells. Homing of effector T cells into joint tissue was significantly reduced in βig-h3 deficient CAIA mice compared with that of wild type CAIA mice ($P < 0.05$).

Conclusion: The present data indicate that βig-h3 may play a critical role in the regulation of inflammation by the selective recruitment of memory/effector T cells into the synovial tissues of RA through the interaction with $\alpha5\beta1$ integrin. These results implicate a soluble βig-h3-based therapeutic strategy for the treatment of inflammatory arthritis.

The I50V *IL4R* SNP Is Associated with Increased Th17 Cell Frequency and Poor Clinical Outcome in Rheumatoid Arthritis. Jan Leipe[1], Iryna Prots[2], Markus A. Schramm[1], Matthias Witt[1], Axel P. Nigg[1], Christiane S. Reindl[1], Claudia Dechant[1], Mathias Grunke[1], Hendrik Schulze-Koops[1] and Alla Skapenko[1]. [1]University of Munich, Munich, Germany, [2]Junior Research Group III, Interdisciplinary Center for Clinical Research Nikolaus-Fiebiger Center for Molecular Medicine, Erlangen

Background/Purpose: A single nucleotide polymorphism (SNP) in the IL4R gene (I50V, rs 1805010) has previously been associated with an aggressive destructive course of rheumatoid arthritis (RA). Patients homozygous for the V50 allele, which has been linked to diminished IL-4 signaling, develop more often bone erosions within the first two years of disease. On the other hand, Th17 cells and their cytokine IL-22 have also been associated with cartilage and bone destruction. Development of Th17 cells is negatively regulated by IL-4 signaling through the IL-4R. Because of the functional differences of the two *IL4R* alleles, we investigated a possible association between I50V *IL4R* SNP and Th17 cell frequencies in active RA.

Methods: *IL4R* genotypes were determined in well-defined cohorts of patients with early, treatment-naive RA (n=49) as well as in controls (healthy controls, [n=24] and patients with osteoarthritis [OA, n=15]) by TaqMan SNP assay. IL-17, IL-22 serum levels and *ex vivo* Th17 cell frequencies were analyzed by ELISA and flow cytometry. To assess the inhibitory effect of IL-4 on Th17 cell development, we primed CD4 T cells for 72 h in the presence or absence of IL-4 and determined Th17 cell frequencies. Clinical and radiographic data were evaluated at baseline and after one year after disease onset. Correlation of clinical data and radiographic progression was performed using Pearson rank correlation test or Chi square test.

Results: Gentotyping revealed 10 patients homozygous for the I50 alleles (I50I), 32 heterozygous patients (I50V), and 7 homozygous VV patients (V50V). Clinical activity was consistently higher in homozygous V50V RA patients during follow-up as compared to the i50V and I50I patients, despite similar treatment regimens. Moreover, the loss of functional *IL4R* alleles was associated with the presence of erosions. In all study cohorts T cells from V50V individuals responded weaker to IL-4 inhibition of Th17 cell development as compared to their I50I or I50V counterparts. The inhibitory effect of IL-4 on Th17 development in V50V cells was however even less prominent or even completely absent in RA patients as compared to controls. Accordingly, frequencies of Th17 cells were significantly increased in the V50V group of RA patients. RA patients homozygous for the V50 allele variant demonstrated significantly higher IL-17 and IL-22 serum levels as compared to I50I or I50V RA patients and healthy or OA controls.

Conclusion: Together, the data indicate that the V50 allele of the I50V *IL4R* SNP renders CD4 T cells from RA patients insensitive to IL-4. The V50 allele of the IL-4R might therefore contribute to the increased Th17 cell frequency, clinical activity and radiographic progression in RA.

Alpha-Enolase Facilitates Migration of Fibroblast-Like Synoviocytes in Rheumatoid Arthritis. Kichul Shin[1], Ji Ah Park[2], Seyeon Bae[1], Jae Seung Kang[1] and Yeong Wook Song[3]. [1]College of Medicine, Seoul National University, Seoul, South Korea, [2]Seoul National Hospital, Seoul, South Korea, [3]Seoul National University Hospital, Seoul, South Korea

Background/Purpose: Alpha-enolase (ENO1) is a multifunctional glycolytic enzyme ubiquitously expressed in the cytoplasm. Citrullinated ENO1 is reported to be a candidate autoantigen in rheumatoid arthritis (RA), yet its specific biologic function remains unknown. Histologic analysis indicates that ENO1 is expressed in fibroblast-like synoviocytes (FLS), monocytes, and endothelial cells in the synovium. In pro-inflammatory conditions, ENO1 is translocated to the cell surface where it activates plasminogen. Its expression in monocytes mediates migration of the cells into inflamed lung tissues in animal models. Our aim was to investigate the role of surface-expressed ENO1 in RA FLS, the key constituent of pannus in RA synovium.

Methods: FLS from RA synovial tissues were isolated and cultured *in vitro*. ENO1 expression on the cell surface was assessed by confocal microscopy. Cell surface-expressed ENO1 was treated with a mouse anti-human ENO1-stimulating monoclonal antibody as well as an isotype control. Scratch test of cultured FLS and transwell experiments under platelet-derived growth factor (PDGF) were performed to assess FLS migration. Cytoskeletal rearrangement was analyzed after staining FLS with an anti-fillagrin antibody. Fluo-4 fluorophore was used for calcium-flux assays directly on discs plated with FLS.

Results: Cell surface ENO1 expression was low in (56 passages) cultured FLS under normal condtions. However, overnight TNF-alpha (as low as 0.1 ng/ml) treatment induced ENO1 translocation to the cell surface, which peaked at 24 hours (figure). Stimulation of cell surface-expressed ENO1 induced faster repopulation of FLS in the scratch test assay, and increased PDGF-induced transwell migration. Cytoplasmic actin filament rearrangement in FLS was markedly enhanced with ENO1 stimulation. Moreover, ENO1 stimulation induced a positive calcium flux response in FLS under intravital confocal microscopy.
Conclusion: Translocation of cytoplasmic ENO1 to the cell surface in RA FLS is potentiated by TNF-alpha. Our results indicate that ENO1 can contribute to migration of RA FLS, especially under the pro-inflammatory milieu as in the RA synovium.

Pathway Analysis of Genome-Wide Association Studies On Rheumatoid Arthritis. Young Ho Lee[1], Sung Jae Choi[1], Jong Dae Ji[1] and Gwan Gyu Song[2]. [1]Korea University Medical Center, Seoul, South Korea, [2]Korea Univ College of Med, Seoul

Background/Purpose: Genome-wide association studies (GWASs) have been successfully used to identify novel common genetic variants that contribute to susceptibility to complex diseases, but individual GWASs are limited in terms of identifying new loci. Thus, pathway-based analysis is required to identify further new loci that contribute to susceptibility to complex diseases. The aims of this study were to identify candidate causal single nucleotide polymorphisms (SNPs) and candidate causal mechanisms of rheumatoid arthritis (RA) and generate hypothesis for SNP à gene à pathways.

Methods: An meta-analysis dataset of RA GWASs was used that included 2,554,714 SNPs in 5,539 RA cases and 20,169 controls of European descent. ICSNPathway (Identify candidate Causal SNPs and Pathways) analysis was applied to meta-analysis results of the RA GWAS dataset.

Results: ICSNPathway analysis identified 49 candidate causal SNPs and 37 candidate causal pathways. The top 5 candidate causal SNPs, rs1063478 (p = 5.40E-09), rs375256 (p = 3.44E-09), rs365066 (p = 3.60E-30), rs2581 (p = 2.7E-25), and rs1059510 (p = 2.52E-06) were all at human leukocyte antigen (HLA) loci. These candidate causal SNPs and pathways provide 22 hypothetical biological mechanisms. The most strongly associated pathway concerned HLA: rs1063478 (nonsynonymous coding) à HLA-DMA à antigen processing and presentation of peptide antigen. ICSNPathway analysis identified two candidate causal non-HLA SNPs and ten candidate causal pathways, which provided two hypothetical biological mechanisms. First, rs2476601 (nonsynonymous coding [deleterious]) (p = 6.22E–71) à protein tyrosine phosphatase nonreceptor 22 (PTPN22) à immune response-activation cell surface receptor signaling pathway, and, rs2230926 (nonsynonymous coding) (p = 1.26E–07) à tumor necrosis factor-alpha-induced protein 3 (TNFAIP3) à the CD40L signaling pathway.

Conclusion: The application of ICSNPathway analysis to meta-analysis results of RA GWAS datasets resulted in the identification of candidate causal SNPs and pathways involving HLA-DMA, PTPN22, and TNAIP3 that might contribute to RA susceptibility.

Early Growth Response-1 (EGR-1) Controls Synoviocyte Apoptosis, and Its Expression Is Regulated by the Direct Binding of Fibroblast Growth Factor-1 (FGF1) or Insulin-Like Growth Factor-1 (IGF1) to Integrin $\alpha v\beta 3$. Shino Tanaka[1], Jun Saegusa[1], Seiji Kawano[1], Yoshikazu Takada[2], Shunichi Kumagai[3] and Akio Morinobu[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]University of California, Davis, School of Medicine, Sacramento, CA, [3]Shinko Hospital, Kobe, Japan

Background/Purpose: Growth factors such as fibroblast growth factor (FGF) and insulin-like growth factor (IGF) are of interest in the initiation and development of rheumatoid arthritis (RA) synovial hyperplasia, because of their potent mitogenic and angiogenic activities. The traditional understanding of FGF and IGF signaling has held that their binding to their respective receptor (i.e., the FGF receptor [FGFR] or the IGF receptor [IGFR]) is sufficient to initiate signaling. We recently demonstrated that FGF1 binds directly to integrin $\alpha v\beta 3$, and that an integrin-binding-defective FGF1 mutant (FGF^{R50E}) cannot induce cell proliferation, even though the mutant still binds FGFR; this is also true for IGF1. In both cases, a ternary complex, FGF1-FGFR-integrin $\alpha v\beta 3$ or IGF1-IGFR-integrin $\alpha v\beta 3$, was formed. However, the mechanism underlying the cross-talk between growth-factor-receptor signaling and integrin signaling is unknown. Here we investigated how the growth factor-integrin $\alpha v\beta 3$ interaction is involved in growth-factor signaling in RA synoviocytes.

Methods: Several mutations were introduced at the interface of FGF1 or IGF1 with integrin $\alpha v\beta 3$, and integrin-binding-defective FGF1 and IGF1 mutants (FGF^{R50E} and IGF$^{R36E/R37E}$) were generated. RA synoviocytes were stimulated with FGF1 or FGF^{R50E}, and comprehensive gene-expression profiling was performed by cDNA microarray. Intracellular signaling in synoviocytes treated with FGF1, FGF^{R50E}, IGF1, and IGF$^{R36E/R37E}$was evaluated by real-time PCR and Western blot analyses. Synoviocytes transfected with scramble siRNA or early growth response-1 (EGR-1)-specific siRNA were treated with various apoptotic stimuli, and cell viability was measured by the WST-8 assay.

Results: The integrin-binding-defective mutants (FGF^{R50E} and IGF$^{R36E/R37E}$) showed a markedly reduced ability to induce the cell proliferation

of RA synoviocytes. The cDNA microarray analysis showed significantly reduced EGR-1 mRNA expression in the FGF^{R50E}-treated synoviocytes. Furthermore, EGR-1 mRNA and protein were rapidly induced in RA synoviocytes in response to FGF1 or IGF1, but the EGR-1 expression was significantly impaired in FGF^{R50E}- or IGF$^{R36E/R37E}$-treated synoviocytes. In addition, the down-regulation of EGR-1 by siRNA inhibited the apoptosis of synoviocytes treated with H_2O_2 or doxorubicin.

Conclusion: EGR-1 plays a pivotal role in synoviocyte apoptosis, and its expression is regulated by the direct binding of FGF1 or IGF1 to integrin $\alpha v\beta 3$. This integrin-growth factor interaction may be a novel therapeutic target for RA.

Early Menopause, Smoking and Circulating Antibodies Against Citrullinated Peptides in the Pre-Clinical Phase of Rheumatoid Arthritis. Mitra Pikwer[1], Johan Rönnelid[2], Monika Hansson[3], Ulf Bergström[1], Lennart T.H. Jacobsson[1], Linda Mathsson[2], Per Johan Jakobsson[3], Guy B. Serre[4], Rikard Holmdahl[5], Lars Klareskog[6] and Carl Turesson[1]. [1]Lund University, Malmö, Sweden, [2]Uppsala University, Uppsala, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Centre National de la Recherche Scientifique - Université de Toulouse, Toulouse, France, [5]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [6]Karolinska Institute, Stockholm, Sweden

Background/Purpose: Previous studies indicate that anti-citrullinated peptide antibodies (ACPAs) may be detected in individuals who later develop rheumatoid arthritis (RA) years before onset, and that smoking and early menopause (before age 46) are risk factors for RA. Whereas smoking is a predictor of seropositive RA, early menopause has been associated with a milder, predominantly rheumatoid factor negative, phenotype. The objective of this study was to investigate circulating ACPAs and their relation to age at menopause and smoking before the onset of RA.

Methods: Incident cases of RA were identified among participants (n=30447; 18326 women) in a community based health survey, which was linked to local and national registers, followed by a structured review of the medical records. One control, matched for age, sex and year of inclusion in the health survey, was selected for each validated case. Using a multiplex assay system, sera from 131 female pre-RA cases and 131 controls were investigated for 12 different ACPA fine specificities. For all investigated antibodies, previous studies had shown good correlations between results obtained using this system and standard ELISAs. Corrected net values for ACPA specificity were calculated by subtracting values for arginine control peptides from the corresponding citrullinated peptides. Cut offs were set at the 98th percentile, based on investigation of sera from the matched controls. Analyses were stratified by time from inclusion in the health survey to RA diagnosis (1–4, 5–7 and 8–13 years, respectively), and by age at menopause (≤ 45 years vs > 46 years) or history of ever smoking.

Results: Serum was available from 131 women, who were diagnosed with RA a median of 5.5 years (IQR 3–8; range 1–13) after inclusion in the health survey. Seventy (53 %) of the pre-RA cases were positive for ≥ 1 ACPA. Significantly greater numbers of positive ACPA specificities were detected among pre-RA cases sampled closer to RA diagnosis (p for trend 0.03). A history of early menopause (p=0.001) and ever smoking (p=0.003) were both associated with subsequent development of RA. Ever smokers were more likely to be positive for most ACPAs and had higher numbers of positive ACPA specificities compared to never smokers (p=0.047). Ever smokers were more likely to be positive for ≥ 1 ACPA compared to never smokers, regardless of the time from inclusion to RA diagnosis. By contrast, women with a history of early menopause were less likely to be positive for ≥ 1 ACPA compared to those with normal or late menopause, in particular among cases included ≥ 8 years before RA diagnosis (29 % vs. 48 %).

Conclusion: The early occurrence of ACPA and the increase in ACPA specificities with a shorter time to diagnosis indicate that epitope spreading may precede disease onset. The immune phenotype in the pre-clinical phase of RA may differ between subsets depending on environmental exposures and associated disease mechanisms. The present results suggest that hormonal changes influence pathways in the pathogenesis of RA that are distinct from those associated with smoking.

Single Nucleotide Polymorphisms within the HLA-DRB1 Gene in Relation to Antibodies Against Citrullinated Peptides in Individuals Prior to the Development of Rheumatoid Arthritis. Lisbeth Arlestig[1], Mikael Brink[2], Monika Hansson[3], Per Johan Jakobsson[3], Rikard Holmdahl[4], Linda Mathsson[5], Johan Ronnelid[5], Lars Klareskog[6] and Solbritt M. Rantapaa-Dahlqvist[7]. [1]Umeå University, Umea, Sweden, [2]Umea University, Umea, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [5]Uppsala University, Uppsala, Sweden, [6]Karolinska Institute, Stockholm, Sweden, [7]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umea, Sweden

Background/Purpose: Multiplex analysis has demonstrated the presence of several antibodies against cyclic citrullinated peptides (ACPA) preceding the development of rheumatoid arthritis (RA) by several years. Certain HLA-DRB1* alleles are strongly associated with RA.

To relate the presence of different ACPAs, in individuals before the onset of symptoms of RA, to single nucleotide polymorphisms (SNPs) within the HLA-DRB1 region in order to identify the SNPs most highly associated with the ACPAs analysed in the disease development.

Methods: The study group comprised 406 individuals, with 717 samples, who were identified before the onset of symptoms (median (IQR) 7.4 (9.3) years), as donors to the Medical Biobank of Northern Sweden. A total of 976 population controls were identified from the Medical Biobank for analysis of antibodies against 10 different citrullinated peptides in plasma using a microarray system developed in collaboration withPhadia AB/Thermofisher, Uppsala, based on their ISAC platform. In a previous study the highest frequencies of antibodies were found for fibrinogen (Fib) β36–52, α-enolase (CEP-1), and filaggrin. Anti-CCP2 antibodies were analysed using ELISA (Euro-Diagnostics). Samples from the same individuals were genotyped with the Immunochip custom array according to Illumina protocols (SNP&SEQ Technology Platform, Uppsala, Sweden). 81 SNPs covering the HLA-DRB1* to DQA1* region were analysed. The Haploview software version 4.2 was used for haplotype and association analysis with a permutation test.

Results: Thirty-seven of the SNPs were associated with the pre-diseased individuals compared with controls. After permutation test 22 of them and six haplotypes (7–16 SNPs) remained significantly associated. Anti-CEP-1 antibodies were associated with 15 SNPs although none remained significant after permutation tests. Anti-filaggrin antibodies were related to 4 SNPs, two of which were similar as for anti-CEP-1 (rs9271588 and rs9272363), none remained significant after permutation test. Anti-Fibβ36–52 antibodies were associated with 4 different SNPs compared with the other antibodies and none were significant after permutation test. Of the SNPs analysed 21 were associated with anti-CCP2 antibodies and two of them (rs9271588, rs9271850) and three haplotypes were significantly associated after a permutation test.

Conclusion: The presence of ACPAs is related to a number of SNPs within the HLA- region albeit with somewhat different patterns between the various antibodies.

α(1,2)-Linked Fucosylated Cytokines Are Upregulated in Rheumatoid Arthritis. Takeo Isozaki[1], Jeffrey H. Ruth[1], M. Asif Amin[1], Phillip L. Campbell[1], Christine M. Ha[1] and Alisa E. Koch[2]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: Glycosylation is a common post-translational modification of proteins in eukaryotes. Fucosylated glycans are synthesized by fucosyltransferases (futs). We previously reported that sialyl Lewis[x], synthesized by futs, is involved in angiogenesis. Fucosyltransferase 1 (fut1) is an α(1,2)-fucosyltransferase responsible for synthesis of the H blood group and Lewis[y] antigens. We also reported that soluble H and Lewis[y] antigens are mediators of inflammatory cell adhesion and angiogenesis. However, a direct role of α(1,2)-linked fucose in rheumatoid arthritis (RA) has not been demonstrated.

Methods: Assay of total α(1,2)-linked fucosylated proteins in RA, osteoarthritis (OA) and normal (NL) synovial tissue (ST) homogenates were performed by enzyme-linked immunosorbent assay (ELISA). 2-fucosyl-

lactose bovine serum albumin (2'FL-BSA) was used as a standard. We previously showed that fut1 gene deficient mice in which KRN arthritis has been induced have less joint monocyte chemotactic protein (MCP)-1/CCL2 and interleukin (IL)-1β than wild type mice. Hence, we measured IL-1β and MCP-1/CCL2 in RA, OA and other inflammatory disease synovial fluids (SFs) by ELISA to determine if these cytokines have been modified. We also examined tumor necrosis factor (TNF)-α for fucosylation, as TNF-α is a central cytokine in RA pathology. To determine whether fut1 was expressed by NL and RA synovial fibroblasts, real time polymerase chain reaction (RT-PCR) was performed. To block the expression of fut1, RA synovial fibroblasts were transfected with fut1 small interfering RNA (siRNA). After treatment with fut1siRNA, RA synovial fibroblasts were stimulated with TNF-α for 1 hour. We then measured the expression of cytokines important in RA. MCP-1/CCL2, epithelial neutrophil-activating protein 78 (ENA-78)/CXCL5 and vascular endothelial growth factor (VEGF) mRNA were measured by RT-PCR.

Results: Total α(1,2)-linked fucosylated proteins in RA ST were significantly higher compared to OA STor NL ST [mean $\pm$ SEM 74 $\pm$ 21 ng/ml (n=5), 25 $\pm$ 4 ng/ml (n=7) and 29 $\pm$ 6 ng/ml (n=9), respectivel, p<0.05]. Specifically, α(1,2)-linked fucosylated IL-1β and MCP-1/CCL2 in RA synovial fluids were 6 $\pm$ 2% of total fucosylated proteins (n=9) and 20 $\pm$ 4% of total fucosylated proteins (n=12), respectively. In addition, α(1,2)-linked fucosylated TNF-α in RA synovial fluids was significantly higher than in OA and other inflammatory disease synovial fluids [950 $\pm$ 220 pg/ml (n=22), 150 $\pm$ 90 pg/ml (n=13) and 30 $\pm$ 20 pg/ml (n=11), respectively, p<0.05]. We also found that fut1 messenger RNA (mRNA) in cultured RA synovial fibroblasts was significantly elevated compared to NL synovial fibroblasts (p<0.05). Additionally, RA synovial fibroblasts transfected with fut1 siRNA had significantly lower mRNA expression for MCP-1/CCL2, ENA-78/CXCL5 and VEGF than did control siRNA transfected synovial fibroblasts.

Conclusion: These data show that α(1,2)-linked fucosylated proteins are upregulated in RA ST compared to other STs. We also show that fut1 in RA synovial cells is necessary for production of variety of cytokines. Targeting fut may be a novel way to alter joint cytokine production.

First-Degree Relatives without Rheumatoid Arthritis Exhibit Reactivity to Multiple Anti-Citrullinated Protein Antibodies in Association with Rheumatoid Arthritis-Related Clinical Characteristics: Studies of the Etiology of Rheumatoid Arthritis. Kendra A. Young[1], Kevin D. Deane[2], Lezlie A. Derber[3], Jan M. Hughes-Austin[4], Michael H. Weisman[5], Jane H. Buckner[6], Ted R. Mikuls[7], James R. O'Dell[8], Richard M. Keating[9], Peter K. Gregersen[10], V. Michael Holers[2] and Jill M. Norris[1]. [1]Colorado School of Public Health, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Colorado Anschutz Medical Campus, Aurora, CO, [4]Colorado School of Public Health/University of Colorado Anschutz Medical Campus, Aurora, CO, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]Benaroya Research Institute at Virginia Mason, Seattle, WA, [7]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [8]Univ of Nebraska Med Ctr, Omaha, NE, [9]University of Chicago, Chicago, IL, [10]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY

Background/Purpose: Prior to diagnosis of rheumatoid arthritis (RA), there are increases in the number of citrullinated proteins that anti-citrullinated protein antibodies (ACPA) target, suggesting an expansion of autoimmunity in early RA development that, if fully understood, may provide insight into the earliest antigenic targets important in disease pathogenesis. Anti-CCP assays are currently the most widely used ACPA assessments; however, the specific epitopes recognized by these commercial assays are unknown, thereby limiting the ability to make inferences about the type and expansion of ACPA responses. Our objective was to utilize multiplex technology to examine ACPA reactivity to specific citrullinated proteins and peptides in the pre-diagnosis period of RA development by performing this analysis in first-degree relatives (FDRs) of RA probands, who do not have RA, but are at increased risk of future RA.

Methods: We selected 113 FDRs (Ab+) who had been positive at $\geq$1 research visit for any of 5 Ab: rheumatoid factor (RF) by nephelometry; RF by ELISA for isotypes IgM, IgG, or IgA; or anti-CCP2; and 100 FDRs (Ab-) who had never been autoantibody positive. A panel of 18 ACPA was measured using a bead-based assay in serum from 397 visits by these FDRs. Cut-offs for positivity for each ACPA were determined using receiver

operating characteristic (ROC) curves of data from 200 patients with established RA (1987 ACR criteria), and 98 blood-bank controls, where we found that positivity for ≥ 9 ACPAs had 67% sensitivity and 92% specificity for RA, comparable to the 70% sensitivity and >95% specificity for anti-CCP2. In FDRs, we examined reactivity to ACPA and associations between ACPA (number positive and positivity for ≥ 9 ACPA) and RA-related characteristics including positivity for RF (nephelometry or isotypes) and swollen or tender joints on exam. While we had too few anti-CCP2 positive FDRs to test (n=8), associations were examined with the high-risk autoantibody profile (i.e., anti-CCP2 and/or ≥2 RF isotypes), which was shown to be highly specific (>96%) for future RA.

Results: Both Ab+ and Ab- FDRs showed reactivity to multiple ACPA, although Ab+ FDRs were positive for a greater number of ACPA than Ab- FDRs (mean 3.1 ± 4.3 vs. 2.1 ± 2.8, p=0.04). Of the 8 anti-CCP2 positive FDRs, 5 were positive for at least 9 ACPA, and 4 were positive for 16 or more ACPA. 76% of anti-CCP2 negative FDRs were positive for ≤ 2 ACPA, and 10% were positive ≥ 9 ACPA. Being positive for a greater number of ACPA is associated with being positive for RF (OR=1.22, 95%CI 1.09–1.35), with the IgM (OR=1.17, 95% CI 1.00–1.3) and IgA (OR=1.14, 95% CI 1.02–1.28) RF isotypes, and for those positive for anti-CCP2 and/or ≥2 RF isotypes (OR=1.22, 95%CI 1.09–1.35). FDRs positive for at least 9 ACPA had significantly greater odds of having least one tender joint on exam (OR=7.59, 95% CI 1.97–29.25). A similar association was observed for increasing number of ACPA (OR=1.21, 95% CI 1.05–1.39).

Conclusion: These results indicate that there may be RA-related autoimmunity and even early inflammatory arthritis in FDRs without 1987 ACR classified RA, even in FDRs negative for RF and anti-CCP2. Prospective follow-up is needed to further asses these findings.

Hypoxia-Induced Endogenous Prostaglandin E2 Negatively Regulates Hypoxia-Enhanced Aberrant Overgrowth of Rheumatoid Synovial Tissue. Hirofumi Mitomi[1], Hidehiro Yamada[1], Toshiko Nozaki Shibata[1], Hiroshi Ito[1], Yoshioki Yamasaki[1], So Nomoto[2], Atsushi Kusaba[3], Hiroki Yamashita[3] and Shoichi Ozaki[1]. [1]St. Marianna University, Kawasaki, Japan, [2]Saiseikai Yokohamashi Tobu Hospital, Yokohama, Japan, [3]Ebina General Hospital, Ebina, Japan

Background/Purpose: During isometric exercise, the synovial joint tissue is prone to hypoxia, which is further enhanced in the presence of synovial inflammation. Hypoxia is also known to induce inflammatory cascades, suggesting that periodic hypoxia perpetuates synovitis in rheumatoid arthritis. We previously established an *ex vivo* cellular model of rheumatoid arthritis using the synovial tissue-derived inflammatory cells, which reproduced aberrant synovial overgrowth and pannus-like tissue development *in vitro*. Using this model, we investigated the regulatory mechanism of synovial cells against hypoxia in rheumatoid arthritis.

Methods: Inflammatory cells that infiltrated synovial tissue from patients with rheumatoid arthritis were collected without enzyme digestion, and designated as synovial tissue-derived inflammatory cells. Under normoxia or periodic hypoxia twice a week, their single-cell suspension was cultured in medium alone to observe an aberrant overgrowth of inflammatory tissue *in vitro*. Cytokines produced in the culture supernatants were measured by enzyme-linked immunosorbent assay (ELISA) kits.

Results: Primary culture of the synovial tissue-derived inflammatory cells under periodic hypoxia resulted in the attenuation of the spontaneous growth of inflammatory tissue *in vitro* compared to the culture under normoxia. Endogenous prostaglandin E2 (PGE2) production was enhanced under periodic hypoxia. When endogenous PGE2 was blocked by indomethacin, the aberrant tissue overgrowth was more enhanced under hypoxia than normoxia. Indomethacin also enhanced the production of TNF-alpha (TNF-α), macrophage colony-stimulating factor (M-CSF), matrix metalloproteinase-9 (MMP-9) under periodic hypoxia compared to normoxia. EP4-specific antagonist reproduced the effect of indomethacin. Exogenous PGE1 and EP4-specific agonist effectively inhibited the aberrant overgrowth and the production of the inflammatory mediators under periodic hypoxia as well as normoxia.

Conclusion: The enhancing effect of periodic hypoxia on the aberrant overgrowth of rheumatoid synovial tissue was effectively down-regulated by

the simultaneously induced endogenous PGE2. It is suggested that long-term use of non-steroidal anti-inflammatory drugs (NSAIDs) enhances hypoxia-induced synovial overgrowth in rheumatoid arthritis.

Dyslipidaemia in Early Rheumatoid Arthritis Patients Is Common and Not Influenced by Two Years of Effective DMARD Therapy. the Opera Study. Torkell Ellingsen[1], Kim Horslev-Petersen[2], Merete L. Hetland[3], Peter Junker[4], Jan Podenphant[5], Mikkel Ostergaard[5] and Kristian Stengaard-Pedersen[6]. [1]Regional Hospital, Silkeborg, Denmark, [2]Southern University, Denmark, [3]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [4]Odense University Hospital, Denmark, [5]Copenhagen University Hospital at Glostrup, Denmark, [6]Arhus University Hospital, Denmark

Background/Purpose: In a cohort of early (<6 month duration) treatment-naïve rheumatoid arthritis (ERA) patients (the OPERA-study (1)) to measure lipid levels at baseline, year one and two. Further, to analyze for changes in lipid levels in relation to effective DMARD treatment during two years.

Methods: In 180 ERA patients total s-cholesterol, s-HDL, s-LDL, s-VLDL, s-triglyceride were measured by standardized techniques. All patients were treated with methotrexate (MTX) (20 mg/week) and triamcinolone intraarticularly in any swollen joint for 2 years and in addition randomized to receive adalimumab (ADA) or placebo (PLA)) during the first year. After year 1, ADA and PLA were withdrawn. If patients had DAS28 (CRP) > 3.2 during year 2, sulphasalazine (SZS) and hydroxychloroquine (HCQ) were added to MTX and if active disease persisted after withdrawel of ADA/PLA, ADA replaced SZS and HCQ in both treatment arms (1). Analysis was by ITT with last observation carried forward. Comparisons by Wilcoxon's test.

Results: Baseline characteristics and disease activity were similar in the MTX+PLA and MTX+ADA groups: age 54 vs 56 years; women 69% vs 63%; disease duration 83 vs 84 days; anti-CCP positive 70% vs 60%; IgM-RF positive 74% vs 70%; DAS28 (CRP) median 5.6 (range3.8–7.3) vs. 5.5 (3.8–7.8) respectively. The treatment had an excellent effect on inflammation but no effect on the dyslipidaemiae:

DAS28 Lipid levels mmol/L	Baseline Median (range)	Year 1 Median (range)	Year 2 Median (range)	Baseline % abnormal
DAS28(CRP)	5.6 (3.3–8.6)	2.0 (1.7–4.7)	2.0 (1.7–6.5)	–
Total s-cholesterol	4.8 (2.2–7.8)	5.1 (3.1–8.4)	5.1 (3.1–9.2)	50% >5.0
s-HDL	1.4 (0.7–2.7)	1.7 (0.8–3.6)	1.5 (0.7–2.8)	Male 53%>1.0 Female 84%>1.2
s-LDL	2.8 (0.8–6.1)	2.9 (0.9–6.1)	2.8 (0.9–5.9)	40%>3.0; 93%>1.8
S-VLDL	0.6 (0.1–1.7)	0.5 (0.2–1.6)	0.5 (0.2–1.7)	
s-triglyceride	1.3 (0.3–3.8)	0.9 (0.4–3.5)	1.1 (0.4–3.8)	27%>1.7
s-Cholesterol/ s-HDL	3.4 (1.7–9.8)	3.2 (1.3–7.2)	3.2 (1.8–7.3)	–

No effect of the efficient DMARD treatment strategy was observed after one or two years in any of the treatment arms regarding the levels of total s-cholesterol, s-HDL, s-LDL, s-VLDL or s-triglyceride (p-levels between 0.07–0.97). At baseline more than half of the 180 ERA patients had abnormal lipid concentrations compared to the reference levels.

Conclusion: In a Danish cohort of ERA patients (OPERA study) more than half of the patients had abnormal serum lipid concentrations at the time of diagnosis. Two years of effective synovitis suppression with MTX and glucocorticoid intraarticular and addition of ADA or PLA during the first year did not influence the dyslipidaemiae. The Potential Role of *PTPRD* Gene Copy Number Variation in Susceptibility to Rheumatoid Arthritis. Seung Cheol Shim, Donghyuk Sheen, Mi Kyoung Lim and Hyo Park. Eulji University Hospital, Daejeon, South Korea

Background/Purpose: Since it is important to explore genetic variations associated with rheumatoid arthritis (RA), genome-wide association studies (GWAS) have led to the identification of RA genetic variants putatively associated with susceptibility. Recently, copy number variation (CNV) may also affect susceptibility to diseases, which have been already observed in diverse autoimmune diseases. Protein tyrosine phosphatase receptor D (PTPRD) is a member of the receptor-like PTP which expresses in the B cell lines and thymus and could be involved in the pathogenesis of autoimmune diseases. In this study, we investigated whether the variation of the *PTPRD* gene copy number related with susceptibility to RA.

Methods: To investigate whether the variation of the *PTPRD* gene copy number influence the pathogenesis to RA, blood samples and clinical records were obtained from 217 RA patients (184 females, 33 males) and 205 healthy controls. The genomic DNA of RA patients and healthy controls was extracted from leukocytes in peripheral blood using the Genomic DNA Extraction kit (iNtRON Biotechnology, Korea). To measuring the copy number of *PTPRD* gene, the quantitative real-time PCR (QPCR) was carried out using Mx3000P QPCR system (Stratagene, La Jolla, CA) and each sample for each gene was assayed in triplicate. Western blot was conducted to detect expression levels of *PTPRD*

Results: The copy number of *PTPRD* gene in RA patients was compared with that in healthy controls. The proportion of the individuals with <2 copy of *VPREB1* was significantly higher in patients than in controls, while that of the individuals with >2 copy was lower in patients than in controls. The average relative copy number of the *PTPRD* gene in RA patients (1.14, 95 % CI (1.12–1.16)) was significantly lower than that in healthy controls (1.65, 95 % CI (1.12–1.16), p < 0.0001) (Figure 1). Furthermore, we also investigated association between copy number of *PTPRD* and RA phenotype such as RF factor and anti-CCP levels, which showed no association between copy number of *PTPRD* and both RA phenotypes. Western blot showed the lower expression of *PTPRD* in patients with RA compared to control subjects (Figure 2).
Conclusion: This is the first evidence showing the association between low copy number of the PTPRD gene and susceptibility to RA, which may help understanding the pathogenesis of RA and other autoimmune disorders like affecting maturation and differentiation of T cell and B cells.

Disclosure: S. C. Shim, None; D. Sheen, None; M. K. Lim, None; H. Park, None.

Immediate Early Response Gene X-1 Is Over-Expressed and Regulates Apoptosis and Cytokine Production in Rheumatoid Arthritis Synovial Fibroblasts. Akio Morinobu[1], Masaaki Fujita[2], Shino Tanaka[3], Jun Saegusa[2] and Shunichi Kumagai[4]. [1]Kobe university graduate school of medicine, Kobe 650-0017, Japan, [2]Kobe University Graduate School of Medicine, Kobe, Japan, [3]Rheumatology and Clinical Immunology, Kobe, Japan, [4]Shinko hospital, Kobe, Japan

Background/Purpose: Histone deacetylase inhibitors (HDACi) are potential therapeutic drugs for the treatment of rheumatoid arthritis (RA). We found that an HDACi up-regulates the gene expression of immediate early response gene X-1 (IEX-1) in rheumatoid arthritis synovial fibroblasts (RA-SF). IEX-1 is regulated by various stress stimuli and involved in apoptosis and cell growth. Since the role of IEX-1 has never been examined in RA, we examined the expression and function of the molecule in RA-SF.

Methods: Synovial fibroblasts from RA and OA patients were cultured and used between 2–4 passages. Gene and protein expression was determined by qPCR and Western blotting, respectively. Apoptosis was detected by annexin V staining using a flow cytometer. To examine the function of IEX-1, IEX-1 was knocked down by siRNA or over-expressed with lipofection.

Results: (1) IEX-1 mRNA levels were higher in RA-SF than in OA-SF. LPS and TNFa up-regulated the IEX-1 mRNA expression in RA-SF. (2)Over-expression of IEX-1 induced apoptosis and promoted anti-Fas mAb-mediated apoptosis in RA-SF, while knockdown of IEX-1 protected RA-SF from anti-Fas mAb-mediated apoptosis. Also, over-expression of IEX-1 augmented anti-Fas mAb-induced caspase-8 activation, while knockdown of IEX-1 suppressed it. Thus, IEX-1 promotes anti-Fas mAb-induced apoptosis through up-regulating caspase-8 activity. (3) IEX-1 was up-regulated by TSA, an HDACi. Interestingly, apoptosis induced by TSA plus anti-Fas mAb in RA-SF was partially inhibited by knockdown of IEX-1, indicating that TSA-induced apoptosis was mediated, at least in part, by the up-regulation of IEX-1. (3)When IEX-1 expression was down-regulated with siRNA, LPS-induced IL-6 production was decreased, showing that IEX-1 is also involved in cytokine production from RA-SF.
Conclusion: IEX-1 is over-expressed in RA-SF and further induced by TNFa. IEX-1 facilitates anti-Fas mAb-induced apoptosis by enhancing caspase activation, and regulates cytokine production. IEX-1 is likely to play an important role in RA pathogenesis.

Epigenome Analysis of Rheumatoid Arthritis Synovial Fibroblasts Revealed TBX-5 As a Novel Transcription Factor in Chemokine Regulation. Emmanuel Karouzakis, Michelle Trenkmann, Renate E. Gay, Beat A. Michel, Steffen Gay and Michel Neidhart. Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Changes in DNA methylation and histone marks have been associated with diseases such as cancer, rheumatoid arthritis (RA) and systemic lupus erythematosus. Previously, we performed methylation immunoprecipitation (MeDIP) in combination with human promoter arrays and identified TBX5 as a differentially methylated gene in RA synovial fibroblasts (SF). Now, we want to further examine its role in the pathogenesis of RA and identify specific TBX5 gene targets.

Methods: Methylation immunoprecipitation assay was used to analyze DNA extracts from OASF (n=5) and RASF (n=7) cell cultures. Bisulfite sequencing was used to confirm the MeDIP results. Transient transfections were done in OASF cell cultures with a TBX5 overexpression vector. RNA and cDNA were prepared and used to hybridize an Affymetrix human microarray. The microarray expression array was confirmed by quantitative SYBR PCR in OASF cultures (n=7). DAVID bioinformatics software was used to functional annotate the microarray data.

Results: The TBX5 gene was significantly more methylated in OASF than RASF, as shown by MeDIP assay (OASF 17±2.9 and RASF 5±3.5 fold enrichment, p<0.04, n=6). The MeDIP results were confirmed by bisulfite sequencing of the TBX5 promoter. TBX5 transcripts were significantly more expressed in RASF than OASF (RASF dCt: 16.0 ± 0.6; OASF dCt: 19±0.3, p<0.005, n=8). In addition, Western blot showed that the TBX5 protein was expressed in RASF, but not in OASF. Overexpression of TBX5 in OASF revealed 640 genes commonly up regulated from 1.2 to 3-fold. Analysis of these genes by DAVID bioinformatics tool identified that the chemokines IL8, CXCL2 and CCL20 were common targets of TBX5 in OASF. The expression of chemokines was significantly upregulated in seven different OASF cell cultures (IL8: 2 fold change ±0.9, CXCL2: 1.97 fold change±0.9, CCL20:2.07±0.8, p<0.05).

Conclusion: Promoter specific DNA hypomethylation and an open chromatin are responsible for the intrinsically up-regulated TBX5 expression in RASF. TBX5 may be a novel regulator of chemotaxis thereby associated with the ability of RASF to attract inflammatory cells to the synovium.

Loss-of-Co-Homozygosity Mapping and Exome Sequencing of a Syrian Pedigree Identified the Candidate Causal Mutation Associated with Rheumatoid Arthritis. Yukinori Okada[1], Namrata Gupta[2], Daniel Mirel[3], Stacey Gabriel[3], Thurayya Arayssi[4], Faten Mouassess[5], Walid AL Achkar[5], Layla Kazkaz[6] and Robert M. Plenge[7]. [1]1.Brigham and Women's Hospital, Harvard Medical School, 2.Program in Medical and Population Genetics, Broad Institute, Boston, MA, [2]The Broad Institute, Cambridge, [3]The Broad Institute, Cambridge, MA, [4]Weill Cornell Medical College-Qatar, Doha, Qatar, [5]Molecular Biology and Biotechnology, Damascus, Syria, [6]Tishreen Hospital and the Syrian Association for Rheumatology, Damascus, Syria, Damascus, Syria, [7]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Although there are >50 rheumatoid arthritis (RA) risk loci that contain common variants, there are no known genomic loci that harbor rare mutations that influence RA risk in a Mendelian fashion. Here, we perform whole exome sequencing to search for rare, causal mutations in a 4-generation, 48-person consanguineous Syrian pedigree in which 8 individuals were affected with seropositive rheumatoid arthritis (RA).

Methods: We performed GWAS genotyping on 16 family members (affected and unaffected) and genome-wide exome sequencing in 4 CCP+ RA cases. To search for rare causal mutations, we developed a novel non-parametric linkage analysis we term "Loss-of-co-Homozygosity" (LOcH) mapping that extends homozygosity mapping to include any type of inheritance mode. The fundamental principal underlying LOcH is that a disease-causing mutation in a pedigree resides on a single ancestral haplotype, and that affected individuals will carry at least one copy of the mutation – but are never homozygous for the non-mutated allele. We used LOcH mapping to search the genome for regional stretches that lose one or both homozygous genotypes (i.e., lose "co-homozygosity") in affected cases, which serve as candidate regions harboring rare causal mutations. Within the detected LOcH stretches, we performed imputation of mutations identified by exome sequencing. We evaluated the presence of the LOcH stretches in other non-exome-sequenced subjects, and calculated a P-value for association with case-control status using Fisher's exact test.

Results: Using GWAS data and LOcH mapping, we identified 12% of the genome in which the same ancestral haplotype was shared among all RA cases. Within these regions, we identified 13 nonsense or missense mutations shared among all cases but not observed in dbSNP, the 1000 Genomes Project, or the Exome Sequencing Project. We imputed these 13 candidate mutations in all unaffected family members, and found that 1 mutation preferentially segregated in cases compared to controls: all 4 RA cases inherited this mutation, but only 3/12 controls were heterozygous for the mutation (P = 0.02). The mutated gene is *phospholipase B1* (*PLB1*), which has been implicated in human epidermal barrier function but not yet implicated in RA or other autoimmune diseases.

Conclusion: While additional investigation of this mutation is required to confirm the association with risk of RA, the approach highlights a novel method of statistical analysis of genome-wide sequence data.

421

Rheumatoid Factor, Not Antibodies to Citrullinated Proteins, Are Associated with High Disease Activity. Josef S. Smolen[1], Farideh Alasti[2] and Daniel Aletaha[2]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria

Background/Purpose: Autoantibodies in general, and rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) in particular, are a hallmark of RA. After their characterization, ACPA have been regarded as more specific than RF in relation to diagnostic and prognostic utility. However, these data have not been unequivocally shared throughout the literature and most of them have come from observational studies, often from a single or few centers. While it has been known for long that RF+ patients have more active and severe disease than RF- ones, it is not clear if this effect is due to RF, ACPA or both in the light of the high (usually >80%) overlap of RF and ACPA positivity and the above controversy. Here we compared the extent of disease activity in RF+ and/or ACPA+ patients to understand the impact of these autoantibodies on disease activity of RA.

Methods: We were kindly provided a large database of patient level data from an international multicenter clinical trial comparing methotrexate (MTX) and rituximab plus MTX in patients with early (<4 years) arthritis who had to be MTX-naïve and fulfill a predefined level of active disease (≥8 swollen and tender joints) and be RF+ or have erosive disease at entry (IMAGE trial)[1]. Core set variables as well as levels of RF (by nephelometry) and ACPA (by ELISA) were available from the database. For the purpose of this analysis, we focused on baseline data and pooled the patients of all three treatment groups. The following groups were formed four groups according to the presence/absence of RF and ACPA. We compared disease activity variables and indices (disease activity score, DAS28; simplified and clinical disease activity index, SDAI and CDAI) across these groups using the Kruskal Wallis test for overall assessment, and the Wilcoxon test for subsequent pairwise comparisons if appropriate. A main focus of the latter was the comparison of the RF+/ACPA- and RF-/ACPA+ populations compared to each other.

Results: At baseline, disease activity was 6.9, 7.1, 7.1 and 6.6 by the DAS28 for RF-/ACPA- (n=64); RF+/ACPA+ (n=611); RF+/ACPA- (n=40); RF-/ACPA+ (n=29), respectively; and 47.8, 49.8, 53.1, 42.3 for the SDAI, significantly different among the four groups for both measures. The lowest values of disease activity measures were seen for the RF-/ACPA+ population, and significantly lower than in the RF+/ACPA- group (p=0.014 for DAS28, and p=0.004 for SDAI). Similar findings were made for CDAI, swollen and tender joint counts, while for ESR and CRP there was a numerical trend in this direction (not shown). Interestingly, patients positive for both RF and ACPA tended to have slightly lower disease activity than RF+/ACPA-, and higher than RF-/ACPA+ ones. Importantly, similar findings were made for the baseline values of each of the three trial arms when assessed individually (not shown).

Conclusion: The data presented suggest that RF may contribute more strongly to disease activity than ACPA and, therefore, may have more direct pathogenetic implications. Confirmation of these findings in other trial databases would shed more light on this insight.

Acknowledgment. We thank Roche for kindly providing the data of this study.

Antibodies to Citrulline From Rheumatoid Arthritis Patients Also Bind Homocitrulline. Mathias Scinocca, Radha Joseph, David A. Bell, Ewa Cairns and Lillian J. Barra. Schulich School of Medicine and Dentistry, Western University, London, ON

Background/Purpose: Antibodies to citrullinated proteins/peptides (ACPA) are specific for Rheumatoid Arthritis (RA). One of ACPA's targets is citrullinated fibrinogen (citfib) and it is found in inflamed synovium. Recently, it has been reported that antibodies to homocitrullinated proteins/ peptides (AHPA) also occur in RA. Citrulline and homocitrulline are structurally similar. Both can be generated during inflammation, but by different processes. ACPA from RA patients, including those targeting citfib, are arthritogenic. However, the role of AHPA in RA is not known. The purpose of this study was to determine whether: **1)** RA patients have antibodies to homocitrullinated fibrinogen (AHFA) and **2)** ACPA and AHPA are cross-reactive.

Methods: Serum was obtained from patients who met ACR criteria for RA, Psoriatic Arthritis or Systemic Lupus Erythematosus and were compared to healthy controls. It was tested against the following antigens: fibrinogen (fib), citfib, homocitrullinated fibrinogen (homocitfib), JED (a proprietary synthetic citrullinated peptide) and homocitrullinated JED (homoJED). Citrullination was done *in vitro* using peptidyl arginine deiminase enzyme (PAD2) [1]. Homocitrullination was done using potassium isocyanate. Both modifications were confirmed by mass spectrometry using ESI-MSMS and MASCOT server analysis. Shared Epitope (SE) binding was predicted by a computer algorithm [2]. ACPA was purified by affinity chromatography using JED. Antibodies to the above antigens and cyclic citrullinated peptide 2 (CCP2) were detected by ELISA. Inhibition assays using fib and homocitfib were conducted by ELISA.

Results: Mass spectrometry of modified fibrinogen revealed 55/79 (70%) of arginines were citrullinated and 89/103 (86%) of lysines were homocitrullinated. Approximately 25% of MHCII-binding peptides were both citrullinated and homocitrullinated. Five of these peptides were predicted to bind to the SE. The majority of RA patients were anti-CCP2 positive (89%) and 50% expressed AHFA. None of the normal controls and <5% of PsA and SLE were AHFA positive. All AHFA positive patients were also anti-CCP2 positive. Reactivity to homocitrullinated sites on fibrinogen was confirmed by inhibition assays. Affinity purified ACPA using a citrullinated peptide (JED) had reactivity to JED, anti-CCP2, as well as the homocitrullinated peptides, homoJED and homocitfib.

Conclusion: Antibodies to homocitrullinated peptides/proteins are specific for RA. These antibodies bind citrullinated and homocitrullinated antigens, suggesting cross-reactivity and possible pathogenicity.

Sputa Autoantibodies in Patients with Established Rheumatoid Arthritis and Subjects At-Risk for Future Clinically Apparent Disease. Van C. Willis[1], M. Kristen Demoruelle[1], Lezlie A. Derber[1], Catherine J. Chartier-Logan[1], Mark Parish[1], Isabel Pedraza[2], Michael H. Weisman[3], Jill M. Norris[4], V. Michael Holers[1] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Cedars Sinai Med Ctr, Los Angeles, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Colorado School of Public Health, Aurora, CO

Background/Purpose: Elevations of rheumatoid arthritis (RA)-related autoantibodies (Abs) prior to the symptomatic onset of inflammatory arthritis (IA) suggest that autoimmunity in RA is initiated outside of the joints. Furthermore, emerging data suggest a potential site may be the lung, supported by the association of inhaled factors such as smoking with RA, our published findings that inflammatory airways abnormalities can precede the onset of symptomatic IA in RA, and known mechanisms for generation of autoimmunity in the lung such as bronchus-associated lymphatic tissue (BALT) (Rangel-Moreno et al 2006). Prior work suggests that comparison of sputa and sera can be used to identify lung generation of autoantibodies (Schiotz et al 1979); therefore, to investigate the role of the lung as a site of initial generation of RA-related autoimmunity, we tested RA-related Abs from sera and sputa from subjects with established RA and subjects at-risk for future RA due to a family history of RA.

Methods: Simultaneous collection of sera and induced sputa (5% nebulized saline) was performed in 17 healthy controls, 29 first-degree relatives (FDR) of RA probands without IA by clinical examination, and 12 subjects with early seropositive RA (1987 criteria; <1 year from diagnosis). Samples were tested for CCP2 (IgG), CCP3.1 (IgG/IgA), and IgM, IgG and IgA rheumatoid factors (RFs) using commercial ELISAs. In sera, CCP positivity was set from kit standards, and RF positivity was determined as a level elevated in <5% of 491 blood donors. Sputa positivity for each Ab was determined using the control mean plus 2 standard deviations. Chi-squared testing was used to compare groups, and matched-pair analyses were used to compare the frequency of Ab positivity in sputa and sera.

Results: There were no significant differences in age, sex, smoking status or history of lung disease between Early RA and FDR subjects. All of the Early RA and 8/29 (28%) of FDR subjects were positive in their sera for at least 1 Ab. Overall, a greater proportion of Early RA subjects were positive for each Ab in their sera vs. sputa. However, 8 of the 21 seronegative FDRs were positive in their sputa for at least 1 Ab. Specifically, the assays that detected IgA were elevated in significantly more FDR subjects' sputa than sera: CCP3.1 31% positive in sputa vs. 7% positive in sera, p=0.03; RF-IgA 14% vs. 0%, p=0.03).

Conclusion: Sputa elevations of RA-related Abs in seronegative FDRs without IA suggest that in some cases RA-related autoimmunity may be initially generated in the lung. Because sputum largely reflects airway responses, these findings also suggest that RA-related autoimmunity may be initially limited to the airways, and IgA predominant. However, the higher number of patients with RA with sera vs. sputa Ab positivity also suggests that after the symptomatic onset of RA the generation of Abs occurs at other sites, leading to autoantibodies in the circulation instead of sputa. These findings show the utility of sputa testing to assess RA-related autoimmunity in the lung, as well as demonstrate a need for prospective studies of subjects at-risk for future RA to determine the role of immunologic responses in the lung in the earliest phases of RA development.

Influence of Pregnancy On Disease Activity-Associated Genes in Rheumatoid Arthritis. Erik J. Peterson[1], Shreyasee Amin[2], Hatice Bilgic[1], Emily Baechler Gillespie[1], Jane E. Salmon[3], Ann M. Reed[2], Weihua Guan[4] and Daniel L. Mueller[1]. [1]University of Minnesota Medical School, Minneapolis, MN, [2]Mayo Clinic, Rochester, MN, [3]Hospital for Special Surgery, New York, NY, [4]University of Minnesota School of Public Health, Minneapolis, MN

Background/Purpose: Rheumatoid arthritis (RA) disease activity can often quiesce during pregnancy. Nevertheless, most women will experience a disease flare postpartum (PP). We hypothesized that changes in blood immune cell gene expression patterns during healthy pregnancy, which promote fetal tolerance in order to protect against fetal loss, will also be relevant in regulating RA disease activity.

Methods: Whole-blood gene expression profiles (15,050 expressed; p<0.05) from 19 pregnant RA subjects and 13 pregnant age-matched healthy controls (CON) were assayed at first trimester of pregnancy (T1), T2, T3, and PP using Illumina HumanHT-12 v3 and v4 BeadChip arrays. At identical time points, disease activity in RA women was assessed using the DAS28-CRP. A Generalized Estimating Equations (GEE) approach was applied to model gene expression changes during pregnancy (T1-T3) and between pregnancy and PP, to take into account the correlation within samples. A version effect (v3 vs v4) was also included in the model.

Results: Within the CON samples, 581 blood cell genes demonstrated either a >20% change in mRNA expression between T1—>T2 or T2—>T3 of pregnancy, or a >20% change in expression between the average of T1—T3 and the PP period (BH q<0.05). Many of these genes mapped to Ingenuity Pathways associated with (p<0.01) hematopoietic system development and function (n=149 molecules), cell death (n=185), and immunological diseases (n=127). These 581 "pregnancy-related" genes were then selected for further study in the pregnant RA cohort. Of the 581 genes, 74 were found to be significantly associated with the DAS28-CRP score after correcting for multiple hypothesis tests (Bonferroni correction, $p<8.6\times10^{-5}$), with 11 of these demonstrating a >20% change in mRNA expression for every 1 unit change in DAS28-CRP score either during pregnancy or in the PP period. For the 50 pregnancy-related genes whose expression fell PP in association with rising DAS28-CRP, 7 genes (*CD247, CD5, CD6, FLT3LG, IL7R, RBM38, and TUBB*) were functionally associated with autoimmune diseases by Ingenuity Pathways Analysis; likewise, of the 24 genes whose expression directly correlated with DAS28-CRP PP, 5 genes (*IL1B, MYD88, NCF4, PFKFB3, and SLC22A4*) were associated with autoimmune diseases (p=0.0015).

Conclusion: Our experiments identify 74 RA disease activity-correlated blood cell genes whose expression is modulated during normal pregnancy. Insofar as these genes reflect alterations in immune cell reactivity normally associated with pregnancy and promotion of fetal tolerance, they may represent a window into processes and pathways with a capacity to regulate disease activity in RA patients. Pregnancy-modulated genes that fluctuate with RA disease activity may also have utility as disease activity biomarkers.

Slug **Is Induced by Benzo(a)Pyrene and EGF Through PI3K/Akt/mTOR Pathway and Is Closely Involved in the Regulation of the Invasive Properties of FLS in Rheumatoid Arthritis.** Jaejoon Lee[1], Jiwon Hwang[2], Chan Hong Jeon[3], Joong Kyong Ahn[4], Hoon-Suk Cha[1] and Eun-Mi Koh[5]. [1]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Soonchunhyang University College of Medicine, Bucheon, South Korea, [4]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Seoul, South Korea

Background/Purpose: Slug, a Snail family of zinc finger transcription factor, plays a critical role in tumor proliferation, invasion and metastasis. We have previously shown that Slug is overexpressed in RA synovial tissue and suppression of Slug facilitates apoptosis of RA FLS. However, the precise mechanism through which Slug is induced in RA FLS remains unclear. Smoking is an important environmental risk factor for RA and influences RA disease susceptibility and severity. Benzo(a)pyrene (BaP) is a polycyclic aromatic hydrocarbon found in cigarette smoke. BaP can be metabolized to active compounds that induce the production of reactive oxygen species. The effect of Bap on Slug expression in RA FLS has not been studied thus far.

The present study was undertaken to investigate the biological effects of BaP on the expression of Slug, signaling pathway through which Slug is expressed, and the effect of BaP/Slug on the invasive properties of RA FLS.

Methods: Expression of Slug was measured by real-time PCR following stimulation of FLS with different concentrations of BaP, EGF, H_2O_2, TGF-β, and TNF-α (n=7, each). Phosphorylation of the key enzymes in the signal transduction pathway was analyzed by Western blot. Inhibitors targeting the PI3K/Akt/mTOR pathway were used to confirm critical signaling pathway for Slug expression (n=7). An in vitro cell invasion assay was performed using RA FLS treated with Slug siRNA or with control siRNA (n=4).

Results: Slug expression was significantly increased following treatment with BaP (4μM, p=0.0014), EGF (100ng/ml, p=0.027) and H_2O_2(0.25mM, p=0.029), but not with TGF-β and TNF-α. Stimulation with BaP and EGF induced phosphorylation of Akt kinase activity, but no significant change was observed in ERK, JNK and p38 activity. Slug mRNA expression by BaP and EGF decreased significantly following treatment with PI3K/Akt/mTOR inhibitors (p=0.026, p=0.002, respectively). Slug siRNA treatment induced a significant reduction in the invasive function of FLS compared to those treated with control siRNA (p=0.029). In addition, stimulation with BaP increased invasive function of control siRNA-treated FLS (p=0.01), but no such change was observed in Slug siRNA-treated FLS.

Conclusion: Our data show that BaP, one of major toxic components in cigarette smoke, induce Slug expression in RA FLS through PI3K/Akt/mTOR pathway, and may regulate invasive properties of RA FLS. This mechanism may provide a novel explanation for the increased RA susceptibility and severe clinical phenotype in those who smoke.

Dickkopf-1 Stimulates Fibroblast-Like Synoviocyte Migration Through Janus Kinase Activation. Yubin Luo[1], Bryan Dieffenbach[2], Jung-Soo Song[3], Jinseok Kim[4], David L. Boyle[1], Michael Karin[1], Gary S. Firestein[1] and Maripat Corr[5]. [1]UCSD School of Medicine, La Jolla, CA, [2]UCSD School of Medicine, la Jolla, CA, [3]Chung-Ang University College of Medicine, Seoul, South Korea, [4]Jeju National University, Jeju, Korea, South Korea, [5]Univ of California-San Diego, La Jolla, CA

Background/Purpose: Wnt (wingless) pathway signaling has been implicated in patterning in embryogenesis and in adult wound healing and homeostasis. A canonical Wnt antagonist, Dickkopf-1 (DKK-1), has been described as an embryonic bone morphogen. DKK-1 expression is stimulated by TNF in inflammatory disease and is elevated in the sera of rheumatoid arthritis patients. This Wnt signaling antagonist has been linked to the depression osteoblast activity and bone loss. Here we examined a novel role for the pathogenic activity of this protein by virtue of its ability to activate JNK and increase migration of fibroblast-like synoviocytes (FLS).

Methods: Human and mouse FLS were cultured and the plates were scratched. Migration was measured by serial photography of a marked area and Image J quantification. **Results** were confirmed with an Oris™ stopper assay, and cell entry into the central clearing was measured by calcein AM fluorescence. FLS were treated with rDKK-1, rWnt5a, PDGF, SB216763 (a GSK3β inhibitor), SP600125 (a JNK inhibitor), and IWP-2 (a porcupine inhibitor). In some cases, FLS were lysed for Western blot and qPCR analyses.

Results: Human and mouse FLS exhibited faster migration in the scratch wound assay and the stopper assay when stimulated with DKK-1 (50, 100 or 150ng/ml). DKK-1 increased percent wound closure from 31+4to 46+5 (p<0.04) for human and 41+4 to 58+18 (p<0.04) for mouse FLS. DKK-1-induced migration was inhibited by the JNK inhibitor SP600125. On the other hand, SB216763 and IWP-2 had minimal or no effect, indicating that it is independent of endogenously produced Wnt. DKK-1 stimulated JNK phosphorylation in FLS within 10 minutes, which was also not abrogated by IWP-2. To determine which JNK isoform is responsible, JNK1 null and JNK2 null mouse FLS were studied in the migration assays. Unexpectedly, DKK-1 treatment still induced the migration of JNK1 deficient, but not JNK2 deficient cells. In association with increased migration, DKK-1 treated FLS increased expression of MMP-1 (1.4 fold), MMP2 (1.4 fold) and MMP13 (1.6 fold). In contrast, MMP9 and MMP3 expression was decreased.

Conclusion: DKK-1 stimulates migration of FLS, which is associated with JNK phosphorylation and increased expression of selected metalloproteinases. DKK-1-induced migration was mediated by JNK2 signaling, suggesting that this pathway plays a critical role in synoviocyte migration and cartilage damage in rheumatoid arthritis

Epigenetic Features As Predictive Markers of Responsiveness to Epitope-Specific Therapy in Rheumatoid Arthritis. Roberto Spreafico, Maura Rossetti, Theodorus Van Der Broek, Olivia Morrow and Salvatore Albani. Sanford-Burnham Medical Research Institute, La Jolla, CA

Background/Purpose: The focus of current research for new therapeutic approaches in Rheumatoid arthritis (RA) is shifting from mere suppression to induction and maintenance of tolerance. Adaptive immunity, specifically the balance and functions of effector and regulatory CD4[+] T cells, is central in this context. We have recently developed a protocol of oral tolerance induction to an epitope (dnaJP1) derived from a heat shock protein (HSP), a key component of the mechanism of perpetuation and amplification of chronic autoimmune inflammation. Phase II trial results showed clinical efficacy and an intriguing immune deviation of T cell immunity. In order to

dissect further the mechanism of action and also to identify biomarkers predictive of susceptibility to treatment, we employed here whole genome DNA methylation analysis, which can be correlated to gene expression and is relatively more stable compared to mRNA, the basis of the well-known whole transcriptome analysis.

Methods: Total CD4[+] T cells from 12 patients taken at baseline, equally segregated in placebo responders/non-responders (R/NR) and HSP peptide R/NR, were sorted from PBMCs. DNA was extracted and bisulfite converted to analyze the cytosine methylation pattern. Converted DNA was analyzed using Illumina Infinium HumanMethylation450 BeadChip, yielding the methylation percentage of more than 485,000 CpG sites across the genome.

Results: A nearly perfect segregation of R and NR was observed when Principal Component Analysis (PCA) was applied to the whole dataset. When sites selected for discriminating R from NR (based on p-value and fold change) were used, PCA was also able to discriminate, based on average DAS-28 scores, weak responders from strong responders. Weak responders were more frequent among placebo treated subjects, while HSP peptide-treated subjects comprised stronger responders. In order to enrich for sites discriminating R and NR with high confidence without losing power due to the high number of CpG sites, pre-filtering of sites with low variance was performed. With this method, we found 51 sites differentially methylated between R and NR, clearly supporting the potential of the whole genome methylation analysis for discovery of new candidate biomarkers. As a control, mock comparisons, such as between all placebo against all HSP peptide-treated subjects irrespective of clinical outcome (which is not meaningful at baseline due to patient randomization) were run and consistently yielded fewer hits.

Conclusion: We found significant differences in the general pattern of DNA methylation between RA patients responding or not responding to an epitope-specific therapy. We have also identified a set of CpG sites with high predictive and prognostic power for discriminating the responsiveness to treatment, which may be developed as a screening tool. The functions of the genes found to be differentially methylated is currently under investigation.

TNFα Modulates the Expression of Circadian Clock Gene, *Per2*, Via D-Box Motif in the Promoter Region in Rheumatoid Synovial Cells. Kohsuke Yoshida[1], Akira Hashiramoto[2], Takaichi Okano[3], Nao Shibanuma[4] and Shunichi Shiozawa[5]. [1]Hyogo Prefectural Rehabilitation Center at Nishi-harima, Tatsuno, Japan, [2]Department of Internal Medicine, Kobe University Graduate School of Medicine/The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [3]Kobe University Hospital, Kobe, Japan, [4]The Center for Rheumatic Diseases, Kobe University Hospital/Departmant of Orthopaedic Surgery, Kobe Kaisei Hospital, Kobe, Japan, [5]Kyushu University Beppu Hospital, Beppu, Japan

Background/Purpose: The mammalian clock genes including *Clock* (circadian locomotor output cycles kaput), *Bmal1* (brain and muscle Arnt-like protein 1), *Per* (Period) and *Cry* (Cryptochrome) regulate the circadian rhythm. We previously showed that arthritis was significantly accelerated in $Cry1^{-/-}Cry2^{-/-}$ mice due to the activation of TNFα (tumor necrosis factor α) transcription, and TNFα inhibited the expression of *Per2* mRNA in primary cultured human rheumatoid synovial cells. Here, we tried to elucidate the effects of TNFα on the transcription of *Per2* gene in rheumatoid synovial cells.

Methods: Primary cultured rheumatoid synovial cells were synchronized upon incubation with 50% horse serum for 2 hours, and then stimulated with 10 ng/ml TNFα. Total RNA was extracted from synovial cells every 8 hrs until 32 hrs' culture period, and mRNA expression of D-box binding protein genes, including *Dbp* (D site of albumin promoter binding protein), *Hlf* (hepatic leukemia factor), *Tef* (thyrotroph embryonic factor) and *E4BP4* (E4-binding protein 4), were analyzed by real-time PCR. Synovial cells were transfected with the luciferase reporter vector containing the human *Per2* promoter to measure the transcriptional activity of *Per2* gene.

Results: The expression of *Dbp*, *Hlf*, and *Tef* mRNA were significantly inhibited ($P < 0.01$), while those of *E4bp4* mRNA was significantly increased ($P < 0.01$) upon incubation with TNFα in rheumatoid synovial cells. Since *Dbp*, *Hlf*, *Tef* and *E4bp4* genes could transactivate and suppress the expression of *Per2* gene, respectively, by binding to D-box motif in the promoter region, we next introduced site-directed mutations into the D-box 1 (TTATGTAA, −372 to −365) and/or D-box 2 (TTACGTAA, −47 to −40) motif in the promoter, and then transfected rheumatoid synovial cells with luciferase

reporter gene constructs driven by the *Per2* promoter. As results, TNFα inhibited the transcriptional activity of the wild type of *Per2* gene. However, when the promoter containing a mutated both D-box 1 and D-box 2 motif was transfected, TNFα-mediated transcriptional inhibition did not observed as compared with the wild type and the D-box 1 mutated promoter ($P < 0.05$ and $P < 0.05$, respectively).

Conclusion: TNFα significantly modulates the expression of *Per2* gene via D-box binding protein, DBP, HLF, TEF and E4BP4, in rheumatoid synovial cells, and thereby may contribute to the pathogenesis of RA.

The Significance of the Apoptosis Level and the Apoptosis Related Signal Proteins of CD4[+]t ACD4[+]Foxp3[+]t Cell in Patients with Rheumatoid Arthritis. Ning Li[1], Tianrui Ma[2], Jie Han[1], Jieru Zhou[1] and Songguo Zheng[3]. [1]Shanghai East Hospital, Shanghai, China, [2]Ningbo Pediatric Hospital, Ningbo, China, [3]Keck School of Medicine of the University of Southern California, Los Angeles, CA

Background/Purpose: To investigate the apoptosis of CD4[+]T cell and Tregs in the pathogenesis and disease activity of rheumatoid arthritis patients.

Methods: Isolated lymphocytes from human peripheral blood, the expressive levels of Annexin V, Caspase-3/8, Fas and Bcl-2 of CD4[+]T lymphocytes and Tregs in RA patients and controls were analysed by using flow cytometry. The correlation between the apoptosis level, the apoptosis signaling proteins expression of CD4[+]T, Tregs and clinical activity parameters were analysed. The effects of IL-10 and anti-IL-10 were also observed.

Results:

1. Compared with the controls, the level of CD4[+]T cells was higher in RA patients, while their apoptosis was lower ($p < 0.05$); the frequency of Tregs was lower in RA patients, while their apoptosis was higher ($p < 0.05$).

2. Compared with the controls, the expression of Fas ($p < 0.01$) and Caspase-8 ($p < 0.05$) by CD4[+]T cells decreased in RA patients, the expression of Bcl-2 by CD4[+] T cells ($p < 0.05$) increased; the expression of Fas ($p < 0.01$), Caspase-8 ($p < 0.05$) and Caspase-3 ($p < 0.05$) by Tregs elevated in RA patients.

3. The expression of AnnexinV and Fas by CD4[+]T cells in RA patients were negatively correlated with DAS28 ($r = -0.84$, $p < 0.01$ and $r = -0.89$, $p < 0.05$, respectively), the expression of Bcl-2 by CD4[+]T cells was positively correlated with DAS28 ($r = 0.91, p < 0.01$). There was positive correlation between the expression of Annexin V and Caspase-3 by Tregs and DAS28 in RA patients ($r = 0.82, p < 0.01$ and $r = 0.79, p < 0.05$, respectively).

4. After IL-10 treatment, the apoptosis of CD4[+] T cells increased ($p < 0.05$), and that of Tregs decreased ($p < 0.05$); the apoptosis of CD4[+] T cells in anti-IL-10 group decreased ($p < 0.05$), and that of Tregs increased ($p < 0.05$); the expression of Caspase-8 by CD4[+] T cells in IL-10 group increased ($p < 0.05$), the expression of Bcl-2 by CD4[+] T cells in IL-10 group decreased ($p < 0.05$); the expression of Caspase-8 by CD4[+] T cells in anti-IL-10 group was lower than that of the blank group ($p < 0.05$), the expression of Bcl-2 by CD4[+]T cells in anti-IL-10 group was higher ($p < 0.05$); the expression of Caspase-8/3 by Tregs in IL-10 group decreased ($p < 0.01$), while the expression of Caspase-8/3 by Tregs in anti-IL-10 group was significantly elevated than that of the blank group ($p < 0.01$).

Conclusion:

1. The higher level of CD4[+] T cells and the lower frequency of Tregs may be caused by the decreased apoptosis of CD4[+] T cells and the increased apoptosis of Tregs, which may be the reason of the abnormal autoimmune response in RA.

2. Fas, Caspase-8 and Bcl-2 may play a role in the the apoptosis of CD4[+]T cells. The apoptosis of Tregs may be related to the higher expression of Fas, Caspase-8/3.

3. The expression of AnneinV, Fas and Bcl-2 by CD4[+]T cells and the expression of AnnexinV and Caspase-3 by Tregs in RA patients might be sensitive indicators of the clinical activity of RA.

4. IL-10 has different immunoregulatory functions in different cells. It can downregulate the expression of Bcl-2, stimulate the expression of Caspase-8 in CD4[+] T cells and inhibit the expression of Caspase-8/3 in Tregs of RA patients.

Comprehensive Microrna Analysis Identifies Mir-24, Mir-26a, and Mir-125a-5p As Plasma Biomarkers for Rheumatoid Arthritis. Koichi Murata, Moritoshi Furu, Hiroyuki Yoshitomi, Masahiro Ishikawa, Hideyuki Shibuya, Hiromu Ito and Shuichi Matsuda. Kyoto University Graduate School of Medicine, Kyoto, Japan

Background/Purpose: MicroRNAs (miRNAs) are present in human plasma in a stable form despite the endogenous RNase activity. Plasma miRNAs are non-invasive biomarker for cancer detection and tissue injuries. We previously showed the potential ability of the plasma miRNAs as biomarkers for rheumatoid arthritis (RA) and designed this study to identify plasma miRNAs specific for RA by a comprehensive array approach.

Methods: We performed a systematic array-based miRNA expression analysis on plasma samples from patients with RA and healthy controls (HCs) (n=3, respectively). The expression of plasma miRNAs in the first comprehensive analysis with more than four times change or with significant (p<0.05) change between RA and HCs, or that of detectable plasma miRNAs only in RA plasma, were followed by confirmation analysis of eight patients with RA and eight HCs using real-time quantitative PCR (qPCR). Plasma miRNAs consistently detectable in our system and significantly different between RA and HC were chosen for further validation with 102 RA patients and 104 HCs. Receiver operation curves were generated, and correlations between miRNAs and other biomarkers of RA were statistically examined.

Results: The array analysis and the subsequent confirmation by qPCR in larger patient cohort identified eight RA-associated circulating miRNAs, including miR-24, miR-26a and miR-125a-5p (Table 1). The area under curve (AUCs) of each miRNA was 0.80, 0.81 and 0.83 respectively (Figure 1A). Logistic regression analysis provided a formula for estimated probability for RA by plasma miR-24, miR-30a-5p, miR-125-5p (ePRAM) with increased the diagnostic accuracy (AUC: 0.86, Figure 1B). The diagnostic ratio was not influenced by the antibody values against anti-citrullinated peptide. These miRNAs levels in OA patients were as low as in HC and these miRNA levels in RA patients showed no significant changes with the administration of biologics.

Figure 1.

Conclusion: Plasma levels of miR-24, miR-26a, miR-125a-5p, and ePRAM can be diagnostic biomarker for rheumatoid arthritis.

Basic and Clinical Significance of Interleukin 6 (IL-6) in AA Amyloidosis with RA. Kazuyuki Yoshizaki, Prabha Tiwari, Lokesh P. Tripathi, Shandar Ahmad, Kenji Mizuguchi, Teppei Nishikawa-Matsumura, Tomoyasu Isobe and Soken-Nakazawa J. Song. Osaka University, Osaka, Japan

Background/Purpose: Cytokine-induced hepatic serum amyloid A (SAA) is associated with the pathogenesis of AA amylodosis, a fatal disease with deposition of AA amyloid fibril on systemic organs, especially on kidney, thyroid and intestine in chronic inflammatory disease such as rheumatoid arthritis (RA). This study was to provide our recent results on SAA activation by IL-6-induced STAT3 and clinical analysis of IL-6 blocking therapy in AA amyloidosis complicating RA.

Methods: STAT3 contributing to transcriptional activation of SAA by forming a complex with NF-kB was analyzed by using the super shift assay, ChIP assay, and DNA affinity choromatography systems. A set of candidates for non-consensus STAT3 binding sites on SAA promoter was identified by using a new mathematics calculation theory. The binding of STAT3 to the non-consensus STAT3 binding sites was also confirmed by means of Luciferas assay and DNA affinity choromatography assay.

Results: We demonstrated that IL-6 activated STAT3 is essential for inducing SAA mRNA expression, and that NF-kB p65 complementally augments SAA mRNA induction by IL-6 stimulation combined with IL-1or TNF-α.We found a non-consensus STAT3 response element (RE) at the 3'-down stream of NF-kB site on SAA promoter region for STAT3 binding. Anti-IL-6 receptor antibody can completely inhibit SAA expression and stat3-NF-kB complex formation induced by IL-6+IL-1+TNF-α.

Conclusion: We identified a non-consensus STAT3 binding site in SAA promoter based on a new statistical analysis method of protein-DNA complex structures, and confirmed that STAT3 binds to the predicted site followed for SAA expression induced by IL-6+IL-1. Our basic results may explain why IL-6 blockade completely inhibit the SAA production in AA amyloidosis patients with RA, and IL-6 is a pivotal cytokine for induction of SAA. Our results also indicated that STAT3 may activate more broad genes during inflammation through non-consensus RE, and IL-6 inhibition may inactivate more broad inflammatory genes.

Identification and Characterization of Fibrinogen-Specific T Cells in Patients with Rheumatoid Arthritis. Laura Su and Mark M. Davis. Stanford University School of Medicine, Stanford, CA

Background/Purpose: Rheumatoid arthritis (RA) is a common, highly debilitating systemic inflammatory condition. To date, little is known about which autoantigens are involved in RA and how T cells which recognize self-proteins may become pathogenic in disease. Fibrinogen is a common target of autoantibodies in RA patients, and a putative T cell autoantigen involved in disease development. The goal of this study is to identify and characterize fibrinogen-specific CD4$^+$T cells.

Methods: Autoantigen-specific T cells were identified directly *ex vivo*using peptide-MHC tetramers. To identify individuals carrying the HLA-DRB1*0401 (DR4) allele, HLA typing was performed on healthy blood donors and RA patients using sequence-specific primer PCR. To identify antigen-specific T cells, tetramer staining was performed at room temperature for 1 hour using tetramers loaded with several fibrinogen peptides. Memory phenotyping was performed using antibodies against CD45RO and CCR7. Tetramer tagged cells were magnetically enriched and analyzed by flow cytometry. Single cell TCR amplification and sequencing was performed to trace T cell clonality.

Results: We identified several populations of T cells recognizing citrullinated and uncitrullinated fibrinogen peptides. The frequency of fibrinogen-specific T cells in RA patients ranges between 3 to 19 per million CD4$^+$T cells. Many of these lymphocytes express the memory marker CD45RO, particularly among cells that recognize citrullinated forms of the fibrinogen peptides. Examination of the same antigen-specificities in healthy people demonstrated that the frequency and memory characteristics of these cells appear similar in individuals without disease. Moreover, we also found in some healthy people the presence of clonally expanded T cells that recognize citrullinated fibrinogen.

Conclusion: T cells that recognize citrullinated fibrinogen can be detected in the peripheral blood of RA patients and healthy individuals. These fibrinogen-specific populations contain large numbers of antigen-experienced T cells with some showing evidence of clonal expansion.

Genome Wide Association Analysis of Pain Reduction in Rheumatoid Arthritis Patients Treated with Anti-TNF Medication. Results of the DREAM and Danbio Registries. Marieke J.H. Coenen[1], Masha Umicevic-Mirkov[1], Hans Scheffer[1], Sophine B. Krintel[2], Sita H. Vermeulen[1], Julia S. Johansen[2], Wietske Kievit[1], Mart A.F.J. van de Laar[3], Piet L.C.M. van Riel[1], Barbara Franke[1] and Merete L. Hetland[4]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [3]Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [4]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Patients with rheumatoid arthritis (RA) rate pain relief as the highest priority in treatment outcome, and tumor necrosis factor inhibitors (anti-TNF) have proven very successful in pain reduction. Interestingly, recent research indicates that inflammation and pain pathways are important, but partly independent, targets of anti-TNF. Therefore the identification of genetic factors predicting pain relief is important in efforts to personalize treatment.

Objective: We aimed to identify and replicate genetic factors predicting pain reduction upon anti-TNF treatment in patients with RA using a genome-wide association approach.

Methods: We included 508 RA patients treated with anti-TNF agents from the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry. Single nucleotide polymorphism (SNP) markers were genotyped using the Illumina HumanHap550-Duo or Human660W-Quad BeadChip. Association analysis using the change of Visual analogue scale of pain (VASpain) after 14 weeks of treatment initiation as outcome was performed on an imputed dataset under an additive genetic model with adjustment for baseline VASpain. SNPs demonstrating association with VASpain change with a p-value$<10^{-5}$were selected for replication in 207 RA patients treated with anti-TNF from the Danish DANBIO registry. We performed a meta-analysis using METAL. Pathway analysis was performed in Ingenuity.

Results: 2,557,253 SNPs and 406 patients passed quality control. No findings reached the threshold for genome-wide significance (p-

value $\leq 1 \times 10-8$) in the Dutch discovery cohort. 46 SNPs showed p-values$<10-5$, five of these (rs7921473, rs2237199, rs2237204, rs1424441, rs2615233) reached nominal significance (p<0.05) in the Danish DANBIO registry. Meta-analysis led to the identification of three SNPs with a p-value $<1 \times 10^{-7}$. These SNPs can be linked to functions that might involve pain processing in the brain. They are located within or nearby *ATXN1* (rs2237204, rs2237199), a gene involved in the pathology of spinocerebellar ataxia type 1, a neurodegenerative disorder characterized by progressive degeneration of cerebellum and *NRG3* (rs7921473) which influences neuroblast proliferation, migration and differentiation. Pathway analysis, including all SNPs with a p-value$<10^{-3}$ (n=2649) from the discovery cohort also point to the brain. The analysis shows that genes involved in neuritogenesis are overrepresented in our dataset (p=6.78×10^6). In addition, six SNPs map to the α-adrenergic signaling pathway (p=6.16×10^{-4}), an important target for pain medication.

Conclusion: Significant findings will be replicated in a third patient population. Confirmed biomarkers can be used to personalize medication for the individual patient.

IL–22 Mediated Pannus Formation in Autoimmune Arthritis Is PI3K/Akt/mTOR Dependent. Siba P. Raychaudhuri[1], Anupam Mitra[1], Ananya Datta Mitra[2], Christine Abria[2] and Smriti K. Raychaudhuri[2]. [1]VA Sacramento Medical Center\UC Davis School of Medicine, Mather, CA, [2]VA Sacramento Medical Center, Mather, CA

Background/Purpose: IL-22, a Th17 cytokine plays a key role in the formation of "pannus" in autoimmune arthritis such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA), by inducing proliferation of synovial fibroblasts (FLS) [1, 2]. Among diverse functions of PI3K/Akt/mTOR signaling cascade, cell proliferation is an important one and is emerging as a potential therapeutic target for various malignant diseases. Here we are reporting that IL-22 induced FLS proliferation is PI3K/Akt/mTOR dependent.

Methods: FLS were derived from synovial tissues of PsA (n=5) and RA (n=5) patients. MTT assay in presence or absence of dual kinase (PI3K/mTOR) inhibitor, NVP-BEZ235 (BEZ) and mTOR inhibitor, Rapamycin were performed to determine the role of PI3K/Akt/mTOR in IL-22 induced FLS proliferation. Further we substantiate our findings by determining the expression of Akt/mTOR in presence or absence of IL-22, BEZ and Rapamycin with western blotting.

Results: IL-22 significantly increased proliferation of FLS (OD: 1.70 $\pm$ 0.09 vs. 0.86$\pm$0.04, p<0.0001, ANOVA) (Figure 1) derived from patients of autoimmune arthritis. Both Rapamycin and BEZ significantly inhibited IL-22 induced FLS proliferation. BEZ showed more inhibitory effect than rapamycin. In western blot, we observed that IL-22 significantly induced phosphorylation of Akt and mTOR in FLS (Figure 2). IL-22 induced phosphorylation of Akt and mTOR in FLS was significantly reduced by BEZ and Rapamycin respectively. This indicates that IL-22 induces FLS proliferation through the PI3K/Akt/mTOR pathway.
Conclusion: This is the first study showing the regulatory role of PI3K/Akt/mTOR signaling cascade in the IL-22 mediated FLS proliferation in autoimmune arthritis and thus provides a new insight in the signaling cascade of IL-22 in autoimmune arthritis.

CIP2A Facilitates Apoptotic Resistance of Fibroblast-Like Synoviocytes in Rheumatoid Arthritis Independent of c-Myc Expression. Jaejoon Lee[1], Jiwon Hwang[2], Jinseok Kim[3], Joong Kyong Ahn[4], Hoon-Suk Cha[1] and Eun-Mi Koh[5]. [1]Samsung Medical Center, Sunkyunkwan University School of Medicine, Seoul, South Korea, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Jeju National University Hospital, Jeju, South Korea, [4]Kangbuk Samsung hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Seoul, South Korea

Background/Purpose: Cancerous inhibitor of protein phosphatase 2A (CIP2A) is a recently identified oncoprotein that leads to cellular proliferation in cancer cells by stabilizing c-Myc protein. The effect of CIP2A in stabilizing c-Myc by inhibition of protein phosphatase 2A activity is a prerequisite step in tumor cell growth and in vivo tumor formation. We have previously shown that CIP2A is expressed in rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS), and that its expression is strongly associated with histopathological synovitis score and invasive function of RA FLS. The aim of this study is to investigate the effects of CIP2A on the apoptosis of RA FLS and to determine the signaling pathway through which dysfunctional apoptosis is facilitated.

Methods: Proliferation and apoptotic activity of RA FLS following treatment with CIP2A siRNA or control siRNA were analyzed using MTT assays and Cell Death Detection ELISA kit. RA FLS was treated with CIP2A siRNA or control siRNA in 3, 6, and 9 day intervals for a Western blot analysis to determine C-Myc expression. To evaluate the signal transduction pathways engaged in apoptosis, caspase-3 activity, caspase-9 activity, PARP, and phosphorylation of the Akt kinase were analyzed by Western blot analysis.

Results: Cell viability of RA FLS, as measured by MTT assay, was significantly lower in the CIP2A siRNA-treated group compared with the control after 7 days (p=0.022). Apoptosis of RA FLS, as measured by DNA fragmentation, was significantly higher in the CIP2A siRNA-treated group compared with the control when incubated for 3, 6 and 9 days (p= 0.029, p=0.021, p=0.043, respectively). Interestingly, c-Myc expression, as determined by Western blot analysis, did not change with the different incubation periods. CIP2A siRNA-treated FLS expressed higher level of activated caspase-3, caspase-9, and PARP (p=0.014, p=0.020, p=0.021, respectively) and lower level of phosphorylated Akt (p=0.001) compared with those treated with the control siRNA.

Conclusion: Our data show that CIP2A expression in RA FLS is an important mediator of dysfunctional apoptosis independent of c-Myc stabilization. Expression of CIP2A may contribute to apoptotic resistance of RA FLS through activation of Akt and deactivation of caspase-3, caspase-9, and PARP. Inhibition of CIP2A may therefore constitute a novel, promising therapeutic target in RA.

Synthetic Anti-CCP Antibody Aggravated Severity of Animal Arthritis and Captured Citrullinated Antigen in the Serum of Patients with Rheumatoid Arthritis. Youngkyun Kim[1], Su-Jin Moon[1], Hyoju Yi[1] and Ji Hyeon Ju[2]. [1]College of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]College of Medicine, The Catholic University of Korea & Stanford University, Seoul & Palo Alto, CA

Background/Purpose: Auto-antibodies against citrullinated protein antigens (ACPA) have shown their relevance for the prognosis and diagnosis of rheumatoid arthritis (RA), and have been implicated in disease pathogenesis. However, the exact pathologic relevance of these antibodies remains unclear. To obtain insight into this question, we tried to synthesize ACPA and then apply it to animal model and human samples.

Methods: Using hybridoma technology, an IgG monoclonal antibody (mAb), 12G1 was developed against a cyclic-citrullinated peptide (CCP). Clones were selected on the basis of not reacting with control peptide (CRP) which was included one arginine instead of citrulline on the same peptide sequence and structure, but reacting well with synthetic CCP. After successful establishment of hybridoma for anti-CCP Ab, we analyzed the characteristics

of this synthetic anti-CCP Ab. 12G1 was challenged to collagen induced arthritis (CIA) model. Western blot with 12G1 was done on the serum samples of RA patients (n=25) and non-RA control (n=23). Synovium of CIA and RA patients were immunostained with 12G1.

Results: Immunohistochmical analysis with 12G1 revealed positive staining result in CIA and RA patients in comparison with control samples of wild type mice and osteoarthritis. Western blot analysis of sera from RA patients had stronger 12G1-positive bands of citrullinated protein compared with non-RA controls. Average band density was four times higher in RA than non-RA (p=0.001). These western results showed the meaningful correlation with 2nd generation commercial Anti-CCP Ab diagnostic kit (n=48, p=0.02). Moreover, to evaluate the direct role of generated anti-CCP Ab, mice were immunized with CII and then injected with 12G1 instead of second boosting. Immunized mice with 12G1 demonstrated significantly increased disease severity and incidence compared with mice challenged with negative control.

Conclusion: In conclusion, we generated a synthetic monoclonal antibody against CCP. This antibody exacerbated arthritis in CIA model and had the potential to detect citrullinated Ag in human RA serum. Application of this anti-CCP Ab may contribute to understanding the pathophysiology of RA and developing synthetic Ab-driven diagnostic strategy.

SIRT6 Regulates Cigarette Smoke Induced MMP1 Expression in Rheumatoid Arthritis Synovial Fibroblasts. Anna Engler, Renate E. Gay, Beat A. Michel, Steffen Gay and Caroline Ospelt. Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland

Background/Purpose: Cigarette smoking is the best-known environmental risk factor for the development of rheumatoid arthritis (RA). However, the molecular mechanisms involved in the association of smoking and progression of RA are not well investigated. Sirtuins (SIRTs) are recently discovered regulators of inflammation. The aim of the current study was to investigate the impact of cigarette smoke extract (CSE) on the expression of interleukins (ILs) and matrix metalloproteinases (MMPs), and the possible function of SIRTs in the cigarette smoke induced inflammatory response in RA synovial fibroblasts (RASF).

Methods: Synovial tissues were obtained from RA patients undergoing joint replacement surgery. RASF from non smokers (n=16) were stimulated with 5% CSE or 10 ng/ml TNFα for 24 hours. Expression of SIRTs, ILs and MMPs was measured at the mRNA level by Real-time TaqMan and SYBR green PCR. Protein levels of SIRTs were detected by immunoblot in cell lysates and of ILs and MMPs in cell culture supernatants by ELISA. For silencing of SIRT6, RASF (n=10) were transfected with siRNA targeting SIRT6 or control siRNA for 48h prior to stimulation.

Results: Stimulation of RASF with CSE significantly increased protein levels of IL8 (by 1.9-fold$\pm$0.26, p=0.03) and MMP1 (by 1.8-fold$\pm$0.13, p=0.01), but did not affect the protein expression of IL6 and MMP3. Also at the mRNA level IL8 was 4.1-fold$\pm$0.7 (p=0.03) and MMP1 was 5.8-fold$\pm$1.4 (p=0.02) increased in CSE stimulated RASF, indicating that cigarette smoke regulates the expression of IL8 and MMP1 at the transcriptional level. Analysing the expression of SIRTs 1–7 revealed that CSE increases significantly the expression of SIRT6. Furthermore, SIRT6 protein levels were elevated upon TNFα stimulation. Basal expression as well as induction of SIRT6 after stimulation was successfully blocked by transfection of RASF with SIRT6-specific siRNA. Basal production of MMP1 increased significantly by 31$\pm$6% (p=0.008) after silencing of SIRT6. After stimulation with CSE, silencing of SIRT6 enhanced the levels of MMP1 protein by 35$\pm$8.8% (p=0.01) compared to control transfected, CSE stimulated cells. Also stimulation with TNFα had a significantly stronger effect on MMP1 expression in SIRT6 silenced, compared to control transfected cells (control: 4.1-fold $\pm$1.4 induction, siSIRT6: 6.4-fold $\pm$2.1 induction; p=0.004). Expression of IL6, IL8 and MMP3 was not affected by silencing of SIRT6 under basal as well as in stimulated conditions.

Conclusion: In the current study we found that CSE increases the expression of IL8 and MMP1 in RASF. Most interestingly, we could show that both CSE and TNFα induced production of MMP1 is specifically regulated by SIRT6. Therefore, we conclude that SIRT6 acts as a protective regulator attenuating CSE as well as TNFα induced MMP1 production in

RASF. This protective function of SIRT6 must be considered in the development of therapies using pan sirtuin inhibitors that target also SIRT6 activities.

Methyl Supplementation of Rheumatoid Arthritis Synovial Fibroblasts Regulates the Expression of Transcription Factors and Matrix Metalloproteinases. Edvardas Bagdonas, Emmanuel Karouzakis, Astrid Jungel, Caroline Ospelt, Renate E. Gay, Steffen Gay, Beat A. Michel and Michel Neidhart. Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Previously we reported that methyl supplementation can reverse the global hypomethylation of rheumatoid arthritis synovial fibroblasts (RASF) and attenuate their aggressive behaviour. Now we analysed the molecular changes occurring in matrix metalloproteinases (MMPs) and transcription factors after treatment with methyl supplementation.

Methods: RASF (n=6 patients) were cultured in DMEM/F12 + 10% FCS as a control and in medium supplemented with 10-fold excess amount of folic acid (70 μM), vitamin B12 (6 μM) and L-methionine (1,1 mM) (high supplementation - HS) for 10 days. After the treatment, cells were counted to determine doubling time, their RNA isolated and supernatants were tested using MMPs ELISA assays. The gene expression of MMPs and transcription factors was evaluated by real time-PCR and gene expression array (QIAGEN RT^2 Profiler PCR Human Transcription Factors Array), respectively. The untreated and treated RASF were implanted together with normal human cartilage into SCID mice. The cartilage sample slides were scored by three independent investigators.

Results: After 10 days of culturing in HS medium, the expression of MMP1 gene was significantly down regulated (p = 0.034) while changes in the mRNA level of MMP3 were not significant (p = 0.56). There was also a significant reduction in the level of MMP1 protein in RASF grown in HS medium (p = 0.027) and no significant reduction of MMP3 protein level (p = 0.49). The effect of HS on the state of DNA methylation and gene expression is dependent on cell proliferation. Indeed, MMP1 expression strongly correlated with the cell population doubling time – r = 0.9455, p = 0.0044. The expression of 6 out of 84 analyzed genes was significantly changed by methyl supplementation. ELK1, HDAC1, HSF1 were up regulated while JUN, NFATC3 and SMAD9 were down regulated (p < 0.05). Most interestingly, HS treated RASF showed reduced invasion and perichondrocytic degradation in the SCID mouse invasion model *in vivo* (invasion score: control 2.25±0.27; HS 1.26±0.26, p<0.03, n=5; perichondrocytic score: control 1.91±0.18; HS 1.17±0.23, p<0.01, n=5).

Conclusion: Methyl supplementation reduced the expression of MMP1, significantly altered expression pattern of 6 transcription factors and inhibited the invasive properties of RASF *in vivo*. Therefore, this supplementation might be used as a novel therapeutic approach to inhibit joint destruction in rheumatoid arthritis.

Interaction of Antibodies Against Citrullinated Peptides with HLA Shared Epitope, PTPN22 1858T Variant, and Smoking in Individuals Prior to and After the Development of Rheumatoid Arthritis. Heidi Kokkonen[1], Mikael Brink[2], Monika Hansson[3], Linda Mathsson[4], Ewa Lassen[5], Per Johan Jakobsson[3], Rikard Holmdahl[6], Johan Rönnelid[4], Lars Klareskog[7] and Solbritt M. Rantapaa-Dahlqvist[8]. [1]Umeå University, Umea, Sweden, [2]Umea University, Umea, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Uppsala University, Uppsala, Sweden, [5]Umeå University, Umeå, Sweden, [6]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [7]Karolinska Institute, Stockholm, Sweden, [8]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umea, Sweden

Background/Purpose: The presence of antibodies against cyclic citrullinated peptides (ACPA) has been demonstrated to precede the development of rheumatoid arthritis (RA) by several years. The gene-environment interaction for these antibodies has not been elucidated.

The aim was to analyse for the development of reactivity against citrullinated peptides during the pre-disease phase of RA and after disease onset in relation to genetic and environmental factors.

Methods: This study comprised 406 individuals, providing 717 samples, who were identified before onset of symptoms of RA (median (IQR) 7.4 (9.3) years), as donors to the Medical Biobank of Northern Sweden. Among these, 204 were also sampled at the time of diagnosis. Population controls (1305) were identified from the Medical Biobank. Analysis of antibodies against 10 different citrullinated peptides; fibrinogen (Fib) β36–52, Fib α72, Fib α74, Fib α573, Fib α591, α-enolase (CEP-1), collagen citC1, filaggrin, vimentin (Vim) 2–17, and Vim 60–75 was performed using a microarray system developed in collaboration with Phadia AB/Thermofisher, Uppsala, based on their ISAC platform. All samples were also analysed for anti-CCP2 antibodies by ELISA (Euro-Diagnostica). HLA-DRB1 alleles were genotyped using polymerase chain reaction sequence-specific primers. Genotyping of the PTPN22 1858C/T polymorphism was performed using a Taqman instrument.

Results: The frequency of antibodies against Fibβ36–52, CEP-1, and filaggrin and anti-CCP2 increased significantly during the pre-dating time with the highest frequency of all antibodies before onset of symptoms. The number of positive antibodies against citrullinated peptides increased the closer to onset of symptoms and was significantly higher in individuals carrying HLA-SE or T-variant compared with those without. Individually antibodies against Fibβ36–52, CEP-1, and filaggrin were in combination with HLA-SE, PTPN22 T variant and smoking associated with the development of RA, even stronger than for anti-CCP2 antibodies. Development of antibodies against the various citrullinated peptides after disease onset in individuals who were negative for these antibodies prior to onset of symptoms was associated with the presence of HLA-SE and smoking e.g. antibodies against Fib β36–52, CEP-1, Fib α74, and Vim 60–75 were significantly associated with HLA-SE. Positivity for antibodies against Fib β36–52, CEP-1, Vim 60–75, collagen citC1, Fib α591, and Fib α573 was all significantly associated with smoking.

Conclusion: These results indicate that the development of an ACPA immune response is restricted to individuals carrying HLA-SE or the PTPN22 1858T variant, is strengthened by smoking and conversion to positivity for several of the antibodies is associated with the presence of HLA-SE and/or smoking

440

Effects of Fetal Microchimerisms On Disease Onset and Severity in Women with Rheumatoid Arthritis and Systemic Lupus Erythematosus. Marianne Kekow[1], Sara Fill Malfertheiner[2], Maria Barleben[1], Susanne Drynda[3], Joern Kekow[3] and Thomas Brune[1]. [1]Univ of Magdeburg, Children's Hospital, Magdeburg, Germany, [2]Univ of Magdeburg, Department of Obstetrics and Gynecology, Magdeburg, Germany, [3]Univ of Magdeburg, Vogelsang-Gommern, Germany

Background/Purpose: The major source of naturally acquired microchimerisms (MC) is the transplacental traffic of fetal cells between a mother and the fetus during pregnancy. Fetal cells have been found to persist in maternal blood for many years post partum. It was the aim of this study to analyze the prevalence of fetal MC in patients with inflammatory rheumatic diseases and to investigate the association of MC with disease severity.

Methods: A total of 143 women who had delivered at least one male offspring were recruited: 73 women with rheumatoid arthritis (RA), 16 women with systemic lupus erythematosus (SLE) and 54 women as non-affected controls. The mean age was 62.5 years (RA), 56.2 years (SLE), and 40.5 years (control cohort). Women who had received a blood transfusion in the past were not included in this study.

For the analysis of fetal MC in DNA from maternal circulation a nested PCR was used to detect a male fetal sequence in the TSPY gene on the Y chromosome.

For both disease groups age at disease onset and markers for disease activity were compared for MC+ and MC- patients, this includes for RA patients anti-CCP-antibodies (anti-CCP), rheumatoid factor (RF) and radiographic progression (Steinbrocker score); and for SLE antinuclear antibody

(ANA) and anti-dsDNA antibody, serum C3, C4, CH50, and soluble interleukin 2 receptor (sIL2R) levels.

Results: The prevalence of fetal MC was 18% in RA patients and 31% in patients with SLE, which is significantly increased compared to 3.7% in non-affected controls (p=0.02 and p=0.006, resp.).

The mean age at disease onset was comparable in MC+ and MC- RA patients with about 43.3 years. Disease onset occurred 18.7 and 19.8 years post partum of the first son for MC+ and MC- patients, respectively. The presence of anti-CCP and RF did not differ significantly: anti-CCP were found in 75% of MC+ and 87% of MC- RA patients, RF in 75% of both MC+ and MC- patients. A higher mean Steinbrocker Score in MC+ patients (3.2 vs. 3.0) was associated with a longer disease duration: 19.4 years (MC+) vs. 16.5 years (MC-).

In SLE patients mean age at disease onset was 42.6 years in MC+ and 49.1 years in MC- patients. Disease onset occurred 24.0 and 26.4 years post partum of the first son for MC+ and MC- patients, respectively. The presence of ANA and anti-dsDNA antibodies, sIL2R, C3, C4, and CH50 did not differ significantly. In MC+ patients sicca symptoms were found most frequently (80%), followed by involvement of joints (60%), central nervous system (20%) and kidneys (20%). In contrast, in MC- patients joints were affected mostly (70%), followed by skin (60%), central nervous system (30%) and sicca symptoms (20%).

Conclusion: In a cohort of RA patients as well as in patients with SLE the prevalence of MC was significantly increased compared to a cohort of non-affected controls. The disease severity in patients with RA or SLE did not differ depending on the presence of MC.

In conclusion our results indicate that the long persistence of microchimerism as a marker of a pathologic clearance of semi-allogeneic DNA is associated with rheumatic diseases without effect on disease severity.

441

Performance of Anti-Cyclic Citrullinated Peptide Assays Differs in Healthy Subjects At Elevated Risk for Future Rheumatoid Arthritis and Subjects with Established Disease.
M. Kristen Demoruelle[1], Mark Parish[2], Lezlie A. Derber[2], Michael H. Weisman[3], William R. Gilliland[4], Jess Edison[4], James R. O'Dell[5], Ted R. Mikuls[5], Richard M. Keating[6], Peter K. Gregersen[7], Jane H. Buckner[8], Jill M. Norris[9], V. Michael Holers[1] and Kevin D. Deane[1]. [1]University of Colorado School of Medicine, Aurora, CO, [2]University of Colorado Anschutz Medical Campus, Aurora, CO, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Walter Reed National Military Medical Center, Bethesda, MD, [5]University of Nebraska Medical Center, Omaha, NE, [6]University of Chicago, Chicago, IL, [7]North Shore University Hospital Research Center, Manhasset, NY, [8]Benaroya Research Institute at Virginia Mason, Seattle, WA, [9]Colorado School of Public Health, Aurora, CO

Background/Purpose: The 2010 ACR/EULAR RA criteria include autoantibodies to cyclic citrullinated peptides (CCP) that are highly specific for RA in the setting of inflammatory arthritis (IA). In addition, multiple studies demonstrate that CCP positivity can occur years prior to the onset of IA. Therefore, there is hope that CCP testing can be used to identify healthy subjects with sufficiently high risk for future RA who can be studied to understand the natural history of RA, as well as to identify subjects most likely to benefit from preventive interventions. However, while there are multiple types of CCP assays, there is limited data in subjects with and without RA comparing the performance of each assay or the ability of a positive test to predict future development of clinically-apparent RA.

Methods: CCP testing was performed using 2 commonly used ELISA assays [CCP2 (IgG) (Axis-Shield) and CCP3.1 (IgG, IgA) (INOVA)] in sera from the following: 1) RA cases from the Studies of the Etiology of RA (SERA) project, 2) RA cases from the Dept of Defense Serum Repository (DoDSR) with pre- and post-diagnosis samples available, 3) SERA first degree relatives (FDR) of probands with RA who are at elevated risk for future RA due to familial RA, and 4) controls (case-matched DoDSR subjects and randomly selected blood donors). The diagnostic accuracy of assays for established RA was calculated comparing cases (probands and DoDSR) and controls. Prevalence of positivity was compared using chi-squared/Fishers exact testing.

Results: For established RA, CCP2 was more specific but less sensitive than CCP3.1 (Table). As cut-off levels for positivity were increased, specificity increased. In all subjects, CCP3.1 was more prevalent than CCP2. In DoDSR samples prior to RA diagnosis, there was a strong association of CCP

levels >2× normal with a diagnosis of RA within 2 years [CCP2 OR 7, 95% CI 3–17, p<0.01; CCP3.1 OR 7, 95% CI 3–16, p<0.01]. Assay agreement was good in established RA (kappa 0.7), but poor in subjects without RA (k 0.2). However, agreement improved (k 0.5) in FDRs using cut-offs >2× normal suggesting the moderate range CCP titers encompass most of the discordant samples.

Results of CCP2 and CCP3.1 Assay Testing in Subjects with and without Rheumatoid Arthritis

	Sensitivity (or prevalence)			Specificity†		
	Standard kit cut-off‡	Cut-off >2× normal	Cut-off >3× normal	Standard kit cut-off‡	Cut-off >2× normal	Cut-off >3× normal

CCP2 and/or CCP3.1 (95% CI)	66.3 (55.0–76.0)	—	—	91.6 (82.9–96.3)	—	—
SERA FDRs (N = 681)*						
CCP2	2.2	1.6	1.5	—	—	—
CCP3.1	9.5	4.3	3.2	—	—	—

†Specificity calculated for SERA RA cases compared to random blood donor controls (N = 200); for DoDSR RA cases compared to DoDSR matched controls
‡standard kit cut-off levels used, for CCP2 >5 units and for CCP3.1 ≥20 units
*Prevalence of positivity; comparing CCP2 and CCP3.1, p-value <0.01 for all 3 cut-offs

Conclusion: CCP assays differ in established RA to an extent that may have a clinically meaningful impact on diagnosis. Also, as CCP3.1 is more often elevated in pre-RA DoDSR cases and in subjects at-risk for future RA, it may represent a more sensitive test, albeit less specific, to identify subjects for investigations into the pathogenesis of RA and potential candidates for preventive interventions. Furthermore, in DoDSR cases, the association of higher CCP levels with a shorter time to the onset of RA suggests that CCP levels can be used to predict the timing of future onset of RA in currently asymptomatic subjects. These findings, as well as potential mechanisms underlying the differences (such as isotype or antigen detections) in these 2 commonly-used tests need further investigation.

442

Joint Effects of Known Genetic Markers of Rheumatoid Arthritis Risk and 25-Hydroxyvitamin D On Rheumatoid Arthritis Risk.
Linda T. Hiraki[1], Chia-Yen Chen[2], Jing Cui[3], Susan Malspeis[4], Karen H. Costenbader[5] and Elizabeth W. Karlson[5]. [1]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Womens Hospital, Boston, MA, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Rheumatoid arthritis (RA) is a complex disease with both genetic and environmental risk factors. A number of susceptibility genes have been identified. Past studies have also observed an association between decreased levels of vitamin D and RA. We aimed to examine the joint effects of genetic markers of RA, and circulating vitamin D levels on RA risk.

Methods: We selected incident Caucasian RA cases (n=133) who contributed blood samples prior to first RA symptom and matched controls (n=134) from the Nurses' Health Study and Nurses' Health Study II cohorts. We genotyped 36 RA risk alleles identified by previous GWAS and meta-analysis, and 8 *HLA-DBR1* shared epitope (SE) genotypes at 4 digit resolution. We measured 25-hydroxyvitamin D (25(OH)D) levels by chemi-luminescence immunoassay. We used conditional logistic regression to examine the marginal genetic and 25(OH)D effects, as well as testing for

additive and multiplicative interaction between the genetic markers and 25(OH)D (sufficient vs. insufficient (^{2}20ng/mL)). We ran unconditional logistic regression analysis stratified by seropositive (n=66) and seronegative (n=67) RA phenotypes additionally adjusted for matching factors. We adjusted for multiple comparisons with Bonferroni correction.

Results: We found statistically significant main effects of *HLA-DBR1* SE and RA (p=0.0013) and seropositive RA (p=4×10^{-5}). There was no significant main effect association between vitamin D insufficiency and RA. Among all RA cases we observed a statistically significant additive interaction between *FCGR2A* (rs7552317) and insufficient 25(OH)D (p=0.004). For subjects with having any *FCGR2A* alleles and insufficient 25(OH)D there was an >2-fold odds of RA (2.18 (95% CI 1.11, 5.81)) when compared to those without *FCGR2A* alleles and sufficient 25(OH)D (Table). Among seropositive RA we observed a statistically significant additive interaction between *HLA-DRB*0101* and insufficient 25(OH)D (p= 0.0002) where having any *HLA-DRB*0101* and insufficient 25(OH)D was associated with an >2-fold increase in odds of RA (2.18 (95% CI 0.82, 5.79)).

Table. Gene-vitamin D interactions between *FCGR2A* and *HLA-DRB1*0101* polymorphisms and vitamin D insufficiency in relation to risk of all rheumatoid arthritis (RA) and seropositive RA.

RA phenotype	Genetic factors	Categories of 25(OH)D*	No. cases/ No. controls	OR (95% CI)	Attributable proportion (p-value)	Multiplicative p-value
All RA	*FCGR2A*	Sufficient vitamin D	28/14	1.0 (ref)	0.66 (0.0043)	0.07
	None		11/12	0.93 (0.51–1.70)		
	None	Insufficient vitamin D	61/72			
	Any	Sufficient vitamin D	25/25	0.94 (0.36–2.48)		
	Any	Insufficient vitamin D		2.54 (1.11–5.81)		
Seropositive RA	*HLA-DRB1*0101*	Sufficient vitamin D	15/11	1.0 (ref)	0.92 (0.0002)	0.03
		Insufficient vitamin D	3/8	0.55 (0.27–1.12)		
	None		27/81			
	None	Sufficient vitamin D	19/31	0.62 (0.14–2.67)		
	Any	Insufficient vitamin D		2.18 (0.82–5.79)		
	Any					

Conclusion: We observed significant gene-vitamin D interactions when assessing RA risk and seropositive RA risk. *FCGR2A* (Fc fragment of IgG, low affinity IIa, receptor) and *HLA-DRB1* play important roles in the immune system. *FCGR2A* has been associated with receptor aggregation, neutrophil activation, SLE and lupus nephritis. These results offer clues into the pathophysiology of RA and support a role for vitamin D in inflammatory pathways in pre-RA.

Secreted Frizzled-Related Protein 5 Exerts the Anti-Inflammatory Role in Rheumatoid Arthritis Via Down-Regulation of c-Jun N-Terminal Kinase. Yong-Jin Kwon, Tae-Yeon Kim, Sang-Won Lee, Yong-Beom Park, Soo Kon Lee and Min-Chan Park. Yonse University College of Medicine, Seoul, South Korea

Background/Purpose: Secreted frizzled-related protein 5 (Sfrp5) is a novel adipokine that has beneficial effects on metabolic dysfunction by controlling inflammatory cells within adipose tissue. Sfrp5 acts as a soluble modulator that binds and sequesters Wnt proteins in the extracellular space and that prevents the activation of frizzled and attenuating non-canonical Wnt signaling. Consequentially, c-Jun N-terminal kinase (JNK), a downstream target of non-canonical Wnt signaling, is inhibited. The purposes of this study are to determine the expression of Sfrp5 in fibroblast-like synoviocyte (FLS) from rheumatoid arthritis (RA) patients and to investigate the correlation between the expression levels of Sfrp5 and that of pro-inflammatory genes in RA FLS.

Methods: FLS were isolated and cultured from synovial tissues obtained from patients with RA or osteoarthritis (OA) during total knee replacement surgery. The mRNA expressions of Sfrp5 in peripheral blood mononuclear cells (PBMCs) and FLS from patients with RA or OA were determined using real-time quantitative RT-PCR. Adenovirus containing Sfrp5 transcript was constructed and delivered into RA FLS to strengthen Sfrp5 expression, then, Sfrp5 RNAi plasmid was transfected to abrogate Sfrp5 expression in RA FLS.

The mRNA expressions of TNF-α, IL-1β, IL-6, CCL-2, CCL-7, COX-2 and MMP-9 were also determined using quantitative real-time PCR and western blot analysis was performed to assess MKK4, MKK-7, ATF-2, c-Jun and JNK activity in RA FLS.

Results: Expression of Sfrp5 mRNA in PMBCs from RA patients was significantly decreased compared to those from OA patients, and this decrease was more accentuated in RA FLS compared to OA FLS (more than 10-fold in OA FLS). The mRNA expressions of TNF-α, IL-1β, IL-6, CCL-2, CCL-7, COX-2 and MMP-9 were remarkably increased in Sfrp5 RNAi plasmid-transfected RA FLS, compared to non-silencing RNAi plasmid-transfected RA FLS. However, adenoviral vectors encoding Sfrp5 significantly reduced the mRNA levels of TNF-α, IL-1β, IL-6, CCL-2, CCL-7, COX-2 and MMP-9 as compared with control vector. The activity of MKK4, MKK-7, ATF-2, c-Jun and JNK were up-regulated in RA FLS with no Sfrp5 expression by Sfrp5 RNAi plasmid; and were down-regulated with strong Sfrp5 expression by adenoviral vectors encoding Sfrp5.

Conclusion: Sfrp5 suppressed various pro-inflammatory gene expressions via modulation of JNK. These findings suggest that Sfrp5 may have a certain role in RA pathogenesis and have an anti-inflammatory effect.

Tocilizumab Improves Bone Mineral Density Compared with Abatacept in Patients with TNF Blockers-Resistant Active Rheumatoid Arthritis. an Open Label Randomized Controlled Trial. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1], Kazuhiko Hatta[2], Kuniki Amano[3], Noriko Kuwaba[4] and Hiroyuki Ohta[5]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hatta Clinic, Kure, Japan, [3]Sky Clinic, Hiroshima, Japan, [4]Sanki Clinical Link, Hiroshima, Japan, [5]Hiroshima, Japan

Background/Purpose: To compare the effect of tocilizumab(TCZ) plus methotrexate (MTX), with the effect of abatacept(ABT) plus MTX on bone mineral density(BMD) in TNF blockers resistant active rheumatoid arthritis(RA; without osteoporosis) patients, in a prospective open label randomized study design.

Methods: RA patients were eligible if they had active disease despite treatment with MTX plus TNF blockers. All patients have no previous history of lumbar and hip fractures. Patients receiving or having received bisphosphonates or hormone replacement therapy, steroids, or any biologics were excluded. 52 patients with moderate to severe active RA patients (DAS28 >3.2) were randomly assigned to receive TCZ plus MTX (n=26) or ABT plus MTX (n=26). All patients with worsening disease activity at week 12, the patients were allowed to escape to another group (by clinician's judgment). The primary outcomes were changes in lumbar and femoral BMD by dual-energy X-ray absorptiometry, secondary outcome were changes in biomarkers of bone turnover (procollagen type I amino-terminal propeptide(P1NP) from baseline to 52 weeks. Clinical data were collected at regular visit. All patients were taking calcium (1 g/day) and vitamin D (800 IU/day).

Results: The characteristics of each group at baseline were not significantly different. 24 patients each in the TCZ and ABT groups completed 52 weeks. Lumbar and femoral BMD were attenuated significantly by TCZ (weeks 52-baseline: lumbar BMD: 0.09±0.011 g/cm^2, $p < 0.001$; femoral BMD: 0.08±0.01 g/cm^2, $p < 0.001$). On the other hand, lumbar and femoral BMD were not attenuated significantly by ABT (weeks 52-baseline: lumbar BMD: 0.01±0.039 g/cm^2, p =0.66; femoral BMD: $-$0.004±0.014 g/cm^2, p =0.87. The change (weeks 52-baseline) lumbar and femoral BMD of the TCZ group were significantly improvement than those of the ABT group (TCZ vs. ABT, lumbar BMD: p <0.05; femoral BMD: p <0.05).P1NP was significant increase by TCZ (weeks 52-baseline: 4.2 ±0.15μg/L, p <0.05), but was not attenuated significantly by ABT (weeks 52-baseline: 0.98 ±0.83μg/L, p=0.65).DAS28 and CRP improved significantly in both groups (weeks 52-baseline; DAS28, TCZ: $-$1.87±0.45, ABT: $-$1.81±0.42) (CRP, TCZ: $-$18.6±4.2 mg/l, ABT: $-$17.7±4.3mg/l) (p <0.05). They were no significant difference between groups.

Conclusion: TCZ plus MTX improves bone mineral density compared with ABT plus MTX in TNF blockers resistant RA. If RA patients were resist TNF blocker, we might think the patients were treated by TCZ than ABT.

Combination of Intra-Articular Steroid Injection and Infliximab More Effective Than Infliximab in Rapid Radiographic Progression Patients with Rheumatoid Arthritis: A Randomized, Open Label, x Ray Reader Blinded Study. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1], Kazuhiko Hatta[2], Kuniki Amano[3], Hiroyuki Ohta[4] and Noriko Kuwaba[5]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Hatta Clinic, Kure, Japan, [3]Sky Clinic, Hiroshima, Japan, [4]Hiroshima, Japan, [5]Sanki Clinical Link, Hiroshima, Japan

Background/Purpose: Treatment of rheumatoid arthritis (RA) should aim at full remission. However, recent publications described rapid radiographic progression (RRP) existed despite initial biologics and methotrexate combination therapy in early RA. In RRP, initial biologics and methotrexate might be inadequate.To compare remission and radiographic non-progression in RRP patients treated with infliximab or with infliximab plus intra-articular steroid injection.

Methods: We designed a single-blind(X ray reader and assessment physician), randomized controlled trial. We screened 48 RRP (CRP> 35mg/L, RF +, and ACPA+) early (disease duration<6 months) RA patients for inclusion. 39 were randomly allocated infliximab group (I group) or infliximab plus intra-articular steroid injection group (I plus I group). All patients were taking methotrexate (from 14 to 22mg a week). For I plus I group, palpate examinations of both MP and PIP joints, wrists, elbows, shoulders, and knees were performed every 4 weeks. If swollen joints were existed, intra-articular steroid injections were intensified in each swollen joints. Co-primary endpoints were proportion of patients showing clinical remission (SDAI <3.3) and radiographic non-progression (Δ modified total Sharp score ≤0.5) at 52 weeks. Analysis was by intention-to-treat with last observation carried forward to missing data.

Results: The characteristics of each group at baseline were not significantly different. Clinical remission at 52weeks was achieved by more patients in the I plus I group (32%) than in the I group (19%) (p<0.05). Radiographic non-progression at 52 weeks was achieved by more patients in the I plus I group (37%) than in the C group (24%) (p<0.05).

Conclusion: Results of this reveal that combination of intra-articular steroid injection and infliximab can achieve a high clinical and radiological remission rate in early RRP RA.

Clinical Remission and Rate of Relapse After Tocilizumab Withdrawal in Rheumatoid Arthritis Patients. Cesar Vargas-Serafin[1], Luis Aguilar-Lozano[1], Jorge Padilla-Ibarra[1], Carlos Sandoval-Castro[1], Jose Dionisio Castillo-Ortiz[1], Jorge Morales-Torres[2], Claudia Hernandez[2] and Cesar Ramos-Remus[1]. [1]Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico, [2]Hospital Aranda de la Parra, Leon, Mexico

Background/Purpose: Although there is much discussion regarding when to initiate a biological agent in rheumatoid arthritis (RA) patients, data on when to stop these agents is scant. Disease activity outcomes after the ending of an industry sponsored clinical trials may provide useful information regarding the duration of drug-free remission for a given biological agent. The aim of this study was to assess the length of remission and rate of relapse of disease activity after ending the open label, long-term extension study (5 yrs) using tocilizumab in RA patients enrolled in the OPTION[1] trial.

Methods: Patients who no longer received tocilizumab because of the ending of the extension study (5 yrs) of the OPTION trial were analyzed. All patients were: a) in remission (DAS28 < 2.6, 0 swollen joints) at the time of the last tocilizumab administration (week 260), b) followed thereafter every 8 weeks until relapse (≥ 1 swollen joints), c) on a stable methotrexate dose during the follow-up.

Results: Forty-five patients were analyzed, 87% females with a mean age of 52 yrs and a mean disease duration of 14 yrs. During the first 12 months of follow-up, 26 (58%) patients maintained remission, and at the last visit (17 months) 17 (38%) patients continued in remission. Relapses occurred in 28 (62%) patients: 14 (50%) of them during the first three months after the last tocilizumab administration. No variables were identified to predict length of remission.

Conclusion: Long-term clinical remission is possible in a substantial number of RA patients after suspension of tocilizumab. Additional data are required to support recommendations for discontinuing a biological agent after achieving remission. These recommendations would impact in patients' safety and the economic burden imposed by these treatments.

447

Long-Term Safety and Efficacy of Tabalumab, an Anti-B-Cell Activating Factor Monoclonal Antibody, in Patients with Rheumatoid Arthritis: A 52-Week, Open-Label Extension Study. Maria W. Greenwald[1], Leszek Szczepanski[2], Alastair C. Kennedy[3], Chin H. Lee[4], Emery Polasek[5], Melissa Veenhuizen[5], Rebecca Jones-Taha[6] and Pierre-Yves Berclaz[5]. [1]Desert Medical Advances, Palm Desert, CA, [2]Wydz. Fizjoterapii, Wyzsza Skola Spoleczno-Przyrodnicza, Poland, [3]Alastair C. Kennedy, MD, Vero Beach, FL, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly & Company, Indianapolis, IN, [6]PharmaNet/i3, Blue Bell, PA

Background/Purpose: Tabalumab, a monoclonal antibody that neutralizes membrane-bound and soluble B cell activating factor (BAFF), has been shown to reduce rheumatoid arthritis (RA) signs and symptoms[1]. This open-label study evaluated the long-term safety and efficacy of tabalumab in RA patients (pts).

Methods: This 52-week (wk), open-label, flexible-dose extension study enrolled pts who completed 24 wks of a randomized, controlled trial (RCT) of tabalumab vs placebo (pb) and received study drug for ≥6 or 12 wks. Pts remained on stable MTX doses throughout. In RCT 1, pts received pb or tabalumab 30 or 80 mg IV every 3 wks for 6 wks and followed-up for 18 wks. In RCT 2, pts received pb or tabalumab 1, 3, 10, 30, 60, or 120 mg SC every 4 wks (Q4W) for 24 wks. At extension study start, all pts received SC tabalumab 60 mg Q4W for 48 wks; a 1-time increase to tabalumab 120 mg Q4W (60/120 mg) and 1-time decrease to 60 mg Q4W per pt was allowed (60/120/60 mg).

Results: Of those who completed RCT 1 or 2, 98% (N=182, safety population) enrolled: tabalumab 60 mg (n=60), tabalumab 60/120 mg (n=121), and 1 pt after taking tabalumab 120 mg then returned to 60 mg. Baseline (pre-tabalumab) RA activity levels were generally higher for the 60/120 mg group. Overall, both groups appeared to maintain efficacy with long-term treatment (Table 1). One pt died due to myocardial infarction (60/120 mg). In each group, 5% discontinued due to an adverse event (AE). There was a higher frequency of serious AEs (SAEs) and treatment-emergent AEs (TEAEs, including severe events) as well as events of interest, including infections and injection-site reactions in the 60/120 mg group. Most infections involved the upper respiratory tract. One pt (60/120 mg) reported a fungal skin infection. No clinically significant differences in hematologic or chemistry values, vital signs, or ECGs were seen. Total B lymphocyte counts decreased by 40% from pre-tabalumab baseline for all groups. The incidence of treatment-emergent, anti-tabalumab antibodies was 4.4% (8/182). Table 2 shows more detailed safety data.

Sustained and Cumulated Response Over Time in Rheumatoid Arthritis Patients Treated with Rituximab After Initial Failure of Anti Tumor Necrosis Factor Agents. Ioan Ancuta[1], Catalin Codreanu[2], Ruxandra Ionescu[3], Magda Parvu[4] and Mihai Bojinca[1]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [3]Clinic Hospital "Sf. Maria", Bucharest, Romania, [4]"N.Gh. Lupu" Clinical Hospital, Bucharest, Romania

Background/Purpose: Although anti-TNF therapies moved forward the treatment of rheumatoid arthritis (RA), failure of the first anti-TNF medication is not uncommon. Many times modifying dosage/frequency of the initial drug or prescribing a different TNF inhibitor proves to be still inadequate. Using instead a biologic with a different mechanism of action, such as Rituximab (RTX), may be beneficial in terms of RA treatment to target.

Based on EULAR-T2T and ACR criteria we analysed response following each RTX course (2 g at every 24 weeks).

Methods: Longitudinal (2002 to date), observational, population-based, cohort study. The analysis was performed based on data from the National Health Insurance House (NHIH) for 400 out of 1126 patients treated with RTX for RA in October 2011 in the NHIH database. The patients' selection is statistically representative and homogenous at national level. All patients had an anti-TNF medication as first treatment stage for 2.5 years (average). In the second stage, 208 patients were switched to RTX after the initial anti-TNF failure. The remaining 192 patients followed one or two more anti-TNF therapy and only then continued with RTX. A total of 5 RTX courses were administered to both groups. Before each RTX course patient were monitored for DAS28 and EULAR response.

Results: Average DAS28 before RTX was 6.7 (N=400), reaching 4.5 (before C2), then 3.41 (before C3). At the time of this analysis 335 patients followed C3 and 211 C4. Before RTX start, 93% of the total number of patients was in HDA and 8% in MDA. After 2 RTX courses 38.25 % of the patients reached LDA or remission. After 18 months (before C4) 63.88 % patients were in LDA or remission, while before C5 86.73% of the 211 patients having C4 were in LDA or remission (48.82% in remission). In terms of EULAR response after 4 RTX cycles 84.36% had a good response and 15.64% a moderate response, compared to previous treatment with anti-TNF in the same interval (2 years): 5.03% good response and 91.82% moderate response.

	Baseline	W24	W48	W72	W96
DAS28	6.7	4.5	3.41	3	2.6
LDA %	0	5.25	26.25	37.91	37.91
Remission %	0	0.00	12.00	25.97	48.82
Eular Good Response %	0	2.00	32.25	60.90	84.36
Eular Moderate Response %	0	85.5	67.25	38.51	15.64

Conclusion: Each RTX course led to an increased and cumulative clinical DAS28 response compared to the previous one. With each following RTX course all patients registered consolidation of lower DAS28 response, and continuously growing LDA or remission percentage. Response was sustained and cumulated regardless their rheumatoid factor status. Introducing Rituximab to patients with no response or intolerance to anti-TNF agents proved to be an adequate choice, therefore we consider its prescription after the first anti-TNF failure as a preferred option in terms of clinical response.

449

Rituximab After First Anti Tumor Necrosis Factor Failure Is More Efficient with High Impact in Reducing Time and Costs to Achieve Superior Rates of Low Disease Activity and Remission. Ioan Ancuta[1], Catalin Codreanu[2], Ruxandra Ionescu[3], Magda Parvu[4] and Mihai Bojinca[1]. [1]"Dr. I. Cantacuzino" Hospital, Bucharest, Romania, [2]"Dr. I. Stoia" Center for Rheumatic Diseases, Bucharest, Romania, [3]Clinic Hospital Sf. Maria, Bucharest, Romania, [4]"N.Gh. Lupu" Clinical Hospital, Bucharest, Romania

Background/Purpose: Significant steps were done in creating new medications for treatment of rheumatoid arthritis (RA). As RA seriously affects the patients' quality of life, the effectiveness of selected approaches is a primary concern for the National Health Insurance House (NHIH). Also being a chronic disease and having finite budgets it is important to find also the best results/costs approach. In case of first anti-TNF medication failure, options are prescribing a different anti-TNF or switching to Rituximab (RTX).

Our objective was to identify the best results/costs ratio by comparing two RA therapeutic alternatives: (1) switch to RTX after first anti-TNF failure versus (2) switching after 2–3 anti-TNF failure.

Methods: Based on data from NHIH, we analysed clinical results and the corresponding costs for N=400 RA patients, within a longitudinal (2002–2011), observational, population-based, cohort study. All patients had an anti-TNF medication as first treatment stage for 2.5 years (average). In the second stage, 208 patients (Group 1) were switched to RTX after first anti-TNF failure, and 192 (Group 2) had one or two more anti-TNF before switched to RTX. We evaluated the clinical effectiveness of the 2 approaches using: DAS28 and EULAR response. For efficiency assessment we calculated in each set-up indicators like: average spending to obtain the treatment target (LDA or remission), average cost per decreased DAS28 point and duration of treatment versus target.

Results: In Group 1, after the first 2 RTX cycles (12 months) medium ΔDAS28 was -3.36 (compared to its value before the RTX switch). Group 2 evidenced first development of resistance to the anti-TNF medication, medium ΔDAS28 was $+0.26$ and after switch to RTX, ΔDAS28 decreased in 12 months with -2.72. By September 1st 2011 (four RTX cycles), 91% of Group 1 patients experienced LDA (36.1%) and remission (54.9%) vs. 80.8% of the patients in Group 2 (40.4% LDA, 40.4% remission). While the groups are comparable in size, with respect to the total expenditure for N=400 patients, Group 1 represents 38% while Group 2 is 62% of the total costs. In terms of treatment objectives 51% of the patients in Group 1 after 12 months achieved LDA or remission vs. 23.4% in Group 2. Considering the budget spent to obtain these results, NHIH spent in average 58% more per patient per DAS28 point with Group 2 vs. Group 1.

Conclusion: Switching on RTX after the first anti-TNF failure allows the achievement of a sooner and better EULAR response than RTX therapy after 2 or 3 anti TNF stages. DAS28 decreased consistently for all

RTX patients, irrespective of their group, but those in Group 1 achieved a lowest value faster. RTX after first anti-TNF is clearly more efficient, the costs to obtain superior clinical response being almost half of those involved in the second therapeutic option. The savings could be used for higher number of RA treated patients with the same budget and shortening the RA patient's waiting list. The balance cost-benefits being in favour of initiating a RTX medication after the first anti-TNF therapy (follow NICE recommendation) this is our recommendation for NHIH.

Late Onset Neutropenia After Rituximab Treatment for Rheumato-logical Conditions. Gabriel S. Breuer[1], Michael Z. Ehrenfeld[2], Itzhak Rosner[3], Alexandra Balbir-Gurman[4], Devy Zisman[5] and Daphna Paran[6]. [1]Shaare Zedek Medical Center, Jerusalem, Israel, [2]Chaim Sheba Medical Center, Tel HaShomer, Israel, [3]Bnai Zion Medical Center/Technion Faculty of Medicine, Haifa, Israel, [4]Rambam Health Care Campus, Haifa, Israel, [5]Carmel Medical Center, Haifa, Israel, [6]Tel Aviv Sourasky Medical Ctr, Tel Aviv, Israel

Background/Purpose: Rituximab is a monoclonal chimeric antibody targeting the CD20 on the surface of normal and abnormal maturing B cells. Late onset neutropenia (LON) is defined as an unexplained absolute neutrophil count of $<1.5 \times 10^9$/liter occurring at a time point at least 4 weeks after therapy. LON following rituximab treatment has been described extensively in hematological malignancies. However it has been reported infrequently in association with rheumatological diseases. To the best of our knowledge only 29 such cases have been published so far in the English literature. The aim of this work is to review cases in Israel and to compare them to published cases in the literature thus adding to the body of knowledge regarding this unusual phenomenon.

Methods: Members of the Israeli Rheumatology Association were encountered by e-mail, requesting reports of cases of LON after therapy with rituximab. Submitted cases were reviewed, with demographics and clinical data collated and tabled. Current cases were compared to previously published rheumatology cases.

Results: Eight episodes in seven patients were reported throughout the country after encounting 150 Israeli rheumatologists. Five of the patients had RA, one SLE and one MCTD. The average neutrophil count was 0.275/cubic mm in compare to 0.380/cubic mm in previously published cases. One patient had cellulitis of the forearm and all other patients did not have any infection. Five patients were treated with G-CSF. All patients had complete recovery. In comparison to published cases, a larger percentage were RA patients reflecting current usage of the medication in Israel. The average time to LON diagnosis was 177 days as compared to 148 days in published cases.

Table 1. LON: current series compared to previous published cases

Age/Gender	Dg	No of tx	Additional tx	Days since tx	WBC (% neu)	Repeat tx	Infection	Action taken
32/F	RA	4	MTX PRED	151	1100 (10)	Yes	No	G-CSF
34/F	MCTD	1	CYC AZA PRED	105	1000 (42)	Yes	No	G-CSF
22/F	SLE	1	CYC	240	0	No	Cellulitis	G-CSF
38/F	RA	1	MTX PRED	120	0	No	No	G-CSF
68/F	RA	1	PRED ABITREN	330	1270 (50)	No	No	G-CSF
50/F	RA	1	MTX HCQ	138	2300 (47)	Yes	No	MTX D/C
51/F (same patient on following year)	RA	2	HCQ	180	2600 (45)	No	No	
78/F	RA	1	MTX PRED	150	1800 (39)	No	No	MTX D/C Increase PRED
Published cases average age: 52 17 (60%) Females8 (40%)Males	RA −12 GPA =12 SLE =3 VASCULITIS=1 JRA=1	n/a	MTX −8 MMF −4	148	380 neutrophiles	n/a	Sepsis −5 Fever − 3	G-CSF − 11

Conclusion: LON is a well described finding and should be taken into consideration when following rheumatological patients treated with rituximab. In most cases it can be managed with a single dose of G-CSF and does not put the patient in an additional risk. Periodic complete blood count monitoring is recommended.

Pilot Study of Stimulation of the Cholinergic Anti-Inflammatory Pathway with an Implantable Vagus Nerve Stimulation Device in Patients with Rheumatoid Arthritis. Frieda A. Koopman[1], Sanda Miljko[2], Simeon Grazio[3], Sekib Sokolovic[4], Kevin Tracey[5], Yaakov Levine[6], Ralph Zitnik[6] and Paul-Peter Tak[7]. [1]Academic Medicalq Center/University of Amsterdam, Amsterdam, Netherlands, [2]University Clinical Hospital, Mostar, Bosnia, [3]Clinical Hospital Center Sestre Milosrdnice, Zagreb, Croatia, [4]University Clinical Center, Sarajevo, Bosnia, [5]Feinstein Institute for Medical Research, Manhasset, NY, [6]SetPoint Medical Corporation, Valencia, CA, [7]Academic Medical Center/GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: The inflammatory reflex regulates innate and adaptive immunity (Andersson O, Tracey K, Annu. Rev. Immunol. 2012; 30:313). Activation of its efferent arm (the Cholinergic Anti-inflammatory Pathway (CAP)), by electrical vagus nerve stimulation (VNS) reduces systemic inflammation and ameliorates disease in many acute and chronic animal models. We determined whether VNS could similarly improve clinical manifestations of rheumatoid arthritis (RA).

Methods: This is an open label study of patients with active RA ($>/=$ 4 tender and 4 swollen joints (28 joint scoring), and CRP of at least 7 mg/L) despite stable methotrexate dose for 3 months. Patients failing TNF antagonists (only for safety or tolerability reasons) could also be enrolled after washout. After a pre-implantation baseline visit, patients were surgically implanted with a Cyberonics VNS system. The device delivered the first VNS during its standard intraoperative diagnostic check sequence. Two weeks following implantation patients returned for initial in-clinic VNS. One week after the first clinic visit (day 7), patients began self-delivery of 60 second, once daily home stimulations, escalated in output current intensity as tolerated, through day 28. At day 28 patients without a EULAR good or moderate response were increased to four times daily VNS. Primary endpoint results at day 42 are reported.

Results: 8 patients (4 female, 7/8 RF+, 6/8 ACPA+, mean age 56 [range 39–70], mean disease duration 8 yrs [range 0.5–13]) were enrolled and implanted. Implantation and stimulation were generally well tolerated. Moderate postoperative hoarseness occurred in one patient. Pre implantation baseline values (mean, SD) were: DAS28-CRP: 6.06 (0.87), CRP: 17.5 mg/L (9.9), HAQ-DI: 1.63 (0.90). Changes at day 42 visit from pre-implantation values were: DAS28-CRP: −2.28 (1.65), CRP: −3.46 (17.95) mg/L, HAQ-DI: −0.44 (0.48). Similar levels of improvement were seen across all ACR core set assessments. ACR 20/50/70 response rates from pre-implantation baseline to day 42 were 75% (6/8), 50% (4/8), and 25% (2/8), respectively.

Conclusion: In this pilot study VNS was generally well tolerated and improved signs and symptoms of RA. This is the first demonstration in humans that stimulation of the CAP can favorably impact clinical manifestations of systemic inflammation. If efficacy and safety are confirmed in larger controlled studies, implantable medical devices may offer a feasible alternative approach to the treatment of RA and other chronic inflammatory diseases.

Effectiveness and Tolerance Infiltration Intraarticular Corticosteroid According to Dose. Daniele F. Pereira[1], Rita N.V. Furtado[2], Natalia P. Machado[3] and Jamil Natour[3]. [1]Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil, [2]Universidade Federal de São Paulo-UNIFESP, São Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: The optimal dose of corticosteroid to be used in intraarticular injection is not well established. The objective of this study is to compare the effectiveness and tolerance in the medium-term between small and large doses of triamcinolone hexacetonide (TH) used in intraarticular injection (IAI) of medium size joints of patients with rheumatoid arthritis (RA).

Methods: A controlled, randomized, prospective, double-blind study was carried out in patients with RA. It was evaluated 60 wrists joints (representing medium size joints) from the outpatient clinic at the Rheumatology Division UNIFESP, Brazil. Inclusion criteria were: patients with established RA, age between 18 and 65 years, disease modifying anti-rheumatic drugs (DMARDs) stable for at least 3 months, synovitis in wrist with pain visual analogic scale (VAS) between 4 and 8cm. Patients with overlap syndromes, polyarticular synovitis, diabetes mellitus or uncontrolled hypertension and those with suspected local or systemic infection were excluded. Patients were randomized (Clapboard randomization) in two groups of 30 patients each: group 1 (high dose) was injected with 40mg (2ml) of TH and group 2 (low dose) was injected 20mg (1ml). Only one joint was injected per patient (IAI blindly). Evaluation was conducted by a blinded observer at five times: baseline (T0), one week (T1), four (T4), eight (T8) and twelve (T12) weeks and the following assessment instruments were used: visual analogue scale for pain and swollen (swelling) (VAS 0–10cm); wrist goniometry; chronic disease activity index (CDAI). Side effects and related events were reported in a medical questionnaire. The level of statistical significance was 5%.

Results: A total of 60 patients were injected (50 women, 37 white). Mean age was 50.0 ($\pm$ 12.5) years old in the high dose group and 51.7 ($\pm$ 11.6) in the low dose group (p=0.586). No statistically significant difference between groups was observed for VAS for pain, VAS for swelling, CDAI, HAQ and goniometry. But all study variables improved over time in both groups and particularly T0 improved statistically significant from all other times for VAS for pain and swelling,CDAI and HAQ (all p<0.008). Wrist goniometry was statistically different in some periods and only in the high dose group was the improvement maintained until T12 (p<0.004). There was a significant increase of the use of nonsteroidal anti-inflamamatory (NA) and analgesics necessary to relieve pain soon after IAI, but this use decreased after T1 equally between groups (p<0.692). Very few adverse effects and related events were reported in both groups (p=0.195).

Conclusion: There is no difference in effectiveness of the intraarticular injection between high and low doses of TH used in medium size joints of patients with RA.

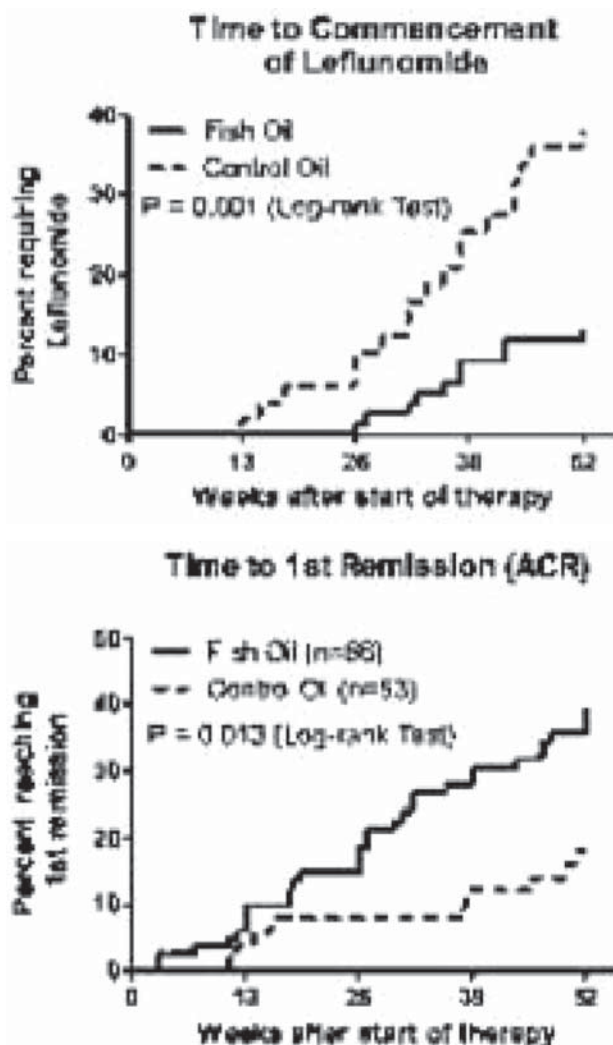
Fish Oil in Rheumatoid Arthritis: A Randomised, Double Blind Trial Comparing High Dose with Low Dose. Susanna Proudman[1], Llew Spargo[1], Cindy Hall[1], Leah McWilliams[1], Anita Lee[1], Maureen Rischmueller[2], Robert Gibson[3], Michael James[1] and Leslie G. Cleland[1]. [1]Royal Adelaide Hospital, Adelaide, Australia, [2]Queen Elizabeth Hospital, Adelaide, Australia, [3]University of Adelaide, Adelaide, Australia

Background/Purpose: The symptomatic benefit and NSAID-sparing effects of fish oil (FO) in RA are well known but effects on disease outcomes are less well established, especially in the context of contemporary treatment of early RA. The aim of this investigator-initiated randomized controlled trial was to assess the effects of high vs. low dose FO on disease outcomes in patients with early RA receiving a "treat-to-target" protocol of combination DMARDs.

Methods: Patients with RA according to ACR criteria with active polyarthritis of <12 months' duration and who were DMARD-naïve, received MTX, sulphasalazine and hydroxychloroquine. They were randomized 2:1 to fish oil at a high dose (FO) or low dose (control) providing 5.5 and 0.4 g/day respectively, of the marine omega-3 fats, EPA+DHA. DMARD doses were adjusted according to a pre-defined protocol taking disease activity and

toxicity into account. DAS28-ESR, mHAQ, remission and plasma phospholipids were assessed 3 monthly. In a novel study design, the primary outcome was DMARD use at 52 weeks, defined as the addition of leflunomide to triple therapy ("failure of triple therapy").

Results: After 52 weeks, there were no significant differences between treatment groups for the outcomes of MTX dose, DAS28 or mHAQ; but compared with controls (16/46, 35%), fewer FO patients (9/75, 12%) had commenced leflunomide (p= 0.005, Fisher's exact test). In FO patients, the rate of commencement of leflunomide was lower (Hazard Ratio 0.27, 95%CI 0.12–0.59) whereas the rate of achieving first ACR remission was higher (HR 2.22, 95%CI 1.18–4.18) compared with controls (Kaplan-Meier estimate).


There was considerable overlap in plasma omega-3 levels between the FO and control groups. Results were analysed by plasma omega-3 quartiles (t12AUC/unit time). Compared with the lowest quartile, patients in the highest quartile had significantly higher odds of achieving remission, by either DAS28 or ACR criteria (respectively, OR =3.30, 95% CI; 1.13–9.71, OR = 3.53, 95%CI; 1.05–11.90).

Conclusion: FO was associated with benefits additional to those achieved by combination "treat-to-target" DMARDs with similar MTX use. The benefits included reduced likelihood of progression to leflunomide ("failure of triple therapy") and a higher rate of ACR remission. High plasma n-3 fatty acids were associated with higher odds of achieving remission.

Long-Term Efficacy of Tocilizumab Monotherapy in Patients with Rheumatoid Arthritis Previously Methotrexate Naive or Methotrexate Free for 6 Months. Graeme Jones[1], Anthony Sebba[2], Denise Lepley[3], Jenny Devenport[3], Corrado Bernasconi[4], Devi Smart[5], Chiedzo Mpofu[4] and Juan J. Gomez-Reino[6]. [1]Menzies Research Institute Tasmania, Hobart, Australia, [2]University of South Florida, Tampa, FL, [3]Genentech, South San Francisco, CA, [4]Roche, Basel, Switzerland, [5]Roche Products Ltd, Welwyn Garden City, United Kingdom, [6]Hospital Clinico Universitario, Santiago, Spain

Background/Purpose: Treatment with tocilizumab (TCZ) monotherapy has been studied in 3 randomized clinical trials: AMBITION,[1] ACT-RAY,[2] and ADACTA.[3] AMBITION[1] was the first trial to demonstrate clinical superiority of a biologic monotherapy over methotrexate (MTX) monotherapy: in pts who were MTX naive or MTX free for 6 mos before entry, treatment with TCZ 8 mg/kg monotherapy resulted in statistically greater ACR 20/50/70 responses than MTX at 24 wks. Numeric differences favoring TCZ monotherapy were observed for other endpoints and pt-reported outcomes as early as 2 wks. TCZ was generally well tolerated. In this post hoc exploratory analysis, long-term efficacy was evaluated in pts from AMBITION who remained on TCZ monotherapy in the ongoing long-term extension (LTE) period up to 240 wks. The rate, timing, and nature of the addition of disease-modifying antirheumatic drug (DMARD) for TCZ pts who added DMARDs were also characterized.

Methods: Pts randomized to TCZ 8 mg/kg monotherapy in AMBITION (n=286) who entered the LTE (n=243) were included. During the LTE period, MTX/other allowable DMARD could be added according to the investigator's practice and as tolerated by the pt for those pts who did not achieve a 50% reduction in the number of tender and swollen joints from baseline of the core study. Efficacy assessments and DMARD status were evaluated up to 240 wks.

Results: Of 243 pts assigned to TCZ monotherapy who entered the LTE, 57.2% (n=139) remained on monotherapy in the LTE until withdrawal or data cut, 9.9% (n=24) added a DMARD before LTE entry, and 32.9% (n=80) added a DMARD after LTE entry (18.5% [n=45] ≤3 wks post-entry and 14.4% [n=35] >3 wks post-entry). Added DMARDs included MTX (93% [97/104]), hydroxychloroquine (3% [3/104]), leflunomide (2% [2/104]), and parenteral gold (2% [2/104]). Of the 139 pts who remained on TCZ monotherapy, 102 (73%) reached 240 wks of treatment for this data cut and 37 (27%) withdrew. Mean SJC, TJC, and DAS28 (data not shown) decreased sharply during the first 24 wks, and levels continued to decrease or were maintained thereafter (Table). Similar trends in improved disease state were observed, as shown by 40.1% and 16.7% of pts achieving DAS28 <2.6 and clinical disease activity index (CDAI) remission by wk 24, respectively; rates increased or were maintained thereafter; absolute numbers achieving these endpoints increased to wks 192 and 120 (Table). Absolute numbers of pts achieving DAS28 '3.2 and CDAI low disease activity increased to wks 120 and 96 (data not shown for wk 96), respectively.

Table. Efficacy over time in patients on TCZ monotherapy

	n = 138	n = 138	n = 124	n = 121	n = 112	n = 109	n = 103	n = 90
CDAI remission (≤2.8) n (%)	0 (0)	23 (16.7)	36 (29.0)	52 (43.0)	43 (38.4)	43 (39.4)	39 (37.9)	37 (41.1)
CDAI low disease activity (≤10), n (%)	0 (0)	66 (47.8)	77 (62.1)	85 (70.2)	77 (68.8)	84 (77.1)	80 (77.7)	72 (80.0)

For TJC and SJC, missing data were handled by using the last-observation-carried-forward method. For the physician and patient global assessments of disease activity, no imputation of missing post-baseline values was performed.
[a]Assessed numbers of patients decreased over time because some had not yet reached later assessments or had withdrawn. [b]Baseline in AMBITION. [c]LTE entry.

Conclusion: For the large proportion of pts continuing treatment in the LTE, TCZ monotherapy provided durable efficacy over time, as demonstrated by increasing proportions and/or numbers achieving low disease activity and remission thresholds.

Lack of Additive Benefits of Concomitant Methotrexate Use to Tocilizumab Monotherapy for Rheumatoid Arthritis in Daily Clinical Practice. Keisuke Izumi[1], Yuko Kaneko[2], Hidekata Yasuoka[2], Noriyuki Seta[3], Hideto Kameda[1], Masataka Kuwana[1] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Keio Univ School of Medicine, Shinjuku-ku, Japan, [3]Keio university, Tokyo, Japan

Background/Purpose: To explore the benefit of concomitant use of methotrexate (MTX) for the effectiveness of TCZ in rheumatoid arthritis (RA) patients in daily clinical practice.

Methods: A total of consecutive 115 RA patients initiating TCZ treatment in KEIO university hospital from July 2008 to March 2011 were enrolled. They received 8 mg/kg of TCZ every 4 weeks, and were observed for 52 weeks to evaluate the clinical and structural outcomes as well as safety.

Results: Baseline patient characteristics were as follows: mean age of 55.6 years; mean disease duration of RA of 8.54 years; prior treatment with TNF inhibitors in 46.6%; concomitant use of methotrexate (MTX) in 57.3% and use of concomitant glucocorticoid was in 43.7%. Baseline patients' characteristics were comparable between the combination group of TCZ and MTX and the TCZ monotherapy group. TCZ improved disease activity measured by DAS28-ESR from 5.02 at baseline to 1.97 at week 52; 68.9% of patients achieved DAS28 remission (DAS28-ESR < 2.6 LOCF method), and 50.0% of patients achieved CDAI remission. Structural remission (DTSS≤0.5) was achieved in 60.9% of the patients. The percentages of DAS28 remission, CDAI remission and structural remission in patients who received TCZ as monotherapy were comparable to those in the patients who received TCZ in combination with MTX. The retention rate of TCZ at week 52 was 81.4% in TCZ monotherapy and 86.4% in TCZ plus MTX group. Safety data was comparable between the 2 groups and was as reported in previous study reports.

	TCZ combination with MTX (n=59)	TCZ monotherapy (n=44)	Total (n=103)	p
DAS28-ESR (mean ± SD, at week 52)	2.07 ± 1.18	1.99 ± 0.73	1.97 ± 0.93	0.937*
DAS28-ESR remission (%, at week 52)	62.7	77.3	68.9	0.114**
CDAI remission (%, at week 52)	43.2	57.9	50.0	0.184**
TSS (mean ± SD, at week 52)	0.73 ± 1.52	1.05 ± 3.15	0.87 ± 2.34	0.726*
No progression of joint damage (%, at week 52)	60.9	70.7	60.9	0.266**

* Wilcoxon test between TCZ+MTX and TCZ monotherapy
** Pearson's χ^2 test between TCZ+MTX and TCZ monotherapy

Conclusion: The efficacy of TCZ was observed in RA patients regardless of the concomitant use of methotrexate in real-world clinical practice.

Factors Influencing Choice of Rituximab Versus an Alternative Tumor Necrosis Factor Inhibitor Following Tumor Necrosis Factor Inhibitor Failure in Patients with Rheumatoid Arthritis: Sub-Analysis of a Global, Observational Comparative Effectiveness Study. Axel Finckh[1], Jacques-Eric Gottenberg[2], Chiedzo Mpofu[3], William G. Bensen[4], Andrea Rubbert-Roth[5], Fedra Irazoque[6], Victor Martínez Taboada[7], Carol Chung[8], Lykke Hinsch-Gylvin[3], Clodoveo Ferri[9] and Paul Emery[10]. [1]University Hospital of Geneva, Geneva, Switzerland, [2]CHU Strasbourg, Strasbourg, France, [3]F Hoffmann-La Roche Ltd, Basel, Switzerland, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON, [5]University of Cologne, Cologne, Germany, [6]Hospital Angeles Mocel, Mexico City, Mexico, [7]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [8]Genentech Inc., South San Francisco, CA, [9]University of Modena and Reggio Emilia, Modena, Italy, [10]University of Leeds, Leeds, United Kingdom

Background/Purpose: SWITCH-RA is a global, observational study evaluating the effectiveness of switching to an alternative TNFi or rituximab (RTX) following initial TNFi failure in patients with RA. The study also assessed the reasons for discontinuation of initial TNFi therapy and factors that drive choice of RTX vs alternative TNFi as subsequent therapy.

Methods: Reasons for initial TNFi discontinuation and rationale for selection of subsequent therapy were recorded. The association between various factors and choice of RTX or alternative TNFi as second biologic were analyzed using logistic regression with a stepwise method for variable selection.

Results: A total of 1107 enrolled patients (mean age 55.5 yrs; mean disease duration 8.3 yrs) were analyzed. Reasons for discontinuing initial TNFi were: lack of efficacy (n=824 [74%]); intolerance (n=264 [24%]); other (n=19 [2%]). In all, 602 (54%) received RTX and 505 (46%) an alternative TNFi as second biologic. Factors associated with choice of RTX or alternative TNFi are shown in the Figure.

Factors associated with choice of RTX or alternative TNFi
Factors most clearly associated with selection of RTX were generally associated with treatment characteristics related to the safety profile (no lymphoma risk, low infection risk, and good long-term tolerance after infusion) and frequency of administration. Factors most clearly associated with selection of an alternative TNFi were associated with treatment (route of administration, rapidity of action, short administration duration) and patient (treatment being compatible with patient's professional life) characteristics.

Conclusion: Lack of efficacy was the main reason for discontinuation of an initial TNFi. Factors associated with selection of RTX over an alternative TNFi tended to be associated with treatment characteristics related to the safety profile and frequency of administration, while those associated with selection of an alternative TNFi were associated with administration and patient characteristics.

Biologic Disease-Modifying Anti-Rheumatic Drugs and the Risk of Non-Vertebral Osteoporotic Fractures in Patients with Rheumatoid Arthritis Aged 50 Years and Over. Jean-Pascal Roussy[1], Louis Bessette[2], Sasha Bernatsky[3], Elham Rahme[3] and Jean Lachaine[1]. [1]University of Montreal, Montreal, QC, [2]Centre Hospitalier Universitaire de Québec, pavillon CHUL, Sainte-Foy, QC, [3]McGill University, Montreal, QC

Background/Purpose: Chronic inflammation in rheumatoid arthritis (RA) may interfere with bone remodelling. Inflammation mediators such as TNF-α stimulate osteoclast formation which favors bone destruction. Small prospective studies have suggested biologic DMARDs preserve bone mineral density at 6–12 months, but impact on fracture risk is yet to be characterized. Our objective was to determine the risk of non-vertebral osteoporotic fractures in RA subjects aged $\geq$50, comparing outcomes in patients who were exposed or unexposed to biologic DMARDs.

Methods: A population based, retrospective, nested case-control study from January 1 2002 to December 31 2008 was conducted, using Quebec physician billing and hospital discharge data. RA subjects were identified from ICD-9/10 codes in billing (2 RA codes, $\geq$2 weeks apart but within 2 years) and hospitalization (any RA code) data. Subjects were followed until the earliest of: 1) non-vertebral osteoporotic fracture (index date), 2) death, or 3) end of study period. A validated algorithm identified non-vertebral osteoporotic fractures from physician claims. Controls were selected with incidence density sampling, matched to cases (4 to 1 ratio) on age, sex, and date of study entry. Biologic DMARD exposure was defined as being on treatment for $\geq$180 days pre-index. Conditional logistic regression was used, adjusting for: RA duration, comorbidity, history of previous fracture/arthrosplasty, use of traditional DMARDs, osteoporosis medication, hormone replacement, corticosteroids, proton-pump inhibitors, anticonvulsants, opioids, non-steroidal anti-inflammatories, antidepressants, anxiolytics, antipsychotics, medical visits and hospitalizations.

Results: The cohort included 29,666 RA subjects aged $\geq$50. Over the study period, 1,963 fractures were captured (incidence rate: 13.4 per 1000 person-years). Of these, 160 were excluded because they either occurred during the first 180 days of follow-up (where by definition, one could not be exposed to biologic) or controls could not be found. The final number of cases was 1,803 (with 7,175 controls). The most frequent fracture site was hip/femur (43.7%). Cases and controls were mainly older women and most (n=1,233, 68.4%) had a RA duration $\geq$5 years at the index date. In total, 190 subjects (53 cases, 137 controls) were exposed to biologic DMARDs for $\geq$180 days. We were unable to demonstrate a statistically significant association between biologic DMARDs and fracture risk (Odds Ratio, OR [95% Confidence Interval, CI]: 1.16 [0.51–2.62]). RA duration had the strongest impact on fracture risk; for subjects of RA duration $\geq$10 years (vs. <5 years), the OR was 6.40 (95% CI 3.57–11.46), while those with RA duration 5–10 years (vs. <5 years) had an OR of 3.05 (95%CI 1.90–4.89). The inability to detect an effect remained when varying exposure definition, induction period, and definition of corticosteroid use, and when restricting by history of fracture, RA duration, or follow-up time.

Conclusion: Despite the positive impact of biologic DMARDs on bone remodelling observed in small prospective studies, we were unable to demonstrate a reduction in the risk of non-vertebral osteoporotic fractures in older adults with RA.

Better Retention RATE At 5 YEARS of ANTI-TNF Agents USED in Conjonction with Methotrexate Over Time in Patients with Rheumatoid Arthritis: REAL-Life DATA From Rhumadata Computerized Database. Denis Choquette[1], Diane Sauvageau[2], Boulos Haraoui[2] and Jean-Pierre Raynauld[2]. [1]Institut de Rhumatologie De Montréal, Montreal, QC, [2]Institut de Rhumatologie de Montréal, Montreal, QC

Background/Purpose: Anti-TNF agents have been in used in Canada for the last ten years. Although a vast body of clinical experience has been accumulated since that time, there are still areas of uncertainty in their usage. One of them is whether usage in monotherapy has a similar clinical efficacy profile than usage in combination with a DMARDS. Products monograph actually disclosed that both usage are officially indicated base on short term Phase III and Phase IV trials results.

Methods: The primary objective of this study is to compare the survival rates of two different anti-TNF agents, adalimumab (ADA) and etanercept (ETA) used as first biologic agent with and without associated DMARDS in the treatment of rheumatoid arthritis (RA) using the data coming from the Rhumadata computarized database at the Institute of Rheumatology of Montreal.

The secondary objective is to evaluate the influence of baseline demographic and clinical data on the primary outcome.

Data for all patients with rheumatoid arthritis according to the ACR criteria included in the database since 2005 and exposed for the first time only to an anti-TNF agents were extracted. Only patients exposed to adalimumab and etanercept were included in this analysis to standardize route of administration. Demographics and baseline clinical data are: age, gender, disease duration, tender joint count (TJC), swollen joint count (SJC), disease activity score including DAS 28 ESR and CRP 3–4 variables, CDAI, SDAI, Rheumatoid Factor and Anti-CCP baseline status, ESR and CRP at baseline, HAQ score, VAS fatigue scale, VAS pain Scale, morning stiffness duration, Dmards and glucocorticoid usage.

Results: Data from 249 patients with rheumatoid arthritis are used. 95 and 154 patients were respectively using adalimumab or etanercept. All baseline demographic and clinical variables were comparable for both group (p≥0.05). There was slightly more usage of Dmards with ADA than ETA (89% vs 78%, p=0.02). TJC slightly lower for ETA than ADA (7.3 vs 9.5, p=0.04). There were more female patients in the monotherapy group than in the combination group (75% vs 90%, p=0.01). The 4 year survival rates (Kaplan-Meier survival proportion) for ADA+DMARDS vs ADA mono are respectively 56% and 11% (p=0.03 Log-rank statistic), for ETA+DMARDS vs ETA mono, 67% vs 47% (p=0.007), for combined ETA-ADA+DMARDS vs ETA-ADA MONO, 62% vs 40% (p=0.001) and for ADA or ETA both on MTX, 67% vs 57% (p=0.12).

Conclusion: Combination of etanercept or adalimumab with a traditional DMARDS agent such as methotrexate exhibit a far better survival rate at 5 years than adalimumab or etanercept used in monotherapy.

Long-Term Safety of Rituximab: 10-Year Follow-up in the Rheumatoid Arthritis Global Clinical Trial Program. Ronald F. van Vollenhoven[1], Paul Emery[2], Clifton O. Bingham III[3], Edward Keystone[4], Roy M. Fleischmann[5], Daniel E. Furst[6], Nicola Tyson[7], Abdul Mehbob[7] and Patrica B. Lehane[7]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]University of Leeds, Leeds, United Kingdom, [3]Johns Hopkins University, Baltimore, MD, [4]Mount Sinai Hospital, Toronto, ON, [5]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX, [6]UCLA, Los Angeles, CA, [7]Roche Products Limited, Welwyn Garden City, United Kingdom

Background/Purpose: This analysis evaluated the long-term safety of rituximab (RTX) in RA patients (pts) in a global clinical trial program.

Methods: Pooled observed case analysis of safety data from pts with moderate to severe active RA treated with RTX+MTX. Pts were retreated based on physician's determination of clinical need and evidence of active disease (defined as either SJC and TJC ≥8 or DAS28 ≥2.6). Subgroup analysis of pts with follow-up >5 yrs was undertaken. Pooled data from pts who received placebo during placebo-controlled study periods were also analyzed.

Results: As of Sep 2011, 3595 pts (All-Exposure population) had received ≤19 courses of RTX over the 10-yr observation period (14008 pt-yrs). Of these pts, 1145 had follow-up >5 yrs (7716 pt-yrs) (>5 yr). The placebo population comprised 818 pts (1107 pt-yrs) with a mean follow-up of 1–1.5 yrs. In the All-Exposure population, infusion-related reaction (IRR) was the most frequent adverse event (AE); most were grade 1 or 2, were rarely serious, and generally occurred following the 1st infusion of the 1st course (789/3595 pts; 22%). Rates of AEs, serious AEs (SAEs), and infections were comparable across analysis populations and generally remained stable over time and multiple courses (Table). Overall serious infection (SIE) rates in the RTX All-Exposure and >5 yr sub-population were comparable to that observed in the placebo population. Pneumonia was the most frequently reported SIE (2% of RTX pts). There were no cases of hepatitis B reactivation. Two cases of pulmonary tuberculosis (TB), treated with anti-TB medication, occurred in the All-Exposure population, as reported previously.[1] No cases of extra-pulmonary TB, atypical mycobacterial infection, or multidrug-resistant TB were reported. Serious opportunistic infections were rare (0.05/100 pt-yrs in RTX pts vs 0.09/100 pt-yrs in placebo). No further cases of PML in the RA clinical trial program have been reported other than the single case previously described.[2] No increased risk of malignancy over time or course was evident, and MI rates (0.40/100 pt-yrs) were consistent with rates in the general RA population (0.48–0.59/100 pt-yrs).[3]

	AE rates per 100 pt-yrs (95% CI)		
	RTX All-Exposure (n=3595) 14008 pt-yrs	RTX Long-term (>5 yrs) (n=1145) 7716 pt-yrs	Pooled placebo (n=818) 1107 pt-yrs
AEs	249.34 (246.74–251.97)	237.25 (233.83–240.71)	315.43 (305.14–326.06)
SAEs	14.03 (13.42–14.66)	12.25 (11.49–13.05)	13.82 (11.79–16.19)
Infections	78.60 (77.14–80.08)	75.10 (73.19–77.06)	90.39 (84.96–96.17)
Serious infections	3.80 (3.50–4.14)	2.76 (2.41–3.16)	3.79 (2.80–5.13)

Conclusion: These long-term data from 3595 pts treated with RTX over 10 yrs (14008 pt-yrs) of follow-up in clinical trials confirm that RTX remains well tolerated over time and multiple courses with a consistent safety profile. No new safety signals were observed with increasing duration of exposure, including within a subgroup of pts with >5 yrs' follow-up. Apart from IRRs, the overall safety profile of RTX remains similar to that of the pooled placebo population and is consistent with published data for moderate to severe RA and with previous analyses of this pt cohort.

Real-World Efficacy and Safety of Abatacept Treatment for Rheumatoid Arthritis: 12-Month Interim Analysis of the Action Study. H. Nüβlein[1], R. Alten[2], M. Galeazzi[3], H. M. Lorenz[4], Dimitrios Boumpas[5], M. T. Nurmohamed[6], W. Bensen[7], G. R. Burmester[8], H.-H. Peter[9], F. Rainer[10], Karel Pavelka[11], M. Chartier[12], C. Poncet[13], C. Rauch[14] and M. Le Bars[15]. [1]University Erlangen, Nürnberg, Germany, [2]Schlosspark-Klinik, University Medicine, Berlin, Germany, [3]University of Siena, Siena, Italy, [4]University Hospital Heidelberg, Heidelberg, Germany, [5]Panepistimio Kritis, Rethymnon, Greece, [6]VU University Medical Center/Jan van Bremen Research Institute, Amsterdam, Netherlands, [7]St. Joseph's Hospital and McMaster University, Hamilton, ON, [8]Charité-Universitätsmedizin, Berlin, Germany, [9]University Medical Center Freiburg, Freiburg, Germany, [10]Hospital Barmherzige Brueder, Graz, Austria, [11]Institute of Rheumatology, Prague, Czech Republic, [12]Chiltern International, Neuilly, France, [13]Docs International, Sévres, France, [14]Bristol-Myers Squibb, Munich, Germany, [15]Bristol-Myers Squibb, Rueil Malmaison, France

Background/Purpose: Randomized controlled trials (RCTs) of abatacept (ABA) in patients (pts) with RA have demonstrated sustained, long-term efficacy, high pt retention, and consistent safety.[1] Data from the clinical setting can determine if benefits translate into the real world. We evaluate 1-yr retention, efficacy and safety of ABA in RA pts treated in routine clinical practice (according to label at time of enrollment) in Europe and Canada.

Methods: AbataCepT In rOutiNe clinical practice (ACTION) is an ongoing, non-interventional, prospective cohort of ABA-treated RA pts with inadequate response to MTX or anti-TNF therapy in Europe and

Canada, initiated Mar 2008.[2] At data cut-off in Feb 2012, all pts had reached 1-yr follow-up. Retention rate (Kaplan–Meier estimate) and disease activity (EULAR response) are reported over 12 mths for pts on treatment and with available data, according to whether pts received ABA as a first biologic, or after failure of 1 or ≥2 anti-TNFs. Safety is reported for all enrolled pts, up to data cut-off.

Results: 1138 pts were enrolled and 1120 were evaluable. 1000 (89.3%) had previously failed on biologic treatment, 982/1000 (98.2%) of whom failed ≥1 anti-TNF agent. 120 (10.7%) had not received biologic treatment prior to ABA initiation. Baseline characteristics for the three groups are shown in the Table. Retention rates, reasons for discontinuation and % moderate and good EULAR responders at Mth 12 are presented for ABA when used as the first biologic, first switch agent, and after ≥2 anti-TNFs, and suggest that earlier usage results in higher pt retention (Table). 106 serious adverse events were reported in 60/1138 (5.3%) pts (21 discontinuations). 11 deaths were reported, including 3 due to serious infections (sepsis [4 mths after last ABA infusion; pt was receiving tocilizumab]; *Pneumocystis jiroveci* [4 mths after last ABA infusion, pt had deep vein thrombosis]; and urosepsis) unrelated to ABA. 23 pts experienced serious infections; 9 malignancies; 5 serious cardiac disorders; and 3 serious vascular disorders. No TB occurred, two opportunistic infections were reported (*cytomegalovirus* and *P. jiroveci)*.

Baseline characteristics	ABA first biologic n=120	ABA first switch (1 previous anti-TNF) n=481	ABA after ≥2 previous anti-TNFs n=501
Mean age (SD), years	59.0 (13.8), n=120	56.2 (12.4), n=481	56.0 (12.4), n=501
Mean RA duration (SD), years	7.0 (7.8), n=118	9.8 (8.0), n=465	13.1 (9.4), n=484
≥1 CV risk or comorbidity, n (%)	86 (71.7%), n=120	336 (69.9%), n=481	365 (72.9%), n=501
Mth 12 outcomes			
Retention, Kaplan–Meier estimate (95% CI)	83.6% (74.9, 89.5)	73.2% (68.8, 77.2)	64.1% (59.5, 68.4)
Discontinuation for lack of efficacy, n (%)	11 (9.2%), n=120	75 (15.6%), n=481	101 (20.2%), n=501
Discontinuation for intolerance, n (%)	3 (2.5%), n=120	11 (2.3%), n=481	15 (3.0%), n=501
Good EULAR response	34.5%, n=29	34.5%, n=194	27.3%, n=165
Moderate EULAR response	37.9%, n=29	41.8%, n=194	45.5%, n=165

EULAR response criteria: Moderate/good=DAS28 improvement of ≥0.6 and a DAS28 of ≤5.1; Good=DAS28 improvement of >1.2 and a DAS28 of <3.2; Moderate=DAS28 improvement of >1.2 and a DAS28 of ≥3.2, or DAS28 improvement of 0.6–1.2 and a DAS28 of ≤5.1

Conclusion: This large-scale, international, observational real-life study showed that the use of ABA as the first biologic in MTX-inadequate responders, or after first or later switching from anti-TNFs, was associated with good pt retention over 12 mths, particularly when used earlier in the course of treatment. ABA was clinically effective and well tolerated. These data are consistent with previous RCT findings,[1,3] and national registry data for biologics.[4–6]

Vila Fayos[10], A.B. Romero Silva[11] and A. Balsa[12]. [1]Hospital General Universitario de Elche, Alicante, Spain, [2]Hospital Universitario Virgen de las Nieves, Granada, Spain, [3]Hospital Universitario 12 de Octubre, Madrid, Spain, [4]Hospital Universitario La Princesa, Madrid, Spain, [5]Complejo Hospitalario Universitario de Ourense, Ourense, Spain, [6]Hospital General de Castellón, Castellón, Spain, [7]Hospital Universitario Virgen de la Arrixaca, Murcia, Spain, [8]Hospital de Navarra, Navarra, Spain, [9]Complejo Hospitalario Universitario de Santiago, Santiago de Compostela, Spain, [10]Hospital Comarcal de Vinaroz, Castellón, Spain, [11]Roche Farma, Madrid, Spain, [12]Hospital La Paz, Madrid, Spain

Background/Purpose: Currently, the available evidence about tocilizumab (TCZ) use for the treatment of rheumatoid arthritis (RA) in daily clinical practice is scarce. This study was devised to describe usage patterns of TCZ and reasons for dosage modification (reduction/interruption/discontinuation) in the routine clinical practice, as well as its effectiveness and safety profile under real conditions of use.

Methods: This is a 12-month prospective observational study in 40 Spanish centers. Patients with moderate or severe RA of ≥6 months duration initiated on treatment with TCZ after failure of at least one previous DMARD or TNF inhibitor were included. We present preliminary results at 6-month follow-up

Results: A total of 390 patients were evaluable with a median age of 57 years (47–66) and 83% female. At baseline, patients had mean RA duration of 11.4±8.3 years, 70% were positive for rheumatoid factor and 68% for anti-CCP. Mean DAS28, SDAI, HAQ scores and CRP levels were 5.4±1.2, 22.4±14.9, 1.6±0.7 and 5.8±12.9 mg/dL, respectively. Patients had previously received a mean of 3±1.5 DMARDs and a mean of 2.3±1.2 biological agents, and 97.7% of them initiated TCZ at dose of 8 mg/kg. At the 6-month follow-up, the mean DAS28 decreased significantly from baseline (5.5±1.2 *vs* 2.9±1.4; p<0.001, paired t-test, n=143), and disease remission (DAS28<2.6) was achieved in 48% of patients. Based on EULAR response criteria, 59.4% of patients were good responders, 31.5% moderate responders and 9.1% non-responders. Of all patients, premature withdrawal from the study during the first 6 months was reported in 34 (9%), 14 (41.2%) as a result of adverse events and 12 (35.3%) due to inadequate response. Grade 3/4 neutropenia occurred in 14 (3.6%) patients and grade 3/4 elevation of liver transaminases in 12 (3.1%). No cases of grade 3/4 thrombocytopenia were observed. One hundred and one (25.9%) patients required at least 1 dose reduction and 56 (14.4%) at least 1 temporary dose interruption. In patients intolerant or non-responders to DMARDs, delta DAS28 was significantly higher than in those previously treated with biological agents (3.2±1.2 *vs* 2.4±1.2; p<0.001). No differences in delta-DAS28 were found when TCZ was administered as monotherapy or in combination with DMARDs. Patients with intolerance or inadequate response to DMARDs showed significantly higher percentage of dose reduction than those intolerant or non-responders to biologic agents (36.7% *vs* 23.9%; p<0.05).

Conclusion: These results show that in daily clinical practice, tocilizumab is a safe and effective treatment for moderate or severe RA, with the majority of patients having a good EULAR response and a disease remission being achieved in approximately 50% of patients. Tocilizumab appears more effective when administered as a first-line biological agent. Additionally, TCZ proves to have a similar safety profile regardless of the use pattern as monotherapy or in combination, and the line-biological option may be used.

Subcutaneous Abatacept: Long-Term Data From the Acquire Trial.

Nasonov[12], P. Durez[13], I. Delaet[14] and R. Alten[15]. [1]Stanford University, Palo Alto, CA, [2]Universidad Autónoma de Chihuahua, Chihuahua, Mexico, [3]Centro Medico De Las Americas, Merida, Mexico, [4]Instituto De Ginecologia Y Reproduccion, Lima, Peru, [5]Organización Médica de Investigación, Buenos Aires, Argentina, [6]Pontifical Catholic University School of Medicine, Porto Alegre, Brazil, [7]Arthritis Center of Nebraska, Lincoln, NE, [8]University of Queensland, Brisbane, Australia, [9]Centro De Especialidades Médicas/Universidad Marista, Merida, Mexico, [10]Box Arthritis & Rheumatology of the Carolinas, Charlotte, NC, [11]Low Country Rheumatology, Charleston, SC, [12]Institute of Rheumatology, Moscow, Russia, [13]Université Catholique de Louvain, Brussels, Belgium, [14]Bristol-Myers Squibb, Princeton, NJ, [15]Schlosspark-Klinik, University Medicine, Berlin, Germany

Background/Purpose: The Abatacept (ABA) Comparison of Sub-[QU]cutaneous (SC) versus Intravenous (IV) in Inadequate Responders to MethotrexatE (MTX) (ACQUIRE) study showed comparable efficacy and safety of SC vs IV ABA over 6 mths;[1] here, we present 32-mth data from the long-term extension (LTE), during which all patients (pts) received SC ABA.

Methods: ACQUIRE was a Phase IIIb, 6-mth, double-blind (DB) study of pts with active RA ($\geq$10 swollen and $\geq$12 tender joint count [TJC and SJC], C-reactive protein (CRP) $\geq$0.8 mg/dL) refractory to MTX. Pts were randomized to SC ABA (125 mg/wk) with IV ABA loading (10 mg/kg) on Day 1 or IV ABA (10 mg/kg every 4 weeks) for 6 mths, plus MTX. After 6 mths, pts could enter the open-label LTE to receive SC ABA 125 mg/wk. Safety and efficacy were assessed for pts treated in the LTE, with efficacy presented according to original DB treatment group (as observed). Not all pts had reached later time points at time of analysis, as a result of differential enrollment in the trial.

Results: Of 1372 pts entering the LTE, 1134 (82.7%) remained on therapy at time of reporting. Mean baseline RA duration was 8 yrs, TJC and SJC were 30 and 20, and HAQ-DI was 1.7. The median (range) ABA exposure was 33 (8–44) mths. The incidence rate (IR; events/100 pt-yrs) of serious adverse events for pts treated with SC ABA in the LTE (8.76 [95% CI: 7.71–9.95]) was comparable with that for SC ABA in the DB period (9.02 [6.31–12.90]) and did not increase with increasing exposure (not shown). The IR of overall and serious infections in the LTE (44.80 [41.81–48.01] and 1.72 [1.30–2.27], respectively) did not increase vs the DB period (84.62 [74.50–96.11] and 1.48 [0.62–3.56], respectively). Bacterial, viral and hospitalized infections occurred at IRs of 27.28 (25.16–29.57), 18.25 (16.61–20.06) and 1.55 (1.16–2.07) during the LTE. The IR of malignancy did not increase in the LTE (1.19 [0.86–1.66]) vs the DB period (0.59 [0.15–2.36]). Injection-site reactions occurred in 27 (2.0%) pts in the LTE (none serious) and 19 (2.6%) pts in the DB period. Overall, 139/1365 (10.2%) and 1/153 (0.7%) pts experienced immunogenicity (ECL) during the LTE and DB periods. ACR responses were maintained from Mth 6 to 32 and were comparable for original SC and IV groups (Figure). DAS28 (CRP) <2.6 rates (95% CIs) were 24 (21–27) [n=685] and 25 (22–28) [n=667] at Day 169 and 39 (33–44) [n=288] and 35 (29–40) [n=275] at Day 981 for the original SC and IV groups, respectively. HAQ-DI responses (change from baseline $\geq$0.3) were 73 (95% CI: 69–76) [n=691] and 68% (65–72) [n=672] at Day 169 and 74 (69–79) [n=313] and 70% (65–75) [n=303] at Day 981 for the original SC and IV groups, respectively.
Conclusion: Over 32 months, SC abatacept showed consistent safety with high patient retention (82.7%). ACR, HAQ-DI responses and DAS28 remission rates were maintained through the long-term extension.

Drug Survival, Efficacy and Predictors for Survival On Tocilizumab in Real-Life Patients with Rheumatoid Arthritis; Results From the Swedish Biologics Register.

Helena Forsblad-d'Elia[1], Karin Bengtsson[1], Lars-Erik Kristensen[2] and Lennart TH Jacobsson[1]. [1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology, University Hospital of Skåne, Lund, Sweden

Background/Purpose: To evaluate drug survival, clinical response and predictors for drug survival for tocilizumab in patients with rheumatoid arthritis (RA) with inadequate response and/or adverse effects to previous treatment or contraindications to other medications in ordinary clinical practice, based on prospectively registered data from the Swedish biologics register, Anti-Rheumatic Therapies in Sweden (ARTIS).

Methods: All Swedish RA patients who had started treatment with tocilizumab from Sept, 2006 until March, 2012 were identified in ARTIS. Patients without DAS28 value at start and without known disease duration were excluded and were censored if the duration since the last follow-up extended 18 months. Clinical response was assessed by DAS28 and by EULAR response criteria. Kaplan Meier survival analyses with log-rank test and Cox Proportional Hazard Regression analyses were performed.

Results: 646 RA patients had started with tocilizumab of which 522, 81% were included in this report. 420 (80.5%) were females. The mean (SD) age, disease duration, HAQ, DAS28 and CRP at start was 57.8 (12.8) years, 14.2 (10.7) years, 1.4 (0.6) score, 5.4 (1.3) score and 27 (32) mg/L, respectively. 389 (75.5%) patients had seropositive RA. 185 (35.4%) were on monotherapy whereas 337 (64.6%) were treated with concomitant DMARDs of which 295 (56.5%) methotrexate (MTX). 325 (62.3%) were on corticosteroids. 63 (12%) patients were bionaïve, 278 (53.3%) were treated with $\geq$ 1 TNF-inhibitor, 126 (24.1%) $\geq$ 1 TNF-inhibitor and rituximab/abatacept and 49 (9.4%) with $\geq$ 1 TNF-inhibitor and rituximab and abatacept.

The overall 1 and 2-year estimated drug survival was 63% and 50%, respectively. 390 (74.7%) had $\geq$ 1 DAS28 value between 2.5 and 8 months follow-up, the first value was chosen. The percentages of EULAR Good/Moderate/No responders were 47.2/33.1/19.7%. 55% had DAS28 < 3.2 and 37% was in DAS28 remission. Univariate analyses revealed that men had significantly longer drug survival as compared to women (p=0.013). High CRP or ESR divided into quartiles were associated with longer drug survival, (p=0.0022 and p=0.013, respectively). Patients with HAQ <1.5 had longer drug survival compared to those with HAQ values $\geq$1.5 (p=0.014). Having been exposed to none or increasing number of biologics were associated with inverse drug survival (p=0.0002). Age, disease duration, seropositive RA, DAS28, being on MTX, on any DMARD or on steroids was not associated with drug survival. In the multivariate analysis with the above significant predictors as independent covariates, adjusted for age, the Hazard Ratios were: sex 0.79 (95% CI 0.52–1.19), HAQ 1.34 (95% CI 1.05–1.70), previous biologics 1.39 (95% CI 1.17–1.67) and CRP 0.80 (95% CI 0.69–0.91, per 1 SD change).

Conclusion: In this cohort of real-life patients with longstanding RA treated with tocilizumab the estimated 1-year drug survival was 63%, about 80% of the patients achieved a EULAR Good/Moderate response and drug survival was predicted by high CRP, low HAQ and no/low exposure of biologics. Treatment with concomitant MTX, DAS28, disease duration or age was not predictors for drug survival.

Rituximab for Treatment of Rheumatoid Arthritis: Treatment Effectiveness in the Corrona Database. Leslie R. Harrold[1], George W. Reed[1], Robert P. Magner[1], Katherine C. Saunders[2], Jeffrey D. Greenberg[3], Joel M. Kremer[4], Ani John[5], William Reiss[5], Steve Zlotnick[5] and Ashwini Shewade[5]. [1]University of Massachusetts Medical School, Worcester, MA, [2]CORRONA, Inc., Southborough, MA, [3]New York University School of Medicine, New York, NY, [4]Albany Medical College, Albany, NY, [5]Genentech Inc., South San Francisco, CA

Background/Purpose: Rituximab (RTX) in combination with methotrexate is used for the treatment of adult RA with an inadequate response to TNF antagonists. We aimed to describe the real-world use and effectiveness of RTX in a large cohort of patients enrolled in the Consortium of Rheumatology Researchers of North America (CORRONA) registry.

Methods: All patients with RTX initiations in CORRONA between Feb 2006 and May 2011, with available clinical disease activity index (CDAI) score at baseline and at 12-months and not in remission (CDAI ≤2.8) at the time of RTX initiation, were included. Demographic and disease characteristics at baseline; change in CDAI at 12 months (overall and based on number of prior TNFs); and reported safety events were summarized.

Results: Overall, 615 patients (mean 2.3 previous non-biologic disease-modifying anti-rheumatic drugs [DMARDs] and 2.2 prior biologic DMARDS) initiated RTX. Lack of efficacy was most commonly (65%) reported reason for discontinuing prior biologic. Of these, 265 patients (80% female; median age 57 years; median disease duration 13 years) met the inclusion criteria. Approximately 43% of the patients had received 1 prior TNF and 57% had ≥2 prior TNFs. Approximately 77% patients started RTX in combination with DMARDs and 42% with concomitant prednisone. Mean change in CDAI was −8.1 (95% CI: −9.8; −6.4) for all RTX initiators not in remission, with similar results when stratified by number of prior TNFs. Among the subset of patients with active disease (moderate/high disease activity; CDAI >10) at baseline (Table), 8% went into remission and 29% achieved low disease activity (LDA). The mean change in CDAI in these patients was −10.3 (95% CI: −12.3; −8.4) with similar results when stratified by 1 or ≥2 prior TNFs. However, more patients with 1 prior TNF went into remission or achieved LDA versus patients with ≥2 prior TNFs. Patients with 1 prior TNF were more likely to achieve remission or LDA (unadjusted odds ratio 0.40 [95% CI: 0.22; 0.73]). Among patients who started RTX with concomitant prednisone, 43% decreased and 26% had no change in their prednisone dose at 12 months. Reported rates of all cardiovascular events, serious infections, and malignancies were 1.9 (95% CI: 0.6; 4.0), 1.6 (95% CI: 0.5; 4.9), and 1.5 (95% CI: 0.6; 4.0) per 100 person-years, respectively.

Change in disease activity in patients with moderate/high disease (CDAI >10) at baseline

CDAI at 12-months	All RTX initiators (n=218)	IR to 1 prior TNF (n=87)	IR to ≥2 prior TNFs (n=131)
Remission (CDAI ≤2.8) (n, %)	18 (8.3)	9 (10.3)	9 (6.9)
Low disease activity (2.8<CDAI ≤10) (n, %)	64 (29.4)	35 (40.2)	29 (22.1)
Mean change in CDAI (95% CI)	−10.3 (−12.2; −8.4)	−10.1 (−13.2; −7.0)	−10.5 (−12.9; −8.0)

Conclusion: RTX appeared effective in usual care in patients with previous exposure to one or more prior TNFs, with a safety profile comparable to randomized controlled trials of RTX. More patients with 1 prior TNF versus ≥2 prior TNFs appeared to achieve improvement in disease activity at 12 months after initiating RTX. The magnitude of response in CDAI seemed to be similar regardless of number of prior TNFs, even with ≥2 prior TNFs, suggesting good response in more refractory RA patients.

CDAI = clinical disease activity index; CI = confidence interval; TNF = tumor necrosis factor-α antagonist.

The Comparative Effectiveness of Oral Methotrexate Versus Subcutaneous Methotrexate for the Treatment of Early Rheumatoid Arthritis. Glen S. Hazlewood[1], J. Carter Thorne[2], Janet Pope[3], Gilles Boire[4], Boulos Haraoui[5], Carol A. Hitchon[6], Edward Keystone[1], Diane Tin[2], CATCH Investigators[7] and Vivian P. Bykerk[8]. [1]University of Toronto, Toronto, ON, [2]Southlake Regional Health Centre, Newmarket, ON, [3]Schulich School of Medicine and Dentistry, Western University, London, ON, [4]CHUS - Sherbrooke University, Sherbrooke, QC, [5]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [6]University of Manitoba, Winnipeg, MB, [7]Toronto, ON, [8]Hospital for Special Surgery, New York, NY

Background/Purpose: To determine the comparative effectiveness of subcutaneous (sc) versus oral methotrexate (MTX) as initial therapy for patients with early rheumatoid arthritis (ERA) in routine clinical care.

Methods: Patients with early inflammatory arthritis initiating methotrexate therapy were included from the Canadian Early Arthritis Cohort (CATCH), a multicenter, prospective cohort study of patients with ERA. In CATCH patients are treated at the discretion of the rheumatologist and followed every 3 months over the first year according to a standardized protocol. For this study, all patients had an age >16 years, a diagnosis of RA by 2010 criteria, symptom duration < 1 year, used MTX within 3 months of study entry and were MTX-naïve or minimally exposed to MTX. The exposure was route of MTX (oral vs. sc) and the outcome was DAS-28 over the first year (3, 6, 9, 12 months). A multilevel random-effects linear regression model was used to account for repeated measures within patients while adjusting for potential confounders: age, gender, comorbidities, smoking, education, symptom duration, serological status, erosions, baseline DAS-28, functional status (HAQ-DI), and other concurrent DMARDs or corticosteroids. The analysis was performed with and without adjusting for the starting dose of MTX and clustering of patients by treatment center.

Results: 653 patients were included (442 oral MTX, 211 sc MTX); mean age 54 (SD 14), 72% female, mean symptom duration 5.3 (SD 2.7) months, mean baseline DAS-28 4.6 (SD 1.2). Patients treated with sc MTX were more likely to have erosions at baseline (35% vs. 25%, p=0.01), were less likely to receive other DMARDs (38% vs. 58%, p<0.01), and had a higher median starting dose of MTX (25 mg vs. 15 mg, p<0.01). Other characteristics were similar between groups. In the repeated measures model, after adjusting for all potential confounders except starting dose of MTX, sc MTX was associated with a reduction in the average DAS-28 score over the first year of 0.23 [(95%CI:0.08, 0.38), p<0.01]. After adjusting for starting dose, the route of MTX (oral/sc) was no longer significant (p=0.22), but for each additional mg of MTX, the average DAS-28 decreased by 0.02 [(95%CI:0.004, 0.03), p=0.02]. After controlling for treatment center, neither route nor starting dose was significantly associated with DAS28 at follow-up.
Conclusion: Sc MTX was associated with lower DAS28 scores over the first year of treatment, which may be mediated through the higher starting dose used in clinical practice. There was no relationship after adjusting for treatment center, suggesting caution in generalizing the results and highlighting the importance of considering a treatment center effect when reporting comparative effectiveness research from observational studies.

Synovialitis Plus Articular Cartilage Monitoring Via Magnetic Resonance Imaging and Ultrasound Under Tocilizumab Therapy in Patients with Rheumatoid Arthritis. Maria Hoehle[1] and Michael Finkenstaedt[2]. [1]Rheumatology, Hamburg, Germany, [2]Private Practice for Radiology and Neuroradiology, Hamburg, Germany

Background/Purpose: To determine remission in RA, recent publications point out the importance of radiological parameters, besides scores like DAS28, TJC, SJC, CrP, patient global assessment, or the SDAI. [1] Inflammatory activity can remain despite clinical remission in RA.[2] This process can be monitored with modern imaging without radiation exposure – high-field MRI and colour and power Doppler sonography. These diagnostic methods are also valuable for the determination of an OFF therapy or an individual dose adaption.[3] The latest adaptions allow the precise monitoring of cartilage and subchondral bone under cytokine therapy in clinical practice.

The course of chronic active inflammation at affected joint structures can be quantitatively and qualitatively measured by aforementioned techniques. The aim is to optimize and control biologic therapy.

Methods: 22 RA-patients (12 men, 10 women, between 20 and 72 years of age) with high disease activity at baseline (DAS 28 over 3.3, CRP over 10, ESR over 20, fibrinogen over 470 mg/dl, RF positive, high erosion tendency (anti-CCP positive)) were treated 8mg TCZ/kg body weight from 08/2008 until now, data were analyzed retrospectively. 3 female patients from each group received TCZ (iv q4w) in combination with MTX, while all other patients received TCZ in monotherapy.

Examination criteria at baseline and before infusion administration were DAS 28, serum fibrinogen, colour and power Doppler ultrasound examination, and every 3 to 6 months high-field MRI (T1 T2 STIR KM 3.0 T; panorama image) of the affected joints' inflammation activity, the cartilage, or the subchondral bone. The evaluation was carried out using MRI (RAMRIS) and sonography score.

Results: Of the 22 patients observed 10 patients (6 men, 4 women) exhibited early or very early RA (group A); 5 patients (1 man, 4 women) established RA with low articular cartilage destruction and erosion (Sharp score of up to 2; group B); and 7 patients (3 men, 4 women) chronically established RA (Sharp Score 3; group C) at baseline.

After 12 week, all inflammation parameters, including DAS 28, were within the normal range. Inflammation activities could still be detected by Doppler ultrasound imaging and MRI. Cartilage imaging showed no erosions and changes in the subchondral bone in group A during the course of the therapy. In group B, the cartilage and bone erosion also stopped. In group C, the cartilage or subchondral bone destruction progressed, despite the decrease of inflammation parameters.

Conclusion: The cytokine therapy with tocilizumab leads to a rapid decrease in the inflammation parameters and hence to a normalization of DAS 28. The inflammation-verifying imaging such as the aforementioned Doppler sonography and the high-field MRI still registered inflammation activities during the course of the therapy. The use of TCZ as mono therapy for early and very early RA extensively decreases the inflammation process and prevents cartilage/bone destruction. In chronically established, advanced RA (Sharp score 3), the systemic inflammation can be inhibited, while the cartilage and subchondral bone destructions remained progressive during the course of the disease.

Seropositive Rheumatoid Arthritis Patients with an Inadequate Response to Tumor Necrosis Factor Inhibitors Achieve Improved Clinical Effectiveness After Switching to Rituximab Versus Switching to an Alternative Tumor Necrosis Factor Inhibitor. Andrea Rubbert-Roth[1], Axel Finckh[2], Piercarlo Sarzi-Puttini[3], Jacques-Eric Gottenberg[4], Denis Choquette[5], Victor Martínez Taboada[6], Leonor Barile-Fabris[7], Carol Chung[8], Lykke Hinsch-Gylvin[9] and Paul Emery[10]. [1]University of Cologne, Cologne, Germany, [2]University Hospital of Geneva, Geneva 14, Switzerland, [3]L Sacco University Hospital, Milan, Italy, [4]CHU Strasbourg, Strasbourg, France, [5]University of Montreal, Notre-dame Hospital, Montreal, QC, [6]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [7]Hospital de Especialidades Centro Médico Nacional Siglo XXI, Mexico City, Mexico, [8]Genentech Inc., South San Francisco, CA, [9]F Hoffmann-La Roche Ltd, Basel, Switzerland, [10]University of Leeds, Leeds, United Kingdom

Background/Purpose: RA patients (pts) with an inadequate response (IR) to a tumor necrosis factor inhibitor (TNFi) may achieve greater benefit by switching to rituximab (RTX) than to an alternative TNFi.[1] Seropositive pts achieve greater clinical responses to RTX than seronegative pts.[2,3] SWITCH-RA, a global, multicenter, prospective, observational, clinical practice study, evaluated the relative effectiveness of RTX vs an alternative TNFi in pts with an IR to a single previous TNFi. The objective of this subanalysis was to compare the relative effectiveness of RTX vs an alternative TNFi according to serotype.

Methods: This was a prospective, observational cohort study, designed to evaluate in routine practice the relative clinical outcomes of RTX or a second TNFi to which pts were switched following a single TNFi failure. Primary endpoint was 6-month change from baseline in DAS28 based on DAS28(3)-ESR. Analysis of covariance adjusting for unbalanced baseline characteristics was used for treatment cohort comparisons, with missing DAS28(3)-ESR values imputed with nearest-timepoint values.

Results: Overall, 728 pts were included (RF+ and/or anti-CCP+ [seropositive], n=559; seronegative, n=169). Of seropositive pts, 331 and 228 received RTX or an alternative TNFi; corresponding numbers for seronegative pts were 74 and 95, respectively. In both seropositive and seronegative pts, at time of switch, baseline DAS28(3)-ESR (SD) scores were higher in the RTX than in the alternative TNFi group (5.2 [1.2] vs 4.8 [1.3] p<0.0001, and 5.3 [1.1] vs 4.7 [1.3] p=0.0019, respectively). After adjusting for baseline differences, in seropositive pts receiving RTX, DAS28(3)-ESR improved significantly at 6 months vs pts switching to an alternative TNFi (table). The relative benefit of RTX varied in seropositive pts according to the reason for interrupting the previous TNFi (inefficacy/intolerance). In seronegative pts, improvements in DAS28(3)-ESR at 6 months were not significantly different between RTX and alternative TNFi pts. At 6 months, greater decreases in ESR (LS mean [SE]) were observed in seropositive pts receiving RTX than in those receiving an alternative TNFi (−14.4 [4.5] vs −7.3 [4.8] p=0.006); corresponding results in seronegative pts did not reach statistical significance (−13.4 [8.3] vs −10.4 [9.0] p=0.582).

Changes in DAS28(3)-ESR at 6 months

LS mean (SE)	Seropositive patients (n=559)			Seronegative patients (n=169)		
	RTX	TNFi	p-value	RTX	TNFi	p-value
All patients	−1.6 (0.3)	−1.2 (0.3)	0.011	−1.3 (0.4)	−1.1 (0.4)	0.449
Inefficacy	−1.9 (0.3)	−1.5 (0.4)	0.021	−0.5 (0.6)	−0.2 (0.7)	0.472
Intolerance	−0.5 (0.5)	−0.5 (0.5)	0.997	−2.1 (1.2)	−1.9 (1.3)	0.815

Patient numbers (all/inefficacy/intolerance): seropositive RTX=331/253/74; TNFi=228/171/51; seronegative RTX=74/58/15; TNFi=95/65/28

Conclusion: Following discontinuation of a first TNFi, seropositive pts switching to RTX achieved significantly improved effectiveness over 6 months, in particular those interrupting therapy due to inefficacy, compared with pts switching to an alternative TNFi. These differences were not evident in seronegative pts.

Adalimumab Treatment Is Associated with Decreased Concomitant Rheumatoid Arthritis Medication Use Over 24 Months. Daniel E. Furst[1], Neelufar Mozaffarian[2], Shannon Grant[3], Mary Cifaldi[2], Jerry Clewell[2], Joel M. Kremer[4] and James Shaw[2]. [1]University of California at Los Angeles, Los Angeles, CA, [2]Abbott Laboratories, Abbott Park, IL, [3]Axio Research LLC, Seattle, WA, [4]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Adalimumab (ADA) is an effective medication in the treatment of rheumatoid arthritis (RA). However, it is not clear whether the use of ADA is associated with altered use of concomitant RA medications. A study was conducted to examine changes in the use of concomitant RA medications after initiation of ADA.

Methods: The Consortium of Rheumatology Researchers of North America, Inc. (CORRONA) registry is a multi-center, longitudinal rheuma-

tology database (for physical examination data, laboratory tests, and patient outcomes) from more than 90 academic and private sites across the US. We examined RA patients enrolled in CORRONA between March 2002-September 2011 who initiated ADA and had at least one follow-up visit. RA-related concomitant medications (methotrexate [MTX], prednisone, nonsteroidal anti-inflammatory drugs [NSAIDs], intra-articular joint injections [IAs]), antidepressant use, comorbidities (high blood pressure, cardiovascular disease, lymphoma, other cancers, liver disorders, asthma, chronic obstructive pulmonary disease, diabetes mellitus, psoriasis), and demographics (age, sex, disease duration, insurance status) were examined. Trends in medication use over time were estimated using random effects logistic regression adjusting for sex, age, the number of comorbidities at initiation, and the use of ADA at each time point. Analyses included all patients with follow-up at 6, 12, 18, or 24 months after ADA initiation.

Results: Of the 1,173 patients who initiated treatment with ADA, available follow-up decreased over time to 417 patients by 24 months. The mean (SD) age and disease duration were 54.2 (12.3) and 10.1 (9.2) years, respectively, and 79.3% of patients were female. At baseline, 67% of patients were treated concomitantly with MTX, 30% with prednisone, 61% with NSAIDs, 8% with IAs, and 30% with antidepressants. Multivariable trend analysis revealed MTX and prednisone use to decrease over 24 months following ADA initiation (table). Controlling for time of follow-up and other factors, patients with $\geq$2 comorbidities were less likely to use MTX and more likely to use antidepressants than those with no comorbidities. The number of comorbidities was unrelated to prednisone, NSAID, or IA usage.

Concomitant Medication	Multivariable Trend Analysis 24 Months vs. Initiation OR (95% CI)	P-Value	Influence of Comorbidities $\geq$2 vs. 0 Comorbidities OR (95% CI)	P-Value
MTX	0.68 (0.48 − 0.95)	0.05	0.48 (0.29 − 0.80)	0.01
Prednisone	0.61 (0.43 − 0.86)	0.003	0.90 (0.56 − 1.44)	NS
NSAIDs	0.77 (0.57 − 1.04)	NS	1.15 (0.75 − 1.76)	NS
Antidepressants	1.00 (0.71 − 1.40)	NS	2.45 (1.55 − 3.88)	<0.001
Intra-articular injections	1.05 (0.67 − 1.64)	NS	1.06 (0.63 − 1.77)	NS

Abbreviations: OR, odds ratio; CI, confidence interval; MTX, methotrexate; NSAIDs, non-steroidal anti-inflammatory drugs; NS, not significant.

Conclusion: Among RA patients who initiated treatment with ADA, MTX and prednisone decreased over 24 months. This suggests the clinical efficacy of ADA in RA disease control across a medically diverse patient population.

469

Intra Articular Injections in Patients with Rheumatoid Arthritis: Analyses From the Behandelstrategiën Study. E. Gvozdenovic[1], L. Dirven[1], M. van den Broek[1], Kh Han[2], T.H.E. Molenaar[3], R. Landewe[4], W.F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Maasstad hospital, Rotterdam, Netherlands, [3]Groene Hart Hospital, Netherlands, [4]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: Intra articular (IA) corticosteroid injections aim at amelioration of symptoms of local inflammation in rheumatoid arthritis (RA). Some patients also report a systemic effect. In treat-to-target strategies IA injections may help to achieve low disease activity. Our aim was to investigate the immediate and late effects on pain, disease activity and functional ability over time of IA injections and to compare the subsequent disease course in injected versus non-IA injected RA patients.

Methods: In the BeSt study IA injections were allowed in all four treatment strategy arms at the discretion of the treating rheumatologist. We evaluated the effect of IA injections administered in large joints in the first year of treatment. We compared pain scores (Visual Analogue Scale (VAS)), Disease Activity Score (DAS) and local joint swelling and tenderness before and after injection. The subsequent disease course in IA injected versus non-IA injected patients was compared using a linear mixed model (LMM) to model the DAS and the Health Assessment Questionnaire (HAQ) score over time. Considered confounders were age, gender, DAS at baseline, treatment strategy, body mass index (BMI), anticitrullinated peptide antibodies

(ACPA), rheumatoid factor (RF) and DAS at time of outcome HAQ or HAQ at time of outcome DAS.

Results: 61 patients received >=1 IA injections in the large joints, mostly in shoulders (34%) and knees (31%). Pre-injection, local joint swelling was scored in 48% of injected joints, and local tenderness in 64%. Three months after the injection, 56% of the swollen joints were no longer swollen and 52% of the tender joints were no longer tender. Mean (SD) DAS before was 3.7 (1.3) and after was 3.3 (1.4) respectively (p<0.01), with a mean (SD) VAS for pain of 52 (26) before and 39 (26) after IA injection (p<0.01). Significantly more IA injections were given in the first year of treatment with initial methotrexate monotherapy than in the initial combination therapy arms (including either prednisone or infliximab), p<0.01. LMM showed a significantly higher DAS and HAQ in patients who received IA injections in year 0–1 compared to those who did not (mean DAS (SD) 3.07 (0.10) versus 2.75 (0.04), p<0.01) mean HAQ (SD) 0.90 (0.04) versus 0.82 (0.02), p=0.03), and no significant difference in subsequent years (table 1). Patients who were injected in year 0–1 had a similar number of treatment adjustments in subsequent years compared to patients who were not. Radiological damage after 8 years was present in 18% of the X-rays of injected joints, and in14% of the X-rays of non-injected joints.

Table 1. Mean DAS and mean HAQ in injected patients versus non injected patients

| | Injected in the first year (yes/no) | | |
	yes	No	P-value
Year 0–1			
Mean DAS (SE)	3.06 (0.10)	2.75 (0.04)	<0.01
Mean HAQ (SE)	0.90 (0.04)	0.82 (0.02)	0.03
Year 1–2			
Mean DAS (SE)	2.03 (0.10)	1.86 (0.04)	0.10
Mean HAQ (SE)	0.62 (0.05)	0.58 (0.02)	0.39
Year 1–8			
Mean DAS (SE)	1.81 (0.08)	1.68 (0.03)	0.13
Mean HAQ (SE)	0.64 (0.05)	0.58 (0.02)	0.3

Conclusion: Our data suggest that IA injections have moderate short term and limited long term efficacy in patients with early RA.

470

Concomitant Assessment of Clinical and Ultrasound Efficacy and Safety of Tocilizumab in Patients with Moderate to Severe Rheumatoid Arthritis: The Torpedo Study. Thierry Schaeverbeke[1], Philippe Gaudin[2], Aleth Perdriger[3], Christian Roux[4], Muriel Vray[5], Stephanie Rouanet[6], Ghislaine Steinberg[6] and Fabien Etchepare[7]. [1]Groupe Hospitalier Pellegrin, Bordeaux, France, [2]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [3]Hôpital Sud, Rennes, France, [4]Paris Descartes University, Paris, France, [5]Paris, France, [6]Roche, Boulogne, France, [7]G.H. Pitié-Salpêtrière, Paris, France

Background/Purpose: The anti-IL6-R tocilizumab (TCZ), indicated for the treatment of moderate to severe rheumatoid arthritis (RA), has demonstrated its clinical and structural efficacy in phase III, but little information is available on concomitant ultrasound and clinical evolution.

Methods: 103 patients with moderate to severe RA were treated with TCZ 8 mg/kg+ methotrexate (MTX) in the Torpedo study every 4 weeks during 12 months. 40-joint ultrasound (US) examinations (B and Doppler (D) modes scores 0 to 120) were performed at baseline, 12, 24 and 48 weeks of treatment in parallel with usual clinical parameters assessments (DAS28, SJC, TJC). Doppler score was semi-quantitative, graded as 0(normal), 1, 2 or 3 (worst) for each joint and for each US mode following a pre-established coding guideline. Analysis was performed on the intent-to-treat population (patients with at least one TCZ infusion). Non-responder imputation was performed for DAS 28 and CDAI remissions.

Results: 103 patients main characteristics at baseline were: mean age 52±12, disease duration 4±3 years, 75% women, 66% DMARD IR*, 74% with concomitant steroid treatment, mean DAS 28 = 5.5±1.0. *Efficacy*: under TCZ + MTX, percentage of patients in DAS28 and CDAI remission increased in parallel with decrease in B and D modes ultrasound scores (table 1). Among the patients on DAS 28 remission at W48, 28 were on DAS28 remission for at least 6 months, and 15% of them had no synovitis in B mode

and 56 % had no Doppler signal (D mode). At week 48, 17% /39% of patients under steroids at baseline could discontinue/decrease steroid dose below 5mg equivalent prednisone/day at W 48. *Safety*: reported AE's** (97% of patients with at least one AE) and SAE's** (23% of patients with at least one SAE) were in accordance with the known safety profile of TCZ.

Table 1. Clinical and ultrasound evolution of patients

	Baseline	W12	W24	W48
Number of patients in the analysis	*103*	*103*	*103*	*103*
% patients in remission DAS 28	0	36	42	46
% patients in remission CDAI	0	8	16	22
Number of patients in the analysis	*103*	*94*	*87*	*77*
40-joint US D mode mean score±Sd	10.4±12.4	5.2±6.9	4.0±5.1	3.2±5.2
Median[Q1; Q3]	7[2; 14]	3[1; 7]	2[0; 6]	1[0; 5]
40-joint US B mode mean score±Sd	26.2±17.5	18.2±14.3	14.3±11.0	11.4±10.9
Median[Q1; Q3]	21[12; 37]	14[8; 25]	11[6; 21]	9[3; 18]

*IR = inadequate responder **AE = adverse event, SAE = serious adverse event

Conclusion: In this study, parallel efficacy was shown in RA patients treated with TCZ on clinical, ultrasound scores together with steroid sparing effect. However, long term clinical remission could be associated with persistence of Doppler signals and synovitis on ultrasound. Safety profile was consistent with the previously published data.

Efficacy and Safety of Golimumab As Add-On Therapy to Disease-Modifying Antirheumatic Drugs. Bernard Combe[1], Bhaskar Dasgupta[2], Ingrid Louw[3], Sarvajeet Pal[4], Jürgen Wollenhaupt[5], Cristiano Zerbini[6], Andre D. Beaulieu[7], Hendrik Schulze-Koops[8], Patrick Durez[9], Ruji Yao[10], Nathan Vastesaeger[11] and Holly Weng[10]. [1]Hôpital Lapeyronie-Service d'Immuno-rhumatologie, Montpellier, France, [2]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [3]Panorama Medical Centre, Cape Town, South Africa, [4]Advance Rheumatology Clinic, Hyderabad, India, [5]Schön-Klinik, Hamburg, Germany, [6]Centro Paulista de Investigações, Sao Paulo, Brazil, [7]Centre de Rhumatologie, St. Louis, QC, [8]University of Munich, Munich, Germany, [9]UCL Saint-Luc, Brussels, Belgium, [10]Merck Sharp and Dohme, Kenilworth, NJ, [11]Merck Sharp and Dohme, Brussels, Belgium

Background/Purpose: This study evaluated golimumab (GLM) as add-on therapy in patients with active RA despite treatment with non-biologic DMARDs. Two GLM treatment strategies (subcutaneous [SC] vs intravenous [IV]/SC combination) for induction and maintenance of remission were evaluated.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients with active RA (DAS28-ESR ≥3.2). In Part I, patients received 50-mg SC GLM once monthly for 6 months. The primary outcome was the percentage of patients with good or moderate EULAR DAS28-ESR response at 6 months. Effects of several variables on response were evaluated: MTX dosage, type of concomitant DMARDs, corticosteroid (CS) use, and number of failed DMARDs. In Part II, patients who achieved good or moderate response but not remission at 6 months were eligible for random assignment to treatment up to month 12 with either continued 50-mg SC GLM once monthly or a combination of IV GLM and SC GLM. The coprimary efficacy endpoints in Part II were the percentage of patients with EULAR DAS28-ESR remission at the beginning of month 11 and the end of month 12. Treatment effects were evaluated with chi-square tests.

Results: At baseline of Part I, 3280 efficacy-evaluable patients had mean age 52.3 (SD=12.8) years, median disease duration 4.9 years, mean HAQ-DI 1.44 (SD= 0.67), and mean DAS28-ESR 5.97 (SD=1.10). Concomitant MTX was used by 81.1% of patients; concomitant CSs by 63.4% of patients. 34.4%, 35.9%, and 29.7% of patients failed 1, 2, and 3 DMARDs, respectively. At month 6, 82.07% (2692/3280) of patients achieved a good or moderate EULAR DAS28-ESR response and 23.90% (784/3280) achieved remission. No statistically or clinically significant differences were seen when treatment response was compared for patients who received concomitant MTX or CS vs those who did not, for high- vs low-dose MTX, or for patients who failed multiple vs only 1 DMARD. In Part II, 490 responders who were not in remission were evaluable for efficacy. The 2 treatment arms had similar

DAS28-ESR remission rates at the month-11 and -12 endpoints (ranging from 24% to 27%) and were similar in the time to first remission. GLM was generally well tolerated. Observed SAEs were consistent with those observed in RA patients treated with anti-TNF agents. In Part 1, SAEs occurred in 5.7% of patients and 10 deaths (0.2%) occurred. In Part II, SAEs occurred in 6.9% and 2.4% of patients in the IV/SC and SC arms, respectively, and 1 death occurred in the IV/SC arm.

Conclusion: In patients with active RA despite DMARD therapy, addition of GLM 50-mg once monthly resulted in moderate or good EULAR DAS28 response at 6 months for 82.07% of patients. Response to GLM was not impacted by use of concomitant MTX or CS, dose of concomitant MTX, or number of failed DMARDs. Of patients with response but not remission at month 6, approximately 25% achieved remission after 6 additional months of GLM treatment. The IV/SC regimen provided no additional efficacy over the SC regimen and was associated with a higher incidence of AEs. The safety profile for the SC regimen was consistent with previous studies of GLM.

More Positive Expectations of Treatment with Golimumab for Rheumatoid Arthritis Are Associated with Greater Improvement in Clinical Outcomes. Bhaskar Dasgupta[1], Bernard Combe[2], Ingrid Louw[3], Sarvajeet Pal[4], Jürgen Wollenhaupt[5], Cristiano Zerbini[6], Andre D. Beaulieu[7], Hendrik Schulze-Koops[8], Patrick Durez[9], W. Bensen[10], V. Wolff[11], Ruji Yao[12], Holly Weng[12] and Nathan Vastesaeger[13]. [1]Southend University Hospital, Westcliff-on-Sea, United Kingdom, [2]Hôpital Lapeyronie-Service d'Immuno-rhumatologie, Montpellier, France, [3]Panorama Medical Centre, Cape Town, South Africa, [4]Advance Rheumatology Clinic, Hyderabad, India, [5]Schön-Klinik, Hamburg, Germany, [6]Centro Paulista de Investigações, Sao Paulo, Brazil, [7]Centre de Rhumatologie, St. Louis, QC, [8]University of Munich, Munich, Germany, [9]UCL Saint-Luc, Brussels, Belgium, [10]St. Joseph's Hospital and McMaster University, Hamilton, ON, [11]Hospital del Salvador, Santiago, Chile, [12]Merck Sharp and Dohme, Kenilworth, NJ, [13]Merck Sharp and Dohme, Brussels, Belgium

Background/Purpose: Little is known about how patient and physician expectations relate to clinical outcomes. This study investigated the expectations that patients and physicians have at the start and after 3 months of treatment with golimumab (GLM) for RA and evaluated the relationship between these expectations and treatment outcomes.

Methods: GO-MORE was an open-label, multinational, prospective study in biologic-naïve patients who had active RA despite DMARD treatment. All patients received 50-mg subcutaneous GLM once monthly for 6 months. At baseline and after 3 months of treatment, patients rated their overall expectation of how well their treatment would control RA symptoms. They also rated the ability of the treatment to relieve specific symptoms and improve quality of life 3 months later using 5-point Likert scales (1=good outcome, 5=poor outcome). Patients were then divided into tertiles of expectation scores: high (≤1.5), medium (>1.5 to <1.86), or low (≥1.86). Patients indicated which attribute they wanted to improve most. Physicians were asked to predict patient disease state 3 months later and selected (from the same list used by patients), the attribute they thought patients most wanted to improve.

Results: At baseline, 3280 patients had mean age of 52.3 (SD=12.8) years, median disease duration of 4.9 years, mean HAQ-DI of 1.44 (SD=0.67) and had moderate (21.3%) or high disease activity (78.7%). Prior to starting treatment, 95.9% of patients expected GLM to be better than their

current DMARD treatment. After 3 months of treatment, 85.1% expected the treatment to be more effective still by month 6. The attributes patients wanted to improve most were pain and quality of life, with pain selected by most patients at baseline and quality of life selected by most following 3 months of treatment. Patients with more positive expectations about treatment had greater improvement in DAS28-ESR and HAQ scores and were more likely to show good EULAR response at month 6 than patients with less positive expectations (**Table 1**).

Table 1. Relationship Between Patients' Baseline Treatment Expectations and Improvement in Outcomes

Baseline Treatment Expectation	DAS28-ESR			HAQ			DAS28-CRP	
	Baseline, Mean (N)	Change at Month 6, Mean (SD)	P Value[a]	Baseline, Mean (N)	Change at Month 6, Mean (SD)	P Value[a]	Achieved EULAR Response, n/N (%)	P Value[a]
High (≤1.5)	6.03 (1212)	−2.43 (1.377)		1.40 (1211)	−0.65 (0.691)		1030/1212 (84.98)	
Medium (>1.5 to<1.86)	6.00 (1009)	−2.28 (1.386)	NS[b]	1.43 (1009)	−0.55 (0.610)	<0.0001	827/1009 (81.96)	NS[b]
Low (≥1.86)	5.86 (1054)	−2.04 (1.344)	<0.0001	1.48 (1053)	−0.44 (0.583)	<0.0001	805/1054 (76.38)	<0.0001

[a]P values are for pairwise comparison with high expectation group.
[b]P values >0.001 are considered to be nonsignificant.

At baseline, physicians expected 29.6% of patients to attain remission and 59.2% to attain low disease activity after 3 months of treatment. At the end of month 3, they expected 38.8% to attain remission and 53.1% to attain low disease activity by the end of month 6. Physicians identified pain and tender and swollen joints as the issues they thought their patients most wanted to improve.

Conclusion: Despite similar baseline scores, patients with more positive expectations about outcomes of GLM treatment demonstrated better outcomes than patients with less positive expectations.

473

The Addition of Another Disease-Modifying Anti-Rheumatic Drug to Methotrexate in Place of Infliximab Reduces the Flare Rate During 2 Years After Infliximab Discontinuation in Patients with Rheumatoid Arthritis. Hideto Kameda[1], Takahiko Kurasawa[1], Hayato Nagasawa[2], Koichi Amano[3] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical Ctr, Kawagoe, Japan, [3]Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan

Background/Purpose: The treatment strategy for rheumatoid arthritis (RA) should be divided into remission-induction phase and its maintenance phase. To date, the usefulness of the combination therapy of disease-modifying anti-rheumatic drugs (DMARDs) has been exclusively examined in remission-induction phase. Therefore, we examined whether the addition of another conventional DMARD to methotrexate (MTX) in place of infliximab (IFX) could decrease the rate of disease flare after discontinuing IFX in well-controlled RA patients. The BuSHIDO (Bucillamine Study of Holding remission after Infliximab Dose-Off) trial is a prospective, randomized, controlled study comparing MTX monotherapy with MTX plus bucillamine (Buc), a DMARD structurally related to d-penicillamine, as to flare rate during the following 2 years.

Methods: RA patients who had been receiving 6 or more infusions of IFX, maintaining DAS28-CRP > 2.6 (or DAS28-ESR<3.2) for more than 6 months, were randomized to either the addition of Buc 200 mg/day to MTX (the group 1) or non-addition of bucillamine (the group 2) upon discontinuing IFX. Primary endpoint was the flare rate (DAS28-ESR>3.2 and DAS28-CRP>2.6) within 2 years. The proportions of patients who met given criteria were compared with Fisher's exact test.

Results: Finally, 24 and 31 patients, providing a written informed consent, were assigned to the group 1 and 2, respectively. Patients discontinuing MTX during the study period (2 in the group 1, and 4 in the group 2) had been excluded from the subsequent analyses. Seven patients experienced flares in the group 1, while 17 patients did in the group 2. Notably, Buc treatment was discontinued in seven patients because of rash (n=5), reversible proteinuria (n=1) and incompliance (n=1). Three of those seven patients experienced disease flare. The flare rates were 26.7% in Buc-continuing patients and 42.9% in Buc-discontinuing patients, respectively, in the group 1, while it was significantly higher in the group 2 (63.0% versus 31.8% in the whole group 1, p=0.045). Moreover, the flare rates sorted by the achievement of Boolean remission upon IFX discontinuation were significantly different in the group 2 (40.0% in patients achieving remission versus 91.7% in non-remission patients; p=0.014), while the flare rates were similarly reduced in the group 1 (29.4% versus 40.0% in remission and non-remission, respectively).

Conclusion: The combination therapy of non-biological DMARDs, such as bucillamine plus MTX, may be a better treatment strategy rather than MTX monotherapy for maintaining RA remission after the discontinuation of biological agents.

474

Dose Reduction in Rituximab Retreatment May Delay Achievement of Optimal Responses. Mohammed I. Sharif[1], Sudipto Das[2], Paul Emery[3], Helen MacIver[1], Wendy Shingler[1], Philip S. Helliwell[2], Katharina Sokoll[1] and Edward M. Vital[2]. [1]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom, [2]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

Background/Purpose: The best long-term treatment strategy for rituximab has not been established. Retreatment at a fixed interval of 6 months maintains stable disease activity[1] and half-dose is equally effective in first-cycle responders[1]. In first-cycle non- or moderate responders, responses may improve further after a second cycle at full dose[2,3.]

We used a strategy of fixed 6-monthly retreatment at half-dose following an initial full dose cycle in responders and non-responders, and looked for changes in clinical response.

Methods: Patients received 2×1000mg rituximab at month 0 (C1), 2×500mg rituximab at month 6 (C2) and 2×500mg at month 12 (C3) regardless of C1 response. All patients were positive for RF and/or anti-CCP. 18/41 were taking concomitant MTX and 9/41 other DMARDs. 2 patients were taking concomitant oral prednisolone. DAS28 was measured at baseline and at 3–6 months after each cycle and compared to baseline of the first cycle.

Results: To date, 41 patients received C1, 34 C2, 17 C3 and 14 C4 with outcome data. For all patients, mean(SD) DAS28 at baseline and after C1, C2 and C3 were 6.15(0.74), 4.14(1.10), 3.82(1.14) and 3.13(1.06) respectively. EULAR Non/Moderate/Good responses were achieved by 5, 28 and 8/41 patients (12/68/20%) in C1; 5, 18 and 11/34 patients (15/53/33%) in C2; 1, 6, 10/17 patients (6/35/59%) in C3; and 1, 3 and 10/14 patients in C4 (7/21/71%). 3/5 patients with Non response in C1 responded to C2.

Proportions of patients with a change in EULAR response between C1-C2 and C2-C3 was compared for the 17 patients who received 3 cycles. For C1-C2: 53% patients maintained the same EULAR response, 18% improved and 29% worsened. For C2-C3, 47% maintained the same response, 41% improved and 12% worsened. DAS28 for these patients is shown in Figure 1. There was no significant difference between C1 and C2 and a trend to reduction in DAS28 after C3 (p=0.128, paired t-test).
Figure 1. DAS28 at baseline and after C1(2×1000mg) and C2 and C3 (2×500mg).

Conclusion: Some C1 non-responders responded to retreatment with half-dose at 6 months, but response rate across all patients was similar. Incremental improvements in C1 non- or moderate responders were seen more frequently after a second half-dose retreatment. This suggests that dose reduction may delay achievement of optimal responses in C1 non- or moderate responders, and these patients should have 2 full-dose cycles before reducing doses. Future work will analyse B cell depletion in this cohort.

Immunologic Responsiveness in Patients with Juvenile Idiopathic Arthritis On Methotrexate and Etanercept: 23 Valent Pneumococcal Vaccination. Ankur A. Kamdar[1], Patricia C. Giclas[2] and Barry L. Myones[3]. [1]University of Texas Medical School at Houston, Houston, TX, [2]National Jewish Health, Denver, CO, [3]Baylor College of Medicine, Houston, TX

Background/Purpose: There is a paucity of data regarding response to vaccinations in patients with juvenile idiopathic arthritis (JIA) treated with methotrexate (MTX). It is also unclear whether biologic agents affect vaccination response. Data was previously reported on the secondary response to protein vaccination with tetanus. This study investigates the primary response to polysaccharide vaccination in this same cohort.

Methods: Patients with a diagnosis of polyarticular JIA on stable doses of NSAIDS and/or MTX for a minimum of 3 months were enrolled into this prospective study. All patients were naïve to both Pneumovax and Prevnar (7-valent) vaccines. All patients received 0.5 cc Pneumovax (23-valent) subcutaneously. Serum was obtained at vaccination and after 4–6 weeks. 12 Pneumoccocal serotypes were measured (1, 3, 4, 6b, 7f, 8, 9n, 12f, 14, 18c, 19f, 23) by standard EIA. Positive response was considered a 2-fold increase in titer. 200 ng Ab N/mL was considered clinically protective by the clinical laboratory. Serum was subjected to C4 allotyping, immunoglobulin and complement levels to examine alternative causes for non-response. Statistical analysis was performed using parametric and non-parametric methods when appropriate.

Results: 50 patients were included for analysis. 3 additional patients were excluded because of reaction to vaccination requiring steroid treatment. Patients were subdivided into MTX and non-MTX groups for primary analysis. 38 patients were on MTX (n=16 on MTX + etanercept) & 12 patients were on NSAIDS. There was no statistical difference between the 2 groups in the 2-fold response for all serotypes. In addition, there was no difference in 2-fold response in the etanercept+MTX vs MTX vs non-MTX groups. The number of serotypes each group responded to was similar. 39 patients had a response to at least 1 serotype (36 to at least 2). In 11 patients who did not respond, there were no differences in proportion of patients on MTX or etanercept. For each serotype, the pre-dose geometric mean concentrations (GMC) were all greater than 200 ng Ab N/ml. Post immunization GMCs were similar in 9 of 12 serotypes between the MTX and non-MTX groups. Etanercept use did not influence this result. In the other 3 serotypes (1, 6b, 23), the MTX group had significantly higher post-GMCs. There were significant increases in post-GMCs for all serotypes. There was no difference in geometric mean ratio (GMR) for 10 of 12 serotypes between the 2 groups. Of interest, for the other serotypes (1, 18c), the MTX group had a significantly higher GMR when compared to the non-MTX group. Serotype 14 was the most immunogenic (GMR 2.57, 95% CI 1.92, 3.44) while serotype 3 was the least (GMR 1.37, 95% CI 1.08,1.74). Baseline age, MTX dose, or etanercept use did not predict response to pneumococcal vaccine.

Conclusion: In a non-immunized population of patients that were Prevnar naive, with only environmental exposure to Pneumoccocus, use of MTX and etanercept did not diminish humoral response to Pneumovax. All serotypes had post GMCs that were clinically protective. In addition, despite extended use of MTX and etanercept, most patients had protective pre-immunization titers. Future studies will address response to live virus vaccines.

Effects of Vitamin D Repletion and Maintenance Therapy On Clinical Indicators of Disease Activity in Rheumatoid Arthritis. Uzma J. Haque[1], Clifton O. Bingham III[2] and Susan J. Bartlett[3]. [1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]McGill University, Montreal, QC

Background/Purpose: Low Vitamin D levels are prevalent in Rheumatoid Arthritis (RA). We have previously reported that low vitamin D levels are associated with higher disease activity indicators and poorer patient reported outcomes (PROs). Our goal was to investigate the effect of vitamin D repletion and maintenance therapy in vitamin D deficient patients on clinical indicators of disease activity.

Methods: 139 persons who met 1987 ACR RA criteria were enrolled in an RCT at routine clinic visits from 1/2009 – 4/2011. Exclusion criteria included hypercalcemia and hyperparathyroidism. Tender and swollen joint counts (TJC, SJC) and evaluator disease assessments were performed. 25(OH)D levels were assessed using the Diasorin radioimmunoassay. Patients with 25(OH)D levels < 30 ng/ml were randomly assigned to receive either standard intensive therapy [50,000 IU ergocalciferol/week for 8 or 16 weeks] till repletion (25(OH)D > 30 ng/ml was achieved] + 16 weeks of maintenance therapy (50,000 IU ergocalciferol /month) or placebo for 16 weeks, followed by the above vitamin D protocol. At baseline visit, 83 of 139 (60%) patients had 25(OH)D levels < 30 ng/ml. **Results** show the effects of vitamin D repletion and maintenance therapy (independent of original treatment assignment).

Results: Patients had a mean (SD) age of 52.5 (12.8) yr, RA duration of 9.8 (9.6) yr and BMI of 31.8 (6.8) kg/m2 and were mostly female (83%),

white (76%), well-educated (60% reported some college education) and non-smokers (61%). Of 73 who began repletion therapy, 58 were sufficient after 8 wks of therapy; 6 were sufficient after 16 weeks of therapy and 3 failed to achieve adequate levels. During maintenance, 62 people completed 8 wk and 61 completed 16 wk of therapy. Vitamin D increased an average of 71% (mean increase 17.3 [12.9]; range $-22.4 - +57.8$ ng/ml) during repletion then declined steady during maintenance (see Table). Increases in Vitamin D were inversely and moderately associated with baseline vitamin D (r=-.43; p<.001) but not with age, sex, minority status, BMI, RA duration or smoking status. Disease activity score (DAS) and TJC significantly (p<.05) increased during treatment and decreased during maintenance; other clinical indices were not significantly different at any time point.

	Repletion		Maintenance	
	Start	End	8 weeks	16 weeks
25(OH)D	24.0 ± 7.9	41.6 ± 11.7	33.9 ± 9.1	29.5 ± 6.7
DAS-28 CRP	**3.0 ± 1.4**	3.3 ± 1.4	–	3.0 ± 1.5
CDAI	11.9 ± 12.4	12.9 ± 13.5	13.3 ± 14.3	12.5 ± 12.4
Tender Joints	**5.3 ± 7.1**	6.4 ± 8.1	6.8 ± 8.8	5.3 ± 7.4
Swollen Joints	3.1 ± 4.1	3.4 ± 4.6	2.5 ± 4.1	3.1 ± 4.1
MD GAF	17.6 ± 19.4	15.1 ± 16.4	15.8 ± 17.3	15.2 ± 15.0

Conclusion: Intensive repletion therapy modestly increased vitamin D levels in RA patients with 25(OH)D < 30 ng/ml. However, patients were unable to maintain adequate levels over 16 weeks of maintenance therapy. With the exception of tender joints which increased during treatment then returned to baseline levels following maintenance, other clinical indices remained stable throughout treatment. Thus, in RA patients who are insufficient, standardized intensive vitamin D protocols appear to only modestly increase circulating levels of 25(OH)D and do not impact clinical indicators of RA disease activity.

Impact of Etanercept On Incident Cancer in Taiwanese Patients with Rheumatoid Arthritis. Jiunn Horng Chen[1] and Wen-Miin Liang[2]. [1]China Medical University Hospital, Taichung City, Taiwan, [2]China Medical University, Taichung, Taiwan

Background/Purpose: The recent Taiwanese report has indicated an elevated risk of malignancy in RA patients[1]. Etanercept, one of the tumor necrotic factor inhibitors (TNF-I) to treat severe rheumatoid arthritis (RA), has been approved in Taiwan for 10 years. Its effect in ameliorating inflammation in RA has been shown prominent. Although the potential risk of TNF-I on cancer in RA patients has been reported, the impact of TNF-I in Asian RA patients is still lacking. We used the National Health Insurance Database in Taiwan to investigate if etanercept impacts on incident cancer in RA patients.

Methods: A prospective one-to-one case-control study matched with age, gender, index day (prescription date of etanercept), RA duration (from the date of RA diagnosis to the index day), dosage and duration of methotrexate usage was conducted. Cancer incidence, including solid-tumor and hematological malignancy, was compared in RA patients between etanercept users and those who were naïve to the TNF-I. Cox proportional hazard model was used for analysis.

Results: Among the 1,931 matched pairs (3,180 women and 682 men with the mean age of 53.8 years) during a mean follow-up of 3.7 years, 36 subjects were found cancer in the case-cohort (31 solid-tumor and 5 hematologic malignancy), and 48 in the control-cohort (46 solid-tumor and 2 hematologic malignancy). The incidences of total cancer in subjects with RA duration within 1 year and 1–2 years were 37.0 x10^{-3} and 11.6 x10^{-3} person-years in the case-cohort, which were lower than those of 127.2 x10^{-3} and 27.9 x10^{-3} person-years in the control-cohort, respectively (the corresponding p=0.002 and 0.03). On the other hand, the incidences of total cancer in subjects with RA duration within 2–3 years and more than 3 years were 12.8 x10^{-3} and 2.8 x10^{-3} person-years in the case-cohort, which were higher than those of 6.7 x10^{-3} and 1.9 x10^{-3} person-years in the control-cohort, respectively (the corresponding p=0.15 and 0.35). The incidence of hematologic malignancy in the case-cohort was 0.95 x10^{-3} person-years, which was 2.5 times higher than that of 0.38 x10^{-3} person-years in the control-cohort (p=0.26). Although no statistically significant risk of etanercept was noted for total cancer after multivariate adjustment, hazard ratios for solid tumor and hematologic malignancy were 0.70 (95% confidence interval, 0.44–1.33) and 2.17 (0.42–11.23), respectively.

Conclusion: A potential benefit of etanercept was shown for patients with shorter RA duration by a trend of lower cancer incidence in the etanercept users compared with controls, which was contrasted to the findings noted for patients with RA duration more than 2 years. Although a trend of higher risk of hematologic malignancy for etanercept users than controls was noted in the current study, we may not conclude a significantly higher risk for RA patients received etanercept than those who received the convention treatment to develop cancer. Further investigation is needed in the future.

Body Mass Index Negatively Influences the Response to Infliximab in Rheumatoid Arthritis. Sébastien Ottaviani[1], Anais Gardette[2], Emilie Quintin[2], Karen Dawidowicz[2], Ghislaine Gill[2], Elisabeth Palazzo[3], Olivier Meyer[3] and Philippe Dieude[2]. [1]APHP, Paris, France, [2]APHP, Hopital Bichat, Paris, France, [3]Hopital Bichat, Paris, France

Background/Purpose: The excess of adipose tissue in obese individuals may have immunomodulating properties and pharmacokinetics consequences. Adipose tissue is potentially involved in the regulation of inflammation in rheumatoid arthritis (RA). Recently, an exploratory study suggested that body mass index (BMI) could affect infliximab (IFX) treatment responses in RA patients (1)

The aim of this study was to investigate whether body mass index (BMI) affects the response to IFX in RA patients

Methods: In this retrospective study were included RA patients fulfilling the ACR 1987 criteria and receiving infliximab therapy. All individuals provided informed written consent as approved by the local ethic committee board. The BMI was assessed before the initiation of IFX treatment (3 mg/kg intravenously). After 6 months of treatment, changes in disease activity (DAS28) were assessed. The primary end point was the EULAR DAS28 response. The following covariates were included for the analysis: gender, anti-CCP antibodies and RF status, mean disease duration, erythrocyte sedimentation rate (ESR), CRP level, DAS28, concomitant DMARDS therapy and corticosteroids consummation.

Results: A total of 73 RA patients (age: 48.5 ± 10.5 years, 82% of females, disease duration: 8.8 ± 6.9 years, 77% RF+, 86% anti-CCP +) were included. At M0, BMI was 27.1 ± 6.9 kg/m^2. Patients were classified in 3 distinct groups according to their BMI: normal (BMI < 25 kg/m^2), overweight (BMI [25–30] kg/m^2) and obesity (BMI > 30 kg/m^2). At baseline no difference was observed between the 3 BMI subgroups according to the RA covariates, notably the DAS28. The EULAR non-response was found to be only influenced by 2 independent factors: a lower initial DAS28 (4.9 ± 1.4 *vs* 5.9 ± 1.0, $P = 0,012$) and a higher BMI (29.5 ± 8.7 vs 25.2 ± 3.9 kg/m^2, $P = 0.013$). When the 3 BMI subgroups were independently analyzed, the negative influence of BMI on response to IFX was only found in obese patients ($P = 0.008$, OR 5.2 [1.3–23.2]) in comparison to normal BMI group.

Conclusion: Our study supports the previously reported negative correlation between BMI and infliximab response in RA. Further prospective studies, including assessment of the fat mass, pharmacokinetics and adipokines dosages are mandatory to elucidate the role of obesity and the fat mass in modulating the RA IFX response.

Active Immunization with TNF-Kinoid in Rheumatoid Arthritis Patients with Secondary Resistance to Tumor Necrosis Factor-Alpha Antagonists Is Safe and Immunogenic. Patrick Durez[1], Pedro Miranda[2], Antoaneta Toncheva[3], Alberto Berman Sr.[4], Oscar L. Rillo[5], Yves Boutsen[6], Tatjana Kehler[7], Eugenia Mociran[8], LiAn Soto Saez[9], Bruno Fautrel[10], Xavier Mariette[11], Panayot Solakov[12], Eleonora Lucero[13], Tonko Vlak[14], Simeon Grazio[15], Ksenija Mastrovic[16], Rodica Chiriac[17], Géraldine Grouard-Vogel[18], Olivier Dhellin[18], Stéphane Ouary[18], Pierre Vandepapeliere[18] and Marie-Christophe Boissier[19]. [1]Université Catholique de Louvain, Brussels, Belgium, [2]Centro de Estudios Reumatologicos, Santiago de Chile, Chile, [3]National Multiprofile Transport Hospital, Sofia, Bulgaria, [4]Hospital Padilla, Tucuman, Argentina, [5]Hospital Tornú, Buenos Aires, Argentina, [6]UCL Mont-Godinne, Godinne, Belgium, [7]Thalassotherapia Opatija, Opatija, Croatia, [8]Emergency County Hospital Dr Constantin Opis, Maramures, Romania, [9]Sociedad Medica del Aparato Locomotor SA, Santiago de Chile, Chile, [10]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [11]Université Paris-Sud, Le Kremlin Bicetre, France, [12]Diagnostic and Consulting Center, Plovdiv, Bulgaria, [13]Centro Investigaciones Reumatológicas, Tucumán, Argentina, [14]University Hospital Split, Split, Croatia, [15]Clinical Hospital Center Sestre Milosrdnice, Zagreb, Croatia, [16]Clinical Hospital Sveti Duh, Zagreb, Croatia, [17]Rehabilitation clinical Hospital Iasi, Iasi, Romania, [18]NEOVACS SA, Paris, France, [19]Hopital Avicenne, Bobigny, France

Background/Purpose: Blocking TNF alpha (TNFα) with monoclonal antibodies (mAbs) has been successful in the treatment of rheumatoid arthritis. However secondary resistances are frequent and impose treatment changes. Active immunization with a TNF-Kinoid that safely induces self polyclonal anti-TNFα antibodies (Abs) could be an alternative to anti-TNFα mAbs. We evaluated the immunogenicity and safety of TNF-K in patients with rheumatoid arthritis and secondary resistance to TNF blockers.

Methods: TNFα-Kinoid (TNF-K, Neovacs SA, Paris, France) is an immunotherapeutic composed of recombinant human TNFα conjugated to KLH, inactivated and adjuvanted with ISA-51 emulsion. 40 patients with active rheumatoid arthritis (DAS28$\geq$3.2) with history of positive clinical response to at least one TNF-blocker followed by secondary failure (35% IFX, 30 % ADA, 42.5% ETA) were enrolled in a double-blind, placebo-controlled, phase 2 study to evaluate three different intramuscular doses of TNF-K (90, 180, 360 mcg) and two immunization schedules (D0 and 28 or D0, 7 and 28). Humoral immune responses were evaluated through titration of anti-TNFα and anti-KLH Abs and neutralization assay. The T cell response was assessed by lymphoproliferative assay with tritiated thymidine incorporation. Clinical response was evaluated by the ACR and EULAR core set response.

Results: No related serious adverse event has been reported. Few minor transient local and systemic reactions have been recorded following immunization. Anti-TNFα Abs were induced in 50%, 75% and 91% of patients at 90 mcg, 180 mcg and 360 mcg, respectively. 100% of patients with three injections of 180 or 360 mcg had immunogenic response against TNF versus 67% in the groups receiving two injections. The anti-TNF antibody geometric mean titres were higher in patients who received 3 injections of 360 mcg. No lymphoproliferative response could be measured after stimulation with native TNF. Among the 21 patients who developed anti-TNF Abs, 48% present a moderate to good response according to EULAR score as opposed to only 31% of the 16 patients without Abs. A mean decrease of -14% of the C reactive protein level is measured in patients with Abs while in patients without Abs, the mean CRP level increased by 5%.

Conclusion: Active immunization with TNFα kinoid to induce a polyclonal, self-anti-TNFα antibody response is safe and immunogenic. A clear dose-response was observed for the dose of kinoid as well as for the number of administrations. Association of anti-TNF Abs induced by the kinoid with clinical and biological responses were observed in patients included in this preliminary phase 2 study. Further studies are needed to confirm this new approach in RA.

Etanercept Induces A Significant Decrease of Oxidative Stress and Osteoprotegerin Compared with Sdmard in Patients with Rheumatoid Arthritis. Claire I. Daien[1], Anne-Marie Dupuy Gorce[1], Edith Pinot[1], Thibault Mura[2], Jean-Paul Cristol[1], Bernard Combe[1] and Jacques Morel[1]. [1]Hopital Lapeyronie, Montpellier, France, [2]Hopital Gui De Chauliac, Montpellier, France

Background/Purpose: TNF-inhibitors are known to decrease cardiovascular events in rheumatoid arthritis (RA) as compared with synthetic disease modifying anti-rheumatic drugs (sDMARD). However, mechanisms involved remain to be explored. Osteoprotegerin (OPG) is increased and independently associated with coronary-artery atherosclerosis in patients with RA. Adiponectine has cardioprotective functions and joint-destruction role in RA. Oxidative stress, especially urinary F(2) isoprostanes, predicts cardiovascular mortality and is increased in RA. We aimed to explore metabolic parameters changes after 6 months of anti-TNF therapy or sDMARD in patients with RA.

Methods: Twenty-four patients were included in the etanercept (ETN) group and 17 in the sDMARD group. Metabolic parameters were evaluated at baseline and at 6 months. HOMA was calculated as (insulin*glycemia)/22.5. Urinary F(2) isoprostanes were assessed using negative ion chemical ionization gas chromatography-mass spectrometry. OPG and total adiponectine levels were determined by enzyme linked immunosorbent assay. Changes were evaluated using paired-t-tests or Wilcoxon matched-pairs signed rank tests and correlations using spearman tests.

Results: Patients of the ETN group had a significantly longer RA duration, were more often RF and ACPA positive and had more often erosions and steroids. Patients had similar blood pressure, body mass index (BMI), glycemic and lipid parameters, homocystein, OPG and isoprostanes at baseline in both groups. Adiponectine tended to be higher in ETN group (196 [126–228] vs 136 [196–286] μg/ml, p=0.08).

Isoprostanes at baseline correlated with triglycerides (r=0.42, p<0.05) and inversely correlated with HDL (r=$-$0.37, p<0.05), HbA1c (r=$-$0.38, p<0.05).OPG at baseline correlated with age (r=0.48, p<0.01), DAS28 (r=0.38, p<0.05), CRP (r=0.53, p<0.01), HbA1c (r=0.51, p<0.01).

A significant decrease of BMI at 6 months was observed in the ETN group (-0.6 ± 1.4 kg/m^2, p<0.05 and 1.8 ± 0.62 kg/m^2 in ETN and sDMARD group respectively). The BMI variation was significantly different between the 2 groups (p=0.02). No correlation was found between BMI change and steroid changes. No change in mean blood pressure, HOMA, HbA1c, cholesterol and homocystein was observed after 6 months of either treatment. A significant decrease of OPG (-0.93 ± 1.64 pmol/l, p=0.03 vs 0.35 ± 2.05 pmol/l, NS; respectively in ETN and sDMARD groups), isoprostanes (-227 ± 243 pmol/mmol of urinary creatinine, p=0.01 vs -18 ± 141, NS) and a tendancy to adiponectine increase (62 ± 217 μg/ml, p=0.08 vs -13 ± 67 μg/ml, NS) was found in patients treated with ETN at 6 months whereas no change was observed in the sDMARD group. Variations were different between the 2 groups for isoprostanes (p<0.05), with a tendancy for OPG (p=0.06) and adiponectine (p=0.09). Isoprostanes and OPG changes were not correlated with DAS28 or CRP variations between baseline and 6 months.

Conclusion: ETN induced a decrease of oxidative stress and OPG which may partially explain the protective cardiovascular effect of TNF inhibitors.

Duration of Sustained Remission and Differences in Responce Between Medications, in Tumor Necrosis factor inhibitor Treated Rheumatoid Arthritis Patients. Jon T. Einarsson[1], Pierre Geborek[2], Tore Saxne[3] and Meliha C. Kapetanovic[4]. [1]Dept of Clinical Sciences, Lund, Section of Rheumatology, Lund University, Sweden, Lund, Sweden, [2]Lund University, Lund, Sweden, [3]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden, [4]Dept of Clinical Sciences Lund, Lund, Sweden

Background/Purpose: Remission is increasingly becoming a treatment goal in rheumatoid arthritis (RA) patients and DAS28 remission criteria are widely used, despite their limitations.

The purpose of this study was to study frequency, duration, and timing of sustained remission (SR) defined as DAS<2.6 for at least 6 months, and to compare efficacy of different therapies, in patients with established RA treated with Tumor Necrosis Factor inhibitors (aTNF) in the observational setting of Southern Sweden.

Methods: aTNF treatments in RA patients registered in the SSATG register were eligible for this study. Remission time was defined as time between first visit after treatment initiation with DAS28<2.6 and subsequent visit with DAS28>2.6.

The comparison of the drugs was done using logistic regression analysis, adjusting for baseline variables, and the ORs for achieving SR 12 and 24 months were adjusted for baseline age, disease duration, DAS28, HAQ, concomitant MTX and prednisolone. Life-table techniques were used to estimate SR time, looking only on first biologic treatments.

Results: Of 3446 initiated treatments, 481 (14 %) fulfilled the criteria. Of those who reached SR 63.2% did so within the first year.

Among patients naïve to biologic treatments and after correction for baseline variables, the ORs for achieving SR within the first 12 months of treatment were 1.9 for etanercept and 1.7 for adalimumab, with infliximab as the reference drug, while etanercept and adalimumab were not significantly different, see figure 1.

Median estimated SR survival time was 3.9 years (etanercept 4.4y, adalimumab 4.8y and infliximab 3.0y). Estimated SR survival was significantly longer for etanercept and adalimumab compared to infliximab (p < 0.05), with no significant difference between etanercept and adalimumab. The estimated SR survival, at 12, 24, and 48 months was 94%, 68% and 48% respectively. After 120 months 11% remained in SR.
Figure 1. Odds of having achieving sustained remission on first biologic after 12 and 24 months, and for all treatments after 24 months. Drug on right the reference drug.

Adjusted for age, sex, disease duration, concomitant methotrexate and prednisolone treatment, CRP, DAS28 and HAQ score at baseline.

Conclusion: Differences were seen in remission rates and duration between different medications. Within 12 months etanercept and adalimumab had significantly higher likelihood of reaching remission than infliximab, and the estimated remission survival was significantly longer for etanercept and adalimumab compared to infliximab.

B-Lymphocyte Count Is Not Associated with an Increased Risk of Infection in Patients Treated with Rituximab for Auto-Immune Diseases. Ilias Lazarou, Axel Finckh, Lara Fischer, Camillo Ribi, Joerg Seebach and Pierre A. Guerne. University Hospitals of Geneva, Geneva, Switzerland

Background/Purpose: B-Lymphocyte (B-Ly) depletion therapy with the monoclonal anti-CD20 antibody rituximab (RTX) is widely used in a variety of autoimmune (AI) diseases. The risk of severe infection related to RTX use in this population is estimated to be 5–14.1/100 patient-years. Additional risk factors for severe infection, such as low IgG levels, age, and concomitant immunosuppressive therapy, have been recognized.

In practice, many clinicians are reluctant to use RTX if B-Ly levels are decreased. Our aim was to examine whether B-Ly counts, the direct target of RTX, are associated with an increased risk of infection in patients with AI diseases.

Methods: We conducted an observational cohort study of all 161 patients treated with RTX between 2002 and 2012 in the Rheumatology and Immunology Divisions of the Geneva University Hospital. Primary outcome was severe (iv antibiotics, hospitalization, related death) and non-severe infection (requiring antibiotics). Primary predictor of interest was absolute B-Ly count, assessed by flow cytometry before RTX treatment. Time-to-infection was analyzed by Cox proportional hazard model, adjusting for potential confounders (glucocorticoid and other immunosuppressants use, diabetes and other chronic comorbidities, RA versus other AI diseases, age and sex).

Results: A total of 161 patients were included and followed for a mean period of 2.4 years; 85 (53%) had RA, and the remaining 76 (47%) mainly connective tissue disorders and vasculitides. During follow-up, 63 severe and 111 non-severe incident infections were observed. The incidence rate of severe infection was 15 /100 patients-years in non-RA patients compared to 3.5 in RA patients (p<0.001). The most recent B-Ly level before RTX treatment was not associated with subsequent infections (HR 0.999, p=0.78). Significant predictors of infection were an AI condition other than RA (HR 3.4, p<0.001), age (HR 1.03, p=0.03) and low IgG levels (HR 0.91, p=0.02).

Conclusion: In this population treated with RTX for AI diseases, B-Ly counts before RTX infusion were not associated with incidence of infections. This data does not support the common concern of infection with low B-Ly counts, and does not encourage assessing B-Ly before RTX treatment. We confirm the higher risk of infection conferred by low IgG levels, older age and AI disease other than RA.

An Evaluation of Literature On Discontinuation Rates of Biologics in Rheumatoid Arthritis. Setareh A. Williams[1], Victoria Porter[2], Victoria Zarotsky[3], Sujatha Sundaram[4], Elisabeth Nyman[5], Cassie K. Gregson[6] and Paul S. J. Miller[6]. [1]AstraZeneca LP, Wilmington, DE, [2]OptumInsight, Mastic Beach, NY, [3]OptumInsight, Calabasas, CA, [4]OptumInsight, Hanover, NH, [5]AstraZeneca, Mölndal, Sweden, [6]AstraZeneca, Macclesfield, United Kingdom

Background/Purpose: To assess reasons for biologic discontinuation or switching in the treatment of rheumatoid arthritis (RA).

Methods: A text mining strategy was developed to identify, from the biomedical information published through July 2011, data relevant to discontinuation or switching due to adverse events (AEs) or lack of efficacy or patient preference. Searches encompassed Medline, ACR and EULAR conference abstracts, and > 20,000 selected full-text documents. The abstracts of the identified documents were manually assessed to determine whether they reported on the incidence/duration of and/or reasons for discontinuing/switching therapy. Expert opinions including non-systematic reviews, case studies, and editorials and commentaries were excluded.

Results: 234 full-text articles and 45 meeting abstracts were identified as reporting on discontinuation due to AEs/lack of efficacy. Fourteen articles/abstracts reporting on discontinuation due to patient preference were identified. Sixty-one articles on discontinuation due to AEs/lack of efficacy met inclusion criteria (4 systematic reviews/meta-analyses, 17 randomized controlled trials, 7 registry studies, 21 prospective studies, and 12 observational studies), and 9 studies on patient preference met inclusion criteria (3 registry studies, 4 retrospective analyses, 1 cross-sectional, and 1 prospective study). AEs accounted for 5% to 40% of discontinuations within the 1st year of therapy. Injection/infusion site reactions were the most common discontinuation-related AE, most frequently reported with infliximab use and in patients with history of allergic reactions. Discontinuation due to lack of efficacy varied from 1% to 52% in studies with a 6-month follow-up duration and from 17% to 47% per year over a 10-year period. Patients were more

likely to start on a 2nd biologic if their 1st biologic was discontinued due to lack of efficacy than if discontinued due to AEs. Patient preference accounted for 4% to 29% of the total discontinuations. Infliximab, followed by etanercept, were the most widely evaluated biologics. Limited data on withdrawal rates were available for 2nd generation and non-TNF inhibitor biologics.

Conclusion: Despite the availability of 9 RA biologics, a substantial proportion of patients discontinue treatment largely due to AEs or lack of efficacy. Heterogeneity in RA disease is well-known; hence, new therapies with different mechanisms of action may help mitigate this issue. Treatments offering equivalent efficacy to that of currently available biologics that can be sustained over longer time periods would benefit RA patients with inadequate response to available treatments.

Comparison of Rheumatoid Arthritis-Related Health Care Resource Use and Comorbidities Among Patients with Rheumatoid Arthritis Treated with Adalimumab Vs. Etanercept. Jipan Xie[1], Arijit Ganguli[2], Hongbo Yang[1], Kejal Parikh[1], Eric Q. Wu[1] and Mary Cifaldi[2]. [1]Analysis Group Inc., Boston, MA, [2]Abbott Laboratories, Abbott Park, IL

Background/Purpose: Adalimumab (ADA) and etanercept (ETN) are two commonly used tumor necrosis factor (TNF)-α antagonists for the treatment of rheumatoid arthritis (RA). The study is aimed to compare the rate of experiencing RA-related urgent care and surgery, and the risk of developing new comorbidities between ADA- and ETN-treated patients with RA.

Methods: Adult RA (ICD-9-CM: 714) patients who initiated ADA or ETN were identified from the Thomson MarketScan database (2005–2009). The date of the first prescription of ADA or ETN was defined as the index date. Patients were required to have continuous eligibility for at least 6 months prior to (baseline period) and 12 months after (study period) the index date. In addition, patients were required to be free of other medical conditions (e.g., Crohn's disease and psoriasis), for which ADA or ETN is indicated, during the baseline period. Baseline characteristics (demographics, comorbidities, prior treatments for RA and health care resource use) were compared between the ADA and ETN cohorts using Chi-square tests for categorical variables or Wilcoxon rank-sum tests for continuous variables. The rate of experiencing RA-related urgent care (i.e., inpatient or emergency room visits associated with RA diagnoses), RA-related surgery, and the risk of developing new comorbidities (including gastrointestinal disease, cardiovascular disease, diabetes, hypertension, osteoporosis) during the study period were compared between the two cohorts using Cox proportional hazards models, adjusting for the above baseline characteristics.

Results: A total of 3,109 ADA-treated RA patients and 3,972 ETN-treated RA patients met the study inclusion and exclusion criteria. Compared to ETN-treated patients, ADA-treated patients were older (50.2 vs. 49.4, p=0.006), and had a higher baseline use of methotrexate (62.9% vs. 58.7%, p<0.001). After adjusting for baseline characteristics, ADA was associated with a significant lower rate of experiencing RA-related urgent care (hazard ratio [HR]=0.82, 95% confidence interval [CI]=0.67–0.99) and RA-related surgery (HR=0.65; 95% CI=0.47–0.91). ADA was also associated with a lower risk of developing new gastrointestinal disease compared to ETN (HR =0.85; 95% CI: 0.76–0.95). The risks of developing other comorbidities including cardiovascular diseases, diabetes, hypertension, and osteoporosis were not significantly different between the two cohorts.

Conclusion: Compared to those treated with ETN, patients with RA treated with ADA, were less likely to experience an RA-related urgent care or RA-related surgery, and to develop new gastrointestinal disease.

485

Immunogenicity of Infliximab Is Related to Reduction of Frequency of Infliximab Administration in Rheumatoid Arthritis and Spondyloarthritis Patients. Mathieu Verdet[1], Clément Guillou[2], Marie-Laure Potier[2], Martine Hiron[2], Fabienne Jouen[3], Olivier Boyer[4], Thierry Lequerré[5] and Olivier Vittecoq[6]. [1]Rouen University Hospital, Bois Guillaume, France, [2]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [3]Rouen University Hospital, Rouen Cedex, France, [4]INSERM U905, University of Rouen, Rouen, France, [5]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France, [6]Rouen University Hospital & Inserm905, University of Rouen, Rouen Cedex, France

Background/Purpose: To analyze the clinical and biological characteristics associated with presence of antibodies to Infliximab, in rheumatoid arthritis (RA) and spondyloarthritis patients (SpA).

Methods: Sera from RA (n=22) or SpA (n=23) patients receiving Infliximab have been analyzed with a commercial multiplex enzyme-linked immunosorbent assay kit (LISA-Tracker Infliximab BMD®). Antibodies toward Infliximab (ATI) and Infliximab trough concentrations were measured in their serum. Result was considered positive if ATI concentrations were >10ng/mL. Clinical and biological data were retrospectively collected from the patient's medical file.

Results: Infliximab was given in association with methotrexate in 31 patients (69%). The time between two consecutive Infliximab adminstration was higher than 8 weeks in Fifteen patients (33%). Fifteen patients were in remission at time of analysis. Time between two Infliximab administration was significantly longer in patients who had obtained remission(9.27 weeks) compared to other patients(6.83 weeks; Mann-Whitney Test, p=0.0005).

Seven patients(15%) were ATI+. Time since beginning of Infliximab was not different between ATI+ and ATI- patients.

Posology of Infliximab at time of analysis was not different between ATI+ (4.29mg/kg) and ATI- patients(4.13mg/kg; Mann-Whitney Test, p=0.74).

Longer time between infliximab infusions was associated with presence of ATI(ATI +: 9.57 weeks; ATI -: 7.29 weeks; Mann-Whitney Test p=0.02). As expected, Infliximab concentration was significantly lower in ATI+ patients(0.18μg/mL) compared to ATI- patients(2.1μg/mL; Mann-Whitney Test, p=0.0005). There was a significant inverse correlation between ATI titer and Infliximab concentration in the serum(Spearman test, p=0.0001). In contrast, no association was found between the posology of Methotrexate and presence of ATI.

Conclusion: Immunogenicity against Infliximab was associated to a longer interval between infusions. This result could impact on treatment strategy for patients in clinical remission since decreasing the frequency of Infliximab administration may favor the development of ATI.

Impact of Adalimumab Therapy On Laboratory Parameters of Interest in Patients with Early or Long-Standing Rheumatoid Arthritis. De Furst[1], Ana P. Lacerda[2], Nupun Andhivarothai[3], Jasmina Kalabic[4] and Neelufar Mozaffarian[3]. [1]University of California at Los Angeles, Los Angeles, CA, [2]Abbott Laboratories, São Paulo, Brazil, [3]Abbott Laboratories, Abbott Park, IL, [4]Abbott GmbH & Co. KG, Ludwigshafen, Germany

Background/Purpose: The systemic inflammation of rheumatoid arthritis (RA) can have detrimental effects on the hematopoietic and cardiovascular systems. Additionally, effective DMARD treatments for RA can be hemato- or hepatotoxic. The effects of adalimumab (ADA) in combination with methotrexate (MTX) therapy on these systems in patients with early or long-standing RA have not been previously summarized. This analysis evaluates the effects of ADA+MTX therapy compared to MTX monotherapy on laboratory and vital sign parameters relevant to hematopoietic, cardiovascular, and hepatic organ systems.

Methods: Clinical trials DE013 and OPTIMA (MTX-naïve patients, early RA, mean duration=0.8 yrs in DE013, 0.35 yrs in OPTIMA) and DE019 (MTX-incomplete responders, long-standing RA, mean duration=11 yrs) were double-blind studies that compared ADA+MTX therapy to MTX monotherapy for ≥6 months. This *post hoc* analysis determined the percentage of patients who developed neutropenia, lymphocytopenia, thrombocyto-

nonenone

Conclusion: In these early RA patients, baseline disease activity resulted in substantial functional impairment. Patients who responded to early treatment with either ADA+MTX or PBO+MTX had low ACT-HAQ and DAM-HAQ values at wk 26 that were sustained through week 78. Patients with an inadequate response after 22 and 26 wks of PBO+MTX or ADA+MTX therapy showed significant improvement in HAQ even though not achieving LDA, and further improvement when treated with O-L ADA+MTX. Notably, even among initial inadequate responders, the disability at week 78 mostly consisted of ACT-HAQ, suggesting the potential for further improvement in these patients with further adjustment of treatment regimen.

Patient Preferences for Biologic Treatments in Rheumatoid Arthritis.
Beenish Nafees[1], Andrew Lloyd[1], Carol L. Gaich[2], Julie Birt[2] and Rodney A. Hughes[3]. [1]Oxford Outcomes, Oxford, United Kingdom, [2]Eli Lilly and Company, Indianapolis, IN, [3]St. Peters Hospital, Chertsey Surrey, United Kingdom

Background/Purpose: Patients with rheumatoid arthritis (RA) and their physicians face a range of treatment choices. The treatments that patients receive should be driven partly by their views and preferences regarding different aspects of the treatments. The present study was designed to elicit the treatment preferences of people with RA.

Methods: A stated preference survey was developed based on published literature, discussion with clinicians (n=4) and qualitative interviews with patients (n=5). The survey presented hypothetical treatments that varied in terms of six key attributes: *Mode of administration & frequency, Time medication stays in the body, Effectiveness in treating pain, Functional ability, Number of RA flares in next 12 months,* and *Out of pocket cost.* Socio-demographic, and clinical data were also collected. Participants (US n=150; UK n=150) completed the survey following IRB approval. Survey data were analysed using the conditional logit model whereby the attributes were the independent variables and patient choice data were the dependent variable. The coefficients obtained from the logit model provided an estimate of the (log) odds ratios (ORs) of preference for treatment attributes.

Results: 287 participants (143 patients in UK and 144 in US) completed all study questionnaires. Participants reported a median current pain VAS of 5.0 (0–10 scale) and poor quality of life (EQ-5D score = 0.41 (US) and 0.45 (UK) on a 0 (dead) to 1.0 (full health) scale. Over 90% of the sample reported experiencing at least 7 flares in the last 12 months. All attributes were significant predictors of choice where all or some levels were significantly more important than the reference case as shown by the ORs. The three most important drivers of preference were number of symptom flares per year, effectiveness in reducing pain and functional ability (Table 1). Treatments which reduced the number of symptom flares per year from 5 to 0 were of high importance to participants. Participants preferred treatments that reduced pain (assessed on a visual analogue scale) score by 80%. Avoiding functional difficulties was also very important to participants (Table 1). Oral (daily or twice-daily) and subcutaneous treatments (weekly or bi-weekly) were preferred to intravenous therapies (every 4 weeks or 8 weeks), but this was less important to participants; and time medication is in body was not important to participants. Cost was somewhat a significant predictor of choice, whereby participants were willing to pay more for improvements of therapy.

Table 1. Results of logit model by country

Attribute and level	Odds Ratios (Lower – Upper 95% Confidence intervals)	
	US	UK
Administration & Frequency – Sub-cutaneous weekly (reference)‡		
Oral daily	1.03 (0.78–1.36)	1.45 (1.11–1.90)
Oral twice daily	0.82 (0.56–1.18)	1.40 (0.99–2.0)
Intravenous-8 weeks	0.52 (0.35–0.77)	1.06 (0.73–1.55)
Intravenous-4 weeks	0.44 (0.29–0.66)	0.85 (0.58–1.26)
Sub-cutaneous-biweekly	0.95 (0.71–1.27)	0.93 (0.74–1.30)
Time in Body-8 weeks (reference)		
1 day	0.77 (0.65–0.09)	0.82 (0.70–0.96)
4 weeks	1.19 (1.01–1.41)	1.12 (0.95–1.32)
Level of pain while taking treatment–Current pain level reduced by 20% (reference)		
Current pain level reduced by 80%	6.25 (5.12–7.63)	4.44 (3.71–5.30)
Current pain level reduced by 40%	2.68 (2.24–3.20)	2.12 (1.80–2.49)
Functional Ability-Some difficulty & moderate discomfort (reference)		
No difficulty	2.29 (1.89–2.77)	2.20 (1.86–2.62)
Some difficulty & mild discomfort	1.73 (1.44–2.08)	1.37 (1.16–1.62)
Number of Flares-5 (reference)		
0	5.28 (4.32–6.46)	3.85 (3.22–4.60)
2	3.09 (2.55–3.74)	2.60 (2.19–3.09)
Cost		
Cost ($)	1.0 (1.0–1.0)	0.99 (0.99–0.99)

‡ - reference case is the base profile in each attribute.

Conclusion: The results show the relative importance of different features of RA treatments to patients. Improving pain control, functioning, and avoiding flares were the most important aspects of treatment. Participants were much less concerned about the mode or frequency of administration.

The Comparative Effectiveness of Anti-TNF Medications Among Older and Disabled Rheumatoid Arthritis Patients in the U.S. Medicare Population.
Huifeng Yun[1], Fenglong Xie[2], Elizabeth S. Delzell[2], Lang Chen[2], Shuo Yang[2], Kenneth G. Saag[3] and Jeffrey Curtis[2]. [1]University of Alabama-Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Evaluating the real world effectiveness of biologic DMARDs in rheumatoid arthritis (RA) patients using administrative claims data has previously not been feasible due to the lack of clinical information present in such databases. A novel, recently published, validated administrative data-based algorithm (Curtis et. al., Arthritis Res Ther 2011) provides the potential to compare the effectiveness of different biologics to one another, with focus on older and vulnerable populations that are sometimes excluded or not present in large numbers in clinical trials or registries.

Methods: We evaluated the effectiveness of etanercept, adalimumab, and infliximab in 100% of Medicare beneficiaries with RA and with >= 24 months of fee-for-service + drug coverage, 2006–2009. Patients included those eligible for Medicare on the basis of age >= 65 or disability. New users of anti-TNF agents had a 12 month baseline during which no prescription or infusion of any biologic medication was given. The outcome was effectiveness at 12 +− 2 months according to the algorithm, which required six dichotomous conditions be met (Table). We calculated the proportion meeting effectiveness criteria by anti-TNF medication and compared effectiveness between them using robust Poisson regression to compute risk ratios (RRs), adjusted for demographics, income, comorbidities and other medications.

Results: We identified 1,635, 2,077 and 3,181 new users of adalimumab, etanercept and infliximab, respectively. Overall, 35% of patients were disabled, almost all of whom were younger than age 65. The algorithm classified the medication as effective for 27% of adalimumab users, 31% of etanercept users, and 29% of infliximab users. After multivariable adjustment, the RRs for effectiveness were 0.99 (95% confidence interval (CI): 0.90–1.10) for adalimumab, and 1.11 (95% CI: 1.02–1.22) for etanercept compared to infliximab. Across all anti-TNFs, patients who were not disabled had

higher effectiveness for anti-TNF medications than patients who were disabled (RR=1.26, 95% CI: 1.15–1.39).

Table. Components of the effectiveness algorithm† for adalimumab, etanercept, and infliximab at 1 year*

	Adalimumab %	Etanercept %	Infliximab %
Effectiveness Criteria, %			
High adherence to the index drug	55	59	65
No switch to a different biologic	87	85	89
No addition of a new non-biologic DMARD	90	90	91
No biologic dose increase compared to starting dose	94	99	84
For patients not using glucocorticoids at baseline, no initiation of glucocorticoids; for patients using glucocorticoids at baseline, no increase in dose	84	88	84
No more than one joint injection on unique days after the 3 months of new treatments	89	90	88
Satisfied all 6 effectiveness criteria	**27**	**31**	**29**

† The gold standard outcome was low disease activity (Disease Activity Score using 28 joint counts (DAS28) <= 3.2) or improvement in DAS28 by >1.2 units at 12+2 months with high adherence to therapy. This newly published claims-based effectiveness algorithm was validated using the clinical information in Veterans affairs RA registry as the gold standard.
* assessed between the first exposure date and the outcome rheumatologist visit date (10–14 months later)

Conclusion: A recently-published claims-based effectiveness algorithm provides opportunities to assess the comparative effectiveness of RA medications using administrative data. Etanercept was associated with somewhat higher effectiveness among new anti-TNF users compared to infliximab. Effectiveness of all anti-TNF medications combined was significantly higher among older patients who were not disabled compared to younger, disabled RA patients.

12- and 24-Week Patient-Reported Outcomes From a Phase 2b Dose-Ranging Study of Baricitinib, an Oral Janus Kinase 1/ Janus Kinase 2 Inhibitor, in Combination with Traditional Disease-Modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis.
Josef S. Smolen[1], Douglas E. Schlichting[2], Kimberly L. Sterling[2], Edward Keystone[3], Peter Taylor[4], Mark C. Genovese[5], Louise Johnson[6], Juan C. Rizo Rodriguez[7], Chin H. Lee[2] and Carol L. Gaich[2]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Eli Lilly and Company, Indianapolis, IN, [3]University of Toronto, Toronto, ON, [4]Kennedy Institute of Rheumatology, London, United Kingdom, [5]Stanford University Medical Center, Palo Alto, CA, [6]PharmaNet/i3, Eden Prairie, MN, [7]Centro de Alta Especialidad en Reumatología e Investigación del Potosí, San Luis Potosi, San Luis Potosi, Mexico

Background/Purpose: Baricitinib (formerly, LY3009104/INCB028050) is a novel, oral inhibitor of the JAK1 and JAK2 in the JAK-STAT pathway known to be of importance in the pathobiology of rheumatoid arthritis (RA) and has previously been shown to improve the signs and symptoms of RA after 12 weeks of treatment.[1] This study evaluates the patient-reported outcomes (PROs) within a 24-week blinded phase 2b study for 1 mg, 2 mg, 4 mg, and 8 mg baricitinib once daily (QD) at 12 weeks, and 4 mg and 8 mg at 24 weeks.

Methods: Patients with active RA and on stable doses of methotrexate were randomized (2:1:1:1:1) to receive either placebo (PBO) or 1 of 4 QD baricitinib doses (1, 2, 4, or 8 mg) for 12 weeks. Patients assigned to placebo or 1 mg were reassigned to an exploratory 4 mg QD or 2 mg BID group between weeks 12 and 24 and were excluded from the primary 24-week analysis; patients initially assigned to 2 mg, 4 mg, or 8 mg remained on the same treatment. PROs included patient global assessment (PtGA) of disease activity (Visual Analog Scale [VAS]), pain (VAS), physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]), health-related quality of life (Medical Outcomes Study [MOS] Short Form 36 [SF-36]), fatigue

(Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]), and duration of morning stiffness. Analyses were done using analysis of covariance (ANCOVA). Statistical comparisons of means were conducted for each active treatment group against the PBO group; p-values were not adjusted to correct for multiple comparisons.

Results: Of 301 randomized patients, those who received baricitinib experienced clinically meaningful improvements in most PROs as early as week 2 vs. PBO as well as at 12 weeks (Table 1). These improvements were maintained or continued to improve through 24 weeks (e.g., change from baseline for 4 and 8 mg groups, respectively, FACIT-F: 5.32 [SEM: 1.31], 5.00 [SEM: 1.52]; SF-36 PCS: 7.32 [SEM: 0.97], 7.67 [SEM: 1.23]).

Table 1. Patient-Reported Outcomes at 12 Weeks Showing Mean Change From Baseline (LOCF), (Mean [SEM])

Measure	PBO (N=98)	1 mg (N=49)	2 mg (N=52)	4 mg (N=52)	8 mg (N=50)
PtGA (VAS)	−10.3	−24.9*** (3.89)	−16.2 (3.11)	−25.4*** (3.03)	−29.8*** (3.00)
Pain (VAS)	−8.8	−22.8*** (3.91)	−14.2 (2.47)	−25.0*** (2.69)	−25.3*** (2.87)
Physical function (HAQ-DI)	−0.10	−0.35** (0.08)	−0.18 (0.07)	−0.33*** (0.06)	−0.39*** (0.07)
SF-36 Mental Component Score	0.88	2.54 (1.73)	1.89 (0.96)	2.39 (1.11)	3.03 (1.51)
SF-36 Physical Component Score	3.22	6.66* (1.17)	4.15 (1.08)	7.07*** (1.03)	7.00* (1.28)
Fatigue (FACIT-F)	2.02	4.48 (1.51)	3.80 (1.28)	4.41* (1.21)	4.11 (1.41)
Morning Stiffness Duration (minutes)	−33.9	−49.5* (10.51)	−30.7 (6.64)	−75.0*** (20.09)	−62.7*** (12.48)

* p≤0.05, ** p≤0.01, ***p≤0.001

Conclusion: In this phase 2b study in patients with RA, those who received baricitinib reported clinically meaningful improvements as early as week 2 in most PROs relative to PBO as well as at 12 weeks. These improvements were maintained or continued to improve through 24 weeks.

Predictors of Initiating Biologic Monotherapy in Biologic Naïve Patients with Rheumatoid Arthritis (RA) in a US Registry Population.
Dimitrios A. Pappas[1], George W. Reed[2], Ani John[3], Ashwini Shewade[3], Katherine C. Saunders[4], Jenny Devenport[5], Jeffrey D. Greenberg[6] and Joel M. Kremer[7]. [1]Columbia University, College of Physicians and Surgeons, New York, NY, [2]University of Massachusetts Medical School, Worcester, MA, [3]Genentech Inc., South San Francisco, CA, [4]CORRONA, Inc., Southborough, MA, [5]Genentech, South San Francisco, CA, [6]NYU Hospital for Joint Diseases, New York, NY, [7]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Published data have shown that approximately one-third of patients with RA are treated with biologic (Bio) monotherapy (MT) (without concomitant DMARD) and a considerable portion of these patients are previously Bio naïve (Yazici et al. 2008). The purpose of this analysis is to determine the predictors of initiating a biologic as MT versus in combination with a DMARD (CMB) in previously Bio naïve patients in the Consortium of Rheumatology Researchers of North America (CORRONA) Registry.

Methods: Data on patients previously Bio naïve and initiating their first biologic therapy were included in this analysis. Demographic and baseline clinical characteristics were evaluated and logistic regression models were used to assess potential predictors of Bio MT initiation. The following independent variables, selected for clinical relevance and significant in the univariate model, were entered in the models simultaneously as fixed effects in various combinations: a) medical history of neutropenia, hepatic disease and malignancy, b) swollen joints counts and presence of erosions, c) whether

the biologic is approved for MT in the US, and d) and if the biologic was initiated prior to 2006 which marks the increased availability of biologics approved for MT. A random effect of individual physician's prescribing patterns was also included in the model to estimate a median odds ratio (Larsen et al., 2000).

Results: Between October 2001 and April 2012, 3,923 previously Bio naïve patients initiated biologic therapy, of which 19% initiated as MT. Baseline characteristics of patients initiating Bio MT and Bio CMB were similar: age (years; mean±SD) 57±15 vs. 58±13, female 74% vs. 76%, duration of RA (years; mean±SD) 9±9 vs. 8±9, and CDAI (mean±SD) 19±14 vs. 19±14. A significantly higher proportion of patients initiating a Bio CMB had a history of non-biologic DMARDs (86% vs. 97%, p<0.0001) and specifically, a history of methotrexate (MTX) (72% vs. 92%, p<0.0001). The most frequently reported reason for discontinuing MTX was due to toxicity (Bio MT 45% vs. Bio CMB 36%, p = 0.05); similar results were seen for history of leflunomide.

Table 1. Adjusted Odds Ratios[a] for Biologic Monotherapy Versus Combination in Biologic Naïve Patients

	Model 1[b] N=3861[c]	Model 2[b] N=2823[c]	Model 3[b] N=644[c]
History of Hepatic Disease	6.5 [3.20, 13.07]	7.49 [3.19, 17.58]	5.20 [0.95, 28.49]
History of Malignancy	3.79 [1.64, 8.73]	2.78 [1.02, 7.59]	1.00 [0.19, 5.40]
Swollen Joint Count	0.97 [0.95, 0.99]	0.96 [0.95, 0.98]	0.98 [0.94, 1.02]
Use of Mono Approved Biologic	1.47 [1.20, 1.81]	1.45 [1.13, 1.86]	1.93 [1.08, 3.43]
Initiated after 2006	0.83 [0.68, 1.00]	0.79 [0.63, 0.99]	
Erosions		0.84 [0.68, 1.03]	0.96 [0.62, 1.49]
History of Neutropenia			4.89 [1.16, 20.59]
Random effect of individual physician's prescribing patterns	1.89 [1.66, 2.23]	1.86 [1.61, 2.25]	1.58 [1.23, 2.72]

Notes:
[a] OR > 1 implies monotherapy more likely.
[b] Three different models with various combinations of fixed effects from independent variables described above and a random effect of individual physician's prescribing patterns were fitted.
[c] Models fitted using available data among 3,923 previously Bio naïve patients initiating a biologic therapy.

Conclusion: Biologic approved for MT and effect of individual physician prescribing patterns consistently influenced the likelihood of Bio MT use along with significant effects in some instances of less severe disease, history of conditions potentially influencing use of concomitant DMARDs and year of initiation.

492

Divergent Toxicity of TNF Inhibitors On Demyelinating Disorders and Neurological Events. Sergio Schwartzman[1], John Clark[2] and John J. Cush[3]. [1]Hosp for Special Surgery, New York, NY, [2]RiskBenefits LLC, Flourtown, PA, PA, [3]Baylor Research Institute, Dallas, TX

Background/Purpose: There are currently five anti-TNF agents that have been approved for various autoimmune illnesses. There is no convincing evidence that any one of these is superior to the others in terms of efficacy. However, some differences in safety, such as tuberculosis risk, have been described. There is no single source of information on the safety of these agents that is universally precise. The Adverse Event Reporting System (AERS) maintained by the US Food and Drug Administration (FDA) receives spontaneous reports of adverse reactions to approved medications licensed for use in the United States. These are submitted by health care professionals or through the manufacturer. It is widely accepted that this type of reporting underestimates the number of actual cases of toxicity that occur and at times may be biased. Therefore any comparisons should be approached with caution. We sought to evaluate the frequency and type of neurologic events seen with TNF inhibitor (TNFi) therapy.

Methods: The AERS database was queried to identify neurological toxicity events following TNFi use reported from date of approval to end 2011 for etanercept, infliximab, adalimumab, golimumab and certolizumab. The frequency of these events is influence by time and total market exposure for each agent. Groupings of preferred terms were used to retrieve the following adverse events: acoustic neuritis (AN), central demyelination other (CDO), chronic inflammatory demyelinating polyneuropathy (CIDP), demy-

elination NOS (DN), Guillain-Barre (GB), multiple sclerosis (MS), optic neuritis (ON), and peripheral neuropathy (PN). The results were calculated as report proportions, i.e. number of cumulative AE reports divided by number of cumulative total reports and expressed as percentages.

Results: The following cumulative report proportions were calculated from data received in AERS between the time of initial marketing through December 2011 (values in %).

Neurologic Event Reported	Etan	Infl	Adal	Goli	Cert
Acoustic Neuritis	0.00	0.00	0.00	0.00	0.00
Central Demyelination Other	0.00	0.00	0.00	0.00	0.00
Chronic Inflammatory Demyelinating Polyneuropathy	0.01	0.02	0.00	0.00	0.00
Demyelination NOS	0.12	0.36	0.10	0.00	0.07
Guillain Barre	0.04	0.17	0.06	0.00	0.01
Multiple Sclerosis	0.18	0.15	0.15	0.35	0.02
Optic Neuritis	0.08	0.14	0.06	0.12	0.08
Peripheral Neuropathy	0.20	0.41	0.17	0.00	0.20
Presumed Central Toxicity[1]	0.38	0.65	0.32	0.47	0.16
Presumed Peripheral Toxicity[2]	0.25	0.60	0.23	0.00	0.21

1. AN + CDO + DN + MS + ON 2. CIDP + GB + PN
* All adverse events were coded using MedDRA; **NOS=Not Otherwise Specified.

Conclusion: From initial marketing in 1998 until December 31 2011 patients treated with different anti-TNF agents exhibited differing patterns of neurological injury. Compared to other anti-TNF agents, presumed central demyelination and conditions such as multiple sclerosis were less likely to be reported in patients receiving certolizumab. The peripheral nerve events, Guillain-Barre and peripheral neuropathy, were more likely to be reported in patients receiving infliximab, as were non-specific terms that referred only to demyelination (DN). Golimumab had no peripheral neurological events, but had disproportionately more multiple sclerosis. Although spontaneously reported data does not allow conclusions regarding causality, these results suggest that different anti-TNF agents may be associated with different rates of adverse neurological effects and with different sites of neurotoxicity within the nervous system.

Effect of Infliximab On Employment Status in Patients with Rheumatoid Arthritis or Ankylosing Spondylitis. W. Bensen[1], J. Carter Thorne[2], Saeed A. Shaikh[3], Maqbool K. Sheriff[4], Susan M. Otawa[5], Allen J. Lehman[6] and Hayssam Khalil[7]. [1]St. Joseph's Hospital and McMaster University, Hamilton, ON, [2]Southlake Regional Health Centre, Newmarket, ON, [3]McMaster University, St Catharines, ON, [4]Nanaimo Regional General Hospital, Nanaimo, BC, [5]Janssen Canada Inc, Mississauga, ON, [6]Janssen Inc, Toronto, ON, [7]Janssen Canada Inc, Toronto, ON

Background/Purpose: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are associated with significant functional impairment and work disability. In the absence of treatment, approximately 80% of RA patients will show evidence of joint abnormalities or disability, while 50% will have work disability after 10 years (1). Similarly, the prevalence of work disability in AS ranges from 13% to 45% based on the patient population (2–4). The purpose of this analysis was to evaluate the prevalence of unemployment due to work disability and determine the effect of treatment with infliximab (IFX) in patients with RA and AS in a real-world, Canadian, routine clinical practice setting

Methods: BioTRAC is an ongoing, prospective, registry of patients initiated on treatment with IFX or golimumab as first biologics or after having been treated with a biologic for less than six months. A total of 798 RA patients and 290 AS patients initiated IFX between 2002 and 2012 and were included in this analysis.

Results: Among the total number of RA and AS patients, 179 (22.4%) and 57 (19.7%), respectively, reported being unemployed due to their disability, while 335 (42.0%) and 77 (26.6%) were unemployed due to other reasons.

Table 1 shows the baseline patient characteristics by employment status. Patients reporting being unemployed due to disability had significantly higher disease severity. Furthermore, patients unemployed due to disability had RA

for a longer period, while disease duration was comparable in AS patients across employment statuses.

Table 1. Patient Characteristics at Baseline by Employment Status

Diagnosis RA	Parameter: Mean (SD) or n (%)	Unemployed due to Disability n=179	Unemployed due to Other Reasons n=335	Employed n=284	P-value
	Female	138 (78.4%)	266 (82.4%)	184 (66.7%)	<0.001
	Age: years	53.8 (10.0)	64.5 (13.5)	49.0 (10.9)	<0.001
	Disease duration: years	11.2 (10.0)	11.4 (10.4)	7.7 (8.0)	0.008
	HAQ-DI	1.9 (0.5)	1.8 (0.7)	1.3 (0.7)	<0.001
	SJC-28	12.0 (7.1)	11.6 (7.1)	9.2 (6.4)	<0.001
	TJC-28	15.4 (8.0)	13.3 (7.9)	10.3 (7.5)	<0.001
	PtGA: VAS mm	67.4 (20.0)	62.1 (23.1)	55.6 (25.6)	<0.001
	Pain: VAS mm	64.7 (20.7)	58.7 (23.2)	52.1 (25.2)	<0.001
	DAS28-ESR	6.3 (1.3)	6.0 (1.4)	5.3 (1.5)	<0.001
	DAS28-CRP	5.9 (1.2)	5.5 (1.2)	5.1 (1.4)	<0.001
AS		n=57	n=77	n=156	
	Female	23 (42.6%)	32 (44.4%)	51 (33.3%)	0.205
	Age: years	49.4 (9.1)	50.4 (15.7)	43.9 (10.0)	<0.001
	Disease duration: years	9.0 (8.7)	11.7 (12.3)	9.2 (9.5)	0.318
	HAQ-DI	1.5 (0.6)	1.3 (0.6)	1.1 (0.5)	<0.001
	BASDAI	7.2 (2.1)	6.6 (2.1)	6.1 (2.0)	0.002
	ASDAS	4.0 (0.9)	4.0 (0.9)	3.9 (1.1)	0.859

By 6 months on IFX treatment, clinically meaningful and statistically significant (P<0.05) improvements in all parameters studied were observed in all three employment status groups in both RA and AS patients. No significant between-group differences in the absolute change of these disease parameters were observed upon adjustment for baseline values with the exception of BASDAI and ASDAS which showed a greater improvement in employed AS patients. Among the RA and AS patients unemployed due to disability, 10.6% and 14.0%, respectively, returned to full-time or part-time employment post baseline, the majority of whom (63.0%) within 6 months of treatment. The mean (SD) time to employment for this patient subpopulation was 10.8 (13.6) months in RA patients and 12.1 (6.6) months in AS patients.

Conclusion: At IFX initiation, patients with work disability had more severe disease compared to patients unemployed due to other reasons or employed patients. Furthermore, RA patients had longer disease duration before being treated with IFX. However, treatment with IFX was equally effective in reducing disease severity and symptoms regardless of employment status and most importantly enabled a portion of patients to return to employment.

Are There Gender Specific Differences in Patient Characteristics At Initiation of Biologic Treatment in Rheumatoid Arthritis? William Bensen[1], Denis Choquette[2], Isabelle Fortin[3], Alice V. Klinkhoff[4], Susan M. Otawa[5] and Hayssam Khalil[6]. [1]St. Joseph's Hospital and McMaster University, Hamilton, ON, [2]University of Montreal, Notre-dame Hospital, Montreal, QC, [3]Centre de Rhumatologie de l'Est du Québec, Rimouski, QC, [4]The Mary Pack Arthritis Ctr, Vancouver, BC, [5]Janssen Canada Inc, Mississauga, ON, [6]Janssen Canada Inc, Toronto, ON

Background/Purpose: The prevalence of rheumatoid arthritis (RA) is 2–4 times higher in women compared to men depending on age. Furthermore, in women RA incidence increases from the age of menarche peaking around menopause, while it is rare in men under the age of 45 years (1). Several studies have shown that treatment outcomes are worse in women (2). This analysis examined gender-specific differences with respect to patient and disease parameters at initiation of the first anti-TNF agent for the treatment of RA in a Canadian routine clinical practice setting.

Methods: BioTRAC is an ongoing Canadian registry of RA, AS or PsA patients initiating treatment with infliximab (IFX) or golimumab (GOL) as first biologics or after having been treated with a biologic for less than six months. This analysis is based on 781 biologic naive RA patients initiating infliximab treatment between 2002 and 2012.

Results: Among the 781 patients, 593 (75.9%) were female and 188 (24.1%) were male. Mean age and disease duration at initiation of infliximab treatment were comparable between groups.

Overall patient characteristics differed significantly between genders (Table 1). Mean morning (AM) stiffness, HAQ-DI, pain, patient global assessment of disease activity (PtGA), CDAI, and RAPID 3 were statistically significantly higher in female patients. Furthermore, a higher proportion of women were rheumatoid factor (RF) positive and unemployed. However, physician assessment of global disease activity (MDGA), TJC, SJC, CRP, DAS28-CRP, and SDAI were comparable between genders.

Table 1. Patient Characteristics at Baseline by Gender

Parameter Mean (SD)	Male (n=188)	Female (n=593)	P-Value
Age: years	54.3 (13.1)	55.6 (13.7)	0.228
Disease duration: years	7.9 (8.2)	9.0 (9.7)	0.557
AM stiffness: min	63.8 (44.2)	72.9 (43.4)	0.012
HAQ-DI	1.4 (0.7)	1.7 (0.7)	<0.001
Pain: VAS cm	5.4 (2.5)	5.9 (2.3)	0.019
CRP: mg/L	21.5 (27.8)	18.2 (22.7)	0.142
SJC-28	10.2 (7.4)	11.1 (6.9)	0.058
TJC-28	12.3 (8.5)	13.0 (7.9)	0.245
MDGA: VAS cm	6.3 (2.3)	6.6 (2)	0.137
PtGA: VAS cm	5.6 (2.6)	6.2 (2.3)	0.012
DAS28-CRP	5.2 (1.4)	5.5 (1.3)	0.068
SDAI	36.4 (18.5)	39.3 (16.6)	0.056
CDAI	34.5 (17.5)	37.2 (15.8)	0.035
RAPID 3	15.6 (6.7)	17.7 (6.0)	<0.001
RF-positive: n (%)	112 (67.1%)	425 (76.6%)	0.028
Employed: n (%)	92 (49.2%)	184 (31.3)	<0.001

Conclusion: Objective measures (SJC, TJC, MDGA, CRP) were similar for male and female patients at infliximab initiation. However, patient reported outcomes (HAQ-DI, Pain and PtGA) were worse at baseline for female patients at initiation of biologic treatment in this Canadian rheumatoid arthritis population.

Comparison of Discontinuation Rates by Biologic Since 1998 in US Patients with Rheumatoid Arthritis. Sofia Ramiro[1], Frederick Wolfe[2], David J. Harrison[3], George Joseph[3], David H. Collier[3], Désirée van der Heijde[4], Robert Landewé[5] and Kaleb Michaud[6]. [1]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Amgen Inc., Thousand Oaks, CA, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Academic Medical Center, University of Amsterdam and Atrium Medical Center, Heerlen, Netherlands, [6]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Since discontinuation may be a surrogate for ineffectiveness, we measured rates and reasons for biologic discontinuation in a real-world setting.

Methods: From 1998 to 2011, all medication use was measured every 6 months via questionnaire in a US-wide longitudinal study of RA patients. We limited our analysis to patients with a baseline observation immediately before initiating their first (1st) or second different (2nd) biologic and at least one observation after initiation. Patients reported their primary reason for discontinuation. Time-on-drug survival analyses were conducted for individual biologics and groups and annual rates reported. Survival of anti-TNFs and non-anti-TNFs was compared, in crude and adjusted in propensity score analyses.

Results: A total of 2,340 RA patients initiated their 1st biologic; 1,148 (49%) discontinued and 1,128 initiated their 2nd; 567 (50%) discontinued. The vast majority initiated one of the following: etanercept (1st 44%, 28% 2nd), infliximab (1st 37%, 38% 2nd), and adalimumab (1st 13%, 19% 2nd). The annual discontinuation rate of all 1st biologics was 18% (95% CI 17–19%) and 2nd was 21% (19–23%). Annual discontinuation rates for 1st and 2nd by drug was 15% (14–16%) and 16% (14–19%) for etanercept; 19% (17–21%) and 18% (16–20%) for infliximab; and 20% (17–23%) and 26% (22–32%) for adalimumab. Anakinra had the highest annual rates, 1st 59% (44–78%) and 2nd 106% (74–151%). Patients who started a biologic after 2005 had higher annual discontinuation rates, 1st 25% (22–29%) and 2nd 31% (27–35%). Anti-TNF had lower annual discontinuation rates vs non-anti-TNF (1st); crude HR 0.48 (0.34–0.69) and after propensity score adjustment, HR of 0.60 (0.40–0.90). For 2nd line, a crude HR of 0.64 (0.48–0.84) and adjusted HR of 0.81 (0.59–1.11) (see Figures). Reporting a side effect had the highest discontinuation rate, 1st 63% and 2nd =81%, followed by reporting the drug was "not working", 1st 49% and 2nd 60%.
Conclusion: In this large cohort, RA patients tend to remain on their initial and second biologic for relatively long periods suggesting the drugs' effectiveness. Discontinuation rates were higher for non-anti-TNFs and in patients who initiated a biologic more recently when more treatment options were available. Contrary to recent findings, there was no statistically significant difference in discontinuation rates of anti-TNFs and non-anti TNFs as second biologic treatment.

496

Real-World Effectiveness of Infliximab in Improving Routine Assessment of Patient Index Data 3 Outcomes: The Canadian Experience.
Andrew Chow[1], Majed M. Khraishi[2], Jude F. Rodrigues[3], Susan M. Otawa[4] and Hayssam Khalil[5]. [1]Credit Valley Rheumatology, Mississauga, ON, [2]Memorial University of Newfoundland, St Johns, NF, [3]Windsor, ON, [4]Janssen Canada Inc, Mississauga, ON, [5]Janssen Canada Inc, Toronto, ON

Background/Purpose: The routine assessment of patient index data 3 (RAPID3) was recently designed as a pooled index of 3 patient-reported outcomes (PROs): physical function, pain and patient global estimate. Compared to other simplified disease activity scores RAPID3 may be more desirable in a clinical setting due to the shorter scoring time required. The study objective was to assess in a Canadian real-world setting the RAPID3 outcomes in rheumatoid arthritis (RA) patients treated with infliximab (IFX).

Methods: BioTRAC is an ongoing Canadian registry of RA, AS or PsA patients initiating treatment with IFX or golimumab (GOL) as first biologics or after having been treated with a biologic < 6 months. A total of 806 RA patients initiated IFX between 2002 and 2012 and were included in this analysis. RAPID3 was assessed both in continuous and categorical scales defining high activity (>12), moderate activity (6.1–12), low activity (3.1–6), and remission (≤3).

Results: Mean (SD) age of the patient cohort was 55.3 (13.5) yrs, and mean (SD) duration since diagnosis was 8.9 (9.3) yrs. Mean (SD) patient characteristics at baseline were: ESR = 32.5 (24.2) mm/hr; CRP = 19.0 (24.0) mg/L; SJC-28 = 10.8 (7.0); TJC-28 = 12.7 (8.0); HAQ-DI = 1.7 (0.7); DAS28-CRP = 5.4 (1.3); Pain-VAS= 5.8 (2.4); PGA-VAS = 6.6 (2.1); SGA-VAS = 6.1 (2.4) and CDAI = 36.4 (16.2). By 6 months of treatment, clinically meaningful and statistically significant (P<0.05) improvements were observed in all parameters which were sustained over 24 months. Similarly, the mean (SD) RAPID3 score significantly decreased from 17.3 (6.2) at baseline to 11.4 (6.9), 10.5 (7.0), and 9.3 (6.9) at 6, 12, and 24 months, respectively. Figure 1 shows the RAPID3 disease categories over time upon IFX treatment. The proportion of patients with high disease activity decreased from 80.6% at baseline to 34.2% at month 24. Furthermore, the proportion of patients with low activity or remission increased from 6.0% at baseline to 41.6% at month 24.
Figure 1. RAPID3 Disease Activity Categories Over Time

The positive correlation over time between DAS28-CRP and RAPID3 (rho=0.748; P<0.001) and between SDAI and RAPID3 (rho=0.743; P<0.001) further confirms the validity of the RAPID3 as disease activity score in real-life RA patients.
Figure 2. Correlation between RAPID3 and DAS28-CRP Over Time

Conclusion: The results of this Canadian real-world observational study demonstrate that, over 2 yrs of treatment, IFX is effective in reducing symptom severity and improving patient-reported outcomes in RA patients. Furthermore, the data from this registry confirmed the validity of the RAPID3 index as disease activity measure in a real-world RA cohort.

497

Golimumab Drug Utilization Patterns in Canada – Higher Retention Rate in Golimumab Treated Rheumatoid Arthritis Patients Compared to Etanercept and Adalimumab. Hayssam Khalil[1] and Amir Tahami[2]. [1]Janssen Canada Inc, Toronto, ON, [2]Janssen Canada Inc., Toronto, ON

Background/Purpose: Golimumab is a monthly self-injected anti-tumor necrosis factor alpha therapy for patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA). It was approved by Health Canada in April 2009 and this is the first Canadian report of golimumab's utilization in a real-world setting. The purpose of this project was to assess the utilization patterns of rheumatoid arthritis patients who received golimumab (GLM), etanercept (ETA) or adalimumab (ADA) in a large private drug plans database.

Methods: RA patients initiating therapy with GLM, ETA or ADA between January 1, 2009 and June 30, 2010 were selected from the IMS Brogan Canadian private drug plans database. Patients were included if they had ' 3 claims for GLM, ETA or ADA and were naïve to biologics prior to initiation of treatment. The 6-month period preceding the first GLM, ETA or ADA claim (index date) for each patient was used as a baseline to ensure that the patient were naïve to biologics. Patients were tracked for a maximum of 12 months after their index date to assess dosing patterns. The average dose in mg/week and the % of discontinuation (defined as the gap between 2 consecutive claims exceeding 60 days or switching to another drug) were evaluated.

Results: A total of 146, 1436 and 1171 RA patients receiving at least three prescriptions of GLM, ETA or ADA respectively were identified. Within the period of analysis, patients treated with ETA had a numerically higher discontinuation rate (44%) followed by ADA patients (41%) whereas patients treated with GLM had the lowest discontinuation rate (34%). The average dose of GLM, ETA or ADA were respectively 51.6 mg/month, 46.7 mg/week and 42 mg/q2weeks in accordance with their respective label in Canada for RA.
Figure 1. Treatment discontinuation rate within a period of 12 month following initiation (Bionaïve at initiation)

Conclusion: Results of these descriptive claims analyses show that in a real-world setting, the use of golimumab in RA patient's naïve to biologics is in accordance with the approved dose of 50 mg/month and that a numerically higher drug survival rate is observed for GLM (76%) compared to ETA and ADA 1 year after initiation of treatment. This is the first time that drug utilization patterns of GLM in comparison to ETA and ADA is reported in a real-world setting. Further research is needed to compare the relationship between drug utilization patterns on healthcare resource utilization and outcomes.

LIGHT (TNFSF14), Cathepsin-K, DKK-1 and Sclerostin in Rheumatoid Arthritis Patients: Effect of ANTI TNF-α Treatment in the WNT/β-Catenin Network Signaling. Alberto Cauli, Grazia Dessole, Giovanni Porru, Matteo Piga, Alessandra Vacca, Valentina Ibba, Pietro Garau and Alessandro Mathieu. University of Cagliari, Cagliari, Italy

Background/Purpose: We previously reported increased expression of cell membrane RANKL in PBMC of patients with active rheumathoid arthritis (RA) which was down-regulated by anti TNF-α treatment with adalimumab, while soluble RANKL and OPG were scarcely affected. We speculated that anti TNF-α induced down-regulation of membrane RANKL could be important in preventing articular damage in RA patients. Joint damage may also be mediated by the balance of other mediators involved in osteoclast functions such as LIGHT (TNFSF14) and cathepsin-K, while osteoblast functions are influenced by DKK-1 and sclerostin, although the data available is still contrasting and the significance under debate. The aim of this study was to investigate the impact of anti TNF-α treatment on the major soluble mediators involved in bone homeostasis in RA patients.

Methods: The effects of anti TNF-α therapy on bone homeostasis was studied in 15 active RA patients (DAS28 5.9 $\pm$ 0.9) and compared with 20 healthy controls (HC); data were collected at baseline, after 6, 12 and 24 weeks. Adalimumab 40 mg (ADA) was administered every other week according to guidelines, all patients experienced a satisfactory clinical response according to EULAR criteria. The serum levels of DKK-1, Sclerostin, Cathepsin-K were measured by enzyme-linked immunoassorbent assay (ELISA), all purchased from Biomedica (Vienna, Austria); LIGHT protein was detected with Quantikine ELISA (R&D System, Europe, UK). Values are presented as the median and interquartile range. Serum levels at different times after treatments were compared with those before therapy and HC. The significance of the results was analysed using the non parametric Mann-Whytney U-test or Wilcoxon, as appropriate, using Prism 5.0 software (GraphPadInc). P values less than 0.05 were considered significant.

Results: Cathepsin-K levels were found to be higher in active RA patients (12.7 IQR 11.3–15.3) compared to HC (9.1 IQR 45-14.3 pmol/mL, p=0.019) and after ADA at W6 (15.5 IQR 12.5–26.8 p=0.001), W12 (16.4 IQR 12.1–20.5 p=0.003), W24 (15.0 IQR 12.9–16, p=0.003). LIGHT levels were also consistently higher in the active RA group (96,6 IQR 65.3–179.2) compared with HC (66.0 IQR 42.6–112.0 pg/L, p=0.03) and after ADA, W6 (101.6 IQR 88.7–203.1 p=0.006), W12 (150.4 IQR 88.8–192.2 p=0.003) and W24 (138.9 IQR 66–228.5 p=0.015). Sclerostin levels were higher in the untreated RA group (31.5 IQR 26.3–48.7 pmol/L) compared to HC (24.5 IQR 18.7–29.6 p=0.007). It is noteworthy that long term adalimumab treatment induced a significant reduction in sclerostin levels at W24 (19.50 IQR 14.6–29.9 p=0.002); conversely, no significant differences in DKK-1 levels were observed in active RA (21.1 IQR 7.9–57pmol/L) compared to HC (19.0 IQR 11–27) and following ADA, W6 (19.5 IQR 6.7–59.5), W12 (20.1 IQR 9.2–57.5), W24 (11.1 IQR 5.2–54.6).

Conclusion: The decreased levels of sclerostin following anti TNF-α treatment may reduce the inhibition of the WNT/β-catenin pathway leading to increased osteoblast activity which may balance the increased osteoclast function in RA patients (as mirrored by the persistent increase in cathepsin-K and LIGHT) and therefore contributing to the inhibition of joint damage seen in patients treated with anti-TNF-α drugs.

What Is the Right Dose to Start Methotrexate (7.5 or 15mg) in Rheumatoid Arthritis? (A Randomized Controlled Trial). Varun Dhir, Mandeep Singla, Palvi Goyal, Vinay Sagar, Aman Sharma and Shefali K. Sharma. Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background/Purpose: Recent recommendations have suggested higher starting doses of methotrexate, i.e. 15 mg/week (3E initiative) in rheumatoid arthritis. However, studies comparing conventional (7.5mg) and newer (15mg) starting dose are limited. Unclear if any difference in control of disease activity or adverse effects with these starting doses.

Methods: This randomized controlled trial included 100 rheumatoid arthritis patients (fulfilling 1987 ACR), having active disease ('Disease activity score 28 joints 3 variables' DAS28-3v≥5.1) and not on methotrexate[3] 3 months. Using random number tables, patients were allocated (concealed by envelopes) to two groups—starting methotrexate at 7.5mg or 15 mg/week. Methotrexate escalated by 2.5 mg every 2 weeks; similar folic acid dose (10 mg/week). Patients assessed 4 weekly (blinded assessor) for disease activity (DAS28-3v). In addition, minor adverse effects (symptoms like nausea etc) determined using a performa and major adverse effects determined using blood tests (cytopenias- WBC<4000, Platelet<1lac or transaminitis- ALT or AST>80) or CXR (PA) if required. Analysis by intention to treat; difference in disease activity, adverse effects compared using students t and chi-square test respectively (or Fishers exact). (Trial Reg# NCT01404429)

Results: Patients in the two groups—7.5 mg and 15 mg had similar age (44.5±10.3, 42.8±11.2 yrs, p=0.4), gender (F:M=36:11, 42:11, p=0.4),

disease duration (4.8±4.8, 4.7±4.5 yrs, 0.9), disease activity (DAS28-3v=6.2±0.7, 6.2±0.8, p=0.9) and HAQ (1.3,1.3,p=0.9). In the 7.5 and 15 mg groups, 38 and 46 patients completed study, reaching final methotrexate dose of 19.3±1.8 mg and 24.3±2.0 mg per week respectively. Significant reduction in disease activity in both groups at 12 weeks (p<0.001), however, there was no intergroup difference at 4, 8 or 12 weeks (Figure 1), nor in HAQ at 12 weeks (1.1,0.9,p=0.4). No difference in 7.5 and 15mg groups in episodes of cytopenias (1,2, p=0.9) or transaminitis (6,7, p=0.8) or pneumonitis (0,0). However, minor adverse effects lower in 7.5mg compared to 15mg group (Relative Risk=0.58, 95% CI:0.36–0.95). Common were nausea (more in 15mg), loss of appetite, fatigue and uneasiness (Table 1).

Table 1. Frequency of minor adverse effects (symptoms) in the two groups

Minor adverse effect (Symptom)	7.5 mg group	15 mg group	P value	Relative Risk 7.5 versus 15 mg (95% confidence intervals)
Any	31.9	54.7	0.02*	0.58 (0.36–0.95)
Nausea	19.2	39.6	0.02*	0.48(0.25, 0.94)
Fatigue	6.4	13.2	0.43	0.48(0.13, 1.76)
Loss of appetite	12.8	11.3	0.80	1.13(0.39, 3.26)
Diarrhea	0.0	5.7	0.29	0.18 (0.01, 3.62)
Uneasiness or dizziness	17.0	13.2	0.59	1.29 (0.51, 3.28)

*statistically significant

Time →	0 weeks	4weeks	8 weeks	12 weeks
DAS28-3 7.5 mg	6.22	6.00	5.88	5.75
15 mg	6.16	6.05	5.83	5.61
Figure 1. Disease activity in the two groups at 4 weekly visits.

Conclusion: Starting treatment with either 7.5 mg or 15 mg per week of methotrexate followed by similar fast escalation (5mg/month) is equivalent in control of disease activity at 12 weeks. Although, no difference in transaminitis or cytopenia, higher minor adverse effects, especially nausea in 15mg group.

Comparison of Tolerability Between Tumor Necrosis Factor-Inhibitors and Tocilizumab for the Treatment of Rheumatoid Arthritis. Yoshihiro Hishitani, Yoshihito Shima, Toru Hirano, Keisuke Hagihara, Kosuke Ebina, Yasuo Kunugiza, Kenrin Shi, Masashi Narazaki, Atsushi Ogata, Tetsuya Tomita, Toshio Tanaka and Atsushi Kumanogoh. Osaka University Graduate School of Medicine, Suita, Japan

Background/Purpose: Some patients with rheumatoid arthritis (RA) receiving tumor necrosis factor-inhibitors (TNF-Is) show inadequate response to TNF-Is. But it has not been clarified what is better as the second biological agents by clinical trials, so observational study is necessary. We conducted a retrospective cohort study, especially focused on the difference of the drug retention rates between bio-naïve patients and switching patients.

Methods: We retrospectively reviewed the medical records of patients with RA, who were administered biologics (tocilizumab (TCZ) or TNF-Is

(infliximab, etanercept, adalimumab, and golimumab)) in our institute from September 1999 to April 2012, and analyzed the retention rates and causes of the discontinuation of the biologics. Kaplan-Meier estimate and log-rank test were used to analyze the differences of the drug continuation rates between bio-naïve patients and switching patients.

Results: TCZ was administered to 97 bio-naïve patients and 53 switching patients. TNF-Is were administered to 318 bio-naïve patients and 89 switching patients. Median (range) administration duration of TCZ was 2.54 years (0.08–12.6) for bio-naïve patients and 1.78 years (0.08–3.87) for switching patients, respectively. And that of TNF-Is was 1.87 years (0–11.3) for bio-naïve patients and 0.94 years (0–5.95) for switching patients, respectively. Kaplan-Meier Curves of the time to discontinuation due to unfavorable causes were shown (Figure 1, 2). Regarding TCZ, there was no significant difference of the drug retention rates between bio-naïve patients and switching patients (p = 0.9561), while regarding TNF-Is, there was a significant difference (p = 0.0037). To clarify the reason for this difference between TCZ and TNF-Is, we conducted Kapran-Meier estimate for cause-specific rates of discontinuation. About TCZ, the cumulative occurrence of discontinuation due to lack or loss of efficacy and adverse events were not statistically different between bio-naïve patients and switching patients (p = 0.1376, p = 0.3683, respectively). But about TNF-Is, discontinuation due to lack or loss of efficacy was significantly more in switching patients than in bio-naïve patients (p < 0.0001), while cumulative discontinuation due to adverse events was not statistically different (p=0.8334).
Figure 1. Tocilizumab. Bio-naïve vs Switching.
Figure 2. TNF-i. Bio-naïve versus Switching.

Conclusion: TCZ showed high tolerability in both bio-naïve patients and switching patients, while TNF-Is showed significantly lower tolerability in switching patients than in bio-naïve patients. This high retention rate of TCZ for switching patients was considered to be due to durability of its efficacy.

TNF Inhibitor Treatment in Rheumatoid Arthritis (RA) Patients with Moderate Versus High Disease Activity At Baseline: A Comparison of Utility Gains, Response and Remission Rates. Elisabeth Lie, Siri Lillegraven, Karen M. Fagerli, Till Uhlig and Tore K. Kvien. Diakonhjemmet Hospital, Oslo, Norway

Background/Purpose: Randomized clinical trials in RA have until recently focused on patients (pts) with high disease activity, but the majority of pts in the clinic have moderate disease activity. A specified threshold of disease activity for institution of TNF inhibitors (TNFi) has not been mandatory in Norwegian health care, thus pts with low or moderate disease activity have gained access to these therapies. Our objective was to assess what proportion of pts starting TNFi therapy had moderate disease activity at baseline, and to compare the outcomes in these pts to those with high disease activity.

Methods: Data for this study were provided by NOR-DMARD – a Norwegian multicentre, longitudinal observational study of consecutive pts with arthritides starting new DMARD regimens. The current analyses included biologics naïve pts with moderate (DAS28 3.2–5.1) or high (DAS28 >5.1) baseline disease activity who started treatment with TNFi + methotrexate (MTX). Baseline characteristics, utility gains (SF-6D and EQ-5D), ACR responses as well as remission rates at 3 and 6 months were compared by Chi^2 test, two-samples t test and Mann-Whitney U test as appropriate. 2-yr drug survival was compared by Kaplan-Meier analysis with log-rank test.

Results: The study included 296 pts with moderate (DAS28 3.2–5.1) and 347 pts with high (DAS28 >5.1) disease activity. 73 pts with DAS28 ≤3.2 at baseline were excluded. Mean(SD) DAS28 were 4.30(0.49) vs. 6.18(0.76), respectively. Overall, 73% were female, mean/median disease duration was 9.2/5.4 years, 75% were rheumatoid factor positive and 30% current smokers (no significant differences between the groups). The pts with moderate disease activity were significantly younger (mean 52 vs. 54 years, p=0.03) and had better baseline scores for 28-SJC, 28-TJC, patient and physician global, CRP, ESR, pain VAS and fatigue VAS (all p<0.001). Further, mean(SD) MHAQ scores were 0.57(0.41) vs. 0.97(0.52), SF-6D 0.62(0.11) vs. 0.54(0.11), and EQ-5D 0.56(0.28) vs. 0.32(0.31) in the moderate vs. high disease activity group (all p<0.001). Three- and 6-month utility gains were significantly larger in the high disease activity group while there were no statistically significant differences in ACR responses (table). As expected, remission rates were significantly higher in the moderate disease activity group (table). 2-yr drug survival was similar in the 2 groups (estimated 57% vs. 56%, p=0.42) and reasons for discontinuation were also similar.

	3 months			6 months		
	Moderate	High	*P*	Moderate	High	*P*
ΔEQ-5D [mean (SD)]	0.10 (0.29)	0.27 (0.33)	<0.001	0.09 (0.26)	0.31 (0.34)	<0.001
ΔSF-6D [mean (SD)]	0.07 (0.12)	0.10 (0.12)	0.005	0.07 (0.13)	0.11 (0.13)	0.006
ACR20 response	47.9%	54.4%	0.14	56.7%	64.4%	0.10
ACR50 response	26.1%	25.1%	0.80	33.8%	38.0%	0.36
ACR70 response	14.3%	13.8%	0.87	19.4%	23.6%	0.28
ACR/EULAR remission (Boolean)	9.1%	3.9%	0.013	12.0%	6.7%	0.049
SDAI remission (SDAI ≤3.3)	15.8%	5.0%	<0.001	21.0%	10.5%	0.003
DAS28 remission (DAS28 <2.6)	32.3%	12.7%	<0.001	42.6%	18.3%	<0.001

Conclusion: Of biologics naïve pts starting TNFi + MTX, 52% had a baseline DAS28 <5.1. Pts with moderate disease activity when starting their first TNFi achieved higher remission rates but lower utility gains than pts with high disease activity, while ACR responses and drug survival were similar. Such comparisons can provide information for cost-effectiveness analyses which are increasingly important and necessary to guide decision making in this field.

Safety and Efficacy of Rituximab in Patients with Rheumatoid Arthritis and Lung Involvement. Elena Becerra, Geraldine Cambridge and Maria J. Leandro. University College London, London, United Kingdom

Background/Purpose: Lung involvement is common in patients with Rheumatoid Arthritis (RA), including interstitial lung disease (ILD), pleural disease and small airway disease. There are no full reports in the literature analyzing the influence of Rituximab (RTX) in patients with RA with pre-existing lung disease, although it is a rising question in daily clinical practice. We aim to evaluate the safety and efficacy of RTX in our cohort of RA patients with pre-existing lung involvement.

Methods: Retrospective observational study of the RA cohort treated with RTX at University College Hospital, identifying patients treated with RTX with any lung involvement. Data were collected on type of lung disease, mortality, respiratory infections and stabilization/progression of symptoms.

Results: 264 patients with RA have received RTX in our unit between 1998 and 2012. A total of 38 patients (14%) had lung involvement, 24 of them (63%) were female, mean age was 64 years (range 37–79), mean disease duration was 19 years (range 3–42), mean number of RTX cycles was 4 (range 1–10), total follow up duration was 146.7 patient years (median 2.5 years, range 0.5–13.5). 19 of them (50%) had ILD: 3 usual interstitial pneumonitis (UIP), 5 nonspecific interstitial pneumonitis (NSIP, 2 of those had an overlap antisyntetase syndrome), 4 organizing pneumonia (OP) and 7 undetermined ILD. 15 patients (40%) had bronchiectasis. The remaining 4 patients had diagnosis of chronic obstructive pulmonary disease (COPD), small airway disease, pleural effusion requiring decortication and pleural plaques. 6 of the above patients had concomitant COPD.

Lung disease has remained clinically and radiologically stable in most patients. One patient with severe UIP before RTX showed slow lung progression over 4 years of follow up, and Mycophenolate mofetil is being considered. The 2 patients with antisynthetase syndrome have stable NSIP but on combination therapy (1 azathioprine, 1 mycophenolate mofetil). 25 patients (66%) reported respiratory infections but in only 6 of these patients was an increased frequency of infections after starting rituximab treatment noted. 2 of these 6 patients had low serum immunoglobulins (1 IgG only, 1 IgG and IgM). 2 patients had serious infections requiring hospitalization.

There were 2 deaths, both in patients with bronchiectasis and multiple comorbidities, none directly related to rituximab treatment.

Conclusion: RTX seems to be a relatively safe therapy in the cohort of RA patients with lung involvement. There is no definite evidence for improvement in lung involvement in RA patients treated with rituximab, but nor there is data suggesting that RTX can lead to a progression of lung symptoms. Only one patient with severe UIP before RTX showed lung progression after 4 years of follow up.

Safety Update On Certolizumab Pegol in Patients with Active Rheumatoid Arthritis with Long Term Exposure. Xavier Mariette[1], RF. van Vollenhoven[2], Vivian P. Bykerk[3], Marc de Longueville[4], Catherine Arendt[4], Kristel Luijtens[5] and John J. Cush[6]. [1]Université Paris-Sud, Le Kremlin Bicetre, France, [2]The Karolinska Institute, Stockholm, Sweden, [3]Hospital for Special Surgery, New York, NY, [4]UCB Pharma, Brussels, Belgium, [5]UCB, Brussels, Belgium, [6]Baylor Research Institute, Dallas, TX

Background/Purpose: The safety of certolizumab pegol (CZP) in rheumatoid arthritis (RA) has been reported in previous pooled analyses of clinical trials. An update of long-term safety data of CZP in RA with a cut-off date of 30 Nov 2011 is provided.

Methods: The pooled analysis included 10 completed randomized controlled trials (RCTs) of CZP in RA and their open-label extensions (OLEs). Pooling was done across all doses. Some patients (pts) received CZP 400 mg Q2W (twice the registered dose) as per protocol. Adverse events were defined as those occurring after first dose and within a maximum of 84 days of last dose. Serious adverse events (SAEs) were defined conservatively by the regulatory definition[1] with the addition of opportunistic infections (OIs), malignancies and medical events important to the investigator. Serious infectious events (SIEs) were defined according to the regulatory definition with addition of the need for IV antibiotics. Search terms for OIs were defined by 6 external experts and validated by the steering committee (JC, VB, RVV and XM). All cases of death, SIEs (including OIs) and malignancies were manually reviewed by external experts, classified according to pre-defined standard procedures and validated by the study authors. Deaths were categorized as primarily associated with cardiovascular (CV), infectious, malignant or other causes; malignancies were classified as non-melanoma skin cancer (NMSC), solid tumors or lymphoma. Incidence rates (IR) and event rates (ER) per 100 pt-years (PY) are presented.

Results: By 30 Nov 2011, 4049 RA pts had received CZP in all studies (RCTs and OLEs) for a total of 9277 PY. Mean exposure to CZP in all studies was 2.1 yrs (Y) (min 0.04, max 7.6); median exposure was 0.7 Y. SIEs were the most common SAEs. In total, 43 tuberculosis (TB) infections occurred in 43 pts, of which 39 occurred in Central and Eastern Europe (CEE). 58 deaths occurred in CZP pts (IR: 0.63/100 PY) as a result of 19 CV events, 13 infections, 13 malignancies and 18 other causes. 65 CZP pts in all studies developed malignancies (ER: 0.72/100 PY), with 60 pts developing solid tumors (ER: 0.67/100 PY) and 5 developing lymphoma (0.05/100 PY).

| | RCTs | | | | | | | | All studies (RCTs and OLEs) | | | |
	PBO N=1137				All CZP doses N=2965				All CZP doses N=4049			
Total exposure (PY)	373				1302				9277

All malignancies excluding NMSC	0.81	1.34	3	0.3	0.69	0.77	9	0.3	0.70	0.72	65	1.5
OIs*	0	0	0	0	1.0	1.08	13	0.4	0.67	0.69	62	1.5

* Treatment-emergent adverse events of oesophageal candidiasis were included as OIs

ADDIN EN.REFLIST

Conclusion: No new safety signals associated with CZP have emerged in this updated long-term safety analysis. While SIE rates were higher for CZP than for PBO in the RCTs, they did not increase with continued exposure to CZP. Due to the shorter duration of PBO treatment compared with CZP, comparisons between the CZP and PBO groups should be interpreted cautiously. TB incidence may be explained by high recruitment in CEE prior to 2007. The rates of malignancies and serious infections are in line with CZP data reported in the product label and anti-TNF registry data.[2,3]

ACR Poster Session A
Sjögren's Syndrome - Pathogenesis
Sunday, November 11, 2012, 9:00 AM–6:00 PM

504

Pathogenic Autoantibodies to the Anti-Muscarinic Type 3 Receptor Act by Competitive Inhibition of Acetylcholine-Mediated Receptor Signalling in Sjögren's Syndrome. Michael W. Jackson[1], Isabell Bastian[2] and Thomas P. Gordon[3]. [1]Flinders University, Adelaide, Australia, [2]Flinders University and Flinders Medical Centre, Adelaide, Australia, [3]Flinders Medical Centre, Bedford Park, Australia

Background/Purpose: Primary Sjögren's syndrome (SS) is a systemic autoimmune disorder characterized by exocrine failure and widespread autonomic dysfunction. Functional autoantibodies (Abs) directed against the muscarinic type 3 receptor (M3R) have been postulated to underpin gastrointestinal, bladder and cardiac dysfunction in SS, and we have recently demonstrated that SS IgG acts specifically at the M3R to disrupt cholinergic neurotransmission and motility in murine gastrointestinal tissues.To date, the mechanism by which anti-M3R Abs exert an effect on receptor signalling has remained difficult to determine, due to a lack of suitable functional assays. In the current study, we use a novel, real-time cell bioassay of M3R signalling to explore the physiological mechanism by which anti-M3R Abs inhibit M3R activity.

Methods: HEK293 cells (2×10^5) were transiently transfected in 96 well culture plates for 24 hours with DNA encoding the human M3R, and with the pGL4.33 vector (Promega) containing a luciferase gene driven by the serum response element promoter. Cells were then incubated for 4 hours in the presence of the cholinergic agonist, carbachol, (0.3 to 300 μM) and patient IgG (4 mg/ml) characterised as positive (M3R+; n = 4) or negative (M3R-; n = 2) for inhibitory anti-M3R activity, as determined by in vitro bladder strip assays. IgG from healthy donors (n = 6) was used as controls. Luciferase gene activity was determined on a DTX 880 MultiMode Detector (Beckman Coulter).

Results: All M3R+ IgGs, but not control or M3R- IgG, significantly inhibited carbachol-induced luciferase activity at carbachol concentrations ranging from 0.3 to 30 μM, with a maximum inhibition of approximately 40%. In contrast, inhibition of luciferase activity by anti-M3R Abs was lost at carbachol concentrations of 100 and 300 μM, consistent with competitive antagonist activity by the Abs at the carbachol-binding site. Anti-M3R Abs had no effect on luciferase activity in M3R-expressing cells in the absence of carbachol.

Conclusion: We have used a real-time cell-based bioassay incorporating a luciferase reporter to characterise inhibitory anti-M3R antibodies in IgG from patients with SS. The bioassay allows a functional measure of receptor signalling activity, thereby facilitating investigation of the mechanism by which patient Abs alter M3R activity. We found that Ab inhibition of carbachol-mediated M3R activity was reversible at high agonist concentrations, consistent with competitive displacement of agonist at the carbachol-binding site. These findings contrast previous studies suggesting non-competitive interactions between anti-M3R Abs and receptor agonists, and confirm the carbachol binding site as the target of the functional anti-M3R Abs in SS. The ability of the assay to detect anti-M3R Abs compare favourably with whole-tissue in vitro assays, thereby combining the sensitivity of ex-vivo tissues with the convenience of a 96-well assay format. The bioassay should facilitate both detailed pharmacological characterization of the mechanism of antibody action at the M3R, and the studies required to establish the role of anti-M3R antibodies in the autonomic dysfunction associated with SS.

Characterization of an in Vitro Model of Human Salivary Gland for Studying Sjögren Syndrome (SS).

M. Jesus Dominguez-Luis[1], M.Teresa Arce-Franco[1], Estefania Armas-Gonzalez[1], Ada Herrera-Garcia[1], Teresa Giraldez[2], Pablo Miranda[2], Diego Alvarez de la Rosa[3], Jose Garcia-Verdugo[4], Carlos Martinez-Jimeno[5] and Federico Diaz-Gonzalez[1]. [1]Rheumatology Service. Hospital Universitario de Canarias., La Laguna, Spain, [2]Unidad de Investigación of Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain, [3]Department of Physiology. Universidad de La Laguna,, La Laguna, Spain, [4]Cellular Morphology Laboratory, Centro de Investigación Príncipe Felipe., Valencia, Spain, [5]Maxilofacial Department, Hospital Universitario de Canarias,, La Laguna, Spain

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune exocrinopathy of unknown etiology that is characterized by decreased salivary secretion (xerostomy) and lacrimal (xerophthalmy). Histopathological lesions of the glandular tissue in SS are characterized by the presence of mononuclear cell infiltrates and acinar atrophy. Studies on the pattern of inflammatory mediators have shown high amounts of IL-2, IFN-γ, IL-10, IL-1β, IL-6, SDF-1α and TNF-α. However, little is known about the implication of this cytokine profile in de SS pathogenesis.

Objectives: 1) to establish and characterize a model of human salivary gland in vitro, and 2) analyze if this model the functional effect of proinflammatory mediators present in the glandular microenvironment of SS patients.

Methods: human epithelial cells from biopsies of non-cancerous parotid gland, were enzymatically dispersed, cultured and expanded in medium MCDB153 supplemented with insulin, hydrocortisone and epidermal growth factor. Proliferation assays were performed using a cell proliferation kit. The expression of amylase, VAMP-2, SMA1 and epithelial sodium channels (ENaC), were studied by immunofluorescence in confocal microscopy. The gene expression of the mineralocorticoid receptor, sodium channels (α, β, γ) and a number of genes characteristic of ducts or acini were analyzed by real-time RT-PCR. For the functional study of sodium channels in the plasma membrane were determined by patch clamp assays. Amylase activity in cell-free supernatant was assayed by a fibril-degradation assay and was used as a surrogate marker of exocrine gland function.

Results: Cells from human salivary gland had morphology of epithelial cells and were able to proliferate in culture. The pattern of gene expression of these cells was more compatible with an acinar rather than ductal origin. Furthermore, the functionality of epithelial sodium channel in their surface was analyzed by patch clamp experiments. The presence of 10μM isoproterenol and 2 mM Ca^{++} for 24 hours increased three times the basal activity of amylase in the cell-free supernatant of these cells. Moreover, the presence of TNF-α and SDF-1α caused a significant dose-response reduction in the amylase activity in the cell-free supernatant.

Conclusion: It is possible to set up a functional model of human salivary gland in vitro that allows the development of studies which could lead to better understanding of the pathogenesis of SS and may help to develop therapeutic interventions for this disease.

Ebv-Mir-Bart13 Affects the Expression of AQP5 in Human Salivary Gland Cell Lines Contributing to the Pathogenesis of Sjögren's Syndrome.

Alessia Gallo[1], Mayank Tandon[1], Shyh-Ing Jang[1], Hwei Ling Ong[1], Indu Ambudkar[1], Gabor G. Illei[2] and Ilias Alevizos[3]. [1]NIDCR, Bethesda, MD, [2]NIDCR/ NIH, Bethesda, MD, [3]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: Loss of secretory function of salivary glands is one of the most important functional effects of Sjögren's syndrome (SS), a chronic systemic autoimmune disease. We have previously shown that an EBV microRNA (ebv-miR-BART13) is significantly over-expressed in minor salivary gland biopsies of SS patients, when compared to the healthy volunteers. We have also shown that the over-expression of ebv-miR-BART13 in human salivary gland cell line is responsible of the down regulation of STIM1, an ER-Ca2+ sensor protein regulating SOCE and to the consequent decrease in Calcium influx. We demonstrated that the decrease of Calcium influx, due to the presence of ebv-miR-BART13, is responsible of the loss of translocation of NFAT, a transcriptional factor that drives the transcription of several genes, but most interestingly AQP5. The objective of this work is to establish if ebv-miR-BART13 leads to the decreased level of AQP5 not only trough the Calcium-NFAT pathway but also by directly binding the 3'UTR of the AQP5 mRNA.

Methods: We checked the AQP5 messenger lever by Real-time PCR in a primary salivary epithelial cells line. To investigate if the viral microRNA is able to bind the 3'UTR the AQP5 messenger we transfected HSG cells and a primary salivary epithelial cells line derived by human minor salivary gland biopsy with a luciferase plasmid containing the AQP5 3'UTR fused with the luciferase firefly coding sequence and ebv-mir-BART13.

Results: We first checked if the mRNA level of the endogenous AQP5 is affected by the presence of ebv-miR-BART13. For this, we used as system primary salivary epithelial cells because they maintain their acinar phenotype thus expressing AQP5 mRNA level, compared to established salivary cell lines such as HSG cells. After 48 hour of transfection with ebv-miR-BART13, the AQP5 mRNA was decreased (4 fold change) by the presence of this viral miRNA.

In order to examine if ebv-miR-BART13 also exerts its effect by binding directly the AQP5 mRNA, we used a plasmid containing the AQP5 3'UTR sequence fused with the luciferase firefly sequence. The luciferase plasmid was co-transfected with ebv-miR-BART13 analogues and antagonists in both HSG cells (human submandibular salivary gland cells) and primary salivary epithelial cells line derived from human minor salivary gland biopsies. After 48 hour of transfection, the cells were collected, proteins were extracted and the luciferase activity was measured. Luciferase expression decreased by 30 % in HSG cells and by 40 % in the primary cell line, confirming that ebv-miR-BART13 directly targets the 3'UTR of AQP5 mRNA.

Conclusion: We first checked if the mRNA level of the endogenous AQP5 is affected by the presence of ebv-miR-BART13. For this, we used as system primary salivary epithelial cells because they maintain their acinar phenotype thus expressing AQP5 mRNA level, compared to established salivary cell lines such as HSG cells. After 48 hour of transfection with ebv-miR-BART13, the AQP5 mRNA was decreased (4 fold change) by the presence of this viral miRNA.

Expression of Micrornas (miRNAs) Predicted to Target Ro/SSA and La/SSB Autoantigens in Sjögren's Syndrome (SS).

Vasiliki C. Gourzi[1], Efstathia K. Kapsogeorgou[1], Nikolaos C. Kyriakidis[1], Menelaos N. Manoussakis[1], Haralampos M. Moutsopoulos[2] and Athanasios G. Tzioufas[3]. [1]School of Medicine, National University of Athens, Greece, Athens, Greece, [2]School of Medicine, University of Athens, Athens, Greece, [3]School of Medicine, National University of Athens, Athens, Greece

Background/Purpose: microRNAs (miRNAs) are key post-transcriptional regulators of gene expression and might be implicated in the over-expression of Ro/SSA and La/SSB autoantigens in the salivary gland (SG) tissues and epithelial cells (SGEC) of SS patients. We have previously identified 11 miRNAs (let-7b, miR-16, miR-129-5p, miR-153, miR-181a, miR-200b, miR-200b*, miR-223, miR-483-5p, miR-573, miR-583) that are predicted to target the Ro/SSA (TRIM21 or TROVE2) and La/SSB mRNAs. Herein, we sought to investigate the expression of these miRNAs in SS. Therefore, we studied their expression in SG-tissues, SGECs and peripheral blood mononuclear cells (PBMC) of SS patients and sicca-complaining non-SS controls (CT), as well as their association with the expression of target mRNAs.

Methods: miRNAs and mRNAs expression of Ro52/TRIM21, Ro60/TROVE2 and La/SSB were investigated by real-time PCR in total RNA from SG-tissues, SGECs and PBMCs obtained from 27 SS patients and 22 sicca-CT. Significant differences between SS patients and CT and associations between miRNAs and mRNAs expression were evaluated by non-parametric Mann-Whitney and Spearman's rank correlation tests, respectively.

Results: From the 11 microRNAs studied, miRs 129-5p, 153, 573 and 583 were not expressed in any of the samples studied, whereas miR-200b* was not detected in PBMCs. All others miRNAs were found to be expressed in all samples tested. Differential miRNA expression between SS and controls involved miR-16 and miR-223 in SG tissues, miR-200b in SGECs and miR-223 in PBMCs (mean±SE: 12.71±5.26 vs 2.47±0.67, p=0.05, 8671±2430 vs 3519±777, p=0.008, 2353±367 vs 1116±196.5, p=0.02 and 447200±224400 vs 50470±9577, p=0.01 in SS vs CT, respectively; Mann-

Whitney analysis). miR-16 and miR-200b levels were positively associated with Ro52/TRIM21 mRNA expression (r=−0.5858, p=0.003, r=−0.4930, p=0.02 respectively) and miR-16 negatively associated with Ro60/TROVE2 mRNA expression (r=−0.4270, p=0.04) in SG-tissues. In SGECs, miR-181a expression was negatively associated with Ro52/TRIM21, whereas miR-200b with Ro60/TROVE2 mRNA expression (r=−0.3071, p=0.04, r=−0.3292, p=0.03 respectively; Spearman's test). In addition, miR-200b* levels were positively associated with Ro52/TRIM21, Ro60/TROVE2 and La/SSB mRNA expression (r=0.3366, p=0.03, r=0.3580, p=0.02, r=0.4398, p=0.003 respectively). In PBMCs, miR-16 and miR-483-5p levels were found to positively correlate with Ro52/TRIM21 mRNA expression (r=−0.3202, p=0.05, r=−0.4698, p=0.003 respectively).

Conclusion: Our findings indicate that miR-16, miR-200b and miR-223 are deregulated in SS. Attention should be noted to the role of miR-200b in the regulation of Ro/SSA and La/SSB mRNAs. Further functional studies are now undertaken to enlighten the role of the deregulated miRNAs in disease pathogenesis and autoantigen expression.

TLR3-Signaling Induces the Expression of Ro/SSA and La/SSB Autoantigens in Salivary Gland Epithelial Cells (SGECs). Nikolaos C. Kyriakidis[1], Efstathia K. Kapsogeorgou[1], Vasiliki C. Gourzi[1], Haralampos M. Moutsopoulos[2] and Athanasios G. Tzioufas[3]. [1]School of Medicine, National University of Athens, Greece, Athens, Greece, [2]School of Medicine, University of Athens, Athens, Greece, [3]School of Medicine, National University of Athens, Athens, Greece

Background/Purpose: Previous studies have shown that the mRNA expression levels of the Ro52/TRIM21, Ro60/TROVE2 and La/SSB intracellular autoantigens are elevated within the immunopathologic lesions of SS. High surface constitutive expression of TLR-3 has been described in long-term cultured SGECs, whereas stimulation of TLR-3 via synthetic analogues or viral RNA has been shown to be potent inducer of several immune-modulatory molecules, interferons and other cytokines, as well as apoptosis, in SGEC. Given that TLR3-mediated inflammatory responses have been shown to be negatively regulated by Ro52/TRIM21 autoantigen we sought to investigate whether TLR3 stimulation has a reciprocal effect in Ro52/TRIM21, as well as Ro60/TROVE2 and La/SSB mRNA, expression by SGECs.

Methods: SGEC lines from SS patients (n=5) and non-SS controls (n=10), were treated with the analogue of the TLR3 ligand polyinosinic:cytidylic acid (polyI:C; 5 μg/ml) and the TLR4-ligand lipopolysaccharide (LPS, 1 μg/ml, control TLR treatment) for various time-points. The expression of Ro52/TRIM21, Ro60/TROVE2 and La/SSB mRNAs was analyzed by real-time PCR at 0, 6, 12, 24, 48 and 72 hrs of treatment. The results were normalized by the expression of the HPRT1 gene and calculated by the ΔΔCT method using HeLa as calibrator. The expression of Ro52, Ro60 and La/SSB proteins was analyzed by immunoblotting, using specific antibodies. Mann-Whitney test was employed to analyze statistical significances.

Results: SGECs obtained from SS patients and controls were found to respond similarly to TLR3 signaling. The basal (constitutive) La/SSB and Ro60/TROVE2 mRNA levels were significantly upregulated following treatment of SGECs with polyI:C for 48-hrs (mean fold induction±SE: 0.86±0.18, p=0.003 and 3.29±1.75, respectively; p<0.0001 each). PolyI:C was found to be a strong inducer of Ro52/TRIM21 mRNA expression by SGECs at 6-hrs of treatment (mean fold induction of basal expression±SE: 13.12±4.5, p<0.0001). The polyI:C-induced Ro52/TRIM21 mRNA expression remained stable until 12-hrs of treatment, whereas a further increment was observed at 48-hrs of treatment (mean fold induction: 34.3±9.1 compared to basal levels, p<0.0001). The effect of polyI:C treatment in Ro52, Ro60 and La/SSB expression by SGECs was further confirmed at the protein level by immunoblotting. Treatment with LPS was not found to affect the mRNA expression of the molecules studied (Ro52/TRIM21, Ro60/TROVE2 and La/SSB). PolyI:C or LPS treatment of HeLa cells did not show any effect on the expression levels of Ro52/TRIM21, Ro60/TROVE2 and La/SSB mRNAs.

Conclusion: Our findings indicate a reciprocal regulation of TLR3 signaling in SS-related intracellular autoantigens, and particularly Ro52 expression, by SGECs. Further investigation is needed to clarify the mechanisms involved in this regulation.

IL-7 and Toll-Like Receptor 7 Synergistically Increase Th1/Th17/Th22 Cytokine Secretion and Activity of B Cells. A. Bikker[1], A.A. Kruize[1], F. Redegeld[2], W. de Jager[3], F.P.J.G. Lafeber[1] and J.A.G. van Roon[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Dept Pharmacology UU, Utrecht, Netherlands, [3]Dept Immunology, UMC Utrecht, Utrecht, Netherlands

Background/Purpose: IL-7 is a potent T cell activating cytokine that has been shown to cause proliferation, survival and differentiation of T cells as well as T cell-dependent activation of myeloid cells in numerous conditions. In inflamed tissues of patients with several autoimmune diseases (RA, pSS, psoriasis) increased IL-7 production by tissue cells and immune cells has been documented. Although reduced serum immunoglobulin levels in IL-7-deficient individuals suggested that IL-7 might play a role in activation of mature human B cells, direct evidence for this is lacking. Previously, it has been demonstrated that EBV, one of the suggested triggers of pSS, induces TLR7-dependent B cell activation and that EBV-transformed B cells express significant levels of the IL-7R as well as IL-7. Furthermore, we have shown that both intracellular IL-7R and IL-7 expression is up regulated in vitro upon TLR7 triggering of B cells. Our purpose was to investigate the potential synergy of IL-7-driven T cell-dependent and TLR7-mediated B cell activation and to assess the additive effects of monocyte/macrophages in this respect.

Methods: Isolated CD19 B cells and CD4 T cells from HC (n=7) were co-cultured (1:1) with and without IL-7, TLR7 agonist (TLR7A, Gardiquimod) or the combination of IL-7/TLR7A with and without CD14 monocytes/macrophages (T/B/mono; 1:1:0,1). Proliferation of T and B cells was measured using 3H-thymidine incorporation and by Ki67 expression (FACS analysis). Activation marker (CD19, HLA-DR, CD25) expression was measured by FACS analysis. In addition, in culture supernatants cytokines (IFNg, IL-17A, IL-22, IL-6 and IL-10) and IgM and IgG were measured by Luminex and ELISA, respectively.

Results: Exogenously added IL-7 did not activate B cells directly, in line with the absence of surface IL-7R. However, in the presence of T cells, IL-7 activated both T and B cells (Ki67+ CD4 cells from 1.1% to 14.4%, p<0.01 and Ki67+ B cells from 1.9% to 4.10.9%, p<0.05). TLR7A induced B cell activation, as measured by increased proliferation (%Ki67 from 1.2% to 9.3%) and up regulation of activation markers on B cells, which was facilitated in the presence of monocytes. TLR7-induced B cell activation in T/B or T/B/monocyte co-cultures was not associated with T cell activation. IL-7 added to TLR7A synergistically increased both B cell (TLR7A *vs*. IL-7/TLR7A; 9.3% *vs*. 33.4%) and T cell proliferation (IL-7 vs. IL-7/TLR7A; 0.8% *vs*. 29.2 %), which for B cells again was further increased by monocytes (TLR7A *vs*. IL-7/TLR7A; 30.2% *vs*. 63.0%)(all p<0.05). Similar results were observed for activation marker expression on B cells (CD19, HLA-DR CD25) and on T cells (HLA-DR, CD25). More important, IL-7 and TLR7, in the presence of monocytes, synergistically induced Th1/Th17/Th22 cytokine secretion and IgG production (all p<0.05)

Conclusion: IL-7 and TLR7 signaling synergistically activates T and B cells, which is markedly enhanced by the presence of monocytes/macrophages. Our results indicate that previously described increased local expression of IL-7 and TLR7 and increased numbers of macrophages in patients with pSS could contribute to enhanced lymphocyte activation and immunopathology in these patients.

IL-7 and IL-7 Receptor Blockade to Selectively Inhibit TLR7-Induced B Cell Activation in Primary Sjögren's Syndrome. A. Bikker[1], C.R. Willis[2], A.A. Kruize[1], J.W.J. Bijlsma[1], F.P.J.G. Lafeber[1] and J.A.G. van Roon[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Amgen Inc., Seattle, WA

Background/Purpose: Toll-like receptors (TLRs) are involved in the recognition of nucleic acids (viral, bacterial, and possibly self) and have been implicated in several auto-immune diseases. In primary Sjögren's syndrome (pSS) TLR7-induced B cell activation (e.g. by EBV) has been implicated in the immunopathology. An increased expression of TLR7 mRNA has been found in the parotid gland of pSS patients. In addition, TLR7 specifically

recognizes ssRNA from viruses, and possibly self-ssRNA, with which Ro- and/or La-proteins form complexes, facilitating anti-SSA/SSB auto-antibody production, one of the hallmark disease parameters of pSS. Interestingly, EBV-transformed B cells have been shown to express the IL-7R and secrete IL-7. Recently, we found increased levels of IL-7 and its receptor in the minor salivary gland of pSS patients. Our purpose was to investigate the role of IL-7/IL-7 receptor-mediated immune activation in TLR7-induced B cell activation in pSS patients.

Methods: Isolated CD4 T cells and CD19 B cells from HC (n=7) and pSS patients (n=5) were co-cultured with and without a TLR7 agonist (TLR7A, Gardiquimod) in the presence or absence of CD14 monocytes/ macrophages. Additionally, PBMCs (HC n=5, pSS n=8) were cultured with TLR7A with and without soluble human IL-7R (shuIL7R) and fully human anti-human IL-7 mAb. Proliferation of T cells and B cells was measured using ^{3}H-thymidine incorporation and Ki67 expression (FACS analysis). Activation markers (CD19, HLA-DR, CD25) and intracellular IL-7 and IL-7Rα expression by B cells were measured by FACS analysis.

Results: A strongly TLR7A-increased proliferation of T and B cell co-cultures was associated with significant and selective increases in Ki67-proliferating CD19 B-cells (HC from 1.2% to 9.3%, p<0.01 $vs.$ pSS from 1.2% to 7.0%, p<0.05), but not CD4 T-cells. Additionally, markers of activation on CD19 B cells (HC: CD25+ from 42.2% to 80.1%; CD19 MFI from 26.8% to 63.4%; HLA-DR MFI from 214 to 649) were significantly increased as well, equally effective in HC and pSS (all p<0.05). TLR7-induced B cell activation was increased in the presence of monocytes (Ki67+ B cells: HC from 0.9% to 30.2% $vs.$ pSS from 1.0% to 11.6%, both p<0.05). IL-7R blockade markedly inhibited lymphocyte proliferation of TLR7A stimulated PBMCs from HC (from 8880 to 2289 cpm; p<0.05) and pSS patients (from 8580 to 4802 cpm; p<0.01), which was associated by a selective inhibition of Ki67-proliferating B cells (from 47.5% to 9.4%). The specific role of IL-7R-mediated activation was supported by an increase in intracellular IL-7Rα and IL-7 upon TLR7 triggering in B cells. The role of IL-7 was confirmed by blockade of TLR7-induced B cell activation with a fully human anti-IL-7 mAb (mean inhibition 50%, p<0.05).

Conclusion: TLR7A-induced B cell activation is potently and selectively inhibited by IL-7 and IL-7R blockade. Together with the up regulation of IL-7 and IL-7R in B cells upon TLR7 activation, these results suggest that shuIL-7R/anti-IL-7 mAb blocks an autocrine function of IL-7 in B cells. This indicates that IL-7/IL-7R blockade, targeting not only T cells as previously shown, but also B cells, represents an interesting new therapeutic approach in pSS.

A New Pathogenic Role of Salivary Gland Epithelial Cells in the Costimulation of T Lymphocytes in Primary Sjögren's Syndrome: 0×40 Ligand Expression, T-Cell Induction of OX40 and Promotion of T-Cell Survival, Proliferation and Activation. Yazhuo Gong, Ghada Alsaleh, Jean Sibilia and Jacques-Eric Gottenberg. EA4438 Laboratoire Physiopathologie des Arthrites, Illkirch-Strasbourg, France

Background/Purpose: OX40/OX40L interaction is a pivotal costimulatory pathway involved in multiple autoimmune diseases. It provides a key signal for T-cell proliferation and differentiation in effector and memory subsets. Polymorphisms of OX40L are involved in the genetic predisposition to primary Sjögren's syndrome (pSS). Since SGECs express other costimulatory molecules such as CD80, CD86 or ICOSL, we investigated the expression of OX40L by salivary gland epithelial cells (SGECs) and the expression of OX40 by T cells cocultured with SGECs.

Methods: Primary culture of salivary epithelial cells was derived from minor salivary gland biopsies isolated from patients with SS or control subjects (complaining from dry symptoms without any feature of autoimmunity). Expression of OX40L by SGEC was measured using qPCR and immunohistochemistry. Naïve CD4$^+$ T cells were activated by anti-CD2, anti-CD3 and anti-CD28 and cultured alone or with SGECs. T-cell expression of OX40 was analyzed using flow cytometry. T-cell proliferation and survival were assessed by CFSE dilution and propidium iodide (PI)/DiOC6 staining, respectively. Levels of IFN-γ, IL-2, IL-4 and IL-6 were assessed in culture supernatants using ELISA.

Results: SGECs isolated from pSS patients (n=4) or controls (n=4) expressed OX40L mRNA and protein. Coculture of T cells with SGECs from patients with pSS (n= 7) significantly increased the expression of OX40 by CD4+T cells (67.3% ± 9.2) compared to T cells cultured alone (33.9% ± 6.9, $p= 0,02$). A similar induction of OX40 expression was observed in coculture of T cells with SGECs from controls.

In addition, SGECs isolated from pSS patients promoted T cell survival and proliferation: 82% vs 22% living T cells (PI negative DiOC6 positive) were detected when cultured with SGEC, compared to cultured alone. IFN-γ and IL-2, markers of T-cell proliferation and activation, were detected in the supernatant of cocultures (8.3 ± 0,2ng/ml for IFN-γ and 4.8 ± 0,4 ng/ml for IL-2) but not in the supernatant of SGEC or of T cells cultured alone. IL-6 was also increased in the supernatants of cocultures (2,7 ± 0,6 ng/ml, compared to SGECs isolated from pSS cultured alone (1,2 ± 0,7 ng/ml), or T cells cultured alone (0 ng/ml). The induction of T-cell expression of OX40 was not altered when the coculture of T cells and SGECs was performed using a transwell or not (n=3), which demonstrates that this OX40 induction depends on cytokine(s) and not of cell-cell contacts.

Conclusion: SGECs are capable to induce a dramatic increase of OX40 expression, and promote T-cell survival, proliferation and activation. This crosstalk between epithelial and T cells might also result in subsequent B-cell activation as shown by the increase of IL-6 in coculture supernatants. Further analyses are ongoing to determine the mechanisms involved in the induction of OX40 and consequences on T-cell polarization. These results demonstrate a new mechanism by which salivary gland epithelial cells play a pathogenic role in this autoimmune epithelitis. These results also suggest that OX40/ OX40L might represent relevant therapeutic targets in pSS.

Memory B Cell Phenotypic and Gene Expression Profiling in Primary Sjögren's Syndrome: Implications for Disease Diagnosis. Mustimbo E. P. Roberts[1], Craig Maguire[1], Alex Rosenberg[2], Andreea Coca[3], Jennifer H. Anolik[2] and Inaki Sanz[4]. [1]University of Rochester School of Medicine and Dentistry, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]Univ of Rochester, Rochester, NY, [4]Rochester, Rochester, NY

Background/Purpose: A paucity of known causative mechanisms in primary Sjögren's Syndrome (pSS) contributes to inadequate classification criteria. However, known memory-phenotype B cell aberrations could enrich diagnostic criteria if such alterations precede clinical disease onset. Therefore, to determine diagnostic potential, we compared the phenotype and gene expression of B cells in pSS patients, $sicca$ patients (individuals with symptoms but without pSS diagnosis), and healthy controls (HCs).

Methods: CD19^{pos} B cells from pSS (n=26), from $sicca$ symptomatic patients (n=27), and from healthy controls (n=22) were analyzed using flow cytometry to identify canonical B cell subsets. Sub-groups of these subjects were further analyzed for expression of CD21, CD23, CD24, CD95 CXCR5 and CD1c. Additionally, purified B cell subsets (n=3–5, per group, per test) were analyzed for gene expression using Affymetrix gene arrays.

Results: pSS patients had lower frequencies and numbers of CD27^{pos}/ IgD^{neg} switched memory (SM) and CD27^{pos}/IgD^{pos} unswitched memory (UM) phenotype B cells compared with HCs. A sub-group of sicca patients shared a B cell profile similar to pSS. Interestingly, lower UM B cell frequencies were evident in $sicca$ patients before disease-associated autoantibodies were detectable. Importantly, patient UM B cell frequency significantly associated with serologic hyperactivity. Extended phenotypic profiling in pSS revealed that the deficient UM cells had marginal zone B cell characteristics, whereas the SM cells were enriched for likely pathogenic effectors. CD27^{pos} memory B cell gene-expression profiling identified 135 differentially expressed genes between pSS patients and HCs. Additionally, clustering analysis identified a subgroup of $sicca$ patients with a gene expression profile similar to pSS. Whereas SM B cells gene expression analysis was similar in pSS and HCs, UM B cell gene expression analysis identified 187 differentially expressed genes between pSS patients and HCs. Interestingly, some of the these genes encoded signaling molecules and transcriptional factors associated with many B cell related biological pathways.

Conclusion: Collectively, these findings suggest that UM B cells contribute to regulating autoimmunity and also that B cell profiling could enhance diagnosis of pSS onset. Thus, B cell profiling in pSS has the potential to identify early disease-onset candidates for earlier therapeutic intervention and for novel therapies under investigation.

Regulatory B Cells in Primary Sjögren's Syndrome. Gabriela Hernandez-Molina, Janette Furusawa-Carballeda, Guadalupe Lima, Yahaira Rivera and Luis Llorente. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background/Purpose: B cells have traditionally been considered as positive regulators of humoral immune response, however their negative regulatory role has recently being recognized. **Objective.** To characterize the phenotypes of regulatory B cells in peripheral blood of primary Sjögren syndrome (pSS) patients and compare their presence according to the clinical and/or serologic activity disease status.

Methods: We included 50 pSS patients according to the AECG classification criteria, all of them were evaluated by a rheumatologist. We defined clinical activity as the presence of parotid enlargement or any extraglandular manifestation assessed by the SDAI or the ESSDAI indexes (except fatigue, fever or arthralgias). We defined serologic activity as IgG immunoglobulin >16 g or low C3, C4 or serum viscosity >1.9 cp. Twelve healthy age matched subjects were used as controls. PBMCs were isolated by centrifugation over a Lymphoprep gradient. CD19-mAb-coated microbeads were used to purify B cells by positive selection. We used the following mAbs: anti-CD38-PECy5, anti-CD38-PE, anti-CD24-FITC, anti-IgA-PE, anti-IgD-PE, anti-IgG-PECy5, anti-IgM-APC, anti-CD5-APC, anti-CD10-APC, anti-CD20-APC, anti-CD27-APC, anti-CXCR4-APC and anti-CXCR7-Cy5. Cells immunofluorescent staining was analyzed by a FACScalibur flow cytometer. The relative % of the subtypes of Il-10 cells producers was calculated on basis of the total positive selection of the phenotype $CD19^+$/$CD38^{bright}$/$CD24^{bright}$. We used One way ANOVA analysis (post-hoc analysis Dunn method) with the Sigma Stat 11.2 software.

Results: Patients were predominantly females, mean age 53 ± 12 years and median disease duration of 9.7 years. Seventeen patients (34%) were clinical active (parotid enlargement, vasculitis, arthritis, leucopenia, lymphopenia, pneumonitis or optic neuritis). Patients with or without clinical activity were similar in age, disease duration but received more frequently prednisone and azathioprine. Twenty-seven (54%) patients had serologic activity regardless their clinical status. $IL-10^+$ B cells represented the 0.55% of the total pSS B cell population and was higher in clinical inactive patients(0.63%), whereas controls had a lower prevalence (0.22%, p<0.05). We found a statistically significant increment in the following subtypes of Bregs cells: $CD19^+$/$CD38^{bright}$/IgA^+/$IL10^+$ cells (pSS 79%, clinical inactive 80% vs. control 66%), $CD19^+$/$CD24^{bright}$/$CD38^{bright}$/$CD5^+$/$IL10^+$ (clinical inactive 24% vs. control 14%), $CD10^+$/$IL10^+$ (pSS 23%, clinical inactive 26% vs. control 15%). IgD^+ cells and $CD27^-$/$IL10^+$ cells were increased in all the groups regardless their clinical activity when compared vs. controls. The phenotypes $CD19^+$/$CD24^{bright}$/$CD38^{bright}$$IL10^+$/$CD20^{+,}$ $CD27^{+,}$ $CXCR4^+$ and $CXCR7^+$ were similar among groups. We did not find a difference when we analyzed by serologic activity.

Conclusion: Most of the studied Bregs phenotypes were increased in pSS patients, particularly in those without clinical activity. The presence of these cells emphasizes the importance of the immunobiology of B cells in pSS.

Frequencies and Numbers of Circulating IL-10 Producing Regulatory B Cells Are Not Disturbed in Pss-Patients but Correlate Negatively with the EULAR Sjögren Syndrome Disease Activity Score (ESSDAI). Wayel H. Abdulahad, Gwenny Verstappen, Arjan Vissink, Minke G. Huitema, Petra M. Meiners, Hendrika Bootsma and Frans Kroese. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: Recently, a specific and functionally important subset of regulatory B cells (B$_{reg}$) that negatively regulate autoimmunity and inflammation has been described. B$_2$ cells exert their suppressive role through the production of interleukin-10 (IL-10), and can be *immunophenotypically identified by high expression of CD38 and CD24. Possible involvement of B$_{reg}$ cells in primary Sjögren's syndrome (pSS) has not been yet elucidated. This study aimed to assess the frequency and number of B$_{reg}$ cells in pSS-patients, the impact of rituximab (RTX) treatment on B$_{reg}$ cell reconstitution, and the association between B$_{reg}$ cells and pSS disease activity score.*

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from 12 pSS-patients (at baseline and 48 weeks after RTX-treatment) and from 8 age- and sex-matched healthy controls (HC). Frequency and number

of circulating $CD38^{high}CD24^{high}CD19^+$ B$_{reg}$ cells were assessed by flow cytometry. Next, since IL-10 secretion was recognized as a functional mechanism of suppression in B$_{reg}$ cells, we determined the frequency and number of IL-10 producing B-cells after *in vitro* stimulation of PBMCs with CpG (0.5mg/ml) for 3 days and re-stimulation with PMA (5ng/ml) and Ca-I (0,2mg/ml) in the presence of Brefeldin A (10mg/ml) during the last 16 hours. E*xpression of TNFα was used to discriminate between B$_{reg}$ cells (IL-10$^+$ TNFα$^-$) and TNFα$^+$ effector B cells (IL-10$^-$ TNFα$^+$; B$_{eff}$).* Intracellular production of IL-10 and *TNFα* in B cells were determined by flow cytometry. In addition, EULAR Sjögren Syndrome Disease Activity scores (ESSDAI) were calculated for each patient before and after RTX-treatment, and compared to the B$_{reg}$ results in order to assess the clinical relevance of data.

Results: At baseline, based on the surface phenotype of B$_{reg}$cells ($CD38^{high}CD24^{high}CD19^+$), pSS-patients displayed higher frequencies and numbers of B$_{reg}$ cells in blood compared to HCs. Following RTX-treatment, a significant increase in $CD38^{high}CD24^{high}CD19^+$ B$_{reg}$ cell frequencies and numbers was observed in pSS-patients when compared to baseline and HCs. Since IL-10 production is the hallmark of B$_{reg}$ cells, we also measured IL-10 production by B-cells. Frequencies and numbers of IL-10 producing B$_{reg}$ cells (*IL-10$^+$ TNFα$^-$) did, however, not differ between pSS-patients before and after RTX-treatment and HCs. Ratios of* B$_{reg}$:B$_{eff}$ did not significantly change after RTX-treatment too. Frequencies and numbers *of both IL-10$^+$TNFα$^-$ B$_{reg}$ cells as well as* $CD38^{high}CD24^{high}CD19^+$ B$_{reg}$ cells at baseline correlated negatively with ESSDAI.

Conclusion: Frequencies and numbers of IL-10 producing B$_{reg}$ cells were not impaired in pSS-patients, neither before nor after RTX-treatment. Given that circulating IL-10 producing B$_{reg}$ cells correlate negatively with ESSDAI, these B$_{Reg}$ cells might serve as a monitor to assess disease activity in pSS-patients.

Disclosure: **W. H. Abdulahad**, None; **G. Verstappen**, None; **A. Vissink**, None; **M. G. Huitema**, None; **P. M. Meiners**, None; **H. Bootsma**, None; **F. Kroese**, None.

Stages of Sjogren's Syndrome Defined by Immune Mediators. Lakshmanan Suresh[1], Julian Ambrus Jr.[2] and Long Shen[3]. [1]IMMCO Diagnostics Inc., Amherst, NY, [2]State University of New York at Buffalo, Buffalo, NY, [3]SUNY at Buffalo, Buffalo, NY

Background/Purpose: Sjogren's syndrome (SS) is characterized by destruction of the salivary and lachrymal glands but also systemic manifestations such as lung disease, kidney disease and lymphomas. We have utilized an animal model for SS, the IL-14alpha transgenic mouse (IL14aTG; *J. Immunol.* 177: 5676 – 5686, 2006; *Clin. Immunol.* 130: 304–312, 2009) to understand factors regulating various aspects of the disease. Previous studies had demonstrated that IL14aTG mice lacking lymphotoxin did not develop any features of SS (IL14aTG.LTa−/−; *J. Immunol.* 185: 6355 – 6363, 2010).

Methods: IL-14aTG mice lacking the type 1 interferon receptor (IL14aTG.IFNR−/−) or marginal zone B cells (MZB; IL14aTG.CD19Cre.RBP-J−/−) were compared to IL14aTG mice with regards to autoantibodies (determined by Western blots), salivary gland secretions (determined after Pilocarpine stimulation), and histology of the salivary glands.

Results: Both IL14aTG mice and IL14aTG.IFNR−/− developed IgM autoantibodies at 6 months, but only IL14aTG mice developed IgG antibodies at 12 months of age. IgM antibodies were eliminated in IL14aTG.CD19Cre.RBP-J−/− at 6 months of age. Salivary gland secretions were normal in IL14aTG.LTa−/− and IL14aTG.CD19Cre.RBP-J−/− mice, mildly decreased in IL14aTG.IFNR−/− and severely decreased in IL14aTG mice at 12 months of age. Both IL14aTG and IL14aTG.IFNR−/−mice had lymphocytic infiltration of their submandibular and lachrymal glands at 10 months of age. Only IL14aTG mice had lymphocytic infiltration of the parotid glands at 14 months of age. Neither IL14aTG.LTa−/− nor IL14aTG.CD19Cre.RBP-J−/− had lymphocytic infiltration of any salivary or lachrymal glands.

Conclusion: These studies suggest a model for SS in which early injury to the submandibular and lachrymal glands is regulated by MZB that produce IgM antibodies and lymphotoxin. Later development of IgG autoantibodies and parotid gland injury is dependent upon type 1 interferon. Further studies will be needed to investigate these observations in patients with SS.

Characterization of Dominant B- and Plasma Cell Clones in Patients with Primary Sjögren's Syndrome and Patients with Sicca Syndrome.

Marieke E. Doorenspleet[1], Erlin Haecke[2], Paul L. Klarenbeek[1], Annie Visser[3], Rebecca E. Esveldt[1], Fred Spijkervet[3], Paul-Peter Tak[1], Hendrika Bootsma[3], Niek de Vries[1] and Frans Kroese[3]. [1]Academic Medical Center of the University of Amsterdam, Amsterdam, Netherlands, [2]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [3]University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: Primary Sjögren's syndrome (pSS) is an auto-immune exocrinopathy characterized by chronic inflammation and destruction of the salivary and lacrimal glands. Infiltration of B and T-cells and sometimes plasma cells in the salivary glands as well as the presence of lympho-epithelial lesions are characteristic for pSS. Recent studies showed clinical improvement upon rituximab therapy up to 9 months, enforcing the notion that B cells and to a lesser extent plasma cells are important in the pathogenesis. To further unravel BCR involvement in the development of pSS we characterize B-cell and plasma cell clones in an early stage of parotid gland inflammation.

Objectives: 1) to compare B cell and plasma cell clonality in patients with pSS and sicca in the absence of an auto-immune disease. 2) To determine isotypes in clones identified and compare these between pSS and sicca.

Methods: Five patients with pSS and 5 patients with complaints of sicca without any auto-immune disease (sicca) were included. All pSS patients fulfilled the AECG criteria for pSS and were antibody (ANA, SSA, SSB, Rf) positive. All sicca patients were antibody negative. Immunohistochemistry stainings were performed on formalin-fixed paraffin embedded sections using antibodies against CD22, CD138, IgA, IgG and IgM and scored semi-quantitatively. mRNA was isolated from all parotid gland biopsies and full-repertoire analysis of the immunoglobulin heavy-chain was performed. All amplified products encode the CDR3, a unique sequence that defines a unique clone. The number of sequences reflects the amount of immunoglobulins produced by that clone and can be used as a measure for 'dominance' of that particular clone. Of each sample >10,000 BCR sequences were obtained. Clones with a frequency of > 0.5% were arbitrarily considered as dominant clones.

Results: In all patients, almost 3000 clones were recovered (mean 2910 and 2946 and SD 704 and 783 in pSS and sicca resp., p=n.s.) Multiple dominant clones were detected in the parotid gland of all pSS patients (mean 6.2 clones, SD 1.5), only a few dominant clones were detected in the sicca patients (mean 2.4 clones, SD 1.1, p=0.02). Immunohistochemical stainings of the pSS parotid gland biopsies showed that the majority of the infiltrate consisted of B-cells, although a few plasma cells were detectable in all 5 pSS patients. In sicca patients, much less B cells and plasma cells were detectable. Further isotyping revealed that the plasma cells in pSS were mainly expressing IgG (55% IgG, 30% IgA, 15% IgM), while plasma cells from sicca patients were only IgA+ (100% IgA). In line, the highly dominant clones in pSS patients were mainly of the IgG isotype (80% IgG, 16% IgA, 4% IgD), or showing a micture of isotypes, often including IgG. In sicca patients, the very few dominant clones all expressed IgA (100%).

Conclusion: Our observations suggest that the inflamed parotid gland in pSS can be distinguished from sicca based on the expression of IgG by the most dominant B-cell and plasma cell clones. This provides the opportunity to further study the IgG+ B-cell and plasma cell clones in particular for their potential auto-reactive properties. This in turn might lead to understanding of the pathogenesis of pSS and might lead to more targeted therapy.

Overexpression of BMP6 Is Associated with Loss of Salivary Gland Activity in Sjögren's Syndrome Patients and Mice.

Hongen Yin[1], Javier Cabrera-Perez[1], Zhennan Lai[1], Drew Michael[1], Melodie Weller[1], Bill Swaim[1], Noreen Rana[1], Xibao Liu[1], Ilias Alevizos[2], Indu Ambudkar[3] and John A. Chiorini[1]. [1]NIH/NIDCR, Bethesda, MD, [2]NIDCR/ NIH #10 1N110, Bethesda, MD, [3]NIDCR, Bethesda, MD

Background/Purpose: A hallmark of Sjögren's syndrome (SS) is the loss of activity in secretory epithelia, specifically the larcrimal and salivary glands. The mechanism(s) driving this disorder are poorly understood and may involve a combination of environmental and genetic factors. To date exten-sive efforts have been focused on understanding the changes in the immune system in these patients, however little is understood regarding the changes in the epithelia associated with the loss of gland activity.

Methods: To identify genes associated with changes in the epithelia, RNA was isolated from patients with both low flow and low lymphocytic infiltrates (focus score) and used to probe customized high density microar-rays. After normalization, the signal from the patient RNA samples was then compared to the signal from RNA isolated from healthy volunteers. The list of differentially expressed genes was then filtered for genes associated with salivary gland specific cell types.

Results: A significant increase in expression of the bone morphogenic protein 6 (BMP6) was observed in RNA isolated from patients compared with healthy volunteers. Overexpression of BMP6 locally in the salivary gland or lacrimal glands of mice resulted in the loss of fluid secretion as well as changes in the connective tissue of the salivary gland. Assessment of the fluid movement in either isolated acinar cells of mice overexpressing BMP6 or HSG cells cultured in the presence of BMP6 identified a loss in volume regulation in these cells. Loss of fluid movement also correlated with a decrease in sodium concentration in the saliva. Lymphocytic infiltration in SMG of BMP6 overexpressing mice was increased. No significant changes were found in proinflammatory cytokines production, neither the auto-antibodies associated with SS, such as anti-Ro/SSA, anti-La SSB and anti-nuclear antibody (ANA) after BMP6 overexpression.

Conclusion: Our study identified BMP6 as a novel gene associated with xerostomia associated with Sjögren's syndrome, which may become a new target for therapeutic intervention. In mice, a loss of salivary and lacrimal gland function can be induced by overexpression of BMP6, which further support our finding in patients. This study suggests the loss of salivary gland function can be separated from the autoantibodies and proinflammatory cytokines associated with this disease.

Spontaneous Sialadenitis Like Sjögren's Syndrome in Orphan Nu-clear Receptor γt (RORγt) Transgenic Mice.

Mana Iizuka[1], Hiroto Tsuboi[1], Hiromitsu Asashima[1], Yuya Kondo[1], Satoru Takahashi[2], Isao Matsumoto[1] and Takayuki Sumida[1]. [1]Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Department of Anatomy and Embryology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

Background/Purpose: The nuclear receptors retinoic-acid-receptor-related orphan receptors gt (RORγt) is required for the generation of Th17 cells expressing the proinflammatory cytokine IL-17. Th17 cells expressing IL-17 are involved in various autoimmune diseases including Sjögren's syndrome (SS). Recent studies reported the expression of IL-17 and IL-23 in the salivary glands and serum from patients with SS. However, the patho-logical roles of RORγt in SS remain to be elucidated. We examined the RORγt transgenic (Tg) mice in order to clarify the role of RORγt in the pathogenesis of SS.

Methods: (1) Histological analysis of salivary glands from RORγt Tg mice and C57BL/6 mice were determined and saliva flow was measured. (2) Infiltrating cells were isolated from the salivary glands and then analyzed their character by fluorescent immunostaining and flow cytometer. (3) Cytokine expressions in salivary glands were detected by quantitative PCR. (4) CD4+ T cells from RORγt Tg mice were transferred to Rag2−/− mice (RORγt Tg→Rag2−/− mice).

Results: (1) RORγt Tg mice developed the severe sialadenitis like SS and focus score was significantly increased in RORγt Tg mice ($2.33\pm0.88/4$ mm^2, $p<0.05$, Mann-Whitney U Test), compared with C57BL/6 mice ($0.22\pm0.38/4$ mm^2). Saliva flow collected from RORγt Tg mice (6.11 ± 1.08 μl/g, $p<0.05$, Mann-Whitney U Test) was significantly decreased than that of C57BL/6 mice (8.63 ± 0.76 μl/g). (2) The majority of infiltrating cells were CD4+ T cells at the early phase of sialadenitis, and B220+ cells were gradually increased at the late phase. (3) Expression of IL-17 and IL-21 mRNA was significantly increased in salivary glands of RORγt Tg mice by the side of C57BL/6 mice ($p<0.05$, Mann-Whitney U Test). (4) In RORγt Tg→Rag2−/− mice, cellular infiltrations were observed in salivary glands.

Conclusion: These results suggested that the overexpression of RORγt on CD4+ T cells showed play a crucial role in the development of spontaneous sialadenitis like SS.

Sex-Specific Regulatory T Cell Dysfunction in a Mouse Model of Sjögren Syndrome. Scott M. Lieberman[1], Portia A. Kreiger[2] and Gary A. Koretzky[3]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Nemours/A.I. DuPont Hospital for Children, Wilmington, DE, [3]University Pennsylvania, Philadelphia, PA

Background/Purpose: CD4+Foxp3+ regulatory T cells (Tregs) are a specialized population of lymphocytes which prevent autoimmunity in normal hosts. Treg dysfunction has been implicated in autoimmunity; however results are conflicting. Sjögren syndrome is an autoimmune disease characterized by destruction of lacrimal and salivary glands resulting in profound ocular and oral dryness. In the nonobese diabetic (NOD) mouse model of Sjögren syndrome, females develop earlier and more severe sialadenitis while males develop primarily dacryoadenitis. We previously reported that female NOD mice harbor a lacrimal gland-protective Treg population (Arthritis Rheum 2011;63 Suppl 10:495). Here, we characterize the role of sex-based Treg dysfunction in the sexually dimorphic disease manifestations in our NOD mouse-based transfer model of Sjögren syndrome.

Methods: Sjögren-like disease was induced by transfer of cervical lymph node cells, either whole or depleted of the Treg-enriched CD4+CD25+ population, to lymphocyte-deficient NOD-SCID mice, which do not develop spontaneous autoimmunity. Five to seven weeks following adoptive transfer, dacryoadenitis and sialadenitis were quantified by an experienced, blinded pathologist using a standard focus score.

Results: Transfer of whole cervical lymph node cells from NOD mice to sex-matched NOD-SCID mice recapitulated sexually dimorphic features (i.e., males develop dacryoadenitis; females develop sialadenitis). Moreover, dacryoadenitis developed in female and male recipients of sex-matched donor cervical lymph node cells depleted of Tregs. Interestingly, in a male environment, female NOD donor cervical lymph node cells (not depleted of Tregs) induce dacryoadenitis; whereas, in a female environment, male NOD donor cervical lymph node cells fail to induce dacryoadenitis unless Tregs are depleted prior to transfer.

Conclusion: These data demonstrate that females harbor a population of lacrimal gland-protective Tregs that become dysfunctional in a male environment and suggest that dacryoadenitis in males is due to an underlying lacrimal gland-specific Treg defect. Studies to identify the sex-specific factors responsible for these findings are underway.

Genetic Associations to Germinal Centre Formation in Primary Sjögren's Syndrome. Tove Ragna Reksten[1], Malin V. Jonsson[2], Roland Jonsson[1], Gunnel Nordmark[3] and The Swedish-Norwegian Sjögren's syndrome Network[4]. [1]Broegelmann Research Laboratory, the Gade Institute, University of Bergen, Bergen, Norway, [2]University of Bergen, Bergen, Norway, [3]Rheumatology, Uppsala, Sweden, [4]Bergen

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune rheumatic disease mainly affecting the salivary and lacrimal glands causing xerostomia and keratoconjunctivitis sicca. Focal mononuclear cell inflammation in the form of germinal center-like structures (GC) is found in the minor salivary glands of 20–25 % of patients. We have previously shown that GC+ pSS patients presented with elevated serum levels of IL-1RA, IL-4, IL-17 and MCP compared to GC- patients. In this follow-up study, we aimed to assess the genetic variations in GC+ and GC- pSS patients.

Methods: In a Swedish-Norwegian pSS cohort (n=540), GC+ (n=76) and GC- (n=244) patients were identified. 1536 single-nucleotide polymorphisms (SNPs) were analysed in whole blood DNA by the Illumina GoldenGate assay (Illumina Inc.). Minor allele frequencies in GC+ and GC- patients were compared using Fisher's exact test and associations were considered significant when p<0.001 and suggestive when p<0.01. Statistical analysis were performed using the PLINK software.

Results: In this case-only analysis of 320 pSS patients with known GC status, we identified two SNPs in *Eotaxin* associated with GC+ patients with OR 0.45 and 0.41. Furthermore, we found suggestive associations with *BANK-1, ICA-1, IL-17, PRKCL1, CARD-8, Bcl-2, TANK, IKBKE, AID* and *APRIL*. We also detected weak associations (p<0.05) with SNPs in the BLK, STAT1, STAT4, SSA1, SSB, IL15RA, IL-6 and TNF-a genes. Serum eotaxin (CCL11) has previously been identified as a key discriminator between GC+ and GC- pSS patients. The formation of GCs depends on B cell stimulation by helper T cells via the CD40-CD40L system, which also contribute to the expression of activation induced deaminase (AID). Genetic variations in *CD40L* and *AID* suggest that GC+ patients may be genetically predisposed for ectopic GC formation. B lymphoid kinase (BLK) has a role in the development and activation of marginal zone B cells present in the GC formations, and Bcl-2 is an anti-apoptotic protein which gene is implicated in a number of cancers and autoimmunity. CARD-8, IKBKE and TANK are regulators of the NF-κB pathway, a pathway with a well-established role in secondary lymphoid organ development.

Conclusion: Taken together, our findings suggest that genetic variations may help explain why ectopic GC-like structures are present in some pSS patients but not all

Differences in Genome-Wide DNA Methylation Profiles Across Multiple Cell and Tissue Types in Sjögren's Syndrome (SS). Lindsey A. Criswell[1], Diana Quach[2], Hong L. Quach[2], Emon Elboudwarej[2] and Lisa F. Barcellos[2]. [1]University of California San Francisco, San Francisco, CA, [2]University of California, Berkeley, Berkeley, CA

Background/Purpose: Increasing evidence supports a role for epigenetic factors, including DNA methylation status, in autoimmune disease risk and severity. Our goal is to characterize DNA methylation profiles in SS, including multiple cell and tissue types relevant to disease.

Methods: We generated genome-wide DNA methylation profiles using Illumina HumanMethylation450 bead chips in minor salivary gland biopsy tissue, parotid saliva, PBMCs, and the following cell subpopulations: CD14+ monocytes, CD19+ B cells, and CD4+ T cells in a subset of participants from the Sjögren's International Collaborative Clinical Alliance (SICCA) repository (http://sicca.ucsf.edu/). All subjects were Caucasian females. SS cases (n=5) had severe disease, meeting all 3 of the ACR classification criteria for SS (Arth Care & Res 2012; 64:475), including focal lymphocytic sialadenitis on minor salivary gland biopsy, keratoconjunctiva sicca based on ocular staining pattern (ocular staining score ≥ 3), and presence of SSA and/or SSB autoantibodies. A single control individual with no evidence of SS based on the aforementioned and other objective tests was also studied. Sorting of freshly collected blood samples was performed using MACS® technology. Labial salivary gland biopsy tissue, parotid saliva and PBMCs were collected at entry to the SICCA repository, and a second blood sample was collected from each subject for isolation of the aforementioned cell subpopulations an average of 4.4 years following the baseline visit. Genome-wide DNA methylation profiles (450k sites) were compared across the 7 cell and tissue types within the 6 study subjects to characterize cell and tissue differences in DNA methylation status.

Results: DNA yields for all cell and tissue types were high, with the exception of parotid saliva, which yielded between 0.75 – 1.07 μg DNA but was still sufficient for whole genome methylation profiling. Assessments of purity for sorted cell subpopulations ranged from a mean of 59% (for CD4+ T cells) to 80% (for CD14+ monocytes). Within-individual comparisons of tissue-specific genome wide DNA methylation profiles revealed striking differences, with r^2 ranging from 0.105 (for saliva vs. B cells) to 0.998 (baseline vs. followup PBMCs).

Conclusion: These preliminary results emphasize the cell and tissue specificity of DNA methylation status, which is an important epigenetic process with potential to influence patterns of gene expression in health and disease. Additional work, including detailed analysis of site-specific DNA methylation differences in larger samples of SS case and control individuals,

followed by studies of gene expression for regions associated with disease risk or severity will be required to fully define the role of DNA methylation in SS.

522

Genetic Variation in the *NCR3* Locus Is Associated with Anti-SSA/SSB Positive Primary Sjögren's Syndrome in Scandinavian Samples.
Gunnel Nordmark[1], Maija-Leena Eloranta[1], Per Eriksson[2], Elke Theander[3], Helena Forsblad-d'Elia[4], Roald Omdal[5], Marie Wahren-Herlenius[6], Roland Jonsson[7] and Lars Rönnblom[1]. [1]Rheumatology, Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [2]Rheumatology/AIR, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden, [3]Skane University Hospital, Lund University, Malmö, Sweden, [4]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [5]Clinical Immunology Unit, Department of Internal Medicine, Stavanger University Hospital, Stavanger, Norway, [6]Karolinska Institutet, Stockholm, Sweden, [7]Broegelmann Research Laboratory, the Gade Institute, University of Bergen, Bergen, Norway

Background/Purpose: Candidate gene studies in primary Sjögren's syndrome (pSS) have identified polymorphisms in genes involved in the type I interferon (IFN) system and the type I IFN system is activated in pSS. NK cells have been shown to increase the immune complex stimulated IFN-alpha production by plasmacytoid dendritic cells but the role for NK cells in pSS autoimmunity has not been well studied. The natural cytotoxicity triggering receptor 3 (*NCR3*) gene locus (6p21.3) encodes the NKp30 activating receptor on NK cells. A French study identified an association between two rare alleles in the *NCR3* promoter region and pSS, independent of the association to *HLA-DRB1–03* (6p21.3) (1). The aim of this investigation was to analyze if the two *NCR3* single nucleotide polymorphisms (SNPs) were associated with pSS in Scandinavian samples. The potential association with anti-SSA/SSB positivity or clinical phenotypes was investigated. In addition, the association with the *HLA-DRB1–03* SNP proxy was studied.

Methods: A total of 671 Caucasian pSS patients from Sweden (n=478) and Norway (n=193) and 1586 healthy controls (Sweden, n=1369 and Norway, n=217) were included in the study. Two SNPs in the *NCR3* locus, rs11575837 and rs2736191 and the SNP rs2187668 as a marker for *HLA-DRB1–03* were selected. Genotyping was performed by single base extension with Fluorescent Polarization Template Dye Incorporation (FP-TDI). Data on anti-SSA and/or anti-SSB positivity and clinical manifestations were extracted from the patient files. Case-control and case-only allelic association analyses were performed using PLINK.

Results: In our case-control analysis we did not find any association between the *NCR3* SNPs and pSS in Sweden or Norway or in meta-analysis of the two cohorts. In case-only analysis of the combined cohorts, comparing anti-SSA/SSB positive (n=496, 74%) versus negative (n=175, 26%) pSS patients, we found an association between the SNP rs11575837 and anti-SSA/SSB positivity, p=0.006, OR 0.27 (95% CI 0.10–0.73). There were no associations between the *NCR3* SNPs and clinical phenotype. The *HLA-DRB1–03* SNP marker rs2187668 was strongly associated with pSS, $p=1\times10^{-51}$, OR 3.2 (95% CI 2.8–3.8). When analyzing only anti-SSA/SSB positive patients versus controls the association was even stronger, $p=6.9\times10^{-67}$, OR 4.1 (95% CI 3.5–4.9). In case-only analysis rs2187668 was associated with major salivary gland swelling and leucopenia (p<0.05), dermal vasculitis (p<0.01), hypergammaglobulinemia ($p=7.4\times10^{-8}$) and anti-SSA/SSB positivity ($p=1.6\times10^{-12}$, OR 3.0, 95% CI 2.2–4.1).

Conclusion: We found an association between anti-SSA/SSB positivity and genetic variation in the *NCR3* locus and confirmed the strong *HLA-DRB1–03* association with anti-SSA/SSB positive pSS. We conclude that different mechanisms, possibly involving NK cell functions, might contribute to this autoimmune disease in anti-SSA/SSB positive versus negative patients. The potential functional implications for this rare promoter SNP on NKp30 receptor activity has yet to be elucidated.

Background/Purpose: Sjögren's syndrome (SS) is a progressive autoimmune exocrinopathy characterized by symptoms of dry eyes and mouth. We previously reported overexpression of interferon-inducible (IFI) genes in a subset of SS patients. Using global gene expression profiling (GEP) and autoantibody serologies, we characterized SS patients who underexpress IFI genes in order to better understand a potentially divergent SS subgroup.

Methods: A total of 48803 mRNA transcript levels from whole blood were measured using the Illumina HumanWG-6 v3.0 BeadChip in 201 SS cases and 79 healthy controls. After quality control, Welch's t-tests, q-values, and fold changes (FC) were calculated for 20342 probes (15607 genes). Differentially expressed (DE) transcripts were selected by: q<0.05; and FC >1.25 or <0.87. Hierarchical clustering was performed and cases were divided according to underexpression (UNDER; n=53) or overexpression (OVER; n=128) of 32 IFI genes; both groups were then compared to healthy controls. Pathway analysis for DE genes was carried out in Genomatix. Antibodies to Ro, La, centromere B, chromatin, dsDNA, Jo-1, ribosomal P (riboP), ribonucleoprotein (RNP), Scl-70, Sm and Sm/RNP were determined using Bioplex assays. Antinuclear antibody (ANA) and rheumatoid factor (RF) were determined by immunofluorescence and ELISA, respectively. Autoantibody composition was compared using Fisher's exact test.

Results: Comparing the UNDER group (n=53) vs. controls (n=79) and removing IFI genes yields 1767 DE genes involved in cellular metabolism (725/7548 genes; P<10E-13); RNA processing (89/618 genes; P<10E-7); viral transcription (31/140 genes; P<10E-6); and viral reproduction (41/224 genes; P<10E-6). These genes comprise canonical pathways that include: protein import into the nucleus (6/12 genes; P<10E-3); TCR signaling in naïve CD8+ T cells (13/56 genes; P<10E-3) and CD4+ T cells (14/69 genes; P<10E-3); and BCR signaling (14/69 genes; P<10E-2). Additional genes of interest include ANTXR2 (q=2.6×10E-4; FC=1.35) and CTAGE5 (q=3.2×10E-4; FC=1.45). ANTXR2, an anthrax toxin receptor that binds collagen IV and laminin with potential involvement in extracellular matrix adhesion, has been associated with ankylosing spondylitis, while mutations in this gene cause juvenile hyaline fibromatosis. CTAGE5 encodes an antigen found in T-cell lymphoma and other cancers. Anti-Ro and anti-La are more common in the OVER group compared to the UNDER group (P<10E-12 and P<10E-7, respectively), as is ANA alone (P<10E-5) and in combination with RF (P<10E-3). Interestingly, by excluding subjects positive for anti-Ro, anti-La, RF, and ANA, we find that patients in the UNDER group are more likely to produce any combination of antibodies to centromere B, chromatin, dsDNA, Jo-1, riboP, RNP, Scl-70, Sm, or Sm/RNP autoantibodies than are those in the OVER group (P=0.015).

Conclusion: SS patients who underexpress IFI genes are more likely to produce non-traditional antibodies and are less likely to produce anti-Ro, anti-La, ANA, or ANA/RF than their counterparts. Additionally, GEP within this subphenotype has identified novel candidate genes and molecular pathways for further study that may help elucidate complex SS pathophysiology.

RNA-Sequencing Identifies Novel Differentially Expressed Coding and Non-Coding Transcripts in Sjögren's Syndrome.

[1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Hefner Eye Care and Optical Center, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]University of Minnesota, Minneapolis, MN, [5]Valley Bone & Joint Clinic, Grand Forks, ND, [6]Universidad del Rosario-Corporacion para Investigaciones Biologicas, Bogota, Colombia, [7]Hennepin County Medical Center, Minneapolis, MN, [8]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH, [9]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK, [10]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, [11]Oklahoma Medical Research Foundation; University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background/Purpose: Sjögren's syndrome (SS) is a common, clinically heterogeneous autoimmune disease characterized by exocrine gland dysfunction that involves both innate and adaptive immune responses. SS etiology is complex, with both environmental and genetic/genomic factors contributing. Recent genetic studies in complex disease have shown that 80% of associations map to transcriptionally active non-protein coding DNA sequences that comprise 60% of the human genome. Microarray technology, which requires prior knowledge of the transcripts being interrogated, has been extensively used to study gene expression of mRNA. Far more powerful, emerging RNA-sequencing (RNA-seq) technology allows for unbiased transcript identification and quantification across the genome. We used RNA-seq to identify differentially expressed (DE) protein-coding (3% of the genome) and non-coding transcripts in 60 SS cases and 30 healthy controls.

Methods: RNA samples were isolated from whole blood and prepared for sequencing using the NuGEN Encore kit, and sequencing was performed using the Illumina HiSeq 2000. Quality of raw sequence data was assessed using FASTQC. Raw FASTQ files were aligned to the human genome (hg19) using TOPHAT. Probable transcripts were assembled using CUFFLINKS, and DE transcripts were determined using CUFFDIFF using a false discovery rate (FDR) q-value of 0.1. Fold change (FC; positive values = overexpressed and negative values = underexpressed) calculations were obtained using the $\log2(FPKM_{Cases}/FPKM_{Control})$, where FPKM is the fragments per kilobase of exon model per million mapped fragments. Transcripts were verified using the Integrated Genome Viewer (IGV).

Results: The average number of reads per sample was 38.6 million, representing 346,234 transcripts across the genome. Of the protein-coding regions, TGF-beta activated kinase 1/MAP3K7 binding protein 1 (TAB1) was the most statistically DE locus ($p=3.03\times10E-7$, $q=0.049$, FC=1.56). TAB1, regulates MAP kinase kinase kinase MAP3K7/TAK1 and is involved in TGF beta, interleukin 1, WNT-1, NF-□B pathways. Genome-wide association studies of primary biliary cirrhosis and Crohn's disease have reported association to 22q13.1. Two other DE protein-coding transcripts of interest were identified: GRIN2D (glutamate receptor, ionotropic, N-methyl D-aspartate 2D; $p=1.36\times10E-5$, $q=0.088$, FC=2.123) and SH2D4B (SH2 domain containing 4B; $p=3.35\times10E-6$, $q=0.070$, FC=1.78). Biological functions of these genes are unclear. Among non-protein coding transcripts, we observed DE of a long non-coding RNA (lncRNA) at 11p15.2 ($p=3.77\times10E-6$, $q=0.070$, FC=1.69). lncRNAs are important regulators of the human genome with diverse functions. Bioinformatic evaluation in the 11p15.2 region showed transcription of lncRNA sequences and transcription factor binding sites using immunologically-relevant cell lines.

Conclusion: In this first of its kind SS RNA-seq study, we identified four novel candidate loci: TAB1, GRIN2D, SH2D4B and, for the first time, a DE lncRNA in SS. Future studies in SS are warranted to further elucidate the functional consequences of these novel RNA associations.

Gene Expression Profiling in a Large Cohort of Europeans with Sjögren's Syndrome Reveals Candidate Genes in Viral, Immune, and Interferon-Related Pathways.

He Li[1], John A. Ice[2], Jennifer A. Kelly[2], Indra Adrianto[2], Stuart B. Glenn[2], Kimberly S. Hefner[3], Evan G. Vista[4], Donald U. Stone[5], Raj Gopalakrishnan[6], Glen D. Houston[5], David M. Lewis[5], Michael Rohrer[6], Pamela Hughes[6], John B. Harley[7], Courtney G. Montgomery[2], James Chodosh[5], James A. Lessard[8], Juan-Manuel Anaya[9], Barbara M. Segal[10], Nelson L. Rhodus[6], Lida Radfar[5], Mark B. Frank[2], R. Hal Scofield[2], Christopher J. Lessard[1] and Kathy Moser Sivils[2]. [1]Oklahoma Medical Research Foundation; University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Hefner Eye Care and Optical Center, Oklahoma City, OK, [4]University of Santo Tomas, Taguig City, Philippines, [5]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [6]University of Minnesota, Minneapolis, MN, [7]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH, [8]Valley Bone & Joint Clinic, Grand Forks, ND, [9]Universidad del Rosario-Corporacion para Investigaciones Biologicas, Bogota, Colombia, [10]Hennepin County Medical Center, Minneapolis, MN

Background/Purpose: Sjögren's syndrome (SS), characterized by lymphocytic infiltration of exocrine glands, is a progressive autoimmune exocrinopathy present in 0.7–1% of Europeans. To better understand the molecular pathways involved in SS pathophysiology, we performed global gene expression profiling (GEP) on SS cases and healthy controls.

Methods: GEP was determined on 48803 probes from the Illumina HumanWG-6 v3.0 BeadChip microarray using whole blood from 162 primary SS cases and 58 healthy controls of European ancestry. Analyses were performed in the R Bioconductor suite. After quality control assessments, 20035 probes were quantile normalized, and differentially expressed (DE) genes were determined using q-values and mean expression fold change (FC) (significance thresholds: q<0.05; and FC >1.25 or <0.87). Pathway analysis for DE genes was carried out in Genomatix. Subsequent *cis*-expression quantitative trait loci (*c*-eQTL) analysis was performed in SS cases on selected genes using Matrix eQTL package.

Results: In total, 2410 genes were DE between SS cases and controls. *OTOF* was the most upregulated gene in SS patients (FC=94.87, q<1E-7, expressed in 86/162 cases compared to 2/58 controls), while *LRRN3* was the most downregulated (FC=0.39, q<1E-3). Interestingly, mutations in *OTOF* are responsible for hearing loss, a symptom observed in approximately one third of SS patients. Several DE genes overlap with genetic associations identified through genome-wide association studies in SS, including the MHC genes *TRIM38* (q<10E-12), *TAP1* (q<1E-14), and *TAP2* (q<1E-13), in addition to those identified previously by candidate gene approaches, including *IL1RN* (q<1E-5), *FAS* (q<1E-2), and *EBF1* (q<1E-2). Additionally, *c*-eQTL analysis identified 51 single-nucleotide polymorphisms (SNPs) within and flanking *TAP2* associated with gene expression levels (1E-10<q<0.01). The most significant canonical pathways of DE genes were apoptotic DNA-fragmentation/tissue homeostasis (7/11 genes; p<1E-4) and antigen processing/presentation (5/12 genes; p<1E-2). DE genes were also involved in several biological processes, including immune response (171/906 genes; p<1E-16), translational termination/elongation (42/105 genes; p<1E-15), viral transcription and genome expression (47/140 genes; p<1E-13), and type I interferon (IFN)-mediated signaling (31/70 genes; p<1E-13). Thirteen of the top 50 upregulated genes belong to the IFN pathway, which mirrors the IFN signature observed in lupus patients. Of note, elevated IFN expression levels were found to be correlated with anti-Ro and anti-La in SS. Nearly all DE genes in viral pathways were down-regulated with the notable exception of SP100 (q<1E-12, FC=1.58), an interferon-inducible protein believed to play a role in transcriptional regulation and the innate immune response following viral infection toward which antibodies are made in primary biliary cirrhosis.

Conclusion: These results highlight alterations in immunologically-relevant pathways in SS, reveal several new candidate expression quantitative trait loci, and provide focus for the development of novel hypotheses for further studies of this complex autoimmune disorder.

Use of a Novel Probe to Demonstrate Granzyme B Activity in Sjogren's Syndrome Salivary Glands. Kimberly Doering Maurer[1], Laura Gutierrez-Alamillo[1], Efstathia K. Kapsogeorgou[2], Athanasios G. Tzioufas[3], Livia Casciola-Rosen[4] and Antony Rosen[5]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]School of Medicine, National University of Athens, Greece, Athens, Greece, [3]School of Medicine, National University of Athens, Athens, Greece, [4]Johns Hopkins University, Baltimore, MD, [5]The Johns Hopkins University, Baltimore, MD

Background/Purpose: Salivary glands are a prominent target organ in Sjögren's syndrome (SS), with patients having abnormal secretory function and inflammatory infiltration of these glands. Little is currently known about the mechanisms whereby the immune system contributes to ongoing tissue damage and dysfunction in this disease. IRF1 is one of the most efficiently cleaved granzyme B substrates ever defined. The purpose of this study was to define whether cytotoxic lymphocytes in the gland actively induce proteolysis in salivary gland epithelial cells in situ by using an antibody highly specific for granzyme B (GrB)-cleaved IRF-1 to probe for activity of the GrB pathway *in vivo* in SS salivary gland biopsies.

Methods: Immunohistochemical staining of salivary gland paraffin sections was used to assess the presence of CD8 infiltrates, and the extent of GrB staining. Lysates generated from frozen salivary gland biopsies were immunoblotted to detect CD8 and IRF1 expression. ^{35}S-methionine labeled IRF1 was generated by *in vitro* transcription and translation, and was used to demonstrate cleavability by GrB, and as a template for site-directed $D^{204}A$ mutagenesis to confirm the GrB cleavage site in IRF1. Using this information, an antibody detecting exclusively the N-terminal GrB cleaved IRF1 fragment (R6017) (and not the intact molecule) was generated. This antibody was carefully validated and used for immuno-histochemistry and immunoblotting on salivary gland tissue and lysates obtained from SS patients.

Results: CD8 infiltrates were prominent in 60% of SS salivary glands by immunoblotting and immunohistochemistry. IRF1 is expressed at high levels in SS salivary glands, but not control salivary glands. IRF1 is efficiently cleaved by GrB at D^{204}. Using the antibody R6017 that is highly specific for the N-terminal fragment generated by GrB cleavage, we demonstrated the presence of GrB-induced fragments by immunoblotting and immunohistochemistry performed on SS patient but not control salivary gland tissue.

Conclusion: These studies provide the first direct in *vivo* evidence that the cytotoxic lymphocyte granule pathway is actively modifying salivary epithelial cells in patients with SS. Defining granzyme-induced effects on salivary epithelial function may provide important understanding of the mechanisms of salivary epithelial function in this disease, with therapeutic implications.

Multiplexed Nanostring Screening for Salivary Gland Viral Elements in Sjogren's Syndrome. Kristin Haffizulla[1], Glen Barber[1], Juan Chen[2] and Eric L. Greidinger[3]. [1]University of Miami Miller School of Medicine, Miami, FL, [2]The First Afflicted Hospital of Xiamen University, China, Miami, FL, [3]University of Miami, Miami, FL

Background/Purpose: To test the hypothesis that viruses are associated with Sjogren's syndrome, salivary gland RNA extracts from Sjogren's patients and non-Sjogren's controls were screened for virus-associated sequences using a multiplexed NanoString nCounter chip designed to detect sequences from all known human viral and endogenous retroviral families.

Methods: Samples were obtained following IRB approved protocols from study subjects recruited at the rheumatology clinics of The First Afflicted Hospital, Xiamen University, China who had minor salivary gland biopsies performed as part of routine clinical care. Using the classification criteria from the American-European Consensus Group, subjects were classified as having (cases, N = 12) or not having Sjogren's Syndrome. Subjects who did not meet Sjogren's classification criteria, and who did not have any salivary inflammatory process were designated the controls (N = 7). RNA was extracted from a 10 μm whole FFPE tissue section for each sample on a Siemens VERSANT robotic kPCR Molecular System. RNA was then directly assayed by Nanostring nCounter gene expression system for 334 viral, retroviral, and human immune gene sequences at once.

Results: Cases (11 female, 8 primary SS, 4 in RA) were confirmed by serology, histopathology, and parotid sialography. Controls were 7 patients (6 female) with normal histopathology, including 4 with negative ANA, SS-A, and SS-B. RNA extract quality and nCounter internal controls were robust for all tested samples. Gene expression in all samples was normalized to GAPDH expression. Cases and controls were compared for expression levels of the studied sequences. The 45 genes with the highest fold difference between cases and controls were all increased in the Sjogren's cases. Genes represented in this group included primarily HPV and polyoma-derived viral sequences but not endogenous retroviruses. The SS group had two distinct subsets, one of which (N = 6) showed increased expression of multiple viral genes compared to controls, and one of which (N = 6) showed reduced expression of multiple viral genes compared to controls. Subgroup analysis of the cases with high viral expression revealed multiple HPV Type 35 and 56 genes that were at least 2 fold overexpressed compared to controls. CD79a was the only tested gene at least 2 fold upregulated in the patients without high viral gene expression when compared to controls. A trend toward more Primary SS was present in patients with high viral expression (5/6 vs 2/6 for other SS, Fisher's Exact p = 0.2).

Conclusion: Using a new highly sensitive and specific technique, we find evidence of overexpressed viral elements in salivary tissue in a subset of a Chinese Sjögren's Syndrome cohort. This data increases scrutiny of HPV and polyoma subtypes for potential pathogenic roles in SS, but does not support a role for endogenous retroviruses. This work also for the first time identifies two distinct subsets of SS patients with regard to salivary viral expression.

Mxa As a Biomarker for Systemic Interferon Type I Activation in Primary Sjögren′s Syndrome. Naomi I. Maria[1], Zana Brkic[1], Matti Waris[2], Cornelia G. van Helden-Meeuwsen[1], Kim Heezen[1], Joop P. van de Merwe[1], Paul L. van Daele[1], Virgil A. Dalm[1], Hemmo A. Drexhage[1] and Marjan A. Versnel[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]University of Turku, Turku, Finland

Background/Purpose: To establish an easy and practical assay for detection of systemic Interferon (IFN) type I activation in primary Sjögren's syndrome (pSS). The monocyte IFN type I signature is present in over half of pSS patients and identifies a subgroup of patients with higher clinical disease activity [Z. Brkic *et al.*, 2012]. Currently, detection of the IFN type I signature is performed via laborious mRNA expression profiles of multiple IFN type I inducible genes.

Methods: In a cohort of 35 pSS patients Myxovirus resistance protein A (MxA) was tested as potential biomarker for systemic IFN type bioactivity. An MxA-enzyme immunoassay (EIA) on whole blood was compared with flow cytometric detection of MxA in CD14$^+$ monocytes. In addition CD64 (Fcγ RI), CD169 (Siglec-1) and BAFF (B-cell activating factor), previously described as biomarkers for IFN type I in other systemic autoimmune diseases, were assessed in CD14$^+$ monocytes using flow cytometry. The IFNscore, a measure for total IFN type I activation, was calculated using expression values of the IFN type I signature genes – IFI44, IFI44L, IFIT3, LY6E, MX1 – in CD14$^+$ monocytes, determined by real-time quantitative PCR. pSS patients were stratified in an IFN-positive (IFNscore>10) and IFN-negative pSS subgroup (IFNscore<10).

Results: Twenty-one out of 35 pSS patients were IFN-positive (IFNpos), whereas HC were negative for the IFN type I signature. Significant correlations were found between IFNscores and CD14+ monocyte protein expression of MxA (p<0.001;r=0.733), CD64 (p=0.007;r=0.436), CD169 (p<0.001;r=0.495) and MxA protein expression in whole blood (p<0.001;r=0.717). MxA assessed by the MxA-EIA showed significantly elevated levels in IFNpos patients with a median of 212.5 (10–1295) μg/l, whereas IFNneg patients [1μg/l(1–330)] expressed MxA at levels equal to HC [15μg/l(1–150)] (p<0.001). Similar results were obtained for MxA assessed by flow cytometry (p<0.001). MxA-EIA protein levels correlated with the EULAR Sjögren's syndrome Disease Activity Index score; Immunoglobulin levels; rheumatoid factor; haemoglobin levels and neutrophil counts.

Conclusion: MxA protein analysis is a promising tool for assessment of IFN type I activation in pSS. MxA levels determined by MxA-EIA correlated with features of disease activity. The EIA was shown to be a functional assay and could contribute to future studies on disease pathogenesis and pSS subclassification, possibly leading to more targeted treatment strategies.

The Axis P2X7 Receptor-Inflammasome: A Role in Modulating Inflammatory Response in Primary Sjögren's Syndrome? Chiara Baldini[1], Chiara Rossi[1], Eleonora Santini[1], Francesco Ferro[1], Alessia Gallo[2], Daniela Martini[1], Francesca Sernissi[1], Valentina Donati[1], Camillo Giacomelli[1], Nicoletta Luciano[1], Anna Solini[1] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]NIDCR, Bethesda, MD

Background/Purpose: The exact cause of exocrine gland dysfunction in primary Sjögren's syndrome (pSS) has not been fully delineated, but it is thought that both innate and adaptive immunity may contribute significantly. Recent data have unveiled the structure and function of the P2X7 receptor/NLRP3 inflammasome pathway in stimulating caspase-1 activation and the subsequent release of the inflammatory cytokines IL-1β and IL-18. Thus, the growing evidence for the presence of P2X7R in salivary gland has suggested a fascinating scenario for the initiation and amplification of the innate immune response in pSS exocrinopathy.

Aim of the study: 1) to assess the expression of P2X7 receptor in minor salivary gland biopsies (MSGBs) and in peripheral lymphocytes of pSS patients; 2) to explore any correlation among P2X7 receptor, the other components of the inflammasome (i.e.NLRP3, caspase-1) and salivary levels of the released IL-18; 3) to correlate P2X7 receptor to patients clinico-serological and histopathological features

Methods: Consecutive patients with a diagnosis of pSS (AECG criteria) were enrolled in this proof of concept study. The control group consisted of subjects with suspected SS who did not fulfill the AECG criteria for pSS. Analysis of P2X7R, NLRP3 and caspase-1 gene expression was performed by real-time PCR on an ABI PRISM 7900 sequence detector (Applied Biosystems). Levels of IL-18 were assessed in patients unstimulated whole saliva by Western blot. Patients' clinico-serological and histopathological data were prospectively collected. For statistical comparisons, the t-test, the chi square test and logistic regression analysis were employed. P-values <0.05 were considered significant.

Results: Out of the 36 consecutive patients included in the study, 21/36 met the AECG criteria for pSS while the other 15/36 no-SS represented the control group. The P2X7R-mRNA was represented in MSGBs and in peripheral lymphocytes of both pSS and no-SS but its expression was significantly higher in pSS subjects than in no-SS control group (MSGBs p<0.0001; peripheral lymphocytes p=0.002). Similarly NLRP3 (p=0.0002) and caspase-1 (p=0.0004) gene expression was significantly higher in pSS and this was paralleled by an increased expression of IL-18 in pSS salivary samples. The P2X7R-mRNA was significantly higher in pSS patients with positivity for anti-Ro/SSA (p<0.0001) and correlated with MSGBs focus score (p=0.01).

Conclusion: This study suggests a potential involvement of the P2X7R/inflammasome-caspase-1- IL-18 axis in the pathogenesis of pSS exocrinopathy and opens novel opportunities for studying the complex mechanisms underlying pSS.

S100A8/A9 Is Upregulated and Triggers the Secretion of Pro-Inflammatory Cytokines in Primary Sjögren's Syndrome. Laura Weichselbaum[1] and Muhammad S. Soyfoo[2]. [1]Department of rheumatology,Hôpital Erasme, Brussels, Belgium, [2]Hôpital Erasme,Université Libre de Bruxelles, Brussels, Belgium

Background/Purpose: To determine the involvement of S100A8/A9 in the pathogenesis of primary Sjögren's syndrome (pSS)

Methods: The serum levels of S100A8/A9, IL-17A and IL-17C were determined by ELISA. The expression of S100A8/A9, TLR4, IL-17A, IL-17C, IL-17RA, IL-17RC and IL-17RE was assessed by immunohisto-chemistry. PBMCs were isolated from 10 pSS patients and 10 healthy controls, stimulated with increasing concentrations of S100A8/A9 and interferon-γ. The cytokine profile was next investigated by flow cytometry and ELISA.

Results: Serum levels of S100A8/A9 were increased in pSS patients compared to controls. The expressions of S100A8/A9, TLR4, IL-17A, IL-17C, IL-17RA, IL-17RC, IL-17RE were enhanced in the salivary glands of pSS patients. No significant serum levels of IL-17A and IL-17C were detected in both groups of patients. S100A8/A9 significantly increased the production of TNF-α and IL-1β in pSS patients. We observed increased production of IL-17A following stimulation with S100A8/A9 but not achieving statistical significance. No secretion of IL-17C was detected upon PBMC's stimulation by S100A8/A9. Moreover, S100A8/A9 with IFN-γ synergistically increased significantly the production of TNF-α and IL-1β.

Conclusion: S100A8/A9 is increased in pSS and contributed to the increased production of TNF-α and IL-1β alone and in synergy with IFN-γ. S100A8/A9 induced the secretion of IL-17A in controls and pSS patients. IL-17A, IL-17C and their respective receptors were upregulated in the salivary glands of pSS patients.

Developmen and Validation of a New Instrument to Asess Health Related Quality of Life in Psoriasis Arthritis: The Vitacora Questionnaire. Juan Carlos Torre-Alonso[1], J. Santos-Rey[2], JM Ruiz-Martin[3], P. Valdazo-De Diego[4], Mireia Moreno[5] and Juan-Antonio Fernández[6]. [1]Hospital Monte Naranco, Oviedo, Spain, [2]Rheumatology, Toledo, Spain, [3]Rheumatology, Viladecans, Spain, [4]Rheumatology, Zamora, Spain, [5]Corporació Sanitària Parc Taulí, Sabadell, Spain, [6]MP, Oviedo, Spain

Background/Purpose: To develop and validate a specific questionnaire to measure health-related quality of life (HRQoL) in adults with psoriasis arthritis (PA) for use in clinical studies and clinical practice.

Methods: Item selection was generated through an extensive literature review, the experience of patients with PA, and discussion with PA expert rheumatologists. Item reduction was performed using clinimetric and psychometric approaches after administration of the item selection to 66 PA patients. The resulting questionnaire, named VITACORA, consists of 19 items. The factorial analysis explained its unidimensionality and an overall HRQoL score. Internal consistency, test–retest (10 days) reliability, sensitivity analysis, known groups and convergent validity were tested in a prospective, observational, multicenter study conducted in 10 Spanish hospitals with 323 subjects, who also completed the Euro-QoL 5 Dimensional questionnaire (EQ-5D) and a health status transition item. Three study groups were defined: group A (n=209) comprised PA patients; group B (n=71) comprised patients with arthritis no psoriasis; and group C (n=43) comprised healthy people. All subjects attended baseline visit and group A patients also test-retest and final visits (10 days and 6 months later, respectively).

Results: VITACORA questionnaire was considered easy or very easy to answer by 94.7% of PA patients. Missing response rate was less than 3.8% in all questionnaire items. Floor and ceiling effects were less than 2% for the overall score. Cronbach's alpha values and intraclass correlation coefficient values for the overall score exceeded 0.90. Statistically significant differences (p<0.001) were observed on the overall score between groups: subjects from group C (healthy people, mean overall score 93.7, SD 9.1) had a better HRQoL, following from group B (patients with arthritis no psoriasis, mean overall score 69.2, SD 24.8), and finally group A (PA patients, mean overall score 56.2, SD 24.8) had the worse HRQoL. As expected, the VITACORA scores showed significant correlations (p<0.001) to EQ-5D and to perceived health state scores. Likewise, lower correlations to clinical variables were found. At follow-up, the VITACORA scores showed significant correlations to health state change reported by PA patients and investigators. Effect sizes for the global score changes between two study visits (baseline and 6 months later) among PA patients ranged from 0.20 to 0.80, reporting an improvement in health status. The minimum important difference was established as an 8-point change in the global VITACORA score.

Conclusion: This new, developed instrument to measure HRQoL in PA patients has shown good reliability, validity, and sensitivity to change. It has also proved easy to use and administer in daily clinical practice and future research projects.

The Prevalance of Autoimmune Thyroid Disfunction in Ankylosing Spondylitis. Hakan Emmungil[1], Mehmet Erdogan[2], Melike Kalfa[1], Gonca Karabulut[1], Hayriye Kocanaogullari[1], Vedat Inal[1], Yasemin Kabasakal[3], Fahrettin Oksel[3], Kenan Aksu[4] and Gokhan Keser[1]. [1]Dept. of Internal Medicine, Division of Rheumatology, Ege University, Izmir, Turkey, [2]Dept. of Internal Medicine, Division of Endocrinolgy, Ege University, Izmir, Turkey, [3]Ege University, Izmir, Turkey, [4]Dept. Of Internal Medicine, Division of Rheumatology, Ege University, Izmir, Turkey

Background/Purpose: Although the association of autoimmune thyroid dysfunction and primary Sjögren's syndrome (SjS) is well known, it is less clear whether a similar relationship also exists between autoimmune thyroid dysfunction and ankylosing spondylitis (AS). Therefore, we aimed to define the frequency of autoimmune thyroid dysfunction in patients with AS, to find out whether the frequency was significantly different from the healthy controls.

Methods: Eighty patients with AS (mean age: 40.57 ± 10.13 years; M/F: 50/30) fulfilling the 1984 Modified New York Criteria and 80 healthy subjects, age and sex-matched with AS patients were included. As the positive control group, 62 female patients with primary SjS (mean age: 50.27 ± 10.84 years) fulfilling the diagnostic criteria of the European Consensus Group were also studied. All cases underwent thyroid ultrasonography by a single endocrinologist to evaluate the size, nodularity and homogeneity of the thyroid gland. Besides, serum free triiodothyronine (fT3), thyroxine (fT4), thyroid-stimulating hormone (TSH), and thyroid autoantibodies were measured. The diagnosis of Hashimoto's thyroiditis was made only if the patient had thyroid autoantibody positivity plus at least one of the following criteria, namely diffuse goiter with physical examination, abnormality in thyroid function tests and ultrasonographic thyroid hypoechogenicity. Statistical analysis was performed with SPSS.15 for Windows. The chi-squared test and Fisher's exact test, when appropriate, were used to compare cases and controls. p values < 0.05 were considered statistically significant.

Results: The frequency of Hashimoto's thyroiditis was significantly higher in patients with AS compared with age and sex-matched healthy controls (10% vs 1.3% p: 0.034). Similarly, the frequencies of any thyroid autoantibody positivity (13.8% vs 2.5% p: 0.017) and ultrasonographic thyroid hypoechogenicity (30% vs 11.3% p: 0.045) were also significantly higher in AS group. Other parameters such as thyroid gland volume and nodularity, and thyroid function tests did not differ significantly between AS and healthy control groups. As expected, frequencies of Hashimoto's thyroiditis, thyroid autoantibodies and thyroid hypoechogenicity were highest in primary SjS group, however differences did not reach to statistically significant levels between the SjS and AS groups.

Conclusion: The present study showed that the frequency of autoimmune thyroid dysfunction was significantly higher in AS group, compared with healthy controls. It should be kept in mind that, patients with AS may have concomitant autoimmune thyroid dysfunction, and in case of clinical suspicion, such patients should be further evaluated with clinical and laboratory parameters.

NT-Probnp and Inflammation in Active Ankylosing Spondylitis Receiving TNF Blockers: Is There a Link? Julio C. B. Moraes[1], Ana C. M. Ribeiro[2], Carla G.S. Saad[3], Alessandro C. Lianza[4], Nadia E. Aikawa[2], Clovis Artur Silva[5] and Eloisa Bonfa[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]University of Sao Paulo, São Paulo, Brazil, [4]Radiology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [5]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Cardiovascular disease plays a central role in morbidity and mortality in rheumatic patients. N-terminal pro-brain natri-uretic peptide (NT-proBNP) is a strong marker of cardiovascular risk with recent evidence that inflammation may also influence its levels. The discrimination of this confounding variable is of particular interest in rheumatic diseases. Therefore, we evaluated NT-proBNP in ankylosing spondylitis (AS) patients pre- and post-TNF blockage therapy to determine the possible association between NT-proBNP levels and inflammatory parameters.

Methods: Forty-five consecutive AS patients without previous/current cardiovascular disease or systolic myocardial dysfunction, who were eligible to anti-TNF therapy, were prospectively enrolled. All patients received TNF blockers (infliximab, adalimumab and etanercept in their regular schedule) and they were evaluated for circulating NT-proBNP levels, clinical and laboratory parameters of disease activity including BASDAI, ASDAS, ESR and CRP, traditional cardiovascular risk factors including blood pressure, body mass index, waist circumference and dyslipidemia; conventional and tissue Doppler imaging echocardiography and treatment data at baseline (BL) and six months after (6M). Statistical analysis included: Spearman rank order correlation, Mann-Whitney test or t-test to observe differences between patients with high or normal NT-proBNP levels at BL; paired-sample t tests or the Wilcoxon signed-rank test to observe differences between measurements at BL and 6M; Fisher exact test to compare categorical variables and multivariable linear regression analysis. All analyses used a two-sided significance level of 0.05.

Results: At BL, all patients had active AS, NT-proBNP levels had a median of 36 (20–72)pg/ml and 11% were high in spite of no systolic alteration. Multiple linear regression analysis revealed that this peptide, at BL, was independently correlated with ESR (p<0.001), age (p=0.01) and pulse pressure (p=0.01). After 6M, all disease parameters improved and NT-proBNP levels were significantly reduced [24 (16–47) pg/mL, p=0.037] compared to BL. Changes in NT-proBNP were positively correlated with ESR changes (r=0.41, p=0.006). Cardiovascular risk factors remained stable during follow-up.

Conclusion: Elevations of NT-proBNP should be interpreted with caution in active AS patients with no evidence of cardiovascular disease. The short-term reduction of NT-proBNP levels in these patients treated with anti-TNF therapy appears to reflect an improvement in inflammatory status. (ClinicalTrials.govnumber:NCT01072058).

Increased Risk of Acute and Chronic Renal Comorbidity in Ankylosing Spondylitis: Results From a Population-Based Study. Walter P. Maksymowych[1], Shelagh Szabo[2], Sumati Rao[3], M. Cifaldi[3] and AR Levy[4]. [1]University of Alberta, Edmonton, AB, [2]Oxford Outcomes, Vancouver, BC, [3]Abbott Laboratories, Abbott Park, IL, [4]Oxford Outcomes Ltd, Vancouver, BC

Background/Purpose: Clinical evidence points to an increased risk of renal comorbidity in ankylosing spondylitis (AS) compared to the general population. However, there are no population-based estimates available in the literature. An increased risk of renal comorbidity would have substantial implications for the monitoring and treatment of AS because the mainstay of pharmacological treatment is the use of non-steroidal anti-inflammatory agents (NSAIDs). We aimed to estimate the prevalence and age- and sex-standardized increased risk of renal comorbidity, including acute and chronic kidney disease, and amyloidosis in a population-based cohort of persons diagnosed with AS in Québec between 1996 and 2006, compared to the general population.

Methods: A retrospective cohort study was conducted using the administrative physician-billing database of the Régie de l'Assurance Maladie du Québec. The cohort included individuals with at least one International Classification of Diseases, 9th Revision (ICD-9) billing code for AS between 1996 and 2006. A comparison cohort was generated using a 1% random sample of individuals without AS. Renal complications were identified by ICD-9 codes for amyloidosis, hypertensive chronic renal disease, acute and chronic renal disease. Age- and sex-stratified prevalence, and standardized prevalence ratios with 95% confidence intervals (CI), of renal complications in AS compared with the general population were calculated. Sensitivity analysis was conducted using two ICD-9 codes for AS.

Results: There were 8,616 individuals identified with AS; 56% were male and the median age at diagnosis was 42 years. Overall, renal complications were diagnosed among 3.4% and 2.1% of males and females with AS, compared to 2.0% and 1.6% of males and females in the general population cohort, respectively. Prevalence of renal complications increased with age in both the AS and general population cohort. Age- and sex-stratified prevalence ratios, comparing the risk of renal complications among those with AS to the general population, demonstrated a significantly excess risk of renal complications that was highest among younger individuals with AS. Overall, individuals with AS were at a significantly increased risk of renal complications compared to members of the general population (irrespective of a coding for hypertension), with a standardized prevalence ratio of 1.7 (1.5–2.0). Standardized prevalence ratios were 6.0 (2.0–18.0) for amyloidosis, 1.7 (1.4–2.0) for chronic kidney disease, 3.2 (0.8 – 12.4) for hypertensive kidney disease, and 1.9 (1.5 – 2.3) for acute kidney disease. The excess risk was highest among younger individuals with AS, and results were similar when two ICD-9 codes were used to identify AS.

Conclusion: This population-based analysis shows that individuals with AS are at increased risk of many types of renal complications, including acute kidney disease, with the point estimates of excess risk being greatest among younger individuals. These data highlight the importance of careful monitoring for renal complications among those with AS, particularly during long-term continuous use of NSAIDs.

Reduced Joint Counts Misclassify Psoriatic Arthritis Patients with Oligoarthritis and Miss Significant Active Disease. Laura C. Coates[1], Oliver M. FitzGerald[2], Dafna D. Gladman Gladman[3], Neil J. McHugh[4], Philip Mease[5], Vibeke Strand[6], Philip S. Helliwell[7] and GRAPPA Composite Exercise (GRACE) collaboration[8]. [1]Division of Rheumatic and Musculoskeletal Disease, Leeds, United Kingdom, [2]St. Vincent's Univ Hospital, Dublin, Ireland, [3]Toronto Western Hospital and University of Toronto, Toronto, ON, [4]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [5]Swedish Medical Center, Seattle, WA, [6]Stanford University, Portola Valley, CA, [7]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [8]Leeds

Background/Purpose: Despite recommendations to use full joint counts to assess patients with PsA, reduced joint counts designed for RA are often used for reporting outcomes in PsA registry studies and are used in clinical practice to assess patients with PsA. Analysis of RCTs suggested that 28 joint counts were responsive in PsA but this analysis was based on polyarticular patients enrolled into drug trials. The aim of this analysis was to investigate full and reduced joint counts in patients with oligoarticular PsA.

Methods: The study was an analysis of baseline visits for patients in the GRACE study, an international observational cohort recruited to develop new outcome measure in PsA. Oligoarthritis was defined as less than 5 tender and swollen joints. At baseline, full 66/68 tender and swollen joint counts were assessed. Active joint counts were calculated with an active joint defined as either tender and/or swollen. Reduced joint counts used for RA including the 28 and 44 joint count were analysed for comparison. In addition, new proposed shortened joint counts for PsA were tested to investigate their possible future use: PsA-44 (elbows, wrists, MCPs, PIPs, DIPs, knees and MTPs) and PsA-56 (as before plus ankles and PIP toes). ROC analysis was used to see how well different joint counts predicted treatment change for high disease activity. The proportion of patients with active disease missed by reduced joint counts was also analysed.

Results: In the cohort of 503 patients, 270 were classified as oligoarthritis. ROC analysis revealed that tender or active joint counts did not predict treatment change for high disease activity even when using a full 66/68 joint count (tender: AUC 0.56,p=0.18, active: AUC 0.55,p=0.23). A 66 SJC did predict treatment change (AUC 0.60, p=0.018) as did the SJC PsA44 and PsA56 (p<0.04). Neither of the RA reduced joint counts showed a significant relationship with treatment change. Of the 270 patients, 164 patients did not have any tender joints identified on a 28 joint count. However, of these 164, 38 did have 1 or more tender joints that had been missed (23%), leaving 126 patients with no tender joints. The PsA-44 and PsA-56 missed tender joints in 18 and 7 patients respectively. When considering swollen joints, 256 patients did not have any swollen joints identified on a 28 joint count but 48 of these (19%) did have swollen joints elsewhere. The PsA-44 and PsA-56 missed swollen joints in 26 and 7 patients respectively.

Conclusion: Patients with oligoarticular PsA cannot be assessed using joint counts borrowed from RA. Ideally full joint counts should be performed to assess PsA patients with the 66/68 joint count being the preferred measure due to difficulties distinguishing between the PIPs and DIPs of the toes. Reduced joint counts designed specifically for PsA do show correlation with treatment change but can still underestimate disease activity.

Psoriasis and Psoriatic Arthritis in a Diverse Ethnic Cohort. Gail S. Kerr[1], Seema Qaiyumi[2], John S. Richards[2], Chesahna Kindred[3], Sean A. Whelton[4] and Florina M. Constantinescu[5]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]Washington DC VA and Georgetown University, Washington, DC, [3]Howard University Hospital, Washington, DC, [4]Georgetown University, Washington, DC, [5]Washington Hospital Center, Washington, DC

Background/Purpose: Few clinical studies describe psoriasis (PSO) and psoriatic arthritis (PsA) in ethnic minority groups. Previous patient-reported data show PSO/PsA to be less frequent in African Americans (AA) compared to Caucasians, but of equal severity. We describe the clinical characteristics of a diverse ethnic cohort of patients with PSO and PsA in an urban setting.

Methods: IRB consented patients with PSO diagnosed by a dermatologist and PsA satisfying CASPAR criteria, were enrolled from 4 academic outpatient clinics. Socio-demographic data, disease duration, time to diagnosis, disease phenotype and activity, quality of life measures, comorbidities, use of disease modifying anti-rheumatic drugs (DMARD) and biologic therapies were recorded.

Results: There were 160 PSO/PsA patients enrolled; 41.9% were non-Caucasian, 90% of whom were AA (Table). Mean PSO and PsA disease duration was 18.1 (SD14.3) and 13.3 (SD10.9) years, respectively. Mean BMI was 30.3 (SD5.7) kg/m^2 and PsA patients had a mean DAS28 of 2.7 (SD1.7). Non-Caucasians had worse PASI scores. Compared to Caucasians, AA had a lower frequency of PsA, worse SF-36 mental component and psoriasis related quality of life scores, received less years of education, had lower frequencies of private insurance coverage, DMARD and biologic use, and lower Vitamin D levels. AA also had higher frequencies of tobacco use, hypertension, diabetes, hyperlipidemia and cerebrovascular accidents. There were no differences in alcohol use, uric acid levels or other psoriatic disease-related parameters.

Variable, n (%)	Cohort	Caucasian	Non Caucasian**	African American	p-value

* Indicates corresponding p-value
** Includes African American, Hispanic and Asian

Conclusion: Compared to Caucasians, African Americans had less frequent PsA but experienced greater impact on quality of life from psoriatic disease. Improved implementation and evaluation of disease activity and quality of life measures are needed in psoriatic disease, particularly in African American patients. Ours is the first study to use validated clinical measures to describe psoriatic disease in a diverse ethnic cohort.

The Association of alpha7 Nicotinic Acetylcholine Receptor Polymorphisms with Psoriatic Arthritis and Its Interaction with Smoking. Lihi Eder[1], Vinod Chandran[2], Fawnda Pellett[2], Remy Pollock[2], Fatima Abji[2], Adele Carty[2], Sutharshini Shanmugarajah[2], Cheryl Rosen[2] and D. D. Gladman[2]. [1]Carmel Medical Center, Haifa, Israel, [2]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Alpha7 nicotinic acetylcholine receptor (CHRNA7) is an ion channel that is gated by the binding of nicotinic ligands. Nicotine interacts with CHRNA7 leading to down-regulation of intracellular pro-inflammatory pathways. It has been suggested that smoking may protect against the development of PsA among patients with psoriasis. We aimed to study the association of *CHRNA7* gene polymorphisms with PsA and their interaction with smoking.

Methods: We genotyped three groups of Caucasian individuals: patients with PsA, patients with psoriasis without arthritis (PsC) and healthy controls, for the following Single Nucleotide Polymorphisms (SNPs): rs904952, rs6494223, rs12915265, rs3826029 and rs6494165 within the *CHRNA7* locus. PsA patients satisfied the CASPAR criteria. The psoriasis patients were assessed by a rheumatologist to rule out inflammatory arthritis. The control DNA was from a commercial bio-bank. Smoking status was defined as current smoker for smokers and lifetime non-smoker for non-smokers. SNP genotyping was performed using Taqman SNP Genotyping Assays run on an ABI 7900HT Real-Time PCR system. The differences in allelic and genotype distributions were compared by Chi square test and trend test using PLINK software. The frequencies of rs6494223*TT/C genotypes were then compared across the patient groups within smokers and non-smokers and the interaction term of genotype and smoking was tested using logistic regression analysis.

Results: 238 PsA patients, 219 PsC patients and 210 healthy controls were included in the study. A significant inverse association was found between the rs6494223*T/C genotype and PsA (Table 1) compared to PsC (p=0.01) and to healthy controls (p=0.01), although no significant association was found between the minor allele rs6494223*T and PsA compared to PsC (p=0.14) and to healthy controls (p=0.26). Among smokers, the minor allele rs6494223*T was inversely associated with PsA compared to PsC (Odds Ratio (OR) 0.65, p[-allele]=0.04, p[-genotype]=0.02) and to healthy controls (OR 0.63, p[-allele]=0.02, p[-genotype]=0.004). Among non-smokers, the association between rs6494223*T and PsA compared to PsC and to healthy controls was not significant (p[-allele] =0.79 and 0.54, respectively). A statistically significant interaction between smoking status and rs6494223*TT genotype was found when PsA patients were compared to healthy controls (p=0.02). The remaining SNPs were not found to be associated with PsA compared to either PsC patients or to healthy controls in the entire study population and after stratification by smoking status.

Table 1. The association between rs6494223*T/C genotype and PsA vs. PsC and healthy controls by smoking status

		PsA	PsC	P allele	P genotype	Control	P allele	P genotype
All	TT	24 (10.1%)	43 (19.7%)	0.14	0.01	39 (19.1%)	0.26	0.01
	TC	137 (57.8%)	105 (48.2%)			96 (47.1%)		
	CC	76 (32.1%)	70 (32.1%)			69 (33.8%)		
Smoker	TT	6 (6.5%)	27 (29.6%)	0.04	0.02	26 (23.9%)	0.02	0.004
	TC	53 (57.6%)	45 (49.5%)			49 (45%)		
	CC	33 (35.9%)	19 (20.9%)			34 (31.1%)		
Non-Smoker	TT	18 (12.3%)	24 (18.9%)	0.79	0.14	13 (13.4%)	0.54	0.47
	TC	85 (58.2%)	60 (47.2%)			49 (50.5%)		
	CC	43 (29.5%)	43 (33.9%)			35 (36.1%)		

Conclusion: A *CHRNA7* gene polymorphism is associated with PsA. The rs649223*TT genotype may protect against the development of PsA particularly among smokers. This effect was not significant among non-smokers. This finding may explain why psoriasis patients who smoke are less likely to develop PsA.

Association Between Biomarkers (Metalloproteinase-3, Dikkopf-1 and Sclerostin) with Disease Activity and Prediction of Anti-TNFα Therapy Response in Patients with Ankylosing Spondylitis. Victoria Navarro-Compán, Rafael Ariza, Rufino Mondéjar-García, Virginia Moreira-Navarrete, Enrique Melguizo-Madrid, Blanca Hernández-Cruz, Concepción González-Rodríguez and Federico Navarro-Sarabia. University Hospital Virgen Macarena, Sevilla, Spain

Background/Purpose: Better objectives measures for evaluating disease activity and anti-TNFα response in patients with ankylosing spondylitis (AS) are needed. MMP-3 seems to be the most promising biomarker but published data are not conclusive. The aim of this study was to investigate the association between serum biomarkers (MMP-3, DKK-1 and sclerostin) levels with disease activity parameters and to evaluate if these biomarkers are useful to predict anti-TNFα response in patients with AS.

Methods: From November 2010 to July 2011, consecutive patients with AS (New York criteria) who initiated anti-TNFα therapy in a University hospital were included. Before and after 3 months of therapy, disease activity was measured using BASDAI, ASDAScrp, CRP, patient's VAS of pain and patient's and physician's VAS of global disease activity (GDA). Blood samples for determination of serum levels of biomarkers by enzyme immunoassay were also collected at both visits. Spearman correlation test was used to evaluate association between biomarkers and disease activity parameters. Biomarkers change was compared in responders versus non-responders, based on BASDAI50 and ASDAS response using Mann-Whitney U test. Accuracy to predict response (ROC analysis) was performed.

Results: Twenty AS patients were included; 80% received adalimumab and 20% received etanercept. Median (IQR) age and disease duration were 42.4 (31–49) years and 6.8 (3–10) years, respectively; 86% were men, and 83% HLA-B27 positive. Inverse correlation between patient's VAS pain and MMP-3 at baseline was the only significant observed correlation between investigated biomarkers and disease activity parameters (table 1). MMP-3 levels decreased only in patients who responded to anti-TNF therapy but increased in patients who did not response (table 2). Baseline biomarkers serum levels (including CRP) for both groups were similar except for MMP-3 (122.9 vs 58.9; p<0.05). The area under the curve for MMP-3 to predict BASDAI50 and ASDAS response was 0.73 and 0.78, respectively. The best cut-off was established for levels higher than 59.5, with sensibility of 79–85% and specificity of 50–57%.

Table 1. Correlation between serum levels of biomarkers with disease activity parameters.

	BASDAI	ASDAScrp	Pt GDA	Pt VAS pain	Phy GDA	CRP
At baseline						
MMP-3	−0.318	−0.086	−0.334	−0.477*	−0.551	0.222
DKK-1	−0.017	−0.045	0.003	0.149	0.234	0.107
SOST	−0.096	−0.039	−0.074	0.066	−0.154	0.002
CRP	−0.288	0.577**	0.122	0.039	0.032	1.000
After 3 months						
MMP-3	−0.135	−0.144	−0.169	−0.154	−0.156	−0.024
DKK-1	−0.007	0.168	0.155	0.179	0.270	0.296
SOST	−0.006	0.114	0.306	0.166	0.427	0.172
CRP	0.003	0.457*	0.177	0.173	0.266	1.000

* p<0.05 ** p<0.01

Table 2. Change in serum levels of MMP-3, DKK-1, sclerostin and CRP after 3 months of anti-TNFα therapy based on the clinical response.

	Responders N=13 (65%)			Non−responders N=7 (35%)		
	Baseline	3 months	p	Baseline	3 months	p
MMP-3 (ng/dl)	122.2	64.1	0.01	58.9	75.5	0.6
DKK-1 (ng/dl)	6.9	8.1	0.6	7.3	6.7	0.6
SOST (pmol/dl)	23.6	23.4	0.9	18.1	21.3	0.2
CRP (mg/l)	16.3	4.0	0.002	8.3	5.3	0.3

Conclusion: No correlation was observed between serum levels of MMP-3, DKK-1 and sclerostin and disease activity parameters in patients with AS. Serum levels of MMP-3 may be useful to predict response to anti-TNFα therapy in patients with AS.

Efficacy and Safety of Adalimumab for the Treatment of Peripheral Arthritis in Spondyloarthritis Patients without Ankylosing Spondylitis or Psoriatic Arthritis. Jacqueline E. Paramarta, Leen De Rycke, Tanja F. Heijda, Carmen A. Ambarus, Koen Vos, Huib J. Dinant, Paul P. Tak and Dominique L. Baeten. Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: The treatment of spondyloarthritis (SpA) has improved dramatically since the introduction of TNF-blockade. However, this therapy is only approved and reimbursed for the treatment of ankylosing spondylitis (AS) and psoriatic arthritis (PsA), which are the best described and studied phenotypic subtypes of SpA. Approximately one third of the SpA population can not be classified as AS or PsA. Randomized clinical trials (RCTs) in non-radiographic axial SpA have recently been performed and showed good results, but for peripheral non-AS, non-PsA SpA patients RCTs are lacking. This study aimed to assess the efficacy and safety of adalimumab in patients with peripheral SpA not fulfilling the criteria for AS or PsA.

Methods: Forty patients with active peripheral SpA fulfilling the ESSG or Amor criteria but not the criteria for AS or PsA were included in a randomized, double-blind, placebo-controlled clinical trial. Patients were treated 1:1 with adalimumab or placebo for 12 weeks, followed by an open label extension up to week 24. Safety and efficacy measurements were performed every 6 weeks, with as primary endpoint the patient's global assessment of disease activity at week 12.

Results: The baseline demographic and disease characteristics were similar across both treatment arms, except for HLA-B27 positivity which tended to be higher in the adalimumab group (55%) versus the placebo group (25%) (P=0.053), and the physician's global assessment of disease activity which was somewhat higher in the placebo (57.0 $\pm$ 12.6 mm) versus the adalimumab treated patients (47.8 $\pm$ 11.8 mm) (P=0.022). At week 12 the patient's and physician's global assessment of disease activity, swollen joint count, BASDAI, ASDAS and ESR improved significantly in the adalimumab group compared with the baseline values and compared with placebo (Table 1). A similar improvement was seen upon adalimumab treatment from week 12 to 24 in the patients originally randomized to placebo, whereas the clinical response was maintained or even augmented at week 24 in the patients who received adalimumab from the beginning. ASDAS inactive disease and BASDAI50 responses were met in 42% of the adalimumab group versus 0–5% in the placebo group at week 12 (P=0.001 and P=0.008 respectively), and were further increased at week 24. Quality of life and disability scores also improved upon adalimumab treatment. Multiple regression analysis showed that features such as gender, HLA-B27 status and concomitant DMARD treatment did not act as confounders in this trial. The number of adverse events was not different between the adalimumab and placebo group.

Table 1. Mean changes in disease activity from baseline to week 12 by treatment group

| | Baseline to week 12 | | |
	Adalimumab	Placebo	*P*-value
Patient's global assessment, 0–100 mm VAS	−31.0 (23.3)	−5.9 (21.4)	0.001
Physician's global assessment, 0–100 mm VAS	−19.8 (19.5)	−4.1 (16.4)	0.011
Swollen joint count, 0–66 joints	−2.5 (4.0)	−0.4 (1.8)	0.046
Tender joint count, 0–68 joints	−1.8 (9.2)	1.7 (6.5)	0.174
BASDAI	−1.8 (2.6)	−0.3 (1.5)	0.030
ASDAS	−1.0 (1.0)	−0.1 (0.6)	0.003
CRP, mg/l	−5.7 (12.4)	4.0 (22.9)	0.112
ESR, mm/hour	−6.0 (12.5)	1.7 (9.3)	0.039

Values are the mean change (standard deviation) from baseline to week 12.
Significance of the comparisons is determined by an independent sample t-test.

Conclusion: Adalimumab is effective and safe in SpA patients with active peripheral disease, also in those patients not fulfilling the AS or PsA criteria. Therefore, this treatment should be considered and made available for these patients when their peripheral SpA is refractory to conventional treatments.

The Predictors of Reduced Work Productivity in Patients with Psoriatic Arthritis. Anjali Papneja[1], Matthew Kennedy[2], Arane Thavaneswaran[3], Daniel Pereira[3], Vinod Chandran[3] and Dafna D. Gladman[3]. [1]University of Toronto, Toronto, ON, [2]University of Toronto, TOronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Psoriatic arthritis (PsA) is a unique inflammatory musculoskeletal disorder associated with psoriasis. Related to its detrimental impact on health and quality of life, PsA patients have also been affected with reduced work productivity. Work productivity is an essential determinant of health because it affects a patient's physical and psychological wellbeing. The purpose of this study was to identify the factors that predict reduced work productivity, as measured by the Work Limitations Questionnaire (WLQ), among patients with PsA. These predictors can be divided into demographic factors, clinical factors, and work related factors.

Methods: Patients attending a single centre Psoriatic Arthritis Clinic were recruited for participation. Employed participants (including home makers) first completed a Questionnaire for the Assessment of Work Related Factors (QAWRF), to shed light upon the nature of their work. Eligible participants then completed the WLQ. The WLQ scores were used as the dependent variable in a linear regression analysis. The independent variables assessed in this study included work characteristics, demographic factors, and clinical measures, such as PASI, active joint count, damage joint count, and ESR.

Results: 152 patients participated (53% males) with a mean age of 50.7 years, disease duration of 14.6 years, and 85.6% with a post-secondary school education. The mean actively inflamed joint count was 5.3. The damage joint count was 10.4. The mean PASI was 3.2. All patients completed the WLQ, of whom 137 completed both the WLQ and the QAWRF. 18.8% of patients lost 1 or more full days at work and 28.3% lost 1 or more partial work days, due to their health. On both univariate and multivariate linear regression education status, PASI, active joint count, and ESR were associated with reduced work productivity among working PsA patients. Support in the workplace was negatively correlated with reduced work limitations.

Table 1. Univariate and multivariate linear regression to determine associates of WLQ (N=137)

| | Univariate Model | | Multivariate Models | | | |
| | | | Full Model | | Reduced Model | |
Covariate	Estimate	P-value	Estimate	P-value	Estimate	P-value
Age at visit	0.06	0.1543	0.03	0.56	–	–
Sex	−3.89	<0.0001	−1.28	0.18	–	–
Duration of PsA	−0.04	0.41	−0.08	0.11	–	–
Education status	−2.96	0.026	−2.57	0.03	−3.13	0.0003
PASI	0.25	0.061	0.26	0.03	0.27	0.017
Active joint count	0.36	<0.0001	0.33	<0.001	0.33	<0.0001
Damage joint count	−0.007	0.87	0.06	0.13	–	–
ESR	0.19	<0.0001	0.07	0.09	0.096	0.012
Physical labour work	0.50	0.1521	−0.19	0.61	–	–
Control work schedule	−0.38	0.2440	−0.06	0.87	–	–
Support at work	−1.32	0.0002	−0.35	0.38	–	–

Conclusion: Work productivity is associated with demographic, clinical, and work related factors. This endorses the use of an effective drug to control disease activity and advocates for a more supportive work environment for these patients.

Prevalence of Sacroiliitis in the General Population: Comparative Analysis with Cutaneous Psoriasis and Psoriatic Arthritis. Jose Luis Fernandez-Sueiro[1], Carlos Fernandez-Lopez[1], S. Pertega-Diaz[1], JA Pinto[1], E. Gonzalez[1], Francisco J. de Toro-Santos[1] and Francisco J. Blanco[2]. [1]Complejo Hospitalario Universitario La Coruña, La Coruña, Spain, [2]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain

Background/Purpose: At least grade 2 unilateral sacroiliitis in the presence of spinal symptoms (defined as a combination of inflammatory back pain plus back stiffness) in our criteria allows to classify axial psoriatic arthritis (axPsA). However it is unknown to what extent this sacroiliac involvement is specific for axPsA. The objecive was to determine the prevalence of at least grade II unilateral radiological sacroiliitis in the general population, cutaneous psoriasis and PsA.

Methods: Descriptive cross sectional study of 3 cohorts: a) general population: consecutive digitalized pelvis x ray films taken to patients that acceded to the emergency room of the Complexo Hospitalario Universitario A Coruña (CHUAC) between January-March 2010 for spinal pain (1174 x-rays out of 928 patients, 621 patients met inclusion criteria for the analysis), b) patients of a follow up cohort of cutaneous psoriasis (Ps) (n=106), c) PsA patients from CHUAC (n=168) and Complexo Hospitalario Universitario de Orense (CHOU) (n=89). X ray films were red independently by two expert's rheumatologist, x ray films were discarded if: absence of vision of both sacroiliac joints, blurred x rays, age <18 years old, prosthesis, dysplasia, Paget's disease and osteitis condensans ilii. If there was a discrepancy consensus was reached between both readers. Prevalence of sacroiliitis, together with its 95% confidence interval (CI), was estimated in each cohort. Odds ratio and prevalence ratio values were estimated from a multivariate logistic regression model, adjusted by age and gender.

Results: 621 sacroiliac x-rays in the general population, 106 in Ps and 257 in PsA were analysed. Medium age was 58,7±20,1, 54,6±13,1 and 54,6±15,9 years, respectively. The percentage of males in each cohort was 43%, 39,6% y 63%, respectively. Prevalence of at least unilateral grade II sacroiliitis or higher was significantly higher in Ps (16,0%; 95% IC: 8,6%–23,5%) and in PsA (34,2%; 95% IC: 28,2%–40,2%) than in the general population (0,6%; 95% IC: 0,2%–1,6%). Logistic regression analysis showed that the prevalence of sacroiliitis was significantly higher in Ps (OR=35,2; p<0,001) and in PsA (OR=78,6; p<0,001) independently of age and sex. Older age (OR=1,02; p=0,016) and male sex y (OR=4,02; p<0,001) were associated to a higher prevalence of sacroiliitis.

Conclusion: The prevalence of at least grade 2 unilateral sacroiliitis or higher was 34,2% in PsA and 16% in Ps, both were higher than in the general population. Prevalence was higher in PsA than in Ps. Prevalence of sacroiliitis increased with age and male gender. These data suggest that the presence of at least grade II unilateral sacroiliitis is specific of PsA and may be used to classify a patient with axial involvement.

Validation of a Reference Imaging Module for Calibration of Readers Scoring with the Modified Stoke Ankylosing Spondylitis Spine Score. Walter P. Maksymowych[1], Thomas J. Learch[2], Robert GW Lambert[1], Michael M. Ward[3], Nigil Haroon[4], David Salonen[5], Robert D. Inman[6] and Michael H. Weisman[7]. [1]University of Alberta, Edmonton, AB, [2]Cedars-Sinai, Los Angeles, CA, [3]NIAMS/NIH, Bethesda, MD, [4]University Health Network, Toronto Western Research Institute, University of Toronto, Toronto, ON, [5]University Health Network, Toronto, ON, [6]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON, [7]Cedars-Sinai Medical Center, Los Angeles, CA

Background/Purpose: The modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) is used to assess progression in AS based on the lateral spinal radiograph but the methodology is not well standardized and the role of the lumbar antero-posterior (AP) radiograph is unclear. In the Spondyloarthritis Research Consortium of Canada (SPARCC) and the SPondyloArthritis Research and Treatment Network (SPARTAN) conjoint imaging group (SPAR) we aimed to develop and validate a reference image module to calibrate readers using the mSASSS.

Methods: The group readers comprised 5 rheumatologists and 3 musculoskeletal radiologists with special expertise in AS. We conducted the following: 1. Systematic review of the literature to identify aspects of the mSASSS requiring methodological clarity. 2. Independent assessment by 6 readers of baseline and 2 year radiographs from 25 patients with AS (exercise 1). 3. Consensus development of an imaging module (SPAR module) which clarifies definitions, scoring methodology, and a set of extensively annotated reference images. In exercise 2 the same 6 readers assessed radiographs from 39 patients with AS, which included 15 from exercise 1 (Subgroup 1), where baseline and 2 year radiographs were scored blinded to time point. Readers first scored only the lateral radiographs of the lumbar (LS) and cervical spine (CS), then only the AP radiograph, and then both radiographs simultaneously. Inter-observer reliability of the mSASSS was assessed by the intraclass correlation method (ICC).

Results: The first exercise demonstrated excellent reliability for status scores (ICC for 6 readers (range) = 0.92; Median (range) ICC for 15 reader pairs = 0.92 (0.84–0.96)) but poor reliability for change scores (ICC for 6 readers = 0.46; Median (range) for 15 reader pairs = 0.52 (0.11–0.66)). In particular, ICC for change score for the radiologist reading pair was only 0.46. In exercise 2, the ICC for change score for the radiologist reading pair improved substantially to 0.62 while improvement from 0.49 to 0.57 was also noted for the overall group in the subgroup of patients scored in both exercises. Reliability was not further enhanced when lateral and A-P radiographs were assessed simultaneously for either status or change mSASSS score. There was substantial variation between readers in the contribution of the AP radiograph to staging (mean (range) 27.2% (21.1–42.1)) and progression (mean (range) 15.4% (5.3–31.6)) and was most consistent for staging.

Exercise	All readers ICC	Radiologist pair ICC
All patients (n = 25) Exercise 1		
Status reliability	0.92	0.94
Change reliability Subgroup (n = 15)	0.46	**0.46**
Status reliability	0.93	0.98
Change reliability	**0.49**	0.64
All patients (n = 39) Exercise 2		
Status reliability	0.91	0.95
Status reliability	0.90	0.96
Change reliability	**0.57**	0.68

Conclusion: Calibration according to the standardized methodology developed for the SPAR module led to improved reliability in the scoring of the mSASSS even for expert readers. The contribution of the AP radiograph affects a substantial proportion of patients and requires further systematic study.

543

Wnt Pathway Inhibitors in Patients with Psoriatic and Rheumatoid Arthritis Treated with Anti-TNF Therapy. Agnes Szentpetery[1], Harjit P. Bhattoa[2], Peter Antal-Szalmas[2], Zoltan Szekanecz[3] and Oliver M. FitzGerald[4]. [1]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland, [2]Department of Laboratory Medicine, University of Debrecen, Medical and Health Science Center, Debrecen, Hungary, [3]Department of Rheumatology, University of Debrecen Medical and Health Sciences Center, Debrecen, Hungary, [4]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Both rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are characterised by bone erosion but aberrant bone formation is also a feature in PsA. Wnt proteins have recently been identified as key promoters of osteoblastogenesis hence new bone formation in inflammatory arthritis. Dickkopf-1 (Dkk-1) and sclerostin are natural inhibitors of Wnt signalling. Dkk-1 induces sclerostin expression by osteocytes and promotes osteoclastogenesis through suppression of osteoprotegerin (OPG). It has been shown that TNF-alpha inhibits bone formation by inducing Dkk-1 and sclerostin expression. The effect of anti-TNF on endogenous antagonists of the Wnt pathway in RA and PsA has not been studied previously in a prospective study design.

The aim of this study was to: (1) investigate serum levels of Dkk-1 and sclerostin in patients with RA and PsA; (2) compare both the very early (1 month) and more long-term (12 months) effects of anti-TNF treatment on

inhibitors of Wnt signalling; and (3) explore associations between serum levels of Dkk-1 and sclerostin and acute phase response measures.

Methods: RA and PsA patients with active disease were recruited prior to starting anti-TNF therapy. Serum levels of Dkk-1, sclerostin and OPG were measured by ELISA at baseline, 1 month and 12 months and were related to CRP levels at all time points. OPG/Dkk-1 and OPG/sclerostin ratios were calculated from previously measured OPG levels.

Results: 62 patients (35 RA, 27 PsA) were recruited with a median age of 53 years (28–74) and median disease duration of 7 years. Older age was associated with lower sclerostin levels in the entire group (r=-0.316 p= 0.023).

No significant difference in Dkk-1 and sclerostin levels was observed between RA and PsA at any time point, though Dkk-1 levels were lower in PsA at 12 months approaching significance (p=0.08). Serum Dkk-1 and sclerostin levels did not change significantly with anti-TNF therapy in either RA or PsA during the course of the study. There were significant positive correlations between both DKK-1 and sclerostin levels across the different time points with the exception of DKK-1 between baseline and 1 year in both diseases. High serum sclerostin levels were associated with low Dkk-1 levels in PsA (r=−0.605 p= 0.04) and in the entire group (r=−0.453 p= 0.001) after 12 months of anti-TNF therapy.

OPG/Dkk-1 and OPG/sclerostin ratios reflecting remodeling balance were similar and did not change significantly in either RA or PsA during the study. There was no correlation between Dkk-1 or sclerostin and CRP levels.

Conclusion: This study provides data suggesting differences in the cross-talk between TNF-alpha, Dkk-1 and sclerostin between RA and PsA. After 12 months of anti-TNF treatment Dkk-1 levels were lower in PsA compared to RA. This may contribute to an imbalance in bone remodeling in favour of bone formation in PsA. High serum sclerostin levels were associated with low Dkk-1 levels in PsA and in the entire group after 12 months only suggesting that DKK-1 but not sclerostin might be altered with anti-TNF therapy. Neither Dkk-1 nor sclerostin correlated with CRP at any time point indicating that these Wnt inhibitors may not linked to inflammation.

544

Anterior Chest Wall Pain in Recent Inflammatory Back Pain. Data From the DESIR Cohort. Daniel Wendling[1], Clément Prati[2], Christophe Demattei[3], Damien Loeuille[4], P. Richette[5] and Maxime Dougados[6]. [1]Minjoz University Hospital, Besancon, France, [2]CHU J Minjoz, Besancon, France, [3]CHU, Nimes, France, [4]CHU Brabois, Vandoeuvre les Nancy, France, [5]Hôpital Lariboisière, Paris, France, [6]Paris-Descartes University, APHP, Cochin Hospital, Paris, France

Background/Purpose: Anterior chest wall pain (ACW) may be suggestive of spondyloarthritis (SpA), but little is known about this clinical feature in recent inflammatory back pain (IBP).

Objective: To determine the prevalence of ACW in patients with recent IBP suggestive of SpA, and to investigate the influence of ACW on the overall features of patients presenting with recent IBP.

Methods: The DESIR cohort is a prospective, multicenter French cohort of patients with early IBP (Calin or Berlin criteria) (>3 months and <3 years of duration) suggestive of SpA according to the investigator, including 708 patients (mean age 33.8 years, 53.8% female, 57.3% HLA B27 positive). ACW was defined by at least one episode of chest wall pain attributed to SpA by the rheumatologist, after ruling out other causes of chest pain. Data on the baseline demographic characteristics, functional status and quality of life, imaging features (standard X-Rays, MRI, Ultrasounds), BMD, and blood tests were compared in patients with and without ACW. Both the date of the first symptom of IBP and the symptoms of ACW were recorded, as well as the date of the visit. Factors associated with ACW were identified both by uni and multivariate analysis (logistic regression).

Results: The prevalence of ACW in the DESIR cohort was 44.6 % [95%CI 40.9–48.3] (n=316/708 patients). ACW occurred after the first symptoms of IBP in 62 %, before in 14 %, and simultaneously (±1month) in 24 % of the cases. Localization was diffuse in 41% of the positive cases, sterno costal (35%), manubrio sternal (29%) or sterno clavicular (26%). Presence of ACW was significantly associated in univariate analysis with pain in cervical and thoracic spine, buttock, peripheral arthritis and

enthesitis, fulfilment of ASAS and ESSG criteria, associated reactive arthritis and SAPHO, increased BASDAI, ASDAS, BASFI, BASG, SF-36, BASMI, articular index, increased CRP, radiographic sacro iliac involvement and reduced BMD. ACW was not associated with HLA-B27, uveitis, psoriasis, smoking, age and MRI findings. A stepwise multivariate analysis found an association between ACW and (Table): the enthesitis score, involvement of the thoracic spine, diagnosis of ankylosing spondylitis and radiographic abnormality of the sacro iliac joints.

	ACW (n=316)	No ACW (n=392)	Adjusted OR	p-value
Global enthesitis score (0–13)	3,65 ± 3,57	1,91 ± 2,53	1.213 [1.148–1.282] For an increase of 1 unit	<0.0001
Involvement of the thoracic spine (pain) Yes versus no	212 (67%)	192 (49%)	2.201 [1.582–3.062]	<0.0001
Diagnosis before inclusion: Ankylosing Spondylitis Yes versus No	150 (47%)	148 (38%)	1.642 [1.176–2.293]	0.0036
Radiographic sacro iliac score	142(46%)	209 (55%)	1.692 [1.128–2.538]	0.0109
0: normal	81 (26%)	75 (20%)	1.295 [0.863–1.943]	0.2121
1: doubtful	76 (24%)	96 (25%)	7.299 [1.938–27.48]	0.0033
2: established	12 (3.90%)	3 (0.78%)		
3: fusion				

Conclusion: In recent IBP suggestive of SpA, presence of ACW is associated with enthesitis, thoracic spine involvement, radiographic sacro iliitis and the diagnosis of ankylosing spondylitis. Since there are no differences in symptoms duration between ACW positive and ACW negative patients, ACW could be interpreted as an independent diagnosis feature for ankylosing spondylitis.

545

Correlates of Inflammatory Back Pain in a Nationally Representative Sample of the US Population. Shervin Assassi[1], Michael H. Weisman[2], Zhongxue Chen[1], Mohammad Rahbar[1], Daniel O. Clegg[3], Robert A. Colbert[4], Atul A. Deodhar[5], Laurie M. Savage[6], Tiffany Graham[1], James P. Witter[7] and John D. Reveille[1]. [1]Univ of Texas Health Science Center at Houston, Houston, TX, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]George E. Wahlen VA Medical Center, Salt Lake City, UT, [4]NIAMS NIH, Bethesda, MD, [5]Oregon Health & Science University, Portland, OR, [6]Spondylitis Association of America, Van Nuys, CA, [7]NIH, Bethesda, MD

Background/Purpose: There are no published studies on correlates of inflammatory back pain (IBP) based on a large-scale nationally representative sample. In the present study, we examine the demographic and clinical features that are associated with IBP among adults with chronic back pain who participated in the US National Health and Nutrition Examination Survey (NHANES) 2009–2010.

Methods: NHANES 2009–2010 surveyed 5106 adults (ages: 20 to 69), representative of the US population. The study participants were interviewed and examined by trained personnel to obtain demographic and clinical data. A detailed questionnaire focused on back pain and associated features was administered. Chronic back pain was defined as back discomfort present on most days for more than 3 months. Based on this definition, 980 (19.2%) had chronic back pain. Two published sets of criteria for IBP were utilized to identify participants with IBP in the chronic back pain group. Specifically, the outcome variable was IBP as defined by presence of four (out of five) European Spondyloarthritis Study Group (ESSG) or two (out of four) 2006 Berlin Criteria. The investigated independent variables included a comprehensive list of demographic features including age, gender, ethnicity, education, income, exercise habits, body mass index (BMI), alcohol use, and smoking status. In addition, laboratory and clinical features including C-reactive protein, presence of diabetes, hepatitis C, arthritis, uveitis, inflammatory bowel disease, psoriasis, rapid response to NSAIDs, and heel pain were also investigated. Specifically, presence of arthritis was determined by affirmative response to the question "has a doctor ever told you that you had arthritis". Obesity was defined as BMI >30. Among patients with chronic back pain, the association of demographic and clinical features with IBP was assessed with weighted logistical regression analysis in univariable and multivariable models in order to identify the independent correlates of IBP.

Results: First, correlates of IBP according to the ESSG criteria were examined. Among participants with chronic back pain, absence of morbid obesity (OR: 1.86, p<0.001), presence of arthritis diagnosed by a physician (OR: 1.6, p=0.021), rapid response to NSAIDs (OR: 1.6, p=0.032), younger age (20–49 versus 50–65 age group, OR: 3.68, p<0.001) were independent correlates of IBP in the multivariable model. Next, correlates of IBP according to Berlin Criteria were investigated. For this purpose, participants over 50 year of age were excluded because the Berlin Criteria are not applicable to this age group. The presence of arthritis diagnosed by a physician (OR=1.7, p=0.039), psoriatic skin disease (OR=3.2, p=0.04), current smoking (OR: 1.8, p=0.017), and lower education level (high school diploma or less versus the rest, OR=1.6, p=0.04) were independently associated with IBP in the multivariable model.

Conclusion: Certain demographic features including younger age, lower BMI, lower educational level, and current smoking, as well as several clinical characteristics, specifically arthritis, psoriasis, and rapid response to NSAIDs are associated with IBP in adults with chronic back pain in the US population.

The Immunogenicity to the First Anti-TNF Therapy Determines the Outcome of Switching to a Second Anti-TNF in Spondyloarthritis Patients. Chamaida Plasencia[1], Dora Pascual-Salcedo[2], Sara Garcia-Carazo[1], Gema Bonilla[3], Leticia Lojo[1], Laura Nuño[3], Alejandro Villalba[1], Diana Peiteado[1], Concepcion Castillo-Gallego Jr.[4], Florencia Arribas[2], Daniel Nagore[5], E. Martin-Mola[4] and Alejandro Balsa[6]. [1]RHEUMATOLOGY UNIT, Spain, Spain, [2]Hospital La Paz. IdiPaz, Madrid, Spain, [3]Hospital La Paz-IdiPaz, Madrid, Spain, [4]Hospital Universitario La Paz, Madrid, Spain, [5]Proteomika S.L., [6]Hospital La Paz, Madrid, Spain

Background/Purpose: Spondyloarthropathies (SpAs) encompass a heterogeneous group of diseases that primarily affect the axial skeleton and entheses. Although anti-TNF drugs have proven to be effective against SpA, approximately 30% of patients fail to respond or experience adverse events leading to treatment discontinuation. In rheumatoid arthritis, it has been shown that the development of antibodies (Abs) against the first anti-TNF treatment determines the response to the second anti-TNF treatment. Our aim was to assess whether the response to a second anti-TNF treatment after failing to respond to a first TNF antagonist is related to the previous development of Abs to the first TNF inhibitor.

Methods: We studied 33 patients diagnosed with SpA who began treatment with a second anti-TNF after failing to respond to the first anti-TNF: 23 (69.7%) patients with ankylosing spondylitis (AS), 6 (18.3%) with undifferentiated SpA, 3 (9%) with psoriatic SpA and 1 (3%) with SpA secondary to reactive arthritis. Clinical activity was assessed by the Ankylosing Spondylitis Disease Activity Score (ASDAS) at baseline (at the beginning of the 1° and 2° anti-TNF treatments) and at 6 months after switching. Clinical improvement was evaluated using the delta-ASDAS. The drug and anti-drug Ab (ADA) levels were measured by ELISA before each administration.

Results: Of the 33 patients examined, 18 (54.5%) were male. The mean age was 50.1±10.2 years, and 75% (21/28) were positive for HLA B27. All patients were initially treated with anti-TNF drugs; 14/33 (42.4%) were treated with infliximab (Ifx), 3/33 (9.1%) with adalimumab (Ada) and 16/33 (48.5%) with etanercept (Eta). Nine of 33 (27.3%) developed ADAs during the first biologic treatment [8 Abs to Ifx (ATI) and 1 Abs to Ada (ATA)]. Mainly due to inefficacy, the first anti-TNF was exchanged for a second anti-TNF: 7 (21.2%) switched to Ifx, 16 (48.5%) to Ada, 5 (15.2%) to Eta and 5 (15.1%) to golimumab (Gol). No differences in ASDAS were not observed at baseline in patients with or without ADAs to the first (3.35±0.87 with ADAs vs 3.51±1.04 without ADAs, p=0.953) and second (2.99±0.96 with ADAs vs 3.31±0.97 without ADAs, p=0.392) anti-TNF treatments. At six months after switching, patients who had previously developed ADAs had lower disease activity (1.76±0.98 with ADAs vs 2.79±1.11 without ADAs, p=0.020), and a trend was observed towards greater clinical improvement (delta-ASDAS 1.23±1.22 with ADAs vs 0.52±1.08 without ADAs, p=0.065). At six months after switching, most patients without ADAs were classified as having high or very high disease activity state by the ASDAS (18 out of 24 (75%) without ADAs vs 3 out of 9 (33.3%) with ADAs, p=0.022), and more patients with ADAs had inactive disease (2 out of 9 (22.2%) with ADAs vs 1 out of 24 (4.2%) without ADAs, p=0.022).

Conclusion: In SpA, the failure to respond to the first anti-TNF treatment due to the development of ADAs predicts a better clinical response to a second anti-TNF treatment. The study of immunogenicity in biological treatment failure may help predict the response to a second biological treatment for SpA.

Comparison and Validation of Screening Questionnaires for Psoriatic Arthritis in Patients with Psoriasis. Devy Zisman[1], Lihi Eder[1], Bosmat Zamir[2], Arie Laor[1] and Joy Feld[1]. [1]Carmel Medical Center, Haifa, Israel, [2]Clalit Health Services, Haifa and Western Galilee District, Haifa, Israel

Background/Purpose: Several self-administered screening questionnaires are available to identify patients suspected as suffering from psoriatic arthritis (PsA) among patients with psoriasis, thus facilitating their referral to a rheumatologist. Two questionnaires, the Toronto Psoriatic Arthritis Screen (ToPAS) and the Psoriatic Arthritis Screening and Evaluation tool (PASE), were found to have high sensitivity and specificity among Canadian and American psoriasis patients. The aim of our study was to validate and compare the Hebrew versions of PASE and ToPAS questionnaires among Israeli psoriasis patients.

Methods: A cross-sectional study included 99 patients with psoriasis attending dermatology clinics and 15 patients from a combined rheumatology-dermatology clinic who completed the PASE and ToPAS questionnaires. Psoriasis patients who had PASE scores of ≥44 and ToPAS scores of >8 were considered to be suspected PsA cases. Specialized rheumatologists, blind to the questionnaires' results, evaluated all participants for symptoms and signs of PsA. Patients with inflammatory arthritis underwent laboratory and radiology work-ups. A definitive diagnosis of PsA was made by a rheumatologist applying the CASPAR criteria. The questionnaires' performance was assessed using the receiver operating curve (ROC) analysis and the magnitudes of sensitivity and specificity.

Results: The questionnaires were completed by 114 patients with psoriasis, of which 38 (33.3%) met the CASPAR criteria for PsA (group A) and 76 (66.7%) did not (group B). The two groups were comparable with regard to age, gender, duration of psoriasis, family history of psoriasis, ethnicity and education. A statistically significant difference was noted between the average scores of patients with PsA and those with psoriasis but without arthritis (Mean (95% Confidence Interval)): PASE symptoms (24.2 (21.67–26.76), 12.3 (11.01–13.52) P<0.0001, respectively), PASE functional (26.02 (23.28–28.77), 11.75 (10.42–13.08) P<0.0001, respectively), PASE total (50.24 (43.32–55.15), 24.04 (21.63–26.45) P<0.0001, respectively) and ToPAS (8.26 (7.58–8.95), 4.4 (3.92–4.9) P<0.0001, respectively). The sensitivity and specificity of the PASE questionnaire were 71.1% and 89.5%, respectively, and those of the ToPAS questionnaire were 52.6% and 93.4%, respectively. The area under the ROC curve (AUC) was 0.9093 and 0.8901 for the PASE and ToPAS questionnaires, respectively. The difference between the AUC's (0.0192) was not significant (P=0.59).

Conclusion: The ToPAS and PASE questionnaires identified PsA patients with moderate to high sensitivity and specificity among Israeli patients with psoriasis. No statistically significant difference in the performance of the two questionnaires appeared, although the PASE questionnaire had higher sensitivity. Administering the questionnaires may facilitate early detection, referral and treatment of psoriatic arthritis patients.

Assessment of the T1-Weighted Sequence Is Essential in Defining a Positive MRI Scan of the Sacroiliac Joints in Spondyloarthritis. Ulrich Weber[1], Veronika Zubler[1], Susanne Juhl Pedersen[2], Kaspar Rufibach[3], Robert GW Lambert[4], Stanley Chan[4], Mikkel Ostergaard[5] and Walter P. Maksymowych[4]. [1]Balgrist University Hospital, Zurich, Switzerland, [2]Glostrup Hospital, Copenhagen, Denmark, [3]University of Zurich, Zurich, Switzerland, [4]University of Alberta, Edmonton, AB, [5]Copenhagen University Hospital at Glostrup, Glostrup, Denmark

Background/Purpose: Inflammation on MRI of the sacroiliac joints (SIJ) in patients with spondyloarthritis (SpA) is a major criterion in the Assessment of SpondyloArthritis (ASAS) classification criteria for axial SpA, which are

based on expert clinical opinion as gold standard. The definition of a positive SIJ MRI in the ASAS criteria was generated by consensus among experts. Studies using a data-driven approach are scarce. We aimed to assess candidate definitions for a positive SIJ MRI using both clinical gold standard and confidence in the diagnosis of SpA according to global assessment of MRI (T1-weighted and STIR sequences) by expert readers.

Methods: The study population comprised 2 independent cohorts (cohort A/B) of 157 consecutive patients with back pain ≤50 years newly referred to 2 university clinics, and 20 healthy controls. Patients were classified according to clinical examination and pelvic radiography as having non-radiographic SpA (n=51), ankylosing spondylitis (n=34), or mechanical back pain (n=72). SIJ MRI were assessed by 4 blinded readers according to a standardized module. Readers recorded their level of confidence in the diagnosis of SpA by global evaluation of the MRI scan on a 0–10 scale (0 = definitely not SpA; 10 = definite SpA). An MRI-based gold-standard criterion for SpA was pre-specified as the majority of readers (≥3/4) recording a confidence of 8–10. We estimated the type and extent of involvement according to number of affected SIJ quadrants attaining specificity of '90% for SpA using ROC analysis according to both clinical and MRI-based gold-standard criteria.

Results: The agreement between 4 readers regarding confidence for MRI-based global assessment of SpA was substantial with kappa of 0.76/0.80 for cohort A/B. BME was recorded in up to 30.0%/24.2% of controls in cohort A/B, whereas erosion was seen in only 0%/12.1% of controls. The combination of erosion and/or BME increased sensitivity compared to either lesion alone without reducing specificity irrespective of which gold standard criterion was used.

Sensitivity and cut-off for number of affected SIJ quadrants for a pre-defined specificity ≥0.90, and AUC, for the 2 gold standards and for cohort A/B

Gold standard	Lesion	Sensitivity	Number of SIJ quadrants	AUC
MRI criterion	BME	0.91/0.83	3/2	0.97/0.91
Clinical evaluation	BME	0.73/0.48	4/4	0.91/0.75
MRI criterion	ER	1.00/1.00	1/1	1.00/1.00
Clinical evaluation	ER	0.83/0.58	1/2	0.94/0.79
MRI criterion	BME+ER	1.00/1.00	3/2	1.00/1.00
Clinical evaluation	BME+ER	0.83/0.58	4/6	0.96/0.83

AUC: Area under the curve. BME: Bone marrow edema. ER: Erosion. Number of SIJ quadrants: Cut-off for the number of affected SIJ quadrants

Conclusion: This data driven study shows that assessment of the T1-weighted sequence enhances diagnostic certainty when viewed simultaneously with the STIR and supports the case for revision of the ASAS definition of a positive MRI in SpA.

A Randomized, Open-Label Study of Maintenance of Partial Remission with Naproxen Vs No Treatment: Results of the Infliximab As First Line Therapy in Patients with Early Active Axial Spondyloarthritis Trial, Part II. Joachim Sieper[1], Jan Lenaerts[2], Jürgen Wollenhaupt[3], Vadim Mazurov[4], L. Myasoutova[5], Sung-Hwan Park[6], Yeong W. Song[7], Ruji Yao[8], Denesh Chitkara[8] and Nathan Vastesaeger[9]. [1]Charité, University Medicine Berlin, Berlin, Germany, [2]Reuma-instituut, Hasselt, Belgium, [3]Schön-Klinik, Hamburg, Germany, [4]St. Petersburg Medical Academy, St. Petersburg, Russia, [5]Kazan State Medical University, Kazan, Russia, [6]Catholic University of Korea, Seoul, South Korea, [7]Seoul National University, Seoul, South Korea, [8]Merck Sharp and Dohme, Kenilworth, NJ, [9]Merck Sharp and Dohme, Brussels, Belgium

Background/Purpose: In patients with axial SpA who have achieved partial remission, it is unclear whether continuous treatment with NSAIDs is superior to stopping treatment.

Objectives: To investigate whether continued treatment with naproxen (NPX) was superior to discontinuing all treatment in order to maintain disease control for 6 months in early, active axial SpA patients who were in partial remission after 28 weeks of therapy with either infliximab (IFX)+NPX or placebo (PBO)+NPX.

Methods: Part I of the INFAST study was a double-blind, randomized controlled trial of IFX in biologic-naïve patients 18–48 years of age with early, active axial SpA. Patients were randomized (2:1) to receive 28 weeks of treatment with either IV IFX 5 mg/kg (weeks 0, 2, 6, 12, 18, and 24)+NPX 1000 mg/d or IV PBO+NPX 1000 mg/d. In Part II of INFAST, patients who had achieved ASAS partial remission at week 28 continued in Part II of the study with no IFX treatment. These patients were randomized in a 1:1 ratio to continue on NPX or to stop NPX until week 52. Patients from the 2 treatment arms in Part I were equally balanced over the 2 groups in Part II. The main outcome was the proportion of subjects who maintained ASAS partial remission at week 52. Treatment group differences were analyzed using Fisher exact tests or ANCOVA. Predictors of remission were explored using Cox regression models. A flare was defined as BASDAI ≥30 mm (on a 100 mm VAS) during 2 consecutive visits within 1–3 weeks.

Results: 41 patients were randomized to NPX and 41 to no treatment in Part II of INFAST. 78% of patients in Part II had been in the IFX+NPX arm in Part I. At week 52, similar numbers of patients in the NPX group (19/40, 47.5%) and the no-treatment group (16/40, 40.0%) met the ASAS partial remission criteria, P=0.6525. In regression analyses, patients who received NPX in Part II stayed in remission longer than those who stopped all treatment (HR=0.21, 95% CI: 0.08, 0.52). Initial therapy with IFX+NPX was a significant predictor of the duration of partial remission and sustained remission to week 52. Overall, the group data reflected low disease activity status through week 52 (BASDAI and ASDAS results in Table 1) with a slight, nonsignificant advantage for the NPX group over the no treatment group. The overall low disease activity status was consistent with the low flare rates in both groups (NPX, 1/40, 2.5% vs no treatment, 3/40, 7.5%; P=0.6153).

Table 1. Efficacy Outcomes by Treatment Group

	NPX (N=40)			No Treatment (N=40)			
Outcome	Week 28, mean	Week 52, mean	Change, mean (SD)	Week 28, mean	Week 52, mean	Change, mean (SD)	P Value
BASDAI (100 mm VAS)	7.1	12.2	5.8 (10.64)	5.4	16.9	10.9 (13.74)	0.1079
ASDAS	0.9	1.5	0.6 (0.71)	1.0	1.6	0.6 (0.63)	0.8374
ESR (mm/hr)	7.1	14.7	7.6 (11.63)	9.4	13.6	5.1(10.10)	0.4637
CRP (mg/dL)	0.37	0.69	0.29 (0.924)	0.53	0.72	0.26(0.707)	0.9930

During the follow-up period, 1 serious adverse event was reported in the no-treatment group. No deaths occurred.

Conclusion: In patients with axial SpA who reached partial remission after treatment with either IFX+NPX or NPX alone, disease activity remained low during 6 months in which NPX was maintained or all treatment was discontinued. About half of patients remained in clinical remission for 6 months. A slight advantage may occur for patients continuing NPX treatment vs no treatment at all.

Differences in the Prevalence of Inflammatory Articular Disease in Psoriatic Patients, Applying Clinical, Ultrasound and/or Radiological Data. Implications in the Classification of Psoriatic Arthritis according to Caspar Criteria. Jose Luis Fernandez-Sueiro, S. Pertega-Diaz, JA Pinto and E. Gonzalez. Complejo Hospitalario Universitario La Coruña, La Coruña, Spain

Background/Purpose: a) To determine differences in the prevalence of inflammatory articular disease (IAD) in patients with cutaneous psoriasis when applying clinical, ultrasound (PDUS) or radiological diagnostic criteria.

b) To determine the prevalence of PsA in these patients, applying different definitions for the initial stem of the CASPAR criteria, and to compare this prevalence with that based on clinical judgment.

Methods: Descriptive, observational, cross-sectional study of 122 patients referred from the primary care with a confirmed diagnosis of cutaneous psoriasis, without arthritis.

For the diagnosis of IAD, the following criteria were used:

Peripheral arthritis: a) Clinical (TJC>0 or SJC>0 (78/76)), b) PDUS (carpal, MCP, PIP, MTsP, carpal tendons, hands, feet tendons), c) Radiological (hands and/or feet erosions).

Spine: a) Clinical (inflammatory back pain (IBP) (4/5) and/or nocturnal and VAS overall spinal pain past week >5), b) Radiological (sacroiliitis grade II unilateral or higher).

Entheseal: a) Clinical (MASES plus lateral and medial epycondile, quadriceps tendon, proximal and distal patella, plantar aponeuroses). b) PDUS (lateral and medial epycondile, quadriceps tendon, proximal and distal patella, aquilles tendon plantar aponeuroses)

Prevalence of IAD was obtained, according to different definitions. PsA prevalence was also determined according to CASPAR criteria and clinical judgement. Agreement was evaluated by the Kappa's index.

Results: Criteria for peripheral arthritis: clinical criteria 12 (9.8%), PDUS 16 (15%) and erosions 20 (19%). Of 122 patients, 41 (41.4%) met at least one of the criteria for peripheral arthritis. None of them met all three criteria.

Criteria for spinal disease: IBP 8 (12.3%), VAS overall spinal pain in the past week>5 22 (18%), unilateral sacroiliitis grade II or higher 17 (15.5%). Of the patients studied, 5 (4.4%) met the radiological criteria plus one of the clinical criteria. None of them met the 3 criteria altogether.

Criteria for enthesal disease: clinical 13 (10.7%), PDUS 40 (32.8%). Of the 122 patients, 45 (36.9%) met one of this two criteria, 8 patients met both of them.

Prevalence of inflammatory articular disease, based on clinical criteria, was 44.2% (95% CI: 33.1%–52.3%). By combining clinical, ultrasound and radiological results, the prevalence was 61.8% (95% CI: 51.8%–71.7%).

Using only clinical criteria for the diagnosis of inflammatory articular disease, PsA prevalence according to CASPAR criteria was 27.2% (95% CI: 16.9%–37.5%). Combining clinical, ultrasound and radiological criteria, the prevalence was 34.7% (95% CI: 24.6%–44.8%). Only 12 (9.8%) of the patients had PsA according to clinical judgment. Agreement between clinical judgment and CASPAR criteria was low, both when clinical criteria (Kappa=0.247) or clinical+ultrasound+radiologic criteria (Kappa=0.140) were used to define IAD.

Conclusion: The prevalence of PsA in patients with psoriasis varies from 27.2% to 34.7%, according to the definition of the initial stem in CASPAR criteria. On the other hand, only 9.8% were diagnosed of PsA based on clinical judgment. These data suggest the need for clarifying the stem definition of CASPAR criteria.

Prevalence of Enthesitis in Psoriatic Patients: Agreement Between Clinical and Power Doppler Ultrasonography Exploration and Its Implications for the Classification of Psoriatic Arthritis. Jose Luis Fernandez-Sueiro[1], JA Pinto[1], S. Pertega-Diaz[1] and Carlos Fernandez-Lopez[2]. [1]Complejo Hospitalario Universitario La Coruña, La Coruña, Spain, [2]INIBIC- Complejo Hospitalario Universitario La Coruña(CHUAC). Rheumatology Division., La Coruña, Spain

Background/Purpose: Enthesitis constitutes one of the CASPAR stem criteria for the classification of psoriasis arthritis, however as enthesitis may be clinically silent many psoriatic patients may have unnoticed enthesitis and may in fact have silent psoriatic arthritis. Objective: To determine the prevalence of enthesitis by PDUS examination in a cohort of psoriatic patients without a diagnosis of PsA. To determine the agreement between clinical exploration and ultrasound results, and the prevalence of "silent" disease according to CASPAR criteria.

Methods: Descriptive and observational cross-sectional study of 122 patients referred from the primary care with cutaneous psoriasis without arthritis, 20 healthy subjects were used as controls. The entheseal examination was performed by the MASES plus lateral and medial epycondile, quadriceps tendon, proximal and distal patella and plantar aponeuroses. PDUS was performed in longitudinal and transverse multiplanar examination (Logiq 5 PRO; General Electric Healthcare, Kyunnggi-do, Korea), using multifrequency linear array transducers (7–12 MHz) in the following enthesis: lateral and medial epycondile, quadriceps tendon, proximal and distal patella, aquilles tendon plantar aponeuroses. Active enthesitis was defined by the presence of thickness or altered echogenecity as well as the presence of vascularisation. Intraobserver realiability was verified by blindly assessed the stored baseline images 3 months after the real time examination. Prevalence of enthesitis between psoriatic patients and controls was compared with the chi-squared test. Considering PDUS results as the gold standard, sensitivity, specificity and predictive values of clinical exploration were estimated. Agreement was evaluated with the Kappa index.
