Background/Purpose: Once ANCA-associated vasculitis (AAV) remission has been achieved with CS and cyclophosphamide (CYC), maintenance therapy usually relies on azathioprine (AZA) or methotrexate. However, 18- and 28-month relapse rates remain high, 15% and 28%, respectively. Although rituximab (RTX) has been demonstrated to be as effective as CYC for induction of complete remission by 6 months, some retrospective studies showed that more than half of the patients without maintenance relapsed within 2 years. The results of a prospective, randomized, controlled trial of RTX vs AZA to maintain AAV remission are reported (MAINRITSAN, NCT 00748644). (Sponsor: Assistance publique Hôpitaux de Paris, Grants: Programme Hospitalier de Recherche Clinique, Rituximab was provided in part by Roche).

Methods: Once remission was obtained with a conventional regimen, patients with newly diagnosed (2/3 of the enrollments) or relapsing (1/3) AAV were randomly assigned to receive a 500-mg RTX infusion on D1, D15, 5.5 months later, then every 6 months for a total of 5 infusions over 18 months, or AZA for 22 months at the initial dose of 2 mg/kg/d. The primary endpoint was the major relapse rate (EULAR/ACR criteria) at 28 months. Other outcome measures were the severe adverse event (SAE) rate (WHO definition) associated with each maintenance regimen. We hypothesized that the RTX arm would have a 50% lower relapse rate than that of AZA, and a similar safety profile.

Results: Among the 114 patients (50 men/64 women; mean age, 55±13 years; 91 newly diagnosed and 23 relapsers) participating in the study (59 in the AZA arm, 55 in the RTX arm): 86 had granulomatosis with polyangiitis, 23 microscopic polyangiitis and 5 kidney-limited diseases. The main clinical manifestations at diagnosis or last relapse included ENT involvement in 88 (77.2%), lung in 69 (60.5%) and kidney in 82 (71.9%). Eighty-four (73.7%) patients have already completed their 28 months of follow-up; the last patient visit and trial closure are scheduled in 10/2012. So far, major relapses have occurred in 18 (15.7%) patients: 2 (3.6%) in the RTX arm and 16 (27.1%) in the AZA arm, with 3 AZA-arm deaths (1 sepsis, 1 pancreatic cancer, 1 mesenteric ischemia). Thirty-three experienced SAE: 18 related to AZA, 15 to RTX. In the AZA arm, 12 infections (1 fatal) and 1 skin cancer were observed vs 11 infections (none fatal) in the RTX arm.

Conclusion: The results of this study demonstrated that 500 mg of RTX every 6 months was superior to AZA to maintain AAV remission. The infection frequencies were comparable in the 2 arms, and other SAE were infrequent and resolved in most patients.

Outcomes in Patients with Granulomatosis with Polyangiitis (Wegener's) Treated with Short Vs. Long-Term Maintenance Therapy. Jason Springer, Benjamin Nutter, Carol A. Langford, Gary S. Hoffman and Alexandra Villa-Forte. Cleveland Clinic Foundation, Cleveland, OH

Background/Purpose: Disease remission can be successfully achieved in the majority of patients (pts) with Granulomatosis with polyangiitis (Wegener's) (GPA). After remission (rem) is achieved continued treatment with immunosuppressive agents is used to maintain rem. There is limited data on long term outcomes for pts continuing maintenance therapy beyond 18 months (mo). The aim of this study was to determine rem maintenance outcomes in pts treated long term (>18 mo) vs. short term (≤18 mo). The primary outcome was relapse rate.

Methods: A retrospective chart review was performed of pts with GPA from a single Vasculitis Center from 1992 to 2010. Inclusion criteria: 1) 1990 ACR criteria for GPA, 2) induction therapy provided with daily cyclophosphamide (CYC) or weekly methotrexate (MTX); 3) rem achieved; 4) maintenance therapy initiated immediately following discontinuation of induction therapy; 5) maintenance therapy with either MTX or azathioprine (AZA); 6) duration of remission ≥18 mon; 7) chronologic documentation of rem and relapse. Rem was defined as a BVAS/WG score of 0 and relapse was defined as a score that changed from 0 to ≥ 1 following a period of rem.

Results: 157 pts were included out of 797 screened. Median age at diagnosis was 46. Follow-up ranged from 18 mo to 16.8 years(yr) (mean 3.1 yr). Induction therapy with CYC was used for severe disease (78% cases) and MTX (22% cases) for mild to moderate disease. Mean starting doses of maintenance medications were prednisone (pred) 19 mg/d, MTX 16.5mg/wk and AZA 112mg/d. There was no difference between groups in regards to initial organ manifestations, pred dose at rem, maintenance drug used or pulse dose methylprednisolone (MP) at diagnosis. When duration of treatment was compared using a univariate model the long term group showed a 29% reduction in hazard ratio for relapse (HR0.71 [95%CI 0.43, 1.18], p=0.18). Treatment for > 36 mo showed 66% reduction in hazard ratio for relapse (HR0.34 [95%CI 0.15, 0.76], p=0.008). When length of treatment was considered as a continuous factor, longer courses had an inverse relationship with the risk of relapse (HR0.77 [95%CI 0.65, 0.92]; p= 0.003). After adjusting for pred dose, length of maintenance therapy continued to show a significant inverse relationship with risk of relapse (HR0.58 [95%CI 0.4, 0.83]; p=0.003). Univariate analysis revealed no association with risk of relapse and BVAS at diagnosis, ANCA status or pulse MP. When relapse characteristics were compared between groups there was no difference in severity of relapse as measured by BVAS/WG, but a higher rate of relapse with peripheral neuropathy (15% vs 1.43%, p=0.033) occurred in the short term group. Relapses in the long-term group occurred in 88.9% after stopping therapy. Of pts on therapy at relapse 52% were on < 15mg/wk MTX and 75% on ≤ 50mg/d AZA. No differences between the two groups in overall adverse events or GPA related morbidity.

Conclusion: Our data demonstrate that pts receiving long term maintenance therapy have fewer relapses and have a similar adverse events profile as pts treated for < 18 mos. Discontinuation and low doses of maintenance therapy are associated with a high relapse rate.

1654

Primary Endpoint Failure in the Rituximab in ANCA-Associated Vasculitis Trial. Eli Miloslavsky[1], Ulrich Specks[2], John H. Stone[3] and RAVE/ITN Research Group[4]. [1]Massachusetts General Hopsital, Boston, MA, [2]Mayo Clinic, Rochester, MN, [3]Massachusetts General Hospital, Boston, MA, [4]Bethesda

Background/Purpose: The RAVE trial demonstrated that rituximab (RTX) is non-inferior to cyclophosphamide (CYC) for remission induction in severe ANCA-associated vasculitis. The primary endpoint was a disease activity score (Birmingham Vasculitis Activity Score/Wegener's granulomatosis; BVAS/WG) of 0 and a prednisone dose of 0 mg/d at month 6. We explored the reasons for primary endpoint failure (PEF) in RAVE.

Methods: PEFs were classified according to one of the following hierarchical reasons: early treatment failure (ETF) (advance of disease in one or more organs or failure to respond to treatment by BVAS/WG reduction in the first month); severe flare; limited flare; adverse event (AE); BVAS/WG > 0 at 6 months; prednisone > 0 mg/d at 6 months despite BVAS/WG of 0; or other.

Results: Eighty-two of 197 pts (42%) were PEFs: 36 (36%) in the RTX group, 46 (47%) in CYC (P=0.09). Nine were ETFs (7 RTX, 2 CYC; P=0.17). Baseline characteristics of pts classified as ETFs did not differ from those of other pts in age, sex, ANCA type, disease, new diagnosis vs relapse, baseline BVAS/WG, or creatinine. Most ETFs were due to progressive glomerulonephritis (5/9: 4 RTX, 1 CYC) or recurrent pulmonary hemorrhage (3/9). All ETFs were treated with CYC. One ETF (RTX) died from sepsis/respiratory failure. All other ETFs improved, with resolution of pulmonary disease and improvement of renal function.

Fifteen RTX pts were PEFs because of disease flares (4 severe, 11 limited), compared with 23 CYC pts (9 severe, 14 limited). Neither B cell detectability nor ANCA titer predicted disease flare well in the first 6 months, and the correlation was particularly poor among RTX-treated pts. B cells remained undetectable in 65% of flares (50% CYC, 92% RTX). Among disease flares, only 24% had rises in ANCA titers at the time of flare (36% CYC, 0% RTX).

Of the 13 severe flares, 11 were treated by blinded crossover. Nine of 11 blinded crossovers achieved remission (BVAS of 0 and prednisone dose of 0mg) within 6 months after crossover. Limited flares were typically controlled by an increase in prednisone dose. Among pts with limited flares, the mean BVAS/WG at 6 months was 0.9 and the mean prednisone dose 9.3 mg/d. Six pts were PEFs because of BVAS/WG > 0 at 6 months (2 RTX, 4 CYC; mean 2.0), and 11 were PEFs because of failure to taper prednisone to 0 mg/d (7 RTX, 4 CYC; mean 9.3 mg/d). Twelve pts (9 CYC, 3 RTX) discontinued because of AEs.

Table 1 Reasons for primary endpoint failure in RAVE

	RTX	CYC/AZA	P
ETF	7	2	0.17
Severe flare	4	9	0.16
Limited flare	11	14	0.53
Adverse event	3	9	0.08
BVAS/WG > 0	2	4	0.45
Prednisone dose > 0mg	7	4	0.54
Other	2	4	0.45
Total	36	46	

Conclusion: There were multiple reasons for PEF but the distribution of causes was similar between groups. ETFs and pts who flared typically improved following a treatment intervention according to best medical judgment, blinded crossover, or increase in prednisone dose. B cell detectability and ANCA titers correlated poorly with flares in the first 6 months, particularly those in the RTX group.

1655

An Open-Label Trial of Abatacept in Mild Relapsing Granulomatosis with Polyangiitis (Wegener's). Carol A. Langford[1], David Cuthbertson[2], Gary S. Hoffman[1], Jeffrey Krischer[2], Carol McAlear[3], Paul A. Monach[4], Philip Seo[5], Ulrich Specks[6], Steven R. Ytterberg[6], Peter A. Merkel[3] and for the Vasculitis Clinical Research Consortium[3]. [1]Cleveland Clinic, Cleveland, OH, [2]University of South Florida, Tampa, FL, [3]University of Pennsylvania, Philadelphia, PA, [4]Boston University, Boston, MA, [5]Johns Hopkins Vasculitis Center, Baltimore, MD, [6]Mayo Clinic, Rochester, MN

Background/Purpose: Granulomatosis with polyangiitis (Wegener's, GPA) is a primary systemic vasculitis that carries a high predilection for relapse. An area of unmet need has been treatment options for patients with mild relapsing GPA, many of whom require long-term glucocorticoids. T-cell activation has been implicated in the pathophysiology of GPA. We conducted an open-label trial to examine the safety and efficacy of abatacept (CTLA4-Ig) in patients with mild relapsing GPA.

Methods: Standardized definitions were used to identify patients with mild relapsing GPA. 20 patients were treated with abatacept 10mg/kg IV days 1, 15, 29 and monthly thereafter. Patients on methotrexate (MTX), azathioprine (AZA), or mycophenolate mofetil (MMF) at enrollment continued these agents without dosage increase. Prednisone ≤ 30 mg daily was permitted at entry, but the dose had to be tapered down to the pre-relapse dose by month 2. Safety and efficacy data were collected at each infusion, disease activity was assessed by the BVAS/WG, damage was assessed by the Vasculitis Damage Index (VDI). Patients received abatacept until meeting criteria for early termination or until the common closeout date of 6 months after enrollment of the last patient.

Results: Disease characteristics of the 20 enrolled patients are outlined in the Table.

Variable	Value at Study Entry
Age (range)	45 years (17–73)
Female/Male	9/11
PR3-cANCA	80%
MPO-pANCA	10%
GPA duration mean (range)	100 months (5–326)
BVAS/WG mean (range)	3.1 (1–6)
VDI mean (range)	2.5 (0–7)

Organ Involvement	Before Study Entry (Ever)	Active Disease at Study Entry
Constitutional	85%	30%
ENT	100%	90%
Musculoskeletal	75%	50%
Cutaneous	60%	40%
Mucous membranes	25%	5%
Lung	70%	30%
Kidney	40%	-
Eye	30%	-
Nerve	20%	-

Of the 20 patients, 14 (70%) were on either MTX (N=7), AZA (N=3), or MMF (N=4). 14 patients had taken prednisone during the 12 months prior to enrollment, 13 were on at the time of enrollment, and 15 (75%) received prednisone during the first 2 months of study treatment. The maximum prednisone doses were 30 mg (N=3), 20 mg (N=3), 12–15 mg (N=2), 10 mg (N=4), 7.5 mg (N=1), 5 mg (N=2) with only 5 having a dose increase at trial entry. During the study, 11 of the 15 patients on prednisone reached a dose of 0 mg. 10 of the 14 patients who had been on long-term prednisone were able to discontinue prednisone and 7 of these remained off the drug until common closing. Of the 20 patients, 18 (90%) had disease improvement, 16 (80%) achieved remission (BVAS/WG=0) at a median of 3.75 months (range 1–19), and 14 (70%) reached common closing. 6 (30%) met criteria for early termination due to increased disease activity but none had severe disease; 3 of 6 achieved remission and relapsed at a median of 8.33 months (range 6–10). The median duration of remission before common closing was 12 months (range 4–21). 9 serious adverse events occurred in 7 patients, including 7 infections that were successfully treated.

Conclusion: In this population of patients with mild relapsing GPA, abatacept was well tolerated and was associated with disease remission and discontinuation of prednisone in a high percentage of patients. These findings suggest that abatacept warrants further study as a possible treatment option for patients who have non-severe, relapsing GPA.

Background/Purpose: To optimize the therapeutic strategy for the elderly with systemic necrotizing vasculitides (SNV; polyarteritis nodosa (PAN), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) or eosinophilic GPA (EGPA)).

Methods: We conducted a multicenter randomized controlled trial on patients ≥65 years old with newly diagnosed SNV to compare conventional therapy (based on Five-Factor Score-assessed disease severity: for all, ≥28 mo of corticosteroids (CS) alone or combined with 500-mg/m[2]cyclophosphamide (CYC) IV pulses every 2–3 wk until remission for EGPA or PAN with FFS≥1 and GPA or MPA, then switched to maintenance azathioprine (AZA) or methotrexate (MTX)) and an experimental regimen, specifically designed for faster CS dose-tapering and systematic but reduced CYC exposure (for all, ≥9 mo of CS and 500-mg fixed-dose IV CYC pulse, given every 2–3 wk, and switched after a maximum of 6 pulses to maintenance AZA or MTX). Trial follow-up closure was scheduled 3 yr after enrollment of the last patient. The primary judgment criterion was time to first severe adverse event (SAE: morbidity and mortality) hypothesizing a 30% reduction of experimental arm SAE rate. Secondary endpoints included first remission, death, relapse rates and quality-adjusted time without symptoms or toxicity (Q-TWiST).

Results: Between July 2005 and February 2008, 108 patients were randomized; 4 were excluded (early consent withdrawn, wrong diagnosis, protocol violations). Mean age at diagnosis of the analyzed patients (52 in each arm; 55 males, 49 females; 8 PAN, 13 EGPA, 37 GPA, 46 MPA; 91 ANCA-positive) was 75.2±6.3 yr, with a maximum of 92 yr for 1 MPA patient. FFS=0 for 7 PAN (4 in the conventional arm, 3 in the experimental arm) and 10 EGPA patients (5 in each arm). Baseline clinical features were evenly distributed between arms (fever, 53%; arthralgias, 38%; lung, 64%; ENT, 40%; kidney, 69%; heart, 20%; skin, 35%; peripheral nervous system, 25%; central nervous system, 3%); mean serum creatinine level at diagnosis was 234±199 μmol/l and C-reactive protein 102±87 mg/l. Mean follow-up was 28±11 mo. Hazard ratio for first SAE (primary endpoint) for experimental vs conventional treatment was 0.61 [95% CI, 0.38–0.97], i.e., 39% lower SAE rate (3-yr event-free survival: 37.6% [95% CI, 26.4–53.7] in experimental vs 19.2% [95% CI, 10.9–34.1] in conventional treatment arms; p=0.04). Ninety-one (88%) patients achieved remission with their assigned treatment (47 in experimental treatment arm vs 44 in conventional; p=0.37); 21 (20%) patients died (8 vs 13, respectively; p=0.22) of uncontrolled vasculitis for 7 of them (2 vs 5) and/or infection for 6 (2 vs 4); 16 vs 11 patients suffered ≥1 relapse(s), with comparable 3-yr relapse-free–survival rates (53.2% [CI 95%, 40.7–69.6] vs 54.2% [95% CI, 41.9–70]). Respective Q-TWiST rates were 30.97 and 28.72 (mean difference, 2.25 [95% CI, –1.72 to 6.76]; p=0.29).

Conclusion: Treating SNV in the elderly with a specific regimen limiting exposure to CS and fixed low-dose IV CYC pulses coud become the standard of care because of its lower SAE risk, and similar 3-yr remission and relapse rates, compared to conventional therapy.

Peg-IFNa/Ribavirin/Protease Inhibitor Combination Is Highly Effective in HCV-Mixed Cryoglobulinemia Vasculitis. David Saadoun[1], Stanislas Pol[2], Pascal Lebray Sr.[3], François Blanc[4], Gilles Pialoux[5], Alexandre Karras[6], Dorothée Bazin[7], Emmanuelle Plaisier[8] and Patrice Cacoub Sr.[9]. [1]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpêtrière, Paris, France, [2]Hepatology, Cochin Hospital, Paris, France, [3]Hôpital Pitié Salpétrière, Paris, France, [4]hôpital Montpellier, Montpellier, France, [5]hôpital Tenon, Paris, France, [6]Hôpital Européen Georges Pompidou, APHP, Paris, France, [7]Nouvel Hôpital Civil, Strasbourg, France, [8]Nephrology, Tenon Hospital, Paris, France, [9]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: The standard of care treatment of patients presenting a HCV-mixed cryoglobulinemia (MC) vasculitis includes Peg-IFNa plus Ribavirin, w/wo Rituximab. Thirty to 40% of patients are non-responders or relapsers to such combination.

To analyze the safety and efficacy of a Peg-IFNa/Ribavirin/Protease inhibitor combination on HCV-MC vasculitis.

Methods: Open label prospective single-center cohort study, 27 patients with HCV-MC vasculitis entered the study, of whom 13 with sufficient follow-up were analysed. Peg-IFNa/Ribavirin was associated to Telaprevir (375 mg three times daily, 8 patients) or Boceprevir (800 mg three times daily, 5 patients).

Results: Mean age 61 years, 54% women, all 13 HCV genotype 1 patients received previous antiviral therapy with Peg-IFNa/Ribavirin, including 5 (38%) relapsers and 8 (62%) non-responders; 10 (77%) had been also treated by Rituximab. Mean HCV RNA level was 5.85Log copies/mL; Metavir fibrosis score was of stage 4 in 6 cases, stage 3 in 4 cases and stage 2 in 3 cases. Twelve patients (92%) had a type II IgMk MC and 1 had a type III. Main HCV-MC manifestations included purpura (n=10), polyneuropathy (n=10), arthralgia (n=6), and kidney involvement (n=3). The mean serum MC, C4 and rheumatoid factor levels were of 1.3 g/l, 0.09 g/l and 157 IU/ml, respectively. After 1 month of Peg-IFNa/Ribavirin/protease inhibitor, 11 (85%) patients showed an early virological response (HCV RNA level <1.1 Log copies/mL). Nine (69%) patients showed a complete clinical response of MC vasculitis and 4 (31%) were partial responders. After 3 months of Peg-IFNa/Ribavirin/protease inhibitor, MC serum level dropped from 1.3 to 0,3g/l while C4 level increased from 0.09 to 0.13g/l. All 13 patients experienced at least one treatment side effect including asthenia in 92%, anaemia in 84%, neutropenia and bacterial infection in 53%, nausea and low grade (<3) skin eruption under Telaprevir in 30% and thrombocytopenia in 15%.

Conclusion: Peg-IFNa/Ribavirin/protease inhibitor combination seems highly effective in HCV-MC vasculitis. Such therapeutic regimen should be administered cautiously considering the high rates of side effects.

Signal Transducer and Activator of Transcription 3 Induced Synovial Invasion and Migration Is Mediated in Part Through the Notch/Hypoxia-Inducible Factor 1α Pathways. Wei Gao[1], Douglas J. Veale[2] and Ursula Fearon[3]. [1]Translational Rheumatology Research Group, Dublin, Ireland, [2]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [3]Translation Rheumatology Research Group, Dublin, Ireland

Background/Purpose: To examine the role of Signal Transducer and Activator of Transcription 3 (STAT3) in mediating synovial cell-cell interactions, migration/invasion and key downstream signaling pathways in the inflamed synovial tissue.

Methods: Phospho-STAT3 (p-STAT3) expression in synovial tissue was quantified by immunohistology/immunoflourecence and Western blot. Notch-1 IC, HIF1α, p-STAT3 and total-STAT3 protein levels were assessed in synovial fibroblasts under normoxic and hypoxic (3%) conditions by Western Blot. In parallel gene expression of the Notch-1 receptor, its ligand DLL-4 and downstream target genes (*hrt-1, hrt-2*) were quantified by Real-time PCR. Synovial fibroblast migration, invasion, matrigel network formation and MMP2/9 in-gel zymography were quantified under normoxic and hypoxic (3%) conditions in the presence of STAT3 inhibitor (WP1066). Using RA synovial explants *ex-vivo*, the effect of the STAT3 inhibitor (WP1066) on IL-6, IL-8 and IL-10 expression were assessed by ELISA.

Results: Nuclear expression of p-STAT3 was demonstrated in RA synovial tissue, localised to the sub-lining and lining layer regions. p-STAT3 expression was significantly higher in inflamed synovial tissue compared to normal synovial tissue. Hypoxia (3%) induced p-STAT3, Notch-1 IC, HIF1α protein expression in synovial fibroblasts, an effect that was inhibited by the presence of WP1066. Similarly hypoxia-induced Notch-1 receptor, DLL-4 and *hrt-1, hrt-2* gene expression were inhibited in the presence of WP1066. Functionally hypoxia-induced synovial fibroblast invasion, matrigel network formation, migration, and pro-MMP-2/-9 activities, were inhibited in the presence of STAT3 inhibitor. Finally we demonstrated in RA synovial explants *ex-vivo* that WP1066 significantly decreased IL-6, IL-8 expression and significantly increased anti-inflammatory cytokine IL-10 expression.

Conclusion: p-STAT3 is increased in RA synovial tissue and mediates synovial fibroblast migrational and invasive processes. Furthermore these effects may in part be mediated through Notch-1/HIF1α interactions.

Ptpome Profile of Rheumatoid Arthritis Fibroblast-Like Synovio-cytes: A Novel Role for the Tyrosine Phosphatase SHP-2 As a Modulator of Invasion and Survival. Stephanie Stanford[1], Michael Maestre[1], Beatrix Bartok[2], David L. Boyle[2], Heather Arnett[3], Tomas Mustelin[4], Gary S. Firestein[2] and Nunzio Bottini[1]. [1]La Jolla Institute for Allergy and Immunology, La Jolla, CA, [2]UCSD School of Medicine, La Jolla, CA, [3]Amgen, Inc., Seattle, [4]Sanford-Burnham Institute for Medical Research, La Jolla, CA

Background/Purpose: Fibroblast-like synoviocytes (FLS) in the synovial intimal lining are key mediators of inflammation and joint destruction in rheumatoid arthritis (RA). These cells assume a tumor-like phenotype in RA, aggressively invading the extracellular matrix and producing cartilage-degrading proteases and inflammatory cytokines. The behavior of synovial fibroblasts is controlled by multiple interconnected signal transduction pathways involving reversible protein phosphorylation. However, little is known about the role of the protein tyrosine phosphatases (PTPs) in FLS function. The objective of this study was to define all of the PTP genes (PTPome) expressed in FLS and determine if any play a role in the rheumatoid synoviocyte phenotype

Methods: Comparative screening was conducted of the PTPome expression in FLS from patients with RA or osteoarthritis (OA) by qPCR. Cell permeable anti-sense oligonucleotides were used to suppress PTPs, such as SHP-2, and achieved 90% knockdown. Transwell FLS invasion assays were performed using Matrigel-coated inserts. FCS or PDGF were used as chemoattractants, and invasion was quantified by propidium iodide (PI) staining of insert membranes. Transwell FLS migration assays were carried out using FCS as a chemoattractant, and migration was quantified by staining cells with Celltracker green. FLS apoptosis was quantified by flow cytometry staining with PI and Annexin V. MMP and cytokine gene induction after TNF stimulation were quantified by qPCR. Western blotting of cell lysates using phosphospecific antibodies was used to assess activation of signaling pathways.

Results: FLS display abundant expression of genes belonging to all of the known subfamilies of PTPs. Of these, only *PTPRK*, *PTPN11*, *PTPN14* and *DUSP3* expression were increased in RA (n=11) compared to OA (n=10) FLS (p<0.05). Subsequent studies focused on *PTPN11*, which encodes SHP-2, because that it is a well-documented proto-oncogene. SHP-2 knockdown in RA FLS with antisense led to increased basal apoptosis (162% increase, p<0.05) and impaired invasion (71% decrease, p<0.05) and migration (44% decrease, p<0.05) in response to FCS or PDGF. SHP-2-deficient RA FLS displayed decreased activation of focal adhesion kinase and mitogen-activated

protein kinases, such as JNK, in response to PDGF. Knockdown of SHP-2 also significantly suppressed TNF-mediated induction of MMPs and adhesion molecules, including MMP-1 (79% decrease, p<0.05), MMP-2 (64% decrease, p<0.05), VCAM-1 (93% decrease, p<0.05), and Cadherin-11 (77% decrease, p<0.05). Decreased gene expression correlated with a dramatically reduced induction of JNK phosphorylation in cell lysates.

Conclusion: These findings demonstrate a novel role for the proto-oncogene SHP-2 as a key mediator of FLS function. SHP-2 promotes the invasiveness and survival of RA FLS and, due to its higher expression in RA compared with OA FLS, could contribute to the unique aggressive phenotype of the rheumatoid cells. Therefore, SHP-2 could be a novel therapeutic target for RA.

Development of a Bruton's Tyrosine Kinase (Btk) Inhibitor, ONO-4059: Efficacy in a Collagen Induced Arthritis (CIA) Model Indicates Potential Treatment for Rheumatoid Arthritis (RA). Toshio Yoshizawa, Yuko Ariza, Yoshiko Ueda, Shingo Hotta, Masami Narita and Kazuhito Kawabata. Ono Pharmaceutical Co., Ltd., Osaka, Japan

Background/Purpose: Rheumatoid arthritis (RA) is characterized by leukocyte infiltration, synoviocyte hyperplasia and osteoclastogenesis, and tyrosine kinases have key roles in the signaling pathways that regulate these processes. Bruton's tyrosine kinase (Btk) is a key regulator of B-cell receptor (BCR) function. B-cell receptors play a central role in signal transduction pathways regulating survival, activation, proliferation, and differentiation of B-lineage lymphoid cells. Furthermore, Btk mutations in humans cause X-linked agammaglobulinaemia, an inherited disorder characterized by severe B-cell specific defects, including the complete absence of B-cells in the periphery. The effectiveness of B-cell targeted therapy in the treatment of RA (e.g., Rituximab), further supports the role of B-cells in RA. ONO-4059 is a highly potent and selective Btk inhibitor with an IC$_{50}$ in the sub-nmol/L range. The activity of ONO-4059 was evaluated in a mouse collagen induced arthritis (CIA) model.

Methods: Male DBA/1J mice were immunized on days 0 and 21 with Freund's Complete Adjuvant containing bovine type II collagen. Mice were randomized to three treatment groups starting from day 22 to 36 and received oral ONO-4059, once daily at doses of 1 mg/kg, 3 mg/kg and 10 mg/kg respectively. The mice were weighed weekly and scored daily for signs of arthritis. Each paw was scored and the sum of all four scores was recorded using the Arthritic Index (AI). The maximum possible AI score was 16. Joint histology on day 36 was evaluated for cartilage damage, bone damage, extra-articular inflammation and pannus. To further characterize the effect of ONO-4059 in the CIA model, human monocytes were stimulated with immobilized hIgG or TLR-9 ligand (CpG-B) for 18 hr. TNFα and IL-6 production was determined by Luminex.

Results: Treatment with ONO-4059 resulted in a dose-dependent inhibition of arthritis severity and bone damage in the CIA model. The mean disease score of the ONO-4059-treated animals was 10.9, 5.3 and 2.3 for the 1, 3 and 10 mg/kg dose groups respectively. In comparison, the mean score in the vehicle-treated animals was 13. In a cell-based assay, ONO-4059 prevented FcγR-induced TNFα and IL-6 production in monocytes with IC$_{50}$ values of 5.66 nM and 22.4 nM, respectively. ONO-4059 also suppressed TLR9-induced TNFα and IL-6 production in monocytes with IC$_{50}$ values of 4.45 nM and 12.4 nM, respectively. Furthermore, ONO-4059 prevented B-cell activation in the 10 nM range but it had no effects on T-cell activation.

Conclusion: ONO-4059 is a highly potent and selective oral Btk inhibitor. We have demonstrated that ONO-4059 potently and dose-dependently reversed clinical arthritis and prevented bone damage in the CIA model. The cellular and molecular mechanisms by which Btk mediates inflammation are not fully understood. This data supports that ONO-4059 inhibits immune-receptor signaling in multiple cells through Btk inhibition and these preliminary results suggest that ONO-4059 may be a promising therapeutic approach for patients with rheumatoid arthritis and warrants further investigation.

CCR1 Potentiates Gouty Inflammation Following Initial CXCR2-Dependent Neutrophil Recruitment to Sites of Monosodium Urate Crystal Deposition in Mice. Robert P. Friday[1], Terry K. Means[2], Melissa Tai[2], Christian D. Sadik[2] and Andrew D. Luster[2]. [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Charlestown, MA

Background/Purpose: During attacks of acute gouty arthritis, monosodium urate (MSU) crystals elicit a potent neutrophilic inflammatory response in the affected joint, causing exquisite pain and often signs of systemic inflammation such as fever. IL-1β plays a critical role in the development of gouty arthritis, as demonstrated by studies of IL-1β and NLRP3 knockout mice and the effectiveness of IL-1 blockade in treating or preventing gouty arthritis in humans. However, mechanisms of neutrophil trafficking to sites of MSU crystal deposition during gouty inflammation have not been fully characterized, and our understanding of these pathways depends upon knowledge of the chemokine responses elicited by MSU crystals and their interface with chemotactic receptors on neutrophils. Deletion of the chemokine receptor CXCR2 in mice has been shown to impair initiation of MSU crystal-induced inflammation in the air pouch model of gouty arthritis, but the other major murine neutrophil chemotactic receptors – CCR1, BLT1 and C5a – have not been systematically studied.

Methods: Using the murine air pouch model of gouty arthritis, we have: (1) characterized the chemokine and cytokine profile of MSU crystal-induced inflammation using a multiplex bead immunoassay and (2) probed the time course of chemokine and cytokine production and neutrophil recruitment in CCR1-null, CXCR2-null, and CCR1-CXCR2 double knockout mice.

Results: While our findings confirm that CXCR2 is critical for the initiation of neutrophilic inflammation in MSU crystal-challenged air pouches, mice lacking CCR1 also fail to achieve the expected maximal neutrophilic response to MSU crystal challenge (at 8 hours post crystal challenge). Although CXCR2-null mice generate a very high level of KC and LIX (ligands for CXCR2) in the air pouch within 2 hours of MSU crystal challenge, MIP-1α and MIP-1β (ligands for CCR1), which typically appear 3–4 hours after crystal challenge, are not produced in these mice.

Conclusion: We propose that CXCR2 and CCR1 act sequentially to initiate and potentiate neutrophil infiltration during gouty inflammation, with CCR1 chemokine ligand generation being dependent upon neutrophils entering the inflammatory site in response to CXCR2 chemokine signals. These data broaden our understanding of coordinate chemokine-mediated neutrophil recruitment in a model of MSU crystal-induced arthritis and suggest that there may be a role for chemokine receptor modulation in the management of acute gouty arthritis in humans.

Anti-IL-6 Therapy Impairs Intestinal Repair Through Inhibition of Epithelial Proliferation After Injury. Kristine Kuhn, Hiroyuki Miyoshi, Nicholas A. Manieri, Nicole P. Malvin, Vinieth Bijanki, Paul Allen and Thaddeus S. Stappenbeck. Washington University School of Medicine, St. Louis, MO

Background/Purpose: Inhibition of IL-6 is used for treatment of rheumatoid arthritis and now being investigated as biologic therapy for a wide variety of autoimmune conditions, including systemic lupus erythematosus, spondyloarthritis, vasculitides, and inflammatory bowel disease. Many of these conditions are complicated by intestinal inflammation. Yet little is known about the role of IL-6 in the bowel. Animal models have suggested that IL-6 signaling protects intestinal epithelial cells from apoptosis during toxin mediated injury with oral dextran sodium sulfate and C. rodentium infection.

Methods: We have begun to investigate the role of IL-6 in the intestine using two in vivo models of intestinal disease. First, we utilized the dnKO murine model of spontaneous colitis. These mice are transgenic for a dominant negative *Tgfbr2* on T cells and are deficient in the *IL10rb* gene; both of these signaling pathways contain genes with risk alleles for autoimmunity. Antibiotics can inhibit spontaneous colitis that develops in these mice, and cohousing with unmanipulated littermates leads to colitis within days. We then utilized a biopsy wound model in which a colonoscope is used to introduce forceps which biopsy the colonic mucosa and make a wound which can then be evaluated as the tissue repairs itself.

Results: We found that treatment of dnKO mice with an inhibitory antibody for IL-6 at the time of cohousing led to more severe colitis as observed by increased inflammatory infiltrates and crypt drop-out when compared to control antibody treated mice. Evaluation of the intestinal epithelium with BrdU staining demonstrated significantly increased epithelial proliferation in dnKO mice treated with control antibody but nearly absent staining in the anti-IL-6 treated mice. After biopsy wound injury of wild type mice, IL-6 levels peak early, within 24 hours, and decline to undetectable levels by day 6. Mice deficient for IL-6 demonstrate impaired intestinal wound healing due to a severe epithelial proliferative defect. By in situ hybridization, we identify intestinal epithelial cells and endothelial cells as significant producers of IL-6 in both models. In order to further define the mechanism by which IL-6 could be controlling intestinal epithelial proliferation and repair, we evaluated its role in primary 3D cultures of intestinal crypt organoids. In these cultures, cellular proliferation was significantly inhibited when the inflammatory cytokines TNF-α and IFN-γ were added. However, the addition of IL-6 to the cultures resulted in the restoration of cellular proliferation, even in the presence of TNF-α and IFN-γ.

Conclusion: These data demonstrate the importance of IL-6 for intestinal epithelial proliferation after injury. The absence of IL-6 early after injury in the intestine, such as the case when anti-IL-6 therapy is used, may lead to severe defects in healing, increasing the risk for adverse events.

G Protein Signaling Modulator 3 Is a Key Regulator of Monocyte-Driven Inflammatory Arthritis. Matthew J. Billard, Patrick M. Giguére, Brian Buckley, Marcus W. McGinnis, Roman Timoshchenko, Peng Liu, David P. Siderovski and Teresa K. Tarrant. University of North Carolina at Chapel Hill, Chapel Hill, NC

Background/Purpose: Monocytes are critical to rheumatoid arthritis (RA) disease pathogenesis and are recruited to the inflamed synovium by inflammation-driven chemokines. G protein signaling modulator 3 (GPSM3) is a newly discovered member of the novel family of GoLoco motif proteins known to regulate G protein heterotrimer assembly and function, a mechanism by which chemokine receptors signal. GPSM3 is selectively expressed in monocytes and may regulate monocyte function through chemokine G protein coupled receptor (GPCR) interactions, which in turn may affect inflammatory arthritis disease expression.

Methods:
• GPSM3-deficient monocytic cells were generated from the parental THP-1 cell line and a GPSM3-deficient mouse was created.
• A monoclonal antibody to GPSM3 (mAb 35.5.1) was developed and GPSM3 expression was analyzed by immunoblotting lysates from hematopoietic lineage-derived human cell lines.
• Migration studies of Ly6C+ splenocytes were conducted using Transwell inserts (5 μm pore size) and analyzed for chemotaxis by flow cytometry.
• Monocytic subsets in the spleen were enumerated using multicolor flow cytometry.
• Collagen Antibody Induced Arthritis (CAIA) was induced using the 5 clone Chondrex antibody cocktail and LPS booster on GMSM3$-/-$ and wild type mice per manufacturer's instructions.
• The levels of various intra-articular proinflammatory chemokine receptors and cytokines known to be important to RA and CIA disease pathogenesis were evaluated by quantitative PCR.

Results: GPSM3 expression is predominantly restricted to the monocytic lineage and modulated during monocyte differentiation. Data with GPSM3-deficient mice show that CAIA is blunted clinically and histopathologically with specifically reduced intra-articular *IL-6,IL-1β*, *CCR2,* and *CX3CR1* expression. *Ex vivo* results show a GPSM3-dependent decrease in ligand-specific migration of Ly6C+ CD11b+ spenocytes to the proinflammatory monocyte chemokines CCL2, CX3CL1, and chemerin.

Conclusion: Proinflammatory functions of monocytes critical to RA development are reliant on GPSM3 function. Having a single protein target for RA therapeutic intervention that appears to selectively affect proinflammatory monocyte infiltration into the joint represents a paradigm shift from previous therapeutic attempts at single cytokine or chemokine neutralization.

Autoantibodies Are Associated with Subclinical Atherosclerosis and Cardiovascular Endpoints in Caucasian and African American Women in a Prospective Study: the Multi-Ethnic Study of Atherosclerosis (MESA). Darcy S. Majka[1], Rowland W. Chang[1], Richard M. Pope[2], Marius C. Teodorescu[3], Elizabeth W. Karlson[4], Thanh Huyen T. Vu[5], Joseph Kang[6] and Kiang Liu[1]. [1]Northwestern University, Chicago, IL, [2]Northwestern Univ Med School, Chicago, IL, [3]TheraTest Laboratories Inc, Lombard, IL, [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [5]Northwestern University, Feinberg School of Medicine, Chicago, IL, [6]Northwestern University, Feinberg School of Medicine, Chicago, IL

Background/Purpose: Although the association between rheumatoid arthritis (RA) and cardiovascular disease (CVD) is established, the exact mechanism is not known. Subjects who later develop RA were shown to have increased risk of myocardial infarction (MI) in the preclinical period prior to RA symptoms indicating that autoimmunity might be a risk factor for CVD. Therefore, we tested the hypothesis that RA-related autoantibodies are independent risk factors for subclinical atherosclerosis and subsequent clinical CVD events.

Methods: MESA is a multicenter population based study cohort prospectively collecting CVD outcome and risk factor data in 6814 middle-aged to elderly multi-ethnic participants since 2000. At MESA baseline, rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP-2) by ELISA and coronary artery calcium (CAC) by CT were measured in 6557 AA, Caucasian, Hispanic and Chinese participants who were then followed for 7.1 years for coronary heart disease (CHD) Hard endpoints (MI, resuscitated cardiac arrest, CHD death) and CVD Hard endpoints (MI, cardiac arrest, CHD death, stroke, stroke death). We assessed the associations between baseline RF/anti-CCP and CAC stratified by race/gender using logistic regression adjusting for traditional CVD risk factors. We used Cox regression to determine race/gender-specific associations between RF/anti-CCP and clinical CVD endpoints.

Results: 12.2% had CAC >=300; After 7.1 years, 3.0% had Hard CHD endpoints; 4.8% had Hard CVD endpoints. RF IgM, RF IgA and anti-CCP were positive in 15.9%, 8.7%, and 2.0%, respectively. 4.0% were positive for both and 20.6% were positive for either RF isotype. RA-related autoantibody positivity varied with race and was highest in AA's (RF: p<0.001, anti-CCP: p<0.003). RF and anti-CCP were associated with CAC in Caucasian and AA women after adjustment for traditional risk factors (Table 1). Table 2 demonstrates strong associations between RA-related autoantibodies and clinical CVD events in AA women. There were no clear associations in Hispanic and Chinese participants.

Table 1. Adjusted* Odds Ratios (95% CI) of Having Degrees of CAC by Autoantibody Positivity in Caucasian Women and AA Women

RA-related Autoantibodies	CAC Levels		
	0<CAC<99 vs. CAC=0	99<CAC<300 vs. CAC=0	CAC>300 vs. CAC=0
Caucasian Women (N=1,323)

*Adjusted for age, smoking status, BP, BMI, HDL-c, LDL-c, DM, aspirin use, and cholesterol and BP medication use.

Table 2. Adjusted* Hazard Ratios (95% CI) for the Incidence of Clinical Cardiovascular Events over 7.1 Years Follow Up by Autoantibody Positivity

	Caucasian Women	
RA-related Autoantibodies	CHD Hard Endpoints (N=31)	CVD Hard Endpoints (N=56)
RF IgM	1.2 (0.4–3.0)	1.8 (0.9–3.4)
RF IgA	1.1 (0.3–4.5)	0.5 (0.1–2.2)
Either RF isotypes	1.2 (0.5–3.0)	1.6 (0.8–3.0)
Both RF isotypes	0.8 (0.1–6.1)	0.4 (0.1–3.1)
CCP	NA	NA
AA Women		
	CHD Hard Endpoints (N=19)	CVD Hard Endpoints (N=37)
RF IgM	1.7 (0.7–4.5)	**2.1 (1.1–4.0)**
RF IgA	**5.0 (1.9–12.7)**	3.4 (1.7–6.9)
Either RF isotypes	**2.5 (1.0–6.4)**	2.7 (1.4–5.1)
Both RF isotypes	**4.5 (1.6–13.0)**	3.3 (1.5–7.3)
CCP	1.1 (0.1–8.3)	2.3 (0.7–7.7)

*Adjusted for age, smoking status, BP, BMI, HDL-c, LDL-c, DM, aspirin use, and cholesterol and BP medication use. CHD Hard event outcomes include MI, resuscitated cardiac arrest, and CHD death. CVD Hard events include MI, cardiac arrest, CHD death, stroke, and stroke death.

Conclusion: This study demonstrates that RA-related autoantibodies are associated with subclinical and clinical atherosclerosis in a population based cohort. These findings indicate autoimmune factors may play a role in the pathogenesis of atherosclerosis, even in individuals without RA.

Associations of Race and Ethnicity with Overall Mortality and Cardiovascular Events Among Patients with End-Stage Renal Disease Due to Lupus Nephritis. Jose A. Gomez-Puerta[1], Sushrut Waikar[2], Graciela S. Alarcon[3], Jun Liu[4], Daniel H. Solomon[1], Wolfgang C. Winkelmayer[5] and Karen H. Costenbader[1]. [1]Division of Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [2]Division of Nephrology, Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [5]Stanford University School of Medicine, Stanford, CA

Background/Purpose: Patients with SLE and lupus nephritis (LN) are at elevated risks of cardiovascular disease. Past studies have suggested that African American patients with SLE may be at higher cardiovascular risk than White patients. A large recent study of individuals with end-stage renal disease (ESRD) of any cause showed effect modification of the race-mortality association by age and demonstrated increased mortality among young African American compared to White patients. However, there is little information about mortality and cardiovascular risks among patients with ESRD due to LN, differentiated by race and ethnicity. We tested for differences in mortality and cardiovascular event rates in patients with ESRD due to LN, by race and ethnic group.

Methods: Individuals age ≥18 years with incident LN ESRD (ICD-9 code 710.0) between 1995 and 2008 were identified in the US Renal Data System (URDS). Covariates at baseline were ascertained from the Medical Evidence Report (a standardized form including sociodemographics, clinic data and laboratory measures collected at dialysis initiation). LN was consider as primary cause of renal failure according to the attending nephrologist. Multiple imputation was used for missing baseline data [albumin, body mass index and estimated glomerular filtration rate (eGFR)]. The hazard ratios (HR) for mortality and cardiovascular events (myocardial infarction, heart failure, hemorrhagic and ischemic stroke) during follow-up through December 31, 2008 were estimated using multivariable-adjusted Cox regression

Results: We identified 12,533 patients with ESRD due to LN. Mean age at ESRD onset was 40.7 ± 14.9 years; 81.6% were women and 49% were African American. The total number of deaths, cardiovascular events and their incident rates are shown in Table. Compared to Whites, African Americans had higher risk of death (1.30 [95%CI 1.21–1.39]) and heart failure (1.35 [95%CI 1.24–1.47]). Conversely, Asian patients had lower risk of mortality 0.68 [95%CI 0.65–0.92] and heart failure (0.67[0.50–0.90]).

Hispanic patients had lower rates of mortality (0.74 [95%CI 0.66–0.82]), heart failure (0.82;95%CI 0.71–0.97), myocardial infarction (0.69;95%CI 0.49–0.98), and ischemic stroke (0.68; 95%CI 0.48–0.85) than non-Hispanics.

Table. Hazard Ratios for Mortality and Cardiovascular Events in 12.533 patients with ESRD due to Lupus Nephritis, US patients 1995–2008

	Mortality Total events=4789 Fully-Adjusted HR	Heart Failure Total events=2276 Fully-Adjusted HR	Myocardial Infarction Total events=464 Fully-Adjusted HR	Ischemic Stroke Total events=456 Fully-Adjusted HR	Hemorrhagic Stroke Total events =162 Fully-Adjusted HR
Race					
White	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)
Asian	0.68 (0.65–0.92)	0.67 (0.50–0.90)	0.88 (0.50–1.56)	0.62 (0.33–1.16)	1.95 (0.93–4.11)
African American	1.30 (1.21–1.39)	1.23 (1.07–1.41)	0.97 (0.77–1.23)	0.85 (0.67–1.07)	1.09 (0.71–1.65)
Native	1.17 (0.86–1.58)	1.20(0.81–1.78)	0.57 (0.18–1.8)	0.51 (0.16–1.60)	2.05 (0.72–5.83)
Ethnicity					
Non-Hispanic	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)	1.0 (Ref)
Hispanic	0.74 (0.66–0.82)	0.83 (0.71–0.97)	0.69 (0.49–0.98)	0.68 (0.48–0.85)	0.81 (0.46–1.45)

IR: Incidence rate
*Multivariable model adjusted for sex, age at ESRD onset, sex, calendar year of ESRD onset, race, Hispanic ethnicity, smoking, comorbidities (hypertension, diabetes, coronary artery disease, chronic heart failure, cerebrovascular disease, peripheral vascular disease, cancer, chronic obstructive pulmonary disease), body mass index, albumin, eGFR, employment status, Medicare A+B, and region of residence (Northeast, South, Midwest or West US).)

Conclusion: Race and ethnicity are associated with mortality and cardiovascular outcomes among LN ESRD patients. While African American patients had significantly higher rates of death and heart failure than Whites, Asian and Hispanic patients had lower rates of these outcomes. The causes of these disparities are not understood, but are likely multifactorial, including genetic, socioeconomic, and environmental factors. Moreover, lower than expected mortality among Hispanic patients has been observed in other studies as well and may be due to people returning to their native countries for end of life care (Borrell LN, Am J Public Health, 2012).

Short Term Use of Glucocorticoids Is Not Associated with Acute Risk of Myocardial Infarction. Steven C. Vlad[1], David T. Felson[1], Donald R. Miller[2] and Yuqing Zhang[1]. [1]Boston University, Boston, MA, [2]Edith Nourse Rogers Memorial VA Hospital, Bedford, MA

Background/Purpose: Observational studies of both chronic and short term glucocorticoid (GC) use have suggested an elevated risk of acute myocardial infarction (MI). However this could be a result of confounding by indication; i.e. some condition for which a GC is prescribed is also a risk factor for MI. This study's aim was to examine whether 'burst' GC use serves as a trigger for acute MI or whether any effect is likely to be the result of confounding by indication.

Methods: We used national Veterans Administration (VA) data from fiscal year 1998 through 2008 to compare the risk for MI during and around periods of GC use compared to periods of non-use using the self-controlled case series study design, a case only design which compares risks within persons, thus limiting confounding. Based on prescription records we first developed a cohort of subjects who had only used 'burst' GCs, defined as dispensed oral prescriptions of [2] 30 days with at least 42 days between consecutive prescriptions; we excluded persons who received GCs during their first 60 days of follow-up or who could have received GCs during a prior hospitalization. From these, we selected those persons who had a first MI requiring hospitalization (cases) using validated ICD-9 codes; we excluded cases who had an MI within the first year of follow-up (to limit the number with possible recurrence). We focused on the period in which each subject was using GCs, as well as 42 days before and after to account for confounding by indication and any residual GC effects. The risk of MI in each of these periods was compared to that in the remaining follow up time period. We controlled for age in 5 year bands (18–24, 25–29, 30–34, > 80).

Results: There were 1632 cases of MI among burst GC users. 97.5% were men. Mean age at MI was 66.8 (sd 11.4) years; 66.9 (11.4) in men, 59.5 (12.9) in women. 75.4% of subjects were white, 10.1% African American, 5.0% Hispanic, 10.0% other. All cases had only 1 GC prescription for a median duration of 6 (Q1, Q3: 6, 10) days and median

average daily prednisone equivalent dose of 17.5 (17.5, 22.0) mg. The incidence rate ratio (IRR) of MI rose over the 42 days prior to the GC prescription from baseline to 7.5, and then dropped while the GC was being used. The risk essentially returned to baseline after GC was discontinued. See table.

	No. cases of MI in risk period	Incidence rate ratio	95% CI
Total number of cases	1632		
Reference risk period	1469	1.0	-
Time before GC prescription			
42–29 days prior to prescription	13	1.4	0.8, 2.4
28–15 days prior to prescription	22	2.3	1.5, 3.6
14–8 days prior to prescription	33	7.5	5.3,10.7
7–1 days prior to prescription	30	6.8	4.7, 9.8
Time while GC is being used			
days 0–6 on GC	16	4.4	2.7, 7.3
days 7–30 on GC	5	2.9	1.2, 7.1
Time after GC prescription			
1–7 days after discontinuation	5	1.1	0.5, 2.7
8–14 days after discontinuation	6	1.4	0.6, 3.0
15–28 days after discontinuation	21	2.2	1.4, 3.4
29–42 days after discontinuation	12	1.2	0.7, 2.2

Conclusion: Our results suggest that any elevated risk of MI from GC use could be due to confounding by indication: in this study the risk rose before the GC prescription was issued, suggesting that the MI was associated with some other factor for which the GC might also have been prescribed at a later time.

Impact of Rheumatoid Arthritis On Recognition of Hypertension in a Medically Homed Population. Christie M. Bartels[1], Heather Johnson[2], Katya Voelker[2], Patrick Mc Bride[2] and Maureen Smith[1]. [1]Univ of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Univ of Wisconsin School of Medicine and Public Health, Madison

Background/Purpose: Numerous studies report increased cardiovascular disease (CVD) events and others describe increased arterial stiffness in patients with rheumatoid arthritis (RA). Still, hypertension diagnosis rates in RA reports are often lower than expected by age. We tested the hypothesis that RA is a risk factor for missed hypertension diagnosis, given the importance of hypertension for CVD risk.

Methods: Using a cohort design we studied all medically homed adult patients from a large multispecialty practice who met Joint National Committee-7 (JNC-7) hypertension diagnostic criteria but lacked baseline diagnosis or treatment to compare new recognition of hypertension in patients with and without RA. "Medically homed" definitions required ≥2 primary care visits over ≥12 months (2009–11), and RA/inflammatory arthritis algorithms required two ICD-9 claims of 714 in 24 months. Cox proportional hazard modeling was used to examine the impact of RA on hypertension recognition.

Results: Among 33,947 medically homed patients with baseline undiagnosed and untreated hypertension, 575 patients had RA codes. After an average of 14 months follow up, 49% of RA patients compared to 42% without RA remained undiagnosed. RA patients had equal annual primary care visits (mean 1.5 v. 1.6), more total provider visits (mean 7.5 v. 4.6) and longer mean observation time, yet were less often diagnosed. In multivariate modeling controlling for socio-demographic factors, comorbidity, and utilization factors, the presence of rheumatoid arthritis decreased the likelihood of hypertension diagnosis or treatment by 21% [Hazard Ratio 0.79, Confidence Interval 0.71–0.89].

Hypertension recognition was lower in RA than other comorbidities (Table 1), and contrasted with increased hypertension recognition in patients with diabetes or kidney disease. RA patients were older (mean 62 v. 57 years), more female, weighed less, and were more likely to see an internist for primary care, and in the final adjusted model, younger age, white race, Medicaid, and non-internal medicine primary care provider predicted lower hypertension recognition.

Table 1. Cox Proportional Hazards Model for Hypertension Recognition

	Unadjusted % Diagnosed	Adjusted HR	95% CI
Rheumatoid Arthritis	51	0.79	0.71–0.89
Depression	51	0.88	0.83–0.93
Hyperlipidemia	68.7	1.33	1.29–1.37
Diabetes	71.4	1.22	1.18–1.27
Chronic Kidney Disease	64.1	1.13	1.06–1.20
Ischemic Heart Disease	66.8	1.00	0.95–1.06
Peripheral Vascular Disease	67.1	1.09	1.03–1.16
Congestive Heart Failure	65.1	0.9	0.84–0.96
TIA/Stroke	55.3	0.9	0.84–0.96

Model also includes age, gender, weight, language, Medicaid, and utilization

Conclusion: In this sample of medically homed patients meeting JNC-7 criteria for hypertension those with RA were 21% less likely to be diagnosed or treated despite more total visits, compared to those without RA. Given that both hypertension and RA increase cardiovascular risk, rheumatologists may need to actively help to improve hypertension recognition to modify CVD risk.

1668

Improving the Accuracy of Cardiovascular Risk Prediction in Rheumatoid Arthritis with a New Predictive Model Using the 10-Year Prospective Carre-Study. Alper M. van Sijl[1], Inge A.M. van den Oever[1], Mike J.L. Peters[2], Vokko P. van Halm[3], Alexandre E. Voskuyl[2], Yvo M. Smulders[2] and Mike T. Nurmohamed[1]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands, [3]Academic Medical Centre, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease which is associated with an increased cardiovascular (CV) risk. Traditional CV risk factors do not fully explain the increased CV risk and prediction of future CV disease in RA by CV risk estimates (Framingham and Reynolds) has shown to be inadequate. The present study investigated whether future CV disease in RA can be accurately predicted by demographic factors, CV risk factors, RA-related factors, CV risk estimates and surrogate markers of CV disease, or a combination of all.

Methods: 10-year incidence rate of CV disease was determined in a prospective cohort of 353 RA-patients. CV risk factors, RA-related factors and surrogate markers of CV disease were assessed at baseline. Predictive models of separate variables or in combinations were created using stepwise backward logistic regression analyses and areas under the curve (AUC) were calculated using receiver operating curves (ROC) analyses.

Results: After 10 years, there were 58 events over 2361 patient years of follow-up. CV disease incidence was 16.4%, while 10-year CV risk estimates with SCORE and Framingham underestimated this risk with 5.9% and 13.0%, respectively. From ROC analyses, a model was created which seemed to predict CV disease incidence better than the already available 10-year CV risk estimates (AUC 0.801 vs. 0.712, respectively). For RA patients without prior CV disease, the model consisted of age, gender, use of statins and prednisone, body-mass index, diastolic blood pressure, LDL cholesterol, total cholesterol to HDL-cholesterol ratio, C-reactive protein, HAQ and ESR.

Table 1. Comparison of incident cardiovascular (CV) disease with 10-year CV risk estimates

	All RA-patients (n=349)	Prior CV disease excluded (n=295)
Follow-up characteristics		
Total follow-up, years	2361	2042
Cases of CV disease, number	58	41
Incidence rates/1.000 patient years		
Total CV disease	24.6	20.1
CV mortality	3.4	3.4
Coronary artery disease	14.4	12.2
Cerebrovascular disease	6.3	4.9
Peripheral arterial disease	4.7	2.9
Observed and predicted 10-year CV disease incidence		
Observed 10-year CV disease incidence, %	16.4	13.9
Predicted 10-year CV disease risk at baseline according to SCORE-formula, %	5.9	4.9
Predicted 10-year CV disease risk at baseline according to Framingham-formula, %	13.0	11.0
Figure 1. ROC curve for the prediction of incident CV disease using a model consisting of demographical factors, CV risk factors and RA related factors

Conclusion: 10-year CV risk estimates did not accurately predict the actual CV risk in a population of RA patients. A combined model of demographic factors, CV risk factors and RA related factors more accurately predicted the actual CV risk. Future studies should corroborate these findings and consider whether modification of pre-existing risk models will improve the CV risk assessment in RA patients.

1669

Infection Risk After Orthopaedic Surgery in Patients with Inflammatory Rheumatic Diseases, with Focus On Discontinuation of TNF-Alpha-Inhibitors. Catrina B. Scherrer[1], Anne AF Mannion[1], Diego Kyburz[2], Markus Vogt[3] and Ines A. Kramers-de Quervain[1]. [1]Schulthess Clinic, Zürich, Switzerland, [2]Center of Exp. Rheumatology, Zurich, Switzerland, [3]Cantonal Hospital Zug, Baar, Switzerland

Background/Purpose: Infections after orthopaedic surgeries are feared complications, leading to costly treatments and successive interventions. A higher postoperative infection risk is discussed in patients with inflammatory rheumatic diseases (IRDs). This is especially relevant since patients with aggressive diseases frequently need orthopaedic surgery. In a retrospective study of a large cohort of orthopaedic surgeries the risk of postoperative infections was examined in relation to diagnosis, type of surgery and preoperative management of conventional disease modifying medication (cDMARDs) and tumor necrosis factor alpha (TNF-α)-inhibitors.

Methods: 37'137 patients (50'359 surgeries) were followed in the hospital's surgery registry over 8 years. Diagnoses were categorized as inflammatory or degenerative/posttraumatic and operation-related infections were registered. In a subgroup with known medication prior to surgery the preoperative management and influence on the infection rate was analyzed. Chi-squared test was used to assess associations between two discrete variables. Univariate and multiple logistic regression analyses were used to identify risk factors for infection. Odds ratios (OR) together with the corresponding 95% confidence intervals (95%CI) were provided.

Results: Among the 50'359 surgeries 422 (0.8%) surgery-related infections were identified, 373/47'887 (0.8%) cases in the degenerative group and 49/2'472 (2.0%) in the IRD group, indicating a significantly higher infection rate in the IRD group (OR=2.576, 95%CI 1.907, 3.479; p<0.001). Complete information on medication use and its discontinuation or otherwise prior to surgery was available for 1'329/2472 (54%) cases in the IRD group. The use of TNF-α-inhibitors was documented in 171/1'329 (13%) cases. In 49/171 (29%) cases, TNF-α-inhibitors were discontinued more than three adminis-

tration intervals before surgery. These were considered "ex-users". This occurred more often with drugs having a short administration interval. In the remaining 122/171 (71%) cases, the time lag was 3 administration intervals or less, and these were considered "at risk". The use of more than one cDMARD (OR=2.425, 95%CI 1.034, 5.688; p=0.042) and TNF-α-antagonists before surgery (OR=2.627, 95%CI 1.119, 6.168; p=0.027) were each associated with an increased infection rate. The risk of infection was almost 10-fold when surgery was performed within one administration interval (OR=10.047, 95%CI 1.170, 86.286; p=0.035). Approximately 81% of the patients treated with infliximab were in this group ($\leq$1 administration interval), whereas only 33% of the users of adalimumab and 24% of the etanercept users had their last intake of the drug one administration interval or less before surgery.

Conclusion: The risk of postoperative infection is elevated in patients with IRDs compared to degenerative/posttraumatic cases. Special attention should be paid when more than one cDMARD or TNF-α-inhibitors with long administration intervals are used. The last intake of TNF-α-inhibitors should be at least more than one administration interval before surgery, as the risk of postoperative infection is significantly increased if surgery occurs within this period.

ACR Concurrent Abstract Session
Muscle Biology, Myositis and Myopathies:
Pathogenesis in Idiopathic Inflammatory Myopathies
Monday, November 12, 2012, 4:30 PM–6:00 PM

1670

Microarray Analysis for miRNA Expression in Juvenile Dermatomyositis (JDM). Dong Xu[1], Akadia Kachaochana[2], Gabrielle A. Morgan[2], Elio F. Vanin[3], Marcelo Bento Soares[3] and Lauren M. Pachman[1]. [1]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Children's Hospital of Chicago Research Center, Cure JM Myositis Center, Chicago, IL, [3]Cancer Biology & Epigenomics Program, Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: JDM, the most common of the idiopathic inflammatory myopathies, is a systemic vasculopathy, associated with premature development of cardiovascular disease. Studies by others had implicated miRNA −10a in atherosclerosis. MicroRNAs (miRNAs) are short, non-coding RNAs and inhibit mRNAs by binding to complementary sequences on target mRNAs, resulting in translational repression or target degradation and gene silencing. **Hypothesis:** miRNA-10a may play a role in the vasculopathy of untreated JDM.

Methods: After informed consent (IRB# 2008–13457) and under MRI guidance a diagnostic muscle biopsy was obtained from the involved area in untreated children with definite/probable JDM. The patient population consisted of 10 girls and 7 boys, the mean age was 6.0 ± 2.9 years old, and their race was: White 77.8%, Hispanic 16.7%, White/Indian 5.6%; for the controls, the 3 girls, 3 boys were white and their mean age was 12.1 ± 3.8 years old. Total RNA was extracted from muscle biopsy samples and used for Exiqon miRNA DNA microarray analysis. Validation of differentially expressed miRNAs and their putative target mRNAs was conducted by TaqMan qPCR.

Results: Of 1435 mature human miRNAs on the Exiqon miRNA DNA microarray, 335 miRNAs were expressed in JDM and control samples. The expression analysis identified 20 miRNAs that were significantly differentially expressed (p<0.05). Several of these miRNAs, e.g. miR-10a [Fold Change (FC)= −1.96], miR-10b (FC= −1.62) and miR-142-5p (FC= 2.17), regulate inflammatory pathways. To validate those differentially expressed miRNAs, we performed qPCR for miR-10a, miR-10b and miR-142-5p. Our results showed that miR-10a and miR-10b levels were decreased by 3.58 and 2.41 fold respectively; and miR-142p level was increased by 2.90 fold. Those altered microRNA expression levels were consistent with the results from miRNA DNA microarray data. Homeobox A1 (*HOXA1*) gene is a well-known target of miR-10a and it is negatively regulated by miR-10a. To confirm whether *HOXA1 gene* was up-regulated because miR-10a expression was decreased significantly in JDM, we conducted qPCR for the *HOXA1* gene. The results documented that the *HOXA1 gene* was significantly increased by 2.12 ± 1.14 fold (p<0.01) in JDM compared to controls.

miR-10a plays an important role in regulation of NFkB pathway: decreased miR-10a lowers NFkB degradation and promotes inflammatory biomarker gene expression. Further investigation showed that inflammatory biomarker genes, *IL-6* and *VCAM-1*, were significantly elevated in JDM compared with controls: *IL-6* and *VCAM-1* gene expression levels were increased by 2.81 ± 2.16 and 2.93 ± 1.45 fold respectively (p<0.01).

Conclusion: Profiling identified 20 differentially expressed miRNAs in JDM compared to controls. Decreased miR-10a expression and increased *HOXA1*, *IL-6* and *VCAM-1* gene expression demonstrated that specific miRNAs, miR-10a and 10b may play a role in the regulation of the inflammatory pathway in JDM. We speculate that miRNA-10a may be associated with the vasculopathy characteristic of JDM and that their mimics may be of value in therapy.

Characterization of Jo-1 Autoantibodies in Patients with Inflammatory Myopathy and Interstitial Lung Disease. Kyle P. Chiang[1], Varun Gauba[1], Darin Lee[1], Minh-Ha T. Do[1], Jie J. Zhou[2], Feng Wang[2], Ying Buechler[1], Leslie Nangle[1], Zhiwen Xu[2], John Mendlein[1], Melissa Ashlock[1] and Jeffrey M. Greve[1]. [1]aTyr Pharma, San Diego, CA, [2]Hong Kong University of Science and Technology, Kowloon, Hong Kong

Background/Purpose: Anti-Jo-1 autoantibodies (Jo-1 Abs), directed against histidine tRNA synthetase (HisRS1), are detected in a high proportion of patients with both autoimmune inflammatory myopathy (IM) and interstitial lung disease (ILD), progressive and debilitating conditions for which no drugs are specifically approved. These patients receive immunosuppressive therapy which can be needed on a chronic basis to control their symptoms. In some individuals continued respiratory deterioration may occur despite immunosuppressive treatment, and may lead to fatal outcomes. Several lines of evidence indicate that Jo-1 Ab may have pathogenic roles in IM and ILD. We and others have demonstrated that HisRS1 and HisRS1-derived proteins possess immune-regulatory activities in addition to their roles in protein synthesis. As a key element of our effort to develop novel therapies for IM and ILD, we performed a detailed characterization of the Jo-1 Abs present in diverse populations of patients.

Methods: A large panel of sera from healthy volunteers, IM patients with and without Jo-1 Abs, and patients with Jo-1 Abs for which the formal clinical diagnoses were unknown was obtained from a commercial vendor. Plate-based immunoassays were developed to determine: i) the Jo-1 Ab titers by ELISA; (ii) Jo-1 Ab isotypes; (iii) the absolute concentration of IgM and IgG Jo-1 Ab; iv) epitopes recognized by Jo-1 Abs using a panel of recombinant human HisRS1 protein fragments and alternatively-spliced forms (including those expressed in muscle and lung); v) Jo-1 Ab affinity (by surface plasmon resonance); and vi) circulating levels of HisRS1.

Results: A wide range of Jo-1 Ab titers were found and these values correlated with the absolute amount of Jo-1 Abs. The Jo-1 Ab titers and concentrations exhibited a broad range, with higher concentrations found in patients diagnosed with IM compared to those without a formal clinical diagnosis. Jo-1 Ab IgM was detected in some patients. The specific epitopes recognized by Jo-1 Abs were distributed across the entire HisRS protein and were interpreted in reference to the recently determined 3-D structure of human HisRS. The epitopes recognized varied considerably among subjects. Jo-1 Ab affinities measured were in the range of 10 – 0.01 nM. Circulating levels of HisRS1 protein were detected in some individuals.

Conclusion: This molecular characterization of Jo-1 Abs provides deeper insight into the human autoimmune response to HisRS1 that occurs in a population of human subjects with autoimmune diseases. Ongoing serial analysis of individual patients will provide greater insight into the progression of Jo-1 Abs with respect to isotypes, affinities, recognized epitopes, and their relationship to disease status. These data provide a framework for developing strategies to address the impact of Jo-1 Abs in IM and ILD.

Myosin Skews Effector Immune Cells of Scurfy Mice to Target Muscles in an Adoptive Transfer Model of Myositis. Nicholas Young[1], Rahul Sharma[2], Alexandra Friedman[1], Benjamin Kaffenberger[1] and Wael N. Jarjour[3]. [1]The Ohio State University Medical Center, Columbus, OH, [2]University of Virginia Health System, Charlottesville, VA, [3]Ohio State University, Columbus, OH

Background/Purpose: Myositis is associated with an inflammatory process that results in pronounced muscle weakness and is observed in some regulatory T cell (Treg) deficient mouse models. Autoimmune pathogenesis has been strongly implicated in myositis and is the focus of both standardized and emerging therapeutics. It has been shown that patients with dermatomyositis have decreased numbers of Tregs in peripheral blood and at skin lesions when compared to healthy controls. Scurfy (Forkhead box P3, FOXP3-/y) mice lack Tregs and display autoimmune inflammation of multiple organs, but exhibit very little evidence of myositis. In contrast, Syt7 (Synaptotagmin 7) mice which have no Treg deficits develop an inflammatory response involving the muscles. We hypothesized that Treg deficient myositis could be induced by myosin protein and that muscle-specific inflammatory effector cells could be suppressed through Treg supplementation.

Methods: We crossed scurfy mice with Syt7 mice, which results in a double knockout that is deficient in Treg cells and membrane resealing. Lymph node preparations of these double knockout mice or scurfy mice were adoptively transferred into Rag1[null] males with or without Tregs isolated using Dynabeads from wild-type mice or with purified myosin protein. Histology of muscle tissue was examined four weeks post-injection. Immunohistochemistry was performed on flash frozen and/or paraffin embedded tissue.

Results: Scurfy lymph node preparations injected into Rag1[null] males intraperitoneally in conjunction with purified myosin protein induced robust skeletal muscle inflammation. The infiltrates consisted predominantly of $CD4^+$ and $CD8^+$ T cells, limited macrophages, but no B cells. Even more robust myositis was seen in similar experiments using lymph node preparations from Syt7/FOXP3 double knockout mice. However, myositis was not seen in adoptive transfers using single knockout mice. This myositis was completely suppressed with the co-transfer of purified Treg cells from wild type mice.

Conclusion: Taken together, these data demonstrate the critical role of the muscle antigen, myosin, in the pathogenesis of myositis. Hence, myosin could be one possible target antigen of the immune response. We also demonstrate the roles of Treg deficiency and aberrant muscle antigen release in the induction of myositis and the role of Treg as a therapeutic tool to treat myositis.

This novel model has the potential of examining the interplay between chemical injury and inflammatory pathogenesis in myositis. Ongoing work will use this model to examine the myopathy associated with statins and will examine the role of other endogenous muscle tissue antigens in this disease.

1673

Clinical Phenotypes of Caucasian Adult and Juvenile Dermatomyositis Patients with Anti-MDA5 Autoantibodies. Zoe Betteridge[1], Sarah Tansley[1], Harsha Gunawardena[2], Lucy R. Wedderburn[3], Hector Chinoy[4], Robert G. Cooper[5], Jiri Vencovsky[6], Lenka Plestilova[7], Ingrid E. Lundberg[8], Katalin Danko[9], Melinda Vincze[9], Neil McHugh[1], UK JDRG[10] and EuMyoNet[11]. [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]North Bristol NHS Trust, Bristol, United Kingdom, [3]University College London (UCL), London, United Kingdom, [4]The University of Manchester, Manchester, United Kingdom, [5]Hope Hospital, Salford, United Kingdom, [6]Institute of Rheumatology, Prague, Czech Republic, [7]Institute of Rheumatology, Prague 2, Czech Republic, [8]Karolinska Institutet, Stockholm, Sweden, [9]University of Debrecen, Debrecen, Hungary, Debrecan, Hungary, [10]London, United Kingdom, [11]Stockholm, Sweden

Background/Purpose: Autoantibodies to MDA5 have been previously reported in Japanese patients with dermatomyositis (DM) and are associated with clinically-amyopathic DM and rapidly progressing interstitial lung disease (ILD). These autoantibodies also occur in juvenile Japanese DM patients in association with ILD. Anti-MDA5 has also been reported in a cohort of mixed ethnicity, where it was found to be associated with ILD and severe vasculopathy. Here we report on the frequency and clinical manifes-

tations of anti-MDA5 autoantibodies in a large international multicenter cohort of Caucasian adult and juvenile myositis patients.

Methods: Serum was available from 1331 adult myositis patients (480 DM) recruited to the EuMyoNet repository and 172 JDM patients recruited to the UK JDRG. Sera were screened for autoantibodies by immunoprecipitation (IPP) using radio-labelled K562 cell extract. Sera with immunoprecipitates at approximately 140 kDa were tested for anti-MDA5 autoantibodies by ELISA using recombinant MDA5 (Cambridge BioSciences). Clinical data were collected on standardised proformas. Sera from 169 systemic sclerosis, 40 SLE and 50 healthy controls were also analyzed by IPP. Statistical analysis was performed using SPSS and Fishers Exact Test.

Results: Anti-MDA5 autoantibodies were found in the sera of 12 JDM patients and 25 adults. The frequency in the JDM cohort was 7.0%, in comparison to 1.9% in the overall adult myositis population and 3.8% in the adult DM group. Anti-MDA5 autoantibodies were not found in any patients with PM or any control sera. As with previous reports, there was an association between ILD and anti-MDA5 (p=0.044) in the adult DM patients. However, contrary to previous reports, this was not seen to be rapidly progressing, with no known ILD related fatalities in the anti-MDA5 positive group. In comparison, ILD was not found to be a significant association in the JDM anti-MDA5 positive group, with no patients having ILD reported as a clinical manifestation. Similarly to previous report, anti-MDA5 positive patients had significantly more ulceration (skin: p=0.047 and mouth: p=0.039), in the JDM cohort, compared with the anti-MDA5 negative group. Whilst ulceration data was unavailable in the adult population, the presence of anti-MDA5 was significantly associated with Gottron's papules (p<0.001).

Conclusion: We report the presence of anti-MDA5 autoantibodies in a large cohort of Caucasian JDM and adult myositis patients. The frequency of anti-MDA5 autoantibodies varies between adults and children, along with differences in the clinical profile. As with previous reports, the presence of anti-MDA5 is associated with the presence of severe cutaneous features in both JDM and adults. However, in this study ILD was only an association in the adult population, suggesting differences in pathogenesis or aetiology. This study also highlights differences in clinical manifestations between different ethnic groups, with the ILD in our adult patients being much less severe in comparison to previous reports on Japanese patients.

1674

Myeloid Related Proteins Induce Muscle Derived Inflammatory Mediators in Juvenile Dermatomyositis. Kiran Nistala[1], Hemlata Varsani[1], Helmut Wittkowski[2], Thomas Vogl[3], Petra Krol[4], Vanita Shah[1], Kamel Mamchaoui[5], Paul Brogan[1], Johannes Roth[3] and Lucy R. Wedderburn[1]. [1]University College London (UCL), London, United Kingdom, [2]Muenster, Germany, [3]University of Muenster, Muenster, Germany, [4]Prague, Czech Republic, [5]Paris, France

Background/Purpose: The etiopathogenesis of Juvenile Dermatomyositis (JDM) remains poorly understood. In particular the contribution of monocytes or macrophages, which are frequently observed to be an infiltrate within muscle tissue very early in the disease process, is unknown. We hypothesised that these cells secrete the pro-inflammatory S100 proteins myeloid related peptide (MRP)-8/14 which may then contribute to muscle pathology in JDM.

Methods: In this study of 75 JDM patients, serum MRP8/14 levels were compared with clinical measures of disease activity. Muscle biopsies taken early in disease were assessed by immunohistochemistry to determine the frequency and identity of MRP-expressing cells. The effects of MRP stimulation and ER stress on muscle were tested *in vitro*. Serum or supernatant levels of cytokines were analysed by multiplex immunoassay.

Results: Serum MRP8/14 correlated with physician's global assessment of disease activity in JDM (r^2=0.26, p=0.006), functional assessment (CHAQ, r^2=0.31, p=0.0498), and strength/stamina (CMAS, r^2=0.28, p=0.028). MRP8/14 was widely expressed by CD68+ macrophages in JDM muscle tissue. When cultured with human myoblasts, MRP8 led to the secretion of MCP-1 and IL-6, which was enhanced by ER stress. Both inflammatory mediators were detected in significantly higher levels in the serum of JDM patients compared to healthy controls.

Conclusion: This study is the first to identify serum MRP8/14 as a biomarker for disease activity in JDM. We propose that tissue infiltrating macrophages secreting MRP8/14 may contribute to myositis, by driving the local production of cytokines directly from muscle.

1675

Myositis Autoimmunity and Muscle Weakness Are Linked to TNF-Alpha Suppression of Micrornas-1, 133, and 206 in Myoblasts and Myocytes.
Robert Georgantas III[1], Katie Streicher[1], Steven A. Greenberg[2], Lydia Greenlees V[3], Wei Zhu[4], Philip Brohawn[4], Brandon W. Higgs[4], Megan Czapiga[5], Chris Morehouse[4], Laura Richman[3], Bahija Jallal[4], Koustubh Ranade[5] and Yihong Yao[3]. [1]Medimmune, Inc, Gaithersburg, MD, [2]Brigham Women's Hospital, Harvard Medical School, Boston, MA, [3]MedImmune, Gaithersburg, MD, [4]MedImmune, LLC, Gaithersburg, MD, [5]MedImmune, Inc, Gaithersburg, MD

Background/Purpose: The molecular basis of myopathies such as dermatomyositis, polymyositis and inclusion-body myositis, which are characterized by chronic muscle inflammation followed by long term skeletal muscle wasting, are poorly understood.
Methods: We compared expression levels of inflammatory cytokines and microRNAs to identify those differentially expressed between muscle biopsies from myositis patients (N = 24) and healthy donors (N = 17). We then used human and mouse *in vitro* myoblast-to-myocyte differentiation models to determine those differentially expressed cytokines and microRNAs that affect myoblast differentiation.
Results: We observed increased expression of inflammatory cytokines including TNF-alpha (fold change = 3.8 to 8.8-fold, P-values < 0.045), and decreased expression of microRNAs miR-1 (fold changes = -2.8 to -8.7, P-values $< 2.0\times10^{-4}$), miR-133a (fold changes = -3.9 to -5.0, P-values $< = 4.0\times10^{-4}$), miR-133b (fold changes = -2.7 to -7.8, P-values $<4.2\times10^{-4}$), and miR-206 (DM = -2.8-fold, P = 0.012) which are known to be critical to adult skeletal muscle differentiation. TNF-alpha inhibited expression of miR-1, 133a/b, and 206 and suppressed differentiation of C2C12 myoblasts to myocytes/myotubes in an NF-kb dependent manner. This block in differentiation by TNF-alpha was relieved by overexpression of *miR-1*, miR-*206* or *miR-133*.
Conclusion: Taken together these results provide a new mechanistic link between a pro-inflammatory cytokine and the degenerative pathology of myositis, and suggest new therapeutic approaches for this disease.

1676

Abatacept As First Line Biological Treatment for Severe Juvenile Idiopathic Arthritis-Related Uveitis. A Multicenter Study.
Carolina Birolo[1], Maria Elisabetta Zannin[1], Svetlana Arsenyeva[2], Rolando Cimaz[3], Elisabetta Miserocchi[4], Margarita Dubko[5], Chantal Deslandre[6], Fernanda Falcini[7], Maria Alessio[8], Francesco La Torre[9], Ekaterina Denisova[10], Irina Nikishina[11] and Francesco Zulian[12]. [1]University of Padua, Padua, Italy, [2]Scientific Research Institute of Rheumatology RAMS, Moskow, Russia, [3]A. Meyer Children's Hospital, Florence, Italy, [4]Scientific Institute San Raffaele, University Vita-Salute, Milan, Italy, [5]Saint-Petersburg Pediatric Medical Academy, Saint-Petersburg, Russia, [6]Cochin Hospital, Paris, France, [7]Department of Internal Medicine, Rheumatology Section, University of Florence, Florence, Italy, [8]University of Naples Federico II, Naples, Italy, [9]DIMIMP-University, Rheumatologic Section, Bari, Italy, [10]Helmgoltz Moscow Recearch Institute of Eye Diseases, Moskow, Russia, [11]Scientific Research Institute of Rheumatology RAMS, Moskow, Moskow, Russia, [12]University of Padua, Padova, Italy

Background/Purpose: Anterior uveitis is a serious complication of Juvenile Idiopathic Arthritis (JIA). Recently, Abatacept (ABA) has been used in children with JIA-uveitis who had failed previous anti-TNF agents but little is known about its efficacy as first-line biological agent in severe JIA-related uveitis. Aim of the present study was to compare safety and efficacy of ABA used as first biological agent (ABA1st) with ABA used after one or more anti-TNF agents (ABA2nd), in patients with severe JIA-related uveitis.
Methods: A retrospective multicenter collection of data of patients with severe, MTX-resistant JIA-related uveitis treated with ABA at a monthly dosage of 10 mg/kg, administered intravenously as first line or second line biological agent, was performed. Absolute frequency of uveitis flares before and after ABA treatment, changes in ocular complications and ABA-related side effects have been recorded. The number of active joints was also assessed at each visit.
Results: Thirty-five JIA patients (33 females, 2 males) with a mean 12.5 years of age, and 7.7 years of uveitis duration have been treated with ABA for 19.6 months (range 5–42). Twenty-seven patients with MTX-refractory uveitis and at least 12 months follow-up entered study. 11 were included in the ABA1st group and 16 in the ABA2nd group. Age at uveitis onset, number of uveitis flares during 12 months before ABA and number of complicated uveitis were comparable in the two groups. The mean uveitis duration was significantly shorter in ABA1st (5.1 versus 9.5 years, $p=0.009$). The mean frequency of uveitis flares during the 12 months before and after ABA decreased from 4.1 to 1.0 in ABA1st ($p=0.001$) and from 3.5 to 1.1 in ABA2nd ($p=0.001$). The efficacy was comparable in both groups and in all ABA showed a better performance after the first six months of treatment as 21/30 (70%) uveitis flares occurred during the first semester. Pre-existing ocular complications improved or remained stable in all but 2 patients. 15/22 patients (68.2%) with active arthritis at baseline were in remission at 12 months follow-up; in the others, the mean number of active joints decreased from 10.1 to 7.0. In this regard, no significant difference was observed between the two ABA treatment modalities. Two patients (7.4%) experienced adverse events (1 post-infusion headache, 1 weight gain) but no serious events were observed. Two patients (7.4%) withdrew from the study (after 5 and 9 months) because of ABA inefficacy on both ocular and articular symptoms.
Conclusion: Abatacept, used as first-line biological treatment or after one or more anti-TNF agents, induced a comparable sustained improvement of refractory JIA-related uveitis. Efficacy was more evident during the second semester in both groups. Abatacept represents a treatment of choice in patients failing standard immunosuppressive treatment and/or anti-TNF agents for severe JIA-related uveitis.

1677

Safety and Efficacy of Intra-Articular Infliximab Therapy for Treatment Resistant Temporomandibular Joint Arthritis in Children.
Matthew L. Stoll, Anthony B. Morlandt, Suwat Teerawattanapong, Daniel Young, Peter D. Waite and Randy Q. Cron. University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Temporomandibular joint (TMJ) arthritis occurs in as much as 80% of children with juvenile idiopathic arthritis (JIA) and can result in substantial facial deformity. TMJ arthritis often responds poorly to systemic immunosuppressive therapy. Intra-articular corticosteroid injections (IACI) are of benefit in approximately 50% of JIA patients with TMJ arthritis, but repeated injections are often ineffective. Multiple studies have shown benefit of IA infliximab injections (IAII) in treating chronic arthritis, including to the TMJ in one case report, so we used IAII of the TMJs in JIA patients with TMJ arthritis refractory to both repeated IACI and to systemic arthritis therapy.
Methods: Chart review was performed for all children with JIA treated at a single center who received one or more IAII (5–10 mg/injection) to the TMJs. Outcomes assessed were maximal incisal opening (MIO) measurements and pre- and post-contrast magnetic resonance imaging (MRI) findings. Specifically, we compared pre- versus post-IACI and pre- versus post-IAII MRI studies for changes in the acute (synovial fluid, synovial enhancement, marrow edema) and chronic (synovial hypertrophy, condylar head flattening and erosions, disc displacement) findings associated with TMJ arthritis. Assessments of improved, unchanged, or worsened were made by two independent reviewers based upon the official reports, and adjudicated by a radiologist based upon the actual films in instances of disagreement. Institu-

tional Review Board, and Hospital Pharmacy and Therapeutics Committee, approvals were obtained prior to reporting and treating, respectively.

Results: 24 children with JIA and treatment-refractory TMJ arthritis underwent bilateral IAII of the TMJs, of whom 23 had MRIs at all three timepoints (pre-IACI, post-IACI, post-IAII). 23/24 (96%) were on a biologic, with or without concurrent conventional disease-modifying agents; 1 child received methotrexate as monotherapy. Their MIOs (mean ± SEM; in mm) were unchanged before and after both IACI (44.0 ± 1.3 versus 44.6 ± 0.7, p = 0.813) and IAII (44.6 ± 0.7 vs 44.5 ± 0.9, p = 0.840.) However, MRIs revealed improved or halted progression of acute changes in 31 out of 46 TMJs (67%) and of chronic changes in 29 out of 46 TMJs (63%), compared to 15/46 (33%) and 19/46 (41%), respectively, with repeated use of IACI (p = 0.002 and 0.052, respectively). No side effects (infections, nerve damage, cosmetic alterations, prolonged discomfort) were noted after 7.4 person-years of follow-up among 22 patients.

Conclusion: IAII halted or reversed the progression of TMJ arthritis in the majority of JIA patients who were refractory to systemic arthritis therapy and repeated IACI TMJ injections. The IAII TMJ injections were safe in the short term. It remains unknown whether repeated injections of IAII will be of benefit to treatment refractory TMJ arthritis in children with JIA. Future studies will evaluate the efficacy of infliximab versus long-acting corticosteroid injections as initial therapy for TMJ arthritis in children with JIA.

1678

Safety and Efficacy of Adalimumab in Children with Active Polyarticular Juvenile Idiopathic Arthritis Aged 2 to <4 Years or ≥4 Years Weighing <15 Kg. Daniel J. Kingsbury[1], Pierre Quartier[2], Gina Patel[3], Vipin Arora[3], Hartmut Kupper[4] and Neelufar Mozaffarian[3]. [1]Legacy Emanuel Children's Hospital, Portland, OR, [2]Unite d'Immuno-Hematologie et Rhumatologie Pediatriques, Paris, France, [3]Abbott, Abbott Park, IL, [4]Abbott GmbH and Co. KG, Ludwigshafen, Germany

Background/Purpose: Adalimumab (ADA) is approved for use in moderate to severe JIA in patients (pts) ≥4 yrs old in the US, EU, and Japan. ADA has not been studied in pts <4 yrs old, and limited data are available in pts ≥4 yrs old weighing <15 kg. The primary objective of this study was to assess the safety of ADA in pts 2 to <4 yrs old or ≥4 yrs old weighing <15 kg with moderately to severely active polyarticular onset/polyarticular course JIA. The secondary objectives were to evaluate the pharmacokinetics (PK) and clinical effectiveness of ADA in these pts.

Methods: This is an interim analysis of the multicenter, open-label, phase 3b ADA study in pts 2 to <4 yrs old or ≥4 yrs weighing <15 kg with moderately to severely active JIA in the US and EU. ADA was given subcutaneously every other wk, 24 mg/m^2 BSA up to 20 mg/dose, for a minimum of 24 wks and continued until pts reached 4 yrs old and weighed 15 kg. Concomitant methotrexate use was allowed. Adverse events (AE) were collected throughout the treatment period and include safety data up to 96 wks. Serum trough concentrations of ADA were determined for each subject using validated methods. Key effectiveness endpoints were the proportion of pts achieving PedACR30/50/70/90 at wk 24. Other outcomes included tender joint count (TJC), swollen joint count (SJC), Pain on Passive Motion (POM75), Limitation on Passive Motion (LOM69), Active Joint Count (AJC73), Child Health Assessment Questionnaire (DICHAQ), and Physician's and Parent's Global Assessment of Disease (PhGA and PaGA).

Results: 88% of the pts were female. At baseline, mean age=3 yrs, mean weight=13 kg, mean duration of JIA=12 months, and 39% had elevated CRP (≥0.9 mg/dL). AE incidence rates through 96 wks included: any AEs (84%, 27/32), serious AEs (16%, 5/32), infectious AEs (69%, 22/32), and serious infections (9%, 3/32). No deaths, malignancies, opportunistic infections/TB, congestive heart failure, demyelinating disease, allergic reactions, lupus-like syndrome, or blood dyscrasias were reported. The mean serum ADA trough concentrations achieved a steady-state of 7–8 μg/mL at weeks 12 and 24 (n=15). Of 32 pts enrolled, 31 completed 24 wks of ADA treatment; 90% achieved PedACR30 and 70% achieved PedACR70 (**Table 1**).

Table 1. PedACR Response at Week 24

	Response Rate[a] N=30	Response Rate[b] N=32
PedACR30, n (%)	27 (90.0)	27 (84.4)
PedACR50, n (%)	25 (83.3)	25 (78.1)
PedACR70, n (%)	22 (73.3)	22 (68.8)
PedACR90, n (%)	11 (36.7)	11 (34.4)

[a]Observed. [b]Nonresponder imputation.

Improvements in other JIA outcomes were also seen at wk 24 of ADA treatment (**Table 2**).

Table 2. JIA Outcomes at Week 24[a]

	Mean Change (SD) from Baseline
Tender Joint count (TJC75)[b]	-3.0 (5.5)
Swollen Joint Count (SJC66)[b]	-6.3 (5.8)
Pain on Passive Motion (POM75)[b]	-3.9 (7.3)
Limitation on Passive Motion (LOM69)[b]	-5.6 (5.6)
Active Joint Count (AJC73)[b]	-7.0 (5.7)
Child Health Assessment Questionnaire (DICHAQ)[b]	-0.5 (0.7)
PhGA of Disease Activity[b] (VAS 0–100 mm)	-45.3 (21.3)
PaGA of Disease Activity[b] (VAS 0–100 mm)	-32.2 (29.7)
PaGA of Pain[b] (VAS 0–100 mm)	-29.5 (28.3)
CRP[c] (mg/dL)	-0.2 (3.2)

[a]Observed data. [b]n=30; [c]n=28.

Conclusion: The safety profile, PK, and effectiveness of ADA were similar to that seen in older pediatric patients with JIA, demonstrating that ADA is also safe and effective in younger patients 2 to <4 yrs old or ≥4 yrs old weighing <15 kg with active polyarticular JIA.

1679

Cumulative Long-Term Safety and Efficacy of Abatacept in Children with Juvenile Idiopathic Arthritis: Results up to 7 Years of Follow-up. D. J. Lovell[1], N. Ruperto[2], R. Mouy[2], E. Paz[2], N. Rubio-Perez[2], C. A. Silva[2], C. Abud-Mendoza[2], R. Burgos-Vargas[2], V. Gerloni[2], J. A. Melo-Gomes[2], C. Saad-Magalhaes[2], J. Chavez[2], C. Huemer[2], A. Kivitz[2], F. Blanco[2], I. Foeldvari[2], Michael Hofer[3], H. Huppertz[2], C. Job Deslandre[2], K. Minden[2], A. Flores Nunez[4], A. J. Block[5] and A. Martini[2]. [1]Cincinnati Children's Hospital, Cincinnati, OH, [2]PRINTO, IRCCS G. Gaslini, Genoa, Italy, [3]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genoa, Italy, [4]PRINTO, IRCCS Hospital para el Niño Poblano, Puebla, Mexico, [5]Bristol-Myers Squibb, Princeton, NJ

Background/Purpose: We previously reported the efficacy and safety of abatacept (ABA) in patients with juvenile idiopathic arthritis (JIA) in the AWAKEN trial[1], during the 4-month open-label ABA lead-in phase and 6-month double-blind (DB) (ABA vs placebo [PBO]) period. Long-term efficacy and safety were also described for 153 patients who received open-label ABA in the long-term extension (LTE) for ≥21 months.[2] We now report efficacy and safety data from the cumulative LTE for an additional ~30 months of exposure up to 7 years of total follow-up.

Methods: Patients entered the LTE and received open-label intravenous ABA if they were a non-responder (NR) in the 4-month open-label lead-in phase, or if they either experienced a flare or completed the 6-month DB withdrawal phase while receiving ABA or PBO. Efficacy is reported up to Day 1681 of the LTE (~Year 5.5 of the study), and safety is reported up to 7 years of treatment at study completion.

Results: 190 patients entered the AWAKEN trial, with 153 entering the LTE (58/60 patients from the DB ABA group, 59/62 from the DB PBO group, and 36/47 NR patients from the open-label phase). Cumulative exposure was 606.2 years. At the start of the LTE, 46/58 (79%, ABA) and 31/59 (53%, PBO) had achieved an ACR Pediatric 50 response. Mean response of those who received PBO during the DB phase recovered completely within 6 months after re-instating ABA therapy in the LTE and these results were combined with those of patients in the ABA group starting from LTE Month 6 (Figure). ACR Pediatric 50, 70 and inactive disease rates are shown. Of the open-label responders, 32/110 (29%, Day 169) to 36/79

(46%, Day 1177) had inactive disease status. Of the NR, 4/13 (31%) achieved inactive disease at the end of the trial. There was one death (accidental; unrelated). The major reason for discontinuation in the LTE was lack of efficacy in 24 patients (15.7%, 11 were NR); 6 discontinuations due to AEs (3/6 due to serious AEs); 13, loss to follow-up; 10, withdrawal of consent; and 18 "other" (not efficacy or safety). Thirty patients (19.6%) had serious AEs; most were unrelated and were primarily musculoskeletal or infectious events. Incidence rate (per 100 patient-years [pt-yrs]) of SAEs in the LTE (5.6/100 pt-yrs) did not increase versus the 6-month DB rate (6.8/100 pt-yrs). No malignancy was reported. Of the 153 patients entering the LTE, 69 patients completed the trial (29, 27 and 13 in the original ABA, PBO and NR groups, respectively).

ACR Pediatric 50, 70 and Inactive disease response rates during LTE for all Period A responders who entered LTE (as observed data)
Conclusion: These data demonstrate the sustained efficacy of abatacept in JIA patients. Additional exposure of ~30 months did not change the safety profile of abatacept in these patients when compared to prior LTE experience.[2]

1680

Diagnostic Value of the Assessment of Spondyloarthropathy International Society (ASAS) Criteria for Children with Enthesitis Related Arthritis (ERA): A Single Center Study of 124 Patients.

Mehul Jariwala, Manjari Agarwal and Sujata Sawhney. Sir Ganga Ram Hospital, New Delhi, India

Background/Purpose: Enthesitis Related Arthritis (ERA) is a common subtype (36%) of Juvenile Idiopathic Arthritis (JIA) seen in India [1]. These criteria do not distinguish between axial and peripheral arthritis. The new ASAS criteria [2,3] do, and have to date been applied only to the adult population. This distinction is important from both the diagnostic and therapeutic viewpoint. Therefore, we applied the ASAS criteria to our ERA patients. This is the first study of its kind.

Methods: Data on JIA patients at our centre is collected on detailed proformas at onset and thereafter quarterly. All ERA patients seen over a three year period from May 2009–12 were included. ASAS axial and peripheral spondyloarthritis (SpA) criteria were retrospectively applied to this cohort, taking all features within 6 months of disease onset.

Results: *ERA:* 124 children were identified, 102 were boys. Median age of onset was 10.9 years; median delay to diagnosis 5months. ERA features: 64 had arthritis *and* enthesitis; 60 had Enthesitis *or* Arthritis with ≥ 2 of the following: SI tenderness and/or inflammatory spinal pain 28%, HLA-B27 97.6%, Family history of medically confirmed HLA-B27-associated disease 9.7%, Anterior uveitis 16.1%, Onset of arthritis in a boy after 6 yr of age 83.8%.

ASAS criteria: All 124 ERA patients could be classified per the ASAS criteria. The prevalence of each item is in Table1. No patient in this cohort had

isolated inflammatory back pain (IBP) without any other feature of SpA. Thirty five children had axial and 89 peripheral SpA. Only 1 patient had imaging evidence of sacroiliitis with no back pain. All children in this study with axial complaints had IBP.

Table 1.

SpA features	Axial SpA	Axial SpA	Peripheral SpA	Peripheral SpA
	Low back pain >3months + Sacroiliac imaging + ≥1 SpA feature n=29	Low Back Pain + HLAB27 + ≥2 SpA features n=6	Arthritis or Enthesitis or Dactylitis + ≥1 SpA feature n=88	Arthritis or Enthesitis or Dactylitis + ≥2 SpA feature n=1
IBP	29 (100%)	6 (100%)	NA	NA
Arthritis	25 (86.2%)	5 (83.3%)	88 (100%)	1 (100%)
Enthesitis (heel)	9 (31%)	0 (0%)	NA	NA
Uveitis	3 (10.3%)	1 (16.67%)	16 (18.18%)	NA
Dactylitis	0 (0%)	0 (0%)	3 (3.4%)	0 (0%)
Psoriasis	0 (0%)	0 (0%)	0 (0%)	NA
Crohn's/Ulcerative Colitis	1 (3.4%)	1 (16.67%)	1 (1.13%)	NA
Good response to NSAIDs	23 (79.3%)	5 (83.33%)	NA	NA
Family h/o SpA	7 (24%)	0 (0%)	NA	0 (0%)
HLAB27	29 (100%)	6 (100%)	87 (98.86%)	NA
Elevated ESR*	20 (69%)	4 (100%)	NA	NA
Preceding infection	NA	NA	6 (6.81%)	NA
SI imaging	NA	NA	5 (5.68%)	NA
Enthesitis (any)	NA	NA	46 (52.27%)	0 (0%)
IBP ever	NA	NA	NA	0 (0%)

*CRP replaced by ESR

Additional data: 97.6% patients were HLAB27 positive, 19.4% had hip disease and 28.2% of SI joint MRIs were positive. A further 12 patients developed new onset inflammatory back pain over the observation period of 3 years.

Conclusion: The ASAS axial and peripheral SpA criteria can be applied to all children with ERA and have a sensitivity of 100%, peripheral SpA is 2.5 times as common as the axial SpA. Thus in the pediatric population the entry criteria should be peripheral and not axial disease. This has important implications for deciding therapeutic pathways in children with axial or peripheral disease and gives an oppurtunity to childen with SpA to be recruited into clinical trials with same diagnostic criteria as for adults. We plan to expand the application of these criteria to the undifferentiated and psoriatic arthritis categories of JIA as well.

Increased Arterial Stiffness in Juvenile Idiopathic Arthritis (JIA) Patients Compared with Matched Controls - a Pilot Study.

Hanne Aulie[1], Mette-Elise Estensen[2], Anne Marit Selvaag[1], Patrick Segers[3], Oyvind Molberg[1], Vibke Lilleby[1], Svend Aakhus[2] and Berit Flatø[1]. [1]Department of Rheumatology, Oslo University hospital, Rikshospitalet, Oslo, Norway, [2]Department of Cardiology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [3]IBiTech-bioMMeda, Ghent University, Ghent, Belgium

Background/Purpose: Systemic arterial properties in adult patients with JIA are not well described. The aim of this study was to evaluate arterial properties in young adults with JIA compared with age- and sex-matched controls.

Methods: Nineteen patients (37.7±3.4 years) were randomly selected from a cohort of 88 JIA-patients who were followed from their first referral to Oslo University Hospital in 1980 −85 and had active disease more than 14 years after disease onset. Of the 19 patients, 2 had systemic JIA, 3 polyarticular RF negative, 1 polyarticular RF positive, 3 oligoarticular persistent, 5 oligoarticular extended, 3 enthesitis related, 1 psoriasis arthritis and 1 had undifferentiated arthritis. The patients were investigated after a mean disease duration of 29.2 ±1.3 years and compared with 19 age- and sex-matched controls.

Aortic root pressure and flow data were obtained non invasively by brachial arterial blood pressure, calibrated carotid arterial pulse trace and aortic annular Doppler flow recordings. The systemic arterial properties were described by the total arterial compliance (C), characteristic aortic impedance

(Z_0), and peripheral arterial resistance (R) obtained from estimation of 3-element windkessel model (WK) parameters (C, Z_0, R), by Fourier analyses of central aortic pressure and flow data (Z_0).

Results: (table)

Table.

Variables	JIA-patients Mean ± SD	Controls Mean ± SD	P-value (unpaired t-test)
BMI	25.7 ± 4.9	25.3 ± 4.0	0.785
Systolic blood pressure (mmHg)	117 ± 15	114 ± 11	0.443
Diastolic blood pressure (mmHg)	69 ± 9	68 ± 9	0.535
Heart rate (beats/s)	67 ± 11	60 ± 8	0.043
Cardiac output(l min −1)	5.3 ± 1.1	5.3 ± 0.9	0.982
R (mmHg/(ml/s))	1.04 ± 0.21	1.00 ± 0.23	0.564
Z_0 Windkessel Model (WK) (10^-3 mmHg/ml/s)	77 ± 25	58 ± 20	0.016
C Pulse pressure method (PPM) (ml/mmHg)	1.21 ± 0.24	1.44 ± 0.34	0.022

The proximal aortic stiffness, evaluated by Z_0,was significantly higher in the JIA-patients compared to the healthy controls (p=0.016). The patients also had lower total arterial compliance (C) (p=0.022), but the arterial resistance (R) was not different (p= 0.564). The heart rate was higher in the patients than in the controls (p=0.043), but the blood pressure did not differ between the groups (p=0.443, p=0.535).

Conclusion: In spite of similar blood pressure, JIA patients have stiffer proximal aorta and lower total arterial compliance than matched controls. This indicates that JIA-patients with long term active disease experience significant alteration of arterial function.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects III:
Rheumatoid Arthritis and Cardiovascular Disease
Monday, November 12, 2012, 4:30 PM–6:00 PM

1682

Sustained Clinical Remission (Disease Activity Score 28 Elke.E.A. Arts[1], Jaap Fransen[1], Alfons A. den Broeder[2], Calin Popa[1] and Piet L.C.M. van Riel[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands

Background/Purpose: Chronic inflammation appears to be an independent risk factor for CVD in rheumatoid arthritis (RA), but there is no clear difference in CVD risk between RA patients with low or high disease activity [(1;2)]. Possibly, only if disease activity is very low ('remission') it may protect against CVD. The objective of this study was to investigate the association between clinical remission (DAS28<2.6) and the risk of CVD in patients with RA.

Methods: RA patients from the Nijmegen inception cohort were selected if they had at least one year follow-up. Patients were seen at 3-month intervals and the DAS28 was assessed at each visit. Cardiovascular events included myocardial infarction (MI) and stroke, transient ischemic attack, angina pectoris and peripheral arterial disease. Remission was defined as DAS28<2.6. A continuity rewarded score (ConRew) was calculated: a score of 1 was rewarded if DAS28<2.6 and a score of 2 was rewarded if DAS28<2.6 at the previous visit too. The ConRew score was divided by the maximal possible score (100% if always in remission) and this was used in the analysis. The crude data were analysed using Kaplan-Meier survival analysis, divided in two groups according to the median of the ConRew ratio. The risk of CVD in RA patients was analysed using a Cox-proportional hazard model, with ConRew ratio as the independent variable, and time to CVD event as the dependent variable. Considered confounders were age, gender, prior CVD, rheumatoid factor (RF), anti-CCP and DAS28, HAQ, medication for CVD prevention, glucocorticosteroid use, cholesterol levels and systolic blood pressure at baseline. Missing values were imputed using multiple imputation, results of the analysis are based on the pooled data.

Results: A total of 770 RA patients were selected for analysis. Patients had a mean±SD age of 56±13 at baseline, 61% female, 76% RF positive with a mean±SD DAS28 at baseline of 5.1±1.4. In total, 153 CV events were registered. Age, gender, prior CV event, and TC:HDL ratio, medication

for CV prevention, HAQ and DAS28 at baseline were included as confounders. Results from the Kaplan-Meier survival analysis in the crude data (figure 1) showed that patients who were less in remission, maximum ConRew score <10%, were more likely to develop CVD than patients who scored ≥ 10%, (p<0.001). In the Cox proportional hazards model, it was shown that a higher ConRew score had a protective effect for developing CVD (OR 0.48 [95% CI 0.66–0.83]), corrected for confounders.
Figure 1. Cumulative survival curves for RA patients with a ConRew score (% of maximum score) <10% and ≥10%.

Conclusion: Sustained remission in patients with RA is significantly associated with a reduced excess risk of CVD. Maintaining tight control of disease activity in RA patients to achieve remission is therefore important for the prevention of CVD events.

Associations Between Lipid and Rheumatoid Arthritis Genetic Factors, and Low Density Lipoprotein Levels in RA Patients. Katherine P. Liao[1], Dorothee Diogo[1], Tianxi Cai[2], Jing Cui[3], Raul N. Guzman P.[4], Vivian Gainer[4], Shawn N. Murphy[4], Susanne Churchill[4], Isaac Kohane[1], Elizabeth W. Karlson[5] and Robert M. Plenge[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard School of Public Health, Boston, MA, [3]Brigham and Womens Hospital, Boston, MA, [4]Partners Healthcare Systems, Boston, MA, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: In epidemiologic studies, low density lipoprotein (LDL), a major risk factor for cardiovascular disease (CVD), is lower in RA patients than the general population; despite this RA patients have a higher risk of CVD. Recently, the genetic determinants of LDL in the general population have been elucidated. We hypothesized that these LDL genetic factors are associated with higher LDL levels in RA and further, that RA genetic factors also influence LDL levels.

Methods: We studied an RA cohort of 1837 subjects based in a large academic center. We genotyped subjects' blood samples for published alleles associated with higher LDL levels (26 alleles) and RA risk (48 alleles including HLA shared epitope). To study associations between genetic factors and LDL levels, we created LDL and RA composite genetic risks scores (GRS): an aggregate count of the number of LDL and RA alleles for each individual. We selected the 1st LDL measurement in the electronic medical record as the outcome and excluded subjects with ≥1 statin prescription prior to the 1st LDL. We tested the associations between the LDL GRS and LDL, and the RA GRS and LDL levels by fitting separate linear regression models adjusted by age, gender and LDL measurement year. To determine whether RA genetic factors in aggregate were independently associated with LDL, we fitted a linear regression model with both the LDL and RA GRS, adjusted by age, gender and LDL measurement year. We further stratified each model by gender.

Results: 1072 RA subjects had LDL measured prior to a statin prescription. Characteristics: 81% female, 68% ACPA positive, mean LDL 119 mg/dL. We observed a significant association between the LDL GRS and higher LDL (p=8.0×10^{-4}); carriage of 1 additional LDL allele was associated with a 2.3 mg/dL increase in LDL. The RA GRS was not associated with LDL in all RA cases, however the association was significant among female RA cases: carriage of 1 additional RA risk allele was associated with a 0.75 mg/dL decrease in LDL (p=0.03) (FIGURE). Among female RA cases, the RA GRS remained significantly inversely associated with LDL (p=0.02) when added to a model with LDL GRS.
Figure. Mean LDL levels among female RA cases grouped by tertiles of LDL and RA genetic risk scores (GRS).
[Note: Subjects in the highest LDL GRS tertile carry the highest number of LDL alleles; similarly subjects in the highest RA GRS tertile carry the highest number of RA risk alleles in the cohort. No significant interaction was observed between RA GRS tertiles and LDL GRS tertiles.]

Conclusion: LDL genetic factors were significantly associated with higher LDL levels in RA cases. Our finding that RA genetic factors were significantly associated with lower LDL levels in female RA cases provides a genetic link to epidemiologic observations of lower LDL levels in RA compared to the general population.

Increased Risk of Major Cardiovascular Events in a Nationwide Cohort of Rheumatoid Arthritis Patients Treated with Biological Agents. Signe Abitz Winther, Peter Riis Hansen, Søren Lund Kristensen, Lene Dreyer, Ole Ahlehoff, Louise Linde, Christian Torp-Pedersen and Jesper Lindhardsen. Copenhagen University Hospital Gentofte, Hellerup, Denmark

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular disease, but in contrast to the well-established risk of myocardial infarction (MI), the results from studies on RA-related risk of stroke have been inconsistent. Also, we recently found an association between RA and atrial fibrillation (AF), which is an important risk factor for stroke. Most of these data, however, stem from more dated cohorts where the RA-specific treatment was less aggressive than today. Consequently, this study examined the incidence of MI, stroke and AF in a large, unselected, nationwide cohort of biologically treated RA patients.

Methods: In Denmark, biological RA treatment is provided at no cost, but patients are required to be registered and followed in the DANBIO registry. All RA patients treated with biological agents during the period 2001–2009 were matched with 10 individuals from the general population by age and sex at the start of biological therapy. Through individual-level linkage to the National Patient Register, the National Register of Medicinal Products (national prescription database) and the National Civil Register, participants were characterized with respect to comorbidity, pharmacotherapy and socio-economic status and subsequently monitored for the outcomes of interest (MI, stroke, or AF) until emigration, death, or December 31, 2010. Incidence rates were calculated and multivariable proportional hazard models were fitted to estimate risk of outcomes in terms of hazard ratios.

Results: A total of 3872 RA patients and 38720 controls were included. Cohort participants were predominantly women (74%) and had a mean age of 56 years. Cardiovascular and RA-specific characteristics are listed in Table 1.

The cohort was followed for a mean of 4.5 years during which 639 MIs, 867 strokes and 804 cases of AF occurred. The risk of all outcomes was significantly increased in biologically treated RA patients with a 95% excess risk of MI, 31% excess risk of stroke, and 35% excess risk of AF in the fully adjusted analysis (Table 2).

Table 1. Baseline characteristics

	Biologically treated RA patients n=3872	Controls n=38720
Age	56 (±13) years	56 (±13) years
Females	2861 (74%)	28610 (74%)
Follow-up	4.5 years	4.5 years
Pharmacological treatment		
Aspirin	403 (10.4%)	3604 (9.3%)
Beta blockers	462 (11.9%)	3574 (9.2%)
RAS inhibitors	554 (14.3%)	5057 (13.1%)
Lipid-lowering drugs	333 (8.6%)	3917 (10.1%)
NSAIDs	2710 (70.0%)	8691 (22.4%)
DMARDs	2944 (76.0%)	0 (0.0%)
Charlson co-morbidity index	0.06 (±0.36)	0.06 (±0.39)
Previous CV disease		
Myocardial infarction	107 (2.8%)	704 (1.8%)
Stroke	68 (1.8%)	795 (2.1%)
Atrial fibrillation	103 (2.7%)	777 (2.0%)
Socioeconomic status (1=low to 4=high)	2.51 (1.04)	2.50 (1.13)
RA-specific characteristics		
RA duration	8 (3–16) years	-
HAQ score	1.25 (0.73–1.75)	-
DAS28crp score	5.1 (4.1–5.9)	-
CRP	14 (7–32) mg/l	-

HAQ, Health Assessment Questionnaire; DAS, Disease activity score; RAS, Renin-angiotensin system; NSAID, Non-steroidal anti-inflammatory drug; DMARD, Disease-modifying anti-rheumatic drug; CV, cardiovascular; CRP, C-reactive protein. Numbers are means (±SD), n (%) and medians (interquartile range) as appropriate.

Table 2. Risk of adverse cardiovascular events in biologically treated RA patients versus controls (reference)

	Myocardial infarction		Stroke		Atrial Fibrillation	
	RA	Controls	RA	Controls	RA	Controls
Events (n)	106	533	98	769	103	701
Incidence rate (events per 1000 py)	5.7	2.8	5.2	4.1	5.7	3.9
Risk models	**Hazard ratios (95% CI)**					
Unadjusted	1.98 (1.60–2.44)		1.31 (1.06–1.62)		1.41 (1.14–1.73)	
As above + co-morbidity and socioeconomic status	2.02 (1.63–2.49)		1.33 (1.08–1.65)		1.42 (1.15–1.75)	
As above + CV medication and previous CV disease*	1.95 (1.57–2.43)		1.31 (1.05–1.63)		1.35 (1.09–1.68)	

py, person-years; CI, confidence interval; CV, cardiovascular.
* Covariates included individually (as outlined in Table 1).

Conclusion: In a large, nationwide and well-characterized cohort of RA patients treated with biological agents, the risk of MI was approximately two times higher than in the general population, while the excess risk of stroke and AF was less pronounced. The results indicate that despite aggressive treatment of RA the risk of major cardiovascular events is increased in these patients.

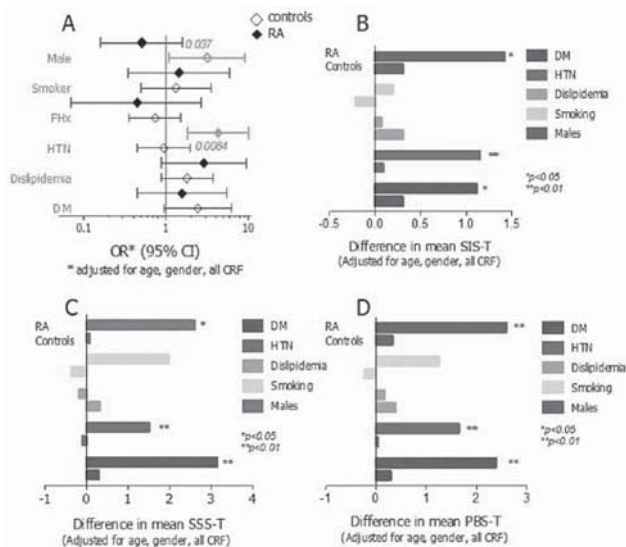
Differential Impact of Cardiac Risk Factors On Coronary Plaque Presence and Features in Asymptomatic Patients with Rheumatoid Arthritis Compared to Controls. George A. Karpouzas[1], Jennifer Malpeso[2], Tae-Young Choi[2], Silvia Munoz[1] and Matthew Budoff[2]. [1]Harbor-UCLA, Torrance, CA, [2]Harbor-UCLA Medical Center, Torrance, CA

Background/Purpose: Traditional cardiac risk factors (CRFs) associate with myocardial infarction (MI) risk in both Rheumatoid arthritis (RA) and

the general population. Subclinical atherogenesis has been linked to higher risk of future clinical events. However, the independent role of individual CRFs on coronary plaque presence and characteristics in asymptomatic, coronary artery disease (CAD)-naïve subjects with RA is unknown. We evaluated potential differences in the contribution of traditional CRFs on coronary plaque presence, quantitative and qualitative features in asymptomatic subjects with RA compared to controls.

Methods: One hundred and fifty RA subjects and 150 age and sex-matched controls underwent 64-slice coronary computed tomography angiography (CTA), a modality that reliably evaluates plaque presence, severity, burden, and composition as non-calcified (NCP), mixed or partially calcified (MP), or fully calcified (CP). A 15-segment American Heart Association model was used for evaluation. Quantitative plaque characteristics included segment involvement score (SIS- number of affected segments out of 15 evaluated/ patient), segment stenosis score (SSS-degree of luminal stenosis per segment, graded 1–4 and averaged over 15 evaluated segments/ patient), and plaque burden score (PBS-plaque extent per segment, graded 1–3 and averaged over 15 segments/ patient). Logistic and multivariable regression analysis models adjusted for age, gender, and all CRFs were used to assess differences in plaque prevalence and quantitative measures, between groups.

Results: Quantitative plaque measurements were significantly higher in RA; SIS=2.02±2.28 vs. 0.9±1.25, SSS=3.03±4.43 vs. 0.98±1.7, and PBS= 2.75±3.82 vs. 0.98±1.44, all with p<0.0001. Hypertension was significantly and differentially associated with higher risk of plaque prevalence in RA [adjusted OR=4.3 (1.83–10.1)- figure 1a]. Additionally, in the context of RA, the presence of male gender, hypertension and diabetes were associated with higher mean differences in the proportion of involved segments, plaque severity, and burden vs. their absence, compared to those imparted in controls (all with p<0.05- figure 1b, c, d respectively). Importantly, these differences segregated exclusively in MP and CP but not NCP.


Conclusion: Hypertension strongly and differentially associates with coronary plaque presence in CAD-naïve, asymptomatic subjects with RA compared to controls. In RA, male gender, hypertension and diabetes are associated with significant differences in plaque severity, burden and number of involved segments compared to presence of those factors in controls, specifically for MP and CP.

Vertebral Fracture Assessment-Detected Abdominal Aortic Calcification Enhances Cardiovascular Disease Risk Stratification of Rheumatoid Arthritis Patients. Ausaf Mohammad[1], Derek Lohan[1], Diane Bergin[1], Sarah Mooney[1], John Newell[2], Martin O'Donnell[1], Robert J. Coughlan[1] and John J. Carey[1]. [1]Galway University Hospitals, Galway, Ireland, [2]National University of Ireland, Galway, Ireland

Background/Purpose: Osteoporosis and cardiovascular disease (CVD) are major comorbidities and CVD is the leading cause of death among patients with rheumatoid arthritis(RA). Traditional CVD risk prediction tools i.e., Framingham risk score(FRS) under-estimate the risk of CVD in RA. Novel biomarkers and better risk prediction tools are needed. Many RA patients undergo DXA today as part of an osteoporosis assessment, which may include a vertebral fracture assessment(VFA). VFA technology has been shown to reliably detect and quantify abdominal aortic calcification-(AAC). VFA-detected AAC is an independent robust marker of CVD in other populations. It is unknown whether VFA-detected AAC is a useful marker of CVD in RA. We aimed to determine whether VFA-detected AAC is independently associated with CVD in RA patients and compared its utility to the FRS for CVD risk assessment in RA patients.

Methods: A cross-sectional study of our RA cohort at a University Hospital. We included RA patients aged ≥40 years who met 1987 ACR criteria for RA, had a DXA and VFA scan available for analysis and access to their medical records to ascertain their CVD risk factors and details. The study was approved by our local I.R.B. Two blinded consultant musculoskeletal radiologists independently reviewed all VFA scans to determine AAC using an established 24-point scale. We determined if AAC was independently associated with prevalent CVD using multivariable logistic regression. The ability of the FRS and AAC for determining the presence of CVD was assessed using ROC curve analyses.

Results: 1330 patients were screened. 603 met the inclusion criteria: mean age 56 years, 74% female, 76% sero-positive and 43% smokers. 230 had ≥1documented CVD event. Overall AAC was present in 211 of subjects: 11% was mild (<9 points), 57% moderate (9–16) and 32% severe(>16 points). The proportion of patients with AAC was substantially greater in subjects with CVD than those without(76% Vs 10%, p <0.05). VFA-detected AAC was significantly better than traditional risk factors for determining the presence of CVD. In multivariable analyses both the presence and severity of AAC was significantly and independently associated with prevalent CVD (OR 2.70; 95% CI 1.8 to 3.2). Both the FRS (AUC 0.58) and AAC (AUC 0.85) were significant predictors of CVD events (Fig. 1). The addition of VFA-detected AAC to the FRS significantly enhanced the performance of the FRS for determining CVD (AUCs increased from 0.58 to 0.79, p<0.001).
Fig. 1. Additive Effect of AAC on FRS for Predicting CVD in RA Patients*

Conclusion: VFA-detected AAC is an important marker of CVD risk in RA patients, and out-performs traditional risk prediction tools. Further studies are needed to examine the utility of DXA-detected AAC in CVD assessment in RA patients.

1687

The Risk of Atrial Fibrillation in Patients with Rheumatoid Arthritis Compared to the General Population: A Large Cohort Study. Seoyoung C. Kim[1], Jun Liu[2] and Daniel H. Solomon[3]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: It is well-known that rheumatoid arthritis (RA) is associated with cardiovascular disease such as myocardial infarction. However, little evidence exists on the risk of atrial fibrillation (AF) in patients with RA. The objective of this study was to estimate the incidence rates (IR) and rate ratios (RR) of AF among patients with RA compared to those without RA.

Methods: We conducted a large population-based cohort study using the US commercial insurance claims data. The RA cohort included adults with at least two diagnoses of RA and at least one prescription for a disease-modifying anti-rheumatic drug (DMARD). Subjects who never had a diagnosis of RA matched on age, sex, and index date with a 5:1 ratio were selected as a comparison cohort. Follow-up began with the first prescription for a DMARD for RA patients and the 2nd physician visit date for non-RA patients after a 12-month baseline period. Patients with history of any cardiac arrhythmia, cardiovascular surgery and anticoagulant users during the baseline period were excluded. Primary outcome was an inpatient diagnosis of AF and secondary outcome was an outpatient or inpatient diagnosis combined with a dispensing of anticoagulant within 10 days after the first diagnosis of AF. We calculated IRs and RRs of AF with 95% confidence intervals (CI). Multivariable Cox proportional hazards models compared the risk of AF between RA and non-RA patients.

Results: The study population included 20,891 RA and 104,455 non-RA patients. Mean (SD) age was 52 (12) years and 74% were women. During a mean follow-up of 2 years, 0.8% of RA patients and 0.6% non-RA patients developed AF as inpatient. **Table** shows the IRs for primary outcome and secondary outcome. The RR was 1.4 (95% CI, 1.2–1.7) for primary and 1.3 (95% CI, 1.0–1.6) for secondary outcome in RA patients, compared to age- and sex- matched subjects without RA. After adjusting for comorbidities such as cardiovascular disease and thyroid disease, various medications and health care utilization characteristics, the risk of AF was not increased in RA (hazard ratio 1.0, 95% CI: 0.8–1.3) compared to non-RA patients.

Table. Incidence rates per 1,000 person-years (95% confidence interval) and rate ratios (95% confidence interval) of atrial fibrillation (AF) in patients with and without rheumatoid arthritis (RA).

	RA	Non-RA	Age- and sex-matched RR	Fully adjusted RR
Inpatient AF	4.1 (3.5–4.8)	2.9 (2.7–3.2)	1.4 (1.2–1.7)	1.0 (0.8–1.3)
Inpatient and outpatient AF with an anticoagulant dispensing	2.6 (2.2–3.2)	2.1 (1.9–2.3)	1.3 (1.0–1.6)	1.0 (0.7–1.3)

Conclusion: Our results showed that the incidence of AF was similar in both RA and non-RA patients. The risk of AF was not increased in patients with RA compared to non-RA patients after adjusting for various comorbid conditions and medications.

1688

Evolution of Preclinical Autoimmunity in Individuals At Risk for Development of Rheumatoid Arthritis. Hani S. El-Gabalawy[1], David B. Robinson[1], Irene Smolik[1], Donna M. Hart[1], Elizabeth D. Ferucci[2], Marianna M. Newkirk[3], Marvin J. Fritzler[4], Catriona Cramb[5], Jeremy Sokolove[5] and William H. Robinson[5]. [1]University of Manitoba, Winnipeg, MB, [2]Alaska Native Tribal Health Consortium, Anchorage, AK, [3]McGill University Health Centr, Montreal, QC, [4]University of Calgary, Calgary, AB, [5]Stanford University, Palo Alto, CA

Background/Purpose: Rheumatoid arthritis (RA) is prevalent, severe, and predominantly seropositive in many North American Native (NAN) populations. We have shown a strong tendency towards familial clustering of RA, and high prevalence of RA autoantibodies and other risk factors in the first-degree relatives (FDR) of NAN RA patients. We have prospectively followed a large cohort of NAN FDR to better understand the preclinical events that lead to RA onset.

Methods: In total we recruited 310 FDR of NAN RA patients who were followed annually with questionnaires and joint examination. Plasma samples were gathered at each visit for biomarker analysis. Individuals who developed new joint symptoms between the annual visits were assessed, and the visit at which at least one swollen joint was detected was deemed to be the onset of inflammatory arthritis (IA).

We used a custom multiplex bead-based autoantigen array on the BioPlex platform to analyze the profile of autoantibodies against citrullinated antigens exhibited by FDR at various time points prior to, and during, the period of disease onset. The autoantigen targets were chosen based on proteomic analysis of synovial tissue and on previous analyses of a large number of RA patients and healthy controls. Levels of total circulating IgG and IgM immune complexes (IC) were measured using a C1q capture assay.

Results: At the baseline visit, 22% FDR had anti-citrullinated protein antibodies (ACPA) and/or rheumatoid factor (RF). This longitudinally followed cohort had a mean age at study enrollment of 35 ± 13 yrs. and 65% were female. Three FDR had definite RA at study entry and were followed as probands. Six FDR met the criteria for new onset IA after a median follow-up of 62 mo. (range 12–73). Of these 6 individuals, 2 were ACPA+ at baseline, one of whom was also RF+. In the period leading up to the development of IA, epitope spreading was evident in the ACPA response, with new targeting of citrullinulated epitopes from fibrinogen, vimentin, clustrin, biglycan. Notably, development of detectable IgM RF in most cases occurred subsequent to ACPA epitope spreading, and was within months of development of IA. An increase in IC levels was also detected in these FDR. A further 4 FDR demonstrated ACPA epitope spreading and had persistent arthralgia but no detectable synovitis at the time of reporting. To date, none of the 16% FDR who were initially RF+ but ACPA- have developed ACPA or IA. The 3 FDR who had RA at study entry were strongly positive for multiple ACPA autoantigens and did not demonstrate epitope spreading during the follow-up period.

Conclusion: The observations made in this prospectively followed cohort of high-risk NAN FDR who ultimately developed ACPA positive IA are consistent with the hypothesis that the autoimmune responses preceding the development of synovitis exhibit three stages: 1) initial breaking of immunological tolerance to citrullinated antigens; 2) epitope spreading of the ACPA response; and 3) development of RF. The latter event, which is likely associated with the formation of pathogenic immune complexes, may be the most proximal event preceding the development of clinically detectable synovitis. This hypothesis provides the framework for actionable stages of preclinical RA autoimmunity.

1689

Anti-Peptidylarginine Deiminase 3/4 Cross-Reactive Antibodies: A Novel Biomarker with Clinical and Mechanistic Implications in Rheumatoid Arthritis. Erika Darrah[1], Jon T. Giles[2], Herbert Bull[3], Felipe Andrade[1] and Antony Rosen[1]. [1]The Johns Hopkins University School of Medicine, Baltimore, MD, [2]Columbia University Medical Center, New York, NY, [3]Consultant, Westfield, NJ

Background/Purpose: Peptidylarginine deiminases (PADs) have emerged as key participants in the pathogenesis of rheumatoid arthritis (RA) due to their expression in inflamed RA synovium and ability to citrullinate autoantigens. In addition, PAD4 autoantibodies are present in 35% of RA patients. The unexpected expression of PAD3 in neutrophils prompted us to investigate PAD3 as a potential autoantigen in RA.

Methods: Anti-PAD3 antibodies were detected by immunoprecipitation of [^{35}S]Methionine-labeled PAD3. Sera were obtained from 36 healthy controls, 44 RA patients from a convenience sample, and 194 patients from a longitudinal cohort study of subclinical cardiovascular disease in RA (ESCAPE RA). In ESCAPE RA, disease activity and severity were assessed at baseline and two additional time points, with the final visit occurring an average of 39±4 months post-baseline. Radiographs of the hands and feet were obtained at the first and third visits and scored according to the

Sharp-van der Heijde (SvdH) method. Recombinant human PAD3 and PAD4 were used for anti-PAD competition assays. The effect of autoantibodies on PAD4 enzymatic activity was accessed by measuring citrullination of benzoyl-arginine ethyl ester (BAEE) and histone H3 following pre-incubation with patient or control IgG.

Results: Anti-PAD3 autoantibodies were present in 18% of RA sera in the convenience sample, 12% of ESCAPE RA sera, and 0% of healthy controls. Anti-PAD3 antibodies were only detected in anti-PAD4 positive sera and were found through competition experiments to be PAD3/PAD4 cross-reactive autoantibodies. Analysis of clinical features revealed that patients with PAD3/PAD4 antibodies had a higher baseline SvdH score compared to anti-PAD4 only patients (2.5 fold; p=0.039) and anti-PAD negative patients (4.5 fold; p<0.001), even after adjusting for cohort-specific indicators of radiographic damage. Furthermore, patients with anti-PAD3/PAD4 antibodies had a 50% higher rate of radiographic progression (i.e. any longitudinal increase in SvdH) compared to PAD antibody negative individuals (p=0.004), despite equivalent therapeutic intervention. Strikingly, PAD3/PAD4 autoantibodies increased the catalytic efficiency of PAD4 (160-fold at 0.2mM Ca^{2+}) by dramatically decreasing the enzyme's requirement for calcium from a $K_{0.5}$ of 3.0 mM to a $K_{0.5}$ of 0.5mM, rendering the enzyme responsive to calcium concentrations now within the physiological range (0.2–1mM). This effect was observed with the macromolecular substrate histone H3 but not with the small molecule BAEE, indicating that anti-PAD3/PAD4 antibodies do not affect the fundamental catalytic properties of PAD4. These autoantibodies influence the binding and catalysis of histone H3, and achieve activities of PAD4 which normally require supraphysiologic calcium concentrations. It remains to be determined how broadly this property extends to other macromolecular substrates.

Conclusion: These studies describe a novel biomarker associated with erosive joint damage in RA. PAD3/PAD4 cross-reactive antibodies may contribute to disease pathogenesis by activating PAD4 enzymatic function and identify a patient subgroup in whom PAD inhibition may be particularly beneficial therapeutically.

Citrullination within the Atherosclerotic Plaque: A New Potential Target for Anti-Citrullinated Protein Antibodies. Jeremy Sokolove[1], Orr Share[1], Matthew Brennan[1], Lauren J. Lahey[1], Amy H. Kao[2], Eswar Krishnan[3], Mary Chester Wasko[4] and William H. Robinson[5]. [1]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [2]Allegheny Singer Research Institute, Pittsburgh, PA, [3]Stanford University, Stanford, CA, [4]Temple University School of Medicine, Pittsburgh, PA, [5]Stanford University, Palo Alto, CA

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for cardiovascular disease due to accelerated atherosclerosis. This risk has mainly been limited to seropositive population as measured by the presence of rheumatoid factor (RF). We hypothesized that citrullination of proteins within the atherosclerotic plaque, including citrullinated fibrinogen (cFb), could be targeted by circulating anti-citrullinated protein antibodies (ACPA) thus forming stimulatory immune complexes which further propagate the progression of atherosclerosis.

Methods: We performed proteomic and immunohistochemical studies of atherosclerotic lesions to identify citrullinated proteins. Lysates were prepared from atherosclerotic segments of human aortic arch obtained at autopsy, subjected to 1 and 2-D PAGE, and probed by western blot for the presence of citrulline modified proteins and fibrinogen. Plaque lystates were immunoprecipitated with anti-fibrinogen antibody and subjected to immunoblot with anti-modified citrulline antibodies. Paraffin sections of several human coronary artery plaques were examined by immunohistochemistry for the presence of citrullinated proteins, PAD4 enzyme, and fibrinogen. Levels of anti-CCP2, anti-citrullinated vimentin (cVim), and anti-cFb were measured in a cohort of 135 women with RF+ RA (93% anti-CCP2+) of at least 2 years duration who were well characterized for the presence of atherosclerosis by electron beam CT scan for levels of coronary artery calcification, and multiple linear regression performed to assess the association of these antibodies with calcified plaque burden.

Results: 1 and 2-D western analysis demonstrated several citrulline modified proteins within plaque lysate and the presence of cFb was confirmed by re-probing of the western blot membrane for fibrinogen. Immunoprecipitation of plaque lysate with anti-fibrinogen showed strong citrullination demonstrated by anti-citrulline antibody staining and mass spectroscopy.

Additionally, immunoprecipitation of plaque lysate with RA patient-derived IgG again identified citrullinated fibrinogen by mass spectroscopy. Immunohistochemistry demonstrated co-localization of (i) citrullinated proteins, (ii) PAD4, and (iii) fibrinogen within the coronary artery atherosclerotic plaque. Finally, levels of anti-cFb, anti-cVim, and anti-CCP2 were associated with the increased atherosclerosis as measured by coronary calcium score. In age adjusted models, ACPA titers accounted for approximately 35% of variance in total calcium score and for each standard deviation increase in level of each ACPA, there was an increase in coronary artery calcium score of 400–500 units (anti-cFb P=0.02, anti-cVim P<0.01, anti-CCP2 P=0.01).

Conclusion: Citrulline modified proteins including citrullinated fibrinogen are prevalent within the atherosclerotic plaque and levels of ACPA are associated with degree of atherosclerotic burden. This observation suggests that humeral targeting of citrullinated epitopes, specifically cFb, within the atherosclerotic plaque could provide a mechanism for accelerated atherosclerosis observed in patients with ACPA+ RA.

Early Signs of Subclinical Inflammation and Local Antibody Production in Early Rheumatoid Lungs. Gudrun Reynisdottir[1], Reza Karimi[2], Jimmy Ytterberg[3], Vijay Joshua[1], Helga Olsen[2], Aase Haj Hensvold[1], Anders Harju[3], Johan Grunewald[2], Sven Nyren[4], Anders Eklund[2], Lars Klareskog[5], Roman Zubarev[6], Magnus Skold[2] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Division of Respiratory Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Rheumatology Unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [5]Karolinska Institute, Stockholm, Sweden, [6]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: The aims of the current study was to investigate if inflammatory lung changes are present in RA patients early in the disease process and to address the contribution of these changes to disease initiation.

Methods: 105 RA patients with symptom duration less than 1 year at the time of diagnosis and naive to DMARD treatment and 43 non-RA individuals, matched for age, smoking and gender were subject to high-resolution computer tomography (HRCT) of the lungs. In a subgroup of patients (n=21) bronchoscopy was performed and BAL samples as well as mucosal large bronchial biopsies were retrieved. Histological analysis for identification of inducible bronchia associated lymphoid tissues (iBALT), PAD enzymes, CD3, and HLA-DR expression were performed. Presence of ACPA was tested by ELISA in the serum and BAL. Mass spectrometry was used for identification of citrullinated epitopes in 6 of the lung biopsies and additional 8 synovial RA biopsies. Contingency tables and chi-square test as well as a generalized linear model were used for analysis of the clinical data. Man-Whitney test was used to analyze differences in immunohistochemistry double blind semi-quantitative scores between independent groups.

Results: A large majority of ACPA+ RA patients (59%, 41/70) presented with HRCT lung abnormalities, as compared to only 34% (12/35) of ACPA- patients and 28% (12/43) of the controls (p<0.05). ACPA positive smokers had increased levels of expression of PAD enzymes in BAL. iBALT formation and higher expression of HLA-DR was observed in bronchial biopsies of ACPA positive RA. A majority of serum ACPA positive RA patients subjected to lung bronchoscopy had detectable levels of ACPA in the BAL fluids both IgA and IgG. IgG from BAL fluids of ACPA-positive patients showed a higher ACPA reactivity as compared to serum IgG from the same patients. Mass spectrometry identified 5 proteins in the synovium (in total 8 sites) and 4 in the lungs (in total 6 sites) containing citrullinated residues. Two vimentin derived citrullinated peptides were present in a majority of both synovial and lung biopsies with slightly higher citrullinated/unmodified peptides ratios in the smokers as compared to non-smokers.

Conclusion: Lung HRCT abnormalities and subclinical inflammation are present already at the earliest visit to a rheumatology specialist early after disease onset in ACPA+ RA patients. These findings suggest that the lungs might be the primary local initiation sites of the anti-citrulline response in RA.

Lung Microbiome Differs in Subjects with Rheumatoid Arthritis-Related Autoimmunity without Inflammatory Arthritis Compared to Healthy Seronegative Controls. M. Kristen Demoruelle[1], Jill M. Norris[2], V. Michael Holers[1], Kevin D. Deane[1] and J. Kirk Harris[3]. [1]University of Colorado School of Medicine, Aurora, CO, [2]Colorado School of Public Health, Aurora, CO, [3]Aurora, CO

Background/Purpose: Emerging data suggest that microorganisms and mucosal inflammation may play a role in the etiology of rheumatoid arthritis (RA). Furthermore, our published findings of inflammatory airways disease in a high proportion of RA-related autoantibody positive subjects without inflammatory arthritis (IA), some of whom later developed classifiable RA, suggest that the lung may play a role in early RA pathogenesis. Therefore, investigations of the lung microbiome in subjects at risk for future RA may provide insight into RA pathogenesis.

Methods: 13 CCP positive cases without IA and 9 healthy seronegative controls were identified through community screening. Induced sputa was collected from all subjects. DNA extractions for microbiome analysis were performed using Qiagen EZ1 Advanced platform. Established protocols with barcoded PCR primers were used to construct multiplexed amplicon pools and assign sequences to the appropriate subject sample. Microbial prevalence and median relative abundance in sputa were compared using Explicet.

Results: Cases were older and more frequently male than controls (Table), and more cases had been smokers, although they had quit smoking a median of 9 years prior to sputa collection. Bacteria were identified by rRNA pyrosequencing ($>1,000$ sequences per sample). Good's coverage was $>98.9\%$ for all samples. 80 genera were identified across all samples with an average of 30 per sample. Relative abundance of *Haemophilus* and *Neisseria* was elevated in cases compared to controls (p=0.04) (Table), and there was a trend toward increased relative abundance of *Streptococcus* in cases. There was no significant difference in *Porphyromonas*, *Prevotella* and *Mycoplasma* between groups.

Lung Microbiome Differences in Subjects with and without Serum Positivity for Rheumatoid Arthritis-Related Autoantibodies

	Autoantibody positive cases N=13	Autoantibody negative controls N=9	p-value
Age, median (range)	57 (30-85)	33 (26-56)	<0.01
Female, N (%)	5 (39%)	8 (89%)	0.02
Current smoker, N (%)	0 (0%)	1 (11%)	0.23
Ever smoker, N (%)[1]	7 (54%)[2]	1 (11%)	0.05
Anti-CCP3.1 positive, N (%)[1] Median (range)	13 (100%) 49 (32 to >400)	0 (0%) 3 (1-8)	<0.01
Genus classification			
Haemophilus			
% Prevalence[3]	85	100	0.04[5]
Relative abundance (%)[4]	2.0	0.6	
Neisseria			
% Prevalence[3]	100	77	0.04[5]
Relative abundance (%)[4]	4.9	1.0	
Streptococcus			
% Prevalence[3]	100	100	0.20[5]
Relative abundance (%)[4]	30.4	18.0	
Prevotella			
% Prevalence[3]	100	100	0.20[5]
Relative abundance (%)[4]	12.4	25	
Porphyromonas			
% Prevalence[3]	85	100	0.87[5]
Relative abundance (%)[4]	1.1	1.5	
Mycoplasma			
% Prevalence[3]	100	67	0.90[5]
Relative abundance (%)[4]	1.4	0.1	

1. CCP3.1 (IgA/IgG) ELISA, Inova Diagnostics, Inc. Positive level ≥20 units
2. Median duration of smoking cessation prior to sputa testing = 9 years (range 3-20)
3. % Prevalence = number of subjects with organism present
4. Median relative abundance of each organism compared to all organisms in the sample
5. P-value comparing prevalence and relative abundance in Ab(+) cases and Ab(-) controls

Conclusion: These results show differences in sputa microbiota between RA-related autoantibody positive cases without IA and controls. This is particularly intriguing because our prior work has shown that 9 of these autoantibody positive cases had inflammatory airways disease on lung imaging, raising the possibility of a mechanistic link between the microbiome, mucosal inflammation and generation of RA-related autoimmunity in the lung. A caveat in this small pilot study is the unknown influence on the lung microbiome of differences in age and sex between groups. Also, differences in smoking history between groups may affect results as smoking is known to alter the lung microbiome. However, smoking is also associated with CCP positivity in established RA, albeit through unknown mechanisms. As such, it is possible that a mechanism that drives CCP generation is smoking (or other inhaled factor)-related changes in the lung microbiota. Additional study, including speciation of organisms and prospective

follow-up of larger numbers of subjects and controls, is needed to determine the biologic relevance of the lung microbiome to the pathogenesis of early RA.

Oncogenic Activation of MAPK in Rheumatoid Arthritis Synovial Fibroblasts. Niloofar L. Farmani[1], Keith K. Colburn[2], Grace Chan[3], Erica Li[3], Emil Heinze[1], Antonia Rubell[3], Robert Nishimura[4] and Richard H. Weisbart[3]. [1]Olive View-UCLA Medical Center, Sylmar, CA, [2]Loma Linda Univ Medical Center, Loma Linda, CA, [3]VAGLAHS, Sepulveda, CA, [4]The David Geffen School of Medicine at UCLA, Los Angeles, CA

Background/Purpose: Transformed synovial fibroblasts (SF) mediate joint-specific damage in rheumatoid arthritis (RA) by expressing integrins and metalloproteinase that promote adhesion to and invasion of cartilage. The mechanism of SF transformation is unknown, but is critical for the rational design of specific therapies to prevent joint erosion in RA. We recently identified aberrant BRAF splice variants in synovial fibroblasts from some RA patients and demonstrated their role in RA fibroblast proliferation, results that suggest a primary role for oncogenic transformation of RA SF. The current studies were designed to further evaluate the role of oncogenesis in RA SF transformation.

Methods: Aberrant BRAF splice variants and mutations in KRAS were identified in RA SF by RT-PCR. The function of aberrant BRAF splice variants was evaluated in NIH-3T3 fibroblasts transfected with an expression vector containing cDNA of BRAF splice variants. Mitogen-activated protein kinase (MAPK) activation in transfected NIH-3T3 cells was determined by phosphorylation of MEK and ERK. The role of BRAF and CRAF in SF transformation was determined by RNAi, and Membrane-Type 1 Matrix Metalloproteinase (MT1-MMP) was identified in cells with MT1-MMP-specific antibodies. Collagen invasion by transfected NIH-3T3 cells was evaluated in an *in vitro* collagen invasion assay.

Results: SF from 6/9 RA patients had kinase "Dead" aberrant BRAF splice variants. NIH-3T3 cells transfected with aberrant BRAF splice variants constitutively activate MAPK, produce MT1-MMP, and invade collagen. Since "Dead" BRAF forms dimers with CRAF to activate MAPK we evaluated the role of CRAF in MAPK activation by RNAi. MAPK activation was inhibited by siRNA specific for BRAF and CRAF. Since MAPK activation by "Dead" BRAF also requires activated KRAS we looked for KRAS mutations in RA SF and identified mutations in 7/9 RA patients.

Conclusion: Our results suggest that joint-specific oncogenesis is responsible for synovial fibroblast transformation in some patients with RA.

Infection Risk in Patients with Low Immunoglobulins Following Rituximab Treatment in Rheumatoid Arthritis. Ronald F. van Vollenhoven[1], Gregg J. Silverman[2], Clifton O. Bingham III[3], Patrick Durez[4], Patrica B. Lehane[5], Nicola Tyson[5] and Elena Fisheleva[5]. [1]Karolinska University Hospital, Stockholm, Sweden, [2]NYU School of Medicine, New York, NY, [3]Johns Hopkins University, Baltimore, MD, [4]University Hospital St Luc, UCL, Brussels, Belgium, [5]Roche Products Limited, Welwyn Garden City, United Kingdom

Background/Purpose: This study analyzed infection rates in patients (pts) with low immunoglobulin (Ig) serum concentrations following rituximab (RTX) treatment in RA clinical trials.

Methods: Pooled analysis of clinical trial data from the All-Exposure population (all pts exposed to at least one/part of a RTX infusion) who developed low IgM or IgG (defined as below lower limit of normal [LLN] for ≥ 4 mth [or 2 consecutive study visits]) after ≥ 1 RTX course. Low IgG/IgM at baseline screening (IgG <5.65 and IgM <0.55 mg/mL) were exclusion

criteria for trial entry. Igs were generally measured every 8–16 wks. Pts with low Ig were permitted to receive RTX retreatment. Infection rates were assessed before and during/after low IgM/IgG and compared with pts who never developed low Ig and the All-Exposure population. Pts received IV methylprednisolone prior to RTX infusions and concomitant MTX. In addition, stable background doses of oral corticosteroids (≤10 mg/day prednisone or equivalent) and NSAIDs were permitted throughout.

Results: Of 3194 pts who received ≤17 RTX courses over 9.5 yrs, 22.4% (n=717) developed low IgM and 3.5% (n=112) low IgG for ≥4 mth. All had measurable Ig levels. No increases in overall infection rates were observed in pts during/after low IgM/IgG vs before documentation of low Ig (Table). For IgG, serious infection (SIE) rates were similar before and during/after low IgG, but both were significantly higher than in pts who never developed low IgG. At baseline these pts were on average older, had longer disease duration, lower mean CD19+ count, lower mean IgG levels (8.4 vs 13.2 mg/mL), higher mean anti-CCP levels, and had received more non-biologic DMARDs vs those who did not develop low IgG. Baseline oral steroid use was similar across subgroups and all pts received 100 mg IV corticosteroid prior to RTX infusion. For IgM, SIE rates were not significantly higher during/after low IgM vs before low IgM, and were similar to rates in pts who never developed low IgM. In pts with low IgG or IgM, the SIE profile was consistent with RTX clinical experience as most infections affected the lower respiratory tract. Analysis of SIE onset in relation to timing of low Ig was limited due to discrete protocol-defined time points for Ig assessments. Other limitations included low pt numbers in some subgroups and lack of placebo comparator.

Infection rate in pts with low Ig

	Pts with IgG <LLN*			Pts with IgM <LLN*		
	Before <LLN (n=112)	During/after <LLN (n=112)	Pts who never had IgG <LLN (n=3082)	Before <LLN (n=717)	During/after <LLN (n=717)	Pts who never had IgM <LLN (n=2477)
Total PY	223	307	11432	1171	2084	8707
Infections, n	325	262	9179	1264	1699	6803
Rate/100PY (95% CI)	146 (131–162)	85 (76–96)	80 (79–82)	108 (102–114)	82 (78–86)	78 (76–80)
SIE, n	18	28	425	34	98	339
Rate/100PY (95% CI)	8.0 (5.08–12.80)	9.13 (6.30–13.22)	3.72 (3.38–4.09)	2.9 (2.07–4.06)	4.70 (3.86–5.73)	3.89 (3.50–4.33)

*below LLN for ≥4 mth

Conclusion: Following RTX treatment, low Ig concentrations (particularly IgM, less often IgG) were observed. Pts with low IgM had no increased risk of infection or SIE. For the small subgroup of pts with low IgG (112/3194 [3.5%]), a higher SIE rate was seen both before and during/after the development of low IgG, suggesting that these pts had a higher *a priori* risk of developing SIEs, possibly associated with demographic and/or clinical characteristics rather than with low IgG itself. Thus, for both Ig classes, SIE rates were similar before and during/after development of low Ig.

1695

Prolonged Exposure to Subcutaneous and Intravenous Abatacept in Patients with Rheumatoid Arthritis Does Not Affect Rates of Infection, Malignancy and Autoimmune Events: Results From Pooled Clinical Trial Data. M. C. Genovese[1], M C. Hochberg[2], R. B. Cohen[3], M. E. Weinblatt[4], J. Kaine[5], E. Keystone[6], P. Nash[7], I. Delaet[8] and R. Alten[9]. [1]Stanford University, Palo Alto, CA, [2]Department of Medicine, University of Maryland, Baltimore, MD, [3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [4]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [5]Sarasota Arthritis Research Center, Sarasota, FL, [6]Mount Sinai Hospital, Toronto, ON, [7]University of Queensland, Brisbane, Australia, [8]Bristol-Myers Squibb, Princeton, NJ and Bristol-Myers Squibb, Hopewell, VA, [9]Schlosspark-Klinik, University Medicine, Berlin, Germany

Background/Purpose: Disease-modifying therapies for RA have proven efficacy, but these drugs may have selective toxicities, such as malignancy, that may increase with duration of treatment. Periodic re-evaluation of incidence rates (IRs) allows assessment of any cumulative or new events over time. Using the largest pool of integrated abatacept clinical trial data to date, we investigated the long-term (LT) safety of subcutaneous (SC) and intravenous (IV) abatacept.[1,2]

Methods: Data were pooled from the cumulative (double-blind and open-label short-term [ST] and open-label LT extension) periods of 13 clinical studies, including one Phase II and four Phase III trials with SC abatacept,[1] and two Phase II and six Phase III trials with IV abatacept.[2] IRs for adverse events (AEs), serious AEs (SAEs), infection, malignancy and autoimmune AEs were calculated as events per 100 patient-years (pt-yrs) of exposure (Poisson 95% CI). IRs for the cumulative period were compared with IRs originally estimated from the pooled ST periods of the eight IV abatacept clinical studies.[2]

Results: A total of 6028 patients received IV or SC abatacept during the cumulative period, with abatacept exposure of 16,670.56 pt-yrs; 1167 patients received abatacept for >5 yrs. IRs of AEs, SAEs, infections or serious infections did not increase in the cumulative relative to ST periods (Table). The most frequently reported serious infections in the cumulative period were pneumonia (IR: 0.43 [0.34, 0.54]), upper respiratory tract infection (0.18 [0.12, 0.26]) and cellulitis (0.15 [0.10, 0.23]). There was no increase in IRs between the ST and cumulative periods for hospitalized, opportunistic or tuberculosis infections. The IRs of overall malignancy, combined lymphomas and lung cancers did not increase in the cumulative versus the ST periods; the most common malignancies in the cumulative period were basal cell carcinoma (IR: 0.46 [0.36, 0.58]), squamous cell carcinoma (IR: 0.15 [0.09, 0.22]), breast cancer (IR: 0.12 [0.07, 0.19]) and squamous cell carcinoma of the skin (0.08 [0.04, 0.14]). The IR of autoimmune AEs during the cumulative period was comparable to the ST period, the most common event being psoriasis (IR: 0.51 [0.40, 0.63]).

	ST period (N=3173)	Cumulative (ST + LT) period (N=6028)
Exposure, pt-yrs	2330.82	16,670.56
AE	386.70 (372.31, 401.51)	213.95 (208.33, 219.68)
SAE	18.10 (16.37, 19.97)	13.24 (12.63, 13.88)
Death	0.51 (0.27, 0.90)	0.60 (0.49, 0.73)
Infection	98.00 (93.20, 102.99)	66.33 (64.33, 68.37)
Hospitalized	3.33 (2.63, 4.16)	2.37 (2.14, 2.63)
Serious infection	3.68 (2.94, 4.55)	2.57 (2.32, 2.83)
Malignancy	1.55 (1.09, 2.15)	1.35 (1.18, 1.55)
Autoimmune event	2.07 (1.53, 2.75)	1.83 (1.62, 2.05)

Presented are incidence rates, calculated as events/100 pt-yrs (Poisson 95% CI), unless otherwise stated; includes events occurring up to 56 and 60 days post-last dose for Phase III and II studies, respectively; ST=Short-term; LT=Long-term

Conclusion: Based on the cumulative short-term and long-term exposure of 6028 patients to IV or SC abatacept (16,670.56 pt-yrs), the incidence rates and events reported with long-term abatacept treatment were similar to those reported in the short-term, with no increase in rate for any event with increasing exposure. These findings demonstrate that IV and SC abatacept are both well tolerated over the long-term.

Quantitative Evaluation of Dermal Atrophy by High-Resolution Ultrasonography, Comparing Between Patients Under Long-Term Treatment with Prednisolone or Methylprednisolone. Tim Pottel[1], Christoph Schäfer[2] and Gernot Keyβer[2]. [1]06114 Halle (Saale), Germany, [2]06120 Halle (Saale), Germany

Background/Purpose: The katabolic effects of a systemic treatment with glucocorticoids can lead to a progressive atrophy of the skin. Clinical observation suggests a more pronounced effect of methylprednisolone compared with prednisolone. Therefore, a study was undertaken to correlate the cumulative doses of the respective steroids with the skin thickness measured by high-resolution sonography, comparing patients with rheumatic disorders

receiving long-term prednisolone and patients with renal transplants taking methylprednisolone.

Methods: The study included 92 patients, 47 of them after renal transplantation and immunosuppressive therapy with methylprednisolone, 45 with rheumatic diseases and prednisolone treatment, including 29 cases with rheumatoid arthritis. The cumulative steroid doses were recorded by chart review. Patients were included, if they had at least two years of glucocorticoid treatment, had a complete documentation of their steroid intake at least every three months and were free of relevant dermal diseases. The measurement of dermal thickness was performed by high-resolution ultrasound, using an 18 MHz probe, at three standardized locations at volar and dorsal forearm.

Results: There were no differences in the cumulative steroid doses between both groups, after adjusting for equivalent doses. However, patients receiving methylprednisolone revealed a significantly more pronounced dermal atrophy, compared with patients taking prednisolone. (mean dermal thickness 0,77 mm, standard error 0,023 in group with prednisolone treatment; 0,65 mm, standard error 0,018 in methylprednisolone group) (t-test; $p=5*10^{-4}$). By Pearsonxs correlation we identified a statistical interaction between the mean dermal thickness and type of glucocorticoid used (Pearsonxs r $= -0,41$; $p=2*10^{-5}$). Multiple regression analysis revealed, that methylprednisolone had a more pronounced negative influence on skin atrophy than prednisolone (regression coefficient $\beta= -0,15$; p$= 2,3*10^{-7}$). The association between cumulative dose of the last two years and degree of atrophy was significantly represented by $\beta= -0,011$; p$=0,035$, however only significant for cumulative steroids of last or last half year in methylprednisolone.

Dermal Thickness of Standardised Location at Dorsal Forearm
Conclusion: In our study, the long-term use of methylprednisolone was associated with a more pronounced dermal atrophy compared with prednisolone, particularly prominent in the last half year before data collection by measurement. The katabolic effects of methylprednisolone may be more pronounced that those of prednisolone, even after the adjustment for equivalent doses.

1697

Meta-Analysis of Malignancies, Serious Infections, and Serious Adverse Events with Tofacitinib or Biologic Treatment in Rheumatoid Arthritis Clinical Trials. Sima Ahadieh[1], Tina Checchio[1], Thomas Tensfeldt[1], Jonathan French[2], Sriram Krishnaswami[1], Richard Riese[1], Sujatha Menon[1], Mary G. Boy[1] and Jamie L. Geier[3]. [1]Pfizer Inc., Groton, CT, [2]Metrum Research Institute, Tariffville, CT, [3]Pfizer Inc., New York, NY

Background/Purpose: Patients with rheumatoid arthritis (RA) experience adverse events (AEs) attributed to both the disease and its treatment. Tofacitinib is a novel oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. To contextualize events within the tofacitinib clinical trial program, a meta-analysis was completed in patients with RA receiving biologic drug therapy within a randomized clinical trial (RCT) setting to identify and quantify safety endpoints of: malignancies excluding non-melanoma skin cancer (NMSC), serious infections (SIs), and serious AEs (SAEs).

Methods: Medline, Embase, PubMed, and summary basis of approvals from regulatory submissions were searched to identify RCTs for abatacept, rituximab, etanercept, infliximab, certolizumab, golimumab, adalimumab, and tocilizumab in RA. The search identified >300 papers from which data from 80 RCTs, representing more than 31,000 subjects, were extracted for analysis for the three endpoints. Non-RCTs, long-term extensions, and observational studies were excluded from the literature results. Tofacitinib results from five RCTs (Phase 3 [P3]) are presented. The dependent variable for the analysis was the incidence rate (IR) of an event/100 patient-years (pt-yrs). Data were analyzed using a random effects meta-analysis model. The IR data were log transformed to avoid negative confidence intervals (CIs). An imputation methodology was applied to account for IRs of zero and a sensitivity analysis was performed to assess the effects of adjustment on the individual and overall mean, as well as the impact on the estimated variance surrounding each study arm.

Results: Estimated IRs for endpoints of malignancies, SIs, and SAEs revealed similar rates among biologic therapies used to treat RA. Across all biologic therapies, point estimates ranged from 0.8 to 1.4 events/100 pt-yrs for malignancies; 2.5 to 6.5 for SIs; and 10.7 to 22.0 for SAEs. Event rates for tofacitinib were 0.62 (95% CI 0.36, 1.07) events/100 pt-yrs for malignancies (Figure 1); 2.91 (2.27, 3.74) events/100 pt-yrs for SIs; and 10.3 (9.00, 11.78) events/100 pt-yrs for SAEs, all in P3. The 95% CIs for tofacitinib were contained within the range of published estimates.

Drug	Number of trials	Malignancy Events / 100 pt-yrs (95% CI)	No. of patients	Patient years
Abatacept	3		1989	1187
Rituximab	2		1020	738
Tocilizumab	6		2801	1289
Infliximab	8		1859	2025
Etanercept	5		1409	1314
Certolizumab	2		603	271
Golimumab	5		2227	1284
Adalimumab	9		1803	1489
TNF inhibitor*	28		8211	6502
Tofacitinib Phase 3	5		3030	2098
* Estimate from 28 TNF inhibitor studies

Conclusion: This RCT meta-analysis provides a quantitative assessment of the incidence of important safety events reported with therapies for the treatment of RA. Overall, tofacitinib event rates for malignancies, SIs, and SAEs were comparable to published rates for approved biologic therapies. Future analyses are warranted to estimate relative effects (treatment comparisons), model studies with no events (IR=0), and account for study population differences.

1698

Predictors of Discontinuation of Biologics in 2,281 US Patients with Rheumatoid Arthritis. Sofia Ramiro[1], Frederick Wolfe[2], David J. Harrison[3], George Joseph[3], David H. Collier[3], Désirée van der Heijde[4], Robert Landewé[5] and Kaleb Michaud[6]. [1]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Amgen Inc., Thousand Oaks, CA, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Academic Medical Center, University of Amsterdam and Atrium Medical Center, Heerlen, Netherlands, [6]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Identifying predictors of discontinuation of biologic treatment for Rheumatoid Arthritis (RA) has clinical and research importance given the chronicity of RA and high costs and potential side effects of these agents. Our aim was to identify predictors of biologic discontinuation in patients with RA.

Methods: We studied patients with RA starting their first biologic while participating in an ongoing US longitudinal cohort study (1998 –2011). Patients provided all medication use, demographics, and clinical status via semiannual questionnaires. Discontinuation was analyzed through Cox multivariable regression models with baseline predictors adjusted by the biologic drug class patients were on (anti-TNF vs other) and a variable reflecting the onset after Jan 1, 2005, when more biologic treatment options became available. Three pre-specified prediction models were developed, a "research" model, with all significant variables, a "clinical" model, reflecting variables

more commonly used in clinical practice and one restricted to patients that started a biologic after Jan 1, 2005. Forward selection was performed until the best-fit model was obtained, taking confounding effects into account.

Results: A total of 2,281 RA patients initiated their first biologic; 1,100 (48%) discontinued. Age, smoking status and comorbidity index were positive baseline predictors of discontinuation (Table). Methotrexate use and higher SF-36 PCS and MCS scores were associated with less risk of discontinuation. In the "clinical" model, patient global assessment was positively associated with discontinuation. The discontinuation among patients starting biologics after 2005 was associated with a higher patient global assessment and inversely predicted by BMI.

Table. Hazard ratios (95% CI) of baseline predictors of biologic discontinuation in RA

	Research model	Clinical model	≥2005 model
Age (years)	1.01 (1.00;1.01)	1.01 (1.00;1.01)	**
BMI (kg/m2)	§	§	0.97 (0.94;0.99)
Patient global (0–10)	**	1.05 (1.03;1.08)	1.13 (1.06;1.20)
Comorbidity index (0–9)	1.08 (1.04;1.13)	1.11 (1.06;1.15)	**
Smoking	1.21 (1.01;1.45)	1.23 (1.03;1.47)	§
MTX	0.83 (0.73;0.94)	0.84 (0.74;0.95)	§
SF-36 MCS (0–100)	0.99 (0.98;0.99)	¥	**
SF-36 PCS (0–100)	0.99 (0.98;0.99)	¥	§

Adjusted for biologic drug class (anti-TNF vs other) and onset≥2005
§ Not included in the multivariable model (not significant in the univariable model) **Not selected during multivariable regression analysis (p≥0.05)
¥ Not included in this short "clinical" model (to present a model with variables more used in clinical practice)

Conclusion: Worse overall health strongly predicted biologic discontinuation in RA. Co-medication with methotrexate independently contributed to a lower biologic discontinuation. A higher number of comorbidities and a smoking status were also predictive of biologic discontinuation. The predictors of discontinuation might guide the clinician when starting a biologic therapy. While these are important factors leading to discontinuation, their impact is lessened when there are more biologic therapies to choose from.

Neutropenia After Rituximab in Rheumatoid Arthritis and Other Autoimmune Diseases Is a Rare Events: Date From the Autoimmunity and Rituximab Registry. Jean Hugues Salmon[1], Patrice P. Cacoub Sr.[2], Bernard G. Combe[3], Jean Sibilia[4], Beatrice Pallot Prades[5], Olivier Fain[6], Alain G. Cantagrel[7], Maxime Dougados[8], Olivier Meyer[9], Philippe Carli[10], Edouard Pertuiset[11], Isabelle Pane[12], Philippe Ravaud[13], Xavier Mariette[14] and Jacques-Eric Gottenberg[15]. [1]Rheumatology, Reims, France, [2]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [3]Hopital Lapeyronie, Montpellier, France, [4]CHU Hautepierre, Strasbourg, France, [5]Saint Etienne university hospital, Saint Etienne, France, [6]Service de médecine interne, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France., Bondy, France, [7]Place du Docteur Baylac, Toulouse, France, [8]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [9]Hopital Bichat, Paris, France, [10]Toulon, France, [11]Ch Rene Dubos, Pontoise, France, [12]Hotel Dieu University Hospital Paris, France, [13]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [14]Université Paris-Sud, Le Kremlin Bicetre, France, [15]Strasbourg University Hospital, Strasbourg, France

Background/Purpose: Limited data are available regarding the proportion and severity of late onset neutropenia after RTX in large and unselected populations of patients with various autoimmune diseases. The largest series included 209 patients followed up to 1 year (162 patients with rheumatoid arthritis (RA) and 47 patients with other autoimmune diseases) and identified 11 RTX-induced neutropenia (5.2%) (Tesfa D, A&R 2011).
Methods: The AutoImmunity and Rituximab registry (AIR) has included 2653 patients (2000 patients with RA including 1975 patients with at least 1 follow-up visit, and 653 patients with AIDs, including 649 patients with at least 1 follow-up visit). Patients are prospectively followed up every 6 months

for 5 years. For each neutropenia episode registered, the clinician in charge of the patient was asked to fill a specific questionnaire.
Results: A neutropenia was confirmed by clinicians in 85 patients (48 RA and 37 AIDs (17 systemic lupus erythematosus, 12 vasculitis, 1 primary Sjögren's syndrome, 1 myositis, and 6 other AIDs). In 35 patients, neutropenia resulted from other reasons than RTX (chronic autoimmune-disease related neutropenia, other drug-induced neutropenia, blood malignancies). RTX-induced neutropenia according to the clinician was observed in 50 patients (32 RA [1.6% of all patients with RA], 18 AIDs [2.8% of patients with AIDs]: 8 SLE, 7 vasculitis, 1 myositis, 2 other AIDs). 6 patients (12%) (1 RA, 5 AIDs) had neutrophils < 500/mm^3, 9 (18%) (8 RA, 1 AIDs) had neutrophils between 500 and 1000/mm3 and 35 (70%) (23 RA and 12 AIDs)patients had neutrophils between 1000 and 1500/mm3.

RTX-induced neutropenia occurred after a median of 6.7 months in RA and 6.3 months in AIDs after the last infusion of the 1st cycle (25 patients, 50%), 2d cycle (16 patients, 32%), 3d cycle (2 patients, 4%), 4th or subsequent cycle (7 patients, 14%). 5 patients 1 RA, 2 SLE, 1 vasculitis and 1 other AID, 4 with neutrophils < 500/mm3, 1 between 500 and 1000/mm3) (5.9%) developed a non opportunistic serious infection (2 urinary and 1 bronchopulmonary infections, 12 isolated fevers) and required G-CSF injections, with a favorable outcome. 25 patients (50%) were retreated with RTX after resolution of their neutropenia and a new episode of neutropenia occurred in 8 of them.
Conclusion: Late-onset neutropenia can occur after RTX and infrequently results in serious infections. One third of the patients with RTX-induced neutropenia recurred in case of realization of a new cycle of RTX. Thus, monitoring of white blood count should be performed after RTX. However, in this large registry of patients with autoimmune diseases, the frequency of RTX-induced neutropenia is much lower than that previously reported in patients treated with RTX for lymphoma.

Prevalence of Spondyloarthritis in Anterior Uveitis Patients: The Sentinel Study. Miguel Cordero Coma[1] and Xavier Juanola[2]. [1]Unidad de Uveítis. Hospital Universitario de León, León, Spain, [2]Hospital Universitari de Bellvitge, Barcelona, Spain

Background/Purpose: Anterior uveitis (AU) is the most common form of uveitis in western countries with an annual incidence rate of about eight new cases for every 100,000 inhabitants. AU may occur in the absence of associated systemic disease. However, it has been reported that about 25% of AU patients have an associated systemic condition; the most commonly associated one being seronegative spondyloarthritis (SpA). Since many of the conditions initially diagnosed as idiopathic anterior uveitis are later found to be a SpA-associated disorder, we hypothesised that a higher than expected rate of associated-SpA might be found by using a systematic clinical evaluation protocol in AU patients.
Methods: Prospective multicentre non-comparative cohort study. Patients with no previous diagnosis of any associated immune-mediated condition and clinically significant AU were included in this study. Clinically significant AU was defined as either recurrent AU (at least two episodes) or non-recurrent HLAB27 + associated AU. All patients included in the study underwent a complete physical and ophthalmologic examination and a thorough check-up of their systems including x-ray and MRI study of the sacroiliac joints, for those in which SpA was clinically suspected.
Results: A total of 199 patients from 29 tertiary referral centres were included in the study. From all included patients suffering from AU, 148 patients (74.3%) were HLAB27+. After an initial systematic clinical evaluation protocol, 122 patients (61.3%) were newly diagnosed with a type of spondyloarthritis, of which 94 patients (47.2%) fullfilled the ASAS criteria for axial spondyloarthritis and 28 patients (14%) fullfilled the ASAS criteria for peripheral spondyloarthritis. A positive HLAB27 haplotype was found in 89 (94%) of patients newly diagnosed with axial spondyloarthritis and in 20 (71.4%) of those patients newly diagnosed with peripheral spondyloarthritis.

Other associated diagnoses included ankylosing spondylitis, diagnosed based on New York criteria, in 78 patients (39.2%), psoriasis in 10 patients (5%), inflammatory bowel disease in 3 patients (1.5%), and reactive arthritis in 1 patient (0.5%).

Conclusion: These preliminary results show that in a large prospective cohort almost 75% of patients with clinically significant idiopathic AU have an associated underlying SpA which more than double that of previously reported prevalence. The diagnosis of idiopathic uveitis seems to depend greatly on the extent of the evaluation for an underlying condition. These results should be considered in the management and therapeutic decision-making for patients with recurrent AU.

1701

Validation of the New ASAS Criteria for Classification of Early Spondyloarthritis in the Esperanza Cohort.

Eva Tomero[1], Loreto Carmona[2], Juan Mulero[3], Eugenio De Miguel[4], Milena Gobbo[5], Carmen Martínez[6], Miguel A. Descalzo[5], Pedro Zarco[7], Eduardo Collantes-Estevez[8] and Esperanza Group[9]. [1]Hospital Universitario La Princesa, Madrid, Spain, [2]Universidad Camilo José Cela, Villanueva de la Cañada, Spain, [3]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda (Madrid), Spain, [4]Hospital Universitario La Paz, Madrid, Spain, [5]Spanish Society of Rheumatology, Madrid, Spain, [6]Sociedad Española de Reumatología, Madrid, Spain, [7]Fundación Hospital Alcorcon, Alcorcon, Madrid, Spain, [8]IMIBIC-Reina Sofia Hospital, Cordoba 14012, Spain, [9]Madrid

Background/Purpose: To validate the new axial and peripheral ASAS criteria in patients with early spondyloarthritis (SpA) and the full spectrum of clinical manifestations under clinical practice conditions.

Objectives: 1) To analyze the validity of the ASAS classification criteria for SpA in an early multisite cohort; 2) to describe the characteristics of the new-onset SpA cohort from the ESPERANZA program and 3) to analyze the positive and negative predictive value of the ASAS, Amor, and ESSG criteria in this cohort.

Methods: Cross-sectional study of all patients with new-onset SpA referred to units within the ESPERANZA program. Selection criteria for the program are: Patients under 45 years of age with, at least, one of the follow: a) a two-year history of inflammatory back pain; b) back or joint pain in the presence of psoriasis, anterior uveitis, radiographic sacroiliitis, family history of SpA or positive HLA-B27; or c) asymmetric arthritis. A validation analysis of criteria sets was performed with the rheumatologist opinion as gold standard. We excluded patients who did not meet the referral criteria and those in which the radiograph on HLA-B27 were not available. The predictive ability of individual criteria was analyzed versus the physician's opinion, thus only patients with a diagnosis could be included.

Results: 1179 patients were included for Esperanza program, but only 775 met inclusion criteria. Low-back pain was the primary reason for referral (73.7%). The mean age of the sample was 33.1 ± 7.1 years and 55.4% were men. The mean time from symptoms was less than a year (11.9 ± 6.6 months). A percentage of 69.5% (538) of patients were diagnosed with SpA, and 30.5% (237) were diagnosed with No SpA. The most frequent joint manifestations in patients with SpA were inflammatory back pain (67.5%) and the presence of peripheral arthritis (18%); the prevalence of HLA-B27 in this population was 55.6%, and the most frequent extra-articular manifestation was psoriasis (13.9%). A total of 67.9% patients with chronic back pain met the ASAS axial criteria, peripheral ASAS in 56.3% (without chronic back pain) and full ASAS in 65.1%. Sensitivity and specificity of the full ASAS criteria set was 65% and 93%, a little higher or axial ASAS, 68% sensitivity and 95% specificity; and for peripheral ASAS, 56% and 85%, respectively. Sensitivity and specificity for ESSG criteria, and Amor criteria are presented in Table 1.

Table 1. Results of the validation analysis and predictive ability (N = 775)

Criteria	Sensitivity (CI 95%)	Specificity (CI 95%)	Positive predictive value (CI 95%)	Negative predictive value (CI 95%)
ASAS axial	68 (63,73)	95 (91,98)	97 (94,98)	58 (53,64)
ASAS axial-imaging	43 (38,48)	98 (95,99)	98 (94,99)	45 (40,50)
ASAS axial-HLA B27	50 (45,55)	96 (93,99)	97 (93,99)	48 (43,53)
ASAS peripheral	56 (48,65)	85 (71,94)	92 (83,97)	40 (30,50)
ASAS total	65 (61,69)	93 (89,96)	95 (93,97)	54 (49,59)
ESSG	58 (54,62)	90 (86,94)	93 (90,96)	49 (44,53)
Amor	59 (55,63)	86 (81,90)	90 (87,93)	48 (43,53)

Conclusion: The sensitivity and specificity of the ASAS criteria are higher than the ESSG and Amor criteria, so in early SpA forms the ASAS criteria may replace both criteria. However, the sensitivity for the ASAS criteria in this new-onset SpA is lower than in previous studies, what may limit their ability to detect early forms, particularly in populations in which MRI is not available under standard clinical practice or in population with a low prevalence of HLA-B27.

Tumor Necrosis Factor Blocking Agents Inhibit the Progression of Preclinical Atherosclerosis in Patients with Ankylosing Spondylitis.

Alper M. van Sijl[1], Izhar C. van Eijk[2], Mike J.L. Peters[2], Erik H. Serne[2], Yvo M. Smulders[2] and Mike T. Nurmohamed[1]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: Ankylosing spondylitis (AS) is associated with an increased cardiovascular (CV) risk that might be due to the chronic underlying inflammatory process. It is still unknown whether strong anti-inflammatory treatment with tumor-necrosis factor (TNF) inhibitors reduce the increased CV risk in AS. We investigated whether preclinical atherosclerosis and elasticity of the carotid arteries in patients with AS changed after use of TNF-inhibitors.

Methods: 67 out of 82 AS patients who underwent ultrasonography at baseline were measured again after 5 years. Assessments of medication use, AS related factors, CV risk factors and arterial parameters (including intima-media thickness (IMT) and Young's elastic modulus (YEM)) were repeated at follow-up. Spearman's rank correlation were used to investigate the correlation between changes in AS related factors or CV risk factors with changes in arterial wall parameters.

Results: After a mean follow-up of 5 years, 11 AS patients (16%) discontinued their use of TNF inhibitors. IMT did not change significantly ($+0.012$, p-value= 0.561) in those who continued the use of TNF inhibitors as compared to AS patients who discontinued use of TNF inhibitors ($+0.060$, p-value=0.025). Also, vascular elasticity (as measured with YEM) improved significantly in patients who continued TNF inhibitors ($+0.031$, p-value=0.002) but not in patients who discontinued TNF inhibitors. Correlations were found between 1. Unfavourable changes in BASDAI, BASG, BASMI and increase in IMT, and 2. Unfavourable changes in total cholesterol, LDL-cholesterol, total-HDL-cholesterol ratio and decrease in vascular elasticity (as measured with YEM).

Table 1. Correlations between changes in AS- and CV related factors and changes in arterial wall characteristics

	Intima-media Thickness		Young's Elastic Modulus	
	Correlation coefficient	p-value	Correlation coefficient	p-value
AS related factors				
BASDAI	0.308*	0.013	-0.201	0.117
BASFI	0.113	0.368	0.081	0.533
BASG	0.311*	0.012	-0.167	0.195
BASMI	0.327*	0.007	-0.062	0.632
ESR	0.030	0.822	-0.085	0.533
CRP	0.042	0.752	-0.114	0.401
CV risk factors				
Systolic blood pressure	-0.075	0.559	-0.102	0.440
Diastolic blood pressure	-0.109	0.395	-0.016	0.902
Pulse pressure	0.002	0.986	-0.100	0.446
Body-mass index	-0.084	0.516	0.005	0.968
Total cholesterol	0.309*	0.042	-0.276	0.076
HDL-cholesterol	0.081	0.612	0.137	0.401
LDL-cholesterol	0.251	0.123	-0.277	0.097
Total- to HDL-cholesterol ratio	0.117	0.462	-0.319*	0.045

* $p < 0.05$
Figure 1. Changes in IMT and BASMI, YEM and Total cholesterol to HDL-cholesterol ratio.

Conclusion: Continuous use of TNF-inhibitors might stabilize or slow down IMT progression in AS patients, reflecting a decreased CV risk in these patients. Unfavourable changes in IMT were associated with equally unfavourable changes in AS related factors and unfavourable changes in vascular elasticity (as measured with YEM) were associated with unfavourable changes in lipid levels. The exact mechanism by which TNF inhibition modulates CV risk might be explained by different mechanisms (AS related factors and IMT vs. lipid levels and YEM).

1703

Relationship Between Tobacco Smoking and Radiographic Spinal Progression in Axial Spondyloarthritis: The Role of Inflammatory Activity.
Denis Poddubnyy[1], Hildrun Haibel[1], Joachim Listing[2], Elisabeth Märker-Hermann[3], Henning Zeidler[4], Jürgen Braun[5], Martin Rudwaleit[6] and Joachim Sieper[7]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]Dr. Horst Schmidt Kliniken, Wiesbaden, Germany, [4]Medizinische Hochschule, Hannover, Germany, [5]Rheumazentrum Ruhrgebiet, Herne, Germany, [6]Endokrinologikum Berlin, Berlin, Germany, [7]Charité Universitätesmedizin Berlin, Berlin, Germany

Background/Purpose: Cigarette smoking is associated with functional impairment [1, 2] and radiographic severity of ankylosing spondylitis (AS) [3, 4]. Moreover, smoking status at baseline was found recently to be an independent predictor of radiographic spinal progression in the whole group of axial spondyloarthritis (SpA) [5]. However, the nature of relationship between smoking and radiographic spinal progression in SpA remains unclear.

The objective of the current analysis was to investigate a relationship between smoking intensity, radiographic spinal progression and activity of systemic inflammation in patients with axial SpA.

Methods: In total, 210 patients with axial SpA (115 with AS according to the modified New York criteria and 95 with nrSpA) from the German Spondyloarthritis Inception Cohort (GESPIC) were selected for this analysis of spinal radiographs at baseline and after 2 years of follow-up. Spinal radiographs were centrally collected, digitized, and subsequently scored according to the mSASSS independently by two trained readers, who were blinded for time point and all clinical data. Smoking status and smoking intensity (non-smoker, 10 cigarettes a day and less, 11 to 20 cigarettes, and more than 20 cigarettes a day) were assessed retrospectively every 6 months during 2 years of follow-up.

Results: 139 patients (66.2%) were considered to be non-smokers throughout the entire follow-up period of 2 years, 43 patients (20.5%) smoked 10 cigarettes a day and less (as a mean over two years), 22 patients (10.5%) smoked 11–20 cigarettes and only 6 patients (2.9%) smoked more than 20 cigarettes a day and, therefore, were pooled with the group of 11–20 cigarettes a day. The mean mSASSS change over 2 years was 0.52 ± 1.72 in non-smokers vs 0.47 ± 1.48 in a ≤10 cigarettes/day group (p=0.30) vs 2.2 ± 4.6 in >10 cigarettes/day group (p=0.077 vs. non-smokers, p=0.35 vs. ≤10 cigarettes/day group). Significant radiographic progression (defined as an mSASSS worsening by 2 units and more over 2 years) was observed in 10.1% of non-smokers vs 18.6% in smokers of ≤10 cigarettes a day (p=0.14 vs non-smokers) vs 28.6% in smokers of >10 cigarettes a day (p=0.012 versus non-smokers). Importantly, the same trend was observed for the serum level of C-reactive protein as a marker of inflammatory activity: 6.3 ± 6.6 mg/l in non-smokers vs 8.6 ± 10.3 mg/l in smokers of ≤10 cigarettes a day vs 12.4 ± 12.9 in smokers of >10 cigarettes a day (p=0.021 vs non-smokers).

Conclusion: Tobacco smoking has a clear dose-dependent effect on radiographic spinal progression in axial SpA, which is likely to be related to a non-specific augmentation of inflammation by the components of the tobacco smoke.

1704

New Threshold Values for Spinal Mobility Measures Based On a Large Nationally Representative Sample of U.S. Adults Ages 20–69 Years.
Shervin Assassi[1], Michael H. Weisman[2], Zhongxue Chen[1], Mohammad Rahbar[1] and John D. Reveille[1]. [1]Univ of Texas Health Science Center at Houston, Houston, TX, [2]Cedars-Sinai Medical Center, Los Angeles, CA

Background/Purpose: Spinal mobility measures are widely utilized for diagnosis and assessment of disease severity in patients with Ankylosing Spondylitis. The previously proposed threshold values for spinal metrology were determined based on distributions of these measures in convenience samples of healthy volunteers. Herein, we report population based percentile reference range values for selected spinal mobility measures in a <u>nationally representative sample</u> of 5103 U.S. adults ages 20–69 years examined in the 2009–10 U.S. National Health and Nutrition Examination Survey (NHANES).

Methods: Occiput-to-Wall Distance (OWD), Thoracic Expansion (TE), Anterior Lumbar Flexion (modified Schober) were measured by trained examiners in a standardized fashion. Specifically, the difference in chest circumference expansion between complete exhalation and maximal inhalation was measured at the xiphisternum level. For the modified Schober test, the initial measurement point was a line marked at the level of the superior margin of the lateral iliac crests, then a second mark was placed 10 cm above it. NHANES sample weights and survey design variables were used.

Results: In this nationally representative sample, 4% of subjects had an OWD of more than zero. Based on the commonly used thresholds of 2.5 or 5 cm for chest expansion, 13.6% and 62.4% of the sample had "out of range" values, respectively. Assuming that lumbar flexibility has a similar range if the measurements start at the level of lateral iliac crest rather than at the L5-S1

level, the commonly used threshold of 3.5 cm for the modified Schober was applied, resulting in 44.2% of the general population having "out of range" values.

In the present study, the upper 95th percentile of OWD measurement was zero while the 5th percentile measurements for TE and modified Schober were both 2.0. The mean (±standard error) OWD, Thoracic Expansion, and modified Schober test were 0.21 (±0.03), 4.8 (±0.06), and 3.8 (±0.03) cm, respectively. The spinal metrology parameters were significantly associated with body mass index, gender, and age. Therefore, we next excluded participants with morbid obesity (body mass index>35). This did not change the threshold values for OWD and modified Schober test but the 5th percentile for TE increased to 2.3. Furthermore, we calculated the percentiles for the spinal mobility measures stratified according to age and gender (Table 1).

Table 1. Percentile Cut Points[1] in cm. for Arthritis Body Measures: NHANES 2009–10

Age (years)	Occiput-Wall Distance		Thoracic Expansion		Modified Schobers	
	Men	Women	Men	Women	Men	Women
20–35	0	0	2.7	2.5	2.3	2.2
36–49	0	0	2.4	2.3	2.2	1.8
50–69	6.3	0	1.9	1.8	1.9	1.6

[1] Occiput-to-Wall Distance-upper 95th percentile; Thoracic Expansion/Modified Schober-lower 5th percentile.

Conclusion: In this nationally representative sample, we verified the threshold of zero for OWD. However, the currently utilized clinical cut points for TE and Schober Test appear to assign "abnormal" values to a large portion of the general population. Using population based percentile reference range values, we recommend new threshold values for TE and the modified Schober Test in the overall population or stratified by age and gender.

1705

Effect of Certolizumab Pegol On Inflammation of Spine and Sacroiliac Joints in Patients with Axial Spondyloarthritis: 12 Week Magnetic Resonance Imaging results of a Phase 3 Double Blind Randomized Placebo-Controlled Study. Désirée van der Heijde[1], Walter P. Maksymowych[2], Robert B. M. Landewé[3], Christian Stach[4], Bengt Hoepken[4], Andreas Fichtner[4], Danuta Kielar[5] and Jurgen Braun[6]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Alberta, Edmonton, AB, [3]Academic Medical Center/University of Amsterdam & Atrium Medical Center, Amsterdam, Netherlands, [4]UCB Pharma, Monheim am Rheim, Germany, [5]UCB Pharma, Brussels, Belgium, [6]Rheumazentrum Ruhrgebiet, Herne, Germany

Background/Purpose: Axial spondyloarthritis (axSpA) includes both ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) and is defined by the ASAS criteria.[1] It is characterized by bone marrow edema of sacroiliac joints (SIJ) and spine leading to chronic back pain. RAPID-axSpA (NCT01087762) is the first report of the effect of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, on inflammation of spine and SIJ in axSpA pts, including both AS and nr-axSpA pt populations, using MRI.

Methods: The ongoing 158-Wk RAPID-axSpA trial is double-blind and placebo controlled to Wk24, dose-blind to Wk48 and then open label to Wk158. Recruited pts had adult-onset active axSpA defined by the ASAS criteria,[1] Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) ≥4, spinal pain ≥4 on a 10 point NRS, and CRP > upper limit of normal or sacroiliitis on MRI. Pts must have failed ≥1 NSAID. Pts could have been secondary failures to 1 previous TNF inhibitor. The pt population reflected the broad axSpA population, including AS pts also meeting the modified New York criteria and nr-axSpA pts who met the ASAS MRI or clinical criteria. Pts were randomized 1:1:1 to placebo (PBO), or 400mg CZP at week (Wk) 0, 2 and 4 (loading dose, LD) followed by either 200mg CZP every 2 weeks (Q2W) or 400mg CZP every 4 weeks (Q4W). MRI scans of the SIJ and spine[2], using short-tau-inversion recovery sequences, were performed at baseline (BL) (±3 days) and Wk12 and evaluated using an analysis of covariance model. MRI endpoints were change from BL in the Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ score for inflammation

and in the Berlin modification of AS spine MRI score for disease activity in the spine (ASspiMRI-a). MRIs were performed in a subset of the pts. Data are reported for all pts who had MRI scans at both BL and Wk12 (the MRI set).

Results: 325 pts were randomized, of which 153 were included in the MRI set. In the MRI set, BL characteristics were similar between treatment groups (PBO/CZP 200mg/CZP 400mg), apart from C-reactive protein (23.9/14.7/15.3 mg/L) and prior anti-TNF exposure (30.0/12.2/9.3%). AS pts had longer symptom duration at BL compared to nr-axSpA pts (mean 12.4 vs. 8.5 yrs). Within the MRI imaging set, BL SPARCC MRI SIJ scores were comparable between AS and nr-axSpA populations while Berlin ASspiMRI-a scores were higher in AS patients. Improvements in SPARCC MRI SIJ scores and ASspiMRI-a Berlin modification were observed in both CZP dose arms compared to PBO in the overall and in both AS and nr-axSpA populations (Figure). Greater reductions in SIJ inflammation were observed for pt subgroups with <5 yr symptom duration, age <45 yrs and in males.
Figure. LS mean difference to placebo for change from BL in SPARRC scores in SIJ (**A**) and in the ASspiMRI-a Berlin Modification in the spine (**B**) at Week 12

Conclusion: CZP reduced inflammation in the SI joints and spine, as assessed by MRI in pts with axSpA, and in both AS and nr-axSpa populations.

Predictive Atherosclerotic Risk Factors At Inception in a Multicentre, Multinational Cohort. Murray B. Urowitz[1], Dominique Ibanez[1], D. D. Gladman[1] and SLICC[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto, ON

Background/Purpose: Patients with systemic lupus erythematosus (SLE) develop premature atherosclerosis (AS). This study examines predictive factors at inception for atherosclerotic vascular events (AVE) over a maximum 10 years of followup in a multicenter, international inception cohort.

Methods: An inception cohort of SLE patients from 31 centres from 12 countries has been assembled according to a standardized protocol between 2000 and 2012 to study risk factors for atherosclerosis. At yearly visits demographic and cardiovascular risk factors are collected and vascular events (VE) are described and attributed on a specialized form. Events recorded include myocardial infarction (MI), angina, congestive heart failure (CHF), intermittent claudication (PVD), stroke, and transient ischemic attack (TIA). Diagnosis of an event was confirmed using standard clinical criteria and diagnostic tests where appropriate. Attribution to AS was made by physicians on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Analysis was done using descriptive statistics and Cox proportional Hazard model.

Results: Of the inception cohort of 1844 SLE patients 93 had VE due to non-AS causes (e.g. active SLE or thrombosis) and 350 patients had only enrolment data leaving 1401 patients. 31 patients had 41subsequent AVE after enrollment. The mean time to AVE or last clinic followup was 5 years. distribution Patients' race/ethnicity distribution was as follows: 51% Caucasian, 16% Black, 17% Asian 12% Hispanic 4% other. At enrollment risk factors for AS are shown in the table 1.

	Patients without AVE no=1370	Patients with AVE n=31	P value
Age	34.6 ± 13.1	56.0 ± 13.8	<0.0001
Sex, %	90.6	58.1	<0.0001
Diabetes, %	3.2	10.7	0.06
Framingham risk Score Mod/High, %	1.5	25.0	0.001
Smoker ever, %	35.7	61.3	0.004
Obese, %	29.3	53.6	0.01
Hypertension, %	32.6	60.0	0.003
Hypercholesterolemia, %	34.7	50.0	0.12
Increased LDL*, %	33.3	33.3	1.00
Increased Creatinine, %	23.5	47.8	0.01

*LDL=low density lipoprotein

Table 2. Time to Event Analysis 1 risk factor at a time

	Hazard Ratio	95% CI	p value
One risk factor at a time			
Age	1.09	1.07,1.12	<0.0001
Caucasian	3.39	1.46,7.87	0.005
Male	6.30	3.09,12.87	<0.0001
FRS Mod/High	13.15	3.99,43.22	0.0001
Smoker ever	2.95	1.43,6.09	0.003
Obesity	2.92	1.39,6.14	0.005
Hypertension	3.10	1.49,6,43	0.002
Hypercholesterolemia	1.85	0.90,3.77	0.09
Stepwise regression with all above variables			
Age	1.09	1.06,1.11	<0.0001
Male	4.07	1.84,9,04	0.0006

*FRS=Framingham Risk Score

Conclusion: Only age and male sex remain significant risk factors for AVE in a multivariate analysis of a multicentre inception cohort followed for a mean of 5 years.

The Association of Serum Biomarkers and Metabolic Syndrome with Subclinical Atherosclerosis in Systemic Lupus Erythematosus: A Controlled Analysis in Patients with No Clinical Disease Activity. Semra Ertan-Demir[1], Ahmet Yasar Cizgici[1], Gaye Erten[2], Bahar Artim-Esen[1], Yasemin Sahinkaya[1], Özlem Pehlivan[1], Nilüfer Alpay-Kanitez[1], Kadri Atay[1], Huseyin Oflaz[1], Gunnur Deniz[2] and Murat Inanc[1]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Istanbul University, Institute of Experimental Medicine (DETAE), Istanbul, Turkey

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of developing atherosclerotic cardiovascular disease (CVD). In addition to traditional CVD risk factors or metabolic syndrome (MetS), SLE related factors may contribute to increased risk. The aim of this study was to assess subclinical atherosclerosis and the potential role of inflammatory mediators, vascular endothelial cell activation markers and adipocytokines in SLE in presence or absence of MetS.

Methods: We studied 82 female SLE patients (35 with Mets, 47 without Mets) and 28 female healthy controls (HC) with no history of CVD. Mets were defined according to NCEP ATP III. Disease activity according to SLEDAI and SLICC damage score were determined. Subclinical atherosclerosis was screened by measuring carotid intima media thickness (CIMT) by B-mode ultrasonography. Serum levels of high sensitivity C-reactive protein(hs-CRP), tumor necrosis factor α(TNFα), interleukin 6(IL-6), soluble interceluler adhesion molecule 1 (sICAM-1), sE-selectin, leptin and visfatin

were measured. Additional analysis were done for premenopausal patients. The comparison of groups was done by variance analysis and chi-square test when appropriate.

Results: The mean age of MetS+ SLE was 45± 11, MetS- was 33±9, HC was 28±6 mean disease duration of the patients were 84 ± 62 months. Most of the SLE patients (%79) were premenopousal. SLE patients were in clinical remission (mean SLEDAI= 1.06). Mean SLICC damage score was 0,29. CIMT values were higher in SLE patients than HC (mean CIMT left: 1.35±2,52mm vs 0.54±0,08mm right 1,28±2,40mm vs. 0,55±0,07mm, p=0,001). Only hsCRP, sICAM-1 and leptin levels were higher in SLE patients than HC (p=0,001) and were correlated with carotid IMT values (left r= 0,3, p=0,02; r=0,47, r=0,35, p=0,001). The biomarkers studied were not related to serological or hematological activity. SLE mets+ group has higher CIMT values than SLE mets- (mean CIMT left: 1,74±3,17mm vs 1,06±1,91mm right: 2,11±3,54mm vs. 0,66±0,07mm p=0,001). hsCRP and leptin levels were significantly higher in SLE Mets + than SLE Mets- (p= 0,003, p=0,001). When SLE patients in premenopause were analysed, CIMT values were higher in SLE patients than HC (CIMT left: 1,1±1,9mm vs 0,54±0,08mm, p=0,02, right: 1±1,6mm vs 0,55±0,07mm, p=0,03). hsCRP, sICAM-1 and leptin levels were higher in SLE patients (p=0,03, p=0,001, p=0,014). Only leptin levels were correlated with CIMT values (right r= 0,315, p=0,002). In premenopausal SLE patients, mets+ group has higher IMT values than mets- (mean CIMT left: 1,21±2,07mm vs 1,07±1,92mm p=0,013, right: 1,72±2,83mm vs. 0,66±0,12mm p=0,001). Only leptin levels were higher in Mets+ than Mets- patients (p=0,005).

Conclusion: In mainly premenopausal women with SLE without a history of CVD, CIMT values were found increased and related to Mets. This implies the importance of investigating Mets in identifying patients with subclinical atherosclerosis. Some biomarkers in SLE, especially leptin was increased in patients with Mets and correlated with carotid IMT values, suggesting a relationship with subclinical atherosclerosis. The longitudinal follow-up of Mets and biomarkers may facilitate the prevention of overt CVD in SLE.

Systemic Lupus Erythematosus Cardiovascular Risk Equation. Michelle Petri[1] and Laurence S. Magder[2]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Accelerated atherosclerosis remains the major late cause of death in SLE. Yet, the "traditional" cardiovascular risk equations (Framingham, Reynolds, SCORE) consistently underestimate the risk. This may lead to under-recognition and under-treatment. We sought to construct a data-driven risk equation of cardiovascular risk in SLE, based on data collected in a longitudinal cohort.

Methods: To derive the score, risk factors were calculated based on variables measured in the first two years of cohort participation (mean systolic blood pressure, mean SLEDAI, etc). Cox Proportional Hazards models were constructed to determine the variables that affected the risk of a subsequent CVE. Using the results, a formula to calculate the risk of a CVE within the next 10 years was derived. There were 1342 patients, 93% female, 56% Caucasian, 38% African-American, and 6% other ethnicities. There were 109 cardiovascular events: 52 strokes, 26 MI, 18 angina/CABG, and 13 claudications.

Results: Table 1 shows the estimates for the association between predictors and risk of a CVE.

Table 1.

	Beta	Hazard Ratio (95% CI)	P-value	Integer Score
Age (for each 5 years over 40)	0.252	1.29 (1.15,1.44)	<0.0001	1
Male (vs. female)	0.552	1.74 (0.98,3.09)	0.060	2
Systolic Blood Pressure 140 or more	0.791	2.21 (1.37,3.56)	0.0012	3
Cholesterol over 160	0.743	2.10 (1.16,3.83)	0.015	3
Smoking	0.677	1.97 (1.31,2.96)	0.0012	3
Diabetes	0.407	1.50 (0.91,2.48)	0.11	2
Mean SLEDAI of 2 or more	0.730	2.08 (1.22,3.53)	0.0069	3
History of Lupus Anti-coagulant	0.744	2.10 (1.40,3.16)	0.0003	3
Low Mean C3	0.583	1.79 (1.14,2.82)	0.012	2

Using this model, the risk of a CVE within 10 years is $1-0.9875^{(Hazard\ Ratio)}$. For example, if someone is 50 years of age, male, with high systolic blood pressure, then the hazard ratio is $(1.0510)x(1.74)x(2.21) = 6.26$. The risk of a CVE in 10 years is then $1-0.9875^{(6.26)} = 7.6\%$. In the absence of SLE risk factors, the estimated 10-year risk from our formula is higher than would be projected based on the Framingham formula. This is especially true if there are SLE-related risk factors. Table 2 shows a few scenarios.

Table 2. Examples

	Estimated 10-year risk based on our formula	Estimated 10-year risk based on Framingham formula
Woman, age 50, SBP=150, Chol=150	4.5%	4.7%
Woman, age 50, SBP=150, Chol=220	9.2%	7.8%
Woman, age 50, SBP=150, Chol=220, Lupus Anticoagulant	18.3%	7.8%
Woman, age 50, SBP=150, Chol=220, High disease activity	18.1%	7.8%
Woman, age 50, SBP=150, Chol=220, Low complement	15.8%	7.8%

Using the approach employed by the Framingham study, the regression coefficients were rounded to integers (Table 1) to create a simpler score. The score is the sum of the number of points earned for each risk factor. For example, a 50 year old man with high SBP would get a score of $2+2+3=7$. Then, to calculate the 10 year risk, use Table 3.

Table 3. Percent risk of a CVD within 10 years

Score	0	1	2	3	4	5	6	7	8	9	10
% Risk	1.3	1.6	2.1	2.6	3.4	4.3	5.5	7.0	8.9	11.3	14.2

Conclusion: A data-driven SLE Cardiovascular Risk Score can better estimate 10-year cardiovascular risk than the Framingham equation. Its use can lead to appropriate use of imaging and intervention.

Biomarkers of Atherosclerosis Are Associated with Progression of Non-Cardiovascular Damage in Patients with SLE. Sarah J. Kim, Jennifer M. Grossman, Brian Skaggs, Elaine Lourenco, Lori Sahakian, John D. FitzGerald, Nagesh Ragavendra, Christina Charles-Schoeman, Alan H. Gorn, Bevra H. Hahn and Maureen A. McMahon. UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Studies have shown that even after taking traditional cardiac risk factors into account, SLE patients have up to 50-fold higher risk of developing atherosclerotic (ATH) cardiovascular disease. We previously identified several biomarkers associated with the progression of atherosclerosis in SLE, including pro-inflammatory high-density lipoprotein (piHDL), leptin, sTWEAK, and homocysteine. These 4 biomarkers plus increased age combined into a "high oxidative stress" variable was also highly associated with progression of ATH in SLE. The goal of this study was to investigate the association between biomarkers of ATH and overall progression of non-ATH, lupus-related damage.

Methods: Systemic Lupus International Collaborating Clinics/ACR damage index (SDI) was used to score damage progression in 159 SLE patients enrolled in the longitudinal "Biomarkers of Atherosclerosis in SLE" cohort study between January 2004 and September 2008. Lupus-related damage scores were determined using the SDI at baseline and at the time of the 2–3 year follow-up carotid ultrasound excluding scores in cardiovascular domains. The associations between accumulation of any lupus-related non-ATH damage and biomarkers of atherosclerosis were examined using the chi-square test for dichotomous variables and Student's t-test for continuous variables (SPSS Inc, Chicago, IL).

Results: After excluding cardiovascular and cerebrovascular events from the SDI score, new carotid plaque at 2 year follow-up was present in 34% of patients with non-ATH SDI score increase as opposed to 18% in patients without SDI change (p=0.01). In patients with SDI increase, mean homocysteine (p=0.037), sTWEAK (p=0.043) and leptin (p=0.02) levels were significantly higher than in those without SDI change. The combination

high-oxidative stress variable was found in a higher proportion of patients with SDI increase (50% vs 28.9%, p=0.02), and was associated with a higher mean SDI increase (0.52±0.94 vs 0.19±0.47, p=0.02). In multivariate analysis controlling for lupus medications, baseline SDI, and other potential confounders, high-oxidative stress was associated with a 2.9-fold increased odds for progression of non-atherosclerotic damage (p=0.02), and lifetime cumulative prednisone use >20g was associated with 2.6-fold increased odds (p=0.046).

Conclusion: Non-atherosclerotic lupus-related damage as measured by SDI scoring is associated with presence of carotid plaque, high-oxidative stress and elevated levels of homocysteine, sTWEAK, and leptin. Patients with baseline biomarkers for atherosclerosis progression have higher incidence of overall progression of non-ATH disease damage which may serve as important predictors for lupus disease course.

Increase in Vitamin D Improves Disease Activity and Systolic Blood Pressure in Systemic Lupus Erythematosus. Kayode J. Bello[1], Hong Fang[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Vitamin D deficiency has also been associated with different chronic conditions including cardiovascular diseases such as coronary artery disease, cardiac failure and hypertension. In SLE, it may be associated with the interferon gene signature. We investigated whether an increase in vitamin D levels was associated improvement in disease activity and blood pressure in SLE patients.

Methods: 1006 SLE patients were followed in a prospective observational study for 138 weeks (July 2009–March 2012). Serum 25-hydroxyvitamin D levels were measured at routine clinic visits. Patients with low 25-hydroxyvitamin D levels (<40 ng/mL) were supplemented with 50,000 units Vitamin D_2 weekly, and $Ca/D_3$200 units twice daily. Data analysis was done using longitudinal regression models with one-slope and two-slope models, controlling for race, age, age squared, sex, prednisone, hydroxychloroquine, and date (SAS Institute Inc. Cary, North Carolina, SAS 9.2).

Results: There were a total of 5935 visits with serum 25-hydroxyvitamin D measurements from 1006 different SLE patients. They were 91% female, mean age was 49.6 (SD = 13.2), 54% Caucasian, 37% African-American and 8% other ethnicity. The number of visits per patient ranged from 1 to 16. 110 (11% had 1 visit, 313 (31%) had 2–5 visits, 517 (51%) had 6–9 visits, and 65 (6%) had 10–16 visits.

Table. Difference in mean disease measure per 20 ng/mL increase in vitamin D based on longitudinal regression models with one or two slopes

Disease Measure	One-slope Model		Model allowing slope to differ before and after 40 ng/mL			
	Slope[1] (95% CI)	P-value	Slope[1] over range of 0–40 ng/mL (95% CI)	P-value	Slope[1] over range of 40+ ng/mL (95% CI)	P-value
Physician Global Assessment	-0.01 (-0.03,0.01)	0.21	-0.04 (-0.08,-0.01)	0.026	0.01 (-0.02,0.04)	0.68
SLEDAI-SLEDAI	-0.02 (-0.11,0.07)	0.65	-0.22 (-0.41,-0.02)	0.032	0.12 (-0.01,0.24)	0.065
Systolic BP	-2.13 (-2.79,-1.48)	<0.0001	-3.91 (-5.21,-2.63)	<0.0001	-0.86 (-1.73,0.02)	0.055
Log Urine Protein/Creatinine	-0.02 (-0.03,-0.01)	<0.0001	-0.04 (-0.05,-0.02)	0.0004	-0.01 (-0.01,0.00)	0.24
Log HSCRP	-0.02 (-0.09,0.06)	0.64	-0.06 (-0.20,0.09)	0.45	0.02 (-0.12,0.15)	0.82

[1]Slopes are interpretable as difference in mean level of disease per 20ng/mL increase in vitamin D.

There was significant improvement in both the PGA and SELENA-SLEDAI in those with low vitamin D (<40ng/mL), when vitamin D was increased by 20 ng/mL. There was also improvement in systolic blood pressure and urine protein/creatinine.

Conclusion: After a long follow-up in this SLE Cohort, there was statistically significant improvement in disease activity in those with low

vitamin D levels, who increased their vitamin D levels. We also found significant improvement in both systolic blood pressure and urine protein/creatinine with increase in vitamin D. This analysis suggests vitamin D supplementation in SLE patients with low vitamin D levels may have beneficial effects on disease activity and on blood pressure, one of the major predictors of accelerated atherosclerosis in SLE.

Association of Vascular Calcification and Perivascular Adipose Tissue of the Descending Aorta with Cardiovascular Events in SLE. Kelly J. Shields[1], Emma Barinas-Mitchell[2], Amy H. Kao[3], Susan Manzi[4] and Kim Sutton-Tyrrell[2]. [1]Lupus Center of Excellence/ASRI/West Penn Allegheny Health System, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Allegheny Singer Research Institute, Pittsburgh, PA, [4]West Penn Allegheny Health System, Pittsburgh, PA

Background/Purpose: Women with systemic lupus erythematosus (SLE) have an increased risk of cardiovascular disease (CVD). We have shown that clinically CVD-free women with SLE have an increased volume of descending aortic perivascular adipose tissue (aPVAT). This small adipose depot was also associated with aortic calcification (AC) independent of overall adiposity. Thus, we hypothesized that clinically CVD-free women with SLE increased aPVAT volume and premature vascular calcification measured by AC and coronary artery calcification (CAC) will predict cardiovascular events. (CVE).

Methods: Women participating in the "Heart Effects on Atherosclerosis and Risk of Thrombosis in SLE" (HEARTS) study were clinically CVD-free and diagnosed with SLE for at least 2 years. CAC/AC were measured using electron beam computed tomography (EBCT) and quantified by Agaston scoring. The aPVAT was quantified using commercially available software and standard attenuations values for adipose tissue (−190 to −30 HU). Participants were followed for incident CVE confirmed by a physician. (SLE without CVE, n=128; SLE with CVE n=28). CVE included myocardial infarction, congestive heart failure, stroke, transient ischemic attack, angina, blood clot, percutaneous coronary intervention, and catherization.

Results: Twenty eight participants (17%) experienced a first CVE within 4.6 +/− 12 months (Mean +/− SD) with three participants having multiple CVE. There were no differences in surrogate adiposity measures such as waist-to-hip ratio (p=0.58) or BMI (p=0.23) by CVE status suggesting similar adipose distribution. Traditional CVD risk factors such as age (p=0.008), systolic blood pressure (p=0.0053), pulse pressure (p=0.0047), hypertensive status (p=0.0039), CRP (p=0.0081) and homocysteine levels (p=0.017) were all significantly greater in SLE women with CVE. The SLE women with CVE were more likely to have AC (p=0.0052). There were no differences in CAC (p=0.21) or aPVAT (p=0.17) between SLE groups with and without CVE. Aortic PVAT was associated with adiposity measures such as BMI (r_s=0.515,p<0.0001), waist-to-hip ratio (r_s=0.332,p=0.0001), and circulating inflammatory markers such as CRP (r_s=0.393,p<0.0001). In univariate models using Cox proportional-hazards regression, CAC (Hazard ratio/HR [95%CI]: 2.43 [1.1–5.5], p=0.03) was a predictor of first CVE, but AC (p=0.74) and aPVAT (p=0.20) were not predictors. In the multivariable Cox regression models, age per 5 years (HR 1.61 [1.3–2.1], p=0.0001) and CRP (HR 1.10 [1.0–1.2], p=0.0055) remained predictors of first CVE.

Conclusion: Traditional CVD risk factors were independent predictors of first CVE in women with SLE in this study. The clinically CVD free SLE women experiencing a CVE were more likely to have hypertension along with AC indicating premature vascular dysfunction. CAC was an independent predictor of first CVE emphasizing the significant influence of calcification in this vascular bed. Aortic PVAT was found to be significantly associated with traditional CVD risk factors, but not found to be predictive of first CVE. Considering our previous findings, aPVAT and AC may be considered precursors to measurable subclinical CAC.

The Submaximal Heart and Pulmonary Evaluation: A Novel Noninvasive Test to Identify Pulmonary Hypertension in Patients with Systemic Sclerosis. Elana J. Bernstein[1], Jessica K. Gordon[1], Robert F. Spiera[1], Lisa A. Mandl[1] and Evelyn M. Horn[2]. [1]Hospital for Special Surgery, New York, NY, [2]New York Presbyterian Hospital/Weill Cornell Medical College, New York, NY

Background/Purpose: Pulmonary hypertension (PH), defined as a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg on right heart catheterization (RHC), is a leading cause of death in patients with systemic sclerosis (SSc). Although RHC is the gold standard for diagnosing PH, it is an expensive, invasive test with significant associated risks. Transthoracic echocardiogram (TTE) and pulmonary function testing (PFT) are standard noninvasive screening methods used to assess SSc patients for PH. However, both are limited in their ability to distinguish between SSc patients with and without PH. The existence of an accurate, noninvasive technique to screen for PH in the SSc population is an important unmet need.

The submaximal heart and pulmonary evaluation (SHAPE) is a noninvasive, submaximal stress test that consists of a 5.5 inch high step that patients step up and down on for 3 minutes. During the test, end tidal carbon dioxide, which is equivalent to the ratio of cardiac output to pulmonary blood flow and reflects the severity of PH, is monitored. Our aim was to assess the correlation between change in end tidal carbon dioxide (ΔP_{ETCO2}) from rest to end-exercise on the SHAPE test and mPAP on RHC. We hypothesized that ΔP_{ETCO2} would be strongly negatively correlated with mPAP.

Methods: This is a retrospective cohort study of patients with limited cutaneous (lc) or diffuse cutaneous (dc) SSc who underwent a SHAPE test and RHC between November 2008 and May 2012. Charts of 679 patients in an academic cardiology practice were reviewed; 70 patients had a diagnosis of SSc, 19 of whom had undergone both a SHAPE test and RHC and were included in this study. The primary outcome was correlation between ΔP_{ETCO2} and mPAP. Statistical analysis was performed using Spearman's correlation and multivariable linear regression.

Results: The mean age of subjects was 61 years (± 12.5); 84% were female, 84% had lcSSc, and 79% had PH. ΔP_{ETCO2} was significantly negatively correlated with mPAP (r = −0.82, p < 0.0001) (see Table). In a multivariable linear regression model evaluating the relationship between ΔP_{ETCO2} and mPAP, and controlling for age, sex, time between SHAPE and RHC, and change in medications between SHAPE and RHC, ΔP_{ETCO2} remained significantly associated with mPAP (β = −1.91, p < 0.001). The SHAPE had better sensitivity, specificity, positive predictive value, and negative predictive value for PH than did TTE or PFTs.

Performance Characteristics and Correlation of SHAPE, TTE, and PFTs with RHC (N=19)

Test*	Sensitivity**	Specificity**	Positive Predictive Value (PPV)**	Negative Predictive Value (NPV)**	Spearman's Correlation†	P-value for Spearman's Correlation
SHAPE (ΔP_{ETCO2} < 4 mmHg)	100%	75%	93.8%	100%	-0.82	0.0001
TTE (systolic pulmonary artery pressure [sPAP] > 35 mmHg)	80%	25%	80%	25%	0.74	0.0004
PFTs (forced vital capacity/ diffusion capacity [FVC/ DLCO] > 1.6)††	91.7%	75%	91.7%	75%	0.53	0.034

* Cut-points were derived from the literature
** Using RHC as the gold standard for diagnosis of PH (mPAP ≥ 25 mmHg)
† Correlation is with mPAP on RHC
†† 16 of the 19 patients had PFTs with DLCO

Conclusion: ΔP_{ETCO2} as measured by the SHAPE has a very strong, statistically significant negative correlation with mPAP on RHC, and is better correlated with mPAP than are sPAP on TTE or FVC/DLCO. The SHAPE has excellent sensitivity, specificity, PPV, and NPV in this small group of SSc patients with a high prevalence of PH. The SHAPE may be a better screening test for PH in patients with SSc than TTE or PFTs. Larger prospective studies investigating the ability of the SHAPE to distinguish between SSc patients with and without PH are needed.

Developing an Index for Disease Activity and Therapeutic Response in Connective Tissue Disease Related Interstitial Lung Disease: Results From A Delphi Exercise: Delivering A Consensus On Domains.

Lesley Ann Saketkoo[1], Dörte Huscher[2], Dinesh Khanna[3], Paul F. Dellaripa[4], Kevin Flaherty[3], Chester V. Oddis[5], Kristine Phillips[3], Athol U. Wells[6], Christopher P. Denton[7], Oliver Distler[8], Otylia M. Kowal-Bielecka[9], Romy Christmann[10], Nora Sandorfi[11], David Pittrow[12], Vibeke Strand[13], James R. Seibold[14], Kevin K. Brown[15] and Eric L. Matteson[16]. [1]Louisiana State University Health Science Center, New Orleans, LA, [2]German Rheumatism Research Centre and Charité University Medicine, Berlin, Germany, [3]University of Michigan, Ann Arbor, MI, [4]Brigham and Womens Hospital, Boston, MA, [5]University of Pittsburgh, Pittsburgh, PA, [6]Royal Brompton Hospital, United Kingdom, [7]UCL, London, United Kingdom, [8]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [9]Department of Rheumatology and Internal Medicine, Medical University in Bialystok, Bialystok, Poland, [10]Boston University, Boston, MA, [11]Thomas Jefferson Univ Med Coll, Philadelphia, PA, [12]Dresden, Germany, [13]Stanford University, Portola Valley, CA, [14]Scleroderma Research Consultants LLC, Avon, CT, [15]National Jewish Hospital, Denver, CO, [16]Mayo Clinic, Rochester, MN

Background/Purpose: Lack of reliable and valid measures of disease activity and clinical response in patients with connective tissue disease (CTD)-related interstitial lung disease (ILD) makes clinical trial design difficult. From a multi-tiered investigation to develop consensus on criteria in both CTD-ILD and idiopathic pulmonary fibrosis (IPF), we report results of expert voting from a 3-tiered Delphi exercise to identify domains 'important' to measure in a 1 year randomized controlled trial (RCT) in IPF and CTD-ILD.

Methods: Using OMERACT methodology, 270 experts nominated 23 "domains" and 616 "instruments" that were assembled into an initial voting survey for a 3-tiered Delphi exercise with survey items anchored by degree of importance on a 9-point Likert scale with <insufficiently familiar> as a voting option. All stages of data collection used a custom-designed secure web-site that included related articles and opportunities for participants to upload commentary supporting or refuting importance of each item.

Tier 1 Analysis: A cut-off median <4 was applied to the results. Final review demanded 100% consensus agreement for dismissal of an item based on lack of: 1. Face validity, 2. Content validity (more suited to diagnostic, demographic, or inclusion criteria) and 3. Feasibility in a multicenter trial.

Tiers 2 and 3 Analysis: To protect against bias introduced by using an arbitrary cut-off, cluster analysis was implemented to identify patterns of consensus within the data.

Results: 90% of invited experts: 137 pulmonary, 102 rheumatology and 4 cardiology specialists from 32 countries/6 continents participated. 74% and 69% of participants considered ILD and rheumatologic lung disease respectively as their primary field of research or clinical interest. Recidivism after Tier 1 was <1% with each subsequent Tier. Five common domains with their candidate instruments were identified for CTD-ILD and IPF (Table 1). Three domains identified for CTD-ILD: biomarkers, cough and medications await nominal group decisions.

Table 1. Results of Tier 3

DOMAINS (median/mean ratings)		Candidate Instruments
Dyspnea		Borg Dyspnea Index
CTD-ILD	IPF	Dyspnea 12
(8.0/7.8)	(8.0/8.1)	Medical Research Council (MRC) Breathlessness (Chronic Dyspnea) Scale
		Modified MRC Dyspnea Scale
		Borg Dyspnea Index - Pre and Post Exercise
Health Related Quality of Life (HRQoL)		Medical Outcomes Trust Short Form-36 Health Survey
CTD-ILD	IPF	St. George's Dyspnea Respiratory Questionnaire
(8.0/7.7)	(8.0/7.8)	Visual Analogue Scale of Patient Assessment Disease Activity
		Ability to Carry Out Activities of Daily Living (ADLs)
		Health Assessment Questionnaire Disability Index (HAQ-DI)
Lung Imaging		Extent of Honeycombing on HRCT
CTD-ILD	IPF	Extent of Reticulation on HRCT
(9.0/8.3)	(9.0/8.3)	Extent of Ground Glass Opacities on HRCT
		Overall Extent of Interstitial Lung Disease on HRCT
Lung Physiology/Function		Supplemental Oxygen Requirement
CTD-ILD	IPF	Forced Vital Capacity on Spirometry
(9.0/8.7)	(9.0/8.7)	Diffusion Capacity of Lung for Carbon Dioxide
		6 MWT with Maximal Desaturation on Pulse Oximetry
		6 MWT for Distance
Survival		Time to Decline in Forced Vital Capacity
CTD-ILD	IPF	Progression Free Survival
(8.0/8.2)	(9.0/8.4)	Time to Death

Conclusion: Development of valid, discriminatory and feasible outcome measures to assess disease progression and therapeutic responses is essential for performing RCTs in CTD-ILD. This is the first comprehensive, multi-disciplinary, international effort to assess domains for study of ILD. Experts identified a core set of domains including radiographic, physiologic and patient-reported outcomes culled from a large number of candidate items. A research agenda focusing on candidate biomarkers and domains requiring instrument development has emerged. Broad participation from a multidisciplinary ILD research community reflects the high perceived need in this area.

1714

Gender Differences in Systemic Sclerosis: Relationship to Disease Specific Clinical Manifestations and Estradiol Levels.

Christine Peoples, Mary Lucas, Zengbiao Qi, Thomas A. Medsger Jr. and Carol A. Feghali-Bostwick. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune disease characterized by inflammation, autoantibody production, and increased production of extracellular matrix (ECM), resulting in fibrosis. We demonstrated that estradiol (E2) promotes the development of a fibrotic phenotype, and serum levels of E2 were significantly elevated in female patients with diffuse cutaneous SSc (dcSSc) (postmenopausal, no hormone replacement therapy [HRT]) when compared to controls. Prompted by these findings, we compared gender differences in disease type, disease specific clinical manifestations, disease severity, and analysis of serum E2 levels in patients with SSc.

Methods: Using the University of Pittsburgh Scleroderma Databank and Serumbank, we identified a total of 2,503 patients (1985–2011) with a clinical diagnosis of SSc. Differences between male and female patients were examined, including disease type, disease specific clinical manifestations including organ system involvement and autoantibody profile, and disease severity using the modified Medsger Disease Severity Scale. Serum levels of E2 in male dcSSc patients (N = 89) were measured using ELISA. We utilized t-test, Chi-square test of proportions, and Fisher's exact where appropriate.

Results: There were 1,994 female and 509 male patients with SSc. Most patients were Caucasian (89% in males, 91% in females, p = 0.37). Men with SSc were significantly more likely to have dcSSc than women (p < 0.0001). Males had significantly higher incidence of pulmonary fibrosis (PF) (p < 0.0001), cardiac involvement (p < 0.0001), mean maximum modified Rodnan skin score (p < 0.001), and presence of tendon friction rubs (p = 0.0002). Males also had a significantly higher prevalence of anti-Scl-70 autoantibody as compared to females (p < 0.0001), whereas females had a significantly higher prevalence of anti-centromere antibody (p < 0.0001) with a trend of higher prevalence of anti-U1RNP (p = 0.068) and anti-PM-Scl (p = 0.055). Males also had more severe vascular (p = 0.012), joint (p = 0.013), skin (p = 0.046), pulmonary (p < 0.0001), and cardiac involvement (p = 0.011) in addition to PF (p = 0.0001). For patients with dcSSc, there were 317 males and 939 females. Males had significantly higher incidence of PF (p = 0.0001) and GI involvement (p = 0.0488). There were no significant differences in regards to peripheral vascular, muscle, pulmonary arterial hypertension, or renal involvement. The mean Health Assessment Questionnaire score was significantly higher in females vs. males (p < 0.001). Serum E2 levels were elevated in patients with dcSSc compared with controls. E2 levels were also significantly higher in male dcSSc patients as compared to female dcSSc patients (p = 0.035).

Conclusion: SSc is more severe in male than female patients, especially regarding skin, pulmonary, cardiac, and GI involvement. This can be explained, in part, by increased circulating levels of E2, a pro-fibrotic hormone. Blocking the actions of E2 represents a viable therapeutic approach, especially with the wide availability of estrogen receptor antagonists and aromatase inhibitors.

Imatinib Mesylate (Gleevec™) in the Treatment of Diffuse Cutaneous Systemic Sclerosis: Results of a 24 Month Open Label, Extension Phase. Jessica K. Gordon[1], Morgana L. Davids[1], Kamini Doobay[1], Jamie N. Mersten[1], Cynthia Magro[2], Horatio F. Wildman[2], Stephen L. Lyman[1], Mary K. Crow[1] and Robert F. Spiera[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill-Cornell Medical Center, New York

Background/Purpose: Imatinib mesylate (IM) has been shown to decrease fibrosis in preclinical models and is a treatment of interest for Systemic Sclerosis (SSc). We have previously reported the results of our open label trial. In that study, 24/30 of patients tolerated 1 year of therapy and demonstrated a 22% improvement in the Modified Rodnan Skin Score (MRSS) as well as improvement or stability in measures of pulmonary function. Patients from the initial phase of that trial were eligible to continue treatment with IM in a 24 month extension phase of this open label trial.

Methods: This was a phase IIa, open-label, single-arm clinical trial in extension-phase. Patients with dcSSc were treated with imatinib at 200 to 400 mg daily and were assessed every 3 months for safety, MRSS, and measurement of additional outcome measures for an additional 24 mos. Pulmonary function testing, high resolution CT of the chest, and echocardiography were performed as part of standard clinical care.

Results: 24 patients completed the 12 month initial phase of the imatinib trial. 17/24 patients enrolled in the extension phase and 13 continued treatment with imatinib for 24 months. The median age was 48 (18,61). 76% were female. 65% were Caucasian. The mean disease duration from the first non-Raynaud's symptom of SSc was 2.7 ± 2.1 years in this group at the time of enrollment in the initial phase. 29% were anti-scl70-positive. The baseline MRSS was 23.8 ± 9.2 at the start of the extension phase. Patients who entered the extension phase had experienced a mean improvement in MRSS of 7.1±4.8 points during the initial one year trial.

92 AEs were recorded, 43% of which were felt to be at least possibly related to IM and these were all Grade 1 or 2. 7 SAEs occurred, none of which were felt to be related to the IM. The most frequently noted side effects were muscle pain, fatigue, nausea, and edema.

The MRSS decreased from a median of 24 (IQR 18, 31) at the beginning of the extension phase to 18 (13, 29) after an additional 12 months of IM extension (n=15, p=0.08) and to 16 (13, 24) with an additional 24 mo of IM extension (n=13, p=0.002.) In 12 patients, the FVC at baseline of extension was 92 (71.0, 105.0) and was 85 (67.0,

105.0) % predicted after 24 months, p=0.09. The hemoglobin adjusted DLCO at baseline was 77% predicted (63.0, 108.0) and was 74.5% (53.5, 92.0) at 24 mo, p=0.019. When the subgroup of patients with ILD is examined (n=6), the FVC is 61% (59.0, 90.0) at baseline and 62.5% (54.5, 70.0) at 24 mo, p=0.25, and the DLCO is 63% (55.0, 63.0) to 50% (46.0, 53.5), p=0.13. Two patients developed incident mild interstitial lung disease as seen on CT during the 24 month period of follow-up. Significant changes were not observed in ESR, SHAQ, or SF-36 mental and physical components.

Conclusion: A total of 36 months of imatinib treatment was tolerable to a subset of patients with dcSSc. Although improvement in MRSS is observed in this subset, conclusions cannot be drawn regarding efficacy given the open label nature of this study. The utility of imatinib and/or other TKIs should be evaluated in a controlled fashion to better evaluate efficacy in the treatment of SSc patients.

Outcomes Linked to Intensive Treatment Trials in Systemic Sclerosis. Svetlana I. Nihtyanova[1], Voon H. Ong[2] and Christopher P. Denton[3]. [1]Royal Free Hospital, Medical School, London, England, [2]UCL Medical School, London, England, [3]UCL, London, United Kingdom

Background/Purpose: A number of clinical trials using intensive immunosuppression followed by autologous haematopoietic stem cell transplantation (HSCT) in systemic sclerosis (SSc) are underway or have been recently completed. Inclusion criteria for these trials aim to recruit cases with poor outcome, so that potential treatment-related complications, including significant early mortality are justified. Exclusion criteria are selected to minimise treatment related mortality, especially from the conditioning regimen, by defining severe organ-based disease that might preclude HSCT.

We explored morbidity and mortality in a cohort of SSc patients that fulfil the eligibility criteria for one of those trials (ASTIS) but who have been treated with standard immunosuppression.

Methods: Patients were identified from a cohort of 398 incident SSc cases with disease onset between 1995 and 1999, using ASTIS trial inclusion criteria (age 16–65 years; diffuse cutaneous (dc)SSc with disease duration ≤ 4 year *plus* modified Rodnan skin score (mRss) ≥ 15 *plus* either respiratory, renal or cardiac involvement *or* dcSSc with disease duration ≤ 2 years *plus* mRss ≥ 20 *plus* ESR > 25mm/1st h and/or Hb < 11g/dL) and exclusion criteria, relating to severe organ disease (respiratory, renal or cardiac) and malignancy.

Results: Of the 146 dcSSc cases, 87 fulfilled the inclusion and 66 satisfied both inclusion and exclusion criteria for the ASTIS trial. The final group was 82% female and 82% Caucasian. At the time patients fulfilled the trial eligibility criteria, mean age was 47 (range 17–65) years and disease duration was 20 months (range 1–44). Mean mRss was 30 (range 15–54), 23 (35%) of the patients carried anti-topoisomerase I antibody, 11 (17%) anti-RNA polymerase antibody and 4 (6%) anti-U3RNP antibody. Smoking status was known for 57 of the patients - 21% were current, 21% past and 58% were non-smokers.

Pulmonary fibrosis (PF), confirmed by high resolution CT was present in 55 (83%) of the patients, scleroderma renal crisis (SRC) in 2 patients (3%) and cardiac SSc in 5 patients (7.5%). Cumulative incidence of severe organ disease at 5 and 10 years of follow-up were 44% and 53% for clinically significant PF, 5% and 15% for PH, 5% and 7% for SRC and 13% for cardiac SSc.

Survival among the 66 patients was 95% at 2, 89% at 5 and 72% at 10 years. Survival among patients with present or past smoke exposure was marginally worse (87% at 5 and 74% at 10 years) compared to non-smokers (97% at 5 and 81% at 10 years), but difference was not significant. We also analysed all 87 patients who fulfilled the inclusion criteria only, not excluding those with severe organ disease or malignancy and survival among those was marginally worse (86% at 5 years and 68% at 10 years) confirming that the more severe cases that would be excluded from HSCT protocols do indeed have a worse outcome.

Conclusion: Our findings demonstrate that survival of cases that would have been eligible for ASTIS trial is substantially better than might have been predicted historically, especially when excluding patients with severe organ disease that are not suitable for HSCT. This must be taken into account when long-term outcomes for trials such as ASTIS are considered.

Autologous Lipostructure in the Treatment of Fibrotic Perioral Changes in Systemic Sclerosis: A Pilot Study. Nicoletta Del Papa[1], Fabio Caviggioli[2], Domenico Sambataro[1], Eleonora Zaccara[1], Gabriele Di Luca[1], Valeriano Vinci[2] and Marco Klinger[3]. [1]G. Pini Hospital, Milano, Italy, [2]UOC Chirurgia Plastica, Multimedica Holding SpA, Università degli Studi di Milano, Milano, Italy, [3]Istituto Clinico Humanitas, Università degli Studi di Milano;, Milano, Italy

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by varying degree of fibrosis in skin and other tissues. Therapeutic options for fibrotic changes are very limited. Particularly aesthetic and facial dysfunctions are followed by important oral and facial manifestations with loss of skin folds around mouth, thinned and rigid lips and tongue rigidity. Limitation of mouth opening leads to deterioration in dental health and decreases the quality of life in SSc patients.

We performed a prospective pilot study to evaluate whether the autologous fat administration in SSc patients can improve the functional limitations related to the impairment of the perioral sclerotic tissue.

Methods: 20 patients with the diffuse form of SSc (mean age + SD $34.5+15$ yrs and disease duration of $11+10$ yrs) were treated by topical perioral administration of autologous fat graft. All the patients had perioral skin fibrotic changes with limited opening of the mouth ($< 50mm$) and limited accessibility to the oral cavity. Lipofilling was performed according to the Coleman tecnique, with scar release and implantation into parallel tunnels on multiple layers under the scars. A volume of 5 to 7 cc was injected using an 18-gauge needle. Follow-up was performed at 1, 3 and 6 months postoperatively by evaluating measure of inter-incisal distance and dermal thickness by high frequency ultrasound (US). A pre-treatment and 24 week post-treatment evaluation of microcirculatory abnormalities was made using labial video capillaroscopy and skin biopsy.

Results: All patients made good postoperative recovery without major complications. Sixteen of 20 patients had an immediate subjective improvement of their skin stiffness obviously attributable to release of severe scar contractures. One month after lipofilling, the median measure of inter-incisal distance was significantly increased in comparison with the score before treatment (p=0.038). Three and 6 months after treatment, the median measures were increased further (p<0.02). US evaluations showed that skin thickness resulted significantly lower after treatment (p<0.001). Four patients underwent two lipofilling sessions because of improvement with the first lipofilling but had remaining sclerotic perioral areas. Interestingly 2 patients reporting trigeminal neuropathy, showed the complete resolution of painful syndrome. Finally, labial capillaroscopy of treated patients showed significant improvement in microvascular patterns after lipofilling in term of a more homogeneous capillary density, increased length and reduced diameter shapes. Skin capillary density measured by Hematoxylin Eosin and Safran staining showed upregulation of vessel number by 1.80-fold after lipostructure.

Conclusion: Our study suggest that fat grafting treatment of fibrotic perioral changes in SSc can provide immediate and long-lasting benefits in terms of both aesthetic and functional improvement, and should be considered as a component of comprehensive care. In addition, we provides evidences that adipose tissue graft has the potential to favour neovascularization in SSc. The cellular and/or tissue mechanisms underlying these changes need further investigation.

Cost Effectiveness of Nurse-Led Care for People with Rheumatoid Arthritis: A Multicentre RCT. Mwidimi Ndosi[1], Martyn Lewis[2], Claire Hale[1], Howard Bird[1], Sarah Ryan[2], Helen Quinn[1], Elizabeth McIvor[3], Julia Taylor[4], Gail Burbage[5], Deborah Bond[6], Jo White[7], Debbie Chagadama[8], Sandra Green[9], Lesley Kay[10], Adrian V. Pace[11], Victoria Bejarano[12], Paul Emery[13] and Jackie Hill[1]. [1]University of Leeds, Leeds, United Kingdom, [2]Keele University, Staffordshire, United Kingdom, [3]Stobhill Hospital, Glasgow, UK, Glasgow, United Kingdom, [4]Poole Hospital NHS Trust, Poole, United Kingdom, [5]King's Mill Hospital, Mansfield, United Kingdom, [6]Queen Elizabeth Hospital King's Lynn, King's Lynn, United Kingdom, [7]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [8]Royal London Hospital, London, United Kingdom, [9]Weston General Hospital, Weston-Super-Mare, United Kingdom, [10]Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [11]Russells Hall Hospital, Dudley, United Kingdom, [12]Barnsley Hospital, Barnsley, United Kingdom, [13]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

Background/Purpose: Despite the establishment of the innovative rheumatology nurse-led clinics (NLC) in the UK, the evidence of their cost-effectiveness is unknown. This study aimed at determining the cost effectiveness of NLC in patients with rheumatoid arthritis (RA).

Methods: This was a 10-centre, RCT where patients were randomized to either NLC or rheumatologist-led clinic (RLC). Adults with both stable and active RA were recruited. The interventions were delivered by 9 clinical nurse specialists (Mdn experience = 10 years) and 10 rheumatologists (Mdn experience = 9 years).

The primary outcome was the average change (from baseline) in disease activity score (DAS28) assessed at weeks 13, 26, 39 & 52. The EQ-5D was used to derive Quality-of-Life-Adjusted-Year (QALY) utility values.

Mean differences (MD) between the groups were estimated using linear models controlling for baseline covariates following per-protocol (PP) and intention-to-treat (ITT) strategies. The economic evaluation jointly estimated cost relative to quality adjusted life years (QALYs) and DAS28. Only ITT results are reported here: missing data being accounted through multiple imputation. Joint parameterization was achieved via bootstrap evaluation of the imputed datasets, and estimates plotted using cost-effectiveness planes and cost effectiveness acceptability curves.

Results: Demographics and baseline characteristics of patients under NLC (n = 91) were comparable to those under RLC (n = 90). They had a mean age (SD) of 58.5 (11.6), disease duration of 9.9 (10.7) years and 74% were female.

Average DAS28 change scores were higher in the NLC group (MD = −0.15, 95%CI = −0.45, 0.14) while average QALYs were higher in the RLC group (MD = 0.018, 95%CI = −0.037, 0.073).

Overall mean healthcare and National Health Service costs (UK-pounds) were higher in the RLC group compared to the NLC group (MD = 230, 95%CI = −406, 865 and MD = 223, 95%CI = −405, 850 respectively (approx. 360 US-dollars per person).

Figure 1 shows cost utility planes for healthcare costs. NLC was 'dominant' in respect of costs relative to change in DAS28 but not in respect of cost relative to QALY. Cost-effectiveness of NLC in relation to QALY is dependent on willingness-to-pay (WTP); this being the most likely cost-effective strategy for a WTP not in excess of ≤12,777 (i.e. 20,073 US-Dollars) for the healthcare perspective, and slightly less for the NHS perspective.

RLC = Rheumatologist-led clinic; NLC = Nurse-led clinic
Incremental health care cost / QALY / DAS28 change values denote bootstrap mean difference for the RLC group minus NLC group (adjusted for age, gender, centre, baseline DAS28 and baseline EQ-5D)
Percentages in the four quadrants (Graphs A&B) denote the percent of the total (5000) bootstrap cost-effect estimates that fell within each quadrant.

Figure 1. Economic evaluation (healthcare costs − ITT results).

Conclusion: This was the first economic evaluation of rheumatology NLC in the UK. While the findings indicate that NLC is likely to be a cost-efficient service under a cost-minimisation approach, we are not able to draw firm conclusions on cost-effectiveness given the variation in results between DAS28 and QALY.

What Do Patients Put up with for the Benefit They Get From Methotrexate? Sandra M. Robinson[1], Peta S. Heslop[1] and David Walker[2]. [1]North Tyneside General Hospital, North Shields, United Kingdom, [2]Freeman Hospital, Newcastle Upon Tyne, United Kingdom

Background/Purpose: As with all effective drugs, Methotrexate (MTX) comes with a range of side effects. Some such as pneumonitis are severe enough to require the drug to be stopped. Others such as nausea are more about what a patient will tolerate. We were aware that many patients were tolerating side effects in order to take MTX. If the benefits outweigh the problem, then the medical advice would be to continue. This also applies to patients taking methotrexate in combination with TNFis where there is considerable advantage from taking the combination. For this reason there was little interest in exploring methotrexate "tolerability". However, there is now good evidence that Tocilizumab works as well alone as in combination with Methotrexate. This offers the possibility that some patients struggling with methotrexate may be better off on Tocilizumab monotherapy rather than a TNFi and their MTX. We were interested to quantify the tolerability problems of patients continuing on Methotrexate therapy.

Methods: 100 consecutive patients seen in outpatient clinics, who were taking a stable dose of MTX and planning to continue, were surveyed. A study sheet was completed seeking information on the effectiveness of the MTX, their concordance with treatment and any side effects they were getting. They were specifically asked about: nausea; fatigue; mouth ulcers and hair loss and asked to rate them on a VAS.

68 were female and 32 were male with an average age of 59 (24 – 84 yrs). 89 were on oral and 11 on subcutaneous injections. 75 patients were suffering from RA, 18 patients from psoriatic arthritis with 7 patients having other indications.

Results: Efficacy averaged 6.5 being similar in men and women (6.7 & 6.4). 56% complained of at least one side effect. The side effects and the judged severity are shown in the table. VAS scores for severity averaged in the range 3.5 to 5. Sex differences were apparent. Men were less likely to complain of problems, in particular hair loss and nausea. Whether this relates to tolerance or intolerance is not clear. Only 10% "forgot" to take their MTX for an average of 2 weeks in a year. 5 chose not to take an average of 2.6 doses in a year. These patients had higher intensity of side effects (6–9.5).

	Nausea*	Mouth Ulcers	Hair Loss**	Fatigue	Other S/Es	Any Side Effect
WOMEN n=68	4.3 (±2.5) n=22 (32%)	4.3 (±2.9) n=18 (26%)	3.5 (±2.2) n=13 (19%)	5.0 (±1.9) n=17 (25%)	5.5 (±3.4) n=6	4.6 n=43 (63%)
MEN n=32	3.4 (±2.1) n=4 (13%)	2.7 (±2.0) n=9 (28%)	0.0 n=0 (0%)	4.3 (±0.8) n=3 (9%)	2.8 (±0.6) n=3	2.8 n=13 (41%)
TOTALS	n=26	n=27	n=13	n=20	n=9	n=56

Chi Test x^2
*p<0.05 **p<0.01

Conclusion: Patients are putting up with a lot of side effects, which are outweighed by the benefits of MTX for them. When a biologic is necessary to control their disease, some patients may be attracted by one that does not require combination with MTX.

1720

Cardiovascular Risk Management in Rheumatoid Arthritis Is Nurse Led Intervention Effective? Fiona Niddrie[1] and Gabor AC Major[2]. [1]Bone and Joint Institute; Royal Newcastle Centre, Newcastle, Australia, [2]Bone&Joint Institute; Royal Newcastle Centre, Newcastle, Australia

Background/Purpose: There is a recognised increase in the incidence of heart disease in patients with rheumatoid arthritis (RA)

Surveys of usual practice however frequently show a significant gap in the management of cardiovascular (CV) risk factors[1].

This study was undertaken with the aim of reviewing our experience and if a management gap was found, to see if this could be effectively and efficiently addressed by a nurse led initiative

Aim:

To identify the extent of awareness and management of CV risk factors in patients with RA attending a general rheumatology clinic

To explore the feasibility of a nurse led assessment programme and evaluate its effectiveness in managing CV risk

Methods: The medical records of all patients with RA were audited at the time of their scheduled review visit for the extent of CV risk assessment that had been completed and recorded by the treating rheumatologist in the previous 12 months.

Patients were then asked about their knowledge of CV risk and about assessments that had been undertaken through their family physician

A standard letter highlighting the increase in CV risk in RA together with the patient's CV risk factor assessment was then sent to the family physician, with recommendation to address any apparent deficiencies

Patients were seen again 6 months later and the completeness and effectiveness of CV risk management reviewed

Results: *Patient awareness* of the increased CV risk in RA was only 19%

Initial review showed that in the prior 12 months 86% of patients had had a blood pressure (BP) check; 31% had adequate serum lipid and 39% had glucose/HbA1c measurement; 42% had their weight and height recorded and 75% of smokers had received counselling

At the 6 month review of the first 150 patients all patients had had their BP checked. 79 (53%)were on active treatment. 17 had their treatment changed and 1 was newly started

Comprehensive assessment of lipids rose from 31% of patients to 60%; and for glucose/Hba1c from 39% to 62%. Two patients had treatment changes and one was newly started

Counselling of the 30 patients who smoked and the 103 with abnormal body mass index (BMI) resulted in 2 patients quitting smoking. 59 (39%) showed an improved BMI with 2 returning to ideal body weight

Average time per patient encounter was 26 mins at an estimated cost, excluding laboratory costs, of $21.03 AUS per patient encounter

Conclusion:

1 A significant gap in the routine management of CV risk factors was identified
2 Patient awareness of the increased risk of CV disease in RA is low
3 A nurse led intervention programme is feasible and effective in addressing the problems of CV risk factor management in patients with RA, but needs to be adequately resourced

Development of User-Focused Standards of Care for Rheumatoid Arthritis the www.Eumusc.Net Project - Work Package 5. Michaela Stoffer[1], Josef S. Smolen[2], Anthony D. Woolf[3], Tanja A. Stamm[4] and EUMUSC.net working group WP 5[5]. [1]Medical University of Vienna, A-1090 Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [3]Royal Cornwall Hospital, Truro Cornwall, United Kingdom, [4]Medical University of Vienna, Vienna, Austria, [5]Truro Cornwall, United Kingdom

Background/Purpose: The EUMUSC.net project facilitates cooperation between EU Member States and promotes a comprehensive European strategy to optimise musculoskeletal health.

The purpose of Work package 5, as a part of the EUMUSC.net project, was to develop evidence based and user-focused standards of care (SOC), for Rheumatoid Arthritis (RA).

Methods: A systematic review of international documents covering SOC for RA was conducted. National scientific societies, social leagues and health professional associations were contacted via the EULAR secretariat and asked to provide relevant documents. Documents concerning pharmacological and non-pharmacological interventions published after 2002 were included.

The obtained documents were evaluated based on the AGREE II criteria (www.agreetrust.org). All recommended methods to treat RA were extracted, as well as information on them and all recommendations given. Each of these methods was discussed in a consensus group meeting of 21 EUMUSC.net researchers and patient representatives from different countries regarding

priority and relevance in their home countries as well as possible interrelation with other methods. A scheme was developed with groups of interventions and formulated in a way that could be understood by users. To this end, conventional DMARDs, biological agents, NSAIDs, were grouped under pharmacological treatment. Giving up smoking, weight control and physical activity were grouped under Lifestyle Interventions.

Results: 49 types of therapies or other interventions, such as DMARDs, biological agents, exercise based-, activity based interventions, were extracted from the documents and could be grouped into seven types of interventions, namely Pharmacological Treatment, Monitoring, Lifestyle Interventions, Surgery, Education/Information/Self Management, Non-Pharmacological Treatment and Access to care.

From these data 16 user-focused standards of care were formulated.

SOC Table

Examples for the 16 Standards of Care

SOC 1	People with symploms of RA should have timely access (6 weeks) to a clinician/health professional competent in making a (differential) diagnosis.
SOC 3	People with RA should receive a treatment plan individually developed between them and their clinician.
SOC 5	People with RA should be fully assessed for symptoms, disease activity, damage, comorbidity and function at diagnosis; these assessments should also be done annually; if disease is not within target, clinical assessment should be done at least 3 monthly (all clinical variables) and possibly more frequently upon significant worsening.
SOC 6	People with RA should have rapid access to care when they experience significant worsening of the disease.
SOC 7	People with RA should be treated with a disease modifying anti-rheumatic drug as soon as the diagnosis is made.

Conclusion: The lay version of the user-focused SOC will be available in all 23 official languages of the European Union for the information of people with RA across all member states. This work should contribute to the harmonization of RA treatment in Europe.

Exploring How Patients with Rheumatoid Arthritis Use a Methotrexate Decision Aid for Making Treatment Choices. Linda C. Li[1], Anne F. Townsend[2], Paul M. Adam[3], Catherine L. Backman[1], Sydney Brooks[4], Gwen A. Ellert[5], Allyson Jones[6], Otto Kamensek[2], Cheryl Koehn[7], Diane Lacaille[2], Jenny Leese[8], Colleen Maloney[2], Elaine Yacyshyn[6], Charlene Yousefi[2] and Dawn Stacey[9]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada, Vancouver, BC, [3]Mary Pack Arthritis Centre, Vancouver, BC, [4]The Arthritis Society, Ontario Division, Toronto, [5]Trelle Enterprises Inc, Vancouver, BC, [6]University of Alberta, Edmonton, AB, [7]Vancouver, BC, [8]Arthritis Research Centre, Vancouver, BC, [9]University of Ottawa, Ottawa, ON

Background/Purpose: For patients with rheumatoid arthritis (RA), making treatment decisions can be overwhelming. The literature describes a sense of ambivalence among patients with chronic diseases toward medication use. For people considering methotrexate (MTX) for RA, we have developed a web-based decision aid called ANSWER. It consists of six animated patient stories and narrated information on the evidence of MTX for RA, and questionnaires to clarify individuals' treatment preferences. ANSWER asks patients to consider two options: 1) take MTX as prescribed, or 2) discuss options other than MTX with their doctors. At the end of the program, it produces a one-page summary with the patient's preferred treatment choices and questions, which can be presented to the doctor at the next medical visit. The current study aimed to understand patients' experiences with this new MTX decision aid.

Methods: This qualitative study was conducted within a proof-of-concept study on the ANSWER. Individuals were recruited from rheumatologists' clinics, patient groups and social networking sites. Eligible participants were those who had been diagnosed with RA, had been prescribed MTX but were unsure about starting it, and with access to the internet. Of the 30 participants enrolled, 11 were randomly selected to participate in an in-depth telephone interview on 3 broad topics: 1) their experience with the ANSWER, 2) their use of the Internet for health information, and 3) their views on disseminating

the ANSWER to others with RA. We conducted thematic content analysis to understand their experiences.

Results: Eight women and 3 men, aged 31 to 65 years, were interviewed. All participants were MTX naïve at the time of enrolment, with disease duration from less than 1 week to 16 years. Of the 11 participants, 7 were able to make a decision after using ANSWER, and 4 remained unsure. Our analysis identified 3 main themes: 1) *Seeking confirmation*: regardless of their prior level of knowledge on RA and MTX, participants constantly compared what they learnt from ANSWER and sought confirmation with their own knowledge, even some of which was inaccurate. 2) *Amplifying reluctance*: while using ANSWER, participants' doubts about using MTX increased when they encountered information that did not align with their own experience with the disease. 3) *Clarifying thoughts*: By completing the ANSWER's preference clarification questionnaire, some participants were able to reach the 'best option' for them. Several participants commented that ANSWER legitimized the practice of asking questions during medical visits and advocating for themselves.

Conclusion: Our preliminary findings highlight the power of patients' prior knowledge and experiences with RA on how they approach the information presented in a decision aid. This suggests that decision aids should address myths about RA, in addition to presenting the evidence of treatment options. Moreover, as the ANSWER serves only to initiate the discussion between patients and their doctors about MTX, further strategies are needed to support ongoing patient-doctor communication during medical visits.

1723

The Development of the Rheumatoid Arthritis Patient Priorities in Pharmacological Intervention Outcome Measures. Tessa Sanderson[1], John R. Kirwan[2], Marianne Morris[1], Jon Pollock[1], Robert Noddings[2], Anne Watts[2] and Sarah Hewlett[1]. [1]University of the West of England, Bristol, United Kingdom, [2]Bristol Royal Infirmary, Bristol, United Kingdom

Background/Purpose: Previous research developed a set of 8 priority treatment outcomes generated by patients to complement the professionally developed ACR core set for RA. These outcomes were pain, activities of daily living (ADL), visible joint damage, mobility, life enjoyment, independence, fatigue, and valued activities.[1] This abstract reports face validity in existing instruments (Phase 1), and the construction of new Numerical Rating Scales (NRS) where validated measures did not exist (Phase 2).

Methods: Phase 1: Two consultation meetings with patient research partners (N=18) were held. Patient research partners discussed and voted on their preferences for scales identified in the literature for each of the 8 priorities, except VJD (no scales could be found).

Phase 2: Two focus groups with RA patients (N=8) were facilitated. Draft scales constructed from the Phase 1 discussions were used. Feedback on the stem question, time frame, anchors and layout was recorded and transcribed verbatim.

Results: Existing NRS for pain[2], ADL[2] and fatigue[3] were voted as acceptable. However, patient research partners strongly recommended that severity of, importance of and ability to cope with each priority outcome be assessed, resulting in 24 questions (21 new). Visual joint damage created the most discussion, with concerns that the word 'damage' would be upsetting to newly diagnosed patients. PRP understood 'mobility' diversely, but a consensus was reached that it should focus on 'getting around outside the home'. In relation to valued activities, patients stressed that the stem question should focus on current activities, not those valued pre-diagnosis: "It needs to say 'currently'. You know, if you're asking about how a drug changes your life over four months, or six months or whatever it is, you know, it's kind of what your current expectation, how that's changed" (PE, p.30). Feedback on layout included making the questions in each domain visually separate using shaded boxes, underlining key words and putting the instructions in bullet points.

Conclusion: Existing instruments did not capture the patient perspective in 5 of the 8 priority outcomes. User involvement has been essential in developing the new patient-reported outcomes. An ongoing study will test the sensitivity of the 24 RAPP-PI NRS compared to the Disease Activity Score.

Pandemic Influenza Immunization in Primary Antiphospholipid Syndrome (PAPS): A Trigger to Autoantibody Production? Danielle M. Medeiros[1], Cleonice Bueno[1], Ana Cristina M. Ribeiro[1], Ana L. G. Calich[1], Karina Rossi Bonfiglioli[1], Vilma S. Viana[1], Jozelio F. Carvalho[1], Clovis Artur Silva[2] and Eloisa Bonfá[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: There are scarce data suggesting that pandemic influenza vaccination may induce antiphospholipid (APL) autoantibodies in inflammatory rheumatic diseases, particularly in systemic lupus erythematosus patients. However, there is no study evaluating the APL autoantibodies induction in primary antiphospholipid syndrome (PAPS) patients. The objective was to perform short and long-term evaluations of a large panel of APL autoantibodies following pandemic influenza A/H1N1 non-adjuvant vaccine in PAPS patients and healthy controls. Lupus specific antibodies were also investigated in these patients.

Methods: Forty-five PAPS patients (Sapporo criteria) and 33 healthy controls were vaccinated with monovalent, inactivated H1N1 vaccine (Butantan Institute/Sanofi Pasteur, São Paulo, Brazil). They were prospectively assessed at pre-vaccination, 3 weeks and 6 months after vaccination. APL autoantibodies were determined by an enzyme-linked immunosorbent assay (ELISA) and included: anti-cardiolipin (aCL) IgG/IgM and anti-β2GPI IgG/IgM antibodies (Inova Diagnostics, USA); anti-annexin V IgG/IgM, anti-phosphatidyl serine IgG/IgM and anti-prothrombin IgG/IgM (Orgentec Diagnostica, Germany). Anti-Sm was determined by ELISA (Inova Diagnostics, USA) and anti-dsDNA by indirect immunfluorescence. Arterial and venous thromboses were also clinically assessed. The statistical analyses were carried out with qui square test, McNemar′s test and one-way repeated measures analysis of variance (ANOVA).

Results: Pre-vaccination frequency of at least one APL antibody was significantly higher in PAPS patients compared to controls (58% vs. 21%, p=0.003). The overall frequencies of APL antibody at pre-vaccination, 3 weeks and 6 months after immunization remained unchanged in patients (p=0.89) and controls (p=0.83). Further analysis of each evaluated antibody in PAPS revealed that their percentages at pre-vaccination and after 3 weeks and 6 months were also comparable (p>0.05): aCL IgG (42%, 38% and 42%), aCL IgM (22%, 20% and 24%), anti-β2GPI IgG (22%, 22% and 20%), anti-β2GPI IgM (15%, 15% and 18%), anti-annexin V IgG (4.5%, 4.5% and 2.5%), anti-annexin V IgM (uniformly negative), anti-phosphatidyl serine IgG (38%, 35% and 38%), anti-phosphatidyl serine IgM (15%, 13% and 13%), anti-prothrombin IgG (20%, 15% and 18%) and anti-prothrombin IgM (2.5%, 2.5% and 2.5%). The same pattern was observed for the control group (p>0.05). At 3 weeks, 2 PAPS patients developed a new but transient APL antibody (moderate titer aCL IgG and IgM) whereas at 6 months, new APL antibodies were observed in 6 PAPS patients: 3 moderate titer aCL IgM, 1 moderate anti-β2GPI IgM, 1 low anti-phosphatidyl serine IgG and 1 low anti-prothrombin IgG. Fluctuations of antibody levels were not detected for any evaluated antibody (p>0.05). Of note, anti-Sm and anti-dsDNA autoantibodies were consistently negative during all evaluations. No new arterial or venous thrombosis events occurred during the study period.

Conclusion: This was the first study to demonstrate that pandemic non-adjuvant influenza A/H1N1 in PAPS patients does not trigger a change in APL antibody profile or induce lupus specific autoantibodies.

1725

ANTI-Factor Xa Antibodies ARE Significantly Increased in Patients with Systemic LUPUS Erythematosus and Antiphospholipid Syndrome. Bahar Artim-Esen, Charis Pericleous, Ian Mackie, Yiannis Ioannou, Anisur Rahman, David A. Isenberg and Ian Giles. University College London, London, United Kingdom

Background/Purpose: Increased levels of antibodies against different serine proteases (SP) have been identified in patients with the Antiphospholipid Syndrome (APS) compared with healthy controls. These anti-SP antibodies have been shown to alter the function of these coagulation factors, hence may be important in the pathogenesis of thrombotic manifestations of the APS. Few studies however, have examined the prevalence of anti-SP antibodies in patients with other autoimmune rheumatic disease (ARD). Previously, we found raised levels of IgG against the SP - thrombin (Thr) in patients with APS as well as patients with systemic lupus erythematosus (SLE) who lacked APS compared with healthy controls. Therefore, in this study, we examined the prevalence and specificity of anti-SP antibodies in patients with APS compared with other ARD and healthy controls.

Methods: Serum was obtained from 265 patients (at University College London Hospital) with: APS, n=59; SLE and no APS (SLE/APS-), n=106; rheumatoid arthritis (RA), n=30; Sjögren's syndrome (SS), n=25, myositis (Myo), n=23; systemic sclerosis (SSc), n=22; and 40 healthy controls (HC). Of the patients with APS: 34 had primary APS and 25 had SLE/APS; whilst 46 had thrombotic and 13 non-thrombotic APS. In patients with SLE/APS-57 were aPL positve (SLE/aPL+) and 49 aPL negative (SLE/aPL-). All other ARD and HC were aPL negative. Serum was tested for the presence of IgG directed against: - Thr; Factor Xa (FXa); Factor VIIa (FVIIa); and phosphatidylserine (PS)/FXa complexes by ELISA. Results were expressed as percentage of binding compared with a positive serum control and a positive value was defined as being $\geq$ 3SD above the mean of healthy controls.

Results: IgG anti-FXa antibodies were only found in patients with SLE (n=52, 49.1%) and APS (n=20, 34.5%) whilst healthy and all other disease control groups completely (n=0) lacked these IgG (p<0.05). IgG anti-Thr antibodies were also found in patients with APS (n=21,36.2%) and SLE/APS- (n=59, 55.7%) more frequently than in HC (n=2, 5%, p<0.05). In contrast, to anti-FXa IgG the detection of anti-Thr IgG lacked specificity as they were also found in patients with RA (n=9, 30%), SS (n=10, 40%), Myo (n=11, 47.8%) and SSc (n=6, 27.3%) at frequencies which were not significantly different compared with APS but significantly increased in SLE/APS- compared with RA (p<0.05) and SSc (p<0.01). IgG against anti-PS/FXa complexes were found more frequently (p<0.05) only in patients with SLE/APS- (n=35, 33%) compared with APS (n=8, 13.8%), SS (n=1, 4%), Myo (n=1, 4.3%), SSc (n=0) and HC (n=0) groups. There were no significant correlations between frequency of any of the anti-SP antibodies tested or with aPL positivity. Furthermore, the prevalence of anti-SP IgG in the APS group was not specific to patients with SLE/APS.

Conclusion: Anti-Thr, anti-FVIIa, anti-FXa and anti-PS/FXa IgG are not specific to patients with APS. Our finding that anti-FXa IgG were unique to patients with APS and SLE/APS- may indicate that these IgG interfere with the inflammatory rather than coagulant effects of FXa. Further experiments are now underway to clarify the precise pathological and diagnostic significance of anti-FXa IgG in these patients.

1726

Lack of Correlation Between Mannose-Binding Lectin Gene Polymorphisms and the Thickness of the Carotid Artery Intima-Media (IMT) in Primary Antiphspholipid Syndrome. Antonio Barrera-Cruz[1], Luis J. Jara-Quezada[2], Gabriela Medina[3] and Miguel A. Saavedra Salinas[4]. [1]Instituto Mexicano del Seguro Social, México, Mexico, [2]Hospital de Especialidades Centro Médico La Raza, IMSS, Mexico City, Mexico, [3]Hospital de Especialidades Centro Medico Nacional La Raza, Mexico City, Mexico, [4]Hospital de Especialidades, Mexico City, Mexico

Background/Purpose: Serum mannose-binding lectin (MBL) is a recognition molecule of the lectin pathway of complement with antimicrobial and anti-inflammatory actions. Several polymorphisms have been reported for the MBL2 gene. These variants are associated with low MBL serum concentration and are risk factors of infectious diseases, atherosclerosis and autoimmune diseases (1).Systemic lupus erythematosus patients with associated antiphospholipid syndrome have a higher prevalence of MBL-deficient

genotypes. (2). Patients with primary antiphospholipid syndrome (PAPS) have carotid intima-media thickness, a marker of accelerated atherosclerosis. However, the role of MBL-deficient genotypes in PAPS is unclear.

Objectives: To investigate the prevalence of MBL-deficient genotypes in PAPS and its association with carotid intimamedia thickness (IMT).

Methods: Blood samples were obtained from 48 patients with PAPS and matched with 111 healthy controls by age and gender, in a relation 1:2. Demographic, clinical data, cardiovascular risk factors and antibody profile were recorded. Total DNA was extracted from total blood with DNA isolation kit for mammalian blood (ROCHE). PCR-RFLP (Restriction Fragment Length Polymorphisms) reactions were performed on 50 ng of genomic DNA. MBL exon 1 PCR products were incubated with Mbo II, Ban I at 37°C, and Mwo I at 60°C for 1 h. MBL promoter gene region PCR products were incubated with Drd I and Btg I overnight at 37°C. The products were analyzed by electrophoresis using silver staining of polyacrylamide gel electrophoresis. Colour Doppler with high resolution B mode carotid ultrasonography was performed in patients to measure intima-media thickness (IMT).

Results:

Table 1. Descriptive statistics of population

Variables	PAPS (n=48)	Controls (n=111)	p
Female gender,%	85.4%	82%	0.65
Age, y (mean± SD)	44.4 ± 11.50	42.64 ± 9.87	0.31
Exón region			
AA, C54,%	72.9%	73.9%	0.52
AD, C52,%	27.1%	26.1%	0.52
Promotor region			
LX/LY	22.9%	9%	*0.02
LY/LY	77.1%	91%	*0.02
LYA/A	54.2%	66.7%	0.15
LXA/A	18.8%	7.2%	*0.04
LXA/D	4.2%	.9%	0.21
LYA/C	0	0	–
LYA/D	22.9%	25.9%	0.84

*Statistically significant p < 0.05

Table 2. Correlation between MBL-deficient genotypes and carotid IMT in PAPS

Promotor region	ACC right p Sig. (2-tailed)	Correlation Coefficient	ACC left p Sig. (2-tailed)	Correlation Coefficient
LYA/A	.056	.277	.977	.004
LXA/A	.326	−.145	.957	−.008
LXA/D	.671	−.063	.357	.134
LYA/D	.264	−.164	.674	−.061

Conclusion: This study shows a high prevalence of MBL-deficient genotypes in the promotor region of the MBL2 gene (LX/LY, LXA/A) in patients with PAPS. However, MBL variant alleles were not significantly associated with carotid IMT. The accelerated atherosclerosis in PAPS could be consequence of genetic, immunological, and environmental risk factors. A prospective study is necessary in order to confirm these results.

1727

Affinity Purified Antibodies Directed to Domain I of β2GPI Are Pathogenic in a Mouse Model of Thrombosis. Charis Pericleous[1], Patricia Ruiz-Limon[2], Zurina Romay-Penabad[2], Ana Laura Carrera Marin[2], Acely Garza-Garcia[3], Lucy Murfitt[3], Paul C. Driscoll[4], Ian Giles[1], Yiannis Ioannou[1], Anisur Rahman[1] and Silvia S. Pierangeli[2]. [1]University College London, London, United Kingdom, [2]University of Texas Medical Branch, Galveston, TX, [3]MRC National Institute of Medical Research, London, London, United Kingdom, [4]MRC National Institute of Medical Research, London, United Kingdom

Background/Purpose: Circulating IgG antiphospholipid antibodies (aPL) against β2-glycoprotein I (aβ2GPI) are a serological hallmark for diagnosis of the antiphospholipid syndrome (APS). We and other groups have shown that aPL targeting domain I (DI) of β2GPI (aDI) are APS-specific, predominantly correlating with (venous) thrombosis. We have also demonstrated that recombinant DI inhibits aPL-induced thrombosis in a mouse microcirculation model. To date however, no study has confirmed a direct pathogenic link between aDI and features of the APS. We have now employed the same mouse model to determine the thrombogenic potential of affinity purified polyclonal aDI IgG derived from APS sera.

Methods: Serum from one female APS patient was incubated with his-tagged DI coupled to nickel beads to adsorb aDI antibodies. The bead-serum mix was then spun, serum re-collected and antibodies bound to DI-coupled beads were eluted. IgG from re-collected serum (aDI-poor) and eluted fractions (aDI-rich) was then obtained by protein G purification. Serum and IgG fractions (100mg/mL) were tested for aCL (GPLU), aβ2GPI (GBU, in-house calibrator) and aDI (GDIU, in-house calibrator) activity.

For in vivo experiments, CD1 mice weighing between 32–39g were injected twice with $100\mu g/mL$ aDI-poor or aDI-rich IgG, or IgG from healthy volunteers (NHS-IgG) as a control (4–5 animals per group). 72h after the first injection, the size (μm^2) of induced thrombi in the femoral vein was determined (Circulation 1996;94:1746–1751). Tissue factor (TF) activity (pM/mg.mL^{-1}protein) was determined in homogenates of pooled carotid arteries and peritoneal macrophages using a chromogenic assay. Mouse serum was obtained on the day of surgery and tested for the presence of circulating whole human IgG.

Results: Purified aDI-rich IgG displayed high aCL (90GPLU), aβ2GPI (95GBU) and aDI (50GDIU) activity whilst aDI-poor IgG displayed high aCL (90GPLU) but reduced aβ2GPI (47GBU) and aDI (17GDIU) activity. NHS-IgG was negative in all assays. aDI-rich IgG induced significantly larger thrombi compared to aDI-poor and NHS-IgG (p<0.001). In addition, aDI-rich IgG induced the greatest increase in TF activity in carotids (1.4 fold) and peritoneal macrophages (3.3 fold) compared to NHS-IgG. In contrast, aDI-poor IgG induced smaller thrombi and less macrophage TF activity compared to aDI-rich IgG and did not increase carotid TF activity above that of NHS-IgG (Table 1).

Table 1. Effects of polyclonal IgG in an in vivo model of thrombosis

Mice/ treatment	Thrombus size (μm^2)	TF activity (†) carotids (pM/mg.mL^{-1}protein)	TF activity (†) peritoneal macrophages (pM/mg.mL^{-1}protein)
NHS-IgG	525 ± 136	149.8 ± 21.1	30.6 ± 4.1
aDI-poor	953 ± 258 *	134.9 ± 29.1	55.3 ± 10.1
aDI-rich	2076 ± 511**	212.9 ± 49.7	101.2 ± 14.1

(*) *Statistically significant <0.001 to NHS-IgG*
(**) *Statistically significant <0.001 to NHS-IgG and aDI-poor*
(†) *mean of two measurements*

Conclusion: This is the first study to directly demonstrate the thrombogenic potential of affinity purified aDI IgG in vivo. Despite aDI-poor IgG retaining aCL and, to a lesser extent, aβ2GPI activity, significantly larger thrombi and elevated TF activity were induced with aDI-rich IgG. Our findings support the concept that although circulating aPL recognizing different domains of b2GPI can be pathogenic, the major population that drive thrombosis are directed against DI.

Purified IgG From Antiphospholipid Syndrome Patients with Pregnancy Morbidity Alone Inhibit Trophoblast Migration and Activate a TLR4 MyD88 Independent Pathway. Katie Poulton, Vera Ripoll, Charis Pericleous, Yiannis Ioannou, Anisur Rahman and Ian Giles. University College London, London, United Kingdom

Background/Purpose: Patients with the Antiphospholipid Syndrome (APS) have circulating antiphospholipid antibodies which cause vascular thrombosis (VT) and/or pregnancy morbidity (PM). Previously we have shown that IgG isolated from patients with APS-VT alone caused activation of p38MAPK and NFκB signalling pathways and up-regulation of tissue factor activity in monocytes. These effects were not seen with IgG from patients with APS-PM alone or healthy controls. TF up-regulation caused by the APS-VT samples was reduced by p38MAPK, NFκB, and TLR4 inhibitors, thus implicating a TLR4-MyD88 dependent signalling mechanism (J Immunol, 2010;184:6622). Therefore, in this study we examine whether IgG isolated from patients with different manifestations of the APS have differential effects upon similar pathways leading to activation and migration of trophoblast cells which are more relevant to PM.

Methods: IgG was isolated by protein G purification from serum of 5 patients with APS and VT alone (IgG-VT), 5 patients with APS and PM alone (IgG-PM) and 5 healthy controls. To investigate the intracellular signalling

pathways induced by these IgG, a single sample for each of the 3 groups was produced by pooling IgG from the 5 subjects in that group. A human first trimester trophoblast (HTR-8) cell line was incubated with 100 μg/mL IgG from each group. Time course experiments were then performed and mRNA expression of TLR4 and related adaptor protein TRIF was measured using quantitative PCR. The activation of p38MAPK, ERK and NFκB signalling pathways was also examined in cell extracts by immunoblot. Trophoblast migration was determined using a collagen-based cell invasion assay.

Results: Only IgG-PM increased TLR4 mRNA expression (at 6 and 24 hours) and TLR4 (non-MyD88 dependent) adaptor protein TRIF mRNA levels (at 6 hours) compared with IgG-VT and healthy control IgG in HTR-8 cells. None of the APS (VT or PM)-IgG however, increased phosphorylation of TLR4-MyD88 dependent p38MAPK, ERK or NFκB signalling pathways at any (15 minutes, 2 and 6 hour) time points measured in these cells compared with control IgG. IgG-PM caused the greatest inhibition of trophoblast (HTR-8) migration (with 27% inhibition) compared to untreated controls at 48 hours. In contrast, IgG-VT caused minimal (8%) inhibition of trophoblast migration comparable to levels seen with healthy control IgG.

Conclusion: IgG isolated from patients with APS-related PM preferentially inhibit trophoblast cell migration compared with IgG from patients with VT alone. IgG isolated from patients with APS-related PM also activate trophoblast cells via a TLR4 MyD88 independent pathway. This is the reverse of our previous finding in monocytes that were only activated by APS-IgG from patients with VT and not from those with PM. Further experiments are now required to characterise the mechanistic and prognostic implications of these findings.

1729

Ribophorin II Is Involved in the Tissue Factor Expression Mediated by Phosphatidylserine-Dependent Antiprothrombin Antibody On Monocytes.
Yuichiro Fujieda[1], Olga Amengual[1], Yusaku Kanetsuka[1], Toshio Odani[1], Kotaro Otomo[1], Kenji Oku[1], Toshiyuki Bohgaki[1], Tetsuya Horita[1], Shinsuke Yasuda[1], Kimiko Kuroki[2], Katsumi Maenaka[2], Masaki Matsumoto[3], Shigetsugu Hatakeyama[4] and Tatsuya Atsumi[1]. [1]Hokkaido University,Medicine II, Sapporo, Japan, [2]Hokkaido University,Laboratory of Biomolecular Science, Sapporo, Japan, [3]Kyusyu University,Divison of proteomics, Multi-scale Reserch Center for Prevention of Medical Science, Fukuoka, Japan, [4]Hokkaido University,Biochemistry, Sapporo, Japan

Background/Purpose: Antiphospholipid syndrome (APS) is characterized by thrombosis and the presence of antiphospholipid antibodies (aPL). Tissue factor (TF), the major initiator of the extrinsic coagulation system, is induced on monocytes by aPL in vitro. Phosphatidylserine-dependent antiprothrombin antibody (aPS/PT) recognized the phophatidylserin/prothrombin (PS/PT) complex, and is highly associated with APS. We have previously reported that 231D, a mouse monoclonal aPS/PT, induced TF expression on monocytes. However, the cell surface receptor for the binding of PS/PT complex leading to the activation of cell signaling pathways and TF expression is unknown.To investigate the membrane protein involved in the binding of Prothrombin (PT) and aPS/PT to cell surface and the induction of TF expression on monocytes.

Methods: 1) Unknown PT binding membrane protein on monocyte was screened by a proteomics technique using immunoaffinity chromatography and mass spectrometric analysis. FLAG-tagged human PT (FLAG-PT) was constructed and the expression vector encoding FLAG-PT was transfected into HEK293T cells. The expression of full length FLAG-PT in the culture supernatant was evaluated by immunoblotting. RAW 264.7 cells with FLAG-PT were incubated and applied for affinity chromatography with anti-FLAG antibody-conjugated Sepharose beads. The purified fraction was subjected to SDS-PAGE and detected with Coomassie Brilliant Blue staining. Immunopurified proteins were analyzed by an online-nano LC-MS/MS. Obtained MS/MS data were searched against nrNCBI database MASCOT algorithm. 2) The binding between PT and Ribophorin II (RPN2) was analyzed by enzyme-linked immunosorbent assay (ELISA) with purified His-tagged human RPN2 (His-RPN2). 3) RPN2 expression on cell surface of CD14 positive cells and RAW 264.7 cells was analyzed by flowcytometeric analysis. 4) To elucidate the role of RPN2 in TF mRNA expression, RAW 264.7 cells treated with RPN2 small interfering RNA (siRNA) expression and TF mRNA was determined by real-time PCR.

Results: 1) Amoung many proteins confirmed in the spectrometry, RPN2 a part of an N-oligosaccharyl transferase complex was identified as the candidate molecule to be the membrane protein involved in the PT binding to

cell surface. 2) The binding between PT and His-RPN2 was confirmed by ELISA. 3) Flowcytometoric analysis showed the expression of RPN2 on monocyte cell surface. 4) Treated cells with RPN2 siRNA showed significantly reduction of the TF expression mediated by PT and 231D (Fig).
Fig. RAW264.7 cells transfected with RPN2-siRNA were incubated with monoclonal aPS/PT (231D). TF mRNA was quantitated by Real Time PCR.

Conclusion: RPN2 was detected as a major PT binding molecule by proteomics analysis. RPN2 may be involved in the pathophysiology of thrombosis in patients with APS.

Antiphosphatidylethanolamine Is Not Associated with Thrombosis or Pregnancy Loss in Systemic Lupus Erythematosus.
Ehtisham Akhter[1], Hong Fang[1], Nathalie Bardin[2], Marielle San Marco[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Hopital de la Conception, Marseille, France

Background/Purpose: Phosphatidylethanolamine, a zwitterionic phospholipid, is a major component of the cell plasma membrane. Phosphatidylethanolamine exerts both anticoagulant and procoagulant activities in different conditions. The prevalence of anti-phosphatidylethanolamine antibodies has been reported to be higher in patients with recurrent pregnancy losses or a history of thrombosis. We studied the association of anti-phosphatidylehtanolamine (anti-PE) with thrombosis and pregnancy loss in SLE, compared with the lupus anticoagulant.

Methods: Stored plasma samples from 268 SLE patients were tested for IgG and IgM antiphosphatidylethanolamine by ELISA. The lupus anticoagulant (LAC) was detected using dRVVT with confirmatory testing.

Results: Anti-PE was found in 9 (6.6%) patients with a history of any thrombosis, 6 (6.8%) with a history of venous thrombosis and in 2 (4.6%) with stroke. Table 1 shows the association of any thrombosis, venous thrombosis, stroke and pregnancy loss with anti-PE and with the lupus anticoagulant. No significant association was found between anti-PE and thrombosis, venous thrombosis, stroke or pregnancy loss. Anti-PE was significantly associated with the lupus anticoagulant (Table 2).

Table 1. Associations of aPE and Lupus Anticoagulant with Thrombosis and Pregnancy loss

	Assay	Group with the event N (% positive)	Group without the event N (% positive)	Odds Ratio	95% CI	P-value when age, gender, and ethnicity were controlled
Any Thrombosis	Anti-PE	9 (6.6)	8 (6.1)	1.1	0.4,3.1	0.85
	LAC	47 (39.2)	14 (12.2)	4.4	2.1,8.90	<0.0001
Venous Thrombosis	Anti-PE	6 (6.8)	11 (6.1)	1.2	0.4,3.3	0.76
	LAC	32 (41.6)	29 (18.4)	3.1	1.6,5.90	0.0005
Stroke	Anti-PE	2 (4.6)	15 (6.7)	0.7	0.1,5.4	0.71
	LAC	16 (41.0)	45 (23.0)	2.5	1.20,5.40	0.018
Pregnancy Loss	Anti-PE	0 (0.0)	4 (9.3)	0.62	0.03,15.9	0.78
	LAC	1 (16.7)	7 (18.4)	0.98	0.93,1.0	0.34

Table 2. Association of Anti-PE with Lupus Anticoagulant

Assay	Lupus anticoagulant Positive (n = 61) N (% positive)	Lupus anticoagulant Negative (n = 174) N (% positive)	Odds Ratio	(95% CI)	P-value
Anti-PE(IgG or IgM)	8 (13.1)	8 (4.6)	3.1	(1.1,8.7)	0.036

Conclusion: Anti-PE (IgG or IgM) is associated with the lupus anticoagulant by dRVVT. We found that the lupus anticoagulant by dRVVT was a stronger predictor of any thrombosis, venous thrombosis and stroke than anti-PE. In contrast to other studies, there was no association of anti-PE with thrombosis or pregnancy loss. In SLE, neither the lupus anticoagulant nor anti-PE was associated with a history of pregnancy loss.

IgA Anti-$\beta_2$glycoprotein I Antibodies Are Pathogenic in a Mouse Model of APS. Patricia Ruiz Limon[1], Zurina Romay-Penabad[2], Ana Laura Carrera Marin[1], Elizabeth Papalardo[2] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Univ of TX Medical Branch, Galveston, TX

Background/Purpose: Recently exclusive IgA anti-b$_2$Glycoprotein I (ab$_2$GPI) seropositivity - in the absence of any other antiphospholipid (aPL) antibodies- has been reported particularly in SLE patients. A significant proportion of those (70–80%) were found to have Antiphospholipid Syndrome (APS)-clinical manifestations (e.g. thrombosis and/or pregnancy losses). APL antibodies of the IgG and IgM isotypes have been shown to be pathogenic *in vivo*, but whether IgA ab$_2$GPI antibodies are thrombogenic in mice is unknown. Here we examined the effects of affinity purified IgA ab$_2$GPI antibodies isolated from patients with exclusive IgA ab$_2$GPI positivity on thrombus formation and tissue factor (TF) upregulation in mice.

Methods: IgA was isolated from pooled sera of four patients (IgA-APS) with isolated IgA ab$_2$GPI titers ($\geq$80 SAU) - two had strokes, one had a confirmed deep vein thrombosis and one had two pregnancy losses - and from normal human serum (IgA-NHS) using a Immobilized Jacalin column (Pierce Biotechnology). IgA ab$_2$GPI in the IgA-APS and in the IgA-NHS preparations was determined by ELISA (INOVA Diagnostics), the protein concentration by the Bradford method and the lupus anticoagulant by using a modified silica clotting time (SCT). CD1 mice weighing between 26–30 g were injected twice with 100 μg/ml of IgA-APS or IgA-NHS. Seventy hours after the first injection, the size of induced thrombi in the femoral vein was determined as described (Circulation 1996; 94: 1746–1751). Tissue factor activity was determined in homogenates of pooled carotid arteries and in peritoneal macrophages using a chromogenic assay. Student's t test was used to determine differences in mean thrombus sizes between IgA-APS and IgA-NHS treated mice.

Results: IgA-APS and IgA-NHS were rendered endotoxin free by the Limulus amebocyte lysate assay, and did not have detectable levels of IgG or IgM. The IgA-APS preparation but not the IgA-NHS was positive for IgA ab$_2$GPI (103.7 SAU) and LA (SCT ratio IgA-APS/IgA-NHS) =2; normal <1.2. Results of thrombus sizes and TF activities in mice treated with IgA-APS and IgA-NHS are shown in the table.

Mice Treatment (n= # of animals)	Thrombus size (μm^2) Mean $\pm$ SD	TF activity in carotid homogenates (pM/mg/ml) protein. Mean $\pm$ SD	TF activity in peritoneal macrophages (pM/mg/ml) protein. Mean $\pm$ SD
IgA-NHS (n=5)	389 $\pm$ 70	214.8 $\pm$ 8.6	154.3 $\pm$ 63.7
IgA-APS (n=5)	675 $\pm$ 210*	628.0 $\pm$ 70.7 [2.6 fold increase over IgA-NHS]	532.5 $\pm$ 13.6 [3.5 fold increase over IgA-NHS]

*statistically significant, p=0.02.

Conclusion: This data show for the first time that IgA ab$_2$GPI antibodies are thrombogenic and upregulate TF in mice. Detection of IgA ab$_2$GPI antibodies - currently not included in the classification criteria for APS - may further identify a group of patients with APS-associated clinical manifestations that otherwise would have been missed with tests used routinely in the clinical laboratory to confirm APS.

Annexin A5 Resistance Identifies a Subset of Thrombosis Patients in Systemic Lupus Erythematosus. Ehtisham Akhter[1], Hong Fang[1], Xiao Xuan Wu[2], Jacob Rand[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Montefiore Medical Center, Bronx, NY

Background/Purpose: Annexins are a family of structurally related proteins that bind to phospholipids in a calcium dependant manner. Annexin A5 (AnxA5), present on the surfaces of human endothelial cells, platelets and trophoblasts has potent anticoagulant activity that is a consequence of its forming 2-dimensional crystals over phospholipid bilayers, shielding the phospholipids from availability for coagulation. Antiphospholipid antibodies (aPL) disrupt the crystallization of AnxA5 over phospholipid membrane and expose the underlying phospholipid membrane for coagulation reactions. aPL-mediated disruption of AnxA5 has been correlated with thrombosis in the antiphospholipid syndrome. We investigated the association of resistance to AnxA5 anticoagulant activity (A5R assay) with thrombosis in SLE, compared with the lupus anticoagulant (LAC).

Methods: Stored plasma samples from 296 SLE patients, 150 of whom had prior thrombosis, were assayed for annexin 5 resistance. The A5R assay was performed as previously described (Blood. 2007; 109: 1490–94). We considered assay results that were < 3 SD below the mean (<140%) of 30 normal healthy control plasmas to be abnormal, and between 2–3 SD (147–153) to be borderline. The lupus anticoagulant (LAC) was detected using dRVVT with confirmatory testing.

Results: Resistance to AnxA5 anticoagulant activity was found in 45 SLE patients (15%). Table 1 shows the association of any thrombosis, venous thrombosis and stroke with A5R and with LAC. A5R was consistently associated with increased risk for thrombosis. A5R was also highly associated with a positive LAC (p<0.0001). In the small number of SLE patients with negative LAC, no association between A5R and thrombosis was found.

Table 1. Association of AnxA5 Resistance and Lupus Anticoagulant with Thrombosis

	Assay	Thrombosis Number (%) positive	No thrombosis Number (%) positive	Odds Ratio	95% CI	P-value when age, sex, and race were controlled
Any Thrombosis	A5R	27 (18%)	18 (13%)	2.1	(0.90,5.20)	0.097
	LAC	50 (39%)	14 (11%)	0.96	(0.94,0.98)	<0.0001
Venous Thrombosis	A5R	22 (23%)	23 (12%)	2.3	(0.90,5.90)	0.070
	LAC	34 (41%)	30 (17%)	0.97	(0.95,0.98)	<0.0001
Stroke	A5R	10 (20%)	35 (14%)	2.7	(0.80,8.40)	0.095
	LAC	18 (43%)	46 (22%)	0.98	(0.96,0.99)	0.0021

Conclusion: We found that, in SLE patients, the lupus anticoagulant by dRVVT was a stronger predictor of any thrombosis, venous thrombosis and stroke than A5R. Annexin A5 resistance was strongly associated with the lupus anticoagulant. In patients negative for lupus anticoagulant, there was no association of A5R and thrombosis. In summary, A5R identifies a subset of about half of of SLE patients with thrombosis in whom this specific mechanism for thrombosis is operative. We speculate that this finding may allow the development of treatments that target this specific mechanism.

Effect of Hydroxychloroquine (HCQ) On the Annexin A5 Resistance Assay (AnxA5-RA) in Antiphospholipid Antibody (aPL)-Positive Patients: Preliminary Results of an Ongoing Prospective Study. Alana B. Levine[1], Jacob H. Rand[2], Xiao Xuan Wu[2], JoAnn Vega[1], Glendalee Ramon[1], Stephen L. Lyman[1], Doruk Erkan[1] and Michael D. Lockshin[1]. [1]Hospital for Special Surgery, New York, NY, [2]Montefiore Medical Center, Bronx, NY

Background/Purpose: One proposed mechanism of aPL-mediated thrombosis is disruption of the AnxA5 shield, allowing initiation of coagulation reactions on phospholipid surfaces. The AnxA5-RA measures the resistance to AnxA5 anticoagulant activity in the plasmas of aPL-positive patients. Based on *in vitro* studies, HCQ interferes with aPL binding to cell surfaces and helps repair disrupted AnxA5 shields; however, no *in vivo* human studies exist. The purpose of this ongoing prospective study is to determine the effect of HCQ on the AnxA5-RA in aPL-positive patients; here we present the preliminary baseline results.

Methods: As part of the ongoing study, aPL-positive patients (positive lupus anticoagulant [LA], anticardiolipin antibody [aCL] $\geq$ 40GPL/MPL, and/or anti-β_2-glycoprotein-I [aβ_2GPI] antibody $\geq$ 40 SGU/SMU at two time points at least 12 weeks apart) starting HCQ are recruited to give blood at baseline, 6 weeks, and 12 weeks (primary outcome measure: AnxA5-RA; secondary outcome measures: LA, aCL, aβ_2GPI, D-dimer and anti-domain-I β_2GPI antibody [aDI-β_2GPI]). As a control group, aPL (LA, aCL, and aβ_2GPI)-negative systemic lupus erythematosus (SLE) patients starting HCQ are also recruited. For the purpose of this preliminary analysis, we compared the baseline characteristics of aPL-positive patients to aPL-negative SLE patients (Mann-Whitney test).

Results: Baseline data from 15 aPL-positive patients (mean age 43.3 ± 12.0 years [range 27–61], 10 [67%] female, 13 [87%] Caucasian; 10 had antiphospholipid syndrome, 5 asymptomatic aPL) were compared to 7 aPL-negative SLE patients (mean age 40.0 ± 16.3 years [range 22–64], 7 [100%] female, 4 [57%] Caucasian). Thirteen (87%) of the 15 aPL-positive patients had positive AnxA5-RA; 9/13 (69%) were triple aPL-positive, 2/13 (15%) were double aPL-positive (both aCL- and aβ_2GPI-positive) and 2/13 (15%) were single aPL-positive (one aCL- and one aβ_2GPI-positive only). Seven (47%) of 15 aPL-positive patients had aDI-β_2GPI; 5/7 (71%) were triple aPL-positive and 2/7 (29%) were single aPL-positive (aβ_2GPI). No patients in the control group had positive AnxA5-RA or aDI-β_2GPI. Baseline AnxA5-RA and aDI-β_2GPI results, but not D-dimer levels, differed in aPL-positive patients versus aPL-negative SLE controls (Table).

	aPL (+), n:15	aPL (−) SLE, n:7	p	Reference Range
AnxA5-RA (%)				Negative ≥ 153
- Mean ± SD	130.1 ± 15.6	175.7 ± 24.5		Borderline 140–152.9
- Median (IQR)	127.9 (117.7–132.2)	173.9 (156.8–193.7)	0.0004	Positive <140
aDI-β2GPI (mg/L)				Negative <1.66
- Mean ± SD	4.11 ± 3.94	0.70 ± 0.56		Borderline 1.66–2.29
- Median (IQR)	2.14 (1.52–7.16)	0.70 (0.20–1.09)	0.002	Positive >2.29
D-dimer (µg/mL)				Normal
- Mean ± SD	1.87 ± 0.67	1.93 ± 1.64		0.8–2.3
- Median (IQR)	1.73 (1.60–2.34)	1.28 (1.14–2.00)	0.37	

AnxA5-RA: Annexin-A5 resistance assay; aDI-β_2GPI: anti-domain-I β_2-glycoprotein-I antibody; SD: standard deviation; IQR: interquartile range

Conclusion: Based on the preliminary baseline results of our ongoing prospective study, aPL-positive patients detected based on criteria tests also have positive AnxA5-RA and aDI-β_2GPI; our findings support the use of these non-criteria tests to detect aPL in the clinical setting. The effect of HCQ on outcome measures will be determined by the analysis of our longitudinal data.

Clinical Accuracy for Diagnosis of Antiphospholipid Syndrome in Systemic Lupus Erythematosus: Evaluation of 23 Possible Combinations of Antiphospholipid Antibody Specificities.

Savino Sciascia[1], Veronica Murru[1], Giovanni Sanna[2], Dario Roccatello[3], Munther A. Khamashta[1] and Maria Laura Bertolaccini[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Louise Coote Lupus Unit, St. Thomas' Hospital, London, United Kingdom, [3]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare (CMID), Università di Torino, Torino, Italy

Background/Purpose: The clinical accuracy of testing for antiphospholipid antibody (aPL) both, as individual tests and/or in combination, is still being investigated. We aimed to identify a panel of tests that may provide the best accuracy for diagnosing the antiphospholipid syndrome (APS) in a wide cohort of patients with Systemic Lupus Erythematosus.

Methods: This study included 230 patients (218 women, mean age 42.7±11.9 years, mean disease duration 12.2±8.7years), all fulfilling the 1982 criteria for Systemic Lupus Erythematosus. Lupus anticoagulant (LA), anti-cardiolipin (aCL), anti-$\beta_2$glycoprotein I (anti-b2GPI), solid phase anti-prothrombin (aPT), anti-phosphatidylserine/prothrombin (aPS/PT), and anti-phosphatidylethanolamine (aPE) antibodies were tested in all. Sensitivity, specificity and predictive values were calculated. The diagnostic accuracy for each combination of tests was assessed by ROC and their area under the curve analysis (AUC) as well as by the Youden's index (YI).

Results: Testing for 6 aPL derived in 23 possible combinations of results. Among them, LA+ anti-β_2GPI+aPS/PT had the best diagnostic accuracy for APS as a whole, and individually for both thrombosis and pregnancy loss (AUC 0.712, OR3.73 [95% CI 1.82–5.38], p=0.0001, YI= 0.32; AUC 0.709, OR3.75 [95% CI 2.13–6.62], p=0.0001, YI=0.37 and AUC 0.677, OR4.82 [95%CI 2.17–10.72], p=0.0007, YI=0.38; respectively) and the best specificity when compared to all the other obtainable combination of tests. Triple positivity for LA+anti-β_2GPI+aPS/PT was more strongly associated with clinical events (thrombosis and/or Pregnacy Loss) than double or single positivity (OR23.2 [95%CI 2.57–46.2] vs. OR7.3 [95%CI 2.21–25.97], OR5.7 [95%CI 2.12–17.01] or OR3.11 [95%CI 1.56–7.8] for single positivity for LA, aPS/PT and anti-β_2GPI, respectively).

Conclusion: Combining LA, anti-β_2GPI and aPS/PT improves the diagnostic power and helps in stratifying the risk for each patient, according to their aPL profile.

1735

Independent Validation of the Antiphospholipid Score (aPL-S) for the Diagnosis of Antiphospholipid Syndrome (APS).

Savino Sciascia[1], Maria Laura Bertolaccini[1], Dario Roccatello[2] and Munther A. Khamashta[1]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare (CMID), Università di Torino, Torino, Italy

Background/Purpose: The so called "antiphospholipid score (aPL-S)" was recently developed and validated (1). This score was shown to be a useful quantitative index for diagnosing APS and to be valuable as a predictive marker for thrombosis in autoimmune diseases. We aimed to independently validate the aPL-S by applying the proposed score system to our cohort of SLE patients. (1. Otomo et al. Arthritis Rheum 2012; 64: 504).

Methods: We applied the aPL-S to a cohort of 211 consecutive SLE patients, all attending our Lupus Clinic. aPL-S was calculated for each patient by adding together the points corresponding to the risk factors as described. To validate the aPL-S, we adapted the proposed score using our in house cut-off values for aPL testing as previously reported or according to the current guidelines, as appropriate.

Results: Overall, 81 patients fulfilled criteria for APS and 73 patients had a history of thrombosis (48 arterial, 41 venous). Out of 144 women who had ever been pregnant, 61 had a history of pregnancy loss. Higher values of aPL-S were seen in patients who experienced thrombosis and/or pregnancy loss when compared to those without clinical events (median 17 [0–86] vs. 4 [0–31], p<0.001). When analysing clinical subgroups, patients who experienced thrombosis or pregnancy loss showed higher aPL-S compared to those without clinical events (median 18 [0–86] vs. 4 [0–27], p<0.001 for thrombosis; 7 [0–69] vs. 3 [0–29], p=0.029 for pregnancy loss). When the cut-off level for the aPL-S was defined as 30, as per the original study (1) the sensitivity and specificity of the aPL-S were 39% and 95%. The PPV of an aPL-S ≥30 was 36%, whereas the NPV was 91%.

Conclusion: We demonstrated that the aPL profile can be successfully quantified by the aPL-S in an independent cohort of SLE patients. The aPL-S correlated with a history of thrombosis and pregnancy loss in our cohort, suggesting that the aPL-S is a suitable quantitative marker for APS.

The Estimated Prevalence of Antiphospholipid Antibodies in the General Population with Pregnancy Morbidity.

Cecilia B. Chighizola[1], Guilherme Ramires de Jesus[2], Laura Andreoli[3], Alessandra Banzato[4], Guillermo J. Pons-Estel[5], Michael D. Lockshin[6], Doruk Erkan[6] and On Behalf of APS Action[7]. [1]Istituto Auxologico Italiano, University of Milan, Milan, Italy, [2]Department of Obstetrics, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [3]Rheumatology Unit, University of Brescia, Brescia, Italy, [4](2) Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua Italy, Padua, Italy, [5](4) Department of Autoimmune Diseases, Institut Clìnic de Medicina i Dermatologia, Hospital Clìnic, Barcelona, Spain, [6]Hospital for Special Surgery, New York, NY[7].

Background/Purpose: AntiPhospholipid Syndrome Alliance For Clinical Trials and InternatiOnal Networking (APS ACTION) is an international research network created to conduct well-designed clinical trials in persistently antiphospholipid antibody (aPL)-positive patients. One of the first needs of APS ACTION was to know the true prevalence of aPL in the general population with pregnancy morbidity (PM).

Methods: The search for "aPL" and multiple keywords regarding the pregnancy outcomes of interest (early/late pregnancy loss [PrL], intrauterine growth restriction [IUGR], preeclampsia [PEC] and HELLP syndrome) was completed in PubMed. A total of 47 full-text papers were collected and analyzed for the type of outcome, the aPL tests used (criteria tests *vs.* non criteria), the definition of "positive aPL" (low, medium, high, other), the confirmation of aPL (at least 6–12 weeks apart), and the prevalence of positive aPL in the study population. The median prevalence and interquartile range (IQR) of different aPL tests were calculated based on the combine analysis of all the papers.

Results: Out of 47 papers, the outcome of interest was PrL in 32 (68%), IUGR in 6 (13%), PEC in 20 (42%), and/or HELLP syndrome in 6 (13%). Despite the limitations of the literature, the table demonstrates the estimated aPL prevalence in patients with different type of PM. These limitations were: *a) the definition of "pregnancy outcome"* was highly heterogeneous (66% of the studies did not define the PrL based on the Updated Sapporo Criteria; 31% did not specify the number and/or the gestational week of the PrL; 47% of the early PrL studies included patients with less than 3 events; and 85% included patients with events before and after 10 weeks in the same analysis); b) *nomenclature of late PrL* was controversial due to the overlap between terms such as abortion, intrauterine fetal death, and stillbirth; fetal malformations were rarely excluded (36%); c) *IUGR* was defined as <5th percentile in 33% of the studies and <10th percentile in 50%; 17% of the papers included no cut-off values; d) *PEC severity* was identified only in 50% of the studies; e) *the numbers of patients* included in all studies were relatively small (median 70; IQR 29–162); f) *aPL type* (6%) *or isotype* (32%) has not been specified in 38% of the studies; g) *aCL and/or aβ2GP-I ELISA cut-off* was not available in 11% of the studies and "low titer" (<20U) was used in 21% of the papers; and h) *the confirmation of aPL* was performed only in 9 studies (19%).

Median, % (IQR)	LA	aCL[**]	ab2GPI[***]	aPL[****]	Average (%)
PrL	9.5 (7.3–12.5)	6 (2–16)	5 (2–8)	14.5 (13.8–15.3)	9
– Early PrL	0	2 (2–5)	4.5 (2.8–7.8)	–	5
– Late PrL	22 (12.5–25.5)	9 (1–10.5)	4 (3–5.3)	21.5 (15.3–27.8)	11
IUGR	2 *	17 (8.5–24)	–	–	13
PEC	2 (1.5–5.5)	3 (1–12)	5 (4.5–6)	7 (4–11)	7
Severe PEC	16 (12.5–17.25)	9 (0.1–25)	5 (3.5–6.5)	16 (14.5–18)	15
HELLP	53 *	2 (2–10)	4 (2–4)	43.5 (23.8–63.3)	16

* Only one study; ** aPL tests were reported as aCL, aCL IgG, and/or aCL IgM; *** aPL tests were reported as ab₂GPI, ab2GPI IgG, and/or ab2GPI IgM; **** aPL tests were not specified

Conclusion: The current best estimates of aPL prevalence in patients with PM are impaired by several limitations of the literature including the definition of obstetric outcomes and "positive aPL". One of the goals of APS ACTION is to improve upon existing literature in order to address the precise magnitude of the problem.

Diffuse Alveolar Hemorrhage Caused by Primary Antiphospholipid Syndrome.

Rodrigo Cartin-Ceba, Tobias Peikert, Karina Keogh, Steven R. Ytterberg, Aneel Ashrani and Ulrich Specks. Mayo Clinic, Rochester, MN

Background/Purpose: Diffuse alveolar hemorrhage (DAH) is an uncommon but severe complication of primary antiphospholipid syndrome (APS). The available literature is limited to very few case reports. We aim to describe the clinical characteristics, treatment and outcomes of patients with DAH due to primary APS managed at our institution.

Methods: A retrospective review of the medical records of all consecutive adults evaluated at Mayo Clinic with DAH secondary to primary APS between January 1, 1997 and December 31, 2011 was conducted. APS was diagnosed using the revised Sapporo classification criteria. DAH was defined as the presence of bilateral alveolar pulmonary infiltrates with a confirmatory bronchoalveolar lavage (BAL) documenting bloody return and/or >20% hemosiderin laden macrophages (HLM). Patients with documented connective tissue diseases, ANCA associated vasculitis or anti-GBM disease were excluded.

Results: A total of 17 patients (men=12) were identified, all of them white. The median age (interquartile range, IQR) was 43 years (36–47). The median time from diagnosis of APS to development of DAH was 1661 days (495–3605). Three patients underwent lung biopsy showing capillaritis. The median percentage of HLM was 87% (81–98), BAL differential cell count was predominantly neutrophilic, median 30% (18–60). All patients were treated with high doses of glucocorticoids; six of whom did not respond, requiring more aggressive immunosuppression. Mycophenolate mofetil was used in seven patients; none achieved remission. Azathioprine was used in six patients; no remission was noted in five and one patient did not tolerate it. Cyclophosphamide was used in seven patients; remission was achieved only in three patients. Plasma exchange was performed in two patients with no response. Intravenous gamma-globulin was used in four patients with remission seen only in one patient. Rituximab was used in 6 patients; two patients achieved remission and one was lost to follow up. Only the two patients treated successfully with rituximab are off glucocorticoids. Five patients died, four from complications of uncontrolled DAH and one from complications of autologous stem cell transplant conditioning regimen for treatment of refractory DAH/ APS. Median time to death from diagnosis of DAH was 70 days (44–721).

Conclusion: To the best of our knowledge, we present the largest series of DAH secondary to primary APS. There is a long gap between the diagnosis of APS and the first episode of DAH. Alveolar fluid shows predominantly neutrophilic inflammation. This disease carries a very poor prognosis with very limited successful therapeutic options. B-cell targeted immunosuppression with either cyclophosphamide or rituximab may have the highest likelihood to induce remission and should be considered early.

Myocardial Dysfunction and Valvulopathy Worsens with Time in Patients with Antiphospholipid Syndrome: A 10-Year Follow-up Study.

MG Tektonidou[1], CF Kampolis[1], I. Moyssakis[2], GE Tzelepis[1], Haralampos M. Moutsopoulos[1] and P. Vlachoyiannopoulos[1]. [1]University of Athens Medical School, Laiko Hospital, Athens, Greece, [2]Laiko Hospital, Athens, Greece

Background/Purpose: Valvular disease represents the most common cardiac manifestation among patients with antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE) positive for antiphospholipid antibodies (aPL). Diastolic dysfunction of the left and right ventricle has also been observed in these groups of patients. The purpose of the present study is to describe the evolution of valve involvement and myocardial dysfunction over time in patients with SLE and/or APS and investigate possible associations with clinical and laboratory characteristics.

Methods: One hundrend and fifty patients had been assessed by transthoracic echocardiography 10 years ago. Structural and functional (regurgitation or stenosis) valvular abnormalities and diastolic function parameters ('E' and 'A' waves, E to A ratio, deceleration time (DT), isovolumic relaxation time (IVRT)) for the left and right ventricle had initially been

Tuesday, November 13

recorded. The longitudinal arm of the study finally included 17 patients with primary APS (PAPS), 23 with SLE-asscociated APS (SLE/APS), 19 with SLE positive for aPL without APS and 23 with SLE negative for aPL, for the present echocardiographic re-evaluation.

Results: The proportion of patients with valvulopathy increased from 39.3% in the initial cohort to 64.7% among PAPS and 61.5% among SLE patients. Worsening of valvular lesions during the 10 year follow-up period was detected in approximately one third of the examined population including PAPS and SLE patients, either positive or negative for aPL. Disease duration and presence of SLE/APS were the only significant risk factors for progression of isolated mitral and combined valvular disease; there was an 1.5 times higher risk for progression for every 5 years of increase in disease duration (OR:1.54, 95% C.I:1.05–2.25, $p=0.027$ and OR:1.63, 95% C.I: 1.13–2.36, $p=0.009$, respectively) and 3.5 times higher risk for SLE/APS patients (OR:3.57, 95% C.I:1.19–10.70, $p=0.023$ and OR:3.51, 95% C.I:1.27–9.67, $p=0.015$, respectively). Presence of aPL, aPL titres, presence of comorbidities and other clinical characteristics did not have any significant effect on progression of valvular lesions. No treatment regimen seemed to have a prophylactic role in preventing occurrence of de novo valvular lesions or in halting progression of preexisting valvulopathy. Left ventricular diastolic dysfunction similarly progressed over time with DT and IVRT being equally prolonged in each of the 4 groups ($p<0.05$). Right ventricular DT was significantly prolonged in each of the 3 SLE groups ($p<0.001$), but IVRT increased only in SLE/APS patients ($p=0.040$).

Conclusion: Progression of valvulopathy, as detected by transthoracic echocardiography, was observed in the majority of patients with either SLE or APS, despite treatment of underlying disease. Secondary APS in SLE and disease duration were independent risk factors for progression of valvular disease. Ventricular diastolic dysfunction, primarily of the left ventricle, similarly progressed over the 10 year period.

Primary and Secondary Antiphospholipid Syndrome in Childhood.
Senq-J Lee, Leonardo Brandao, Earl D. Silverman, Mahendranath Moharir, Julie Barsalou and Deborah M. Levy. The Hospital for Sick Children, Toronto, ON

Background/Purpose: Antiphospholipid syndrome (APS) is an auto-immune disease characterizered by positive antiphospholipid antibodies and potentially life-threatening thrombotic events. APS can be classified as primary or secondary to other disease. In childhood, secondary APS is frequently associated with Systemic Lupus Erythematosus (SLE). Few longitudinal childhood APS cohorts have been described, and the proportion of patients who present with APS prior to an eventual diagnosis of SLE in childhood is unknown. The aims of the study are: (1) To determine the proportion of patients with primary versus secondary APS in childhood; (2) To determine the proportion of patients initially diagnosed with primary APS who eventually develop SLE.

Methods: A retrospective single centre cohort study of all patients diagnosed with APS at The Hospital for Sick Children between 1999 and 2011 was conducted. Data from the neurology (stroke/sinus venous thrombosis), haematology (thrombosis) and rheumatology databases were collected. All patients who fulfilled the Revised Sapporo Criteria for the diagnosis of APS prior to their 18th birthday were included. Chart reviews were conducted to extract relevant data, including demographic, clinical and laboratory data.

Results: Fifty three children were identified; 13 (25%) with primary APS (pAPS); 40 (75%) with secondary APS, of which 13 (33%) were diagnosed with APS secondary to SLE (APS-SLE), and 27 (67%) with APS secondary to other disease (sAPS) (Figure 1). Demographics and clinical characteristics are in Table 1. Three (23%) APS-SLE patients were initially diagnosed with pAPS who were later diagnosed with SLE after a mean of 2.8 years; the remainder of SLE patients developed APS after a mean of 1.3 years. 15% (2/13) of pAPS patients had persistent features of incipient SLE (<4/11 of the ACR classification criteria for SLE) after mean follow-up of 4.2 years. Majority of patients with APS were males, except patients with APS-SLE. Only 26% of sAPS patients met LAC laboratory criteria. In the sAPS group, arterial strokes were the most common thrombotic event.

Table 1. Basic demographic and clinical characteristics of patients diagnosed with APS.

	Primary APS	Secondary APS to SLE	Secondary APS to other disease	Overall cohort
Gender (M:F)	9:4	5:8	21:6	35:18
Age at diagnosis in years mean, (range)	12 (0–17)	13.7 (4–17)	4.1 (0–16)	8.4 (0–17)
Duration of follow-up from APS diagnosis mean, (range)	3.5 (1–6.1)	3.0 (1–7.6)	7.4 (1–13.2)	5.3 (1–13.2)
LAC criteria for APS met	77% (10/13)	92% (12/13)	26% (7/27)	55% (29/53)
ACL IgG criteria for APS met	69% (9/13)	77% (10/13)	78% (21/27)	75% (40/53)
Thrombosis site (number of events)				
Deep vein thrombosis	5	6	8	19
Pulmonary embolus	5	4	1	10
Arterial Stroke	5	2	14	21
Sinus venous thrombosis	3	3	4	10
Hepatic/portal vein	3		1	4
Inferior vena cava	1	1	2	4
Renal vein		1	1	2
External iliac artery			2	2
Jugular vein	1			1
Splenic vein		1		1
Retinal vein		1		1
Aorta			1	1
Figure 1. APS secondary to other diseases, divided into aetiology.

Conclusion: The majority of childhood APS are secondary to underlying disease, with SLE being the most frequent cause. Five patients with primary APS had incipient SLE, 3 later developed SLE. For children diagnosed with APS, we recommend a thorough evaluation for SLE at diagnosis and during follow-up.

Background/Purpose: Quality of life (QoL) is an important outcome in clinical care especially in patients with chronic disease such as systemic lupus

erythematosus (SLE). In antiphospholipid syndrome (APS) which can be associated to SLE, QoL has not been clearly evaluated. Therefore our objective was to assess QoL in patients with antiphospholipid antibodies (aPL) and/or SLE in particular according to their APS status (thromboembolic history or obstetrical morbidity).

Methods: QoL was assessed in a multicentre cohort study using The Medical Outcomes Study Short-Form 36 (MOS-SF-36) in patients with aPL and/or SLE without anticoagulant treatment at inclusion. A score from 0 to 100 was calculated for each dimension and each component was normal at 50. QoL scores were compared between groups of patients and to the general population.

Results: One hundred and fifteen patients were included (mean age 42 ± 14 years-old, 85 women). Seventeen patients had SLE and aPL, 16 only SLE and 82 only aPL. Fifty-eight patients were asymptomatic (i.e. without thrombotic or obstetrical history), while 57 patients had a history of one or several thrombotic manifestations and in 54 patients APS was diagnosed. The presence of APS was associated to a significant impairment of QoL on both mental component summary (MCS) (40.4 ± 11.9 vs 45.7 ± 10.4, p=0.01) and physical component summary (PCS) (46.6 ± 9.6 vs 49.3 ± 8.4, p=0.03) scores compared to those without APS (Fig. 1). Furthermore, in patients with history of arterial thrombosis compared to those without, Qol was dramatically impaired on all dimensions and both MCS (35.9 ± 12.8 vs 44.6 ± 10.6, p=0.008) and PCS (40.3 ± 10.2 vs 49.5 ± 8.1, p<0.001) scores (Fig. 2). Comparisons of QoL scores between patients with SLE and/or aPL and general population according to age and sex, showed a significant impairment of the majority of dimensions of QoL especially in men between 35 to 54 years-old, and in women between 25 to 54 years-old.
Conclusion: In patients with aPL and/or SLE, the presence of APS is associated with a significant impairment of QoL assessed by MOS-SF-36. History of arterial thrombosis was associated to the greatest impairment of QoL. Compared to the general population, we showed that these young patients experienced a decreased QoL which should be taken into account on everyday APS patient management.

Suppression of Glomerulonephritis in NZB/W F1 Mice by a Selective Inhibitor of Bruton's Tyrosine Kinase (RN486). Paola Mina-Osorio, Jacob LaStant, Natalie Keirstead, Toni Whittard, Stella Stefanova, Alka Patel, Jennifer Postelnek, John Woods, Soo Min, Yong Kim, Julie Demartino, Satwant Narula and Daigen Xu. Hoffmann-La Roche, Nutley, NJ

Background/Purpose: Bruton tyrosine kinase (Btk) is a Tec family kinase that participates in B cell receptor (BCR), Toll-like Receptor (TLR) and chemokine receptor signaling. It is expressed in all cell lineages of the hematopoietic system, except for T cells, and it plays a critical role in B cell development and function. We have recently reported a potent and highly selective competitive inhibitor of Btk RN486, which blocks the Btk kinase activity with an IC50 of 4.0 nM. This compound inhibits BCR and FcR-mediated signaling and is efficacious in murine models of arthritis. Here we tested RN486 in the NZB/NZBW model of lupus.

Methods: Animals were randomized into two groups based on the serum anti-dsDNA antibody levels and proteinuria measured at 30 weeks of age. Beginning at 32 weeks of age one group of mice was fed chow formulated with 30mg/kg of RN486 equivalent to 0.225 mg/g of chow, while the other group received regular chow *ad libitum* for 8 weeks.

Results: Treatment of NZB/W F1 mice with RN486 completely prevented the progression of proteinuria in 32 week-old mice. In contrast, a normal progression of the proteinuria scores until the termination of the study at 40 weeks of age was observed in animals fed with regular chow. This effect was associated with decreased IgG antibody deposition and decreased glomerular nephritis at the histological level. At the cellular level, there was a dramatic inhibition of B cell activation upon BCR crosslinking in vitro in peripheral blood B cells, as determined by the induction of CD69 by flow cytometry which is used as a pharmacodynamic marker. The IgG anti-dsDNA antibody secretion was almost completely abolished in the treated group as determined by ELISA and total splenocyte ELISpot. In contrast, the anti-dsDNA antibody secretion from bone-marrow derived plasma cells was not significantly inhibited, suggesting that similarly to other B-cell depleting therapies, the main target population corresponds to short-lived plasma cells in the spleen. This hypothesis was confirmed by flow cytometry data demonstrating complete depletion of a CD138hi population of cells in the spleen that was not detectable in the bone marrow. Interestingly, the compound inhibited IgG but not IgM anti-dsDNA secretion suggesting that pharmacological blockade of Btk resembles the previously reported transgenic expression of low endogenous Btk levels in B cells. Finally, we studied the effect of our compound in acute TLR9-mediated responses in vivo and found a dose-dependent inhibition of CpG-induced IL-12 secretion. In line with this result, the animals treated with RN486 for eight weeks had lower levels of IL-12 in the serum.

Conclusion: Our results demonstrate that Btk selective inhibition is efficacious in an animal model of lupus via plasma cell depletion and inhibition of BCR and TLR9-dependent stimulation.

A Novel Murine Model of B Cell-Mediated Proteinuria Suggests Cytokines Mediate Podocyte Injury. Alfred H. Kim[1] and Andrey S. Shaw[2]. [1]Washington Univ School of Med, St. Louis, MO, [2]Washington University School of Medicine, Saint Louis, MO

Background/Purpose: B cell depletion therapies have been efficacious in several glomerulopathies. The contributions of B cells to proteinuria and foot process effacement remain unknown. The development of a murine model of B-cell induced proteinuria would enhance our understanding of immune-based glomerular diseases.

Methods: The B cell model antigen model hen egg lysozme (HEL) was biotinylated and complexed to avidin. Following intravenous (IV) injection in mice, purified naïve HEL-specific B cells were adoptively transferred and proteinuria assessed using PAGE. Kidneys were processed for immunofluo-

rescence (IF), H&E and PAS staining, and scanning electron microscopy (SEM). Cultured podocyte membrane ruffling was assessed with DIC videomicroscopy.

Results: HEL embedded within the glomerular basement membrane (GBM) following IV injection. Proteinuria occurred after the transfer of HEL-specific B cells and was associated with foot process effacement. No antibody or complement deposition was observed in the GBM. 2-photon microscopy of live mice demonstrated that HEL-specific B cells arrested trafficking within glomeruli in the presence of HEL.

The rapid kinetics of proteinuria induction suggested cytokines secreted by activated intraglomerular B cells may be responsible. We hypothesize that activation of the small Rho GTPase Rac is important in podocyte injury by virtue of its ability to regulate the actin cytoskeleton. Using murine cultured podocytes, we measured membrane ruffling in the presence of cytokines as a surrogate for Rac activation. IL-4 significantly increased cultured podocyte membrane ruffling and induced foot process retractions on ex vivo fragments of renal cortex. Hydrodynamic DNA immunization of wild-type 129 mice with plasmid encoding IL-4 lead to proteinuria.

Conclusion: We have developed a novel model of B cell-induced proteinuria with foot process effacement. Furthermore, these data demonstrate that cytokines can induce alterations in foot process morphology, leading to proteinuria. This has important implications in therapies preserving podocyte function in glomerular disease.

IL-5-Induced FasL[+] Regulatory B Cells Are Inhibited by IL-4 and Cyclosporine. Matthew W. Klinker[1], Brian R. Alzua[1], Tamra J. Reed[1], David A. Fox[2] and Steven K. Lundy[1]. [1]University of Michigan, Ann Arbor, MI, [2]Univ of Michigan Med Ctr, Ann Arbor, MI

Background/Purpose: We previously identified a subset of regulatory B cells that express the apoptosis-inducing molecule Fas ligand (FasL), and reported that these B cells were expanded by IL-5. This study tested the effects of IL-4, another type 2 cytokine, on the growth and function of FasL[+] B cells, and sought to identify pathways downstream of the IL-5 receptor important for FasL[+]B cell function.

Methods: B cells were purified from mouse splenocytes by CD19[+] MACS beads and cultured with a monolayer of CD40L-expressing fibroblasts in the presence or absence of cytokines. After culture, surface expression of phenotypic markers was assessed by flow cytometry. Cytokine release from stimulated B cells was measured by ELISA. The ability of stimulated B cells to induce apoptosis was measured by culturing B cells with activated T cells from TCR-transgenic mice and assessing apoptosis in CD4[+]cells by Annexin V/propidium iodide staining. Cyclosporine was used to determine the effects of inhibiting the calcineurin signaling pathway on regulatory B cell function.

Results: B cells stimulated with IL-5 displayed regulatory B cell functions, including increased expression of FasL, antigen-specific killing of CD4[+]T cells, and secretion of IL-10. Unexpectedly, the addition of IL-4 to B cell cultures completely abrogated the ability of B cells to induce apoptosis in target T cells and secrete IL-10, and instead induced the secretion of IL-6. Both IL-4 and IL-5 stimulated similar levels of B cell proliferation, and the combination of both cytokines had an additive effect on proliferation. IL-5-stimulated B cells resembled marginal zone B cells, with increased surface expression of CD80, CD86, CD9 and CD5, and reduced CD23 expression. This change in surface phenotype was also inhibited by IL-4. Finally, the calcineurin inhibitor cyclosporine prevented the induction of FasL expression and IL-10 secretion mediated by IL-5.

Conclusion: IL-4 inhibits the regulatory B cell functions induced by IL-5, such as FasL-mediated induction of apoptosis in CD4[+] T cells and secretion of IL-10. The IL-5 receptor utilizes a calcineurin-dependent pathway for induction of FasL[+] regulatory B cells. These findings suggest that while IL-4 has regulatory effects on T cells in inflammatory diseases such as rheumatoid arthritis, it may have an opposing role on B cells by antagonizing the IL-5-mediated induction of FasL[+] regulatory B cells.

1744

Regulatory B Cells Supress the Progression of Fatal Autoimmunity in Lupus-Prone Mice. Yuriy Baglaenko[1], Nan-Hua Chang[1], Evelyn Pau[2] and Joan E. Wither[1]. [1]Toronto Western Research Institute, University Health Network, Toronto, ON, [2]Toronto Western Hospital, University Health Network, Toronto, ON

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex multisystem autoimmune disorder characterized by the production of anti-nuclear antibodies (ANA) which form immune complexes and promote end-organ damage. Studies in our lab have focused on identifying genetic defects that contribute to a loss of immune regulation in autoimmune prone New Zealand Black (NZB) mice. Previous work has shown that the introgression of a NZB chromosome 1 (c1) interval extending from 135 to 179 Mb onto the non-autoimmune C57BL/6 (B6) background results in increased B and T cell activation, elevated ANA levels, and fatal kidney disease. Despite the presence of mapped susceptibility loci on NZB c4, introgression of an interval extending from 30 to 150Mb onto the B6 background resulted in the expansion of splenic NKT and CD5[+] B cells in the absence of autoimmunity. To further investigate the role of NZB c4 in autoimmunity, bicongenic (c1c4) mice were produced with both NZB c4 and c1 intervals. Although bicongenic mice had c1 autoimmune augmenting genes, c1c4 mice had reduced renal disease, increased survival, and a shift towards less pathogenic IgG1 autoantibodies. Interestingly, bicongenic mice retained the expansion of splenic CD5[+] B cells. Recent studies on experimental autoimmune encephalitis and arthritis models have identified a non-redundant role for a population of IL-10 producing CD5[+]CD1d[hi] regulatory B cells in preventing disease progression. Given the consistent expansion of splenic CD5[+] B cells in bicongenic mice, we sought to investigate their role in the suppression of fatal autoimmunity.

Methods: Cellular phenotypes were examined by flow cytometry of de novo splenocytes. Intracellular production of IL-10 or IFNγ and IL-17 was measured following 4 to 5 hour stimulation with LPS, PMA and Ionomycin or PMA and Ionomycin, respectively. Serum levels of anti-nuclear antibodies were measured by ELISA. Adoptive transfer experiments were performed by injecting 5–10 million B cells intravenously into c1.Thy1[a]IgH[a] recipients.

Results: There was a significant increase in IL-10 producing B cells in bicongenic and c4 mice when compared to B6 and c1 controls. Interestingly, the expansion of IL-10 producing cells in c1c4 and c4 mice is distinct from previously documented B regulatory populations and localizes to the CD5[+]CD1d[int] B cell compartment. There was an inverse correlation between the levels of anti-ssDNA IgG and the frequency of IL-10 producing B cells in c1c4 but not B6 mice suggesting that they may play a role in disease suppression. There was no correlation between the proportion of conventional Treg or iNKT cells and anti-ssDNA IgG antibodies. In support of a direct suppressive capacity for the expanded CD5[+] B cells, adoptive transfer of total B cells from c4, but not B6, mice into autoimmune prone c1.Thy1[a]IgH[a] recipients reduced the proportion of activated B cells, germinal centre B cells, memory/effector T cells, and IFN-g or IL-17-secreting T cells.

Conclusion: Taken together, these data indicate the presence of a phenotypically novel IL-10 producing B cell population in c4 mice which can suppress the progression of fatal autoimmunity.

Amelioration of Experimental Autoimmune Arthritis by Adoptive Transfer of Foxp3-Expressing Regulatory B Cells Is Associated with the Regulatory T Cell/T helper 17 cell Balance. Young Ok Jung[1], Yu Jung Heo[2], Mi Kyung Park[3], Mi-La Cho[4], Seung Ki Kwok[5], Ji Hyeon Ju[2], Kyung Su PARK[2], Sung Hwan PARK[2], Ho Youn Kim[2] and Jun-Ki Min[6]. [1]Seoul, South Korea, [2]Catholic University, Seoul, South Korea, [3]The Catholic University of Korea, Seoul, South Korea, [4]Catholic University of Korea, Seoul, South Korea, [5]The Catholic University, Seoul, South Korea, [6]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea

Background/Purpose: Foxp3 is a key regulator of the development and function of regulatory T cells (Tregs), and its expression is thought to be T cell-restricted. We hypothesized that B cells can express Foxp3 and B cells expressing Foxp3 may play a role in preventing the development of collagen-induced arthritis (CIA).

Methods: Protein and mRNA expression of Foxp3 in CD19[+] B cells from mice was determined by flow cytometry, western blotting, and RT-PCR. Confocal microscopy was used to visualize the location and expression of Foxp3 in B and T cells. Foxp3 expression was modulated in CD19[+] B cells by transfection with shRNA or using an over-expression construct. *In vitro* suppressive activity of Foxp3-expressing B cells on T cell proliferation was assessed by a ^{3}H-thymidine incorporation assay. In addition, Foxp3-transfected B cells were adoptively transferred to CIA mice. Therapeutic effects were evaluated by clinical symptoms and joint histopathology.

Results: We found that lipopolysaccharide (LPS) or anti-IgM stimulation induced Foxp3 expression in B cells. Foxp3-expressing B cells were found in the spleens of mice. To generate Foxp3-expressing B cells *in vitro*, we transfected CD19[+] B cells with a Foxp3 over-expression construct. Over-expression of Foxp3 conferred a contact-dependent suppressive ability on proliferation of responder T cells. Down-regulation of Foxp3 by shRNA caused a profound reduction in proliferation of responder T cells. Adoptive transfer of Foxp3[+]CD19[+] B cells attenuated the clinical symptoms of CIA significantly with concomitant suppression of IL-17 production and enhancement of Foxp3 expression in *CD4[+] T cells* from splenocytes.

Conclusion: Our data indicate that Foxp3 expression is not restricted to T cells. The expression of Foxp3 in B cells is critical for the immunoregulation of T cells and limits autoimmunity in a mouse model.

Semaphorin 3A Increases the Regulatory Characteristics of B-Regulatory Cells. Zahava Vadasz[1], Aharon Kessel[2] and Elias Toubi[2]. [1]Bnai-Zion Medical Center, Haifa, Israel, [2]Bnai-Zion Medical Center, Israel

Background/Purpose: Semaphorin3A (sem3A) and neuropilin-1 (NP-1), are important regulatory molecules, previously reported by us to play role in lupus glomerulonephritis. In a recent study we demonstrated that sema3A expression on B-regulatory cells (B-regs) of systemic lupus erythematosus (SLE) patients is significantly decreased when compared to that on B-regs of normal individuals. Aiming to achieve a better characterization of B-regs (previously identified by us as CD19+CD25[high]CD1d[high]IL-10[high] TGF-β[high]), we asked whether other regulatory/stimulatory molecules are differently expressed on B-regs of SLE patients. We also asked whether the addition of sem3A into a culture of B cells could possibly immuno-modulate the expression of these molecules on B-regs.

Materials and Methods: The expression of CD72 and TGF-β (inhibitory molecules), and of CD100 (a stimulatory molecule) was assessed on B-regs of both normal individuals and SLE patients. We then added sema3A to cultured B cells and assessed their regulatory properties after 24 hours. Cell cycle analysis was also done in order to evaluate

Results: 1. The expression of both CD72 and TGF-β was significantly decreased (37.88%, 8.6%) and of CD100 (12.78%) on B-regs of SLE patients vs that on normal B-regs. (49.26%, 14.74%, 21.55% respectively; P=0.001)

2. Twenty four hours following the addition of sema3A to cultured B cells, a significant increase of TGF- β, CD72 and NP-1 molecules and decrease of CD100 on B-regs was noticed. However, this effect of sema3A on B cells was altered in SLE patients when compared to that of normal B cells.

Conclusion: 1. This is the first study were the above studied regulatory molecules are shown to be altered on B regs of SLE patients. 2. Sema3A enhances the regulatory properties of B regs, but this effect is also shown to be altered in SLE.

Gemin5 Is a New Target of Autoantibodies That Are Produced in Tight Connection with Antibodies to Snrnps and Survival of Motor Neuron (SMN) Complex. Jason YF Chan, Yi Li, Angela Ceribelli, Eric S. Sobel, Westley H. Reeves, Edward K.L. Chan and Minoru Satoh. University of Florida, Gainesville, FL

Background/Purpose: Most targets of autoantibodies in systemic rheumatic diseases are multiprotein-nucleic acids complex. Small nuclear ribonucleoproteins (snRNPs, Sm and U1RNP), key functional components of the mRNA splicing, are one of the most common targets of autoantibodies in systemic lupus erythematosus (SLE) and other systemic autoimmune dis-

eases. Survival of motor neuron (SMN) complex that plays a key role in snRNPs assembly and interacts with snRNPs has recently been identified as a novel target of autoantibodies in polymyositis/dermatomyositis (PM/DM). Autoantibodies to gemin5 that interacts with SMN complex were examined in unselected cohort of rheumatology clinic.

Methods: Sera from patients seen at the Center for Autoimmune Disease (n = 1966, including 453 SLE, 132 scleroderma, 125 PM/DM, 130 Rheumatoid Arthritis, 61 Sjögren's syndrome) were screened for autoantibody specificities by immunoprecipitation (IP) using ^{35}S-labeled K562 cells extract. Anti-gemin5 antibodies were initially screened by IP of ~170kD protein and confirmed by IP-western blot (IP-WB) and antigen-capture ELISA using anti-gemin5 monoclonal antibodies. Sera of interest were also tested by WB using purified gemin5 and immunofluorescent antinuclear (ANA)/cytoplasmic antibodies

Results: Nineteen sera with anti-gemin5 antibodies were identified. All except one (18/19) also had anti-snRNPs (13 anti-U1RNP, 5 anti-U1RNP+ Sm) and one had anti-SMN complex antibodies without anti-snRNPs. Among 18 with anti-snRNPs, 13 clearly had anti-SMN complex antibodies, 3 were inconclusive while 2 were negative. Anti-gemin5 sera were also positive for anti-snRNPs, thus showed nuclear speckled pattern and Cajal body ANA staining. In WB using affinity-purified gemin5, 10 sera were clearly positive, confirming their direct reactivity with gemin5. Anti-gemin5 was found in 6% of anti-snRNPs positive Caucasian or African American and 15% in Latin American. Diagnoses include 10 SLE, one each of SSc and PM and 7 undifferentiated connective tissue disease (UCTD). Clinical features of SLE in anti-gemin5+snRNPs (+) patients were similar to those of anti-snRNPs (+) patients except for absence of discoid lesions, seizures, and anti-phospholipid antibodies (0% vs 48%, P < 0.0001) in the former group. Among anti-gemin5 (+), 4 cases had symmetrical muscle weakness and elevated muscle enzymes and 32% (7/19) had at least one of these, suggesting muscle involvement may be common in this subset. Raynaud's phenomenon was seen in 73%, interstitial lung disease (ILD) in 25%, and sclerodactyly in 14% of anti-gemin5 patients. A case of PM with anti-TIF1beta and U1RNP antibodies developed anti-gemin5 and SMN antibodies a few months later, consistent with the idea of epitope spreading within macromolecular complex.

Conclusion: Anti-gemin5 antibodies are produced in tight association with anti-snRNPs and anti-SMN complex antibodies in SLE and other systemic rheumatic diseases. Clinical features of anti-gemin5+snRNPs antibody positive patients are similar to those with anti-snRNPs although muscle involvement may be more common.

Antibody Secreting Cells Arising After Vaccination of Lupus Patients May Produce High Affinity Autoantibodies. Kenneth Smith[1], Jennifer Muther[1], Angie Duke[1], Emily McKee[1], Alina Lorant[1], Patrick C. Wilson[2] and Judith A. James[3]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Chicago, Chicago, IL, [3]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Vaccinating SLE patients with influenza and pneumococcal vaccines is generally considered safe and effective. However, conflicting reports regarding the impact of vaccination on autoantibody production exist. Whether vaccination might facilitate affinity maturation of autoantibody specificities or cause novel specificities to arise is difficult to determine from serum antibody measurements alone. In order to study this question on a *per antibody* basis, we have isolated and expressed human monoclonal antibodies from SLE patients following vaccination with both the influenza vaccine and Pneumovax23. Our technique utilizes antibody secreting cells arising from a memory response to produce antibodies specific to the vaccine. Furthermore, in autoimmune donors we can further characterize the antibodies with respect to common autoimmune specificities.

Methods: We developed a technology that allows us to make fully human monoclonal antibodies from any antigen currently approved as a vaccination in humans. This allows us to make human monoclonal antibodies which are highly specific to the vaccine antigen(s). This technology is based on the discovery of a population of B cells (ASCs), which arise 7 days after vaccination and produce antibody that is specific for the vaccine antigen. These cells can be sorted and their antibody genes cloned to express the antigen-specific antibody from each ASC. We are also capable of reverting the antibodies to their germline configurations to examine the role of somatic hypermutation in their auto-specificities.

Results: Two interesting antibodies were characterized from two SLE donors, one following vaccination with the influenza vaccine (2_156p1E05) and the other following vaccination with Pneumovax23 (pn134p1D02). Although antibody 2_156p1E05 does not bind to influenza virus, it is the first example of a fully human high affinity antibody to Sm (8×10^{-10}M). By line immunoblot, we show that it binds to SmD. When reverted to its naïve/germline configuration, this antibody loses all binding to Sm indicating that such binding arose during somatic hypermutation. Unlike 2_156p1E05, pn134p1D02 does bind to *S. pneumoniae* serotype 5 polysaccharide with high affinity (2×10^{-10}M). However, by line immunoblot, we show that it also binds to nRNP A.

The serum of the donor of 2_156p1E05 was also carefully analyzed over a three year period and this patient's antibody response to Sm clearly affinity matured, increasing in overall affinity in each year. Since this antibody does not bind influenza, it is unclear whether the vaccine played a role in this maturation, however, pn134p1D02 clearly binds polysaccharide and arose or matured after vaccination with Pneumovax23.

Conclusion: The ability to analyze the autoimmune response of a patient with SLE after vaccination on a *per antibody* basis allows us to determine whether new auto-specificities may occur after vaccination. Although this does not appear to be a common event, the fact that it can occur does indeed indicate that vaccination has the potential to increase autoantibody production and potentially clinical flares in select SLE patients.

1749

Targeting of CD22 by Epratuzumab Potentially Raises the Threshold of B Cell Receptor Activation. N. Sieger[1], S.J. Fleischer[1], K. Reiter[1], H.E. Mei[1], A. Shock[2], G. Burmester[1], C. Daridon[1] and T. Dorner[1]. [1]Charité University Medicine Berlin, Berlin, Germany, [2]UCB Pharma, Slough, United Kingdom

Background/Purpose: CD22, a member of the sialic acid-binding immunoglobulin-like lectins (Siglec) family, is exclusively expressed on B cells at mature stage and is lost upon plasma cells differentiation. CD22 mediates migration by modulating cell-cell interaction and negatively regulates B-cell receptor (BCR) signaling. By recruiting a tyrosine phosphatase to its intracellular tail, CD22 acts as an inhibitory co-receptor of the BCR via de-phosphorylation of signaling molecules such as spleen tyrosine kinase (Syk) and subsequent phospholipase C (PLC)-γ2-triggered Ca^{2+} fluxes. The ligand of CD22 is α-2,6-sialic acid residues present on many proteins, including CD22. Sialo-interactions appear to be crucial for optimal CD22 function and can occur in *cis* (to ligands on the same cell surface) or *trans* (to ligands on neighboring cells). The humanized anti-CD22 monoclonal antibody epratuzumab, currently in phase III clinical trials in SLE, modulates adhesion molecule expression and B cell migration *in vitro*; however, the potential of CD22-ligation with sialic acid to regulate BCR signaling has not been delineated.

Methods: To investigate the impact of epratuzumab on the B cells response, the recruitment of CD22 to the BCR after epratuzumab incubation on peripheral blood B cells from healthy volunteers was studied by confocal microscopy. The *In vitro* effects of epratuzumab on BCR-induced signaling was evaluated by analyzing the phosphorylation status of the BCR-signaling molecules Syk and PLC-g2 by flow cytometry. To assess the importance of sialo-interactions on epratuzumab-induced effects, peripheral blood mononuclear cells were treated with neuraminidase (to remove sialic acid) and BCR-induced phosphorylation (Syk and PLC-γ2) was monitored with or without epratuzumab incubation. Finally, to monitor B cell activation after epratuzumab incubation, the concentration of intracellular Ca^{2+} was monitored by flow cytometry after BCR stimulation.

Results: We have shown by confocal microscopy that incubation with epratuzumab or a F(ab$'$)$_2$ fragment of epratuzumab specifically induced the recruitment of CD22 to the CD79a molecule associated to the BCR on B cells. When B cells are pre-treated with epratuzumab, we observed a reduction of the phosphorylated Syk and PLC-γ2 induced by BCR stimulation. This reduction was observed in the same manner when the cells were pre-incubated with F(ab$'$)$_2$ fragment of epratuzumab which excludes an inhibitory effect dependent on FcR signaling. The reduction of BCR-induced kinase phosphorylation was demonstrated in both CD27$^-$ naïve and CD27$^+$ memory B cells. Interestingly, preventing sialo-interactions of CD22 partially reduced the inhibitory effect of epratuzumab on Syk and PLC-γ2 phosphorylation. In addition, a F(ab$'$)$_2$fragment of epratuzumab reduced the BCR-induced calcium flux.

Conclusion: Taking these data together, these data show that targeting CD22 with epratuzumab potentially raises the threshold for BCR activation and therefore would provide additional control of B cell function. Furthermore, the analysis of CD22 ligation by epratuzumab would provide further understanding of CD22 biology in human autoimmune diseases.

1750

Phosphoprotein Changes Induced with Epratuzumab, an Antibody Targeting CD22 On B Cells. S. Lumb[1], N. Torbett[2], I. Vandrell[2], H. Turner[2], M. Page[1], P. Hales[1], A. Maloney[1], B. Vanhaesebroeck[2], P. Cutillas[2] and A. Shock[1]. [1]UCB Pharma, Slough, United Kingdom, [2]Activiomics Ltd., London, United Kingdom

Background/Purpose: Epratuzumab is a monoclonal antibody targeting CD22 that is currently in phase III clinical trials in systemic lupus erythematosus (SLE) patients. CD22 is found almost exclusively on B cells and *in vitro* culture with epratuzumab down-regulates B cell receptor (BCR)-dependent cell signaling and B cell activation events. The objective of this study was to investigate epratuzumab-dependent changes in phosphoprotein signals in activated B cells using a recently developed LC-MS/MS methodology (TIQUAS™ or Targeted Quantification of Cell Signalling).

Methods: B cells were purified from human tonsils (n=8 donors) by mechanical homogenisation followed by Ficoll-Hypaque gradient centrifugations. T cells were depleted by E-rosetting using 2 aminoethylisothiouronium bromide (AET) treated sheep red blood cells. The resulting B cells were counted and analysed by flow cytometry for purity, typically B cells preparations were >90%pure. 4×10^7 cells B cells were then stimulated through the BCR using anti-IgM for 2 minutes with or without prior pre-incubation with epratuzumab or IgG1 isotype control for 1 hour. Immediately following stimulation the cells were harvested in ice cold PBS buffer containing phosphatase inhibitors, pelleted by centrifugation and lysed in a urea based lysis buffer containing phosphatase inhibitors. The cell lysates were sonicated on ice and quantitated by BCA protein assay. 500μg of cell extracts were subject to protease digestion and TiO2 phosphopeptide enrichment. LC-MS-MS phosphoproteomic analysis was performed using a label-free quantification strategy. A mixed linear effect statistical model was applied to the quantitation output which comprised data for 3825 distinct phosphorylation sites. The phosphopeptide data set was imported into Ingenuity Pathway Analysis (IPA) and mapped to canonical pathways for further analysis.

Results: This analysis was able to identify statistically significantly regulated phosphorylation sites in response to pre-incubation with epratuzumab using adjusted p- and q- threshold values of <0.05, although the most significant changes generally showed no more than a 2-fold difference from signals induced by BCR stimulation alone. Among the changes observed were BCR-specific downstream signals on a broad range of protein family types: adaptor proteins (SHC1), kinases (ERK1/2, p38delta), phosphatases (SHIP1), histones (H1) and transcription factors (NFAT). Additionally, there was down-modulation of the phosphorylation of Ser717 on CD22 itself.

Conclusion: Pre-incubation of human tonsil-derived B cells with epratuzumab induced discrete but statistically significant changes in phosphoprotein signals after BCR activation. Such observations may enable a better understanding of how epratuzumab modulates B cell functions *in vitro* and possibly in patients with SLE.

1751

Effect of Repeated Infusions of Rituximab in Patients with Primary Sjögren's Syndrome. Maria Perez-Ferro, Sheila Recuero, Fredeswinda I. Romero, Cristina Serrano, Maria J. Rodriguez-Nieto, Julio Gomez-Seco, Teresa Presa, Javier R. Godo, Gabriel Herrero-Beaumont and Olga Sanchez-Pernaute. Jimenez Díaz Foundation University Hospital, Madrid, Spain

Background/Purpose: To assess the safety and efficacy of repeated infusions of rituximab (RTX) in patients with primary Sjögren syndrome (PSS).

Methods: Patients with PSS were selected for RTX treatment in case of severe glandular disease or any potentially threatening extra-glandular manifestations. Patients received 2 doses of 1000 mg RTX with a 2-week interval. RTX courses were thereafter programmed every 6 months, for 2 years. The patients were evaluated every 3 months. Criteria for discontinuation were disease progression, appearance of adverse events or inactive disease. At baseline, activity measures and B cell subsets in peripheral blood were studied. Global disease activity was scored with ESSDAI. Descriptive data are expressed in average (limits). Statistical differences between baseline and final measures and the association of disease characteristics at baseline with a favorable outcome were analyzed with non-parametric tests.

Results: 12 patients (11 women) fulfilling inclusion criteria, with a mean age of 60 (42–82) year-old and disease duration of 5.9 (1 – 16) years have been enrolled. Eleven patients had extra-glandular active disease at baseline, consisting of arthritis (6 p), ILD (6 p), Raynaud's phenomenon (5 p), peripheral neuropathy (3 p), and exanthema (3 p). Anti-Ro antibodies were positive in 10 cases, anti-La were found in 4 and rheumatoid factor in 6 cases. At baseline, global B cell counts were within normal range, with a prominent shift towards naïve cells (68% of all CD19+ cells). Interestingly, this appeared to be a favorable marker, since percentage of naïve cells was negative correlated with RF titers (rho −0.84, p < 0.02) and was significantly associated to prednisone dose reduction at end points (rho 0.983, p < 0.005).

The patients have received a total dose of 42500 mg RTX, 3750 mg (500–6000) per patient, over an observation period of 13 (3 – 23) months. During this period, 2 treatments were withdrawn, 1 due to an acute Epstein Barr virus infection at the first RTX course and the second one due to sustained remission. Two additional infections were observed during follow-up, neither of them leading to discontinuation. At endpoints, daily prednisone was tapered in 10 mg/d (Z −2.2, p 0.028). The average ESSDAI dropped from 4.1 (1–9) to 2.2 (0–4), Z −2.33, p 0.02, and showed an adjusted change of −4.22 points per year of follow-up. The change in ESSDAI was correlated to the cumulative dose of RTX (rho 0.665, p < 0.02). Reduction of prednisone was positively correlated to the number of RTX courses and the cumulative dose of RTX. Finally, no reconstitution of the B cell subpopulations has been found over the observation period.

Conclusion: In this cohort of patients with Sjögren's syndrome, RTX showed a favorable safety profile as well as a possible benefit in the short-term control of the process. Although these results should be taken with caution, they suggest that B cell depletion can fill a gap in the management of difficult to treat Sjögren's syndrome.

1752

Depletion of CD4-Effector Memory T Cells and Clonally Expanded IgG4 Memory B Cells May Explain the Therapeutic Efficacy of Rituximab in IgG4-Related Disease: Studies Using Flow Cytometry and Single-Cell Sequencing. Hamid Mattoo[1], Arezou Khosroshahi[2], Vinay Mahajan[1], Mollie Carruthers[2], John Stone[1] and Shiv Pillai[2]. [1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, MA

Background/Purpose: The clinical effectiveness of rituximab-mediated B cell depletion in chronic inflammatory disorders such as multiple sclerosis and Type I diabetes, which are not believed to be autoantibody-driven conditions, has not been explained satisfactorily. A mechanistic explanation is also lacking for the efficacy of rituximab in IgG4-related disease (IgG4-RD), a chronic inflammatory disorder characterized by fibrosis that might be T cell mediated. Although CD4+ T cells contribute to the activation of B cells during T-B collaboration, activated B cells are required in turn both for the generation of T follicular helper cells and for the induction and maintenance of CD4+ memory T cells. We hypothesize that in IgG4-RD, some as yet unidentified antigens induce T follicular helper cell-mediated B cell activation and the subsequent generation of a Th2 type of CD4+ effector and memory T cell response. The fibrosis that characterizes this disorder may reflect the generation of a B cell-dependent pathogenic Th2 cell response to these uncharacterized antigens.

Methods: We performed detailed flow cytometry studies on B and T cell populations before and after treatment with rituximab in four patients, accompanied by single cell cloning studies of IgG4 memory B cells.

Results: We have detected an expansion of circulating IgG4 memory B cells and of CD4+ effector memory T cells in subjects with active IgG4-RD (a, b). Rituximab therapy not only mediates the depletion of all circulating B cells in IgG4-RD, including the expanded IgG4 memory B cells, but also of the CD4+ effector memory T cell population. Single cell cloning of IgG4 memory B cells from subjects with active disease followed by sequencing of matched Ig heavy and light chains reveals the possible expansion of a few IgG4 B cells with common V_H and V_L usage.
Conclusion: These results support the notion that B cell depletion with rituximab mediates loss of the disease-promoting effector memory CD4+ T cells in IgG4-RD. These studies offer the possibility that the inciting antigen(s) in IgG4-RD may be identified in due course as a result of the identification of clonally-expanded B cells.

1753

A Rheumatoid Factor Paradox: Inhibition of Rituximab-Induced Complement Dependent Cytotoxicity of B Cells. Jonathan D. Jones[1], Irene Shyu[1], Marianna M. Newkirk[2] and William F. C. Rigby[1]. [1]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [2]McGill University Health Centr, Montreal, QC

Background/Purpose: Rheumatoid factor (RF) is an autoantibody directed against the Fc portion of IgG antibodies. It is found in ~80% of patients with rheumatoid arthritis (RA). It has been postulated that RF potentiates immune complex disease in RA by enhanced fixation of complement. Rituximab (RTX), an antibody targeting CD20 on B cells, exhibits increased efficacy in seropositive patients with refractory RA. We hypothesized that this improved efficacy was due to the ability of RF to enhance the ability of RTX to mediate complement dependent cytotoxicity, leading to enhanced synovial depletion of B cells.

Methods: We developed a model assay system of RTX to mediate complement dependent cytotoxicity (CDC) using the Daudi human B cell line modified to grow in serum-free media. CDC was determined by propidium iodide staining 30 minutes after combining Daudi cells with RTX 10 μg/ml and human sera (1%; as a source of complement) from healthy donors and patients. The effect of RF on RTX-CDC was determined by the following methods: i) Comparison of CDC by RF+ sera vs RF- sera; ii) Addition of monoclonal IgA or IgM RF to seronegative sera; iii) Mixing studies of RF+ and RF- sera.

Results: In the presence of 1% human sera, RTX resulted in rapid (minutes) and profound (>50%) Daudi cell death. This effect was complement dependent as proven by a lack of Daudi cell death by RTX in serum free media, heat-inactivated serum, and C5 deficient serum. A surprising variation in the ability of human sera to mediate RTX-CDC was observed. The mean percent of RTX-CDC ranged from healthy donors 54% (n=15), RF+ RA patients 47% (n=40), RF- RA patients 88% (n=15), non-RA patients 83% (n=15). Remarkably, sera with an IgM RF >250 IU/ml resulted in a mean CDC of 13% compared to sera with IgM RF 9–100 IU/ml having a mean CDC of 74%. A similar effect of increasing IgA RF concentration was seen but was not as profound an effect as IgM RF. Mixing of RF+ sera with RF-sera demonstrated the reduced RTX-CDC, indicating the presence of an inhibitor. The identity of RF as the inhibitory factor was demonstrated by the ability of either purified monoclonal IgM RF or monoclonal IgA RF added to RF- sera to mediate near complete inhibition of CDC at concentrations of 50 μg/ml and 10 μg/ml, respectively. The inhibitory effect of RF could be blocked by excess IgG. In addition, we observed that RF did not alter RTX binding to CD20 on B cells. Therefore, we conclude that RF blocks the ability of early complement components to be recruited to the IgG Fc portion of RTX.

Conclusion: Contrary to our original hypothesis, RF inhibits RTX induced CDC *in vitro*. Thus, the enhanced efficacy of RTX in seropositive RA patients cannot be easily attributed to modulation of B cell depletion through CDC. This result is surprising given the roles of RF in immune complex clearance and complement activation. Not only does this generate a new set of insights into the biologic role of RF, it indicates that high RF levels may potentially modulate the efficacy of any therapeutic monoclonal antibody.

1754

Disruption of Dominant B-Cell and Plasma Cell Clones in Rheumatoid Arthritis Synovium by Rituximab Correlates with Treatment Response.

Marieke E. Doorenspleet[1], Paul L. Klarenbeek[1], Maartje J. Boumans[1], Rogier M. Thurlings[1], Rebecca E. Esveldt[1], Barbera D. van Schaik[1], Antoine H. van Kampen[1], Danielle M. Gerlag[2], Frank Baas[1], Paul-Peter Tak[1], Robert M. Plenge[3] and Niek de Vries[1]. Background/Purpose: Autoreactive B lymphocytes are thought to play an important role in rheumatoid arthritis (RA). B-cell depletion therapy by rituximab (RTX) has shown that targeting B-cells can result in clinical improvement. Unfortunately, the depletion is transient and might result in disease relapse. Hence, analysis of the B-cell/plasma cell compartment in synovium (ST) in patients undergoing RTX therapy might help to identify autoreactive cells responsible for disease persistence and relapse.

Objective: To compare the B-cell/plasma cell repertoire in ST at baseline, 4 weeks and 16 weeks after RTX treatment using a newly developed high-throughput sequencing protocol.

Methods: Eleven RA patients were included and treated with two intravenous infusions of 1000mg RTX without additional methylprednisolone. At baseline, all patients fulfilled ACR criteria for RA, were ACPA+ and had a DAS28score >3.2. At week 24, nine patients demonstrated moderate to good EULAR responses, two patients were marked as non-responders. Immunohistochemistry stainings were performed on formalin-fixed paraffin embedded sections using antibodies against CD22 and CD138. mRNA was isolated from consecutive samples and full-repertoire analysis of the B-cell receptor (BCR) heavy-chain was performed with primers for all V(ariable)-genes. All amplified products encode the CDR3, a unique sequence that defines a unique clone. The number of sequences reflects the amount of BCRs produced by that clone and can be used as a measure for 'dominance' of that particular clone. >40,000 bead-bound sequences were analyzed using a Genome Sequencer FLX (Roche/454). Clones with a frequency of >0,5% were arbitrarily considered as dominant clones.

Results: Clones were detected in equal numbers at baseline and 4 weeks after RTX in all patients. However, after 16 weeks the number of dominant clones significantly increased compared to baseline (mean +55,3%, p=0.04). In line, there was a significant decrease in the number of non-dominant clones compared to baseline (mean −47.7%, p=0.03). This mirrored the regression of clinical symptoms measured by the DAS28 score as well as subsequent declines in the number of CD138+ plasma cells in the synovium 16 weeks after the infusion. In 5 patients, 17.9% of the dominant clones at baseline was still detectable after 16 weeks (mean, SD 8.0%), half of these were dominant at both time points (mean 8.8%, SD 4.6%). In the remaining 6 patients dominant clones at baseline were not at all retrieved 16 weeks after RTX. Interestingly, the latter group showed better treatment responses determined by the ΔDAS28score (−0.76 (SD 0.37) and −2.2 (SD 0.79) DAS28 points resp., p=0.005, r^2=0.58).

Conclusion: Our observations suggest a disruption of dominant clones and a repopulation of distinctly different clones 16 weeks after rituximab. The persistence of dominant clones was associated with decreased treatment response. Further analysis of clones persistence, amongst others during disease relapse, might help to characterize disease-associated B-cells and/or plasma cells, and identify novel biomarkers for treatment response.

The Alternative ΔCD20 Transcript Variant Is Not Expressed in B Cells and Synovial Tissue From Patients with Rheumatoid Arthritis.

Clémentine Gamonet[1], Marina Deschamps[2], Béatrice Gaugler[3], Philippe Saas[4], Isabelle Auger[5], Christophe Ferrand[6], Eric Toussirot[7] and CIC BT506[8]. [1]INSERM UMR1098/Etablissement Français du Sang/Université de Franche Comté, France, [2]INSERM UMR1098/Etablissement Français du Sang/Université de Franche Comté, Besançon, France, [3]INSERM UMR1098/Etablissement Français du Sang/Université de Franche Comté, Besançon, France, [4]INSERM UMR1098/Plateforme de Biomonitoring, Besançon, France, [5]INSERM UMR1097, Marseille, France, [6]INSERM UMR1098 Etablissement Français du Sang/Université de Franche Comté, Besançon, France, [7]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France, [8]Clinical Investigation Center Biotherapy 506, Besançon, France

Background/Purpose: Determining predictive factors for response to biologics may help to select appropriate treatment in patients with RA. Rituximab (RTX) is a chimeric monoclonal antibody directed against the membrane CD20 protein present on B cells. Predictive factors for good response to RTX therapy in RA have been identified and included the presence of rheumatoid factors and anti-CCP antibodies. A spliced mRNA transcript of CD20 (ΔCD20) has been observed in B cell lines from patients with lymphoma and leukaemia (1). This transcript is coding for a non anchored membrane protein and its expression is associated with resistance to RTX in patients with haematological malignancies.

Objectives: To determine whether ΔCD20 is expressed by circulating B cells and synovial tissue from patients with RA and whether it could be a factor for non response to RTX therapy in RA.

Methods: 23 RA patients (17 F, age (mean ± SEM): 60.1 ± 2.7 years; disease duration: 13.3 ± 1.7 years, positive rheumatoid factors: 19/23; positive anti- CCP antibodies: 19/23) and 20 healthy controls (HC) (15 F, age: 59.6 ± 2.5 years) were evaluated. Patients were under DMARDs, low corticosteroids (< 10 mg/l) or anti TNFa agents, but none received or had received RTX. Five patients with RA requiring treatment with RTX were also evaluated prior to the first RTX infusion and during a one year follow- up study. CD20 mRNA expression study was performed using RT-PCR assay allowing first to discriminate full length CD20 (membrane CD20) from ΔCD20 transcripts. A more sensitive RT-PCR assay, using a specific primer spanning the splice fusion area was then used to detect specifically only the ΔCD20 transcript. This analysis was performed on peripheral blood B cells from patients with RA and HC and synovial tissue from RA patients obtained during surgery.

Results: RA patients had mild active disease (DAS28 score: 3.3 ± 0.3; CRP levels: 6.8 ± 1.9 mg/l). Number of circulating B cells per μl was not different between RA patients and controls (mean ± SEM, range: 184 ± 22, 18–437 *vs* 211± 27, 63–408, respectively). Among all the 23 RA samples, although full length CD20 expression was always detected, we were unable to detect ΔCD20, even with the more sensitive RT-PCR assay permitting to identify the spliced transcript form. Among the 5 patients who received RTX, 4 well responded to the treatment. Both responders and non responder patients did not express ΔCD20 before RTX administration and during the follow-up study. ΔCD20 was also not detected in synovial tissue samples from 5 patients with RA.

Conclusion: The present study showed that, on the contrary of leukemic or lymphoma B cells, RA B-cells and synovial tissue from RA patients do not express ΔCD20, suggesting that this transcript may be a molecular marker of malignancies rather than a factor predictive to RTX response in auto-immune diseases like RA. We are currently examining whether B cell stimulation may help to evidence ΔCD20 expression in RA B-cells.

Peripheral Blood B Cell Subsets and BAFF/APRIL Receptor Expression, Together with Circulating BAFF and APRIL Levels, Are Disturbed in Rheumatoid Arthritis but Not in Ankylosing Spondylitis.

Béatrice Gaugler[1], Caroline Laheurte[2], Ewa Bertolini[3], Daniel Wendling[4], Philippe Saas[5], Eric Toussirot[6] and CIC BT506[7]. [1]INSERM UMR1098/Etablissement Français du Sang/Université de Franche Comté, Besançon, France, [2]INSERM UMR1098/Plateforme Biomonitoring, Besançon, France, [3]Rheumatology, Besançon, France, [4]Minjoz University Hospital, Besançon, France, [5]INSERM UMR1098/Plateforme de Biomonitoring, Besançon, France, [6]CIC Biotherapy 506 and Rheumatology and EA 4266 Pathogens and Inflammation, Besançon, France, [7]Clinical Investigation Center Biotherapy, Besançon, France

Background/Purpose: B cells play a critical role in systemic autoimmune disease and especially rheumatoid arthritis (RA). BAFF and APRIL are involved in B cell activation and survival. B cell depletion therapies may target specific B cell subsets and/or B cell activating factors or receptors. Few studies have evaluated the distribution of the different peripheral blood B cell subsets in RA as well as the expression of BAFF/APRIL receptors. Ankylosing spondylitis (AS) is an inflammatory rheumatic disease without current evident contribution of B cells to the inflammatory response.

Objectives: To evaluate the distribution of circulating B cell subsets and their expression of BAFF/APRIL receptors (TACI, BCMA and BAFF-R) as well as the circulating levels of BAFF and APRIL in patients with RA or AS compared to healthy controls (HC).

Methods: 59 patients with RA (ACR criteria, 12 M, age [mean ±SEM; years]: 58 ± 1.5, disease duration: 10.1 ± 1.5; all under traditional DMARDs, no biologics, corticosteroids < 10 mg/day N= 33), 61 patients with AS (modified NY criteria; 46 M; age: 46 ± 1.8, disease duration:11.6 ± 1.2; all under NSAIDs or traditional DMARDs) and 61 HC (13 M; age: 43.6 ± 1.8) were evaluated. For each subject, peripheral blood B cell subsets were assessed using multi-color flow cytometry. B cell subsets were analysed according CD27, CD38 and IgD staining (naive B cells: CD27- IgD+ CD38lo, transitional: CD27- IgDlo CD38hi, pre-GC: CD27+IgD+CD38hi, post-GC: CD27+IgD-CD38lo). The expression of BAFF-BR3, TACI and BCMA was analysed on each subset. RFI was calculated by dividing the MFI of the marker divided by MFI of the isotype-matched mAb. Cells were analysed using a FACSCantoII and FACSDiva Software (BD Biosciences). BAFF and APRIL serum levels were determined by ELISA using commercially available kits (Bender MedSystems and R&DSystems) respectively.

Results: Circulating BAFF and APRIL levels were increased in RA compared to HC (1100.5 ± 62.5 vs 904.9 ± 29.4 pg/ml, p= 0.01 and 19116.3 ± 4918.6 vs 5699.2 ± 1034.5 pg/ml, p < 0.001, respectively), while no difference was observed in the levels of these activating B-cell factors in AS and HC. The ratio BAFF levels/peripheral B cell count was also significantly increased in RA (p = 0.04). The following B cell subsets were decreased in RA compared to HC: total B cells (p= 0.004), naïve B cells (p = 0.02), transitional B cells (p < 0.001), while post GC and CD27[+] B cells were not different. B-cell subsets were comparable in AS and HC. Expression of BAFF and APRIL receptors were increased in the RA group, especially TACI on CD19[+] B cells, transitional B cells and pre GC B-cells (all p < 0.05) and BCMA on CD19[+], naive B cells, transitional B cells, memory B cells, pre-GC and post-GC B-cells (p < 0.05) while BAFF-R RFI was comparable in RA and HC. The expression of BAFF/APRIL receptors did not differ between AS and HC.

Conclusion: Overall, our data confirm that B cell responses are altered in RA with biased repartition of B cell subsets, elevated levels of B cell activating cytokines and increased expression of their receptors. These results may be helpful for guiding and /or monitoring B cell targeted therapies in RA. In contrast, no alteration was observed in AS patients excluding an involvement of disturbed B cell responses in AS.

1757

B Cell Activating Factor Receptor Expression After Rituximab: Comparison of Patients with Rheumatoid Arthritis and Thrombotic Thrombocytopenic Purpura.

Elena Becerra[1], Maria J. Leandro[1], Edward O. Heelas[2], John P. Westwood[2], Inmaculada de la Torre[3], Marie A. Scully[2] and Geraldine Cambridge[1]. [1]Rheumatology, University College London, London, United Kingdom, [2]Hematology, University College London, London, United Kingdom, [3]Rheumatology, Gregorio Marañón Hospital, Madrid, Spain

Background/Purpose: B cell depletion therapy based on rituximab (RTX) is an effective therapy for Rheumatoid Arthritis (RA) and for Thrombotic Thrombocytopenic Purpura (TTP). Serum B cell activating factor (BAFF) levels are within normal limits in patients with RA prior to RTX therapy, but may be raised in TTP. BAFF levels rise after RTX in both diseases. Nearly all mature B cells express BAFF-receptor (BAFF-R) in normal individuals. We have previously described lower % of naïve and memory B cells expressing BAFF-R in RA at relapse following RTX. Here, we present B cell phenotypes and %BAFF-R+ve cells in TTP patients at repopulation and in both diseases in repopulated patients in remission after RTX. **Results** were also analyzed in relation to serum BAFF levels.

Methods: Phenotypes and %BAFF-R+ve naive (CD27-) (NB) and memory (CD27+) (MB) B cells were performed using FACS analysis. Healthy controls (HC), patients with TTP, either repopulating or in remission were compared with RA repopulated patients remaining in remission after RTX (Mann Whitney U test).

Results: Median time to repopulation in TTP patients was 6 months, range 4–7. Time of sampling after RTX in repopulated patients ranged from 8–38 months in RA remission patients and 10–68 months in TTP remission patients. In remission, NB cells remained high with slow regeneration of MB in both RA and TTP. As previously shown in RA, % BAFFR +ve cells in TTP were low at repopulation in both NB and MB cells. However, % BAFFR +ve cells reached normal levels in TTP patients remaining in remission months after repopulation, but stayed low in patients with RA, independent of time after last RTX cycle or number of cycles. BAFF levels remained elevated in RA patients in remission as opposed to TTP. There was a significant inverse correlation between BAFF levels and % BAFF-R +ve NB and MB cells in TTP patients in remission (p<0.001; r^2>0.70 in both) but not in patients with RA.

Median + range	HC (n:5)	TTP Repopulation (n:4)	TTP Remission (n:14)	RA Remission (n:9)
Naïve B cells %	71 (59–84)	86 (35–98)	93 (86–98)	96 (66–98)
Memory B cells %	29 (16–40)	13 (1.3–64)	6 (1.1–13)	3 (1–34)
%BAFFR+ve in NB	100 (99–100)**	66 (17–80)**	95 (29–99)*	52 (18–88)*
%BAFFR+ve in MB	99 (98–99)**	44 (18–86)**	88 (41–98)*	42 (22–62)*
BAFF levels (ng/ml)	1 (0.98–1.09)	2.3 (1.70–2.70)	1.42 (0.90–3.30)*	6 (1.70–11.70)*

*p <0.01
**p<0.05

Conclusion: Repopulation of B cells after RTX follows similar patterns in patients with TTP and RA, with naïve B cells predominant. The finding that %BAFF-R+ve B cells was lower in remission in RA but not in TTP after RTX suggests a disease specific dysregulation, consistent with an auto-immune phenotype already present in repopulating B cells.

Serum BAFF Levels and Relationship with BAFF Binding Receptors in Patients with Rheumatoid Arthritis Relapsing After B Cell Depletion Therapy.

Elena Becerra[1], Inmaculada de la Torre[2], Maria J. Leandro[1] and Geraldine Cambridge[1]. [1]University College London, London, United Kingdom, [2]Gregorio Marañón Hospital, Madrid, Spain

Background/Purpose: B-cell-activating-factor (BAFF) coordinates differentiation of B cells into immunoglobulin secreting cells (ISC) by binding to 3 different receptors (BBRs), namely BAFF-R, transmembrane activator and Calcium signal modulating cyclophilic ligand interactor (TACI) and B cell maturation antigen (BCMA). BAFF levels rise after B cell depletion therapy based on rituximab (BCDT) and remain raised in some patients at relapse. BAFF-R expression is reduced in relapsing patients after BCDT. We examined the level of BBR expression at relapse in relation to serum BAFF levels.

Methods: BBRs % expression was examined on B cell sub-populations defined using combinations of CD19, CD38 and IgD. Serum BAFF levels were determined using a Human Quantikine[O] BAFF/BLyS Immunoassay ELISA kit. We studied 10 Healthy Controls (HC), 10 RA patients before BCDT (Pre-BCDT) and 20 patients with RA at relapse, including 10 patients who had relapsed within 3 months after repopulation (Concordant Relapse:

C-R) and 10 patients who had relapsed >3 months after repopulation (Discordant Relapse: D-R).

Results: Following BCDT, BAFF levels rose and were significantly raised at relapse in both patient groups (C-R: median 2.19 ng/ml; 0.96–4.55, D-R: median 1.90 ng/ml; 1.14–6.47) when compared to HC (median 1.11 ng/ml; 0.89–1.24; p=0.02; p=0.002, respectively) and D-R only compared with patients pre-BCDT (1.39 ng/ml; 0.84–2.39; p=0.05). In the C-R group, 5/10 patients and in the D-R group 4/10 patients had BAFF levels > 2.4 ng/ml. In patients with raised BAFF levels, in all B cell subsets except plasmablasts, %BAFF-R+ cells were significantly reduced compared with HC. % TACI+ cells were significantly reduced only in post-Germinal Center (GC) B cells in both relapsing patient cohorts. When serum BAFF levels were within normal limits, %BAFF-R+ transitional B cells in C-R patients were significantly lower than in D-R patients and HC, with other B cell populations following similar patterns as in total cohorts. %TACI positive cells remained significantly reduced in post-GC populations in D-R patients only, compared with HC.

Conclusion: Patients with a C-R pattern of relapse maintained lower % BAFF-R+ B cells in transitional population compared with HC and D-R patients, independent of BAFF levels. This suggests that a proportion of this newly repopulating naïve B cell population is already committed to differentiation to ISC in patients with a concordant pattern of relapse. Reduced %TACI+ B cells in post-GC populations from D-R patients with normal BAFF levels may reflect a lack of up-regulation of TACI or downregulation due to internalisation or shedding of bound BAFF. Our results highlight probable differences in B cell biology in patients with different patterns of relapse following BCDT.

1759

Expression of Surface APRIL and Its Receptor, TACI, Is Upregulated On B Cells From Systemic Lupus Erythematosus and Rheumatoid Arthritis Patients. Abby Jones Weldon[1], Sheri Hsu[2], Seyed K. Nazeri[3], Saru Sachdeva[2], Jennifer Gonzalez[1], Andrea D. Parra[1], Abigail Benitez[1], Keith K. Colburn[4], Ioana Moldovan[4] and Kimberly J. Payne[1]. [1]Loma Linda University, Loma Linda, CA, [2]Loma Linda University Medical Center, Loma Linda, CA, [3]Loma Lida University Medical Center, Loma Lida, CA, [4]Loma Linda Univ Medical Center, Loma Linda, CA

Background/Purpose: Autoimmune disease affects more than 23 million Americans. Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA) are chronic, systemic B-cell mediated autoimmune diseases. During normal B cell development, autoreactive B cells are eliminated by negative selection processes that include receptor editing, anergy, or apoptosis. The increased numbers of autoreactive B cells in SLE and RA suggests that these patients have defects in negative selection that occurs during the immature stages of B cell development. The tumor necrosis factor (TNF) family members APRIL and BAFF have been shown to promote the survival of immature and naive B cells in mouse models of autoimmune disease. Elevated levels of BAFF and APRIL may contribute to the breakdown of negative selection mechanisms. Serum levels of APRIL and BAFF are elevated in patients with SLE and RA and surface forms of these proteins have been detected on normal and/or malignant B lineage cells. Using flow cytometry we found surface forms of APRIL and BAFF on peripheral blood B cells from SLE and RA patients. The aim of this study is to compare surface expression of APRIL and BAFF and their receptors on B cells from SLE and RA patients to normal B cells and to elucidate their roles in B cell-mediated autoimmunity.

Methods: Venous peripheral blood (PB) samples were collected from normal, RA, and SLE patients through an IRB-approved protocol. SLE and RA diagnosis was confirmed using American College of Rheumatology (ACR) criteria. Peripheral blood mononuclear cells (PBMCs) were separated from whole blood by red blood cell lysis. Human adult peripheral blood samples were stained for seven-color flow cytometry to assess co-expression of CD24, CD21, IgD, IgM, CD38, CD27, CD256 (APRIL), CD257 (BAFF), CD267 (TACI), and BR3 (BAFF-R). Stained cells were analyzed using a MACSQuant Analyzer (Miltenyi) and FlowJo analysis software (Tree Star). Mean fluorescence intensities (MFI) for surface APRIL and other markers on B cells from RA and SLE patient samples were compared to normal controls by one-tailed, unpaired t-test, p<0.05.

Results: Peripheral blood B cells obtained from normal (n=11), SLE (n=13), and RA (n=12) were characterized by flow cytometry. The MFI of APRIL, BAFF, BAFFR and TACI on CD19+IgM+ B cells of RA and SLE patients were compared to normal PB. Surface APRIL expression was significantly higher on B cells from RA (p=0.0083) and SLE (p=0.0146) patients as compared to normal donors. The receptor, TACI, which binds both APRIL and BAFF was also increased on B cells from RA (p=0.0114) and SLE (p=0.0146) patients.

Conclusion: Expression of surface APRIL and the TACI receptor are significantly higher on B cells from RA and SLE patients as compared to normal B cells. These results show that in SLE and in RA the patient's B cells themselves serve as a reservoir of surface APRIL that provides a potential source of stimulation for the TACI receptors that are also upregulated on these cells. These data implicate surface APRIL and TACI in B-cell mediated autoimmune disease. Ongoing studies are focused on establishing the relationship between the level of surface APRIL expression and disease activity.

1760

A Gene Expression Signature to Monitor Depletion of Plasma Cells Following MEDI-551 (anti-CD19) Administration. Katie Streicher, Chris Morehouse, Christopher Groves, Bhargavi Rajan, Fernanda Pilataxi, Kim Lehmann, Philip Brohawn, Kathleen McKeever, Volker Knappertz, Ronald Herbst, Yihong Yao and Koustubh Ranade. MedImmune, LLC, Gaithersburg, MD

Background/Purpose: Production of pathogenic autoantibodies by inappropriately self-reactive plasma cells (PC) is a hallmark of autoimmune diseases. MEDI-551 is an anti-CD19 antibody which is expected to significantly deplete PC, distinct from anti-CD20 targeted therapy which does not deplete PC. Low PC numbers in whole blood (usually 0.5% of total cells) and their instability, make it challenging to implement routine flow cytometry assays to measure PC levels in clinical trials. To address this limitation, we developed a robust gene-expression based assay which can be easily implemented in clinical trials to measure the PC population.

Methods: Based on literature and whole genome microarray analysis of sorted cellular fractions and purified PC, we identified genes (IGHA, IGJ, IGKC, IGKV, and BCMA) whose expression is highly significantly enriched in PC. We developed a signature score combining expression levels of these genes to estimate PC counts in whole blood. Flow-sorted cells obtained from healthy volunteers were used to assess the sensitivity, specificity, and reliability of detecting alterations in PC numbers using this gene expression signature.

Results: We demonstrated clinical utility of this PC signature using samples from patients enrolled in CP-200, a Phase I single dose-ranging trial (N = 27) of MEDI-551 in scleroderma. MEDI-551 caused a robust depletion of the PC gene signature in whole blood and skin, with maximum depletion reaching approximately 98% and 90%, respectively. Up to 90% B cell depletion was observed in blood and skin. At 85 days following MEDI-551 administration, the last timepoint evaluated, PC and B cell levels recovered up to 65% of baseline.

Conclusion: This newly developed gene-expression based PC signature provides a robust and straightforward way to accurately measure PC levels in the clinic. By applying this PC signature, we demonstrated significant depletion of PC cells by MEDI-551, an anti-CD19 monoclonal antibody. In combination with flow cytometry data, this PC signature will help inform dosing decisions for future trials of MEDI-551, as well as provide the ability to correlate clinical activity with baseline PC levels or with the extent/duration of PC depletion.

1761

Suppression of Rheumatoid Arthritis B Cells by XmAb5871, an Anti-CD19 Monoclonal Antibody That Co-Engages the B Cell Antigen Receptor and the FcγRIIb Inhibitory Receptor. Seung Y. Chu[1], Karen Yeter[2], Roshan Kotha[2], Erik Pong[1], Yvonne Miranda[1], Hsing Chen[1], Sung-Hyung Lee[1], Irene Leung[1], John R. Desjarlais[1], William Stohl[2] and David E. Szymkowski[1]. [1]Xencor, Inc., Monrovia, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA

Background/Purpose: XmAb®5871 is a humanized and Fc-engineered antibody that coengages CD19, part of the B cell receptor (BCR) complex, with the inhibitory receptor FcγRIIb (CD32b). This antibody is in clinical development as a potential therapy for RA and SLE, and we have previously characterized its immunosuppressive effects on B cells from normal and SLE donors. In this study, we assessed whether XmAb5871 similarly inhibits activation of RA B cells. Because XmAb5871 activity requires its Fc domain to bind with high affinity to FcγRIIb, we also assessed whether rheumatoid factor (RF), an anti-IgG Fc autoantibody, could interfere with its therapeutic mechanism.

Methods: Blood from RA (N = 50) and normal (N = 72) donors was obtained with IRB approval. PBMC were analyzed by flow cytometry for expression of CD19, CD27, CD32b and CD86. Phosphorylation of FcγRIIb following incubation of PBMC with XmAb5871 was determined by phosphowestern blotting. XmAb5871-mediated suppression of intracellular calcium flux triggered by anti-CD79b in PBMC loaded with Fluo-4 NW dye was quantified by flow cytometry. Inhibition by XmAb5871 of CD86 expression on anti-CD79b-stimulated B cells was determined in whole blood. Plasma RF and ACPA levels were measured by ELISA. Demographic and clinical characteristics of RA patients were correlated with results from in vitro assays.

Results: RA and normal B cells expressed CD19 and CD32b, the targets of XmAb5871. There was a smaller memory (CD27+) B cell compartment in RA (P = 0.003). CD32b expression was higher on naive (CD27-) (P = 0.0018) but not on memory B cells (P = 0.85) from RA vs. normal donors. BCR-mediated calcium flux was suppressed by XmAb5871 in RA and in normal B cells (67% vs. 50%, respectively; P = 0.0038). This inhibition was associated with FcγRIIb activation in RA and normal B cells (average 10-fold induction in both). Baseline CD86 expression was increased in naive and particularly in memory B cells of RA donors (P = 0.04 and < 0.0001, respectively). XmAb5871 efficiently inhibited CD86 induction in RA and normal B cells (76% vs. 62%, respectively; P = 0.0055). Notably, there was no effect of RF or ACPA levels on drug efficacy (R^2= 0.002 and 0.021, respectively). Among RA patients, functional effects of XmAb5871 did not correlate with age, sex, years from diagnosis, extra-articular manifestations, tender or swollen joint counts, DAS28, erosive disease, or use of methotrexate, hydroxychloroquine, corticosteroids, or TNF antagonists. A history of rituximab treatment was associated with fewer memory B cells and reduced CD32b expression (P = 0.003 and 0.040, respectively). Nonetheless, the functional effects of XmAb5871 on B cells from these patients were not different from those in the RA cohort at-large.

Conclusion: The FcγRIIb inhibitory pathway in B cells from RA patients can be amplified by an antibody engineered to co-engage FcγRIIb and CD19 with high affinity. The potency observed across multiple measures of B cell function in RA and normal donors and the lack of interference by physiological levels of RF and ACPA in RA patient sera suggests that XmAb5871 may represent a new therapeutic strategy to suppress autoreactive B cell populations in RA and related autoimmune diseases.

IL-6 Receptor Inhibition by Tocilizumab Modulates Double Negative (CD19+IgD-CD27-) B Cells in RA. Zafar Mahmood[1], Khalid Muhammad[1], Petra Roll[1], Stefan Kleinert[1], Thomas Dörner[2] and Hans Peter Tony[1]. [1]University of Würzburg, Würzburg, Germany, [2]Charite Universitätsmedizin Berlin and DRFZ, Berlin, Germany

Background/Purpose: Double negative (CD19+IgD-CD27-) B cells have been reported to be part of human memory B cell compartment. Detailed studies of DN B cells in autoimmune diseases like rheumatoid arthritis (RA) and during different B cell targeted therapies are sparse. Therefore we analyzed in detail these cells in RA patients under IL-6 R inhibitor tocilizumab.

Methods: DN B cells were phenotypically analyzed from RA patients (mean age ~61 years) at baseline and 12, 24 and 48 weeks after tocilizumab treatment. Additionally, single B cell sorting technology followed by nested PCR approach was used to study mutational pattern of Ig- receptors VH genes.

Results: The phenotypic analysis of DN B cells in RA patients (n=33) and healthy individuals (n=22) showed a significantly expanded population (p=0.034) of these cells in RA. DN B cells showed a heterogeneous mixture of IgA, IgG and IgM expressing cells with clear dominance of IgG+ cells. Pre-therapy analysis of rearranged IgR sequences from patients (n=7) revealed comparable but diversified mutational pattern of DN B cells comprising mutated and non-mutated sequences. During tocilizumab, DN B cells showed significantly reduced mutational frequency in their Ig-receptors with a marked reduction of the mutated Ig-receptors at week 12 (p<0.0001), 24 (p=0.0147) and 48 (p=0.0017) during treatment.

Conclusion: Our data suggest expanded DN B cells population in RA which are susceptible to IL-6R inhibition in vivo by tocilizumab. Particularly, acquisition of mutations was substantially altered in DN B cells. These results indicate that DN B cells have dependence on the IL6/IL6R system for differentiation in vivo which can be modulated by anti-IL6R therapy.

The Role of SYK in Human B CELL Activation and Its Relevance to Autoimmune Diseases. Shigeru Iwata[1], Kunihiro Yamaoka[1], Hiroaki Niiro[2], Kazuhisa Nakano[1], Sheau-Pey Wang[1], Koichi Akashi[2] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Kitakyushu, Japan, Kitakyushu, Japan, [2]Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, Fukuoka, Japan

Background/Purpose: B cells play a pivotal role in pathological processes of autoimmune diseases. Spleen tyrosine kinase (Syk) functions as a key molecule in B-cell receptor (BCR)-mediated signaling. However, the underlying mechanisms of Syk in autoimmune diseases such as RA and SLE remain unclear.

Methods: Purified naïve (CD27−) and memory (CD27−) B cells from healthy donor were stimulated with BCR cross-linking, soluble CD40L, and CpG-ODN2006. The role of Syk was evaluated with a specific Syk inhibitor: BAY61–3606. B cell line (Raji) and PBMCs from RA and SLE patients were utilized to assess the detailed molecular mechanism of activated B cells and involvement in the pathology of RA and SLE.

Results: BCR-crosslinking, in conjunction with CD40 and TLR-9 stimulations, efficiently activate B cells and induced various functions such as proliferation and differentiation especially in memory B cells, while specific Syk inhibitors completely abrogated them to background levels. It is noteworthy that BCR-crosslinking markedly induced expression of TNF receptor-associated factor (TRAF)-6 but not TRAF-2,-3 and -5. Additional CD40 and TLR9 stimulations further induced expression of TRAF-6 and phosphorylation of NF-κB, while a Syk inhibitor again significantly inhibited them. Strong phosphorylation of Syk were observed in B cells from RA (n=62) and SLE patients(n=58) compared with healthy donors (n=27). Levels of Syk phosphorylation were higher in SLE patients positive for anti-dsDNA antibodies than those negative for them and also well correlated with the disease activity score such as SLEDAI. On the other hand, Syk phosphorylation were higher in RA patients most positive for anti-CCP antibodies than those negative for them, however, not correlated with the disease activity score such as DAS28, CDAI and SDAI.

Conclusion: Syk-mediated BCR-signaling is prerequisite for optimal induction of TRAF-6, thereby allowing efficient propagation of TLR9-signaling critical for proliferation and differentiation of human memory B cells. Moreover, we suggest that Syk-mediated signaling on B cells is involved in pathological process in autoimmune diseases via producing autoantibody, however, more dominantly in pathology of SLE compared with RA.

1764

B Cells in Early Rheumatoid Arthritis: ZAP-70 More Than SYK Characterize Seropositive Disease. Anna Laura Fedele, Barbara Tolusso, Elisa Gremese, Silvia Laura Bosello, Angela Carbonella, Silvia Canestri and Gianfranco Ferraccioli. Division of Rheumatology, Institute of Rheumatology and Affine Sciences, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: B cells are involved as central players in the pathogenesis of rheumatoid arthritis (RA). Our aim was to define whether a specific B cell subset characterizes the early phases of the disease and is associated with a peculiar RA phenotype.

Methods: 105 ERA patients (81.0% females; mean age 54.7 ± 15.2 years; 73.3% autoantibodies-AAB positive) and 30 healthy controls (HC) were studied. Baseline clinical and immunological characteristics and inflammatory status were assessed. Peripheral blood samples were analyzed by flow cytometry for the distribution of circulating B cell subsets by staining with surface markers CD19, CD45, CD38, CD27 and IgD and intracellular marker ZAP70. Plasma levels of IL-6 and BAFF were also determined with ELISAs. The expression of ZAP-70 and SYK was analized in B cells of 22 ERA patients, using the RealTime ready Assay method.

Results: ERA patients showed a higher percentage of naïve-activate B cells and a lower percentage of memory B cells compared to HC, as confirmed by a higher ratio between Bm2+Bm2'/eBm5+Bm5 (3.4±3.5 in ERA and 1.7±0.9 in controls, *p=0.003*). AAB positive patients showed a higher percentage of CD19+/CD38+CD27+ (4.0±5.0%) compared to AAB negative ones (2.2±2.8%, *p=0.05*). The expression of ZAP-70 in B cells was similar in ERA patients and controls. Dividing patients for the AAB seropositivity, AAB+ ERA patients showed higher percentage of CD19+/ZAP70+ cells compared to AAB- (5.1±6.3 vs 2.5±2.4, *p=0.01*) and also to HC (2.2±1.4, *p=0.05*). In ERA patients, the percentage of ZAP70+ B cells correlated directly with the percentage of CD19+/IgD-CD27- cells (r=0.338, p=0.001), plasma BAFF levels (r=0.26, p=0.01) and with Anti-MCV (r=0.27, p=0.01), ACPA (r=0.23, p=0.02) and RF-IgA (r=0.28, p=0.01) AAB titers. ZAP-70 transcription in B cells of subjects seropositive for autoantibodies was significantly higher than in seronegative ones (3.4 ± 2.8 vs 1.2 ± 1.0 respectively; p=0.04), data confirmed by an higher ratio ZAP70/SYK in AB+ compared to AB- (2.9 ± 1.6 vs 1.2 ± 1.0 respectively; p=0.01). Moreover, the expression of ZAP-70 correlated positively with the expression of SYK (r=0.66, p=0.003) and showed a trend for an association with the espression of ZAP70 protein, evaluated by flow-cytometry (r=0.41, p=0.09).

Conclusion: ZAP-70 positive B cells characterize AAB positive RA and the expression of ZAP-70 might be a possible complementary biomarker of seropositive disease.

Rheumatoid Arthritis Is Associated with Signaling Alterations in Naturally Occurring Autoreactive B-Lymphocytes. Taras Lyubchenko, Ganna Liubchenko, Holly C. Appleberry, Christopher C. Striebich, Karen E. Franklin, Lezlie A. Derber and V. Michael Holers. University of Colorado Denver, Aurora, CO

Background/Purpose: Alterations in B cell immune tolerance are important in the development of autoimmune rheumatoid arthritis (RA). Recent studies in healthy human subjects have identified a subset of potentially autoreactive CD19+CD27-IgD+IgMlow/- late transitional cells that constitute ~2.5% of peripheral blood B cells and have anergic signaling properties. These cells are hyporesponsive to antigen receptor stimulation *in vitro* and have the capacity to produce autoreactive antibodies (Abs). The function and signaling properties of these cells have not been characterized in RA (or any other human autoimmune disorder to date). Early alterations in signaling profile of these cells are of significant value for the prediction of the onset of autoimmunity as pathogenic Abs and other clinical manifestations of RA are detectable only after a prolonged period of autoantibody expansion.

Methods: Phosphorylation of intracellular signaling proteins and intracellular Ca2+ levels in CD19+CD27-IgD+IgMlow/- B cells at baseline and in response to *in vitro* BCR stimulation with polyclonal anti-human Ig were measured by multicolor flow cytometry in the peripheral blood cells from 32 normal healthy control donors and 20 patients with RA. Signaling properties of anergic B cells were compared to other peripheral blood B cell populations both in normal controls and RA patients.

Results: B cell signaling profiles at baseline and in response to anti-BCR stimulation were examined in 32 healthy donors (mean age 35.7; male/female ratio 0.68) and 20 RA patients (mean age 55.9; male/female ratio 0.54) from UC Denver Hospital Rheumatology Clinic. RA patients were recently diagnosed; most were serum RF and/or anti-CCP positive and have not undergone B cell targeted treatments. No significant phenotypic or quantitative differences were found between IgM+ and CD19+CD27-IgD+ IgMlow/- B cell subsets obtained from RA patients and normal controls. CD19+CD27-IgD+IgMlow/- B cells from RA patients demonstrated increased baseline total phospho tyrosine (pTyr) protein phosphorylation as compared to normal controls. In contrast to the control group, in RA patients, CD19+CD27-IgD+IgMlow/- B cells total pTyr and Ca2+ responses to anti-BCR stimulation resembled those of normal non-anergic IgM+ B cells. Comparison of baseline phosphorylation levels of individual signaling molecules between unstimulated RA and control CD19+CD27-IgD+IgMlow/- B cells revealed pronounced increases in Blnk, SHP2 and Jnk in the RA group. Comparison of signaling properties CD19+CD27-IgD+IgMlow/- B cells in RA patients and healthy controls revealed a reversal of pTyr and Ca2+ anergic signaling features in patients, accompanied by phosphorylation decreases of Blnk, Syk, SHP2, CD19.

Conclusion: CD19+CD27-IgD+IgMlow/- B cells under normal conditions showed characteristic signaling inhibition, which was reversed in this cell population in RA patients. A distinct phosphoryation pattern for major signal transduction proteins in CD19+CD27-IgD+IgMlow/- B cells in RA patients as compared to healthy controls at baseline and in response to BCR stimulation was demonstrated.

Synovial Gene Expression and Response to Rituximab: Preliminary Data. Yasser El-Sherbiny[1], Sarah Churchman[1], Frederique Ponchel[1], Paul Emery[2] and Edward M. Vital[1]. [1]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom

Background/Purpose: Quality and duration of response to rituximab in rheumatoid arthritis have not been completely explained. In the synovium, three studies have indicated a relationship between higher plasma cell numbers at baseline and worse, or shorter lasting responses[1,2,3]. In this study we measured synovial expression of genes involved in B-cell biology, cell survival and trafficking and inflammation.

Methods: Synovial arthroscopic biopsies were collected and snap frozen from patients at baseline and 26 weeks after rituximab. Immunohistochemistry was performed for CD3, CD19, CD20cy, CD138 and CD68 using the Menarini universal staining kit and scored for positive cells/mm[2] using digital image analysis. The remainder of the tissue was used for RNA extraction. A 48 gene custom Taqman array was designed, including cell lineage markers (CD19, CD20, CD3, CD138, CD68), genes of the BAFF-APRIL system, immunoglobulins, cytokines, chemokines and adhesion molecules implicated in RA synovitis or cell trafficking, and a reference gene (HPRT). Informative data are available from 32 biopsies before and 23 post treatment.

Results: As previously reported, IHC showed complete B-cell depletion in synovium in 22/25 patients using both CD19 and CD20cy antibodies.

Plasma cells (CD138) were not significantly reduced and post-treatment. CD138 IHC-score was lower in patients with sustained clinical response (>12 months), and these patients also had significantly lower post-treatment rheumatoid factor titre. CD138 IHC score correlated with baseline CXCL13 (R=0.738, p<0.001), and negatively with baseline EGF (R=−0.617, p=0.006). Post-treatment plasma cell IHC-score also correlated significantly with immunoglobulin kappa and heavy constant chain gene expression, but none of the immunoglobulin genes was significantly associated with sustained response.

Comparing EULAR responders and non-responders, there were trends to higher baseline CD20 gene expression in non-responders (p=0.079) and greater reduction in CXCL13 (p=0.066) and MMP (p=0.024) in responders.

Lower expression of ICAM (p=0.021), FGF (p=0.044), CD20 (p=0.055) and p53 (p=0.025) and higher expression of APRIL (p=0.029) at baseline was associated with normalisation of CRP after therapy. Furthermore, these patients also showed a significantly greater reduction in expression of CD4, CD55, CD68, CXCL12, EGF, FGF, ICAM, PECAM, STAT5, TGF-beta, APRIL and BAFF (all p<0.05).

Conclusion: Preliminary results indicate important differences in synovial gene expression in patients with clinical response to rituximab, notably in relation with genes involved in cell trafficking and survival.These results may help elucidating reasons for, and consequences of plasma cell survival.

Circulating Plasmablasts As a Source of Anti-Citrullinated Protein Antibodies in Patients with Rheumatoid Arthritis. Priscilla Kerkman, Ellen I.H. van der Voort, Leendert A. Trouw, Tom W.J. Huizinga, René E.M. Toes and Hans Ulrich Scherer. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Anti citrullinated protein antibodies (ACPA) are highly specific for rheumatoid arthritis (RA) and predict disease onset and severity. Accumulating evidence indicates that ACPA could play an important role in RA pathogenesis by contributing to inflammation and joint destruction. So far, however, little is known on the characteristics of ACPA producing B cells. In this study, we set out to define ACPA producing B cells in more detail in order to allow for specific targeting of these cells.

Methods: Peripheral blood CD19 positive B cells from patients with ACPA positive RA (n=30) were isolated using magnetic beads. In addition, B cell subsets were purified by FACS-sorting based on the expression of surface markers CD19, CD20 and CD27. Isolated B cell populations were either cultured in vitro in the presence of anti-IgM, IL-21 and BAFF on a layer of irradiated CD40L transfected fibroblasts, or left in medium without additional stimulation. Following culture for 6 and/or 13 days, supernatants were assessed for the presence of ACPA-IgG and non-specific total IgG by ELISA.

Results: Following stimulation, ACPA could be detected in up to 100% of culture wells. Both the average ACPA titer in the wells as well as the percentage of positive wells correlated with measures of disease activity. No reactivity was observed against the arginine containing control antigen. No ACPA production was detectable by B cells isolated from ACPA negative RA patients or healthy controls. Of interest, ACPA were also produced spontaneously ex-vivo without stimulation. Active ACPA production was detectable for extended periods of time (up to 4 weeks). FACS-sorting experiments comparing isolated B cell subsets indicated that spontaneous ACPA production resides, for a large part, in the circulating plasmablast population. Spontaneous ACPA production was still observed after depletion of the CD20 positive B cell population.

Conclusion: We show that ACPA producing plasmablasts circulate in the peripheral blood of ACPA positive RA patients in a disease activity dependent manner. Ex vivo, these plasmablasts were not short-lived and were not targeted by an anti-CD20 antibody. These observations enhance our understanding of ACPA producing B cells and could be relevant for future targeted therapies.

The Absolute Concentration of Anti Citrullinated Protein Antibodies in Serum and Synovial Fluid in Relation to Total Immunoglobulin-Concentrations. Annemiek Willemze, Jing Shi, Marlies Mulder, Gerrie Stoeken-Rijsbergen, Tom W. J. Huizinga, René E. M. Toes and Leendert A. Trouw. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The presence of anti-citrullinated protein antibodies (ACPA) is one of the most predictive factors for the development of rheumatoid arthritis (RA). Nonetheless, relatively little information is present on the absolute concentration ACPA in serum and synovial fluid in relation to total Ig-concentrations. Here, we estimated the relatively abundance of ACPA immunoglobulins in serum and synovial fluid using a quantitative approach.

Methods: ACPA from synovial fluid and serum samples were purified using high affinity strep columns coupled with biotinylated Cyclic Citrullinated Peptide (CCP). A control column (CCP-arginine) was used to guarantee the specificity of the antibody. Total IgG, IgA, IgM and anti-CCP isotype reactivity were measured by Enzyme-linked immunosorbent assay (ELISA).

Results: ACPA were successfully isolated as substantial amounts of antibodies were eluted from sera of ACPA positive patients and neglectable amounts of antibodies were eluted from sera of ACPA negative patients. In serum samples and synovial fluid of ACPA-positive RA patients with high ACPA-levels at least one percent of total IgG was IgG ACPA. Furthermore IgM-ACPA was most abundant in synovial fluid samples as compared to serum samples (with the highest enrichment in the range of 1 IgM ACPA for every 33 total IgM antibodies). IgA, IgG and IgM ACPA were more abundantly present in synovial fluid as compared to paired serum and plasma samples.

Conclusion: IgG-ACPA is present in high concentrations in synovial fluid and serum, as at least 1 in every 100 antibodies present are ACPA in patients with high ACPA-levels. Strikingly, IgM-ACPA is abundantly present in synovial fluid. Given the short half life of IgM, these data indicate the presence of a continuous ongoing autoimmune response in the synovial compartment that is hallmarked by the activation of IgM-ACPA producing B cells.

1769

Affinity Purification and Characterisation of Anti-CCP Antibodies From Plasma and Synovial Fluids of Patients with Rheumatoid Arthritis. Elena Ossipova[1], Catia Cerqueira[1], Evan Reed[1], Nastya Kharlamova[1], Lena Israelsson[1], Rikard Holmdahl[2], Anca Irinel Catrina[1], Vivianne Malmström[3], Yngve Sommarin[4], Lars Klareskog[1], Per Johan Jakobsson[1] and Karin Lundberg[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Euro-Diagnostica AB, Malmö, Sweden

Background/Purpose: Autoimmunity in rheumatoid arthritis (RA) is characterized by autoantibodies to citrullinated proteins/peptides (ACPA). These antibodies (present in 60–70% of patients) antedate clinical onset and associate with an erosive disease course, suggesting a direct pathogenic involvement in disease initiation and progression. With this study, we aimed to utilise plasma and synovial fluids (SF) from patients with RA, for the purification of ACPAs reactive with the peptides used in the CCP2 ELISA assay. Furthermore, to characterise their frequency in plasma and SF as well as reactivity with different autoantigen-derived peptides.

Methods: Plasma (n=16) and SF (n=26) samples were collected, with informed consent and ethical approval, from RA patients with anti-CCP2 IgG levels above 300AU/ml. Total IgG was isolated on Protein G columns, and subsequently applied to CCP2 affinity columns, kindly donated by EuroDiagnostica. Flow through and eluate fractions were assayed for antibody responses using the CCP2 ELISA, as well as in-house ELISAs, for analysis of reactivity to citrullinated peptides from a-enolase, vimentin, fibrinogen and collagen type II.

Results: Pure and intact anti-CCP IgG antibodies were efficiently isolated from plasma and SF samples. No citrulline-reactivity was detected in the CCP2 column flow through fractions. Purified anti-CCP IgG from different patients showed differences in binding to CCP2 ELISA plates (assayed at the same antibody concentration), still a majority showed reactivity with the four citrullinated autoantigen-derived peptides. Purified anti-CCP IgG also bound citrullinated, but not uncitrullinated, human fibrinogen, by Western blot, while the corresponding CCP2 column flow through IgG bound neither citrullinated nor uncitrullinated fibrinogen. A median of 1.5% of the IgG pool in plasma and 2.2% in SF, with four SF samples reaching 6%, were CCP2-reactive.

Conclusion: Here we demonstrate an efficient and robust method to isolate anti-CCP IgG from plasma and SF. Furthermore, that ACPAs reactive with epitopes on different citrullinated autoantigens (i.e. a-enolase, vimentin, fibrinogen and collagen type II), which are largely non-cross-reactive, are captured by the CCP2 column. These purified anti-CCP IgG molecules will provide us with new opportunities to investigate functional and structural aspects of human anti-citrullinated protein/peptide antibodies, including pathogenicity.

1770

Recognition of Citrullinated and Carbamylated Proteins by Human Antibodies: Specificity, Cross-Reactivity and the "AMC-Senshu" Method. Jing Shi[1], George Janssen[1], Peter van Veelen[1], Janwouter Drijfhout[1], Antony Cerami[1], Tom Huizinga[2], Leendert A. Trouw[3] and René E.M. Toes[3]. [1]LUMC, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Leiden University Medical Centre, Leiden, Netherlands

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) play an important role in the diagnosis and prognosis of Rheumatoid Arthritis (RA). The Anti-Modified Citrulline (AMC) ('Senshu') method is the most frequently used method to detect citrullinated proteins. Recently, we identified antibodies against carbamylated proteins (anti-CarP) and wished to know whether the 'AMC-Senshu' method could discriminate citrullinated and carbamylated proteins. More importantly, we also wished to know to what degree human autoantibodies can discriminate between these two modifications.

Methods: We analyzed the reactivity of the 'AMC-Senshu' method and selected sera of RA patients on western blots targeting citrullinated, carbamylated or non-modified Fetal Calf Serum (FCS) and Fibrinogen (Fib). The levels of ACPA and anti-CarP antibodies in sera before and after ACPA depletion were compared and potential cross-reactivity analysed.

Results: The 'AMC-Senshu' method strongly stained both citrullinated and carbamylated FCS and as well as citrullinated and carbamylated Fib but not the non-modified counterparts. This indicates that this method can not discriminate between these two modifications. Using patient sera we demonstrate that autoantibodies present in human serum can be specific for either carbamylated Fib or citrullinated Fib. In addition many RA patients can be double positive for both reactivities. To analyze if these patients are double positive because of cross-reactivity or because they contain two antibody families we used ACPA depletion columns to deplete all ACPA followed by analysis of ACPA levels and anti-CarP levels. After ACPA depletion, more than 98% of ACPA in the sera were depleted while more than half of anti-CarP antibodies remained in the flow through in 5 out of 7 samples tested. These data indicate that part, but not all anti-CarP antibodies are cross-reactive to citrullinated epitopes.

Conclusion: In conclusion, the 'AMC-Senshu' method identifies both citrullinated and carbamylated proteins. In contrast human autoantibodies can discriminate between these two modifications indicating the presence of two separate families of autoantibodies, one directed against citrullinated protein and one directed against carbamylated proteins with a limited degree of cross-reactivity.

1771

Anti Carbamylated Protein Antibodies (Anti-CarP) Are Present in Arthralgia Patients and Predict the Development of Rheumatoid Arthritis. Jing Shi[1], Lotte van de Stadt[2], Nivine Levarht[1], T.W.J. Huizinga[3], R. E. M. Toes[3], Leendert A. Trouw[4] and Dirkjan van Schaardenburg[2]. [1]LUMC, Leiden, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Leiden University Medical Centre, Leiden, Netherlands

Background/Purpose: Recently, we discovered a new autoantibody system in rheumatoid arthritis (RA): anti carbamylated protein antibodies (anti-CarP). These antibodies have additional prognostic value in predicting joint destruction when compared to anti-citrullinated protein antibodies (ACPA). However, it is not yet known whether anti-CarP antibodies are present before the diagnosis of RA and whether they have predictive value for the development of RA. Therefore we studied whether anti-CarP antibodies are present in arthralgia patients and whether their presence associates with the development of RA.

Methods: Sera of 340 arthralgia patients without clinical signs of arthritis and 32 healthy controls were measured for the presence of anti-CarP IgG antibodies. One hundred eleven arthralgia patients (33%) were IgM-rheumatoid factor (IgM-RF) positive/anti-cyclic citrullinated peptide 2 (aCCP2) negative and 229 (67%) were aCCP2 positive. Patients were followed for the development of RA (2010 criteria). The median follow up time was 36 months. Cox regression analysis was performed to compare the risk of developing RA between Anti-CarP positive and negative arthralgia patients in follow up time.

Results: The arthralgia cohort consisted of 340 IgM-RF and/or aCCP positive patients. Anti-CarP antibodies were present in sera of 113 (39%) of the tested patients. A total of 120 patients developed RA after a median (IQR) of 12 (6–24) months. The presence of anti-CarP antibodies was associated with the development of RA in the whole arthralgia cohort even after correction for RF and aCCP2 status (HR: 1.56; 95%CI: 1.06–2.29; p = 0.023), as well as in the aCCP2 positive subgroup (OR: 2.231; 95%CI: 1.31–3.79; p = 0.003).

Conclusion: Anti-CarP antibodies were present in arthralgia patients and their presence predicted the development of RA independent of aCCP2 antibodies.

Expansion of Autoreactive Unresponsive CD21$^{-/\text{Low}}$ B Cells in Sjögren's Syndrome Associated Lymphoproliferation. David Saadoun[1], Benjamin Terrier Sr.[2], J. Bannock Sr.[3], T. Vazquez Sr.[4], C. Massad Sr.[3], Florence Joly Sr.[5], Michelle Rosenzwajg Sr.[6], Damien Sene Sr.[7], Philippe Benech Sr.[5], David Klatzmann Sr.[6], Eric Meffre Sr.[3] and Patrice Cacoub Sr.[8]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Cochin Hospital, Paris, France, [3]Yale University School of Medicine, New Haven, CT, [4]CNRS UMR 7211 and INSERM U959, Paris, France, [5]Prediguard, Marseille, France, [6]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Paris, France, [7]Groupe Hospitalier Pitié-Salpétrière, Université Pierre et Marie Curie, Paris, France, [8]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Primary Sjögren's syndrome (pSS) is the autoimmune disease associated with the higher risk of developing non-Hodgkin lymphoma.

Objective: To determine the nature of B cells driving lymphoproliferation in pSS.

Methods: B cell subsets and function were analyzed in peripheral blood from 66 adult patients with pSS [including 15 patients with B-cell lymphoproliferative disorder (LPD)] and 30 healthy donors, using flow cytometry, calcium mobilization, and gene array analysis. We tested by ELISA the reactivity of recombinant antibodies isolated from single B cells from pSS-LPD.

Results: We report here the expansion of an unusual CD21$^{-/\text{low}}$ B-cell population which correlates with lymphoproliferation in pSS patients. A majority of CD21$^{-/\text{low}}$ B cells from pSS patients expressed autoreactive antibodies, which recognized nuclear and cytoplasmic structures. These B cells belonged to the memory compartment because their immunoglobulin genes were mutated. They were unable to induce calcium flux, become activated, or proliferate in response to B-cell receptor and/or CD40 triggering, suggesting that these autoreactive B cells may be anergic. However, CD21$^{-/\text{low}}$ B cells from pSS remained responsive to TLR9 stimulation. Gene array analyses of CD21$^{-/\text{low}}$ B cells revealed molecules specifically expressed in these B cells and that are likely to induce their unresponsive stage.

Conclusion: pSS patients who display high frequencies of autoreactive and unresponsive CD21$^{-/\text{low}}$ B cells are susceptible for developing lymphoproliferation. These cells remain in peripheral blood controlled by functional anergy instead of being eliminated, and chronic antigenic stimulation through TLR stimulation may create a favorable environment for breaking tolerance and activating these cells.

Hyperammaglobulinemia in Primary Sjögren's Syndrome Is Induced by Triggering of TLR7 and 9. Susanna Brauner[1], Marika Kvarnstrom[1], Gunnel Nordmark[2] and Marie Wahren-Herlenius[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology, Uppsala, Sweden

Background/Purpose: Multiple B cell aberrances have been linked to primary Sjögren's syndrome (pSS), including autoantibody production and a skewed B cell differentiation. Further, approximately 50% of all patients with pSS display hypergammaglobulinemia.

Chloroquine-derived antimalarial drugs, commonly used in treatment of pSS, are thought to mediate their therapeutic effect by inhibiting the endosome, and thereby affecting TLR7 and 9 signaling. However, so far little is known about why chloroquines have a beneficial effect.

Methods: Freshly prepared PBMCs from untreated and chloroquine-treated pSS patients and healthy controls were sorted by flow cytometry. Naïve IgD+ B cells were cultured eight days with class-switch inducing agents; anti-CD40, BAFF, Imiquimod (TLR7) and CpG (TLR9), all supplemented with IL-10. Culture supernatants were analyzed for IgM and IgG concentrations and cells were phenotyped by flow cytometry. Microarray-based mRNA expression analysis was performed on PBMC from untreated pSS patients and controls.

Results: Upon induction of class-switch, B cells will secrete IgM and subsequently IgG and some will develop further into plasma cells expressing CD138.

When stimulating with TLR7 and 9 agonists significantly higher titers of IgM and IgG were observed in supernatants of cells from pSS patients compared to controls. Further, a significantly increased proportion of CD138+ plasmablasts were observed in the cultures established from pSS patients compared to controls. No significant differences were observed when stimulating with other class-switch inducing agents (CD40, BAFF). To further support our findings an mRNA expression analysis of unmanipulated PBMCs from pSS patients (n=14) and controls (n=18) was performed. Key genes in the endosomal TLR pathways, including TLR7 and 9, TNFAIP3 and IRF5, were significantly up regulated in pSS patients. However, the signaling pathways of CD40 and BAFF were unaffected.

Class-switch was also induced in B cells from patients treated with antimalarial drugs. Interestingly, lower levels of IgG and IgM were seen in chloroquine treated patients, compared to untreated pSS patients. In concordance, fewer plasmablasts were detected in the choloroquine-treated patients.

Conclusion: More than 50% of patients with primary Sjögren's syndrome display hypergammaglobulinemia. We show here that B cell class switch and IgG production is increased in pSS patients after endosomal TLR triggering, and that this can be inhibited *in vivo* by treatment with antimalarials. Our data confirm the importance of TLR7 and 9 pathways in driving the disease and clinical phenotype of pSS.

Identification of Target Antigens of Anti-Endothelial Cell Antibodies in Patients with ANCA-Associated Systemic Vasculitis: A Proteomic Approach. Alexis Régent[1], Hanadi Dib[2], Guillaume Bussone[1], Mathieu C. Tamby[1], Nicolas Tamas[2], Christian Federici[3], Cédric Broussard[3], Loic Guillevin[4] and Luc Mouthon Sr.[1]. [1]Hopital Cochin, Paris, France, [2]Université Paris Descartes, Paris, France, [3]Inserm U1016, Institut Cochin, CNRS UMR 8104, Paris, France, [4]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France

Background/Purpose: Anti-endothelial cell antibodies (AECA) are frequently detected in anti-neutrophil cytoplasm antibodies (ANCA)-associated systemic vasculitis (AAV) and are considered to play pathological roles but their antigenic specificities are still unknown. We used a proteomic approach combining two-dimensional electrophoresis and immunoblotting to identify the target antigens of AECA in patients with ANCA-associated vasculitis.

Methods: Sera from 30 ANCA-associated vasculitis patients (12 with Granulomatosis with polyangeitis (GPA), 9 with microscopic polyangeitis (MPA), 9 with Churg Strauss syndrome (CSS)), tested in pools of 3 sera, were compared to a sera pool from 12 healthy controls (HC). Serum IgG reactivity was analyzed by use of a 2-D electrophoresis and immunoblotting technique with normal human umbilical vein endothelial cell (HUVEC) antigens.

Results: Serum IgG in the HC sera pool recognized 85 protein spots and serum IgG from patients with AAV recognized 134±65 different protein spots. We focused on protein recognized by at least 3/4 pools of patients with GPA and 2/3 pools of patients with MPA and CSS and not by HC and identified 20, 7 and 8 proteins, respectively. In addition, among the 330 spots recognized by at least one pool of patients with AAV, ten different spots were recognized by at least 6/10 pools. Among identified proteins, IgG reactivity was detected against alpha-enolase, lamin A/C and protein disulfide-isomerase A3. Interestingly, Ingenuity Pathway Analysis revealed that most of these antigens interact with TGF-β, immunoglobins and inflammatory complexes such as Jun and MAPK.

Conclusion: AECA detected in patients with AAV recognize cellular targets playing key roles in cell biology. Target antigens interact with protein and complexes known to play a crucial role in AAV pathophysiology.

The Phosphoinositide 3-Kinase Pathway Regulates Fibroblast-Like Synoviocyte Invasion. Beatrix Bartok[1], Deepa Hammaker[2] and Gary S. Firestein[3]. [1]UCSD, La Jolla, CA, [2]Univ of California San Diego, La Jolla, CA, [3]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Cartilage destruction mediated by invasive fibroblast-like synoviocytes (FLS) plays a central role in pathogenesis of RA. Increased cell migration and degradation of extracellular matrix are fundamental to these processes. The Class I phosphoinositide 3-kinases (PI3K) control cell survival, proliferation and migration, which might be involved with cartilage damage in RA. PI3Kdelta isoform expression was recently identified as a key regulator of FLS growth and survival, suggesting that it could contribute to synoviocyte aggressive behavior. Therefore, we assessed the role of PI3Kdelta in synoviocyte invasion and matrix degradation using isoform selective PI3K inhibitors.

Methods: FLS were cultured in Matrigel coated transwells. PI3K inhibitors or vehicle were added to the upper chamber and PDGF was used as a chemoattractant in the lower chamber. The invading cells were quantified by staining the filters with 1% crystal violet. F-actin was visualized with Rhodamin phalloidin and analyzed with fluorescent microscopy. Rac1 activation was measured using PAK1/PBD GST pull down and quantified by Western blot analysis. PI3K inhibitors included: pan (GDC-0941), PI3Kalpha (A66), PI3Kbeta (TGX-221), PI3Kgamma (AS-252424), PI3Kdelta (INK007 and CAL-101) and PI3K-delta/gamma (INK055 and IPI-145).

Results: PDGF-directed invasion was completely inhibited by the pan PI3K inhibitor (1 uM). To define the role of the individual isoforms, we tested the effect of the isoform selective PI3K inhibitors. PI3Kdelta inhibition (INK007) significantly decreased the number of invading cells, with 60±5% inhibition at 1 uM (p< 0.04). Similar results were observed with two other inhibitors with distinct chemical structures (CAL-101 and INK055). The PI3Kalpha inhibitor decreased invasion by 40±5% while PI3Kbeta and PI3Kgamma inhibitors had no effect. Phalloidin staining was then used to visualize FLS actin rearrangement in response to PDGF with or without PI3K inhibitors. PI3Kdelta inhibition by INK007, CAL-101 and IPI-145 decreased lamellipodia formation by 50±6% (p<0.05). Similar inhibition was seen with the pan PI3K inhibitor, while the selective inhibitors of PI3Kalpha, PI3Kbeta or PI3Kgamma had no effect. We then hypothesized that PI3Kdelta might modulate activation of Rho GTPases in synoviocytes, which regulate actin organization. PI3Kdelta inhibition with INK007 had no effect on baseline Rac1 activation but blocked activation in response to PDGF by 95±6% (p<0.03). Similar findings were observed with the pan PI3K inhibitor, while PI3Kalpha inhibition had no significant effect.

Conclusion: PI3Kdelta is a major regulator of FLS migration and invasion and functions by inhibiting Rac1 activation and modulating F actin cytoskeleton rearrangement. These observations, together with previous findings that PI3Kdelta regulates FLS growth and survival, suggest that PI3Kdelta inhibition could be chondroprotective in RA by modulating synoviocyte growth, migration and invasion.

1776

Anti-SSA/Ro Mediated Injury to the Endothelium Via Urokinase Plasminogen Activator Receptor/Tgfbeta Activation: Implications in the Pathogenesis of Congenital Heart Block. Paraskevi Briasouli[1], Mark Halushka[2], Jill P. Buyon[3] and Robert M. Clancy[4]. [1]New York University Medical Center, New York, NY, [2]John Hopkins PAthology, Baltimore, MD, [3]NYU School of Medicine, New York, NY, [4]New York University School of Medicine, New York, NY

Background/Purpose: One mechanism by which anti-Ro antibodies are linked to the pathogenesis of (cardiac-NL) neonatal lupus is the increased urokinase plasminogen activator (uPA)/urokinase-type plasminogen activator receptor (uPAR)-dependent plasminogen activation and subsequent triggering of TGFbeta signaling. Immunologic staining of affected hearts reveals cell specific expression of uPA on endothelial cells and infiltrating macrophages in areas of inflammation and fibrosis. Since plasminogen/plasmin-dependent TGFbeta signaling has a documented role in endothelial cell survival, this study evaluated the association of anti-Ro and an injury pathway in the fate of the cardiac vasculature.

Methods: Adhesion, tube formation, TGFbeta activation assays were used to assess the effect of antibodies on endothelial cell function. Immunohistology of cardiac-NL autopsies were conducted to evaluate diseased vasculature.

Results: Human IgGs were used from a healthy control (nl-IgG) and a mother whose serum contained reactivity to all the components of the SSA/Ro-SSB/La complex and whose child had cardiac-NL (CHB-IgG). Adherence was enumerated (colorimetric dye) after vascular endothelial cells (CD3 cell line) were incubated with CHB-IgG (0.03 mg/ml, 2 hr) or nl-IgG, with or without plasmin inhibitor aprotinin (10 μg/ml) or TGFbeta inhibitor SB5543 (10μM). CHB-IgG coincubation significantly reduced EC adhesion on ECM (collagen-coated surfaces) compared with nl-IgG (0.38 ± 0.1 vs 0.89 ± 0.09 respectively (adhesion units, scale 0–3), p=0.02, n=3). The CHB-IgG decreased adhesion was reversed in the presence of either aprotinin or SB5543. Further evidence to implicate a plasmin/TGFbeta axis was provided by the observation that ECs treated with CHB-IgG, but not nl-IgG, increased luciferase activation of a TGFbeta reporter cell line (TMLC) (432 ± 20 vs 138 ± 12 RLU respectively, p = 0.003; n = 3), an effect abrogated by cotreatment with aprotinin or SB5543. Vessel formation was evaluated by visual inspection of networks after ECs were plated on matrigel (8 hr). Exposure of ECs to CHB-IgG but not nl-IgG markedly attenuated blood vessel formation *in vitro* which again was reversed by cotreatments with aprotinin and SB5543 as observed in the adhesion studies (n=4). As further proof of concept, during migration of ECs on collagen-coated surfaces, confocal microscopy revealed colocalization of uPAR with anti-Ro60 (but not anti-Ro52 or anti-RNP) at the tips of migrating cells. Evaluation *in vivo*, showed that in a fetal CHB heart, protein expression of CD31 (a surface marker of endothelium lining blood vessels) was at a substantially lower level in septal regions with involved inflammation when compared with a healthy zone of atrial tissue.

Conclusion: These results suggest that anti-SSA/Ro interference during the remodeling events occurring in angiogenesis results in increased uPAR-dependent uPA activity with generation of active TGFbeta. This then leads to the attenuation of adhesion and new vessel development and ultimately a loss of vasculature in the septal region of affected hearts.

1777

The Bioenergetic Role of HIF-1 and HIF-2 During Angiogenesis of Human Microvascular Endothelial Cells. Martin Hahne, Cindy Strehl, Manuela Jakstadt, Paula Hoff, Timo Gaber, Gerd R. Burmester and Frank Buttgereit. Charité University Medicine, Berlin, Germany

Background/Purpose: Hypoxia and angiogenesis are features of inflamed and injured tissues. The transcription factors Hypoxia inducible factor (HIF)-1 and (HIF)-2 control cellular metabolic response to decreased oxygen tension thereby promoting angiogenesis with implications on the pathogenesis of rheumatoid arthritis (RA). Our studies aims to knockdown HIF-1α and HIF-2α in human microvascular endothelial cells (HMEC), respectively, in order to investigate resulting effects on angiogenesis and bioenergetics under hypoxic versus normoxic conditions.

Methods: Specific knockdown of HIF-1α or HIF-2α was achieved using lentiviral-based shRNA technology. Angiogenesis of transduced HMECs was studied by investigating both tubuli and node formation under hypoxia (<1% O_2) versus normoxia (~18% O_2). Expression of hypoxia driven genes involved in metabolic response to hypoxia *(GAPDH, PGK, GLUT1)* was quantified by realtime RT-PCR. Bioenergetic state of the cells was investigated via ADP/ATP measurements.

Results: Knockdown of HIF-1α led to a loss in the hypoxia induced node (p=0.007) and tubuli formation (p=0.09). HIF-2α knockdown also resulted in a significant loss of hypoxia induced formation of tubuli (p=0.04). Focussing on bioenergetics, we found hypoxia to significantly induce *PGK* (p=0.0004) and *GAPDH* (p=0.049) in control cells. Interestingly, HIF-1α knockdown – but not HIF-2α knockdown – resulted in a loss of hypoxic induction of *PGK*expression.

In both HIF-1α (p=0.01) and HIF-2α (p=0.13) knockdown cells, hypoxia was still capable of inducing *GAPDH*, but the effect was much less pronounced in HIF-1α knockdown cells.

Hypoxia did not up-regulate *GLUT1*, neither in control nor in HIF-1α and HIF-2α knockdown cells, respectively.

We also found the ADP/ATP ratio to be similar in control and HIF-1α or HIF-2α knockdown cells under normoxia. Under hypoxic conditions, however, HIF-1α knockdown cells showed a significantly enhanced ADP/ATP ratio (p<0.05) – indicating that less ATP is available – compared to control cells. This was not the case in HIF-2α knockdown cells.

Conclusion: HIF-1α and HIF-2α are both key regulators of angiogenesis. However, they do differ in their ability to regulate cellular energy metabolism. This leads us to conclude that HIF-2α does directly influence angiogenesis via regulating the synthesis of proangiogenic factors (1), whereas HIF-1α affects angiogenesis via effects on cellular energy metabolism.

These findings provide new insights into regulation of angiogenesis in inflamed (hypoxic) tissues and are, therefore, considered to be of clinical relevance in RA.

Adenosine A2A Receptor (A_{2A}R) Activation Stimulates Increased Expression of Collagen-1 and Collagen-3 by Different Signaling Pathways in Normal Human Dermal Fibroblasts. Miguel Perez Aso[1] and Bruce N. Cronstein[2]. [1]NYU Univ Medical Center, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Pathological fibrosis in the skin and other organs is the hallmark of scleroderma and other fibrosing diseases. Adenosine, acting at A_{2A}R, plays a critical role in wound healing and fibrosis of the skin and previous studies have demonstrated that blockade or deletion of A_{2A} receptors prevents dermal fibrosis in response to bleomycin, a murine model of scleroderma. Moreover, A_{2A}R blockade enhances the strength of scars by, in part, diminishing the collagen 3 (Col3) content of the scar relative to Col1 content. Here we determined whether expression of Collagen-1 (Col1) and Col3 proceed by different signaling pathways.

Methods: Col1 and Col3 expression were determined by Western-Blot analysis of normal human dermal fibroblasts (NHDF).

Results: Surprisingly the concentrations of the A_{2A}R agonist CGS21680 required to increase Col1 expression were significantly lower than those required to increase Col3 (0.1μM: $147\pm6\%$ for Col1 [p<0.01, n=23] vs 1μM: $155\pm16\%$ for Col3, [p<0.01, n=18] although increases in both were completely blocked by the A_{2A}R-antagonist SCH58261 (0.1μM). The selective Protein kinase A (PKA) activator 8-Cl-cAMP markedly increased Col1 expression (0.1μM: $280\pm74\%$ [p<0.01, n=3), but inhibited Col3 expression by as much as $68\pm11\%$ (p<0.01, n=4). PKA inhibition by PKAi prevented the CGS21680-stimulated increase in Col1 but elicited an increase of Col3 at lower concentrations than in the absence of PKAi (0.1μM, $110\pm10\%$ versus $182\pm30\%$ [p<0.05, n=4). In contrast, stimulation with the specific Epac activator 8-CPT-2'-O-Me-cAMP did not affect Col1, but increased Col3 production by $362\pm85\%$ (p<0.05, n=3). Inhibition of AKT, erk, p38 and JNK with LY294002 (10μM), U0126 (1μM), SB203580 (1μM) and SP600125 (20μM), respectively, demonstrated that increased expression of Col1 and Col3 depend on AKT and p38. However, CGS21680 0.1μM increased Col3 only upon ERK or JNK blockade, an effect similar to PKA inhibition.

Conclusion: Our work strongly suggests that at nanomolar concentrations of CGS21680 PKA activity prevails over Epac, thereby activating Col1 expression and inhibiting Col3 but in the mmolar range, the PKA/ERK/JNK inhibition of Col3 is overcome by activation of Epac/p38 and Pi3K/AKT. These observations may explain the dramatic decrease of the Col1/Col3 ratio in hypertrophic and immature scars, where adenosine is present in μmolar ranges, when compared to normal skin, where adenosine concentration varies from 30 to 300nM.

1779

The Loss of Syndecan-4 Aggravates Inflammatory Colitis in Mice.

Athanasios Stratis[1], Dominik Bettenworth[1], Mareike Fröhling[1], Peter Paruzel[1], Adelheid Korb-Pap[1], Corinna Wehmeyer[1], Berno Dankbar[1], Frank Echtermeyer[2], Andreas Lügering[1] and Thomas Pap[1]. [1]University Hospital Muenster, Muenster, Germany, [2]University Hospital Hannover, Hanover, Germany

Background/Purpose: Syndecan-4 (sdc4) is a transmembrane heparan sulfate proteoglycan. Several studies have implicated sdc4 in cell-matrix adhesion, cell migration, differentiation, proliferation and play an important role during the inflammation in rheumatoid arthritis. Modulation of inflammatory signals by sdc4 may occur either through mere binding of cytokines, in which case sdc4 acts as decoy receptor or through initiation of sdc-dependent signalling following sdc4 complex formation. While arthritic cartilage damage is decreased in sdc4-deficient mice most likely due to reduced sdc4 signaling, osteopontin- mediated liver damage has been shown to be increased in these mice due to the lack of scd4 decoy receptor function. Based on this dual effects of sdc4, we investigate if the loss of sdc4 changes the natural course of murine experimental colitis.

Methods: Colitis was induced in sdc4$^{-/-}$ mice and in C57BL/6 WT mice by DSS. The course of colitis was monitored by weight loss as well as assessment of colon length and blinded histological scoring of colonic changes at the end of the experiment. In addition, sdc4$^{-/-}$ and C57BL/6 WT mice were orally gavaged with 5×10^8 colony-forming units (CFU) of *Citrobacter rodentium (C. rodentium)*. Fecal excretion of *C. rodentium* and changes of body weight were monitored. At day 21 post infection, inflammatory changes of the colon were evaluated histologically.

Results: Beginning from day 5 after start of DSS-administration, sdc4$^{-/-}$ mice lost dramatically more body weight compared to WT animals (day 8: 24.8%±1.9 vs. 9.2%±3.1; p=0.008). In accordance with the increased loss of body weight, the colon length of sdc4$^{-/-}$ mice was significantly shortened (63.3 mm±2.4 vs. 74.8±2.3; p=0.01) and the histological damage according to the Dieleman-Score was markedly aggravated (16AU±3.7 vs. 3.4AU±0.2; p=0.016). At day 19 post infection, the fecal excretion of *C. rodentium* in sdc4$^{-/-}$ was prolonged compared to WT animals (2.5×10^5±6.8×10^3 vs. 9.6×10^3 ±6.5×102; p=0.01). Histological damage of colonic mucosa, reflected by lengthening of crypts, was increased in Sdc4$^{-/-}$ mice (14.3AU±1.3 vs. 10.2AU±0.9; p=0.03).

Conclusion: Our results show that like in inflammatory liver damage, sdc4 seems to have protective effects in intestinal inflammation. Future studies are needed to analyze the underlying mechanisms and to determine if these effects are due to a decoy receptor function of sdc4 or whether sdc4 complex formation and signalling is involved.

1780

Association Between Chondrocyte Hypertrophy and Angiogenesis of Cartilage in Osteoarthritis

Laurence Pesesse[1], Christelle Sanchez[2], Jean-Pierre Delcour[3], Caroline Baudouin[4], Philippe Msika[4] and Yves Henrotin[5]. [1]University of Liège, Liège, Belgium, [2]Bone and Cartilage Research Unit, Liege, Belgium, [3]Centre hospitalier du Bois de l'Abbaye, Seraing, Belgium, [4]Laboratoires Expanscience, Epernon, France, [5]Univ of Liege/Pathology Inst, Liege, Belgium

Background/Purpose: Chondrocyte hypertrophy is commonly observed in OA cartilage, associated with matrix mineralization and vascularization. In our previous work, we demonstrated that hypertrophic differentiation of chondrocytes is initiated by serum-enriched medium in long-term culture in alginate beads suggesting a role played by blood supply in the hypertrophic differentiation of chondrocytes in OA.

As hypertrophic differentiation of chondrocytes is an important feature of osteoarthritis (OA), we developed a model of culture in order to study the functional consequences of hypertrophic OA chondrocytes. The aim of this study was to investigate the link between hypertrophic differentiation of chondrocytes and angiogenesis in OA in order to demonstrate that OA hypertrophic chondrocytes expressed an angiogenic phenotype and that some specific factors could be implicated in both processes.

Methods: Articular OA chondrocytes were cultured for 28 days in alginate beads in medium containing 2% Ultroser G (UG) or 10% Fetal Bovine Serum (FBS). DNA was quantified by fluorimetry. The expression of hypertrophy markers genes type X collagen (col10a1), runt-related factor 2 (runx2) and matrix metalloprotease 13 (MMP13) and a screening of angiogenic factors was evaluated by RT-PCR. Alkaline phosphatase (AP) activity and 5'phosphodiesterase activity of NTPPPH were quantified by specific enzymatic methods. Non-hypertrophic and hypertrophic human OA chondrocyte conditioned media were used to perform functional tests with huvecs: migration, invasion and wound healing assays. Data were analyzed by one-way ANOVA.

Results: In alginate beads, chondrocytes cultivated in serum-supplemented medium underwent a hypertrophic differentiation process characterized by significant increased expression of hypertrophic markers and mineralization enzymes (col10a1: p<0.05; runx2: p<0.01; MMP13: p<0.001; PA: p<0.001; NTPPPH: p<0.001). Functional angiogenesis assays showed that chondrocyte hypertrophy positively influenced migration (p<0.0001), invasion (p<0.0001) and wound healing (p=0.0005) of endothelial cells. Among the screened angiogenic factors, bone sialoprotein (BSP) was highly upregulated in hypertrophic chondrocytes (p<0.05).

Conclusion: Our culture model allowed to mimic hypertrophic differentiation of chondrocytes and to investigate the relationship between this process and functional invasion and migration of endothelial cells, two functional steps in the process of angiogenesis. The results obtained in this study highlighted BSP as a specific factor that could be implicated in hypertrophic differentiation of chondrocytes and cartilage angiogenesis.

1781

Functional Analysis of the Primary Cilium in Rheumatoid Arthritis Synovial Fibroblasts.

Kerstin Klein[1], Beat A. Michel[1], Alexander Vogetseder[2], Renate Gay[1], Steffen Gay[1] and Caroline Ospelt[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Zurich, Switzerland, [2]Department of Pathology, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: The primary cilium is a microtubule-based, polarized, antenna structure that emanates from the cell surface of most mammalian cell types. It serves as a sensor that mediates reactions to mechanical and chemical signals from the environment and is therefore, a crucial factor in the communication with neighbouring cells and the environment.

We aimed to investigate the functional role of the primary cilium expressed on synovial fibroblasts (SF) in the pathogenesis of rheumatoid arthritis (RA).

Methods: The expression of the primary cilium was verified in serum-starved RASF by immunofluorescence microscopy using acetylated tubulin as a marker and by transmission electron microscopy. Ciliogenesis of RASF was disrupted by transfection of siRNA targeting the ciliary components kinesin family member 3a (KIF3a) and intraflagellar transport 88 homolog (IFT88). RASF were stimulated with TNF-α (10ng/ml) and IL-1β (1ng/ml). Differentially expression of transcripts in RASF transfected with KIF3a siRNA with and without cytokine stimulation was screened using Microarrays (Affymetrix). Migration and adhesion properties of transfected RASF were analysed by scratch assay (n=3) and a fibronectin-based adhesion assay (n=7), respectively.

Results: The primary cilium was detected on the surface of RASF. Migration of RASF with blocked formation of the primary cilium due to transfection with siRNA targeting KIF3a or IFT88 was reduced compared to RASF transfected with scrambled siRNA. RASF adhesion to fibronectin was induced by TNF-α (2.1 fold ± 0.9, n.s.) and IL-1β (2.3 fold ± 1.3, p<0.05), and was reduced in KIF3a siRNA transfected RASF (TNF-α: 1.2 fold ± 0.7, p<0.05; IL-1β: 1.3 fold ± 0.7, p=0.1142). In the whole genome expression analysis, 1321 transcripts were more than 2-fold up or down regulated in

RASF transfected with *KIF3A* siRNA and 1243 transcripts were more than 2-fold up or down regulated in the *KIF3A*siRNA transfected group stimulated with cytokines compared to control groups. 213 transcripts appeared to be differentially expressed under stimulated as well as under unstimulated conditions.

Conclusion: Our data show a functional role of the primary cilium in the migratory and adhesive properties of RASF. Since disruption of ciliogenesis in RASF altered their response to stimulation with TNF-α and IL-1β, we hypothesise that the primary cilium also plays a key role in the transmission of pro-inflammatory signals in RASF.

Dual Effects of Soluble FasL and Membrane Bound FasL On Fibroblast-Like Synoviocytes Cells (FLS) From Rheumatoid Arthritis (RA) Patients. Rachel Audo[1], Flavia Calmon-Hamaty[1], Bernard Combe[2], Michael Hahne[1] and Jacques Morel[2]. [1]IGMM, CNRS UMR5535, Montpellier, Montpellier, France, [2]Hopital Lapeyronie, Montpellier, France

Background/Purpose: Membrane bound FasL (mFasL) is able to induce fibroblast-like synoviocytes (FLS) cell death. In experimental arthritis mouse models, injection of agonistic antibody (Ab) anti-Fas decreased the symptoms. However, soluble FasL (sFasL) is increased in RA patients serum and correlated with disease activity. These results indicated that mFasL could be protective whereas sFasL could be deleterious suggesting that they could have different functions. We therefore analyzed the effect of different FasL preparation mimicking sFasL or mFasL on RAFLS proliferation, apoptosis and cytokines production.

Methods: RAFLS were treated with different FasL preparations (FasL-Flag± Ab anti-Flag, FasL-Fc or sFasL) or with agonistic Ab anti-Fas. Apoptosis was then analyzed by FACS on basis of the annexin V-FITC binding and TOPRO-3 up-take. Proliferation was measured using tritiated thymidine. Signaling pathways was analyzed by western blot and their influence was assessed using chemical inhibitors. VEGF, IL-6 and IL-8 were measured using commercial ELISA.

Results: FasL-Flag alone (mimicking sFasL) was not able to induced FLS apoptosis (8%±8 n=5) while proliferation was significantly activated (3.3±1 fold; n=5; p<0.05). Similarly, sFasL was only able to strongly induce RAFLS proliferation (8.1±3.3 fold; n=3). In an other hand, membrane bound FasL (FasL-Flag+Ab anti-Flag) significantly induced RAFLS apoptosis (52%±18; n=5) but also a slighter but significant proliferation (2.2±0.3 fold; n=4). Duality of mFasL was confirmed using agonistic Ab anti-Fas. (mimicking mFasL) with pro-apoptotic (38%±18; n=2) and proliferative effect (2.5±0.15 fold). Finally, growing concentration of FasL-Fc leads to aggregation of the protein, mimicking mFas or sFasL at high and low concentration respectively. Dose responses confirmed mFasL and sFAsL effects. FasL activated Akt and ERK (n=5) but also activated caspase-8. A pan-caspases inhibitor (z-VAD-FMK) prevented mFasL-induced apoptosis, but also blocked mFasL and sFasL-induced proliferation (n=4). Moreover, sFasL but not FasL-Fc, induced significant production of VEGF, IL-6 and IL-8 in RA FLS. In addition, we observed that FasL-Fc was also able to induce OAFLS apoptosis but in contrast to RAFLS, neither FasL-Fc nor sFAsL was able to significantly induced apoptosis of OAFLS (n=3).

Conclusion: mFasL induces preferentially RAFLS apoptosis, whereas sFasL only induces RAFLS proliferation and cytokines production. Proliferative effect of sFasL was only seen on RAFLS but not on OAFLS. According to what we have already described for TRAIL, caspases are involved in FasL-induced apoptosis and proliferation. This is the first demonstration of sFasL and mFasL have different effects on RAFLS proliferation and cytokines production. sFasL by enhancing RAFLS proliferation and cytokines could have a deleterious role in RA. Therefore, its blockage could be a therapeutic tool to prevent RA.

TNFα Influences *RasGRP1* and *RasGRP3* Expression Levels in PBMC, B and T Cells. Marie-Laure Potier[1], Martine Hiron[1], Clément Guillou[1], Céline Derambure[1], Olivier Boyer[2], Xavier Le Loët[3], Olivier Vittecoq[3] and Thierry Lequerré[3]. [1]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Inserm 905, Institute for Biomedical research, University of Rouen, Rouen, France, [3]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen Cedex, France

Background/Purpose: Rheumatoid arthritis (RA) is the most common inflammatory arthritis. B and T lymphocytes play a central role in the pathophysiology of RA. RasGRP is a member of the CDC25 family of Ras guanyl nucleotide exchange factors. RasGRP1 is expressed in T and B cells whereas RasGRP3 is only expressed in B cells. In previous studies, we have shown that *RasGRP3*expression level significantly decreased in Peripheral blood mononuclear cells (PBMC) from RA patients responders to adalimumab after 3 months, leading to the question of TNFα involvement in pathways including RasGRP1 and RasGRP3. Objectives: To study TNFα effect on RasGRP1 and RasGRP3 expression levels *in vitro*.

Methods: We measured by qRT-PCR, *RasGRP1* and *RasGRP3* expression levels, i) in PBMC from 3 healthy controls (HC), ii) in negative selected B and T cells from PBMC isolated from 3 buffy coat. In each condition, cells were cultured with or without BCR or TCR stimulation for 4 days and TNFα was added for 24 or 48 hours. Immunofluorescence staining was performed to check the cell purity and B and T cells stimulation by flow cytometry. Moreover, IL-2 production was measured by ELISA in T-cells before and after TNFα stimulation. In addition, TNFα effects on cell proliferation were evaluated by [3H] thymidine incorporation by the B and T cells.

Results: In B cells, TNFα induced an increase of *RasGRP1* (p<0.001) and *RasGRP3* (p<0.001) expression levels in absence of BCR stimulation. In the same way, in T cells, TNFα induced an increase of *RasGRP1* (p<0.001) and *RasGRP3* (p<0.001) expression levels in absence of TCR stimulation. Furthermore, TNFα induced a significantly increased of IL-2 production (p<0.05) in unstimulated T-cells. However, TNFα have no effects on B and T cells proliferation

Conclusion: This study suggests the *RasGRP1* and *RasGRP3* regulation by TNFα, independently of B and T cells stimulation. The increasing of *RasGRP3* and *RasGRP1* in B and T cells specifically *via* TNFα binding on its receptors could promote the activation and proliferation of B and T cells using another signaling pathway than BCR and TCR. This second pathway could explain the maintenance of B and T cells activation by an independent antigen pathway.

Dual Function of Interleukin-33 in Fibroblast-Like Synoviocytes in Patients with Rheumatoid Arthritis. Min W. So[1], Bon S. Koo[1], You J. Kim[1], You-G Kim[1], Wook J. Seo[2], Chang-K Lee[1] and Bin Yoo[1]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea

Background/Purpose: IL-33 is a new member of the IL-1 cytokine family. Recent studies in an animal model of murine collagen-induced arthritis and human rheumatoid arthritis (RA) have suggested that IL-33 may be important as an endogenous danger signal (alarmin) in the pathogenesis of RA. IL-33 mRNA and protein expression are induced in RA fibroblast-like synoviocytes (FLS) following TNF-α/IL-1β stimulation, and IL-33 protein is mainly detected in the nucleus of these cells. The nuclear localization of IL-33 in IL-1β/TNF-α stimulated cells suggests that it may have a regulatory function inside the cell, as has been shown previously for IL-1α and IL-1F7b. The purpose of our study was to analyze the role of extracellular and intracellular IL-33 as an alarmin or regulator of nuclear transcription in RA FLS.

Methods: Synovial tissues from RA patients fulfilling the ACR criteria were obtained during open joint replacement. RA synovial samples were digested, subsequently cultured for 7 days and 3-passaged cells were used for all experiments. For analysis, quantitative RT-PCR, confocal analysis, western blot analysis, and ELISA were performed.

Results: IL-33 and ST2 (receptor of IL-33) mRNA expression increased in RA FLS stimulated with poly I:C (10 ug/ml) as a TLR3 ligand, IL-1β (10 ng/ml), and TNF-α (10 ng/ml). However, IL-33 release was not detected in

the culture supernatant. Similar to previous observations, IL-33 was released from damaged FLS. After identification of the ST2 on FLS by confocal analysis, FLS was stimulated with IL-33. Exogenous IL-33 stimulation (10–100 ng/ml) of RA FLS increased IP-10 and RANKL mRNA expression and treatment with anti-ST2 blocked this expression. The role of intracellular IL-33 as a nuclear protein was evaluated using IL-33 siRNA. Silencing of IL-33 increased MMP-1, 3, 13, IL-6, 8, and MCP-1 mRNA expression compared to the scrambled control in RA FLS stimulated with poly I:C, IL-1β, and TNF-α. In addition, we observed that the silencing of IL-33 induced significant degradation of IκBα and increased of NF-κB activity. These findings reveal a novel role for IL-33 as a negative modulator of NF-κB activity.

Conclusion: IL-33 has dual, opposing functions. As a pro-inflammatory cytokine, IL-33 induced the expression of IP-10 and RANKL mRNA. These effects may induce bone erosion by enhancing osteoclastogenesis in RA. In contrast to extracellular IL-33, intracellular IL-33 acted as negative modulator of NF-κB activity and suppressed the expression of many pro-inflammatory cytokines and pro-destructive molecules in RA FLS.

MiR-30* Family Negatively Regulates B-Cell Activating Factor (BAFF) Synthesis in Rheumatoid Synoviocytes. Ghada Alsaleh[1], Antoine Francois[1], Lucas Philippe[1], Jean Sibilia[1], Jacques-Eric Gottenberg[1], Philippe Georgel[2] and Dominique Wachsmann[1]. [1]EA4438 Laboratoire Physiopathologie des Arthrites, Illkirch-Strasbourg, France, [2]Laboratoire d'ImmunoGénétique Moléculaire Humaine, Strasbourg, France

Background/Purpose: In rheumatoid arthritis (RA) resident cells of the joint, fibroblast-like synoviocytes (RA FLS) acquire an aggressive phenotype in response to extrinsic factors such as PAMPs or DAMPs and intrinsic factors such as microRNAs. They produce large amounts of cytokines and among them the B cell-activating factor (BAFF) which allows them to collaborate with auto-immune B cells. We found that the miR-30* family of microRNAs (miR-30a*, d* and e*), which differ only 1 to 3 nucleotides, was predicted to potentially target the 3'-UTR region of BAFF. As BAFF is also up-regulated in the skin and the serum of systemic sclerosis patients, the aim of this study was to evaluate the role of miR-30* in the regulation of BAFF synthesis in fibroblasts isolated from either RA or SSc patients.

Methods: FLS and HDF were isolated from RA synovial tissues (n=6) or from skin from normal individual (n=3) or SSc patients (n=3) and were stimulated with TLR3 ligand (poly I:C) and IFN-γ for 3 days. RT-qPCR was performed to evaluate miRNA and mRNA expression. Transient transfection of RA-FLS and SSc-HDF with mimic miR-30* was performed using the Human Dermal Fibroblast NucleofectorTM kit from Amaxa. All assays were performed 24h post transfection.

Results: We first showed by qRT-PCR that like RA-FLS, SSc-HDF synthesized and released BAFF in response to poly I:C and IFN-γ. Conversely, HDF from normal subjects (NHDF) released BAFF only in response to IFN-γ. Using qRT-PCR, we demonstrated that miR-30a* and miR-30e* expression was strongly down regulated in RA-FLS, SScHDF and NHDF stimulated with either poly I:C or IFN-γ. Interestingly, NHDF which did not release BAFF in response to poly I:C expressed higher levels of miR-30a* and miR-30e* in response to poly I:C. MiR-30d* was not expressed constitutively or after activation by poly I:C and IFN-γ by each cell type. To evaluate whether miR-30* regulates BAFF expression in poly I:C and IFN-γ-activated RA-FLS and HDF, we transfected cells with miR-30* mimics. Transfection of the mimics induced a strong down-regulation of BAFF synthesis and release in response to poly I:C and IFN-γ. Moreover, we transiently transfected into HEK-293 cells a reporter construct that contain the firefly luciferase gene fused to the BAFF 3'-UTR containing the putative miR-30* interactor site along with miR-30*. We observed a downregulation of the luciferase activity, indicating that the 3'-UTR of BAFF mRNA is directly targeted by miR-30*.

Conclusion: Our data strongly suggest a critical role of miR-30* in the regulation of the expression of BAFF which could play an important role in the regulation of the auto-immune response in RA and SSc.

1786

Targeting CD1c-Expressing mDCs to Inhibit Increased Thymus and Activation Regulated Chemokine Levels in RA. M.R. Hillen, F.M. Moret, F.P.J.G. Lafeber, C.E. Hack, T.R.D.J. Radstake and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: Thymus and activation regulated chemokine (TARC) is a chemotactic factor that attracts cells expressing CCR4, including CD4 T cells with Th2, Th17 and Treg phenotypes. TARC is known as a critical mediator in atopic diseases but is also present at sites of inflammation in autoimmune diseases. In synovial fluid (SF) of rheumatoid arthritis (RA) patients CCR4 is expressed on Th17 cells and mast cells that together are indicated to make up most IL-17 producing cells, suggesting that TARC plays an important role in attraction of IL-17 producing cells to the synovium. In addition, TARC can attract myeloid dendritic cells (mDCs) and fibroblasts. Immune cells such as CD1c-expressing mDCs and CD4 T-cells are potent TARC-producing cells. The aim of this study was to investigate if TARC is associated with RA pathogenesis and whether depletion of CD1c mDCs prevents production of high TARC concentrations.

Methods: TARC ELISA was performed on SF of 100 RA and 50 OA patients. Percentages of CD1c mDCs in SF of 10 RA patients were determined using flowcytometry. Mononuclear cells (MC) were isolated from the blood of healthy controls (HC) and blood or SF of RA patients and juvenile idiopathic arthritis (JIA) patients. CD1c mDCs were isolated with MACS and stimulated with TSLP for 24 hours and TARC levels were measured in supernatants. Alternatively, CD1c-expressing cells were depleted from MC using MACS and TARC levels were measured upon stimulation with TSLP or IL-7 (n=6).

Results: SF from RA patients contained significantly higher concentrations of TARC as compared to SF from OA patients (78.9 vs 9.2 pg/mL, p<0.0001). TARC levels in SF of RA patients correlated with percentages of CD1c mDCs present in SF (Rs= 0.68, p=0.035). Isolated CD1c mDCs from the synovial fluid of RA patients produced TARC directly *ex vivo* and produced significantly higher TARC levels compared to paired mDCs from the blood (26.4 vs 1.2 pg/mL, p<0.01). CD1c mDCs and SFMCs from RA and JIA patients produced more TARC compared to paired PB counterparts when stimulated with TSLP (926 vs 128 pg/mL, p<0.01) (or IL-7, p<0.01). Moreover, depletion of CD1c cells from MC significantly reduced TARC production induced by stimulation with TSLP (mean inhibition 76%, p=0.031).

Conclusion: Increased TARC levels in correlate with the percentages of CD1c-expressing mDCs present in RA SF; these mDCs produce enhanced TARC levels directly *ex vivo* and production is increased upon stimulation with TSLP. TARC production is markedly decreased when CD1c cells are depleted. As TARC is an important attractor of a range of inflammatory cells, preventing TARC production by targeting CD1c mDCs could be a novel therapeutic approach in RA.

Evolution of the Cytokine and Chemokine Profile in Patients Receiving Oral Daily Vitamin D: Results From a Randomized Controlled Trial. Benjamin Terrier Sr.[1], Marlène Garrido[2] and Patrice Cacoub Sr.[3]. [1]Cochin Hospital, Paris, France, [2]Pitié-Salpétrière, Paris, France, [3]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Immunomodulatory effects of vitamin D were recently described *in vitro*, notably the expansion of regulatory T cells able to suppress inflammatory responses and the decrease of Th17 cells. However, studies of its effect *in vivo* in humans are lacking.

Objective: To explore the impact on inflammatory markers of a 6-month daily oral administration of vitamin D3 1000 IU versus no vitamin D, in aged patients with vitamin D insufficiency all receiving strontium ranelate.

Methods: A prospective, international phase III study with a 6-month double-blind period was performed to assess the efficacy and safety of a daily oral administration of strontium ranelate 2 g/vitamin D3 1000 IU fixed combination versus strontium ranelate 2 g alone. 150 patients (75 per group) included in this study were selected, after matching between the 2 groups for age, gender and baseline vitamin D level. Serum samples were collected at baseline and after 6 months of treatment. Quantitative analyses of 25 cytokines were performed using Luminex to study the impact of vitamin D daily oral administration on cytokine and chemokine profile. Statistical

analysis was done using Wilcoxon matched pairs test (P value < 0.05 was considered significant).

Results: Sixty-nine women and 6 men were included in each treatment group, with a mean age 67.1 ± 7.0 years in the vitamin D group and 66.8 ± 8.3 years in the non-vitamin D group. Baseline vitamin D serum level was 44.9 ± 15.5 nmol/L in the vitamin D group and 44.6 ± 13.8 nmol/L in the non-vitamin D group.

Some cytokines/chemokines levels decreased over the 6-month follow-up only in the vitamin D group whereas they remained stable in the non-vitamin D group, i.e. IFN-α (40 at baseline vs. 34 pg/mL after 6 months of treatment, P=0.03), IL-1β (16 vs. 11 pg/mL, P=0.07), IL-15 (52 vs. 40 pg/mL, P=0.001), MIP-1α/CCL3 (44 vs. 39 pg/mL, P=0.008) and TNF-α (7.0 vs. 2.9 pg/mL, P<0.0001).

The only cytokine that varied significantly only in the non-vitamin D group and remained stable in the vitamin D group was IL-12 that increased over the 6-month follow-up (127 at baseline vs. 146 pg/mL after 6 months of treatment, P=0.002).

IL-1RA, IL-2R and MCP-1/CCL2 did not differ significantly between the 2 arms of treatment, and remain stable over the 6-month follow-up. GM-CSF, IL-4, IL-8/CXCL8, IP-10/CXCL10 and MIP-1β/CCL4 decreased while eotaxin increased in both groups.

Many other cytokines and chemokines levels remain below the sensitivity threshold of the test used, that preclude any conclusion regarding their evolution i.e. IFN-γ, IL-2, IL-5, IL-6, IL-7, IL-10, IL-13, IL-17, MIG/CXCL9 and RANTES.

Conclusion: In this study designed to assess the efficacy and safety of a daily oral administration of strontium ranelate/vitamin D3 combination versus strontium ranelate alone, a statistically significant decrease of pro-inflammatory cytokines and chemokines serum levels in patients receiving vitamin D was observed. Further studies are necessary to assess the clinical relevance of such vitamin D-induced pro-inflammatory cytokines/chemokines variations.

1788

TSLP Induces TNFα Production by CD1c Myeloid Dendritic Cells and Myeloid DC-Activated T Cells From Rheumatoid Arthritis Patients. F.M. Moret, T.R.D.J. Radstake, J.W.J. Bijlsma, F.P.J.G. Lafeber and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: Thymic stromal lymphopoietin (TSLP) is well known for its potent activation of myeloid dendritic cells (mDCs) to induce Th2-mediated immune responses. Fibroblasts from rheumatoid arthritis (RA) patients produce TSLP upon TLR and TNFα stimulation. Recently, we have shown that increased intra-articular TSLP concentrations in RA patients potently activate TSLPR-expressing mDCs from peripheral blood (PB) and synovial fluid (SF) of RA patients to secrete T cell attractant chemokines and to potently increase T cell activation. In addition, TSLP and its receptor play a crucial role in promoting Th17-driven collagen-induced arthritis. Since TNFα is a crucial pro-inflammatory and tissue-destructive mediator in RA, we assessed the capacity of TSLP to regulate TNFα production by CD1c mDCs and CD4 T cells in RA patients as compared to healthy controls (HC).

Methods: CD1c mDCs, isolated from PB as well as SF of RA patients (n=6), were stimulated with TSLP for 20 hours and TNFα production was measured by multiplex immunoassay. Washed TSLP-activated CD1c mDCs from PB (n=13) and SF (n=5) of RA patients and from PB of HC (n=5) were added to autologous CD4 T cells in the absence of additional stimuli, cultured for 6 days and subsequently proliferation was measured. Additionally, T-cell TNFα production was measured by ELISA upon restimulation with ionomycin/PMA.

Results: TSLP significantly stimulated the production of TNFα by mDCs from PB and SF (PB from 99 to 378 pg/ml, p<0.03 and SF from 170 to 355 pg/ml, p<0.03). Upon incubation with TSLP, TSLPR-expressing mDCs from PB potently stimulated proliferation of autologous CD4 T cells as compared to unstimulated mDCs (ratio T cell:DC 5:1, from 1503 to 16036 cpm, p<0.01). TSLP-mDCs from SF had a strongly increased capacity to activate CD4 T cells (ratio T cell:DC 5:1, from 26395 to 57387 cpm, p<0.05). Enhanced proliferation was associated with increased production of TNFα (ratio T cell:DC 5:1, PB from 3498 to 9225 pg/ml, p=0.001 and SF from 8951 to 18415 pg/ml, p<0.05). TNFα production by TSLP-mDC activated T cells from PB of RA patients was higher as compared to HC (RA from 3498 to 9225 pg/ml and HC from 3522 to 5686 pg/ml), although this was not statistically significant.

Conclusion: TSLP potently induces TNFα production by CD1c mDCs and mDC-activated CD4 T cells from RA patients. Considering the fact that TNFα can induce TSLP secretion by synovial fibroblasts this suggests a novel positive feedback loop of TNFα and TSLP that contributes to immunopathology of RA.

Evidence for an Additive Effect of Tumor Necrosis Factor Alpha and Hypoxia to Promote Bone Destruction in Arthritis. Shankar Revu[1], Akilan Krishnamurthy[1], Vivekananda Sunkari[2], Ileana R. Botusan[2], Xiaowei Zheng[2], Sergiu-Bogdan Catrina[2] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden

Background/Purpose: Hypoxia is a major feature of the inflamed rheumatoid arthritis synovial membrane and promotes osteoclasts formation *in vitro*. We aimed to investigate the molecular mechanisms by which hypoxia contribute to bone destruction in the presence of local inflammation.

Methods: Osteoblast-like cells were cultured in normoxic (21% O_2) or hypoxic (1% O_2) conditions with or without tumor necrosis factor (TNF)-α. Receptor activator of the NF-kB ligand (RANKL) and osteoprotegerin (OPG) were detected by rtPCR, Western blot and ELISA. siRNA deletion of HIF-1a, HIF-2a and VHL was performed in osteoblasts. Interaction between hyocia inducible factor (HIF) and RANKL was investigated by promoter chromatin immunoprecipitation (ChIP). Chemical hypoxia using dimethyloxalylglycine (DMOG) and TNFα were tested on osteoclast formation from peripheral blood mononuclear cells of RA patients and on osteologic bone discs. Statistical analysis was performed using one-way ANOVA.

Results: Exposure of osteoblasts to hypoxia resulted in a significant increase in RANKL mRNA and cellular protein expression and a concomitant decrease of soluble OPG. Small interfering RNA against HIF-2α but not HIF-1α was able to abolish hypoxia effect on RANKL expression. Chromatin immunoprecipiation assay confirmed the direct interaction between HIF-2α with at least one hypoxia responsive element (HRE) in the RANKL promoter. Presence of TNFα had an additive effect with hypoxia to increase RANKL expression. Hypoxia mimicking by DMOG demonstrated an additional direct effect on osteoclastogenesis with an additive effect of hypoxia and TNFα to promote osteoclastogenesis and bone resorption *in vitro*.

Conclusion: Hypoxia promotes HIF-2a dependent RANKL up-regulation and osteoclastogenesis and has an additive effect with pro inflammatory cytokines to promote bone destruction.

Notch Promotes Matrix Metalloproteinase 13 Expression by Inducing Interleukin-6 in Primary Murine Chondrocytes. Stefano Zanotti and Ernesto Canalis. Saint Francis Hospital and Medical Center, Hartford, CT

Background/Purpose: Notch1 to Notch4 are transmembrane receptors that determine cell differentiation and function. Interactions of Notch with its ligands result in the cleavage of the Notch intracellular domain (NICD), which translocates to the nucleus to induce gene expression. Notch suppresses collagen type II a1 (*Col2a1*) and induces collagen type X a1 (*Col10a1*) expression in murine chondrocytes. Activation of Notch signaling was observed in human osteoarthritic chondrocytes, although it was not reported whether Notch plays a role in the progression of osteoarthritis. Matrix metalloproteinase (Mmp)13 is a collagen-degrading enzyme expressed by osteoarthritic chondrocytes, and overexpression of Mmp13 in murine articular chondrocytes causes joint degeneration, demonstrating that Mmp13 contributes to cartilage matrix degradation. Interleukin (Il6) is a secreted inflammatory molecule that suppresses *Col2a1* and induces *Mmp13* expression in chondrocytes. Il6 is expressed by osteoarthritic chondrocytes, and Notch induces Il6 in synoviocytes, but it was not reported whether Notch regulates Il6 expression in chondrocytes. To understand whether Notch regulates the expression of gene markers of osteoarthritis, we investigated the effects of Notch on *Mmp13* and *Il6* expression in primary murine chondrocytes, and tested whether Il6 mediates the effects of Notch.

Methods: Notch was induced in chondrocytes from *Rosa*[Notch] mice, where the *Rosa26* promoter is followed by a STOP cassette flanked by *LoxP* sites, and the NICD coding sequence. Primary chondrocytes from 3 to 4 day old *Rosa*[Notch] mice were infected with an adenoviral vector expressing Cre recombinase, which excises the STOP cassette and induces expression of NICD directed by the *Rosa26* promoter. As controls, parallel cultures of *Rosa*[Notch] chondrocytes were infected with an adenoviral vector expressing green fluorescent protein (GFP).

To document Notch activation, *Rosa*[Notch] chondrocytes were transfected with Notch reporter constructs. To assess the effects of Notch on gene expression, changes in mRNA levels were analyzed by quantitative reverse transcription PCR. To investigate whether Il6 mediates the effects of Notch in *Rosa*[Notch] chondrocytes, cells were cultured in the absence of serum and exposed to an inhibitory monoclonal murine antibody against Il6, or to a murine immunoglobulin G, either under basal conditions or in the context of Notch activation.

Results: NICD overexpression in *Rosa*[Notch] chondrocytes transactivated Notch reporter constructs and induced Notch target genes, demonstrating activation of Notch signaling. The effects of Notch on the expression of *Col2a1* and *Col10a1* were confirmed. NICD induced *Mmp13* and *Il6* mRNA levels, and exposure of *Rosa*[Notch] chondrocytes to an inhibitory Il6 antibody opposed the induction of *Mmp13* by Notch, whereas it did not modify the effects of Notch on *Col2a1* and *Col10a1* expression.

Conclusion: Activation of Notch signaling in primary chondrocytes induces expression of gene markers of osteoarthritis. Induction of *Mmp13* by Notch is mediated by Il6, whereas the effects of Notch on the expression of chondrocyte gene markers are determined by alternate mechanisms.

Different Mechanisms Responsible for IVIG Inhibition of Immune Complex Versus TLR Stimulated Interferon-Alpha. Alice Wiedeman[1], Fabian Käsermann[2], Sylvia Miescher[2] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]CSL Behring, Bern, Switzerland

Background/Purpose: SLE immune complexes (IC) induce IFN-α production by stimulation of TLR7 and 9 in plasmacytoid dendritic cells (pDC). Serum from normal human donors inhibits IC-induced IFN-α *in vitro* and both C1q and IgG have been identified as inhibitory serum components. Since pooled IgG (IVIG) is used for therapy of autoimmune diseases and the sialylated subfraction implicated in its mode of action, we addressed how IVIG regulates IFN-α production by pDC.

Methods: Normal human peripheral blood mononuclear cells (PBMC) or negatively selected pDC were stimulated with SLE IC or the TLR 7 and 9 agonists, Loxoribine (Lox) or CpG-A respectively. IFN-α was quantified in the supernatants by ELISA. Unsorted IVIG or IVIG that had been enriched (SNA+) or depleted (SNA-) of the sialylated subset by a lectin affinity column or digested into Fc or F(ab')2 fragments were added to stimulated cultures. SLE IC containing Alexa Fluor 647 labeled SmRNP antigen was allowed to bind to PBMC with or without pretreatment with FcγRII blocking antibody or IVIG Fc, and the binding to pDC quantified by flow cytometry.

Results: IVIG dose-dependently inhibited SLE IC-induced IFN-α ($\sim$20%, 50%, and 95% inhibition by treatment with 50, 500, and 5000 μg/mL IVIG, respectively). Inhibition was Fc-dependent (500 μg/mL IVIG inhibited 50% of IFN-α compared to molar equivalents of F(ab'2), <10%, and Fc, 60%, p<0.01), but was sialylation-independent. IgG Fc inhibited SmRNP IC binding to pDC (50% of pDC bind IC, which was reduced to 20% with 167 μg/mL Fc, p<0.001). In contrast, TLR agonist-induced IFN-α was only modestly (10–20%) inhibited by high doses (5000 μg/mL) of IVIG and inhibition was significantly higher by the SNA+ versus SNA- fraction of IVIG (Lox: 90% and 40%, p<0.001; CpG 75% and 0%, p<0.001, for SNA+ versus SNA- respectively). Furthermore, the inhibitory activity was contained in the F(ab')2 fragment. The inhibitory activity of sialylated IVIG was not direct on pDC, but required the presence of monocytes (depletion of CD14+ monocytes reduced inhibition by 500 μg/mL SNA+ IVIG after Lox stimulation of IFN-α from 70% to 0%, p<0.05 while depletion of CD19+ B cells or CD56+ NK/NKT cells had no effect). Monocytes produced prostaglandin E2 (PGE2) specifically in response to the sialylated IVIG subset (10–20 ng/mL with SNA+ IVIG compared to undetectable quantities with SNA- IVIG, p<0.05). Furthermore, blockade of PGE2 from the monocyte supernatants reduced inhibitory activity to <10%, and addition of PGE2 blocked IFN-α production.

Conclusion: IVIG Fc directly inhibits production of IFN-α in response to SLE IC by blocking IC binding to FcγRIIa on pDC. In contrast, the SNA+ subset of IVIG inhibits TLR agonist stimulation of IFN-α by inducing the production of PGE2 by monocytes. Understanding these disparate mechanisms of IVIG inhibition of IFN-α will provide novel methods for immunomodulation and may allow use of smaller amounts of subcomponents of IVIG for therapy.

Identification of the Antimicrobial Peptide LL-37 As a Potential Mediator of Synovial Inflammation in Rheumatoid Arthritis. Petra Neregård[1], Marianne Engström[1], Erik Af Klint[1], Birgitta Agerberth[2] and Anca Irinel Catrina[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska Institute, Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden

Background/Purpose: LL-37, a member of the cathelicidin family of host defense peptides, has a broad range of antimicrobial and immunomodulatory effects that potentially can have an impact on the regulation of the adaptive immune system. In this study we aimed to investigate a potential role for LL-37 in mediating chronic synovial inflammation.

Methods: 49 patients meeting the 1987 American College of Rheumatology (ACR) criteria for RA were recruited for this study. We evaluated LL-37 by immunohistochemistry in synovial biopsy samples obtained before and after a mean of 8 weeks of treatment from 15 patients treated with adalimumab, 12 patients treated with etanercept and 11 patients treated with methotrexate, as well as from 11 patients prior to and 2 weeks after injection with intraarticular glucocorticoids. LL-37 was also evaluated in synovial biopsies obtained from 10 healthy volunteers. Microscopic results were analyzed by double-blind semi-quantitative analysis. Synovial localization of LL-37 was performed by double fluorescent stainings for LL-37 and cell surface markers. LL-37 was detected in synovial fluid by Western blots. Statistical analysis was performed using Wilcoxon test for paired comparisons and Man-Whitney test for comparisons of independent samples.

Results: LL-37 was expressed in most of the RA synovial biopsies both in the lining and sublining layers and readily identified in the synovial fluid. Serial and double-fluorescent immunostaining for cell surface markers identifies granulocytes (CD66 positive cells) and macrophages (CD68 positive cells) as main cells expressing LL-37. Inflamed synovial tissue obtained from active arthritis prior to treatment expressed higher levels of LL-37 as compared to healthy individuals. Treatment with adalimumab, etanercept and intraarticular glucocorticoids but not methotrexate resulted in a significant down-modulation of LL-37 expression.

Conclusion: Our results demonstrate presence of LL-37 in the context of chronic synovial inflammation and show specific regulation of this molecule by distinct anti-rheumatic agents. Further investigation to reveal the functional consequences of our findings on synovial antimicrobial and inflammatory activity is needed.

The Cyclooxygenase/Prostaglandin-E$_2$ Pathway Is Critical for Autocrine IL-17A Production by Th17 Cells Upon Synovial Fibroblast Interaction. Sandra M.J. Paulissen[1], Jan Piet van Hamburg[2], Nadine Davelaar[1], Patrick S. Asmawidjaja[3], Johanna M.W. Hazes[4] and Erik Lubberts[3]. [1]Erasmus MC, University Medical Center, Rotterdam, Rotterdam, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands, [3]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [4]Erasmus Medical Center, Rotterdam, Netherlands

Background/Purpose: Recently, we have shown that Th17, but not Th1 cells, from patients with early rheumatoid arthritis (RA) are potent activators of RA synovial fibroblasts (RASF) resulting in autocrine IL-17A production. This IL-17A production results in a pro-inflammatory loop, which is characterized by an up-regulation in pro-inflammatory cytokines and cartilage degrading enzymes. The autocrine IL-17A production by Th17 cells is critical for the perseverance of the pro-inflammatory loop, but the mechanism underlying the autocrine IL-17A induction is unclear. The objective of this study is to investigate the mechanism responsible for the autocrine IL-17A induction upon Th17-RASF interaction.

Methods: CD4+CD45RO+CCR6+ (Th17) and CD4+CD45RO+ CCR6− (Th1) cells were isolated by fluorescence-activated cell sorting

(FACS) sorting from healthy controls and early RA patients. These cells were co-cultured with RASF, in the presence of neutralizing antibodies directed against soluble IL-6R (anti-sIL-6R) and/or IL-1β, and celecoxib. Gene expression profiles were generated and supernatant was collected for cytokine analyses by enzyme-linked immunosorbent assay (ELISA).

Results: Gene expression analyses revealed that the genes encoding for IL-6 and IL-1β were up-regulated in Th17-RASF cultures. These data were confirmed by ELISA and quantitative polymerase chain reaction (Q-PCR), respectively. Since IL-1β and IL-6 may be involved in IL-17/Th17 polarization we examined the contribution of these cytokines on the autocrine IL-17A loop. Blockade of IL-1β and IL-6 significantly suppressed IL-17 production. However the effects of IL-1β and IL-6 blockade were limited, indicating the requirement of an additional mechanism.

Interestingly, the genes encoding for cyclo-oxygenase-2 (COX-2) and prostaglandin-E-synthase (PTGES), which are involved in prostaglandin-E$_2$ (PGE$_2$) synthesis, were also up-regulated in Th17-RASF cultures. This was associated with a dramatic increase of PGE$_2$ production in Th17-RASF cultures compared to Th1-RASF cultures. Treatment of Th17-RASF cultures with celecoxib, a COX-2 inhibitor, resulted in significant and specific inhibition of the fraction of IL-17A producing cells and the IL-17A levels. No inhibitory effects were found on IFN-γ and TNF-α production. Moreover, celecoxib treatment functionally inhibited the pro-inflammatory loop as production of the pro-inflammatory mediators IL-6 and IL-8 and tissue destructive enzymes MMP-1 and MMP-3 were significantly suppressed.

Conclusion: These findings show the critical role of the COX/PGE$_2$ pathway in the autocrine IL-17A production upon Th17 and synovial fibroblast interaction. Inhibition of this pathway down-regulates the pro-inflammatory feedback loop induced by Th17-RASF interaction leading to less production of pro-inflammatory cytokines and destructive mediators.

1794

Matrix Metalloproteinase 3 and Acute Phase Proteins As Markers of Disease Activity and Radiographic Damage in Early Rheumatoid Arthritis. Mahmood MTM Ally[1], Bridget Hodkinson[2], Pieter W.A Meyer[1], Eustasius Musenge[3], Mohammed Tikly[4] and Ronald Anderson[1]. [1]University of Pretoria, Pretoria, South Africa, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]University of Witwatersrand, Johannesburg, South Africa, [4]Division of Rheumatology, University of the Witwatersrand, Johannesburg, South Africa

Background/Purpose: Although matrix metalloproteinase-3 (MMP-3) is believed to be intimately involved in the immunopathogenesis of rheumatoid arthritis (RA), relatively little is known about its relationships to: i) proven genetic markers of disease susceptibility and biomarkers of immune-mediated tissue damage; and ii) disease activity in early RA in comparison with that of the acute phase reactants, C-reactive protein (CRP) and serum amyloid A (SAA).

Methods: Circulating concentrations of MMP-3 were measured by an ELISA procedure in serum specimens from 128 disease-modifying, anti-inflammatory drug-naïve patients with RA of $\leq$ 2 years duration. These were correlated with shared epitope (SE) genotype, a spectrum (16) of circulating chemokines/cytokines representative of various types of inflammatory and structural cells, acute phase reactants, autoantibodies, and a cartilage breakdown product (COMP), as well as with clinical indices of disease.

Results:. While no associations with SE genotype were evident, serum MMP-3, which was elevated in 56,25% of patients (p<0,0001), was broadly, albeit variably, correlated with most of the chemokines/cytokines (r values = 0.18–0.33, P <0.03–<0.0001), COMP (r = 0.22, P <0.014), and, most notably, CRP and SAA (respective r values of 0.40 and 0.41, (P <0.0000). In the case of clinical indices, MMP-3 correlated with the simplified disease activity index (SDAI, r = 0.29, P < 0.0001), but not with radiographic changes, erosions or nodulosis. However, the correlations of CRP and SAA with SDAI were stronger (respective values of 0.63 and 0.54, P <0.001 for both).

Conclusion: In early RA, MMP-3 is significantly associated with disease activity, inflammatory mediators and cartilage breakdown, and is a potential biomarker of disease severity, but is less useful than CRP and SAA in early RA.

1795

Correction for Basophil and Monocyte Frequencies Identifies Specific Gene Expression Differences Associated with SLE Disease Flare: Interim Report From the Bold (Biomarkers of Lupus Disease) Study. Mikhail G. Dozmorov[1], Nicolas Dominguez[1], Stan Kamp[2], Cory Giles[1], Jonathan D. Wren[1], Sudhakar T. Sridharan[3], Joan T. Merrill[1], Judith A. James[4] and Joel M. Guthridge[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma CIty, OK, [3]Pfizer Inc, Collegeville, PA, [4]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: Heterogeneity of clinical manifestations and pathogenic mechanisms has complicated treatment of SLE patients. The BOLD study allows evaluation of gene expression changes associated with disease flare without the impact of background immunosuppressants which have confounded previous studies.
Objectives: 1. Define immune functions or pathways impacted by disease activity. 2. Evaluate gene expression differences due to variations of cell subsets. 3. Uncover cell specific biological pathways that are associated with lupus disease activity.

Methods: The BOLD study enrolled patients with active disease at the baseline visit (BV) who were withdrawn from background immunosuppressive therapy and given intramuscular steroids to induce improvement (IV), and followed until flare (FV). An interim profiling of gene expression on 15 SLE patients was performed. Cell specific significance analysis of microarrays (csSAM) compares gene expression between two groups, each separately deconvolved to yield cell specific expression. The false discovery rate (FDR) for cell specific differentially expressed genes (DEG) between groups is assessed via permutations. csSAM analysis was performed comparing the BV to IV, IV to FV and BV to FV. Bioinformatics analysis of pathways and gene functions was performed using the sets of DEG.

Results: Correction for basophil frequencies yielded a FDR of 25% and identified 502 DEG comparing BV and IV. Genes overrepresented in signaling pathways associated with SLE included LCK, CD44, CD40LG, SOS1, TNFRSF13C (BLyS receptor), SLAMF1, IRF8, TNFAIP3, TNFRSF4, MIF, FCGR1A and FCGR1B. Comparing IV to FV, (representing a transition from low to high disease state without immune suppression on board), deconvolution on monocyte frequencies identified 68 DEG with an FDR of 25% at the FV. Genes in the p38 MAP Kinase, ERK/MAPK, IFN signaling, and IL-12 pathways were enriched. Comparing BV to FV, (same patients with active disease on and off immune suppressants), deconvolution on basophil frequencies using an FDR of 39% yielded 1421 DEG. Pathways overrepresented included antigen presentation and apoptosis. When assessing function enrichment, "antibody response" was overrepresented by 27 genes (p=2.27E-06) including BTK, CD86, TLR2, TNFRSF13B (TACI), and TNFSF13B (BLYS).

Conclusion: Basophil and monocyte adjusted DEG analysis suggests that pathways associated with SLE signaling, apoptosis, antigen presentation, and antibody response functions are associated with changes in gene expression at transitions between high and low disease activity. These biomarkers could identify therapeutic targets or identify patients who are or are not good candidates for different targeted therapies.

1796

Anti-IL-20 Targets Local Tissue Inflammation As Opposed to Systemic Inflammation. Amanda L. Blasius[1], Joshua N. Beilke[1], Hal Blumberg[1], John Bui[1], Jennifer H. Cox[1], Tom Cox[1], Heidi J. Jessup[1], Phillip L. Kong[1], Steven D. Levin[1], Valerie H. Odegard[1], Jason A. Stucky[1], Evan P. Thomas[1], Joseph A. Wahle[1] and John Rømer[2]. [1]Novo Nordisk Inflammation Research Center, Seattle, WA, [2]Novo Nordisk, Måløv, Denmark

Background/Purpose: In a recent Phase 2a clinical trial in patients with rheumatoid arthritis, the novel human anti-IL-20 monoclonal antibody NNC0109-0012 was shown to reduce disease activity (DAS28-CRP) and had a favourable safety/tolerability profile. In RF-positive and anti-CCP-positive patients it also improved the ACR20/50/70 responses. Response to anti-IL-20 therapy was rapid, with patients showing significant improvements in DAS scores as early as 1 week after treatment. Expression of IL-20 and its receptor chains IL-20R1, IL-20R2, and IL-22R has previously been demonstrated in synovium from patients with RA. The safety and efficacy data support the

hypothesis that anti-IL-20 works locally in the joint without modulating systemic inflammation. To test this hypothesis, human peripheral immune cells from blood and lymphoid tissue were evaluated as IL-20 target cells.

Methods: An extensive collection of immune cell subsets derived from human blood and tonsil were analyzed, both directly after isolation and following *ex vivo* activation. Expression of IL-20R1, IL-20R2, and IL-22R was detected by flow cytometry and/or qPCR. In parallel, cell responsiveness to IL-20 was evaluated by measuring the phosphorylation of STAT3 following treatment of cells with IL-20. Further functional readouts of IL-20 responsiveness included measurement of proliferation and cytokine production in response to IL-20 treatment.

Results: The cell types evaluated included B cells, CD8[+] T cells, CD4[+] T cell subsets, NK cells, dendritic cells, monocytes, macrophages, mast cells, basophils, eosinophils, and CD34+ hematopoietic stem cells. The IL-20R2 subunit was detected on several cell types, including monocytes, macrophages, and tonsillar B cells. However, co-expression of the IL-20 receptor beta chain and one of the two alpha chains, requirements for a functional IL-20 receptor, was not detected on human peripheral immune cells under resting or activated conditions. Consistent with this, there was a lack of responsiveness to IL-20 as monitored by phosphorylation of STAT3. Finally, whole blood cultured with IL-20 failed to induce a response as measured by cytokine and chemokine production. This overall lack of response contrasted to non-immune cell types involved in local inflammation, such as keratinocytes.

Conclusion: The paucity of IL-20 receptor expression and IL-20 responsiveness by peripheral immune cells correlates with the absence of systemic immune suppression in the Phase 2a clinical trial of NNC0109-0012. In combination with earlier data showing expression of IL-20 in synovial tissues, these data suggest that IL-20 is restricted to acting locally on inflamed synovium in patients with RA.

1797

Wnt Signaling Pathway Status, Determined by Serum Dkk-1 and R-Spondin 1 Levels, in Rheumatoid Arthritis and Ankylosing Spondylitis. Byoong Yong Choi[1], Hyon Joung Cho[1], Eun Ha Kang[1], Yeong Wook Song[2] and Yun Jong Lee[1]. [1]Seoul National University Bundang Hospital, Seongnam-si, South Korea, [2]Seoul National University Hospital, Seoul, South Korea

Background/Purpose: Dickkopf-1 (Dkk-1), known as inhibitor of Wnt signaling pathway, is involved in joint damage in inflammatory arthritis. While R-spondin 1 (Rspo1) reported to protect against bone destruction through antagonizing Dkk-1 in murine arthritis model, the Rspo1 levels in inflammatory arthropathy such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS) has not been investigated. We determined the circulating levels of Rspo1 and Dkk-1 in patients with RA or AS and investigated their clinical implication.

Methods: Serum sample were collected from 60 RA patients (mean age±SEM 53.3± 1.55, 54 females), 55 AS patients (36.7± 1.61, 8 females), and age-and gender-matched 65 healthy subjects (44.7±1.80, 35 females). Sera from 13 RA patients treated with anti-TNF-α agents were also collected at baseline and 12 weeks. Clinical and laboratory data included age, gender, body mass index, disease duration, medication history, ESR and CRP. Disease activities in RA and AS were measured by DAS28 or BASDAI respectively. Radiographic joint damages in RA were assessed by the modified Sharp/Van der Heijde score (Sharp score). Serum Rspo1 and Dkk-1 levels were determined by sandwich ELISA.

Results: Serum Rspo1 levels were significantly decreased in RA patients when compared to those in healthy subjects (p<0.0001). However, their levels were comparable between AS patients and healthy subjects. While serum Dkk-1 levels in AS patients were significantly lower than those in healthy subjects (p=0.001), those in RA were significantly higher (p<0.0001). Thus, the ratios of Dkk-1/Rspo1 were significantly elevated in RA patients but significantly suppressed in AS patients (both p<0.0001). Dkk-1/Rspo1 ratios in RA patients with high disease activities (DAS28 > 5.1) were much higher than those in RA patients with low disease activities (DAS28 < 2.6, p=0.012). However, Dkk-1/Rspo1 ratios were not correlated with Sharp scores in RA patients and not different between AS patients with

and without syndesmophyte. Serum DKK-1 levels wre not changed but Dkk-1/Rspo 1 ratios were decreased by anti-TNF-α treatment (p=0.0134). Glucocorticoid treatment (p=0.003) or presence of osteoporosis (p=0.044) was associated with increased Dkk-1/Rspo-1 ratios.

Conclusion: This study demonstrated inappropriate suppression of Wnt signaling pathway, presented by high Dkk-1/Rspo1 ratios, in RA and activation of Wnt signaling pathway in AS. However, the ratios of Dkk-1/Rspo1 levels were not directly associated with the cumulative radiographic change in RA patients although their levels were affected by RA disease activity.

1798

Macrophage Migration Inhibitory Factor Regulates Dual-Specificity Phosphatases Via Glucocorticoid Induced Leucine Zipper. Huapeng Fan, Devi Ngo, Ran Gu and Eric Morand. Monash University, Melbourne, Australia

Background/Purpose: Macrophage migration inhibitory factor (MIF) plays a pivotal role in promotion of inflammatory diseases such as rheumatoid arthritis (RA). MIF has previously been shown to oppose the action of glucocorticoids, by regulating the expression of dual-specificity phosphatase (DUSP)-1 (syn. MAPK phosphatase-1 (MKP-1)) and thereby to amplify MAP kinase signalling and up-regulate multiple cytokines and chemokines. Glucocorticoids also act by regulation of glucocorticoid induced leucine zipper (GILZ). Whether MIF opposition of glucocorticoid actions involves modulation of other DUSPs or GILZ is unknown. Therefore, the aim of this study was to examine the effects of MIF on the expression of DUSPs and GILZ.

Methods: Bone marrow derived macrophages and dermal fibroblasts were isolated from WT, MIF[−/−] and GILZ[−/−] mice. The expression of a panel of DUSPs and GILZ, and TNF and IL-6, were investigated by real time RT-PCR, Western blotting and ELISA.

Results: In MIF[−/−] macrophages, multiple DUSPs, including DUSP1/MKP-1, but also DUSP 2, 5, 6, 8, 9, 10, 16, and 19, were significantly increased. GILZ mRNA and protein were significantly increased in MIF[−/−] macrophages and fibroblasts, and GILZ expression induced by Dex was also significantly greater in MIF[−/−] cells. Correspondingly, recombinant MIF inhibited GILZ expression, MIF inhibited the expression and nuclear translocation of the transcription factor FoxO3a, and FoxO3a silencing reversed the effect of MIF deletion on GILZ. The basal and Dex-induced expression of the panel of MIF-regulated DUSPs was significantly reduced in GILZ[−/−] cells, and accordingly, LPS-induced TNF and IL-6 were significantly increased in GILZ[−/−] cells.

Conclusion: These studies indicate a previously unsuspected broad regulatory effect of MIF on multiple DUSPs. Moreover, we identify FoxO3a-dependent regulation of GILZ by MIF, and a corresponding regulatory effect of GILZ on DUSPs and cytokine expression. The results suggest that GILZ-mediated regulation of DUSP expression mediates the antagonistic effect of MIF on glucocorticoid actions.

1799

ONO-4059 - A Novel Small Molecule Bruton's Tyrosine Kinase (Btk) Inhibitor, Suppresses Osteoclast Differentiation and Activation. Yuko Ariza, Toshio Yoshizawa, Yoshiko Ueda, Shingo Hotta, Masami Narita and Kazuhito Kawabata. Ono Pharmaceutical Co., Ltd., Osaka, Japan

Background/Purpose: Bruton's tyrosine kinase (Btk) is primarily expressed in B cells, mast cells, platelets, myeloid cells and osteoclasts. Osteoclast differentiation is regulated by signaling pathways activated by receptor activator of nuclear factor-κB ligand (RANKL), macrophage colony-stimulating factor (M-CSF) and immunoreceptor tyrosine-based activation motif (ITAM). Phosphorylation of ITAM results in the activation of phospholipase C-γ through activation of non-receptor tyrosine kinases Btk and Syk. However, the functional hierarchy of these two kinases has not been fully elucidated. To explore the distinct functions of Btk and Syk, we examined their relative contributions to osteoclast differentiation and activation using inhibitors to both Btk and Syk.

Methods: Human osteoclast precursors were differentiated with 33 ng/mL of M-CSF and 66 ng/mL of RANKL for 7 days. Increasing concentrations

(1 nM to 1000 nM) of ONO-4059 and Syk inhibitors were incubated with the cells for 7 days. Osteoclast differentiation was evaluated by TRAP staining followed by light microscopy and quantitation of TRAP+ cells containing at least three nuclei. To evaluate osteoclast function, cytokine production and Btk and Syk signaling were determined by ELISA and Western Blot analysis, respectively.

Results: Both ONO-4059 and the Syk inhibitor specifically inhibited the activity of Btk and Syk, respectively. ONO-4059 dose-dependently inhibited the M-CSF and RANKL-driven osteoclast differentiation by 70% (IC_{50}: 0.853 nmol/L). Surprisingly, the effect of the Syk inhibitor on osteoclast differentiation was much lower (n=3, 30% inhibition). ONO-4059 also reduced the secretion of MIP-1α and RANTES in bone marrow cell culture, with a weaker effect observed in bone marrow with the Syk inhibitor.

Conclusion: Btk, but not Syk, appears to play a pivotal role in osteoclast differentiation and activation. Rheumatoid arthritis (RA) is often complicated by generalized osteopenia due to increased bone resorption by osteoclasts. These preliminary results suggest that the selective, oral Btk inhibitor, ONO-4059 may be a novel therapeutic target for rheumatoid arthritis (RA) to suppress bone erosion and inflammation.

Macrophages in Hypoxic Rheumatoid Joints Preferentially Express Hypoxia Inducible Transcription Factor-2. Sarah Aynsley[1], Ursula Fearon[2], Anthony G. Wilson[3] and Munitta Muthana[4]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [3]Section of Musculoskeletal Sciences, University of Sheffield, Sheffield, United Kingdom, [4]University of sheffield, Sheffield, United Kingdom

Background/Purpose: In rheumatoid arthritis (RA), the influx of inflammatory cells as well as the aggressive proliferation of fibroblast-like synovial cells (FLS) outstrips the oxygen supply from blood vessels leading to joint hypoxia. Macrophages accumulate in hypoxic disease sites including RA joints where they possess broad pro-inflammatory, destructive and remodeling potential leading to inflammation and joint destruction. Macrophages respond to hypoxia by up regulating the hypoxia inducible transcription factors– HIF-1 and -2 normally degraded in the presence of oxygen. This study will attempt to understand the relative contribution of HIF-1 and HIF-2 expressing macrophages in RA and the genes/mechanisms involved in their activation.

Methods: We obtained arthroscopy sections from RA patients for which tissue oxygen levels had been measured. This consisted of a random sample of mild (~40mmHg), moderate (~15mmHg) & severe (~3mmHg) joint hypoxia. We also used samples from a second cohort of patients scored with mild or severe disease (based upon extent of synovitis and vascularity), a sub group of which were also receiving anti-TNF therapy. Sections were immunostained with anti-HIF 1 and 2 and co-localised with the pan-macrophage marker CD68 as well as other macrophage markers (Flt-1, CD147, CD206 and Tie2).

Results: In patients with mildly hypoxic joints, macrophages (CD68+) predominately expressed HIF-1 (20%) and CD147 and were found in small clusters localised to the lining layer, whilst macrophages in patients with severely hypoxic joints were in greater numbers (73%), throughout the biopsy. These macrophages predominately expressed HIF-2+ (>75%), Flt-1, Tie2 and CD206. A similar pattern was observed in patients with severe disease where sections expressed more HIF-2+Flt-1+ macrophages compared to those with mild scores (15 cells per field of view compared to 5 for mild $p<0.01$). There was no significant difference in HIF-1 expression. Interestingly, this HIF-2+ macrophage subpopulation was absent in patients who had been successfully treated with anti-TNF.

Conclusion: In patients with severely hypoxic joints macrophage numbers were significantly greater than in patients with mild hypoxia and predominantly expressed HIF-2+, which activates genes associated with both inflammation and angiogenesis. These cells expressed M2-like macrophage markers including Flt-1, Tie2 & CD206, important in tissue remodeling and angiogenesis. We are currently investigating the gene expression profile of these subpopulations using laser capture micro-dissection and gene arrays and will further study their relevance in animal models of RA using transgenic mice with targeted deletions of HIF-1 or HIF-2 in myeloid cells.

Biological Roles of C5orf30 in Rheumatoid Arthritis. Munitta Muthana[1], Sachin Khetan[2], Gbadebo Adeleke Adeleke[2], Simon Tazzyman[2], Sarah Aynsley[1], Fiona Morrow[1], Sarah Hawtree[1], Barbara Ciani[1] and Anthony G. Wilson[3]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Dr, Sheffield, United Kingdom, [3]Section of Musculoskeletal Sciences, University of Sheffield, Sheffield, United Kingdom

Background/Purpose: A recent genome wide association study identified the variant rs26232 in the first exon of an uncharacterized gene *C5orf30*. In addition, this variant is also associated with severity of radiological joint damage suggesting a role in tissue breakdown. To date there is no function assigned for *C5orf30* and neither the gene or protein coded show homology to any known functional sequences. However, C5orf30 is highly conserved in chimpanzee, dog, cow, mouse, chicken, and zebrafish (orthologs). The aim of this study is to determine the biological roles of *C5orf30* in health and RA.

Methods: Real time PCR and western blotting was used to determine *C5orf30* transcript and protein levels in fibroblast-like synovial cells (FLS-stimulated with TNF & hypoxia) and peripheral blood leukocytes isolated from RA patients and healthy individuals. Immunohistochemistry using synovial samples was used to determine cellular expression using anti-*C5orf30* and antibodies to macrophages (CD68), fibroblasts (5B5), T (CD3) & B (CD19) cells. To investigate gene function siRNA was used to knockdown *C5orf30* in synovial FLS *in vitro* and we have used morpholino antisense oligonucleotide (MO)-mediated knocked down of *C5orf30* in zebrafish embryos (fms:mcherry) *in vivo*.

Results: Expression of *C5orf30* was detected at lower levels in peripheral blood leukocytes of RA patients compared to healthy controls (117 patients vs. 102 controls, $p=0.00052$). *C5orf30* was expressed in joint FLS and was found to be up regulated following treatment with hypoxia (8-fold) and down-regulated by TNF-a (0.5-fold). Confocal microscopy revealed *C5orf30* was strongly expressed in both the nuclear and cytoplasmic compartment of synovial lining cells including macrophages and fibroblasts but not B & T cells. *C5orf30* was undetectable in arthroscopy sections obtained from osteoarthritis or control (knee replacement) patients. So far, 80% *C5orf30* knockdown has been achieved in FLS without affecting cell viability. Interestingly, MO-mediated knockdown of *C5orf30* impeded zebrafish development and increased total macrophage numbers by 40% compared to knockdown of a scrambled control MO.

Conclusion: *C5orf30* is expressed at both the transcript & protein level in synovial cells but not in circulating PBMC obtained from RA patients, suggesting that *C5orf30* is expressed in a tissue-specific manner. We are currently assessing the morphological phenotype and function arising from *C5orf30* siRNA knockdown in FLS using confocal microscopy and matrigel invasion assays. NMR and mass spectrometry experiments are on the way to determine the three-dimensional structure of *C5orf30* and its potential protein-binding partners.

Interleukin-29 Modulates Proinflammatory Cytokine Production in Synovial Inflammation of Rheumatoid Arthritis. Miaojia Zhang, Fang Wang, Lingxiao Xu and Wenfeng Tan. the First Affiliated Hospital of Nanjing Medical University, Nanjing, CHINA., Nanjing, China

Background/Purpose: The immunoregulatory function of interleukin (IL)-29 has recently been recognized. However, little is known about the involvement of IL-29 in the pathogenesis of rheumatoid arthritis (RA). We here investigated the potential role of IL-29 in the synovial inflammation of RA.

Methods: The transcript levels of IL-29 and its specific receptor IL-28Rα in peripheral blood mononuclear cells (PBMC) and synovium were determined by real-time reverse transcription-polymerase chain reaction (real-time PCR). The concentrations of IL-29 in serum and synovial fluid (SF) were quantified by enzyme-linked immunoassay (ELISA), and the correlation of serum IL-29 levels with disease activity in RA patients was investigated. Furthermore, the expression of IL-29 in RA synovium was examined by immunohistochemistry and double immunofluorescence analysis. Finally, the expression of IL-6, IL-8, IL-10, IL-17 and matrix-metalloproteinase-3 (MMP-3) in synovial fibroblasts upon IL-29 stimulation was determined by real-time PCR.

Results: IL-29 and IL-28Rα mRNA expression in PBMC were significantly increased in patients with RA compared with healthy controls (HC). The serum levels of circulating IL-29 were higher in RA than those in HC. RA SF also conferred the increased IL-29 levels compared to osteoarthritis (OA) SF. However, serum IL-29 levels showed no significant correlation with the RA disease activity. IL-29 was markedly elevated in RA synovium compared to tissues from HC, and was mostly expressed in the lining region of synovium. Moreover, IL-29 was expressed predominately in synovial macrophages and fibroblasts. RA synovial fibroblasts exposed to IL-29 specifically upregulated IL-6, -8 and MMP-3, downregualted IL-10, but showed no effect on IL-17.

Conclusion: The findings in the present study indicate, for the first time, that IL-29 is dysregulated in patients with RA, which may contribute to the RA pathogenesis via inducing the production of proinflammatory cytokines, chemokines or matrix-metalloproteinases in synovial fibroblasts.

Chemokine-Like Receptor 1 (CMKLR1), a G Protein Coupled Receptor Expressed On Proinflammatory Monocytes in Arthritis, Is Negatively Regulated by GRK3. D. Stephen Serafin[1], Roman Timoshchenko[2], Marcus W. McGinnis[3] and Teresa K. Tarrant[4]. [1]Thurston Arthritis Research Center, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina Sch of Med, Chapel Hill, NC, [4]UNC School of Medicine, Chapel Hill, NC

Background/Purpose: Chemokine-like receptor 1 (CMKLR1) is a G protein coupled receptor (GPCR) expressed by inflammatory monocytes that are pathogenic in human diseases such as psoriasis and lupus. Its cognate ligand, chemerin, is a chemoattractant for invading inflammatory cells and is present in the synovial lining of rheumatoid arthritis (RA), osteoarthritis (OA), and psoriatic arthritis (PsA) patients. In OA, chemerin is thought to contribute to both the extracellular matrix breakdown of cartilage as well as joint inflammation.

CMKLR1 is a newly discovered GPCR, which as a class of receptors are phosphorylated by G-protein receptor kinases (GRKs) to turn off GPCR signaling. Due to the significant role of chemerin/CMKLR1 interaction in human inflammatory arthritis, we chose to examine the unknown regulatory mechanism of CMKLR1 by GRKs.

Methods: Isoforms GRK3 and GRK2 were separately knocked down in human monocytic THP-1 cells using shRNA and confirmed via quantitative real time PCR. Migration to chemerin (100 ng/mL) was measured by fluorescence emission through the BD Falcon 96-Multiwell Insert System or flow cytometry through 5 μM Transwells over 3 hrs.

A modified Tango assay was used to measure β-arrestin recruitment to CMKLR1. HTLA cells were over expressed with CMKLR1 and GRK2 or GRK3 via calcium phosphate precipitation. Cells were stimulated with 1 μM of chemerin and after 24 hours, luminescence was measured on a Trilux plate reader.

Results: CMKLR1 recruits β-arrestin in a ligand-dependent dose response. β-arrestin recruitment to CMKLR1 is mediated preferentially by GRK3 as compared to GRK2. THP-1 cells deficient in GRK3 showed enhanced chemotaxis to chemerin when compared to control cells.

Conclusion: We conclude that the chemerin/ CMKLR1 axis plays an important role in targeting monocytes to sites of inflammation and is negatively regulated by GRK3.

1804

TNF-Like Protein 1A/Death Receptor 3 Pathway Regulates Osteoclastogenesis and Is Associated with Erosive Disease in Rheumatoid Arthritis. Fraser L. Collins[1], Michael D. Stone[2], Rhian Goodfellow[3], Ernest Choy[4], Edward C. Wang[1] and Anwen S. Williams[1]. [1]Cardiff University, Institute of Infection and Immunity, Cardiff, United Kingdom, [2]University Hospital Llandough, Cardiff & Vale University Health Board, Cardiff, United Kingdom, [3]Cardiff University, Cardiff, ENGLAND, United Kingdom, [4]Cardiff University School of Medicine, Cardiff, United Kingdom

Background/Purpose: Bone erosion is a characteristic feature of inflammatory arthritides, such as rheumatoid arthritis (RA). Death Receptor 3 (DR3) and its only known ligand TNF-like protein 1A (TL1A) have been identified as key regulators of osteoclastogenesis in murine models of arthritis (Bull MJ, Williams AS et.al. J.Exp.Med. 2008). We investigated the potential mechanisms by which the DR3/TL1A pathway orchestrates osteoclast (OC) formation in humans and assessed the impact of DR3 signalling upon bone pathology in RA.

Methods: CD14$^+$ monocytes were obtained from healthy females (n=8). Cells were cultured on ivory discs (with macrophage-colony-stimulating factor (M) and receptor activator of nuclear factor-κB ligand (R)) for 7, 10 and 14 days $\pm$ TL1A (10 and 100ng/ml). Osteoclastogenesis and area of disc resorbed were quantified. Levels of TNFα and MMP-9 were measured by ELISA. Serum samples were obtained from consenting normal human volunteers (n=12) and RA patients (n=36) attending outpatient clinic who fulfilled the ACR classification criteria.TL1A and TNFα were measured by ELISA. Ethical approval for this study was granted by the Bro-Taf Health Authority. All data is expressed as mean$\pm$SEM value.

Results: A significant dose-dependent increase in osteoclastogenesis was observed after addition of exogenous TL1A ($P<0.01$; 2-way ANOVA) in our *in vitro* human system. Cell counts per mm^2, at end-point, were comparable for each condition tested (M+R=480$\pm$49; M+R+TL1A-10=517$\pm$62 and M+R+TL1A-100=475$\pm$59). However, TL1A (100ng/ml) doubled the number of OC observed on each ivory disk (12$\pm$3; OC per mm^2) when compared against controls (6.8$\pm$2; $P<0.05$). These OC were functionally active, evidenced by their capacity to resorb a bone substrate. TL1A (100ng/ml) induced a potent 5-fold increase in bone resorption (5.19$\pm$3%) over control cultures (1.33$\pm$0.43%, $P<0.01$); the effect was dose-dependent. This was accompanied by a significant ($P<0.01$; 2-way ANOVA) dose and time dependent elevation in bone-matrix degrading MMP-9 secretion. MMP-9(μg/ml) increased from 4.8$\pm$1.1 to 7.5$\pm$1 for controls versus TL1A (100ng/ml) activated cultures on day 14. These data reveal a new mechanism for DR3's resorptive function in bone. This action was independent of TNFα; the cytokine was not detected in any of our culture conditions studied. In serum collected from RA patients, TL1A levels were significantly elevated ($P<0.05$) over normal healthy individuals (3.0$\pm$0.6 versus 0.2$\pm$0.2 ng/ml). Serum levels of TL1A were also significantly higher in RA (rheumatoid factor positive) patients with erosive disease over those who had no detectable radiographic changes at time of sampling (3.9$\pm$0.8 and 0.5$\pm$0.2 ng/ml). TNFα was not detected in any of the samples assayed.

Conclusion: Our findings reveal TL1A to be a key regulator in osteoclastogenesis and imply that the TL1A/DR3 pathway contributes to osteoclast-driven bone pathology associated with RA.

1805

The Pro-Fibrotic Cytokines IL-33 and IL-13 Modulates Dermal Fibrosis Via the A2A Adenosine Receptor. Ross C. Radusky[1], Jessica L. Feig[2], Bruce N. Cronstein[3], Andrew G. Franks[4] and Edwin SL Chan[1]. [1]New York University School of Medicine, New York, NY, [2]New York Univ School of Medicine, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY, [4]New York University, New York, NY

Background/Purpose: We have previously demonstrated that the nucleoside adenosine mediates collagen production and induce dermal fibrosis in *in vitro* and *in vivo* models. IL–13 expression is upregulated in tissues characterized by high levels of adenosine (adenosine deaminase-deficient mice). However, the receptor(s) and mechanism involved in this upregulation are unknown. Here, we further characterize the contributions of endogenous adenosine and adenosine A$_{2A}$and A$_{2B}$receptors in skin fibrosis via IL-33 and IL-13 signaling.

Methods: Human dermal fibroblasts were treated with A$_{2A}$ receptor agonist (CGS-21680), A$_{2A}$ antagonist (ZM241385); A$_{2B}$ (BAY606583), and A$_{2B}$antagonist (MRS1706). Fold changes in the expression of IL-13 and associated receptors were analysed after 2 hours. Message for IL-33, IL-13 and three IL-13 receptor proteins – IL-13Rα1, IL-13Rα2 and IL-4R, were assessed using quantitative real-time PCR and compared to untreated controls.

Results: Stimulation of the A$_{2A}$ receptor with CGS-21680 induces expression of IL-13 and three IL-13 receptors: IL-13Rα1, IL-13Rα2, and IL-4R. A 2.8x increase in expression was found for IL-13Rα1 (p<0.05), 3.4x increase for IL-13Rα2 (p<0.05), and 3.9x increase for IL-4 (p<0.05) was seen. IL-33 expression was increased by 8.6x (p<0.05). These elevations were all blocked by the A$_{2A}$ receptor antagonist. Stimulation of the A$_{2B}$receptor alone does not cause significant changes in the expression of the receptors studied.

Conclusion: Despite efforts at investigating the mechanisms underlying fibrogenesis in the skin of patients with scleroderma, no effective antifibrotic therapy exists. The nucleoside adenosine induces expression of pro-fibrotic cytokine IL-13 and particularly its cognate receptors IL-13Rα1, IL-13R α2, and IL-4. Furthermore, Upregulation of IL-33 may in part contribute to the induction of IL-13 expression by A2A receptors. These findings suggest that blockade of the A_{2A} receptor may be useful as a novel therapeutic modality to prevent dermal fibrosis in scleroderma.

A Novel Angiopoetin2/TEK Tyrosine Kinase Receptor Mediated Effect On Leukocyte Cell Influx and Oxidative Damage in Inflammatory Arthritis. Emese Balogh[1], Chin T. Ng[1], Douglas J. Veale[2], Ursula Fearon[1] and Monika Biniecka[1]. [1]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: The Angiopoietin2 (Ang2)/TEK Tyrosine Kinase Receptor (Tie2) signalling pathway acts synergistically with VEGF/flk as critical regulators of new vessel growth, morphology and stability possibly through TNFα sensitization. The aim of this study was to assess the synovial tissue levels of VEGF, Ang2 and Tie2 in inflammatory arthritis patients and examine the effect of TNF inhibitors (TNFi) on VEGF expression and angiopoietin/Tie2 signaling. Moreover we correlated these data with changes in clinical outcomes, hypoxia and oxidative damage.

Methods: Forty four patients with inflammatory arthritis (RA n=30 and PsA n=14) underwent needle arthroscopy. All subjects had actively inflamed knee joints and were assessed pre-TNFi treatment, with a subgroup (n=20) pre/post TNFi therapy. All patients underwent full assessment including DAS28-CRP, macroscopic vascularity/synovitis, synovial biopsy and *in vivo* tissue pO$_2$ (tpO$_2$) was measured using a novel LICOX probe. Immunohistology and dual-immunofluorescence were used to quantify vascular factors (VEGF, Ang2 and Tie2), cell specific markers (CD3, CD68) and markers of oxidative damage (8-oxo-dG and 4HNE).

Results: At baseline the mean synovial tissue pO$_2$ (tpO$_2$) level was profoundly hypoxic at 25.9 mmHg, equivalent to an ambient oxygen tension 3.4%. VEGF, Ang2 and Tie2 were expressed throughout the synovium localised in the lining layer, sub-lining and vascular regions. VEGF expression correlated with macroscopic synovitis (r=0.41, p=0.031) and vascularity (r=0.40, p=0.034). High Ang2 expression was associated with greater synovitis (r=0.56, p=0.013) and number of CD68+ cells (r=0.53, p=0.013). Tie2 expression was significantly associated with CD3+ cells (r=0.39, p=0.023) and CD68+ cells (r=0.46, p=0.010) and with high ESR and CRP (both r=0.37, p=0.047). Treatment with TNFi showed a significant reduction in expression of Tie2 (p=0.034) and Ang2 (p=0.021) and this was paralleled by an increase in tpO2 levels from mean 22.8 mmHg to 30.3 mmHg. Finally, a significant association between increased ΔVEGF, ΔAng2 and ΔTie2 with high DNA damage (Δ8-oxo-dG) and lipid peroxidation (Δ4-HNE) was demonstrated (both r>0.53, p<0.05), strongly suggesting an interplay between oxidative stress and angiogenesis in a progression of chronic inflammatory arthritis.

Conclusion: This data suggests that the Ang2/Tie2 signalling pathways may mediate in part the downstream effects of TNF blockade. Furthermore, this is the first evidence to suggest that Ang2/Tie2 maybe directly involved in leukocyte cell influx regulation and oxidative damage within the inflamed joint.

Regulation of Inflammatory Responses in Tumor Necrosis Factor-Activated and Rheumatoid Arthritis Synovial Macrophages by Janus Kinase Inhibitors. Anna Yarilina[1], Kai Xu[1], Chunhin Chan[1] and Lionel B. Ivashkiv[2]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Medical College of Cornell University, New York, NY

Background/Purpose: Small molecule inhibitors of the Janus kinases (JAKs) have been developed as anti-inflammatory and immunosuppressive agents and are currently undergoing testing in clinical trials. Tofacitinib/CP-690,550 (more potent in inhibiting JAK3 and JAK1) and Ruxolitinib/INCB-018424 (selective inhibitor of JAK1/2) have demonstrated clinical efficacy in rheumatoid arthritis (RA). However, the mechanisms that mediate the beneficial actions of these compounds are not well understood. In this study, we examined effects of JAK inhibition on inflammatory responses in human blood-derived and RA synovial macrophages, with a focus on the key pathogenic cytokine TNF that activates JAK-STAT signaling indirectly and with delayed kinetics.

Methods: In vitro studies were performed with peripheral blood macrophages from healthy donors treated with TNF and synovial fluid macrophages from patients with RA. Levels of activated signal transducer and activator of transcription (STAT) proteins and other transcription factors were detected by Western blot, and genes expression was measured by real-time PCR. In vivo effects of JAK inhibitors were evaluated in the K/BxN serum-transfer model of arthritis.

Results: JAK inhibitors suppressed activation and expression of STAT1 and downstream target genes encoding inflammatory chemokines (CXCL9, 10, 11) in TNF-stimulated and RA synovial macrophages. Unexpectedly, both compounds attenuated a late wave of *IL1B* induction by TNF. Furthermore, CP-690,550 significantly decreased *IL6* expression in RA synovial macrophages. In addition, both inhibitors decreased nuclear localization of NF-kB subunits in TNF-stimulated and RA synovial macrophages. Both JAK inhibitors augmented nuclear levels of NFATc1 and cJun, followed by increased formation of osteoclast-like cells. However, only CP-690,550 dramatically increased resorptive activity of these cells. CP-690,550 significantly inhibited inflammation and joint swelling in K/BxN arthritis that is dependent on macrophages but not on lymphocytes.

Conclusion: Taken together, our data demonstrate that JAK inhibitors suppress inflammatory functions of macrophages, in part by altering cell responses to the key pathogenic cytokine TNF. These findings suggest that suppression of macrophages and innate immunity may contribute to the therapeutic efficacy of JAK inhibitors in RA.

Immune Activating Effects of Co-Stimulation of TLR Agonists and Cytokines On Primary and Immortalized Keratinocytes From a Patient with a *CARD14* Mediated Pustular Psoriasis (CAMPS) and Healthy Controls. Yongqing Chen[1], Yin Liu[2], Yan Huang[1], Carole Yee[3], Alison MacBride[4], Anne Bowcock[5], Michelle Lowes[6] and Raphaela T. Goldbach-Mansky[7]. [1]Translational Autoinflammatory Disease Section, Office of the Clinical Director NIAMS, Bethesda, MD, [2]NIAMS, Bethesda, MD, [3]NCI, NIH, Bethesda, MD, [4]NIAID, NIH, Bethesda, MD, [5]Washington University, St. Louis, MO, [6]Laboratory for Investigative Dermatology, The Rockefeller University, New York, NY, [7]Translational Autoinflammatory Diseases Section NIAMS NIH, Bethesda, MD

Background/Purpose: Through producing inflammatory cytokines and chemokines, keratinocytes play an important role along with hematopoietic cells in mediating an inflammatory response in psoriasis and other inflammatory skin conditions. Keratinocyte-produced cytokines include IL-1a, IL-6, IL-8, IL-23, TNF, IL-36α, β, and γ, etc. Recently, autosomal dominant mutations in *CARD14* have been shown to cause a disease severity spectrum of plaque psoriasis, pustular psoriasis and pityriasis rubra piliaris. CARD14 is mainly expressed in the keratinocytes in skin. As blockade of IL-12/23 has been very successful in inhibiting skin inflammation in psoriasis and in our pediatric patient with CAMPS, and more recently blockade of IL-17A/F in psoriasis, we hypothesize that keratinocyte activation may be the primary trigger of hematopoietic cell recruitment into the skin and that therapy with IL-12/23 inhibitors and more recently with IL-17 inhibitors may either block keratinocytes directly or through the prevention of IL-17 production, and that inhibition of keratinocyte activation might significantly contribute to the treatment success with these agents in controlling skin inflammation.

Methods: We generated primary and immortalized keratinocyte cell lines from a patient with CAMPS, a patient with *CARD14* negative plaque psoriasis and 3 foreskin samples. We examined the immune function of keratinocytes in co-stimulation assays with a panel of TLR agonists and pro inflammatory cytokines, measuring IL-8 in cell culture supernatant as initial readout for keratinocyte activation. We assayed cytokine receptor expression on keratinocytes. In some experiments gene expression of other cytokines (CCL20, IL-6 and S100A7 (psoriasin)) were assayed by qRT-PCR. Statistical analysis was performed using paired/unpaired t-tests.

Results: Keratinocytes can be activated by the agonists through TLR3, Poly IC; TLR5, Flagellin; and TLR9, Type B CpG oligonucleotides to produce IL-8. Keratinocytes have a number of cytokine receptors, such as IL-1R, IL-6R, IL-17R, IL-23R, IL-36R, TNF-R, etc, and get stimulated through IL-17A, IL-1a/b, and less through TNF, IL-36γ. However, they do not get stimulated through IL-12 or IL-23. IL17A synergizes with Poly IC, Flagellin, and also with TNF but not with IL-36γ, IL-12 or IL-23. Based on all TLRs and cytokine stimulation at 24hr, the keratinocytes from a patient with the *CARD14* mutation have higher IL-8 production than control cells and keratinocytes from a patient with severe plaque psoriasis. Expression studies show that under co-stimulation of TNF and IL-17A, mRNA expression of CCL20 and IL-6 occurs early at 4hr, but S100A7 is maximally expressed later at 24hr.

Conclusion: TLRs stimulating through TLRs 3, 5 and 9 and some hematopoietic-produced cytokines particularly IL-17 have direct synergic effects on keratinocyte activation. *CARD14* mutant keratinocytes are more sensitive to these positive stimulants than keratinocytes from a patient with regular psoriasis and health controls. Our data suggest that *CARD14* mutations sensitize keratinocytes to heightened responses to TLR agonists and co stimulation with other inflammatory cytokines and is likely the crucial cytokine in promoting skin inflammation.

1809

Serum IFNα Activity in Systemic Lupus Erythematosus Drops in Response to Immunosuppressive Therapy Only When There Is Concurrent Clinical Response. Elzbieta E. Jacek[1], Elena Gkrouzman[1], Mikhail Olferiev[2], Nancy Pan[1], Roland Duculan[3], Kyriakos A. Kirou[3] and Mary K. Crow[3]. [1]Mary Kirkland Center for Lupus Research, Hospital for Special Surgery, New York, New York, NY, [2]Mary Kirkland Center for Lupus Research, Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, New York, NY

Background/Purpose: The type I interferon (IFN-I) signature, describing expression in PBMC of a large set of gene transcripts induced by IFN-I, and increased serum IFNα functional activity are characteristic of many patients with systemic lupus erythematosus (SLE) and are candidate biomarkers of disease activity. However, previous studies have not consistently demonstrated whether IFNα activity is useful for monitoring disease activity and assessing the effect of therapy in lupus patients.

Methods: From a cohort of 60 lupus patients with available serum data of IFNa activity, 15 were identified who experienced a) at least 1 severe flare as determined by the SELENA-SLEDAI instrument, and b) had a follow-up visit no longer than 3 months after the occurrence of a severe flare. In the 15 patients identified, there were 21 occurrences of a severe flare, with a follow-up visit no longer than 3 months later. IFNα activity at the time of those visits was measured using an in vitro reporter assay in which WISH epithelial cell line cells (highly responsive to stimulation with IFN-I) were cultured with patient sera and relative expression of IFIT1 and IFI44, IFN-I-responsive genes, was quantified using RT-PCR. The IFN-I score was calculated by converting relative expression values to IFN units/ml, using a standard curve acquired from dose response stimulations of WISH cells with 1–100 units/ml of recombinant IFNα. Clinical improvement was defined according to the SLE Responder Index (SRI) as: 1) improvement in SLEDAI by at least 4 points; 2) no 2 B or 1 A as recorded in the BILAG; 3) no increase in Physician Global Assessment by more than 0.3 points.

Results: Out of 21 severe flares identified, 12 fulfilled the clinical improvement criteria (responses) during the next visit (<3 months). In those cases, IFNα score decreased significantly (from a median of 12.67 to 2.3, p=0.005), and there was also a significant decrease in the SLEDAI score (from a median of 13 to 5, p=0.0025). The remaining 9 cases which did not fulfill the clinical improvement criteria (no responses) showed statistically unchanged IFNα and SLEDAI scores. Immunosuppressive therapies were similar in both groups, including mycophenolate mofetil in 10/12 responses and in 5/9 non-responses. Pulse steroids were used in 6/12 responses and 4/9 non-responses. Only 1 pulse steroid therapy in each group was given less than 7 days before serum was obtained for IFNa levels.

Conclusion: Our data indicate that a decrease in IFN-I serum activity following a severe clinical flare may be a sensitive and reliable tool for monitoring the disease state of lupus patients and confirming the effectiveness of therapies used to treat severe flares.

Disclosure: **E. E. Jacek**, None; **E. Gkrouzman**, None; **M. Olferiev**, None; **N. Pan**, None; **R. Duculan**, None; **K. A. Kirou**, None; **M. K. Crow**, None.

1810

Identification and Characterization of Synthetic Small Molecule Macrocycle Antagonists of Human IL17A. David Livingston, Sethu Alexander, Julian Bond, Timothy Briggs, Andrew Fraley, Stephen Hale, Tanya Landsman, Richard Martinelli, Kelley Shortsleeves, Nick Terrett and Nathan Walsh. Ensemble Therapeutics, Cambridge, MA

Background/Purpose: IL17A has been demonstrated to be a key pro-inflammatory cytokine in human rheumatoid arthritis and in several rodent models of arthritis. Synthetic macrocycles are more amenable to optimization for metabolic stability and oral absorption than biotherapeutics. The aim of this investigation was to identify high-affinity macromolecule binders of human IL17A, to quantify their inhibitory potency against IL17A-dependent cytokine production in human cells, and to determine if active compounds could inhibit a delayed-type hypersensitivity response in mice.

Methods: DNA programmed chemistry (DPC) libraries were generated to synthesize in vitro libraries of non-peptidic synthetic macrocycles of molecular weight 600–1000 kDa. Compounds binding to immobilized IL17A were identified by PCR and DNA sequencing. Two compounds were resynthesized and characterized by 1) competitive ELISA to determine affinity for human IL17A, 2) inhibition of IL17A-driven IL-6 production in human rheumatoid arthritis synovial fibroblasts (RASF) and human HT-29 adenocarcinoma cells, 3) inhibition of other pro-inflammatory human cytokine activities, such as IL-1β, IL-6, IL-22, and TNFα, and 4) efficacy in a delayed-type hypersensitivity (DTH) mouse model. The DTH model used a 1-fluoro-2,4-dinitrobenzene (DNFB) sensitizer, which was applied to the animals at day 0. On day 7, compounds dissolved in DMSO were dosed by intraperitoneal (i.p.) injection at a dose of 10 mg/kg. A second application of DNFB was performed on the left ear 30 min after compound dosing. After 24 hours, left ear edema was measured by change in ear weight compared to the right ear, and levels of INF-γ in ear tissue homogenates were quantified by ELISA.

Results: Two synthetic macromolecules identified in this investigation, E-34935 and E-35018, were characterized by a competition ELISA with human IL17A, and determined to have a dissociation constant (Kd) = 2 nM. E-34935 and E-35018 were found to inhibit IL17A with EC50 of 2.0 and 2.1 μM in RASF, and 45 and 20 nM in HT29 cells, respectively. Both compounds were inactive (EC50 > 25 μM) in a battery of cellular assays for the human cytokines IL-1β, IL-6, IL22, and TNFα. A single i.p. dose of 10 mg/kg of E-34935 or E-35018 in the murine DTH model suppressed edema vs. vehicle control by 50 or 54% respectively (p < 0.05 vs. vehicle control). In comparison, a rat anti-mouse IL17A IgG1 (5 mg/kg, i.p.) resulted in 76% inhibition of edema. INF-γ levels in tissue homogenates were also suppressed by E-34935, E-35018, or anti-IL17A Ab vs. vehicle control by 72%, 62% or 75%, respectively (p < 0.05 for all groups vs. vehicle control group).

Conclusion: Our data provide evidence that synthetic macrocycles can be identified that bind potently and specifically to human IL17A, and act as inhibitors of IL17A-stimulated IL-6 production in RASF and HT29 cells. These compounds are also anti-inflammatory in an IL17-directed murine DTH model. Prior to this investigation, such specific inhibitors of the IL17A-IL17receptor interaction were limited to polypeptides.

1811

On the Origin of the Type I Interferon Signature in Rheumatoid Arthritis. T.D. de Jong[1], Saskia Vosslamber[1], Maija-Leena Eloranta[2], Lars Rönnblom[2], Kyra Gelderman[1], Mary von Blomberg[1], Irene Bultink[1], Alexandre Voskuyl[1] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Section of Rheumatology, Uppsala University, Uppsala, Sweden

Background/Purpose: Presence of a type I interferon (IFN) signature has been described for several autoimmune diseases, including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). For SLE, it was shown that the IFN signature is induced by IFNα from plasmacytoid dendritic cells via specific immune complexes. Although the IFN signature in RA seems to be comparable to SLE, the source of IFN induction is yet unknown. This study aims to investigate the mechanism by which components of RA serum contribute to the IFN signature.

Methods: Healthy PBMCs were exposed to RA or SLE serum. IFNα protein production was measured in an immunoassay after 20h incubation with 5% patient serum. To study the involvement of immune complexes containing antinuclear antibodies, samples were co-cultured with necrotic or apoptotic cells (Lövgren et al., Arthritis Rheum. 2004 Jun;50(6):1861-72). Moreover, IFN response genes (IRG), IFNα and IFNβ mRNA induction were measured by quantitative PCR after 4h and 8h incubation with 25% patient serum. An IFN score is calculated as the average expression of 3 IRGs (RSAD2, IFI44L, MX1). To study the involvement of new protein synthesis on IRG induction, part of the samples were co-cultured with 2μg/ml cycloheximide (CHX).

Results: As expected, SLE serum induced more IFNα protein induction than healthy donor serum (NHS) (p=0.0006, Mann Whitney test), which even further increased with dead cell material (p=0.006, Mann Whitney test). RA serum did not induce significantly more IFNα protein production than NHS, although a small increase was observed in the absence of dead cell material (p=0.0516, Mann Whitney test).

With respect to IRG mRNA induction, both RA and SLE sera induced higher levels than NHS, though with different induction kinetics. SLE serum showed IRG mRNA induction already at 4h, which stayed present after 8h. CHX treatment even slightly increased IRG mRNA induction at 8h, suggesting that the IRG mRNA induction occurs independently of new protein synthesis and is probably mediated directly by IFNα, as described before. RA serum, on the other hand, showed only IRG mRNA induction after 8h. This IRG mRNA induction was downregulated upon CHX treatment, indicating an indirect IRG induction process. To study whether the IRG induction was preceded by IFN mRNA induction, IFNα en IFNβ mRNA expression was determined. The IRG induction by RA serum was positively correlated to IFNβ mRNA induction at 4h and 8h (Pearson correlations, 4h: r= 0.6873, p=0.0023; 8h: r=0.7173, p=0.013), but not to IFNα production.

Conclusion: RA serum did not induce IFNα protein production, and mRNA induction kinetics differed from those of SLE serum. Furthermore, the IRG mRNA induction by RA serum was preceded by IFNβ mRNA induction. Altogether, this indicates a different source of IRG induction in SLE and RA serum and thus possibly a different mechanism behind their type I IFN gene signature.

A Retrospective Evaluation of the Clinical and Economic Implications of Gout in Nursing Home Residents in Hawaii Treated with Allopurinol. Joy Higa[1], Gregory Reardon[2] and Gregory Tong[3]. [1]Long Term Care Research Center, Kaneohe, HI, [2]Informagenics, LLC, Worthington, OH, [3]Deerfield, IL

Background/Purpose: We describe patient characteristics, serum uric acid (sUA) levels while on allopurinol, and activities of daily living (ADL) in nursing home residents with gout.

Methods: On-site chart review of 14 nursing homes in Hawaii (Oct 2010-Mar 2011), including serum creatinine, sUA, the Minimum Data Set (MDS) and medication records. Eligible residents were >65 years of age, had been residents > 30 days, and had recent sUA and ADL assessments. Cases (n=202) were eligible residents with gout using allopurinol. Controls (2 per case, n=404) without gout were identified by simple random sampling from the same time frame. A global ADL score was calculated [BMC Geriatr 2006, 6:7] from the most recent MDS. Multiple regression separately estimated the independent association of gout with ADL score and the use of any opiate medication, adjusting for potentially related factors (eg, demographics, body mass index (BMI), renal function, and comorbid conditions).

Results: Of residents with gout, 69% had sUA ≥6mg/dl, despite allopurinol treatment. Compared with controls, cases were younger (39% vs. 53% <85 years of age; p<0.001) and more likely to be of Hawaiian ancestry (OR=7.3, p<0.001). BMI was 2.3 points higher for cases vs controls (p<0.001). Cases were more likely to have coronary artery disease (OR=4.0, p<0.001), diabetes (OR=3.6, p<0.001), previous myocardial infarction

(OR=7.3, p<0.001), and charted renal failure (OR=4.9, p<0.001). They had a mean Carpenter score of 25.2 (0–28; 28=total dependence) vs 17.1 for controls (p<0.001). Adjusted logistic regression models showed that gout was independently associated with a 7.26-point higher (worsened) Carpenter ADL score (p<0.001). Cases were more likely than controls to receive an opiate (adjusted OR=8.7, p<0.001).

Conclusion: In nursing home residents, gout is independently associated with worsened ADL scores and should be factored into pre-admission evaluation and considered in resident care management. In the institutionalized elderly, renal insufficiency is prevalent. Allopurinol, even when given at maximum renally-adjusted doses, may not be sufficient to achieve target sUA.

Accuracy of Veterans Affairs Database for Gout-Related Health Care Utilization. Jasvinder A. Singh. University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Gout outcome studies have used administrative and claims databases. It is unknown whether administrative-derived data are accurate for gout-related utilization. The goal of the study was to assess the accuracy of Veterans Affairs (VA) administrative and clinical claims databases for gout-related health care utilization.

Methods: This retrospective study utilized the VA administrative and clinical claims databases for the fiscal year 2006. A cohort consisting of randomly mixed sample of two types of visits was identified that included visits with gout as primary or secondary diagnosis versus other diagnoses. An experienced senior epidemiologist (JS) blinded to the database information related to the visit performed review of electronic medical records (EMR). The gold standard was medical record documentation of gout or gout-related terms (gouty arthritis. tophaceous gout, acute gout, chronic gout, podagra, urate renal stones) in the chief complaint, history of present illness or assessment and plan for the visit. This indicated that gout was the main reason or one of the main reasons for the visit. We assessed the accuracy of database-derived gout-related utilization by calculating sensitivity, specificity, and positive and negative predictive values (PPV and NPV).

Results: Of the 108 potential visits, 85 visits to a health care provider (in 85 patients: 84 men, 1 woman with mean age of 63 years) in one of the three settings (outpatient, inpatient or urgent care/emergency room), and retrievable data from medical records, constituted the analyzed dataset. According to the gold standard of chart documentation, 21 visits were related to gout and 64 were not. Administrative claims for visits related to gout were accurate with excellent PPV of 86%, sensitivity of 86%, specificity of 95% and NPV of 95%. There were three visits coded as gout-related visit in databases that did not have medical record documentation related to gout: one visit each to discuss blood pressure medication, for regular follow-up of multiple medical problems, and for increased blood sugar. Three visits coded as not related to gout in administrative databases were related to gout based on medical record documentation: one patient each with continuing acute gout flare, a new diagnosis with documentation of urate crystals in knee joint fluid, and chronic gout stable on allopurinol.

Conclusion: VA databases can be used to identify gout-related visits with good accuracy. This finding supports the use of VA databases for studies of health services outcomes to identify gout-related utilization. It remains to be seen if findings are generalizable to other clinical and/or claims databases.

Comparing Clinical Characteristics and Comorbidities of Gout Patients Treated with Allopurinol or Febuxostat. Michael A. Becker[1], Xiangyang Ye[2], Kasem S. Akhras[3], Rima H. Tawk[4], Sudhir Unni[2], Jason Young[2] and Carl V. Asche[5]. [1]University of Chicago, Chicago, IL, [2]University of Utah College of Pharmacy, Salt Lake City, UT, [3]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [4]University of Illinois at Chicago, Chicago, IL, [5]University of Illinois College of Medicine at Peoria, Peoria, IL

Background/Purpose: Gout is a common acute and potentially progressive disease affecting approximately 8 million Americans. Hyperuricemia (serum urate levels [sUA] >6.8mg/dL) is a major pathogenic factor in gout.

Urate-lowering therapy (ULT), aimed at maintaining sUA in the range <6.0 mg/dL, is the commonly recommended goal for managing the hyperuricemia in gout, with allopurinol (ALLO) being the first line therapy in the majority of patients. ALLO, however, has many limitations, including intolerance and dose-limitations in renally compromised patients. Febuxostat (FEB) is another xanthine oxidase inhibitor approved by the FDA in 2009 with favorable safety and tolerability profiles. Our aim was to compare baseline demographics and comorbid characteristics of gout patients receiving ALLO and FEB.

Methods: Retrospective cohort study using a U.S. ambulatory care-based electronic medical record database with health records of primary care pts. Pts ≥18 years with a prescription for ALLO or FEB from April 1, 2009 to July 31, 2011 and with 13+ months of database activity prior to and a minimum of 6 months of activity after index date were included. Pts prescribed ALLO or FEB with diagnosis of neoplasm or with prescriptions for 2 or more ULTs on index date were excluded. Baseline pt characteristics (age, gender, race, and payer status); gout disease features (duration, sUA, presence of tophi); and comorbidities, (obtained from clinical history and/or body mass index, blood pressure, fasting plasma glucose, estimated creatinine clearance (eCrCL), smoking status, and alcohol use) were recorded. Comorbid status was summarized by Deyo-modified Charlson Comorbidity Index (CCI) and concomitant medication variables. Descriptive statistics, including mean and standard deviation for continuous variables, counts and proportions for categorical variables were utilized to describe the characteristics of ALLO and FEB cohorts. T-tests were used for continuous variables and chi-square tests for categorical variables.

Results: The study identified 35,404 ALLO-treated pts (mean age 63.2($\pm$12.1) years; 77% male) and 2,837 FEB pts (mean age 61.7($\pm$13.1) years; 73% male). Mean baseline sUA was significantly higher in FEB than ALLO pts (8.28 mg/dL vs 6.93 mg/dL, p<0.0001) and more FEB pts had sUA ≥ 9.0 mg/dL (32.7% vs 12.9%, p<.0001). Majority of ALLO-treated pts (57.1%) were receiving 300mg/day and 37.3% were receiving 100mg/day. FEB-treated pts had greater numbers of comorbidities (CCI ≥3, 22.1% vs 17.05 %, p<0.0001), and higher mean CCI scores (1.65 vs 1.51, p=0.0002) than ALLO pts, and more severe renal disease (eCrCL <60 29.8.0% vs 19.4%, p<.0001), presence of tophi (2.22% vs 0.39%), heart failure (5.11% vs 3.01%, p<0.0001), hypertension (HTN) (18.26% vs 16.29%, p=0.0066), and coronary artery disease (CAD) (8.35% vs 7.05%, p=.0097) were also more common in FEB pts than in those receiving ALLO.

Conclusion: A real-world comparison of utilization patterns of ALLO and FEB, shows that ALLO remains the ULT most often used in patients with gout, while FEB is being used in more difficult to treat patients, including those with higher baseline sUA levels and with commonly associated co-morbidities.

Factors Associated with a Prolonged Hospital Length of Stay for Patients with Acute Gout. Rebecca Sharim[1], Meghan Musselman[2] and Marissa Blum[2]. [1]Temple University Hospital, Philadelphia, PA, [2]Temple University School of Medicine, Philadelphia, PA

Background/Purpose: Management of gout in the hospital setting has been poor. This study aimed to describe patient characteristics and the treatment patterns of acute gout for patients hospitalized with gout in a tertiary care hospital. We hypothesized that the effects of treatment for gout and diagnostic delays for those with acute gout would prolong hospital length of stay.

Methods: Medical records of patients hospitalized with a primary or secondary diagnosis of gout (ICD-9-CM: 274.9) were retrospectively reviewed from 2005–2011. Charts were abstracted for demographic data (age, sex, race, insurance status, primary language), co-morbid conditions, length of stay, day of musculoskeletal complaint, medications used to treat gout, day of rheumatology consultation, and day of diagnosis of gout. Bivariate analyses were performed using Fisher's exact tests for categorical variables, and t-tests and analysis of variance for continuous variables. Multivariable regression testing was performed to evaluate factors associated with length of stay after adjustment for age, race, sex, insurance status, Charlson comorbidity Index, diabetes, chronic kidney disease, heart disease, and history of gout. A follow up qualitative chart review was done to evaluate other factors contributing to length of stay for female and male patients.

Results: A total of 205 patients were included. 24.4% (n = 50) were females and 75.6% (n = 155) were males. 7.8% of patients were white, while 82.9% were black and 7.8% were Latino. 83.9% of patients had a prior diagnosis of gout. Co-morbid conditions included cardiac disease (58.5%), pulmonary disease (33.2%), diabetes (45.8%), and chronic kidney disease (44.8%). Rheumatology was consulted in 99.5% of admissions (n=204). 76.6% of patients were treated with intra-articular steroids (n = 157), 40.5% were treated with colchicine (n = 83), 37.1% were treated with systemic steroids (n = 76), and 6.8% were treated with NSAIDs (n = 14). In 45.4% of patients (n = 93), more than one treatment modality was used. Only 31 patients experienced side effects from medications used to treat gout. There was no significant association found between treatment side effects and length of stay. There was a significant association found between time to diagnosis and length of stay (median length of stay for diagnosis within 24 hours of symptom onset vs. greater than 24 hours: 9 vs. 12.5 days, p=0.001), and between sex and length of stay (median length of stay for females vs. males: 14 vs. 9 days, p=0.01). Multivariable regression of log length of stay revealed a diagnosis of gout made after 24 hours of symptom onset and female sex were each significantly associated with an increased length of stay (β-coefficient, p-value [0.49, p=0.000, and 0.29, p=0.02, respectively]). A follow up qualitative analysis revealed that females with longer length of stay had other medical complaints in addition to gout prolonging their length of stay.

Conclusion: In this retrospective cohort study, a later diagnosis of gouty arthritis and female sex were associated with an increased length of stay after controlling for potential confounders. These data should guide future management of gout to reduce length of hospitalization.

Relationship Between Race, Uric Acid Levels, Urate-Lowering Therapy and Resource Use in Patients with Gout. Kim Coley, Melissa Saul and Karen Pater. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Gout is a chronic inflammatory disease caused by the deposition of monosodium urate crystals in joints and soft tissues. The overall prevalence is increasing worldwide, with African-Americans (AA) being affected more than Caucasians. We evaluated the association between race, uric acid levels, urate-lowering therapy (ULT) and resource utilization in patients with gout in a large health system.

Methods: The study population was a cohort of African-American and Caucasian men and women with gout who had an inpatient or emergency department encounter at a large health system in Southwestern Pennsylvania between 10/1/2008 and 9/30/2011. To be included, subjects had to have an ICD-9-CM code for gout (274.xx) as a either primary or secondary diagnosis during the study timeframe. A mean uric acid (UA) level was calculated for each patient across the study period and categorized as either <6 or ≥ 6 mg/dL. ULT was identified during the hospitalization. All patient encounters where gout was listed as the primary diagnosis were collected to assess gout resource use. Chi-square and T-tests were used to compare categorical and continuous data, respectively. Logistic regression was conducted to determine the relationship between race, UA levels, and resource utilization.

Results: There were 8,483 patients who met study criteria: 5,998 (71%) were male and 7,073 (83%) were Caucasian. UA levels were available in 43% of patients; a higher percentage of AA had UA levels assessed compared to Caucasians (53% vs. 41%, p<0.001). After stratifying by sex, mean UA levels were similar for females, however AA men had higher mean UA levels than Caucasian men (7.9 vs. 7.1, p<0.001). Despite having higher UA levels, only 27% of AA received ULT compared to 39% of Caucasians (p<0.001). There were no differences between the sexes with respect to the use of ULT. Multivariate regression analysis revealed that patients with a UA level ≥ 6 mg/dL were more likely to be AA race (OR=1.5), male (OR=1.2), and have chronic kidney disease (OR=1.4) and less likely to be on ULT (OR=0.7). Additionally, after controlling for other variables, AA patients (OR=2.6) and those with high UA levels (OR=2.5) were more likely to have inpatient and emergency department visits for gout (p<0.001).

Conclusion: AA race is associated with higher UA levels and lower use of ULT. AA patients and those with high UA levels were more likely to have emergency department visits or be hospitalized for gout. Improving access to ULT may reduce the burden of gout in African-Americans and reduce overall healthcare costs.

The Role of Repeating Tuberculin Skin Tests During Biologic Therapy.
Joseph R. Lutt[1] and Kevin L. Winthrop[2]. [1]Colorado Center for Arthritis &
Osteoporosis, Boulder, CO, [2]Oregon Health & Science University, Portland,
OR

Background/Purpose: Prior to starting biologic therapy, it is recommended that all patients be screened for tuberculosis (TB).[1] However, for
patients who screen negative at baseline and then subsequently start biologic
therapy, the utility of repeating a tuberculin skin test (TST) is uncertain. This
retrospective study was conducted to evaluate the frequency of TST conversion among patients on biologic therapy in a low incidence region for TB
(1.4 cases per 100,000).[2]

Methods: We retrospectively reviewed records from a community
rheumatology practice in Boulder County, Colorado, to identify patients
screened for TB between March 2005 and August 2010. All patients planning
to start biologic therapy were screened with a TST at baseline. Those with
negative results were screened annually thereafter while on biologic therapy.
We defined ≥5mm induration as a positive TST and "conversion" as
induration of ≥5mm after an initial negative TST.

Results: Five hundred eighty-nine patients were screened prior to biologic therapy initiation. Most were female (n=353, 60%) and had rheumatoid
arthritis (n=359, 61%) or spondyloarthritis (n=198, 34%). Three hundred
twenty-seven patients (56%) underwent a total of 818 repeat TSTs, 9 (1.1%)
of which were positive. Five (56%) of the converters had no apparent risk
factors for TB exposure. All converters had negative chest radiographs. While
continuing biologic therapy, all but 1 completed 8–9 months of isoniazid
(INH). None have developed TB during a median follow-up period of 49
months (range 16 to 70).

Test	Patients tested with TST	Number (%) of +TSTs
TST #1	589	17 (2.9)
TST #2	327	5 (1.5)
TST #3	220	2 (0.9)
TST #4	147	2 (1.4)
TST #5	79	0
TST #6	31	0
TST #7	10	0
TST #8	4	0
TST #2–8	818	9 (1.1)
Overall	1407	26 (1.8)

Conclusion: In an area of low TB incidence, annual TST conversion
while on biologic therapy was rare. Checking yearly TSTs on all patients
being treated with biologic agents is of low yield. A small number of
converters were identified, but more than half had no apparent risk factors for
TB exposure. It is unclear if these conversions truly represent new infections,
but all were started on INH and none have developed TB.

**Latent Tuberculosis Detection and Tuberculosis Reactivation in Patients
Receiving Anti-TNFá Drugs: A Nationwide Italian Survey.** Fabrizio
Cantini[1], Ennio Lubrano[2], Alessandro Mathieu[3], Antonio Marchesoni[4], Carlo
Salvarani[5], Raffaele Scarpa[6] and Antonio Spadaro[7]. [1]Ospedale Misericordia
e Dolce di Prato, Prato, Italy, [2]Università del Molise, Campobasso, Italy,
[3]University of Cagliari, Cagliari, Italy, [4]Istituto Ortopedico Gaetano Pini,
Milano, Italy, [5]Arcispedale S Maria Nuova. IRCCS, Reggio Emilia, Italy,
[6]Via Pansini 5, Naples, Italy, [7]Univerità La Sapienza di Roma, Roma, Italy

Background/Purpose: Anti-TNFα drugs are associated with an increased risk of tuberculosis (TB) and several recommendation sets for latent
tubercular infection (LTBI) detection and TB reactivation prevention are
available. Primary end-point of present Italian survey was to investigate the
behavior of Italian rheumatologists regarding LTBI detection and TB prevention. Secondary end-points were the occurrence of TB reactivation during
anti-TNF therapy despite LTBI screening and the association with different
anti-TNF agents.

Methods: An anonymous, 24-multiple-response questionnaire was completed by 393 rheumatologists operating in all Italian regions between January
and March 2012. The questionnaire encompassed several aspects of clinical
practice including the use of different recommendations, the availability of
tuberculin skin test (TST) and interferon-gamma release assay (IGRA), the
strategies to detect active TB in the case of positive LTBI, the type and
duration of TB prophylaxis, the number of patients currently treated with
anti-TNF at the date of March 31,2012 and the recorded active TB cases over
the previous 10 years expressed as total number and divided by the specific
anti-TNF drug.

Results: The Italian Society for Rheumatology recommendations were
used by 323/393 (82%) rheumatologists, other international sets by 60 (15%)
and occasionally by 10 (3%).However, local infectious disease experts were
always consulted by 81(21%) and occasionally by 73 (19%). TBST and
IGRA were available in 78% and 71% of the centers, respectively. LTBI
screening was made using chest radiograph (CR)+TST by 39%, CR+IGRA
by 28%, CR+TST+IGRA by 33%. Isoniazid (9-month course) for TB
reactivation prevention was employed by 324/393 (83%) of rheumatologists,
isoniazid+rifampicin for 4 months by 19/393 (5%), other strategies by 50
(12%). TB prevention was initiated in presence of positive TST by 134 (34%)
rheumatologists, positive TST+IGRA by 211 (54%), positive IGRA by 48
(12%). When TB prevention was indicated, anti-TNF was started 1 month
later in 63% of the cases, after 3 months in 28%, concomitantly in 9%. Over
a 10-year period, 39353 patients (pts) received at least one anti-TNF drug and
317 (0.8%) developed active TB. Active TB occurred during the anti-TB
prophylaxis period in 192 (60.6%) p., in 24 (7.6%) after anti-TB therapy
withdrawal, and in 101 (31.8%) with negative LTBI screening. Active TB
cases distribution by drug was: etanercept 51 (16%), adalimumab 98 (31%),
infliximab 137 (43.2%), golimumab 9 (2.8%),certolizumab 8 (2.5%), 14
(4.4%) in pts switched to multiple agents, with a significant lower frequency
in pts receiving etanercept compared to those treated with monoclonal
anti-TNF (χ^2= P<0.001).

Conclusion: The Italian rheumatologist attitude to detect LTBI and to
prevent TB reactivation in pts requiring anti-TNF is quite variable despite the
availability of multiple sets of recommendations. The elevated number of
active TB cases during anti-TB therapy and in pts with negative LTBI
screening indicate some defects of these procedures. Confirming other
studies, active TB occurrence seems significantly lower in pts receiving
etanercept compared to monoclonal anti-TNF drugs.

1819

**Predictors of Pneumococcal Vaccination in Patients with Rheumatoid
Arthritis and Systemic Lupus Erythematosus.** Anna Gramling[1], Kaleb
Michaud[2], Harlan Sayles[3], Frederick Wolfe[4] and Michelene Hearth-Holmes[5].
[1]University of Nebraska Medical Center, Omaha, NE, [2]National Data Bank
for Rheumatic Diseases & University of Nebraska Medical Center, Omaha,
NE, [3]University of Nebraska Medical School, Omaha, NE, [4]National Data
Bank for Rheumatic Diseases, Wichita, KS, [5]Univ. of Nebraska Medical
Center, Omaha, NE

Background/Purpose: Patients with rheumatoid arthritis (RA) and
systemic lupus erythematosus (SLE) are at high risk for serious infection, including those caused by *Streptococcus pneumoniae*. Administration of 23-valent polysaccharide pneumococcal vaccination (23-PPV)
is recommended for patients with several co-morbidities and age >65 years.
EULAR recommends 23-PPV for all patients with autoimmune inflammatory rheumatic diseases and the ACR recommends it for all patients
with RA. Small observational studies suggest that administration of
23-PPV in RA patients is inadequate while none studied SLE. The
purpose of our study is to determine rates and predictors of 23-PPV
administration in US RA and SLE patients.

Methods: We surveyed patients across the US with RA, SLE, or osteoarthritis (OA) every 6 months from 2007 through 2011 about 23-PPV
along with their demographic and health status. We identified characteristics within each diagnosis that predicted administration of 23-PPV in a
subsequent 6-month period through the use of univariate logistic regression adjusted for sex and age > 65 years. Significant predictors were
combined in a multivariate logistic regression model and eliminated with
backward stepwise selection until all remaining predictors were significant
for an alpha of 0.05. We also selected a subset of cases who had never

received 23-PPV at baseline and used univariate Cox proportional hazards models controlling for diagnosis group to predict the timing of the first administration of 23-PPV. Significant predictors were combined in a multivariate Cox proportional hazards model and eliminated with backward stepwise selection until all remaining predictors were significant for an alpha of 0.05.

Results: A total of 15,954 patients participated in the study (11,952 RA, 1,773 SLE, and 2,229 OA). Among these groups 69.8%, 65.2%, and 67.8% of patients reported having ever received 23-PPV, respectively. SLE patients who reported receiving 23-PPV in the subsequent 6 months were more likely to be over 65 (OR 1.64, p=0.01), taking prednisone (OR 1.38, p=0.01), and to have chronic lung disease (OR 1.68, p<0.01). RA patients age > 65 (OR 1.70, p<0.01), male (OR 1.16, p=0.01), on biologic therapy (OR 1.18, p=0.03) or prednisone (OR 1.20, p<0.01), and suffering from chronic lung (OR 1.53, p<0.01) or heart disease (OR 1.20, p=0.03) were more likely to receive 23-PPV. Age > 65 was the strongest predictor of 23-PPV use in OA patients (OR 2.06, p<0.01). Patients were more likely to receive their first 23-PPV if they were over 65 (HR=2.05, p<0.01), male (HR=1.2, p=0.01), taking a non-biological DMARD (HR=1.32, p<0.01), taking a biological DMARD (HR=1.31, p<0.01), had chronic lung disease (HR=1.33, p<0.01), or had a lower SF36 PCS score (HR=0.99, p<0.01).

Conclusion: Despite current EULAR and ACR recommendations nearly a third of RA and SLE patients have never received a pneumococcal vaccination in a large, contemporary US cohort. Age greater than 65 years and chronic lung disease were the strongest predictors of 23-PPV administration. This is the first study to report that use of immunosuppressive drugs other than prednisone was not associated with pneumococcal vaccination in SLE patients.

Human Papillomavirus Vaccine [Types 6, 11, 16, 18] (Gardasil®) and Autoimmune Disorders: Safety Assessment Using the Pharmacoepidemiologic General Research Extension System. Lamiae Grimaldi-Bensouda[1], Michel Rossignol[2], Elodie Aubrun[1], Pamela Leighton[3], Didier Guillemot[4], Alfred Mahr[5], Jacques Benichou[6], Paul-Henri Lambert[7], Bertrand Godeau[8] and Lucien Abenhaim[9]. [1]LA-SER, Paris, France, [2]LA-SER, Centre for Risk Research, Montreal, [3]LA-SER Europe Ltd., London, United Kingdom, [4]Institut Pasteur (PhEMI)/ INSERM U657 & Université Paris-Ile de France Ouest, Paris, France, [5]Hospital Saint-Louis, Paris, France, [6]INSERM U657 Pharmacoepidemiology and evaluation of the impact of health products on human health, France, and Department of Biostatistics, University Hospital of Rouen, Rouen, France, Rouen, France, [7]Centre of Vaccinology & neonatal immunology, University of Geneva, Geneva, Switzerland, [8]Service de médecine interne, Université Paris Est Créteil, AP-HP, Hôpital Mondor Créteil, France, Creteil, France, [9]LA-SER Europe Ltd, London, United Kingdom

Background/Purpose: This study investigated whether the human papillomavirus (HPV) vaccine [types 6, 11, 16, 18] is associated with a modified risk of autoimmune disorders (AIDs). It carried out a case-control study within the population targeted for HPV vaccination.

Methods: The following AIDs were studied: central demyelination, Guillain-Barré syndrome, connective tissue disorders (lupus, rheumatoid arthritis, myositis, dermatomyositis, undifferentiated connective tissue disorder), type 1 diabetes, autoimmune thyroid disorders (Graves' disease, Hashimoto's thyroiditis) and immune thrombocytopenia. A network of specialist centers (internal medicine, neurology, rheumatology, paediatrics, endocrinology, dermatology) throughout France recruited newly-diagnosed cases in females 14–26 years-old. Cases were diagnosed according to standardized criteria. Controls were recruited from general practice settings and matched to cases on age (within ± one, ± three, ± six or ± 12 months successively if no match was found for cases under 18 years-old, within ± 12 or ± 24 months for cases 18 years-old or older), region of residence (northern or southern France) and recruitment consultation date (within ± three or ± nine months). Vaccinations and other potential risk factors for AIDs were assessed in a standardized telephone interview of patients or their parents. The interviewers were blind to case/control status.

Results: Between December 2007 and April 2011, 113 specialist centers recruited 248 definite cases of AIDs which were matched to 1001 controls. 97.4% of reported vaccinations against HPV [types 6, 11, 16, 18]

were confirmed using medical records from the patients or their general practitioners. A smaller proportion of cases (26 or 10.5%) than controls (232 or 23.2%) received the HPV vaccine [types 6, 11, 16, 18] within predefined time windows up to 24 months before the index date but the difference was not statistically significant (adjusted odds ratio 0.72, 95% confidence interval 0.45, 1.18). No association was found when each AID was considered separately, although these analyses were based on small numbers of cases, or when considering various time windows prior to the index date, the inclusion of uncertain exposures to vaccination and unconfirmed cases. The specialist centers reported no important increase in incidence for any of the AIDs in the population eligible for HPV vaccination.

Conclusion: No evidence of an increased risk of the studied AIDs was observable following vaccination with HPV vaccine [types 6, 11, 16, 18] for the time window of study available. The study lacked the power to conclude on individual disorders taken separately. The study observed no unusual accrual, in a large series of centers specialized in AIDs, of incident cases of any of the diseases surveyed in young females, at a time when one-third of them were getting vaccinated against HPV, mainly by HPV vaccine types 6, 11, 16, 18.

Clinical Predictors of Methotrexate-Induced Liver Enzyme Elevation in Patients with Rheumatoid Arthritis in an Electronic Medical Record. Monica Ramirez[1], Bing Lu[1], Michelle A. Frits[1], Anne H. Fossel[2], Katherine P. Liao[1], Robert M. Plenge[1], Jonathan S. Coblyn[3], Nancy A. Shadick[4] and Elizabeth W. Karlson[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham & Womens Hospital, Boston, MA, [3]Brigham & Womens Hosp, Boston, MA, [4]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Methotrexate (MTX) use for the treatment of rheumatoid arthritis (RA) has been associated with hepatotoxicity, and requires monitoring of liver transaminases. However, elevations in liver transaminases may be transient and may not predict the development of cirrhosis or fibrosis. We aimed to identify clinically relevant factors associated with persistently elevated liver transaminases leading to discontinuation or dose reduction of MTX in RA patients.

Methods: The study population was derived from an EMR-based cohort of 5906 RA cases at a large academic medical center followed since 1992. We used a validated algorithm to identify patients with RA (PPV 94%). We extracted data on any MTX prescription, and any LFT elevation, defined as liver transaminases > 2 times the upper limit of normal (> 2X ULN). From the 1,040 RA patients identified as ever treated with MTX and with LFTs > 2X ULN, we randomly selected 500 patients for detailed chart review; 90 cases (18%) were confirmed as having LFT elevations while receiving MTX, with LFT elevations attributed to MTX. We abstracted data on risk factors for liver toxicity: age, sex, obesity, hyperlipidemia, MTX dose (2.5–7.5mg, 10.0– 17.5mg, or 20–25mg), alcohol use, NSAID use, and statin use. We defined our outcome as continuation of MTX versus discontinuation or dose reduction. We examined the univariable associations of the predictors with outcome and developed a multivariable adjusted logistic regression model to estimate odds ratios and 95% CI.

Results: In our cohort of 90 patients, MTX was discontinued or the dose was reduced in 55 (61%) of patients. The remainder of those that continued MTX had a single transaminase elevation that resolved. Among the patients in whom MTX was discontinued or the dose was reduced, 8 (15%) of patients had biopsies that showed fibrosis attributed to MTX use. In our univariable analysis, obesity was significantly associated with MTX discontinuation or dose reduction (**Table**). In our multivariable model we included age, sex, obesity and hyperlipidemia, and obesity remained significantly associated with MTX discontinuation or dose reduction, OR 2.60 (95% CI 1.01–6.66), p-value 0.05. Fifteen (27%) of obese patients had a clinical diagnosis of nonalcoholic fatty liver disease (NAFLD) in the MTX discontinuation or dose reduction group, and 2 (4%) obese patients had this diagnosis in the MTX continuation group.

Table. Univariable Analysis of Predictors of MTX Discontinuation or Dose Reduction

Predictors	Univariable OR (95% CI)	Univariable p-value
Age	0.99 (0.95–1.03)	0.57
Male sex	0.58 (0.16–2.17)	0.42
Obesity	2.89 (1.20–7.00)	**0.02**
Hyperlipidemia	1.92 (081–4.54)	0.14
Alcohol use	1.58 (0.59–4.25)	0.36
MTX dose		
2.5–7.5 mg (ref)	1.00 (ref)	*
10–17.5 mg	0.76 (0.22–2.64)	0.54
20–25 mg	1.01 (0.27–3.77)	0.76
NSAID use	0.95 (0.41–2.22)	0.90
Statin use	1.15 (0.43–3.12)	0.78

* p for trend = 0.85

Conclusion: In our cohort of RA patients with MTX-related LFT elevation, single LFT elevations resolved in 39% of patients. We found a significant association between obesity and LFT elevations that led to MTX discontinuation or dose reduction. This suggests a potentially heightened risk of hepatotoxicity among obese patients. Further studies are needed to determine whether NAFLD may be an underlying risk factor in this patient population.

Liver Toxicity Monitoring and Its Impact On Methotrexate Discontinuation in a National Cohort of Veterans. Gabriela Schmajuk[1], Yinghui Miao[2], Jinoos Yazdany[3], Mary Margaretten[1] and Michael Steinman[2]. [1]UCSF, San Francisco, CA, [2]San Francisco Veterans Affairs Medical Center, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA

Background/Purpose: The National Quality Forum recently endorsed a controversial quality measure that assesses liver toxicity monitoring for patients receiving oral methotrexate (MTX). Using national data from the Veterans Health Administration (VHA), we assessed the frequency of liver function testing (LFT) and rates of MTX discontinuation after minimally elevated LFTs among patients taking oral MTX.

Methods: We created a national cohort of incident MTX users $\geq$ age 65 using linked pharmacy and laboratory data from the VHA during fiscal years 2007–2008. Patients were included if they had $\geq$ 28-day supply of MTX dispensed and use of VHA services for a minimum of 180 days prior and 90 days after the index MTX prescription. Patients were excluded if they had any diagnosis of inflammatory bowel disease (ICD-9 codes 555.x, 556.x) or if they had evidence of having obtained care outside of the VHA (patients with any medical encounter billed to Medicare during the study period were removed from the sample). We defined performance on the MTX liver toxicity monitoring quality measure through 2 methods (Table). Using the value of the first abnormal LFT after the index MTX prescription, we assessed rates of MTX discontinuation (defined as lack of MTX dispensed for $\geq$ 90 days after the anticipated refill date).

Table. Performance on methotrexate liver toxicity monitoring quality measure in a national cohort of veterans

Definition	Description	Performance in national veteran incident user cohort
NQF technical specification	Proportion of patients in the population who were prescribed at least a 6-month supply of methotrexate during the measurement year that received a liver function test in the 120 days (3 months + 1 month grace period) following the earliest observed methotrexate prescription claim.	77%
Rolling interval method (Agnew-Blais 2009)	Mean of the "percent adherence" for each individual, calculated as the proportion of intervals (ranging in duration from 0–12 weeks) during the time when a patient was exposed to methotrexate in which a liver function test was documented.	65%

Results: 899 new users of MTX met inclusion and exclusion criteria for the study. 97% were male, mean age was 71 years (SD 6.3), and mean follow-up period was 267 days (SD 133). Mean MTX dose received was 11.4 mg weekly (SD 5.1). Performance on the quality measure is described in the Table. 148 (16.5%) patients did not have any LFT testing after MTX was initiated. 136/899 (15%) patients had any abnormality of AST or ALT during the follow-up period; 49/899 (5%) had an elevation of $\geq$ 1.5 $\times$ upper limit of normal (ULN). MTX was discontinued in 28/87 (32%) subjects with LFT elevations < 1.5 $\times$ ULN and 27/49 (55%) subjects with elevations $\geq$ 1.5 $\times$ ULN. Compared to patients with no LFT elevations during the follow-up period, patients with LFT elevations < 1.5 $\times$ ULN had 1.4 greater odds (95% CI 1.1, 1.8) of stopping MTX.

Conclusion: Despite many MTX users not receiving liver toxicity monitoring with the frequency intended by the National Quality Forum quality measure, one third of patients with mild LFT elevations may be having their MTX stopped unnecessarily. These findings suggest that there may be unintended negative consequences to a policy that encourages more frequent liver toxicity monitoring.

Short Periods of Glucocorticoid Use Increase the Risk of Gastrointestinal Bleeding. Steven C. Vlad[1], David T. Felson[1], Donald R. Miller[2] and Yuqing Zhang[1]. [1]Boston University, Boston, MA, [2]Edith Nourse Rogers Memorial VA Hospital, Bedford, MA

Background/Purpose: Short term use of glucocorticoids (GCs) is thought to be relatively benign and most adverse events have been studied in chronic users; there is little if any published evidence about the safety of short term use. We aimed to examine whether short periods of GC use are associate with an elevated risk of gastrointestinal bleeding (GIB).

Methods: We used national US Veterans Administration data from fiscal year 1998 through 2008 to compare the risk for GIB during periods of GC use compared to periods of non-use using a self-controlled case series design. This is a case-only design which compares risks within persons, thus limiting confounding. Based on prescription records we first developed a cohort of subjects who had only used 'burst' GCs, defined as dispensed oral prescriptions of [2] 30 days with at least 42 days between consecutive prescriptions. We excluded persons who received GCs during their first 60 days of follow-up or who could have received GCs during a prior hospitalization so as to limit the amount of unmeasured GC use. From these subjects, we selected those who had a first GIB requiring hospitalization using previously validated ICD-9 codes; we excluded cases who had a GIB within the first year of follow-up (to limit the number with possible recurrences) and those using NSAIDs during the follow-up period so as to eliminate this as a potential confounder. We focused on the period in which each subject was using GCs, as well as 30 days before and after to account for confounding by indication and any residual GC effects. The risk of GIB in each of these periods was compared to that in the remaining period of follow-up time. We controlled for age in 5 year bands (18–24, 25–29, 30–34,..., > 80).

Results: There were 433 cases of GIB among burst GC users. 94.7% were men. Mean age at GIB was 65.2 (sd 11.9) years; 65.9 (11.5) in men, 53.6 (12.4) in women. 71.4% of subjects were white, 13.7% African American, 6.3% Hispanic, 8.6% other. All cases had only 1 GC prescription for a median duration of 8 (Q1, Q3: 1, 14) days and median average daily prednisone equivalent dose of 20 (17.5, 26.8) mg. The incidence rate ratio (IRR) of GIB while using GCs was 5 times that of the baseline risk period. See table.

	No. cases of GIB in risk period	Incidence rate ratio	95% CI
Total number of cases	433		
Reference period (no GC use)	406	1.0	-
1–30 days prior to GC prescription	11	2.0	1.1, 3.7
Time while GC was being used	8	5.1	2.5, 10.4
1–30 days after GC discontinuation	8	1.5	0.7, 3.0

Conclusion: Our results suggest that even short periods of GC use increase the risk of GI bleeding and that the risk corresponds to the time when the drug is being used.

Do Statins Reduce the Incidence of Connective Tissue Disease? A Retrospective Cohort Study. Thomas W. Schmidt[1], Daniel F. Battafarano[1], Christopher R. Frei[2], Eric M. Mortensen[3] and Ishak Mansi[4]. [1]San Antonio Military Medical Center, San Antonio, TX, [2]University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]San Antonio Military Medical Center, San Antonio

Background/Purpose: Due to their anti-inflammatory effects, statins were proposed to lower the incidence of connective tissue diseases (CTD). The objective of this study is to determine if statin use is associated with a lower incidence of CTD in a healthcare setting where patients have similar access to care.

Methods: This was a retrospective analysis of adult patients (30–85 year-old) enrolled as Tricare Prime in a military medical facility. The study period was divided into baseline period (10/1/2003 to 9/30/2005), and follow up period (10/1/2005 to 3/5/2010). "Statin Users" received and dispensed a statin prescription of at least 90 days during the period from 10/1/2004 to 9/30/2005. "Non-users" did not receive a statin at any time during the study period. The outcome measure was the occurrence of any diagnosis code of the *International Classification of Diseases, 9th Revision, Clinical Modification*(ICD-9-CM) consistent with CTD (Rheumatoid arthritis and related disease, Systemic lupus erythematosus, and other connective tissue diseases as identified by the Clinical Classification Software of the Agency for Healthcare Research and Quality). We described comorbidities during the baseline period using the Charlson comorbidity score (CCS). We repeated the analysis in a prespecified subgroup of patients with CCS of 0 (no comorbidities).

Results: 46,488 patients were included: 13,640 statin-users and 32,848 non-users. Statin users were predominately male (58.3% vs 43.8%), older (60.4 years vs 44.8 years), smokers (9.0% vs 5.8%) and had a higher average CCS (1.2 vs 0.3) (p<0.0001). In the subgroup with no comorbidities, there were 6,137 statin users and 27,626 non-users. Regression analysis showed that statin users had a statistically significant lower incidence of connective tissue disease (adjusted odds ratio [OR]: 0.84; 95% confidence interval [CI]: 0.73–0.96; p-value=0.01). However, in the subgroup with no comorbidities, there was no difference between statin users and non-users in the incidence of CTD (adjusted OR: 0.83; 95% CI: 0.67–1.04; p-value=0.1).

Conclusion: Statin use is not associated with a lower incidence of CTD in patients without comorbidities. This finding may suggest that the beneficial effect of statins on CTD in many studies may be due to unadjusted baseline confounders or healthy user bias.

Work Disability and Work Limitations in Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis Are Equal and Increase with Comorbidities. Chanseok Rhee[1], Janet E. Pope[2], Andrew E. Thompson[3], Nicole G. H. Le Riche[4], Gina Rohekar[4] and Sherry Rohekar[4]. [1]Schulich School of Medicine and Dentisty, Western University, London, ON, [2]St. Joseph Health Care London, University of Western Ontario, London, ON, [3]St. Josephs Health Ctr, London, ON, [4]St. Joseph's Hospital, London, ON

Background/Purpose: Few studies directly compare work disability (WD) and work productivity losses in different forms of inflammatory arthritis (IA) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Also, the effect of comorbidities on WD in IA has not been thoroughly examined.

Methods: WD was defined as the inability to work or early retirement due to arthritis. Relationships between the Work Limitations Questionnaire (WLQ) scores, HAQ, Patient Global Assessment (PGA) and Functional Comorbidity Index (FCI) were analyzed in patients seen serially in a rheumatology clinic via standardized forms.

Results: 846 responded (65% response rate with 332 RA, 88 PsA, 58 AS) and 289 had WLQ data as they were working (139 RA, 51 PsA, 35 AS). The mean age was 51.7 (SD 14.5), 74.3% female and 11.3 years (SD 11.3) of disease duration. WD due to arthritis was 22.8% (RA), 29.9% (PsA), and 27.6% (AS) (between groups p <0.35). WD was associated with HAQ, PGA, fatigue, pain and sleep score in all three IA conditions. The average loss of the productivity from WLQ was 4.72% for IA overall and 4.47%, 4.71% and 5.77% for RA, PsA and AS, respectively (no difference between groups, p=0.405). Using Pearson correlation, the WLQ score was significantly correlated with HAQ (0.59; p<0.000), fatigue (0.51; p<0.000), pain score (0.57; p<0.000), sleep score (0.63, p<0.000), and with increasing number of comorbid conditions for all three IA conditions (RA:0.30; p<0.01, PsA:0.30; p=0.03 and AS:0.53; p<0.01) but not disease duration and gender.

Conclusion: WD and productivity loss were not different in RA, PsA and AS. WLQ scores were associated with patient factors in all IAs. Comorbidities increased the likelihood of work productivity loss and WD in all forms of IA, but the correlation was particularly strong in AS.

1826

Intravenously Administered Golimumab Significantly Improves Health Related Quality of Life and Work Productivity in Patients with Rheumatoid Arthritis: Results of a Phase III, Placebo Controlled Trial. Rene Westhovens[1], Michael Weinblatt[2], Chenglong Han[3], Tim Gathany[3], Lilianne Kim[4], Michael Mack[4], Jiandong Lu[4], Daniel Baker[4], Alan Mendelsohn[4] and Clifton O. Bingham III[5]. [1]University Hospital KU Leuven, Leuven, Belgium, [2]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [3]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Johns Hopkins University, Baltimore, MD

Background/Purpose: To evaluate the impact of intravenously (IV) administered golimumab (GLM) on health related quality of life (HRQoL) and work productivity in patients (pts) with rheumatoid arthritis (RA).

Methods: GO-FURTHER was a multicenter, randomized, placebo-controlled study. Adult pts with active RA despite MTX therapy (≥6 tender and swollen joints, CRP ≥1.0mg/dL, and RF and/or anti-CCP positive) were randomized to placebo + MTX (PBO group) or GLM (2mg/kg) plus MTX at week 0, 2, and every 8 week thereafter (GLM group). Pts in PBO group with <10% improvement in tender and swollen joint count from baseline at week 16 entered early escape (EE) and received a 2mg/kg GLM infusion at Weeks 16 and 20 and every 8 weeks subsequent. HRQoL was assessed using Short-Form of 36 items questionnaire (SF-36) and EQ5D. The EQ5D instrument consists of a five-item descriptive system of health states and a visual analog scale (EQ VAS, 0–100). Scores for the five health states were converted into a utility score (EQ5D index, 0–1, 0=dead and 1=full health) using the US D1 model. Impact of disease on daily work productivity was assessed using a visual analogue scale (VAS) of 0–10 (0=no affect at all, 10=affected very much). Clinically meaningful improvements were defined as a change of ≥5 points in SF-36 physical and medical component summary score (PCS and MCS) or a change in magnitude of half of standard deviation in EQ VAS and EQ5D index. Correlation of remission measured by disease activity score (DAS28 using CRP <2.6) with change in PCS and MCS, and productivity scores were analyzed. Comparisons between groups were performed using ANOVA on van der Waerden normal scores for continuous outcomes or Chi-square test for binary outcomes.

Results: At baseline, mean (SD) SF-36 PCS (30.8±6.95) and MCS (37.6±11.28) were notably below the US norm of 50. The impact of disease on daily work productivity was 6.4 (2.32). Compared to the PBO group, significantly greater changes were observed in the GLM-treatment group in SF-36 PCS (5.92 vs. 3.19), SF-36 MCS (4.91 vs. 1.46), EQ VAS scores (11.43 vs. 2.53) and EQ5D index (0.13 vs. 0.09) at week 12, which were sustained through week 16 and 24 (all p-values<0.01). Compared to the PBO group, a greater proportion of pts in the GLM group achieved clinically meaningful improvement in SF-36 PCS, SF36 MCS, EQ VAS and EQ5D index. Similarly, significantly greater improvements in all 8 SF-36 sub-scores for the GLM group, compared to the PBO group, were observed (all p-values<0.001). At week 24, mean change (improvement) from baseline in impact of disease of daily work productivity was significantly better in the GLM group than in the PBO group (−2.78 vs. −1.03, p<0.001). Change in SF-36 and work productivity score were correlated with change in DAS28 score, and those who achieved DAS28 remission had greater improvement in SF-36 PCS, MCS and productivity VAS scores than those who did not achieve remission.

Conclusion: Treatment with IV administered GLM significantly improved HRQoL and work productivity in pts with RA.

1827

Factors That Impact Work Productivity in the Preserve Trial: A Randomized Controlled Trial of Combination Etanercept-Methotrexate Therapy in Patients with Moderately Active Rheumatoid Arthritis. Vibeke Strand[1], Thomas V. Jones[2], Wenzhi Li[3], Andrew S. Koenig[3] and Sameer Kotak[4]. [1]Stanford University, Portola Valley, CA, [2]Pfizer, Inc, Collegeville, PA, [3]Pfizer Inc., Collegeville, PA, [4]Pfizer Inc., New York, NY

Background/Purpose: Active joint inflammation and structural damage in patients with rheumatoid arthritis (RA) often result in impaired physical function and ultimately work disability.[1,2] Lost productivity is associated with higher costs than direct expenditures in determining overall RA costs.[3] In a recent multinational database study, more than one third of patients working at the time of onset of RA symptoms reported work disability.[2] In a 2006 systematic review, two thirds of employed RA patients reported RA-related loss of productivity in the prior year.[4] Despite advances in RA treatment, work disability remains a persistent problem. The objective of the analysis presented here was to assess predictors of impairment in work productivity in patients with moderately active RA (3.2<DAS28≤5.1) enrolled in the randomized, double-blind period of the PRESERVE trial.

Methods: Patients achieving DAS28 low disease activity (DAS28 ≤3.2, avg wk 12–36 and at wk 36) following 36 wks of open-label treatment with etanercept (ETN) 50 mg QW + methotrexate (MTX; E50/M) were randomized to receive E50/M (n=202), ETN 25 mg QW + MTX (E25/M; n=202), or ETN placebo + MTX (P/M; n=200) as double-blind treatment for 52 wks. The Work Productivity Activity Impairment Questionnaire: Rheumatoid Arthritis (WPAI:RA) was administered at baseline (BL) and wk 88, after double-blind treatment. Correlation (Pearson's r) and linear regression analyses were conducted: the dependent variable was % of overall work impairment in WPAI:RA; independent variables were age, gender, and RA duration at BL, and HAQ score ≤0.5 vs >0.5, PtGA of disease activity, pain score, FACIT-Fatigue score, WPAI:RA score, and treatment at wk 36.

Results: No significant association was observed between patients' age and gender at BL or pain or FACIT-Fatigue scores at wk 36 and % overall work impairment at wk 88 (table). In contrast, disease duration at BL as well as HAQ score >0.5, PtGA of disease activity, and WPAI: RA score at wk 36 were significant predictors of work impairment (P<0.05). After controlling for other factors, in comparison with P/M, E50/M provided greater benefit in improving work productivity at wk 88 (P<0.05), whereas E25/M did not.

Table. Factors predicting WPAI:RA % overall work impairment at wk 88 in the PRESERVE trial

Predictor	Regression Coefficient (SE)	P-value
Age	−0.10 (0.13)	0.447
Female	−4.18 (3.18)	0.190
Disease duration	**0.51 (0.19)**	**0.008**
HAQ score >0.5 at wk 36	**8.19 (3.32)**	**0.014**
PtGA of disease activity at wk 36	**3.92 (1.52)**	**0.010**
Pain VAS score at wk 36	−0.34 (0.19)	0.086
FACIT-Fatigue score at wk 36	0.28 (0.21)	0.185
WPAI:RA at wk 36	**0.56 (0.11)**	**<0.0001**
E50/M treatment	**−11.51 (3.17)**	**0.0003**
E25/M treatment	−3.90 (3.00)	0.196

HAQ = Health Assessment Questionnaire; PtGA = patient global assessment; VAS = visual analog scale; FACIT-Fatigue = Functional Assessment of Chronic Illness Therapy-Fatigue; WPAI:RA = Work Productivity Activity Impairment Questionnaire: Rheumatoid Arthritis; E50/M = etanercept 25 mg QW plus methotrexate; E25/M = etanercept 25 mg QW plus methotrexate

Conclusion: Disease duration, HAQ score >0.5, PtGA, and work impairment at baseline were significant predictors of work impairment at end of the study in this population of patients with moderately active RA. Significant improvement in the overall percentage of work productivity was evident in patients receiving etanercept 50 mg plus methotrexate compared with placebo plus methotrexate.

Smoking Is Associated with Worse and More Widespread Pain, Worse Fatigue, General Health and Quality of Life in a Swedish Population Based Cohort of Patients with Psoriatic Arthritis. Ann B. I. Bremander[1], Lennart TH Jacobsson[2], Stefan Bergman[3], Emma Haglund[4] and Ingemar F. Petersson[5]. [1]Halmstad University School of Business and Engineering, Halmstad, Sweden, [2]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [3]R&D Center Spenshult, Oskarström, Sweden, [4]Spenshult Hospital for Rheumatic Diseases, Halmstad, Sweden, [5]Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden

Background/Purpose: Smoking has been found to be associated with an increased risk of developing psoriatic arthritis (PsA). The purpose of this study was analyse possible associations of smoking habits with self-reported clinical features in a large population based cohort of patients with a diagnosis of PsA.

Methods: All health care seeking subjects with a diagnose of PsA according to ICD 10 codes (given at least once by a rheumatologist/internist or twice by any other physician) were identified by a regional health care register during 2003–2007. In 2009 all identified subjects aged 18 years or older (n=2003) were invited to participate in a cross sectional questionnaire survey. The questionnaire included self-reported data on smoking (never smokers or ever smokers), age at disease onset, physical function (HAQ, 0–3 best to worst), pain, fatigue and global health (numerical rating scales 0–10 best to worst) health related quality of life (EQ-5D, 0–1 worst to best), and number of painful regions noted on a pain mannequin (0–16, best to worst). Linear regression analysis was performed and all data were controlled for sex and age.

Results: Response rate was 77% whereof 369 patients (18%) declined participation and 1185 (59%) returned the questionnaire, mean age 57.5 (SD 13.5) years and 58% were women. 1173 subjects responded to the smoking question whereof 448 (38%) were never smokers and 725 (62%) were ever smokers.

Mean age at disease onset was 42.3 (SD 13.4) years in never smokers vs. 46.0 (SD 13.2) in ever smokers. Never smokers vs. ever smokers had mean HAQ 0.59 (SD 0.6) vs. 0.71 (SD 0.6), mean pain 3.9 (SD 2.4) vs.4.4 (SD 2.5), mean fatigue 4.4 (SD 2.8) vs. 5.0 (SD 2.7), mean global health 3.9 (SD 2.4) vs. 4.4 (SD 2.3), mean EQ-5D 0.68 (SD 0.23) vs. 0.63 (SD 0.26) and mean no of painful regions were 7.2 (SD 4.0) vs. 7.9 (SD 4.3).

The regression analysis showed that ever smokers had worse pain with age-sex adjusted parameter estimates (B) = 0.38 (95% CI 0.09; 0.67), worse fatigue B = 0.34 (95% CI 0.02; 0.66), worse global health B = 0.36 (95% CI 0.09; 0.64), worse EQ-5D B = −0.04 (95% CI −0.07; −0.01) and an increased no of painful regions B = 0.54 (95% CI 0.02; 1.07) compared with never smokers.

Conclusion: In this population based PsA cohort, patients who were ever smokers reported worse clinical outcomes compared with never smokers. Further longitudinal studies are needed to better understand cause and effect. However, smoking cessation should be recommended due to general health perspectives and also due to disease specific issues.

1829

Cost of Etanercept, Adalimumab, and Infliximab in Patients with Rheumatoid Arthritis with Employer Provided Health Insurance.
Machaon Bonafede[1], Crystal Watson[2], George Joseph[2], Nicole Princic[1] and David J. Harrison[2]. [1]Thomson Reuters Healthcare, Cambridge, MA, [2]Amgen Inc., Thousand Oaks, CA

Background/Purpose: Tumor Necrosis Factor Inhibitors (TNFi) are the mainstay of treatment for rheumatoid arthritis (RA) in patients with moderate to severe disease. The three most commonly used agents, etanercept (ETN), adalimumab (ADA), and infliximab (INF), differ with respect to frequency of administration, dosing and the approved dose ranges. In addition, INF is administered as infusion by a healthcare professional, whereas ETN and ADA are self-administered subcutaneously. The goal of this study was to determine the annual TNFi drug and administration costs for RA patients on ETN, ADA, or INF.

Methods: The MarketScan Commercial Database was used to identify adult patients (18–64 years) with ≥1 claim for ETN, ADA, or INF between February 1, 2008 and July 5, 2010. Patients were required to have a diagnosis of RA and excluded if they had diagnoses for other conditions treated with TNFi (psoriatic arthritis, psoriasis, ankylosing spondylitis, Crohn's disease, ulcerative colitis, or juvenile idiopathic arthritis) in the six months prior to the start of their index TNFi. The patient's first TNFi claim after 6-months of continuous enrollment was their index claim and defined their index TNFi. If they had at least one claim for the same agent in the 6-months pre-index they were defined as "continuing", otherwise they were "new". Patients were followed for 1 year and the cost of all TNFi used in that year were attributed to their index TNFi. Cost of TNFi was calculated based on total dose and the March 2012 wholesale acquisition costs and the Medicare Physician Fee Schedule was used to determine TNFi drug administration costs.

Results: There were 7,003 patients who met the inclusion and exclusion criteria. ETN was the most frequently used index TNFi agent (3,159) followed by ADA, 2,057 and INF 1,787. The mean age was similar across agents, (51.1 ETN and ADA and 52.0 INF). The majority of patients (77.8%) were female and 76.2% of the patients were continuing on therapy. Preferred provider organizations were the most common insurance type, 58.8%–63.2%. Across new and continuing patients combined, the annual TNFi cost per patient was highest for INF ($27,366), followed by $20,594 for ADA and $17,753 for ETN. The costs among continuing patients were higher than the new patients but the trends were similar across both groups.

Conclusion: TNFi costs differ meaningfully by index TNFi agent in the patients with employer provided health insurance. ADA cost 16% more than ETN and INF cost 54% more than ETN across new and continuing patients combined. The difference was greater in continuing compared to new patients.

Drugs Are the Major Cost Driver of Rheumatoid Arthritis As Soon As the First Year of the Disease: An Economic Analysis Based On the Espoir Cohort Data.
Bruno Fautrel[1], Sandy Lucier[2], Georges Haour[2], Hassani Maoulida[2], Stephanie Harvard[1], Alain Saraux[3], Xavier Mariette[4], Francis Guillemin[5], Isabelle Durand-Zaleski[2] and Karine Chevreul[2]. [1]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [2]APHP - URC Eco, Paris, France, [3]Université Brest Occidentale, Brest, France, [4]Université Paris-Sud, Le Kremlin Bicetre, France, [5]Faculte de Medecin/BP 184, Vandoeuvre-les-Nancy, France

Background/Purpose: Many studies have explored the economic burden of established RA but few data are available about the determinants of costs in early rheumatoid arthritis (RA) cared in real life settings.

The present study aims to describe the determinants of medical costs of early RA during the first 4 years of the disease.

Methods: The ESPOIR cohort is a nationwide cohort that enrolled 813 patients with early arthritis, highly suspect of RA[1], between 2002 and 2005. Data were collected every six months during the first two years then every year. The health resource use was investigated using a validated questionnaire collecting consultations to medical doctors or health professionals, clinical workups, hospitalizations, and treatments. Costs of care (direct costs) were elicited using the national average prices (2007 euros).

After log-transformation of costs, their determinants were explored by multilevel modeling, using unconditional means models to test for structural effects. To investigate the impact of treatment strategies, patients were classified according to time of biologic initiation: "first-year" (n = 42), "later year" (n = 66) and "never" (n = 440). Univariate correlations were first tested (p ≤ 0.05) so as to preselect a set of variables for multivariate analyses. Then, a multilevel regression analysis was conducted to identify determinants of total direct costs during the first 4 years of follow-up.

Results: Complete data were available for 548 patients (mean age 56 yrs, female 77%, ACPA 46%, RF 50%, ACR/EULAR 2010 83%, mean DAS28 5.1, mean HAQ 1). Annual mean direct cost per patient was €3,648, with a range from €18 to €53,739. On average, RA drug costs represented 48% of the overall direct costs, and up to 76% for patients receiving biologics.

With respects to total costs, living with a partner and baseline physician certainty of RA diagnosis less than 50% were each associated with lower total costs. Higher baseline HAQ score, increase in HAQ score ≥ 0.25 between baseline and the 6-month study visit, and positive rheumatoid factor were associated with higher total costs. In addition, the greatest increases in total costs were associated with "first year" use and "later year" use with approximately 9 and 5-fold increases in total costs, respectively (Table below). Patient socioeconomic status had no impact on total medical costs.

Variables		Multiplicative factor	95% CI	p value
Age at baseline		1.07	1.002; 1.13	0.04
Living with a partner	No	1		
	Yes	0.79	0.79; 0.94	0.01
Rheumatoid Factor positivity at baseline	No	1		
	Yes	1.20	1.03; 1.40	0.02
HAQ score at baseline	0–0.5	0.47	0.34; 0.64	<0.001
	0.5–1	0.49	0.36; 0.66	<0.001
	1–2	0.72	0.56; 0.94	0.01
	2–3	1		
Variation in HAQ score ≥ 0.25 between baseline and 6 month visit	No	1		
	Yes	1.07	1.04; 1.12	<0.001
Biologic use	Never	1		
	First year	9.03	6.83; 11.95	<0.001
	Later year	5.30	4.21; 6.67	<0.001
Physician certainty for RA diagnosis < 50% at baseline	No	1		
	Yes	0.74	0.61; 0.90	<0.001
Intercept		10729€	6794; 16943€	<0.001

Conclusion: As in established RA, biologic use is the main cost driver in rheumatoid arthritis care within the first years of the disease.

Evaluation of the Cost-Effectiveness of Rheumatoid Arthritis Treatment with Biologic Agents Using the IORRA Cohort Database.

Eiichi Tanaka, Eisuke Inoue, Daisuke Hoshi, Akiko Kobayashi, Naoki Sugimoto, Kumi Shidara, Eri Sato, Yasushi Inoue, Yohei Seto, Ayako Nakajima, Shigeki Momohara, Atsuo Taniguchi and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Rheumatoid arthritis (RA), a chronic inflammatory disorder, causes a significant decrease in quality of life. Recently developed biologic agents (BAs) have caused a considerable economic burden to society. Several previous studies have investigated the cost-effectiveness of specific BAs; however, they have not adequately considered BA utilization under real-life conditions. In actual clinical conditions, various individual patient-based factors influence BA utilization and timing of selecting, switching, or discontinuing agents. Previous studies on specific BAs considering only a few aspects of the conditions of RA patients in actual clinical practice were frequently based on controlled trials. In this study, we investigated the cost-effectiveness of selecting BAs followed by switching to other BAs or methotrexate (MTX) under actual clinical conditions using RA cohort database, the Institute of Rheumatology, Rheumatoid Arthritis (IORRA).

Methods: A Markov model-based probabilistic simulation from a societal perspective was conducted using a hypothetical population of 10,000 patients. Patients who had failed more than one disease-modifying antirheumatic drug (DMARD) and for whom BAs were selected started one of the four BAs (adalimumab, etanercept, infliximab, and tocilizumab) used in Japan in 2010, switched to other BAs or MTX, or discontinued all drugs comprised the BA group. Patients similar in background to the BA group who started MTX following discontinuation of all drugs comprised the comparator group (MTX group). Almost all model parameters were determined with respect to each group, except those related to effects and costs of the four BAs and MTX, based on clinical data extracted by the matching method from the IORRA. Health states in the model were defined on the basis of physical dysfunction levels stratified according to the Japanese version of the Health Assessment Questionnaire (J-HAQ), which corresponded to cost and utility. Lifetime costs, quality-adjusted life years (QALY), and incremental cost-effectiveness ratio (ICER) were calculated. The threshold ICER was assumed to be 5.0–6.0 million JPY (1 USD = 88 JPY in 2010). A lifetime horizon and a discount rate of 3% per year for both health benefits and costs were assumed. We also conducted a probabilistic sensitivity analysis.

Results: Clinical data from two groups of 454 patients each were used for calculating model parameters (percentages of patients in the BA group started adalimumab, etanercept, infliximab, and tocilizumab were 17.3%, 45.9%, 24.3%, and 12.5%, respectively). Lifetime costs in the BA and MTX groups were 34.8 and 24.1 million JPY and QALYs were 11.4 and 9.3, respectively. The average period with acceptable disability defined by J-HAQ <1.1 was longer in the BA group (15.8 years) than that in the MTX group (10.4 years). The ICER was 5.04 million JPY, with 75.8–89.1% probability of falling below 5.0–6.0 million JPY, respectively, according to probabilistic sensitivity analysis.

Conclusion: This study demonstrated that selecting BAs is cost-effective for RA patients who had failed more than one DMARD according to the analysis of data obtained from an observational cohort representing daily clinical practice in Japan.

Evaluating the Cost-Effectiveness of Personalized Treatment with Adalimumab Using Serum Drug Levels in Rheumatoid Arthritis Patients.

Charlotte L. M. Krieckaert[1], Sandhya C. Nair[2], M. T. Nurmohamed[3], Carlo J.J. van Dongen[1], Willem F. Lems[4], Floris P.J.G. Lafeber[2], J.W.J. Bijlsma[2], Gertjan Wolbink[1] and Paco M.J. Welsing[2]. [1]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]VU University Medical Center/Jan van Bremen Research Institute, Amsterdam, Netherlands, [4]VU University Medical Center, Amsterdam, Netherlands

Background/Purpose: The high costs of biologicals warrant a rational use of these drugs, preferably by tailoring them to the individual patient. The objective was to evaluate the cost-effectiveness of personalized biological treatment for rheumatoid arthritis (RA) using European League Against Rheumatism (EULAR) response and adalimumab drug level tests.

Methods: In 272 rheumatoid arthritis patients treated with adalimumab, Disease Activity Score in 28 joints (DAS28), Health Assessment Questionnaire (HAQ) and biological use was measured over three years. A treatment algorithm for personalized care was defined in which EULAR response and drug levels at 6 months defined whether adalimumab treatment was continued or discontinued, dosing was altered or, in case of non response, a next biological treatment was started.

Using a patient level Markov model, outcome in terms of DAS28 and HAQ and biological use according to the treatment algorithm for a personalized care group was simulated and compared to the observed drug use and disease course. Mean total costs, Quality Adjusted Life Years (QALYs) (both based on DAS28 and HAQ) and the average Incremental Cost-Effectiveness ratio (ICER) with 95 percentile range were calculated.

Results: Effectiveness was higher in the simulated personalized care group and the average difference in QALYs was 3.67 (95 percentile range −6.09 to 13.33). Costs were saved in the personalized care group as compared to observed care group: mean total savings €2.595.557 (95 percentile range -€2.983.760 to -€2.211755). In total €2.562.494 was saved on biological drug costs and testing costs amounted to €10.872. This resulted in an average ICER of -€ 707.236 per QALY gained. In 77.6% of simulations personalized care saved costs and was more effective (dominant) and in 22.4% cost-saving and less effective. Additionally, scenario analyses were performed and these were all cost-saving with variable effectiveness.

	observed care	simulated care	difference		
	mean	mean	mean	2.5%	97.5%
direct costs	€4,263,470	€4,237,086	-€ 26,384	-€391,927	€334,886
productivity	€1,876,147	€1,850,595	-€17,552	-€163,925	€124,873
drug costs	€11,893,326	€9,330,832	-€2,562,494		
testing costs	€0	€10,872	€10,872		
total costs	€18,032,942	€15,437,385	-€2,596,557	-€2,983,760	-€2,211,755
QALYs	587.98	591.65	3.67	−6.09	13.33

Cost effectiveness plane
Conclusion: Tailoring biological treatment to individual RA patients using drug level tests to evaluate short-term outcomes is cost effective. Although specific for adalimumab, the results underline the potential cost-effectiveness for personalized biological treatment in RA.

1833

Healthcare Costs in Psoriatic Arthritis Patients Newly Initiated On a Biologic Disease-Modifying Anti-Rheumatic Drug or Methotrexate.
Frank Zhang[1], Robert Hiscock[2] and Jeffrey Curtis[3]. [1]Celgene Corporation, Warren, NJ, [2]Analysis Group, Inc., Montreal, QC, [3]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Several treatment options are available for psoriatic arthritis (PsA) patients (pts). The healthcare cost associated with the management of PsA pts varies depending on the disease severity and treatments used by pts. Methotrexate (MTX) and biologics are commonly prescribed disease-modifying anti-rheumatic drugs (DMARDs) in PsA. Due to the safety concerns around these DMARDs, frequent monitoring is required during clinical practice. The objective of this study was to describe healthcare costs associated with the management of PsA in pts newly initiated on a biologic DMARD or on MTX, focusing on office care and monitoring costs.

Methods: Adult pts with $\geq$ 2 PsA diagnosis (from office visits) were selected from the MarketScan Commercial Claims database (2005–2009). The first biologic DMARD or MTX prescription date was defined as the index date. Biologic initiators were required to be biologic-naïve prior to the index date but may have used a non-biologic DMARD. MTX initiators were required to be both biologic and non-biologic DMARD naïve prior to index date. Pts with a diagnosis of ankylosing spondylitis prior to the index date were excluded. All patients were required to have continuous enrollment 6-month prior to and 12-month post index date. All-cause and PsA-related total healthcare costs were estimated during the 12-month study period from a payer perspective and expressed in 2011 USD. PsA-related medical costs were identified based on claims for medical services associated with a PsA diagnosis or costs associated with DMARD administration by healthcare professionals. Among medical costs, office care and monitoring costs were defined as the sum of costs for outpatient visits and other medical service costs (excluding costs for drugs administered by healthcare professionals) that were associated with a diagnosis of PsA. Urgent care cost was defined as the sum of costs for inpatient service and ER visits. PsA-related pharmacy costs were identified based on claims for a biologic or a non-biologic DMARD irrespective of a PsA diagnosis.

Results: A total of 1,217 MTX initiators and 3,263 biologic initiators met the eligibility criteria. Over the 12-month study period, MTX initiators had an average total healthcare cost of $14,329 and $6,065 were PsA-related. Pharmacy costs accounted for 80.4% ($4,878) of the PsA-related total costs; office care and monitoring costs ($986) accounted for 16.3%; urgent care costs accounted for 3.3% ($201). Biologic initiators had an average annual total healthcare cost of $30,282 and 67.5% were PsA-related ($20,439). Pharmacy costs accounted for 92.7% ($18,938) of the PsA-related total costs; office care and monitoring cost ($1,041) accounted for 5.1%; urgent care cost ($461) accounted for 2.2%.

Conclusion: PsA patients initiating on a DMARD are associated with substantial healthcare costs. Although pharmacy costs accounted for the majority of the PsA-related costs, office care and monitoring costs accounted for a significant part of the PsA-related costs.

Utilization and Expected Cost of Rheumatoid Arthritis Patients Treated with Golimumab: A Specialty Pharmacy Perspective.
Lorie Ellis[1], Susan Bolge[1], Heidi Hanna[2], Christina White[2] and Patricia Rice[3]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Diplomat Specialty Pharmacy, Flint, MI, [3]CliniRx Research, Naperville, IL

Background/Purpose: Golimumab is a 50 mg, once-monthly, patient-administered anti-tumor necrosis factor alpha (anti-TNF) therapy indicated for moderate to severe rheumatoid arthritis (RA), active psoriatic arthritis, or active ankylosing spondylitis. A substantial proportion of patients receive golimumab through a specialty pharmacy provider (SPP). The purpose of this study is to describe the utilization and expected golimumab cost for RA patients receiving golimumab from a SPP.

Methods: Pharmacy and eNAVIGATOR™ data were analyzed for adult patients with an ICD-9-CM diagnosis code for RA (714.X) who received $\geq$2 golimumab doses between 4/24/2009 and 8/24/2011. Utilization measures included the proportion of 50 mg dose fills and the proportion of compliant fills, defined as 21 to 38 days, corresponding to a 28 to 31 days supply $+/-7$ days. Descriptive statistics were employed. Mean refill interval and wholesale acquisition cost (WAC) for golimumab ($2,075.62 per 50 mg; 2/1/2012-Analysource; First Databank) were used to estimate the annual cost of golimumab.

Results: The study population included 126 golimumab patients and was predominantly female (79%) and aged >45 years (72%). The majority (71%) reported prior biologic use. Of the 109 patients with baseline Health Assessment Questionnaire II (HAQ-II) assessments, a score >1 was found in 62% (n=68). A total of 942 golimumab fills were dispensed during the study period. A 50 mg golimumab dose was dispensed in 100% of patients and 100% of fills. The mean ($\pm$SD) interval between golimumab doses was 35 $\pm$22days (median 30 days). The mean ($\pm$SD) refill interval of patients with prior-biologic use (bio-experienced) was 35 $\pm$25 days with a median of 30 days. The mean ($\pm$SD) refill interval for patients without prior biologic therapy (bio-naïve) was 34$\pm$15 days with a median of 31 days. Approximately 84% of all fills fell within the defined compliance window for the overall population and in bio-experienced and bio-naïve subgroups. Based upon a mean refill interval of 35 days, the average RA patient would have 11 golimumab fills per year at an estimated annual cost of $22,831.82.

Conclusion: In this SPP population over a period of slightly more than two years, golimumab consistently was used at a 50 mg dose with a median refill interval of 30 days and mean refill interval of 35 days. These findings correspond closely with dosing and administration recommendations in the golimumab product label. Overall refill compliance was observed in a high proportion of fills (greater than 80%). Based upon these utilization trends, the average annual cost of golimumab therapy was estimated to be $22,831.82.

1835

Prescription of Biologics in Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS) in 4 Norwegian Regions 2002–2011: A Study of Prescription Rates and Baseline Disease Activity.
Elisabeth Lie[1], Karen M. Fagerli[1], Knut Mikkelsen[2], Åse S. Lexberg[3], Erik Rødevand[4], Till Uhlig[1] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [3]Drammen Hospital, Drammen, Norway, [4]St. Olavs Hospital, Trondheim, Norway

Background/Purpose: Biologics have constituted a major advance in the treatment of RA, PsA and AS. In Norway access to these therapies has been good since their introduction. With increasing focus on early and aggressive therapy, one could expect increasing use of biologics, including use in patients (pts) with moderate disease activity. The objectives were to examine if prescription rates of biologics in RA, PsA and AS continue to increase or have reached a plateau, and whether disease activity at initiation of therapy has changed over the years.

Methods: Data for this study were from the NOR-DMARD register. Prescriptions of biologics to biologics naïve pts with RA, PsA and AS between Jan 2002 and Nov 2011 in 4 centers covering regions in East- and Mid-Norway were studied. Population data were extracted from Statistics Norway (www.ssb.no). Prescription rates per 100,000 inhab. per year were calculated and adjusted for an estimated 15% incompleteness of the register. Numbers were also adjusted for incomplete data for 2 centers in 2002 and all centers in 2011. Further, we calculated rates as % of pts, based on published Norwegian disease prevalence data [0.45% for RA (2 studies), 0.20% for PsA, 0.26% for AS]. Baseline (BL) disease activity [CRP, DAS28 and ASDAS (from 2006)] was examined per diagnosis per year. Potential effects of prescription year were assessed by linear regression with BL variables as the dependent variable and year as a continuous (1–10) independent variable. CRP was Ln-transformed for the analyses.

Results: The material included 1961 prescriptions – 1026 in RA, 375 in PsA and 560 in AS. These were all TNF inhibitor (TNFi) prescriptions in AS, 2 non-TNFi in PsA and 38 non-TNFi in RA (32 rituximab, 3 abatacept, 3 tocilizumab). The population in the study area increased from 1.31 mill to 1.44 mill from 2002 to 2011. Prescription rates per year are shown in Table 1. There was a trend towards increasing prescription rates in AS throughout the study period. Fluctuations in the annual prescription rates were observed for RA and PsA. First biologic was since 2007 prescribed more frequently in AS and PsA together than in RA. (Table 1). BL levels of disease activity measures decreased significantly over time in all 3 diagnoses (Table 2).

Table 1. Prescription rates of biologics in biologics naïve patients 2002–2011

	Prescriptions per 100,000 inhabitants				Percent of patients*		
	Overall	RA	PsA	AS	RA	PsA	AS
2002	5.8	4.8	0.2	0.7	1.1%	0.1%	0.2%
2003	15.3	11.0	2.5	1.8	2.4%	1.3%	0.7%
2004	20.6	12.6	3.5	4.5	2.8%	1.8%	1.7%
2005	13.2	7.5	1.5	4.2	1.7%	0.8%	1.6%
2006	14.0	7.1	1.9	5.0	1.6%	1.0%	1.9%
2007	15.5	7.3	3.0	5.2	1.6%	1.6%	2.0%
2008	23.3	11.4	5.5	6.4	2.5%	2.8%	2.5%
2009	20.7	8.5	5.3	6.9	1.9%	2.7%	2.7%

NA = not applicable. *Linear regression.

Conclusion: The annual rate of first-time prescriptions of biologics to patients with RA, PsA and AS increased from 15 per 100,000 in 2003 to 25 per 100,000 in 2011. During recent years the increase was most pronounced in AS and prescriptions were more frequent in AS and PsA combined than in RA. Baseline disease activity levels at the start of treatment decreased gradually in all diseases, with a marked reduction in patients with RA.

Early Versus Delayed Initiation of Disease-Modifying Antirheumatic Drugs in Rheumatoid Arthritis. Sharon Van Doornum[1], Lynden Roberts[2], Mark D. Reed[3] and Danny Liew[1]. [1]The University of Melbourne, Melbourne, Australia, [2]James Cook University, Townsville, Australia, [3]Sir Charles Gairdiner Hospital, Nedlands, Australia

Background/Purpose: Studies from a number of countries suggest that the time between symptom onset and initiation of DMARD therapy in RA patients is still longer than would be considered optimal, or even acceptable. We sought to assess the health economic impact of this delay in an Australian context.

Methods: Delay in initiation of DMARD therapy was estimated from a 2005 study of 96 Australian patients with RA referred to one public and four private rheumatology practices. RA-associated utilities and costs were sourced from published data. Patients not taking and taking DMARD therapy were assumed to have utilities of 0.443 and 0.543, respectively. The annual direct costs of RA, excluding DMARDs, was AUD $3780, and the annual cost of DMARD therapy was $2658. It was conservatively assumed that DMARD therapy did not reduce non-DMARD RA costs (that is, it was $3780 for all patients).

Results: In the 2005 study, the mean time from time of symptom onset to initiation of DMARD therapy was found to be 17.7 months, or 1.48 years. Over the 1.48 years, a mean of 0.65 QALYs would have been lived per patient and $5579 of direct healthcare costs incurred. Had DMARDs been commenced at the time of symptom onset, 0.80 QALYs would have been lived per patient, and $9503 of direct healthcare costs incurred. The differences of 0.15 QALYs and $3924 in direct healthcare costs equated to an incremental cost-effectiveness ratio (ICER) of $26,583 per QALY saved. Up to $4500 of additional costs could be spent per patient to reduce the time to initiation of DMARDs before the ICER breached the arbitrary cut-off of $50,000 per QALY saved. Our analysis was conservative in it did not consider the long-term health and cost savings associated with avoidance of permanent joint damage.

Conclusion: There is considerable delay in the initiation of DMARD therapy among patients with RA, which leads to significant health loss. Reducing the time to initiation of DMARDs represents a cost-effective means of reducing the burden of RA.

1837

Which Rheumatoid Arthritis, Ankylosing Spondylitis and Juvenile Idiopathic Arthritis Patients Initiate Anti-TNFá Therapy? Alain Saraux[1], Jacques Benichou[2], Chantal Deslandre[3], Loic Guillevin[4], Latifa Idbrik[5], Jean Sibilia[6], Marc Soudan[5], Daniel Wendling[7] and Francis Guillemin[5]. [1]CHU de la Cavale Blanche and Université Bretagne occidentale, Brest Cedex, France, [2]EA4438 Laboratoire Physiopathologie des Arthrites, Rouen, France, [3]Cochin Hospital, Paris, France, [4]Division of Internal Medicine, Hôpital Cochin, University Paris Descartes, Paris, France, [5]Faculte de Medecin/BP 184, Vandoeuvre-les-Nancy, France, [6]EA4438 Laboratoire Physiopathologie des Arthrites, Illkirch-Strasbourg, France, [7]Minjoz University Hospital, Besancon, France

Background/Purpose: Comprehensive guidelines for anti-TNFα were proposed in 2005 by the French Society for Rheumatology (SFR) in France; they did not include any economic considerations and they remained only informative for rheumatologists. Although they were not endorsed by the governmental agency, anti TNF-α were available without reimbursement restriction to all patients fulfilling them. Only limited information is available about patients who are potential candidates for anti-TNFα therapy (anti-TNFα) as well as about the physicians' attitude towards initiation of anti-TNFα.The French authorities initiated the CORPUS (cohorte d'observation rhumatologique des pratiques et des usages) survey to evaluate how rheumatologists prescribe anti TNF in active inflammatory rheumatic disease in case of the eligibility to biologics.

Methods: Between 2007 and 2009, 102 rheumatologists, internists and paediatricians in French University Hospitals and private practice recruited patients having an active IRD [DAS28 > 3.2 despite methotrexate use for rheumatoid arthritis (RA), BASDAI≥4 despite NSAID use for spondyloarthritis (SA) and not responder to methotrexate for Juvenile idiopathic arthritis (JIA)] naïve of biologics. They were followed prospectively for one year.

Results: Overall, 543 RA, 287 SA and 53 JIA patients were included among whom 382 RA, 171 SA and 28 JIA patients had complete follow-up data available at one year. The activity of the disease evaluated by the DAS, BASDAI and CHAQ was elevated in all goups. Both disability and quality of life indicators attested of the severity of the diseases. Among patients with available data, 110/382 (28.8%) RA, 81/171 (47.4%) SA, and 26/28 (92.9%) JIA patients received at least one injection of anti TNF-α during the first year of follow-up. Younger age, smoking, corticosteroid use, previous X-ray progression, higher disease activity (VAS patients, morning stiffness, DAS), higher disability (HAQ) level and poorer quality of life (SF36) at baseline were associated with anti TNF-α initiation among RA patients; by multivariate analysis, only younger age and poorer quality of life remained associated with anti TNF-α initiation. In SA patients, disease activity (high BASDAI), X-ray progression, high handicap (HAQ) level and poor quality of life (SF36) were also associated with anti TNF-α use. According to the physicians, the main reason for non prescription of anti- TNF-α to RA or AS patients was the low level of disease. In only 10% of cases, the lack of prescription was due to patient's refusal and in 5% to contraindications.

Conclusion: In France, anti TNF-α, available without reimbursement restriction, was quite systematically prescribed to JIA patients not responder to methotrexate, to about one half of SA patients with BASDAI score ≥4, and to one third of RA patients with DAS28 score >3.2 despite methotrexate therapy.

1838

10-Year Trends in the Use of Disease Modifying Anti-Rheumatic Drugs (DMARDs) and Biologic Agents in Rheumatoid Arthritis: A National Veteran Affairs Study. Bernard Ng[1], Nancy Petersen[1], Hong-Jen Yu[1], Myrna Khan[1] and Maria E. Suarez-Almazor[2]. [1]Michael E. DeBakey VA Medical Center Health Services Research and Development Center of Excellence, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX

Background/Purpose: It is unclear how recommendations for disease modifying anti-rheumatic drugs (DMARDs) & biological agents in treatment of Rheumatoid Arthritis (RA) have influenced their use over the past decade. Using the department of Veterans Affairs (VA) as a model to represent a large multi-facility health care organization, we studied the trend of MTX dosing and the use of traditional DMARD/biologics in treating Veterans with RA over a 10-year period from 2000 to 2009.

Methods: Using various national administrative databases of the department of VA, we found an incident cohort of 13,254 RA patients with validated algorithms to identify RA. Descriptive statistics were used to characterize trends in MTX start and highest dose and changes in patterns of DMARDs and biologics usage over the study period.

Results: Use of biologics increased from 2.8% in 2000–2001 to 18.9% in 2008–2009. Between 2000 and 2001, etanercept was the main biologic available, and it represented 96.2% of all biologics used. Since the introduction of adalimumab in 2003, its use increased tremendously, and by 2008–2009, it became the most used biological agent for the treatment of RA in our study population (48.5%). For the first DMARD/biologic used in a DMARD-naïve RA patient, there was an increase in use of MTX over time from 39.8% to 52.1%. There was also a gradual decline in both hydroxychloroquine and sulfasalazine as first line agents. Use of biologics as first-line agents remained relatively unchanged over the study period at 1.3–3.6 %. For the subjects who had been on MTX monotherapy for 90 or more days (52.9% of 13,254), between 2001–2002 and 2008–2009, the mean MTX start dose increased slightly but significantly from 10.1 to 11.4mg per week (p<0.01) and the proportion who were started on MTX less than 10mg per week dropped from 43.2% to 22.1% (p<0.01). Over the same time period, the mean maximum MTX dose attained increased significantly from 15.6 to 17.8 mg per week (p<0.01) and the proportion attaining peak dose of MTX of less than 15mg/week dropped from 35.0% to 17.0% (p<0.01).

Conclusion: The use of DMARDs and biologics in treatment of RA has changed markedly over the past decade. The increased use of MTX as the first line agent is consistent with it becoming the anchor drug for RA treatment. Though the start and maximum MTX dose attained have increased significantly over the decade, the average maximum dose at the end of our study is still considered low compared with current standards. Biologics have been gaining acceptance and now play an important role in RA treatment. In the VA system, adalimumab has become the most common biologic used in 2008–2009.

1839

The Progression of the Rate of Biologic Initiation in Early Rheumatoid Arthritis Is Constant Over the First 5 Years in the Espoir Cohort. Stéphanie Emilie[1], Cécile Gaujoux-Viala[2], Benjamin Granger[3], Anne-Christine Rat[4], Bernard Combe[5] and Bruno Fautrel[6]. [1]Paris 6,Pierre and Marie Curie University, AP-HP, Pitié-Salpêtrière Hospital, Department of Rheumatology, Paris, France, [2]Paris 6 – Pierre et Marie Curie University; Rheumatology, Pitié-Salpêtrière Hospital, Paris, France, [3]Université Pierre et Marie Curie - Paris 6; AP-HP, Paris, France, [4]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F-54 000, Nancy, France, [5]Hopital Lapeyronie, Montpellier, France, [6]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France

Background/Purpose: The European League Against Rheumatism recommends tight control of rheumatoid arthritis (RA). However, tight control of RA may depend on several factors, including patient characteristics and disease activity, social and medico-economic parameters.

The purpose of our study is to determine which factors influence the time-to-introduction of first biologic agent in RA patients in the French ESPOIR (study and following of undifferentiated early stage arthritis) cohort.

Methods: Among the 813 ESPOIR patients, 641 RA patients satisfying the ACR/EULAR 2010 RA diagnostic criteria were followed over 5 years. Among them, we excluded patients participating in therapeutic trials, such that 619 RA patients were analysed.

The outcome variable was the delay between the first stable symptoms and the introduction of the first biologic agent. The potential explanatory variables tested were patients and disease characteristics as well as health care system characteristics (medical center of follow-up, time to first rheumatologist consultation, population of city of residence).

Survival rates were estimated using the Kaplan-Meier method. Cox proportional hazards models were used to determine independent predictors of introduction of the first biologic agent.

Results: Among the 619 RA patients (mean age 50.3 years, 50.6% Rheumatoid Factor positive and 43.3% ACPA positive, 27.1% with erosion on baseline X-rays), 121 (19.5%) had received a biologic agent at 5 years (TNF-blockers for most of them, rituximab and abatacept for 14 of them).

The mean time between the first stable symptoms to the introduction of the first biologic agent was 27.9 months (± 17.2), the median was 23.7 months (Q1 13.2, Q3 43.8).

The results of the Cox model are shown in figure 1.

Survival of the RA without any biologic agent
The time-to-introduction of first biologic was significantly decreased by the presence of ACPA (Risk ratio [RR]: 3.4; 95% confidence interval [CI]: 2.1–5.5), younger patient age (RR: 0.97; CI 0.95: 0.95–0.99) and by the use of a DMARD during the first year of evolution of the disease (RR: 2.2, CI 0.95: 1.4– 4.4). There was no protective effect of corticosteroids (RR: 2.5, CI 0.95: 1.5–4.1). The medical center of follow up was related to the time-to-introduction of first biologic (RR: 0.4, CI 0.95: 0.2–06). However, no influence of other socio-economics parameters such as professional activity, employment status, population of city of residence, or time to first rheumatologist consult was noted.

Conclusion: Our results suggest that there was no peak period in the distribution of a biologic agent's introduction in the first five years of follow-up of the ESPOIR cohort. However, the medical center of follow-up shown to have a large impact on the time-to-introduction of the first biologic agent. By contrast, the time to first rheumatologist consult or social parameters do not have any influence on the first biologic agent's start.

Treatment Patterns in Psoriatic Arthritis Patients Newly Initiated On Non-Biologic Disease-Modifying Anti-Rheumatic Drugs. Jeffrey Curtis[1], Genevieve Gauthier[2], Robert Hiscock[2] and Frank Zhang[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Analysis Group, Inc., Montreal, QC, [3]Celgene Corporation, Warren, NJ

Background/Purpose: Several treatment options are available for psoriatic arthritis (PsA) patients (pts). Oral disease modifying anti-rheumatic drugs (DMARDs) are often used as a first-line treatment when non-steroidal anti-inflammatory drugs (NSAIDs) failed to control the PsA symptoms. Few studies have reported the treatment patterns in current PsA management in real-world settings. The objective of this study was to describe treatment changes (i.e., discontinuations and therapy modifications) following the initiation of a non-biologic DMARD in PsA pts.

Methods: Adult pts with ≥2 PsA diagnoses from physician office visits were selected from the MarketScan Commercial Claims database (2005–2009). All pts were required to have continuous insurance coverage ≥6-month prior to and ≥12-month post index date. First prescription date of a non-biologic DMARD was the index date and the preceding 6 months defined the 'baseline'. Pts who used any biologic/non-biologic DMARDs or had a diagnosis of ankylosing spondylitis during the baseline were excluded. Treatment discontinuation was defined as a treatment interruption of ≥60 consecutive days between the end of days' supply of one prescription and the start of the next prescription for the index drug. Switch in therapy was defined as the initiation of a biologic/non-biologic DMARD (not used at the index date or during the baseline) within 60 days of the discontinuation date of the index DMARD. Therapy augmentation was defined as the use of a non-biologic or biologic DMARD (not used at the index date or during the baseline) concomitantly with the index non-biologic DMARD for ≥28 consecutive days after the index date. A treatment change was defined as either a switch in therapy or an augmentation to the index therapy. Treatment patterns were captured over the one-year study period following the index date. Since pts might have used different DMARDs during the study period, the 4 most frequent treatment sequences (excluding treatment interruption) were also reported.

Results: A total of 1,698 PsA pts met the selection criteria; 71.7% initiated on methotrexate, 17.5% on sulfasalazine. Over the 12-month study period, 72.5% of the pts had ≥ 1 therapy change (median time: 86 days). More specifically, 57.7% of pts discontinued the index non-biologic DMARD (median time: 89 days), 13.1% switched to a biologic DMARD (median time: 141 days), 9.3% switched to another non-biologic DMARD (median time: 111 days), 21.4% had a therapy augmentation with a biologic DMARD (median time: 119) and 7.4% had a therapy augmentation with another non-biologic DMARD (median time: 94). The most common treatment sequences observed were 1) pts used MTX only during the study period (42.5%), 2) pts used MTX and a biologic (22.0%), 3) pts used sulfasalazine only (9.8%), and 4) pts used MTX and sulfasalazine (4.2%). Among pts who initiated a biologic during the study period (N=513), 90.8% did not use other oral DMARDs, while 9.2% also initiated another oral DMARD either in combination or sequentially.

Conclusion: This study suggests that PsA pts newly initiated on a non-biologic DMARD do not remain on the index therapy for a long period of time. Most pts switched to or added on biologics quickly without using a second oral DMARD.

1841

Lower Than Expected Levels of DMARD Acquisition Immediately Pre and Post Biologic Initiation in Rheumatoid Arthritis Patients. Denis Choquette[1], Oliver Thomas[2] and Mark Arundine[2]. [1]University of Montreal, Notre-dame Hospital, Montreal, QC, [2]Roche, Toronto, ON

Background/Purpose: Reports suggest that a large proportion of patients who acquire and use biologic DMARD agents (biologics) to treat Rheumatoid Arthritis (RA) do not acquire or adequately consume traditional DMARDs (DMARDs)[1,2]. However acquisition rates of biologics and DMARDs at the point of biologic initiation remains to be determined. The primary objective is to explore the level of DMARD acquisitions in Canadian RA patients in the 6 to 12 months both immediately prior to and post-biologic initiation to quantify the levels of biologic monotherapy vs. biologic + DMARD combination consumption.

Methods: Biologic and DMARD concomitant therapy based on actual patient purchases was examined by tracking a cohort of 1,652 anonymous RA patient records from public and private drug plans in Canada (ON, QC) via unique drug plan identifier numbers (3rd party source).[3] All patients who were initiated on a biologic between August 2009 and July 2010 were tracked for a one-year period prior to and post their biologic initiation date. All cohort patients were compliant on biologics post initiation. Rheumatologist prescribing frequencies of RA therapies were assessed through randomly recruited surveys (n=100).[4]

Results: Physicians prescribed a biologic without a DMARD only 12% of the time[4]. 25% of cohort patients did not purchase any form of DMARD within the 6 months prior to starting a biologic (41% for MTX). 29% did not acquire DMARDs at any point in the 6 months post-biologic initiation (43% for MTX). Data 12 months pre-biologic initiation showed that 22% did not acquire DMARDs (37% for MTX). Data 12 months post-biologic initiation showed that 26% did not acquire DMARDs (41% for MTX).[3] Prescriptions supplied to 2–3 months worth of drug.[4]

Conclusion: A large proportion of Canadian patients do not acquire any form of DMARD in the 6–12 months prior to being initiated on a biologic for the first time. This may negatively influence compliance on DMARDs once a biologic is initiated. Six months post-biologic initiation, 29% do not acquire any form of DMARD (43% for MTX) despite the general physician prescribing rate of biologic monotherapy (12%).[3,4] These results are consistent with other registries, however this study isolates biologic monotherapy levels immediately prior to and post-biologic initiation.[1,2,3] Many patients report reluctance or refusal to take DMARDs due to side effects that include headache, GI discomfort, malaise, fatigue, nausea, hair loss, and lifestyle restrictions[4,5]. Close monitoring of DMARD intake is recommended and/or management of patients on monotherapy. Patient education is of prime importance as sustainability, clinical and radiological efficacy of biologic treatment may be compromised.

1842

Disease Activity and Treatment Strategies in Moderate Rheumatoid Arthritis Patient Population: Data From the Consortium of Rheumatology Researchers of North America. Sameer Kotak[1], Andrew S. Koenig[2], David H. Collier[3], Katherine C. Saunders[4], Ping He[5], Joel M. Kremer[6] and George W. Reed[7]. [1]Pfizer Inc., New York, NY, [2]Pfizer Inc., Collegeville, PA, [3]Amgen Inc., Thousand Oaks, CA, [4]CORRONA, Inc., Southborough, MA, [5]UMASS Medical School, Worcester, MA, [6]Albany Medical College and The Center for Rheumatology, Albany, NY, [7]University of Massachusetts Medical School, Worcester, MA

Background/Purpose: Studies on patients with severe rheumatoid arthritis (RA) are widely reported. However, limited data are available on patients with moderate disease activity (MOD). Recent evidence, including data from the PRESERVE trial, have highlighted the disease burden in MOD patients, and further warrant an understanding of disease progression/remission and impact of treatment strategies in this patient population from longitudinal clinical registries.

Methods: Patients enrolled in CORRONA (a large US multicenter, longitudinal database of RA patients) from March 2002 through April 2012, aged ≥18 years, who moved from LDA (CDAI≤10) to MOD (10<10CDAI<22) were included at baseline. Patients were followed over time to estimate the proportion with Low CDAI/Moderate CDAI/ Severe CDAI at the 6 month and 12 month follow up visit. Additionally proportion of patients accelerating between baseline and 6 month; and 6 month and 12 month follow up visit were reported. Accelerations were defined as (i) add/switch a DMARD (ii) increase dose only (iii) both add/switch DMARD and increase dose. Patients were excluded if (i) time between last LDA and first Moderate CDAI was > 1 year (ii) they moved from LDA to Severe CDAI before Moderate CDAI. We included patients with CDAI at all three visits (first moderate, 6 month follow up, and 12 month follow up).

Results: 4,118 RA patients met the inclusion criteria. At 6 months, the majority (2,451/4,118; 60%) were LDA, while 32% (1,298/4,118) remained MOD, and 9% progressed to severe (CDAI>22). Of those who were at LDA at 6 months (N=2,451), 76% remained at LDA at 12 months; while 46% of those who were MOD at 6 months actually improved to LDA at 12-months. Majority (69%) of those severe at 6-months had either improved to LDA or MOD at 12-months. Between baseline and 6-month visit, 39% (1,590/4,118) accelerated by adding/switching a DMARD (43%), increasing the dose (43%), or both (12%) and in spite of that, 10% patients had progressed to severe (160/1,590) at the 6-month visit. Eight percent of patients with no accelerations from baseline (2,528) worsened (209/2,528) at the 6-month visit. Between 6 and 12 month visit, patients initially accelerated but with LDA or MOD at 6-month did not receive high number of accelerations. Nearly half of those severe at 6-months were accelerated, although a quarter (25%) continued to demonstrate severe disease activity at the 12-month visit.

Conclusion: Patients identified with moderate disease activity (10<CDAI<22) from a longitudinal registry generally regress and progress disease activity levels over a 6-month and 12-month follow-up period. Patients with treatment accelerations were presumably more severe as evidenced in a higher proportion of patients with severe disease activity at the 6-month visit (10%) than those without accelerations (8%). In this patient population, for patients who move from LDA to moderate disease, even at one year there were still substantial numbers who had not moved to LDA. Data demonstrates transition potential and disease instability in an understudied population, even within a short follow-up window of 6-months to a year.

1843

Predictors of Starting and Stopping Disease Modifying Anti-Rheumatic Drugs for Rheumatoid Arthritis: A 23 Year Longitudinal Cohort. Daniel H. Solomon[1], Edward Yelin[2], Jeffrey N. Katz[3], Chris Tonner[4], M. Alan Brookhart[5], Seoyoung C. Kim[1], Bing Lu[1] and John Z. Ayanian[6]. [1]Brigham and Women's Hospital, Boston, MA, [2]University of California San Francisco, San Francisco, CA, [3]Brigham & Women's Hospital, Boston, MA, [4]UCSF, San Francisco, CA, [5]University of North Carolina, [6]Brigham and Women's Hospital

Background/Purpose: DMARDs are the standard of care for rheumatoid arthritis (RA), however multiple studies find that not all patients use these agents. We examined predictors of DMARD stopping and DMARD starting among a large cohort of patients with RA.

Methods: Study participants were drawn from an open longitudinal cohort of 1,346 participants with RA recruited from rheumatologists' practices in Northern California. We examined patterns and predictors of DMARD stopping and starting, including non-biologic and biologic DMARDs, based on annual questionnaires. Stopping was defined as stopping ALL DMARDs and starting was defined as transitioning from NO DMARDs to any DMARD across consecutive years. Predictors were categorized as related to RA (disease duration, HAQ score, tender and swollen joints, and use of oral steroids), sociodemographics (age, gender, race/ethnicity, education, income), or comorbidities (index). Calendar year was also included. Generalized linear mixed regression models for binary outcomes were constructed that accounted for the non-independence of multiple pairs of years from individual participants, and model fit was assessed using the c-statistic.

Results: The analysis of determinants of starting DMARDs included 471 subjects with 1,974 pairs of years with no DMARD use in the first of two consecutive years from which 313 (16.3%) started DMARD use before year two. The analysis of determinants of stopping DMARDs included 1,026 subjects with 7,595 pairs of years with DMARD use in the first of two consecutive years from which 423 (5.6%) stopped DMARD use before year two. Over the 23 years of follow-up (1987–2009), the percent starting DMARDs between two consecutive years was stable at approximately 10%, but the percent stopping DMARDs from one year to the next decreased from 9% to 3%. In fully adjusted models, significant predictors of starting DMARDs included younger age (OR 0.85, 95% CI 0.75–0.95, per 5-year decrease), Hispanic ethnicity (OR 1.88, 95% CI 1.06–3.33), shorter disease duration (OR 0.90, 95% CI 0.80–1.00, per 5-year decrease), and the use of oral steroids (1.90, 95% CI 1.36–2.66). In separate fully adjusted models, predictors of stopping DMARDs included older age (OR 1.05, 95% CI 1.00–1.10, per 5-year increase), Hispanic ethnicity (OR 1.54, 95% CI 1.02–2.30), lowest annual income quartile (OR 1.83, 95% CI 1.13–2.96, compared with highest), and more tender joints (OR 1.03, 95% CI 1.00–1.07 per joint increase). The c-statistics for RA-related factors were 0.60 (stopping a DMARD) and 0.62 (starting a DMARD), suggesting that they were relatively weak predictors of stopping or starting a DMARD. Including sociodemographic factors and comorbidities in the fully adjusted models improved the model fit for both sets of models – c-statistics 0.68 (stopping a DMARD) and 0.69 (starting a DMARD).

Conclusion: Predictors of stopping and starting DMARDs include non-RA related factors as well as RA-related factors. More frequent starting and stopping of DMARDs in Hispanic subjects may reflect barriers to continued use. The significance of non-RA related factors such as race/ethnicity and income suggest that there are disparities in DMARD use despite clear clinical guidelines about their use.

1844

Inequities in Access to Biologic Disease-Modifying Anti-Rheumatic Drugs for Patients with Rheumatoid Arthritis Across 46 European Countries. Polina Putrik[1], Sofia Ramiro[2], Milena Pavlova[1], Tore K. Kvien[3], Tuulikki Sokka[4], Till Uhlig[3], Annelies Boonen[5] and Equity In Access To Treatment of RA Across Europe[6]. [1]Maastricht University, Maastricht, Netherlands, [2]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [5]University Hospital Maastricht, Maastricht, Netherlands, [6]European Region

Background/Purpose: In the treatment of patients with RA, EULAR recommends to initiate biologic DMARDs after failing synthetic DMARDs. However, biologics are costly, and it is not known to what extent limited access to these drugs can hamper implementation of the EULAR recommendations. A poor ability to adhere to these recommendations might contribute to health disparities previously seen in RA patients across countries [1]. The purpose of the study was to explore access to biologics across Europe along the three dimensions of access: availability, affordability and acceptability.

Methods: Number of reimbursed drugs, prices of biologics, and data on cultural acceptability of biologics were collected by questionnaire sent to one representative rheumatologist in 49 countries of the European Region. To ensure comparability, national prices were converted into international dollars ($) to adjust for the countries' purchasing power parity (PPP). Data on socio-economic welfare (gross domestic product (GDP), health expenditure, median income and minimum wage) were retrieved from web-based sources. Data on RA health status (DAS28, HAQ, TJC, SJC, ESR) were retrieved from the literature (QUEST RA) [1]. Indicators of access in each axis were correlated with indicators of welfare and RA health status using Spearman correlations.

Results: In total, 46 countries (response rate 94%) provided data. With respect to *availability*, in 10 countries no biologics were reimbursed, while 5 or more were reimbursed in 27 countries. With respect to *affordability*, annual average prices per patient of all available biologics varied from €9,431 (Turkey) to €21,349 (Germany), corresponding to a price ratio of 2.3. However, after adjusting the prices for PPPs, prices ranged from int.\$14,446 to int.\$61,552 (price ratio 4.3). Cultural *acceptability* ranged from 0 to 10 (10 poorest acceptability). Number of reimbursed drugs showed moderate to very strong positive correlation with the economic welfare and inverse correlation with the RA health status. While national prices seemed to be slightly lower in low income countries, after adjusting to PPP prices were strongly inversely correlated with economic welfare and positively with RA health. The sum-score of the acceptability was negatively associated with the economic indicators, and positively with the RA health status (table).

	Range	Mean (SD)	Median	Correlations with GDP	Correlations with median income	Correlations with mean DAS28	Correlations with SCJ
Total number of biologics reimbursed	0–8	4.9 (3.3)	7	0.88	0.59	−0.78	−0.61
Average annual price of biologics, int.\$	14,446–61,552	28,548.1 (10,768.5)	27,632.13	−0.84	−0.75	0.75	0.72
Average acceptability score	0–10	5.1 (3.3)	2.5	−0.63	−0.37	0.69	0.71

Conclusion: European countries with lower socio-economic status seem to have less access to biologics in terms of lower availability, affordability and acceptability (more barriers), while health of RA patients is worse. This implies inequity in access for innovative care disfavoring patients in poorer societies.

1845

Inequalities Across 46 European Countries in Clinical Eligibility Criteria for the Start of A First (Reimbursed) Biologic in Patients with Rheumatoid Arthritis. Polina Putrik[1], Sofia Ramiro[2], Tore K. Kvien[3], Tuulikki Sokka[4], Till Uhlig[3], Annelies Boonen[5] and Equity in Clinical Eligibility Criteria for RA treatment[6]. [1]Maastricht University, Maastricht, Netherlands, [2]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [5]University Hospital Maastricht, Maastricht, Netherlands, [6]European Region

Background/Purpose: In the treatment of patients with RA, strategies that include biologics have resulted in a better outcome for patients with regard to disease activity, need for surgery and work participation. Across the countries, reimbursement criteria and/or recommendations/guidelines have been formulated to regulate access to these costly treatments. The objective of this study was to explore clinical eligibility criteria for the start of a first reimbursed biologic in patients with RA and compare them across different European countries.

Methods: A questionnaire was sent via email to one representative rheumatologist in 49 countries of the European Region to collect data on the eligibility criteria for a first biologic in patients with RA, as of May 2011. First, rheumatologists were asked whether either reimbursement or clinical recommendations or both were mainly regulating prescription in clinical practice. Further information was collected on (a) minimal disease duration required, (b) number of previous DMARDs needed to be failed and (c) requirements for disease activity or severity, mandatory before the start of a biological. A simple score was developed to evaluate the level of restrictions in access to reimbursed biologics across the countries (table). This score varied between 0 and 5, the higher the score, the easier the access. Study results are presented using descriptive statistics.

Results: Forty-six countries (response rate 96%) provided data. In 10 countries (22%) no biologic was reimbursed. Among the remaining 36, Luxemburg had no regulation of access to reimbursed biologics, in 13 (36%) the reimbursement criteria were the major source of eligibility criteria, while in 7 (19%) the clinical recommendations predominated, and in 15 (42%) both reimbursement criteria and clinical recommendations were used (usually because they were similar).

Among those with at least 1 biologic reimbursed, 21 countries (58%) had no requirement for disease duration in order to initiate a biologic, and for the remaining countries a duration of 3 to 12 months was mandatory. The majority of the countries (47%) required a failure of 2 synthetic DMARDs to qualify for therapy with biologics. Thirty-one out of 36 countries specified a minimum level of disease activity that had to be fulfilled before treatment with biologics (table). Three countries (8%) had the maximum (5) eligibility score (most liberal), 19.5% had a score of 4, 19.5% a score of 3, 22% a score of 2, 28% of 1 and 3% (1 country) a score of 0 (more restrictive). Countries from Eastern Europe and former Soviet Union were more likely to be classified in the more restricted scores.

Criterion	Cut-off	Score for eligibility for biologics	Number of countries (%)
Disease duration	No limitation	1	21 (58%)
	Yes	0	15 (42%)
Disease activity	No requirement	2	5 (14%)
	DAS28≥3.2 or equivalent as major criteria	1	12 (33%)
	Stricter requirement than DAS28≥3.2	0	19 (53%)
Number of synthetic	≤1	2	15 (42%)
	2	1	17 (47%)
DMARDs to be failed>2	0	4 (11%)	

Conclusion: Clinical criteria for biologic therapy differ significantly across the countries, suggesting inequalities in access to treatment in RA. These findings should alert stakeholders to further strive for optimal standards of rheumatologic care and implement them across all European countries.

1846

Observation of Persistence Rates and Potential Costs Savings Associated with Certolizumab Pegol Treatment for Rheumatoid Arthritis in England, Wales and Northen Ireland Clinical Practice. Mike Russell[1], Jen Timoshanko[1], Graeme Duncan[2], Angela Spandley[1] and Samantha Roskell[3]. [1]UCB Pharma, Slough, United Kingdom, [2]Healthcare at Home Ltd, Burton on Trent, United Kingdom, [3]Rheumatology, Cannock Chase Hospital, Cannock, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) therapy in the UK is standardized by the National Institute for Health and Clinical Excellence (NICE). To be eligible for anti-TNF therapy RA patients (pts) must show inadequate response to 2 synthetic DMARDs (including methotrexate [MTX]) and high disease activity (DAS28>5.1). To continue therapy pts must show a change in DAS28>1.2 at 24 weeks (wks).[1] Certolizumab pegol (CZP) studies in RA have shown the majority of pts respond by Wk 12[2,3], and response at 12 wks is predictive of clinical outcome at 1 year[2–4]. Continued CZP therapy should be carefully reconsidered in pts who show no therapeutic benefit in the first 12 wks[5]. In the UK, CZP is available via a Patient Access Scheme (PAS), which provides the first 12 weeks of CZP free of charge. This analysis examines persistency and actual versus potential cost savings realized with a 12 wk decision with CZP.

Methods: This retrospective analysis used anonymised data from Healthcare at Home (HAH), the UK's largest home healthcare service provider. A crude unadjusted persistence rate was calculated for pts receiving CZP between March 2010 - March 2012. Persistence was defined as the percentage of pts continuing to receive deliveries of CZP with pts censored according to the date of first delivery. Treatment start was first delivery date and treatment status was determined as current or finished at specified time points (13, 26, 39, 52 weeks). Pts were defined as naive or switch (≥1 prior anti-TNF, according to HAH records). Pts who temporarily discontinued therapy were excluded. A cost analysis was performed by calculating a) the savings from the PAS and b) the potential reinvestment which could be made by removing non-responders at 12 wks versus 26 wks.

Results: This analysis included 2,737 pts receiving CZP (mean age 57 years). At 52 wks, the persistence rate was 64% in anti-TNF naive and 48% in switch pts (table). Analyzing first-line biologic drug costs only, the NHS would save ≤2,363.14 per pt in the first year if CZP were used in place of adalimumab, assuming similar persistence rates; largely due to the PAS. Stopping treatment for non-responders at Wks 12 (CZP) vs Wk 24 (adalimumab), could allow the UK NHS to re-invest ≤ 2145 per pt whilst avoiding unnecessary drug exposure.

Table. Persistence for Total population. Naive and Switch.

Duration of treatment	Persistence		
	TOTAL	Naive	Switch
13 wks	92% (N = 2,737)	93% (N = 2,032)	88% (N = 705)
26 wks	75% (N = 2,404)	78% (N = 1,717)	68% (N = 687)
39 wks	65% (N = 2,027)	69% (N = 1,392)	56% (N = 635)
52 wks	59% (N = 1,604)	64% (N = 1,030)	48% (N = 574)

Conclusion: In this UK cohort, CZP persistence was 64% at 52 wks in naive pts. Reinforcing a 12 wk treatment decision could result in more efficient spend on drugs as well as avoiding unnecessary drug exposure and delayed initiation of alternative treatment in non-responders.

Status of the Rheumatology Clinical Trials Portfolio: Data From Clinicaltrials.Gov. Ankoor Shah[1], Samuel Broderick[2], Karen Chiswell[2], Asba Tasneem[2] and John S. Sundy[1]. [1]Duke University Medical Center, Durham, NC, [2]Duke University Medical Center, Durham

Background/Purpose: In an effort to provide a comprehensive listing of clinical trials Congress initiated the creation of the ClinicalTrials.gov (CT-

.gov) registry in 1997. In 2007 the FDA Amendment Act mandated registration of most non-phase I interventional drug, biologic, and device trials. Until recently, there has been no systematic analysis of the clinical trial enterprise, either broadly or for rheumatologic diseases. As part of the Clinical Trials Transformation Initiative we analyzed the CT.gov database to describe the current state of clinical trials in rheumatology and compare these findings to other specialties.

Methods: A dataset of 96,346 studies was downloaded from CT.gov on 9/27/2010 and was restricted to 40,970 interventional studies registered between 10/2007 and 9/2010. Clinical specialists annotated medical subject heading terms and common disease terms for relevance to rheumatology. An initial dataset identified studies with ' 1 disease relevant term. Manual review of individual studies, and additional keyword searching yielded the final rheumatology study dataset (R). Studies were further divided into disease and sponsorship subcategories and comparisons were made between these sub-categories, and with non-rheumatology (NR) studies.

Results: 1,622 rheumatology trials were identified, representing 4% of the CT.gov dataset. Disease groups were classified as: osteoarthritis (24.4%), rheumatoid arthritis (19.4%), lupus/connective tissue disease (8.6%), spondyloarthritis (4.1%), scleroderma (2.3%), gout (2.2%), vasculitis (0.7%), and all others (38.2%). Median (quartiles) enrollment for R trials was 80 (35,200) compared to (64 (30,180)) for NR studies. The primary purpose was treatment in the majority of studies (86.8%). Prevention (5.0%) and diagnostic (2.3%) were less represented than in NR studies (11.1% and 4.0% respectively). 59.4% were industry-sponsored compared to 45.4% of NR studies. Biologics were used in 23.2% of R studies. There was double-blind masking in 49.0% and randomization in 75.2%, versus 32.4% and 68.6% for NR studies, respectively. 33.1% reported using a data monitoring committee (DMC) which was less than that among NR studies (40.9%). Industry sponsored studies were less likely to utilize a DMC compared to non-industry (26.1% v. 39.1%) and more likely to utilize a biologic and focus on treatment (compared to prevention and diagnosis). Only 3.6% of the rheumatology studies had posted results to the CT.gov website by date of download, compared to 2.2% among NR studies.

Conclusion: The rheumatology clinical trial enterprise represents a small number of trials in the CT.gov database between 10/2007 and 9/2010. Rheumatologic diseases with high prevalence and substantial unmet need are under represented relative to less common rheumatologic diseases. Half of clinical trials had enrollment of 80 participants or less. Double-blind masking and use of a DMC were employed in a minority of studies and only a small fraction of rheumatology studies have reported results. Our results indicate that there is an opportunity to improve the quality of clinical trials in rheumatology and initiate a policy discussion on whether resources are optimally focused on the highest priorities.

Impact of Biologics On Total Knee Replacement and Total Hip Replacement Rates in Rheumatoid Arthritis Patients: Results From US Marketscan Database. Andrew S. Koenig[1], Jack Mardekian[2] and Sameer Kotak[3]. [1]Pfizer Inc., Collegeville, PA, [2]Pfizer Inc, New York, NY, [3]Pfizer Inc., New York, NY

Background/Purpose: Joint replacement surgery patterns continue to change in patients with rheumatoid arthritis (RA), possibly reflecting the widespread adoption of disease modifying antirheumatic drugs, earlier intervention and better supportive care. In a study of a population based RA sample from Rochester, Minnesota, a decline in cumulative incidence of orthopedic surgery by decade of RA diagnosis was reported.(1) Previous analyses based on the Swedish Hip Arthroplasty Register demonstrated a decline in the proportion of total hip arthroplasties due to inflammatory joint disease from 5% during 1992–2002 to 2% in 2007.(2)

Methods: We performed a retrospective analysis of pharmacy and medical claims data from 2003–2010 in the United States utilizing the MarketScan database. Patients were required to be continuously enrolled preceding 1–3 years post RA diagnosis. We used a coding algorithm to identify all patients having a diagnosis of RA and no prior use of biologics ≤1 yr preceding the diagnosis. From this pool, we stratified patients who did

and did not receive a biologic within 6 months, 1, 2, and 3 yrs post diagnosis. We further coded the analyses to identify total hip or knee replacement events (THR/TKR) and mean days to THR/TKR in these sub-groups and estimated general population rates of THR/TKR.

Results: From 2003–2010, 90,545 patients were identified with a diagnosis of RA; mean age 56.5 yrs; majority were female (71%) with low comorbidity [Charlson Comorbidity Index (CCI) 0.77]. Of these, 10,492 (11.5%) initiated a biologic and nearly half (5,054/10,492; 48%) received the biologic ≤1 yr of diagnosis. No differences in age and other demographic variables between groups at baseline; however the biologic cohort had higher proportions of rheumatologic disease in the CCI. Proportions of THR/TKR in the non-biologic cohort were 7% vs. 11% in the more severe biologic cohort over the follow-up period (p<0.0001). In spite of the higher event rate, patients in the biologic cohort were event free for an additional mean 221 days compared to the non-biologic cohort (p<0.0001). THR/TKR event rates in the general population in MarketScan were 0.49% (484,107/98,414,730) compared to 6.91% (10,927/158,187) in the RA specific cohort (regardless of treatment).
[1]da Silva E, Doran MF, Crowson CS, O'Fallon WM, Matteson EL: Declining use of orthopedic surgery in patients with rheumatoid arthritis? Results of a long-term, population-based assessment. Arthritis Rheum 2003, 49:216-220.
[2]Swedish Hip Arthroplasty Register. Annual Report 2007. Dept. of Orthopedics, Gothenburg University. [http://www.jru.orthop.gu.se/].

Conclusion: The rates of THR/TKR were slightly higher in the supposedly more severe RA population who initiated a biologic (CCI 0.88), as opposed to those who did not (CCI 0.76). The mean time to THR/TKR was significantly delayed in the biologic cohort by up to 7 months, despite the higher proportion of rheumatologic disease in CCI. These results are compatible with the extensive evidence for delayed peripheral joint damage in RA patients treated with TNF inhibitors. Results must be interpreted by acknowledging the non-randomized nature of the claims data and inability to adjust for RA severity at baseline due to lack of relevant database variables.

1849

Value of Matrices Developed to Identify Early Rheumatoid Arthritis Patients with Rapid Radiographic Progression Despite Methotrexate Therapy: A Comparison of Their Performance in the Early Rheumatoid Arthritis Espoir Cohort. Bruno Fautrel[1], Benjamin Granger[2], Bernard Combe[3], Francis Guillemin[4], Alain Saraux[5] and Xavier Le Loët[6]. [1]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [2]Université Pierre et Marie Curie - Paris 6; AP-HP, Paris, France, [3]Lapeyronie Hospital, Montpellier, France, [4]Faculte de Medecin/BP 184, Vandoeuvre-les-Nancy, France, [5]Université Brest Occidentale, Brest, France, [6]Rouen University Hospital and Inserm U 905, Rouen, France

Background/Purpose: Rapid radiographic progression (RRP)—i.e., increase of the Sharp/van der Heijde score (vSHS) ≥ 5 points during the 1st year – is a marker of poor prognosis in early rheumatoid arthritis (ERA). The study aims to test the validity of five matrices have been proposed recently (ASPIRE[1], BEST[2], SWEFOT[3], ESPOIR[4], SONORA[5]).

Methods: Between 2002 and 2005, the ESPOIR cohort enrolled 813 patients with recent arthritis in at least 2 joints with 6 weeks to 6 months disease duration. During the 2 first years of follow-up, patient data were collected every 6 months and structural damage progression on X-ray was measured by the vSHS. For the purpose of the study, only patients treated

with methotrexate or leflunomide for $\geq$ 3 months within the 1st year of follow-up were selected. Baseline radiographic damage was assessed either by the present of RA erosions (at least 1 or more than 3) or vSHS value.

The validity of the different matrices, i.e., the capacity of the matrices to efficiently identify RRP patients at 1 year, was tested by Receiver Operation Curve (ROC) analysis in which the area under the curve (AUC) reflected the discriminating power of each matrix.

Results: 398 ESPOIR patients started MTX or leflunomide during the 1st year. Their main characteristics were: mean age 49.3 yrs, female 73.6%, FR+ or ACPA+ 62%, typical RA erosion 18.1% (central reading), ACR/EULAR 2010+ 86.4%, mean DAS28 5.35, mean swollen joint count 8.1, mean tender joint count 8.9, mean CRP 25.4 mg/L, mean HAQ 0.27. During the 1st year, the mean vSHS progression was 1.7 ±5.0 and 46 patients (11.6%) were classified RRP.

The performance of the ASPIRE and SWEFOT matrices displayed only moderate validity in the ESPOIR population, with AUC below 0.7 (Figure). The BEST matrix seems to perform optimally and its AUC was in the same range of the ESPOIR matrix, with an AUC of 0.79 and 0.75 respectively. The matrices using baseline vSHS value (ESPOIR+ and SONORA) displayed higher discriminating power than that using erosion information.

Figure: ROC analysis assessing the performance of the 4 matrices
Conclusion: The BeSt matrix performs adequately in the ESPOIR cohort. However, the matrices using vSHS instead of erosion status seem to display higher discriminating power to identify ERA patients with RRP despite initial MTX or leflunomide therapy.

Association of Clinical Trial Characteristics with Positive Study Outcome Reporting in Randomized Controlled Trials of Rheumatoid Arthritis Therapy. Fatima M. Khan[1], Juan I. Lombeida[2], Horace Spencer[1], Karina D. Torralba[3], Winnie K. Pang[3] and Nasim A. Khan[4]. [1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Mercy Medical Center, Rogers, AR, [3]University of Southern California Keck School of Medicine, Los Angeles, CA, [4]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

Background/Purpose: Randomized controlled trials (RCTs) are considered the best research design for assessing healthcare intervention. Concerns have been raised about the increased likelihood of positive RCT outcome (bias) with trial characteristics such as financial conflicts of interests (FCOIs) and inadequate methodological quality parameters reporting. Our objective was to assess whether reported trial characteristics are associated with outcome of RCTs of rheumatoid arthritis (RA) drug therapy.

Methods: We identified original, non-phase 1, parallel-group, drug therapy RCTs of RA published in English in the years 2002–3, 2006–7, and 2010–11 by searching Medline and CENTRAL databases. RCT efficacy was assessed for primary outcome as positive (statistically significant result favoring experimental intervention) or negative. RCT characteristics [experimental intervention (traditional anti-rheumatic drugs, biologics, small molecules, others), study phase (phase 2, non-phase 2), funding source (industry, non-profit), FCOIs of authors related to industry sponsor (honoraria/consultation fee, employment, research grant, stock ownership), number of subjects enrolled, study center (single, multiple), study duration, and placebo use], and reported methodological quality measures [adequate description of random sequence generation, allocation concealment, blinding, subject follow-up, intent-to-treat analysis] were assessed independently by two investigators. Univariable associations of trial characteristics and methodological quality measures with positive study outcome were assessed using Chi-square, Fisher's exact test, likelihood ratio, or t-test. Multivariable logistic regression (MLR) was performed by including funding source and all variables associated with positive outcome with P≤0.1

Results: 146 eligible RCTs were identified. Efficacy outcome could be assessed for 125 (85.6%) RCTs. Studies were excluded for the following reasons: primary outcome safety (11), no intervention declared experimental a priori(10). Positive outcome was noted in 86 (68.8%) RCTs. Non-phase 2, higher number of enrolled patients and author FCOI (honoraria/consultation fee) increased likelihood, while adequate random sequence generation description decreased this likelihood of positive outcome on univariable analysis. Author FCOI (honoraria/consultation fee), number of enrolled patients, and adequate description of randomization were independently associated with positive outcomes in MLR analysis (Table 1).

Table 1. Univariable and multivariable analysis of clinical trial characteristics and study outcome.

Variable	Referent	Univariable analysis		Multivariable analysis	
		OR (95% CI)*	P	OR (95% CI)*	P
Funding source, industry**	Non-profit	0.89 (0.40–1.97)	0.769	0.53 (0.18–1.53)	0.241
Honoraria/consulting fee receipt by author, yes	No	2.41 (0.99–5.88)	0.043	3.24 (1.06–9.88)	0.039
Non-phase 2	Phase 2	3.45 (1.41–8.45)	0.005	2.68 (0.88–8.11)	0.082
Number of patient enrolled***	Δ 1	1.59 (1.09–2.32)	0.013	1.73 (1.11–2.69)	0.016
Duration of study, months***	Δ 1	1.49 (0.95–2.32)	0.075	1.28 (0.78–2.10)	0.321
Adequate reporting of random sequence generation, yes	No	0.40 (0.18–0.89)	0.022	0.32 (0.13–0.78)	0.013

*OR: odds ratio; CI: confidence interval
*RCTs with partial or complete funding by industry were considered as industry funded, while those with explicit non-profit source or unspecified funding source were considered non-profit.
**log transformed

Conclusion: Certain trial characteristics (number of enrolled subjects, author's receipt of honoraria/consultation fee) and reported trial quality measure (random sequence generation description) were independently associated with positive outcomes of RA drug therapy RCTs.

Exploring the Relationship of Anti-Tumor Necrosis Factor Drugs and Methicillin Resistant Staphylococcus Aureus Nasal Colonization in Patients with Rheumatologic Conditions and Psoriasis. Daniel E. Kreutz[1], Santosh P. Reddy[1], Guy P. Fiocco[2], Colleen Colbert[1] and Juhee Song[1]. [1]Scott & White Healthcare/Texas A&M University, Temple, TX, [2]Scott & White Clinic, Temple, TX

Background/Purpose: Infection with methicillin-resistant *Staphylococcus aureus* (MRSA) is a source of significant morbidity/mortality. Healthcare entities spend large amounts to prevent spread of MRSA. Most MRSA colonization literature is for surgical inpatients, with little exploration of the possible influence of immune-modifying drugs on colonization. These drugs are being used more commonly in treatment of chronic conditions, such as rheumatologic diagnoses. This study attempted to identify the influence of Tumor Necrosis Factor inhibitor (anti-TNF) drugs on MRSA carrier state in patients with diagnoses of psoriasis, psoriatic arthritis, rheumatoid arthritis, or ankylosing spondylitis.

Colonization with MRSA leads to greater risk of infection with MRSA.Screening and intervention decrease blood borne infections, leading to use of screening programs.Studies in various environments have attempted to describe the carriage rate for MRSA, now estimated to be 1.2–14%.

There has been some investigation into the relationship between MRSA colonization and immunosuppression, but it has been limited to transplant patients, cancer patients, and those with HIV.Currently there are no data on the relationship between immunosuppresive drugs and MRSA colonization in those being treated for rheumatologic conditions and psoriasis.

Methods: Medical records of patients admitted to two large referral hospitals between 1/1/07 and 3/31/10 were reviewed. All admitted patients 18 years and older with psoriasis, psoriatic arthritis, rheumatoid arthritis, or ankylosing spondylitis during this period were included for retrospective chart review (1001 persons). Of these, 436 were screened for nasal MRSA during the study period. Demographics, comorbidities and length of stay were noted

as was information on treatment of their conditions and MRSA screen result. The rate in this group was compared to known MRSA rate for all patients screened in the two hospitals for the period (6.7%).

Results: Records from 436 patients were used; 10 (2.3%) had psoriatic arthritis, 15 (3.4%) had ankylosing spondylitis, 72 (16.5%) had psoriasis, and 341 (78.2%) had rheumatoid arthritis. MRSA colonization was noted for 53 (12.2%) patients, which is much higher than the overall rate of 6.7% for adults. A TNF inhibitor was in the medical regimen for 54 (12.4%) patients. Of those prescribed anti-TNF drugs, 11.1% were MRSA positive. The study population with MRSA tended to have a longer length of stay (p = 0.0529), and come from a nursing home (27.5%). There was a strong association between nursing home residence and MRSA result (p = 0.0003).

Conclusion: Patients with psoriasis and rheumatologic conditions had a higher rate of MRSA colonization than the general patient population at these referral centers. Patients treated with anti-TNF drugs were no more likely than those being treated with traditional immune modulating agents to have a positive MRSA screen. Those patients coming to the hospital from a nursing facility were more likely to have a positive MRSA screen.

Tumour Necrosis Factor-Alpha Antagonists and Alopecia: A Case/Non-Case Study in a Nationwide Pharmacovigilance Database. Johana Béné[1], Guillaume Moulis[2], Marine Auffret[1], Claire Fessier[1], Guillaume Lefevre[3] and Sophie Gautier[1]. [1]Lille University Hospital, Lille Pharmacovigilance Regional Centre, Lille, France, [2]Toulouse University Hospital, Clinical Pharmacology Department, University of Toulouse, UMR INSERM-UPS 1027, Toulouse, France, [3]Lille University Hospital, Internal Medicine Department, Lille, France

Background/Purpose: Cases of alopecia occurring on TNF-alpha antagonists have been described. Nevertheless, no epidemiological study has been conducted to assess the link between TNF-alpha antagonists exposure and occurrence of alopecia. The aim of this study was to describe the cases of TNF-alpha antagonist-related alopecia reported in the French Pharmaco-Vigilance Database (FPVD), and to assess the putative association.

Methods: All spontaneous reports of TNF-alpha antagonist-related alopecia recorded in the FPVD between January 2000 and April 2012 were described. We conducted disproportionality analyses (case/non-case method) to assess the link between alopecia and exposure to TNF-alpha antagonists. Cases were all reports of alopecia recorded during the study period. Non-cases were all other reports recorded during the same period. Exposure to TNF-alpha antagonists was searched in cases and non-cases. Reporting odds ratios (ROR) were calculated to assess the association. To assess the validity of the method we used exposure to docetaxel (well-known as alopecia inducer) as positive control and to acetaminophen as negative one.

Results: During the study period, 283 658 spontaneous reports were colligated in the FPVD, of which 4742 (1.7%) involved TNF-alpha antagonists. Among these 4742 reports, 51 (1.1%) were alopecia (mainly, alopecia areata): 18 involved infliximab, 17 adalimumab, 15 etanercept and 1 certolizumab. Male:female sex-ratio was 0.18 and mean age was 39 years. Seventeen patients were treated for rheumatoid arthritis, 13 for ankylosing spondylitis, 11 for Crohn disease and 6 for psoriasis. Mean delay from TNF-alpha antagonist introduction to alopecia onset was 11.3 months (extremes: 4 days–8 years). An improvement was observed in 12 cases after TNF-alpha antagonist withdrawal (available data for 24 reports). Association between TNF-alpha antagonist exposure and alopecia was significant for all TNF-alpha antagonists pooled (ROR=3.0; 95%CI [2.3–4.0]), as well as for infliximab, ROR=2.0; 95%CI [1.2–3.1], adalimumab, ROR=4.7; 95%CI [2.9–7.7] and etanercept, ROR=3.3; 95%CI [2.0–5.4]. The ROR with docetaxel was 29.9; 95%CI [25.3–35.5] and with acetaminophen was 0.3; 95%CI [0.2–0.4].

Conclusion: These results suggest a link between TNF-alpha antagonists exposure and occurrence of alopecia. A channeling bias cannot be excluded, but improvement in half of the cases after TNF-alpha antagonist withdrawal is a strong argument for the drug responsibility.

Rheumatoid Arthritis Patients' Experiences of Medication Side Effects and Subsequent Decision Making about Medications. Yomei Shaw[1], Ilinca D. Metes[2], Susan L. Zickmund[2], Dawn McBride[2], Kelly A. Reckley[2], Stephen R. Wisniewski[1], Larry W. Moreland[2], Mark S. Roberts[1] and Marc C. Levesque[2]. [1]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA

Background/Purpose: Medication adherence in rheumatoid arthritis (RA) patients can be influenced by their previous experiences with medication side effects. Negative experiences may lead patients to become fearful towards medications, increasing rates of non-adherence and rejection of physician recommendations to add medication therapy. To better understand how patients' experiences of adverse drug reactions affect perceptions of medication risk and subsequent decisions to take recommended medications, we conducted an analysis of patient narratives of their experiences with adverse drug reactions due to medications for RA. Our goal was to describe features of RA patients' experiences of medication side effects, and to compare narratives of patients who self-report discontinuing medications on their own or rejecting physician recommendations for medications ('Non-adherent' group) with narratives of patients who do not ('Adherent' group).

Methods: A qualitative analysis was conducted of transcripts from semi-structured interviews with 20 RA patients. Interviews were from a pilot study testing patient education materials for usage in the RA Comparative Effectiveness Research (RACER) registry (n = 1,000). Subjects were recruited from RACER enrollees treated at a participating clinic. During interviews, subjects were asked whether they had ever experienced side effects due to their medications for RA, and if so, to describe the side effects. Comments of all subjects describing any experiences of side effects were analyzed. A coding scheme was developed to index statements about: 1) medications in general, 2) the side effects experienced and relevant medications, 3) the patient-provider relationship, and 4) RA and treatment related information. The first 2 authors coded the interview transcripts separately, then discussed and reached a consensus on assignment of codes for each transcript. Codes for patients in the Non-adherent group were compared to the Adherent group.

Results: Fourteen of 20 patients reported side effects. The inter-observer agreement was high (mean kappa = 0.90). Among the 14 subjects with side effects, subjects in the Non-adherent group (n = 6) and Adherent group (n = 8) reported a similar mean number of side effects which they perceived as important (2.83 vs. 2.13) and non-important (0.67 vs. 1.25). However, patients in the Non-adherent group were more likely than patients in the Adherent group to discuss fear (66.7% vs. 12.5%), unacceptability of side effects (66.7% vs. 25%), unsatisfactory resolution of side effects (66.7% vs. 25%), and negative aspects of medications (83.3% vs. 25%).

Conclusion: Fear, viewing side effects as unacceptable, dissatisfaction with how side effects were resolved, and negative perceptions of medications played a more central role in the experiences of patients who discontinued medications on their own or rejected physician recommendations, compared to patients who did not. This suggests that interventions to address these patient concerns may be critical for improving patient adherence to medications.

1854

The Safety of Anti-TNF Biologic Agents in Rheumatoid Arthritis - A Meta-Analysis of 35 RCTs. Tzuyu Lin[1], Tatyana Shamliyan[1], Hyon Choi[2], Young Hee Rho[2] and Karen Kuntz[1]. [1]Division of Health Policy and Management, School of Public Health, University of Minnesota, Minneapolis, MN, [2]Boston University School of Medicine, Boston, MA

Background/Purpose: The objectives of this systematic review were to study and update the safety of anti-TNF agents. We examined whether etanercept (ETN), compared to the anti-TNF antibody therapies, infliximab (INF) and adalimumab (ADA), had an inverse impact on adult patients with rheumatoid arthritis (RA) in terms of malignancy, serious adverse events (SAEs), serious infection, and discontinuation due to adverse events (AEs).

Tuesday, November 13

Methods: We conducted a systematic-literature review of randomized controlled trials (RCTs) that studied one of the three biologics used for rheumatoid arthritis and reported on our pre-specified adverse outcomes of malignancy, SAEs, serious infections, and discontinuation due to AEs. We searched various databases including MEDLINE® via OVID and PubMed®, the Cochrane Library, Google Scholar, and ClinicalTrials.gov, and further mined the reference lists from systematic reviews and original publications to identify all English-language studies published from January 1, 1990 until September 30, 2011. In addition, we searched the US Food and Drug Administration (FDA) database to review drug approval reports that could provide eligible trials. The search strategy and data extraction processes were duplicated by independent reviewers. For the meta-analysis, we performed random effect inverse variance, maximum-likelihood estimation (MLE), arcsine transformed, and Bayesian models. We abstracted the studies with 0 events in both arms and used software default correction coefficients for 0 events or missing data. Furthermore, we compared the results from randomized trials with published large nationally representative cohort studies and administrative databases.

Results: Thirty-five trials met our inclusion criteria, including 5,524 patients who received anti-TNF biologic agent treatment and 3,257 patients who received MTX/placebo. The risk of malignancy in patients treated with INF was significantly higher than that among those treated with MTX (risk difference=0.02 [95% CI, 0.00 to 0.05]) in the arcsine transformed model. The risk of serious infections in patients treated with ADA or INF was significantly higher than that among those treated with MTX or placebo (OR=7.8 and 2.07; ARD=0.03 and 0.03), both in the Bayesian and arcsine transformed models (Table). In contrast, patients treated with ETN tended to have non-significant lower risks of SAEs, serious infections, and discontinuation (ORs=0.84, 0.71, and 0.84, respectively) (Table).

Table. GRADE evidence profile: Anti-TNF agents for adults with rheumatoid arthritis

No. of studies (Design)	Risk of bias	Inconsistency	Imprecision	Indirectness	Active arm	Control arm	Bayesian odds ratio (95% CI)	Arcsine transformed risk difference (95% CI)	Number needed to treat (NNT) (95% CI)	Attributable events (95% CI)	Strength of evidence
Serious adverse events											
3 (RCT)	Low	No serious inconsistency	No	No	Adalimumab 58/544	Placebo 21/220	1.1 (0.59, 2.06)	0.01 (−0.04, 0.06)	Not Sig.	Not Sig.	High

2 (RCT)	Low	No	No	No	Etanercept + MTX 10/321	MTX 5/327	2.18 (0.59, 9.37)	0 (−0.01, 0.02)	Not Sig	Not Sig	High
5 (RCT)*	Low	yes	No	No	Infliximab + MTX 10/1169	MTX 3/473	1.35 (0.35, 7.15)	0.02 (0.00, 0.05)	19 (0.48)	53 (21, 2.991)	Moderate
Serious infections											
2 (RCT)[a]	Low	No	No	No	Adalimumab 17/479	Placebo 1/157	7.8 (1.12, 198.6)	0.03 (0.00, 0.07)	30 (4, 72)	33 (14, 239)	High
2 (RCT)	Low	No	No	No	Adalimumab + MTX 20/475	MTX 7/356	2.21 (0.72, 7.77)	0 (−0.02, 0.02)	Not Sig.	Not Sig.	High
2 (RCT)	Low	No	No	No	Etanercept + MTX 30/321	MTX 37/327	0.71 (0.20, 1.90)	−0.02 (−0.06, 0.03)	Not Sig.	Not Sig.	High
5 (RCT)*	Low	No	No	No	Infliximab + MTX 96/1853	MTX 21/829	2.07 (1.18, 3.73)	0.03 (0.01, 0.04)	25 (9, 44)	40 (23, 115)	High
Discontinuation due to adverse events											
4 (RCT)	Low	No	No	No	Adalimumab 39/763	Placebo 10/276	1.5 (0.70, 3.46)	0.02 (−0.01, 0.05)	Not Sig.	Not Sig.	High
3 (RCT)	Low	No serious inconsistency	No	No	Adalimumab + MTX 51/703	MTX 17/335	1.24 (0.47, 2.68)	0.02 (−0.01, 0.08)	Not Sig	Not Sig	High
2 (RCT)	Low	No	No	No	Etanercept + MTX 82/638	MTX 60/445	0.76 (0.40, 1.38)	0.02 (−0.02, 0.07)	Not Sig.	Not Sig.	High
2 (RCT)	Low	No	No	No	Etanercept + MTX 20/321	MTX 24/327	0.84 (0.33, 2.14)	0.01 (−0.03, 0.05)	Not Sig	Not Sig	High
5 (RCT)	Low	No	No	No	Infliximab + MTX 103/1897	MTX 26/902	1.48 (0.65, 2.91)	0 (−0.01, 0.02)	Not Sig	Not Sig	High

Conclusion: The findings of this meta-analysis suggest potential differences in adverse outcomes among ADA-, INF-, and ETA-treated RA patients. The risk of malignancy may be increased among INF-treated RA patients, whereas the risk of serious infection may be increased ADA- or INF-treated patients. These findings call for further post-marketing surveillance to clarify these risks with longer term exposure.

1855

Prevalence of Potential Drug-Drug and Drug-Condition Interactions in Fibromyalgia Patients Newly-Initiating Pregabalin or Duloxetine.

Stephen Johnston[1], Margarita Udall[2], Joseph C. Cappelleri[3], Barbara H. Johnson[1], George Shrady[1] and Stuart L. Silverman[4]. [1]Truven Health Analytics, Washington, DC, [2]Pfizer Inc., New York, NY, [3]Pfizer Inc., Groton, CT, [4]Cedars-Sinai Medical Center, UCLA Center of Excellence, Beverly Hills, CA

Background/Purpose: Drug-drug and drug-condition interactions (DDI/DCI) can present a significant challenge to the appropriate prescribing of drugs. The risk of DDI/DCI may be elevated in patients who are treated with polypharmacy or have many comorbid conditions, which is often the case in fibromyalgia (FM) patients. This study quantified the prevalence of potential DDI/DCI in FM patients newly-initiating either pregabalin or duloxetine.

Methods: Retrospective cohort study using a large U.S. administrative claims database. Studied patients had newly-initiated either pregabalin or duloxetine between 7/1/2008–10/1/2010 (initiation date=index), were aged ≥18 years at index, had continuous insurance enrollment for ≥12 months pre-index (pre-period) and ≥6 months post-index (post-period), and had ≥1 inpatient or ≥2 outpatient medical claims with a diagnosis of FM (≥1 of which was incurred ≤60 days prior to or on index). Patients were excluded if during the pre- to post-period they resided in a long-term care facility for ≥90 total days or had evidence of epilepsy, post-herpetic neuralgia, transplant surgery, or cancer.

Potential DDI were measured using software (DRUG REAX) which identified instances in which prescriptions that carry a potential for DDI with pregabalin or duloxetine were filled within 180 days before to 30 days after index, with days supply of the potentially interacting drug extending beyond index. Potential DCI were medical conditions listed in the Contraindications and Warnings and Precautions sections of the prescribing information for pregabalin and duloxetine. With the assistance of medical coders, each DCI was assigned an administrative claims-based identification algorithm. The presence of potential DCI was measured during the pre-period. Chi-squared tests compared the prevalence of potential DDI/DCI across the pregabalin and duloxetine initiators.

Results: Study sample comprised 7,751 pregabalin and 7,785 duloxetine initiators; mean age 49 years, 88% female. Among pregabalin initiators, 1.4% had ≥1 potential pregabalin DCI, the most common of which was dizziness (0.9% of patients); none had potential pregabalin DDI. Among duloxetine initiators, 67% had ≥1 potential duloxetine DDI/DCI, largely driven by concomitant drugs carrying a potential for major (45% of patients) or moderate (35% of patients) duloxetine DDI; the most common of which were with tramadol (19% of potential major DDI) and amitriptyline (16% of potential moderate DDI). The prevalence of potential DDI/DCI was significantly different across pregabalin and duloxetine initiators (p<0.001). Of the 107 pregabalin initiators with ≥1 potential pregabalin DCI, 17% had no potential duloxetine DDI/DCI. Of the 5,184 duloxetine initiators with ≥1 potential duloxetine DDI/DCI, 98% had no potential pregabalin DDI/DCI.

Conclusion: In FM patients initiating pregabalin or duloxetine, the prevalence of potential duloxetine DDI/DCI was substantially higher than that of pregabalin. Most duloxetine initiators with a potential duloxetine DDI/DCI had no potential pregabalin DDI/DCI. These findings may have implications to the appropriate prescribing of drugs for the treatment of FM.

1856

Burden of Adverse Events Associated with Immunosuppressant Therapy for the Treatment of Systemic Lupus Erythematosus: A Systematic Literature Review.

Alan Oglesby[1], Arthur Weinstein[2], Greg Dennis[3], Alissa Shaul[4], Tiffany Pokora[4], Clark Paramore[5], Lael Cragin[6] and Siva Narayanan[3]. [1]GlaxoSmithKline, Research Triangle Park, NC, [2]Washington Hospital Center, Washington, DC, [3]Human Genome Sciences, Inc., Rockville, MD, [4]United BioSource Corporation, Bethesda, MD, [5]United BioSource Corporation, Lexington, MA, [6]United BioSource, Bethesda, MD

Background/Purpose: Past systematic literature reviews on adverse events (AEs) associated with immunosuppressants in patients with systemic lupus erythematosus (SLE) focused mostly on cyclophosphamide (oral: CYC; IV: IVC) and mycophenolate mofetil (MMF). The aim of this research

is to quantify the incidence of AEs, identify discontinuation rates due to AEs and resource use and cost associated with AEs from CYC/IVC, MMF, azathioprine (AZA), methotrexate (MTX), and cyclosporine (CsA) in SLE patients.

Methods: A systematic review of English-language, MEDLINE- and EMBASE-indexed literature published between January 1980 and September 2011 was conducted using terms related to SLE, AEs, discontinuation, resource use and costs. After excluding case reports, case series, non-systematic reviews, studies of fewer than 50 patients, and articles without abstracts, 38 eligible non-review articles were identified (14 randomized controlled trials (RCTs) & 22 observational studies (OBS); results are presented here.

Results: The development of AEs ranged from 42.8% to 97.3%. Commonly noted AEs are shown in the table. Discontinuation rates due to AEs were 1.4–13% in short-term (<12 months) RCTs, 2.3–44.4% in long-term (>12 months) RCTs, and 0–21.8% in OBS. Eight studies reported resource use in terms of hospitalizations due to AEs; however, frequency measures used to report hospitalization varied among the studies resulting in an inability to make comparisons between studies. No studies reported costs associated with AEs.

Table. Summary of Commonly Reported AEs by Intervention

	>1 AE	Infections	GI	Amenorrhea and/or Ovarian Complications	Hematological	Death
AZA						
RCTs (n=7)	NA	2.4–42.4%	3.2–21.4%	8.0–36.0%	6.0–50.0%	0.0–25.0%
OBS (n=3)	NA	NA	1.3%	1.4–5.6%	16.7%	NA
IVC						
RCTs (n=8)	95.0%	11.8–77%	29.4–66.7%	2.2–56.3%	1.4–38.7%	2.7–20%
OBS (n=13)	57.5–65.0%	12.5–67.9%	18–58.8%	1.9–58%	2.5–7.7%	3.0–20%
Oral CYC						
RCTs (n=3)	NA	33–40%	3.2%	36.0–71.0%	25.8%	6.5–22.2%
OBS (n=5)	NA	26–61%	7.0%	28.0–37.0%	7.0%	NA
CsA						
RCTs (n=2)	NA	6.4–19.4%	17.0–30.6%	N/A	11.1–38.3%	4.3%
OBS (n=1)	62.5%	NA	3.9%	NA	NA	NA
NA: Not Available						
MTX						
RCTs (n=1)	93.0%	4.9%	56.1%	NA	26.8%	NA
OBS (n=0)	NA	NA	NA	NA	NA	NA
MMF						
RCTs (n=5)	96.2–97.3%	12.5–68.5%	9.1–61.4%	0–6%	0.0–21.7%	1.9–5.0%
OBS (n=5)	42.8–66.7%	3.9–44.4%	4.2–38.9%	NA	0.5–5.6%	NA

Conclusion: The development of AEs associated with immunosuppressant medications in SLE patients was consistently high as reported in the SLE literature, while discontinuation due to these AEs varied from 0% to 44%. Studies describing costs and resource use associated with these AEs were sparse and warrant further study.

Identifying Core Symptom Domains in the Fibromyalgia Impact Questionnaire: Principal Component Analysis of Data From Milnacipran Clinical Studies. Philip Mease[1], Robert M. Bennett[2], Robert H. Palmer[3] and Yong Wang[3]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]Oregon Health & Science Univ, Portland, OR, [3]Forest Research Institute, Jersey City, NJ

Background/Purpose: The Fibromyalgia Impact Questionnaire (FIQ) is a multidimensional instrument that encompasses many of the core domains recommended by OMERACT for evaluation in fibromyalgia (FM) clinical trials, including pain, tenderness, fatigue, global wellbeing, functioning, sleep disturbance, depression, anxiety, and stiffness. In randomized clinical studies, significant decreases in FIQ total scores were found with milnacipran (MLN) vs placebo (PBO), indicating overall improvements in FM severity with this treatment. A Principal Component Analysis (PCA) of data from MLN clinical studies was conducted to determine which FIQ items may be most relevant to FM patients and to further evaluate the effects of MLN on these specific items.

Methods: FIQ data were pooled from 3 double-blind trials in which FM patients were randomized to MLN 100 mg/d (n=1139), MLN 200 mg/d (n=837), or PBO (n=1133). For the PCA analysis, correlations were performed among all FIQ items based on changes from baseline in all patients receiving either MLN or PBO. Principal components with optimally weighted variables were then extracted to identify groups of FIQ items that accounted for most of the variance in FIQ results. Mean changes in FIQ scores were analyzed to evaluate whether items in the extracted components discriminated the effects of MLN treatment in this study population.

Results: Three independent groups of FIQ items were identified by PCA: Component 1 ("Core Symptoms") primarily composed of FIQ items 2 (feel good), 4 (do job), 5 (pain), 6 (fatigue), 7 (rest), and 8 (stiffness); Component 2 ("Depression/Anxiety") primarily composed of FIQ items 9 (anxiety) and 10 (depression); and Component 3 ("Physical Function") primarily composed of FIQ items 1 (physical impairment) and 3 (work missed). Each FIQ item above represents a meaningful loading with at least a correlation of 0.4 with its component. Component 1 accounted for 37.3% of the total variance in the data, suggesting that this selected set of FIQ items has the strongest relevance in FM patients. Components 2 and 3 accounted for 17.5% and 17.2% of the total variance, respectively, also indicating clinical relevance. Mean changes in FIQ by treatment group indicated significant improvements with MLN ($p<.01$; both doses vs PBO) for all FIQ items in Components 1 and 2; discrimination of treatment effect was less consistent with the FIQ items in Component 3.

Conclusion: This PCA analysis of the FIQ resulted in 3 independent components of FM symptom domains. In the population of FM patients included in this analysis, improvements in FIQ scores were largely explained by core FM symptoms, including pain, fatigue, global wellbeing, and stiffness. Independent of these core symptoms, depression/anxiety, and physical functioning also explained a meaningful portion of the FIQ improvement. Additionally, treatment with MLN was associated with improvements in all of the items in these symptom groups.

1858

Hypervigiliance in Fibromyalgia. Robert S. Katz[1], Ben J. Small[2], Susan Shott[1] and Sharon M. Ferbert[3]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical School, Chicago, IL, [3]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL

Background/Purpose: Patients with fibromyalgia syndrome (FMS) experience severe chronic pain and usually are tender to touch. They are hyperactive to weather changes and stress. Do FMS patients perceive physical pain the way they are hypersensitive to their environment? Are FMS patients more likely to be hypervigilant? Hypervigilance is a symptom associated with post-traumatic stress disorder, experience an exaggerated sense of threat in their surroundings that is disproportionate to reality. They are easily set off and startled by mild stimuli and feel anxious in public.

Methods: 128 office patients with fibromyalgia (FMS) or rheumatoid arthritis (RA) (111 women, 17 men; mean age 51 ± 13) completed a questionnaire about hypervigilance symptoms. 100 patients had FMS and 28 had RA. The chi-square test of association and Fisher's exact test were used to compare the responses of FMS and RA patients, with a two-sided 0.05 significance level. As a part of an Internet survey administered by the volunteer community fibromyalgia organization AFFTER, 763 female self-identified FMS patients and 115 female controls without FMS responded to questions asking if they experience the symptoms common to hypervigilance. Only women's responses were analyzed to eliminate confounding by gender. Percentages were compared using the chi-square test of association with a 0.05 significance level.

Results: FMS patients were more likely than RA patients to report hypervigilance symptoms: waking up more than once during the nights, FMS 75.0%, RA 46.4% (p = 0.004); feeling uncomfortable in crowded places, FMS 57.6%, RA 25.0% (p = 0.002); feeling uncomfortable if people are standing behind them, FMS 33.0%, RA 10.7% (p = 0.021); and easily startled, FMS 59.4%, RA 29.6% (p = 0.006)

In the Internet questionnaire: The mean respondent age was 49.8 ± 11.4 years. 73.9% of FMS and 45.4% of controls were easily startled (p < 0.001).

57.4% of FMS and 30.2% of controls reported that they did not feel at ease around strangers (p < 0.001). 77.2% of FMS reported feeling uncomfortable in crowded places, versus to 42.7% of controls (p < 0.001). 44.9% of FMS and 16.5% of controls reported feeling uncomfortable if people are standing behind them (p < 0.001). For, easily "let their hair down", only 39.1% of FMS said yes, versus 66.0% of controls (p < 0.001). 32.7% of FMS and 15.5% of controls do not find it easy to trust people (p = 0.001). Easy for other people to pull the wool over their eyes, FMS responded yes (45.9%) more often than controls (32.0%) (p = 0.009). 32.5% of FMS and 11.3% of controls found themselves disliking people for no reason (p < 0.001). 75.0% of FMS and 21.6% of controls had trouble falling asleep(p < 0.001). 86.8% of FMS said they wake up more than once a night to 48.5% of controls (p < 0.001).

Conclusion: Results suggest that FMS patients are more aware of social and environmental stressors and more likely to be hypervigilant. They have trouble sleeping and are more easily startled. They are less likely to trust their surroundings. Hypervigilance might confer a survival advantage in threatening circumstances, but the hyper-reactivity associated with the condition could also be associated with the central sensitization of pain and dysesthesias, insomnia and other symptoms associated with FMS.

The Polysymptomatic Distress Scale and the Effect of Age On Polysymptomatic Distress and Fibromyalgia: A Survey in a Representative Population Sample. Winfried Häuser[1], Frederick Wolfe[2], Johannes Rasker[3], Elmar Brähler[4] and Heide Glaesmer[4]. [1]Technische Universität München, Munich, Germany, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]University Twente, Enschede, Netherlands, [4]University of Leipzig, Leipzig, Germany

Background/Purpose: Recent advances in the definition of the fibromyalgia syndrome (FM) have led to the development of the polysymptomatic distress (PSD) scale, providing a quantitative measure of the PSD continuum and an alternative definition of fibromyalgia. We examined PSD and FM in the general population.

Methods: We studied a representative random sample of 2,322 subjects from the German general population between the ages of 20 and 90 years. Patients completed the widespread pain index (WPI) and measures of fatigue, somatic symptom intensity, depressed mood and the Short Form Health Survey SF-12, including physical function, bodily pain, and vitality. The effect of age was assessed with quantile regression at the 25th, 50th, 75th and 95th percentiles, and the mediated effect of age with 2-stage least squares (2SLS) instrumental variable regression.

Results: The PSD score was substantially skewed to the right with a mean and median of 5.3 (SD 4.6) and 3.8. All FM-related variable scores worsened with age and with increases in PSD. Age explained 11% of the variance of PSD, but the effect of age was mediated through bodily pain. In quantile regression of PSD on age, PSD increased 50% faster in patients in the 75th and 95th percentiles of PSD than the 50th percentile. Abnormal somatic symptom intensity scores and widespread pain appeared at the 80th percentile of PSD, cutpoints for somatization and depressive distress at the 85th percentile, the WPI criterion for FM at the 90–95th percentile, and the PSD FM criteria and FM diagnosis at the 95th–100th percentile of PSD.

Table 1. Values of key covariates at percentiles of polysymptomatic distress (PSD).

Percentile of PSD	PSD	WPI	VAS Fatigue	SF12 PCS	SF12 PF	SF12 BP	Age	PHQ 15	PHQ9	FMS (%)	WP (%)
>0–5	0.2	0.0	0.0	57.0	99.7	98.7	41.1	0.4	0.3	0.0	0.0
>5–20	1.1	0.1	0.9	56.1	98.7	97.7	40.8	0.7	0.9	0.0	0.0
>20–35	2.0	0.3	1.7	55.3	97.3	94.8	45.2	1.2	1.1	0.0	0.0
>35–40	2.9	0.8	2.2	54.1	95.3	92.6	45.3	2.1	2.0	0.0	0.0
>40–50	3.8	1.3	2.7	52.4	90.9	88.8	47.1	2.8	2.1	0.0	0.0
>50–55	4.7	1.8	3.2	52.6	92.5	87.7	49.8	3.0	2.4	0.0	0.0
>55–65	5.6	2.1	3.9	51.6	89.8	86.2	49.6	3.6	2.9	0.0	0.0
>–65–70	6.5	2.6	4.4	50.8	87.3	83.5	51.5	4.6	3.5	0.0	0.0
>70–75	7.4	3.1	4.9	48.5	77.7	75.0	54.0	4.6	4.1	0.0	0.0
>75–80	8.3	4.0	5.0	49.0	78.2	77.5	53.2	*5.1*	4.5	0.0	*2.0*
>80–85	9.2	4.9	5.1	44.8	68.6	67.9	59.3	*6.3*	5.2	0.0	11.4
>85–90	10.5	5.9	5.5	44.6	64.0	64.1	57.6	6.7	5.8	0.0	24.1
>90–95	12.9	*7.9*	*6.2*	42.2	57.6	56.1	60.6	8.3	6.6	0.0	53.4
>95–100	*18.7*	13.8	6.6	37.8	46.0	43.1	64.3	11.3	8.2	*100.0*	100.0
Mean	5.2	2.5	3.0	51.6	86.8	84.7	48.9	3.4	2.8	4.2	8.8
Correlation With PSD	1.0	0.91	0.78	0.63	0.61	0.64	0.35	0.75	0.61		

Conclusion: The PSD scale supports the hypothesis that FM represents the end of a continuum of distress. Age is causally associated with PSD and FM, but is mediated primarily by pain. The effect of age on PSD and fibromyalgia is greatest in persons with more than average PSD.

Fibromyalgia and the Disease and Statistical Manual Classification As a Somatic Symptom Disorder. Frederick Wolfe[1], Brian T. Walitt[2] and Winfried Häuser[3]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Washington Hospital Center, Washington, DC, [3]Technische Universität München, Munich, Germany

Background/Purpose: Fibromyalgia was first defined by rheumatologists, and is often thought of as a disorder of widespread pain and decreased pain threshold. In the wider literature, however, including non-US studies, fibromyalgia is considered to be one of a series of "medically unexplained syndromes." These illnesses are sometimes called somatic symptom disorders (SSD) or functional somatic syndromes because the main symptoms, pain, fatigue, cognitive disturbance, and unrefreshed sleep, are somatic and have no clear etiological explanation. This definition, however, comes into conflict with the Diagnostic and Statistical Manual-5 (DSM) of SSD mental illnesses draft criteria of April–27–2012. DSM-5 defines a SSD as a mental illness when all of A and B are present chronically: A) one or more somatic symptoms that are distressing and/or result in significant disruption in daily life; B) persistently high level of anxiety about health or symptoms OR excessive time and energy devoted to these symptoms or health concerns.

Methods: We studied 13,229 rheumatic disease patients, including 3,657 who satisfied ACR 2010 criteria for fibromyalgia modified for survey research and 9,572 who did not meet criteria. We calculated the criteria Symptom Severity score (SS4) and omitted the non-somatic depression symptom of SS4. We defined patients as probably DSM-5 positive if they had at least one of the following symptoms, fatigue, cognitive disturbance, unrefreshed sleep present which was defined at a severity level of "Severe: continuous, life-disturbing problems." DSM-5 status was defined as definite if they had at least 2 of the 3 symptoms at a severe level or had an average SS4 of at least 10 of a possible 12.

Results: See Table 1. 35.0% of FM positive patients were positive at a definite level, 2.6% of non-FM criteria patients were positive. Probable DSM positivity in FM patients was indicated by 39.3% with severe fatigue scores, 42.2% with severe unrefreshed sleep, and 15.8% with severe cognitive problems.

Percent satisfying DSM-5 criteria

Category	Percent Positive
Possible DSM (+)	
Severe fatigue	39.3
Severe unrefreshed sleep	42.2
Severe cognitive problems	15.8
Definite DSM (+)	
At least 2 of 3 positive	33.6
At least 2 of 3 positive or SS4 score >=10	35.0

Conclusion: Using severity measures from survey modified ACR 2010 fibromyalgia criteria, we noted high rates of DSM-5 SSD positivity. At least 35% of FM patients would be classified as having an SSD mental disorder using our definitions. These results are inconsistent with clinical experience and call into question the use of proposed DSM criteria in clinical populations. Moreover, many, including us, would argue that all FM patients have an SSD, though not necessarily a mental disorder. Our results should be regard with caution because our definitions used *ad hoc* measures based on FM assessments, and it is possible that different levels of abnormalities might have been found using the Whitely Index mentioned in DSM-5. However, such an index is not used outside of psychiatric clinics and does not appear germane to FM symptoms. The DSM-5 continues to be revised.

Efficacy and Safety of Pregabalin in Japanese Patients with Fibromyalgia: A Randomized, Double-Blind, Multicenter, Placebo-Controlled Phase III Trial and Open-Label Extension Study. Hiroyoshi Ohta[1], Masayuki Ohkura[1], Makoto Suzuki[1], Hiroshi Oka[2], Chie Usui[3] and Kusuki Nishioka[4]. [1]Pfizer Japan Inc, Tokyo, Japan, [2]Tokyo Medical University Hachioji Medical Center, Tokyo, Japan, [3]Juntendo University Nerima Hospital, Tokyo, Japan, [4]Tokyo Medical University, Tokyo, Japan

Background/Purpose: Fibromyalgia (FM) is a common, chronic pain disorder, however, at the time of this study there was no approved medicine for FM patients in Japan. This study aimed to assess the efficacy and safety of the $\alpha_2\delta$ ligand pregabalin for the symptomatic relief of pain in Japanese patients with FM.

Methods: In a randomized, double-blind, multicenter, placebo-controlled phase III trial conducted at 44 centers in Japan, patients aged ≥18 years who had met the 1990 American College of Rheumatology criteria for FM were randomized to receive either pregabalin, starting at 150 mg/day and increasing to a maintenance dose of 300 or 450 mg/day, or placebo, for 16 weeks (3-week dose-escalation/optimization phase; 12-week fixed-dose treatment phase; 1-week taper phase). The primary endpoint was mean pain score at final assessment. Secondary endpoints included Patient Global Impression of Change (PGIC), Fibromyalgia Impact Questionnaire (FIQ), and measures of sleep (quality of sleep score and Medical Outcomes Study-Sleep Scale). Patients completing the double-blind study were eligible for a 53-week open-label extension study to evaluate the longer-term safety and efficacy of pregabalin (maintenance dose 300–450 mg/day).

Results: In total, 498 patients (89% female) were randomized to receive either pregabalin (n = 250; mean age 47.9 years) or placebo (n = 248; mean age 46.7 years). Pregabalin significantly reduced mean pain score at final assessment (p = 0.0046) and at every week during the study (p < 0.025). Key secondary endpoints were also significantly improved with pregabalin treatment compared with placebo, including PGIC (percentage of patients reporting symptoms "very much improved" or "much improved"; p = 0.0078); pain visual analog scale (p = 0.0013); FIQ total score (p = 0.0144); and quality of sleep score (p < 0.0001). The safety profile of pregabalin was consistent with previous clinical trials. Somnolence, dizziness, nasopharyngitis and increased weight were the most frequently reported adverse events; the majority of adverse events were mild to moderate in severity. A total of 106 patients completing the double-blind trial entered the open-label extension study. Total exposure to pregabalin in the open-label study was 100 person-years, with no new patterns in the type, incidence or severity of adverse events observed. Improvements in measures of pain, sleep and physical functioning were also maintained throughout the 53 weeks of the open-label extension study.

Conclusion: Pregabalin, at doses of up to 450 mg/day, was safe and efficacious for the symptomatic relief of pain when compared with placebo in the double-blind trial. Treatment also improved measures of sleep and physical functioning. Treatment was generally well tolerated and no new safety signals were observed over 53 weeks' treatment in the open-label extension study. Together, these results indicate that pregabalin is an effective treatment option for Japanese patients with FM.

1862

The 2012 Canadian Fibromyalgia Guidelines: Clinically Applicable Recommendations for the Management of Fibromyalgia. Mary-Ann Fitzcharles[1], Peter A. Ste-Marie[2], Don L. Goldenberg[3], John X. Pereira[4], Susan Abbey[5], Manon Choinière[2], Gordon Ko[5], Dwight Moulin[6], Pantelis Panopalis[7], Johanne Proulx[8] and Yoram Shir[1]. [1]McGill University, Montreal, QC, [2]University of Montreal, Montreal, QC, [3]Newton-Wellesley Hosp, Newton, MA, [4]University of Calgary, Calgary, AB, [5]University of Toronto, Toronto, ON, [6]University of Western Ontario, London, ON, [7]McGill University Health Center, Montreal, QC, [8]Patient Representative, Montreal, QC

Background/Purpose: The healthcare community remains challenged regarding the care of fibromyalgia (FM) patients. Previous guidelines have mostly addressed treatment options rather than provide an overall approach to FM care. With new evidence concerning pathogenesis and more diverse treatment strategies, updated direction for global care in FM is needed. These evidence-based guidelines for the diagnosis, management, and patient trajectory of persons with FM were developed taking into account these new advances and new ACR 2010 diagnostic criteria.

Methods: A needs assessment by structured consultation with 139 healthcare professionals from relevant disciplines across Canada generated 18 key questions. Questions drove a literature search to identify evidence, which was graded according to the classification system of the Oxford Centre for Evidence Based Medicine, and supporting recommendations were drafted. Recommendations were edited and appraised by an advisory panel to reflect meaningful clinical practice. The whole document was reviewed by an international expert.

Results: Sixty recommendations pertaining to the identification, evaluation, and management of persons with FM, incorporating new clinical concepts were drafted. The essence of the recommendations is as follows: FM represents a composite of symptoms, with body pain present as the pivotal symptom. There is a spectrum of severity which associates with functional outcome, with fluctuating symptoms over time. The diagnosis of FM is clinical, not one of exclusion, not needing specialist confirmation, and requires only limited laboratory testing. A physical examination is required to exclude other conditions presenting with body pain, but tender point examination is not required to confirm the diagnosis. There is no confirmatory laboratory test and excessive testing is strongly discouraged. Ideal care for most patients is in the primary care setting. Treatments should be multimodal, incorporating non-pharmacologic and pharmacologic strategies, with focus towards reduction of symptoms and improvement of function. Patients must be active participants in their healthcare and non-pharmacologic strategies are imperative. Patient-tailored management that is symptom-based is recommended. In the absence of an ideal pharmacologic treatment, an agent impacting multiple symptoms is desirable. Doses of medications lower than those used in clinical trials and combination of medications may facilitate adherence. Emphasis on proper lifestyle practices, periodic assessment of the need for continued medication, and evaluation of efficacy/side effects of ongoing treatments is recommended. New symptoms should be evaluated according to good clinical practice to exclude another illness without summarily attributing symptoms to FM.

Conclusion: These new Canadian guidelines for the care of patients with FM should provide the health community with more confidence in the global care of these patients and thereby improve patient outcome.

1863

Resetting the Naming Speed Clock with Methylphenidate (Ritalin). Robert S. Katz and Frank Leavitt. Rush University Medical Center, Chicago, IL

Background/Purpose: Abnormalities in naming speed are an unappreciated feature of cognitive dysfunction in fibromyalgia (FMS). Approximately 50% of FMS patients with memory problems name words at a rate that is 203 milliseconds slower than the norm. The connection between naming speed and memory loss in FMS is unclear. Stimulant medications like methylphenidate have been known to influence naming speed and could provide clues to the relationship between cognitive functioning and naming speed. The purpose of this paper is to determine if faster naming speed is connected to a positive change in cognitive functioning.

Methods: A word naming speed measure (Stroop Color and Word Test) and a measure of cognitive functioning (Mental Clutter Scale:MCS) were administered to 15 patients with FMS, before receiving methylphenidate and post methylphenidate. The FMS patients were female, met 2010 ACR criteria for FMS and had memory problems. Methylphenidate dosage was clinically determined and ranged from 10 to 30 mg. The median methylphenidate usage at retesting was 30 days. Naming speed was determined by the number of words named in a 45 second time period.

Results: The mean age of the FMS sample was 46.3±11.6 years with 14.1±2.1 years of education. Twelve of 15 FMS patients showed a significant reduction in time needed to name words post methylphenidate. Pre-methylphenidate, they read 77.4 words in 45 seconds or 605 milliseconds (45/77.4) per word. Post methylphenidate, they read 93 words in 45 seconds or 498 milliseconds (45/93) per word. This represents a 107 millisecond benefit from methylphenidate. The normative sample reads 108 words in 45

sec. or 417 msec. per word. Post methylphenidate changes on the Cognition and Mental Clarity subscales of the MCS are shown in Table 1. FMS patients showed a 17 point improvement with methylphenidate on Cognition, and a 19 point improvement on mental clarity. Both changes were significant at $p<0.01$.

Table 1. Pre-methylphenidate and Post-methylphenidate Scores on the Cognition and Mental Clarity Subscales of the Mental Clutter Scale

	Pre-methylphenidate	Post-methylphenidate
Cognition	52.8 ± 15.6	35.1 ± 11.3**[a]
Mental Clarity	48.1 ± 16.5	29.2 ± 13.6**

**$p<0.01$
[a]Lower scores represent improved performance

Conclusion: Methylphenidate appears to have short term benefits for naming speed and cognitive functioning in fibromyalgia. It quickly allows patients with FMS to operate at a more normal pace in naming words and broadly improves cognitive functioning. Elimination of the 107 millisecond time lag is thought to reset the neural clock in FMS so that word information is back in sync with other streams of neural information. The benefits of methylphenidate clearly show a connection between faster naming speed and improved cognition, however, it remains to be determined whether positive changes in cognition are brought on by faster neural transmission that likely underlies faster naming speed.

1864

Swimming Is As Effective As Walking for Treating Fibromyalgia: A Randomized Controlled Trial. Giovana Fernandes, Fabio Jennings, Michele V. Nery, Ana Leticia P. de Buosi and Jamil Natour. Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Fibromyalgia (FM) is a chronic widespread pain syndrome that causes deterioration of physical capacity. Exercises are fundamental in the treatment of FM and walking is the most common aerobic exercise studied. However, it is not known the effects of swimming in patients with FM. The purpose of this study was to evaluate the effects of swimming on pain, functional capacity, health-related quality of life, general quality of life and aerobic capacity in patients with FM, compared to walking.

Methods: Seventy-five women with diagnosis of FM according to ACR criteria with age between 18 and 60 years were selected. The patients were randomized to swimming group (SG) or walking group (WG). The SG performed swimming in front-crawl style and the heart rate (HR) training was defined by subtracting 10 beats from anaerobic threshold heart rate to compensate underwater horizontal position. The WG performed walking at anaerobic threshold HR. Exercise sessions had duration of 50 minutes and were performed three times a week for 12 weeks. The outcome measures were visual analogue scale (VAS) for pain, Time Up and Go Test (TUG) for functional capacity, Fibromyalgia Impact Questionnaire (FIQ) for health-related quality of life and SF 36 for general quality of life. Aerobic capacity was measured by an incremental cardiopulmonary exercise testing protocol by treadmill. The evaluations were done by a blinded assessor at baseline (T0), 6 (T6) and 12 weeks (T12) after randomization. It was used intention-to-treat analysis.

Results: Thirty-nine patients were randomized to SG and 36 to WG. The groups were homogeneous at baseline regarding clinical and demographic characteristics. Five patients (3 in SG and 2 in WG) withdrew after few exercise sessions because of pain worsening. After 12 weeks, both groups improved pain, functional capacity and quality of life (FIQ and SF 36) compared to baseline, however there were no differences between groups. Regarding aerobic capacity, both groups did not show changes over time. Tolerance to exercise, measured by adherence to programs, was similar in both groups (77.8% in SG and 72.2% in WG).

Conclusion: Swimming is as effective as walking in improving pain, functional capacity, health-related quality of life and general quality of life in patients with FM. In addition, swimming is well-tolerated by patients with FM. However, clinical improvements are not associated to aerobic capacity. More studies are necessary to define the mechanisms by with aerobic exercises lead to symptom improvements in FM.

1865

Emotional Pain and Catastrophizing Influence Quality of Life in Fibromyalgia. Neda Faregh[1], Peter A. Ste-Marie[2] and Mary-Ann Fitzcharles[1]. [1]McGill University, Montreal, QC, [2]University of Montreal, Montreal, QC

Background/Purpose: Fibromyalgia (FM) is a composite of symptoms with the pivot symptom of pain, traditionally measured as intensity with little attention to other qualities. Emotional pain is an important component of the global pain experience, although seldom measured in the clinical setting. The McGill Pain Questionnaire (MPQ) evaluates pain beyond intensity through subgroups of descriptor words. We have examined the associations of pain quality as measured by the subsections of the MPQ with quality of life, psychological status and function.

Methods: In a prospective cohort of FM patients attending a multi-disciplinary pain clinic, emotional pain was measured by the affective component of the McGill Pain Questionnaire (MPQ). The MPQ has 4 subsections, measuring sensory, evaluative, affective and miscellaneous pain. Other measures included pain intensity by a visual analog scale (VAS), patient global assessment (PGA), the Fibromyalgia Impact Questionnaire (FIQ), the Health Assessment Questionnaire (HAQ), the Pain Disability Index (PDI), the Pain Catastrophizing Scale (PCS), and the Arthritis Impact Measurement Scale (AIMS) for anxiety and depression.

Results: 229 FM patients (91% females, mean age and symptom duration, years, 48 and 11) had pain VAS 6.5, PGA 6.5 and MPQ 41. With the exception of unemployment, no demographic variable correlated with the MPQ. MPQ (total and subsections) was significantly correlated with pain VAS, PGA, FIQ, HAQ, PDI, PCS, and AIMS anxiety and depression. Stepwise hierarchical multiple regression analysis examining the association with the MPI total score retained FIQ, PCS, and HAQ. A MANOVA assessed if there were differences in measures (FIQ, HAQ, PGA, included on clinical judgement) based on a linear combination of MPI scores, while taking catastrophizing into account. The miscellaneous subsection correlated highly with the sensory subsection ($p <.001$) and was eliminated. A significant effect was found for the affective subscale (Wilks' Lambda $\Lambda=.941$, F= (3, 222) = 4.64, $p <.005$, multivariate $\eta^2=.06$), but not for evaluative or sensory subscales. The main effect of covariation for catastrophizing was significant (Wilks' lambda $\Lambda=.880$, F (3, 222) = 10.1, $p <.001$, multivariate $\eta^2=.12$). Follow-up ANOVAs indicate that affective scores contribute significantly to FIQ and PGA; evaluative scores contribute significantly to PGA, and the sensory scores contribute significantly only to HAQ. Catastrophizing contributes significantly to PGA and FIQ. Catastrophizing is the variable with the largest and significant Beta weights for each of the MPQ variables.

Conclusion: Higher scores on emotional pain and catastrophizing were predictors of poor quality of life, whereas sensory scores better predicted function. Emotional pain, especially when associated with high levels of catastrophization has important negative effects on well-being for FM patients. Psychological interventions targeting these aspects may offer additional benefits to the standard pharmacological management of pain.

1866

Association of Opioid Use with Symptom Severity and Quality of Life in Patients with Fibromyalgia. Terry H. Oh[1], Chul H. Kim[2], Connie A. Luedtke[1], Jeffrey Thompson[1], W. Michael Hooten[1] and Ann Vincent[1]. [1]Mayo Clinic, Rochester, MN, [2]Kyungpook National University, Daegu, South Korea

Background/Purpose: Chronic widespread pain is a cardinal symptom in patients with fibromyalgia. Current pharmacotherapies for fibromyalgia targets central neurochemical abnormalities and pain processing pathways. Analgesics and opioids are currently not standard of care for patients with fibromyalgia. Our objective was to evaluate the frequency of opioid use and clinical characteristics, symptom severity and quality of life (QOL) associated with opioid use in patients seen in a fibromyalgia treatment program (FTP) at a tertiary medical center.

Methods: We studied 971 patients (917 women and 54 men) with fibromyalgia who met the 1990 ACR clinical criteria for fibromyalgia. Comprehensive medication review was conducted when they were seen at the FTP. Opioid users and nonusers were compared with respect to demographic characteristics, numeric rating scale (NRS) for current pain, Fibromyalgia Impact Questionnaire (FIQ) and Short Form-36 Health Survey (SF-36) scores, and tender point count. Univariate logistic regression models were used to model the

endpoint of opioid use (Yes vs No). Variables significant at the alpha = 0.05 level were entered into a multivariable logistic regression model.

Results: Mean age of patients was 49 (SD, 12.8) years and mean duration of symptoms was 130 months (SD, 134.8). Two hundred thirty-six patients (24%) who presented to the FTP used opioids for pain. In a univariate analysis, the opioid users had higher rates of tobacco use ($p<0.001$), unemployment ($p<0.001$), tender point ($p=0.001$) and NRS scores ($P<0.0001$) and lower alcohol use ($p=0.009$), when compared to the nonusers. There were no significant differences in age, sex, race, marital status, abuse history, education level or BMI status between the 2 groups. The opiod users also had higher symptom severity as measured by the FIQ total ($p<0.001$) and all subscales ($p\leq0.01$) and worse QOL as measured by all SF-36 subscales ($p\leq0.04$) and physical and mental components ($p<0.001$). Multivariate analysis confirmed that opioid use was independently and significantly associated with increased tobacco use ($p=0.003$), unemployment ($p=0.002$), increased symptom severity ($p=0.009$) and worse SF-36 physical component score ($p=0.02$). However, no significant associations were found between opioid use and alcohol use, NRS scores, tender points or SF-36 mental component score.

Conclusion: The frequency of opioid use was 24 % in patients with fibromyalgia seen in the FTP at a tertiary medical center. Our results demonstrate that opioid use is associated with adverse social factors and worse symptom severity and physical health in patients with fibromyalgia. To better deal with this problem in clinical practice, factors that predispose to opiod use in patients with fibromyalgia need to be further investigated.

Assessment of ART Therapy Program for Women with Fibromyalgia: Randomized, Controlled, Blinded Study. Andreia S. Baptista[1], Anamaria Jones[1], Fernanda P. Cardoso[1], Betina C. Schaffir[1], Elisa R. W. Coelho[1], Aline Orlandi[1] and Jamil Natour[2]. [1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil

Background/Purpose: Fibromyalgia (FM) is a chronic non-inflammatory syndrome characterized by diffuse pain throughout the body, sleep disorder, stiffness, fatigue, depression and other psychological problems. Patients with FM feel incapable of performing the majority of activities of daily living. Medication offers only short-term benefits. Thus, it is necessary to include other measures for treatment, such as physical activity and patient education. Art therapy combine the field of psychology with artistic activities, working with therapeutic and instructive aspects as well as the potential for personal growth contained in all forms of art. The aim of the present study was to assess the effectiveness of an art therapy program for the treatment of pain and improvements in both quality of life and body image of patients with fibromyalgia.

Methods: A randomized, controlled study with a blinded evaluator and 20-week follow-up period was carried out involving 80 patients with fibromyalgia. A visual analog scale (VAS) pain and sleep the six-minute walk test, Fibromyalgia Impact Questionnaire (FIQ), Medical Outcome Survey Short Form 36 (SF-36), Beck Depression Inventory and Body Dysmorphic Disorder Examination (BDDE) questionnaire were used for the assessments, which were performed at baseline and after 10, 20 (end of intervention) and 40 weeks.

Results: The groups were homogeneous at baseline regarding clinical and demographic characteristics. The art group achieved statistically significant improvements in VAS for pain ($p=0.001$), VAS for sleep ($p=0.027$), FIQ ($p=0.001$), Beck Depression Inventory ($p=0.038$) and the physical functioning ($p=0.027$), role-physical, ($p<0.001$), bodily pain ($p=0.002$), vitality ($p=0.001$), role-emotional ($p=0.002$) and mental health ($p=0.010$) subscales of the SF-36. Regarding body image no differences between groups was found over time.

Conclusion: Art therapy can be used in the treatment of fibromyalgia, leading to a reduction in pain and improvements in degree of depression and quality of life.

Clinical Outcome in Fibromyalgia Patients Treated with Milnacipran Is Largely Independent of Symptom Duration. Philip Mease[1], Robert M. Bennett[2], Robert H. Palmer[3] and Yong Wang[3]. [1]Swedish Medical Center and University of Washington, Seattle, WA, [2]Oregon Health & Science University, Portland, OR, [3]Forest Research Institute, Jersey City, NJ

Background/Purpose: Patients with fibromyalgia (FM) usually experience pain, fatigue, and other debilitating symptoms for years. In clinical studies ranging from 3 months to >3 years, treatment with milnacipran was found to improve these symptoms. A post hoc analysis of milnacipran study data was conducted to examine whether duration of FM symptoms affected treatment outcomes.

Methods: Data were pooled from 2 double-blind trials that included patients randomized to milnacipran 100 or 200 mg/day (n=1311) or placebo (n=910). Outcomes were assessed in patients categorized into subgroups based on duration of FM symptoms at study baseline. Outcomes included percentage of patients with pain response ($\geq30\%$ improvement in visual analog scale [VAS] recall pain scores) and composite response ($\geq30\%$ pain improvement plus Patient Global Impression of Change score ≤2), as well as mean changes from baseline in VAS pain, Multidimensional Fatigue Inventory (MFI), Fibromyalgia Impact Questionnaire (FIQ), and Beck Depression Inventory (BDI) scores. Analyses were conducted using descriptive statistics.

Results: The mean duration of FM symptoms at baseline was 10.2 years (range = ≤3 month to 55 years); 33% of patients had experienced symptoms for <5 years and 10.4% for >20 years. Baseline pain, FIQ, and MFI were similar across the range of symptom durations; BDI scores were slightly higher in patients with shorter (1–2 years) symptom duration. Examination of treatment response trends across symptom duration subgroups indicated that the placebo responses were remarkably similar, regardless of treatment duration. Consistent with the percentage of composite responders observed in FM duration subgroups (Figure), improvements in pain, FIQ, MFI, and BDI were generally greater with milnacipran versus placebo across symptom durations >1 year. The milnacipran response was generally smaller for pain, FIQ, MFI, and BDI for patients with very short symptom durations (≤1 year) when compared with patients in other symptom duration subgroups.
Figure. Percentage of patients with pain + global improvements by FM symptom duration.

Conclusion: Baseline levels of pain and other FM symptoms appeared to be largely independent of symptom duration. Treatment effects with milnacipran were relatively consistent across symptom duration for all symptom domains except for an unexplained smaller treatment effect size in patients with symptoms of shorter duration.

1869

Predictors of Fatigue in Fibromyalgia. Ann Vincent[1], Mary O. Whipple[1], Debra L. Barton[1], Daniel J. Clauw[2], David A. Williams[3], Terry H. Oh[1] and Loren L. Toussaint[4]. [1]Mayo Clinic, Rochester, MN, [2]University of Michigan, Ann Arbor, MI, [3]Univ of MI Hlth System-Lobby M, Ann Arbor, MI, [4]Luther College, Decorah, IA

Background/Purpose: Previous research suggests that fatigue in chronic diseases is multifactorial and that fatigue in fibromyalgia is worse than fatigue

in rheumatoid arthritis or osteoarthritis. Although fatigue along with widespread pain is a cardinal symptom in patients with fibromyalgia, the predictors of fatigue in fibromyalgia have not been comprehensively assessed. Our objective was to examine the predictors of fatigue cross-sectionally in patients with fibromyalgia.

Methods: Measures of fatigue, mood, pain, sleep, and autonomic symptoms were gathered from a random sample of 1303 patients with fibromyalgia identified through an existing fibromyalgia registry. Validated self-report questionnaires were mailed which included the Multidimensional Fatigue Inventory (MFI-20), Brief Pain Inventory (BPI), Medical Outcome Study Sleep Scale (MOS), Profile of Mood States – Short Form (POMS-SF), and Autonomic Symptom Profile (COMPASS). Eight hundred fifty-eight (66%) patients returned completed questionnaires. Data were analyzed using multiple linear regression.

Results: The overall model fit was $R^2 = 0.44$. The most significant predictors of fatigue were depression/dejection ($\beta = -.326$, $p<.001$), sleep problems index ($\beta = .247$, $p<.001$), pain severity ($\beta = .182$, $p<.001$), BMI ($\beta = .148$, $p<.001$), and autonomic symptoms ($\beta = .126$, $p<.001$). Neither age ($p=.28$) nor tension/anxiety ($p=.88$) were significant predictors of fatigue.

Conclusion: Cross-sectional results indicate that depression, sleep, pain severity, BMI, and autonomic symptoms are significantly associated with fatigue in patients with fibromyalgia. Among predictors of fatigue identified in this study, depression was the strongest predictor. If these results can be replicated in a longitudinal study, improving mood, sleep, pain, etc. could all be potential targets to decrease fatigue.

1870

Financial Conflicts of Interest and Industry Sponsorship Are Associated with Positive Outcomes in Fibromyalgia Randomized Controlled Trials. Winnie K. Pang[1], Karen Yeter[1], Nasim A. Khan[2] and Karina D. Torralba[1]. [1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

Background/Purpose: Fibromyalgia randomized controlled trials (RCTs) have become more common in the past 15 years, in part due to industry sponsorship. Recently, there has been growing concern that financial conflicts of interest (FCOIs) among authors and funding source may affect reporting of results in RCTs. These issues have not yet been adressed for fibromyalgia RCTs. The objective of this study was to determine the prevalence of pharmaceutical industry funding and and FCOIs among authors of RCTs of drug therapy for fibromyalgia and assess their association with study outcome.

Methods: MEDLINE and Cochrane Central Register of Controlled Trials databases were searched for fibromyalgia drug therapy RCTs published between 1997 and 2011. Eligible studies were original, randomized, parallel design drug trials with clinical efficacy as primary outcome. Two reviewers independently assessed each RCT for funding source (industry, non-profit, mixed), FCOI disclosure by author, and outcome [positive (statistically significant result favoring experimental drug for the primary outcome) or not positive]. RCTs with and without different types of FCOIs were compared using Chi-square, Fisher's exact or likelihood ratio test.

Results: Of 47 eligible RCTs, study sponsors were industry (25, 53.2%), non-profit (9, 19.1%), mixed (5, 10.6%), and unspecified (8, 17%). A higher likelihood of positive outcomes was associated with industry sponsorship (22/25, 88%) and unspecified funding (6/8, 75%) compared to other funding types [non-profit 4/9 (44.4), mixed 3/5 (60%); P = 0.073]. Industry funded RCTs were significantly associated with positive outcome compared to non-profit funded RCTs (P = 0.017). FCOIs among authors were reported in 30 (63.8%) RCTs. RCTs with author(s) employed by the industry sponsor or author(s) who received consultancy fee/honoraria from the industry sponsor had significantly higher likelihood of positive outcome (Table). All RCT's (15/15) of the three Food and Drug Administration-approved drugs (duloxetine, pregabalin, and milnacipran) were industry sponsored and all had positive outcomes. Adjustment for potential confounding factors, such as type of experimental drug, study duration, and number of enrolled patients, could not be performed due to small number of eligible RCTs.

Table. Association of positive study outcome with types of financial conflicts of interest

Relationship to drug industry	FCOI present n/N (%)	FCOI absent n/N (%)	p-value
Any FCOI	25/29 (86.2)	10/18 (55.6)	0.037
Employee status	19/19 (100)	16/28 (57.1)	0.001
Consultancy fees/honoraria	15/16 (93.8)	20/31 (64.5)	0.037
Stock ownership	10/11 (90.9)	25/36 (69.4)	0.244
Research grant	16/20 (80)	19/27 (53.8)	0.517

n: Number of RCTs with positive outcome within each group
N: Total number of RCTs in each group

Conclusion: Industry sponsorship and FCOIs are common in published fibromyalgia drug therapy RCTs and are more likely to be associated with positive outcomes. The small number of eligible trials precluded adjustment for potential confounders to assess whether these represent independent association with study outcome.

1871

Tender Point Count and Pressure Pain Threshold As Predictors of Chronic Widespread Pain and Health Status in a Seven Year Prospective Study. Emma Jacobsen[1] and Stefan Bergman[2]. [1]R&D center Spenshult, Oskarström, Sweden, [2]R&D Center Spenshult, Oskarström, Sweden

Background/Purpose: Chronic widespread pain is common in the general population with a prevalence ranging between 4.2% and 13.3%. It has been identified as a major health problem. The aim of this study was to evaluate the prognostic value of tender point count, pressure pain thresholds and pain group classification with regard to chronic widespread pain report and self-reported SF-36 quality of life measurements in persons with a history of chronic widespread pain.

Methods: A cohort of 303 individuals was identified as having self-reported chronic widespread pain in a cross-sectional survey with 3928 participants. 146 of the 303 individuals underwent clinical examination with palpation of tender points, dolorimeter pressure pain threshold examination and pain grouping (no chronic pain, chronic regional pain, and chronic widespread pain) based on a report of painful regions on a drawing of the body with predefined regions. Chronic widespread pain was evaluated according to the American College of Rheumatology 1990 criteria for fibromyalgia. Two and seven years later, pain classification and SF-36 quality of life assessments were collected from postal questionnaires. Sex and age adjusted OR were calculated for each clinical baseline factor separately.

Results: Having more than four tender points significantly (p<0.05) predicted a four time higher risk of reporting chronic widespread pain at the two (OR=4.33) and seven (OR=3.89) year follow up. Having 11– 18 tender points at baseline was superior to a report of chronic widespread pain in predicting a low SF-36 vitality score. Chronic widespread pain at baseline strongly predicted chronic widespread pain two and seven years later. Low pressure pain thresholds did predict chronic widespread pain and a low health status although the associations were subordinated the prognostic value of tender point counts and widespread pain classification.

Conclusion: Easy attainable anamnestic and clinical findings such as a report of chronic widespread pain and a tender point count above four can be used as prognostic signs in the clinical evaluation of patients with a history of longstanding pain.

Disclosure: E. Jacobsen, None; **S. Bergman**, None.

1872

Quality of Reporting in Pharmacological Randomized Controlled Trials for Fibromyalgia. Karen Yeter[1], Winnie Pang[1], Nasim A. Khan[2] and Karina D. Torralba[1]. [1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR

Background/Purpose: Randomized controlled trials (RCTs) are considered the gold standard for assessment of healthcare interventions. Recently, there have been growing concerns about the quality of reporting of results in RCTs. Factors such as pharmaceutical industry sponsorship and financial conflicts of interest among authors are may create bias and influence study quality. No studies have addressed these issues in fibromyalgia RCTs. Our

objective was to assess the quality of reporting in drug therapy randomized controlled trials (RCTs) of fibromyalgia and their effect on study outcome.

Methods: MEDLINE and Cochrane Central Register of Controlled Trials databases were searched to identify original fibromyalgia drug therapy RCTs published between 1997 and 2011. Eligible studies were identified by screening the title and abstract for original, randomized, parallel design drug trials with clinical primary outcome(s). Two reviewers independently assessed each RCT for study characteristics, outcome [positive (statistically significant result favoring experimental drug for the primary outcome) or not positive], and quality measures (sample size calculation, adequacy of randomization, allocation concealment, double-blinding, follow-up description, and intention-to-treat (ITT) analysis). RCTs with and without different types of quality measures were compared using Chi-square, Fisher's exact or likelihood ratio test.

Results: 47 eligible RCTs were identified. In 21 (44.6%) RCT's, random sequence generation and allocation concealment were described adequately. Statistical power calculation was reported in 28 (62.2%) RCTs (2 RCTs were excluded as they were phase 2 studies). Double-blinding was reported in 21 (44.6%) of trials. In 30 (63.8%) RCTs, ITT analysis and prospectively defined follow-up schedule were also described. There were no significant assocations between specific quality measures and study outcome (Table).

Table. Association of positive study outcome with types of study quality measures.

Study Quality Measure	Quality measure present n/N (%)	Quality measure absent n/N (%)	p-value
Sample Size Calculation	20/28 (71.4%)	14/17 (71.4%)	0.493
Randomization	18/21 (85.7%)	17/26 (65.4%)	0.179
Allocation concealment	16/20 (80.0%)	19/26 (70.4%)	0.517
Double-blinding	14/21 (66.7%)	21/26 (80.8%)	0.326
Description of follow-up	23/30 (76.7%)	12/17 (70.6%)	0.733
Intention-to-treat analysis	24/30 (80.0%)	11/17 (64.7%)	0.306

n: Number of RCTs with positive outcome within each group
N: Total number of RCTs in each group

Conclusion: Study quality measures are not consistently reported in fibromyalgia drug therapy RCTs. The presence of specific types of study quality measures in RCTs was not associated with higher likelihood of positive study outcome.

1873

Clinical Characteristics and Health Care Utilization Patterns Among Patients with Fibromyalgia Newly Prescribed Amitriptyline, Duloxetine, Gabapentin or Pregabalin: A Large Cohort Study. Seoyoung C. Kim[1], Joan E. Landon[1] and Daniel H. Solomon[2]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: Patients with fibromyalgia (FM) tend to use a number of different medications and have high health care costs. Treatment for FM generally consists of symptom management. The objective of this study was to describe clinical characteristics and health care utilization patterns in patients with FM newly prescribed amitriptyline, duloxetine, gabapentin or pregabalin.

Methods: We conducted a large population-based cohort study using US health care utilization data (1/2007–12/2009). Adult patients were categorized into four groups if they were newly prescribed amitriptyline, duloxetine, gabapentin or pregabalin after their first diagnosis of fibromyalgia (ICD-9 code 729.1). A 180-day baseline period free of any of the four drugs was required prior to the first prescription date (index date). Demographic characteristics and comorbidities during the baseline period and their relationship with use of FM-related drugs and health care utilization patterns during the follow-up period were examined.

Results: The study population included a total of 74,378 patients with FM with a mean follow-up period of 141 to 195 days. The mean ages were 48 to 51 years and 72% to 81% were women, depending on the prescribed drug. Comorbidities were similar across the four groups ranging from a mean of 0.5 to 0.8 conditions. Back pain (48%–65%) was the most frequent comorbidity in all four groups and hypertension (29%–38%), headache (22%–30%), depression (11%–24%), sleep disorder (16%–19%) and inflammatory arthritis (10%–15%) were also common across the four groups. Median daily dose (in milligram) at both index date and the last day of follow-up was 25 for amitriptyline, 60 for duloxetine, 300 for gabapentin, and 75 for pregabalin. The mean number of physician visits ranged from 6.6 to 9.0 and mean number of prescription drugs were from 7.9 to 9.6 during the follow-up. **Table** shows a slight decrease in the use of various FM-related drugs after the index date across the four groups. Opioids and antidepressants were most commonly taken with drugs for FM.

Table. Use of fibromyalgia-related drugs before and after the index date (%)

	Amitriptyline (n=13, 404)		Duloxetine (n=18, 420)		Gabapentin (n=23, 268)		Pregabalin (n=19, 286)	
	Before	After	Before	After	Before	After	Before	After
Opioids	54	45	56	51	66	56	69	61
Anti-convulsants	10	19	13	23	40	100	39	100
Antidepressants	55	100	68	100	38	37	41	43
COX2/NSAIDs	34	26	33	28	38	29	42	33
Sleep disorder drugs	19	14	25	22	19	15	23	20
Muscle relaxants	30	24	31	27	36	28	40	32

Conclusion: Patients who were newly prescribed one of the four common drugs for FM similarly had multiple comorbidities, a great number of other medication use and high health care utilizations. Median daily dose for all four drugs remained the same during the follow-up.

1874

Genomic Categories of Fatigue in Women with Fibromyalgia. Nada Lukkahatai[1], Brian T. Walitt[2], Majors Benjamin[1], Gelio Alves[3] and Leorey Saligan[1]. [1]National Institute of Nursing Research, National Institutes of Health, Bethesda, MD, [2]Washington Hospital Center, Washington, DC, [3]National Center for Biotechnology Information, National Library of Medicine, Bethesda, MD

Background/Purpose: FM is the chronic experience of body-wide pain, fatigue, cognitive dysfunction, and disordered sleep that occurs in the absence of any clear cause. Fatigue is a cause of significant morbidity and disability in FM. Most genomic studies in the FM population focus on pain symptoms. Only a few studies had investigated the fatigue experience in FM and no genomic studies investigated FM-specific fatigue symptoms. The purpose of this study is to identify genomic categories of fatigue in fibromyalgia (FM) and describe behavioral characteristics of these fatigue categories.

Methods: Under an active Medstar Research Institute protocol, FM participants diagnosed by 2010 diagnostic criteria and pain-free, race, age, and gender-matched controls were enrolled in the study. Participants completed questionnaires. RNA from peripheral blood samples collected using Paxgene tubes® were analyzed for differential gene expression using microarray technology with Affymetrix GeneChip® human genome U133 Plus 2.0. Cluster analysis was used to determine genotypic categories. The differences of symptoms between two clusters were analyzed by the analysis of variance (ANOVA).

Results: Thirty one Caucasian women diagnosed with FM, experiencing significant fatigue (MFI-general fatigue $\geq$ 13) and 20 pain and fatigue free, age-, race-, gender-matched controls were enrolled. Microarray data showed differential upregulated expression of centromere protein K (CENPK) gene after the probesets passed filtering criteria of 1% false discovery rate (FDR) and a slope of $>$ log2 (over 2.0-fold change, $p <$ 0.05). This CENPK gene is related to centromere function. Cluster analysis was conducted on the expressed genes from FM subjects which revealed two distinct clusters. Forty nine genes were differentially expressed over 2-fold change ($p < 0.05$) between the two clusters. One cluster showed significantly higher pain interference ($p = 0.028$) and higher depression ($p = 0.027$). Genes that upregulated in the high pain interference and high depression cluster include genes related to immune response, iron absorption and GABA transport. Genes related to calcium iron binding were differentially expressed in the other FM cluster with lower pain interference and depression.

Conclusion: Within FM women with high fatigue, there appears to be two distinct patterns of gene expression. These genomic patterns correspond with differences in behavioral characteristics. Further investigation of these genomic patterns may provide some insights into the mechanisms behind the relationship of fatigue with other FM behavioral symptoms.

1875

A Patient and Physician Survey of Impact and Management of Fibromyalgia Across Latin America and Europe. Patricia Clark. Hospital Infantil de México Federico Gómez, Mexico City, Mexico

Background/Purpose: Differences in healthcare practices around the world have been reported; however any impact on management of chronic conditions is often unclear. We surveyed patients and physicians from three Latin American (LA) and six European countries to ascertain differences in journey to diagnosis and management of fibromyalgia (FM).

Methods: Data from 900 FM patients (300 LA; 600 Europe) and 1824 GPs/specialists (604 LA; 1220 Europe) were collected between 2008 and 2010.Patients and physicians completed separate questionnaires. which included questions on symptoms (14 common symptoms), management, and impact of FM. Patient interviews (face-to-face or via telephone; 25mins) were conducted in local languages (Spanish, Portuguese). Rating scales were used throughout. Data were analyzed using cross tabulations and descriptive statistics; no multivariate analysis. Significance determined at $P < 0.05$ (indicated by *).

Results: Patients from LA reported FM symptoms for longer time (100.8 vs 83.7* months), took longer to be diagnosed (42.3 vs 31.1* months), and saw more physicians to receive a diagnosis (5.4 vs 4.0*) vs European patients, respectively. FM was characterized by multiple symptoms in both regions, although a higher proportion of patients from LA vs Europe reported common FM symptoms, including widespread pain (92% vs 62%*), sleep problems (84% vs 49%*), and fatigue (88% vs 46%*). Patients from LA rated their pain higher on a 10-point scale vs European patients (8.0 vs 7.2*). Patients from both regions reported common FM symptoms as disruptive to their quality of life (pain: 86% vs 78%*; sleeping problems: 80% vs 76%; fatigue: 80% vs 75%). Patients from LA more often reported that FM had impacted their ability to work and/or earn an income vs patients from Europe. LA patients were managed by different healthcare professionals, while European patients were mostly treated by GPs (47% vs 96%*). Physicians principally considered widespread pain as a typical FM symptom and being disruptive to patient's. Although >50% of patients considered them common symptoms, <10% of GPs or specialists from either region considered problems sleeping or fatigue typical FM symptoms. Physicians from LA more often considered problems sleeping*, difficulty concentrating*, anxiety*, depression*, numbness/tingling*, and leg cramps* disruptive vs European physicians.

Conclusion: Differences between FM characteristics, treatment practices, and opinions were noted by physicians and patients from LA and Europe. Improved understanding of these complexities involved in FM in different healthcare settings may help target educational/training programs towards improving aspects of chronic care. Improving alignment between perception of FM from the patient and physician's perspective may also improve patient management.

1876

The Assessment and Treatment of Nonsurgical Periarticular Post-Traumatic Soft Tissue Injuries of the Knee. Dan Nemes[1], Elena Amaricai[1], Liliana Catan[1], Daniel Popa[1], Simona Cerbu[2] and Paula Bicov[1]. [1]"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, [2]Telescan Imaging Centre, Timisoara, Romania

Background/Purpose: In spite of the fact that periarticular post-traumatic soft tissue injuries of the knee were considered less important than the knee joint pathology itself, they are disorders with a high risk of disability, with potential to affect functioning and quality of life causing thus important socioeconomic implications. The main objectives of our study are to point out the necessity of an ultrasonography score that can be correlated with a functional score (in order to quantify the evolution of nonsurgical periarticular post-traumatic soft tissue injuries of the knee) and to prove the importance of a long-term rehabilitation treatment of this pathology.

Methods: We included into 1-year randomized, prospective study a number of 159 patients diagnosed with different types of nonsurgical periarticular post-traumatic soft tissue injuries of the knee: soft tissues edema, quadriceps tendon lesions (tendinitis or partial tear), prepatellar or infrapatellar bursitis, bursitis of the pes anserinus, lesions of the patellar retinaculum (elongation or partial tear), lesions of the medial collateral ligament (elongation, partial or total tear) and lesions of the iliotibial band (friction syndrome with or without bursitis). Group A suffered traumatic events on healthy knee joint. Group B patients had pre-existing knee lesions. Group A_1 (41 patients) and B_1(38 patients) followed a medical treatment, while group A_2 (39 patients) and B_2 (41 patients) followed both medical and rehabilitation therapy. All patients were assessed initially, after 6 months and after 1 year using functional evaluation (KOOS: Knee injury and Osteoarthritis Outcome Score) and knee ultrasonography (quantified in a self-developed ultrasonography score).

Results: At the beginning of the study we found no statistically significant difference of total US scores and of total KOOS scores between group A_1 (US=6.95 ± 1.378; KOOS=143.71 ± 7.497) and A_2 (US=6.92 ± 1.403; KOOS=144.33 ± 8.358), and between group B_1 (US=8.58 ± 1.328; KOOS=187.26 ± 12.326) and B_2 (US=8.51 ± 1.287; KOOS=187.17 ± 10.89). At the final assessment group A_2 and B_2 had significant decrease both of total US scores ($p < 0.01$) and total KOOS scores ($p < 0.001$) (US=3.10 ± 1.142 and KOOS=57.44 ± 5.702, respectively US=4.54 ± 1.14 and KOOS=95.8 ± 9.988) in comparison to group A_1(US=3.76 ± 0.994; KOOS=95.15 ± 8.519), respectively B_1(US=5.32 ± 1.068; KOOS=130.89 ± 10.506). When compared to group B_2, group A_2 had statistically very significant decreased total US scores (U=311; z=-4.83; $p < 0.001$) and total KOOS scores (U=3; z=-7.70; $p < 0.001$). No statistic correlation between the two assessment scores (ultrasonography score and KOOS score) was revealed.

Conclusion: The best functional results were recorded in patients with post-traumatic soft tissue injuries on a healthy knee joint and that followed both a medical treatment and a long-term rehabilitation. We propose a self-ultrasonography protocol that can monitor the progression in time of this pathology. Both functional and ultrasonography assessment scores are necessary in evaluation of periarticular soft tissue injuries of the knee.

Is the Amount of T and B Lymphocytes, Natural Killer Cells and Macrophages in Biopsies From Non-Ruptured Chronic Tendinopathic Achilles Tendons Predictive for Long Term Outcome? A >3 Years Prospective Study of 37 Patients. Maja S. Kragsnæs[1], Ulrich Fredberg[2], Katrine Stribolt[3], Søren G. Kjær[1], Knud Bendix[3] and Torkell Ellingsen[1]. [1]Region Hospital Silkeborg, Silkeborg, Denmark, [2]Diagnostic Centre Region Hospital Silkeborg Denmark, 8600 Silkeborg, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark

Background/Purpose: In biopsies from non-ruptured chronic tendinopathic Achilles tendons, presence of T and B lymphocytes, natural killer cells and macrophages has been reported. Whether the amount of these cells at baseline is predictive for long term outcome (>3 years) remains to be examined.

The purpose of this study was to evaluate the prognostic value of the amount of immune competent cells present at baseline in biopsies from non-ruptured chronic tendinopathic Achilles tendons.

Methods: 17 women and 20 men suffering from non-ruptured chronic Achilles tendinopathy were followed prospectively for more than 3 years. At baseline, a biopsy was obtained from each tendinopathic Achilles tendon (n=37). In addition to the following immunohistochemical cell markers: CD3, CD4, CD8, CD20, CD56, CD68(PG-M1), Granzyme-B and S100, the biopsies were stained with hematoxylin/eosin, Van Gieson, toluidin blue, Pearls Blue and NASDCL. The numbers/counts (n/c) of positive cells for each marker in each sample were determined and calibrated to a standard area in 4 μm thick slides (equals n/c in standard volume) using unbiased stereological techniques.

At follow-up, patients completed the Scandinavian (Danish) version of the VISA-A questionnaire in addition to a self-composed questionnaire evaluating presence of Achilles tendon symptoms.

The Mann-Whitney rank sum test and the Fishers exact test were used ($p < 0.05$ was considered significant).

Results: At baseline, the median age of the patients was 55 years (range: 32–69) and the median symptom duration was 12 months (range: 4–156). 18 patients (49%) had never received anti-inflammatory treatment.

Patients were instructed to perform Achilles tendon eccentric loading exercises and were followed for a median time of 6 years (range: 3–11). During this period, the majority of patients (n=31) received additional local tendon injections of steroid (n=12), sclerosis (n=6), TNF-α antagonist (n=6) or interleukin-1 receptor antagonist (n=6). 5 patients had an Achilles tendon operation.

At follow-up, the median VISA-A score was 75 (range: 41–94), and 15 patients (41%) reported having no Achilles tendon symptoms.

No differences in presence of symptoms at follow-up were observed between patients receiving different injection treatments during follow-up (p=0.81).

IMMUNOHISTOCHEMICAL CELL MARKERS AT BASELINE	ASYMPTOMATIC AT FOLLOW-UP N = 15	SYMPTOMATIC AT FOLLOW-UP N = 22	
	Cell numbers/count (median, (range))		*P*
CD3	12 (0–45)	27 (0–83)	0.16
CD4	10 (0–42)	18.5 (0–51)	0.63
CD8	1 (0–35)	2 (0–22)	0.67
CD20	0 (0–2)	0 (0–6)	0.31
CD56	5 (0–73)	0 (0–26)	0.07
CD68-PGM1	35 (0–158)	30.5 (0–84)	0.39
Granzyme-B	0 (0–2)	0 (0–14)	0.77
NASDCL	6 (0–31)	9 (0–50)	0.36
S100	13 (0–53)	5.5 (0–24)	0.28
Presence of iron *(yes/no)*	7/8	3/19	0.06

Conclusion: 37 patients suffering from non-ruptured chronic Achilles tendinopathy were followed for more than 3 years. At follow-up, 15 patients (41%) had no Achilles tendon symptoms. When comparing the asymptomatic group of patients (n=15) to the symptomatic group (n=22), no differences in numbers per count of baseline immune competent cells in standard volume of Achilles tendon biopsies were observed.

Thus, the amount of immune competent cells at baseline cannot predict long term outcome of chronic Achilles tendinopathy.

1878

Cognitive Manifestations of Fibromyalgia and Lupus. Robert S. Katz and Frank Leavitt. Rush University Medical Center, Chicago, IL

Background/Purpose: Similar cognitive complaints for patients with fibromyalgia and systemic lupus erythematosus (SLE) have been reported; however, inherently different deficits can share superficial similarities. The major purpose of this study is to determine if the two syndromes have deficits in cognitive functioning in common as measured by the new Mental Clutter Scale.

Methods: The Mental Clutter Scale is a new 16 item scales that focuses on 8 dimensions of the tradition cognitive skills such as memory and concentration, and 8 dimensions of disturbed mental clarity such as cluttered thinking and mental fog. The measure was administered to 52 patients who met ACR criteria for fibromyalgia and 35 patients who met ACR criteria for Lupus. The classification criterion for cognitive dysfunction was the upper boundary of the 95% confidence interval (CI) of the normative sample. This score provided prevalence rates of cognitive dysfunction in the two samples.

Results: The two groups were predominantly female (81.5% vs. 82.9%0), with those in the fibromyalgia group significantly older [mean ($\pm$SE) age (49.0 $\pm$ 12.7 vs. 32.2.3$\pm$ 10.6 p<0.001)]. Cognitive dysfunction was present in 63.5% (33/52) of the sample with FMS and in 28.6% (10/35) of the sample with Lupus. The differences were significant (p<0.001). Both the traditional cognitive symptoms (52.7$\pm$ 10.0 vs. 32.2$\pm$ 10.6; p<0.004) and the disturbance in mental clarity (45.5 $\pm$ 15.5 vs. 30.6$\pm$ 10.7; p<0.01) were more pronounced in fibromyalgia. Endorsement of the 16 subscales is shown in Table 1. As can be seen, patients with FMS report significantly higher severity on 5 of 8 cognitive scales, and 7 of 8 mental clarity scales.

Conclusion: The cognitive findings suggest that there is considerable difference in the cognitive functioning of people with fibromyalgia and Lupus. The majority of patients with FMS report cognitive dysfunction; whereas only a minority of patients with lupus report cognitive dysfunction. Among those reporting cognitive dysfunction, cognitive deficits are more pronounced in FMS. Fog like features as measured by the mental clarity scale

are more prominent in fibromyalgia, providing strong support for the notion of fibrofog. Fog like features play less of a role in lupus, providing weak support for the notion of brain fog in most lupus patients.

1879

Work Related Injuries Causing or Aggravating Fibromyalgia in the Medicolegal Arena: A Jurisprudential Analysis. Mary-Ann Fitzcharles[1], Peter A. Ste-Marie[2] and Yoram Shir[1]. [1]McGill University, Montreal, QC, [2]University of Montreal, Montreal, QC

Background/Purpose: Up to 40% of persons report onset of fibromyalgia (FM) following a "triggering event". Injuries, which may occur in the workplace, may be implicated in some, hence linking FM to compensation. In Ontario, Canada, work injury causing physical abnormality is compensated according to the American Medical Association guides, with apportionment for pain, whereas injury without body changes, ie soft tissue, is compensated according to a chronic pain policy. FM, without tissue damage, falls under this policy. The Workplace Safety and Insurance Appeals Tribunal (WSIAT) is the final level of appeal for workers who request compensation for a work-related injury as causation for FM, with decisions available in the public domain.

Methods: Between June 2006 and December 2011, 150 Tribunal decisions relevant to FM were examined by predetermined search protocol. Twelve did not meet inclusion criteria; FM was not the central issue in 4, and 8 were for increased awards. New onset FM was appealed in 123, and aggravation of pre-existing FM in 15. Information in the aggravation cases was limited.

Results: All injuries were of a soft tissue nature, without any persistent physical findings to explain continued symptoms. Of the 15 cases pleading *aggravation of FM* (14 female, mean age 50 $\pm$ 8 years), 5 were manual, 3 clerical, 7 health care or education workers. Thirteen injuries were acute, 2 occurred gradually, with low back or neck identified in 13, and the Tribunal accepted 10/15 (67%). In the 123 *new onset FM,* (104 female, mean age 52 $\pm$ 9 years), 60 were manual, 29 clerical, 30 health care or education workers, 4 unknown, with 32% reporting repetitive work activity. Time from injury to diagnosis of FM (available for 117) was 4.3 $\pm$ 4.1 years, with 6.3 $\pm$ 2.8 physicians cited for each worker. Previous psychological illness, injuries, neck pain or back pain were recorded as present for 17%, 22%, 10%, and 13% respectively, whereas there was no statement of previous health status for 39%. Injuries were a single event in 68%, and gradual in 32%, with location of injury in low back for 44%, and shoulder/upper limb in 40%. The FM diagnosis was based on report by a rheumatologist in 74%, and family physician in 13%, with 73 (59%) appeals accepted by the Tribunal.

Conclusion: Over half of appeals for aggravation or causation of FM following a work related soft tissue injury were upheld by the Tribunal. Claimants were demographically similar to other FM cohorts, although healthcare utilization was very high. Low back and upper limb injuries predominated as causation, with over two thirds reporting FM following a single incident. The attribution of causation of FM to a single workplace traumatic event is contentious and requires further examination.

1880

A Brazilian Portuguese Validation of the Revised Fibromyalgia Impact Questionnaire (FIQR). Eduardo S. Paiva[1], Roberto E. Heymann[2], Marcelo C. Rezende[3], Milton Helfenstein Jr.[4], José E. Martinez[5], José R. Provenza[6], Aline Ranzolin[7], Marcos Renato Assis[8], Vivian D. Pasqualin[9] and Robert M. Bennett[10]. [1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil, [3]Santa Casa de Campo Grande, Campo Grande, Brazil, [4]Universidade Federal de de São Paulo, São Paulo, Brazil, [5]Pontifícia Universidade Católica de São Paulo, Sorocaba, Brazil, [6]Pontifícia Universidade Católica de Campinas, Campinas, Brazil, [7]Universidade Federal de Pernambuco, Recife, Brazil, [8]Faculdade de Medicina de Marilia, Marilia, Brazil, [9]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil, [10]Oregon Health & Science Univ, Portland, OR

Background/Purpose: General health evaluation questionnaires are important instruments in assessing the impact of disorders that affect multiple domains of a patient's life. The Fibromyalgia Impact Questionnaire (FIQ) was specifically developed to assess disease severity and functional ability in

fibromyalgia patients. Since its initial publication in 1991, it has been widely used in clinical trials and clinical practice, with many translated versions around the world. In 2009, a revised version of the FIQ was published, the FIQR; this attempted to correct some of the problems that had emerged in the use of the original FIQ over the ensuing 18 years in aiming to achieve a better balance among different domains (Function, Overall Impact, Symptoms) and provide an easier scoring system. Here we present the validity and reliability of the Brazilian version of the Revised Fibromyalgia Impact Questionnaire (FIQR).

Methods: Female fibromyalgia patients (n=106) completed an online survey consisting of demographic data, the SF-36 questionnaire, the original FIQ (both in validated Brazilian Portuguese Translation), and the Brazilian Portuguese FIQR, which was translated by a standard method. Validity was established with correlational analyses between FIQR, FIQ and SF-36 items. Three domains were established for FIQR (Function, Overall Impact, Symptoms) and their contribution for the SF-36 subscales was also scrutinized.

Results: The Brazilian Portuguese FIQR validation process showed that the questions performed in a very similar way to the English FIQR. Four new questions in the FIQR symptoms (memory, balance, tenderness and environmental sensitivity) showed strikingly similar results to the original FIQR, revealing a significant impact in FM patients. The Brazilian Portuguese FIQR demonstrated excellent reliability, with a Cronbach alpha of 0.96. The correlation with the original FIQ was also good (r=0.854, p<0.001). There was a gain the weight of the function domain, with little change of the overall impact domain, and a decrease of the symptom domain, leading to a better balance among FM domains. FIQR predicted a great number of SF-36 subscales, showing both convergent and discriminant validity.

Conclusion: The Brazilian Portuguese version of the FIQR was validated, and found to be a reliable and easy-to-use and score FM specific questionnaire that should prove useful in routine clinical practice and FM-related research.

1881

Increased Psychosocial Stress Is a Major Component of Fibromyalgia Triggers. Emma K. Guymer[1], Kathleen Elford[2] and Geoffrey O. Littlejohn[1]. [1]Monash Medical Centre and Monash University, Clayton, Victoria, Australia, [2]Monash Medical Centre, Clayton, Victoria, Australia

Background/Purpose: Fibromyalgia is a common, chronic pain disorder. Initial development of symptoms occurs under conditions unique to each patient. Psychological and physical triggers are recognized, however their frequency and contribution to illness onset is less defined.

The aim of this study was to examine fibromyalgia triggers and identify clinical features linked to specific triggering situations.

Methods: Fibromyalgia patients seen in a public outpatient clinic were questioned using a standardized interview regarding the circumstances of their symptom onset. Demographic and clinical data were collected, including the Widespread Pain Index (WPI), Symptom Severity Score (SSS) and the Fibromyalgia Impact Questionnaire (FIQ). Patients were divided into groups based on whether or not they reported a trigger for their fibromyalgia, and if this involved increased levels of psychosocial stress, physical illness or injury. These groups were then compared for differences regarding clinical and demographic features.

Results: Information was collected on 260 consecutive patients. 232 (89.2%) patients reported a specific triggering situation corresponding to the onset of their symptoms. 77 (29.7%) described a triggering situation of purely increased psychosocial stress and a further 107 (41.3%) described a physical illness or injury combined with increased psychosocial stress. 46 (17.8%) described a purely physical trigger. Patients with a trigger involving increased psychosocial stress had a higher number of coexisting fibromyalgia-associated conditions (e.g. irritable bowel syndrome, temporomandibular joint disorder, etc) (p<0.005), higher levels of anxiety (p<0.05) and depression (p<0.05) than those patients who did not. If patients who had a psychosocial stress component of their trigger were currently regularly exercising, they had significantly lower FIQ scores (p<0.05), better physical function (p<0.05), less reported pain (p<0.05),

less sleep disturbance (p<0.05), fewer positive tender points (p<0.05), and a lower WPI (p<0.05) and SSS (p<0.05) than those patients who were not regularly exercising. Patients without a trigger involving increased psychosocial stress who were regularly exercising had lower FIQ scores (p<0.05) and less anxiety (p<0.05) only. If patients with psychosocial stress triggers were currently using medications with proven benefit in fibromyalgia (amitriptyline, duloxetine or pregabalin), they had better reported physical function (p<0.05) than those patients not using these medications. There was no significant clinical difference found between those using pain management psychology and those who were not, in the group of patients who had reported increased psychosocial stress as part of their trigger.

Conclusion: Most patients report a specific trigger for their fibromyalgia. The majority of these involved increased levels of psychosocial stress, including those with injury or illness. Patients with an increased psychosocial stress component to their trigger had less severe clinical features if they regularly exercised.

1882

Predictors of a Favorable Outcome in Patients with Fibromyalgia: Results From the 1-Year Follow-up. Dong-Jin Park[1], Shin-Seok Lee[1], Seong-Ho Kim[2], Seong-Su Nah[3], Ji Hyun Lee[4], Seong-Kyu Kim[5], Yeon-Ah Lee[6], Seung-Jae Hong[6], Hyun-Sook Kim[7], Hye-Soon Lee[8], Hyoun Ah Kim[9], Chung-Il Joung[10] and Sang-Hyon Kim[11]. [1]Chonnam National University Medical School, Gwangju, South Korea, [2]Inje University Haeundae Paik Hospital, Busan, South Korea, [3]Soonchunhyang University, South Korea, [4]Maryknoll Medical Center, Busan, South Korea, [5]and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu, South Korea, [6]Kyung Hee University, Seoul, South Korea, [7]Internal Medicine, Chosun University Hospital, Gwangju, South Korea, [8]Hanyang University Guri Hospital, Guri, South Korea, [9]Ajou University School of Med, Suwon, South Korea, [10]Konyang University Medical School, Daejeon, South Korea, [11]Dongsan Medical Center, Keimyung University, Daegu, South Korea

Background/Purpose: To determine the outcomes in Korean patients with fibromyalgia (FM) and identify the prognostic factors associated with improvement at 1-year follow-up.

Methods: Forty-eight patients with FM were enrolled and examined every 3 months for 1-year. We interviewed these patients using a structured questionnaire that included sociodemograhpic data, current or past FM symptoms, and current use of relevant medications at the time of enrollment. Tender point counts and scores were assessed by thumb palpation. Patients were asked to complete a Korean version of the Fibromyalgia Impact Questionnaire (FIQ), the Brief Fatigue Inventory, the SF-36, the Beck Depression Inventory, the State-Trait Anxiety Inventory, the Self-Efficacy Scale, and the Social Support Scale. During follow-up, tender points, FIQ, and current use of relevant medications were recorded during 1 year follow-up period.

Results: Of the 48 patients, 32 (66.7%) had improved FIQ scores 1 year after enrollment. The improved patients had higher baseline FIQ scores (68.4±13.9 vs 48.4±20.8, p=0.001) and higher Trait Anxiety Inventory scores (55.8±10.9 vs 11.5±11.5, p=0.022). The patients treated with pregabalin which was added during the follow-up period were more likely to be improved after 1-year (71.9 % vs 37.5 %, p=0.031). In multivariate logistic regression analyses, the additional use of pregabalin and higher Trait Anxiety Inventory scores at baseline were the predictor of improvement (p=0.026 and p=0.043) and this statistical significance persisted after adjustment for age, gender, and disease duration (p=0.016 and p=0.037).

Conclusion: Two-thirds of the Korean FM patients experienced some clinical improvement by 1-year after enrollment. The use of pregabalin and anxiety were shown to be important predictors of improved FM. Interventions, particularly medications, may be associated with good outcome in a significant number of these patients.

1883

Efficacy and Safety of Joint and Soft Tissue Injections; A Retrospective Study. Jenny Cabas-Vargas[1], Leah Alon[2], Nina Ramessar[2], Dimitre Stefanov[2], Jose B. Toro and Deana M. Lazaro[4]. [1]SUNY Downstate, Brooklyn, NY, [2]SUNY Downstate Medical Center, Brooklyn, NY, [3]Brooklyn VA, Brooklyn, NY

Background/Purpose: Despite wide use of corticosteroid injection in the treatment of soft tissue and articular disorders, there is little data about its efficacy. We conducted a retrospective study to evaluate the effectiveness of corticosteroid (CS) and local anesthetic (LA) injections for treatment of musculoskeletal disorders (MSD).

Methods: The study was conducted at VA NYHHS; Brooklyn facility. Patients 18–85 years old who underwent CS or LA injection for MSD were identified by billing codes. The patients were invited to participate in a 28-question telephone survey. Information was collected regarding informed consent, impact on pain using pain score (PS 0–10), patient global assessment (PGA 0–100, 0 very poor-100 very well), functional status (M-HAQ) and side effects. Additional data was obtained by chart review. Descriptive analysis of all data collected and comparison of PS and PGA before and after the procedure were conducted.

Results: 116 patients were included in the final analysis. The average patient age was 60 years old, 85.3% men and 14% women.

The procedures were performed by different specialties, Rheumatology (30.17%), Podiatry (28.45%), Orthopedics (17.24%), Physical Medicine and Rehabilitation (12.07%), and Pain Management (12.07%). The most common indications were knee osteoarthritis (20.68%), plantar fasciitis (15.92%), rotator cuff tendinitis/impingement (15.92%) and trigger finger (8.62%). LA were used in combination with CS in the majority of procedures (91.96%).

Patients' overall satisfaction with their procedure was 85%. The average PS prior to the procedure was 8.6; post-procedure average PS decreased to 2.8 (p<0.001Wilcoxon signed rank test). 69.93% of patients reported immediate relief after the injection. PGA before and after the procedure improved from an average 24 to 75 (p<0.001Wilcoxon signed rank test). 87.9% of patients reported that they experienced improvement in functional status; patients reported improvement in the ability to dress (34%), ability to get in and out of bed (45%), ability to lift a cup to their mouth (24%), ability to walk outdoors on flat ground (50%), ability to turn regular faucets (23%), ability to get in and out of a vehicle (49%). 57.76% of patients reported less analgesic use after the procedure; the average benefit of the injection was 6.18 months (range 0–24 months). 25.86% of the patients had a second injection and 12.93% of the patients underwent surgery for the same MSD. No serious adverse effects were reported; 3 patients reported bruising, 1 patient mild bleeding with the injection, 3 patients reported skin changes and 1 uncontrolled hypertension afer the procedure. No infections were reported.

Conclusion: This retrospective study found that CS injections for MSD are associated with significant self-reported reduction in pain and improvement in functional status. There was high reported satisfaction with the procedures and benefits were long-lasting (average 6 months). Corticosteroid injections should be considered an important tool for clinicians treating musculoskeletal conditions. This study is limited by recall bias and diversity of procedures.

1884

Fibromyalgia Patients Who Meet the ACR 1990 Criteria Have More Severe Disease. Carmen E. Gota[1], Benjamin Nutter[2] and William Wilke[3]. [1]The Cleveland Clinic Desk A50, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH

Background/Purpose: To compare the fibromyalgia patients who meet the 1990 ACR criteria for fibromyalgia with those who do not.

Methods: All new consecutive patients diagnosed with fibromyalgia that were seen in the Rheumatology Department at the Cleveland Clinic by two physicians between September 1st, 2008 and January 31st, 2011, were enrolled in the study.

Enrollment in the study was based on clinician's overall impression of patient suffering from fibromyalgia.

Three hundred and six patients were enrolled.

Data collected included: demographics, detailed fibromyalgia symptoms, physical examination findings (tender points, brisk deep-tendon reflexes and carotid artery tenderness on palpation), family history of fibromyalgia and

mood disorders and comorbidities. All patients were asked to complete the following questionnaires: Brief Patient Health Questionnaire Mood Scale (PHQ-9), Epworth Sleepiness Scale (ESS), Mood Disorders Questionnaire (MDQ), Fibromyalgia impact questionnaire (FIQ), Symptom Intensity Scale (SIS) and Health Assessment Questionnaire Disability Index (HAQ-DI).

Results: We compared 240 fibromyalgia patients who met the ACR 1990 criteria with the other 66 patients who did not (lacked widespread pain or had <11 tender points). Patients who met the ACR 1990 criteria, compared to the rest of the patients, had higher depression scores, PHQ-9 12 (7.75, 16) vs 9.5 (5, 14.7), p<0.03; higher regional pain scores 12 (9, 15) vs 9 (6, 12), p<0.001; higher VAS fatigue 8 (7, 9) vs 7.25 (5, 9), p =0.022; higher symptom intensity score SIS 7 (6.21, 8.25) vs 6.25 (5.25, 6. 75), p <0.001; higher FIQ score 69.03 (65.1, 80.8) vs 59.95 (46.11, 72.74), p =0.001; higher difficulty with daily activities involving large muscle groups - FIQ-1 score 16 (7, 24) vs 12 (7, 20), p 0.039; less days when they felt well in the course of a week - FIQ-2 score 1(0, 2) vs 2 (0, 3), p = 0.003.

Conclusion: Fibromyalgia patients who meet the ACR 1990 criteria represent a more severe subset, manifested by more disability, and higher depression scores.

Disclosure: C. E. Gota, None; **B. Nutter**, None; **W. Wilke**, None.

Rheumatologists' Ultrasound Confidence and Interpretation of Normal Anatomy Are Improved by a Cadaver Based Sonoanatomy Course. Iain Goff[1], David Wright[2] and Debra Patten[3]. [1]Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Sunderland Royal Hospital, Sunderland, United Kingdom, [3]School of Medical Sciences Education and Development, Newcastle upon Tyne, United Kingdom

Background/Purpose: Correct interpretation of musculoskeletal ultrasound (MSUS) requires thorough knowledge of normal 3D anatomy, but several authors report deficiencies in anatomy skills among rheumatologists. Cadaver-based anatomy review courses improve clinical and injection skills, but the value of such courses in MSUS training is unclear. During 2010-12 we delivered two cadaver based, MSUS anatomy courses for the British Society of Rheumatology (BSR), and a self assessment questionnaire was devised to measure confidence to perform key MSUS learning objectives before and after the course.

Methods: The two day course in March 2012 consisted of orientation lectures with MR imaging; expert led, small group workshops handling cadaveric specimens; simultaneous access to real-time ultrasound on live models; and ultrasound practice on patients with pathological anatomy. Ten item confidence logs based on BSR core competency outcomes and ability to diagnose EULAR pathologies were completed by the delegates before, after and four weeks following the course. Standardised imaging protocols with anatomy checklists devised by tutors from the BSR ultrasound special interest group were used to guide scanning technique and to assess delegate ability to locate specific anatomic structures with ultrasound.

Results: Twenty delegates attended the course. Delegate feedback rated the course very highly (Overall mean satisfaction score = 4.25, 1=poor, 5=excellent). Confidence logs collected from all 20 delegates demonstrated low levels of confidence in core domains pre-course (mean 3.5/10), improving to mean 5.5/10 immediately post-course (paired t test p< 0.001) with significantly improved confidence at 4 weeks compared to baseline in 7/10 domains (paired t test p< 0.05, see table).

Competency outcome	Delegate Confidence (0–10)		
	Pre-Course	End of course (all p< 0.001)	Four Weeks (* p< 0.05)
Perform structured assessment of each anatomic area	3.3	6.0	5.7*
Identify, demonstrate and interpret anatomy	3.4	6.0	6.0*
Identify, demonstrate and interpret pathology	3.2	5.5	6.0
Use US to guide aspiration and injection	3.4	5.1	5.8*
Correlate US with other imaging modalities	3.2	5.7	6.5*
Prepare a written report and archive images	2.7	4.5	5.5
Understand clinical relevance and apply to patient management	5.3	6.3	7.8*
Correctly diagnose EULAR basic pathology	4.3	5.6	6.5
EULAR intermediate pathology	3.4	5.1	5.3*
EULAR advanced pathology	2.3	3.6	3.1*

Anatomy checklists were completed and returned by 13 delegates. Most structures were located at the shoulder, elbow, wrist, knee and ankle (68–72% of structures located) though fewer structures were visualised at the hip (44%).

Conclusion: This cadaver based anatomy review course produced significant improvement in confidence across a range of MSUS competencies including interpretation of normal anatomy, which was maintained after 4 weeks. Expert led, small group workshops handling cadaveric specimens with simultaneous practice of MSUS on live models is an effective model for MSUS anatomy training. This method of teaching was highly regarded by the delegates, and imaging protocols and checklists are a useful tool for self assessment.

Evaluation of a New Educational Tool: A Resident's Guide to Pediatric Rheumatology. Tania Cellucci and Ronald M. Laxer. The Hospital for Sick Children, Toronto, ON

Background/Purpose: "A Resident's Guide to Pediatric Rheumatology" was specifically designed to address a gap in pediatric rheumatology teaching resources. It was intended for medical students and residents who participate in pediatric rheumatology rotations as part of their training program. The aims of this study were to determine whether the Guide was reaching its target population and to evaluate its perceived utility, frequency of use, and user satisfaction.

Methods: The Guide was developed by rheumatology staff and fellows at The Hospital for Sick Children in 2011 and provides a summary of common pediatric rheumatology topics. It was distributed electronically at no cost to interested training programs. All individuals who requested a copy of the Guide were contacted via email to solicit their participation in an online survey. The survey collected information on: (1) participant demographics; (2) frequency and methods in which the Guide was used; (3) ratings of user satisfaction on a 5-point Likert scale (level 1 outcome of Kirkpatrick's evaluation model); and (4) identification of perceived positive and negative features of the Guide.

Results: An invitation was sent to 261 recipients of the Guide and 81 (31% response rate) completed the survey. Participants included 45 staff pediatric rheumatologists, 18 residents, 7 pediatricians, 5 pediatric rheumatology fellows, 3 adult rheumatology fellows, 2 occupational therapists, and 1 nurse practitioner. The Guide was used for teaching by 63% of participants and for learning by 48%. As expected, no staff physicians used the Guide as a learning tool; however, fellows and residents reported using the Guide to study as well as to teach. Most teachers (90%) provide the Guide to trainees to read independently during rotations, while a smaller group use the Guide to stimulate discussion (37%) or as part of case-based teaching (35%). Frequency of use was described as weekly (20%), monthly (30%), or every few months (30%). Overall, participants were satisfied with the Guide as a teaching resource (69% very satisfied, 20% somewhat satisfied) and learning resource (65% very satisfied, 22% somewhat satisfied). The most commonly cited positive features were its' free availability, and balance between comprehensive and concise information.

Conclusion: The Guide appears to fill an identified gap in pediatric rheumatology resources for non-rheumatology trainees. Uptake of the Guide as a learning tool was broader than the intended audience since fellows report using it for teaching and learning. Further study is required to determine if the Guide increased knowledge in non-rheumatology trainees (Kirkpatrick level 2 outcome) and changed teaching behaviours by pediatric rheumatology teachers (Kirkpatrick level 3 outcome).

Facebook Support Groups in Systemic Lupus Erythematosus: Content Analysis. Evelyne Vinet[1], William Shihao Lao[2], Christian A. Pineau[1], Ann E. Clarke[3] and Sasha Bernatsky[4]. [1]McGill University Health Centre, Montreal, QC, [2]McGill University, Montreal, QC, [3]MUHC, Montreal, QC, [4]Research Institute of the McGill University Health Ctre, Montreal, QC

Background/Purpose: Facebook is the most important social network site, with over 600 million registered users worldwide. Many disease-specific groups exist on Facebook, offering a convenient way to exchange information and support, particularly for patients affected with a rare disease such as systemic lupus erythematosus (SLE). However, no one has explored the content of SLE-related groups on Facebook. We aimed to evaluate the purpose of the SLE-related groups on Facebook, and assess the patterns of use and the information shared on the groups dedicated to support.

Methods: We searched Facebook groups using the term "lupus", from 10/08/2011 to 01/04/2012. We selected groups related to SLE, operating in English or French, and publicly accessible. We extracted information on the purpose of the group and its administrator, as well as on the number and type of user-generated contributions. We analyzed the content of support groups using a previously developed coding scheme.

Results: We found 173 SLE groups on Facebook containing a total of 42 240 members. Half (49%) of the groups were created for support, while 32% were for disease awareness and 14% for fundraising. The largest group included 30 972 members and was intended for awareness. 3469 members were found in support groups, representing 31% of the overall membership (when excluding the largest group), and the median number of members was 11 (interquartile range, IQR, 39). The most frequent support group locations of origin were the United States (46%), Canada (10%), and United Kingdom (10%). In support groups, the total number of user-generated contributions was 1932, including wall posts (54%), comments (32%), discussion posts (10%), and discussion threads (4%), while the median number of user-generated contributions was 5 (IQR 20).

Conclusion: Support groups represent a substantial proportion of Facebook groups dedicated to SLE. Given their convenience, accessibility, and potential audience, Facebook support groups might represent an efficient way to reach patients with SLE and improve their wellbeing. Further research should evaluate the effect of this type of support groups on patients with SLE.

Immunology for Rheumatology Residents: Working towards a National Curriculum Consensus. Shirley L. Chow[1], Dharini Mahendira[2], Sari Herman-Kideckel[3] and Heather McDonald-Blumer[4]. [1]University of Toronto, Toronto, ON, [2]St Michael's Hospital, Toronto, ON, [3]University of Toronto, North York, ON, [4]Mt. Sinai Hospital, Toronto, ON

Background/Purpose: Immunologic mechanisms play an integral role in the understanding of rheumatic conditions. Currently, there is limited access to standardized formal instruction in immunology for trainees across Canada. A comprehensive immunology curriculum is essential for adult rheumatology trainees to meet the competencies required for practice and mandated by the national accrediting body.

The purpose of this project is to review the current immunology curriculum amongst adult rheumatology training programs across Canada. We will compare the self identified learning needs of rheumatology residents with the perceived learning needs of rheumatology program directors and will seek to integrate these needs into a focused nationwide immunology curriculum for rheumatology training programs

Methods: Rheumatology trainees and program directors from rheumatology programs across Canada were asked to complete an online questionnaire and rank a comprehensive list of immunology topics. A modified Delphi approach was used to obtain consensus on topics to be included in the curriculum.

Results: 38 rheumatology trainees and 15 program directors were contacted between March 1 to May 31 2012. 42% of trainees and 66% of program directors responded, with a total 49% response rate. Of the rheumatology trainees, 67% had prior experience in immunology, which consisted of undergraduate and graduate courses. Teaching formats and formal teaching hours varied between sites. Only 31% of trainees and 42% of program directors felt the current method of teaching immunology was effective. Preliminary results reveal high concordance between the majority of topics ranked by Trainees and Program Directors. However, discordance was seen with the topics of diagnostic laboratory immunology and therapeutics, immunomodulators and immunosupressants.

Conclusion: There is a need to improve immunology teaching in rheumatology training programs. Preliminary results show a high concordance between the majority of topics ranked by trainees and program directors, however discordance is seen with others. Final completion of the Delphi will allow for a national consensus and more definitive conclusions. This study provides the groundwork for development of future national immunology curricula.

1889

The Effects of Physical & Mental Health Rehabilitation Program (PMHRP) for Hemophilic Arthritis Patients. Won Sook BAK[1], Myung Chul Yoo[1], Nam Su Cho[1], Sang Hack Lee[1], Yoon Hee Kim[2] and Ki Young Yoo[1]. [1]Kyung Hee University Hospital at Gangdong, Seoul, South Korea, [2]Seoul, South Korea

Background/Purpose: Most of the rehabilitation program for patients with hemophilic arthritis are focused on only the improvement of physical activities. However, the actual hemophilic arthritis patients are accompanied by mental problems as well as physical disabilities, so a rehabilitation program to improve physical and mental problems simultaneously is needed. PMHRP was developed to solve these problems through increasing the interpersonal relationship, developing each potentials, self-development and understanding others. PMHRP was analysed by two different groups to verify the clinical effectiveness.

Methods: This study used a nonequivalent control group quasi-experimental research based on data acquired through a pre-post test. The subjects for this study were a total of 53 patients with hemophilic arthritis who underwent lower extremity joint surgeries at the orthopedic. The experimental group(n=24)was attended PMHRP 5 times(4hours/time) for 4 weeks, and the control group(n=29) was not given any physical & mental health rehabilitation program. The measurement tools of this study were Numerical Rating Scale for 100mm Pain VAS, 100mm Fatigue VAS, self efficacy, self esteem, quality of life, SCL-90-R(Symptom Checklist-90-Revision) and WOMAC Scale. The data was analyzed with X^2-test and t-test using SPSS/Win18.0.

Results: After PMHRP application, self efficacy score increased significantly in the study group and self esteem score also increased (p<.001). On the contrary, these scores decreased after 4 weeks in the control group. 100mm Pain VAS & 100mm Fatigue VAS, and quality of life scores improved significantly in the study group(p<.001). SCL-90-R scores decreased significantly after the program (p<.001). Although there were no statistically significant differences in WOMAC scores between two groups, however, the average score was changed from pre-treatments(M=36.51) to post-treatment(M=30.08) and it revealed the alleviation of arthritic symptoms and improvement of activities.

Conclusion: In conclusion, PMHRP showed much more satisfactory results than the simple physical therapy to treat the physical and mental disabilities including psychosocial stresses in patients with hemophilic arthritis by increasing the self esteem and quality of life by themselves. These results suggest that PMHRP is highly recommended as a distinguished method of rehabilitation for patients with hemophilic arthritis.

1890

The Current State of Mentoring Among Pediatric Rheumatology Fellows and Junior Faculty in the United States and Canada. Meredith P. Riebschleger[1], Eyal Muscal[2], Matthew M. Davis[3], Hermine Brunner[4], B. Anne Eberhard[5], C.J. Inman[6], Marisa S. Klein-Gitelman[7], Lakshmi N. Moorthy[8], Marc D. Natter[9], Sampath Prahalad[10], Rayfel Schneider[11] and Peter A. Nigrovic[12]. [1]University of Michigan Health System, Ann Arbor, MI, [2]Baylor College of Medicine, Houston, TX, [3]University of Michigan, Ann Arbor, MI, [4]Cincinnati Children's Hospital Medical Center and PRSCG, Cincinnati, OH, [5]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [6]University of Utah, Salt Lake City, UT, [7]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [8]Robert Wood Johnson-UMDNJ, New Brunswick, NJ, [9]Children's Hospital Boston, Boston, MA, [10]Emory Children's Center, Atlanta, GA, [11]The Hospital for Sick Children, Toronto, ON, [12]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Prior studies have shown that mentoring increases professional success among physicians. Many pediatric rheumatology (PR) divisions are small, which may limit options for mentoring. The ACR/Childhood Arthritis and Rheumatology Research Alliance (CARRA) Mentoring Interest Group (AMIGO) is a new collaborative effort to promote professional development within PR via cross-institutional mentoring. In this study, we describe the pre-AMIGO state of mentoring among PR fellows and junior faculty in the US and Canada.

Methods: A cross-sectional web-based survey of all pediatric rheumatologists in the US and Canada was conducted Nov 2011-Jan 2012. The survey was distributed via ACR, CARRA, and McMaster PR email lists. Where possible, survey items were drawn from validated scales. For this study, the analysis cohort was limited to include fellows and junior faculty, as AMIGO targets those groups. Independent variables included respondent demographics; dependent variables included the reported presence and location of mentors and overall satisfaction with mentoring received on a 5-point Likert scale. Chi square tests were used to assess associations.

Results: 135 respondents were included in the analysis cohort. 42% of the analysis cohort were fellows (estimated subgroup response rate 64%) and 58% were junior faculty (estimated subgroup response rate 70%). 74% of the analysis cohort were female; 95% were employed in academic institutions; and 96% were fellowship-trained. Most respondents had a clinical mentor, while fewer had mentors for important career-related tasks such as identifying funding sources, defining career goals, and understanding how to achieve career goals (Figure 1). Fellows and junior faculty were equally likely to have clinical mentors, but fellows were more likely to have research mentors; 5% of fellows and 26% of junior faculty reported no research mentoring (p<.01). Both fellows and junior faculty reported finding mentors outside their home PR divisions.

Figure 1: Location of Mentors

Do you have a mentor who you go to for:
Overall, 74% of fellows and 64% of junior faculty were somewhat or very satisfied with the mentoring they receive. The presence of a mentor in any domain was associated with an increased likelihood of satisfaction with mentoring (all p<.01). This association was strongest for having a mentor who helped respondents understand how to achieve their career goals; 84% of those with a mentor in this domain were satisfied with mentoring, compared to only 17% of those without (p<.001).

Conclusion: Many PR fellows and junior faculty members lack mentors in specific areas of career development. Programs such as AMIGO may have a role in providing cross-institutional mentors in critical career-related domains. Future studies will assess changes in mentee satisfaction and academic achievement for pediatric rheumatologists engaged in the AMIGO program and for the PR community at large.

Moorthy**, None; **M. D. Natter**, None; **S. Prahalad**, None; **R. Schneider**, None; **P. A. Nigrovic**, None.

1891

Teaching Medical Students Principles of Chronic Disease: Medicine of the 4th and 5th Dimension At Weill-Cornell. Michael D. Lockshin[1], Greg McDermott[2], Lester Zambrana[2] and Alana B. Levine[1]. [1]Hospital for Special Surgery, New York, NY, [2]Weill-Cornell Medical College, New York

Background/Purpose: Medical students learn about acute illness and sometimes have experience with longitudinal care, but they do not encounter concepts specific to the management of chronic, non-lethal, intermittent, disabling illness, such as the rheumatic diseases. Here we describe a novel curriculum designed to address this gap.

Methods: We initiated a pilot course on chronic illness at Weill-Cornell Medical College, Medicine of the 4th and 5th Dimension (time and communication). The course did not focus on biology or treatment. Each of 7 seminar sessions focused on one or more of the following themes: *time scales* (making decisions for immediate, short-term, and long-term needs); *communication* (patient priorities, hearing the unsaid, seeing the unseen, physician arrogance); *living with disability*; *managing co-morbidity*; *decision-making when the evidence is incomplete* or the patient disagrees; *working with other medical personnel*; attending to *externalities* (family, insurers, society); and *maintaining an identity* other than that of a person with a chronic illness. At the conclusion of the course students submitted essays on strengths and weaknesses of the course; patients were interviewed separately.

Results: Two first-year and one fourth-year students, one rheumatology fellow, one parent-patient advocate, one parent, and 9 patients participated. Patients had lupus, scleroderma, Sjogren's with and without cryoglobulinemia, Wegener's, kidney transplant, and undefined autoimmune illnesses. Patients were 17–60 years old, female, and of Caucasian, Hispanic, and Asian ethnicities (two African-Americans initially volunteered to participate but did not). All patients, recruited from rheumatology practices, were articulate and well-informed about their illnesses.

Students particularly valued the ability to learn *from* rather than *about* patients. They noted that: there is a distinction between "staying healthy" and "getting well"; patients are not defined by their disease; fear of future pain can be worse than current pain; humble and arrogant physicians have different effects on patients; lectures on empathy do not substitute for hearing a patient's words and observing her body language; not all problems have right answers; external influences affect patients' decisions.

Students asked for more didactic instruction on how to speak to a patient when knowledge is uncertain. They asked for a session how to manage stalled progress (keeping up patients' hope) in a chronic illness. Because the patients had been selected for reliable attendance and for articulateness, students felt they did not get a sense of managing a patient across language, cultural, socioeconomic or intellectual barriers. They felt that video-taped interviews or on-line exercises would not substitute for face-to-face interviews.

Conclusion: This pilot program identified important needs of students with regard to learning about chronic illness. With a larger program (more students, more time per year, more years in medical school, broader patient base) these needs can be met.

1892

Impact of a Lupus Patient Education Event On Knowledge about Systemic Lupus Erythematosus. Mithu Maheswaranathan[1], Melissa A. Cunningham[2], Sharon Wolf[1] and Diane L. Kamen[3]. [1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Charleston, SC, [3]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC

Background/Purpose: There is a need for educational interventions to boost chronic disease management skills among patients. To address this need, we created a lupus patient education event comprised of a panel of multidisciplinary experts to provide information to lupus patients. The study objectives were (1) to survey the local lupus population regarding their lupus-related questions and (2) to assess the impact of this event on patient knowledge about lupus.

Methods: A planning team including representatives from the community, medical school, and rheumatology division oversaw the creation and execution of the event. Patients with lupus (n=550) who had given permission to be contacted were invited to the event and those who registered were sent a pre- and post-event lupus knowledge survey via email. Rheumatologists presented topics including a lupus overview, cardiovascular health, reproductive health and contraception for teens and adults, clinical research trials, and answered questions submitted from the audience. A motivational speaker discussed ways to overcome challenges in managing a chronic disease, and a nurse educator presented material on speaking to your doctor about lupus.

Results: 91 individuals attended the Lupus Patient Education Event in October 2011. The pre- and post-event surveys were sent via email to all attendees, of which 39 individuals responded to the pre-test and 22 individuals responded to the post-test. The mean age of responders was 39 +/−14 years. 81% of total responders were lupus patients. Respondents had limited awareness about belimumab as an FDA-approved medication for lupus (59% pre, 86% post), meaning of a positive ANA (64% pre, 73% post), malar rash

as a symptom of lupus (67% pre, 91% post), and age groups most at risk (74% pre, 86% post).

The knowledge questionnaire demonstrated an increase in patients' knowledge about lupus after attending the event, especially regarding risk factors and knowledge about the disease state. Overall patients had less awareness about the meaning of a positive ANA, biologic medications (e.g. belimumab) and some of the characteristics of lupus including symptoms and risk factors prior to the event, with scores improving after attending the event (Table 1).

Table 1. Pre-test and post-test results from participants

Theme	Question	Pre-Test (% Correct)	Post-Test (% Correct)	p value
Etiology	how lupus damages body	100	100	NS
Etiology	what is the cause of lupus?	100	95	NS
Knowledge/Acuity	what SLE stands for	100	100	NS
Knowledge/Acuity	meaning of a positive ANA	64	73	0.472
Knowledge/Acuity	medications safe in pregnancy	89	86	NS
Knowledge/Acuity	FDA-approved medication	59	86	0.036
Knowledge/Acuity	malar rash	67	91	0.036
Knowledge/Acuity	protein in urine	97	100	NS
Risk Factors	age group most at risk	74	86	0.275
Risk Factors	risk in men vs. women	90	86	0.6375
Risk Factors	African Americans and SLE	90	100	0.125
Comorbidities	comorbidities (CVD, Vit D)	92	95	NS

*NS = non-significant

Of 48 individuals who responded to the post-event evaluation, 91.3% said they felt we achieved the goal of providing information and education about lupus which will impact disease management and overall health.

Conclusion: The improvements in scores suggests efficacy of the patient education event in increasing awareness and knowledge about lupus in those who attended. The interactive nature of a symposium enables quality information to be disseminated to patients and families, and for patient questions to be answered. Future events will emphasize topics suggested by participants and provide more interactive sessions.

1893

Eliciting Prescribing Choices of Anti-Tumour Necrosis Factor Therapy From Rheumatology Trainees. Rodney A. Hughes[1] and Alison J. Carr[2]. [1]St. Peters Hospital, Chertsey Surrey, United Kingdom, [2]Hamell Communications, London, United Kingdom

Background/Purpose: A rheumatologist's choice of anti-TNF prescription is likely to be influenced by a number of factors. Doctors believe their prescribing to be evidence-based, rational and justifiable. With greater understanding of health behaviour, it is likely that prescribing decisions about anti-TNF will involve conscious and sub-conscious factors. We conducted a clinical decision exercise with senior rheumatology trainees to try better to understand these influences and whether all doctors take into account patient perceptions and preferences.

Methods: 12 trainees were each given an IPad with details of 30 individual simulated patients, based on real patients with RA. For each individual 'iPad' patient doctors were asked to decide whether to start anti-TNF and which brand they would prescribe if they did. Each doctor was in training at a different hospital with different local anti-TNF guidelines for therapy although all purported to follow UK national guidelines for anti-TNF drug therapy. IPad patients differed in gender, age, disease duration and disease activity score, previous drug history and symptoms of stiffness and function. Work status varied as did quality of life measures and aspects of patient choice. iPads were coded to allow attribution of answers and data were analysed anonymously by a third party from the recorded iPad answers at a later time and place.

Results: The analysis of results indicated that doctors could be fitted broadly into one of two categories; Evidence-based decision makers (EBDs) and Intuitive patient-focused decision makers (IPDs) according to the way that doctors in these two groups made decisions. Prescribing choice appeared independent of the background of the doctor and geographical area of training and extent of rheumatological experience.

EBD's stuck rigidly to guidelines for initiation of anti-TNF therapy and took no account of subjective data or patient specific concerns of preferences. EBD's were rigid in their choice of anti-TNF and chose the same product for all patients who were going to be initiated onto anti-TNF. EBD's appeared not

to feel that patients could make informed decisions or choices about treatment. EBD's did not think that adherence would be a problem with ant-TNF therapy. In contrast IPD's ignored guidelines around the threshold for starting anti-TNF in cases where they felt that patients would benefit from anti-TNF. With IPD's patient factors were important in driving treatment decisions – quality of life and impact of RA on the ability to work strongly influenced decisions. IPD's responded to patient requests, concerns and preferences in making prescribing choices and were more likely to tailor their choice to fit best with patient-specific characteristics. IPD's felt that patients could and should make informed decisions about their treatment and recognised that adherence was potentially a problem even with anti-TNF drugs.

Conclusion: As with many health care decisions there appear to be strong sub-conscious influences on anti-TNF prescribing that introduce variance into treatment decisions. Recognition of different groups of prescribers suggests that information given to doctors might be processed differently by different groups.

Disclosure: R. A. Hughes, None; **A. J. Carr**, None.

1894

Factors Associated with Confidence Level of Rheumatology Fellows in Joint Procedural Skills. Tara J. Rizvi, Min Xu and Nancy Searle. Baylor College of Medicine, Houston, TX

Background/Purpose: Rheumatology fellowship programs in the U.S. lack clear standardized criteria to train fellows in joint procedural skills. More recently, some programs are utilizing joint simulated anatomical models (JSM); some are introducing musculoskeletal ultrasound (MSUS) modalities. We sought to determine whether these instructional modalities, and/ or other factors were associated with fellow's confidence level in procedural skills. The purpose of our study is to determine factors associated with overall level of confidence of rheumatology fellows in the United States, in joint procedural skills.

Methods: An online survey was sent to junior and senior fellows enrolled in rheumatology programs in the United States. Survey included questions pertaining to: fellowship year, training on joint simulated models, training with musculoskeletal ultrasound, other instructional methods employed for procedural skills, attending physician supervision during procedures, number of times 25 individual procedures were performed, fellow's confidence level in 25 individual procedures and overall confidence level in procedural skills. Statistical analysis including chi-square test and spearman correlation coefficiency were performed using SPSS10.0.

Results: Data was obtained from 139 respondents: 63 junior and 76 senior fellows. 80 out of 103 accredited fellowship programs responded, so sample was representative of the majority of adult fellowship programs. 39/ 139 (28%) and 50/139 (36%) fellows reported being trained on JSM and MSUS respectively. Factors associated with fellow's overall confidence level for joint procedural skills are: years of fellowship training and training on joint simulated anatomical models (Table 1). Confidence levels for individual joints significantly correlated with the number of times procedure had been performed (p<0.01). MSUS training, other instructional modalities, and attending physican supervision were not significantly associated with overall confidence level.

Table 1. Factors associated with overall confidence level

ASSOCIATION WITH CONFIDENCE LEVEL	CHI-SQUARE	P-VALUE
Year of fellowship*	15.451	0.004
Joint simulation models*	11.995	0.017
Musculoskeletal ultrasound	6.283	0.179
Videos	7.713	0.103
Cadavers	3.585	0.465
Demonstration on patients	2.186	0.702
Attending physician presence	24.146	0.086

Conclusion: Factors associated with higher confidence level of rheumatology fellows in joint procedures include: training on joint simulated models, year of fellowship training and the number of opportunities to perform individual procedures. To improve fellow's level of confidence and hence improve procedural training, it may be suggested that training authorities encourage use of joint simulated models, and set standarized criteria to ensure adequate exposure for all fellows to procedures thought to be necessary for graduation.

1895

Safety Competences Knowledge and Behavioural Skills of Patients Treated by Biologics in Rheumatology. Anne-Christine Rat[1], Bruno Fautrel[2], Elisabeth Flipon[3], Laure Gossec[4], Benoit-Damien Caritey[5], Laurent Marguerie[6], Henri Nataf[7], Beatrice Pallot Prades[8], Rose Marie Poilvert[9], Valerie Royant[10], Fathia Sadji[11], Christelle Sordet[12], Corinne Thevenot[13] and Catherine Beauvais[14]. [1]Université de Lorraine, Paris Descartes University, APEMAC, EA 4360, F-54 000, Nancy, France, [2]APHP-Pitie Salpetriere Hospital/UPMC, Paris, France, [3]Cochin hospital, Paris, France, [4]Paris-Descartes University, Cochin Hospital, Paris, France, [5]Université de lorraine, Nancy, France, [6]Institut Calot, Berck, France, [7]Mantes-la-Jolie, Mantes-la-Jolie, France, [8]Saint Etienne university hospital, Saint Etienne, France, [9]Saint Antoine Hospital, Paris, France, [10]Chartres, Chartres, [11]Victor Jousselin Hospital, Dreux, France, [12]Strasbourg University Hospital, Strasbourg, France, [13]Laon hospital, Laon, France, [14]Saint Antoine, Paris, France

Background/Purpose: Biologics are known to entail specific risks; therefore teaching patients safety skills, appropriate behaviours in situations of risks and what decisions to take in these situations is necessary. The level of knowledge of safety competences are not well known in patients treated by biologics.The objective of the study was to describe the safety competences of patients treated by biologics for inflammatory arthritis and to determine the factors associated with a lower level of competences.

Methods: Data were obtained from a national cross-sectional survey. To be as representative as possible of the patients treated by biologics, rheumatologists were randomly sampled from the national directory. They were invited to include 3 to 5 consecutive patients treated by biologics whatever their inflammatory arthritis diagnosis.All patients completed a 55-item questionnaire (*BioSecure**) assessing patients' self-care safety skills and sociodemographic characteristics, type of information received, quality of life and coping style data. Rheumatologists completed personal and practice data.The questionnaire measuring knowledge and skills regarding biologics was developed by health professional and patients using 3 steps: elaboration of an exhaustive list of competences, selection via a Delphi technique then elaboration of a questionnaire for the 26 competences selected. The questionnaire includes a series of multiple-choice questions on knowledge and on clinical situations grouped in dimensions.

Results: Of the 671 patients included, 67% were women, 62% had RA and 38% spondylarthritis, 63% were treated by subcutaneous antiTNF. The mean age was 53 ± 13 years old. Patients received information during a medical consultation (90%), a consultation with a nurse (30%), with a written booklet (59%) and during a therapeutic education program (11%). The median total score (percentage of right items) was 73 (interquartile 60–82). Knowledge items had not higher percentages of correct answers than behavioural skills items. Scores and number (%) of patients with a number of correct answers lower than 50% are described in the table. In multivariate analysis, several patients' factors were associated with a lower level of competences: living alone, a lower education level, living in a big city, not to be employed and having not received written information or therapeutic education. Rheumatologists treating more than 80 patients with biologists had an increased risk of having their patients in the moderate skills group compared to the high skills group.

		N° items	Median	Q1	Q3	Patients with a n° of wright items < 50% N	Patients with a n° of wright items < 50% %
Biologics management		11	**100.0**	90.9	100.0	12	**(1.8)**
	General knowledge	4	**100.0**	75	100.0	24	**(3.6)**
	Communication	4	**100.0**	100	100	17	**(2.5)**
When to consult		15	**73.3**	53.3	86.7	145	**(21.4)**
	Fever	11	**81.8**	54.5	90.9	127	**(18.8)**
	Infectious symptoms	4	**75.0**	25	100	188	**(27.8)**
Specific situations		19	**73.7**	52.6	84.2	128	**(18.9)**
	Vaccination. Injuries	8	**62.5**	50	87.5	167	**(24.7)**
	Dental care	2	**100.0**	50	100	79	**(11.7)**
	Surgery	7	**85.7**	57.1	100	86	**(12.7)**
	Planning child conception	2	**50.0**	0	100	336	**(49.6)**
Sub-cutaneous injection		3	**66.7**	66.7	66.7	245	**(36.2)**

Conclusion: Safety competences can be improved, especially competences needed to deal with infectious symptoms, vaccinations, planned surgery and planning child conception. These results provide also elements to

help identifying patients who need therapeutic education or to adapt the messages given.

*L Gossec. Ann Rheum Dis 2010;69(Suppl3):476

1896

Variation in US Pediatric Rheumatology Fellowship Training. Anjali Patwardhan[1], Michael Henrickson[2], Sandy D. Hong[3], Laura Laskosz and Charles H. Spencer[1]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]U of Iowa Children's Hosp, Iowa City, IA

Background/Purpose: Pediatric rheumatology (PR) became an American Board of Pediatrics subspecialty in 1990. This is the first survey to examine training differences between the 31 US PR fellowship programs. We hypothesize that there is infinite variation in the Pediatric Rheumatology Fellowship Training across North America.

Methods: Members of the American Academy of Pediatrics (AAP) Section of Rheumatology and its Executive Committee conducted this cross-sectional study. We developed the survey instrument through extensive literature research and the Delphi consensus technique. Following institutional human subjects research review and approval, we distributed the survey to PR trainees (n=82).

Results: We obtained a 57% response rate (n=47). Respondents' training level followed a normal distribution: initial (8%); completion of 1st year (16%), 2nd year (34%), 3rd year (37%) and 4th year (5%). Their clinical commitments involved the following half-day sessions per week: 1 (28%), 2 (43%), 3 (13%), 5 (11%), and 6 (4%). Sixty percent provided care for either 4 (30%) or 5 (30%) patients per session. Procedural experience included joint injections and musculoskeletal ultrasound. Respondents' average number of joint injections per month comprised 0–1 (55%), 2–4 (37%), and ≥ 5 (7%); 20% received formal ultrasound training. On-call experience at home involved nights and weekends; the latter also included inpatient rounds for 98% of respondents. The range of nights on-call was 0–15, distributed as: 0 (2%), 3 (16%), 7 (27%), 10 (14%) and 15 (7%). The range of weekends on-call was 1–4, distributed as: 1 (37%), 2 (39%), 3 (9%) and 4 (9%). Educational session hours attended varied among trainees: 2 (13%), 3 (35%), 4 (29%) and ≥ 5 (22%). Sessions included journal club presentations (range=1–8/year), trainee-presented PR lectures (97%), resident education (88%), and attendance at specialty conferences with adult rheumatology (81%), radiology (59%), nephrology (48%) and histopathology (43%). Respondents' research activity hours per week (range= 20 to > 60) varied: ≤ 20 (43%), 21–40 (43%), 41–60 (11%), > 60 (2%). Respondents presented abstracts at regional or national academic meetings in a range of 1 (32%) to 8 (6%). Regarding published papers, 41% had one, while 59% had none.

Table. Please indicate the average number of patients you have seen in each group during your fellowship

Disease Groups	'Number of patients seen' subgroup (numbers in italics denote % of responders)						Range of exposure
	0–5	6–10	11–20	>20	Never observed/qatreated	Response Count	
Existing Diagnosis of SLE	11.3	13.6	31.8	43.1	0	44	43.1% of responders see >20 & Only 11.3% responders saw less than 5 of previously diagnosed SLE patients
SLE Nephritis	20.4	25	27.2	27.2	0	44	27.2% of responders saw >20 while 20.4% responders saw <5 patients with SLE nephritis
New Case of SLE	29.5	34	31.8	4.5	0	44	29.5% responders saw <5 cases while only 4.5% responders saw >20 cases of newly diagnosed SLE
Existing Diagnosis of WG	68.1	22.7	4.5	0	4.5	44	68.1% of responders saw < 5 patients while 4.5% responders never saw a patients with previously diagnosed WG
New WG	86.3	6.8	0	0	6.8	44	86.3% of responders saw < 5 patients while 6.8% responders never saw a patients with newly diagnosed WG
Scleroderma	47.7	29.5	20.45	5	0	44	47.7% of responders saw < 5 patients while no one saw <20 patients with scleroderma
Sjogren's Syndrome	62.7	23.2	4.6	0	9.3	43	62.7% of responders saw < 5 patients while 9.3% responders never saw a patients with Sjogren's
Existing Diagnosis of JDM	56.8	29.5	25	13.6	2.2	44	56.8% of responders saw < 5 patients while 2.2% responders never saw a patients with previously diagnosed JDM
New JDM	56.8	29.5	4.5	2.2	6.8	44	56.8% of responders saw < 5 patients while 6.8% responders never saw a newly diagnosed JDM patients
CNS Vasculitis	72.7	18.1	0	0	9	44	72.7% of responders saw < 5 patients while 9% responders never saw a patients with CNS Vasculitis
PAN	65.9	2.2	0	0	31.8	44	65.9% of responders saw < 5 patients while 31.8% responders never saw a patients with PAN
MPA	68.1	6.8	0	0	25	44	68.1% of responders saw < 5 patients while 25% responders never saw a patients with PAN
Poly JIA	4.5	6.8	13.6	75	0	44	4.5 % of responders saw < 5 patients while 75% saw >20 Poly JIA patients
Oligo JIA	5	0	15.9	81.8	0	44	5% of responders saw < 5 patients while 81.8% saw >20 patients with Oligo JIA
Spondyloarthropathies/ERA	6.8	15.9	25	52.2	0	44	6.8% responders saw <5 cases while 52.2% responders saw >20 cases of Spondyloarthropathies/ERA
SOJIA	15.9	46.5	27.9	9.3	0	43	15.9% responders saw <5 cases while only 9.3% responders saw >20 cases of SOJIA
MAS	61.3	29.5	2.3	2.3	0	43	61.3% of responders saw less than 5 cases while 2.3 % saw >20 cases of MAS
Other ANCA related Vasculitis	75	9	27.7	0	13.5	44	75% of responders saw less than 5 cases while 13.5 % saw >20 cases of Other ANCA related Vasculitis
Churg-Strauss syndrome	52.2	0	0	0	47.7	44	52.2% of responders saw less than 5 cases while 47.7% never saw a cases of Churg-Strauss syndrome
Behcet's syndrome	77.4	13.6	2.2	0	6.8	44	77.4% of responders saw less than 5 cases while 6.8% never saw a cases of Behcet's syndrome
Streptococcal Syndromes/RF/Reactive arthritis/PANDA	20.4	38.6	36.6	4.5	0	44	20.4% of responders saw less than 5 cases while 4.5 % saw >20 cases of Streptococcal Syndromes
Kawasaki Disease	20.4	45.4	18.1	13.6	2.2	44	20.4% of responders saw less than 5 cases while 13.6% saw >20 cases while 2.2% never saw a case of Kawasaki Disease
Resistant to treat HSP	53.4	29.5	9.3	0	6.9	43	53.4% of responders saw less than 5 cases while 6.9% never saw a Resistant to treat case of HSP
Chronic Recurrent multifocal Osteomyelitis (CRMO)	59	29.5	4.5	2.2	4.5	44	59% of responders saw less than 5 cases while 2.2 % saw >20 cases of CRMO. 4.5% responders never saw a case of CRMO
Pain Enhancement Syndrome	2.2	15.9	18.1	59	4.5	44	2.2% of responders saw less than 5 cases while 59% saw >20 cases of Pain Enhancement Syndrome. White interestingly 4.5% never saw such case
Sarcoidosis	60.4	23.2	4.6	0	11.6	43	60.4% of responders saw less than 5 cases while 11.6% never saw a case of Sarcoidosis
Periodic Fever Syndromes	29.5	31.8	27.2	11.3	0	44	29.5% of responders saw less than 5 cases while 11.3% saw >20 cases of Periodic Fever Syndromes
Antiphospholipid Antibody Syndrome (APLS)	63.6	25	6.8	2.2	2.2	44	63.6% of responders saw less than 5 cases while 2.2% saw >20 cases of APLS while 2.2% responders never saw a case of APLS

Other (please specify) Others:
Neonatal SLE −4.5%
MCTD −6.8%
Neurosarcoid −2.2%
Takayasu arteritis −2.2%   2
answered question   44
skipped question   3

Conclusion: Both clinical and research experience varies widely between US PR fellowship programs. Our survey data may identify areas for programmatic improvements, best practice benchmarks, and policy development for future training recommendations & workforce development. We hope programs will accomplish similar standards of excellence through the use of comparison data.

Pregnancy and Contraception in Adolescents and Teens with SLE: Are pediatric rheumatologists adequately Screening and Educating Their Patients?. Deirdre I. De Ranieri[1], Karen Onel[1], Linda Wagner-Weiner[2] and Melissa S. Tesher[1]. [1]University of Chicago, Chicago, IL, [2]University of Chicago Hospital, Chicago, IL

Background/Purpose: Pregnancy in patients with systemic lupus erythematosus (SLE) is often complicated by both disease flares and risks to the fetus. It is important that young women with SLE be educated on both the risks of pregnancy and on safe and effective methods of contraception. We aimed to evaluate how often pediatric rheumatologists discuss sexual activity and contraception with their young female patients with SLE. We also aimed to assess the perception of our knowledge and how we educate our patients on both pregnancy risks and contraception in SLE. We compared these responses with those of a small cohort of providers in other medical fields.

Methods: All general pediatricians and nurse practitioners at the University of Chicago, all adult rheumatologists and trainees in Chicago who are registered with the American College of Rheumatology (ACR), and all pediatric rheumatologists and trainees in the United States who are registered with the ACR were identified. An online survey was sent to these providers to evaluate how often they take sexual histories in their adolescent and young adult female patients (ages 11–21) with SLE, the frequency with which they educate their patients on the risks of lupus in pregnancy, and if they offer contraceptive guidance.

Results: Responses were received by 56 pediatric rheumatologists, including 12 trainees, 12 nurse practitioners, 9 general pediatricians, and 7 adult rheumatologists, including 1 trainee. Relatively few pediatric rheumatologists consistently discuss sexual activity, pregnancy risks, or contraception with patients. 32% of pediatric rheumatologists were "very comfortable" taking a sexual history, compared to 16.7% of adult rheumatologists. 88.9% of general pediatricians reported taking a sexual history during at least 75% of adolescent visitis, compared to pediatric rheumatologists (26.5%). Adult rheumatologists reported obtaining sexual histories the least often among those surveyed. Only 58.8% of pediatric rheumatologists surveyed discussed the risks of pregnancy in their young female patients with active lupus, although the majority expressed adequate knowledge of these risks. Only 50% of pediatric rheumatologists reported discussing contraception with patients on teratogenic medications during at least 75% of their clinic visits despite reporting adequate familiarity with medications that can cause birth defects. Written and web-based educational resources were identified as useful tools in educating patients about pregnancy and contraception in women with lupus.

Conclusion: This preliminary survey identified a discrepancy in pediatric rheumatologists' knowledge of the complications of pregnancy in SLE, teratogenic drugs, and contraceptive methods, and their communication of this knowledge to their young female patients with SLE. Implementing tools to help these providers feel more comfortable discussing these important topics is indicated in order to better serve this population. Surveyed physicians identified both online resources and paper handouts explaining the risks of pregnancy in young women with SLE and different methods of contraception as useful tools.

A Competence-Based Model for Teaching Rheumatology in Undergraduate Medical Students in Pontificia Universidad Católica De Chile: A Five Years Experience. Pamela Díaz, Carolina Cuellar, Miguel Gutiérrez and Marcela Cisternas. Pontificia Universidad Católica de Chile, Santiago, Chile

Background/Purpose: Several reports have demonstrated that Rheumatology disorders are increasingly arising. In USA, for example, three of the top eight primary diagnosis groups presenting to ambulatory care visits in 2007 were for musculoskeletal disorders.

In the meanwhile, medical student's surveys have consistently demonstrated their lack of confidence in diagnosing and managing musculoskeletal problems.

Until 2005 the rheumatology teaching in our School of Medicine was predominantly based in lecture classes, some seminars and a written multiple choice test. Since then, in order to improve the rheumatology teaching, we introduced new learning objectives in this field with three domains of learning: knowledge, attitudes, and skills.

To achieve these domains, we added a program consisting of small group tutorials, the use of one-way-mirror offices to direct observation, personalized feedback, formative evaluations and objective structured clinical examinations (OSCEs).

The aim of this study was to describe this novel assessment method, and evaluate the acquisitions of rheumatology teaching domains in undergraduate students with this program.

Methods: We implemented seven consultation offices with one-way mirror, with special audio and video systems.

The students are organized in small groups of six, with a rheumatology professor, and during two weeks they review the most common rheumatology problems: musculoskeletal diseases, osteoarthritis, rheumatoid arthritis, systemic lupus erytemathosus, laboratory test and radiology.

Each day starts with a session discussion about the different diseases, then one student performed a real rheumatology patient evaluation being observed for the group, who is also filling a summary sheet of the interview with special emphasis in the attitudes and the skills observed. After a complete evaluation, the entire group discussed relevant aspects of the interview and of the patient's disease, and gives feedback.

To determine the acquisitions of the contents and competences, we introduce a formative test at the beginning and the end of the program, and an OSCE. Also, each student completes a survey about the program and the methodology.

Results: In the last five years, over 500 students have completed this new curriculum program.

The student's surveys about this methodology showed a high level of satisfaction. They estimated the objectives achievement in more than 90%, and evaluate the overall program with a mean score of 6.8 over 7 (range 6.6–7).

Three hundred and seventy one students filled the formative test at the beginning of the program, and 361 at the end. At the beginning, the percentage of correct answers was 62% vs 92% at the end of the program ($p < 0.01$). In the first formative test, there were 10% of non-respond answers, vs 0.5% at the second test ($p < 0.01$).

In the final OSCE, all the students had a good performance being all approved with over 60% of achievement in the three different domains evaluated.

Conclusion: This new assessment in rheumatology teaching is highly appreciated for the students, and it seems to be a good methodology to the acquisition of knowledge and trainee in competences in rheumatology patient's evaluation.

Factors Contributing to Non-Publication of Abstracts Presented At the American College of Rheumatology/Association of Rheumatology Health Professionals Annual Meeting. Jennifer M.P. Woo[1], De Furst[2], Deborah K. McCurdy[1], Olivia I. Lund[3], Rotem Eyal[3], Cijin Piao[3] and Gil Amarilyo[1]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]University of California at Los Angeles, Los Angeles, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA

Background/Purpose: The American College of Rheumatology/ Association of Rheumatology Health Professionals (ACR/ARHP) Annual Scientific Meeting (ASM) provides a premier forum for the rapid dissemination of novel clinical and basic science research in the fields of rheumatology and immunology. We recently investigated the publication outcomes of abstracts presented at the 2006 ACR/ARHP ASM in Washington, D.C. (November 12–16, 2006). We estimated that 59.1% of all abstracts presented at the meeting were published as full-length peer-reviewed manuscripts within 5 years of presentation. In order to assess the reasons behind non-publication of the remaining research, we administered a survey to a cross-section of authors who we previously identified as presenting abstracts that remained unpublished.

Methods: Of 2156 abstracts presented at the 2006 ACR/ARHP ASM, we classified 879 abstracts as "not published" following an extensive PubMed search for potential publication matches. Primary authors of non-published abstracts were anonymously surveyed via an internet questionnaire to identify factors that prevented presented research from reaching full-length publication status.

Results: A total of 713 primary authors had at least one abstract presented at the 2006 ACR/ARHP ASM that did not result in publication as a full-length manuscript. Abstracts that described studies in rheumatoid arthritis, systemic lupus erythematosus, and systemic sclerosis constituted approximately 39.7% of all presented abstracts and included 38.6% of all unpublished abstracts (non-publication rates: 38, 43, and 41%, respectively). A cross-section of 459 authors, who served as primary author on 599 unpublished abstracts, was surveyed. Sixty-five authors (14.2%) responded to the questionnaire, reflecting 117 abstracts (19.5%). At the time of the survey, 10 abstracts (8.5%) were reported as being published as full-length manuscripts within the 5 years following their presentation and were supported by corresponding citations. Three additional abstracts were confirmed as being published, but reached this status during the period between January-June 2012, which was outside of the defined search period. The primary reasons reported for non-publication included: 1) Insufficient time to prepare manuscript (35.2%); 2) a co-author was responsible for authoring the manuscript (29.6%); and 3) the study was still ongoing (16.7%).

Conclusion: Although most of the abstracts presented at the 2006 ACR/ARHP ASM were eventually published in peer reviewed journals, data indicates that the lack of subsequent publication was related to the presence of time constraints or deferred responsibility for authorship rather than the quality of the data.

1900

Mormed Project: A New 21st Century Web Platform for Multilingual Communication in systemic Lupus Erythematosus and Antiphospholipid Syndrome. Oier Ateka-Barrutia[1], Adriane Rinsche[2], Maria Laura Bertolaccini[1], Munther A. Khamashta[1] and MORMED consortium[3]. [1]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom, [2]Language Technology Center Ltd., Kingston, United Kingdom, [3]EU

Background/Purpose: The internet is used nowadays as the preferred repository where people search for, access and publish information on any topic. However, language barriers prevent efficient international information exchange. This problem is further exacerbated by the fact that information for restricted and highly focused communities, e.g. communities with an interest in rare diseases, is not easily available or easy to find. An example of such a focused community is the community of individuals and stakeholders interested in lupus or antiphospholipid syndrome (Hughes Syndrome).

Language barriers impede the dissemination of interesting information and the exchange of valuable experiences between people from diverse cultures and backgrounds. Thus communication channels between the various stakeholders, e.g. between researchers and general practitioners (GPs), between specialists and GPs, and between GPs and patients, are cumbersome or even non-existent across countries due to language barriers of national languages and specific terminology.

Methods: MORMED (Multilingual Organic Information Management in the Medical Domain, www.mormed.eu) is a European Union-funded project that proposes a multilingual community platform combining Web 2.0 social software applications with semantic interpretation of domain-relevant content, enhanced with automatic translation capabilities and fine-tuned for a specific medical domain. It has been under development since March 2010 and piloted upon the community interested in lupus and Antiphospholipid Syndrome (Hughes Syndrome), involving researchers, medical doctors, general practitioners, patients and patient support groups, since spring 2012.

Organisations involved in this project include: King's College London (UK); Language Technology Centre Ltd. (UK); South East European Research Centre (Greece); Medical and Health Science Centre, University of Debrecen (Hungary); Institute for Clinical Chemistry and Laboratory Medicine, University Hospital Mainz (Germany); Hospital Clinic Barcelona (Spain).

Results: The project promotes online collaboration, where people contribute content and evaluate and exchange information resources, and it supports the diffusion of knowledge within multilingual social networks and online communities. Efficient machine translation, supported by interactive computer-aided human post-editing ensures that all content is seamlessly offered in English, Spanish, German and Hungarian, and at a high quality. Thus, new and innovative translation methods, tools and processes emerge, which set the service offerings of the MORMED service provider apart from those of other providers. A trial version of the platform is available at http://lupus.mormed.eu. The final version of the platform will be released by autumn 2012.

Conclusion: The MORMED platform is a multilingual web-based platform focused on the lupus and antiphospholipid syndrome community. High quality translation tools and resources in four languages (English, Spanish, German and Hungarian), along with social-network applications, are proposed as a new tool for information and experience exchange for clinicians, researches and patients involved in this field.

ACR/ARHP Poster Session C

Chronic Gout. Improvement According to Outcome Meaures in Rheumatology Domains in Daily Clinical Practice. Janitzia Vazquez-Mellado[1], Betsabé Serrano[1], Jaime Mendoza[2], Sergio Garcia-Mendez[1], V. Chantal Hernández[1], Virginia Pascual Ramos[2], Ruben Burgos-Vargas[1] and Marina Rull-Gabayet[2]. [1]Hospital General de Mexico, Mexico city, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background/Purpose: OMERACT has proposed domains to evaluate the effect of treatment in patients with acute and chronic gout. Their frequency, time to improve and percentage of change have not been evaluated in chronic gout patients under conventional treatment.

Methods: This is a prospective, longitudinal and observational cohort study. Since July 2010, we included all patients with Gout diagnosis (ACR criteria), attending for the 1st time to 2 Rheumatology departments. All signed informed consent and were evaluated by a rheumatologist in each visit. Variables: Demographic, clinical/biochemical related to gout and associated diseases, previous treatments. Individualized, regular treatment was prescribed in 1st visit as recommended (Life style modifications, NSAID, ULT, prophylaxis and treatment for associated diseases). Response to treatment evaluations: Number of: painful, swollen, limited to motion joints, tophi and flares/6mo. Main tophi size, VAS pain, general health (patient and physician), HAQ and uricemia. Statistical analysis. Chi square and paired t test.

Results: 178 Gout patients had been included in this prospective study. This report includes 93 patients with baseline and 6 mo evaluations. Males 97%, mean ± SD age, age at onset and duration of the disease: 49.7 ± 11.68; 35.82 ± 12.84 and 13.7 ± 10.46 years respectively; in 40%, disease duration was <3 ys. Tophaceous gout: 61% (29%, ≥ 5 tophi). Most had been irregularly treated, 58% previous auto-prescribed glucocorticoids. More frequent associated diseases: Hypertrygliceridemia 53%, hypertension 52% and obesity 30%. Allopurinol prescribed doses were: 341.9 ± 280.7 and 382.4 ± 215.9 mg/day (baseline and 6mo respectively); although, at 6 mo 69% had uric acid >6 mg/dL, the group improved significantly in 7/11 outcome domains (see table).

Response to treatment

Variable, mean ± SD	Baseline	6mo	P	>25% improvement (%)
Flares/6mo	2.6 ± 3.6	0.6 ± 1.2	0.000	72
Painful joints	2.4 ± 4.5	2.2 ± 4.7	NS	29
Swollen joints	0.53 ± 1.2	0.25 ± 0.8	0.025	21
Limited joints	4.2 ± 7.9	3.5 ± 7.01	0.000	23
Tophi	5.8 ± 8.75	5.8 ± 8.5	NS	10
Main tophi size, cm	3.6 ± 4.06	3.0 ± 3.7	0.004	22
HAQ	0.45 ± 0.6	0.29 ± 0.5	0.012	39
Serum uric acid, mg/dL	7.9 ± 2.2	7.1 ± 1.9	0.001	34
VAS pain	4.6 ± 3.2	3.7 ± 3.2	0.024	36
VAS health, patient	3.8 ± 2.9	3.3 ± 2.9	NS	39
VAS health, physician	3.7 ± 2.6	3.6 ± 2.3	NS	47

Variables according to OMERACT domains.

Conclusion: Before uricemia is controlled and as soon as the first 6 months, patients with longstanding and severe disease under regular treatment, improve significantly in 7/11 OMERACT domains, particularly acute flares and HAQ score.

What Factors Are Associated with Target Serum Urate Concentrations in Patients with Gout? Nicola Dalbeth[1], Meaghan House[1], Anne Horne[1], Keith J. Petrie[1], Fiona M. McQueen[1] and William Taylor[2]. [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Wellington, New Zealand

Background/Purpose: Long term serum urate (SU) lowering to a target of <6mg/dL is recommended for effective gout management. However, many studies have reported low achievement of SU targets. The aim of this study was to examine the clinical and psychological factors associated with SU targets in patients with gout.

Methods: Patients with gout for <10 years were recruited from primary and secondary care settings. SU target was defined as SU concentration <6mg/dL at the time of the study visit. Both clinical and psychological factors associated with SU target were analysed. The relationship between SU target and measures of gout activity including flare frequency in the preceding three months was also analysed.

Results: Of the 273 patients enrolled into the study, 89 (32.6%) had SU concentration <6mg/dL. Urate-lowering therapy (ULT) use was strongly associated with SU target ($p<0.001$). In those patients prescribed ULT (n=181), allopurinol dose, patient confidence to keep SU under control, female sex, and ethnicity were independently associated with SU target (Table). Other patient psychological factors and health-related behaviours, including adherence scores, were not independently associated with SU target in those taking ULT. Creatinine clearance, diuretic use, age, and body mass index were not associated with SU target. Patients at SU target reported lower gout flare frequency, compared with those not at target (p=0.03).

Table 1. Forward stepwise logistic regression analysis of factors associated with SU target in those taking ULT. Model included all factors with p<0.15 between groups in univariate analysis

Variable	OR	95% CI	p	Model
Female sex	4.34	1.65–11.44	0.003	Adjusted R^2=0.35, p<0.001
Mβori or Pacific ethnicity	0.19	0.07–0.52	0.001	
Allopurinol dose (per every 100mg/day)	2.22	1.43–3.44	<0.001	
Confidence to keep serum urate under control (per every point on 0–10 Likert scale)	1.025	1.007–1.044	0.006	

Excluded from model: adherence score, secondary care treatment, age, confidence to have blood tests at recommended frequency, confidence to take gout medications regularly, Brief Illness Perception Questionnaire (BIPQ) treatment control score, BIPQ understanding score.

Conclusion: ULT prescription and dosing are key modifiable factors associated with achieving SU target. These data support interventions focusing on improved use of ULT to optimise outcomes in patients with gout.

Oxidation of Urate to Allantoin by Myeloperoxidase in Gout. Lisa K. Stamp, Irada Khalilova, Mei Zhang, Rufus Turner and Anthony Kettle. University of Otago, Christchurch, Christchurch, New Zealand

Background/Purpose: Hyperuricaemia is critical for the development of gout and may play a pivotal role in the pathophysiology of hypertension, metabolic syndrome, and cardiovascular disease. Urate is a substrate for the neutrophil enzyme myeloperoxidase (MPO) and is oxidized to reactive intermediates that breakdown to allantoin. Monosodium urate (MSU) crystals promote a painful and acute inflammatory response within joints. Our hypothesis is that during inflammation MPO will be released from neutrophils and oxidize urate to reactive intermediates that will contribute to the adverse effects of hyperuricaemia. The aims of this study were to determine whether MPO is released from neutrophils and urate is oxidized in patients with gout and if these effects are attenuated by allopurinol.

Methods: 50 patients with gout and 37 healthy controls were recruited. 10/50 gout patients were commencing allopurinol and had samples collected at baseline and after 4 weeks of allopurinol. 33 of the remaining 40 patients were receiving allopurinol and these 40 patients had samples collected on one occasion only. Serum urate (SU) and plasma oxypurinol (OXYH) were measured by HPLC. Plasma MPO activity was measured by ELISA and allantoin by mass spectrometry.

Results: 43/50 gout patients were male, mean age was 58.2 years (30–91). Mean SU was 6.6mg/dl (3.0–10.6mg/dl). Mean allopurinol dose was 275.8mg/d (50–500mg/d). Plasma MPO activity was significantly higher ($p<0.001$) in patients with gout not receiving allopurinol (12.9 ng/nl IQR 10.5–41.2; n=18) compared to healthy controls (7.5 ng/ml IQR 4.7–9.4; n=37). Plasma allantoin concentrations were significantly higher ($p<0.001$) in patients with gout not receiving allopurinol (5.5 μM IQR 3.3–7.3; n=18) compared to healthy controls (2.0 μM IQR 1.4–3.5; n=37) (**Figure**). There was a significant correlation between MPO activity and plasma allantoin concentrations (r=0.54, $p<0.0001$; n=54). In the ten patients starting allopurinol there was a significant reduction after four weeks in SU (571 ± 48 μM vs. 480 ± 55 μM; $p<0.001$) and plasma allantoin (4.1 ± 1.6 μM vs. 2.9 ± 1.3 μM; $p<0.001$). Those patients receiving allopurinol with plasma OXYH concentrations >50μmol/l had significantly lower MPO protein (18.6 ng/ml IQR 12.3–33.2, n=31 vs. 30.9 ng/ml IQR 19.3–39.2, n=27; p=0.027) but paradoxically higher allantoin (9.9 μM IQR 6.0–12.5, n=31 vs. 4.6 μM IQR 2.9–6.5, n=29; $p<0.001$) compared to those with OXYH <50μmol/l.
Conclusion: During episodes of gout neutrophils release MPO which oxidizes urate. The interaction of MPO and urate will exacerbate oxidative stress in inflamed joints. At low concentrations, oxypurinol should dampen oxidative stress by lowering MPO and urate but at high concentrations it will increase oxidative stress presumably because hydrogen peroxide is also produced when allopurinol is metabolised by aldehyde oxidase.

Patterns of Gout Treatment and Related Outcomes in US Community Rheumatology Practices: the Relation Between Gout Flares, Time in Treatment, Serum Uric Acid Level and Urate Lowering Therapy. Max I. Hamburger[1], John RP Tesser[2], John L. Skosey[3], Allan H. Morton[4] and Karl M. Kilgore[5]. [1]Rheumatology Associates, Melville, NY, [2]AZ Arthritis Rheum Assoc, Paradise Valley, AZ, [3]Illinois Bone & Joint Institut, Chicago, IL, [4]Warren, MI, [5]Cetus Group, LLC, Hunt Valley, MD

Background/Purpose: Study patterns of gout treatment and related outcomes in US community rheumatology practices, specifically the relation between likelihood and severity of gout flares, time in treatment with current physician, serum uric acid (sUA) level and urate lowering therapy (ULT, which included, at any dosage level, allopurinol, febuxostat, pegloticase, probenecid).

Methods: Fifty practices completed retrospective chart abstraction on their 25 most recently seen patients with gout. Data, abstracted from all visits in 2010–2011 using standardized case report forms, included demographics, gout history, co-morbidities, sUA, gout treatment, and visit type (flare-related or follow-up). This report includes all data from the subset of the total cohort which was available at time of abstract submission. Final dataset will comprise 1,250 patients.

Data were analyzed using logistic regression, with visit type (coded as severe flare, mild/moderate flare, non-flare related) as an ordinal response variable, and 3 predictor variables: time in treatment with current rheumatologist at start of chart abstraction (TxTime: new patient vs. $\geq$ 2 months), ULT (absence vs. presence at time of visit) and sUA ($\geq$ 6.0 vs. < 6.0).

Results: The study population consisted of 479 gout patients from 21 sites, 79% male, 77% Caucasian, mean age 62 years, median disease duration 5.5 years.

Patients had a total of 2,460 visits during study period. Of these, 1,465 (59.6%) included all analysis variables and constitute the analysis sample. 273 (18.6%) of visits were flare-related. All 3 main effects were significant. Increased likelihood of a flare was associated with 1) shorter TxTime, 2) absence of ULT, and 3) higher sUA. Data are summarized in the table.

| | | | Type of Visit (%) | | | |
		n	Flare-Related: Severe	Flare-Related: Mild/ Moderate	Not Flare-Related	Any Flare vs. Non-Flare *p-value* OR (95% CI)
TxTime	NewPt.	565	9.6	16.6	73.8	<.001
	>2 mos.	900	5.2	8.7	86.1	1.62 (1.22–2.15)
ULT	Absent	277	18.1	29.2	52.7	<.001
	Present	1188	4.3	7.7	88.0	4.79 (3.52–6.52)
sUA	$\geq$ 6.0	729	9.9	15.9	74.2	.004
	<6.0	736	3.9	7.6	88.5	1.64 (1.21–2.22)

The only significant interaction effect was ULT by TxTime (p <.01). Patients who were already on ULT when referred to the current rheumatologist were no more likely to flare than the physician's current ULT patients. For patients not on ULT, however, new patients had triple the odds of flaring compared with current patients (OR=3.04, 95%CI=1.86–4.95).

Conclusion: Data depict aspects of current usage of gout therapy in US community practices and underscore importance of managing sUA levels. All patients regardless of sUA levels or treatment had some risk of flare, but risk was greatly mitigated by ULT therapy. These data suggest that failure to treat hyperuricemia in gout patients is associated with a greatly increased likelihood of a flare.

1905

Increase of Thyroid Stimulating Hormone in Patients On Febuxostat Treatment. Fernando Perez-Ruiz[1] and Ana M. Herrero-Beites[2]. [1]Hospital Universitario Cruces, Baracaldo, Spain, [2]Hospital de Gorliz, Gorliz, Spain

Background/Purpose: to evaluate whether TSH increases during febuxostat treatment and factors that could be implicated.

Methods: before starting febuxostat, patients had analysis at baseline and month 3 and 6 including serum urate, estimated glomerular filtration, liver function test, and TSH at baseline and 6-month visit. General characteristics and previous urate-lowering drugs, and concomitant diseases were registered. Patients with altered TSH at baseline were included if T4 was within normal range. All patients showing TSH out of the normal range (0.5–5.0 mU/ml) had to undergo T4 determination while on febuxostat and febuxostat was to be withdrawn if T4 was found not within normal limits. Results are shown as median and interquartile range. Febuxostat was started 80 mg eod for the first month and then all patients escalated to 80 mg/d until the 3-month visit. Febuxostat was then regulated to 80 mg eod for patients showing Sur <3 mg/dl and non-tophaceous gout and to 120 mg/d in patients with serum urate > 6 or > 5 and tophaceous gout.

Results: sixty-eight patients were included, mean age 62 years (51–73), time from onset 8 years (2–15), 59% with tophi present, serum urate 9.5 mg/dl (8.7–10.4) glomerular filtration 78 ml/min (52–101), TSH 2.34 U/ml (1.39–2.89). Three (4.4%) patients showed baseline TSH > UNL, but T4 was

within normal range. At 6-month 5, 3 patients were on 80 mg eod, 5 on 120 mg/d, and 60 on 60 mg/day, 62/68 (91%) showing serum urate < 6 mg/dl. TSH increased from 2.34 to 2.71(1.51–3.27, p<0.001), 5 (7.3%) showing TSH > UNL ranging from 5.56 to 8.92. None of these patients showed altered T4 levels or any symptom related to hypothyroidsm. There was a close correlation between baseline and final TSH (r2=0.75) (Figure 1). Multivariant analysis showed a that baseline TSH and the dose of febuxostat at 6-month visit were independently associated with TSH levels at 6-month visit (model R2=0.855), and with the change in TSH from baseline to 6-month (model R2= 0.396). No patient with baseline TSH < 3 showed TSH above UNL.
Figure 1. Correlation between baseline and final TSH

Conclusion: febuxostat increases TSH levels, both baseline TSH and febuxostat dose being associated with the increase. No patient with TSH above UNLs showed altered T4 levels or symptoms of thyroid dysfunction.

1906

Changes in Gout patient's Clinical Profile in the Last Two Decades. Fernando Perez-Ruiz[1] and Ana M. Herrero-Beites[2]. [1]Hospital Universitario Cruces, Baracaldo, Spain, [2]Hospital de Gorliz, Gorliz, Spain

Background/Purpose: to assess whether changes in the clinical profile of gout are observed in a large cohort of gout patients over the last 20 years.

Methods: a total number of 904 patients have been prospectively included in a cohort of patients with gout from June 1992 to June 2012 with a gout-specific dataset (time from onset, joints involved, flares per year, X-ray involvement, presence of tophi, previous urate-lowering therapy-ULT, ongoing ULT, average serum urate while on therapy) in addition to general characteristics of subjects (age, gender, body mass index), and comorbidities (diabetes, chronic kidney disease, hypertension, hyperlipidemia, renal lithiasis, previous vascular events). For statistical analysis, patients have been stratified in two decades, from 1992 to 2002 (349 patients) and from 2002 to 2012 (555 patients).

Results: As for the second decade, an statistically significant increase in age (57±12 vs. 61±13 years), in the number of flares (2.8±0.1 vs. 4.0±1.2 per patient-year), in BMI (27.5±3.2 vs. 28.2±4.2 kg/sqm) were observed. Serum urate at baseline and time from onset of gout to referral were not statistically different. Polyarticular–> 4 joints–involvement (29.8 vs. 39.5%) and presence of subcutaneous tophi (26.6 vs. 36.4%) were significantly more frequent in the second decade, although the percentage of patients naive to ULT (63.8 vs. 59.3%) or allergic to allopurinol (4.9 vs. 5.7%) were similar. Hypertension (33.4 vs. 51.9%), diuretic prescription (17.8 vs. 30.8%), and previous vascular events (20.7 vs. 31.8%) were significantly more common in the second decade. Although the mean clearance of creatinine were not statistically different, the percentage of patients with CKD stages 3–5 was close to significance (20.1 vs. 25.6%, p=0.059.

Interestingly, while the mean baseline serum urate was numerically higher, the mean reduction and the percentage reduction from baseline were greater in the second decade (3.4 vs. 3.7 mg/dl and 38 vs. 45%, respectively), so that the percentage of patients averaging serum urate < 6 mg/dl while on follow-up remained pretty good (87 and 89%, respectively). This can reflect a trend to more intensive therapy due to more severe disease in the second decade.

Conclusion: the profile of patients with gout seems to have changed over the last two decades as they are older, more commonly hypertensive, on diuretics, with a previous vascular event, and they show more commonly tophaceous and polyarticular gout.

Pharmacological Management of Gout in Italy in the Years 2005–2009: A Nationwide, Population-Based Study. Lorenzo Cavagna[1], Gianluca Trifirò[2], Roberto Caporali[3], P. Morabito[2], C. Ferrajolo[4], S. Pecchioli[5], M. Simonetti[5], G. Medea[6], C. Cricelli[7], A. Caputi[2], G. Mazzaglia[5] and Carlomaurizio Montecucco[8]. [1]University and IRCCS Foundation Policlinico S. Matteo, Pavia, Italy, [2]University of Messina, Italy, [3]Division of Rheumatology, IRCCSPoliclinico S. Matteo Foundation, Pavia, Italy, [4]Second University of Naples, Naples, Italy, [5]Italian College of General Practitioners, Italy, [6]Italian college of General Practitioner, Italy, [7]Italian college of General Practitioner, Pavia (Italy), Italy, [8]University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background/Purpose: Despite the increasing interest on gout, only few nationwide drug utilization studies have been conducted on this topic. The aim of this study was to investigate the Italian prescribing pattern of medications for gout in the years 2005–9

Methods: The data source of the study was the national Database of the Italian College of General practitioner, covering about 1.5 million patients from all around Italy. Patients with incident gout (years 2005–9) were identified using specific ICD9-CM codes and related key words for free text search. In this cohort of patients, we measured the yearly prevalence of use of the following drugs: allopurinol (ATC: M04AA01); colchicine (M04AC01); NSAIDs (M01A*). Moreover, systemic corticosteroids (H02*) were taken into account, because frequently used during acute attacks. Drugs not marketed in Italy, or not reimbursed by National Health System (probenecid, sulfinpirazone and benzbromarone) were not taken into account. For allopurinol rate and predictors of persistence and adherence to the treatment have been evaluated too.

Results: During the study period, 3,069 patients with incident gout were identified. Allopurinol prescription in these patients decreased from 45.2% in 2005 to 41.1% in 2009. Among drugs for the acute attack of gout, NSAIDs (from 41.9% in 2005 to 39.8% in 2009) were significantly more prescribed than colchicine (from 4.5% in 2005 to 4.9% in 2009). Corticosteroids were prescribed in a significant proportion of patients (from 12.3% in 2005 to 12.4% in 2009) during the whole study period. Only 22.7% of patients continued allopurinol after three months from the beginning of the therapy (6.6% after 6 months, 1.6% after one year). For allopurinol, the proportion of days covered (PDC) was on average equal to 39%. The proportion of patients with high adherence to the treatment (PDC >80%) increased with advancing age and was significantly higher in males. Hypertension, obesity, cerebrovascular diseases, congestive heart failure and sUA levels > 9mg/dl, enhanced allopurinol treatment adherence

Conclusion: to our knowledge, this is the first drug-utilization study on pharmacological management of gout in Italian general population. Our results were quite similar to that recently described in US population, although in this study the prevalence of colchicine (16.7%) and corticosteroids (21%) prescription was higher than those we observed. Our data show very low levels of persistence and adherence to allopurinol treatment; non-adherence was particularly common in younger patients, with lower serum urate levels and burden of comorbidities, as suggested in a recent survey. Clinicians should motivate low risk patients to increase the level of adherence to the treatment for the prevention of gout

Wechalekar[10], Daniel Aletaha[11], Claire Bombardier[9], Rachelle Buchbinder[12], Loreto Carmona[13], Christopher J. Edwards[14], R. Landewe[15] and Désirée van der Heijde[16]. [1]Hospital General Universitario de Alicante, Alicante, Spain, [2]Hospital General de Elda, Alicante, Spain, [3]University of British Columbia, Vancouver, BC, [4]Royal Melbourne Hospital, Melbourne, Australia, [5]University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [6]St. Mary's Hospital, Isle of Wight, United Kingdom, [7]Maastricht University Medical Centre, Maastricht, Netherlands, [8]Atrium Medical Center, Heerlen, Netherlands, [9]University of Toronto, Toronto, ON, [10]Flinders University School of Medicine, Adelaide, Australia, [11]Medical University of Vienna, Vienna, Austria, [12]Monash Department of Clinical Epidemiology at Cabrini Hospital, Department of Epidemiology and Preventive Medicine, Monash University, Malvern, Australia, Malvern, Victoria, Australia, [13]Universidad Camilo José Cela, Villanueva de la Cañada, Spain, [14]University Hospital Southampton, Southampton, United Kingdom, [15]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [16]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The 3e (Evidence, Expertise, Exchange) Initiative is a multinational collaboration that aims to promote evidence-based medicine in rheumatology. The 2011–12 3e Initiative aimed to develop evidence-based recommendations for the diagnosis and management in patients with gout by integrating evidence and the expert opinion of a broad international panel of rheumatologists.

Methods: 474 rheumatologists from 14 countries participated. Using a formal voting process, a panel of 78 rheumatologists developed a list of 10 clinical questions, 9 regarding the diagnosis and management of gout, and 1 focused on the management of asymptomatic hyperuricaemia. Bibliographic fellows undertook a systematic literature review for each clinical question. A literature search was performed using MEDLINE, EMBASE, Cochrane CENTRAL, and abstracts from 2010–11 EULAR and ACR meetings. Relevant studies were retrieved for data extraction and synthesis, and assessment of risk of bias. Using this evidence, rheumatologists from each country developed a set of national recommendations. Finally, multinational recommendations were formulated and assessed for agreement among the participants and the potential impact on clinical practice.

Results: In total, 42,823 references were identified, from which 325 studies were included in the systematic reviews. Combining this evidence and clinical expertise, the initial questions led to a set of 10 recommendations. Oxford Levels of Evidence were applied to each recommendation. One recommendation related to the potential role of clinical and laboratory data for the diagnosis of gout in the absence of crystal identification. Two recommendations considered screening for, and the management of cardiovascular and renal co-morbidities. Six recommendations focused on different aspects of the management of gout, with one recommendation considering a suitable treatment target and how to monitor patients. The last recommendation regarded the management of asymptomatic hyperuricaemia in order to prevent gout and renal and cardiovascular outcomes. The level of agreement by participants with the recommendations ranged from 8.1 to 9.2 (mean 8.7) on a 1–10 point scale with 10 representing full agreement. 17% (range 7.5–31.5%) of rheumatologists reported that the final set of recommendations would change their practice, and 79% (range 60.8–88.7%) felt that these recommendations were in accordance with their current practice.

Conclusion: Ten recommendations on the diagnosis and management of gout were established. They are evidence-based and supported by a large panel of rheumatologists from 14 countries, thus enhancing their utility in clinical practice.

1909

Use of Uric Lowering Therapies within a Large Health Care System.
Robert A. Overman[1], Brian F. Mandell[2] and Chad L. Deal[3]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]The Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH

Background/Purpose: Guidelines for initiating urate lowering therapy (ULT) in the treatment of gout recommend treatment to a target serum urate (SUA) level of ≤6mg/dl with monitoring of SUA.

Methods: We reviewed the use of ULT with allopurinol (allop) or febuxostat (febux) in a large health care system between June 2010 and April 2012. Eligible subjects were >18 years at ULT initiation, had a diagnosis of gout, and had ≥ two outpatient prescriptions for a ULT after June 1, 2010. Demographics, ULT dose, prescribing providers, diagnosis, and SUA levels were collected from our *EPIC* EMR using Explorys Inc. proprietary software. A study author checked agreement of data between the subjects EMR and the Explorys data in random cases within the study population. Cleveland Clinic IRB approval was obtained.

Results: 1,870 subjects were eligible for inclusion: 74.1% male, mean age 62.8 (SD 14.2). Study subjects had been prescribed allop alone (82.5%, n=1543), febux alone (5.9%, n=188), or both (11.6%, n=217). Following initiation of ULT, 68.8% of subjects (n=1286) had a repeat SUA within our health system: 56.1% within 6 months and 65.4% within 12 months of their initial prescription. After initiation of ULT, 45.9% of subjects achieved a level of ≤6mg/dl, 22.0% had levels between 6.1–7.0mg/dl, and 32.1% never had a level ≤7.0mg/dl. There were 523 subjects on allop with SUA measurements ≥7.0mg/dl, yet only 2.3% were prescribed a daily dose of >300mg. Subjects treated by a rheumatologist (60.6%) vs non-rheumatologist (42.0%) were more likely to achieve a SUA ≤6mg/dl, odds ratio 2.1 (95% CI 1.7–2.7). The starting dose of allop was <100mg (1.0%), 100mg (59.6%), 101–300mg (38.8%). For subjects prescribed allop the maximum daily dose was ≤ 100mg in 32.4% and 101–300mg in 65.0% of subjects. Maximum dose of allop was greater than 300mg in 2.7% of subjects seen by a rheumatologist and 2.6% of non-rheumatologists. The starting dose of febux was ≤ 40mg in 87.9% of subjects. Of those who did not achieve a SUA level ≤6.0mg/dl, 38.4% had ULT adjusted to a higher dose (ULT adjustment to target may not have been completed by the time of analysis). Only 11.3% of subjects started on febux had documented allop intolerance. A statistically significant difference was found in the mean creatinine level closest to the initiation of ULT (1.3 allop vs 1.5 febux p<0.001) which may indicate renal insufficiency as a perceived reason for febuxostat.

Conclusion: Only 45.9% of patients started on ULT achieved recommended SUA levels, only 38.4% of those not meeting target had a documented dose adjustment and > 97% of patients on allop were on < 300mg per day. This demonstrates a persistent care gap in the treatment of gouty arthritis.

1910

Regulation of Microrna 223 Expression in a Gouty Arthritis.
Gianina Statache[1], Ashleigh-Ann Rainey[1], Seth Masters[2], Andra Balanescu[3], Iain B. McInnes[1] and Mariola Kurowska-Stolarska[4]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Trinity College Dublin, Dublin, United Kingdom, [3]University of Medicine and Pharmacy, Bucharest, Romania, [4]Institute of Infection,Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom

Background/Purpose: Gout is an inflammatory chronic disease caused by deposition of uric acid crystals in the joint and connective tissues causing pain and disability. Current data suggest that gout is mediated by IL-1b that is produced due to the activation of the inflammasome pathway by uric acid crystals. In addition, neutrophil influx in the joint is the key initiator of a gout flare. miR-223 has been identified as a masterswitch molecule limiting neutrophil activation. In addition, we showed previously that this miR negatively regulates NLRP3 (an inflammasome component) and IL-1b production in human macrophages. To investigate miR-223 expression and regulation in monocytes and neutrophils of gout patients.

Methods: CD14+ cells and neutrophils were isolated from gout patients (n=10) and healthy donors (n=6) peripheral blood using CD14 microbeads and polylymphoprep gradient buffer, respectively. CD14+ from healthy donors were stimulated with LPS (10 ng/ml) IL-1beta (100–10ng/ml), IL-6 (100 ng/ml), TNF alpha (10–100ng/ml) or monosodium urate crystals MSU (1mg-1ug/ml) for different time points (24–72h). Cells were harvested and miRNA extracted. Expression of miR-223 and endogenous control snRNA U1 was assessed by qPCR.

Results: miR-223 expression in peripheral blood monocytes of patients with chronic gout was lower compared to healthy controls. This suggest that overproduction of IL-1b in chronic disease might be partially mediated by low levels of miR-223. In vitro studies revealed that MSU, IL-1b, TNFa and IL-6 significantly inhibited miR-223 expression in monocytes in all time points (24–72h). In contrast, IL-10 strongly increased miR-223 expression. Interestingly, the levels of miR-223 in peripheral blood neutrophils were higher in gout patients compared to healthy controls

Conclusion: A decrease in miR-223 expression in monocytes of chronic gout patients may contribute to uric acid crystals induced inflammasome activation and chronicity of disease. Upregulation of miR-223 expression in gout neutrophils may reflect the activation of mechanisms that limits neutrophils activation and lead to the resolution of gout flares.

1911

Efficacy and Safety of Canakinumab Vs Triamcinolone Acetonide in Patients with Gouty Arthritis Unable to Use Nonsteroidal Anti-Inflammatory Drugs and Colchicine, and On Stable Urate Lowering Therapy (ULT) or Unable to Use ULT.
T. Bardin[1], A. So[2], R. Alten[3], M. Bloch[4], M. R. John[5], G. Krammer[5], J. M. Nebesky[5], A. Tao[6] and N. Schlesinger[7]. [1]Service de Rhumatologie, Hôpital Lariboisière, Paris, France, [2]Centre Hospitalier Universitaire Vaudois, University of Lausanne, Lausanne, Switzerland, [3]Charité Univ Medicine, Berlin, Germany, [4]Holdsworth House Medical Practice, Sydney, Australia, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [7]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Background/Purpose: The primary treatment goals for gouty arthritis (GA) are rapid relief of pain and inflammation during acute attacks, and long-term hyperuricemia management. A *post-hoc* analysis of 2 pivotal trials was performed to assess efficacy and safety of canakinumab (CAN), a fully human monoclonal anti-IL-1β antibody, vs triamcinolone acetonide (TA) in GA patients unable to use NSAIDs and colchicine, and who were on stable urate lowering therapy (ULT) or unable to use ULT.

Methods: In these 12-week, randomized, multicenter, double-blind, double-dummy, active-controlled studies (β-RELIEVED and β-RELIEVED II), patients had to have frequent attacks (≥3 attacks in previous year) meeting preliminary GA ACR 1977 criteria, and were unresponsive, intolerant, or contraindicated to NSAIDs and/or colchicine, and if on ULT, ULT was stable. Patients were randomized during an acute attack to single dose CAN 150 mg s.c. or TA 40 mg i.m. and were redosed "on demand" for each new attack. Patients completing the core studies were enrolled into blinded 12-week extension studies to further investigate on-demand use of CAN vs TA for new attacks. The subpopulation selected for this *post-hoc* analysis was (a) unable to use NSAIDs and colchicine due to contraindication, intolerance or lack of efficacy for these drugs, and (b) currently on ULT, or contraindication or previous failure of ULT, as determined by investigators. Subpopulation comprised 101 patients (51 CAN; 50 TA) out of 454 total.

Results: Several co-morbidities, including hypertension (56%), obesity (56%), diabetes (18%), and ischemic heart disease (13%) were reported in 90% of this subpopulation. Pain intensity (VAS 100 mm scale) was comparable between CAN and TA treatment groups at baseline (least-square [LS] mean 74.6 and 74.4 mm, respectively). A significantly lower pain score was reported with CAN vs TA at 72 hours post dose (1st co-primary endpoint on baseline flare; LS mean, 23.5 vs 33.6 mm; difference −10.2 mm; 95% CI, −19.9, −0.4; P=0.0208 [1-sided]). CAN significantly reduced risk for their first new attacks by 61% vs TA (HR 0.39; 95% CI, 0.17–0.91, P=0.0151 [1-sided]) for the first 12 weeks (2nd co-primary endpoint), and by 61% vs TA (HR 0.39; 95% CI, 0.19–0.79, P=0.0047 [1-sided]) over 24 weeks. Serum urate levels increased for CAN vs TA with mean change from baseline reaching a maximum of +0.7 ± 2.0 vs +0.1 ± 1.8 mg/dL at 8 weeks, and +0.3 ± 2.0 vs +0.2 ± 1.4 mg/dL at end of study (all had GA attack at baseline). Adverse Events (AEs) were reported in 33 (66%) CAN and 24 (47.1%) TA patients. Infections and infestations were the most common AEs, reported in 10 (20%) and 5 (10%) patients treated with CAN and TA respectively. Incidence of SAEs was comparable between CAN (gastritis,

gastroenteritis, chronic renal failure) and TA (aortic valve incompetence, cardiomyopathy, aortic stenosis, diarrohea, nausea, vomiting, bicuspid aortic valve) groups (2 [4.0%] vs 2 [3.9%]).

Conclusion: CAN provided superior pain relief and reduced risk of new attack in highly-comorbid GA patients unable to use NSAIDs and colchicine, and who were currently on stable ULT or unable to use ULT. The safety profile in this *post-hoc* subpopulation was consistent with the overall β-RELIEVED and β-RELIEVED II population.

1912

Colchicine, As Assessed by Target Joint Pain Scores, Is Effective At 16 Hours in Patients with Acute Gout Flares. Suman Wason, Thomas Lauterio, Steve Crockett and Matthew W. Davis. URL Pharma, Philadelphia, PA

Background/Purpose: The management of patients with gout remains suboptimal, leading to increasing frequency and severity of recurrent flares that eventually lead to joint destruction and deformity, with patients experiencing a severely compromised quality of life. Colchicine is considered the standard of care in the treatment and prophylaxis of patients with gout flares. The AGREE (Acute Gout Flare Receiving Colchicine Evaluation) trial established that low-dose (LD) colchicine is as effective as high-dose (HD) colchicine in achieving flare control, by reducing the median time to 50% joint pain reduction (HD colchicine 24.5 hrs; LD colchicine 24 hrs). Patients in both colchicine grps also achieved significant reductions ($\geq$2 units) in mean pain scores relative to placebo (PBO) at 24 and 32 hrs after the initial dose. This post-hoc analysis from AGREE examined improvement in target joint pain scores at 16 hours after the initial dose versus PBO, time-to-response, and use of rescue medication.

Methods: 184 patients experiencing an acute gout flare (ACR criteria) were randomly assigned to HD colchicine (4.8 mg: 1.2 mg initially, then 0.6 mg q1hr × 6; n=52), LD colchicine (1.8 mg: 1.2 mg initially, then 0.6 mg at 1 hr; n=74), or PBO (n=58). Mean baseline pain scores were 6.8 for PBO and 6.9 for both HD and LD colchicine (0 to 10 Likert scale)After confirmation of gout flare, pain intensity scores, as well as adverse events (AEs), were recorded over the next 72 hrs. Rescue medications, such as NSAIDs, were permitted if intolerable pain continued after taking at least 1 dose of study drug. Uric acid–lowering therapy was not to be discontinued at the onset of flare.

Results: At 16 hrs there was a significant treatment response in the LD colchicine grp (1.7 unit reduction from baseline in target joint pain score; P=0.0366) versus PBO. After 24 hours, reductions in target joint pain scores were consistently superior to PBO (mean 2.0 and 2.2 unit reductions in the HD and LD colchicine grps, respectively; 0.7 unit reduction for PBO). For time-to-response, the median time to 50% reduction from baseline in target joint pain score was 32 hrs for HD colchicine and 24.5 hrs for the LD colchicine grp. An insufficient number of patients in the PBO grp achieved this target. A significantly greater number of patients (P=0.0273) assigned to placebo used rescue medication through the 24 hour post-dose assessment compared to those received LD colchicine (50% and 31.1%, respectively). The time to the use of rescue medication was also earlier in the PBO grp (24 hrs) versus 36.5 hrs for LD colchicine). Rates of AEs were similar between LD and PBO grps, but greater than PBO in the HD grp.

Conclusion: This study establishes that LD colchicine provides significant pain relief as soon as 16 hr after dosing. By contrast, NSAIDs commonly prescribed for gout flares (Naprosyn, Indomethacin) have shown significant pain reduction by 48 hrs at the earliest. In addition, in this study, use of rescue medication was significantly lower in LD vs.PBO grps while the safety profile for LD colchicine was comparable to PBO. These results further support the use of low dose colchicine for treatment of acute gout flares.

1913

Complete Tophus Response in Patients with Chronic Gout Initiating Pegloticase Treatment. Michael A. Becker[1], Neil J. Gonter[2], Janet E. Pope[3], Raymond L. Malamet[4] and Herbert S. B. Baraf[5]. [1]University of Chicago, Chicago, IL, [2]Rheumatology Associates of North Jersey, Teaneck, NJ, [3]Univ of Western Ontario, London, ON, [4]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [5]Arthritis & Rheumatism Associates, Wheaton, MD

Background/Purpose: Pegloticase, a recombinant modified mammalian uricase that acts via enzymatic degradation of uric acid to allantoin, is approved in the US for the treatment of refractory chronic gout (RCG). Of 212 patients with RCG enrolled in two 6-month randomized, placebo-controlled trials (RCTs) of q2wk or q4wk pegloticase therapy, 155 (73%) had baseline tophi. All tophi were assessed during RCT and subsequent open-label treatment (OLE; up to 2.5 additional years) with regard to the time course of complete resolution by serial, quantitative digital photography evaluated by blinded and experienced central readers. Patients treated with placebo during the RCTs provided an additional opportunity to evaluate long-term tophus response upon initiation of pegloticase in the OLE study.

Methods: Photographs of patients' hands and feet (and up to 2 other sites of tophi) were made at baseline, at weeks 13, 19 and 25 of RCT treatment, and at weeks 13, 25, 53, 77, 101 and final visit of the OLE. Each patient had up to 5 measurable tophi and 2 additional tophi tracked. A complete response (CR) was defined as 100% decrease in the area of the target tophus (or complete disappearance of the additional tophi) in the absence of any new or enlarging tophi.

Results: CR of at least one tophus was significantly more frequent among patients receiving pegloticase q2wk vs. placebo at 13 weeks of treatment and at all subsequent times of measurement in the RCTs. Tophus CR was achieved by 40% of patients after 6 months of q2wk pegloticase (vs. 7% with placebo; p=0.002). Although more patients treated with q4wk pegloticase had tophus CR (21%) vs placebo (7%) at the final RCT visit, this difference was not statistically significant. During the RCTs, 21 patients showed a new incident tophus (all among patients manifesting baseline tophi). New tophi were seen in 6% (4/62), 11% (7/64) and 35% (10/29) of patients receiving biweekly pegloticase, monthly pegloticase, and placebo treatment, respectively.

After 1 year in the OLE study, CR of at least one tophus was recorded for 74% (50/68) of patients receiving q2wk pegloticase. The Kaplan Meier curve below shows the time to first tophus CR for patients treated with placebo during the RCT followed by pegloticase in the OLE study. Despite receiving no urate-lowering therapy during the 6 months of RCT enrollment, approximately one-half of placebo-treated patients had a tophus CR within 6 months of initiation of q2wk pegloticase treatment in the extension study.

Graph: Time to tophus CR for patients who received placebo during the blinded trials and initiated pegloticase (Q2 week and Q4 week) in the OLE study
Conclusion: A significant rate of CR of at least one baseline tophus was achieved for patients treated with biweekly pegloticase within 13 weeks (compared with placebo treatment). Tophus CR rates over time are consistent and rapid for patients initiating pegloticase in both the RCTs and OLE study. The proportion of patients with a tophus CR continued to increase over time for up to 2.5 years of additional pegloticase treatment.

The Diagnosis and Management of Gout in 2012: Survey of US and Canadian Rheumatologists. John J. Cush[1] and Robert T. Keenan[2]. [1]Baylor Research Institute, Dallas, TX, [2]Duke University, Durham, NC

Background/Purpose: The introduction of novel treatment modalities for gout has escalated interest and education on this topic. Although gout is the most common inflammatory arthropathy encountered, it still remains a diagnostic and therapeutic challenge for many. We surveyed a large cohort of North American Rheumatologists (Rheums) for their views, practices and treatment of gout.

Methods: 2401 adult Rheums from the USA and Canada (138) were invited (via emails) to partake in an online survey in early 2012. The survey included 39 questions regarding respondent demographics, practice type, diagnosis of gout, choice of therapy and safety concerns. On-line responses were tabulated using the CSV file downloads to Excel spreadsheets and verify data combing for outliers.

Results: There were 318 respondents (13.2% response), 78.8% male; with a mean age of 57.7 yrs. Responses came from private practice (56%), academic (31%), government (4%); with an overall mean of 25 years in practice (52% > 25 yrs). They see an average of 5.3 gout patients per week and follow 86.4 gout patients in their practice, with 62% seen every 3–6 months. 92% can see an acute gout referral in less than 1 week. Only 8% are followed for asymptomatic hyperuricemia. 22% for acute gout/flare, 70% for intercritical or chronic inactive gout. 78% are PCP referred, 2/3 for acute gout and 24% for hospitalized gout. 37% view gout a metabolic disorder and 34%as a uric acid overload disorder. For the diagnosis of gout, Crystal ID (98%) and clinical hx (96%) were most important and alcohol and family history (40%) least important. 77% have a polarizing microscope and 96% routinely follow urate levels. Indications for urate lowering therapy (ULT) included tophi (72%), >2 attacks/yr (71%) or gouty erosions (68%). Uricosurics were seldom chosen (<20%) and allopurinol therapy predominated (>95%). Surprisingly 28% felt no allopurinol dose adjustments were needed with creatinine levels of 2.5–3.5mg/dl. When initiating ULT, prophylaxis with colchicines (90%) was preferred over NSAID (43%) or prednisone (16%). The primary goal of Rx is attack prevention (94%) more so than urate level < 6.0 (66%). However, acute gout is preferably managed with steroids (86%), NSAIDs (82%) over colchicine (65%). 57% use less Colcrys and 47% use more NSAID and prednisone. Febuxostat is indicated with allopurinol failure/intolerance (93%) or sensitivity (82%). Pegloticase is indicated for allopurinol failure/sensitivity (69%/44%), febuxostat failure/intolerance (65%) or multiple tophi or attacks (58%/46%). Overall, 76.5% achieve a urate < 6.0 and 23% have tophi. Most disappointing is patient noncompliance (78%), management by nonrheumatologist (54%) and confusion between hyperuricemia and gout (41%). The greatest safety concerns were for NSAID or colchicine with renal dz (98% or 54%) and allopurinol with azathioprine (86%). While cherries, febuxostat and allopurinol were ranked as safest, NSAIDs and pegloticase had the most safety concerns.

Conclusion: Tradition continues to dominate Rheum practice standards in gout with the majority relying on MSU crystal ID and clinical features for diagnosis. Prevention of attacks, targeting urate < 6.0, and reliance on ULT continue to guide management.

1915

Elevated Serum Homocysteine Levels Were Related Not with Serum Uric Acid Levels but with Decreased Renal Function in Chronic Gouty Patients. Sang Tae Choi[1], Jung-Soo Song[2], Jin Su Kim[1], Eun-Jin Kang[3], Kwang-Hoon Lee[4] and You-Jung Ha[5]. [1]Chung-Ang University School of Medicine, Seoul, South Korea, [2]Chung-Ang University College of Medicine, Seoul, South Korea, [3]Busan Medical Center, Busan, South Korea, [4]Dongguk University Ilsan Hospital, Goyang, South Korea, [5]Kwandong University college of Medicine, Goyang, South Korea

Background/Purpose: Hyperhomocysteinemia, which is related with cardiovascular diseases and metabolic syndrome, is regarded as one of the important factors in endothelial cell damage processes. It is well known that Gout is associated with metabolic syndrome, and cardiovascular diseases are major causes of mortality that are found in gouty patients. However, there are few reports about the serum homocysteine levels in gouty patients, and

moreover their results showed discrepancy. In this study, we investigated whether or not serum homocysteine levels are elevated in the patients with chronic gout and which factors are associated with the elevated homocysteine levels.

Methods: This cross-sectional study included 91 male patients with chronic gout and 97 age-matched healthy male controls. The averages of age were 51.19 ± 15.08 and 51.57 ± 17.01 years old, respectively. Serum homocysteine, uric acid (UA), blood urea nitrogen (BUN), creatinine (Cr) and other laboratory findings were tested for all participants. Serum homocysteine levels were measured by a competitive immunoassay using direct chemiluminescent (Siemens Centaur Immunoassay Systems, USA). The estimated glomurular filtration rate (eGFR) was uptained using modification of diet in renal disease (MDRD) formula, then the stages of chronic kidney disease (CKD) were classified according to eGFR levels as follows; stage 1, more than 90 mL/min/1.73m^2: stage 2, 60–89 mL/min/1.73m^2: stage 3, 30–59 mL/min/1.73m^2: stage 4, 15–29 mL/min/1.73m^2: stage 5, less than 15 mL/min/1.73m^2.

Results: The chronic gout group were not significantly different from the control group in serum uric acid levels (6.15 ± 2.23 mg/dL vs 5.82 ± 1.22 mg/dL, $p = 0.224$). However, the patients with chronic gout showed much higher serum homocysteine levels than healthy controls (13.96 ± 4.05 μmol/L vs 12.67 ± 3.52 μmol/L, $p = 0.021$). Serum homocysteine levels showed the positive correlations with serum BUN and Cr levels, and the negative correlation with eGFR ($r = 0.429, p < 0.001; r = 0.435, p < 0.001; r = -0.413, p < 0.001$, respectively) in the chronic gouty group. However, serum homocysteine levels are uncorrelated with serum uric acid levels or cholesterol profiles. The patients at stages 1 or 2 of CKD had significantly lower serum homocysteine levels than the patients at stage 3 of CKD (12.99 ± 4.81 μmol/L, 13.17 ± 2.97 μmol/L, and 17.45 ± 4.68 μmol/L, $p < 0.001$). Serum homocysteine levels were not different between the groups that are treated with allopurinol and with benzbromarone. In multiple linear analyses, serum homocysteine level was affected by eGFR ($\beta = -0.385, p < 0.001$), however, was not affected by the serum uric acid level.

Conclusion: Serum homocysteine levels were higher in the male patients with chronic gout than in the healthy male controls. Hyperhomocysteinemia in gouty patients could be related not with serum uric acid levels, but with decreased renal function. Types of uric acid lowering agents did not affect the serum homocysteine levels.

1916

Serum Uric Acid As a Biomarker for Mitigation of Infusion Reactions in Patients Treated with Pegloticase for Refractory Chronic Gout. Herbert S. B. Baraf[1], Robert A. Yood[2], John S. Sundy[3], Faith D. Ottery[4] and Michael A. Becker[5]. [1]Arthritis & Rheumatism Associates, Wheaton, MD, [2]Reliant Medical Group, Worcester, MA, [3]Duke University Medical Center, Durham, NC, [4]Savient Pharmaceuticals, Inc., East Brunswick, NJ, [5]University of Chicago, Chicago, IL

Background/Purpose: Using data pooled from the randomized, placebo-controlled trials (RCTs) of pegloticase, post-hoc analyses of urate-lowering, antibody titers and the patterns of infusion-related reactions (IRs) were carried out to evaluate predictors of risk for IRs. These analyses eventually led to guidance on monitoring uric acid (UA) levels as a biomarker of response to therapy[1]. Here we describe the basis and outcomes of these risk mitigation analyses.

Methods: The 2 RCTs enrolled patients at 56 centers in the US, Mexico and Canada. Patients were > 18 yrs of age, had baseline UA ≥8 mg/dL and at least one of the following: ≥3 self-reported gout flares during the prior 18 mos; ≥1 tophi; or gouty arthropathy; and contraindication to allopurinol or failure to normalize UA during ≥3 mos of treatment at the maximum appropriate dose. Pegloticase was administered as 8 mg infusions q2wks or q4wks; plasma UA was sampled at baseline and immediately preceding each q2wk infusion. All patients received prophylaxis for IRs and flares. A responder was defined by plasma UA <6 mg/dL for 80% of time during mos 3 and 6. IR was defined as any adverse event occurring during or within 2 hours after infusion.

Results: IRs were experienced by 26% and 42% of patients receiving pegloticase q2wks and q4wks, respectively. Post-hoc assessments revealed that the majority of these IRs (91% of IRs with q2wk dosing and 71% with q4wk dosing) occurred when UA exceeded 6mg/dL--suggesting that loss of urate-lowering response was predictive of risk for IRs. This relationship was

not apparent to investigators during the 6 mos of RCT treatment because they were blinded to the pre-infusion UA levels.

Multiple benefit/risk scenarios were tested using UA concentration cut points and IRs to determine the most effective stopping rule for maximizing both safety and efficacy. The Table shows the number of patients reaching the two endpoints in the pooled trial population (no stopping rules) and the number of patients that would have reached these 2 endpoints if the specific stopping rule had been applied to the RCT population. Among the options tested, discontinuation of drug when patients had 2 consecutive serum UA levels >6 mg/dL appears to reduce the proportion of patients with IRs from 26% (observed) to 14% (estimated) with little impact on efficacy.

Table. Risk mitigation scenarios for patients treated with q2wk pegloticase in Phase 3 placebo-controlled trials

Stopping Rule	Observed Number of Pts with IRs Pooled N=85n (%)	Observed Number of Pts Meeting Responder Criteria Pooled N=85n (%)
No Stopping Criteria	22 (26%)	36 (42%)
One SUA >6 mg/dL	7 (8%)	31 (36%)
One SUA >7 mg/dL	7 (8%)	32 (38%)
One SUA >8 mg/dL	9 (11%)	33 (39%)
Two consecutive SUA >6 mg/dL	12 (14%)	35 (41%)
Two consecutive SUA >7 mg/dL	12 (14%)	35 (41%)
Two consecutive SUA >8 mg/dL	13 (15%)	36 (42%)

Conclusion: Post-hoc assessments from the 2 RCTs provided valuable information on the relationship between UA levels and IR risk that was not available during the trials. Multiple benefit/risk analyses informed the recommendation that patients discontinue pegloticase when serum UA is >6 mg/dL, particularly at 2 consecutive time points. Ongoing post-marketing surveillance will be important to assess the risk of IRs in clinical practice and adherence to these recommendations.

Long-Term Follow-up of IgG4-Related Diseases Presenting with Lacrimal and Salivary Gland Involvement. Hiroki Takahashi[1], Motohisa Yamamoto[1], Tetsuya Tabeya[1], Chisako Suzuki[1], Yasuyoshi Naishiro[1], Yasuhisa Shinomura[1] and Kohzoh Imai[2]. [1]Sapporo Medical University School of Medicine, Sapporo, Japan, [2]The University of Tokyo, Tokyo, Japan

Background/Purpose: IgG4-related disease (IgG4-RD) is a recently recognized disease entity that is characterized by tumefactive and hyperplastic lesions in various organs including the lacrimal and salivary glands, pancreas and kidneys. Because patients with IgG4-RD have elevated serum IgG4 levels and characteristic histopathological features including dense infiltration of IgG4-positive plasma cells and storiform fibrosis, such lesions are assumed to have a common etiology and pathogenesis. Organ dysfunction is rarely severe in patients with IgG4-RD at diagnosis and responsiveness to corticosteroid therapy is frequently positive. Although the prognosis of IgG4-RD seems favorable, no long-term follow-up study has been reported. Data regarding the prognosis of IgG4-RD is essential when considering the introduction of intensive immunosuppressive therapy. We describe the clinical characteristics and prognosis of patients who have had IgG4-RD for ≥10 years.

Methods: This retrospective study at Sapporo Medical University Hospital analyzed clinical data at onset, involved organs during the clinical course and prognosis of 15 patients (5 men, 10 women) who had lived with IgG4-RD for ≥10 years. They were basically diagnosed according to the diagnostic criteria for IgG4-related Mikulicz's disease determined by the Japanese Society for Sjögren's syndrome.

Results: The average age at onset was 59 years and the average disease duration was 158 months. The lacrimal and salivary glands were the most frequently involved organs at onset in 12 of the 15 patients. Other initially involved organs included the mammary glands, pancreas and optic nerve. Only the lacrimal and salivary glands were affected in 6 patients during the clinical course (Mikulicz type). The others had multiple lesions (systemic type) of the retroperitoneum (n = 4), pancreas (n = 3), kidney (n = 2), lung (n = 2), liver (n = 1) and pituitary gland (n = 1). However, other lesions developed within 5 years in most patients with the systemic type and autoimmune pancreatitis developed in 1 patient 19 years after onset. The average levels of serum IgG4 at diagnosis in the Mikulicz and systemic types were 703 and 1,111 mg/dL, respectively. All patients initially responded well to corticosteroid therapy. Two patients required additional immunosuppressants due to recurrence during corticosteroid tapering. None of the patients died, progressed to end-stage organ failure or developed malignant lymphoma during the clinical course.

Conclusion: Patients with IgG4-RD presenting with lacrimal and salivary lesions at onset often developed other involved lesions within 5 years. However, only the lacrimal and salivary glands remained affected in a third of the patients over a period of about 10 years. Because the prognosis in terms of both life and function for patients with IgG4-RD is favorable when supported by corticosteroid therapy, careful consideration is required before introducing intensive immunosuppressive therapy.

1918

Cluster Analysis of Organ Involvements Patients with Serum IgG4 Elevation; IgG4–related Disease Is a Distinct Subtype of Patients with Hyper-IgG4. Masamitsu Tatewaki, Kazuhiro Kurasawa, Ayae Tanaka, Junya Nagasawa, Satoko Arai, Reika Maezawa, Takayoshi Owada and Takeshi Fukuda. Dokkyo Medical University, Mibu, Tochigi, Japan

Background/Purpose: IgG4-related disease (IgG4-RD) is a multi-organ affecting disease characterized by fibroinflammatory lesions with a abundant IgG4-positive plasma cells infiltration. This disorder includes many conditions such as autoimmune pancreatitis, Mikulicz disease and retroperitoneal fibrosis. Elevation of serum IgG4 levels is frequently found and is a key clue for diagnosis of IgG4-RD. However, there are patents who do not have fibrotic-sclerotic lesions, characteristics of IgG4-RD, but revealed elevation of serum IgG4. To determine whether IgG4-RD is a distinct subtype of diseases with hyper-IgG4, we conducted cluster analysis of patients with elevation of serum IgG4 levels and examined clinical features of each cluster.

Methods: Subjects were 86 patients with elevation of serum IgG4 (>100mg/dl) among 350 patients whom received IgG4 examination for diagnosis of mass lesions or inflammation. Cluster analysis of organ involvements of the patients were performed through Ward's method. Clinical features of patients in each cluster were e4xamined through reviewing medical records retrospectively.

Results: Through cluster analysis, 5 clusters were identified: cluster1; patients with multiple organ involvements including salivary glands, eyes, pancreas and retroperitoneum (typical IgG4 RD), cluster 2; patients with autoimmene pancreatitis alone (a subset of IgG4-RD), cluster 3; patients with lung involvement alone, cluster 4; patients with pleuritis alone, and cluster 5; patients without specific organ involvements. Renal involvement was found in patients in cluster1; generalized lymphadenopathy was detected in those in cluster 1, and pulmonary involvement was seen in those in cluster 1. Serum IgG4 level were significantly high in patients in cluster 1 compared to those in other clusters. In addition, serum IgG4 levels were increased in correlation with numbers of affected organs in cluster 1. Hypergammaglobulinemia occurred frequently in cluster 1. Serum CRP elevation was not found in cluster 1 and 2. IgG4 plasma cell rich infiltration was found in some biopsy samples from patients in all clusters. Glucocorticoid was effective on inflammatory lesions and systemic inflammation in most cases of all clusters.

Conclusion: Typical IgG4-RD (cluster1) is a distinct subtype of diseases with serum IgG4 elevation, which is characterized by multiple organ involvements, particularly salivary glands, eyes and retroperitoneum, generalize lymphadenopathy, marked IgG4 elevation with hypergammaglobulinemia and absence of systemic inflammation.

Regulatory T Cells in IgG4-Related Disease Patients Presenting with Sclerosing Sialadenitis and Dacryoadenitis. Winnie K. Pang, Ya Liu, Julie Wang, Song Guo Zheng, Kiran Qidwai, Russell K. Brynes and Francisco P. Quismorio Jr., University of Southern California Keck School of Medicine, Los Angeles, CA

Background/Purpose: IgG4-Related Disease (IgG4-RD) is characterized by inflammation and fibrosis of various organ systems. Its diverse clinical presentations include autoimmune pancreatitis, retroperitoneal fibrosis, sialadenitis, and dacryoadenitis. The etiology and pathogenesis are not well understood; however, the role of regulatory T cells (Treg) has been suggested. We evaluated the phenotype and function of Tregs in IgG4-RD patients with lacrimal and salivary gland involvement.

Methods: Three untreated IgG4-RD patients with chronic lacrimal and salivary gland enlargement underwent clinical evaluation at the Los Angeles County Medical Center Rheumatology clinic. Peripheral blood mononuclear cells were obtained from healthy controls and the untreated IgG4-RD patients. Treg subsets were identified with a combination of monoclonal antibodies (anti-CD4, -CD25, -CD45RA, -Foxp3, -CCR7) conjugated to different fluorochromes. Intracellular cytokine production (IL-2, IL-4, IL-5, IL-17A, IFN-g) was assessed in T cells by flow cytometry after PMA/Ionomycin stimulation in vitro. Statistical analysis was performed using Mann-Whitney or Wilcoxon tests.

Results: The patients, initially referred to rheumatology for Sjogren's Syndrome, had clinical and histopathologic features consistent with IgG4-RD. Patient 1 was a 50-year-old Caucasian female with submandibular and lacrimal gland swelling for 3 years. She also had an enlarged right submandibular gland excised in 1989. Patient 2 was a 60-year-old African American female with bilateral parotid and lacrimal gland swelling since 2007. Patient 3 was a 33-year-old Filipino male with a history of hemimandibulectomy for ameloblastoma in 1989 who presented with painless enlargement of the lacrimal and parotid glands for 18 months. All patients underwent PET-CT scan, which showed diffuse lymphadenopathy and metabolically active, enlarged lacrimal and salivary glands. Excisional biopsies were performed. Histopathologic evaluation excluded lymphoma but revealed diffuse fibrosis, lymphocytic infiltration, and elevated IgG4/IgG plasma cell staining ratio (>50%) consistent with the diagnosis of IgG4-RD. Serum IgG4 levels were elevated in two patients.

Compared to healthy controls, the frequency of Treg (CD4+CD25+ FOXP3+) cells was remarkably decreased in IgG4-RD patients, whereas naïve Treg cells (population with naïve phenotype, CCR7+CD45RA+) were increased. IgG4-RD patients were also characterized by increased circulating Th2 (including CD4+IL-4+, CD4+IL-5+) cells compared to healthy controls, while Th1 (CD4+IFN-g) and Th17 (CD4+IL17+) cells did not differ significantly.

Conclusion: IgG4-related sclerosing dacryoadenitis and sialadenitis may mimic Sjogren's Syndrome, prompting referral to rheumatologists. Histopathologic evaluation is essential for diagnosis. Untreated IgG4-RD patients were found to have a higher percentage of Th2 and a lower percentage of Treg, suggesting that correcting the balance of Treg/Th2 cells may be a potential therapeutic approach.

Disclosure: **W. K. Pang**, None; **Y. Liu**, None; **J. Wang**, None; **S. G. Zheng**, None; **K. Qidwai**, None; **R. K. Brynes**, None; **F. P. Quismorio Jr.**, None.

1920

Spectrum of IgG4-Related Disease and Diagnostic Value of Serum IgG4 Determinations. Emma Kotisalmi[1], Tom Pettersson[2], Aaro Miettinen[3], Johanna Arola[4] and Martti Färkkilä[2]. [1]University of Helsinki, Helsinki, Finland, [2]Helsinki University Central Hospital, Helsinki, Finland, [3]Huslab, Helsinki, Finland, [4]University of Helsinki and Huslab, Helsinki, Finland

Background/Purpose: IgG4-related disease is a recently described systemic inflammatory and fibrosing condition that may mimic various other systemic rheumatic diseases. We studied the occurrence of IgG4-related disease over a one year period at a university hospital serving a population of 1.5 million, and assessed the diagnostic significance of a serum IgG4 concentration higher than the upper level of the reference interval.

Methods: Files were scrutinized for a diagnosis of IgG4-related disease over a one year period (May 2010 to May 2011). The diagnosis rested on the combination of a clinical picture consistent with IgG4-related disease and histopathological features showing a characteristic appearance with a dense lymphoplasmacytic infiltration, a pattern of fibrosis, and variable numbers of IgG4 positive plasma cells. In addition, the files of all patients with a serum IgG4 concentration higher than 1.40 g/l, determined for various reasons during the same time period, were examined and the diagnoses were recorded. IgG subclasses in serum were analysed with a BN II nephelometer using N AS IgG1, N AS IgG2, N Latex IgG3, and N Latex IgG4 reagents (Siemens, Marburg, Germany). The reference interval for IgG4 at our laboratory is 0.08–1.4 g/l.

Results: 14 patients (12 men and 2 women, mean age 61 years, range 40–78 years) were diagnosed with IgG4-related disease during the one-year study period. In 3 patients the disease was confined to a single organ, whereas the other 11 had multiorgan involvement. The presenting features and major manifestations were autoimmune pancreatitis in 10, autoimmune cholangitis in 10, Mikulicz disease in 3, Riedel's thyroiditis in 2, retroperitoneal fibrosis in 1, and mediastinal fibrosis in 1. Three had a diagnosis of bronchial asthma. Median serum IgG4 concentration at diagnosis was 7.75 g/l with a range of 1.66–18.20 g/l. No patients with a diagnosis of IgG4-related disease and normal serum IgG4 concentrations were identified. Major diagnoses suspected at referral included pancreatic carcinoma, liver disease, primary Sjögren's syndrome, sarcoidosis, lymphoma, and vasculitis. Over the same time period no less than 238 additional patients with a serum IgG4 concentration higher than 1.40 g/l (median 2.22 g/l, range 1.41–11.50 g/l) were recorded. The most common diagnoses among these patients were bronchial asthma, chronic sinusitis and various allergic conditions, but high values were observed in a wide range of other diseases including sclerosing cholangitis, inflammatory bowel disease, and vasculitis.

Conclusion: We confirmed previous observations that IgG4-related disease occurs predominantly in middle aged or elderly men. Awareness of this newly recognized condition is essential since it constitutes a major differential diagnosis against various systemic inflammatory diseases and other diseases including lymphoma and other neoplasia. In our series a high serum IgG4 concentration was a regular finding among patients with IgG4-related disease. However, serum IgG4 concentrations higher than normal also occurred in a great variety of other diseases.

1921

Diagnostic Utility of Serum IgG4 in IgG4-Related Disease. Mollie Carruthers[1], Tamara Augustin[2], John H. Stone[1] and Arezou Khosroshahi[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Internal Medicine, Northshore Medical Center, Salem, MA

Background/Purpose: IgG4-related disease (IgG4-RD) is a recently recognized fibro-inflammatory disease with multi-organ system involvement, often but not always characterized by elevated serum IgG4 concentrations. The aim of this study was to determine the sensitivity, specificity, and positive and negative predictive values of serum IgG4 levels for the diagnosis of IgG4-RD.

Methods: This study was approved by the Institutional Review Board of our hospital. We searched the Massachusetts General Hospital database using the Research Patient Data Registry tool. Since March, 2001, 193 serum samples from unique patients were found to have elevated serum IgG4 concentrations (normal < 135 mg/dL). We reviewed the electronic medical record to determine the reason for the serum IgG4 assay and the underlying diagnosis in every case. The diagnostic criteria of IgG4-RD were determined according to the IgG4-RD international symposium consensus guidelines. In addition, we randomly selected 193 separate patients with normal serum IgG4 concentrations (from a pool of 3360 patients with normal results) in order to evaluate the test characteristics of IgG4 measurement.

Results: Among the 386 patients analyzed, 73 had either probable or definitive diagnoses of IgG4-RD. Sixty-six of these 73 patients had elevated serum IgG4 concentrations (mean: 404 mg/dL), for a sensitivity of 90%. In contrast, 313 (82%) of the patients analyzed did not have IgG4-RD diagnoses. Among those, 127 had elevated IgG4 concentrations (mean: 232 mg/dL; p <0.0001), for a specificity of 59%. The non-IgG4-RD diagnoses associated

with elevated serum IgG4 levels are shown in the **Figure**. Common causes of false-positive results were chronic sinusitis, recurrent pneumonia, and connective tissue diseases such as lupus, Sjögren's, and vasculitides. The negative predictive value of a serum IgG4 assay was 96%, but the positive predictive value was only 34%.
Figure 1. Diagnoses Associated with Elevated Serum IgG4 Concentrations

Conclusion: With regard to the diagnosis of IgG4-RD, both the sensitivity and the negative predictive value of serum IgG4 assays are high. However, multiple non-IgG4-RD conditions can also be associated with elevated serum IgG4 concentrations, leading to poor specificity and a low positive predictive value for this test.

1922

Articular Involvement in Relapsing Polychondritis: A Case Series. Laura O. Damian[1], Linda Ghib[1], Ioana Felea[2], Alma Maniu[3], Nadia Radics[1], Simona Falaus[1], Ileana Filipescu[4], Siao-pin Simon[3] and Simona Rednic[4]. [1]Emergency County Clinical Hospital Cluj Napoca, Cluj Napoca, Romania, [2]Emergency County Clinical Hospital Cluj Napoca, Cluj-Napoca, Romania, [3]University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj Napoca, Cluj Napoca, Romania, [4]University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj Napoca, Cluj-Napoca, Romania

Background/Purpose: Relapsing polychondritis (RP) is a relatively rare, but progressive disease with predilection for cartilage, with few data available regarding the arthritis in this setting. Purpose: To assess the type of articular involvement and its clinical associations of RP.

Methods: Systematic retrospective analysis of all patients diagnosed with RP in the Rheumatology Department, a tertiary care facility, over a 12-year period (2000 to 2012) using the hospital and outpatient databases. The McAdam diagnostic criteria for RP were employed. The patients were interviewed by the rheumatologist using a standard protocol. Patients self-taking pictures of the ear, eye or other involved organs during the painful episodes was encouraged.

Results: We identified 34 patients (67% women), age of onset 44.8 ± 16.9 years. The mean time to diagnosis was 36 months (1–168), after consultations of 4 other specialists (1–8). Most frequent autoimmune disease associated were vasculitis (10 cases, 2 with Behcet's /MAGIC syndrome), SLE (5), Sjogren's syndrome (2) and psoriatic arthritis (2). Hematological malignancies were seen in 5 cases. The arthritis was present in 30/34 (88%) cases and was intermittent, but symmetric in 17 (56%) cases and asymmetric in 13 (43%), mimicking microcristalline arthritis in 9/30 (30%) cases. Mutilating arthritis was seen in 3 patients (2 with dissecting osteochondritis) and avascular necrosis in 3. Chondrosternal and manubriosternal arthritis were noted in 61% (21/34) and 44% (15/34) cases, respectively; when inaugural, pointed to a diagnosis of Tietze or SAPHO syndrome. In 3 patients signs of vertebral chondritis were present, mimicking ankylosing spondylitis or vertebral chondrocalcinosis. Three patients diagnosed with Lyme disease had acute intermittent arthritis attributed initially to borreliosis, before the appearance of chondrosternal arthritis and later of the ENT involvement. The symmetric arthritis was associated with a shorter time from onset to diagnosis (2.43 vs 4.3 yr, p=0.03) than the asymmetric one. Symmetric arthritis was also correlated with more serious ENT involvement, auricular deformities (p=0.028) and also with ocular inflammation (p=0.03), pericarditis (p=

0.02), leukopenia (p=0.02) and glomerulonephritis (p=0.02). Rheumatoid factor was present in only 4 cases, rather reflecting the presence of cryoglobulinemia or hematological malignancies.

Conclusion: Even in the presence of auricular or nasal chondritis, RP could still be a tricky diagnosis, several consultants being seen before diagnosis. In our series symmetric arthritis was associated with a more complicated disease course, possibly reflecting the underlying pathology. The diagnosis of RP should be considered in recurrent paroxistic chest pain and also in vertebral acute relapsing pain. The instruction of patients to self-report and to document by pictures an evanescent inflammation could add to a better recognition of disease.

1923

Biologics in Relapsing Polychondritis: A Single Center Case-Series. Guillaume Moulis[1], Laurent Sailler[2], Grégory Pugnet[3], Leonardo Astudillo[1] and Philippe Arlet[1]. [1]Toulouse University Hospital, University of Toulouse, Toulouse, France, [2]Toulouse University Hospital, University of Toulouse, INSERM UR 1027, Toulouse, France, [3]Toulouse University Hospital, University of Toulouse, INSERM UMR 1027, Toulouse, France

Background/Purpose: First-line treatment for relapsing polychondritis (RP) is costicosteroids (CS). Dapsone and methotrexate have been proposed as second-line therapies. Only few reports have been published on the use of biologics in RP. There may be a publication bias favouring successful issues. This work was aimed at colligating and describing the effects of biologics in RP patients in our Department.

Methods: Diagnosis codes are given and registered in a computerized medical file for each patient treated in our department since 1993. We performed the extraction of all cases encoded as "RP". The diagnosis was confirmed using Damiani's McAdam-modified criteria. All patients treated with biologics were evaluated for efficacy and adverse drugs reactions until the 20th June 2012 (last follow-up date).

Results: Among 22 patients encoded "RP", 17 fulfilled Damiani's criteria. Among them, 8 were exposed to 19 biologics as CS-sparing drugs. Mean age at diagnosis was 45.7 years and male:female sex-ratio was 1:4. All patients had chondritis and seronegative polyarthritis, 4 had cochlear or vestibular dysfunction and 2 had ocular inflammation. Biologics were used at the same doses as in rheumatoid arthritis. Seven patients were treated with TNF-alpha antagonists (adalimumab, n=7, etanercept, n=3, infliximab, n=2, certolizumab, n=1), 2 with anakinra, 2 with abatacept and 2 with tocilizumab. Treatments used before biologics were CS (all patients), methotrexate (n=3), dapsone (n=2), hydroxychloroquine (n=4), azathioprine (n=1). In 3 cases (patients 4, 6 and 8), biologics were used because of a cortico-dependant and severe disease (tracheal inflammation). Mean delay from diagnosis to first biologic use was 9.75 months. Outcomes are described in table 1. Seven adverse drug reactions were considered as drug-related: reactions at injection site occurred in 2 patients (1 on anakinra, 1 on adalimumab), and infections in 3 patients (1 pneumonia on adalimumab, sinusitis and otitis followed by herpes zoster on tocilizumab, 1 cellulitis on abatacept).

Table 1. Outcomes of the 19 biologic therapies

Patients	Drug	Efficacy	Duration (months)	Reason for withdrawal, if any
1	Etanercept	Partial	3	Insufficient efficacy
	Adalimumab	Partial	3	Insufficient efficacy, pain at injection sites
2	Adalimumab	Yes	15	Loss of efficacy
	Infliximab	No	0.5	Systemic reaction
	Anakinra	No	3	Inefficacy
	Abatacept	Partial	12	Insufficient efficacy
	Tocilizumab	Yes	2	Ongoing
3	Etanercept	Yes	12	Loss of efficacy
	Adalimumab	Yes	26	Inactive disease
4	Etanercept	Yes	9	Loss of efficacy
	Adalimumab	Partial	6	Loss of efficacy
	Infliximab	Yes	10	Loss of efficacy
	Anakinra	No	1.5	Inefficacy
	Abatacept	Yes	33	Minor loss of efficacy
	Certolizumab	No	3	Inefficacy
	Abatacept again	Yes	10	Ongoing
5	Tocilizumab	Yes	5	Ongoing
6	Adalimumab	Yes	20	Inactive disease
7	Adalimumab	Yes	60	Ongoing
8	Adalimumab	Yes	1	Ongoing

Conclusion: All biologics but anakinra and certolizumab in one patient had a consistent effect. Loss of efficacy occurred frequently. Switching from a TNF-alpha antagonist to another TNF-alpha antagonist was frequently efficacious and may be proposed before switchting to abatacept or tocilizumab. The benefit-to-risk ratio of biologics compared with immunosuppressive drugs should be evaluated prospectively in RP.

1924

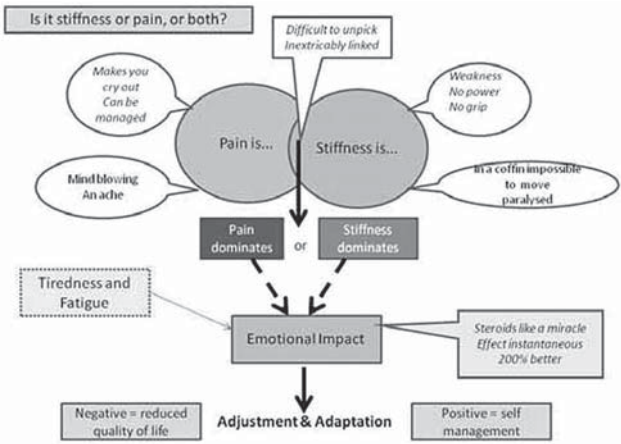
What Do Patients with Polmyalgia Rheumatica Mean When They Describe Stiffness? A Qualitative Study. Rodney A. Hughes[1], Sarah Mackie[2], John R. Kirwan[3], Colin T. Pease[4], Margaret Walsh[1] and Marianne Morris[5]. [1]St. Peters Hospital, Chertsey Surrey, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]Bristol Royal Infirmary, Bristol, United Kingdom, [4]Leeds Teaching Hospitals NHS Trust, Harrogate, United Kingdom, [5]University of the West of England, Bristol, United Kingdom

Background/Purpose: Patients with PMR report significant symptoms of pain and stiffness. Stiffness has usually been included in diagnostic criteria for PMR but has never been clearly defined. Stiffness can prove difficult to measure and to distinguish from pain. To try to establish both a definition and a clearer understanding of stiffness in PMR we have performed a qualitative study designed to elicit appropriate patient experience and perception of stiffness.

Methods: We have conducted 8 focus groups in 3 rheumatology centres in the UK involving 50 patients with PMR. We included one city and two semi-urban units in three regions in the UK to try to explore differences in language or communication across areas. Patients all had English as a first language. Each focus group ran for 1.5 hours, data were transcribed and thematically analysed into codes, sub-themes and themes. Two expert patients with PMR were included in the research from the start of the study. Sample size was designed to reach saturation of themes.

Results: Themes have emerged in response to direct questioning that relate specifically to definitions of stiffness and measurable outcomes for PMR (deductive thematic anaysis). Through inductive analysis additional themes have emerged; that pain and stiffness were inextricably linked, the use of metaphors to describe PMR symptoms, and an in depth understanding of the cognitive and behavioural impact of polymyalgia.

PMR emerges as a disease of 'two halves' with a very close relationship between pain and stiffness. For some, stiffness appears before pain is experienced and can serve as a warning of pain should the person move—'freezing up in anticipation of pain'. From the data set it appears that patients are dominated either by pain, fatigue or stiffness but there is always a background of stiffness. Metaphorical descriptions of disease relating to stiffness have included 'tin soldier', 'rusty hinge', '2 bricks cemented on my shoulders' and being 'trapped in a coffin'. Patients report stiffness in association with sleep disturbance, loss of confidence, mood and stress disorders and a clear temporal variation of symptoms worse at night and in the early morning 'my 24 hour problem', 'a cycle'. Although patients report a very significant improvement in stiffness and pain after treatment with corticosteroids data suggest that they almost always continue to experience stiffness although they may not report this to their physicians. Stiffness both before and after treatment impacts on function, independence and social and working life.

A thematic model of stiffness in PMR


Conclusion: This work has led us towards a clearer definition of the meaning, experience and impact of stiffness. We have devised an initial thematic model of symptoms in polymyalgia that emerges from our work that will enable us to proceed further towards an adequate definition of stiffness ways of measuring it.

1925

Patient Satisfaction and Experience with Golimumab, Adalimumab, and Etanercept for the Treatment of Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis. Susan Bolge[1], Helen Eldridge[2], Dilesh Doshi[1], Lorie Ellis[1], Barbara Roland[3] and John Woelfel[3]. [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Janssen Pharmaceuticals, Inc, Titusville, NJ, [3]The Dominion Group, Reston, VA

Background/Purpose: Golimumab (GLM), adalimumab (ADA), and etanercept (ETN) are subcutaneous (SQ) anti-TNF therapies available for the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS). The purpose of this study was to explore satisfaction with effectiveness and injection experience with GLM, ADA, and ETN from the patient perspective.

Methods: In 2012, RA, PsA, and AS patients currently receiving SQ biologic therapy participated in telephone interviews. Patients rated satisfaction with current SQ therapy on a 7-point Likert scale ($1=$ extremely dissatisfied and $7=$ extremely satisfied). Patients also described their most recent injection experience. Propensity weights were applied to adjust for differences in duration of therapy and past intravenous (IV) biologic use of GLM patients vs. ADA and ETN patients.

Results: A total of 69 GLM, 143 ADA, and 181 ETN patients participated in the study. Before adjustment, GLM patients had shorter duration of therapy than ADA and ETN patients (less than one year GLM: 51% vs. ADA: 21%, $p<0.05$ and ETN: 17%, $p<0.05$). Also, a greater proportion of GLM patients had prior IV biologic exposure (GLM: 41% vs. ADA: 14%, $p<0.05$ and ETN: 13%, $p<0.05$). When propensity weights were applied to adjust for differences in duration of therapy and prior IV biologic experience, GLM patients reported high satisfaction with effectiveness (6–7 on 7-point scale) at similar rates to ADA and ETN patients for prevention/treatment of condition (GLM: 55%, ADA: 55%, ETN: 56%), symptom relief (GLM: 45%, ADA: 51%, ETN: 57%), and time to onset (GLM: 44%, ADA: 42%, ETN: 50%). GLM patients reported lesser degrees of discomfort, pain, stinging, and burning during injection than ADA or ETN patients.

Table 1. Most Recent Injection Experience (Adjusted using Propensity Weights)

		GLM	ADA	ETN
Discomfort	None	49%	32%*	18%*
	Moderate	10%	23%†	23%*
Pain	None	49%	44%	28%*
	Moderate	7%	23%*	15%
Stinging	None	41%	16%*	12%*
	Moderate	4%	28%*	26%*
Burning	None	58%	41%†	40%*
	Moderate	9%	20%†	24%*

*$p<0.05$ compared to GLM; †$p<0.10$ compared to GLM

Conclusion: Patient reported satisfaction with effectiveness is comparable among patients treated with GLM, ADA and ETN, and less discomfort, pain, burning, and stinging with injection is reported by GLM patients. Patient injection experience may be an important consideration in selection of biologic treatment. Future research should explore potential effects of patient injection experience on treatment adherence and patient outcomes.

1926

Evaluation of Strategies to Taper Anti-TNF Drugs in Patients with Inflammatory Rheumatic Disease (Rheumatoid Arthritis, Ankyloing Spondylitis, Psoriatic Arthritis, Adult-age Juvenile Idiopatic Arthritis) in Long-Term Remission. Jakub Zavada, Katarina Hviscova, Katerina Jarosova, Sarka Forejtova, Jiri Stolfa, Liliana Sedova, Dana Tegzova, Jiri Vencovsky and Karel Pavelka. Institute of Rheumatology, Prague, Czech Republic

Background/Purpose: While abrupt discontinuation strategies of anti-TNF drugs have been shown to result in frequent disease flares, tapering of dose may be a feasible option for patients with inflammatory rheumatic disease in long-term remission. We aimed to assess the feasibility to taper anti-TNF drugs (either by dose reduction or by prolongation of dosing interval) in patients with inflammatory rheumatic disease (RA, AS, adult-age JIA, PsA) in long-term remission

Methods: Patients with RA, AS, PsA or adult-age JIA in long-term remission of the disease (>6 months) were eligible for this prospective observational cohort study. Baseline and 3-monthly follow-up visits data concerning medication and activity of the disease were recorded prospectively by a questionnaire. The desicions whether and how to taper (or increase in case of flare) anti-TNF therapy were left solely to the discretion of the treating physician, without any pre-specified protocol. Survival analyses, performed using a Cox proportional hazards model, were used to assess the predictors of failure of the tapering strategies (failure was defined as reinstitution of the usual/baseline dose of the anti-TNF drug).

Results: 132 patients (AS: 55, RA: 45, adult-age JIA: 22, PsA: 10) with at least one follow-up visit after tapering of anti-TNF therapy (corresponding to 176 patient-years of follow-up) have been analyzed. Median time of follow-up per analyzed patient was 189 days (IQR 98–343 days). 70 (53%) patients were treated by etanercept, 37 (28%) by adalimumab, and 25 (19%) by infliximab. 50% fraction (or less) of the baseline dose was reached in 81 (62%) patients. Within respective diagnoses, 50% fraction (or less) of the baseline dose was reached in 34 (62%) pts with AS, 17 (77%) with JIA, 5 (50%) with PsA, and 25 (56%) with RA. In 25 (19%) patients the subsequent flare of the disease activity required increase of the anti-TNF drug back to the baseline dose (i.e. the tapering strategy failed). Within the diagnoses, failures were observed in 7 (13%) of pts with AS, 1 (5%) with adult-age JIA, 3 (30%) with PsA, and 14 (31%) with RA. In univariate survival analyses, the risk of the tapering strategy failure was numerically higher in RA patients (HR 2.39, 95%CI 0.96–5.97), PsA pts (HR 2.38, 95%CI 0.62–9.24), and lower in JIA pts (HR 0.32, 95%CI 0.04–2.60) as compared to AS patients (referent); the risk of failure was also numerically greater in pts treated with infliximab (HR 2.49, CI95% 0.95–6.58) as compared to etanercept (referent), or adalimumab (HR 1.41, CI95% 0.55–3.58).

Conclusion: This observational study from one academic center on patients with inflammatory rheumatic disease (RA, AS, PSA, adult-age JIA) in long-term remission showed, that after tapering of the anti-TNF drug dose (or prolongation of the dosing interval) 19% of pts required reinstitution of the usual/baseline dose of the anti-TNF drug within the limits of the relatively short-term follow-up

1927

Inflammatory Meningeal Involvement in Patients with Rheumatic Diseases Responsive to Rituximab. Jane Park[1], Eyal Kedar[1], Ingeborg Sacksen[1], John Henson[2] and Gregory C. Gardner[1]. [1]University of Washington, Seattle, WA, [2]Swedish Neuroscience Institute, Seattle, WA

Background/Purpose: Inflammatory meningeal involvement can be idiopathic or associated with a variety of inflammatory rheumatic diseases such as ANCA associated vasculitis (AAV), rheumatoid (RA) arthritis, sarcoidosis or the recently described IgG4 related diseases. Clinical symptoms can include headache, cranial neuropathies, cognitive changes, seizures, and encephalopathy. Case reports have described successful therapy with steroids, methotrexate, mycophenolate, cyclophosphamide, and rituximab. We present five cases of inflammatory meningitis unresponsive to various doses of steroids and other immunosuppressive agents treated successfully with rituximab**.**

Methods: All 5 patients with inflammatory meningeal disease seen in rheumatology clinic over the last 5 years and treated with rituximab were reviewed.

Results: The current series consisted of 3 women and 2 men with an age range of 49–84 years. Underlying diseases included 3 patients with AAV (1 localized AAV the other 2 with systemic AAV), 1 patient with RA, and 1 patient with idiopathic disease (possible GCA). Major symptoms and signs included headaches in 4, hearing loss in 2, vision loss in 2, and significant cognitive changes in 2 patients. MRI showed pachymeningeal thickening/enhancement in 4 patients and leptomeningeal in 1. Four of the 5 patients had meningeal biopsies and all showed granulomatous inflammation, a finding not seen with IgG4 disease. All patients had received steroids. Other immuno-suppressants used included methotrexate, azathioprine, leflunomide, myco-phenolate, and abatacept.

Rituximab was used due to continued meningeal symptoms and because it was indicated for the underlying diseases (AAV, RA). The initial rituximab doses were 1000–2000 mg repeated every 6 months. Two patients continued on methotrexate in addition to rituximab. Three of 5 patients had rapid and dramatic reversal of most if not all of the symptoms referable to the meningeal inflammation. One patient with localized GPA has significant improvement allowing the reduction of prednisone from 40–60 mg/day to 5 mg per day. One patient had improvement without resolution of headache and hearing loss but has received only 1 dose. Repeat MRI scans were available on 4 patients and results ranged from complete resolution of MRI changes in 1 patient and improvement in 3. In 1 patient with the shortest treatment course, no MRI improvement has been noted to date. No side effects occurred that are referable to rituximab treatment.

Conclusion: Rituximab is a useful agent in the treatment of refractory inflammatory meningeal disease whether idiopathic or associated with another inflammatory rheumatologic illness

Disclosure: J. Park, None; E. Kedar, None; I. Sacksen, None; J. Henson, None; G. C. Gardner, None.

1928

Evaluating the Therapeutic Effects of B Cell Depletion Therapy with Rituximab in a Longitudinal Cohort of Mixed Connective Tissue Disease Patients. Ragnar Gunnarsson, Inge-Margrethe Gilboe, Torhild Garen and Øyvind Molberg. Oslo University Hospital Rikshospitalet, Oslo, Norway

Background/Purpose: Even though 40 years have passed since MCTD was defined as a distinct disorder, there is still no evidence based therapy available. The choice of treatment is based on data from related connective tissue diseases. Biological agents have been used in a few patients with disease resistant to conventional immune-modulating drugs. Tumor necrosis factor alpha (TNFα) inhibitors have had limited efficacy and/or adverse effects (1, 2). B cell depletion therapy with rituximab (RTX) has only been reported in three MCTD patients, two of these responded to the treatment (3, 4), whereas the last had a treatment related complications (5).

Methods: A retrospective chart review of all the MCTD patients who were treated with RTX at the Rheumatology unit at the Oslo University Hospital from the 1st of June 2006 to the 15th of June 2012 and fulfilled at least one of the four MCTD criteria sets (Kasukawa's, Alarcón-Segovia's, Kahn's and/or Sharp's criteria) were performed.

Results: Four female MCTD patients, all fulfilling all the four MCTD criteria sets, were treated with RTX according to the rheumatoid arthritis protocol with two 1,000 mg RTX infusions two weeks apart. Two of these patients were retreated with RTX after 10 and 21 months. At the start of the RTX treatment, the patient's mean age was 44 years (37 to 65) and their mean disease duration was 8.7 (5 to 12) years. The mean observation time was 46 (23 to 70) months. So far, no adverse effects have been identified

Patient details;

Patient 1: Therapy resistant thrombocytopenia over years. Normalization of platelets 15 weeks after RTX and currently uses low dose prednisolone (GC).

Patient 2: Therapy resistant myositis with high serum creatinine kinase (CK, max 4605 U/L); reduced proximal muscle strength and increased signal intensity on MRI (STIR and T1).

After RTX, normalization of CK and reduced MRI changes and was able to reduce GC dose. She had two minor relapses, the first 12 months after RTX and is currently treated with methotrexate (MTX) and low dose GC.

Patient 3: Therapy resistant myositis with; high CK (max 7076 U/L); MRI changes and reduced muscle strength. Two courses of RTX, ten months apart, with the background of MTX, GC, Hydroxychloroquine (HCQ) led to normalization of CK and increased muscle strength.

Patient 4: MCTD/RA overlap, therapy resistant, destructive arthritis. Non-responder to two TNFα-inhibitors. RTX with a background therapy of MTX, GC & HCQ, led to a complete remission of arthritis and significant relief in Raynaud's phenomenon for 18 months. A recent relapse was treated with a new round of rituximab.

Conclusion: During the observation period, four MCTD patients received B cell depletion therapy with RTX. The treatment was well tolerated and had significant clinical effects on thrombocytopenia, myositis and arthritis. Randomized controlled trials are needed to further evaluate the effects of RTX in MCTD.

Pernicious Anemia and Vitamin B-12 Deficiency in Autoimmune Disease: Neglecting the Feet Will Lead You Astray. Michael R. Lovy Desert Oasis Healthcare, Palm Springs, CA

Background/Purpose: The occurrence of multiple autoimmune disorders in individual patients is commonly observed. Rarely, this is explained by recently recognized genetically based autoimmune polyendocrine syndromes. Pernicious anemia accompanies other autoimmune disorders both in patients with and without these discrete syndromes. The purpose of this study was to detect possible underlying vitamin B-12 (B-12) deficiency or pernicious anemia in a rheumatology clinic based on a simple neurologic exam of the feet.

Methods: Patients seen in a rheumatology clinic over a six month period were examined for evidence of peripheral neuropathy. If typical findings of stocking sensory loss at the ankle level were found a B-12 level was obtained. If B-12 levels were low anti parietal cell and intrinsic factor antibody titers were obtained. Methylmalonic acid (MMA) levels were obtained in patients without either antiparietal cell or intrinsic factor antibodies. Clinical features of antibody positive patients as well as those with B-12 deficiency and elevated MMA levels were reviewed.

Results: 38 patients with low B-12 levels were positive for antiparietal cell or intrinsic factor antibodies. An additional 10 patients with low B-12 and elevated methylmelanic acid levels were indentified. Diagnosis among antibody positive patients included: rheumatoid arthritis 9-including one with vitiligo. one with Grave's disease, 2 with Hashimoto's; lupus 5; primary Sjogren's 3-including one with stiff man syndrome; primary Raynaud's 4; polyarticular CPPD 3; tophaceous gout 3; vasculitis 2; ankylosing spondylitis 1; and pyoderma gangrenosum 1. Diagnosis among antibody negative patients included osteoporotic fracture 4, osteoarthritis 4, lupus 2, rheumatoid 2, ankylosing spondylitis 2, tophaceous gout 1, CPPD 1. Among the lupus and Sjogren's patients there were 2 positive for both SS-A and SS-B, 3 for SS-A, 1 for SS-B, 3 with anticardiolipin antibody, and 3 with false positive VDRL. Paraproteinemia was present in 3 patients. Among the 15 male patients, 7 were being treated for hypogonadism. Four patients had 25-OH vitamin D levels below 10 ng/ml, 9 patients had thyroid disease, 7 had diabetes, and 13 had a positive family history for either diabetes or an autoimmune disease. The MCV level and hemoglobin level was normal in all but 1 patient who drank alcohol excessively.

Conclusion: Pernicious anemia and B-12 deficiency was observed in a wide spectrum of autoimmune and arthritic diseases, especially SS-A and SS-B positive individuals. Other components of autoimmune polyendocrine syndrome including diabetes, thyroid disease, male hypogonadism, and low vitamin D levels, suggesting the possibility of celiac disease, occurred frequently in this study group. Recognition of pernicious anemia should alert the clinician to the possible presence of other components of autoimmune polyendocrine syndrome and vice versa. Also, B-12 deficiency can cause elevated MCV, foot complaints, constitutional symptoms, neuropathy that could be mistaken as a complication of the underlying disease or its therapy, and is associated with osteoporotic fractures. A simple 30 second neurologic exam can lead to the diagnosis of this potentially treatable deficiency.

Progranulin Plays a Protective Role in the Pathogenesis of Inflammatory Bowel Disease. Fanhua Wei[1], Jinlong Jian[1], Yuying Zhang[1], Jiqiang Lin[1], Juan Lafaille[2], Michael Dustin[3], Lloyd Mayer[4] and Chuanju Liu[5]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York, NY, [3]NYU School of Medicine, New York, NY, [4]Mount Sinai Medical Center, New York, NY, [5]New York University, New York, NY

Background/Purpose: Progranulin (PGRN) is a growth factor with multiple functions. We recently reported that PGRN and its derived engineered protein Atsttrin directly bound to TNF receptors, inhibited TNF-α activity and exhibited potent anti-inflammatory effect in inflammatory arthritis models (Tang, W., et al, *Science*, 2011 Apr 22;332(6028):478–484). TNF-α is also known to play a critical role in the pathogenesis of inflammatory bowel disease (IBD), and blockage of TNF-α represents an effective therapeutic option in the treatment of IBD. Thus the objective of this project is 1) to examine the expression profiling of PGRN in the course of IBD, 2) to define the role of endogenous PGRN in IBD, and 3) to determine whether recombinant PGRN or its derivatives represents novel therapeutic interventions for IBD.

Methods: The expression of PGRN in the course of IBD was detected using immunohistochemistry. To elucidate the effects of endogenous PGRN on the initiation and progression of colitis, various colitis models, including DSS- and TNBS-induced colitis model, CD4+CD45Rb^{hi} T cell transfer model were established with WT and PGRN-deficient mice. To determine the therapeutic effect, recombinant PGRN or Atsttrin at a dosage of 5mg/kg body weight was injected into various experimental colitis models. Body weights were recorded and the colon tissues were collected for histological and immunohistochemical assays.

Results: PGRN was highly expressed in the epithelial cell layer and smooth muscle of colon in WT mice, and its expression was significantly induced in the course of DSS- or TBNS-induced colitis. PGRN KO mice suffered from accelerated body weight loss, and exhibited more severe transmural inflammation with extensive ulceration and necrosis compared to WT mice. Transfer of PGRN$^{-/-}$CD4+ CD45RB^{hi} T cells into RAG1$^{-/-}$ recipient mice led to an accelerated onset of disease and to more severe signs of inflammation. In addition, all mice died 35 days after T cell transfer in this group, whereas all mice were still alive following T cell transfer from WT donor mice up to 56 days. These results indicate that CD4+ CD45RB^{hi} T cells-derived PGRN is critical for the augmented inflammation of IBD. Importantly, injection of recombinant PGRN, or its derived engineered molecule Atsttrin, was able to effectively ameliorate the symptoms of colitis, as revealed by significantly delayed body weight loss and less tissue inflammation. In addition, the application of PGRN restored the survival rate in the T cell transfer model.

Conclusion: PGRN plays a protective role in the pathogenesis of inflammatory bowel disease. PGRN, specially its derived engineered molecules, may be used as new anti-TNF/TNFR therapeutic interventions for inflammatory bowel disease.

Influence of Trough Serum Drug Level and Immunogenicity On the Lack of Response to Adalimumab Therapy in Inflammatory Bowel Disease Patients. Shui Long Wang[1], Scott Hauenstein[1], Linda Ohrmund[1], Reshma Shringarpure[1], Douglas C. Wolf[2], Isam A. Diab[3], Jared Salbato[1], Rukmini Reddy[1], Kevin McCowen[1], Shawn Shah[1], Steven Lockton[1], Emil Chuang[1] and Sharat Singh[1]. [1]Prometheus Laboratories, San Diego, CA, [2]Atlanta Gastroenterology Associates, Atlanta, GA, [3]Paramount Medical Research & Consulting, Middleburg Heights, OH

Background/Purpose: Anti-TNF-α therapy is effective for the treatment of inflammatory bowel disease (IBD). Nevertheless, over 30% of IBD patients fail to respond to anti-TNF-α therapy and approximately 60% of the patients who respond initially to the therapy will lose the response over time and will need to either dose escalation or switch to another agent to maintain response. Low serum drug levels and/or anti-drug antibody (ADA) generation may play a role for the failure and, recent data suggest monitoring of patients for serum drug and ADA levels is an important strategy for optimal patient management. Here, we report the application of the homogeneous mobility shift assay (HMSA) method for monitoring of adalimumab (ADL) and

human antibodies-to-adalimumab (ATA) in serum samples from patients who lost response to ADL treatment.

Methods: Serum samples were collected from 100 patients who initially responded to ADL therapy for at least three months but were beginning to lose response. ATA and ADL levels in the serum samples were measured by ATA- and ADL-HMSA as described previously, except that in the ATA-HMSA Alexa Fluor 488 labeled ADL (ADL-488) was used as antigen and rabbit anti-ADL serum as standard. Full analytical method validation of both the ATA- and the ADL-HMSA was performed, and cut points for ADL and ATA levels were established with 100 drug-naïve healthy controls. The relationship of the ADL drug level and ATA generation in these patients was analyzed.

Results: Validation of the ATA- and ADL-HMSA revealed a lower limit of detection to be 0.026 U/mL for ATA and 0.018 μg/mL for ADL in the serum samples. The intra-assay and inter-assay precision determination yielded a coefficient of variation of less than 15%, and the accuracy of the assay is within 20% for both assays. ADL drug tolerance in ATA HMSA is up to 40 μg/ml in the test serum. Serum samples from 100 drug-naïve healthy subjects were tested to set up the cutoff point of 0.55U/mL (Mean+3.0xSD) for ATA and 0.66 μg/mL for ADL. Analysis of 100 serum samples from patients who were losing response showed that 36% of the patients had an ADL level < 3 μg/mL, of these 58.3% were ATA positive. However, only 18% of the patients (4/22) had ATA when their ADL level was over 20 μg/mL. Overall, 40% of the patient (40/100) were positive for ATA.

Conclusion: Analysis of ADL and ATA levels in non-responding IBD patients showed a high incidence of ATA generation and the ADL levels were inversely correlated with the level of ATA generation. Drug and ADA levels are important determinants of patient response to the therapy.

1932

Clinical Features of an Aromatase Inhibitor Associated Syndrome Presenting As Rheumatoid Arthritis Ronald J. Anderson, MD, Brigham &Women's Hospital. Ronald J. Anderson. Brigham & Womens Hospital, Boston, MA

Background/Purpose: The aromatase inhibitors (AI); anastrozole, letrozole and exemestane are used in the treatment of postmenopausal women with estrogen receptor positive breast cancer. Arthralgias occur in close to 30% of patients taking these agents and are a major reason for their discontinuation. Published reports on these arthralgias are primarily in the oncology literature and describe the prevalence of these symptoms but not their clinical features.

Methods: During the five year period, 2005–2010, all new patients taking AI presenting to the practice of the author, a rheumatologist practicing in an academic medical center, were prospectively analyzed. Fourteen out of a total of 1,149 new patients were taking AI. The source of referral was: oncologists (8), internists (4) and rheumatologists (2). Diagnostic studies were performed on the basis of clinical care needs. The diagnosis of a joint abnormality was based on a physical exam which demonstrated soft tissue swelling and limitation of motion. Tenderness, alone, was used as a sign of involvement only in the MTP joints. If the cause of a joint deformity could not be explained by physical exam, radiographs were obtained to exclude osteoarthritis or other structural abnormalities.

Results: The ultimate diagnoses in this group of 14 patients were as follows: osteoarthritis (2), idiopathic frozen shoulder (2), bilateral palmar flexor tenosynovitis (2), fibromyalgia (1), Charcot joints (1) and previously undiagnosed chronic rheumatoid arthritis (RA) (1). The remaining 5 patients presented with a unique syndrome of morning stiffness, joint swelling, limited motion and dysfunction in a pattern consistent with early RA. All 5 patients met both the 1987 ACR and the 2010 ACR/EULAR Classification Criteria for RA. All were negative for ANA and CCP. One patient had a borderline positive RF. ESRs were normal and only one patient had an elevated CRP. Joints involved were wrists and MCPs (5),

MTPs (4), shoulder and elbows (3), hips (2) and the knee in one patient. No joint effusions sufficient for aspiration were seen in this group of patients. All patients with this syndrome were followed for at least one year. Four of the five patients stopped the AI and underwent a complete remission in 3 months. The remission persisted in the 2 patients who did not resume an AI. Two patients restarted another AI and both developed a similar RA syndrome within 3 months. Of these 2 patients, one remitted on stopping the second AI and the other elected to stay on the agent with persistence of the syndrome. One of the five patients chose to stay on the original AI and has had persistent mild disease for over 2 years. The 5 patients had used AI for a mean of 3 months prior to the onset of symptoms. Remissions occurred within 3 months of stopping the drug.

Conclusion: A syndrome with clinical features resembling RA may be seen in association with the use of AI. The patients described in this study fulfilled both the 1987 ACR and 2010 ACR/EULAR criteria for RA. The condition may remit on stopping the agent but can recur on switching to another agent in the same class.

1933

Incidence and Early Detection of Retinal Toxicity in Patients Treated with Chloroquine and Hydroxichloroquine in Rheumatology Practice. Sandra Soro Marin[1], Ana del Carmen Haro Martínez[1], Deseada Palma Sanchez[1], María del Rocío Gonzalez Molina[1], Marta Mayor Gonzalez[2] and Elena Rubio Velazquez[3]. [1]Rafael Mendez Hospital, Spain., Lorca (Murcia), Spain, [2]Rafael Mendez Hospital, Lorca (Murcia), Spain, [3]Rafael Mendez Hospital, Lorca (Murcia)

Background/Purpose: The antimalarial drugs are considered safe and well tolerated, with low risk of side effects. Hydroxychloroquine is considered safer but less effective than chloroquine, although the choice remains a matter of discussion and it generally depends on the experience. Both can cause ocular toxicity by corneal and retinal deposition which produces irreversible visual disturbances and the patient may not perceive its presence at an early stage. The American Academy of Ophthalmology recommendations for screening of chloroquine (CQ) and hydroxychloroquine (HCQ) retinopathy recommend to use more sensitive test than fundus exam such as Spectral Domain Optical Coherence Tomography (SD-OCT) to detect early retinal toxicity. The objective was to study the incidence of retinal toxicity in patients treated with antimalarials in a Rheumatology Unit and to evaluate the effectiveness of SD-OCT in the screening of hydroxichloroquine and chloroquine toxicity

Methods: Descriptive study evaluating 39 patients treated with antimalarials who were referred to ophthalmology to study retinal toxicity during 2011. Data collection included demographic data of patients, type of antimalarial prescribed, daily and cumulative doses, rheumatic disease, corticosteroid use, associated morbidity, visual acuity, examination of the anterior pole, fundus exam, visual field, SD-OCT and, in case that it shows any sign of toxicity, multifocal electroretinogram. Fluorescein angiography (FAG) was made to patients that showed macular disturbances.

Results: Three patients were treated with CQ and 36 with HCQ. Five of 39 patients had alterations in the SD-OCT, two of them had typical fundus appearance and three didn't show significant changes in visual acuity or retinal imaging. Visual field and electroretinogram helped to confirm early toxicity. Among the patients with retinopathy, three (100%) had been treated with CQ and two (5.5%) with HCQ. The average duration of treatment in these patients was 2.37 +/−1.37 years and the mean cumulative dose of CQ was 559 g and 172.5 g for HCQ. There was no statistically significant association between retinal toxicity and sex, age, rheumatic disease, duration or dose of treatment with p value greater than 0.05.

Conclusion: The incidence of retinal toxicity in our patients treated with antimalarial drugs was 12.8%. Despite the small sample size to prove statistical significance, CQ was the antimalarial that caused most of cases of retinopathy and the SD-OCT was the most sensitive test to detect it. It is essential a fluent communication between Rheumatology and Ophthalmology to have a proper follow-up of the patients treated with CQ and HCQ and an early detection of retinopathy.

1934

Improvement in Cryoglobulin Detection Employing a Temperature Controlled Sample Transporter. W. Winn Chatham, Moon Nahm and William H. Benjamin Jr., University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Optimal conditions for detecting serum cryoglobulins in patients with suspected vasculitis requires drawn blood samples remain at 37 degree F or higher temperature until the sample has clotted and the serum is removed. Failure to maintain these temperature conditions during sample transport to the processing laboratory may lead to failure to detect cryoglobulins and false negative test results. We determined the utility of a custom-designed sample transporter for optimizing the quality of blood samples submitted for cryoglobulin detection.

Methods: A quality study was undertaken in a hospital-based clinical immunology laboratory to assess the frequency of samples sent to the lab for cryoglobulin analysis that were deemed acceptable for optimal cryoglobulin analysis (sample temperature at or greater than 37 degrees C). Following the study, a specially designed blood tube carrier (Cryocab) containing a 300 gram 1:1 mixture of n-docosane and n-eicosane was developed for use in the hospital/clinic pneumatic tube transport systems. The mixture in the carrier melts at 38 degrees C, with a high heat of fusion when solidifying and maintaining a temperature of 38°C for several hours as the material undergoes phase transition. Following implementation of Cryocab use, a subsequent study to determine the frequency of acceptable samples arriving to the clinical immunology lab was undertaken.

Results: During a ten month time period prior to routine use of the Cryocab, only 146/226 (34%) of samples arriving in the clinical immunology lab for cryoglobulin assessment had a temperature at or exceeding 37 degrees C. During a four month time frame following implementation of routine Cryocab use by the hospital and clinic phelebotomy services, the percentage of samples arriving to the clinical immunology lab at 37 degrees or higher improved dramatically—;87/90 (97%).

Conclusion: Use of a gel-based transporter to maintain blood samples at temperatures conducive to optimal detection of cryoglobulins can dramatically improve the quality of samples arriving to the analyzing lab, and may improve cryoglobulin detection rates.

Longitudinal Peripheral Blood Lymphocyte Subsets Correlate with Decreased Disease Activity in Juvenile Dermatomyositis. Floranne C. Ernste[1], Cynthia S. Crowson[2], Consuelo Lopez de Padilla[2], Molly Hein[2], Abigail B. Green[2] and Ann M. Reed[2]. [1]Mayo Clinic Rochester, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Perturbations in peripheral blood lymphocyte (PBL) subsets in juvenile dermatomyositis (JDM) are variably and inconsistently reported in active and inactive disease. Decreased PBL CD8+ T cells and increased CD4+ T cells, and CD19+ B cells have been correlated with disease activity in JDM. Increased numbers of CD56+ NK cells have been found in inflamed muscle of JDM patients. Untreated JDM patients have decreased levels of CD3-CD16+, CD54+ (ICAM-1), CD56+ (NK) and CD3+CD8+ T suppressor cells, suggesting that they are contributing to pathogenesis. We sought to determine the subsets of PBLs which correspond with improved disease activity in JDM.

Methods: Peripheral blood mononuclear cell (PBMC) samples from 24 patients with definite JDM were collected between 2007–2011 in two visits, 3–6 months apart. Frozen PBMC samples were analyzed using fluorescence activated cell sorting and flow cytometric analysis. Childhood myositis activity tools validated by the International Myositis Assessment & Clinical Studies Group (IMACS) for the assessment of disease activity were used including visual analog scores (VAS). Spearman correlation methods were used.

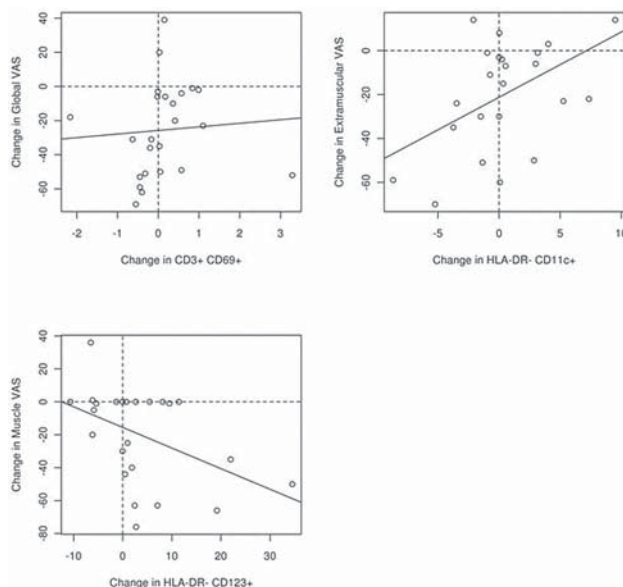
Results: The mean age was 9.5 (min: 3, max: 19) years and 15 (63%) were female. The figure shows significant correlations between the change in VAS scores between visits and change in percentage of lymphocyte subsets. The change in the percentage of CD3+ CD69+ T cells was positively correlated with the change in global VAS (p=0.037). The change in the percentage of HLA-DR- CD11c+ myeloid dendritic cells (mDCs) was positively correlated with change in extramuscular VAS (p = 0.040). The change in the percentage of HLA-DR- CD123+ plasmacytoid dendritic cells (pDCs) cells negatively correlated with change in muscle VAS (p=0.028). Although the results did not reach statistical significance, some trends were noted. The change in the percentage of HLA-DR- CD11c+ mDCs was positively correlated to the change in muscle VAS (p=0.08) and global VAS (p=0.08). The change in the percentage of CD16-CD56+ NK cells and of HLA-DR- CD86+ mDCs was positively correlated with the change in extramuscular VAS (p=0.08, and p=0.09, respectively). In addition, the change in percentage of CD16+ CD56- NK cells was inversely correlated to the change in global VAS (p=0.09).


Figure. Change between visits in peripheral lymphocyte cell subsets vs. change in VAS scores.

Conclusion: This is the first prospective study in JDM patients to identify the relationship of disease activity with PBL subsets: CD3+ CD69+ T cells, HLA-DR- CD11c+ mDCs, and HLA-DR- CD123+ pDCs. Additionally, our findings suggest that NK cells do not correlate with disease activity level in JDM. There is a trend toward decreased levels of CD3-CD16-CD56+ NK cells with decreased extramuscular VAS, and increased CD 16+CD56- NK cells with decreased global VAS.

1936

The human leukocyte antigen DRB1*13:02-DQB1*06:04-DPB1*04:01 haplotype isclosely associated with dermatomyositis patients with Anti-CADM-140 (melanoma differentiation-associated protein 5: MDA5) Antibody. Yuji Hosono[1], Chikashi Terao[2], Ran Nakashima[1], Yoshitaka Imura[1], Naoichiro Yukawa[1], Hajime Yoshifuji[1], Motomu Hashimoto[1], Koichiro Ohmura[1], Takao Fujii[1] and Tsuneyo Mimori[1]. [1]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Kyoto University, Kyoto, Japan

Background/Purpose: Recent studies have revealed that anti-CADM-140 (MDA5/IFIH1)-antibody positive dermatomyositis (DM) patients frequently develop acute or subacute progressive interstitial pneumonia (A/SIP) with poor prognosis. However, genetic background of anti-CADM-140-antibody positive DM is currently unclear. Here, we intended to analyze the relationship between specific human leukocyte antigen (HLA) alleles in anti-CADM-140-positive DM patients.

Methods: Anti-CADM-140-antibody positive DM patients (CADMs, N=20) and healthy controls (HCs, N=2972) were enrolled in this study.

Autoantibodies were screened using immunoprecipitation with [^{35}S]methionine-labelled HeLa cells. HLA class I (A, B, and C) and class II (DRB1, DQA1, DQB1, and DPB1) genotyping was carried out with a high-throughput, high-resolution genotyping method (WAKFlow WAKUNAGA) by combining PCR and sequence-specific oligonucleotide probe protocols with the Luminex 100 xMAP flow cytometry dual-laser system to quantify fluorescently labelled oligonucleotides attached to colour-coded microbeads.Allele frequency was compared between CADMs and HCs by chi-square test or Fisher's exact test. Haplotypes with frequency more than 10% in CADMs were analyzed for comparison between CADMs and HCs with chi-square test.

Results: No specific HLA class I alleles show significant associations with CADMs.CADMs demonstrated higher allele frequencies of DRB1*1302 (15% vs 5.5%; with OR=2.73,0.0854), DQB1*0604 (12.5% vs 5.5%; with OR=2.5,P= 0.0114), and DPB1*0401 (12.5% vs 5□G with OR=2.5,P= 0.03469) than HCs. However, no specific HLA alleles reached significant difference between CADMs and NCs due to lack of power. The observed distribution of HLA class II alleles among patients and controls suggested the notion that specific combinations of alleles at the DRB1, DQB1, and DPB1 loci are associated with the risk for CADMs. Haplotype analysis showed the frequency of the haplotype DRB1*13:02-DQB1*06:04-DPB1*04:01 was higher in CADMs than NCs (12.5% vs 3.6%;OR 3.79, 95%CI 1.47–9.76, P = 0.0030).

Conclusion: HLA-DRB1*13:02-DQB1*06:04-DPB1*04:01 haplotype is closely associated with CADMs, suggesting that the production of anti-CADM-140 may be associated with a certain immunogenetive background.

1937

HLA-DRB1*0101/*0405 Is Associated with Susceptibility to Anti-MDA5 Antibody-Positive Dermatomyositis in the Japanese Population. Takahisa Gono[1], Yasushi Kawaguchi[1], Masataka Kuwana[2], Tomoko Sugiura[1], Takefumi Furuya[1], Kae Takagi[1], Hisae Ichida[1], Yasuhiro Katsumata[1], Masanori Hanaoka[1], Yuko Okamoto[1], Yuko Ota[1], Sayuri Kataoka[1] and Hisashi Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Keio University School of Medicine, Tokyo, Japan

Background/Purpose: The complication of interstitial lung disease (ILD) is associated with the anti-aminoacyl tRNA synthetase antibody (ARS ab) or the anti-melanoma differentiation-associated gene 5 antibody (MDA5 ab) in polymyositis (PM)/dermatomyositis (DM). Anti-MDA5 ab is associated with clinically amyopathic DM (C-ADM) and fatal outcome due to rapidly progressive ILD (RP-ILD) in Asia. The association between genetic factors and anti-MDA5 ab-positive DM has remained unclear. We investigated the HLA-DRB1 genotype in anti-MDA5 ab-positive DM. In addition, we compared genetic differences in HLA between anti-MDA5 ab-positive DM, anti-ARS ab-positive PM/DM and PM/DM without the anti-ARS ab or ILD.

Methods: This retrospective study included patients admitted to Tokyo Women's Medical University Aoyama Hospital or Keio University Hospital from August 1992 to February 2010. Medical records were obtained from 142 and 57 patients diagnosed as having DM and C-ADM, respectively. The anti-MDA5 antibody was detected in 31 patients. DNA samples were obtained from 17 patients with the anti-MDA5 antibody, and all of these patients were enrolled in this study. All of the enrolled patients suffered from skin rashes, myopathy, or respiratory symptoms (or a combination thereof) upon admission. These patients were diagnosed as having DM or CADM based on the criteria of Bohan and Peter or Sontheimer, respectively. To investigate the characteristics of the HLA-DRB1 genotype in anti-MDA5 ab-positive DM, we compared the genetic differences among 17 patients with anti-MDA5 ab-positive DM, 33 patients with anti-ARS ab-positive PM/DM, 33 PM/DM patients without anti-ARS ab or ILD and 265 healthy controls (HCs).

Results: The HLA-DRB1*0101 and DRB1*0405 alleles were identified in 5 (29%) patients and 12 (71%) patients, respectively, which were higher than the frequencies in HCs (10% and 25%, respectively). The HLA-DRB1*0101 or *0405 allele was identified in 16 (94%) of the 17 patients. No patients had homo alleles of HLA-DRB1*0101 or DRB1*0405. One patient had both DRB1*0101 and DRB1*0405. With respect to the clinical phenotype, 16 patients had C-ADM. ILD complication was observed in all of the patients. Moreover, the frequency of RP-ILD was high (65%). No patients

had RA or other connective tissue diseases as complications.The frequency of the DRB1*0101 or 0405 allele was significantly higher in anti-MDA5 ab-positive DM patients compared with PM/DM patients without anti-ARS ab or ILD (P = 1.1e-05, odds ratio 42.7, confidence interval [CI] 4.9–370.2) or anti-ARS ab-positive PM/DM patients (P = 4.5e-03, odds ratio 13.3, CI 1.6–112.6).

Conclusion: HLA-DRB1*0101/*0405, which were defined as 'shared epitope' alleles in RA, is associated with susceptibility to anti-MDA5 ab positive-DM in the Japanese population. These alleles were also associated with ILD complication in PM/DM.

A New Enzyme-Linked Immunosorbent Assay System for Detecting Autoantibodies to Aminoacyl-tRNA Synthetases: Clinical Usefulness in Myositis and Interstitial Pneumonia. Ran Nakashima[1], Yoshitaka Imura[2], Minae Seto[3], Akihiro Murakami[3], Yuji Hosono[2], Kizuku Watanabe[4], Tomohiro Handa[4], Michiaki Mishima[4], Michito Hirakata[5], Tsutomu Takeuchi[6], Keishi Fujio[7], Kazuhiko Yamamoto[8], Hitoshi Kohsaka[9], Yoshinari Takasaki[10], Noriyuki Enomoto[11], Kingo Chida[11], Toshihiro Nukiwa[12] and Tsuneyo Mimori[1]. [1]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Kyoto University Graduate School of Medicine, Kyoto, Japan, [3]Medical & Biological Laboratories Co., Ltd., Ina, Japan, [4]Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, Japan, [5]Keio University, Tokyo, Japan, [6]Keio University School of Medicine, Tokyo, Japan, [7]Graduate school of Medicine, The University of Tokyo, Tokyo, Japan, [8]Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, [9]Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan, [10]Division of Rheumatology, Department of Internal Medicine, Juntendo University, Tokyo, Japan, [11]Hamamatsu University School of Medicine, Hamamatsu, Japan, [12]Department of Respiratory Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan

Background/Purpose: Autoantibodies to aminoacyl-tRNA synthetases (ARS) are the most frequent myositis-specific antibodies and they are useful in the diagnosis and management of polymyositis (PM)/ dermatomyositis (DM) and interstitial pneumonia (IP). However, routine detection of all of them at once is not available. We developed an enzyme-linked immunosorbent assay (ELISA) system using a mixture of recombinant ARS antigens to detect them easily and simultaneously. We tested the usefulness of this system for diagnosing PM/DM and IP in the multicenter study.

Methods: We prepared 6 recombinant ARS antigens; GST-Jo-1, His-PL-12, His-EJ and GST-KS expressed in *Eschericha coli*, and His-PL-7 and His-OJ expressed in Hi-5 cells. After confirming antigenic activity of all the recombinant proteins except His-OJ, using immunoblotting or ELISA, we made an ELISA system mixing the five recombinant ARS antigens. Efficiency was confirmed using the sera from 549 Japanese patients with various connective tissue diseases (PM/DM 273, systemic lupus erythematosus (SLE) 91, systemic sclerosis (SSc) 70, rheumatoid arthritis (RA) 75, Sjögren's syndrome (SS) 27 and other diseases 13), 170 idiopathic IP (IIP) and 30 healthy controls collected from 8 institutes. IIP was classified into two groups according to the radiologic pattern, usual interstitial pneumonia (UIP) (n=36) and non-UIP (n=132). **Results** were compared with those of the standard RNA immunoprecipitation assay.

Results: All of the ELISA results were consistent with those of the immunoprecipitation assay, except for one false-positive sample. Sensitivity and specificity were 100% and 99.8%, respectively when compared with the RNA immunoprecipitation. Anti-ARS antibodies were detected in 34.8% of PM/DM, 2.2% of SLE, 2.9% of SSc, 4% of RA, 0% of SS and 10.6% of IIP. None of the healthy controls were positive for anti-ARS antibodies. The frequency of each anti-ARS antibodies was compatible with previous reports. Anti-ARS-positive PM/DM patients had IP much more frequently than anti-ARS-negative PM/DM patients (87.3% vs. 48.6% respectively, p<0.001). In IIP, anti-ARS antibodies were positive in 5.6% of UIP and 12.1% of non-UIP. Anti-ARS-positive IIP patients were younger and more frequently treated with corticosteroids and/or immunosuppressants than anti-ARS-negative patients.

Conclusion: A newly established anti-ARS ELISA system detected anti-ARS antibodies as efficiently as RNA immunoprecipitation. This system will enable the easier and wider detection of anti-ARS antibodies in patients with PM/DM and IP in daily practice.

Overexpression of Ankyrin Repeat Domain Containing Protein 1 Gene (*ANKRD1*) in Dermatomyositis Muscle Biopsies Is Correlated to Hypoxia and Perifascicular Atrophy. Samuel K. Shinjo, Sueli M. Oba-Shinjo, Miyuki Uno and Suely K. N. Marie. Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: *ANKRD1* codes for ankyrin repeat domain containing protein 1, which belongs to the muscle ankyrin repeat protein family involved in a mechano-signaling pathway that links myofibrillar stress response to muscle gene expression. In addition, *ANKRD1* has an important role in transcriptional regulation, myofibrillar assembly, cardiogenesis, myogenesis and also possibly in angiogenesis. Microvasculopathy is considered as a cornerstone and early pathological change in dermatomyositis (DM), leading to hypoxia, capillary necrosis and muscle perifascicular atrophy. These alterations could upregulate genes involved in myogenesis and angiogenesis like *ANKRD1*. Therefore, we analyzed *ANKRD1* expression in muscle biopsies of DM patients and correlated with other hypoxia parameters.

Methods: RNA was extracted from frozen muscle biopsies samples of 30 untreated adult DM patients (Bohan and Peter's criteria, 1975). As a control group, we analyzed 20 muscle biopsies with no histological change from untreated adult patients with non-inflammatory myopathy diseases. The gene coding for hypoxia-inducible factor 1, alpha subunit (*HIF1A*) was analyzed to estimate hypoxia degree. The *ANKRD1* and *HIF1A* transcript expression levels were determined by quantitative real time PCR using Sybr Green method. Perifascicular atrophy was analyzed histologically by semi-quantitative method of HE stained biopsies. Expression and localization of ANKRD1 and HIF1a in muscle biopsies was accessed by immunohistochemistry.

Results: Higher *ANKRD1* and *HIF1A* expressions levels were observed in DM relative to control group ($p<0.001$ and $p<0.001$). In addition, the expression levels of both genes were correlated (r=0.703, $P=0.001$). We also observed a positive correlation of both genes to perifascicular atrophy (r=0.420, $p=0.023$ and r=0.404, $p=0.030$, respectively). However, *ANKRD1* and *HIF1A* expression levels did not correlate to demographic, clinical and laboratory features ($p>0.05$). Immunohistochemistry showed that ANKRD1 and HIF1a were expressed mainly by atrophic muscle perifascicular cells.

Conclusion: Our results demonstrated *ANKRD1* is overexpressed, correlated to *HIF1A* in perifascicular atrophic fibers of DM muscle specimens. *ANKRD1* involvement in myogenesis and angiogenesis mechanism will be further investigated.

A Comprehensive Study of Novel Serum Markers of ILD Associated with Inflammatory Myopathies. Fang Chen, Xiaoming Shu, Xin Lu and Guochun Wang. China-Japan Friendship Hospital, Beijing, China

Background/Purpose: To investigate and compare the association between serum markers and Interstitial Lung Disease (ILD) in patients with inflammatory myopathies(IIM).

Methods: Serum levels of KL-6, anti-melanoma differentiation-associated gene 5(MDA5), monocyte chemotactic protein-1 (MCP-1),Surfactant protein-A,D (SP-A, SP-D) were detected by ELISA in 119 adult IIM patients and 50 healthy controls. The association between serum levels and clinical signs of ILD in patients with IIM was analyzed.

Results: Serum KL-6, anti-MDA5,MCP-1,SP-A, SP-D were significantly elevated in IIM patients with ILD(all $P<0.05$). KL-6 showed the highest value (sensitivity 90.9% and specificity 80.6%) for diagnosing ILD. Anti-MDA5 could effectively diagnose acute/subacute interstitial pneumonia (A/SIP) in DM patients (sensitivity 88.2%, specificity 94%). Patients with elevated KL-6 showed more frequently ground glass opacity than those with normal KL-6(all $P<0.05$). Inverse correlations were found between serum KL-6/SP-A/SP-D and lung function parameters such as DLCO% and FVC (all $P<0.05$). KL-6 (OR 1.032, 95%CI 1.006–1.059, $P=0.016$) and anti-MDA5 (OR = 8.46, 95% CI 1.77–40.36, P = 0.007) are independent risk factors predicting unfavorable prognosis in IIM patients with ILD.

Conclusion: Serum KL-6, anti-MDA5,MCP-1,SP-A, SP-D are useful markers for ILD in IIM patients, of which KL-6 presented highest diagnosing value. Anti-MDA5 may be a useful marker for A/SIP in patients with DM. these biomarkers can help diagnosing ILD and predicting prognosis in IIM patients with ILD though they cannot replace conventional diagnosing procedure.

Clinical Evaluation of Anti-Aminoacyl tRNA Synthetase Antibodies in Japanese Patients with Connective Tissue Diseases. Masakazu Matsushita, Toshio Kawamoto, Ken Yamaji, Naoto Tamura and Yoshinari Takasaki. Juntendo University School of Medicine, Tokyo, Japan

Background/Purpose: Anti-Jo-1 antibody is an autoantibody specifically detected in sera of patients with polymyositis/dermatomyositis (PM/DM). The antigen corresponding to this autoantibody is histidyl-tRNA synthase, being an aminoacyl-tRNA synthase (ARS), which occurs in the cytoplasm of eukaryotes. Many autoantibodies directed to other ARS have been identified in recent years, and the condition of patients positive for these antibodies is currently termed anti-ARS antibody syndrome in that such condition is characterized by clinical features of pulmonary lesions and cutaneous manifestations. This study was performed to evaluate the clinical usefulness of determination of serum anti-ARS antibody levels in patients with PM/DM or other connective tissue diseases.

Methods: The study included 197 outpatients with connective tissue diseases at this hospital. Of them, 62 patients had PM/DM, 39 had systemic lupus erythematosus (SLE), 31 had rheumatoid arthritis (RA), 21 had Sjögren's syndrome (SjS), 12 had progressive systemic sclerosis (SSc), 11 had mixed connective tissue disease (MCTD), 7 had vasculitis syndrome, 5 had Behçet's disease, 4 had adult-onset Still's disease, and 5 had other diseases. Determination of anti-ARS antibodies was carried out using Myositis Profile 3 Euroline Blot Test Kit commercially available from EUROIMMUN (Lubeck, Germany), in accordance with the manufacturer's instructions. For each clinical entity concerned, anti-ARS antibody positivity rate, antinuclear antibody staining pattern, the presence/absence of concurrent interstitial pneumonia (IP), and dose levels of the corticosteroids or immunosuppressants used were assessed.

Results: Anti-ARS antibodies were detected with a significantly higher frequency among PM/DM patients with concurrent IP. Positivity for anti-ARS antibodies was observed even among RA patients with clinical signs of IP. Patients with PM/DM in whom cytoplasmic stain with antinuclear antibody was evident were frequently positive for anti-ARS antibodies other than anti-Jo-1 antibody even if they had negative results for this antibody. In patients negative for cytoplasmic staining, however, no other anti-ARS antibodies were detected. In patients with PM/DM complicated by IP positive for anti-ARS antibodies, the dosage of corticosteroids and percentage of patients receiving immunosuppressant therapy tended to be higher as compared with those negative for anti-ARS antibodies.

Conclusion: The present data suggest that the determination of serum anti-ARS antibody levels is clinically useful even in patients with IP-complicated connective tissue disease other than PM/DM. A strong association of the autoantibodies with pulmonary lesions was noted particularly in RA patients. The results also suggest that determination of serum anti-ARS antibody levels may be less necessary in myositis patients showing no positive cytoplasmic staining in the antinuclear antibody test using HEp-2.

1942

Increased Levels of Eotaxin and MCP-1 in Juvenile Dermatomyositis Median 17 Years After Diagnosis; Associations with Disease Activity, Duration and Organ Damage. Helga Sanner[1], Thomas Schwartz[2], Berit Flatø[1], Maria Vistnes[2], Geir Christensen[2] and Ivar Sjaastad[1]. [1]Oslo University Hospital, Oslo, Norway, [2]University of Oslo, Oslo, Norway

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic vasculopathic disease of childhood affecting skeletal muscle, skin and other organs. Increased abundance of pro-inflammatory cytokines has been shown in JDM patients in the active phase of the disease. We now wanted to compare cytokine profiles in JDM patients after medium to long-term follow-up with matched controls, and to examine associations between cytokine levels and disease activity, disease duration and organ damage in JDM.

Methods: Inclusion criteria were a probable or definitive diagnosis of Dermatomyositis (DM) according to the Bohan/Peter criteria for DM, disease onset before 18 years and minimum 24 months disease duration. A retrospective inception cohort of JDM patients was established; 54 patients were clinically examined median 16.8 years (range 2–38 years) after disease onset and compared with 54 age- and sex-matched controls (randomly drawn from the Norwegian population register). Concentrations of 26 cytokines in plasma were quantified by Luminex technology or ELISA. In patients, disease activity score (DAS), myositis damage index (MDI) and other disease parameters were collected by clinical examination (at follow-up) or chart review (from one year post-diagnosis).

Results: Serum levels of eotaxin, monocyte chemoattractant protein 1 (MCP-1) and interferon inducible protein 10 (IP-10) were higher in JDM patients compared to controls (31.5%, 37.2% and 43.2%, respectively, all P < 0.05). Levels of eotaxin and MCP-1 correlated with disease duration ($r_s = 0.47$ and $r_s = 0.64$, both P < 0.001) and age in patients, but not with age in controls. MCP-1 levels were associated with MDI, DAS, physical health and cumulative prednisolone dose at follow-up (standardized β = 0.43, 0.29, 0.28 and 0.33 respectively, all P ≤ 0.020), after adjusting for disease duration and sex in a multivariate linear regression model. High MDI 1 year post-diagnosis predicted high levels of eotaxin and MCP-1 at follow-up (standardized β = 0.24 and β = 0.29, both P < 0.05) after adjusting for disease duration and sex.

Conclusion: Patients with JDM had higher eotaxin, MCP-1 and IP-10 levels than controls after median 17 years follow-up. High eotaxin and MCP-1 was predicted by early disease parameters and MCP-1 was associated with disease activity and damage at follow-up. It is not clear whether eotaxin and MCP-1 per se cause sustained inflammation; they might also be markers for disease damage as a result of disease activity caused by other unknown mechanisms. Either way, the novel knowledge on these substances can improve insight and treatment modalities of JDM.

1943

Autophagy Expressions Were Decreased in Circulating T Cells in Inflammatory Myopathies Patients. Fang Chen, Xiaoming Shu, Xin Lu and Guochun Wang. China-Japan Friendship Hospital, Beijing, China

Background/Purpose: The autophagy in circulating lymphocytes in IIM patients has not been clarified yet. Our research is aimed to study the autophagy in circulating T cells in IIM patients and to explore the possible role of aberrant autophagy contributing to the pathogenesis of IIM.

Methods: circulating T cells were isolated from 27 IIM patients and 19 normal controls. The expressions of protein and mRNA level of autophagy-related molecules (LC3, Beclin1) were examined by western blot and quantitative PCR. Transmission electron microscope was applied to detect the formation of autophagosome in circulating T cells.

Results: The formation of autohagosome in circuiting T cells of IIM patients was decreased than those of normal controls (P<0.01). The expression of LC3 and Beclin 1 proteins and mRNA level in circulating T cells of IIM patients (Beclin protein: 0.34±0.08; LC3 protein: 0.08±0.03; Beclin mRNA: 0.014±0.007; LC3 mRNA: 0.11±0.046) were both significantly lower in IIM patients than those in healthy controls (Beclin protein: 0.52±0.13; LC3 protein: 0.13±0.05; Beclin mRNA: 0.021±0.01; LC3 mRNA: 0.17±0.095) (all p<0.05).

Conclusion: Autophagy expression was decreased in circulating T cells in IIM patients. Further study is needed to explore the possible role of aberrant autophagy contributing to the pathogenesis of IIM☐B

1944

Expression of Human Leukocyte Antigen-G in Polymyositis or Dermatomyositis. Xiaolan Tian, Xiaoming Shu, Xin Lu, Qinglin Peng and Guochun Wang. China-Japan Friendship Hospital, Beijing, China

Background/Purpose: Human leukocyte antigen-G is a non-classical MHC--I molecule that may be involved in the pathogenesis of autoimmune diseases, but the significance of HLA-G in polymyositis/dermatomyositis (PM/DM) remains to be determined. The aim of this study was to determine HLA-G expression in patients with PM/DM.

Methods: Consecutive cryosections of muscle biopsies obtained from 30 PM/DM patients(22 DM, 8 PM)and 8 healthy controls were detected by immunohistochemical analysis. Serum soluble HLA-G (sHLA-G) levels of 96 patients (26 PM, 70 DM) and 35 matched healthy controls were measured by ELISA. The relationship between sHLA-G levels and clinical or laboratory variables in PM/DM patients was analyzed.

Results: HLA-G had a higher expression in 18 of 30 cases of PM/DM (60%) than that in 0 of 8 healthy controls (P =0.000). Serum level of sHLA-G in PM/DM patients were significantly higher than healthy controls [(43.96±70.20)U/ml vs (4.22±5.13)U/ml, P= 0.000]. Importantly, serum sHLA-G levels in non-treated PM/DM patients (75.75±99.07 U/ml) were significantly higher than that in treated patients (33.94±51.97) U/ml, P=0.021]. Spearman rank correlation analysis showed serum sHLA-G levels were negatively correlated with CD3+Tcells (r=−0.233, P=0.047) and CD4+Tcells (r=−0.287, P=0.015) in peripheral blood in patients with PM/DM.

Conclusion: HLA-G was found to be highly expressed in muscle tissues and sera from patients with PM/DM. Serum sHLA-G is increased in PM/DM patients and is associated with lower level of CD3+T cells and CD4+T cells. These data support the notion that HLA-G overexpression has a role in the progression of PM/DM through T cells.

1945

Anti-Transcription Intermediary Factor 1-Gamma (TIF1-γ) Autoantibody Detection by ELISA and Immunoprecipitation in a Prospective Myositis Cohort: Predictive Value for Cancer Associated Myositis. Rohit Aggarwal, Noreen Fertig, Danielle Goudeau, Chad Stephans, Qi Zengbiao, Diane Koontz, Mary Lucas, Marc C. Levesque and Chester V. Oddis. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Myositis [particularly dermatomyositis (DM)] is associated with cancer and anti-transcription intermediary factor-1 gamma (TIF1γ) is a serologic risk factor for cancer associated myositis (CAM). Anti-TIF1γ detection by immunoprecipitation is costly, time-consuming and research-based. We used a validated anti-TIF1γ ELISA to determine the frequency of this marker in a large prospective myositis cohort, to compare it with the identification of TIF1γ by IP and to determine whether quantitative anti-TIF1γ levels could identify CAM patients.

Methods: We analyzed a prospectively collected computer and serum database of adult myositis (n=856) patients to identify CAM patients with a non-skin (basal/squamous cell) cancer within 3 years (CAM3) or 5 years (CAM5) (before or after) the myositis diagnosis. A control group of polymyositis (PM), DM and overlap myositis (OM) patients without CAM matched 2:1 by gender and age (+/−10 years) and with a minimum 5 year follow up was selected. Serum was assessed for anti-TIF1γ by ELISA and IP.

Results: Using anti-TIF1γ detection by IP as the gold standard, the ELISA had 91% sensitivity, 96% specificity, 93% positive predictive value (PPV) and 95% negative predictive value (NPV) for anti-TIF1γ detection. There were 34 and 22 PM CAM5 and CAM3 cases (26F/8M), respectively, and 69 PM (53F/16M) controls, who were anti-TIF1γ (−) by IP (n=32) and ELISA (n=22). Six OM CAM5 cases (4F/2M), 3 being CAM3, were also anti-TIF1γ (−) by IP and ELISA (n=5) and 15 OM controls were anti-TIF1γ (−) by IP (n=13) and ELISA (n=14) except for 1 SSc-PM overlap patient. Of 45 CAM3 DM patients (31F/14M), 34 (24F/10M; mean age 58) had anti-TIF1γ IP and ELISA testing along with 95 DM controls (59F/36M; mean age 47). Anti-TIF1γ by IP was (+) in 47% CAM3 and 23% controls with

47% sensitivity, 82% specificity, 50% PPV and 80% NPV. By comparison, anti-TIF1γ by ELISA showed similar test characteristics at a low (+) cutoff (6 units/ml) while higher specificity (98%) was noted with a high (+) (>100 units/ml) cutoff but with a loss of sensitivity (35%). The odds of CAM3 was 3–4x higher in patients with TIF1γ positivity by IP or ELISA, but 25x higher in patients with a high (+) ELISA. Similar results were seen for CAM5 DM. Most DM-CAM patients were diagnosed within 1 year (31/34) before or after the myositis diagnosis and 3 females with high (+) anti-TIF1γ ELISAs decreased markedly after cancer treatment on longitudinal follow up. A high (+) ELISA (>50units/ml) was common in breast, ovarian and lung cancers (13/24) and in CAM within 1 year of myositis diagnosis (6/12).

Conclusion: This is the first case-control study in CAM using anti-TIF1γ by IP and ELISA. Anti-TIF1γ was not seen in PM or OM with or without cancer, but was highly specific for DM. Anti-TIF1γ was also seen in non-CAM DM (23–32% depending on detection method) contrary to previous studies showing a specificity of >90% in DM-CAM. Moreover, ELISA has similar test characteristics to IP for anti-TIF1γ detection with greater specificity and likelihood (i.e. odds) to identify cancer in a myositis patient with high levels of anti-TIF1γ. Finally, longitudinal follow up of anti-TIF1γ by ELISA may be useful prognostically.

1946

Effect of Immunosuppressive Treatment On Gene Expression in Patients with Polymyositis and Dermatomyositis. Ingela M. Loell[1], Yi-Wen Chen[2], Marina Korotkova[1], Kanneboyina Nagaraju[3] and Ingrid E. Lundberg[1]. [1]Karolinska Institutet, Stockholm, Sweden, [2]Children's National Medical Center, Washington, [3]Children's National Medical Center, Washington, DC

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) muscle tissue is characterized by infiltrating T cells, macrophages and dendritic cells, as well as cytokines and chemokines. In addition, the muscle fibers express major histocompatibility complex (MHC) class I. Patients are treated with high doses of glucocorticoids in combination with additional immunosuppressive drugs. However, remaining signs of inflammation in the muscle tissue, such as T cells, MHC class I and cytokines, as well as sustained muscle impairment are common even after prolonged treatment. Our aim was to investigate how the gene expression in pathways of inflammation and muscle remodeling is affected by immunosuppressive treatment in patients with PM and DM.

Methods: Six newly diagnosed, untreated patients (2 PM/4 DM, 2 men/4 women) with biopsies from *m.vastus lateralis* before and after a median of 10 (8–16) months of immunosuppressive treatment were analyzed using microarray.

Results: Alterations in a number of genes coding for immune responses and muscle tissue remodelling were observed.

202724_s_at	forkhead box O1A	FOXO1	2, 2	0, 033

Conclusion: This data indicates that transcriptional alterations in genes involved in muscle tissue structure are taking place during immunosuppressive treatment. The treatment down-regulates the muscle inflammation to some extent but the local milieu might be accountable for the preserved expression of inflammatory cells and mediators seen in treated PM/DM patients.

1947

Muscle Wasting in HTNFtg Mice, an Animal Model for Rheumatoid Arthritis, Due to Increased Cathepsin L and LC3B Expression. Martin Willburger[1], Birgit Niederreiter[1], Ewald Unger[1], Josef S. Smolen[2], Kurt Redlich[1] and Silvia Hayer[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: To investigate the impact of systemic inflammation on skeletal muscles in human tumor necrosis factor transgenic (hTNFtg) animals.

Methods: We isolated triceps surae, quadriceps, tibialis anterior as well as rectus abdominis muscles from hTNFtg animals at different time-points of disease starting at week 4 after birth. Muscle weight and body weight were assessed from these animals. Age and sex-matched wildtype (wt) animals served as controls. We performed quantitative real-time PCR for Cathepsin L, B, S, H, D, LC3-B, MMP-9 and Interleukin (IL)-1 and IL-6 from mRNA isolated from muscle tissues of hTNFtg and wt animals. Moreover, hTNFtg animals were treated for 5 weeks with anti-TNF ab (Infliximab, 10mg/kg, 3x per week, i.p.) starting either at week 6 or week 10 after birth. Muscle tissue sections were also stained for macrophages, neutrophils, T cells and B cells. Mobility of animals was assessed by video-analysis using Ethovision Software (from Noldus, The Netherlands). Functionality of triceps surae muscle was evaluated by electro-stimulation.

Results: We could demonstrate that hTNFtg mice significantly lost muscle weight when compared to sex- and age matched wt animals. Reductions in muscle weight became already manifest at early stages of the disease, at week 4, and continuously progressed until week 16. Bodyweight was also significantly lower in hTNFtg animals compared to their wt littermates. Next, we found significantly increased mRNA expression levels of Cathepsin L, a lysosomal endopeptidase responsible for muscle protein degradation, in muscles from hTNFtg compared to their wt littermates. In contrast, other proteases such as cathepsin B, S, H, D did not significantly increased differ. In addition, we also found LC3B, an enzyme for autophagy-lysosome-mediated proteolysis, to be upregulated in hTNFtg mice compared to wt animals. Moreover, proinflammatory cytokines such as IL-1 and IL-6 were also significantly upregulated in muscles from hTNFtg mice. Interestingly, we observed an increased presence of macrophages and granulocytes in the muscle vascular system but no accumulation of inflammatory cells into the muscle tissue. We also investigated the rectus abdominis muscle, which is not located between inflamed articular joints, and found elevated levels of Cathepsin L and LC3B in this muscle, indicating that hTNFtg mice suffer from a systemic muscle proteolysis due to systemic inflammation. In addition, functionality of muscles was impaired as observed by markedly reduced maximal strength and faster fatigue in triceps surae from hTNFtg mice compared to wt animals. Remarkably, mobility of hTNFtg animals was already significantly reduced at week 6 indicating reduced use of muscles at early stage of TNF driven disease. TNF blockade at both early and late time points could completely rescue mobility to wildtype levels, whereas muscle atrophy could not be prevented by treatment at late stage of arthritis.

Conclusion: Despite spontaneous development of chronic inflamed, erosive arthritis, chronic overexpression of TNF leads to skeletal muscle atrophy due to increased tissue-degrading cathepsin L and LC3B and reduced mobility starting at early phase of arthritis disease in hTNFtg animals.

1948

Decreased C4A Gene Copy Numbers in Children with Juvenile Dermatomyositis: Association with Decreased C4 Protein and Lower Absolute Number of CD3 Negative CD16/56+ Natural Killer Cells.

Lauren M. Pachman[1], Katherine E. Lintner[2], Yee Ling Wu[2], Lori J. Ferguson[3], Gabrielle A. Morgan[3], Chiang-Ching Huang[4] and C. Yung Yu[2]. [1]Division of Pediatric Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]The Research Institute at Nationwide Children's Hospital and The Ohio State University, Columbus, OH, [3]Children's Hospital of Chicago Research Center, Cure JM Myositis Center, Chicago, IL, [4]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: Juvenile Dermatomyositis (JDM), a systemic vasculopathy, is member of the family of autoimmune diseases. In 56% of untreated JDM, a decrease in the absolute number of natural killer cells reflects immune activation and increased disease activity. JDM is also associated with *B*08*, *DRB1*03*, *DQA1*0501*, *C4B1*, *C4AQ0 (null),* and *TNFA*-308A polymorphism, in linkage disequilibrium on chromosome 6. In the families of children with JDM, there is a significant increase in the history of systemic lupus erythematosus (SLE). Patients with SLE, have an overrepresentation *of C4A* null alleles, with associated decreased levels of the C4 protein. The frequency of *C4A deficiency* in children with JDM is unknown.

Objective: To determine the association of C4 protein and other clinical parameters with C4A gene copy number in JDM.

Methods: A cross-sectional cohort of children, n=91, with definite/probable JDM (overlap syndromes excluded) were enrolled (IRB# 2008–13457). There were 78% (71/91) girls, 96.7% (88/91) White, mean age of 5.06 yrs, and 35% (32/91) were untreated at time of first visit. Genomic DNA was assessed for gene copy number (GCN) for total *C4*, *C4A* and *C4B* by real time qPCR; EDTA-plasma was used to determine C4A and C4B polymorphisms and validate genotype data. Data for C4 protein concentrations, disease activity scores (DAS) for skin involvement and muscle weakness were obtained, along with nailfold capillary end row loop number, and absolute cell count of CD3negative, CD56/16 positive natural killer (NK) cells at time of first visit. NHANES normative data obtained from 523 subjects for C4A gene copy number were used as a comparator.

Results: Patients with JDM have lower *C4A* GCN than the general population (30% vs. 17% with 0–1 copy, p=0.009, Chi-square test). The level of C4 protein was significantly associated with the *C4* total gene copy number, p<0.001; the C4 protein levels increases by 3.61 unit/one *C4* copy number. The C4 protein concentration was not significantly associated with any of the following: nailfold capillary end row loop number, DAS skin or DAS muscle. However, there was a significant association of the *C4A* GCN with the absolute number of circulating CD3negative NK cells in JDM (p=0.02).

Conclusion: Children with JDM have decreased levels of C4 protein as a function of significantly decreased GCN of *C4*. Although the decreased C4 was not associated with nailfold capillary end row loop numbers, or clinical disease activity markers, the *C4A* GCN appeared to be associated with the absolute levels of circulating NK cells, suggesting a locus of control on chromosome 6. We speculate that the decrease in C4 as a consequence of *C4A* GCN may contribute to the pathogenetic mechanisms of damage in JDM.

Anti-Transcription Intermediary Factor 1-Gamma (TIF1-γ) Autoantibody ELISA Development and Validation.

Rohit Aggarwal, Chester V. Oddis, Noreen Fertig, Danielle Goudeau, Diane Koontz, Chad Stephans, Zengbiao Qi and Marc C. Levesque. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Anti-transcription intermediary factor 1-gamma (TIF1-γ) autoantibody is disease-specific for myositis and identifies a subset of dermatomyositis patients at risk of cancer. Currently non-quantitative immunoprecipitation (IP) is used to identify anti-TIF1-γ. IP has several limitations and development of a quantitative ELISA would improve anti-TIF1-γ detection, especially for cancer screening in myositis. Our aim was to develop and validate a quantitative anti-TIF1-γ ELISA.

Methods: The ELISA utilizes recombinant purified full length human TIF1-γ (Origene Technologies, Rockville MD) coated on the solid surface of a high-binding ELISA plate (Costar, Corning, NY). Patient serum (dilution ≥1:100) was incubated with TIF1-γ coated ELISA plates and a horseradish peroxidase conjugated secondary antibody that binds human IgG detected anti-TIF1-γ binding. 3,3′,5,5′-tetramethylbenzidine was the horseradish peroxidase enzyme substrate, and the optical density of the resulting chromagen was measured. Units/ml of anti-TIF1-γ were determined using a standard serum sample. Values below the detection range (< 4 U/ml) were considered negative and were assigned a value of 2. Assay validation utilized lP results as the gold standard for anti-TIF1-γ. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), ROC curve and area under the curve (AUC) were evaluated. Mann-Whitney tests were used to compare levels of anti-TIF1-γ. Agreement between ELISA and IP was tested. Test-retest reliability was measured. Myositis patients with positive and negative anti-TIF1-γ by IP and non-myositis patients (scleroderma, lupus and RA) and healthy samples were analyzed.

Results: We identified 55 myositis patients with anti-TIF1-γ by IP and 111 myositis patients without anti-TIF1-γ from our connective tissue disease database. Anti-TIF1-γ positivity by ELISA significantly correlated with IP results (p<0.001) with strong agreement between both methods (kappa 0.867). Median (IQR) anti-TIF1-γ levels in patients with (+) and (−) anti-TIF1-γ IP results was 42 (16–95) and 2 (2–2) units/ml, respectively (p<0.001) (figure 1). The sensitivity, specificity, PPV, NPV and overall accuracy of the anti-TIF1-γ ELISA was 91%, 96%, 93%, 95% and 94%, respectively. The AUC of a ROC curve was 0.938. Test-retest reliability was strong (Pearson r = 0.913, p<0.001). Inter-assay CV: 19.5%

Figure 1.   Anti-TIF1-γ antibody levels by ELISA.

Conclusion: We developed a quantitative ELISA for detecting anti-TIF1-γ autoantibodies and validated the assay using serum samples from patients with myositis and other autoimmune disorders. The anti-TIF1-γ ELISA is simple, sensitive and highly specific. The availability of a validated, quantitative ELISA should improve the detection of anti-TIF1-γ antibodies in myositis and malignancies in these patients.

Anti-Signal Recognition Particle Autoantibody ELISA Development and Validation: Utility in Patients with Necrotizing Myopathy. Rohit Aggarwal, Chester V. Oddis, Danielle Goudeau, Chad Stephans, Noreen Fertig, Qi Zengbiao, Diane Koontz and Marc C. Levesque. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Anti-signal recognition particle (SRP) autoAb identifies a myositis subset with a necrotizing myopathy and poor prognosis. Currently, immunoprecipitation (IP) is used to identify anti-SRP. Our aim was to develop and validate a quantitative anti-SRP ELISA to streamline anti-SRP detection.

Methods: The anti-SRP ELISA utilized recombinant purified full length human SRP54 (Diarect AG product number 18401) coated on a high-binding ELISA plate (Costar, Corning, NY). Patient (pt) serum (dilution $\geq$1:100) was incubated with ELISA plates and a horseradish peroxidase conjugated secondary antibody that binds human IgG quantified anti-SRP binding. Units/ml of anti-SRP were determined using a standard serum sample. Values below the detection range ($<$4 U/ml) were considered ($-$) and assigned a value = 2. Values $>$128 U/ml were assigned a value = 128. Assay validation utilized lP as the gold standard. The following test characteristics were evaluated: sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), accuracy, ROC curve and sensitivity analysis, and area under the curve (AUC). Mann-Whitney tests compared anti-SRP levels and kappa statistics tested agreement between ELISA and IP. Controls included a) anti-SRP ($+$) and ($-$) myositis pts by IP, b) scleroderma (SSc) and lupus pts, and c) other SRP ($-$) necrotizing myopathy pts. Serial samples from 7 SRP ($+$) pts by IP were also tested.

Results: We identified 26 SRP ($+$) myositis pts by IP. 77 SRP ($-$) myositis pts by IP were evaluated as controls (including 37 pts with necrotizing myopathy). Non-myositis control pts included SLE (n=4) and SSc (n=7). Anti-SRP positivity by ELISA correlated with IP results (p$<$0.001) with strong agreement between both methods (kappa 0.94). Median (IQR) anti-SRP levels in pts with ($+$) and ($-$) anti-SRP by IP was 113.3 (15.6–128) and 2 (2–2) units/ml, respectively (p$<$0.001). The sensitivity, specificity, PPV, NPV and accuracy of the ELISA was 88%, 100%, 100%, 96% and 97%, respectively. The AUC of a ROC curve was 0.94. Serial samples showed that anti-SRP levels decreased consistent with clinical improvement in 3 pts, were unchanged at low levels in 2 pts with stable disease, and increased in 1 pt with a myositis flare. Inter-assay coefficient of variance (CV) was 23%.
Figure 1. Anti-SRP antibody ELISA levels in different myositis subsets.

Conclusion: We developed a quantitative ELISA for anti-SRP autoAbs, validating the assay in myositis and other rheumatic disease pts including a group of SRP ($-$) necrotizing myopathy pts. The ELISA is simple to perform, sensitive and highly specific. The availability of a validated, quantitative, easy to perform ELISA should improve anti-SRP autoAb detection in myositis pts facilitating early identification of pts with a refractory necrotizing myopathy necessitating aggressive therapy.

Elevated Level of Tumor Necrosis Factor-Like Weak Inducer of Apoptosis in Patients with Polymyositis or Dermatomyositis. Qinglin Peng, Xin Lu, Ning Zu, Lu Zhang and Guochun Wang. China-Japan Friendship Hospital, Beijing, China

Background/Purpose: TNF-like weak inducer of apoptosis (TWEAK), a member of the tumor necrosis factor (TNF) family, has emerged as a cytokine that regulates multiple cellular responses, including proinflammatory activity, angiogenesis and cell proliferation. Increased levels of TWEAK were observed in many types of autoimmune diseases, such as rheumatoid arthritis, multiple sclerosis, and systemic lupus erythematosus. However, information about TWEAK in polymyositis and dermatomyositis is limited.The aim of the present study was to investigate the expression of TWEAK in patients with polymyositis and dermatomyositis.

Methods: Twenty four patients with polymyositis, twenty two dermatomyositis patients and twenty four healthy controls were recruited in the study. Serum levels of TWEAK were measured by ELISA. TWEAK messenger RNA (mRNA) expression in skeletal muscle from 19 out of 46 PM/DM patients and 11 healthy controls was detected by relative quantification RT-PCR. The results of two groups were compared using unpaired t test.

Results: Serum levels of TWEAK in PM/DM patients were significantly higher compared to healthy controls [(555.34$\pm$124.05) pg/ml vs (346.22$\pm$146.29) pg/ml, $P<0.05$]. However, there was no statistically significant difference between PM patients and DM patients [(533.34$\pm$119.67) pg/ml vs (579.25$\pm$127.06)pg/ml,$P>0.05$]. TWEAK mRNA in skeletal muscle showed a higher level in skeletal muscle of PM/DM patients than healthy controls, using GAPDH gene as reference gene.

Conclusion: The present study shows that serum levels and mRNA expression of TWEAK were elevated in patients PM/DM. TWEAK may possibly be enrolled in pathogenesis of PM/DM.

The Effect of CXCL10 Blockade in C Protein-Induced Myositis. Jinhyun Kim[1], Jiyong Choi[2], Sung Hae Chang[3], Ki Chul Shin[2], Sung-Hye Park[2], Hye Won Kim[4], Hye Jin Oh[2], Myeong Jae Yoon[4], Bong Seung Ku[5], Eun Young Lee[2], Eun Bong Lee[3], Hiroshi Kawachi[6], Hitoshi Kohsaka[7] and Yeong Wook Song[3]. [1]Chungnam National University School of Medicine, Daejeon, South Korea, [2]Seoul National University College of Medicine, Seoul, South Korea, [3]Seoul National University Hospital, Seoul, South Korea, [4]Department of Internal Medicine, School of Medicine, Seoul National University, Seoul, South Korea, [5]Department of Internal Medicine, School of Medicine, Seoul National University Hospital, Seoul, Korea, Seoul, South Korea, [6]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [7]Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan

Background/Purpose: CXCL10 (also called interferon-γ-inducible protein 10 [IP-10]) is a chemokine that plays a critical role in the infiltration of T cell in autoimmune disease such as RA and SLE. CXCL10 is reported to be expressed in muscle tissue of polymyositis, thus we investigated the role of CXCL10 and the effect of CXCL10 blockade in C protein-induced myositis, an animal model of polymyositis.

Methods: C protein-induced myositis model was induced with human skeletal C protein fragment in 8-week-old female C57BL/6 mice. Immunohistochemistry was performed to detect CXCL10 and CXCR3, its receptor in muscle tissue. CXCR3 in mouse splenocyte was investigated by flow cytometry. Migration assay of mouse splenocyte was performed with 5 μm pore transwell system. Mice with C protein-induced myositis were treated with anti-CXCL10 antibody or control IgG 8 days after the induction of myositis and the inflammation in muscle tissue was assessed 3 week after the induction.

Results: Immunohistochemistry showed the expression of CXCL10 and CXCR3 in the muscle of C protein-induced myositis. Flow cytometry demonstrated increased CXCR3+CD4+ T cells (normal mice, 14.14%±1.09% vs. C protein-induced myositis, 37.50%±5.63%) and CXCR3+CD8+ T cells (normal mice, 35.55±2.41% vs. C protein-induced myositis, 79.00%±0.89%) in C protein-induced myositis. Migration of splenocyte was increased in response to CXCL10 (chemotactic index=1.91±0.45). Treatment with anti-CXCL10 antibody (n=10) showed less inflammation score in muscles than treatment with control IgG (n=10; median [range], anti IP-10, 0.75 [0.25–2.00] vs. control IgG, 1.43 [1.125–4.25], p=0.045).

Conclusion: CXCL10 was expressed in the inflammation of C protein-induced myositis model and its blockade suppressed inflammation in muscle.

1953

Antibodies to NXP-2 and Transcriptional Intermediary Factor-Gamma Identify Patients with Cancer-Associated Dermatomyositis. David Fiorentino[1], Lisa Christopher-Stine[2], Lorinda Chung[3], Bharathi Lingala[4], Andrew L. Mammen[5], Antony Rosen[6] and Livia Casciola-Rosen[2]. [1]Stanford University School of Medicine, Redwood City, CA, [2]Johns Hopkins University, Baltimore, MD, [3]Stanford Univ Medical Center, Palo Alto, CA, [4]Stanford University, Redwood City, CA, [5]Johns Hopkins, Baltimore, MD, [6]The Johns Hopkins University, Baltimore, MD

Background/Purpose: Dermatomyositis (DM) is known to be associated with internal malignancy, and identifying patients at high risk is a high priority. Recently, several groups have shown that patients with circulating autoantibodies directed against transcriptional intermediary factor (TIF) isoforms are at increased risk of malignancy. In these studies, anti-TIF antibody positive patients were identified by immunoprecipitation of 140 kD and/or 155 kD proteins from radiolabeled cell lysates. However, this methodology can have suboptimal sensitivity and specificity. This might explain why the sensitivity and specificity of such assays for detecting those patients with cancer-associated DM varies widely in the literature. We wished to use novel sensitive assays to test if anti-TIF-g (or other) autoantibodies were associated with malignancy.

Methods: We designed, optimized and validated novel, sensitive, and highly specific assays to detect antibodies, including those against TIF-g and NXP-2. To detect TIF-g antibodies, HeLa cells were transiently transfected with the appropriate cDNA, resulting in expression levels 33–62 fold above endogenous levels. Immunoprecipitations were performed using these transfected lysates, electrophoresed on SDS-polyacrylamide gels, transferred to nitrocellulose and immunoblotted with an anti-TIF-g monoclonal antibody. NXP-2 antibodies were assayed by immunoprecipitation using ^{35}S-methionine labeled NXP-2 generated by *in vitro* transcription-translation as source material. Patient sera from two DM cohorts seen at the Stanford University Dermatology Outpatient Clinic (n = 111) and the Johns Hopkins University Myositis Center (n = 102) were tested for antibodies against TIF-g and NXP-2 using these assays. We used logistic regression to estimate odds ratios for cancer.

Results: The cohorts were similar in terms of age, gender, ethnicity distribution, as well as proportions of clinically amyopathic patients, and frequency of antibodies against NXP-2 and TIF-g. In the combined group, 17.3% and 36.2% of patients had antibodies against NXP-2 and TIF-g, respectively. Cancer was associated with DM in 35/213 (16.4%) of patients. In the group of 35 cancer patients, 11 (31.4%), 16 (45.7%) and 8 (22.9%) had antibodies against NXP-2, TIF-g, or neither. Thus, reactivity against either NXP-2 or TIF-g identified 77% of patients with cancer-associated DM. On univariate analysis, the odds ratios for cancer in patients with antibodies to NXP-2, TIF-g, or either were 2.6 (95% CI 1.1–6.0, p=0.022), 1.6 (95% CI 0.77–3.3, p=0.212), and 3.6 (95% CI 1.6–8.5, p=0.0027), respectively. This association between cancer and having either NXP-2 or TIF-g antibodies remained significant on multivariate analysis when corrected for other variables (age, gender, ANA, rash on back) that were associated with cancer in univariate analyses.

Conclusion: In this study using 2 large, well defined adult DM cohorts, and novel, highly specific assays to detect antibodies against TIF-g and NXP-2, we show that both of these antibody specificities are associated with an increased risk for cancer in patients with DM.

1954

Immune Responses to NXP-2 and TIF-g Are Associated with Distinct Clinical Phenotypes and Prognosis for Skin Disease in Dermatomyositis Patients. David Fiorentino[1], Lorinda Chung[2], Lisa Zaba[1], Bharathi Lingala[3], Antony Rosen[4] and Livia Casciola-Rosen[5]. [1]Stanford University School of Medicine, Redwood City, CA, [2]Stanford Univ Medical Center, Palo Alto, CA, [3]Stanford University, Redwood City, CA, [4]The Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD

Background/Purpose: Myositis-specific antibodies have been proposed as tools for disease classification as they are correlated with certain clinical and genetic features. Recently, two new DM-specific autoantigens have been described—;TIF-g and NXP-2. Detection of autoantibodies to these proteins has largely been assayed by immunoprecipitation from radiolabeled cell lysates, and thus may not have characterized the patients' immune responses with maximal sensitivity and specificity. We hypothesized that development of sensitive assays for detection of these specificities would enable us to see different patterns of skin and systemic disease associated with these antibodies when applied prospectively to a large DM cohort.

Methods: We designed, optimized and validated novel, sensitive, and highly specific assays to detect antibodies against TIF-g and NXP-2. To detect TIF-g antibodies, HeLa cells were transiently transfected with the appropriate cDNA, resulting in expression levels 33–62 fold above endogenous levels. Immunoprecipitations were performed using these transfected lysates, electrophoresed on SDS-polyacrylamide gels, transferred to nitrocellulose and immunoblotted with an anti-TIF-g monoclonal antibody. NXP-2 antibodies were assayed by immunoprecipitation using ^{35}S-methionine labeled NXP-2 generated by *in vitro* transcription-translation as source material. Patient sera from a large DM cohort at the Stanford University Dermatology Outpatient Clinic (n = 111) were tested for antibodies against TIF-g and NXP-2 using these assays. In order to maximize stringency and clinical utility, we compared the features of patients with a specific autoantibody to those without the antibody (as opposed to those with another antibody). Dichotomous variables were evaluated using Fisher exact tests. We used unpaired t tests (two-tailed) to evaluate differences between continuous variables.

Results: Antibodies to TIF-g and NXP-2 were detected in 37% and 14% of patients, respectively. When compared to those without antibodies to TIF-g, anti-TIF-g patients were associated with female sex, positive ANA, absence of arthralgia, "V" sign, and difficulty with controlling skin inflammation. Antibodies to NXP-2 were associated with male sex, internal malignancy, calcinosis cutis, absence of alopecia/ulceration/Gottron's papules/elbow and knee rash, positive response to hydroxychloroquine, and satisfactory control of skin disease. In the non-amyopathic subgroup, patients with antibodies to TIF-g were significantly associated with lower maximal CK values than those without (488 vs 3467, respectively, p=0.05).

Conclusion: Over 50% of our Stanford DM cohort can be typed by antibodies to either NXP-2 or TIF-g. NXP-2 antibodies are associated with calcinosis cutis, malignancy, and a benign course of skin disease, while TIF-g antibodies are characterized by absence of arthralgia, "V" sign, relatively low CK values, and skin inflammation that is difficult to control.

1955

Is the Pattern of Capillary Deposition of Complement Membrane Attack COPMLEX Useful in the Differential Diagnosis of Inflammatory? Patrick Gordon[1], Nuria Villagra[2], Istvan Bodi[2], Andrew King[2], Stefan Buk[2], Tibor Hortobagyi[2] and Safa Al-Sarraj[2]. [1]Department of Rheumatology, King's College London, London, United Kingdom, [2]Department of Clinical Neuropathology, King's College Hospital, London, United Kingdom

Background/Purpose: Inflammatory myopathies are a heterogeneous group of diseases. We investigated if the location and pattern of deposition of complement membrane attack complex (MAC) can be used in the differential diagnosis of inflammatory myopathies.

Methods: We reviewed histological sections of 227 cases of muscle biopsies in which MAC was requested for diagnosis and analysed 145 cases with clear clinical and pathological diagnosis; 88 inflammatory myopathies, 31 muscular dystrophies and 26 controls. We reviewed the immunohistochemical location of MAC, HLA Class I, utrophin, neo-myosin, together with the standard histological sections of the muscle biopsies.

Results: MAC deposition was demonstrated in 86.2% of dermatomyositis (DM), 86.5% of inclusion body myositis (IBM) and about 50% of patients with

polymyositis (PM) and mixed connective tissue disease (MCTD). Most of the DM cases (55%) showed continuous solid and strong staining pattern in the capillary wall (pattern 1) with clear tendency of perifascicular deposition but with no sarcolemmal labelling. Samples from muscles with IBM, PM and MCD showed lighter granular segmental staining (pattern 2) in the capillaries, which is frequently associated with frequent granular staining in sarcolemma of muscle fibres across the fascicles. About 31% of DM biopsies showed a mixture of patterns 1 and 2.

There were infrequent granular and infrequent granular deposits in the capillaries in about 13% of muscular dystrophies and 11% in control cases.

Conclusion: Pattern 1 deposition of MAC in capillaries appears to be more frequent in DM and could contribute to the diagnosis, in addition to other criteria. This pattern of deposition may indicative of primary humoral mechanism involving capillaries in DM. Pattern 2 deposition of MAC in capillaries and sarcolemma of other inflammatory diseases, such as IBM and PM, could suggest complement system activation secondary to the inflammatory process and muscle necrosis.

1956

A New Linked Set of Autoantibodies in Dermatomyositis: Anti-Mi-2 and Anti-Transcription Intermediary Factor (TIF) 1alpha. Minoru Satoh[1], Jason YF Chan[1], Yi Li[1], Monica Vázquez-Del Mercado[2], Marcelo Petri[3], Luis J. Jara[4], Miguel A. Saavedra[5], Claudia Cruz-Reyes[6], Eric S. Sobel[1], Westley H. Reeves[1], Angela Ceribelli[1] and Edward K.L. Chan[1]. [1]University of Florida, Gainesville, FL, [2]Universidad de Guadalajara, Guadalajara, Jalisco, México, Mexico, [3]Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, Mexico, [4]Hospital de Especialidades Centro Medico La Raza, México City, Mexico, [5]Centro Medico La Raza Instituto Mexicano del Seguro Social Mexico D.F., México D.F., Mexico, [6]Centro Medico La Raza Instituto Mexicano del Seguro Social Mexico D.F., Mexico D. F., Mexico

Background/Purpose: Myositis specific autoantibodies (MSA) produced in patients with polymyositis/dermatomyositis (PM/DM) are clinically useful biomarkers in diagnosis and management. Anti-Mi-2 antibodies that recognize nucleosome remodeling deacetylase complex are classic marker of DM. Anti-p155/140 (transcription intermediary factor 1 gamma and alpha, respectively) antibodies are one of the new MSA that have been studied actively because of their tight link to cancer-associated DM. A well known but poorly explained characteristic in MSA production is the rare coexistence of more than one MSA in each individual patient. We here report frequent coexistence of anti-Mi-2 and anti-TIF1 alpha antibodies as an exception for this concept.

Methods: Sera of patients with PM/DM from United States, Mexico, Italy, and Japan were screened for their autoantibody specificities by immunoprecipitation (IP) of ^{35}S-labeled K562 cells extract. Sera with anti-Mi-2 and anti-p155/140 were further characterized by IP-western blot (IP-WB) using monoclonal antibodies to TIF1alpha and TIF1gamma. Antibodies to TIF1alpha, gamma, and Mi-2 were also tested by ELISA using recombinant proteins. Clinical information was from the database and chart review.

Results: Forty-one anti-Mi-2 and 18 anti-p155/140 positive sera were identified and their characteristics are summarized in Table. Anti-Mi-2 positive sera immunoprecipitated a 140kD protein that comigrates exactly with TIF1alpha. This protein was determined as TIF1alpha that was immunoprecipitated by coexisting autoantibodies to TIF1alpha in majority of human anti-Mi-2 sera based on 1) disappearance of the 140kD protein from human anti-Mi-2 IP by preincubation of cell extract with anti-TIF1alpha mAb, 2) mAb to Mi-2 and rare human sera with anti-Mi-2 do not IP the 140kD protein, 3) human anti-Mi-2 sera were positive for TIF1alpha by IP-WB, and 4) human anti-Mi-2 sera were positive in anti-TIF1alpha ELISA. Autoantibodies to TIF1gamma in human anti-Mi-2 sera appeared uncommon based on 1) the 155kD protein that comigrates with TIF1gamma is not seen in human anti-Mi-2 IP, 2) lack of anti-TIF1gamma reactivity in ELISA, 3) although many human anti-Mi-2 sera were also positive for TIF1gamma, the levels of TIF1gamma immunoprecipitated by human anti-Mi-2 sera are very little compared with those by human anti-p155/140 sera, suggesting that they are via co-IP by TIF1alpha.

Table 1. Reactivity of anti-Mi-2 and p155/140 sera

	Anti-Mi-2	Anti-p155/140	control
n	41	18	5
^{35}S-IP-TIF1alpha	88%	100%	0%
^{35}S-IP-TIF1gamma	0%	100%	0%
TIF1alpha ELISA	88%	83%	0%
TIF1gamma ELISA	2%	83%	0%
TIF1alpha-IP-WB	88%	100%	0%
TFI1gamma-IP-WB	80%	100%	0%

Conclusion: Majority of human sera with anti-Mi-2 also have antibodies to TIF1alpha but not TIF1gamma. This is a new linked set of autoantibodies in DM and an exception of the rare coexistence of MSA in individual patient. This finding will affect identification and classification of PM/DM based on serology and may require reevaluation of clinical significance of anti-TIF1 alpha antibodies as anti-TIF1alpha coexisting with anti-Mi-2 has not been considered in the past.

1957

Prevalence and Associated Factors of Vitamin D Insufficiency and Deficiency in 4,793 Japanese Patients with Rheumatoid Arthritis. Takefumi Furuya[1], Takayuki Hosoi[2], Eiichi Tanaka[1], Ayako Nakajima[1], Atsuo Taniguchi[1], Shigeki Momohara[1] and Hisashi Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]National Center for Geriatrics and Gerontology, Aichi, Japan

Background/Purpose: Vitamin D (25[OH]D) insufficiency and deficiency is reported to be common in patients with rheumatoid arthritis (RA) and is associated with increased disease activity of RA, although there are limited reports of Japanese RA patients in the literature. Among osteoporosis patients treated with bisphosphonates, vitamin D status and concomitant use of active vitamin D3 analogs are both reported to affect the increase in bone mineral density (BMD). Our purpose was to define the prevalence and associations of 25(OH)D insufficiency and deficiency with clinical characteristics in Japanese patients with RA.

Methods: Serum 25(OH)D levels, laboratory data, and clinical data were obtained from 4,793 patients with RA (4,075 women, 718 men, mean age 59.7 years) who participated in the Institute of Rheumatology Rheumatoid Arthritis (IORRA) observational cohort study in April and May of 2011. Their serum vitamin D levels were evaluated using radioimmunoassays. Insufficiency was defined as a concentration < 20 ng/mL and deficiency as < 10 ng/mL. Associations of 25(OH)D insufficiency and deficiency with patient characteristics were examined using multivariate logistic regression.

Results: The mean (SD) serum 25(OH)D level was 16.9 (6.1) ng/mL. The prevalence of 25(OH)D insufficiency and deficiency among all the patients in the study were 71.8% and 11.5%, respectively. Serum 25(OH)D levels were significantly different ($P < 0.05$) between the patients with (n = 507, 10.6%) and without active vitamin D3 analogs. Among the patients treated with bisphosphonates (n = 1,130), insufficiency and deficiency were 71.5% and 10.4%, respectively. In multivariate analyses, female gender (odds ratios [OR] 2.38, 95 confidence interval [CI] 1.88–2.92 and OR 2.01, 95% CI 1.41–2.91), age (per 10 years, OR 0.72, 95% CI 0.68–0.77 and OR 0.67, 95% CI 0.62–0.73), Japanese health assessment questionnaire (J-HAQ) disability scores (OR 1.20, 95% CI 1.07–1.36 and OR 1.63, 95% CI 1.40–1.92), serum total cholesterol levels (per 10 mg/100mL, OR 0.96, 95% CI 0.94–0.98 and OR 0.95, 95% CI 0.92–0.98), serum alkaline phosphate level (per 10 IU/L, OR 1.01, 95% CI 1.00–1.02 and OR 1.02, 95% CI 1.00–1.03), and use of non-steroidal anti-inflammatory drugs (NSAIDs) (OR 1.27, 95% CI 1.11–1.46 and OR 1.25, 95% CI 1.02–1.54) were associated ($P < 0.05$) with vitamin D insufficiency and deficiency, respectively. Body mass index (BMI) and use of active vitamin D3 analogs (OR 0.96, 95% CI 0.93–0.99 and OR 0.69, 95% CI 0.48–0.97, respectively) were significantly associated with vitamin D deficiency alone. The Disease Activity Score including 28 joints (DAS28) was not significantly associated with either vitamin D insufficiency or deficiency in this patient population.

Conclusion: Vitamin D insufficiency and deficiency are common in Japanese patients with RA, as previously reported for patients of other ethnicities. Female gender, younger age, high HAQ disability score, serum levels of total cholesterol and alkaline phosphate and NSAID use appear to be associated with both vitamin D insufficiency and deficiency in Japanese patients with RA. Low BMI and disuse of active vitamin D3 analogs, however, appear to correlate only with vitamin D deficiency in Japanese patients with RA.

1958

Bone Mineral Density in Lupus Erythematosus Women One Year After Rituximab Therapy. Claudia Mendoza-Pinto[1], Mario Garcia-Carrasco[1], Mario Jiménez-Hernández[1], Alma Rodríguez-Gallegos[2], Socorro Méndez-Martínez[1] and Aurelio Lopez-Colombo[3]. [1]HGR 36 CMN Manuel Ávila Camacho, Instituto Mexicano del Seguro Social, Puebla, Mexico, [2]Laboratorios Clínicos de Puebla, Puebla, Mexico, [3]Delegación Estatal, Instituto Mexicano del Seguro Social, Puebla, Mexico

Background/Purpose: Low bone mineral density (BMD) and osteoporosis may be significant complications in patients with systemic lupus erythematosus (SLE). Recent studies have shown that biologic therapy could arrest general bone loss, however, the role of rituximab on BMD in SLE patients has not been analyzed. The aim of this prospective study was to assess the effects of rituximab on BMD at the lumbar spine and femoral neck in women with SLE, one year after rituximab therapy.

Methods: Thirty active female SLE patients treated with rituximab were compared with control SLE women not treated with rituximab. In those patients, rituximab 1 g was administered on days 1 and 15 in addition to current immunosuppressive treatment, which was maintained until disease remission. Since all patients were using steroids when rituximab therapy began, they were all taking calcium and vitamin D. Historical controls included forty-six SLE women with similar lupus activity treated with conventional therapy azathoprine, methotrexate, mycophenolate mofetil, leflunomide and cyclophosphamide) without rituximab therapy. BMD at the femoral neck and lumbar spine was measured using dual energy x-ray absorptiometry before initiating conventional and biologic therapy and after one year.

Results: Seventy-six patients were studied. The mean age was 38.5 ± 2.1 SD, median disease duration was 7 years (range 1 to 26). Thirty patients received rituximab and forty- six controls received conventional treatment. Baseline BMD measurements were higher in the rituximab group. In the rituximab group, after 1 year of follow up femoral neck BMD decreased from 0.980 ± 0.130 g/cm2 to 0.809 ± 0.139 g/cm2 (-17.4%; p = 0.001). Similarly, lumbar spine BMD decreased from 1.062 ± 0.137 g/ cm2 to 0.893 ± 0.194 g/ cm2 (-15.8%; p= 0.001). In controls, femoral neck BMD decreased from 0.914 ± 0.193 g/cm2 to 0.890 ± 0.135 g/cm2 (-2.6%; p= 0.001) and lumbar spine BMD decreased from 0.926 ± 0.128 g/cm2 to 0.867 ± 0.139 g/cm2 (-6.2%; p= 0.09). BMD loss was higher in postmenopausal rituximab patients than in postmenopausal controls (0.324 ± 0.128 g/cm2 vs 0.138 ± 0.099 g/cm2). There was a significant difference in BMD at the femoral neck between responders and nonresponders (p = 0.014) but not in BMD at the lumbar spine.

Conclusion: After one year of follow up, SLE patients had lower BMD at both the femoral neck and lumbar spine, but the loss was greater in patients receiving rituximab than in patients receiving conventional treatment, and in postmenopausal women. Postmenopausal candidates for rituximab should be evaluated closely to prevent further BMD loss.

1959

Low Fracture Incidence Is Maintained in Postmenopausal Women ≥75 Years with Osteoporosis with Long-Term Denosumab Treatment. Socrates Papapoulos[1], Michael R. McClung[2], Nathalie Franchimont[3], Jonathan D. Adachi[4], Henry G. Bone[5], Claude-Laurent Benhamou[6], Jordi Farrerons[7], JC Gallagher[8], Johan Halse[9], Kurt Lippuner[10], Salvatore Minisola[11], Ove Törring[12], Nadia Daizadeh[3], Andrea Wang[3], Rachel B. Wagman[3] and Steven Boonen[13]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Oregon Osteoporosis Center, Portland, OR, [3]Amgen Inc., Thousand Oaks, CA, [4]Charlton Medical Centre, Hamilton, ON, [5]Michigan Bone and Mineral Clinic, Detroit, MI, [6]EA 4708 University Orleans, Orleans, France, [7]Hospital de la Santa Creu I Sant Pau, Barcelona, Spain, [8]Creighton University Medical Center, Omaha, NE, [9]Osteoporoseklinikken, Oslo, Norway, [10]University Hospital, Bern, Switzerland, [11]Sapienza, Università di Roma, Rome, Italy, [12]Karolinska Institutet Sodersjukhuset, Stockholm, Sweden, [13]Leuven University, Leuven, Belgium

Background/Purpose: In the pivotal fracture trial, FREEDOM, denosumab increased bone mineral density (BMD) and reduced the incidence of new vertebral, nonvertebral, and hip fractures in postmenopausal women with osteoporosis (Cummings SR et al, *NEJM* 2009). Denosumab reduced the risk of hip fracture in high-risk subgroups, including a 62% reduction in patients ≥75 years old (Boonen S et al, *JCEM* 2011). The effects of long-term denosumab treatment up to 10 years are being evaluated in the FREEDOM extension study. As fracture incidence increases with age, and in particular, hip fracture in women ≥75, we have further characterized the fracture incidence and BMD gains in women ≥75 who have been treated with denosumab for a total of 6 years.

Methods: During the extension, each woman has received 60 mg denosumab every 6 months and supplemental calcium and vitamin D daily. We evaluated the fracture incidence and BMD gains in women who completed 6 years of denosumab treatment (overall long-term group) and in the subset of these women who were ≥75 at FREEDOM baseline (higher-risk group).

Results: The FREEDOM baseline characteristics for the overall long-term denosumab group (N=2343) and the higher-risk group (N=662) were similar except that those subjects in the higher-risk group were older (mean age: 72 years for overall and 78 years for higher-risk), and had a lower mean total hip BMD T-score (–1.9 for overall and –2.1 for higher-risk). Despite the increase in age of the subjects, denosumab treatment during years 4 to 6 continued to be associated with a low incidence of new vertebral, nonvertebral, and hip fractures. Furthermore, the incidence of fractures in the higher-risk group during years 4 to 6 was similar to what was originally observed in years 1 to 3 in women ≥75 treated with denosumab (Figure).
Fracture incidence is based on crude incidence rate for panel A and Kaplan-Meier estimate for panels B and C.
N=number of subjects in the respective primary efficacy analysis set.

Figure. Subject incidence of fractures in the FREEDOM and extension trial.

BMD progressively increased over 6 years at the lumbar spine and total hip and was similar in women ≥75 compared with women in the overall long-term group. Despite advanced age, adverse events (AEs) and serious AEs in the higher-risk group in the extension were similar to the higher-risk group from FREEDOM, and these events did not increase over time with denosumab treatment.

Conclusion: Patients aged ≥75 are at higher risk of fracture than younger patients. Denosumab is a therapeutic option for the women ≥75 in whom the high risk of hip fracture is of particular concern. These results amplify the robust and consistent anti-fracture efficacy and safety profile of continued denosumab treatment over 6 years.

1960

Initiation of Tumor Necrosis Factor Alpha (TNFα) Antagonists and Risk of Fractures in Patients with Selected Rheumatic and Autoimmune Diseases.

Vivian K. Kawai[1], Carlos Grijalva[1], Patrick Arbogast[1], Jeffrey R. Curtis[2], Daniel H. Solomon[3], Elizabeth S. Delzell[2], Lang Chen[2], Lisa Herrinton[4], Liyan Liu[4], Edward F. Mitchell Jr.[1], C. Michael Stein[5] and Marie Griffin[1]. [1]Vanderbilt University, Nashville, TN, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [4]Kaiser Permanente, Oakland, CA, [5]Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Inflammation mediates bone resorption, in part through TNFα. In experimental models TNFα antagonists reduce inflammation-mediated bone resorption; however, the effect of this class of drugs on fracture risk in patients is unknown. We tested the hypothesis that initiation of TNFα antagonists reduced the risk of fractures compared to nonbiologic comparators in patients with RA.

Methods: Using four large administrative databases we assembled a retrospective cohort of patients with RA from 1998 to 2005 enrolled in Tennessee's Medicaid Program (TennCare), Kaiser Permanente Northern California (KPNC), Pennsylvania Pharmaceutical Assistance Contract for the Elderly (PACE), and multi-State Medicaid programs (MAX) and identified patients who initiated either a TNFα antagonist (n=20,814) or a non biologic disease modifying anti-rheumatic drug (DMARD): hydroxychloroquine (HCQ), sulfazalasine (SSZ) and/or leflunomide (LEF) (n=8,964). We used baseline covariate data to calculate propensity scores (PS) to match treatment groups, and Cox regression to calculate hazard ratios (HRs) and 95% confidence intervals (95% CIs). We compared the risk of the first fracture (hip, radius/ulna, humerus, or pelvic); first hip fracture; and first clinical vertebral fracture between PS-matched cohorts of new users of TNFα antagonists and non biologic DMARDs.

Results: We identified 9,020 new PS matched episodes of TNFα antagonist and non biologic DMARD use. The risk of fractures was similar between new users of TNFα antagonists and non biologic DMARDs: HR:1.17, 95%CI [0.91–1.51] for combined fracture outcome (Figure 1); HR:0.87, 95%CI [0.60–1.27] for hip fracture (Figure 2); and HR:0.71, 95%CI [0.43–1.19] for clinical vertebral fracture (Figure 3). The risk of the combined fracture outcome was associated with an average daily dose of prednisone equivalents >10 mg/day at baseline compared with no glucocorticoid (HR: 1.54, 95%CI [1.03, 2.30]).

Figure 1

Figure 2

Figure 3
Conclusion: The risk of fracture did not differ between new users of TNFα antagonists and non biologic DMARDs in patients with RA. The use of >10mg/day of prednisone equivalents at baseline increased the fracture risk.

1961

In Postmenopausal Women with Osteoporosis, Denosumab Significantly Improved Trabecular Bone Score (TBS), an Index of Trabecular Micro-architecture. Michael R. McClung[1], Kurt Lippuner[2], Maria Luisa Brandi[3], Jean-Marc Kaufman[4], Jose R. Zanchetta[5], Marc-Antoine Krieg[6], Henry G. Bone[7], Roland Chapurlat[8], Didier Hans[6], Andrea Wang[9], Jang Yun[9], Carol Zapalowski[9] and Cesar Libanati[9]. [1]Oregon Osteoporosis Center, Portland, OR, [2]University of Berne, Berne, Switzerland, [3]University of Florence, Florence, Italy, [4]University Hospital of Ghent, Ghent, Belgium, [5]Instituto de Investigaciones Metabólicas and University of Salvador, Buenos Aires, Argentina, [6]Lausanne University Hospital, Lausanne, Switzerland, [7]Michigan Bone and Mineral Clinic, Detroit, MI, [8]Hôpital Edouard Herriot, Lyon, France, [9]Amgen Inc., Thousand Oaks, CA

Background/Purpose: The trabecular bone score (TBS), a novel gray-level texture index determined from lumbar spine DXA scans, correlates with 3D parameters of trabecular bone microarchitecture known to predict fracture. TBS may enhance the identification of patients at increased risk for vertebral fracture independently of bone mineral density (BMD) (Boutroy *JBMR* 2010; Hans *JBMR* 2011). Denosumab treatment for 36 months decreased bone turnover, increased BMD, and reduced new vertebral fractures in postmenopausal women with osteoporosis (Cummings *NEJM* 2009). We explored the effect of denosumab on TBS over 36 months and evaluated the association between TBS and lumbar spine BMD in women who had DXA scans obtained from eligible scanners for TBS evaluation in FREEDOM.

Table. Lumbar Spine TBS and BMD Percentage Change From Baseline Over Time and Pearson Correlation Between TBS and BMD

	Placebo (N = 128)			Denosumab (N = 157)		
Month	TBS % Change	BMD % Change	Pearson Correlation	TBS % Change	BMD % Change	Pearson Correlation
12	0.0	−0.1	0.0036	1.4[a,b]	5.7[a,b]	0.0256
24	0.2	0.1	0.0004	1.9[a,b]	7.8[a,b]	0.0225
36	−0.7	0.0	0.0324	2.4[a,b]	9.8[a,b]	0.0529

N = number of randomized subjects who enrolled in the DXA substudy and had observed TBS data at baseline and ≥1 post-baseline visit. [a]$p \leq 0.0144$ compared with placebo. [b]$p \leq 0.0003$ compared with baseline.

Percentage Change From Baseline in Lumbar Spine TBS

[a]$p \leq 0.0144$ compared with placebo
[b]$p \leq 0.0003$ compared with baseline
Methods: FREEDOM was a 3-year, randomized, double-blind trial that enrolled postmenopausal women with a lumbar spine or total hip DXA T-score < -2.5, but not < -4.0 at both sites. Women received placebo or 60 mg denosumab every 6 months. A subset of women in FREEDOM participated in a DXA substudy where lumbar spine DXA scans were obtained at baseline and months 1, 6, 12, 24, and 36. We retrospectively applied, in a blinded-to-treatment manner, a novel software program (TBS iNsight® v1.9, Med-Imaps, Pessac, France) to the standard lumbar spine DXA scans obtained in these women to determine their TBS indices at baseline and

months 12, 24, and 36. From previous studies, a TBS >1.35 is considered as normal microarchitecture, a TBS between 1.35 and >1.20 as partially deteriorated, and ≤ 1.20 reflects degraded microarchitecture.

Results: There were 285 women (128 placebo, 157 denosumab) with a TBS value at baseline and ≥ 1 post-baseline visit. Their mean age was 73, their mean lumbar spine BMD T-score was -2.79, and their mean lumbar spine TBS was 1.20. In addition to the robust gains in DXA lumbar spine BMD observed with denosumab (9.8% at month 36), there were consistent, progressive, and significant increases in TBS compared with placebo and baseline (Table & Figure). BMD explained a very small fraction of the variance in TBS at baseline ($r^2 < 0.07$). In addition, the variance in the TBS change was largely unrelated to BMD change, whether expressed in absolute or percentage changes, regardless of treatment, throughout the study (all $r^2 < 0.06$); indicating that TBS provides distinct information, independently of BMD.

Conclusion: In postmenopausal women with osteoporosis, denosumab significantly improved TBS, an index of lumbar spine trabecular microarchitecture, independently of BMD.

1962

The Specific Role of Glutaredoxin2 Isoform b (Glrx2b) in RANKL-Induced Osteoclastogenesis Through Activation of the p38-MAPK Signaling Pathway. Chang-Hoon Lee[1], Wan-Hee Yoo[2], Jin-Jung Choi[3], Myong-Joo Hong[2], Ji-Min Kim[4] and Jeong-Tae Yeon[5]. [1]Department of Internal Medicine, School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [3]CHA University Hospital, Seongnam, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Pusan National University Yangsan Hospital, Pusan National University School of Medicine, Yangsan, South Korea, [5]Department of anatomy, school of medicine, Wonkwang university, Iksan, Chonbuk, South Korea

Background/Purpose: Recently, reactive oxygen species (ROS) and antioxidant enzymes were shown to be closely associated with RANKL-mediated osteoclast differentiation. Although glutaredoxin2 (Glrx2) plays a role in cellular redox homeostasis, its role in RANKL-mediated osteoclastogenesis is unclear.

Objectives: The aim of this study was to examine the effect of Glrx2 on osteoclast differentiation

Methods: Osteoclast formation was evaluated in bone marrow cells (BMC) in specific condition with over-expression of Glrx2 or down-regulation of Glrx2 during receptor activator of NF-κB ligand (RANKL)-mediated osteoclastogenesis. The expression of c-fos and NFATc1 mRNA in osteoclast precursor were assessed by RT-PCR. The levels of c-fos and NFATc1 protein were assessed by western blot. Also the mitogen-activated protein (MAPK)s pathways were measured using Western blot analysis.

Results: We found that Glrx2 isoform b (Glrx2b) expression is induced during RANKL-mediated osteoclastogenesis. Over-expression of Glrx2b strongly enhanced RANKL-mediated osteoclastogenesis. In addition, Glrx2b-transduced BMMs enhanced the expression of key transcription factors c-Fos and NFATc1, but pre-treatment with SB203580, a p38-specific inhibitor, completely blocked this enhancement. Conversely, down-regulation of Glrx2b decreased RANKL-mediated osteoclastogenesis and the expression of c-Fos and NFATc1 proteins. Also, Glrx2b down-regulation attenuated the RANKL-induced activation of p38.

Conclusion: Taken together, these results suggest that Glrx2b enhances RANKL-induced osteoclastogenesis via p38 activation. It may be very useful information for treatment of bone-resorbing disorders, such as rheumatoid arthritis and osteoporosis.

1963

Fracture Sites, Frequencies and Causes in 9,720 Japanese Patients with Rheumatoid Arthritis: A Prospective Observational Cohort Study. Kensuke Ochi, Takefumi Furuya, Eisuke Inoue, Katsunori Ikari, Atsuo Taniguchi, Shigeki Momohara and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Although rheumatoid arthritis (RA) is a risk factor for osteoporosis and fracture, limited data exist in the literature concerning fracture site and frequency in patients with RA. We previously reported clinical risk factors for both incident vertebral and nonvertebral fractures in Japanese RA patients using our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort study. Herein we expanded our previous study to evaluate fracture sites, frequencies, and causes in Japanese RA patients.

Methods: The IORRA is a prospective observational cohort study of Japanese RA patients at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan) that was started in 2000. A total of 9,720 patients (82% female; mean age, 56 years) with RA were enrolled in the IORRA cohort study from 2000 to 2010. All participants self-reported whether they had a fracture event within the previous 6 months, the site of fracture (ankle, arm, cervical spine, clavicle, elbow, femoral neck, foot, hand, knee, leg, nose, pelvis, rib, shoulder, thoracic spine, lumbar spine, wrist, and others), and the reasons for fracture (accident, fall, spontaneous event, or sports injury) every 6 months from October 2000 to October 2010. We then analyzed the sites, frequencies, and causes of the fractures to clarify the epidemiology of fractures in Japanese RA patients.

Results: During a mean (SD) duration of 5.2 (3.3) years, 1357 patients reported a total of 2076 incident fractures. Among them, 837 (61.7%) reported a single fracture, 520 (38.3%) reported two fractures, 303 (22.3%) reported three fractures, and 217 (16.0%) reported more than three fractures. Overall, 287 (13.8%) vertebral fractures and 1789 (86.2%) nonvertebral fractures (head: n=35, 1.7%; trunk: n=504, 24.3%; upper limb: n=508, 24.5%; and lower limb: n=742, 35.7%) were reported. The most frequent fresh nonvertebral fracture was rib (n=368, 20.6%), followed by toe (n=276, 15.4%), femoral neck (n=178, 9.9%), ankle (n=132, 7.4%), wrist (n=122, 6.8%), hand (n=117, 6.5%), shoulder (n=105, 5.9%), arm (n=86, 4.8%), knee (n=84, 4.7%), elbow (n=78, 4.4%), pelvis (n=71, 4.0%), leg (n=57, 3.2%), clavicle (n=56, 3.1%), and head including nose (n=35, 2.0%). Causes of overall fractures were fall in 55.5% of patients, followed by spontaneous events in 33.2%, accident in 7.8%, and sports injury in 1.0%; the major causes of vertebral fractures were spontaneous events (63.5%) and fall (27.4%), while fall (60.0%) and spontaneous events (28.3%) were the major causes of nonvertebral fractures.

Conclusion: Fourteen percent of Japanese patients with RA reported one or more incident fractures within a mean duration of 5.2 years. Unlike non-RA elderly subjects, spontaneous events were a major cause of fractures. Differences between RA patients and non-RA subjects should be at least in some part due to the significant osteoporosis seen in RA patients.

1964

Rolofylline, an Adenosine A1R Antagonist, Acts As an Inverse Agonist to Inhibit Osteoclast Differentiation. Wenjie He[1] and Bruce N. Cronstein[2]. [1]NYU, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Previous work from our laboratory has uncovered a critical role of adenosine A1 receptor (A1R) in osteoclast formation both in vivo and in vitro. Adenosine may be generated by hydrolysis of extracellular adenosine nucleotides including ecto-nucleoside triphosphate diphosphohydrolase 1 (CD39), ecto-5′-nucleotidase (CD73) and nucleotide pyrophosphatase phosphodiesterase 1 (NPP-1). Interestingly selective A1R agonists neither affect basal osteoclast formation nor do they reverse A1R-mediated inhibition of osteoclast formation. In this study, we determined whether ectonucleotidase-mediated adenosine production was required for osteoclast formation and, when we saw no effect, determined whether the A1R was constitutively activated and the antagonist was acting as an inverse agonist to mediate its effects on osteoclast formation.

Methods: Osteoclasts were generated from bone marrow mononuclear cells (BMMs) extracted from wildtype, CD39KO, CD73KO and NPP-1KO mice using differentiation factors macrophage colony-stimulating factor (M-CSF) and RANKL. The A1R specific antagonist, Rolofylline, was added to the culture media. TRAP+ staining was performed and Acp5 and Ctsk mRNA expression were examined to study osteoclast differentiation. Intracellular cAMP concentration was determined by ELISA.

Results: A1R blockade inhibits osteoclast differentiation of BMMs derived from wildtype mice in a dose-dependent manner ($IC_{50}=1\mu M$ p<0.05, n=3). A1R blockade similarly inhibits osteoclast formation by marrow precursors from CD73KO, CD39KO and NPP-1KO mice in a dose-dependent manner ($IC_{50}=1\mu M$, and $1\mu M$, and $0.1\mu M$, respectively, p<0.05 for all, n=3) for all three knockouts, although baseline osteoclast formation was significantly less (310 in CD73 KO vs 91 in wildtype, p<0.05, n=3) in precursors from CD73KO mice. Moreover, in the absence of agonist, A1R antagonist, rolofylline ($1\mu M$) caused an increase of cAMP content of BMMs by 9.9 fold (p<0.05, compared with control: M-CSF + RANKL, n=3). Similarly, rolofylline ($1\mu M$) leads to increased cAMP production in human healthy BMMs by 3.6 fold (n=1, compared with control: M-CSF+ RANKL), which is consistent with our findings that A1R blockade by rolofylline inhibits human BMMs-derived osteoclast formation (p<0.001, n=3; $IC_{50}=$ 1nM).

Conclusion: Based on these findings we hypothesize that the A1R is constitutively activated in osteoclast precursors, thereby diminishing basal adenylate cyclase activity, and that the A1R antagonist acts as an inverse agonist to release the A1R-mediated inhibition of basal adenylate cyclase activity. The constitutive activity of A1R promotes osteoclast formation and downregulation of this activity blocks osteoclast formation.

1965

Adenosine Regulates Bone Metabolism Via A_1, A_{2A} and A_{2B} Receptors in Bone Marrow Cells From Normal and Patients with Multiple Myeloma. Wenjie He[1], Amitabha Mazumder[2] and Bruce N. Cronstein[3]. [1]NYU, New York, NY, [2]NYU Cancer Center, New York, NY, [3]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Multiple myeloma is a haematologic malignancy that is characterized by osteolytic bone lesions, wherein coupled bone remodeling is disrupted with increased osteoclast activation and decreased osteoblast differentiation. In this study, we examined the effect of adenosine on osteoblast and osteoclast differentiation derived from multiple myeloma (MM) patients.

Methods: Human bone marrow was collected from multiple myeloma patients. Bone marrow stromal cells (BMSCs) and bone marrow derived mononuclear (BMMs) cells were isolated and osteoblasts and osteoclasts were cultured, respectively. Adenosine A1 receptor agonist CHA and antagonist Rolofylline, A_{2a} receptor agonist CGS and antagonist ZM, and A_{2b} receptor agonist BAY and antagonist MRS 1754, A_3 receptor agonist IB-MECA and antagonist MRS 1191; and dipyridamole, a nucleoside transport inhibitor, were added to the culture media. Alkaline phosphatase (ALP) activity assay was used to quantitate the osteoblast differentiation. In vitro osteoblast calcification was determined by alizarin red staining. TRAP+ staining was used to examine the osteoclast differentiation and bone resorption assay was used to study the osteoclast activity.

Results: We found that $A1_R$ blockade by rolofylline and $A_{2a}R$ ligation by CGS21680 inhibited differentiation of both normal and MM BMMs into TRAP+ multinucleated cells ($IC_{50}=$ 1nM for A1R, $IC_{50}=$ 10μM for A2aR; p<0.001, n=3 for both). The A_{2A} receptor antagonist completely reversed the effects of CGS21680 on osteoclast differentiation. Moreover, enhanced adenosine accumulation in the presence of dipyridamole ($0.5\mu M$) and $A_{2b}R$ activation promoted the differentiation of BMSCs into osteoblasts shown by Arlizarin red staining and ALP activity assay (by 1.8 ± 0.41 and 1.57 ± 0.26 fold, respectively, p<0.05, compared with osteogenic media only, n=3 for both).

Conclusion: These results indicate that adenosine receptors may be useful targets for the treatment and prevention of MM-induced bone disease.

1966

Cost-Effectiveness of Bazedoxifene Compared with Raloxifene in the Treatment of Postmenopausal Osteoporotic Women. Mickaël Hiligsmann, Wafa Ben Sedrine and J.-Y. Reginster. University of Liege, Liege, Belgium

Background/Purpose: Bazedoxifene is a novel selective estrogen receptor modulator (SERM) in development for the prevention and treatment of osteoporosis. In addition to the therapeutic value of a new agent, evaluation of the cost-effectiveness compared with relevant alternative treatment(s) is an important consideration to facilitate health-care decision making. This study evaluated the cost-effectiveness of bazedoxifene compared with raloxifene for the treatment of postmenopausal women with osteoporosis.

Methods: The cost-effectiveness of treatment for 3-years with bazedoxifene was compared with raloxifene using an updated version of a previously validated Markov microsimulation model. Analyses were conducted from a healthcare payer perspective and, the base-case population was women (aged 70 years) with bone mineral density T-score ≤ -2.5. The effects of bazedoxifene and raloxifene on fracture risk were derived from the 3-year results of a randomized, double-blind, placebo- and active-controlled study, including postmenopausal women with osteoporosis.

Results: The cost-effectiveness analysis based on efficacy data from the overall clinical trial indicated that bazedoxifene and raloxifene were equally cost-effective. When the results were examined based on the subgroup analysis of women at higher risk of fractures, bazedoxifene was dominant (lower cost for higher effectiveness) compared with raloxifene in most of the simulations. Sensitivity analyses confirmed the robustness of the results, which were largely independent of starting age of treatment, fracture risk, cost and disutility. In addition, when the cost of raloxifene was reduced by half, bazedoxifene remained cost-effective, at a threshold of €35,000 per quality-adjusted life-years gained, in 85% of the simulations.

Conclusion: Under the assumption of improved anti-fracture efficacy of bazedoxifene over raloxifene in women with high risk of fractures, this study suggests that bazedoxifene can be considered cost-effective, and even dominant, when compared with raloxifene in the treatment of postmenopausal osteoporotic women.

1967

Hypophosphatemic Osteomalacia Induced by Tenofovir in Patients with Human Immunodeficiency Virus Infection. Beatriz Tejera[1], Lourdes Mateo-Soria[1], Susana Holgado[1], Luisa Mariñoso[2], Ricard Pérez[1], Anna Bonjoch[1], Melania Martínez-Morillo[1], Dolors Grados[1] and Alejandro Olivé[1]. [1]Hospital Universitario Germans Trias i Pujol, Badalona, Spain, [2]Hospital del Mar, Barcelona, Spain

Background/Purpose: treatment of human immunodeficiency virus (HIV) infection has dramatically changed survival prognosis of these patients.New drugs included in antiretroviral therapy are much more effective. Tenofovir disoproxil fumarate (TDF) was approved for the treatment of HIV infection in highly active antiretroviral therapy (HAART) combinations in 2001. Increasing evidence has emerged relating TDF use and the development of kidney proximal tubular dysfunction, Fanconi syndrome and renal insufficiency.

Objective: to describe 4 cases of Tenofovir induced hypophosphatemic osteomalacia.

Methods: we describe 4 cases of tenofovir-treated HIV patients from HIV Section setting University Academic Hospital reference area 800.000 inhabitants, who were refered to Rheumatology Service. All patients were having by multilple disabling bone pain. We present clinical manifestations, laboratory and imaging studies, and the results of iliac bone biopsy performed in 3 cases, after labeling with tetracycline.

Results: Four patients, 2 men and 2 women, mean age of 48,2 years, mean duration of HIV infection of 20.2 years. All patients were on Tenofovir in combination therapy with a median duration of 7 years. All patients complained of severe and increasing pain of the lower extremities with considerable functional impairment and inability to walk without assistance during the last 8–24 months (mean symptom duration 14 months) The general characteristics are shown on the Table. In all cases a marked hypophosphatemia with elevated alkaline phosphatase (ALP) and deficiency of vitamin D 25-OH were in 3 patients. Bone scan and MRI showed multiple insufficiency fractures. Histopathological study of iliac bone biopsy (patients 1, 2 and 3) showed increased bone formation and an increased osteoid thickness (more than 5 slides) with laminar structure. There were few osteoblasts, and resorption was diminished with no presence of osteoclasts. The diagnosis was osteomalacia in all patients. The clinical diagnosis was hipophosphatemic osteomalacia induced by tenofovir. In all patients, tenofovir was stopped. This was supplemented with oral vitamin D and calcium supplements. Two patients required oral phosphate salts. A few weeks after starting treatment showed gradual resolution of bone pain (6–8 weeks) and normalization of walking without support. Furthermore, 8–12 weeks later, blood test were strictly normal in all patients.

	Gender	Age	HIV diagnosis (years)	Duration of symptoms (months)	Bone pain	Fractures	Duration of treatment tenofovir (years)	Calcium (mg/Dl) (mmol/L) (N 8.8–10.6) (N 2.2–2.65)	Phosph (mg/dl) (mmol/L) (N 2.5–4.5) (N 0.81–1.45)	FA U/L	25-OH-Vit D (ng/ml)	PTH (pg/ml)
Case 1	M	64	24	8	Hips, ankles	Distal femur, metatarsal	6	10	1.28	355	16.5	39.6
								2.51	0.41			
Case 2	W	46	19	12	Hips, ankles, rib cage	Bilateral femoral neck, rib, sacral	5	8.8	1.83	170	5.9	54
								2.2	0.59			
Case 3	W	41	20	24	Hips, ankles, knee, rib cage	Rib, subtrochanteric, distal tibial epiphysis bilateral, calcaneus	10	8.6	1.36	158	20	28
								2.15	0.44			
Case 4	M	42	18	12	Hips, thoracic-lumbar spine	Subcapital femur, thoracic and lumbar spine	7	8.7	0.99	295	46	15

Conclusion: We described an uncommon complication of HIV patients treated with tenofovir. A high index of suspicion is required to diagnose hipophosphatemic osteomalacia. Serum P and ALP should be monitored to prevent the development of osteomalacia.

The Specific Role of Vesicle-Associated Membrane Protein-Associated Protein B/C(VapB) As a Regulator of Osteoclastogenesis Via Modulation of Phospholipase Cã(PLCã2-Ca2+-NFAT Signaling. Chang-Hoon Lee[1], Wan-Hee Yoo[2], Jin-Jung Choi[3], Myong-Joo Hong[2], Ji-Min Kim[4] and Sik-Won Choi[5]. [1]Department of Internal Medicine, School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea, [2]Department of Internal Medicine, Chonbuk National University Medical School and Research Institute of Clinical Medicine, Jeonju, South Korea, [3]CHA University Hospital, Seongnam, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Pusan National University Yangsan Hospital, Pusan National University School of Medicine, Yangsan, South Korea, [5]School of medicine, Wonkwang university, Iksan, Chonbuk, South Korea

Background/Purpose: Recently, Vesicle-Associated Membrane Protein-Associated Protein B/C(VapB) has been shown to regulate calcium homeostasis in myotrophic lateral sclerosis. Calcium signalingis also important in metabolic bone diseases, but the role of VapB in the generation of osteoclasts for bone resorption during osteoclastogenesis is not known. Therefore, we investigated the role of VapB in RANKL-induced osteoclast differentiation

Methods: Osteoclast formation was evaluated in bone marrow cells (BMC) in specific condition with over-expression of VapB or down-regulation of VapB during receptor activator of NF-κB ligand (RANKL)-mediated osteoclastogenesis. The expression of c-fos and NFATc1 mRNA in osteoclast precursor were assessed by RT-PCR. The levels of c-fos and NFATc1 protein were assessed by western blot. Also the mitogen-activated protein (MAPK)s pathways were measured using Western blot analysis.

Results: We found that VapB is induced during osteoclastogenesis, and regulates osteoclast differentiation by modulating NFATc1. The results suggest that VapB regulates osteoclastogenesis via of Phospholipase Cγ (PLCγ)2-Ca2+-NFAT signaling. The involvement of PLCγ2-Ca2+-NFAT signaling in VapB-regulated osteoclastogenesis was confirmed by a pharmacological study.

Conclusion: Taken together, these results indicate that VapB positively regulates RANKL-mediated osteoclastogenesis via PLCγ2-Ca2+-NFAT signaling and may provide a basis for exploring the therapeutic potential of VapB silencing for metabolic bone diseases, such as osteoporosis and rheumatoid arthritis

1969

Correction of Vitamin D Insufficiency with the Fixed Daily Combination Strontium Ranelate 2 g/Vitamin D$_3$ 1000 IU Over 12 Months. René Rizzoli[1], Bess Dawson-Hughes[2], Jean-Marc Kaufman[3], Patrice Fardellone[4], Maria Luisa Brandi[5], Bruno Vellas[6], Julien Collette[7] and Jean-Yves Reginster[8]. [1]Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [2]Bone Metabolism Laboratory, Tufts University, Boston, MA, [3]University Hospital of Ghent, Ghent, Belgium, [4]Hôpital Nord, C.H.U. d'Amiens, Amiens, France, [5]University of Florence, Firenze, Italy, [6]CHU La Grave, Toulouse, France, [7]Labo RIA, CHU Sart Tilman, Liege, Belgium, [8]University of Liege, Liege, Belgium

Background/Purpose: To assess the efficacy and safety over 1 year of a daily oral administration of the fixed combination of strontium ranelate (SrRan) 2 g/vitamin D$_3$ (vitD$_3$) 1000 IU on the correction of vitamin D insufficiency in the treatment of osteoporotic men and postmenopausal women.

Methods: Prospective, international study, with a 6-month double blind SrRan/vitD$_3$ vs SrRan parallel group period (ratio 4:1), followed by a 6-month open-SrRan/vitD$_3$ extension period in a subgroup of patients. All patients were supplemented with calcium 1 g/d during the whole study. Men and postmenopausal women included were osteoporotic (BMD T-score ≤ −2.5 SD). 80% of the patients had to present insufficient levels of 25-hydroxyvitamin D (25-OHD), i.e.]22.5–50 nmol/L[, and 20% ≥50 nmol/L. 25-OHD level was assessed at 3 months (primary endpoint) and 6 months among assessable patients according to intent-to-treat principle, and in the group of patients treated 12 months with SrRan/vitD$_3$. Other criteria were: BMD, falls, PTH, 1,25-(OH)$_2$D and safety.

Results: 518 patients were randomized: 413 to SrRan/vitD$_3$, 105 to SrRan. Of these, 257 patients continued at M6 in the 5 countries selected into the extension period M6-M12: 53 patients switched from SrRan to SrRan/vitD$_3$ while 204 remained on SrRan/vitD$_3$. 242 patients completed the study at M12. Baseline characteristics were similar between groups. At inclusion, mean age (±SD) was 66.8 ± 8.3 years, mean L1-L4 T-score BMD was −2.85 ± 0.86 and mean 25-OHD was 44.1 ± 14.6 nmol/L.

The proportion of patients with 25-OHD ≥ 50 nmol/L at END (i.e. last post-baseline value over M0-M3) was significantly higher in SrRan/vitD$_3$ group than in SrRan group: 83.8% vs 44.2% (p<0.001). Adjusted odds ratio was 6.7 (95% CI [4.2; 10.9]). Mean 25-OHD reached 65.1 vs 49.5 nmol/L at M3, and 66.9 vs 45.4 nmol/L at M6, in SrRan/vit D$_3$and SrRan groups respectively.

The correction of vitamin D insufficiency was maintained over 12 months of SrRan/vitD$_3$treatment (N = 198) with an increase in the proportion of patients with 25-OHD ≥ 50 nmol/L from 21.2% at baseline to 81.1% at M12. The mean concentration of 25-OHD increased from baseline (44.3 ± 13.8 nmol/L) to M3 (64.3 ± 14.6 nmol/L), then remained stable until M12 (60.8 ± 13.9 nmol/L).

BMD significantly increased at all assessed sites in patients treated with SrRan/vitD$_3$during one year (+5% at L1-L4, +4% at femoral neck and +3% at total hip), consistent with annual BMD changes reported with SrRan in previous studies.

There was a trend to fewer patients falling with SrRan/vitD$_3$ (16.5%) as compared to SrRan (20.2%) at M6. PTH evolution over time was inversely correlated with 25-OHD. Increase in mean 1,25-(OH)$_2$D was higher in SrRan/vitD$_3$ than in SrRan group. Safety of SrRan/vitD$_3$was good, comparable to that of SrRan over M0-M6 and in accordance to that expected with SrRan over M6-M12.

Conclusion: The study demonstrates the efficacy and safety of the fixed combination of SrRan 2 g and vitD$_3$ 1000 IU on the correction of vitamin D insufficiency in osteoporotic men and postmenopausal women aged ≥50 years. The efficacy observed after 3 months was maintained after 6 and 12 months of treatment.

1970

Utility of Spine Bone Mineral Density in Fracture Prediction within the Fracture Risk Assessment Tool (FRAX). Tristan Blackburn[1], Diantha Howard[2] and Edward S. Leib[1]. [1]Fletcher Allen Health Care, University of Vermont College of Medicine, Burlington, VT, [2]Vermont Center for Clinical and Translational Science, Burlington, VT

Background/Purpose: Predicting which individuals are at risk to experience a fracture and modify that risk is important in preventative health. The WHO's Fracture Risk Assesment (FRAX) defines osteopenia and osteoporosis in terms of the femoral neck T-score and allows use of total proximal femur, but the lumbar spine site is frequently used in clinical practice and its use in diagnosis is supported by the International Society of Clinical Densitometry and the National Osteoporosis Foundation. Our study aim is to quantify the impact of spine bone mineral density (BMD) on fracture risk prediction and determine the positive predictive value of fracture prediction by using the lowest BMD value at the femoral neck, total hip, or lumbar spine and compare this to the femoral neck alone.

Methods: We performed a retrospective cross-sectional analysis of our database of 15,033 post-menopausal women combining clinical risk factors (CRF) and bone density (BMD) results collected over 9.2 years utilizing a GElunar densitometer. We validated our database by showing that age, low BMD and CRFs in our population correlate with presence of fracture. We performed a logistic regression to assess the contribution of age, BMI, number of CRFs, T-score, and WHO osteoporosis classification category to the presence of fracture. T-scores were differentiated as femoral neck, total hip, and lumbar spine.

Results: The percent of subjects with fracture was lower than that reported in other studies. In individuals with normal BMD at the femoral neck, there were few who were osteoporotic at the lumbar spine (0.7%) and more who were osteopenic at the femoral neck and osteoporotic at the lumbar spine (9.7%). In patients whose T-scores are 1 or 2 osteoporosis categories lower at the lumbar spine than femoral neck, there is an approximately 30% increased risk of fracture when compared with the femoral neck alone. For patients less than 60 years old, the odds ratio of having a fracture based on presence of lumbar spine osteoporosis was greater than the odds ratio based on femoral neck osteoporosis. This reversed for those ≥ 65 compared with those <65 years old. For each age category, the presence of osteoporosis measured at the total hip correlated best with presence of hip fracture and was better than taking the lowest T-score at any of the three sites (femoral neck, total hip, or lumbar spine).

Conclusion: It is most important to measure BMD at the lumbar spine in younger, post-menopausal women for fracture prediction. In our population total hip BMD is the best predictor of fracture. The spine BMD appears to be a better predictor of fracture than femoral neck in women 60 years and younger. When using the WHO Fracture Prediction Tool (FRAX), we recommend that the 10 year fracture prediction be adjusted when the lumbar spine T-score is 1–2 osteoporosis categories lower than the femoral neck T-score.

1971

Resolution of Effects On Bone Turnover Markers and Bone Mineral Density After Discontinuation of Long-Term Bisphosphonate Use. Kenneth G. Saag[1], Claude-Laurent Benhamou[2], Tobias De Villiers[3], C. Conrad Johnston Jr.[4], Bente Langdahl[5], Andrew Denker[6], Annpey Pong[6], John P. McGinnis[6], Elizabeth Rosenberg[6] and Arthur Santora[6]. [1]Univ of Alabama-Birmingham, Birmingham, AL, [2]EA 4708 University Orleans, Orleans, France, [3]Mediclinic Panorama, Cape Town, South Africa, [4]Indiana University School of Medicine, Indianapolis, IN, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Merck Sharp & Dohme Corp., Whitehouse Station, NJ

Background/Purpose: While bisphosphonates (BP) have been well studied in long-term trials of up to 4 years' duration, relatively less is known about the immediate consequences of continuing vs. interrupting long-term treatment. This report describes changes in bone turnover and BMD in a 1-year trial of the calcium-sensing receptor antagonist MK-5442 in postmenopausal women who, after taking BP for ≥3 years, were randomized to continued alendronate (ALN) 70 mg weekly, switch to placebo (PBO), or switch to MK-5442. Primary results for MK-5442 are presented separately.

Methods: 526 postmenopausal women who had taken ALN for ≥12 months preceding the trial and an oral BP for ≥3 of the 4 years before the trial, with spine or hip BMD T-scores ≤−2.5 (or '−1.5 with ≥1 prior

fragility fracture) and ≥ -4.0, were recruited into a dose-finding study of MK-5442. Statistical tests of within-group changes and comparison between the PBO and ALN groups were performed post-hoc.

Results: At baseline, women switched from ALN to PBO (n=88) or continued on ALN 70 mg weekly (n=87) were of mean age 67 years and had mean T-scores at lumbar spine of -2.5 and total hip of -1.6, and mean baseline urine NTX/Cr= 26.6 nmolBCE/mmolCr and serum P1NP= 26.0 ng/mL. Median length of previous BP use was 5.2 years. After 1 month, women switched from ALN to PBO experienced increases from baseline in urine NTX/Cr (28.4% vs. continued ALN, p<0.0001), while serum P1NP was unchanged. Both NTX/Cr and P1NP increased by 3 months (33.7% and 37.8%, respectively vs. ALN, both p<0.0001). After 12 months of PBO, least squares mean concentrations of NTX/Cr and P1NP rose to 42.2 nmol BCE/mmolCr and 40.1 ng/mL (both p<0.0001, Table). The markers were unchanged from baseline with continued ALN. After 12 months, the women who continued ALN had an increase in lumbar spine BMD while those switched to PBO experienced no change; total hip BMD did not change in those remaining on ALN but was reduced in women switched to PBO. BMD at both sites was significantly lower in women who switched to PBO vs. those who stayed on ALN (Table).

12 Month Least Squares Mean % Change from Baseline (95% CI)

	uNTX/Cr	sP1NP	Lumbar Spine BMD	Total Hip BMD
Continued Alendronate 70 mg	2.3 (-9.2, 15.3)	-5.5 (-16.7, 7.3)	1.5 (0.3, 2.6)	0.4 (-0.4, 1.3)
Switch to Placebo	66.3 (47.3, 87.7)	69.2 (48.6, 92.6)	-0.2 (-1.3, 0.8)	-1.4 (-2.2, -0.6)
p-value*	<0.0001	<0.0001	0.0137	0.0002

* Continued alendronate 70 mg weekly versus switch to placebo.

Conclusion: Discontinuation of alendronate after a median of 5 years resulted in an increase in NTX/Cr as early as 1 month and P1NP by 3 months. After 1 year, both bone turnover markers returned to levels similar to those expected in untreated postmenopausal women. These increases were accompanied by significantly lower spine and total hip BMD vs. continued treatment with ALN.

Assessment of Fracture Risk in Postmenopausal Women with Rheumatoid Arthritis. Sina Esmaeilzadeh, Nurten Eskiyurt, Ekin Sen and Merih Akpinar. Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey

Background/Purpose: The aim of this study is to determine the risk of osteoporotic fracture in postmenopausal women with rheumatoid arthritis (RA) and to examine the effect of glucocorticoids (GCs) use on osteoporotic fracture.

Methods: A total of 51 postmenopausal women with RA who referred to the outpatient clinics and met the eligibility criteria were included in this research. The socio-demographic characteristics and risk factors for secondary osteoporosis were assessed at baseline. The ten-year probability of major osteoporotic fracture and hip fracture were estimated with the World Health Organization Fracture Risk Assessment (FRAX®) tool designed for Turkey. Lateral X-rays of the thoracic and lumbar spine were examined with visual semi-quantitative method to detect the presence of osteoporotic fracture. The FRAX® scores were compared between the patients with radiographic fracture and the patients without it, also between the patients who had a history of GCs use and the patients without it. The data were analyzed with nonparametric tests.

Results: The mean age of the patients was 63.9 ± 9.6 (46–87) years and the mean of body mass index was 27.0 ± 3.5 (20.9–35.4) kg/m². Forty-nine percent of the patients had at least one osteoporotic fracture in the thoracic or lumbar spine radiographic assessment according to the visual semi-quantitative method. Secondary causes of osteoporosis were identified in 33% of patients. Sixty-eight percent of the patients had GCs use and 54% had radiographic fracture on X-ray assessment. The 10-year probability of major osteoporotic fracture risk was 16.2% for the patients treated with GCs and 8.1% for those without it, and the risk of major osteoporotic fracture in the patients treated with GCs was significantly higher than the patients without it.

Moreover, the 10-year probability of hip fracture was 7.4% for the patients treated with GCs and 2.5% for those without it, and the risk of hip fracture in the patients treated with GCs was significantly higher than those without it. The 10-year probability of major osteoporotic fracture and hip fracture were 16.2% and 7.9% for the patients with vertebral fracture, as well as 11.2% and 3.9% for those without it, respectively. There was no significant difference between the patients who had radiographic fractures and those without it with regard to FRAX® scores.

Conclusion: These findings suggest that GCs use increased the risk of osteoporotic fracture in postmenopausal women with RA. Although our data do not support the use of FRAX® scores to predict the presence of vertebral osteoporotic fracture in clinical practice, further large-scale research is needed to confirm these results.

1973

Effect of Adalimumab On the Serum Level of Undercarboxylated Osteocalcin (ucOC), Bone Biochemical Markers and Bone Mineral Density. Yoshitada Sakai[1], Akira Hashiramoto[1], Takaichi Okano[1], Yoshiko Kawasaki[1], Nao Shibanuma[2] and Masahiro Kurosaka[3]. [1]Kobe University Hospital, Kobe, Japan, [2]The Center for Rheumatic Diseases, Kobe University Hospital/Departmant of Orthopaedic Surgery, Kobe Kaisei Hospital, Kobe, Japan, [3]Kobe University Graduate School of Medicine, Kobe, Japan

Background/Purpose: The osteoporotic fracture in patients with rheumatiod arthritis (RA) is caused by systemic osteoporosis as well as periarticular osteoporosis, On the other hand, the serum level of undercarboxylated octeocalcin (ucOC) has been recognized as being a sensitive marker of vitamin K deficiency in bone. A prospective large cohort study showed that increasing the serum level of ucOC predicted hip fracture risk independently of femoral neck bone mineral density (BMD).

Treatments with Adalimumab, a biologic TNF-alfa inhibitor, reduced the hand bone loss of RA patients (PREMIER study), however, the effect of adalimumab on systemic bone metabolism is still unknown.

In this study, we have evaluated the effect of adalimumab on serum ucOC, bone biochemical markers and bone mineral density in patients with RA.

Methods: 20 patients with RA were enrolled; 6 females, 4 males, average age 54.5 ±19.2 yrs, average stage 2.4 ± 1.3 and average class 2.1 ± 0.3. Serum levels of ucOC, cross-linked N-teropeptide of type1 collagen (NTx), bone alkaline phosphatase (BAP) and osteocalcin (OC) were evaluated at 0, 12, 24, 48 weeks after the administration of adalimumab. BMD were also examined by using dual energy X-ray absorptiometry (DXA) with lumbar spine and femoral neck. Patients' disease activities were evaluated by DAS-28 score and mHAQ. The statistical analysis was performed using one-way repeated measures ANOVA followed by Turkey's post hoc test.

Results: The serum levels of ucOC and OC were increased time-dependently and significantly by the administration of adalimumab.(ucOC: p=0.018; 0w vs. 24w, 0w vs. 48w, 12w vs. 48w, OC: p=0.001; 0w vs. 48w, 12w vs. 48w) The serum levels of NTx was decreased significantly by the administration of adalimumab (p=0.048), whereas the serum levels of BAP (p=0.221) and bone mineral density (L-spine: p=0.334, Femoral neck: p=0.069) did not changed (Table 1). Variability of disease activity, DAS28 and mHAQ scores did not correlate to bone biochemical markers.

Table 1.

	0w	12w	24w	48w	p-value
ucOC(ng/ml)	3.3 ± 2.1	3.7 ± 2.4	4.4 ± 2.3	5.2 ± 2.7	0.018
OC(ng/ml)	5.3 ± 1.6	6.0 ± 2.3	6.1 ± 2.7	7.5 ± 2.5	0.010
NTx(nmol BCE/l)	16.7 ± 5.3	15.9 ± 3.9	15.4 ± 5.5	14.9 ± 3.2	0.038
BAP(U/l)	13.8 ± 7.2	12.9 ± 5.9	14.7 ± 8.4	15.3 ± 6.8	0.221
DXA L-Spine(g/cm3)	1.007 ± 0.306	n/a	0.852 ± 0.313	0.837 ± 0.328	0.334
DXA F-Neck(g/cm3)	0.732 ± 0.097	n/a	0.726 ± 0.117	0.724 ± 0.109	0.069

Conclusion: Treatments with adalimumab increased the serum levels of OC, decreased NTx and thus arrested the systemic bone loss at 48 week. The increased serum ucOC is caused by the increase of the Vitamin K demand in the bone, presumably due to up-regulation of OC production. Therefore, during treatments with adalimumab, the vitamin K supplementation is required especially in cases with increased serum ucOC.

1974

Incidence of Atypical Femur Fractures Associated with Bisphosphonate Use for Osteoporosis: A Systematic Review of the Literature. John N. Mecchella[1], John A. Batsis[1], Robin J. Larson[2] and Gautham Suresh[1]. [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH

Background/Purpose: Reports of a link between bisphosphonate use in patients with osteoporosis and atypical femoral fractures--those occurring in subtrochanteric or diaphyseal locations--have generated significant concern among patients and providers. Attempts to estimate the degree of increased risk have varied widely with OR's ranging from 1 to 46. In addition, clinicians and patients may be overestimating the absolute risk of atypical fracture when considering these highly effective drugs. To obtain better estimates of these rates and assist clinicians in determining the risk versus benefits, we systematically identified and summarized studies reporting rates of atypical femoral fractures in subjects receiving bisphosphonates for osteoporosis.

Methods: With assistance of a reference librarian, we searched MED-LINE (1948–2012), and the Cochrane Library (2012) for studies that reported incidence of atypical femoral fractures among subjects exposed to bisphosphonates for osteoporosis. We also reviewed reference lists and consulted with experts. We excluded studies evaluating bisphosphonates in malignancy. We used no language restrictions. Two reviewers independently extracted data. Disagreements were resolved through consensus. Fracture rates were summarized according to study characteristics.

Results: Of 257 initial studies identified, 12 met all inclusion criteria and included three randomized controlled trials, six retrospective cohorts, and three population-based case-control studies. Among a total of 205,466 subjects followed over a range of less than 1 to 10 years of bisphosphonate exposure, there were 1440 subtrochanteric or diaphyseal fractures identified by ICD-9 or 10 coding, of which 160 were also confirmed radiographically. The incidence of atypical femoral fractures per 1000 patient-years of treatment with a bisphosphonate for osteoporosis ranged from 0.02 to 1 in studies that required radiographic verification of atypical nature, 0.23 to 3.4 in observational studies or randomized controlled trials, and 1.55 to 3.4 in studies of secondary prevention.

Conclusion: Currently available evidence suggests the incidence of atypical femoral fractures among patients receiving bisphosphonates for osteoporosis is low. In addition, even at the highest reported estimate of 3.4 per 1000 patient-years, the rate is considerably lower than estimates for recurrent osteoporotic fractures, which occur at approximately 100 per 1,000 patients per year. Discussions regarding bisphosphonate therapy should put both benefits and harms in appropriate context so that decisions are driven by evidence, not fear.

1975

Mortality After Fragility Hip Fracture in Middle Aged and Elderly Men and Women in Southern Norway. Andreas P. Diamantopoulos[1], Mari Hoff[2], Marc C. Hochberg[3] and Glenn Haugeberg[1]. [1]Hospital of Southern Norway HF, Kristiansand, Norway, [2]and St Olavs Hospital, Trondheim, Norway, [3]University of Maryland, Baltimore, MD

Background/Purpose: The mortality of the fragility hip fracture patients has been reported to be higher compared to the general population for both men and women, and higher in men than in women. The highest incidence of fragility hip fracture has been reported from Norway. Our aim was to study mortality rates in patients with fragility hip fracture in Southern Norway after 1 and 5 years and compare them with the general background population.

Methods: The hip fracture patients were identified in the two most southern counties in Norway, Vest-Agder and Aust-Agder County. Six percent of the Norwegian population (4.9 million) lives in this geographic area. Individuals over 50 years resident in the two counties who had a fragility hip fracture between 1 January 2004 and 31 December 2005 were included. The hospital electronic diagnosis registers were used to identify all hip fracture patients in the two year period coded as S72.0–2 according to the International Classification of Diseases 10th Revision (ICD-10). Data on age, gender, date of hip fracture and death date up to five years after the fracture date were collected in all patients. The follow-up time for one person was from the month the fracture occurred to death or the censoring date in January 1, 2009 and 2010. For each fracture patient 3 age and gender matched controls from the same geographic area was randomly selected from Norway's national register. Standardized mortality ratio (SMR) was calculated comparing with mortality rates in the Norwegian population using the SPSS version 17.0 (SPSS, Chicago, IL, USA). Statistical significance was defined as $p < 0.05$.

Results: In the two year period, the final number of fragility hip fractures in the geographic area was 951 (271 men and 680 women). Mean age for all included patients was 81.2 years (men 80.0 years and women 81.8 years). The SMR for men and women compared to the Norwegian population for the 1st year was 2.78 (95% CI 2.24–3.31) and 2.08 (95% CI 1.77–2.38) and after 5 years 3.10 (95% CI 2.21–3.98) and 1.82 (95% CI 1.41–2.22) respectively. The overall mortality rates for patients with a fragility hip fracture older than 80 years at the end of 1st year were 29.4% (44.6% for men and 24.0% for women, $p < 0.005$) and at the end of 5th year 69.2% (85.4% for men and 63.5% for women, $p < 0.005$). The mortality rates in patients with a fragility hip fracture after one year were higher in men than in women (men 32.1% and women 19.0%, $p < 0.005$). The corresponding figures for the controls were 6.5% for men and 5.0% for women ($p < 0.1$). After 5 years the mortality rate was 69.9% for men and 54.3% for women ($p < 0.005$) with a fragility hip fracture and for the controls 24.0 % for men and 21.5 % for women ($p < 0.1$).

Conclusion: Mortality rates in patients with a fragility hip fracture are elevated compared to matched controls and the background population at the first year and continues to be elevated after 5 years, especially in men. Future research should focus on identifying risk factors for this increased mortality in hip fracture patients.

1976

Treatment Satisfaction in Postmenopausal Women Previously Treated with Bisphosphonates Who Transitioned to Denosumab Vs Ibandronate Therapy in an Open-Label Study. Santiago Palacios[1], Giovanni Iolascon[2], Irene Agodoa[3], Hema Viswanathan[3], Prayashi Ghelani[4], Irene Ferreira[5], Cynthia O'Malley[3], Rachel B. Wagman[6] and Sydney Bonnick[7]. [1]Instituto Palacios, Madrid, Spain, [2]Seconda Universita di Napoli, Naples, Italy, [3]Amgen Inc, Thousand Oaks, CA, [4]Ovatech Solutions, London, United Kingdom, [5]Amgen Inc., Cambridge, United Kingdom, [6]Amgen Inc., Thousand Oaks, CA, [7]Clinical Research Center of North Texas, Denton, TX

Background/Purpose: Higher treatment satisfaction is associated with greater persistence with osteoporosis therapy in postmenopausal women (Barrett-Connor *OI* 2012). Greater satisfaction has been reported with subcutaneous injections of denosumab compared with oral alendronate tablets in a randomized, cross-over study where subjects received both treatments (Freemantle *OI* 2012). In this open-label trial, we evaluated treatment satisfaction in postmenopausal women with low bone mineral density (BMD) who were sub-optimally treated with prior bisphosphonate therapy and were transitioned to denosumab or ibandronate.

Methods: This was a multicenter, randomized, open-label, parallel-group study in which postmenopausal women aged 55 and older were randomized 1:1 to receive open-label denosumab 60 mg subcutaneously every 6 months or ibandronate 150 mg orally every month for 12 months. The treatment satisfaction questionnaire for medication (TSQM) version 1.4 was given at baseline and months 6 and 12 or at time of early termination. TSQM is a validated tool that measures the subject's perception of the 4 domains of treatment satisfaction: the medication's effectiveness, convenience, side effects, and global satisfaction (Atkinson *Health Qual Life Outcomes* 2004). Each TSQM domain score is between 0 and 100 and a higher score indicates a more preferred health status. Treatment comparisons of change in TSQM from baseline to months 6 and 12 were analyzed using an ANCOVA model fitted with treatment group and adjusted for baseline TSQM domain score.

Results: The study population included 833 women (417 denosumab; 416 ibandronate) with a mean (SD) age of 66.7 (8.0) years and mean (SD) BMD T-scores of –1.8 (0.7) at the total hip, 2.1 (0.7) at the femoral neck, and –2.5 (0.8) at the lumbar spine. Compared with the TSQM scores at baseline, subjects in both treatment groups reported greater satisfaction in all domains of the TSQM at month 6 and at month 12. However, subjects who transitioned to denosumab therapy had significantly greater improvements among all domains than did subjects who transitioned to ibandronate therapy at month 6 ($P \leq 0.0004$ in all domains; data not shown) and at month 12 ($P \leq 0.0003$ in all domains; Table 1).

Table 1. TSQM Change From Baseline to Month 12

TSQM Domain	Treatment	n	LS Mean	95% CI	P-value*
Effectiveness	Ibandronate	332	17.9	15.6, 20.2	<0.0001
	Denosumab	378	24.1	22.0, 26.3	
Convenience	Ibandronate	338	16.7	14.9, 18.6	<0.0001
	Denosumab	384	26.3	24.6, 28.0	
Side Effects	Ibandronate	337	4.2	2.7, 5.8	0.0003
	Denosumab	385	8.1	6.7, 9.6	
Global Satisfaction	Ibandronate	337	14.9	12.8, 17.1	<0.0001
	Denosumab	382	26.4	24.4, 28.4	

n = number of subjects with non-missing TSQM domain at baseline and at month 12. LS = least squares. CI = confidence interval. *P-value from treatment comparison based on an ANCOVA model fitted with treatment group and adjusted for baseline TSQM domain score.

Conclusion: In summary, postmenopausal women with low BMD who were sub-optimally treated with prior bisphosphonate therapy reported greater satisfaction if they transitioned to denosumab vs ibandronate in an open-label study. Greater treatment satisfaction may lead to better adherence to therapy and thus improvements in treatment efficacy.

1977

Relationship Between Baseline Bone Turnover Marker Levels and Bone Mineral Density Changes in Men with Low Bone Mineral Density Receiving Denosumab or Placebo. Eric Orwoll[1], Ugis Gruntmanis[2], Steven Boonen[3], Yu-Ching Yang[4], Rachel B. Wagman[4], Jesse W. Hall[4] and Paul D. Miller[5]. [1]Oregon Health and Science University, Portland, OR, [2]Dallas Veterans Affairs Medical Center and University of Texas Southwestern Medical Center, Dallas, TX, [3]Leuven University, Leuven, Belgium, [4]Amgen Inc., Thousand Oaks, CA, [5]Colorado Center for Bone Research, Lakewood, CO

Background/Purpose: Denosumab, a fully human monoclonal antibody to RANKL, has been shown to increase bone mineral density (BMD) in postmenopausal women with high or low bone turnover,[1] and reduce the risk for new vertebral, non-vertebral, and hip fractures.[2] ADAMO evaluated denosumab in men with low BMD and demonstrated increases in BMD at all measured skeletal sites and reductions in serum CTX (sCTX).[3] We assessed the efficacy of denosumab to increase BMD in men across a range of baseline bone turnover levels in ADAMO.

Methods: ADAMO was a multicenter, randomized, double-blind, placebo-controlled study. Subjects were randomized 1:1 to receive either 60 mg denosumab or placebo administered subcutaneously once every 6 months over a 12-month period. Subjects were included if they were aged 30 to 85 years; had a BMD T-score ≤ -2.0 and ≥ -3.5 at the lumbar spine or femoral neck, or had a prior major osteoporotic fracture and a T-score ≤ -1.0 and ≥ -3.5 at the lumbar spine or femoral neck. Subjects received ≥ 1000 mg calcium and ≥ 800 IU vitamin D supplementation daily. Percentage change in sCTX was assessed at day 15. Percentage change in BMD from baseline to month 12 at the lumbar spine, total hip, femoral neck, trochanter, and 1/3 radius was assessed according to baseline tertile of sCTX.

Results: A total of 242 subjects (121, placebo; 121, denosumab) were enrolled. As previously reported, 12 months of denosumab treatment significantly increased BMD from baseline at the lumbar spine, total hip, femoral neck, trochanter, and 1/3 radius compared with placebo (all $p < 0.02$, adjusted for multiplicity). Denosumab reduced sCTX by 81% from baseline vs 7% for placebo at day 15. For each tertile of baseline sCTX, subjects treated with denosumab, compared with placebo, demonstrated greater gains in lumbar spine and total hip BMD at month 12 (Figure). Subjects in the highest tertile of baseline sCTX had the numerically greatest gains in BMD when compared with subjects in the lowest tertile, although differences were not statistically significant. Associations between baseline sCTX and 12-month BMD improvements were weaker at the femoral neck and 1/3 radius, sites with greater variability in BMD measurements.[4]
Figure 1. Percent Change From Baseline in Mean BMD at 12 Months by Tertiles of Baseline sCTX

Conclusion: Independent of baseline sCTX, men with low BMD treated for one year with denosumab, compared with placebo, demonstrated greater gains in BMD at key skeletal sites routinely used to diagnose and manage patients with osteoporosis, suggesting that men at all levels of bone turnover may benefit from denosumab therapy.

1978

A Web-Based Intervention Aimed to Improve Bone Health Among Individuals On Chronic Glucocorticoids. Amy H. Warriner[1], Ryan C. Outman[1], Nathan Markward[2], Ronald Aubert[2], Jeffrey R. Curtis[3], Robert Epstein[2], Felix Freuh[2], Julia McEachern[2], David T. Redden[1], Monika M. Safford[1], Eric Stanek[2], Amy Steinkellner[2] and Kenneth G. Saag[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Medco, Bethesda, MD, [3]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Despite a significant associated fracture risk, previous population-based studies document low osteoporosis treatment rates for individuals treated with chronic glucocorticoids (GCs) at risk for glucocorticoid-induced osteoporosis (GIOP). We evaluated the influence of a direct-to-patient web-based educational video on the rates of anti-osteoporosis prescription medication use among chronic GC users who filled GCs online.

Methods: Using integrated medical and pharmacy data, we identified members of a pharmacy benefits management company who were prescribed ≥ 5 milligrams of prednisone (or an equivalent) for ≥ 90 days, but not prescribed GIOP therapies in the prior year. We developed an online video of osteoporosis risk-factors, treatment options, and real-life patient stories. Through an interrupted time series design, the video was automatically shown for 45 days to GC users following completion of an online GC refill. During the subsequent 45-day period, the video was inactivated. Those refilling GCs during the initial 45-days were the exposure group ("Video On") and those refilling GCs during the second 45-day period were the comparison group ("Video Off"). For 3 months following the completion of two Video On/Video Off cycles, the incidence of GIOP prescription use was assessed. Multivariable logistic regression was used to examine the influence of the video on GIOP prescription rates.

Results: Of the 4,659 patients that refilled their GC during the study, 3017 had the potential to view the intervention video. Among these, 59% had measurable video viewing time and 3% self-initiated the video. Most patients were between the ages of 50–70 (53.6%) and were male (56.8%). Commonly associated medical conditions in these patients included gastrointestinal illness (37.6%), history of organ transplant (29.9%), rheumatoid arthritis (17.5%), anxiety or depression (10.7%), and gout (9.2%).

During the 3-month follow-up, the overall GIOP prescription rate in the exposure group was 2.9% compared to 2.7% for the control group. GIOP prescription rates were slightly higher in those patients that self-initiated the video rather than in the automated manner (5.7%, p = 0.1). GIOP prescription rates were higher among older patients (50–70 years old: OR 2.1, 95% CI 1.3 – 3.5 and >70 years old: OR 1.8, 95% CI 1.0–3.2) when compared to those <50 years old and were lower among men (OR 0.2, 95% CI 0.2–0.4) when compared to women.

Conclusion: Among high-risk individuals, GIOP treatment rates were not affected greatly by an online educational video presented at the time of glucocorticoid refill. Women and persons aged 50–70 years old were more likely to be initiated on GIOP medications during the study period. This novel method of approaching patients may be more accepted by certain populations and further tailoring of the intervention could improve effectiveness.

1979

Care Gap in the Treatment of Patients with High Risk for Fractures in a Single Canadian Academic Center.

Arthur N. Lau[1], Michael Branch[2], Robert Bensen[3], Jonathan D. Adachi[4], Alexandra Papaioannou[1], William Wong-Pack[5] and William G. Bensen[6]. [1]McMaster University, Hamilton, ON, [2]CEO, Inovex, Oakville, ON, [3]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [4]Charlton Medical Centre, Hamilton, ON, [5]Hamilton, ON, [6]St. Joseph's Hospital and McMaster University, Hamilton, ON, Hamilton, ON

Background/Purpose: A number of clinical prediction tools are available to stratify patients into low, moderate and high risk for fractures in future. These tools are valuable in determining which patients should be initiated on an anti-resorptive agent. Bone Destiny is a validated tool which can accurately predict a patient's 10 year fracture risk. Patients are stratified into colours (green, yellow, orange, red and purple) which range from low to high 10 year risk. Patients in the purple and red range are deemed to be at very high and high risk respectively (10 year fracture risk >20%), and should be treated with an anti-resorptive agent. The goal of this study is to assess if a care gap exists in patients deemed at high risk of fractures using the Bone Destiny tool, and also if a similar gap exists in patients with a T-score in the osteoporosis range.

Methods: At a large single academic center in Hamilton, Canada, all patients who received a BMD from May 1, 2011 to April 30, 2012 were assessed using the Bone Destiny assessment tool and assigned a colour according to their fracture risk. All prevalent fragility fractures were recorded. We also assessed for the percentage of patients in each colour group being treated with either Prolia, Actonel, Fosavance, Evista, Aclasta or Forteo.

Results: At our center, 26,213 patients received a DXA scan and a Bone Destiny assessment. 3,643 patients were in the purple group, 4,501 patients were in the red group. Overall, 1805/3643 (49.5%) patients in the purple group and only 1817/4501 (40.4%) patients in the red group were on treatment. The younger patients (age<60 years) in the purple group were less likely to be started on treatment compared to older patients in this group (32.5% in age<60 years, while 46.1% in age 60–69 years, 53.9% in age 70–79 years, and 51.7% in age>80 years). The same trend was seen in the patients in the red group, where 32.9% of patients <60 years were on treatment, 41.4% in age 60–69 years, 44.3% in age 70–79 years, and 41.4% in age>80 years.

When we sorted patients in the database based on BMD T-scores, we found 3,367 patients with a T-score between −2.5 to −3.0. Only 1579/3367 (46.9%) patients were being treated with one of the listed agents. A similar trend was noticed, as younger patients were less likely to be on appropriate therapy. Only 33.8% of patients with age<60 years were on treatment, compared with 46.5% in age 60–69 years, 53.6% in age 70–79 years, and 53.7% in age>80 years.

Conclusion: It is important for clinicians to use a risk assessment tool to predict which patients are at high risk for fractures and start them on appropriate treatment. At our center; only 49.5% of patients in the purple group were on appropriate treatment and only 40.4% of patients in the red group. This is quite alarming, as the 67% (2443/3643) of patients in the purple group, and 33.4% (1502/4501) in the red group have a prevalent fragility fracture. This study suggests that a care gap indeed exists in patients at high risk for fractures, despite having the Bone Destiny tool to identify which patients require treatment. These results suggest more education is required to educate physicians and other healthcare providers about the availability and usefulness of such tools.

1980

Intermittent Nitrate Use and Risk of Hip Fracture.

Devyani Misra[1], Christine Peloquin[1], Hyon Choi[1], Tuhina Neogi[2] and Yuqing Zhang[1]. [1]Boston University School of Medicine, Boston, MA, [2]Boston Univ School of Medicine, Boston, MA

Background/Purpose: Nitrates are commonly used anti-anginal medications which have also been found to promote bone formation and decreases bone resorption. Intermittent nitrate use has been associated with increased bone mineral density; however, its effect on fracture risk has been conflicting. Because of potential tachyphylaxis with frequent use and challenge of defining regular vs. intermittent use in an observational study, we conducted a cohort study to examine the relation of incident short-acting nitrate use, a proxy for intermittent use, to the risk of hip fracture among older subjects with ischemic heart disease.

Methods: The Health Improvement Network (THIN) is an electronic medical records database containing anonymized clinical and prescription data entered by general practitioners in the UK. We included participants from THIN followed between 1986–2010 who were ≥ 60 years old with ischemic heart disease, without history of hip fracture prior to prescription of short-acting nitrates, no concomitant long-acting nitrate use, and continuously enrolled in the database for ≥12 months. Intermittent nitrate use was defined by incident nitrate use of short-acting formulations only (Glyceryl Trinitrate sublingual/spray/patch or Isosorbide Dinitrates injection/sprays) using Drug Codes, with ≥2 prescriptions in 1 year. Each intermittent nitrate user was matched by age, sex and enrollment year with a non-user (Never nitrate use). Follow-up started 1 year after the first nitrate prescription. Hip fractures were identified using Read Codes. We plotted Kaplan-Meier survival curves to determine cumulative incidence rate for hip fracture by intermittent nitrate use. Hazard ratios (HR) of incident hip fracture related to intermittent nitrate use was also estimated using Cox proportional hazards regression models, adjusting for BMI, recurrent falls, heart failure, smoking, alcoholism, use of beta-blockers, bisphosphonates, diuretics, estrogens and glucocorticoids.

Results: Included were 14 925 intermittent nitrate users (median # prescriptions in 1 year: 3.0) and 14 925 non-users (mean age 73±7.6, 41% women for each cohort). Hip fracture occurred in 267 intermittent nitrate users and 332 non-users, respectively. Cumulative incidence of hip fracture increased rapidly among non-users compared with intermittent nitrate users (Fig 1). Compared with non-users, rate of hip fracture was 30% lower and did not change substantially after adjusting for other potential confounders (adjusted HR=0.69, 95% CI 0.55–0.86, p=0.001).
Figure 1. Cumulative incidence of hip fracture by nitrate use.

Conclusion: In this large population-based cohort study, we found that intermittent (short-acting) nitrate use was associated with significant reduction in hip fracture risk among older adults with ischemic heart disease. Future studies are warranted, given the potential for nitrates to be inexpensive and readily available anti-osteoporotic agents.

1981

Low Body Mass Index, Medication Use and Social Factors Such As Smoking but Not Secondary Medical Disorders or Older Age May Be More Prevalent in Males with Low Bone Mineral Density. Vandana J. Vedanarayanan, Allison V. Jones and Vikas Majithia. University of Mississippi Medical Center, Jackson, MS

Background/Purpose: Osteoporosis (OP) in Males is prevalent and frequently under-recognized. There are a number of known demographic factors such as age, race and BMI as well as secondary causes of low bone mineral density (BMD) i.e. osteopenia and OP. The effect of these on the prevalence of low BMD has not been well quantified. This study aims to describe the prevalence of the demographic factors and SC in men with low BMD and also assess their impact on the prevalence.

Methods: Retrospective chart review of men who underwent DEXA scan performed at UMC from 2005– 2009 was done. Data regarding BMD, demographics i.e. age, race, height, weight, BMI, secondary medical causes, medications, social factors such as smoking and alcohol use was abstracted, tabulated and analyzed using STATA software. Statistical significance was assessed using T-test and Odds ratio as appropriate.

Results: A total of 237 charts were analyzed. There were 158 whites (W), 79 African-Americans (AA) 66 patients had normal BMD. Low bone density was prevalent and seen in 171 patients (75.9%). Amongst these 61 had T-score < -2.5 (osteoporosis) and 110 had T-score > -2.5 and <-1.0 (osteopenia) BMD. There were no racial differences in prevalence of low BMD and was seen in 77.21 % of AA and 69.62 % of W males tested. The prevalence results are presented in the table with significant differences highlighted.

	NORMAL BONE DENSITY	LOW BONE DENSITY (T-score <−1) includes both osteopenia & Osteoporosis	OSTEOPOROSIS (T-Score <−2.5)	
DEMOGRAPHICS				
AGE (mean)	60.06 years	62.97 years	59.42 years	p-NS
BMI (mean)	31.53	27.28*	26.03*	*p<0.001
SECONDARY MEDICAL DISORDERS (%)				
ANY Disorder	69.69 %	73.09 %	80.32 %	p=0.11
Thyroid Disorders	13.63 %	13.45 %	16.39%	p-NS
Hyperparathyroidism	4.54 %	2.33 %	3.27 %	p-NS
Diabetes	28.78 %	25.14 %	16.39%	p-NS
Asthma/COPD	4.54 %	14.03 %*	18.03 %*	*p<0.05
Rheumatoid Arthritis	10.6 %	12.28 %	16.66 %	p-NS
Other Connective tissue Disorders	7.57 %	11.11 %	13.11 %	p-NS
Malignancy	18.18 %	19.29 %	22.95 %	p-NS
MEDICATIONS				
Any Relevant	42.42 %	60.81 %*	68.85 %*	*p<0.05
Steroids >5 mg	24.24 %	33.91 %	32.78 %	p-NS
SOCIAL FACTORS				
Smoking	15.15 %	32.74 %*	36.06 %*	*p=0.01
Alcohol Use	0	2.92 %	1.63 %	—

In this cohort of patients undergoing DEXA scan, a number of underlying factors are present with low BMD. Amongst these, low BMI, overall medication use, smoking and respiratory disorders were found to be significantly more prevalent than others. No difference was found with older age or race but there was significantly higher prevalence of low BMI with low BMD. Secondary medical disorders were prevalent in the cohort (>70%). But, there was no difference in their prevalence except for asthma/COPD among those with low versus normal BMD. Similarly, medication use was common and was significantly more prevalent with low BMD. Steroid use (>5 mg) was more frequent with low BMD but not statistically significantly. Smoking was significantly more prevalent with low BMD and alcohol use could not be quantified due to small numbers. The results suggest that low BMI, smoking and overall medication use may be better associated with low BMD and potentially better predictors than race, older age and secondary medical disorders. Limitations of this study include its retrospective design and small sample size. Nonetheless these results highlight that the effect of these underlying factors needs to be better quantified in population studies, so that males at risk of OP may be better identified and screened earlier.

Conclusion: Low BMI, asthma/COPD, smoking and overall medication use were found to be more prevalent in the male patients with low BMD as compared to those with normal BMD in patients undergoing bone mass measurement. This may have significant implications on decision to consider screening for OP in males.

1982

Five Years of Treatment to Target in Early Active Rheumatoid Arthritis: Prevalence and Predictors of Vertebral Fractures. L. Dirven[1], M. van den Broek[1], A.J. Peeters[2], N. Riyazi[3], P.J.S.M. Kerstens[4], T.W.J. Huizinga[1], C.F. Allaart[1] and W. F. Lems[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Reinier de Graaf Gasthuis, Delft, Netherlands, [3]Haga Hospital, The Hague, Netherlands, [4]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: Vertebral fractures (VFs) are more common in patients with rheumatoid arthritis (RA) compared to the general population. It is suggested that an appropriate control of disease, generally more effectively achieved with disease activity score (DAS)-steered treatment strategies, may prevent the development of vertebral fractures. The prevalence of vertebral fractures after 5 years of DAS-steered treatment in patients with early active RA was determined and the association of VFs with disease activity, functional ability and bone mineral density (BMD) over time was investigated.

Methods: Five-year radiographs of the lateral thoracic and lumbar spine of 275 patients in the BeSt study, a randomized trial comparing four treatment strategies, were available. Treatment adjustments were made every 3 months aiming at a DAS≤2.4. Vertebral fractures were assessed using the Genant method, with a fracture defined as loss of height reduction >20% in one vertebra. BMDs of the spine and hip were measured with dual energy X-ray absorptiometry. With linear mixed models, DAS and Health Assessment Questionnaire (HAQ) scores over 5 years were compared for patients with and without VFs. With GEE the association between BMD and VFs was determined.

Results: At baseline patients were on average 54 years old and most were female (67%), of whom 18% were postmenopausal. Mean DAS was 4.4 and mean HAQ score was 1.3. After 5 years of DAS steered treatment, VFs were observed in 41/275 patients (15%). No difference in prevalence was found when stratified for gender, treatment with prednisone and menopausal status. Disease activity over time was higher in patients with VFs, with a mean difference of 0.20 (95% CI:0.05–0.36). HAQ scores were higher in patients with VFs, independent of disease activity, with a mean difference of 0.12 (95% CI:0.02–0.2). Although values were slightly lower over time in patients with vertebral fractures, mean BMDs in the spine and hip over time were not independently associated with VFs (OR 0.99, 95%CI:0.78–1.25 and 0.94, 95%CI: 0.65–1.36, respectively). Higher age was independently associated with VFs (OR 1.06, 95%CI:1.02–1.09).

Conclusion: After 5 years of DAS-steered treatment, 15% of these RA patients had vertebral fractures (VFs). Higher age was associated with the presence of VFs, but mean BMDs in the hip and spine were not. VFs are associated with more disability, independent of disease activity. Patients with VFs have a slightly higher disease activity over time, suggesting that optimal disease activity suppression may prevent VFs.

1983

Comparative Risk of Fracture in Men and Women with Human Immunodeficiency Virus. Lydia Gedmintas[1], Elizabeth Wright[2], Jeffrey N. Katz[3], Elena Losina[3] and Daniel H. Solomon[4]. [1]Brigham's Women's Hospital, Boston, MA, [2]Orthopedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: A growing body of evidence suggests that HIV-positive patients have an increased risk of osteoporosis compared to HIV-negative patients, with some studies suggesting a higher risk of fracture as well. Antiretroviral therapy (ART) is thought to contribute to this increased risk as certain therapies are linked to decreased bone mineral density, but the etiology of the higher risk of osteoporosis in HIV-positive patients is likely multifactorial. Expert recommendations suggest screening for osteoporosis in HIV-positive patients starting at age 50, in both men and women. However there is a insufficient evidence as to whether HIV-infected men have fracture rates similar to HIV-infected women.

Methods: We identified HIV-positive adult patients who had been prescribed ART and were seen at least annually at two large tertiary hospitals. An institutional electronic patient registry was used to identify these patients, as well as to identify the outcome of interest - fracture at any site – indicated by diagnosis code or the patient problem list. We reviewed 50 medical records of patients identified by the patient registry as having fracture in order to assess the positive predictive value (PPV) of the algorithm for identifying fracture in the registry database. We estimated the IR per 1,000 person-years for fractures for the entire cohort as well as the IR for fractures occurring at sites associated with osteoporosis (hip, wrist, vertebrae) and the IR for all other fractures. IR of fracture was then calculated stratified by age and gender. As well, IR ratios between men and women were calculated.

Results: We identified a cohort of 3,182 HIV-positive patients prescribed ART (883 women and 2,299 men) with a total of 15,317 person-years of follow-up. 696 total fractures were found in this population. The PPV of a fracture identified in the electronic patient registry was 90% (95% CI 78–97%) as compared with medical record review. The IR of fractures occurring at osteoporotic sites among men of all ages was 15.9 (95% CI 13.6– 18.4) compared with women which was 12.2 (95% CI 9.1–15.9), giving an incidence rate ratio of 1.3 (95% CI 0.95–1.80) (see Table). Men had similar or higher incidence rates of fractures at osteoporotic sites than women across most age groups until age 66, when women had higher rates, although this difference was not statistically significant. In addition, IR of fracture at all other sites were similar in men (IR 29.4, 95% CI 26.4–32.8) and women (IR 33.6, 95% CI 28.4–39.4), with IR ratio of 0.88 (95% CI 0.72–1.07).

	Men, Number of fractures	Men, IR of fracture/ 1000 person-years [95% CI]	Women, Number of fractures	Women, IR of fracture/ 1000 person-years [95% CI]	Incidence rate ratio (men/women) [95% CI]
All fractures, all age groups					
	497	45.3 [41.4–49.4]	199	45.8 [39.8–52.4]	0.99 [0.84–1.17]
Fractures occurring at osteoporotic sites (hip/femur, wrist/forearm, vertebral/spine)					
All age groups	174	15.9 [13.6–18.4]	53	12.2 [9.1–15.9]	1.30 [0.95–1.80]
Age ≤ 35	16	15.4 [8.8–24.9]	8	9.1 [3.9–17.8]	1.70 [0.69–4.60]
Age 36–45	48	11.8 [8.7–15.6]	12	7.1 [3.7–12.4]	1.66 [0.87–3.43]
Age 46–55	64	16.0 [12.3–20.3]	22	16.4 [10.3–24.7]	0.97 [0.59–1.66]
Age 56–65	35	23.0 [16.1–31.9]	7	20.6 [8.3–42.1]	1.12 [0.49–2.99]
Age ≥66	11	34.0 [17.1–60.0]	4	44.2[14.8–105.0]	0.77 [0.23–3.31]
Fractures occurring at all other sites (all other fracture sites)					
All age groups	323	29.4 [26.4–32.8]	146	33.6 [28.4–39.4]	0.88 [0.72–1.07]
Age ≤ 35	18	17.4 [10.3–27.3]	29	32.9 [22.1–46.9]	0.53 [0.28–0.98]
Age 36–45	100	24.5 [20.0–29.7]	42	24.8 [17.9–33.4]	0.99 [0.68–1.45]
Age 46–55	144	35.9 [30.3–42.1]	58	43.2 [33.0–55.5]	0.83 [0.61–1.15]
Age 56–65	47	30.9 [22.8–40.9]	11	32.4 [16.3–57.3]	0.95 [0.49–2.04]
Age ≥66	14	43.2 [23.6–72.5]	6	66.2 [24.3–144.1]	0.65 [0.24–2.07]

Conclusion: Fractures in HIV-positive patients on ART occur at similar rates in men and women. Recent expert recommendations suggest screening all HIV patients for osteoporosis including men. Our data offer support for this recommendation and can be used to further refine evidence-based recommendations for osteoporosis screening in HIV.

Orally Administered Parathyroid Hormone Analog Tablets in a Randomized Phase 2 Study Demonstrated Consistent Exposure and Increased Bone Mineral Density. Morten Asser Karsdal[1], Nozer M. Mehta[2], William Stern[2], Amy M. Sturmer[2], Sheela J. Mitta[2], Roxanne Tavakkol[2], Ali Bolat[2], Jenna Giacchi[2], Kim Henriksen[1], Lorraine A. Fitzpatrick[3], Claus Christiansen[4], Jeffrey A. Wald[3], Antonio J. Nino[3], Peter Alexandersen[4], Bente J. Riis[5], Jeppe Andersen[1], Ivo Valter[6], Bettina Nedergaard[4], Christence Teglbjaerg[4], Felicia Cosman[7] and John M. Trang[8]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Unigene Laboratories, Inc., Boonton, NJ, [3]GSK, King of Prussia, PA, [4]CCBR, Ballerup, Denmark, [5]Nordic Bioscience, Herlev, Denmark, [6]Ctr for Clinical & Basic Rsrch, Tallinn, Estonia, [7]Helen Hayes Hospital, West Haverstraw, NY, [8]PK/PD International Inc., Tucson, AZ

Background/Purpose: PTH is a potent anabolic agent for bone, but patient acceptance is difficult due to the need for daily injections. A solid dosage enteric-coated formulation has been developed that enables oral peptide delivery by a unique mechanism that includes an organic acid as a protease inhibitor and an acylcarnitine as a permeation enhancer. Based on results from phase 1 studies, we tested a 5 mg tablet dose of a differentiated $PTH(1–31)NH_2$ in a Phase 2 proof-of-concept study.

Methods: The Phase 2 study was a 24-week double blind, randomized, repeat dose parallel group study of $rhPTH(1–31)NH_2$, or placebo tablets, compared to open label Forsteo® [teriparatide, PTH(1–34)OH] in 97 post-menopausal women with osteoporosis. The primary endpoint was to characterize percent change from baseline in BMD by DXA at lumbar spine (LS) after 24 weeks of once daily oral treatment of $PTH(1–31)NH_2$ and the secondary endpoint was to determine the effect on bone markers. Plasma samples were collected to characterize the PK profiles of the tablets and the Forsteo®after the first dose and at the end of treatment. Blood samples were collected prior to and at intervals up to 5.75 hr after tablet administration and up to 2 hr after injection.

Results: The trial met the primary endpoint with an increase of 2.2% in LS BMD with $PTH(1–31)NH_2$ compared to baseline (p=0.004). Placebo LS BMD decreased by −0.17% (p=NS) and LS BMD for teriparatide increased by 5.1% (p<0.001). There were statistically significant increases from baseline in the total hip BMD for $PTH(1–31)NH_2$ and teriparatide, with no significant differences between these two groups. CTx-1, a marker of bone resorption, increased by 12.7% (p=NS) in the $PTH(1–31)NH_2$ group and by 124.6% in the teriparatide group at week 24. The increase in the bone formation marker P1NP was fairly modest for the $PTH(1–31)NH_2$group, whereas osteocalcin, another formation marker, increased 23.3% (p=0.015) compared to baseline. This is in contrast to 4.9% (p=0.87) in placebo and 169.3% (p<0.0001) in the teriparatide group at week 24. No clinically significant hypercalcemic events or elevated urine calcium were seen in the oral $PTH(1–31)NH_2$ arm. The PK profile for $PTH(1–31)NH_2$ showed a pulsatile peak with durations of at least 1 hr but less than 5 hr, which is consistent with the requirement for bone anabolic activity. The mean C_{max} of $PTH(1–31)NH_2$ measured at weeks 0 (n=32) and 24 (n=28) was 295 pg/mL and 207 pg/mL, respectively. The mean C_{max} at for patients receiving Forsteo® at weeks 0 and 24 was 120 pg/mL. Thus, the 5 mg dose resulted in higher mean C_{max} values than Forsteo®. The median C_{max} and AUC values were equivalent to those of Forsteo®. The most common adverse event in the oral PTH and placebo arms was GI pain or distress, and these events were mostly mild or moderate.

Conclusion: The efficacy data and safety profile in this study demonstrate that orally delivered $PTH(1–31)NH_2$ offers the potential for a bone anabolic treatment with greater physician and patient acceptance, and warrants evaluation in further late stage clinical studies.

1985

The Effect of Calcium and Vitamin D On Bone Loss in an Epileptic Population. Philip Dussault[1], Samuel Davis Jr.[1] and Antonio A. Lazzari[2]. [1]Boston VA HCS, Boston, MA, [2]Boston VA Medical Center, Boston, MA

Background/Purpose: Accelerated rate of bone loss leading to osteopenia and osteoporosis is a well recognized adverse effect of long term anticonvulsant use, particularly phenytoin, phenobarbital, sodium valproate or carbamazepine. Futher, compared to the general population, epileptics experience a two-fold increase in the incidence of vertebral and non-vertebral fractures.

In this trial, we sought to evaluate whether a bisphosphonate in addition to calcium and vitamin D supplementation can prevent bone loss and fractures in an epileptic population chronically treated with phenytoin, phenobarbital, sodium valproate or carbamazepine.

Methods: This was a phase IV randomized, two year double blinded, placebo-controlled trial of an epileptic male population of veterans. This study involved 80 patients with various types of seizures who were being treated with phenytoin, phenobarbital, sodium valproate or carbamazepine for a minimum of two years. At initial visit, patients underwent DXA scan on 5th generation GE IDXA. Subjects who had a T-score > -2.5 at AP spine or hip were randomized into two one of two groups. Group R received calcium and vitamin D supplementation along with risedronate 35mg weekly, while Group P received calcium and vitamin D supplementation along with a matching placebo tablet weekly. We excluded those subjects who had were found to be osteoporotic according to WHO criteria (BMD T-score < -2.5 at spine or hip) or were found to be vitamin D deficient.

BMD of bilateral proximal femur, LVA, A-P lumbar spine, total body and forearm were evaluated utilizing a GE Lunar Bone Densitometer or an iDXA instrument and had measurements of 25-OH Vit D, NTX, serum calcium and blood chemistries.

Results: 80 patients were randomly enrolled in either the B or P groups. Baseline characteristics of both groups were similar. Average age was $60+/-13$ years. Average bilateral total proximal femur mean BMD was $0.991+/-0.122$ for the B group and $0.992+/-0.213$ g/cm2 for the P group. Lumbar spine baseline BMD was $1.284+/-0.190$ for the B group and $1.237+/-0.249$ g/cm2 for the P group. Total body BMD was 1.229 $+/-0.107$ for the P group and $1.185 +/-0.110$ for the B group. A total of 56 patients competed the study. At the end of the study 12 out 28 patients from group B and 10 out 28 patients from group P had a significant increase of BMD as determined at the total proximal femur which was above the LSC for our site; further, 18 out 28 of group B and 22 out of 28 on group P demonstrated a significant increase of BMD at the L-Spine. Improvement of BMD at different sites was observed in more than 78% of patients who completed the study taking calcium and vit D both in the P or B groups. Five new vertebral fractures were observed only on the P group.

Conclusion: In this cohort, supplementation with calcium and vitamin D or use of calcium, vitamin D and bisphosphonates decrease rate of bone loss and at the same time increased bone mass associated with chronic treatment with phenytoin, phenobarbital, sodium valproate or carbamazepine. Prevention of new vertebral fractures was not observed in the group receiving only calcium and vitamin D.

1986

Impaired Endothelial Function in Post-Menopausal Women with Osteoporosis. Auleen M. Millar[1], Aaron McCann[2], Vivian McClenaghan[2], Paul Hamilton[2], Caroline Bleakley[2], Kristopher Lyons[2] and Gary McVeigh[2]. [1]Musgrave Park Hospital, Belfast, United Kingdom, [2]Belfast, United Kingdom

Background/Purpose: Although traditionally viewed as separate disease entities that increase in prevalence with aging, accumulating evidence indicates that similar pathophysiological mechanisms may underlie cardiovascular disease and osteoporosis. Endothelial dysfunction is the initial step in the atherosclerotic process. The aims of this study were to determine if women with post-menopausal osteoporosis have impaired endothelial function.

Methods: We used non-invasive Doppler ultrasound to assess endothelial function in sixty women with post-menopausal osteoporosis and compared results to 30 age, sex matched controls. After measurement of traditional cardiovascular risk factors, we measured flow mediated dilation (FMD) of the brachial artery in subjects. Flow mediated dilation is a dynamic assessment of endothelium-dependent and -independent dilation of an artery. Subjects were further assessed using radial artery tonometry. Isoprostane levels, which are a marker of oxidative stress, were compared between groups.

Results: Groups were equally matched for age, weight, blood pressure, cholesterol profile and smoking history. Results from radial artery tonometry indicated that cardiac output (p=0.03), large artery elasticity index (p=0.03) and small artery elasticity index (p=0.03) readings were significantly higher in the healthy control group. Systemic vascular resistance (p=0.005) and total vascular impedance (p=0.032) was statistically significantly higher in patients with osteoporosis compared to controls. Flow mediated dilatation of the brachial artery showed a statistically significant better dilatation of the brachial artery post cuff deflation in healthy controls (p=0.006), although there was no difference in endothelium-independent dilation ie. brachial artery dilation after administration of GTN. Isoprostane levels were statistically significantly higher in the osteoporosis group

Conclusion: The differences in flow mediated dilatation between healthy controls and post-menopausal women with osteoporosis may indicate impaired endothelial function and reflect the local distensibility of the brachial artery or the distal microcirculation's response to the ischaemic stimulus. Radial artery tonometry results also support a difference in endothelial function between groups. Changes in vascular reactivity are likely to be multi-factorial but may be related in part to differences in levels of oxidative stress between groups. This study demonstrates that further work is required on the assessment of potential structural remodelling in small arteries and vascular beds that may precede clinically detectable cardiovascular disease in women with post-menopausal osteoporosis. Further work is also required on the complex interaction of common risk factors and genetic or molecular determinants of both conditions.

1987

A Comparison of Unilateral and Bilateral Hip BMD. Steven C. Schaub[1], Edward S. Leib[1] and Diantha Howard[2]. [1]U of Vermont College of Med, Burlington, VT, [2]Vermont Center for Clinical and Translational Science, Burlington, VT

Background/Purpose: The utility of bilateral hip dual energy x-ray absorptiometry scanning for identifying low bone mineral density has been a cause of debate. Intraperson differences in density at the hip can affect categorization of a patient as osteoporotic. Our study was designed to assess the correlation between sides of the hip in individual patients and to compare different sites of the hip for osteoporosis categorization.

Methods: Bilateral hip measurement data on postmenopausal women over age 40 from a single facility scanned on a GELunar Prodigy or Prodigy Advance were retrospectively reviewed. Data included patient demographics, bilateral scan BMD and T-score, presence of historical fragility fractures and data to determine clinical risk.

Results: Scans were evaluable for both proximal femurs in 12,741 women. We found lower density values, reported as T-scores, on the right side of the hip at all regions of interest that were statistically significant. Agreement in osteoporosis categorization between sides of the hip ranged by anatomic site from 82.7%–87.6%. Mean values showed improved agreement (91.0%–93.5%) over the lowest obtained T-score at each hip site. The total hip had the highest correlation in categorization and the closest association to previous fracture at each region of interest. Those categorized as osteoporotic by the mean value were as or more likely to have had a fracture than those with the lowest BMD. Using logistic regression models the adjusted odds ratio for fracture was 3.00 in the osteoporosis category compared to normals. Bilateral scanning effectively eliminated significant differences within an individual patient, but values were minimally divergent from unilateral measurements.

Conclusion: Our study demonstrates that, although there is a small difference between WHO classification of osteoporosis comparing the mean values of the hip to the lowest, the use of the mean value was as good as or better for predicting fractures as the lowest value. This supports the use of bilateral hip scanning for diagnosis of osteoporosis and identifying individuals at risk for fractures.

Zoledronate Efficacy and Safety in Active Paget's Disease Long-Term Follow-up and Retreatment in Clinical Practice. Elsa Vieira-Sousa[1], Ana M. Rodrigues[1], Joana Caetano-Lopes[2], Susana Capela[3], Filipa Ramos[3], Ricardo Figueira[3], Joaquim Polido-Pereira[1], Cristina Ponte[1], Raquel Campanilho-Marques[1], Rita Barros[3], JC Romeu[3] and José A. Pereira da Silva[3]. [1]Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [3]Rheumatology and Metabolic Bone Diseases Department, Santa Maria Hospital,CHLN, Lisbon, Portugal

Background/Purpose: Bisphosphonates are first line therapy in the treatment of Paget's disease (PD). Zoledronate, a third generation bisphosphonate, has showed high efficacy in the inhibition of bone resorption. The objective of this observational study was to assess short and long-term efficacy and safety of zoledronate in the treatment of active PD, in clinical practice.

Methods: Patients with active PD treated with zoledronate 5 mg were consecutively recruited between 2005 and 2011 and followed prospectively. Clinical (bone and joint pain attributed to PD) and laboratory parameters (alkaline phosphatase (ALP), bone specific alkaline phosphatase (BSALP), procollagen type 1 N-terminal propeptide (P1NP), collagen type 1 beta C-terminal telopeptide (b-CTX), seric and urinary calcium and phosphorus and parathormone levels) were determined before, at 3 and then every 6 months after treatment, up to a maximum of 60 months of follow-up. Remission was defined as normalization of ALP. Retreatement was considered when ALP levels increased more than 25% of the upper limit of normal or of the nadir achieve, in cases of non normalization of ALP. Adverse events were registered according to clinical protocol.

Results: 60 patients (60% males), with a mean age of 68 ± 11 years and a mean disease duration of 11 ± 9 years were included. 69% had polyostotic disease and the mean percentage of skeletal involvement (Howarth table) was of $10.8\pm7.6\%$. 68% were symptomatic: 71% of those referring bone and 54% joint pain attributed to PD. 54% were receiving analgesic or non steroidal anti-inflammatory drugs. 48.3% had been previously treated with parental pamidronate, with a cumulative dose of 234 ± 209mg. The mean follow-up period after zoledronate infusion was of 37 ± 13 months (minimum of 12 and maximum of 60). Only 4 patients (6.6%) required retreatment, on average 30 months after the first zoledronate infusion. A marked reduction of ALP ($261,6\pm152,5$ U/L at baseline) was observed at 3 ($70\%;79,6\pm42,6$) and 6 months ($74\%;67,0\pm22,1$) after zoledronate administration, being maximal at 12 months ($75\%;66,3\pm22,2$) ($p<0.001$). The difference of the mean values of ALP between 3 and 6 months was also significant ($p<0.05$). At 3 and 6 months, 95% and 96% of patients respectively, achieved remission. Maximum effect was obtained at 12 months after treatment with 98% of patients being in remission. Significant reductions of the mean levels of BSALP, P1NP, and b-CTX ($p<0.001$) were also verified at 3, 6 and 12 months after treatment. 47% of patients reported pain improvement: 89% at 3 months, 7% at 6 months and 4% at 12 months. Transitory side effects were registered in 15 patients, 18% referred flu-like symptoms, 10% showed asymptomatic hypocalcaemia and 30% asymptomatic hypophosphoremia.

Conclusion: This study confirms the efficacy and safety of zoledronate in a Portuguese population of patients with active Paget's disease. Biochemical remission was achieved in 98% of patients at 12 months and improvement of pain in 47%, the majority 3 months after treatment. Furthermore these benefits were long-term sustained with only 6.6% of patients requiring retreatment during an average follow-up of 37 months.

1989

Risk Factors for Vertebral Fractures in Patients with Rheumatoid Arthritis - the Tomorrow Study -. Tadashi Okano, Tatsuya Koike, Masahiro Tada, Kenji Mamoto, Yuko Sugioka, Atsuko Kamiyama and Hiroaki Nakamura. Osaka City University Medical School, Osaka, Japan

Background/Purpose: Rheumatoid arthritis (RA) is one of the causes for secondary osteoporosis. Osteoporosis as a multifactorial disease might be derived from comorbidity itself, poorer physical activity, treatment with glucocorticoids, or postmenopausal status. Accelerated generalized bone loss often leads to an increased risk of vertebral fractures. The purpose of this study is to determine the prevalence and the risk factors for vertebral fractures in patients with RA.

Methods: We started a 10-year prospective cohort study named TOMORROW (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOWer morbidity and mortality, clinical trial registration number: UMIN000003876) in 2010. This study included 208 patients with RA (biological agents, n = 112; conventional therapy, n = 96) and 205 age- and sex-matched volunteers (total, n = 413). We evaluated the prevalence of vertebral fractures using thoracolumbar spine X-rays and analyzed the factors associated with vertebral fractures. Evaluation of existing vertebral fractures was used for a quantitative assessment of each vertebra from T4 to L4 as a first assessment and a semiquantitative visual assessment of each vertebra considered existing vertebral fractures by first assessment.

Results: The prevalence of vertebral fractures was 45.5% and 30% in the RA and volunteer groups, respectively. Significantly more RA patients than volunteers had semiquantitative (SQ) grade 2 or more (15.2% vs. 5%). Bone mineral density, urine pentosidine, homocysteine and bone specific alkaline phosphatase (BAP) significantly correlated with vertebral fractures among the patients and urinary pentosidine levels in the RA patients with fractures were significantly higher than without fractures. Patients using bisphosphonates was 33.3% in patients with rheumatoid arthritis. Bone mineral density was lower and more vertebral fractures was found in patients using bisphosphonates than in patients without bisphosphonates.

Vertebral fractures	Volunteers (n = 205)	RA (n = 208)
N = 0	70%	54.5%
N = 1	14.5%	10.1%
N = 2	8%	9.6%
N = 3	7.5%	25.8%
SQ grade = 2	5%	15.2%
Thoracic spine BMD	0.750 ± 0.126	0.701 ± 0.125
Lumbar spine BMD	0.930 ± 0.163	0.896 ± 0.164

Conclusion: The incidence of vertebral fractures was higher in patients with RA than in volunteers. Bone quality markers and vertebral fractures are closely linked with RA. We will continue to prospectively investigate the incidence of new vertebral fractures and the progression of osteoporosis in patients with RA.

1990

Risk of Falling Is Equivalent Between Patients with Rheumatoid Arthritis and Healthy Individuals—the Tomorrow Study. Kenji Mamoto, Tatsuya Koike, Tadashi Okano, Atsuko Kamiyama, Yuko Sugioka, Masahiro Tada and Hiroaki Nakamura. Osaka City University Graduate School of Medicine, Osaka, Japan

Background/Purpose: Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falling. The present study prospectively determines the incidence of falls and their risk factors in patients with RA who participated in the TOMORROW (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOW er morbidity and mortality; clinical trial registration number: UMIN000003876) study that was started in 2010.

Methods: We evaluated anthropometric parameters, muscle volume, bone mineral density (BMD), disease activity, general health status and the occurrence of falls for a period of two years in 202 patients with RA (mean age: 58.4 years, 54% administered with biological agents) and 202 age- and sex-matched healthy volunteers (HV, mean age: 57.4 years).

Results: Among the patients with RA and HV, 29.6% and 26.7% respectively reported one or more falls during two years. These values did not significantly differ in the two groups. The fall group had higher age, lower BMD ($p<0.01$), higher whole % Fat mass ($p<0.01$) and tended to have induced walking time. After adjusting for risk factors of falls such as age, gender, smoking and BMI, multiple logistic regression analysis identified that a history of falls was the most significant parameter associated with falls

(odds ratio: 2.39, p=0.001) (Table 1). The RA group also had lower whole muscle volume (37.2 vs. 39.6 kg; p = 0.001), leg BMD (0.967 vs. 1.031 mg/cm[3]; p < 0.001) and shorter exercise periods than HV, but none of these were associated with rates of falling. Furthermore, fall risk did not significantly and linearly increase with disease duration, disease activity score and physical status among the patients with RA.

Conclusion: We concluded that the fall rate is not higher in patients with RA than in healthy volunteers and that only a history of falls plays a role in increasing the risk of falls.

1991

Effects of Odanacatib On the Distal Radius and Tibia in Postmenopausal Women: Improvements in Cortical Geometry and Estimated Bone Strength. Roland Chapurlat[1], K. Brixen[2], A.M. Cheung[3], Sharmila Majumdar[4], B. Dardzinski[5], A. Cabal[6], N. Verbruggen[7], S. Ather[6], Elizabeth Rosenberg[5] and A. de Papp[5]. [1]Hôpital Edouard Herriot, Lyon, France, [2]University of Southern Denmark, Odense, Denmark, [3]University of Toronto, Ontario, [4]University of California San Francisco, San Francisco, CA, [5]Merck Sharp & Dohme Corp., Whitehouse Station, NJ, [6]Merck Sharp & Dohme Corp., Whitehouse Station, [7]MSD Belgium, Brussels, Belgium

Background/Purpose: The cathepsin K inhibitor odanacatib (ODN), a novel antiresorptive that preserves bone formation, is currently in phase 3 development for postmenopausal osteoporosis. In a phase 2 study, 5 years of ODN 50 mg once weekly progressively increased areal BMD at the lumbar spine and total hip (11.9 % and 8.5% from baseline, respectively). ODN reduced bone resorption markers while preserving bone formation markers. In an OVX primate model, ODN has been shown to increase cortical thickness and periosteal bone formation at the central femur and femoral neck.

Figure. Distal Radius HR-pQCT Endpoints in Postmenopausal Women at Month 24
NOTE: HR-pQCT endpoints were exploratory and there was no adjustment for multiplicity.
vBMD=volumetric bone mineral density

Methods: In order to determine the effect of ODN on cortical geometry and to estimate bone strength, we conducted a randomized, double-blind placebo-controlled trial, using high resolution quantitative computerized tomography (HR-pQCT) of the distal radius and distal tibia. A total of 214 postmenopausal women, of mean age 64.0 ±6.8 years and baseline lumbar spine T-score −1.81 ±0.83, were randomized to oral ODN 50 mg or PBO weekly for 2 years.

Results: Lumbar spine areal BMD % change from baseline at 1 year (primary endpoint) was statistically significantly greater for ODN than PBO (3.49% treatment difference, p<0.001). After 2 years, there were significantly greater improvements with ODN than PBO in total, trabecular, and cortical volumetric BMD; cortical thickness; and estimated strength (failure load) of the distal radius using HR-pQCT-based finite element analysis (exploratory endpoints, FIGURE). At the radius, odanacatib attenuated the increase in cortical porosity that was seen in the placebo group (treatment difference in least squares mean % change from baseline −7.68, p=0.066). At the distal tibia, changes in volumetric BMD and cortical thickness were similar to changes at the radius. Safety and tolerability were similar between treatment groups.

Conclusion: Odanacatib increased cortical and trabecular density and improved cortical thickness of the distal radius and distal tibia, and improved the estimated bone strength in the distal radius compared to placebo.

1992

Anti-TNF Therapies Improve Bone Mineral Density At the Lumbar Spine of RA Patients by Decreasing Disease Activity and Suppressing Serum RANKL Levels. Allen P. Anandarajah[1], Jennifer Hossler[2], Kate Burns[2], Kelly Callahan[2], Yahui Grace Chiu[2] and Jennifer H. Anolik[2]. [1]Univ of Rochester Medical Ctr, Rochester, NY, [2]University of Rochester, Rochester, NY

Background/Purpose: Generalized bone loss (osteoporosis or osteopenia) is more common in patients with rheumatoid arthritis (RA) than in the general population. Recent studies suggest that inflammation in RA is a main contributor to this form of bone loss. Inflammation is mediated in turn by multiple cytokines with tumor necrosis factor (TNF) being a key player. Few studies, however, have described the effects of anti-TNF therapies on generalized bone loss.

Objective: To study the effects of anti-TNF therapies on the bone mineral density (BMD) of early RA patients and to correlate the BMD measurements with serum receptor activator of NFkB ligand (RANKL) and osteprotegerin (OPG).

Methods: This is a single center study of 40 subjects with active RA (disease activity scores of 3.2 or more) that are naïve to anti-TNF therapy and receiving stable doses of disease-modifying drugs. Patients were treated with adalimumab 40 mg every other week or etanercept (25 mg twice a week or 50 mg once a week). Subjects were allowed to be on a maximum daily dose of 10 mg of prednisone or an equivalent dose. Subjects did not require or were not willing to take medications for osteoporosis. DAS28 assessments were done at baseline, 12 and 24 weeks. Bone mineral density (BMD) measurements of the lumbar spine (LS) and hips were done using a Lunar Prodigy x-ray absorptiometer prior to the first dose of anti-TNF therapy and at week 52. Serum RANKL and OPG levels were measured by ELISA at baseline and at weeks 24 and 52.

Results: The 8 subjects (females, 5; males, 3) who have completed 1 year of anti-TNF therapy had a mean age of 57 years. The mean DAS28 score improved from 4.8 at baseline to 3.5 at 24 weeks. Five patients had a good DAS28 response, 2 had a moderate response, and 1 was a non-responder. The BMD at the LS increased in 5, decreased in 2, and did not change in 1. The mean BMD for the group as a whole did not change with treatment (1.22g/cm[2] to 1.21g/cm[2]) between baseline and week 52. Among the 5 patients with an increase in BMD, 4 had had a good DAS28 response and one had a moderate DAS28 response; whereas, among the 2 patients with a decrease in BMD, 1 was a DAS28 non-responder and 1 had had a good DAS28 response. The patient with no significant change in BMD had a moderate DAS28 response. Serum RANKL levels decreased significantly with treatment from 2381 pg/ml (+/−3025) at baseline to 921 pg/ml (+/−1630) at week 52 (p=0.03). Interestingly, at 24 weeks, the serum RANKL was decreased in those with improved BMD (mean RANKL 1994.4 pg/ml at baseline and 1298.2pg/ml at week 24), but was essentially unchanged in those with decreased/ unchanged BMD (mean RANKL 3025.7 pg/ml at baseline and 3029.7 pg/ml at week 24). In the 5 subjects with increased BMD, RANKL levels were decreased in 4 of the subjects and

increased in 1 subject. Among the 2 patients with a decrease in BMD, 1 had an increase and 1 had a decrease in RANKL levels. The remaining subject with no change in BMD also had no change in RANKL level. No relationship was noted between BMD at the LS and OPG levels.

Conclusion: Anti-TNF therapy improves BMD at the lumbar spine in a subset of RA patients. The increase in BMD is associated with a decrease in disease activity and may be mediated by a suppression of serum RANKL levels.

1993

Contribution of Lifestyle Factors to Healthy-Adherer Bias in Prevalent Users of Osteoporotic Drugs. Mitsuyo Kinjo[1] and Daniel H. Solomon[2]. [1]Okinawa Chubu Hospital, Uruma City Okinawa, Japan, [2]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: Adherence to drug therapy may be a surrogate marker for overall healthy behaviors leading to healthy-adherer bias in epidemiologic studies. This might be particularly emphasized in osteoporosis supplements and medications. However, individual factors contributing to healthy-adherer effects and their quantitative impacts are not well described. We assessed the association between prevalent use of and adherence to osteoporotic supplements or medications and healthy lifestyle factors in a population-based sample from the National Health and Nutrition Examination Survey, 1999–2008.

Methods: We identified subjects who used calcium plus vitamin D supplements and/or osteoporotic medications (bisphosphonate, calcitonin or raloxifene). We estimated the magnitude of association between prevalent use of these osteoporotic drugs and demographic, lifestyle and comorbid illness factors. Demographic, lifestyle, and comorbid factors of interest included body mass index, exercise, smoking, alcohol consumption, self-reported health status, comorbidities (cancer, coronary artery disease, COPD and diabetes), and steroid use. We also examined the subset of subjects with a history of fracture in the hip, wrist or spine, or those with osteoporosis who were advised to take treatments.

Results: Among 25,290 subjects, 1,529 were users and 23,761 were nonusers of calcium, vitamin D or an osteoporosis medication. Users and nonusers were similar in age (mean age 57 years), but were more likely to be women (64% vs 52%; $P<.05$). After adjustment for age, prevalent female users 50 years or older had significantly less severe obesity (odds ratio 0.7, 95% CI: 0.6, 0.9), current or past smoking (OR 0.8, 95% CI: 0.5, 1.0), more moderate exercise (OR 1.4, 95% CI:1.1, 1.8), lower self-reported poor health (OR 0.8, 95% CI: 0.7, 0.9), less diabetes (OR 0.7, 95% CI:0.6, 0.9) and acute coronary syndrome (OR 0.8, 95% CI:0.7, 1.0). Among subjects with previous fracture or osteoporosis, a similar trend was seen between users and nonusers.

Conclusion: In a large representative US population, prevalent use or adherence to osteoporotic drugs was associated with healthier lifestyle factors. The results suggest that healthy user or adherer can be explained, in part, by the healthier lifestyles in prevalent users or adherers in the elderly.

1994

The Influence of Percentage Body Fat On Bone Mineral Density in Thin Patients. Andrew Blanshard[1] and Marwan Bukhari[2]. [1]Lancaster University, Lancaster, United Kingdom, [2]Royal Lancaster Infirmary, Lancaster, United Kingdom

Background/Purpose: Low Body Mass Index (BMI) is associated with low Bone Mineral Density (BMD) and subsequent risk of fragility fracture. Percentage body fat (%BF), which is measured by most DEXA scanners, has a correlation with BMD, however the relative contribution of %BF on osteoporosis has not been examined in detail. A higher %BF may be associated with a higher BMD when BMI is accounted for. Previous work from this unit has shown that the threshold for poor bone health is a BMI of 22.

Our aim was to determine the relationship between %BF and BMD in a population at risk of fracture.

Methods: Patients with a BMI of less than 22 were identified from a total population of 25896 who had been referred for Dual-Energy X-Ray Absorptiometry (DEXA) scanning between June 2004 and August 2010. The relationship between %BF (as measured by DEXA) and the mean BMD at both the femoral neck and lumbar spine were analysed using Stata 9.0 for Windows. Linear regression was used to determine the relationship between %BF and the BMD at both the lumbar spine and the femoral neck, adjusting for BMI.

Results: 2634 patients were included in the analysis which consisted of 2333 females; 88.6% of the population. Although there was a correlation between %BF and BMI (coeff, 0.06; 95% CI, 0.05, 0.07), the variance explained was low (adjusted-R squared value 0.07). When examining %BF and BMD and adjusting for BMI, there was a statistically significant negative association at the lumbar spine (coeff, -0.004; 95% CI, -0.006, $-.004$) and the femoral neck (coeff, -0.005; 95% CI, -0.007, $-.004$). This relationship was also observed in an only female cohort. A sensitivity analysis was performed using %BF alone, which still showed a negative correlation.

Conclusion: BMD was negatively influenced by %BF in this population with a low BMI, after adjusting for baseline BMI. A possible hypothesis is that body fat in this group has a paradoxical effect on bone health. Further work investigating this relationship in patients with a higher BMI will be performed.

1995

What Are the Most Clinically Relevant and Feasible Pragmatic Osteoporosis Clinical Trial Designs? Nicole C. Wright[1], Ana Oliveira[1], Amy H. Warriner[1], Jeffrey Curtis[1], Neil Binkley[2], Steven R. Cummings[3], Marc C. Hochberg[4], Andrea LaCroix[5], E. Michael Lewiecki[6], John T. Schousboe[7], Daniel H. Solomon[8], Robert B. Wallace[9] and Kenneth G. Saag[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Wisconsin, Madison, WI, [3]San Francisco Coordinating Center, CPMC Research Institute, San Francisco, CA, [4]University of Maryland, Baltimore, MD, [5]Fred Hutchinson Cancer Research Center, Seattle, WA, [6]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, [7]Park Nicollet Health Services, Minneapolis, MN, [8]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA, [9]University of Iowa, Iowa City, IA

Background/Purpose: Pragmatic clinical trials (PCTs) allow for study of real world patients using efficient study designs, facilitating comparative effectiveness research in resource constrained settings. Although the need for osteoporosis PCTs is clear, it is unclear what study questions will most impact the field.

Methods: We conducted a Delphi meeting with 9 experts in osteoporosis trial design and patient care to consider PCT designs with aims of understanding the relative efficacy and safety of osteoporosis drugs. We asked the expert panel to review 2 osteoporosis PCT concepts in a practice-based setting with pre-specified study arms and drugs of interest including 1) active comparator osteoporosis initiation PCT that included 3-arm and 2-arm studies, and 2) osteoporosis therapy discontinuation/switching PCTs that included 2-arm and 3-arm designs among chronic bisphosphonate (BP) users (Table). The primary outcome of both concepts was non-vertebral fracture risk reduction. Participants ranked the clinical significance and feasibility (four domains) of each design (Table). Initial rankings were cast after independent review of the scenarios followed by a webinar discussion and re-ranking of each design.

Results: Rankings associated with initiation studies did not change appreciably pre and post discussion. With 1 being the least and 5 being the most clinically significant, experts ranked the design that compared the fracture reduction of alendronate (ALN), zoledronic acid (ZA), and denosumab (Dmab) as the most clinically significant initiation PCT. The median score was 5 compared to 3.5 for comparing ALN to two strategies of ZA administration (single dose once vs. annual dosing for 3 years), and 3.0 for comparing any oral BP to ZA (Table). Although clinical significance was lower, the panel ranked designs that did not incorporate Dmab as more feasible for recruitment, and human ethics and regulatory approvals (Table). The panel ranked the clinical significance of discontinuation studies with 2-arms higher than designs that incorporated switching (Table). In consideration of switching designs, the panel ranked switching to Dmab more clinically significant than other switching designs. The median recruitment feasibility scores ranged from 2.5–4, lowest designs associated with switching to teriparatide and highest associated with 2-arm studies. The panel ranked human ethics and regulatory concerns greater with switching designs and felt these designs would require more site training and monitoring than 2-arm designs.

Table. Study Arms for Potential Osteoporosis PCTs and Median Likert Scores Rankings on Significance and Feasibility

Initiation Study

Study Arm 1	Study Arm 2	Study Arm 3	Clinical Significance[A]	Recruitment[B]	IRB[C]	Feasibility FDA[C]	Monitoring[C]
ALN	ZA	Dmab	5	3	3	2.5	2.5
ALN	ZA (single dose)	ZA (3 annual doses)	3.5	4	3.5	4	3
Any oral BP	ZA	–	3	3.5	3.5	4	3

Discontinuation/Switching Study among Long Term Bisphosphonate Users*

Study Arm 1	Study Arm 2	Study Arm 3	Clinical Significance[A]	Recruitment[B]	IRB[C]	Feasibility FDA[D]	Monitoring[E]
Continue any BP	Discontinue BP	–	4	4	4	4	5
Continue ALN	Discontinue ALN	–	4	4	4	4.5	5
Continue ALN or ZA	Discontinue ALN or ZA	–	3	4	4	4	4
Continue any BP	Discontinue BP	Switch to Dmab	3	3	3	3	3
Continue any BP	Discontinue BP	Switch to Dmab or TPTD	3	2.5	2.5	3	3
Continue any BP	Discontinue BP	Switch to Dmab, TPTD, or other BP	2	2.5	2	3	3

Likert Scales: [A]Clinical Significance: 1 Least Significant – 5 Most Significant; [B]Recruitment: 1 Least Feasible – 5 Most Feasible; [C]IRB, FDA, Site Training and Monitory: 1 Most Concerns – 5 Fewest Concerns ALN-alendronate; ZA-zoledronic acid; Dmab –denosumab; BP-bisphosphonate; TPTD-teriparatide; IRB-Institutional Review Board; FDA–Food and Drug Administration

Conclusion: The study designs with the highest clinical significance included the 3-arm initiation PCT comparing ALN, ZA, and Dmab and the 2-arm discontinuation PCT that compared continuing any BP or ALN to discontinuing therapy. The 2-arm discontinuation PCTs were also ranked the most feasible, whereas feasibility was higher in other initiation designs.

1996

Are Changes in Bone Mineral Density Different Between Groups of Early Rheumatoid Arthritis Patients Treated According to a Tight Control Strategy with or without Prednisone, If Osteoporosis Prophylaxis Is Applied? Marlies C. van der Goes[1], Johannes W.G. Jacobs[1], Maud S. Jurgens[1], Marije F. Bakker[1], Maaike J. van der Veen[2], Jacobine H. van der Werf[3], Paco M.J. Welsing[1] and Johannes W.J. Bijlsma[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]St. Jansdal hospital, Harderwijk, Netherlands, [3]Diakonessenhuis, Utrecht, Netherlands

Background/Purpose: To describe effects on bone mineral density (BMD) of treatment according to EULAR guidelines with a methotrexate-based tight control strategy including 10 mg prednisone daily versus the same strategy without prednisone in early rheumatoid arthritis (RA) patients, who received preventive therapy for osteoporosis.

Methods: Early RA patients were included in the CAMERA-II trial: a randomized, placebo-controlled, double-blind two-year trial, in which effects of addition of 10 mg prednisone daily to a methotrexate-based tight control strategy were studied. All patients received calcium, and a bisphosphonate. Disease activity was assessed every four weeks. X-rays of hands and feet and dual-energy X-ray absorptiometry of lumbar spine and left hip were performed at baseline, and after one and two years of treatment.

Results: The BMD increased significantly over time in both treatment groups at the lumbar spine with a mean of 2.6 percent during the first year ($p < 0.001$), but not at the hip; at none of the time points the BMD differed significantly between the prednisone and placebo group. Higher age and lower weight at baseline, and higher disease activity scores during the trial, but not glucocorticoid therapy, were associated with a lower BMD at both the lumbar spine and the hip in mixed model analyses.

Conclusion: Addition of 10 mg prednisone daily to a methotrexate-based tight control strategy does not lead to bone loss in early RA patients on bisphosphonates. A small increase in lumbar BMD during the first year of treatment was found, regardless of the use of glucocorticoids.

1997

Safety and Efficacy of Denosumab Vs Ibandronate in Postmenopausal Women Sub-Optimally Treated with Daily or Weekly Bisphosphonates: A Randomized, Open-Label Study. Michael A. Bolognese[1], Edward Czerwinski[2], Henry G. Bone[3], Sydney Bonnick[4], Neil Binkley[5], Alfred Moffett Jr.[6], Suresh Siddhanti[7], Irene Ferreira[8], Prayashi Ghelani[9], Rachel Wagman[7], Jesse W. Hall[7] and Chris Recknor[10]. [1]Bethesda Health Research Center, Bethesda, MD, [2]Krakow Medical Center, Krakow, Poland, [3]Michigan Bone and Mineral Clinic, Detroit, MI, [4]Clinical Research Center of North Texas, Denton, TX, [5]University of Wisconsin, Madison, WI, [6]OB-GYN Associates of Mid Florida, PA, Leesburg, FL, [7]Amgen Inc., Thousand Oaks, CA, [8]Amgen Inc., Cambridge, United Kingdom, [9]Ovatech Solutions, London, United Kingdom, [10]United Osteoporosis Centers, Gainesville, GA

Background/Purpose: Denosumab, a fully human monoclonal antibody that specifically targets RANKL to inhibit osteoclast formation, function, and survival, reduces risk for vertebral, non-vertebral, and hip fractures in postmenopausal women with osteoporosis.[1] In subjects who were treatment naïve or previously treated with alendronate, denosumab was associated with greater gains in bone mineral density (BMD) and decreases in bone turnover markers when compared with alendronate-treated subjects.[2,3]The purpose of this open-label trial was to compare the safety and efficacy of denosumab with ibandronate over 12 months in postmenopausal women with low BMD who were sub-optimally treated with prior bisphosphonate therapy.

Methods: This was a multicenter, randomized, open-label, parallel-group study in which postmenopausal women age 55 years and older were randomized 1:1 to receive open-label denosumab 60 mg subcutaneously every 6 months or ibandronate 150 mg orally every month for 12 months. Percent change from baseline in total hip (primary endpoint), femoral neck, and lumbar spine BMD at month 12; percent change from baseline in serum CTX (sCTX) at 1 and 6 months; and safety were assessed.

Results: Randomized subjects (n=833; 417, denosumab; 416, ibandronate) had a mean (SD) age of 66.7 (8.0) years and mean (SD) BMD T-scores of −1.8 (0.7), −2.1 (0.7), and −2.5 (0.8) at the total hip, femoral neck, and lumbar spine, respectively. Denosumab significantly increased total hip BMD compared with ibandronate at 12 months (2.2% vs 0.9%, respectively; $p<0.0001$). Denosumab also significantly increased BMD compared with ibandronate at the femoral neck (1.7% vs 0.5%) and lumbar spine (4.1% vs 2.1%), $p<0.0001$ for both sites. Denosumab significantly decreased sCTX at 1 month with a median change from baseline of −81.1% compared with −35.0% for ibandronate ($p<0.0001$), and sCTX remained decreased through 6 months of treatment. In this open-label study, overall adverse events were similar between groups. Reports classified as serious adverse events (SAEs) were more frequent in subjects treated with denosumab than with ibandronate. No organ system accounted for a preponderance of these reports. The incidences of SAEs involving infection and malignancy were similar between groups.

Conclusion: Denosumab treatment resulted in greater increases in BMD at all measured skeletal sites compared with ibandronate. No new safety risks were identified in this open-label study.

Relationship Between Changes in Bone Mineral Density and Incidence of Fracture with 6 Years of Denosumab Treatment.

Michael A. Bolognese[1], Paul D. Miller[2], Jean-Yves Reginster[3], Nathalie Franchimont[4], Gerolamo Bianchi[5], Roland Chapurlat[6], Federico G. Hawkins[7], David L. Kendler[8], Beatriz Oliveri[9], Jose R. Zanchetta[10], Nadia Daizadeh[4], Andrea Wang[4], Rachel B. Wagman[4] and Socrates Papapoulos[11]. [1]Bethesda Health Research Center, Bethesda, MD, [2]University of Colorado Health Sciences Center and Colorado Center for Bone Research, Lakewood, CO, [3]University of Liège, Liège, Belgium, [4]Amgen Inc., Thousand Oaks, CA, [5]Azienda Sanitaria Genovese, Genoa, Italy, [6]Hôpital Edouard Herriot, Lyon, France, [7]Hospital Universitario, Madrid, Spain, [8]University of British Columbia, Vancouver, BC, [9]Laboratorio Enfermedades Metabólicas Oseas, Hospital de Clínicas, INIGEM UBA-CONICET, Buenos Aires, Argentina, [10]Instituto de Investigaciones Metabólicas and University of Salvador, Buenos Aires, Argentina, [11]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: During the first 3 years of denosumab treatment in FREEDOM, there were continued increases in bone mineral density (BMD) and a robust reduction in fracture risk (Cummings et al., *NEJM* 2009). The changes in total hip BMD explained a considerable proportion of the reduction in new or worsening vertebral and nonvertebral fracture risk (Austin et al., *JBMR* 2011). Here, we conducted a BMD responder analysis and explored if the progressive BMD gains with 6 years of denosumab therapy continued to relate to the observed fracture incidence.

Methods: The long-term efficacy and safety of denosumab for up to 10 years is being investigated in the open-label extension of the 3-year FREEDOM trial. During the extension, all participants receive 60 mg denosumab every 6 months. For the analyses presented here, women from the FREEDOM denosumab group received 3 more years of denosumab for a total of 6 years. The percentages of women treated with denosumab who achieved BMD increases from FREEDOM baseline at the lumbar spine, total hip, and femoral neck were determined. A logistic regression model was used to examine the relationship between change in total hip BMD and new or worsening vertebral fracture. A comparable approach was employed for nonvertebral fracture using the Cox proportional hazards model.

Results: For women who received 3 additional years of denosumab treatment (N=2343 enrolled), further significant increases in BMD occurred for cumulative 6-year mean gains of 15.2% (lumbar spine), 7.5% (total hip), and 6.7% (femoral neck). At year 6, almost all women treated with denosumab had gains in BMD at the lumbar spine (98%), total hip (96%), and femoral neck (91%). Additionally, 99% of women had gains in BMD at any of these sites, and of these, the gains were >3% in 98% of women and >6% in 95% of women. Fracture incidence remained low during the extension. The relationships between total hip BMD gains and new or worsening vertebral and nonvertebral fractures with 6 years of denosumab treatment are shown in Figures 1 and 2, respectively.

Figure 1.
Figure 2.
The predicted fracture incidence was estimated corresponding to the 5th through the 95th percentiles of the observed total hip BMD percentage changes over 6 years. N=number of subjects with an observed BMD value at FREEDOM extension baseline and at ≥1 follow-up visit.

Conclusion: Almost all women who received 6 years of denosumab treatment had gains in BMD at the lumbar spine, total hip, or femoral neck; and those gains were >6% in 95% of them. While on denosumab treatment, the risk of new or worsening vertebral fracture and nonvertebral fracture decreased with increasing percentage change in total hip BMD over 6 years. This association provides clinical relevance to the progressive and continued BMD gains reported with denosumab over time.

Immunogenicity and Safety of Two Doses of Influenza A H1N1/2009 Vaccine in Young Autoimmune Rheumatic Diseases Patients Under 9 Years Old.

Guilherme Trudes[1], Nadia E. Aikawa[1], Lucia M. Campos[2], Rosa M.R. Pereira[1], Julio C. B. Moraes[1], Ana Cristina Ribeiro[1], Joao Miraglia[3], Maria do Carmo S. Timenetsky[4], Eloisa Bonfa[1] and Clovis Artur Silva[5]. [1]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [2]University of São Paulo Medical School, São Paulo, Brazil, [3]Fundação Butantan, São Paulo, Brazil, [4]Instituto Adolfo Lutz - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [5]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: In 2010 the Advisory Committee on Immunization Practices from the CDC recommended that all children should receive the

trivalent seasonal influenza vaccine containing the A/California/7/2009 (H1N1)-like virus with a specific protocol of two doses in subjects under 9 years old. There is, however, no data regarding this vaccine immunogenicity and safety in young children with autoimmune rheumatic diseases (ARD).

Methods: 42 ARD patients and 12 healthy controls were initially recruited. One juvenile idiopathic arthritis patient had typical uncomplicated febrile seizure after first dose and did not receive the second dose and 3 patients and one control did not complete the study. Therefore, 38 ARD patients [25 juvenile idiopathic arthritis, 5 juvenile dermatomyositis, 3 juvenile systemic lupus erythematosus, 3 juvenile scleroderma and 2 primary vasculitis] and 11 healthy children completed the study and received two doses of a non-adjuvanted preparation of influenza A/California/7/2009 (H1N1) virus-like vaccine. They were clinically evaluated before and 21 days after the second dose of vaccination and serology for anti-H1N1 antibody was performed by hemagglutination inhibition (HI) assay. Seroprotection and seroconversion rates, geometric mean titres (GMT) and factor increase (FI) in GMT (ratio of the GMT after vaccination to the GMT before vaccination) were calculated. Adverse events were also evaluated.

Results: Current age (7 vs. 7.8 years, p=0.55) and female gender (76.3 vs. 63.6%, p=0.45) were comparable in ARD patients and controls. Five (13.2%) patients were not receiving any drug, 18 (47.4%) patients were under non-steroidal anti-inflammatory drugs and 11 (28.9%) under prednisone, with a median current dose of 15mg (4–40). Twenty-three (60.5%) were taking methotrexate, 6 (15.8%) cyclosporine, one (2.6%) azathioprine and 7 (18.4%) anti-TNF agents. Pre-vaccination seroprotection rates (p=1.0) and GMT (p=0.63) were comparable between patients and controls. Three weeks after immunization seroprotection (81.6 vs. 81.8%; p=1.0), seroconversion rates (81.6 vs. 90.9%; p=0.66), GMT (151.5 vs. 282.1, p=0.26) and the FI in GMT (16.7 vs. 36.3; p=0.226) were similar in patients and controls, with both groups achieving adequate response according to the European Medicines Agency and Food and Drug Administration standards. The analysis of the possible factors influencing seroconversion showed no difference in demographic data, leukocytes and lymphocytes count or frequency of immunosuppressive drugs use (including prednisone, methotrexate, cyclosporine, azathioprine and anti-TNF agents) between seroconverted and non-seroconverted patients (p>0.05). No severe adverse events were observed.

Conclusion: Two doses of the non-adjuvanted influenza A H1N1/2009 vaccination induced an effective antibody response in young children with ARD independent of demographic characteristics, lymphocytes count and immunosuppressive treatment. Adverse events were rarely observed suggesting vaccine recommendation for this group of patients. (ClinicalTrials.gov, #NCT01151644)

2000

Whole Body Magnetic Resonance Imaging in Evaluation of Enthesitis in Spondyloarthropathy. Hemalatha Srinivasalu[1], Suvimol C. Hill[2], Gina A. Montealegre Sanchez[1], April D. Brundidge[1], Michael M. Ward[1] and Robert A. Colbert[1]. [1]NIAMS NIH, Bethesda, MD, [2]NIH Clinical Center, Bethesda, MD

Background/Purpose: Enthesitis is a characteristic feature of spondyloarthritis (SpA). Tenderness at enthesial points constitutes clinical enthesitis. However, this may not always correlate with actual inflammation at entheses. We assessed the agreement between enthesitis by clinical exam and whole body MRI (WB MRI).

Methods: Patients enrolled in an observational study on SpA who had undergone WB MRI and clinical exam for enthesitis were included. Patients had one of the following conditions: enthesitis related arthritis (ERA), psoriatic arthritis (PsA) (ILAR criteria); undifferentiated SpA (Amor or ESSG criteria); axial SpA (ASAS criteria); juvenile ankylosing spondylitis (AS) or adult AS (Modified NY criteria). Patients underwent detailed clinical exam including manual palpation of 34 enthesial sites by one of 2 examiners. Patients underwent WB MRI without contrast. Criterion for enthesitis by WB MRI was an increased signal on STIR sequence or presence of bony erosions or bone marrow edema at the sites of tendon attachments to bones. Four healthy volunteers also underwent clinical enthesial exam and WB MRI. Median, IQR calculations were performed for descriptive statistical analysis. Kappa statistics were used to assess agreement between enthesitis by clinical exam and WB MRI.

Results: Thirteen patients had WB MRI (66% were younger than 16 years at symptom onset; 66% male; 100% Caucasian). The median disease duration was 36 months (IQR 17.5–108). Inflammatory back pain by ESSG criteria was present in 92%; Median Schober test was 5 cm (IQR 4.15–6.25). Median ESR was 8 mm/hr (IQR 5–21.5) and CRP was 0.52 mg/L (IQR 0.16–26.72). Seventy seven percent of patients satisfied ILAR criteria for ERA (N=8) or PsA (2); 46% satisfied criteria for axial SpA (6). One patient had AS. All patients had at least one tender enthesis on exam; 77% had more than 4 tender entheses. A total of 108 enthesial sites were present among patients. The most common tender enthesial sites were medial epicondyle (N=7), L5 spinous process (6), anterior superior iliac spine (7), plantar fascia insertion to MTP (8), and 1st costosternal junction (7). None of the patients had tender Achilles insertion. Two patients had any evidence of enthesitis by WB MRI. Greater trochanter (2) and iliac crest (1) were the most common sites of enhancement on MRI.

There was poor agreement between WB MRI and clinical exam for enthesitis when evaluated for all enthesial sites (kappa=0). Agreement at individual sites including Achilles insertion, plantar fascia insertion to calcaneus and MTP; greater trochanter; upper and lower poles of patella; and iliac crest was also poor (k range −0.23 to 0.24). Only one enthesial site in one patient was positive both on WB MRI and clinical exam. Among 4 healthy controls, a total of 4 enthesial sites were positive by clinical exam and none were positive by WB MRI.

Conclusion: There is poor agreement between enthesitis by clinical exam and WB MRI in young patients with SpA. Clinical examination may overestimate enthesitis, or non-contrast WB MRI may have limited sensitivity to detect enthesitis.

2001

Methotrexate and Injectable Tumor Necrosis Factor Alpha Inhibitor Adherence and Persistence in Children with Rheumatic Diseases. Sarah Ringold[1], Shannon Grant[2], Charmaine Girdish[3], Carol A. Wallace[4] and Sean Sullivan[5]. [1]Seattle Children's Hospital, Seattle, WA, [2]Axio Research LLC, Seattle, WA, [3]CVS Caremark, Scottsdale, AZ, [4]Seattle Childrens Hospital, Seattle, WA, [5]University of Washington, Seattle, WA

Background/Purpose: Medication adherence and persistence have been demonstrated to have important implications for treatment effectiveness, cost, and safety. Methotrexate is one of the most commonly prescribed medications for the treatment of pediatric rheumatic diseases. Two injectable tumor necrosis factor alpha inhibitors (iTNFα), etanercept and adalimumab, are approved by the US Food and Drug Administration (FDA) for use in JIA, and recent data suggest that the prevalence of anti-TNFα medication use for JIA is now approaching that for adult rheumatoid arthritis. While JIA is the most common indication for these medications, they are also used in the treatment of additional rheumatic and inflammatory conditions. Despite their frequent use and established efficacy in clinical trials, few studies have examined children's adherence and persistency with these medications.

The objective of this study was to measure adherence and persistence among children who were prescribed methotrexate and the injectable tumor necrosis factor alpha inhibitors (iTNFα) etanercept and adalimumab by an adult or pediatric rheumatologist.

Methods: Data were obtained from CVS Caremark®, a large pharmacy benefits manager. Children were included if they were < 18 years of age, and had ≥ 1 prescription claim between January 2009 and December 2010 for methotrexate or an iTNFα that was prescribed by an adult or pediatric rheumatologist. The medication possession ratio (MPR) was calculated for each medication, with MPRs ≥ 80% indicating good adherence. MPRs were compared by route of administration, age, and by new users versus continuing users. Persistence was measured for new users of each medication from initiation until discontinuation, or for a maximum of one year.

Results: 1,964 children were included. The majority of children had MPRs < 80%. Children taking subcutaneous methotrexate had the lowest mean MPR (46.9%; median 44.9%; IQR 23%–69.6%) and the lowest persistence, with 26% of children continuing the medication at one year. Mean MPR was highest for iTNFα (65.7%; median 70.1%; IQR 46%-89.3%), as was persistence, with 52% of children continuing the medication at one year. Children receiving oral methotrexate had higher MPRs and persistence than those receiving subcutaneous methotrexate. Children < 13 years tended to have higher MPRs, but this was statistically significant only for oral methotrexate (61.1% versus 54.9%; p=0.02).

Conclusion: Adherence and persistence in this cohort varied by medication and route of administration. Both outcomes are important considerations for physicians prescribing these medications in routine clinical care and for the assessment of treatment effectiveness in the research setting.

2002

Randomized Clinical Trial in Pediatric Rheumatology: Are Parents and Patients in Equipoise? Petra C.E. Hissink Muller[1], Bahar Yildiz[1], Cornelia F. Allaart[1], Danielle M.C. Brinkman[2], Marion A. J. Van Rossum[3], J. Merlijn Van den Berg[4], Lisette W.A. Van Suijlekom-Smit[5], Rebecca Ten Cate[1] and Martine C. de Vries[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rijnland Hospital, Leiderdorp, Netherlands, [3]Emma Children's Hospital / Academic Medical Center and Reade Institute, Amsterdam, Netherlands, [4]Emma Children's Hospital / Academic Medical Centre and Reade Institute, Amsterdam, Netherlands, [5]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands

Background/Purpose: It is an ethical requirement for setting up a randomized controlled trial (RCT) that the physician-investigator must have genuine uncertainty about the therapeutic options. This is called equipoise. Ideally patient-participants should also be in equipoise. In pediatric rheumatology, there are no data on whether this uncertainty also consists among parents and patients or if they have a specific preference for a particular treatment strategy. We conducted an interview study on the preferences of parents and children and the influence of the informed consent procedure on preferences in the setting of a randomized clinical trial in Juvenile Idiopathic Arthritis patients.

Methods: Semi-structured interviews with parents (n = 23, 1 father and 22 mothers) and patients aged 12 and older (n = 7) participating in the BeSt for Kids study, a randomized clinical trial with three treatment strategies (arm 1: initial monotherapy with sulfasalazine or methotrexate, arm 2: initial combination therapy with methotrexate and prednisone and arm 3: initial combination therapy with etanercept and methotrexate) in selected categories of newly diagnosed juvenile idiopathic arthritis patients.

Results: All parents had a preference for a particular treatment strategy, 65% had a preference for the combination therapy with etanercept and methotrexate (arm 3). Five parents and two patients participated in the study to have a chance to be initially treated with etanercept, as initial treatment with etanercept in daily practice is currently neither possible nor reimbursed. The preference of parents and patients for arm 3 was based on their idea that etanercept is the best treatment for juvenile arthritis. The parents indicated that these beliefs were mainly based on knowledge they had gained through the internet and from experiences from people in their environment. Four parents had a preference for a non-prednisone arm. Aversion for prednisone was primary due to the fear for side-effects, such as weight gain. According to four parents, the physician-investigator had a preference for arm 3, but the vast majority of parents (n = 19) stated that the physician-investigator had no preferred strategy. Similar results emerged from the interviews with children.

Conclusion: A large part of parents and children in the BeSt for Kids study are not in equipoise. In this study this is not caused by an assumed preference of the physician-investigator but by information on the various treatment possibilities obtained from other sources. The question is whether the absence of equipoise in parents and patients indicates that randomization is unethical or that this equipoise is not feasible in medical research.

2003

Colchicine As a Therapeutic Option in Periodic Fever Aphtous Stomatitis, Pharingitis Syndrome. and Cervical Adenitis (PFAPA). Yonatan butbul Aviel[1], Sameh Tatour[2], Ruth Gershoni[3] and Riva Brik[4]. [1]Rambam Medical center, Haifa, Israel, [2]Rambam Medical Center, Israel, [3]Rambam, Israel, [4]Rambam Medical center

Background/Purpose: PFAPA syndrome is episodic disease characterized by periodic episodes of high fever, aphthous stomatitis, pharyngitis, and cervical adenitis, so far no therapy was shown to be effective in preventing the attacks.

The aim of our study was to evaluate the efficacy of colchicine in reducing attacks of PFAPA.

Methods: We carried a randomized control study among patients diagnosed with PFAPA in the pediatric Rheumatology clinic- Rambam Medical center, Israel.

The patients were randomized into two groups followed for 6 months. In months 1–3 both groups were followed without preventive therapy; In months 4–6, group 1 continued to be followed in the same manner, patients in group 2 received colchicine for three months in a standard dose. During the study patients and physician recorded all PFAPA episodes, in a log book. DNA analysis for the common FMF mutation was done for all patients.

Results: 14 patients 5.8±1.9 years old were evaluated(8 in group 1, 6 in group 2).

The number of episodes in the first 3 months were 3.5±1.3 in group 1 and 4.9±2.45 in group 2 (p=0.187), the number of episodes in group 2 under colchicine therapy were 1.7±1 compared to 4.9±2.4 in the period without therapy (p=0.01).

Seven patients were found to be carrier of one FMF mutation;(4 in group2 and 3 in group1). Patients with PFAPA who carry one mutation for FMF responded to colchicine therapy (6.1±2 episodes before and 2±1.4 after therapy p-0.03).

Conclusion: Colchicine therapy might be effective in increasing intervals between episodes of PFAPA. Larger studies are needed to confirm these findings.

2004

Do We Need a Minimum Standards in Care for Children with Localized Scleroderma- Result of the Consensus Meeting in Hamburg Germany On the 11th of December 2011. Part I. Diagnosis and Assessment of the Disease. Ivan Foeldvari[1], Tamás Constantin[2], Peter Hoeger[3], Monika Moll[4], Clare Pain[5], Dana Nemcova[6], Kathryn S. Torok[7], Lisa Weibel[8] and Philip J. Clements[9]. [1]Hamburger Zentrum Kinder-und Jugendrheumatologie, Hamburg, Germany, [2]Semmelweis Egyetem, AOK, II.sz. Gyermekgyogyaszati Klinika, Budapest, Hungary, [3]Kinderkrankenhaus Wilhelmstift, Hamburg, Germany, [4]University Children's Hospital, Tübingen, Germany, [5]University Children's Hospital, Liverpool, United Kingdom, [6]University Children's Hospital, Prague, Czech Republic, [7]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [8]University Children's Hospital, Zurich, Switzerland, [9]UCLA School of Medicine, Los Angeles, CA

Background/Purpose: Juvenile localised scleroderma (jlSc) is an orphan disease. There are currently no guidelines regarding diagnosis, follow up and treatment. In the frame of the PRES scleroderma working group this consensus meeting was set up to gain consensus regarding these issues.

Methods: Members of the PRES scleroderma working group were invited to participate. Two pediatric dermatologists were invited to reflect the multidisciplinary care for these children. P. Clements was invited to moderate the meeting. A nominal group technique was used. 75% consensus was defined as agreement.

Results: The following agreements were reached regarding diagnosis and follow up:

1. Diagnosis is based on clinical grounds by a rheumatologist or dermatologist, preferably pediatric, with a biopsy as a confirmatory measure if it is unclear based on clinical findings.
2. If a biopsy is needed, a punch biopsy is appropriate. In the case of deep involvement, a deep biopsy is needed.
3. Since progression to systemic sclerosis is unlikely, an evaluation for internal organ involvement, such as HRCT and echocardiogram, is unnecessary.
4. There are no laboratory studies needed to confirm the diagnosis.
5. The group agrees there is no clear evidence for a pathogenic role of Borrelia, therefore we do not recommend investigation for Borrelia infection.
6. In patients with sclerodermatous skin changes of the head (face and/or scalp) the following are suggested:

1. MRI of the brain, preferably with contrast.
2. In the absence of clear evidence, the group suggested to screen every 6 months for uveitis with slit lamp examination for the first 4 years of the disease.
3. Dental assessment is strongly suggested, especially if the lesion crosses the maxilla and mandible.
4. Temporomandibular joint assessment by a pediatric rheumatologist every 6 months is suggested.
5. In the absence of clear evidence, the group suggested to screen every 12 months for uveitis with slit lamp examination for the first 4 years of the disease, if the lesion does not involves the face.
6. All patients besides superficial circumscribed localised scleroderma (plaque morphea), especially those with linear disease, are suggested to be seen at baseline and every 12 months by both a pediatric rheumatologist and pediatric dermatologist, ideally in combined clinic.
7. The group suggested using the LoSCAT (Localized Scleroderma Cutaneous Assessment Tool) to assess cutaneous activity and damage measures, because this is the only validated tool currently available according the OMERACT criteria for LS.
10. There is a need to assess the quality of life of jLS patients and the group suggests using the CDLQI, a generic skin disorder quality of life measure. This is one of the most widely used skin QOL instrument and is validated in most European languages.
11. The group suggested to assess the patients global assessment of disease severity on a VAS scale from 0 to 100.

Conclusion: Although there are no solid guidelines currently present as the 'standard of care' for jLs, these suggestions are part of routine care for most physicians specializing in the care of pediatric localized scleroderma and are non-invasive measures.

2005

Clinical Course and Outcomes of Children with Juvenile Idiopathic Arthritis-Associated Uveitis and Idiopathic Uveitis. Sheila T. Angeles-Han[1], Steven Yeh[1], Courtney McCracken[1], Larry B. Vogler[1], Kelly Rouster-Stevens[2], Christine W. Kennedy[2], Matthew Kent[1], Kirsten Jenkins[3], Scott Lambert[1], Carolyn Drews-Botsch[4] and Sampath Prahalad[2]. [1]Emory Univ School of Medicine, Atlanta, GA, [2]Emory Children's Center, Atlanta, GA, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Emory University School of Public Health, Atlanta, GA

Background/Purpose: Uveitis can lead to vision loss and blindness. Few studies focus on the outcomes of children with both juvenile idiopathic arthritis-associated uveitis (JIA-U) and idiopathic uveitis (I-U). The determination of risk markers for uveitis development and disease severity is important in examining the long-term outcomes of this population. Our objective is to characterize the epidemiology and clinical outcomes of children with JIA-U and I-U in a cohort of children in an urban tertiary care center in the Southeast.

Methods: Children with JIA, JIA-U, and I-U participated. Medical record reviews were performed. Questionnaires were completed on overall quality of life (QOL) (Pediatric QOL Inventory - PedsQL), physical function (Childhood Health Assessment Questionnaire - CHAQ), and visual function (Effects of Youngsters' Eyesight on QOL - EYE-Q).

Results: Our 132 patients were primarily female (72%), non-Hispanic (89.4%) and Caucasian (74.2%). Compared to JIA, children with JIA-U were more frequently African American, diagnosed with oligoarticular extended JIA and had a younger age of arthritis onset (Table 1). There were no significant differences in gender, ANA, RF or HLA-B27. Children with I-U were more frequently HLA-B27 (+) (p=0.023), had worse visual acuity (p=0.005), and more band keratopathy (p=0.028), cystoid macular edema (p=0.032) and cataract extractions (p=0.032).

There were significant differences in the EYE-Q scores in children with uveitis compared to JIA (p=0.043), significant differences in the CHAQ and PedsQL Physical scale scores in children with arthritis compared to I-U (p=0.046), and no differences in PedsQL total and psychosocial QOL scores in all groups (p=0.045, p=0.023) (Table 2).

ANOVA , *p-value <0.05
[a] Effects of Youngsters Eyesight on QOL; [b]Childhood Health Assessment Questionnaire; [c]Pediatric Quality of Life Inventory
** Greater scores indicate better QOL; [++]Greater scores indicate worse QOL
Note: The sample size in each group varies by scoring tool.

Conclusion: Children with I-U may have a poorer visual outcome compared to JIA-U. Race, HLA-B27 (+), age of arthritis onset, and JIA subtype may be important risk factors for developing uveitis, whereas gender, ANA, and RF may not be as significant. As expected, visual disability was worse in uveitis, and physical disability was worse in arthritis. Hence, compared to JIA and I-U, children with JIA-U have more components of disability. All children had similar psychosocial and overall QOL probably secondary to having a chronic illness.

To improve the assessment of outcomes in JIA-U, a comprehensive approach incorporating all aspects of disability should be considered. Likewise, the determination of risk markers leading to poor outcomes in children with uveitis is crucial. Longitudinal studies examining the outcome of children with uveitis are ongoing.

2006

Sexual Health and Substance Abuse in Adolescents with Rheumatic Conditions. Sara M. Stern, Rhina Castillo, Katherine AB Marzan, Jennifer Jackson, Mona Desai, Ellen Iverson, Leslie F. Clark and Diane Tanaka. Children's Hospital Los Angeles, Los Angeles, CA

Background/Purpose: Adolescence is a unique stage with pubertal maturation, individuation from parents and peer group identification. The impact of a rheumatic condition can affect social, emotional and sexual development. We sought to examine the risky behavior of youth with rheumatic conditions, compare it to their unaffected peers, and identify differences between infusion (INF) and non-infusion (OP) patients (pts).

Methods: 50 pts with a rheumatologic diagnosis (RHEUM) from the rheumatology clinic and the ambulatory infusion center at a tertiary children's hospital were surveyed with the Audio Computer-Assisted Self-Interview (ACASI) system to assess their substance use and sexual health. Data from the RHEUM pts was compared to the Youth Behavior Surveillance – United States – 2011 (YRBS) for the region, and between INF and OP pts. The YRBS assesses the prevalence of health-risk behaviors in youth grades 9–12.

Results: 50 pts (42F: 8 M) aged 15–20 yrs were primarily Latino (74%). Diagnoses included arthritis (15), systemic lupus erythematosus (15), mixed connective tissue disease/ overlap syndrome (MCTD) (8), dermatomyositis (4), vasculitis (3) and unidentified (5). OP (n=26) and INF (n=24) pts were almost equal.

RHEUM patients reported lower percentage (%) of alcohol use (28% vs 65.1% CI 62.2–67.9%), binge drinking (10% vs 17.9% CI 15.5 – 20.5%), cigarette use (26% vs 39.2% CI 34.8 – 43.7%) and marijuana use (26%42.4% CI 37.0 – 47.9%) when compared to YRBS. INF and OP pts did not differ significantly in alcohol (63% vs 54%, p = 0.40) and marijuana use (25% vs 27%, p = 0.957), but cigarette use was more prevalent in INF than OP (21% vs 31%, p = 0.54). 14% of RHEUM pts gave health reasons for MJ use and 4% of INF pts had a medical MJ card. 12% of RHEUM pts had tried other street drugs (INF-4% vs OP 12% p=0.12). Prescription drug misuse was similar for RHEUM pts (14%) and YRBS (12.1% CI 10.0 – 14.5%) as well as INF and OP pts (17% and 12%) (p = 0.61).

RHEUM pts and YRBS had similar rates of first sexual experience (42% vs 38.9% (CI 32.4 – 45.7%), with equal results in INF and OP 42% (p = 0.96). RHEUM pts had a slightly higher % of current sexual activity than YRBS (28% vs 25.7% CI 20.1 – 32.1%) with higher % in the INF pts than the OP (33% vs 23%) (p = 0.432).

Of the 14 sexually active RHEUM pts, 57% used condoms, 75% INF vs 33% OP (p = 0.26). Condom use during last sexual intercourse (SI) was similar between RHEUM pts and YRBS (64.3% vs 61.1% CI 55.2 – 66.7%), with 14% of RHEUM pts using other forms of birth control (BC) during last SI vs 10.9% YRBS (CI 7.2 – 16.2).

70% of RHEUM pts had future plans for children but only 46% had discussed this with their rheumatologist. 50% felt that their condition or medication could interfere with a pregnancy with higher % in the INF than OP pts (58% vs 42%, p = 0.014).

Conclusion: Adolescents and young adults in a primarily Latino pediatric rheumatology population participate in risky sexual and substance use behaviors at rates similar to their unaffected peers with no statistically significant difference between INF and OP sub-groups. Routine screening and counseling by healthcare providers is important to decrease morbidity.

2007

Radiological Peripheral Involvement At Hands, Feet and Hips in Young Adults with Polyarticular Idiopathic Juvenile Arthritis. Muriel Elhai[1], Ramin Bazeli[2], Veronique Freire[2], Antoine Feydy[2], Andre Kahan[1], Chantal Job-Deslandre[1] and Julien Wipff[1], [1]Rheumatology A, Paris Descartes University, Cochin Hospital, APHP, Paris, France, [2]Radiology B, Paris Descartes University, Cochin Hospital, APHP, Paris, France

Background/Purpose: Radiographic damage was recently considered to be a feature of poor prognosis in cases of polyarticular juvenile idiopathic arthritis (pJIA). However, most radiographic studies did not differentiate pJIA from other subtypes of JIA and did not include a control group. Furthermore little is known about radiographic damages in pJIA persisting into adulthood. The objective of our study was to describe structural peripheral involvement in pJIA persisting into adulthood and compare observed lesions to those seen in rheumatoid arthritis (RA) using a cross-sectional observational study.

Methods: All consecutive pJIA followed in a transition program were included. Age, sex, disease duration, medical or surgical treatments were collected. Laboratory tests (ESR, CRP, Rheumatoid Factor (RF) and anti-CCP) and standard radiographies of the hands and wrists, feet and hip were performed. A RA control group (<55years), matched for sex and disease duration, was recruited. Radiographs were analyzed by two independent radiologists blinded to the diagnosis. Structural lesions on the hands and feet were assessed by the modified version of Larsen's scoring method. The hands and feet scores range from 0 to 110 and from 0 to 50, respectively. Hips were assessed for presence of coxitis. Student and Fischer exact test were used.

Results: 58 pJIA (48 females/10 males) and 59 RA (52/7) were included. Respectively, mean age was 23.5±10.0 years and 43.2±9.6 years and mean disease duration 13.1±11.1 and 12.2±7.1 years. 60% and 80% were RF positive and 57% and 78% were anti-CCP positive (p=0.02). The inter-observer concordance coefficient kappa was 0.614 between the two investigators. Radiographs showed hand lesions in 45/58 (78%) pJIA and 50/58 (86%) RA-patients, feet lesions in 39/58 (67%) pJIA and 47/59 (80%) RA-patients and coxitis in 16/54 (30%) pJIA and 8/47 (17%) RA-patients (p=NS for all comparisons). Mean hands and feet scores were 17.9±21.8 and 7.7±10.8 in pJIA and 18.5±17.6 and 9.9±11.3 in RA, respectively (p=NS). Specificities to juvenile forms were a lower frequency of proximal inter-phalangeal joints involvement and a higher risk of bilateral coxitis (81% vs. 25% (p=0.007, OR=13 [1.701–99.375]) than adult RA. RF-positive patients differed from RF-negative patients only by a shorter disease duration (10.4±9.3 vs. 17.3±12.6, p=0.02). Comparison between RF positive and negative hand showed a trend for more frequent hand and feet lesions with a higher carpal score in RF-positive patients. There were less coxitis (5/31 vs. 11/23) in RF-positive subgroup (p= 0.01). In pJIA, presence of radiographic damage correlated with a more severe disease phenotype.

Conclusion: Structural peripheral damages are frequent in young adults with pJIA and correlated with a more severe disease. A specific feature to pJIA seems to be a high risk of bilateral coxitis. This requires a particular following and monitoring of pJIA patients with unilateral hip involvement to prevent bilateralization.

2008

Initial Evaluation of a Localized Scleroderma (LS) Clinical Activity Measure. Suzanne C. Li[1], Kathryn S. Torok[2], Christina Kelsey[2], Mara L. Becker[3], Fatma Dedeoglu[4], Robert C. Fuhlbrigge[5], Gloria C. Higgins[6], Sandy D. Hong[7], Maria F. Ibarra[3], Ronald M. Laxer[8], Thomas G. Mason II[9], Marilynn G. Punaro[10], Elena Pope[11], Egla C. Rabinovich[12] and Katie G. Stewart[10],. [1]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Children's Mercy Hospital, Kansas City, MO, [4]Boston Childrens Hosp, Boston, MA, [5]Childrens Hospital, Boston, MA, [6]Nationwide Childrens Hosp, Columbus, OH, [7]U of Iowa Children's Hosp, Iowa City, IA, [8]The Hospital for Sick Children, Toronto, ON, [9]Mayo Clinic Rochester, Rochester, MN, [10]Texas Scottish Rite Hospital, Dallas, TX, [11]Hospital for Sick Children, Toronto, ON, [12]Duke University Medical Center, Durham, NC

Background/Purpose: LS commonly causes severe morbidity for the growing child. Optimal therapy is not known and the lack of an agreed-upon standard for assessing disease state and monitoring treatment response has hindered treatment comparison. To work towards conducting comparative effectiveness studies, an LS-focused Childhood Arthritis and Rheumatology Research Alliance subgroup developed a clinical disease activity measure (LS Activity Score, Arthritis Care Res 2012 DOI: 10.1002/acr.21687), based upon LoSSI and LOCUS studies (J Rheumatol 2008;35:640; Arthritis Rheum 2011;63 Suppl:S955). The LS Activity Score scores for 7 parameters (erythema, violaceous color, waxy or white lesion, skin thickness of lesion edge, lesion warmth, new lesion, change in lesion size) in affected anatomic sites, with body divided into 19 sites.

Objective: To evaluate the validity and reliability of the LS Activity Score.

Methods: A two-day workshop meeting was conducted in which 13 pediatric rheumatologists and a pediatric dermatologist reviewed LS clinical measures and conducted a reliability of scoring study. The 14 raters evaluated 13 juvenile LS (jLS) patient volunteers with the LS Activity Score in a random order twice in one day. For each patient, raters were told which anatomic sites to assess (1–2/patient); new lesion and lesion size change were not scored because they require prior patient evaluation. Raters scored Physician Global Assessment (PGA, 0–100 mm) of disease activity (DA) and

PGA of disease damage (DD) for each patient based upon evaluated anatomic sites. We hypothesized the LS Activity Score would have moderate to high correlation with PGA-DA (convergent validity) and low correlation with PGA-DD (divergent validity). Spearman's rho was calculated to assess level of correlation, and intraclass correlation coefficients (ICC) calculated to assess intra- and inter-rater reliability (0.20–0.39 considered low, 0.40–0.59 moderate, >0.60 high).

Results: Mean age of jLS patients was 13.2 years, most common subtype was linear scleroderma (4 limb, 4 head). Mean patient LS Activity Scores ranged from 0.50 to 9.28 (4–52% of maximum possible score), mean PGA-DA from 4.0 to 59.6. There was a high correlation between LS Activity score and PGA-DA ($\rho=0.94$), and low with PGA-DD ($\rho=-0.121$). Raters showed moderate inter-rater reliability for LS Activity Score and PGA-DA, with nearly all showing moderate to high intra-rater reliability for these scores (Table). Among the different parameters, violaceous color and lesion warmth had the lowest inter-rater reliability.

Table. Inter-rater and intra-rater reliability of LS Activity score

Domains	Round 1 ICC (95% CI)	Round 2 ICC (95% CI)
LS Activity Score:		
Inter-rater reliability	0.564 (.38, .79)	0.628 (.43, .83)
Intra-rater reliability (median)		0.804 [range 0.464–0.910]
PGA-DA:		
Inter-rater reliability	0.566 (.38, .79)	0.516 (.33, .76)
Intra-rater reliability (median)		0.734 [range 0.369–0.955]
LS Activity Score parameters: inter-rater reliability		
Erythema	0.392 (.25, .59)	0.483 (.33, .67)
Violaceous color	0.187 (.09, .36)	0.140 (.06, .29)
Waxy or white lesion	0.429 (.29, .63)	0.518 (.37, .70)
Lesion warmth	0.197 (.10, .37)	0.148 (.07, .30)
Skin Thickness of lesion edge	0.407 (.26, .60)	0.307 (.18, .50)

Conclusion: We demonstrate initial construct validity for LS Activity score, and found moderate inter-rater reliability. Additional studies are needed to fully evaluate this measure's validity. More training for the violaceous color and lesion warmth parameters may improve the measure's reliability.

2009

Does Breastfeeding Influence the Presentation of Juvenile Idiopathic Arthritis? Results From the Childhood Arthritis Prospective Study. Hannah Pickford[1], Eileen Baildam[2], Alice Chieng[3], Joyce Davidson[4], Helen E. Foster[5], Janet Gardner-Medwin[4], Lucy R. Wedderburn[6], Wendy Thomson[1] and Kimme L. Hyrich[1]. [1]Arthritis Research UK Epidemiology Unit, Manchester, United Kingdom, [2]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom, [3]Manchester Children's Hospital, Manchester, United Kingdom, [4]Royal Hospital for Sick Children, Glasgow, United Kingdom, [5]Musculoskeletal Research Group, Newcastle upon Tyne, United Kingdom, [6]University College London (UCL), London, United Kingdom

Background/Purpose: There is extensive research into the association between breastfeeding (BF) and the occurrence of autoimmune diseases, although results have been conflicting. Studies have suggested that BF may influence the presentation of juvenile idiopathic arthritis (JIA), with a higher prevalence of BF among children with polyarticular presentation. The aim of this analysis was to study the influence of BF on the presentation of JIA in a large prospective inception cohort of children with childhood-onset arthritis.

Methods: The Childhood Arthritis Prospective Study (CAPS) recruits children $\leq$ 16 years old with new onset ($\geq$2 weeks) inflammatory arthritis from five tertiary hospitals in the United Kingdom. At presentation to pediatric rheumatology, a physician performs an examination and completes a Physician Global Assessment (PGA). Families also complete a Childhood Health Assessment Questionnaire (CHAQ) including a Parent General Evaluation (PGE) and pain visual analogue scale (VAS). Detailed demographic data is collected including age at onset, gender, ethnicity, and household factors including parental education and income. Families were also asked if the child was BF and for how long. Baseline characteristics were compared between those children who were and were not BF using descriptive statistics. The association between BF and a high CHAQ score (>0.75) at presentation were determined using multivariate logistic regression, adjusted for age at onset, symptom duration, ILAR subtype, hospital, ethnicity

and socioeconomic status (SES). Using postcodes, SES was determined by calculating the Index of Multiple Deprivation score and categorised into three groups: low, medium and high.

Results: 927 children (65% female) were included in the analysis: median age at onset 6.4 years. Overall, 54% were breastfed, although the majority for <6 months. BF children reported a lower median age at onset (5.7 vs 7.5 years; p<0.001), a lower CHAQ score, lower PGE and lower pain at baseline (see Table). There was a trend towards a higher proportion of BF children with rheumatoid factor negative polyarthritis but lesser enthesitis related and psoriatic arthritis. There was a statistically significant inverse association between BF and high CHAQ (OR 0.62, 95% CI 0.41, 0.95) which was no longer significant after adjustment (OR 0.66, 95% CI 0.41, 1.07).

Characteristic, median (IQR) or n(%)	Never Breastfed	Breastfed	p-value
n	424 (45.7)	503 (54.3)	
Duration of breastfeeding (months)	–	3.6 (1.4, 6.9)	
Age at onset of symptoms (years)	7.5 (3.4, 10.7)	5.7 (2.0, 10.1)	<0.001
Symptom duration (months)	5.4 (2.8, 12.1)	4.9 (2.4, 10.3)	0.308
Caucasian	394 (92.9)	441 (87.7)	0.008
ILAR Subtype			0.009
Systemic	23 (5.4)	26 (5.2)	
Oligoarthritis	224 (52.8)	264 (52.5)	
Polyarthritis RF negative	81 (19.1)	135 (26.8)	
Polyarthritis RF positive	11 (2.6)	16 (3.2)	
Enthesitis-related	34 (8.0)	18 (3.6)	
Psoriatic	38 (9.0)	30 (6.0)	
Undifferentiated	13 (3.1)	14 (2.8)	
CHAQ (n=677)	0.88 (0.25, 1.63)	0.63 (0.13, 1.25)	<0.001
Physician Global Assessment	31 (18, 54)	28 (15, 50)	0.057
Parent Global Evaluation	29 (6, 53)	18 (4, 45)	0.006
Pain score	39 (10, 64)	23 (5, 50)	<0.001
Active joint count	2 (1, 5)	2 (1, 5)	0.747
Limited Joint Count	1 (1, 3)	1 (1, 3)	0.151
ESR, mm/hr	18 (6, 45)	21.5 (7, 53)	0.088
Hospital			<0.001
Liverpool	187 (44.1)	195 (38.8)	
Manchester	86 (20.3)	88 (17.5)	
Glasgow	68 (16.0)	71 (14.1)	
Newcastle	31 (7.3)	20 (4.0)	
London	52 (12.3)	129 (25.7)	
Index of Multiple Deprivation Category (n=475)			<0.001
Low	28 (12.6)	61 (24.1)	
Medium	93 (41.9)	123 (48.6)	
High	101 (45.5)	69 (27.3)	

Conclusion: There is an association between breastfeeding and an earlier and less severe presentation of JIA, although this could be explained in part by socioeconomic factors. Further work to elucidate the association between breastfeeding and later presentation of autoimmune diseases is required.

2010

Administration of Routine Preventative Vaccinations in Children with Juvenile Idiopathic Arthritis Receiving Adalimumab. Neelufar Mozaffarian and Vipin Arora. Abbott, Abbott Park, IL

Background/Purpose: Adalimumab, a fully human monoclonal antibody to tumor necrosis factor-alpha (TNF) has been shown to be safe and effective in juvenile idiopathic arthritis (JIA), and is approved for this use in several countries.[1] Patients with JIA are candidates for routine childhood vaccinations. This post hoc report describes the observed use of vaccines in JIA patients receiving adalimumab for up to 3 years in a clinical trial setting.

Methods: Patients with active JIA were enrolled in one of the following trials: M10–444 (ages 2–4 or $\geq$ age 4 weighing <15 kg in US, EU), M10–240 (ages 4–17 in Japan), or DE038 (ages 4–17 in US, EU). Patients received treatment with ADA (weight-based dosing) every other week, either with or without methotrexate use. Any vaccinations administered were based on the judgment of the study investigators. Descriptive statistics were used to summarize all vaccinations, including influenza vaccine. Adverse events (AEs) related to active influenza virus infection were collected by a pre-

defined MedDRA Query, and events occurring within 270 days of influenza vaccination were identified.

Results: A summary of all vaccinations is presented in the **Table**. Among the different types of vaccines, the most frequently administered were: influenza virus vaccine polyvalent in DE038 and M10–240 (n=59 and 63 vaccinations, respectively), and pneumococcal in M10–444 (n=28 vaccinations). In DE038 and M10–240, 2 patients each received >5 vaccinations and in M10–444, 10 patients received >5 vaccinations. The majority of vaccinated patients in each study received >1 type of vaccination. Among those who were never vaccinated for influenza, 12/137 patients (9%) in DE038, 1/5 patients (20%) in M10–240, and 2/28 patients (7%) in M10–444 reported influenza infection-related AEs. In those who received influenza vaccination, 4/34 patients (12%) in DE038, and 3/20 patients (15%) in M10–240 reported influenza infection-related AEs within 270 days of vaccination; none (0%) reported influenza infection-related AEs in M10–444.

Table. Summary of Vaccination Data Among JIA Patients

All Vaccinations	DE038	M10-240	M10-444
Total patients vaccinated, n/N	40/171	20/25	20/32
Females vaccinated, %	83	75	85
Mean age, yrs (SD)	12 (3.6)	14 (3.3)	3 (0.7)
Total vaccinations, n	82	67	122
Patients with >1 vaccination, n	23	17	18
Patients with >1 type of vaccination, n	11	2	18
Different types of vaccinations, n	9	3	29
Mean time to 1st vaccination, days	714	187	96
Mean age at 1st vaccination, yrs[a]	13	14	3
Mean JIA duration at 1st vaccination, yrs[a]	NA	4.5	1.02
Influenza Vaccinations	**DE038**	**M10-240**	**M10-444**
Total patients vaccinated, n/N	34/171	20/25	4/32
Females vaccinated, %	79	75	75
Total vaccinations, n	59	63	6
Patients with >1 vaccination, n	17	17	1
Mean time to 1st vaccination, days	688	189	96

NA=not available. [a]Data for mean age at 1st vaccination and mean time to 1st vaccination are the same for "Influenza Vaccinations" for each study.

Conclusion: These data support the idea that JIA patients treated with adalimumab can be safely immunized with routine, inactive, preventative vaccines, including influenza vaccine.

2011

ACR Criteria, Providers' Global Rating of Change and Role of Patient Self-Report in Evaluating Change in Disease Over Time: A Patient Reported Outcomes Measurement Information System Study. Bin Huang[1], Jennifer Farrell[1], Adam Carle[1], Stacey Niehaus[1], Hermine Brunner[2], Alexei A. Grom[1], Michael Henrickson[1], Jennifer L. Huggins[1], D. J. Lovell[3], Tracy V. Ting[1] and Esi M. Morgan DeWitt[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center and PRSCG, Cincinnati, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH

Background/Purpose: As part of a longitudinal study of Juvenile Idiopathic Arthritis (JIA), providers completed clinical outcomes assessments and patients (pt) completed self-report measures at clinic visits. In addition to measuring ACR Pediatric response based on the 6 core variables (CHAQ, active joint count, loss of motion, ESR, physician global assessment (PGA), and pt's well-being), providers rated the pt's global change of overall health (GRC-health) and JIA (GRC-JIA) between visits on a scale from 1 (very much worse) to 7 (very much better). Pt's report of pain and health-related quality of life (HRQoL) are not part of the core measures. Study Aims: 1) To assess the relationship between JIA improvement at the ACR-Ped70 level with the provider's GRC-health and GRC-JIA ratings; 2) To evaluate whether pain and HRQoL as assessed by the PedsQL Core and Rheumatology modules are associated with the provider's GRC-health and GRC-JIA ratings.

Methods: Inclusion criteria were diagnosis of JIA, age 8–18 yrs at enrollment, and English fluency. Study visits occurred 3–4 times/yr concomitantly with scheduled clinic visits. Analyses considered baseline data and 2nd assessments.

Results: Data on 113 JIA pts was available (mean age=13.1±2.7 yrs; range=8.1–18.4 yrs). Majority (86) were female (71%); 72 had polyarthritis (63.7%), 18 oligoarthritis (16%), 11 systemic JIA (9.7%) and 12 other (10.6%). Mean age at diagnosis was 9.0±4.4 yrs. The GRC-health (N=95) and the GRC-JIA (N=106) were highly correlated (r = 0.73, P <.0001). At 2nd assessment, 10.6% (n=12) achieved an ACR-Ped70 treatment response from baseline. ACR-Ped70, 50 and 30 improvements were all moderately correlated with GRC ratings (r range:.32-.43, P<.001). ACR-Ped70 responders significantly differed from others in their GRC-health (4.1±1.2 vs. 5.8±1.1; P<.001) and GRC-JIA ratings (4.4±1.1 vs. 6.3±0.97; P <.001). All ACR-Ped70 responders had GRC-health and GRC-JIA ratings >4. Both GRC ratings were significantly (P<.05) correlated with ACR core measures except ESR (P<.12) (r range:.18-.46), and with pt's pain (r = 0.4,.45; P<.0001). PedsQL Core and Rheumatology Module total and domain scores were significantly correlated with both GRC ratings and ACR-Ped response levels. The final GRC-health multivariable model included ACR-Ped70, gender, ACR-Ped70 by gender interaction, JIA subtype, active joint count and pt's pain; none of the PedsQL scores remained significant. Age was not significant. The final GRC-JIA model includes PGA as a significant predictor, in addition to those included in the GRC-health model.

Conclusion: Provider's ratings of overall health and JIA change are closely related to the level of improvement as measured by the ACR-Ped Criteria. Provider's GRC are significantly influenced by patient's pain rating, and takes account of the active joint count over and beyond the ACR-Ped70 response level. Nonetheless, in comparison to the ACR-JIA Response Criteria the provider's GRC can serve as a valid measure to assess patient's change over time, but with differential gender effect. This study also suggests that patient reported pain should be considered in the assessment of disease progression.

Pediatric Rheumatology Productivity: Results of the American Academy of Pediatrics 2010 Workforce Survey. Michael Henrickson[1] and Laura Laskosz[2]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]The American Academy of Pediatrics, Elk Grove Village, IL

Background/Purpose: Relative value units (RVUs) are a payer-neutral measure of clinical work. The federal government uses a multi-component formula to convert this measure into reimbursement. The Association of Administrators in Academic Pediatrics (AAAP) surveys its practitioners to derive benchmark RVU data, aided by its affiliation with a leading medical management group (MMG). No other benchmarks exist for pediatric rheumatologists (PRs). While PRs largely practice at academic centers, they also work in a variety of settings. PR reimbursement follows a number of models, lacking uniformity or national consensus for practice diversity. Reimbursement estimates may also derive from adjusted adult rheumatology (AR) or various MMG putative standards. Providers can use RVU data to advocate for additional PR clinical support. Through a cross-sectional survey of all board-certified US PRs administered by the American Academy of Pediatrics (AAP), this study's objective was to determine clinical productivity through annual RVU data, obtain demographic and CPT coding data, and establish national benchmarks independent of an MMG.

Methods: An IRB-approved survey asked PRs (N=206) to provide data about their annual RVUs for fiscal year 2008-09, and detailed demographics including clinical full time equivalent (FTE) status. Statistical analysis included the two-sample Kolmogorov-Smirnov test for distribution and t-test for comparison of means.

Results: The overall response was 65% (n=133); 60% of respondents (80/133) provided RVU data including one high volume outlier. AAAP RVU data obtained from 38 centers in the same survey year served as controls (n=79). AAP and AAAP RVU data were normally distributed (p=0.129); but, their means were significantly different (p=0.013) [Table]. AAP demographic data revealed: median FTE=0.6 (0.1–1); 99% PR and 8% AR board certification; median practice years=16.2 (range by 5-yr intervals: <5 to >30); median patients/week=25; median work weeks/year=48.5 (range by intervals: <30 to 52); academic location: 66% (n=69); states represented=34 of 42 supported by PRs (incl. DC); median salary=$158,000; median initial access to care=6 weeks (1–32), previously 2 weeks (2005 AAP survey). Asked if their institution uses the RVU model to measure clinical productivity, 76% affirmed (n=90); 8% did not know (n=10).

Table. Annual RVUs

Quartile	AAP	AAAP
1st	1000	2073
2nd	1737	3310
3rd	2616	4700
Total	8377	7943
Interquartile range	1616	2627
N	80	79

Conclusion: AAAP RVUs sample only academic sites, limiting generalizability. Further, AAAP adjusts RVUs from partial to full FTE, uniformly inflating data. This practice and AAAP alignment with a commercial MMG preclude its role as the best available PR benchmark. AAP RVUs are normally distributed, representing 81% of the states where PRs practice, with mature demographics and wide practice diversity; they serve as a national benchmark. During the latter half-decade, the shift from a 2 to 6 week wait to access initial PR care is concerning and indicative of the pressing need for sustained workforce advocacy.

2013

Cross-Sectional and Longitudinal comparison of Bone Mass Status, Using pQCT, in a Large Cohort of Juvenile Idiopathic Arthritis and Juvenile Onset Systemic Lupus Erythematosus Patients. Fernanda Falcini[1], Stefano Stagi[2], Loredana Cavalli[3], Giulia Carnesecchi[4], Federico Bertini[1], Laura Masi[3], Marco Matucci-Cerinic[5] and Maria Luisa Brandi[3]. [1]Department of Internal Medicine, Rheumatology Section, University of Florence, Florence, Italy, [2]Mugello's Hospital, Borgo San Lorenzo, Firenze, Italy, [3]University of Florence, Firenze, Italy, [4]University of Florence, Florence, Italy, [5]Univ Florence, Firenze, Italy

Background/Purpose: A small number of prospective data have been published on the use of pQCT in large groups of pts with JIA and JSLE. Moreover, few studies have compared in groups of JIA an JSLE pts, homogenous for age and sex, the parameters of bone status using pQCT. Our aim is to evaluate**,** cross-sectionally and longitudinally, the prevalence of reduced bone mass and density and the differences on the biomechanical parameters, using pQCT, in two cohorts of patients with JIA and JSLE homogenous for age and sex.

Methods: 154 JIA pts (127 F, 27 M, median age 20.3 $\pm$ 7.9 yrs: 84 oligoarticular, 33 polyarticular, 10 systemic, 27 enthesitis-arthritis (ERA) onsets, and 56 JSLE pts (46 F, 10 M, median age 21.5 $\pm$ 6.1 yrs) have been studied. The obtained data have been compared with age and sex matched control groups.

Results: JIA pts do not show any difference in comparison to controls as regard to cortical density (CrtBMD), except for systemic pts ($p <$ 0.0001) while JSLE pts have a higher CrtBMD than controls and JIA pts ($p <$ 0.005). Analyzing bone trabecular density (TrbBMD), all JIA pts regardless of type onsets (except for ERA), and JSLE pts have significant reduced values than controls, with no differences between JIA and JSLE. In addition, JIA pts show a significant reduced muscle area (muscle CSA) than JSLE and controls ($p <$ 0.001). The difference is significant in systemic and polyarticular JIA pts, but no in oligo and ERA subsets. Conversely, fat area (fat CSA) is significantly increased in both JIA and JSLE pts when compared to controls ($p <$ 0.001), with no differences in the two groups. The same results are observed evaluating the polar resistance to stress (SSIp). On longitudinal evaluation, the difference of CrtBMD, TrbBMD, muscle CSA e fat CSA are unchanged; in JSLE pts, SSIp is stable in comparison to JIA and controls without any difference among JIA pts and controls.

Conclusion: The pQCT evaluation of the main parameters of bone density and structure in adolescents and young adults with JIA and JSLE highlights significant differences between the two groups and JIA subtypes. These data might indicate a different pathogenesis of bone damage in the two entities, and suggest a different diagnostic and therapeutic approach to improve the bone mass peak in these patients.

2014

Serum 25(OH)D Levels in Adolescents and Young Adults with Juvenile Idiopathic Arthritis and Juvenile Onset Systemic Lupus Erythematosus: Prevalence and Association with Disease Activity. Fernanda Falcini[1], Stefano Stagi[2], Loredana Cavalli[3], Giulia Carnesecchi[1], Federico Bertini[1], Laura Masi[3], Marco Matucci-Cerinic[1] and Maria Luisa Brandi[3]. [1]Department of Internal Medicine, Rheumatology Section, Transition Clinic, University of Florence, Florence, Italy, [2]Pediatric Unit, Mugello's Hospital, Borgo San Lorenzo, Firenze, Italy, [3]Department of Internal Medicine, Endocrinology Unit, University of Florence, Firenze, Italy

Background/Purpose: Numerous data are available in literature on 25 (OH)D serum levels in general population, few and contradictory in Juvenile Idiopathic Arthritis (JIA), and scarce in Juvenile onset Systemic Lupus Erythematosus (JSLE) pts. Our goals are: 1- to evaluate the serum 25(OH)D status in a large cohort of JIA and JSLE pts; 2- to correlate the 25(OH)D levels with the variables associated with JIA and JSLE. 3.To compare the pts results with healthy controls.

Methods: 144 JIA pts (122 F, 22 M, median age 15.5 $\pm$ 7.2 yrs: 78 oligo, 30 poly, 12 systemic and 24 Entesitis-arthritis [ERA]) onsets, and 46 JSLE pts (38 F, 8M, median age 16.9 $\pm$ 6.8 yrs) were studied after informed consent and Ethical approval. In all, serum 25(OH)D, serum intact parathyroid hormone (PTH), calcium, phosphorus, and bone alkaline phosphatase were measured. 100 sex-matched healthy subjects acted as controls.

Results: No significant difference of 25(OH)D levels has been detected in JIA and JSLE pts in comparison to controls as regard the percentage of those with VD deficiency and insufficiency. Of note, in JIA and JSLE pts with deficiency or insufficiency, a significant difference in comparison to controls with deficit or insufficiency, as regard the percentage of subjects with increased PTH and alkaline bone phosphatase levels ($p <$ 0.0001) was detected. In addition, among 25(OH)D levels and JIA subtypes, the lowest levels were found in systemic and poly than in oligo and ERA onsets. Moreover, systmic and poly pts have a significant lower increase of 25 (OH)D levels after supplementation than oligo, ERA pts, and controls with a high percentage of those who remains with insufficiency ($p <$ 0.001). The same results have been observed in JSLE pts who showed a high percentage of insufficiency, despite supplementation, of 25(OH)D than controls. The persistent low 25 (OH)D levels, despite supplementation, are significantly higher in patients with persistent active disease.

Conclusion: Serum 25 (OH) D levels and the percentage with persistent VD insufficiency seem to correlate to type of disease and disease activity. These preliminary results suggest a higher consumption and a higher request of 25(OH)D in patients with active JIA and JSLE.

2015

Recognizing Two Distinct Clinical Phenotypes in Muckle-Wells Syndrome. J B. Kuemmerle-Deschner[1], Samuel Dembi Samba[1], Isabelle Kone-Paut[2], Isabelle Marie[2], Pascal N. Tyrrell[3] and Susanne M. Benseler[3]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]CHU Bicêtre, Paris, France, [3]The Hospital for Sick Children, Toronto, ON

Background/Purpose: The diagnosis of Muckle-Wells syndrome remains challenging due to the variable and often non-specific clinical presentation**.** The aim of this study was to identify key variables associated with time to diagnosis in patients with MWS.

Methods: A cohort study of consecutive patients with a clinical diagnosis of MWS plus genetic evidence of an *NLRP3*-mutation was conducted at two centres for autoinflammatory diseases. Demographic information, mutation subtype, clinical phenotype, detailed access to care data, and information about duration of symptoms and preclinical evaluation were collected. Presenting variables were compared between groups of patients with a diagnosis in childhood compared to adulthood.

Results: A total of 34 patients were included (16 males, 18 females), the median age at diagnosis of MWS was 31.5 years (0.5–75). Patients diagnosed during childhood most commonly complained of musculoskeletal symptoms (62%), fever (54%), headache (46%) and abdominal pain (31%), while those diagnosed as adults had musculoskeletal symptoms (86%), hearing loss (52%) and decreased performance (29%). Data

driven clustering strategies identified two distinct clinical phenotypes of MWS: the "inflammatory phenotype", most commonly found in patients diagnosed in childhood was associated with fever, rash, headache and abdominal pain. Patients diagnosed as adults showed a more "organ –disease" phenotype characterized by musculoskeletal symptoms, skin rash, hearing loss and eye disease.

Conclusion: Two distinct clinical phenotypes may be identified in patients with MWS. These are closely related to the time of diagnosis. The presence of these two distinct clinical phenotypes has to be considered when developing diagnostic criteria for MWS.

2016

Primary Raynaud's Phenomenon in a Multicenter Cohort of Italian Children and Adolescents: Which Prognostic Relevance for Serological Tests? Fernanda Falcini[1], Valentina Denaro[1], Federica Cuoco[2], Giorgia Martini[3], Susanna Cappelli[1], Antonella Petaccia[2], Fabrizia Corona[2], Giulia Carnesecchi[1], Francesco La Torre[4], Marco Matucci-Cerinic[5] and Donato Rigante[6]. [1]Department of Internal Medicine, Rheumatology Section, University of Florence, Firenze, Italy, [2]Department of Pediatrics, University of Milan, Milan, Italy, [3]University of Padua, Padua, Italy, [4]DIMIMP-University, Rheumatologic Section, Bari, Italy, [5]University of Florence, Florence, Italy, [6]Università Cattolica Sacro Cuore, Rome, Italy

Background/Purpose: Raynaud's phenomenon (RP) is an episodic vasospasm of the peripheral arteries, causing pallor followed by cyanosis and redness with pain and sometimes paraesthesia or rarely ulceration of the fingers and toes. Primary RP (pRP) occurs without an underlying disease, while secondary RP occurs in association with an underlying connective tissue disease (CTD), mostly systemic lupus erythematous, juvenile dermatomyositis and systemic scleroderma. Predictors of a favorable outcome are still unraveled in pRP: the causative role of various autoantibodies remains to be elucidated mostly for pRP starting in childhood or adolescence. Our objective is to identify the potential predictors of outcome in a multicenter cohort of children and adolescents with pRP.

Methods: We performed a prospective data collection of demographic, clinical, laboratory and treatment features of 82 Italian children/adolescents with pRP (58 females, 24 males, median age at disease onset: 13.5 years, median age at diagnosis: 14.8 years), managed in 4 pediatric rheumatologic Units and 1 transition clinic during the last three years. Demographic characteristics included sex, age and ethnicity. The evaluation included clinical pictures, eventual disease associations, pubertal status, laboratory data and nailfold videocapillaroscopy (NVC) at baseline and at regular 6-month-follow-up. Laboratory examinations included erythrosedimentation rate, C-reactive protein, transaminases, serum creatinine, hemoglobin, complement fractions C4 and C3, renal and thyroid function and specific serum autoantibodies (anti-nuclear antibodies [ANA], anti-DNAds, anti-ENA, anti-cardiolipin, anti-Scl-70 and anti-centromere antibodies). Screening for coeliac disease was performed at the first evaluation. Treatment details included the eventual specific drug used, its dosage and overall treatment duration. Out of 82, 20 patients were treated with hydroxicloroquine, 10 with calcium blockers, 1 with low-dose aspirin, 3 with iloprost, while the remaining 48 did not receive any drug. A forward stepwise multiple logistic regression analysis was used to find any association among sex, pubertal status, inflammatory parameters, NVC abnormalities, all serum autoantibodies and the risk of developing a CTD at baseline and at 36-month-follow-up. The software used was STATA 10. A p-value <0.05 was considered significant.

Results: ANA positivity at baseline was significantly associated with the risk of developing a CTD ($p <0.05$). No NVC abnormalities was related to specific patients' outcome**.** No patient was positive at the screening for coeliac disease.

Conclusion: Our data show that ANA positivity appears as the only potential predictor of poor outcome and even progression to CTD in children and adolescents with pRP.

2017

Orthopaedic Treatment of Temporomandibular Joint (TMJ) Damage in Adolescents with Juvenile Idiopathic Arthritis (JIA): Longitudinal Evaluation. Fernanda Falcini[1], Daniela Melchiorre[1], Giulia Carnesecchi[1], Federico Bertini[1], Katia Biondi[2], Mario Bosco[3] and Marco Matucci-Cerinic[4]. [1]Department of Internal Medicine, Rheumatology Section, University of Florence, Florence, Italy, [2]Department of Odontostomatologic Sciences, University of Pavia, Pavia, Italy, [3]Pavia, Italy, [4]University of Florence, Florence, Italy

Background/Purpose: TMJ involvement has been reported in all subsets of JIA. The prevalence of radiographic changes of TMJs varies from 30% to 65%, and 50–80% of children with JIA will have evidence of TMJ arthritis by MRI and by sonographic exam (SE) (effusions, synovial enhancement, condylar flattening and/or erosions, thickness of masseter muscle) before evidence of X-ray damage. At disease onset local injections with steroids or/and anti-TNF alpha blockers are recommended, but when joint damage is late recognized orthopedic treatment is suggested. Our aim is to evaluate the efficacy and safety of orthopedic treatment in a cohort of adolescents and young adults with JIA.

Methods: Our study population included 102 consecutive pts (76 F and 26 M, mean age 14.5±4.4 yrs), mean age at JIA onset 7.9±5 yrs, mean disease duration at first orthodontic evaluation 7.7±5.2 yrs, fulfilling the ILAR criteria for JIA, all treated at Transition clinic of Rheumatology Department between December 2009 and December 2011. Out of 102 pts, 53 had oligo (O-JIA), 34 polyarticular (P-JIA), 4 systemic (S-JIA), 11 enthesitis-related arthritis (ERA-JIA) onsets. The diagnosis of TMJ disease was performed on the presence of at least one Research Diagnostic Criteria for Temporomandibular Disorders (RDC/TMD) diagnosis. The anamnestic and functional data were collected in a medical record used by orthodontists of University of Pavia, Italy. 69/102 pts (68 %) showed recurrent pain localized in the temporomandibular area, crepitation, and jaw stiffness or fatigue. All TMJs were examined by panoramic X-ray, teleradiography with latero-lateral and anteror-posterior view, and by SE by Esaote MyLAB 70 (Genoa Italy linear probe 8–13 MHz). At first orthodontic evaluation 75 pts showed dento-skeletal malocclusions leading to a Class II caused by skeletal retrognathia, post-mandibular rotation, lower height of the mandibular body and ramus that can determine asymmetries in the frontal and/or in the sagittal plane.

Results: 51 pts (50%) undergone to orthopedic therapy with an activator order to help mandibular growth. After orthopedic therapy these pts had worn a bite. 31 pts (30.3%) wore a bite without orthopedic therapy. 20 pts (20%) did not receive any treatment. After two years from first orthodontic evaluation 58/ 75 pts (77.3%) showed improvement in occlusion, masticatory function and cranio-facial morphology. In 69 pts the thickness of masseter muscle, detected by SE after therapy, was similar on left and right side (mean value 7.6 mm) at rest and after contraction (p<0.001). In all pts SE showed bone remodeling of the condyle head, and in 62/102 (61%) pts monolateral erosions were present.

Conclusion: Our data confirm that early diagnosis and treatment should prevent the severe and often intractable damage in TMJ of JIA patients. The irreversible damage as micrognathia, aberrations in mandibulofacial development, and facial asymmetry may compromise the growth cartilage and rapidly progress into bone erosion of the condylar head. In our study, the results suggest that in case of delayed diagnosis and severe destruction of TMJs, an orthopedic treatment may be helpful in reducing the progression of bone injury.

2018

Juvenile Idiopathic Arthritis in Adulthood: Evaluation of Disease Activity, Damage and Quality of Life. Alessandra Salmaso[1], Lorenzo Ceri[2], Serena Capannini[2], Francesco La Torre[3], Maurizio Gattinara[1], Irene Pontikaki[1], Pier Luigi Meroni[4], Fernanda Falcini[2] and Valeria Gerloni[1]. [1]Pediatric Rheumatology, G. Pini Institute, Department and Chair of Rheumatology, Milan, Italy, [2]Department of Internal Medicine, Rheumatology Section, Transition Clinic, University of Florence, Firenze, Italy, [3]DIMIMP-University, Rheumatologic Section, Bari, Italy, [4]Division of Rheumatology, Istituto G. Pini, University of Milan, Milano, Italy

Background/Purpose: Health outcomes in Juvenile Idiopathic Arthritis (JIA) have been a very active area of research in the past several years. Altogether, the available data indicate that a considerable number of patients

with JIA enters adulthood with persistently active disease and a significant proportion of them may develop severe physical disability. In general children with polyarticular course are more likely to have erosive radiological damage on follow-up. The comparison of earlier studies with those published in the last decade shows a decline in the frequency of patients with severe physical disability over the years; however, patients who enter adulthood with active disease do not seem to be diminished. The purpose of this study is to evaluate in patients with JIA in adulthood the functional and anatomic damage and the quality of life.

Methods: All consecutive JIA patients aged >18 yrs, afferent to three different paediatric rheumatology centres in the last year, were assessed with: HAQ; SF36; active joint count; VAS (0–100 mm) for pain, patient and physician global health assessment; radiological evaluation (Steinbrocker classification).

Results: 347 patients with JIA in adulthood, age >18 yrs, were enrolled. The collected data are shown in the following table

Table. JIA in adulthood, age >18 yrs

	JIA all	Syst	Poly RF+	Poly RF-	Oligo pers	Oligo ext	Psor	ERA
# pts	347	41	22	60	122	50	14	38
Mean age	27 (17–52)	30 (18–52)	26 (18–42)	27 (18–51)	26 (18–44)	28 (18–46)	28 (19–44)	25 (18–39)
Mean disease duration	19 (3–51)	21 (3–48)	15 (4–30)	18 (3–51)	19 (6–40)	22 (6–43)	22 (6–43)	14 (3–31)
Active arthritis (%)	40	46	43	48	38	38	29	32
Mean VAS pain	24 (0–100)	36 (0–100)	25 (0–70)	24 (0–88)	22 (0–82)	21 (0–88)	22 (0–62)	22 (0–84)
Mean patient GH	71 (0–100)	62 (0–100)	77 (30–100)	70 (0–100)	74 (24–100)	72 (10–100)	65 (40–90)	72 (20–100)
Mean VAS physician	15 (0–100)	22 (0–100)	19 (0–75)	17 (0–90)	12 (0–70)	15 (0–50)	17 (0–94)	12 (0–60)
% anatomic class III–IV	45	72	71	53	25	60	50	30
% pts with protesis	11	49	10	12	1	15	21	0
Mean HAQ	0, 5 (0–3)	0, 8 (0–3)	0, 4 (0–2)	0, 4 (0–3)	0, 2 (0–1, 6)	0, 3 (0–1, 3)	0, 4 (0–1, 8)	0, 1 (0–0, 8)
Mean SF36 physical health	62 (1–99)	50 (1–97)	62 (25–97)	62 (11–99)	65 (13–99)	66 (15–99)	50 (22–80)	59 (12–98)
Mean SF36 mental health	63 (12–100)	61 (12–93)	63 (22–99)	62 (11–99)	64 (13–100)	68 (20–100)	51 (21–90)	60 (30–98)

Conclusion: this hospital-based study clearly shows a selection bias toward the most serious cases, but underlines the high rate of JIA patients with disease still active in adulthood, confirming the need of a more aggressive and precocious treatment, to improve outcome in the future.

2019

A Novel MRI Scoring System for the Evaluation of Early-Stage Disease Activity of the Wrist in Juvenile Idiopathic Arthritis. Charlotte M. Nusman[1], Robert Hemke[1], Taco W. Kuijpers[2], Eline E. Deurloo[1], Dieneke Schonenberg[2], J. Merlijn Van den Berg[3], Koert M. Dolman[4], Marion A.J. Van Rossum[3] and Mario Maas[1]. [1]Academic Medical Center, Amsterdam, Netherlands, [2]Emma Children's Hospital / Academic Medical Center (AMC), Amsterdam, Netherlands, [3]Emma Children's Hospital / Academic Medical Center and Reade Institute, Amsterdam, Netherlands, [4]St. Lucas Andreas Hospital and Reade Institute, Amsterdam, Netherlands

Background/Purpose: Evidence that early therapeutic intervention prevents structural damage in juvenile idiopathic arthritis (JIA) patients requires focus on early-stage disease activity scores. Most outcome measures in JIA, such as the validated paediatric-targeted MRI scoring system (PTMRIS)[1], are based on adult equivalents with extensive focus on late-stage structural damage. Using our recently validated juvenile arthritis MRI scoring system (JAMRIS) for the knee[2], we have developed a similar analysis tool for the wrist to assess disease activity at an early stage. This focus shift to early-stage disease activity is achieved through extending soft tissue structure scores and specifying the grading of bone items affecting <25% of the bone. The objectives of this study were (1) to assess the intra- and interreader reliability of the JAMRIS system for the evaluation of early-stage disease activity in the wrist and (2) to compare the reliability of JAMRIS and PTMRIS.

Methods: MRI datasets from 20 JIA patients with wrist involvement were evaluated independently by three readers using JAMRIS and PTMRIS. JAMRIS for the wrist comprises synovial hypertrophy (6 locations, grading from 0–3), tenosynovitis (2 locations, grading from 0–1), bone marrow changes (15 locations, grading from 0–3) and bone erosions (15 locations, grading from 0–3) as scoring items. The intraclass correlation coefficient (ICC) or Cohen's kappa was used to assess inter- and intrareader reliability. The ICC of each JAMRIS scoring item was compared with the ICC of its equivalent in PTMRIS.

Results: The interreader reliability (ICC or Cohen's kappa) of JAMRIS varied from 0.62 to 0.89. Interreader reliability for tenosynovitis score was low (0.24 to 0.48). Intrareader reliability (ICC or Cohen's kappa) of JAMRIS

varied with from 0.28 to 0.95 for reader 1 and from 0.41 to 0.97 for reader 2. JAMRIS and PTMRIS showed similar results of interreader reliability.

Conclusion: Early-stage JIA disease activity in the wrist can be reliably evaluated with three-out-of-four JAMRIS scoring items. JAMRIS, especially focussed on early-stage disease presentation, has comparable reliability to PTMRIS. Correlating clinical disease assessment and responsiveness to change will be needed to validate JAMRIS for the wrist as outcome measure and disease monitoring tool.

2020

Assessment of Procedure Safety and Cannula Position in Temporomandibular Joint Puncture Evaluated by Cone Beam Computerized Tomography. Thomas K. Pedersen[1], Kasper D. Kristensen[1], Per Alstergren[2], Peter Stoustrup[1], Annelise Küseler[1] and Troels Herlin[3]. [1]University of Aarhus, Aarhus C, Denmark, [2]Karolinska Institutet, Huddinge, Sweden, [3]Aarhus University Hospital Skejby, Aarhus N, Denmark

Background/Purpose: Temporomandibular joint (TMJ) arthritis frequently occurs in juvenile idiopathic arthritis (JIA). Only sparse information is available concerning the inflammatory activity and the underlying biology and course of arthritis in the TMJ in JIA patients, although it is known to cause severe growth disturbances of the dentofacial complex. Studies evaluating the synovial fluid may lead to a better understanding of the interaction between synovial inflammation, cartilage condition, and the influence on condylar bone formation. TMJ synovial fluid sampling and intraarticular steroid injections are procedures useful to elucidate this issue and to control inflammation. However, the TMJ is also known to be a vulnerable joint where functional disorders also can cause growth disturbances when mandibular function is impaired. Therefore, it is crucial that no or only transient side effects occurs from intervening procedures. The aim of this study was to evaluate safety issues in relation to a synovial sampling technique and to determine the variation in needle position by cone beam computerized tomography (CBCT).

Methods: Twenty healthy, adult volunteers were examined for TMJ dysfunction and mandibular movements were assessed before and after a sample of synovial fluid were taken in local anesthesia using the push-pull technique described previously (1). Samples were obtained from both TMJs and a CBCT-scanning was done to evaluate the needle position in the upper joint compartment. The study was approved by the ethical committee.

Results: All volunteers reported slight TMJ pain after sampling (mean 13.0 on a VAS-scale (from 0–100)). Pain disappeared in all participants after 1–2 days maximum. Objectively, mandibular range of motion was not affected by the procedure. The cannula was clearly visible in 3D in relation to the osseous tissues on the CBCT. The scanning showed a large variety in cannula position. The CBCT scanning lasted approximately 20 sec.

Conclusion: The synovial fluid sampling technique was found to be safe resulting in only minor, transient symptoms. However, the technique visualized in 3D is applicable in studies on TMJ pathology responsible for dentofacial growth abnormalities in growing individuals. A considerable variation was found in needle position and as a therapeutic approach, injection of steroids should be done with caution. CBCT confirmation of cannula position can be advised to substitute medical CT thereby greatly reducing patient radiation exposure.

The Schedule of Administration of Canakinumab in Cryopyrin Associated Periodic Syndrome Is Driven by the Phenotype Severity Rather Than the Age. Roberta Caorsi[1], Loredana Lepore[2], Francesco Zulian[3], Maria Alessio[4], Achille Stabile[5], Antonella Insalaco[6], Martina Finetti[1], Antonella Battagliese[4], Giorgia Martini[3], Chiara Bibalo[2], Alberto Martini[1] and Marco Gattorno[1]. [1]G. Gaslini Institute, Genova, Italy, [2]Ospedale-Infantile Trieste, Trieste, Italy, [3]University of Padua, Padova, Italy, [4]Federico II Hospital, Napoli, Italy, [5]DipartimentoPediatria, Policlinico Gemelli, Roma, Italy, [6]Ospedale Pediatrico Bambino Gesù, Roma, Italy

Background/Purpose: to identify the optimal regimen for the treatment with Canakinumab in CAPS patients and, in patients receiving both Anakinra and Canakinumab during their disease course, to compare the two drugs in term of the efficacy and impact on the quality of life.

Methods: 13 CAPS patients (10 paediatric, 3 adults) treated with Canakinumab were followed for 12 months; 12 patients were previously treated with Anakinra. Clinical and laboratory parameters were collected at each visit and health-related quality of life (HRQoL) was recorded at month 12.

Disease activity, doses of IL-1 inhibitors and HRQoL were analyzed at the time of the last administration of Anakinra and after 12 months of treatment with Canakinumab.

Results: 7 patients were classified as CINCA, 4 patients as Muckle-Wells syndrome (MWS) while 2 patients displayed an overlapping MWS/CINCA phenotype.

Nine modifications of the schedule were necessary in 6/7 CINCA patients, while a single modification was performed in two MWS and MWS/CINCA patients only.

At the last follow-up during Canakinumab treatment 4 patients (2 MWS, 1 MWS/CINCA and 1 CINCA patients) were treated with a stable dose of 2 mg/kg (or 150 mg if weight was higher than 40 Kg) every 8 weeks, all of them displaying a complete response. Two CINCA and one MWS patients were treated with the dose of 2 mg/kg (or 150 mg) every 7, 6 and 6 weeks respectively, with a complete response. Four patients (3 CINCA and 1 MWS/CINCA patients) were treated with the dosage of 300 mg with a frequency of 7, 6, 5 and 4 weeks. All of them displayed a partial response. One MWS patient, in light of the persistent good control of the disease, discontinued the treatment with the aim to use the drug on demand, with a subsequent complete wellbeing for the following 6 months. One CINCA patients withdrew Canakinumab due to incomplete response and poor compliance.

At the last administration of Anakinra the patients were treated with a mean dose of 1,38 mg/kg/day (range 0,66-2). Seven patients (3 CINCA, 1 MWS/CINCA and 2 MWS) displayed a complete response while a partial response was observed in 5 patients (4 CINCA, 1 MWS/CINCA patients), due to a slight increase of acute phase reactants.

The number of complete responders at the last follow up in Canakinumab (8/13) was comparable to that registered at the moment of Anakinra discontinuation (6/12). The evaluation of the quality of life with the CHQ-PF50 questionnaire did not reveal a significant difference of the impact of the two drugs on physical concepts (Phs 51.88 during Anakinra, 51.55 during Canakinumab), while Canakinumab determined a significant amelioration of psychosocial concepts (p < 0.03, Wilcoxon Pairs Test)

Conclusion: the long-term use of Canakinumab is associated with a satisfactory control of disease activity but needs a progressive dose adjustments in more severe patients. CAPS phenotype, rather than the age, represents the main variable able to determine the need of more frequent administrations of the drug at higher dosage. We propose that pediatric MWS patients should be treated with the proposed schedule of 2 mg/kg every 8 weeks. Conversely, patients with a severe CINCA phenotype should be more aggressively treated since the beginning with a monthly administration of 4 mg/kg as the starting dose.

Individual Disease Burden in Children and Adolescents with Chronic Musculoskeletal Pain—Multilevel-Analysis of a Nationwide Prospective Longitudinal Observation Study. Kerstin Gerhold[1], Rebecca Muckelbauer[2], Jacqueline Müller-Nordhorn[2], Angelika Thon[3], Thomas Müller[4], Gerd Ganser[5], Martina Niewerth[1] and Kirsten Minden[6]. [1]German Rheumatism Research Center, a Leipniz Institute, Berlin, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]Kinderklinik der Medizinischen Hochschule Hannover, Hannover, Germany, [4]Universitätsklinikum Halle (Saale), Halle (Saale), Germany, [5]Sankt Josef Stift, Sendenhorst, Germany, [6]German Rheumatism Research Center, a Leibniz Institute, Berlin, Germany

Background/Purpose: Chronic musculoskeletal pain was described to be a frequent complaint in children and adolescents with assumed relevant impairment of health-related quality of life (HRQoL) as crucial indicator of individual disease burden. Since only a few epidemiological data are available, we investigated the course of single dimensions of patient-assessed HRQoL in children and adolescents with either chronic idiopathic musculoskeletal pain (CIMP) or juvenile idiopathic arthritis (JIA) as two entities of chronic musculoskeletal pain.

Methods: The national pediatric database is an ongoing nationwide prospective observation study on health care of patients with rheumatic-inflammatory or other musculoskeletal diseases referring to pediatric rheumatology departments in Germany. Patients diagnosed with CIMP or JIA enrolled between 2000 and 2008 with a minimal observation period of two years were included in the present analyses. They evaluated annually single generic dimensions of HRQoL on numeric rating scales (NRS, 0–10, 0 best): pain severity, physical capability, limitation in daily life activities, and capability of disease coping. The method of linear multi-level analysis was used to predict two-year courses of these patient-reported outcome measures. Each statistical model was adjusted for sex, age at disease onset, disease duration, calendar year of documentation, and medical care level of recruiting departments (private practice, general children's hospital, university children's hospital).

Results: Data of 318 CIMP patients (70% females, age (mean $\pm$ sd) 12.0 ± 3.8 years, disease duration 2.4 ± 2.6 years) and 6,103 JIA patients (65% females, age 9.5 ± 4.5 years, disease duration 2.7 ± 3.1 years) were included. At baseline (t_0), CIMP patients assessed all single generic dimensions of HRQoL with poorer scores than JIA patients: pain severity by plus 1.5 NSR points, limitation in daily life activities by plus 0.9, physical capability and disease coping by plus 0.5 NSR points each, and global health state by plus 0.7 NSR points. Compared to t_0, values of single HRQoL dimensions decreased only in JIA up to one (t_1) und two years (t_2) of follow-up, but not in CIMP patients (t_1 versus t_0 p<0.001; t_2 versus t_0 p<0.001). CIMP patients evaluated single generic dimensions of HRQoL persistently worse than JIA patients; this group difference increased for all scales between t_0 and t_2(p<0.05).

Conclusion: Consistently poorer estimates of all investigated measures of HRQoL in children and adolescents with CIMP over the two-year observation period, compared to children with JIA, are first hints for a relevant and long-term burden of disease in these patients. These results may implicate the need for improving medical care conditions for these patients in Germany in order to avoid a possible long-lasting disease career beyond childhood and adolescence.

Support: The national pediatric database is financially supported by the Children's Arthritis Foundation (Kinder-Rheumastiftung).

Should Joint Ultrasound Contribute to Therapeutic Decisions in Juvenile Idiopathic Arthritis? Marie Halbwachs, Geraldine Durand. Caroline Robin, Catherine Gambert Abdel Rahman, Pierre Ingrand and Elisabeth Solau-Gervais, University Hospital, Poitiers, France

Background/Purpose: Over several years, numerous studies have been published on the interest of joint ultrasound in juvenile idiopathic arthritis. Several authors have demonstrated that ultrasonography is more sensitive in synovitis detection than clinical examination. As of today, we do not know whether or not joint ultrasonography has an impact on therapeutic decisions. The objective of this study is to determine the interest of joint ultrasonography in therapeutic management of juvenile idiopathic arthritis.

Methods: This was a monocentric, open cross-sectional study, conducted on twenty-seven outpatients with JIA between March 2010 and January 2012. Ultrasound (US) evaluations were always carried out by the same rheumatologist, who had been trained in joint US. The ultrasound scanner was an EsaoteMylab 60. The wrists, hands and feet were systematically analysed, as was any painful joint. Therapeutic decisions were taken following clinical

examination and joint ultrasound. In the second step of the study, all of the consultations with ultrasound evaluation were summarized in the form of scenarios and submitted to clinicians, without the US results. Three physicians then expressed their therapeutic decisions (no modification, treatment enhancement or reduced treatment), which were subsequently compared with and without ultrasound data.

Results: Among the twenty-seven children followed, US was carried out in thirteen. 53.8% of the thirteen children had oligoarticular JIA and the other 46.2% had polyarticular onset. Between March 2010 and January 2012, 34 ultrasounds were carried out on thirteen children and thirty-four scenarios were elaborated. Subclinical synovitis was found in 94.1% of the US with a mean of $4.82+/-3.46$. Treatment enhancement ensued after 52.8% of the consultations with ultrasound evaluation, with a mean subclinical synovitis of $5.11+/- 3.31$. Divergent decisions (29.4%) were found when comparing consultation with ultrasound and scenario without ultrasound. Whether there were more than 2 clinical instances of synovitis or none, the decision remained similar. The divergent decisions came about either when children were symptomatic but with no more than two clinical instances of arthritis or asymptomatic with no clinical synovitis.

Conclusion: This study strongly confirms the interest of joint ultrasound in therapeutic decision-making. It establishes a usable therapeutic tool by means of accurate articular evaluation and suggests its interest in the therapeutic management of JIA children, especially when the clinical data are not sufficiently explicit.

Articular Symptoms in Cryopyrin-Associated Periodic Syndrome: Retrospective French Study. Laetitia Houx[1], Pierre Quartier[2], Isabelle Kone-Paut[3], Xavier Guennoc[4], Pascal Pillet[5], Thierry Lequerre[6], Irene Lemelle[7], Mohamed Hamidou[8], Gilles Grateau[9], Eric Hachulla[10], Jean-Marie Berthelot[11], Benedicte Neven[12], Christophe Richez[13], Anne Pagnier[14], Veronique Hentgen[15] and Valerie Devauchelle-Pensec[16]. [1]Brest, France, [2]Necker-Enfants Malades Hospital,, Paris, France, [3]Hospital Kremlin Bicêre, Kremlin-Bicêtre, France, [4]Hopital de Saint Brieuc, France, [5]Paediatry, CHU, Bordeaux, France, [6]Rouen, France, [7]Paediatry, CHU, Nancy, France, [8]Hôtel Dieu, Hôpital Universitaire de Nantes, Nantes, France, [9]Hopital Tenon, Paris, France, [10]Department of Internal Medicine, Claude Huriez Hospital, University of Lille, Lille CEDEX, France, [11]Nantes University Hospital, Nantes, France, [12]Inserm U768, Paris, France, [13]Hôpital Pellegrin and Université Victor Segalen Bordeaux, Bordeaux, France, [14]Service de pediatrie, Grenoble, France, [15]Paediatric Unit, Le Chesnay, France, [16]Brest Occidentale university, Brest, France

Background/Purpose: The cryopyrin-associated periodic syndrome (CAPS) is a rare inherited inflammatory disease associated with a mutation in the NLRP3 gene. Articular symptoms are often described in CAPS, but their frequency has been poorly investigated. Our objective was to describe the type and frequency of articular symptoms present in a cohort of pediatric and adult patients followed for a CAPS in France.

Methods: We conducted a retrospective study concerning articular manifestations (articular symptoms bone and muscle) in patients with CAPS [the familial cold autoinflammatory (FCAS), the Muckle-Wells syndrome (MW), and the neonatal-onset multisystem inflammatory disorder (NOMID or chronic infantile neurologic, cutaneous and articular syndrome (CINCA)] by contacting their referring physicians in the adults or paediatrician departments. Medical data were collected using a standardized questionnaire and radiographs were analyzed when present in the records.

Results: 88 patients were included (16 FCAS, 55 MW, 12 CINCA / NOMID and 5 unclassified). 50% were women, 56 patients were adults (mean age 33 ± 18.4 years) and 32 children (10.8 ± 4.4 years). The onset age is on average about 4.35 ± 7.8 years, and age of diagnosis is delayed to 20 ± 16 years. The first symptoms are usually: a cutaneous manifestation (68%), fever (26%), articular (22%) or neurological manifestation (11%). 65 patients (74%) have a family history of CAPS and 11 patients have a CAPS without genetic mutation. During follow-up, only 17 patients (23%) showed no joint symptoms. 53 patients (60%) had arthralgia and 55 patients (63%) had synovitis. The most affected joint were respectively: knees (65%), ankles (60%), wrist (47%), hands (40%) and feet (20%). Tendinopathy occurred in 13 patients (15%) and myalgia in 29 cases (33%). Only two patients had arthropathy with a typical non-inflammatory enlargement of the growth plates and epiphyses of long bones. Contractures and joint limitations (2%) or synovial masses are rare (2%). 24/88 (27%) were treated with anakinra and 55/88 (62.5%) with canakinumab. When reported delay in statural growth was -2DS for children before anti-IL1 treatment.

Conclusion: Articular symptoms encountered in CAPS are very common and found in 82% of patients with arthralgia and synovitis in knees and ankles. These symptoms are considered predominant for 20% but rarely explored by imaging. Pseudo tumor are rare. Delay of growth is frequent. Most patients benefit from treatment with anakinra or Canakinumab which allows almost complete regression of joint symptoms.

Clinical Characteristics and Therapy Response in a Large Single-Centre Cohort of Patients with Periodic Fever with Aphtous Stomatitis, Pharyngitis and Cervical Adenitis Syndrome. Francesca Ricci[1], Antonella Meini[1], Lucio Verdoni[1], Laura Dotta[1], Marta Bolis[1], Marco Berlucchi[2], Gianfranco Savoldi[3] and Marco Cattalini[1]. [1]Pediatric Immunology and Rheumatology Unit, Brescia, Italy, [2]Department of Pediatric Otorhinolaryngology, Brescia, Italy, [3]Angelo Nocivelli Institute of Molecular Medicine, Brescia, Italy

Background/Purpose: PFAPA (Period Fever with Aphtous stomatitis, Pharyngitis and cervical Adenitis), is a periodic syndrome described for the first time in 1987 by Marshall et al. It is characterized by regular recurrence of fever which associates with aphtous lesions, pharyngitis and cervical adenitis. In 1999 the criteria for diagnosis of PFAPA were formulated by Thomas. PFAPA is considered peculiar to the pediatric age, but in the recent literature there are a few case reports of this syndrome in adults.

Methods: We reviewed medical records of 239 children meeting clinical criteria for PFAPA syndrome.

Results: in our cohort (136 males and 103 females) fever began at a mean of 2.1 ± 2 years of age. The majority of the children had a symptoms onset before the fifth year of life but 9% of the patients had a later onset. Since all the other clinical criteria but age were met in these latter patients, the diagnosis of PFAPA was confirmed. In 37% of the patients' family history there was at least one first- or second-degree relative who underwent tonsillectomy for recurrent fevers or suffered from recurrent fevers in childhood. The PFAPA episodes lasted a mean of 4 ± 2 days, with an interval between episodes of 28.3 days. Fever was accompanied by pharyngitis (98%), cervical adenitis (64%), aphtous stomatitis (39%) and abdominal pain (33%). The parents reported in 10% of their children that some symptoms (irritability, nausea, headache) appeared 24–48 hours before fever onset and the parents learned to interpret these symptoms as prodromes of the PFAPA attack. All the patients were treated with oral steroids, using a single somministration of 1mg/kg of prednisone equivalent the first day of fever. All the patients had a prompt response to steroid treatment and only 12% of the patients experience a free-interval shortening.

In 57% of our patients the disease resolved spontaneously, after a mean period of 3 years. Medium age at PFAPA resolution was $5,7 \pm 3$ years of age.

Among patients who underwent tonsillectomy (25%) only a single patient didn't have complete resolution. Mutation analysis for FMF, HIDS and TRAPS in this patient was negative.

When clustering our population for age at onset (less than 1 yr, 1–5 years, more than 5 years) we observed that patients with onset within the first year had a significantly longer duration of disease ($p<0.00002$).

Conclusion: our study indicates that the 5 years of age cut-off is too strict for considering PFAPA diagnosis and that the onset before the first year of life predicts a longer disease duration. As previously reported abdominal pain are a relevant feature in PFAPA, almost as common as aphtous stomatitis. We also observed "prodromic symptoms" quite commonly. A significant proportion of family histories is indicative of possible PFAPA Syndrome in the first or second degree relatives of our patients. In our experience prednisone in a single given dose is highly efficacious in managing patients with PFAPA, and the free interval reduction happens in a minority of patients. Finally, even though limited to few patients, tonsillectomy had a very high rate of success in our experience, probably due to very strict selection of patients undergoing tonsillectomy.

2026

High Prevalence of Cervical Spine and Temporomandibular Joint Involvement in Patients with Juvenile Idiopathic Arthritis. Nikolay Tzaribachev[1], Catrin Tzaribachev[1] and Bernd Koos[2]. [1]Center for Rheumatic Diseases, Bad Bramstedt, Germany, [2]University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background/Purpose: Detection of involvement of temporomandibular joints (TMJ), which are frequently affected by juvenile idiopathic arthritis (JIA), is only possible on Gadolinium enhanced MRI (GdMRI). A comparative X-ray study on adults with JIA and RA showed a more frequent involvement and destruction of the dens axis in JIA patients. The aim of the retrospective study was to evaluate the involvement of the cervical spine (CS) in children with JIA.

Methods: The first GdMRI TMJ examinations of consecutive patients with defined JIA from our center were re-evaluated for involvement of the cervical spine (dens axis, DA). Clinical parameters were recorded – CS pain on motion, CS limited range of motion (LOM), peripheral disease activity (PDA, peripheral active, painful and LOM joints) and medication. MRI examinations were re-evaluated for TMJ and dens axis arthritis defined as synovitis and synovial hypertrophy.

Results: 40 children (29 female) were included. 21 patients had RF neg. polyarthritis, oligoarthritis was present in 11, ERA and PsA in 4 children equally. Median age at GdMRI was 14 (7–18) years. Median disease duration was 36 (4–192) months. At first GdMRI 47% were on NSAIDs with a median duration of 10 (1–36) months, 49% were on MTX (sc 10–15 mg/m^2) with a median duration of 12 months and 13 patients were on TNF Alpha inhibitors with a median duration of 3 (2–12) months. 10 patients showed no PDA but of these only one had no inflammation in DA and TMJ on GdMRI. 34 patients had arthritis in DA (25) or TMJ (33) and 25 patients had arthritis in both DA and TMJ. Out of all patients only 8 had pain and/or LOM of the CS, which were always correlated with arthritis in TMJ and DA on GdMRI. In all other patients CS involvement was silent. Current medication was not able to control disease activity.

Conclusion: considering that long-term sequels of CS arthritis in adults with JIA tend to be more severe than in RA patients, the high frequency of silent CS arthritis should be kept in mind, where GdMRI is the only tool to detect the extent of disease activity of the cervical spine and help with a proper monitoring of the treatment effect.

Chronic Nonbacterial Osteomyelitis of the Mandible in Children: a Tertiary Center Experience. Daniela S. Ardelean[1] and Ronald M. Laxer[2]. [1]Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) of the mandible is a rare osseous autoinflammatory disease. Diagnosis is based on characteristic clinical, laboratory and imaging features. Our aim was to describe the phenotype and response to treatment in children diagnosed at our center.

Methods: We conducted a retrospective chart review of the patients diagnosed and followed for at least 6 months from 1988–2012. Parameters recorded at the last 2 visits (within 6 months interval): pain, abnormal ESR/CRP, imaging features, including bone and/or soft tissue edema, bone enhancement, ongoing medication and/or surgery. For each of these parameters, an average score was calculated based on the presence (1) or absence (0) of that feature; 0.5=presence at 1 visit, absent/unknown at the 2nd visit. Mean and SEM were reported. Statistical comparison between 2 groups was performed with t-test. P<0.05 was considered statistically significant

Results: 11 patients (8F:3M) with CNO of the mandible were reviewed (Table). Mean age at diagnosis was 8.4 years (3–11 yrs.); follow-up, 67±13 months (9–155 mos). 6/11 (55%) children were followed primarily/exclusively by rheumatologists and 5, by dental surgeons. 9/11 (82%) had isolated CNO of the mandible; the last 2, each had 1 additional femoral lesion. 3/11 children (27%) had other immune manifestations: insulin resistance and antibodies against insulin receptors, autoimmune neutropenia and bilateral granulomatous uveitis. Mandibular biopsies were performed in 10/11 patients (91%); all were consistent with CNO. Blood and bone cultures were negative in all patients tested. All patients were prescribed antibiotics. 5/11 (45%) children underwent surgical interventions. 6/6 patients followed by rheumatologists received NSAIDs; 1/6 (17%), also received biphosphonates. No patient was treated with steroids or biological therapy. The patients followed by surgeons had pain at the last 2 visits (0.62±0.13), vs those followed by rheumatologists (0) (P=0.02).

Table. Demographic, clinical, laboratory, imaging features and treatment approaches in pediatric CNO of the mandible

	Demographics			Treatment					Last 2 visits		
Pt #	Gender	Age at dx (years)	FU (ms)	Medication	# of surgeries	Pain	Abnormal ESR/CRP	Radioogical signs of inflammation	Treatment	Type of treatment	Primary specialist
1	F	11	28	0	1		uk	uk	0	None	Dentist
2	F	10	144	Naproxen prn	5	1	uk	uk	0.5	Surgery; None	Dentist
3	F	6	86	0	2	0.5	uk	0.5	0.5	Surgery; None	Dentist
4	F	10	123	0	4	0.5	uk	uk	0	Surgery; None	Dentist
5	M	5	9	0	1	uk	uk	uk	0.5	Surgery; None	Dentist
6	M	13	73	Naproxen	4	0	0.5	0.5	1	NSAID	Rheum
7	F	10	24	Indocid	0	0	uk	uk	0	None	Rheum
8	F	10	58	Naproxen	0	0	1	0	1	NSAID	Rheum
9	M	3	39	Naproxen	0	0	1	uk	0	None	Rheum
10	F	5	95	Indocid;Pamidronate	0	0	0	0.5	1	NSAID	Rheum
11	F	10	55	Naproxen, then Indocid	0	0	1	uk	0	None	Rheum

FU=follow-up; dx=diagnosis; uk=unknown.

Conclusion: Pain at the last 2 follow-ups is common in patients that received only operative treatment. A major shift in the therapeutic approach of CNO of the mandible occurred in the last two decades, from exclusive surgical interventions to anti-inflammatory therapy and rheumatologic follow-up. CNO of the mandible can be associated with other immune manifestations.

2028

Medication Adherence and Quality of Life in Children with Rheumatic Disease. Stacey E. Tarvin[1], Lisa M. Macharoni[2], Christine M. Raches[1] and Nicole M. Taylor[2]. [1]Riley Hospital for Children, Indianapolis, IN, [2]University of Indianapolis, Indianapolis, IN

Background/Purpose: Children with rheumatic diseases are often prescribed complex medication regimens. Medication side-effects may have a negative impact on physical appearance and subsequently impact adherence. In children with rheumatic disease, non-adherence can lead to serious consequences such as decreased physical function, increased symptomology, and hospitalizations requiring more invasive and costly treatment. The purpose of this study is to examine parent and child report of medication adherence in children with rheumatic disease ages 8–18 years. Additionally, this study examines the extent to which health related quality of life (HRQOL) is associated with medication adherence. Adherence will also be examined for its relationship to other psychosocial variables, risk of depression and pain.

Methods: One hundred fifty children with rheumatic disease followed at a Midwest children's hospital were recruited at an outpatient rheumatology appointment. Each parent-child pair completed measures assessing adherence to the child's medication regimen, demographic variables, HRQOL assessed using the Pediatric Quality of Life Rheumatology module (PedsQLRM), depressive symptoms assessed using the Childhood Depression Inventory, and reported pain as assessed by visual analog scale and individual items from the aforementioned standardized measures. Appropriate parametric statistics were completed to determine statistical significance of demographic variables. MANOVAs were used to determine the relationship between HRQOL, pain, risk of depression and medication adherence. Data was analyzed using SPSS 16.0.

Results: Eighty-seven percent of the children in the sample were prescribed medication for their illness. Parent and child report of medication compliance showed significant correlation (r=.229, p<.009). Twenty percent of parents reported that their child missed two or more doses of medication within the prior week. One third of patients reported missing two or more doses of medication within the past week, with 8.6% reported missing 4 or more doses. One-third of the sample reported complete compliance with medications. Demographic variables that were significantly related to medication compliance were parent marital status (p<.032), parent employment (p<.043), gender (p<.038), and child age (p<.034). Medication non-adherence was associated with trouble sleeping (p<.032), report of side effects (p<.011), worry (p<.013) and total quality of life score (p<.046) based on child report. Neither risk of depression nor pain, as reported on the PedsQLRM, were found to be significantly related to medication compliance.

Conclusion: Rates of medication non-adherence in this population are high, and while children and their parents report a moderate correlation, results suggest that parents underestimate their child's medication adherence. A better understanding of key demographic, psychosocial and HRQOL variables associated with adherence may allow the physician to address non-adherence directly with at risk patients.

Reliability of Scoring a Disease Damage Measure for Juvenile Localized Scleroderma. Kathryn S. Torok[1], Suzanne C. Li[2], Christina Kelsey[1], Mara L. Becker[3], Fatma Dedeoglu[4], Robert C. Fuhlbrigge[5], Gloria Higgins[6], Sandy D. Hong[7], Maria F. Ibarra[3], Ronald M. Laxer[8], Thomas G. Mason II[9], Marilynn G. Punaro[10], Elena Pope[11], Egla C. Rabinovich[12] and Katie G. Stewart[10], [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]Joseph M Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [3]Children's Mercy Hospital, Kansas City, MO, [4]Boston Childrens Hosp, Boston, MA, [5]Childrens Hospital, Boston, MA, [6]PRCSG-Cincinnati Children's Hospital Medical Center, Columbus, OH, [7]U of Iowa Children's Hosp, Iowa City, IA, [8]The Hospital for Sick Children, Toronto, ON, [9]Mayo Clinic Rochester, Rochester, MN, [10]Texas Scottish Rite Hospital, Dallas, TX, [11]Hospital for Sick Children, Toronto, ON, [12]Duke University Medical Center, Durham, NC

Background/Purpose: In order to more accurately capture disease activity and damage in juvenile Localized Scleroderma (jLS) and to develop an accepted outcome measure for treatment protocols, an LS-focused Childhood Arthritis and Rheumatology Research Alliance subgroup developed clinical disease activity and damage measures. The objective of this abstract is to discuss the assessment of the reliability and validity of the LS Damage Score in jLS. The LS Damage Score includes four domains (dermal atrophy, subcutaneous atrophy, dyspigmentation hyper/hypo pigmentation, and skin thickness of lesion center) which are scored for all affected sites.

Methods: Thirteen pediatric rheumatologists and a dermatologist attended a 2-day workshop meeting to review LS clinical measures. Raters ranked 13 jLS patients on damage domains at 2 time points. Patients were presented to raters in random order in efforts to reduce recall bias. For each patient, raters were told which anatomic sites to assess (1–2/patient). Physicians also completed Physician Global Assessment of Disease for Activity and Damage (PGA-A; PGA-D). To examine construct validity, we hypothesized that the LS Damage Score would have a moderate correlation to PGA-D and a low correlation to PGA-A. Spearman's rho was calculated to quantify the relationship with clinical parameters, and intraclass correlation coefficients (ICC) were examined to determine inter/intra rater reliability (0.20–0.39 low, 0.40–0.59 moderate, 0.60–0.79 high).

Results: Median age of LS patients was 13 years (IQR = 9.5–17) and the most common subtype was linear scleroderma (4 limb, 4 head). Mean LS Damage Scores ranged from 3.96 to 16.46 (max score 24); PGA-D ranged from 14.54 to 53.48 (max score 100). There was a low correlation between the LS Damage Score and both PGA-D and PGA-A (ρ =.11, ρ =.14). Raters demonstrated moderate/high inter and intra-rater reliability for the LS Damage score, and low/moderate inter and intra-rater reliability for PGA-D. Among the domains, hypopigmentation showed the lowest inter-rater reliability (Table 1).

Table 1. Inter-rater and intra-rater reliability of LS Damage score

Domains	Round 1 ICC (95% CI)	Round 2 ICC (95% CI)
LS Damage Score:		
Inter-rater reliability	**0.56** (.37, .79)	**0.63** (.43, .83)
Intra-rater reliability *(median, [range])*	*0.81* [0.53–0.93]	
PGA-D:		
Inter-rater reliability	**0.19** (.08, .44)	**0.28** (.14, .54)
Intra-rater reliability *(median, [range])*	*0.51* [0.09–0.75]	
LS Damage Score parameters: inter-rater reliability		
Dermal Atrophy	**0.37** (.23, .58)	**0.48** (.33, .67)
Subcutaneous Atrophy	**0.42** (.28, .62)	**0.51** (.36, .70)
Dyspigmentation:		
Hyperpigmentation	**0.66** (.52, .81)	**0.71** (.58, .84)
Hypopigmentation	**0.22** (.12, 40)	**0.24** (.13, .42)
Skin Thickness of lesion center	**0.61** (.46, .77)	**0.53** (.39, .73)

Conclusion: The LS Damage Score had moderate-high reliability between and among raters, with hyperpigmentation, skin thickness center, and dermal atrophy contributing most to the total score. Overall, the inter-rater agreement of damage components increased in session 2. The PGA-D performed well within the rater's repeat assessment, but poorly in regards to inter-rater reliability. The poor correlation between PGA-D and LS Damage Score may reflect MD inclusion of extracutaneous manifestations (ECM), such as facial disfigurement. In post-hoc analysis, when patients with facial linear scleroderma were removed, the correlations of PGA-D with LS Damage Score increased (ρ =.317). Additional studies are needed to fully evaluate this measure.

A Multi-Modal Amplified Musculoskeletal Pain Treatment Program: Associations of Previous Pharmacotherapy with Subsequent Outcomes. Cara M. Hoffart[1], Pamela Weiss[1], David D. Sherry[2], Chris Feudtner[3] and Margaret Stineman[4]. [1]The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Division of General Pediatrics, Children's Hospital of Philadelphia; University of Pennsylvania Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA, [4]The University of Pennsylvania, Philadelphia, PA

Background/Purpose: Management of Amplified Musculoskeletal Pain (AMP) in children (i.e. juvenile primary fibromyalgia, complex regional pain syndrome, neuropathic pain, central sensitization) remains controversial. Common practice includes the combination of potent medications with physical and behavioral therapy. We hypothesize that functional restoration and pain reduction in patients with AMP does not require potent medications. The objective of this study is to describe a cohort of children with AMP treated with a non-pharmacological highly structured protocol and to test whether previous utilization of pharmacotherapy (as a marker of initial severity) predicts subsequent treatment program outcomes.

Methods: We conducted a retrospective inception cohort study of children with AMP treated with a non-pharmacological multidisciplinary program at The Children's Hospital of Philadelphia between January 2008 and December 2011. All pain medications were discontinued prior to program entry. The primary outcome, function, was measured with the Functional Disability Inventory (FDI) and Bruce Treadmill Score. We tested whether previous utilization of pharmacotherapy predicted treatment outcomes using mixed effects linear regression.

Results: We identified 168 individuals with AMP treated over 4 years. The median age was 14 (IQR: 13, 16 years), and three-quarters of the patients were females. The median pain duration was 18 months (IQR: 9, 36 months) and the median pain score 0–10 at program entry was 7 (IQR: 5, 8). Previous pharmacologic drug therapy exposure included opioids (N=53, 32%), immunosuppressants (N=15, 9%), neurotropics (N=35, 21%), and psychotherapeutics (N=32, 19%). Median FDI at baseline and program completion were 22 (IQR: 15, 30) and 5 (IQR: 3, 18), respectively. Median Bruce Treadmill Score at baseline and program completion were 586.5 (IQR: 415.5, 712.5 seconds) and 796 (IQR: 750, 908 seconds), respectively. Median pain score at program completion was 4 (IQR: 0, 7), which is significantly improved from baseline (P=0.01). Change in FDI and Bruce Treadmill Score from start to finish of the program were significantly improved (P<0.001). After adjustment for patient characteristics, there was no significant variation in functional outcomes associated with previous exposure to pharmacotherapy (P=0.43).

Conclusion: These results suggest that in comparison to those children whom were medication naïve and "less severe", those children with "more severe" disease who were receiving potent pain medications prior to the start of the program were as likely to have restoration of function. Additionally, these results demonstrate that regardless of treatment before program entry, children with AMP have successful restoration of function without pharmacotherapy. Prospective studies are warranted to determine long-term efficacy and effectiveness of this multi-disciplinary program.

Safety and Efficacy of Anakinra in Patients with Deficiency of Interleukin-1 Receptor Antagonist.

Gina A. Montealegre[1], Adriana Almeida de Jesus[2], Dawn C. Chapelle[1], Paul Dancey[3], Joost Frenkel[4], Annet van Royen-Kerkhoff[4], Ronit Herzog[5], Giovanna Ciocca[6], Rafael F. Rivas-Chacon[6], Ann M. Reed[7], Nicole Plass[8], Ivona Aksentijevich[9], Polly J. Ferguson[10], Suvimol C. Hill[11], Edward Cowen[12] and Raphaela T. Goldbach-Mansky[13]. [1]NIAMS, Bethesda, MD, [2]National Institute of Arthritis Musculoskeletal and Skin Disease, National Institutes of Health, Bethesda, MD, [3]Memorial University of Newfoundland, St Johns, [4]University of Utrecht, Utrecht, Netherlands, [5]Cornell University, New York, NY, [6]Miami Children's Hospital, Miami, FL, [7]Mayo Clinic, Rochester, MN, [8]National Institutes of Health Clinical Center, Bethesda, MD, [9]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, [10]University of Iowa Carver College of Medicine, Iowa City, IA, [11]NIH Clinical Center, Bethesda, MD, [12]NCI/NIH, Bethesda, MD, [13]Translational Autoinflammatory Diseases Section NIAMS NIH, Bethesda, MD

Background/Purpose: Deficiency of interleukin-1 receptor antagonist (DIRA) is a neonatal-onset autoinflammatory syndrome caused by mutations in *IL1RN* gene and clinically characterized by a perinatal onset of pustular dermatosis, aseptic multifocal osteomyelitis and marked elevation of acute phase reactants. Individual reports have been shown that these patients present a prompt response to the recombinant human IL-1 receptor antagonist (IL1Ra) anakinra. However, long-term efficacy and safety of anakinra treatment in DIRA patients have not been assessed. Thus, the objectives of this study were to assess the clinical and laboratory findings of patients with DIRA followed at the NIH and enrolled in a natural history study to assess long-term outcomes in autoinflammatory syndromes patients.

Methods: Eight patients with a genetically confirmed diagnosis of DIRA were followed longitudinally. Demographic, clinical and laboratory findings and response to treatment variables were collected for each patient at the enrollment and subsequent clinical visits. Statistical analyses were performed using unpaired t- test with Welch's correction.

Results: Four (50%) patients were female. Age at disease onset ranged from 1 to 15 days of life and age at anakinra starting was 11 (2–114) months. Five patients had been receiving anakinra 4 to 54 months prior to the study enrollment. Before IL1Ra was started, 5 patients presented with intermittent fever; all 8 patients had mild to severe pustular rashes and 5 had nail abnormalities. Various degrees of multifocal osteomyelitis were observed in all patients and 3 had odontoid non-fusion. Unspecific lung disease was observed in 3 patients, 2 patients presented thrombotic events and 2 had vasculitis. Laboratory findings prior to anakinra showed mild to severe anemia and increased white blood cell (WBC) count in all 8 patients and thrombocytosis in 5. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were elevated in all 8 patients. At the last follow-up visit (6 to 48 month), time on anakinra was 35 (20–102) months and anakinra doses ranged from 2.1 to 5.1 (median: 3.5) mg/kg/day. At that time, none of the patients had developed new osteomyelitis lesions, nor pustular skin manifestations and CRP and ESR were 0.21 (0.016–0.579) mg/dL and 7 (3–13) mm/h, respectively. All patients fulfilled criteria for inflammatory and clinical remission, except for one patient that had CRP of 0.579mg/dL. While acute phase reactants had almost normalized at the time of the first NIH visit, a decrease in the platelets (502 $\pm$ 180.0 vs. 273 $\pm$ 32.3 $\times$ 10^3cells/mm^3, p=0.016) and in the WBC (15.96 $\pm$ 6.56 vs. 8.44 $\pm$ 1.98 $\times$ 10^3cells/mm^3, p=0.023) was seen and took longer to normalize. Three serious adverse events were observed: rash and pneumonia in one patient and subarachnoid bleed in one patient. Anakinra was considered well tolerated and an increase of opportunistic or recurrent infections was not observed within the enrolled patients.

Conclusion: DIRA patients on treatment with anakinra for 20–102 months presented with a sustained clinical and laboratory response and no patient developed novel inflammatory lesions while on treatment. Anakinra is well tolerated and none of the patients has discontinued therapy.

Results From a Multicentre International Registry of Familial Mediterranean Fever: Impact of Genetic and Environment Factors On the Expression of a Monogenic Disease in Children.

Seza Ozen[1], Erkan Demirkaya[2], Gayane Amaryan[2], Isabelle Koné-Paut[2], Adem Polat[2], Turker Turker[2], Patricia Woo[2], Yosef Uziel[2], Consuelo Modesto[2], Martina Finetti[2], Pierre Quartier[2], Efimia Papadopoulou-Alataki[2], Sulaiman Al-Mayouf[2], Giovanna Fabio[2], Romina Gallizzi[2], Luca Cantarini[2], Joost Frenkel[2], Susan Nielsen[2], Michael Hofer[2], Antonella Insalaco[2], Huri Ozdogan[2], Nicolino Ruperto[2] and Marco Gattorno[2]. [1]Hacettepe University, Ankara, Turkey, [2]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Familial Mediterranean Fever (FMF) is an auto-inflammatory disease caused by mutations in a single gene, the *MEFV* gene. The disease is very frequent among patients with an eastern European ancestry but may occur in much lesser frequencies in other ethnic groups as well. We present the disease characteristics in patients living in the eastern Mediterranean and how they compare to the eastern Mediterranean patients living in western Europe and to the Europeans.

Methods: The data was extracted from the Eurofever project, that accomplished a multicenter registry for the autoinflammatory diseases in Europe and neighboring countries. From this registry 346 FMF patients whose diagnosis was confirmed were the subjects of this study. We developed a disease severity score that was modified from and harmonized the existing scores in the literature.

Results: The disease manifestations such as fever, abdominal pain, acute phase reactants were similar in all patients. The genetics and demographic features with increased acute phase reactants were similar among eastern Mediterranean patients whether they lived in their countries or western European countries. The mutation distribution of the European patients displayed differences and they were diagnosed later. On the other hand when features suggesting a severe disease expression were analysed, the eastern Mediterranean patients living in Europe were significantly different than those living in their countries and were similar to European patients and displayed milder phenotypic manifestations, with less attacks, less arthritis and less chest pain. When multivariate analysis was applied to assess the effect of residence, not ethnicity but the country of residence positively influenced the severity of disease presentation. Other independent variables were the presence of M694V (also on a. single allele), a positive family history together with disease delay.

Conclusion: We clearly demonstrate the actual impact of environment and genetic factors on the expression of a monogenic disease. We suggest that since FMF is the disease of the innate immune system and since the mutated protein is a component of the inflammasome triggered by microbial products, environmental factors including diet have a significant effect. Epigenetic studies are now in order.

2033

Infliximab Is an Effective Therapy in Pediatric Renal Sarcoidosis.

Elisa Wershba, Laura Lewandowski, Heather Van Mater and Egla C. Rabinovich, Duke University Medical Center, Durham, NC

Background/Purpose: Renal sarcoidosis is an unusual form of a rare multisystem disease, and there is little data to guide therapy. The cytokines implicated in chronic sarcoidosis include IL-8, IL-12, and TNF-α, suggesting potential role of treatment with an anti-TNF-α monoclonal antibody. There are case reports of the use of infliximab in refractory sarcoidosis in adults, and one report in a child with renal sarcoid. There are no current studies investigating infliximab as a steroid sparing agent in pediatric sarcoidosis.

Methods: We identified 3 pediatric patients with an established diagnosis of sarcoidosis based on systemic manifestations, non-caseating granulomas on biopsy, and exclusion of other granulomatous diseases. They had biopsy proven renal manifestations and were treated with infliximab. A retrospective chart review was conducted to evaluate the disease course. All patients had failed a steroid taper prior to initiation of

infliximab. Creatinine levels and concurrent steroid doses were plotted in relation to initiation of infliximab. IRB exemption was granted prior to the start of chart review.

Results: In all 3 patients, a linear plot demonstrates that infliximab allowed for successful tapering of steroids without flare, and stabilization/improvement of serum Cr.

Patient 1 was diagnosed with sarcoidosis at 14 years with an elevated ACE and hepatic biopsy revealing multiple non-caseating granulomas. She was treated with corticosteroids. During an attempt to taper, she developed acute renal failure warranting a renal biopsy showing granulomatous interstitial nephritis. After failure with mycophenolate mofetil and IV methylprednisolone pulses, she was treated with infliximab. IV steroids were weaned over the next 4 months then discontinued. Four months later, her oral steroids were weaned completely. She remains stable on infliximab and mycophenolate mofetil.

Patient 2 was diagnosed at 10 years with sarcoid based on systemic manifestations and lymph node granulomas. She developed renal manifestations 4 years later. She failed chronic steroids and methotrexate. After initiation of infliximab, her steroids were weaned, her creatinine stabilized. After developing renal cell carcinoma, infliximab was discontinued, with an increase in daily oral steroid and eventual renal failure.

Patient 3 was diagnosed with sarcoidosis at 12 years based on elevated serum ACE level, uveitis, and conjunctival biopsy with non-caseating granulomas. His serum Cr was 2 mg/dL prior to initiation of steroids and methotrexate. Methotrexate was an ineffective steroid sparing agent. After initiation of infliximab, he was able to wean on his oral steroids, with stabilization of serum Cr. His Cr rose when infliximab was held for cellulitis and returned to baseline when reinitiated.
Conclusion: Infliximab is an effective steroid sparing agent in our pediatric patients with renal sarcoidosis.

Magnetic Resonance Imaging Is a Reliable Tool to Monitor Chronic Non-Bacterial Osteomyelitis in Children.
Grazia Minardo[1], Giulia Zanon[1], Simone Corradin[1], Pietro Zucchetta[1], Giorgia Martini[1], Fabio Vittadello[1] and Francesco Zulian[2]. [1]University of Padua, Padua, Italy, [2]University of Padua, Padova, Italy

Background/Purpose: Chronic non-bacterial osteomyelitis (CNO) is a rare condition characterized by inflammatory bone lesions with no detectable infectious agents. It may be unifocal (U-CNO) or multifocal (M-CNO) and have a monophasic or relapsing course. Various laboratory or imaging parameters have been proposed as possible outcome measures but none has been validated, yet.

The present study was aimed to define the role of laboratory parameters and imaging tools (MRI and bone scinti-scan, BS) in detecting disease activity in patients with CNO.

Methods: Patients with CNO, lasting longer than 6 months, were followed every 3–4 months. Laboratory inflammatory parameters (ESR, CRP, WBC, Hb, PLT, SAA), MRI and BS were performed at diagnosis, at the time of clinical relapse or at least yearly in all patients. Clinically, active disease was considered in presence of bone pain needing analgesics or second line therapy. Bone lesions were considered active on MRI in the presence of bone marrow edema (BME) associated to soft tissue inflammation (STI) including perilesional effusion and edema. As resulted in recent sport medicine studies (1), BME alone was not considered a parameter of activity (3). Disease activity at BS was defined by signal intensity, number and extension of hyperactive sites. A single radiologist and nuclear medicine practitioner, blinded on patients' clinical status, reviewed all MRI and BS independently. Sensitivity, specificity and positive and negative predictive value (PPV, NPV) for disease activity detection of laboratory markers, MRI and BS were calculated by comparing data with clinical status of the patients at different time points.

Results: 16 CNO patients entered the study. 9 had UF-CNO, 7 had MF-CNO, mean age at disease onset 10,8 years (range 2.33–18.5), 54% were female. Disease duration at diagnosis was longer in patients with UF-CNO (14.2 vs 10.1 months). Localized bone pain was the leading symptom at onset in all patients; systemic symptoms, such as fever and fatigue, were more frequent in MF-CNO. At onset WBC was normal, CRP and ESR were elevated in 69.2%, especially in MF-CNO. After median 3 years follow up, 43.7% of patients had no symptoms and were off-therapy. At disease onset, all patients were evaluated by MRI and BS then, during the follow-up, 11 patients repeated BS once (T1), 13 patients repeated MRI once (T1) and 8 twice (T2). At disease onset, all 16 MRI showed BME with STI. Of the 21 follow up MRIs, 5 (23%) completely normalized, 7 (33%) showed only BME, 9 (42%) showed pathological changes. At disease onset all BS showed active lesions with mean 2.1 hyperactive sites (range 1–5). Of the 12 follow-up BS, 5 showed total remission, 3 partial remission and 4 persistent disease activity.

MRI sensitivity ranged between 0.83 and 1.00, specificity 1.00, PPV was 1.00, NPV ranged between 0.86 and 1.00. BS sensitivity was 0.83, specificity 0.74, PPV 0.76, NPV 0.80. Laboratory parameters correlated poorly with disease clinical status.

Conclusion: MRI is a reliable tool for monitoring CNO in pediatric patients. BS overestimates disease activity, especially in UF-CNO. Laboratory inflammatory parameters are of limited utility. A validation study in a larger patients' cohort is needed to confirm these preliminary findings.

2035

Performance of Icbd (International Criteria for Behcet's Disease) in Iranian Children with Behcet's Disease.
Nahid Shafaie, Bahar Sadeghi Abdollahi and Fereydoun Davatchi. Shariati Hospital-Tehran Univ, Tehran, Iran

Background/Purpose: ICBD is the new international criteria for diagnosis/classification of Behcet's Disease, created in 2006. The scoring system for ICBD depends on 2 points for ocular lesions and genital ulcers each, and 1 point for each of oral aphtosis; skin manifestations; vascular manifestations; and positive-pathergy test. Three or more points are required to consider the patient as a case of Behcet's Disease. The validity of the criteria has been confirmed for Iranian patients in 2010. To determine the performance of ICBD in Iranian children with Behcet's Disease (Diagnosed

before the age of 16), the sensitivity of ICBD is compared with 4 most commonly used diagnosis/classification criteria (Revised Japan, O'Duffy, International Study Group [ISG] and Classification Tree).

Methods: According to the data registry for Behcet's Disease patients in Rheumatology Research Center, Tehran University of Medical Sciences, Iran, all the patients diagnosed before the age of 16 (during 1975–2011) are included in the study. The fulfillment of each of the 5 criteria is evaluated for each patient and the sensitivity of different sets of criteria in childhood BD is calculated.

Results: 180 children out of 6813 BD patients (2.64 %, CI: 0.4) are selected (86 male and 94 female). The mean age was 10.7 years (SD: 3.4, CI: 0.5), mean duration 8.2 years (SD: 6.7), mean follow up 5 years (SD: 6.2) and the diagnosis delay 3.2 years (SD: 2.7).

I) 174 patients fulfilled the ICBD criteria (sensitivity 96.66%); 171 patients met Classification Tree criteria (sensitivity 95%); 156 patients for Revised Japan criteria (sensitivity 86.66%); 126 patients met ISG criteria (sensitivity 70%) and 103 patients fulfilled O'Duffy criteria with sensitivity of 57.2%.

II) Although the majority of the patients met all 5 sets of criteria, some of the patients could fulfill different combinations of criteria sets as described below.

88 patients (48.88%) met all 5 criteria; 30 patients (16.66%) fulfilled ICBD, Japan and Classification Tree; 26 patients (14.44%) met all the assessed criteria except for O'Duffy; 7 patients (3.9%) met all the assessed criteria except for ISG; 6 patients (3.33%) could meet only ICBD and Classification Tree; 6 patients (3.33%) met ICBD, Classification Tree and ISG; 5 patients (2.77%) met all the assessed criteria except for Japan; 3 patients (1.66 %) fulfilled ICBD and Japan Criteria; 2 patients (1.1 %) fulfilled ICBD, O'Duffy and Classification Tree; 2 patients (1.1 %) fulfilled ICBD, Japan and O'Duffy; 1 patient (1.1%) met ISG and Classification Tree and 4 patients (2.22 %) could not meet any of the 5 assessed criteria.

Conclusion: The most sensitive criteria for Iranian children with Behcet's disease was ICBD, followed by Classification Tree, Japan and ISG and O'Duffy. The higher sensitivity in ICBD, Classification Tree and Japan criteria may be explained by the prominence of the eye involvement in children and the importance of ocular lesions in these criteria sets.

Children's Hospital of Pittsburgh Pediatric Onset En Coup De Sabre and Parry-Romberg Syndrome Cohort. Kristin M. Brown[1], Darren Smith[2], Christina Kelsey[3], Katherine Kurzinski[4] and Kathryn S. Torok[3]. [1]University of Pittsburgh, Pittsburgh, PA, [2]university of Pittsburgh Division of Plastic and Reconstructive Surgery, Children's Hospital of Pittsburgh, Pittsburgh, [3]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [4]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA

Background/Purpose: Localized scleroderma is an autoimmune disease characterized by disfiguring thickening and fibrosis of the skin and underlying soft tissues; the majority of cases have onset in childhood. Multiple subtypes exist, including linear scleroderma, which is most common in children. Linear scleroderma involving the face and scalp is known as En Coup de Sabre (ECDS) and hemifacial atrophy that is often associated with ECDS or occurs alone is known as Parry Romberg Syndrome (PRS). Extracutaneous features are often associated with ECDS and PRS, including neurological, eye and dental abnormalities.

Methods: The patients and their associated disease characteristics of our Children's Hospital pediatric onset ECDS/PRS cohort were evaluated from years 2002–2012. This included demographic features, lesion characteristics, laboratory characteristics, extracutaneous manifestations, quality of life, family history, and response to medical and surgical treatment. Descriptive statistics were employed.

Results: Twenty patients in our ECDS/PRS cohort were identified, with mean age onset 5.9 years (± 4.5), time to diagnosis 1.9 years (± 2.3), female to male ratio (3:2), and majority were Caucasian (85%). The majority of patients had features of both cutaneous disease (ECDS) and hemifacial atrophy (PRS). The most common symptom at presentation was hyperpigmentation (65 %), followed by skin and subcutaneous depression (50%). Erythema or violaceous discoloration was common in patients presenting with active disease (55%). Antibody positivity for ANA, ss-DNA and histone ranged from 25–44%. Seven patients (35%) had neurological manifestations including the following: a pontine lesion associated with chronic ataxia, dysarthria, and cognitive dysfunction; a cerebral infarction; and white matter lesions on MRI ipsilateral to cutaneous lesion. One-third of the cohort patients had either an ophthalmologic or dental complication. Autoimmune thyroiditis was the most common familial autoimmune disease (20% 1st degree, 35% 2nd degree).

The majority of cohort patients were treated with prednisone and methotrexate; treatment was successful in halting disease and reversing a few active features, though less successful in reversing chronic disease damage. Mean follow-up of cohort 30.2 months (± 19.4). Four patients underwent surgical repair with lipoaspirated fat injection for volume restoration. Stereophotogrammetry 3-D imaging was used to objectively quantify facial morphology to assess patients' response to both surgical and medical therapy.

Conclusion: Our ECDS and PRS cohort demonstrated similar clinical findings of disease and associated ECM compared to other studies. Screening with brain MRI, ophthalmologic and dental evaluations for associated complications is reasonable in light of one-third of our cohort having neurologic, ophthalmologic, or dental involvement, some of which had a serious impact on daily living and QOL.

Poor Quality of Gout Care Is Strongly Associated with Higher Gout-Related Health Care Utilization. Jasvinder A. Singh[1] and Joshua Richman[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]UAB School of Medicine, Birmingham, AL

Background/Purpose: Proponents of improving quality of gout care have suggested various gout quality indicators, but no study to date has shown the link between good quality care and improved outcomes. The aim of the study was to assess whether appropriate good quality care for gout, including uninterrupted urate-lowering therapy (ULT) and achievement of target serum urate <6 mg/dl, is associated with reduced gout-related utilization.

Methods: This retrospective study utilized the Veterans Affairs (VA) administrative and clinical databases claims from fiscal years 2002 to 2010, using the presence of an International Classification of Diseases, ninth revision (ICD-9) code, 274.xx in a VA outpatient or inpatient visit to define the gout cohort. A 90-day or longer filled VA prescription for allopurinol, probenecid or febuxostat in a patient with gout was considered as exposure to ULT. The two independent predictors of interest were Medication Possession Ratios (MPRs) for each ULT and achievement of target sUA < 6 mg/dl. The MPR denominator was the number of days from index to the exhaustion of the last prescription and the numerator was days of medication supplied over that period from first to last prescription. We used regression analyses with a quasi-Poisson distribution given the type of data, limiting the analyses to patients with >=1-year of follow-up. The outcome was counts of visits with an offset for the number of years in the cohort.

Results: The gout cohort consisted of 376,421 patients with mean age 70 years, 99% were male and 61% were married. Their exposure to various medications for the treatment of gout was as follows: allopurinol, 70%; febuxostat, 0.3%; and probenecid, 3%. Mean follow-up was 6.2 years (standard deviation, 2.9). Higher MPRs for allopurinol, febuxostat, and probenecid were associated with significantly lower outpatient, urgent care, emergency room and overall visits (all p-values <0.0001; **Table 1**). Achievement of target sUA < 6 mg/dl was associated with significantly lower gout-related outpatient, inpatient, urgent care and emergency room visits (all p-values <0.012; **Table 1**). Conversely, a higher proportion of sUA levels >=6 mg/dl was associated with higher gout-related outpatient, inpatient, urgent care and emergency room visits (all p-values <0.00001).

Table 1. Association of MPR for three ULTs and of achievement of target sUA < 6mg/dl with future gout-related health care utilization

	Incidence rate ratio* [p-value]				
	Any visit	**Outpatient visit**	**ER visit**	**Urgent care**	**Inpatient**
Adherence to ULT					
Allopurinol MPR (n=231,131)	**0.50 [p<0.00001]**	**0.50 [p<0.00001]**	**0.32 [p<0.00001]**	**0.38 [p<0.00001]**	**0.80 [p=0.00005]**
Febuxostat MPR (n=759)	**0.64 [p=0.0031]**	**0.66 [p=0.0074]**	**0.38 [p=0.00073]**	**0.28 [p=0.0078]**	0.85 [p=0.661]
Probenecid MPR (n=10,514)	**0.47 [p<0.00001]**	**0.47 [p<0.00001]**	**0.45 [p<0.00001]**	**0.40 [p=0.00374]**	0.89 [p=0.63]
Achieving target sUA					
Any sUA <6 mg/dl (n=161,069)	0.99 [p=0.11]	**1.02 [p=0.0116]**	**0.79 [p<0.00001]**	**0.57 [p<0.00001]**	**0.90 [p=0.0105]**
Proportion of sUA levels >=6 mg/dl (n=161,069)	**1.72 [p<0.00001]**	**1.62 [p<0.00001]**	**2.43 [p<0.00001]**	**4.05 [p<0.00001]**	**2.87 [p<0.00001]**

*Incidence rate ratio for each outcome is for patients with MPR of 1 versus 0

Conclusion: This is the first study to find evidence of association of poor quality of care (lower ULT MPR and non-achievement of target sUA) with greater gout-related health care utilization, especially for emergency room and urgent care visits. Improvement in quality of gout care may reduce expensive gout-related utilization of emergency room and urgent care resources.

2038

Expanding Access in Rheumatology Specialty Care in New Mexico Via an Innovative Community Outreach Program. Arthur Bankhurst[1], Sanjeev Arora[1], Summers Kalishman[1], Jeannie F. Boyle[1], Cynthia Olivas[1], Rebecca Monette[1], Dara Som[2] and Yolanda Hubbard[1]. [1]University of New Mexico School of Medicine, Albuquerque, NM, [2]University of New Mexico School of Medicine, Albuquerque

Background/Purpose: The main objective of this innovative program is to provide training to Primary Care Clinicians (PCCs) in rural communities so they can provide best practice care to patients with rheumatologic disorders.

Methods:: The Rheumatology TeleECHO Clinic uses state-of-the-art technology to link PCCs with the Rheumatology Specialist here at University of New Mexico (UNM). Weekly clinics consist of short didactics, patient case presentations, and open discussions. In order to evaluate the effectiveness of the program, PCCs were given a pre and post self- efficacy survey. Eligibility criteria to participate in the survey included: attend three or more rheumatology TeleECHO clinic sessions or attend an on-site training session with Rheumatology clinic staff, participant completed 50% of questions on either the pre or post survey, and participant is not a TeleECHO clinical facilitator.

Results: Participation in the Rheumatology TeleECHO clinic has improved access to care for patients with rheumatologic disorders as well as improved self-efficacy of PCCs providing specialty rheumatologic care. There was a small but significant increase in overall self-efficacy from pre to post survey evaluation.

Conclusion: Since the induction of the program, 18 Centers of Excellence for Rheumatology have been established throughout New Mexico. A Center of Excellence is defined as a PCC who attends the two-day clinical training at UNM Rheumatology Clinic, who presents 10 individual cases to the Project ECHO™ Rheumatology TeleECHO Clinic and who is recognized in their local communities as a PCC with competence in rheumatologic care. To date, there have been 99 clinics held, with 1,265 attendees, and 644 patient case presentations. In addition, 28 primary care clinicians have attended the two day training program at UNM Rheumatology Clinic. In partnership with the American College of Rheumatology, providers were given the opportunity to enroll in the Advanced Rheumatology Course (ARC). A total of 25 providers have enrolled. As of today, 16 providers have graduated; nine other clinicians are actively working to complete the 16 modules. Project ECHO's TeleECHO Rheumatology clinic is an innovative approach that brings greater access for all patients in New Mexico.

2039

Uveitis Surveillance Through Lean-Six Sigma for Quality Assurance in Juvenile Idiopathic Arthritis. Anjali Patwardhan[1], Kelly Kelleher[1], Jeffery Hoffman[1], Karla B. Jones[2], Stacy P. Ardoin[3] and Charles H. Spencer[1]. [1]Nationwide Childrens Hospital, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Ohio State University, Columbus, OH

Background/Purpose: Chronic asymptomatic iridocyclitis occurs in 10–20% of all patients with JIA leading to insidious but progressive morbidity and possible blindness. Patients with JIA-associated uveitis need to be seen by an ophthalmologist regularly. Lean thinking is based upon the following principles. 1) Identifying the customer value (value adding steps) and alleviating the redundant parts of the process hence minimize waste 2) developing an effective flow production 3) eliminate backflows 4) using "pull" techniques 5) striving to perfection.

Methods: Various tools of lean methodology were used throughout the development of a new process of uveitis surveillance for JIA patients visiting rheumatology clinics at Nationwide Children's Hospital. Problems were identified after paper chart review of 400 JIA patients. The key performance indicators used were 1) number of patients given eye examination request sheet 2) number of eye examination results received back from eye doctors & 3) number of eye examination results documented and available during the clinic visit. The hospital has switched to electronic medical records (EPIC) since 2006. It was found on baseline data that uveitis surveillance was inadequate and ineffective in paper charts. We identified the need to develop an electronic health record-based new surveillance process which can be more effective in improving communication between eye doctors, rheumatologists and patients/parents. We performed value stream mapping by stake holders to sketch the initial process and identify bottlenecks. Delphi survey was then used to reach consensus decisions, though out the project time. We charted current state, future state & ideal state and performed gap analysis. We then developed a pareto- matrix. The project methodology was based on the Deming's PDSA cycles. We developed a standard work based on our initial PDSA cycles. We evaluated the new process through KPIs.

Results: The uveitis surveillance process improved inter-team communication and quality of care. Inbuilt alerts in the process for presence of eye disease and missed eye appointments prompted rheumatologist to take appropriate timely action.

Conclusion: Implementation of lean tools and thinking can make provide smarter, quicker, easier, better and safer uveitis patient care delivery to the JIA patients by use of an effective uveitis surveillance process. We also emphasize the importance of seeing lean thinking as a part of the larger management shift towards planning for changes in mindsets and work places. This new surveillance process can be horizontally deployed for diabetic eye surveillance and drug toxicity monitoring in rheumatic patients on immunosuppressant.

2040

Provisions of Quality Driven Care in Childhood-Onset Systemic Lupus Erythematosus. Matthew C. Hollander[1]. Jessica M. Sage[2], Alexandria J. Greenler[2], Tadej Avcin[3], Michael W. Beresford[4], Graciela Espada[5], Marisa S. Klein-Gitelman[6], Michael Henrickson[2], Tsz-Leung Lee[7], Joshua D. Pendl[2], Marilynn G. Punaro[8], Jennifer L. Huggins[2], Anne M. Stevens[9] and Hermine I. Brunner[2], [1]Seattle Children's Hospital, Seattle, WA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]International Investigator Consortium for MAS Diagnostic Criteria, Ljubljana, Slovenia, [4]Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom, [5]Childrens Hosp Ricardo Gutierrez, Buenos Aires, Argentina, [6]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [7]Queen Mary Hospital, Hong Kong, Hong Kong, [8]Texas Scottish Rite Hospital, Dallas, TX, [9]University of Washington, Seattle, WA

Background/Purpose: Quality Indicators (QI) are retrospectively measurable elements of practice performance for which there is evidence or consensus that can be used to assess the quality of care provided. Previous QI have been developed for adult systemic lupus erythematosus. This project was the second of two Delphi surveys used to identify QI in childhood-onset systemic lupus erythematosus (cSLE) that could serve as international benchmarks to assess quality of patient care.

Methods: Based on medical literature and a previous Delphi survey, a second survey was created and distributed via email to 348 individuals on the member lists of EULAR, PANLAR, PRINTO, PRES, ACR and CARRA. 265 individuals (76%) responded via online or paper survey, with 173 (65%) participants identifying themselves as pediatric rheumatologists. The survey design included a brief summary of relevant literature for each topic prior to the question. Participants had access to the referenced articles for each question through a hyperlink in the survey. Consensus was set at 80% agreement and blank responses were excluded from the analysis.

Results: Important process QI (IF/THEN statements) addressing the following treatment domains achieved consensus: bone health, education on cardiovascular risk factors, lupus nephritis and hypertension management, medication management, ophthalmological surveillance, transfer of care, use

of chronic steroids in cSLE management, and vaccinations (Table 1). A substantial amount of support was noted for clinical evaluation of disease activity every 3 months (71%), while the support for safety monitoring for medications was variable. The safety monitoring variables that reached consensus are displayed in Table 2.

Table 1. Quality indicators for patients with cSLE which yielded at least 80% consensus

Lupus Nephritis and Hypertension Management

1) IF a cSLE patient without known lupus nephritis has developed daily proteinuria of >500 mg or clinically relevant worsening of GFR/urinary sediment, THEN a kidney biopsy should be performed.

2) IF a patient has known lupus nephritis, THEN a clinical assessment for cSLE should occur at least every 3 months regardless of disease activity.

3) IF a cSLE patient has lupus nephritis plus evidence of ongoing proteinuria >500mg/day, THEN an angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blockers (ARB) should be prescribed, unless there are contraindications.

4) IF a patient has LN and/or hypertension, THEN disease co-management with a nephrologist should be considered.

Medication Management

5) IF a patient has cSLE, THEN antimalarial therapy should be prescribed, unless there are contraindications.

6) IF a cSLE patient is receiving a dose of steroids not acceptable for chronic use, then an attempt should be made to taper steroids.

7) IF a patient with cSLE is unable to decrease the dose of steroids acceptable for chronic use, THEN the addition of a steroid-sparing agent, or an increased dose of an existing steroid-sparing agent should be considered.

8) IF a cSLE patient is treated with medications, THEN laboratory surveillance for medication safety should be done at regular intervals (Table 2).

9) IF a patient has cSLE, THEN vaccination against influenza and encapsulated organisms should be prescribed, unless there are contraindications.

Bone Health with cSLE

10) IF a patient has received chronic systemic steroids, THEN the patient should have bone mineral density testing documented in the medical record.

11) IF baseline bone mineral density testing is outside of normal limits (Z-score ≤-2.0), THEN bone mineral density should be re-measured after one year.

12) IF a patient is on any steroid therapy, THEN calcium and vitamin supplementation should be recommended after 3 months.

Ophthalmological Surveillance

13) IF a cSLE patient is treated with corticosteroids, THEN an eye screening does not need to occur prior to treatment.

14) IF a cSLE patient is treated with corticosteroids, THEN eye screening should be done at least annually.

15) IF a cSLE patient is treated with antimalarial therapy, THEN eye screening should be done at least annually.

Transfer of Care with cSLE

16) IF an adolescent has cSLE, THEN a transition plan should be carefully designed to facilitate transfer of care to the appropriate adult health-care providers.

Education on Cardiovascular Risk Factors

17) IF a patient has cSLE, THEN education about cardiovascular risk factors should occur in regular intervals with the parent and the patient age 13 years or older.

Table 2. Medication Monitoring Table

IF a cSLE patient is treated with medications, THEN laboratory surveillance for medication safety should be done regularly as is documented below:

Interval	AZA	NSAIDS HCQ	1-monthly IV CTX	MMF/MPA 3-monthly CTX Cyclo-A	Prednisone	Rituximab	TNF-antagonists
Baseline	CBC Liver			CBC Liver		CBC	CBC
Every month			CBC Liver Renal				
Every 3 months	CBC Liver			CBC Liver Renal		CBC	CBC
Every 6 months	Renal	Liver Renal					Liver
Every 9 months		UA					
Every 12 months		CBC			CBC Renal Liver	Liver	Renal

AZA=azathioprine; HCQ= hydroxchloroquine; CTX=cyclophosphamide; MMF/MPA=mycophenolate mofetil/mycophenolic acid; Cyclo-A=cyclosporine-A; CBC=complete blood count and differential; Liver=liver function tests; Renal=renal function tests; UA=urinary protein excretion

Conclusion: Delphi questionnaires are efficient instruments for reaching international consensus for minimal standards of quality care for cSLE. Additional efforts will help refine items for which there is currently not consensus. The new QI identified through this project can be used to define and standardize best practices for children and adolescents with cSLE across the world.

2041

Improving Access and Patient Education in Rheumatology: the Gout Shared Medical Appointment; a Quality Improvement Initiative. Alicia J. Zbehlik[1] and Nicole M. Orzechowski[2]. [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth-Hitchcock Med Ctr, Lebanon, NH

Background/Purpose: Patients experience long waits for consultations in Rheumatology at Dartmouth-Hitchcock Medical Center (DHMC). The cause of this is multi-factorial, including provider referral patterns, patient preferences, constraints on clinic time in an academic medical practice, and system bottlenecks such as lack of available exam rooms. Regardless of the cause, the results are the same: potential for delayed treatment for rheumatologic diseases, pain and anxiety for patients, frustration for referring providers and poor practice performance. While matching capacity to demand improves access, increasing practice capacity without encroaching on physician teaching, research, and administrative time is challenging. To capitalize on this opportunity, the Rheumatology Access Team (RATE) adapted a shared medical appointment (SMA) to meet the needs of gout patients.

Methods: Following an SMA guide developed at DHMC, the team mapped an "ideal" pathway of patient care for the appointment; verified adequate patient volumes; secured access to meeting space and exam rooms; and produced written and electronic patient education materials. A physician, scribe, nurse, and SMA coordinator staff the SMA. The physician evaluates patients in brief, private exams and develops individual care plans while the scribe uses a template to record the history of present illness and exam findings. The nurse greets patients, takes vital signs, and facilitates discussion amongst the participants. The SMA coordinator schedules patients and enters lab orders (signed by the provider) to ensure labs are actionable at the time of the appointment. Feedback elicited from patients and staff informed iterative changes in the appointments using a continual improvement model. Billing is the equivalent of a regular gout follow up appointment.

Results: A gout SMA takes place every two months and includes education on diet and metabolic syndrome per patient requests. The current appointment has the capacity to serve up to 12 patients in a two-hour session for one provider. This increases potential new patient capacity in the clinic by a net of 4 visits per SMA. During the course of multiple interventions, access to Rheumatology improved steadily from April 2011 to April 2012 (107 to 56 days) but it has not reached our goal of 14 days. Patient satisfaction with the availability of an appointment in Rheumatology "when you wanted it" increased from 35% to 60% excellent during the intervention.

Conclusion: A gout SMA may improve access in Rheumatology, however a robust change in the wait times will require an increase in referrals to the SMA. The SMA is an excellent opportunity to practice principals of team-based iterative change. The SMA allows providers to operate at their level of training by eliminating order and data entry and allows them to focus on patients rather than computers during the visit. This model has potential to work within the framework of an accountable care organization. Further study of outcomes will be helpful in determining if these appointments provide value for patients and the institution beyond increasing access.

Enhancing Shared Decision-Making in Juvenile Idiopathic Arthritis. Jessica M. Sage, Ellen A. Lipstein, William B. Brinkman, Carole M. Lannon and Esi M. Morgan DeWitt. Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a chronic disease that requires long-term treatment. Patients and families face multiple treatment decisions over the course of illness that can often be complex. This project aims to improve the engagement of patients and families facing JIA treatment decisions, improve information exchange with care providers, and identify opportunities for a shared decision-making (SDM) intervention.

Methods: Sixteen pediatric rheumatology providers were recruited from four children's hospitals using purposive and snowball sampling to include a range of provider types (eg, nurse, physician, trainee) with unique approaches to working with families or a particular interest in education or decision-making. The providers participated in semi-structured interviews eliciting how they interact with patients and families in developing and adapting treatment plans. Interviews were audio-recorded and transcribed verbatim. The transcripts were coded by a multi-disciplinary team to determine major and minor themes. Based on the themes identified in the semi-structured interviews, multiple choice questions were presented at a conference of

pediatric rheumatology providers to enrich understanding of data from individual interviews. An audience response system captured the pattern of responses and helped the research team facilitate conversation about the reasons for variation among multi-site participants (n=24). Data was retained for analysis and detailed notes were taken.

Results: Treatment decisions were consistently initiated by the physician, with other providers focused on educating families and assessing barriers to treatment adherence. Physicians differed in their preferred treatment algorithm and options initially presented to families. Physicians' decisions focused on expected improvement with treatment, rather than treatment risks or family preferences. Providers described a range of approaches to inform families about treatment options and to tailor information according to providers' perceptions of a family's information needs, level of comprehension or mood (eg, anxiety). Participants described including families in the decision to initiate JIA treatment after limiting the options to fit the clinical situation and the physician's preferences. In contrast, providers described multiple methods for involving families in decisions related to the implementation of chosen treatments. Family preferences were also seen as particularly integral in the decision to stop treatment after symptom remission.

Conclusion: Decision-making on initial JIA treatment is largely driven by treatment guidelines and physician preferences. Such guidelines do not exist around treatment discontinuation and in that scenario family preferences are more likely to be considered. The uncertainty around standardized procedures for treatment discontinuation may make it the ideal time for a shared decision-making intervention (SDM) between the patient, family and provider. Next steps include engaging a stakeholder panel consisting of providers, educators and parents to discuss and evaluate possible interventions.

2043

Documentation of Improvement Over 2 Months in Osteoarthritis, Systemic Lupus Erythematosus, Spondyloarthropathy and Gout Similarly to Rheumatoid Arthritis According to Function, Pain, Patient Global Estimate and RAPID3 On a Multidimensional Health Assessment Questionnaire (MDHAQ). Isabel Castrejón[1], Martin J. Bergman[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Taylor Hospital, Ridley Park, PA

Background/Purpose: The health assessment questionnaire (HAQ) and multidimensional HAQ (MDHAQ) were developed initially to assess patients with rheumatoid arthritis (RA). The most feasible method to ensure that each RA patient completes an MDHAQ at each visit is for the receptionist to present an MDHAQ to each patient with any diagnosis when registering for the visit, to complete in the waiting area. Data are then available for patients with all diagnoses, providing an opportunity to compare baseline scores and change over 2 months in patients with any rheumatic disease to patients with RA.

Methods: In the private practice of one rheumatologist, every patient with any diagnosis completes a 2-page MDHAQ at every visit before seeing the doctor. The MDHAQ includes 0–10 scores for physical function (MDHAQ-FN), pain and patient global estimate (PATGL), and a 0–30 score for routine assessment of patient index data (RAPID3), an index of the 3 patient self-report RA Core Data Set measures. Mean scores for individual measures and RAPID3 were compared at first visit and 2 months later for 141 new patients with 5 diagnoses: RA (n=39), osteoarthritis (OA) (n=41), systemic lupus erythematosus (SLE) (n=14), spondyloarthropathy (SpA) (n=23) and gout (n=24). Statistical significance was assessed by t test for change from baseline to 2 months later within each diagnostic group, and by analysis of variance (ANOVA) for change across diagnostic groups.

Results: Mean MDHAQ-FN scores at baseline ranged from 1.5 to 2.5, and from 1.1 to 1.9 two months later, documenting improvement of 9.4–26.8% in all diseases but OA ($p <0.05$ for all patients and RA). Mean pain scores at baseline ranged from 4.2 to 5.9, and from 3.0 to 4.7 two months later, documenting improvement of 20.2–35.3% in the 5 diagnoses ($p <0.05$ for all patients, RA, OA and gout). Mean PATGL at baseline ranged from 4.3 to 5.6, and from 3.3 to 5.0 two months later, documenting improvement of 11.2–30.4% ($p \leq 0.05$ for all patients, RA, OA and gout). RAPID3 scores at baseline ranged from 10.1 to 13.7, and from 7.4 to 11.3 two months later, documenting improvement of 16.8–27.5% ($p <0.05$ for all patients, RA, OA and gout). No differences for mean change from baseline to 2 months between diagnostic groups were statistically significant.

	Baseline Mean (SD)	2 months Mean (SD)	P*	Mean change**	% improvement
Physical function (MDHAQ-FN) (0–10)					
All patients (n = 141)	2.2 (1.7)	1.7 (1.7)	0.0028	0.34	15.5%
RA (n = 39)	2.5 (2.1)	1.9 (1.8)	0.02	0.65	26.0%
OA (n = 41)	1.8 (1.4)	1.8 (1.7)	0.95	0.01	0.6%
SLE (n = 14)	1.5 (1.3)	1.1 (1.7)	0.21	0.36	24.0%
SpA (n = 23)	2.2 (2.1)	1.6 (1.7)	0.06	0.59	26.8%
Gout (n = 24)	1.6 (1.3)	1.4 (1.8)	0.45	0.15	9.4%
Pain (0–10)					
All patients	5.2 (2.9)	3.8 (3.0)	<0.0001	1.40	26.9%
RA	5.2 (2.6)	3.9 (3.2)	0.014	1.32	25.4%
OA	5.3 (2.9)	3.9 (2.8)	0.0012	1.45	27.4%
SLE	4.2 (2.8)	3.0 (3.0)	0.10	1.18	28.1%
SpA	5.9 (3.1)	4.7 (3.0)	0.10	1.19	20.2%
Gout	4.9 (3.3)	3.2 (3.1)	0.02	1.73	35.3%
Patient global estimate (PATGL) (0–10)					
All patients	5.0 (2.7)	4.0 (3.1)	<0.0001	0.98	19.6%
RA	4.9 (2.8)	3.4 (3.0)	0.004	1.49	30.4%
OA	5.2 (2.5)	4.6 (3.0)	0.09	0.62	11.9%
SLE	4.5 (2.9)	3.3 (3.5)	0.14	1.18	26.2%
SpA	5.6 (2.6)	5.0 (2.9)	0.31	0.63	11.3%
Gout	4.3 (2.8)	3.3 (3.2)	0.05	1.00	23.3%
RAPID3 (0–30)					
All patients	12.1 (6.3)	9.5 (7.3)	<0.0001	2.71	22.2%
RA	12.6 (6.4)	9.2 (7.6)	0.0037	3.46	27.5%
OA	12.4 (6.0)	10.3 (6.9)	0.012	2.08	16.8%
SLE	10.1 (6.2)	7.4 (7.8)	0.089	2.71	26.8%
SpA	13.7 (6.7)	11.3 (7.1)	0.096	2.42	17.7%
Gout	10.9 (6.6)	8.0 (7.4)	0.024	2.88	26.4%

*P, repeated measures t test (change from baseline over 2 months for each disease)
**P not significant by ANOVA, comparison between RA and each diagnosis for mean change from baseline for all measures.

Conclusion: Disease severity and improvement over 2 months according to MDHAQ-FN, pain, PATGL and RAPID3 scores were similar to RA in OA, SLE, SpA and gout. Physicians appropriately view these 5 diagnoses as distinct, based on differences in their pathophysiology and treatments, emphasizing the need for a knowledgeable physician to establish distinct, accurate diagnoses in individual patients. However, from the patients' perspective, most rheumatic diseases are viewed more similarly than may be recognized by health professionals, documented by MDHAQ/RAPID3 scores.

Trying to Improve Care: A Review of the Morbidity and Mortality Conference in the Division of Rheumotology. Michelle Batthish[1], Shirley Tse[1], Brian M. Feldman[1], G. Ross Baker[2] and Ronald M. Laxer[1]. [1]The Hospital for Sick Children, Toronto, ON, [2]The University of Toronto, Toronto, ON

Background/Purpose: The morbidity and mortality conference (M&MC) is one of academic medicine's most visible fora for discussion of adverse events and errors; however it is unclear whether the M&MC is effective in its role to help reduce these events and thereby improve healthcare. In some contexts, the M&MC has been shown to be an effective forum for addressing patient safety and quality improvement competencies. However, there is marked variability in the process and standards for the M&MC. Little is known regarding the extent to which adverse events and errors are actually discussed in the M&MC. To describe the frequency of reported events as well as system improvement recommendations in the M&MC within the Division of Rheumatology at the Hospital for Sick Children (SickKids).

Methods: A five-year retrospective review of the M&MC minutes within the Division of Rheumatology at SickKids was completed. Descriptive data including the number of cases, attendance and types and location of reported events were collected. All events were categorized using an adaptation of the National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP) index. Recommendations were classified in the categories used by the Institute for Safe Medication Practices (ISMP) Canada.

Results: Between January 2007 and December 2011, a total of 30 regularly scheduled M&MCs were held. The mean attendance was 19 individuals per session. Eighty-one cases were reviewed (mean 2.7 cases/ session) with 2 reported deaths and 4 planned transfers to the intensive care unit. The most common type of events were related to "miscommunication" (35.8% of cases) followed by events related to a treatment/test/procedure

(23.5%). There were fewer events related to medications such as adverse drug reactions (12.3%), medication administration errors (8.7%). Most events occurred in the in-patient setting (40%) followed by the Medical Day Care Unit (26%). Category A events ("an event that has the capacity to cause error") were the most common (46.9%). The next most common events were Category C events ("an event occurred that reached the patient but did not cause harm") followed by Category E events ("an event occurred that may have contributed to or resulted in temporary harm and required intervention") with 24.7% and 19.8% of the cases, respectively. A total of 89 recommendations were made over the 5 year period. Just over half of these were classified as "information" according to ISMP Canada (58.4%). This was followed by 11 "rules and policies" recommendations (12.4%) and 8 "reminders, check lists and double check systems" recommendations (9%). There were 36 action items generated from these recommendations; 36% have been completed while 27.8% are ongoing.

Conclusion: The M&MC within the Division of Rheumatology reviews a varied number of adverse events. Increased reporting and study of adverse events and errors can lead to system improvements and safer health care. Further research is needed to develop innovative models of the M&MC, which focus on patient safety and systems improvement. This could lead to the creation of a standard review process which has greater potential to improve quality of care.

2045

Treatment Patterns and Monitoring of Serum Uric Acid Levels in a Large Cohort of Gout Patients in the United States: Is There Room for Improvement? Yong Chen[1], Kasem S. Akhras[2], Michael Grabner[1], Rima H. Tawk[3] and Ralph Quimbo[1]. [1]HealthCore, Inc., Wilmington, DE, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]University of Illinois at Chicago, Chicago, IL

Background/Purpose: Currently, there are no guidelines in the United States on monitoring serum uric acid (sUA) levels in gout and gout treatment patterns. However, there are guidelines from the European League Against Rheumatism gout task force and the British Society for Rheumatology/British Health Professionals in Rheumatology. Our aim was to assess treatment patterns for gout and laboratory sUA monitoring in a managed care population in the U.S., relative to international guidelines.

Methods: Data were extracted from the HealthCore Integrated Research Database (HIRD^{SM}), which contains integrated medical and pharmacy claims and laboratory result data from a large commercial U.S. health insurer. Eligible patients had either ≥2 medical claims for gout (ICD-9-CM code = 274) or ≥1 pharmacy claim for gout medications (allopurinol, colchicine, febuxostat, probenecid, sulphinpyrazone) between 01/01/2008 and 05/31/2011. The date of the earliest relevant claim was set as the index date. We included patients ≥18 years of age on index date, with ≥12 months of continuous eligibility pre-index date. Key guidelines selected in this study included initiating dose of allopurinol, mean time to dose escalation, maximum dosing levels, and sUA lab testing. We focused on a subgroup of patients initiating urate-lowering therapies (ULTs) after a new gout diagnosis (no pre-existing gout at baseline). Additionally, for a subset of patients with available electronic laboratory data, sUA levels were assessed within a year prior to and after initiation of ULTs. Treatment patterns were assessed until end of eligibility or end of the study period using descriptive statistics.

Results: We identified 93,546 eligible patients; 26% (n=24,555) were female and 35% (n=32,729) initiated ULTs. Mean ($\pm$ SD) age was 58$\pm$14.83 years and Charlson Comorbidity Index score was 1.35$\pm$ 2.02. Allopurinol accounted for 96% (n=31,388) of all first-line ULT fills, followed by probenecid (n=1,032) and febuxostat (n=309). No patients initiated sulphinpyrazone. Compared to guidelines, the mean starting dose of allopurinol was higher (213$\pm$114.48 mg/day vs. 100mg) and mean time to dose escalation was longer (24$\pm$28.6 weeks vs. 2–4 weeks); however, maximum daily dosing levels (244$\pm$117.12 mg/day) were within the recommended range. While 61% (n=19,843) of patients who initiated ULT had ≥1 sUA test prior to ULT initiation, only 34% (n=11,256) had ≥1 sUA test pre- and post-ULT initiation. Among 10,926 patients with sUA levels above target range (sUA >6 mg/dL) prior to ULT initiation, only 11% (n=1,190) achieved the goal of sUA ≤6mg/dL within a year of ULT initiation.

Conclusion: Comparing the results of this study to international guidelines shows room for improvement, specifically in laboratory monitoring of sUA levels relative to gout treatment. The results may be due in part to lack
of U.S. guidelines regarding the appropriate frequency of sUA testing relative to starting ULT, dose adjustment, and achievement of target sUA levels.

Matching of Patients' Actual and Desired Roles in Treatment Decision Making and Trust in Physicians. Akiko Aoki[1], Akiko Suda[2], Shouhei Nagaoka[3], Mitsuhiro Takeno[4], Yoshiaki Ishigatsubo[4], Tatsuto Ashizawa[5], Osamu Takahashi[6], Sachiko Ohde[7] and Sadayoshi Ohbu[8]. [1]Tokyo Medical University Hachioji Medical Center, Tokyo, Japan, [2]Yokohama Minami Kyousai Hospital, Yokohama, Japan, [3]Yokohama Minami Kyosai Hospital, Yokohama, Japan, [4]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [5]Tokyo Medical University Hachioji Medical Center, Chuo-ku,Tokyo, Japan, [6]St Luke's life science instutute, Chuo-ku, Tokyo, Japan, [7]St.Luke's Life of Science Institute, Tokyo, Japan, [8]Rikkyo University, Tokyo, Japan

Background/Purpose: Shared decision-making (SDM), in which the physician and patient work together through all phases of the decision-making process, has been of increasing significance. But the previous studies reported not all patients preferred SDM. This study explored rheumatoid arthritis (RA) patients' preferences and experiences for participation in treatment decision making at the Japanese rheumatology clinics. In addition, we examined how often their actual roles matched their desired roles, and whether the concordance between actual and desired roles was associated with trust in physicians.

Methods: A cross-sectional study was performed using a self-administered anonymous questionnaire between October and December 2010 on 406 RA outpatients who consecutively visited 3 hospitals in Japan. The following variables were investigated; (1) the patients' actual roles; their experiences when the current DMARDs were decided. (2) The patients' desired roles; their preferences for participation in treatment decision making. The patients were asked to choose one actual and one desired role of the following three options; #1 passive role; your doctor chooses the best drug for you. #2 collaborative role; you and your doctor decide the drug together. #3 active role; you choose the best drug and recommend it to your doctor. (3) Patient's trust in the physicians and adherence to the treatment. (4) Patients' evaluations of physician's attitudes of patient-centeredness. (5) The demographic data (e.g. age, gender, and educational status) and the RA-specific characteristics including the past and current use of disease modifying anti-rheumatic drugs (DMARDs). Multivariate analyses were used to assess the relationship between matching of patients' actual and desired roles and patients' trusts.

Results: The response rate was 58.6%. 82% were women, and the mean age was 65.1 $\pm$ 10.1 years. 26.8% of the patients perceived that the doctor chose the DMARDs for them. However, the majority (62%) of the patients preferred to collaborate with their doctors in making the treatment decision. The patients who want the passive roles in the decision making were more likely to have their preferences met than patients who wish to collaborate the doctors (98% vs. 42%, p<0.01). The overall concordance rate was 62%. In multivariate analyses, patients' attitudes of patient-centeredness and the concordance between patients' actual and desired roles were independent predictors of trust in physicians.

Conclusion: Physicians need to assess the decision making preferences on an individual basis to gain the patients' trust in physicians.

2047

Impact of a Rheumatology Consultation Service in Hospitalized Patients. Shirley L. Chow[1], Dafna D. Gladman Gladman[2] and Heather McDonald-Blumer[3]. [1]University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Mt. Sinai Hospital, Toronto, ON

Background/Purpose: Rheumatologists provide hospital in-patient consultation for urgent and emergency referrals. In an increasingly cost-conscious, accountable, and integrated health-care system, the appropriate role of specialty care is under scrutiny. There is currently little information on the influence of inpatient rheumatology consultation on patient outcome.

Tuesday, November 13

The aims of our study were 1) To describe the nature of the hospital rheumatology consultations 10 years apart for educational merit 2) To determine whether a hospital rheumatology consultation service alters diagnostic accuracy, changes or expedites treatment, and whether treatment recommendations was adopted by the primary service. 3) To evaluate if needs are met by assessing the complexity of the rheumatology consult service referrals

Methods: Consecutive patients seen on the consultation service at an academic university hospital from July 1 2010 to December 31 2010 were recorded in a logbook. Using a standardized case form, the charts were reviewed and the patient's demographic information, admitting diagnosis, reason for consultation, referring service, final rheumatologic diagnosis, duration of hospital stay, treatment implemented and outcome were recorded. These were compared to a similar review in 1999.

Results: 268 patients were recorded in the log books over the 6 month period in 2010. These included 163 females and 105 males with a mean age of 55 years (range 19 to 92 years). This is more than the 238 consults seen over a 10 month period in 1999.

The most common diagnoses seen included: 62 connective tissue diseases (23%), 59 crystal induced arthritis (22%), 25 vasculitis (9%), 22 polyarthritis (8%); 15 osteoarthritis (6%); 14 regional syndromes (5%); 14 infections (5%); 10 spondyloarthritis (4%), and 8 others (3%). The remaining 38 had non-rheumatologic conditions (14%). This is similar in breadth as 1999.

The consults were requested from different services, but most commonly internal medicine at 104 (39%). There were 82 emergency referrals (31%), 158 urgent referrals (59%), and 28 non-urgent referrals (10%). The rheumatology team helped establish the diagnosis in 177 patients (66%) and confirmed the diagnosis in 57 consults (21%). 74 of 80 patients with swollen joints had their joints aspirated or injected (93%). 94 patients had steroids or disease modifying therapy initiated or adjusted. 126 patients had follow-up with a rheumatologist (47%).

Conclusion: The rheumatology hospital consultation service provides consultation from various specialties for a variety of rheumatic diseases, thus providing an excellent educational experience. Most referrals were for emergent or urgent rheumatic diseases. The service helped establish or confirm the diagnosis and helped initiate treatment. In general the suggestions were adopted by the team.

2048

Four Physician Global Assessments for Overall Status, Inflammation, Damage, and Unexplained Symptoms Are Useful in Usual Care of Patients with Osteoarthritis, Fibromyalgia, Systemic Lupus Erythematosus, and Spondyloarthropathy, As Well As Rheumatoid Arthritis. Isabel Castrejón[1], Martin J. Bergman[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Taylor Hospital, Ridley Park, PA

Background/Purpose: A physician global estimate (DOCGL) is important in clinical decisions concerning patients with rheumatoid arthritis (RA), and often is the most efficient of the 7 RA Core Data Set measures to distinguish active from control treatments in RA clinical trials. DOCGL is designed to assess inflammatory activity, but may be influenced by organ damage and "unexplained" chronic pain syndromes. Therefore, 3 subscale DOCGL visual analog scales (VAS) have been developed to estimate level of *a*) inflammation, *b*) damage, and *c*) "unexplained symptoms," in addition to overall status, reflecting the expertise of the rheumatologist concerning whether patient symptoms result primarily from one of these 3 bases. We analyzed the 4 DOCGL estimates for inflammation, damage, "unexplained" and overall status in consecutive patients with 5 rheumatic diagnoses: RA, osteoarthritis (OA), fibromyalgia (FM), systemic lupus erythematosus (SLE), and spondyloarthropathy (SpA).

Methods: The study was conducted in the private practice of one rheumatologist. All consecutive patients, regardless of diagnosis, complete a patient questionnaire, and are assigned four DOCGL estimates: overall status, inflammation, damage to any organ (e.g., joint, kidney) and "unexplained symptoms." Overall DOCGL was scored 0–10; the other 3 scales were scored 0–3 and recoded to 0–10, the current practice. Physician estimates at first visit of consecutive patients for the 4 DOCGL scales were analyzed in 5 diagnostic categories: RA (n=39), OA (n=41), FM (n=15), SLE (n=14) and SpA (n=23). Mean (standard deviation) and Spearman correlations were computed for overall physician global estimate with subscale estimates for inflammation, damage and "unexplained," as well as patient global estimate of status.

Results: DOCGL for overall status ranged from 2.6 to 5.0, highest for patients with FM (5.0), followed by RA (3.9), SpA (3.9), OA (3.6), and SLE (2.6). Physician subscale estimates were higher for inflammation than for damage or "unexplained" in RA, SLE, and SpA; higher for damage than for inflammation or "unexplained" in OA; and higher for "unexplained" than for inflammation or damage in FM (Table). Highest correlations of overall DOCGL were seen with physician subscale estimates for inflammation in RA, SLE, and SpA; with damage in OA; and with "unexplained" in FM.

Table. Mean (± SD) of 4 global estimates, and Spearman correlations between physician global for overall status and three physician subscale estimates as well as patient global estimate, according to diagnosis

	RA N = 39	OA N = 41	FM N = 15	SLE N = 14	SpA N = 23
Mean (± SD) for four 0–10 physician global estimates					
Overall Status (0–10 scale)	3.9 (±1.6)	3.6 (±1.9)	5.0 (±2.1)	2.6 (±1.9)	3.9 (±1.8)
Inflammation (0–10)	4.2 (±2.5)	1.3 (±2.0)	1.2 (±1.6)	2.4 (±2.6)	4.4 (±2.4)
Damage (0–10)	1.8 (±2.3)	3.2 (±2.7)	0.7 (±1.4)	1.2 (±2.2)	1.9 (±2.9)
Unexplained symptoms (0–10)	1.2 (±2.1)	0.9 (±2.5)	6.4 (±3.6)	1.5 (±3.1)	1.9 (±2.7)
Spearman correlations with overall physician global estimate					
Inflammation	0.79**	0.09	−0.52	0.61*	0.54*
Damage	0.23	0.51*	−0.22	−0.05	0.13
Unexplained Symptoms	0.01	0.17	0.67*	0.57	0.51*
Patient global estimate	0.41*	0.43*	0.07	0.50	0.29

*$p < 0.01$; **$p < 0.001$

Conclusion: Physician estimates for inflammation, damage and "unexplained symptoms" differ in patients with different rheumatic diagnoses. These 3 subscales reflect the expertise of the rheumatologist to estimate the basis for patient symptoms, and supplement the overall physician global estimate as a quantitative summary of the physical examination to assess and monitor patients with all rheumatic diseases in usual care.

Improving Pneumococcal Vaccination and Documentation for Immunosuppressed Patients At a University-Based Rheumatology Clinic. Christine Peoples, Rohit Aggarwal, Heena Sheth, Aarat Patel, Daniel Lupash, Christine McBurney, Ashima Malik, Swati Modi, Ximena D. Ruiz and Douglas W. Lienesch. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Centers for Disease Control and Prevention Guidelines recommend that all immunosuppressed patients receive the pneumococcal vaccine. The American College of Rheumatology Task Force Panel recommends vaccination for patients initiating therapy with disease-modifying anti-rheumatic drugs (DMARDs) or biologic therapies. Patients with chronic rheumatologic conditions have approximately double the incidence of infection compared to the normal population and those taking immunosuppressive agents show the highest risk, with the majority involving respiratory tract infections by common pathogens including *S. pneumoniae*. Prior studies show the rate of pneumococcal vaccination is low in this population. The aim of this study was to improve both administration and documentation rates of pneumococcal vaccine in immunosuppressed patients taking DMARDs and/or biologic agents at a university-based rheumatology clinic.

Methods: This study is a pre- and post-intervention comparison. Intervention phase data was collected from 1/23/2012–6/15/2012. Pre-intervention data included patients seen between 1/1/2009–12/31/2010 that were prescribed an immunosuppressive medication. Regularly seen patients were defined as having at least 2 visits, with either 1) at least 1 visit within the first 12 months of the measurement period and at least 1 visit within the second 12 months, or 2) 2 visits within only the second 12 month measurement period, with the first and last visits being separated by a minimum of 90 days. Patients eligible for pneumococcal vaccine and patients who were up-to-date with pneumococcal vaccination were determined. For the intervention phase, a report was generated of patients on immunosuppressant medications who had not received the pneumococcal vaccine who had upcoming visits. Clinic staff flagged these patients and a pneumococcal vaccine information sheet along with a brief form for the patient to complete were given to the patient. The medical assistant (MA) gathered information and documented in the electronic record. The MA communicated to RN who ordered and administered the vaccine. In select cases, physician approval and order were required prior to vaccination.

Results: Baseline data included 968 patients. Only 148 (15.3%) patients had received the pneumococcal vaccine. Post-intervention pneumococcal vaccination compliance revealed 361/1044 (34.6%) of patients had received the vaccine. This was a significant improvement from baseline (p<0.0001). An additional 114 (10.9%) patients were offered vaccination but had either already received the vaccine or deferred. A total of 45.5% had documentation, which was also significant improvement from baseline of 15.8% (p<0.0001).

Conclusion: Pneumonia vaccination administration rates in immunosuppressed patients with rheumatologic diseases are low and do not meet published guidelines. Implementation of an e-record and ancillary-staff-based intervention significantly improved vaccination and documentations rates without the need for considerable physician input. Ancillary staff review and physician communication were the key components in improving compliance with vaccination.

Are Patients Meeting the Updated Physical Activity Guidelines? Physical Activity Participation, Recommendation, and Preferences Among Adults with Rheumatic Diseases. Victoria L. Manning[1], Michael V. Hurley[2], David L. Scott[1] and Lindsay M. Bearne[1]. [1]King's College London, London, United Kingdom, [2]St George's University of London, London, United Kingdom

Background/Purpose: Physical activity (PA) reduces disability, comorbidity, and risk of premature mortality in people with rheumatic diseases, and clinical guidelines recommend that PA should be integral to rheumatic disease management (NICE 2008, 2009). Updated PA guidelines (published: US 2008, UK 2011) recommend that adults complete ≥150 minutes of moderate intensity PA or ≥75 minutes of vigorous intensity PA (or equivalent) in bouts of ≥10 minutes/week. Currently, the PA levels of adults with rheumatic diseases, assessed against these guidelines, are unknown. This study evaluates the PA levels of adults with rheumatic diseases against the updated guidelines. It assesses respondents' PA preferences and the proportion who report ever receiving PA advice from a healthcare professional (HCP).

Methods: 508 rheumatology outpatients (24% male, 76% female; 53% rheumatoid arthritis, 13% osteoarthritis, 7% psoriatic arthritis, 6% systemic lupus erythematosis, 5% fibromyalgia, 18% other; disease duration: 27% ≤1 year, 30% >1 to ≤5 years, 15% >5 to ≤10 years, 28% >10 years) were recruited from an inner city UK hospital (July-October 2010). Participants completed the short International PA Questionnaire, and 3 questions: "Has a doctor or other HCP ever suggested PA or exercise to help your arthritis or joint symptoms?" (Answers: yes, no, don't know), "Would you like help from your doctor or health service to become more physically active?" (Answers: yes, no, don't know), and "Which PAs do you enjoy?" (Answers: multiple options including free text response). Descriptive statistics were completed on all data, energy expenditure calculated (metabolic equivalent (MET) minutes/week = METs × weekly minutes × weekly days; walking = 3.3 METs, moderate = 4 METs, vigorous = 8 METs), and associations evaluated with Pearson's chi-square test. Respondents were categorized as: 1) Meeting guidelines (≥500 metabolic equivalent (MET) minutes/week; equivalent to ≥150 minutes of moderate intensity PA/week or ≥75 minutes of vigorous intensity PA/week), 2) Low (<500 MET minutes/week), or 3) Inactive (no PA ≥10 minutes (per activity bout)/week).

Results: 61% of respondents met the updated PA guidelines, and 39% did not meet the guidelines (12% low, 27% inactive). Physical inactivity increased with age (P<0.01). 43% of respondents reported that they had discussed PA with a HCP, and 50% that they would "like help" to become more physically active. Those diagnosed within the last year and those categorized as 'low' PA were least likely to report ever receiving PA advice (both P<0.05). Walking was the most preferred PA (65%), and accounted for 70% of respondents' total weekly energy expenditure.

Conclusion: Two thirds of urban UK adults with rheumatic diseases meet the updated public health guidelines for PA. However, despite the potential health benefits related to even low levels of PA, many are entirely inactive. PA advice may not be routinely included in the management of rheumatic diseases, despite patients reporting that they would like help to become more physically active. HCPs need to increase awareness of PA guidelines, and actively encourage regular PA. Walking may provide an easy and accessible form of exercise for people with rheumatic diseases.

2051

Standardized Data Collection Supports Reliable Reporting of Rheumatoid Arthritis (RA) Measures for the Medicare Physicians' Quality Reporting System. J. Timothy Harrington[1], George Reed[2], Katherine C. Saunders[3], Lisa Lemire[3], Aimee Whitworth[3], Jeffrey D. Greenberg[4] and Joel M. Kremer[5]. [1]University of Wisconsin (retired), Madison, WI, [2]UMass Medical School, Worcester, MA, [3]CORRONA, Inc., Southborough, MA, [4]New York University School of Medicine, New York, NY, [5]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: The Medicare Physicians' Quality Reporting System (PQRS) program encourages physicians to measure and report clinical processes and disease outcomes that correlate with quality care, including an Rheumtoid Arthritis (RA) measures bundle. Physicians typically review patients' records for a single visit to determine how many measures are documented and met, or not. An alternative approach is to proactively collect standardized clinical data at each visit that includes that required for documenting each measure.

Methods: The Consortium of Rheumatology Researchers of North America (CORRONA) registry collects standardized clinical data from RA patients and their rheumatologists during routine office visits, including the data for each RA measure. As examples, patients complete a modified Health Assessment Questionnaire (mHAQ)(Measure 178) and investigators complete a 0 – 10 segmented Physician Global Assessment (Measure 177). All enrolled patients have completed informed consent for the CORRONA registry. In 2011, at least 1 visit report was submitted for 15,615 unique RA patients by 213 CORRONA investigators. Measures evaluated included Measure 108: Disease Modifying Anti-rheumatic Drug (DMARD) Therapy is or is not prescribed, and if not, why not?; Measure 176: For patients started on a first biologic, is a TB skin test or Quantiferon assay documented during the 6 months prior to starting the treatment, or not; Measure 177: Is RA disease activity documented as controlled,-low, moderate or high; Measure 178: Has functional status been assessed during the previous 12 months? Measure 179: Is RA prognosis assessed and documented as good, poor, or undetermined? Measure 180: Is the patient on =>/ 10 mg of prednisone for greater than 6 months or not, and if so, is a management plan documented to either increase other treatments and/or taper the prednisone dose. The most recent 2011 report for each patient was studied.

Results: The number (N) and percent (%) of visit reports meeting or not meeting each measure are shown, as are the number of reports meeting exclusion criteria for each measure, such as patients with controlled disease off DMARD treatment being excluded for Measure 108 (N = 521), and those who were not starting a first biologic being excluded from Measure 176.

Measure Number	Total Sample N	Performance Exclusion n (% of N)	Total Met+UnMet M	Performance Met n (% of M)	Performance Not Met n (% of M)
108	15615	521 (3.3)	15094	14,599 (96.7)	495 (3.3)
176	15615	15,407 (98.7)	208	39 (18.8)	169 (81.2)
177	15615	0 (0.0)	15615	15,588 (99.8)	27 (0.2)
178	15615	0 (0.0)	15615	13,652 (87.4)	1963 (12.6)
179	15615	0 (0.0)	15615	13,866 (88.8)	1,749 (11.2)
180	15615	47 (0.3)	15568	15,545 (99.85)	23 (0.15)

Conclusion: Collecting standardized data assures reliable measures reporting. The percents of Performance Met were high, except for Tb testing before DMARD initiation.

2052

Effect of Community Characteristics On Quality of Care in Systemic Lupus Erythematosus. Edward Yelin[1], Laura Trupin[2], Chris Tonner[3] and Jinoos Yazdany[1]. [1]University of California San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]UCSF, San Francisco, CA

Background/Purpose: In prior studies we established that living in communities of concentrated poverty was associated with fewer physician visits and select SLE outcomes after taking characteristics of the individual into account (Trupin, JRheumatol 2008; Tonner, Arthritis Care Res 2010) and the presence and type of insurance was associated with the quality of SLE

care (Yazdany, J Gen Intern Med 2012). Here we examine whether community characteristics affect performance on quality measures for SLE after taking individual characteristics into account.

Methods: Data derive from 3 annual waves (2009–2011) of the UCSF Lupus Outcomes Study, a prospective cohort study of persons with SLE interviewed annually by telephone. Data on 13 SLE quality indicators covering diagnosis, monitoring, treatment, and preventive services were collected. Participant addresses were matched to information on characteristics of local communities, defined at various levels of aggregation. Community data include the American Community Survey for neighborhood poverty level, Dartmouth Health Care Atlas for nature of health care markets, and Rural Urban Codes to categorize health care markets as rural, small city, or major city. We used general estimating equations to assess the impact of characteristics of communities and individuals on the overall "pass rate" for quality measures in SLE (number received given eligibility) and on 2 important individual quality measures, drug toxicity monitoring (RXTOX) and cardiovascular risk factor evaluation (CVD). All models controlled for age, gender, race/ethnicity, disease duration, disease activity, education, # physician visits for SLE, and presence and type of insurance. Net of 28 subjects without physician visits during the year, data on 869 were analyzed.

Results: Among the 869 participants, 93% were female, 37% non-white, mean age was 50($\pm$13), disease duration was 17($\pm$9), and they were eligible for 5.1 quality measures/year. Overall pass rates averaged 67% (95% CI 66–68%) over the 3 years and did not differ significantly among years. Pass rates were slightly but significantly lower in areas with the highest quartile of rheumatologists/capita (64 vs. 67– 68% in the other quartiles). Pass rates were higher in small cities than in rural or major cities (70 vs. 65–66%) and differed among the 9 major Census regions (range 59 to 71%). Size of health referral region, number of primary care physicians per capita, and concentration of poverty were not associated with overall pass rates. Over the 3 years, 31% (95%CI 29–33%), of those eligible received RXTX and 70% (95% CI 67–73%) received CVD. Health referral areas in small cities were associated with higher rates of RXTX than in major cities (78 vs. 67%). No other community characteristic was associated with RXTX and none were associated with CVD. In all models, lack of health insurance was associated with lower pass rates, while public managed care plans were associated with better quality of care among the insured.

Conclusion: Lack of consistent community effects on quality of care suggests that quality improvement efforts in SLE not be targeted geographically and that the focus should continue to be on increased access to good health insurance coverage.

2053

Tele-Rheumatology: The Future Is Now. Daniel Albert[1], Krista Merrihew[2] and Sarah Pletcher[2]. [1]Dartmouth-Hitchcock Medical Center, Geisel School of Medicine, Lebanon, NH, [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH

Background/Purpose: Access to rheumatologic consultation is limited by available expertise due to inadequate manpower and maldistribution of resources. Rural New England is particularly challenging because of sparse population, prolonged transportation times, and weather conditions that make travel difficult or impossible. Nearly every medical specialty and subspecialty is underrepresented (and often completely absent) in the northern 2/3 of New Hampshire, and this population's poorer health status and outcomes from disease and injury illustrate the 'rural penalty'. Dartmouth-Hitchcock Medical Center (DHMC), a Level 1 quaternary academic medical center located in the Upper Connecticut River Valley, is the only referral center for New Hampshire and parts of Vermont, Maine, and Eastern Upper New York State. Weeks Medical Center–Lancaster is a Rural Health Clinic associated with Weeks Medical Center, a 25 bed rural critical access hospital located in northern New Hampshire approximately 2 ½ hours by car north of DHMC. To provide rheumatologic access; we initiated a Tele-Rheumatology pilot clinic between a physician at DHMC and a trained nurse at Weeks Medical Center.

Methods: A two way live synchronous video conference was set up connecting a conference room at DHMC and an exam room at Weeks. Patients were scheduled at both institutions and referral notes and documentation were faxed to DHMC prior to the visit. Patients were seen at Weeks with a nurse who had shadowed the rheumatologist at DHMC and was instructed on joint examinations prior to the encounter. Vital signs, medications, and a problem list were communicated from the nurse at Weeks to the nurse at DHMC. Patients were interviewed and physical examination was achieved with assistance of the trained nurse at Weeks. The encounter was

documented at DHMC and electronically communicated to the referring physician. Management included medications electronically prescribed to patient's pharmacy, laboratory testing and ancillary services at Weeks. All patients are given the option to be seen at DHMC; however, since none of the patients needed to be seenat DHMC follow-up was arranged at the time of the encounter as a return telemedicine appointment. Issues that needed to be resolved before initiation included a contract between the hospitals, credentialing, billing procedures (both facilities billed, Weeks-facility charges and nurse visit, DHMC-professional fee), coding issues, and distribution of responsibilities. Most of these were facilitated by a face-to-face meeting.

Results: Patient, physician, and staff satisfaction was high. We have plans to extend this regionally to more than two dozen rural sites in the region.

Conclusion: As a substitute for outreach clinics telemedicine appears to be more cost effective and efficient limiting valuable specialist time that would otherwise be spent in travel, learning new computer systems and familiarizing themselves with procedures and protocols of different hospitals. It is possible to extend this service to homebound patients through portable units staffed by visiting nurses. Additionally, it would be possible to extend this to utilize instructional videos, web links to treatment information, or multiway conferencing.

2054

Safety of Joint and Soft Tissue Injections in Patients On Warfarin Anti-Coagulation. Richard Conway, Finbar (Barry) D. O'Shea, Gaye Cunnane and Michele Doran. St James's Hospital, Dublin, Ireland

Background/Purpose: Joint and soft tissue injections are commonly performed in clinical practice. An increasing number of patients are prescribed warfarin. Joint and soft tissue injections are frequently indicated in these patients. The limited available evidence suggests that joint and soft tissue injections are safe in therapeutically anti-coagulated patients receiving warfarin. Many authorities, including the New England Journal of Medicine, continue to recommend reversal of anti-coagulation in patients receiving warfarin who require these procedures. The aim of this study was to evaluate the safety of two approaches to the management of patients prescribed warfarin requiring joint or soft tissue injection

Methods: The protocol in our department prior to September 2011 was to hold warfarin and replace it with low molecular weight heparin for joint and soft tissue injections. A systematic literature review was performed which provided support to the performance of these procedures in patients on warfarin with an INR <3. A retrospective chart review was initiated at this point to assess the safety of the existing protocol. A new protocol was introduced whereby warfarin was continued with an INR check within 1 day of the procedure. The procedure was performed if the INR was <3. All patients receiving joint or soft tissue injections under the care of our service are provided with a helpline phone number to contact if symptoms worsen. In the event of persistent worsening symptoms >48 hours post-procedure arthrocentesis would be performed.

Results: In patients in whom warfarin was held, 32 procedures were performed in 18 patients. Of these 30 were joint injections (24 knee, 5 glenohumeral, 1 elbow) and there were 2 soft tissue injections (1 trochanteric bursa, 1 subacromial bursa). Conditions requiring injection were 13 rheumatoid arthritis, 11 osteoarthritis, 5 spondyloarthritis, and 1 each of adhesive capsulitis, rotator cuff tendinopathy and trochanteric bursitis. There were no clinical hemarthroses or complications. In patients who continued warfarin, 32 procedures were performed in 21 patients. Of these 27 were joint injections (24 knee, 1 glenohumeral, 1 elbow, 1 metatarsophalangeal) and there were 5 soft tissue injections (4 subacromial bursa, 1 carpal tunnel). Conditions requiring injection were 11 rheumatoid arthritis, 7 osteoarthritis, 6 crystal arthritis, 4 rotator cuff tendinopathy, 2 spondyloarthritis and 1 each of adhesive capsulitis and carpal tunnel syndrome. There were no clinical hemarthroses or complications. Full details of the study population are shown in Table 1.

Table 1. Comparison of Procedures Performed with Warfarin Held or Continued

	Warfarin held	Warfarin continued
Procedures, n	32	32
Patients, n	18	21
Joint injections, n (%)	30 (94%)	27 (84%)
Soft tissue injections, n (%)	2 (6%)	5 (16%)
Male, n (%)	14 (44)	14 (44)
Age, mean	77	74
INR, median (IQR)	1.2 (1.1–1.5)	2.4 (2.1–2.6)
Aspirin, n (%)	3 (9%)	1 (3%)
Clopidogrel, n (%)	0 (0%)	0 (0%)
Complications, n	0	0
Clinical haemarthroses, n	0	0

Conclusion: Joint and soft tissue injections appear to be safe in patients receiving warfarin anti-coagulation with an INR <3. Continuation of anti-coagulants reduces staff workload and patient inconvenience with no evidence of increased risk of complications.

2055

TEAM-Managed Care of Biological Patients At A Canadian Centre.
Melissa Deamude[1], Dawn Heap[2], Melanie Kanellos[2], Debbie Kislinsky[3], Kathy Kislinsky[3], Cynthia Mech[4], Helena Ross[3], Peggy Saldanha[3], Lauri Vanstone[3], Kathleen Brown[3] and William G. Bensen[5], [1] Dr. William G. Bensen Medicine Professional Corporation, Hamilton, ON, [2]Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [3]Dr. William Bensen Rheumatology Clinic, Hamilton, ON, [4]Rheumatology Health Team, Dr. Bensen's Rheumatology Clinic, Hamilton, ON, [5]St. Joseph's Hospital and McMaster University, Hamilton, ON, Hamilton, ON

Background/Purpose: Managing complex arthritic patients with biologics is exacting and time consuming. As a result in January 2008 we established a separate biologic clinic with a clinic manager and team of experienced Registered Nurses linked to the general rheumatology clinic and early inflammatory arthritis clinic to assess, initiate, and follow patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS), and Psoriatic Arthritis (PsA) needing to transition to biologic treatment and requiring care and follow-up while on biologics. This team approach using experienced rheumatology nurses allows for triaging and timely access to care.

Methods: Approximately 770 patients, 60% RA, 20% PsA and 20% AS are being followed in the biologic program. All patients are initially assessed by an RN, examined to a standard protocol and then the treatment, assessment and plan of care is reviewed by the attending rheumatologist. The clinic is structured using a primary care nursing model which promotes continuity and a patient centered therapeutic approach to care. Nurses are responsible for assessing their patients providing disease and treatment related heath teaching and providing injection training. The nurses also perform the clinical outcome measurements including spondylarthropathy measures, joint evaluations and administration and scoring of patient reported outcome questionnaires. The team manages and reviews routine labs and diagnostics daily, provides follow-up calls to patients to discuss adverse events, flares, concerns and treatment related inquiries. Patients are seen a minimum of 3 times per year with most followed 6 times per year because of flares, co-morbidities, treatment adjustment or financial issues. The clinic operates as a primary point of contact for organizing management of co-morbidities, infusions and injections and ensures patients are being treated to target. The nurses are occasional speakers at national and regional rheumatology meetings to share best practices on the management of biological patients and how a team-based approach can improve efficiency and promote better patient outcomes.

Results: This rheumatology health team managing patients on biologic treatment has exponentially grown and has worked well over a four-year period. The team approach allows one rheumatologist to follow 5–7 times the number of patients seen by the average rheumatologist who does not have the team support. Currently in Canada we have approximately 1/3 of the rheumatologists we need for optimal care and a team based approach can help fill this gap, reducing the burden on the health care system with fewer visits to urgent care or Emergency departments. The team assesses 3–5 new patients a week for biologics and starts 2–3 patients per week on biologics.

Conclusion: The goal in the biologic clinic is treating to target for remission or lowest disease activity possible within the shortest period of time. This team approach to care has resulted in improved adherence to therapy, less risks and reported adverse events, improved safety monitoring and better patient satisfaction.

2056

Effectiveness of a Focused Educational Intervention in Improving the Supplementation of Vitamin D Deficiency and Insufficiency. Candice Low, Richard Conway, Gaye Cunnane, Michele Doran and Finbar (Barry) D. O'Shea, St James's Hospital, Dublin, Ireland

Background/Purpose: Vitamin D deficiency and insufficiency are important clinical states with the potential for adverse skeletal and non-skeletal consequences. In our experience the management of these states is frequently suboptimal. Focused educational initiatives are a proven means to improve patient care. The aim of this study was to evaluate the effectiveness of a focused educational intervention in improving the supplementation of patients with vitamin D deficiency and insufficiency.

Methods: A prospective study of 100 consecutive patients in the general rheumatology clinic with 25-hydroxyvitamin D deficiency or insufficiency (as defined as <30ng/ml) measured within the previous year was undertaken. A systematic literature review was performed and a consensus decision was made to supplement all patients with 25-hydroxyvitamin D <30ng/ml with 2000 units of vitamin D a day, with repeat testing at the next visit to ensure adequate but not excess supplementation. Following this a teaching session was held educating members of the multi-disciplinary team on the importance of vitamin D supplementation and reminders to supplement patients were placed in the clinic offices. Following the education intervention a further prospective study of 100 consecutive patients with 25-hydroxyvitamin D <30ng/ml measured within the previous year was performed.

Results: In the initial 100 patients screened, 25% were male, mean age was 56 years. Primary diagnosis was inflammatory arthritis (IA) in 62%, connective tissue disease (CTD) in 14%, osteoarthritis (OA) in 12% and other conditions in 12%. 18% had known osteoporosis and 13% had previous fractures. Mean 25-hydroxyvitamin D was 17.8 ng/ml. 20 patients had 25-hydroxyvitamin D <12ng/ml, 40 had 25-hydroxyvitamin D 12–20ng/ml, 40 had 25-hydroxyvitamin D 20–30ng/ml. Pre-education only 28 patients had additional vitamin D prescribed as a result. Following the educational intervention, in the population screened 25% were male, mean age was 55 years. Primary diagnosis was IA in 47%, OA in 16%, CTD in 11% and other conditions in 26%. 15% had known osteoporosis and 12% had previous fractures. Mean 25-hydroxyvitamin D was 16.4 ng/ml. 31 patients had 25-hydroxyvitamin D <12ng/ml, 39 had 25-hydroxyvitamin D 12–20ng/ml, 30 had 25-hydroxyvitamin D 20–30ng/ml. As a consequence of our educational intervention, 80 patients had additional vitamin D prescribed. The change in vitamin D prescriptions following the educational intervention is shown in figure 1.
Figure 1. % of Patients prescribed, and dose prescribed of, vitamin D pre and post an educational initiative.

Conclusion: A focused educational intervention has the potential to improve vitamin D supplementation and patient care in the management of low vitamin D states. Failure to identify and adequately treat vitamin D deficiency has the potential for serious adverse consequences for our patients.

Analysis of the Adherence to the Monitoring of Glucocorticoid Eye Toxicity and of the Prevalence of Cataracts and Glaucoma Among Patients with Systemic Lupus Erythematosus. Linda Carli[1], Chiari Tani[1], Francesca Querci[1], Alessandra Della Rossa[1]. Sabrina Vagnani[1], Anna d'Ascanio[1], Rossella Neri[1], Antonio Tavoni[2], Stefano Bombardieri[1] and Marta Mosca[1], [1]Rheumatology Unit, Department of Internal Medicine, University of Pisa, PISA, Italy, [2]Immunoallergology Unit, Department of Internal Meicine, University of Pisa, PISA, Italy

Background/Purpose: Cataracts and glaucoma are among the main causes of impaired visual acuity and have a prevalence respectively of 9–17% and 1–2% among subjects older than 70 years. Chronic glucocorticoid (GC) therapy is associated with an increased risk of developing cataracts and glaucoma and recommendations have been developed for monitoring these side effects in patients with rheumatic diseases.

The aim of this study was to assess the adherence to the existing recommendations for monitoring eye toxicity of chronic GC therapy and the prevalence of cataracts and glaucoma among systemic lupus erythematosus (SLE) patients followed at our Unit.

Methods: Retrospective analysis of clinical charts to evaluate epidemiological data (disease duration, age at last assessment), cumulative and mean daily dose of GC and administration of GC pulses, number and frequency of eye assessment during follow up. Presence/absence of cataracts and glaucoma as reported in the last available eye assessment.

Results: One hundred and seventy charts were examined, 34 (20%) of these (mean follow up 83.6 ± 66.5; mean age 42.5 ± 14.8 years) never underwent an eye assessment. The remaining 136 (mean follow up 152.5 ± 99.8 months, age 45.4 ± 12.5 years), underwent an eye assessment on average with an interval of 75 ± 61.7 months. However, only 45 (33%) had received an evaluation during the previous 12 months. All these 170 patients were taking chronic CG therapy at a mean daily dose of 5.4 ± 2.4 mg prednisone (PDN), and a mean cumulative dose of 27.6 ± 20.5 gms. Out of the 136 patients with at least one eye assessment (mean PDN 5.5 ± 2.4 mg, mean cumulative dose 29.8 ± 21.5 gms), cataracts were observed in 39 patients (29%) and glaucoma in 4 patients (3%). Cataracts were diagnosed at a mean age of 46.5 ± 10 years; the development of cataracts was associated with age, disease duration and cumulative GC dose (cataracts vs not cataracts: mean cumulative PDN dose 32,8 vs 20,4 gms; p<0,0001). Glaucoma was diagnosed at a mean age of 40.5 ± 16 years; due to the small number of patients no correlations were made.

Conclusion: Although 80% of patients have at least one eye assessment, the adherence to recommendations is suboptimal as only 33% of patients underwent an eye assessment over the previous 12 months. As expected the prevalence of cataracts and glaucoma is higher than in the general population and these conditions occur early in the life of SLE patients. As not all patients have a recent eye evaluation our data could underestimate the real incidence of these two potentially severe conditions. An association between GC and cataracts is confirmed. These data reinforce the need to improve adherence to recommendations to eye monitoring among SLE patients under chronic therapy with GC.

Disclosure: **L. Carli**, None; **C. Tani**, None; **F. Querci**, None; **A. Della Rossa**, None; **S. Vagnani**, None; **A. d'Ascanio**, None; **R. Neri**, None; **A. Tavoni**, None; **S. Bombardieri**, None; **M. Mosca**, None.

Differences in Psychological Characteristics Between Patients with Rheumatoid and Psoriatic Arthritis. Panagiota Tsitsi[1], Athina Theodoridou[1], Foteini Lada[1], Konstantinos Papanikolaou[2], Despina Dimopoulou[1], Georgios Garyfallos[3], Alexios Benos[4] and Alexandros Garyfallos[1]. [1]4th Department of Internal Medicine,Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Psychiatric Hospital of Petra Olympus, Katerini, Greece, Katerini, Greece, [3]2nd Department of Psychiatry, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece, [4]Department of Hygiene, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background/Purpose: Both rheumatoid (RA) and psoriatic arthritis (PsA) seem to have a negative impact on patients' psychological status mostly due to the chronic character of the disease. Literature reports and clinical practice evidence support that patients suffering from PsA express their discomfort and complaints more often than those who suffer from RA, even when the physical disability is similar between them. The aim of the study is to compare aspects of the psychological profile of the two groups of patients and to examine the differences between their behavior

Methods: The study sample consisted of 59 outpatients of the 4th Medical Department of Internal Medicine of Aristotle University of Thessaloniki, suffering from RA and PsA. Disease activity was measured using DAS28 score. Psychological characteristics were evaluated with the use of SCL-90-R questionnaire while other information including quality of life (QoL), general health (GH) and disability were assessed with the use of SF-36, GHQ and HAQ-DI. Patients suffering from extended psoriatic skin lesions (BSA>5) as well as those who presented axial joint damage were excluded in order to ensure clinical similarity between the two groups of patients.

Results: A total of 32 patients suffering from RA and 27 from PsA were recruited. Mean age for RA group was 48.2 ($\pm$10.6) and PsA 49.3 ($\pm$7.6) years. No significant difference in DAS (p=0.843), disability (p=0.466), GH (p=0.801) and VAS score (p=0.855) was found between the two groups. As far as QoL is concerned, the two groups did not demonstrate difference in any of the subscales of SF-36. Patients with RA demonstrated lower scores in Interpersonal Sensitivity (Subscale III of SCL-90-R) (p=0.044) than those with PsA.

In the RA group, DAS was found to correlate with disability (r=0.804, p=0.000), GH (r=0.519 p=0.002), Somatization (I) (r=0.440 p=0.012) and Depression (IV) (r=0.426 p=0.015). Only the physical component (PCS) of the SF-36 correlates with the DAS28 score (r=-0.741 p=0.000). Both disability and GH correlate with I and IV (r= 0.604 p=0.000) (r=0.536 p=0.002) (r=0.416 p=0.018) (r=0.431 p=0.014) respectively.

In the PsA group DAS28 score does not correlate with GH (p=0.702) or IV (p=0.123) but it does correlate with HAQ score (r=0.491 p=0.009), I (r=0.312 p=0.033) and PCS (r=-0.606 p=0.001). HAQ score correlates with IV (r=0.559 p=0.002) as well as the PCS (r=0.812 p=0.000). GH correlates with most of the subscales of SCL-90-R except for the III (p=0.054) while there is no correlation with the PCS (p=0.275) contrary to the Mental Component (MCS) (r=-0.476 p=0.012). Finally the III subscale of SCL-90-R does not correlate with any of the measured clinical parameters.

Conclusion: In consistence with findings from everyday interaction during clinical evaluation, PsA patients rather than RA ones seem to meet with feelings of self- deprivation, uneasiness, discomfort during interpersonal interaction, personal inadequacy and inferiority in comparison with others. Moreover, the differences in psychological characteristics between patients with RA and PsA cannot be attributed to the degree of skin lesion, disease activity or disability.

The Efficacy of Clinical Guidelines in Promoting Co-Prescription of Bone Protection with Glucocorticoids Among Hospital Doctors Treating Inpatients. Leonard C. Harty[1], James Clare[2], Dylan Finnerty[2], Susan Van Der Kamp[2], Fionnuala Kennedy[3], Malachi McKenna[4] and Oliver M. Fitz-Gerald[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland, [3]Pharmacy Department, St. Vincent's University Hospital, Dublin, Ireland, [4]Department of Endocrinology & Metabolic Bone Disease, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Therapeutic glucocorticoids (GC) rapidly decrease bone mineral density, inducing a remodelling imbalance by promoting osteoclast differentiation and activation and by inhibiting osctecoytes. Current guidelines direct that bisphosphonates (BP's) and elemental calcium (Ca^{++}) with Vitamin D (Vit. D) should be given at initiation of GC therapy, as it is known that bone remodelling imbalance occurs early with steroid usage. We circulated these guidelines within our hospital after auditing the existing practice of the hospitals doctors and 1yr later we sought to measure the efficacy of our intervention by completing an audit loop.

Methods: A cross sectional audit was performed of all adult medical and surgical inpatients in a tertiary referral centre teaching hospital. Prescribed GC and concurrent anti osteoporotic medication were noted. Subsequent to the initial audit, guidelines promoting the use of BP's, Ca^{++} and Vit. D when prescribing GC's were advertised on hospital notice boards, in hospital bulletins, hospital prescribing guidelines and on the hospital website. One year after promoting guidelines the audit loop was completed by performing a similar cross sectional audit.

Tuesday, November 13

Results: All inpatient medical records (n=417) were reviewed in Jan 2010. 52% of the inpatients were female and 58% were older than 65. 66/417 (16%) inpatients had been prescribed GC's. Ca^{++} with Vit. D was prescribed for 20% of patients on GC's with 2% also receiving BP therapy. 3% of patients were also receiving-post menopausal hormone replacement therapy.

In Nov 2011 one year after guideline publication, all 452 inpatient medical records (n=452) were reviewed. 63% of the patients were female and 60% were older than 65. 55/452 (12%) inpatients were prescribed GC's. Ca^{++} with Vit. D was prescribed for 55% of patients on systemic steroids with 20% also receiving BP therapy.

The resultant improvement in the co-prescription of Ca^{++} & Vit. D and BP's with GC's by the order of 2.35 and 10 respectively can be attributed in part to the circulation of hospital guidelines. However 45% of patients on systemic steroids continued to receive no bone protection and 80% received suboptimal bone protection from steroid induced osteoporosis.

Conclusion: Publication and advertisement of current bone protection guidelines when prescribing systemic steroids resulted in a substantial but suboptimal improvement by hospital doctors in our hospital in the co-prescription of bone protecting drugs to prevent steroid induced osteoporosis. In this audit it appears that the majority of prescribers do recognise the necessity to protect bone health when a patient requires steroids. However a substantial number of patients did not receive any bone protection. It is our perception that many physicians are not aware that short courses of steroids reduce bone mineral density and therefore greater efforts must be made to enhance doctor awareness of the necessity for bone protection to be prescribed at initiation of systemic steroids.

2060

Using the Electronic Medical Record to Increase Rates of Physician Assessment of Lipids in Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis: A Quality Improvement Initiative. Astrud Lorraine Leyva, Laura L. Tarter, Elizabeth Blair Solow and David R. Karp. UT Southwestern Medical Center, Dallas, TX

Background/Purpose: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Guidelines for the management of both SLE and RA recommend evaluation of and intervention for known cardiovascular risk factors, including dyslipidemia. However, studies suggest that screening rates remain suboptimal. Quality improvement methodology offers a practical approach to bridge this gap in care. The fellowship training setting is an ideal environment in which to pilot such a project, as the American College of Graduate Medical Education requires that fellows demonstrate the ability to continuously improve patient care. Our aim was to improve the rate of recording lipid panel results in patients with SLE or RA to over 50% in a one month period.

Methods: In our busy outpatient rheumatology clinic in a county hospital setting, we examined patient, provider, and health system factors that could be barriers to providing routine cardiovascular risk assessment for our patients. For our first Plan-Do-Act-Check (PDCA) cycle, we examined the frequency with which physicians recorded lipid panel results in clinic notes during routine visits. We obtained baseline data for all RA or SLE patient visits for each of our six clinical fellows one month period. Our hospital district utilizes the EPIC electronic medical record (EMR); thus we devised a simple "dotphrase" to assist providers in ascertaining the date and results of a patient's most recent lipid panel with just a few keystrokes. We then organized an educational session for our providers to inform them about the initiative, the collective baseline data and applying the "dotphrase". Each clinical fellow also received an individual summary of their baseline screening rates.

Results: We reviewed 91 patient visits during the pre-intervention period (69% RA, 31% SLE). Patients were 46.7 years old (SD 14.7) and 83% female. Forty-two percent of patients had a lipid panel sent within the past year. Lipid panels were ordered by primary care physicians (63%), rheumatologists (15%), and other physicians (22%). Twenty percent of patients were on statin therapy. Our providers documented lipid panel results, however, in only 12% of the visits. Following the implementation of the EMR "dotphrase", we reviewed an additional 92 patient visits over a one month period. Baseline characteristics were similar to our pre-intervention group. Our providers augmented their lipid panel recording to a rate of 65% after the intervention.

Conclusion: In our hospital district setting with an integrated EMR, the use of a simple "dotphrase" was effective in improving provider documentation of lipid panel results in patients with RA and SLE. Future PDCA cycles will focus on increasing rates of obtaining screening lipid panels and intervening in patients with documented dyslipidemia.

2061

Physician Variation in Documentation of Rheumatoid Arthritis Quality Measures and Evaluation of Relationship with Radiographic Progression. Sonali Desai[1], Jinoos Yazdany[2], Nancy A. Shadick[3], Siri Lillegraven[4], Chih-Chin Liu[5], Michelle A. Frits[6], Tabatha Norton[7], Jonathan S. Coblyn[8], Michael Weinblatt[5] and Daniel H. Solomon[1]. [1]Boston, MA, [2]University of California San Francisco, San Francisco, CA, [3]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [4]Diakonhjemmet Hospital, Oslo, Norway, [5]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [6]Brigham and Women's Hospital, Boston, MA, [7]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [8]Brigham & Womens Hosp, Boston, MA

Background/Purpose: Documentation of quality measures (QMs) in rheumatoid arthritis (RA) has been proposed as a way to demonstrate quality of care, but data linking appropriate documentation to improved clinical outcomes are lacking. We examined the variation in physician documentation of RA QMs on disease activity and functional status and the association with radiographic outcomes.

Methods: We studied a subset of 286 patients participating in a longitudinal RA cohort followed from 2003–2008 at an academic medical center with complete data on total sharp score (TSS) (2 hand x-rays approximately 2 years apart). All clinical notes from 18 different rheumatologists during a 24-month period preceding the date of the second hand x-ray were examined for the presence or absence of the RA QMs on disease activity and functional status. Disease activity QM documentation was defined as mention of disease activity assessment in the medical record, with details categorizing disease activity into low, medium or high. Functional status QM documentation was defined as mention of how RA impacted activities of daily living. Change in TSS was defined as an annualized progression rate and dichotomized as progression ($\geq$1U per year) or no progression ($<$1U per year). We examined: patient visits per MD per year; RA QM documentation as either disease activity, functional status or both; and mean % of visits with RA QM documentation. We compared the mean change in TSS across patients grouped by percentage of visits meeting a QM, i.e., none or some documentation of disease activity and functional status.

Results: The mean age of our patients was 57.0 ($\pm$14.0) years, 82.0% were female, mean disease duration was 10.4 ($\pm$10.9) years, baseline DAS28 score was 3.7 ($\pm$1.5) and 65.9% were either RF or CCP positive. 76.6% of patients were on a non-biologic and 31.5% were on a biologic DMARD. Radiographic progression of RA was reported in 27.0% of patients. There was at least one chart note with documentation of disease activity for 26.0% of patients and functional status for 75.0%, during the 24-month period. For the seven rheumatologists with at least 10 patients in the study, there was variation in the number of visits per patient per year and documentation of disease activity and functional status in chart notes (**Table**). In unadjusted analyses, there was no relationship between performance on either disease activity (p=0.6) or functional status (p=0.5) and change in TSS.

Table. Differences in RA visits and QM documentation by rheumatologist

MD	Study sample patients N (%)	Patient visits per year mean (min-max)	Disease activity at least once N (%)	Functional status at least once N (%)	Both QMs at least once N (%)	% of visit with QM (mean)	
N=7*	N=242	24-month follow-up	24-month follow-up	24-month follow-up	24-month follow-up	Disease activity	Functional status
A	50 (20.7)	8.6 (3–14)	4 (8)	27 (54)	1 (2)	1.6	22.0
B	20 (8.3)	9 (6–12)	0	12 (60)	0	0.0	11.0
C	28 (11.6)	8.9 (4–15)	9 (32.1)	18 (64.3)	3 (10.7)	8.8	19.2
D	10 (4.1)	6.9 (4–12)	3 (30)	4 (40)	1 (10)	11.3	11.2
E	10 (4.1)	9.4 (5–16)	3 (30)	7 (70)	1 (10)	5.0	18.3
F	21 (8.7)	8 (4–19)	3 (14.3)	21 (100)	1 (4.8)	2.5	46.8
G	103 (42.6)	7.8 (3–18)	42 (40.8)	90 (87.4)	22 (21.4)	8.5	53.7

The 7 rheumatologists represented in this table contributed at least 10 patients to the study sample

Conclusion: Among this cohort of RA patients with established disease, overall documentation of RA QMs on disease activity and functional status was inconsistent across rheumatologists. We did not find an association between the % of visits with an RA QM documented and radiographic outcome over a 24-month follow-up period.

2062

Increasing Pneumococcal Vaccination for Immunosuppressed Patients: A Cluster Quality Improvement Trial. Sonali Desai[1], Lara Szent-gyorgyi[1], Alexander Turchin[1]. Bing Lu[2], Anna A. Bogdanova[1], Michael Weinblatt[3], Jonathan S. Coblyn[4], Jeffrey O. Greenberg[1], Allen Kachalia[1] and Daniel H. Solomon[5], [1]Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [4]Brigham & Womens Hosp, Boston, MA, [5]Division of Rheumatology, Brigham & Women's Hospital, Boston, MA

Background/Purpose: It is important for patients on immunosuppressive medications to receive pneumococcal vaccination. Prior studies suggest that most patients do not undergo vaccination. We evaluated the effects of a point-of-care paper reminder form on being up-to-date with pneumococcal vaccination in a rheumatology practice.

Methods: Selected rheumatologists at five ambulatory practice sites received a point-of-care paper reminder form for patients who were not up-to-date with pneumococcal vaccination. Interrupted time-series analyses were used to measure the effect of the paper reminder form upon the intervention rheumatologists compared to the control rheumatologists. Adjusted Cox proportional hazards models were examined to identify independent predictors of being up-to-date with pneumococcal vaccination.

Results: We evaluated a total of 3,717 patients on immunosuppressive medications. In this group 66.0% had rheumatoid arthritis:74.1% were female, and the mean age was 53.7 years. Rheumatologists who received the intervention had a significant increase in the rate of patients up-to-date with pneumococcal vaccination from 67.6% to 80.0% in the time period following the intervention (p=0.006), whereas rheumatologists in the control group had stable rate from 52.3% to 52.0% (p=0.90). In regression models, the intervention [hazard ratio, HR=3.58, (95% CI 2.46–5.20)], having a primary care physician affiliated with our hospital [HR=1.68, (95% CI 1.44–1.97)], and having a diagnosis of diabetes mellitus [HR =1.57, (95% CI 1.02–2.41)] were positive predictors of being up-to-date with vaccination.

Figure 1 shows the percentage of patients up-to-date with pneumococcal vaccination over time. The intervention was applied in two waves, with ten physicians receiving the intervention in June 2010 and four additional physicians receiving the intervention in October 2010. In order to synchronize these data, time 0 was defined as the time that the intervention was applied to the patients of the treating rheumatologist. The red line represents the 21 rheumatologists in the control group and the blue line represents the 14 rheumatologists in the intervention group.
Figure 1. Pneumococcal vaccination over time, before and after point-of-care reminder intervention.

Conclusion: A simple point-of-care paper reminder for patients on immunosuppressive medications significantly increased the rate of being up-to-date with pneumococcal vaccination among intervention rheumatologists over a six-month period.

2063

Detection of Inflammatory Arthritis and Musculoskeletal Conditions in a First Nations Community: Results of an Onsite Screening Program. Cheryl Barnabe[1], Carrissa Low Horn[2], Margaret Kargard[2], Stephen Mintsioulis[2], Sharon Leclercq[1], Dianne P. Mosher[1], Hani S. El-Gabalawy[3], Tyler White[2] and Marvin J. Fritzler[1]. [1]University of Calgary, Calgary, AB, [2]Siksika Health Services, Siksika, AB, [3]University of Manitoba, Winnipeg, MB

Background/Purpose: RA and SLE are more severe and at least twice as prevalent in the First Nations population of Canada compared to the Caucasian population. Difficulties in accessing rheumatology care have been previously documented. A collaboration between a Blackfoot community (n= 3,700) and rheumatologists from a nearby urban centre was initiated to enable better consultative services for the Nation's members, and allow for established rheumatology patients to receive care in their home community. Parallel to this initiative, we established an arthritis screening program, with the primary goal being to identify new cases of inflammatory arthritis (IA) early in the disease course.

Methods: A weekly community-based screening program started in June 2011. Consenting participants undergo a musculoskeletal (MSK) history and examination by a rheumatologist and complete a Health Assessment Questionnaire (HAQ). Serologic testing (rheumatoid factor (RF), antinuclear antibody (ANA), extractable nuclear antigens (ENA), anti-cyclic citrullinated peptide (anti-CCP)) is offered and further investigations initiated as appropriate to confirm a diagnosis. Management is provided in conjunction with primary care providers. We provide here a descriptive summary of the program's outcomes after 1 year.

Results: 144 individuals have been reviewed (74% female, mean age 52.4 years). Half the cohort have a family history of RA (52%) or SLE (18%). All individuals have at least 1 MSK symptom, and 68% report fatigue. The most common sites of joint pain are the hands (81%), knees (75%), lumbar spine (64%), and shoulders (55%). A primary care provider had been consulted by 72% of the cohort prior to the screening program, with 15% having seen a rheumatologist and 15% an orthopedic surgeon in the past. The median HAQ score was 0.88, the median pain score (0–10 VAS) 5, and the median patient global score 5 (0–10 VAS). Seventeen new cases of rheumatic disease have been diagnosed (10 RA, 3 PsA, 1 JIA, 1 Sjogren Syndrome with arthralgias, 2 crystal arthropathies) and 4 individuals remain under observation. Fourteen patients with established rheumatic diseases (6 RA, 1 PsA, 1 spondyloarthritis, 5 SLE, 1 JIA) have re-engaged in active rheumatology care. OA and/or degenerative disk disease was present in 58% of the participants screened, 42% had soft tissue syndromes, 2% had fibromyalgia and 6% had a neurologic condition causing pain. RF and anti-CCP antibodies were rarely positive; anti-CCP was present in low or medium titres in 4 individuals with either soft tissue syndromes or OA. ANA was positive in 52% of the group, with 28% having titres >1:320. In those with positive ANA, only 5 had a history of SLE, IA or RA.

Conclusion: The screening program has been successful in detecting new cases of early IA and returning established rheumatology patients to active care in this First Nations community. There is a significant burden of OA in the community, and many residents are ANA positive in the absence of apparent connective tissue disorders. These findings highlight the need for a multidisciplinary team of primary care providers, allied health professionals, and specialists to maximize MSK care in the community. Limitations at this early phase include participation bias.

2064

Regular Measure of Disease Activity During the Routine Care of Rheumatoid Arthritis Patients Involves Some Extra Work but Positive Results. Lissiane K. N. Guedes, Ana Cristina Medeiros Ribeiro, Karina Rossi Bonfiglioli, Diogo Domiciano, Carolina Reither Vizioli, Gilmara Franco da Cunha, Andressa Silva Abreu, Filipi M. Mello, Ana Luiza de Aguiar Foelkel, Celio R. Gonçalves and Ieda Laurindo, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: According to treat to target recommendations the use of validated composite measures of disease activity, which include joint assessments, is needed in routine clinical practice to guide treatment decisions with the final objective of reaching remission or low disease activity in patients with RA.Objective: to study the outcome of adding a validated composite measure of disease activity (DAS28) to routine clinical visits.

Methods: Since 2007 all RA patients (ACR-1987 criteria) in regular follow-up at the Rheumatology Service of a tertiary center change to electronic files with a DAS28-ESR calculator and this measure became mandatory in the routine care visits. Inclusion criteria: patients in regular follow-up for at least 2 years before 2007and no use of biologic agents during the study period (January 2007-December 2011). All patients could receive, free of charge, traditional DMARDs (chloroquine, methotrexate, sulfasalazine, leflunomide and azathioprine), corticosteroids (including intra-articular injections), analgesic and antiinflamatory medications as needed and according to a pre-established protocol. The first DAS28 recorded in the electronic files was compared to the last one recorded in 2011, after 4 years of regular measure of disease activity guiding therapeutic decisions (RA-study group). ERA patients (less than one year of symptoms at the beginning of treatment) submitted to a therapeutic strategy of tight control and DAS28 based clinical decisions were also evaluated.

Results: a total of 304 patients was included, 217 consisting our study group(RA-SG) (86% female, mean age 63 ± 11yrs, mean disease duration 22 ± 10yrs) and 87 ERA patients (83% female, mean age 53 ± 12yrs, mean disease duration 6.7 ± 1.6yrs). ERA patients were significantly younger and with shorter disease duration. DAS28 values and different levels of disease activity are depicted below:

	RA-SG n=217		ERA n=87	
	2007	2011	2007	2011
DAS28 mean (SD)	3.9* (1.4)	3.3* (1.3)	3.7** (1.7)	2.9** (1.4)
% DAS28 <2.6	17*	34*	29**	45**
% low disease activity	18	16	12**	24**
% moderate disease activity	47	39	30**	9**
% high disease activity	18	11	24	16

*,** p<0.05

Conclusion: regularly applying validate composite indexes such as DAS 28 leads to better control of disease activity, mainly an increased percentage of patients in DAS28 remission.

Uptake of the American College of Rheumatology's (ACR) Rheumatology Clinical Registry (RCR): Quality Measure Summary Data. Salahuddin Kazi[1], Itara Barnes[2], Jinoos Yazdany[3] and Rachel Myslinski[2]. [1]UT Southwestern Medical Center, Dallas, TX, [2]American College of Rheumatology, Atlanta, GA, [3]University of California San Francisco, San Francisco, CA

Background: The RCR was launched by the ACR to provide members with an infrastructure for quality reporting related to rheumatoid arthritis, gout, osteoarthritis, osteoporosis, and drug safety. The RCR is now in its third year of operation with data on over 26,000 patients. Here we report the uptake of the RCR by U.S. rheumatologists, and performance on measures regarding functional status, DMARD use, TB screening, prognosis, and disease activity assessment for RA patients in rheumatology practice.

Methods: Data derive from retrospective medical records abstractions performed by providers and designated practice staff for a sample of patients seen by the rheumatologist. Reporters submit data on quality measures via a secure, web-based registry system. Patients included in the denominator of all quality measures are >18 years of age with a diagnosis of RA who are receiving treatment by the reporting rheumatology provider. Additional details of each measure are listed in Table 1. We report the mean performance on each quality measure, defined as percentage of eligible patients receiving recommended care.

Table. Performance on RA Measures Assessed through the RCR (01/11–12/11)

	Total eligible patients (n)	Performance on Quality Measure (%)
Functional status assessment performed at least once within 12 months, and documented using a standardized descriptive or numeric scale, or notation of assessment of the impact on patient activities of daily living	8077	70.5%
Patient prescribed, dispensed, or administered at least one ambulatory prescription for a DMARD within 12 months	7808	97.9%
Documentation of TB screening performed and results interpreted within 6 months prior to receiving first course DMARD	1650	73.6%
Assessment and classification of disease prognosis at least once within 12 months	7771	49.5%
Disease activity assessed and classified at least once within 12 months, using a standardized descriptive or numeric scale or composite index	8075	43.3%

Results: 257 rheumatology providers in 143 practices submitted data on 8096 patients with RA from January 1, 2011 to December 31, 2011. Reporting providers practice in sites ranging from solo offices to large academic centers.

Conclusion:

- Rheumatologists across the country used the RCR in 2011 to report quality data establishing RCR as a mechanism for quality reporting (consistent with the ACR goal that RCR provide maximal benefit from data submission).
- Next steps planned for the ACR registry efforts include the continual enhancement of the quality of data collected, analytic reports promoting key performance indicators, and EHR-enabled reporting and quality improvement analysis through a federated registry network.
- RCR provides an opportunity for rheumatology providers to facilitate practice improvement, contribute to collaborative improvement projects, and contribute to national data, led by their professional society.

Improving Outpatient Follow-up for Osteoporosis Management After a Hip Fracture. Anika Alarakhia[1] and Robert Quinet[2], [1] Ochsner Medical Center, New Orleans, LA, [2]Ochsner Medical Center - New Orleans, New Orleans, LA

Background/Purpose: Patients hospitalized for hip fractures are routinely scheduled for a Rheumatology follow-up appointment to assess their risk of future fractures and need for treatment. Follow-up in our clinic after hospitalization for a hip fracture has been notoriously poor. The purpose of this study was to determine the rate of outpatient follow-up after a hip fracture and implement an intervention to increase the rate.

Methods: We conducted a chart review involving 50 hospitalized hip fracture patients prior to intervention, and 50 hospitalized hip fracture patients after intervention. The intervention included an informational handout which explained the risk of osteoporosis and risks that can lead to further fractures, the importance of receiving a bone density scan, and different treatments to help prevent further fractures that can be implemented as an outpatient. This informational handout was given to the patient and/or family prior to hospital discharge. The results were documented comparing clinic follow-up rates prior to intervention and follow-up rates after intervention.

Results: After reviewing 50 charts from July 2006 to March 2011 of hospitalized hip fracture patients, it was noted that only 3/50 (6%) of patients followed up in our clinic. After implementing our intervention, a chart review was then done from May 2011 to February 2012 and 20/50 (40%) of patients have followed up to our clinic following their hospitalization. This shows a significant increase in follow-up rates after the intervention was initiated.

Conclusion: Outpatient follow-up for a patient after being hospitalized for a hip fracture is extremely important to prevent further fractures which can increase a patient's morbidity and mortality. After receiving an informational handout while in the hospital, we found that the outpatient follow-up rate increased dramatically. It is concluded that once patients and their families fully understood the importance of seeing a physician to assist in preventing further fractures, they were more willing to make a follow-up appointment in the outpatient setting.

Access to Technology and Interest in Mobile "app" for Disease Management Among Patients with Systemic Lupus Erythematosus Seeking Care At a Large Referral Center. Wendy Marder[1], Holly Witteman[2], Margaret Hyzy[3], Martha Ganser[1], Emily C. Somers[1] and Lawrence An[3]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]Universitiy of Michigan, Ann Arbor, MI

Background/Purpose: Some of the challenges facing patients with chronic diseases such as systemic lupus erythematosus (SLE) include identifying triggers for disease "flares" and accurately recalling medication changes they make in response to flares, e.g, self-adjustments of daily prednisone doses. We sought to assess interest in and applicability of smartphone technology as a convenient tool for disease self-management, as well as assessing usage patterns among a heterogeneous group of lupus patients at an academic outpatient clinic. These data will inform the design of a mobile application ("app"), a feature of which will allow SLE patients to conveniently and accurately record disease activity trends and prednisone use over time between rheumatology clinic appointments.

Methods: Lupus patients from the University of Michigan rheumatology clinics who met ≥4 ACR criteria and age ≥18 years. Participants completed a survey containing questions on sociodemographics, healthcare information needs and satisfaction, and access to technology, including smartphone usage patterns. Multivariable logistic regression was used to examine the likelihood of mobile app use among three indicators of socioeconomic status, adjusting for age, sex and race.

Results: Among 100 SLE patient respondents, demographics were: 89% female, mean age 40 years (SD 13); race 66% white, 21% black, 13% other/unknown.; education 16% ≤high school, 34% some college or technical school, 16% college graduate, 33% graduate degree; insurance coverage 23% Medicaid/none, 12% Medicare; 65% private. Participants expressed high interest in a mobile app for lupus: 70% rate app usage would be "extremely helpful" (5 on a 1–5 scale) as a "simple way to get in touch with your healthcare team." The majority reported the following mobile app features would be "extremely helpful": automatic reminders (60%), ability to track flares & triggers of disease activity (59%), and sharing this information with healthcare providers (58%). Younger age was associated with increased mobile app usage: 95% among 20–29 yrs, 73% among 30–49 yrs, 22% among ≥50 yrs (OR for 10 yr interval 0.31, 95%CI 0.2–0.5). When adjusted for age, sex, and race, mobile app usage was similar according to education level (all p=NS). According to type of insurance coverage, those with Medicaid/none reported less mobile app use compared to privately insured (OR 0.16, 95% CI 0.03, 0.86), while those with Medicare were comparable to private (OR 0.77, 95% CI 0.14, 4.3).

Conclusion: These data reveal broad interest in a mobile app for lupus, including proposed features for disease management, across sociodemographic groups. The majority of respondents use smartphone/mobile app technology, with younger age being a significant predictor. However, across different indicators of socioeconomic status, various usage patterns emerge. These data can be used to help target efforts to increase accessibility to this technology.

2068

Is There a Difference in Rheumatology Patient Reported Outcomes When Measured At Home Versus the Clinic Setting? C.J. Inman[1], Frederick Wolfe[2] and Kaleb Michaud[3]. [1]University of Utah, Salt Lake City, UT, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Registries have become a common tool for collecting patient-centered outcome measures. Clinical effectiveness research may be improved if data from multiple registries could be combined allowing for richer data sets in that patients in one registry could supplement data which has been collected in a separate registry. However, the question remains as to whether data that is collected in two separate registries are equivalent. While the registries may ask the same clinical question, if they collect it in unique formats, such as online at home versus in the clinical setting, it is not clear if the metrics are equal. We attempted to address this question of data equivalence through evaluating a patient entered registry versus a registry collected at the point of clinical care.

Methods: Patients were participants in a rheumatology clinic research database that collected patient data via paper questionnaires at clinic visits. They were also participants in a longitudinal, observational study that collected patient data at 6-month intervals from their home via paper, web, or telephone-interview questionnaires at patient's preference from 2007–2012. Four patient measures were congruent between the studies: HAQ-II and pain, patient global assessment, and fatigue visual analog scales. General estimating equations (GEE) assessed longitudinal effects between clinical and at-home data collection methods adjusting for sociodemographic status and number of clinic visits.

Results: A total of 1439 patients enrolled in both studies (40% rheumatoid arthritis, 22% osteoarthritis, and 38% other rheumatic diseases). Mean (SD) age at enrollment was 56.5 (14.0) years, 20.5% were male, 92.0% were Caucasian, and mean (SD) education was 14.0 (2.2) years. Primary rheumatic disease duration was 8.2 (9.3) years and rheumatic disease comorbidity index was 2.0 (1.6). Baseline measures were: HAQ-II 0.87 (0.65), pain 4.0 (2.8), global 3.8 (2.5), and fatigue 4.6 (3.1). Results of the GEE are shown in Table 1; clinic paper questionnaire as well as non-clinic formats of web and telephone were compared to non-clinic paper questionnaires.

Table 1. Relative effect of location and questionnaire media on outcomes through general estimating equations

Outcome Measure	Clinic Paper	Paper (ref)	Non-clinic (e.g., at home) Web	Telephone
HAQ-II (0–3)	0.07 (0.06, 0.08)	0.0	0.02 (0.00, 0.04)	0.18 (0.15, 0.21)
Pain (0–10)	0.98 (0.90, 1.06)	0.0	−0.12 (−0.24, 0.01)	0.71 (0.51, 0.91)
Global assessment (0–10)	0.55 (0.47, 0.62)	0.0	−0.02 (−0.14, 0.10)	0.00 (−0.19, 0.18)
Fatigue (0–10)	0.75 (0.67, 0.83)	0.0	−0.02 (−0.15, 0.10)	1.12 (1.01, 1.39)

Conclusion: On average patients report a higher level of disease severity during a clinic visit than when they report from home while those who respond from home via the web do not differ from paper respondents. As expected, patients that choose telephone interviews reported worse outcomes except for global assessment. Patients respond at home when they are willing and available which may delay responses during spans of poorer health. Patients seen in the clinic, notably those seen more often, could have more severe health care needs from increased disease severity. Further study is needed to determine if the accuracy of such assessments differ.

Proteinase Activated Receptor-4 Stimulation Promotes Leukocyte Adhesion in the Rat Knee Joint. Jason J. McDougall. Dalhousie University, Halifax, NS

Background/Purpose: Proteinase activated receptors (PARs) are a family of G protein-coupled receptors that signal by enzymatic cleavage of the receptor in a specific extracellular domain. Since PAR-4 has been shown to cause pain and inflammation in synovial joints, the aim of this study was to examine the effect of PAR-4 activation on leukocyte kinetics in the synovial microvasculature.

Methods: Male c57/bl6 mice were deeply anaesthetised and the right knee joint was exposed. An intravenous injection of 0.05% rhodamine was administered to label circulating leukocytes. Intravital microscopy was used to measure leukocyte trafficking in the joint in response to local adminis-

tration of the PAR-4 agonist AYPGKF-NH2 (50mM). Comparisons were made in wild-type and P-selectin knockout mice. The effect of the PAR-4 antagonist pepducin p4Pal10 on leukocyte kinetics in an adjuvant mono-arthritic knee was also assessed.

Results: In wild-type animals, AYPGKF-NH2 caused a gradual increase in leukocyte rolling and adherence which was not present in P-selectin knockout mice (P<0.0001, n=8). Treatment of arthritic mice with pepducin p4Pal10 reduced leukocyte rolling and accumulation in the joint (P<0.0001).

Conclusion: Activation of PAR-4 in rat knee joints causes leukocyte rolling and adhesion that is P-selectin-dependent. In an arthritic joint, blockade of PAR-4 with pepducin p4Pal10 reversed these pro-inflammatory changes indicating that PAR-4 antagonism can have an anti-inflammatory outcome.

Myeloid-Derived Suppressor Cells Accumulated in Spleens of Mice with Collagen-Induced Arthritis and Inhibited Immune Response of CD4[+] T Cells.

Wataru Fujii[1], Eishi Ashihara[2], Hideyo Hirai[3], Hidetake Nagahara[1], Kazuki Fujioka[1], Ken Murakami[1], Kaoru Nakamura[1], Takahiro Seno[1], Aihiro Yamamoto[1], Hidetaka Ishino[1], Masataka Kohno[1], Taira Maekawa[3] and Yutaka Kawahito[1]. [1]Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Kyoto Pharmaceutical University, Kyoto, Japan, [3]Kyoto University Hospital, Kyoto, Japan

Background/Purpose: Myeloid-derived suppressor cells (MDSCs), firstly reported in patients with cancer, have a myeloid origin and an ability to suppress T cell responses. MDSCs are characterized by the co-expression of the myeloid-cell lineage differentiation antigens Gr1 and CD11b. Many investigators have demonstrated that MDSCs promote tumor progression via T cell tolerance in patients with cancers and tumor-bearing mice. However, as for autoimmune diseases, the roles of MDSCs in autoimmune disease remain controversial. Here we investigate the roles of MDSCs in autoimmune arthritis using collagen-induced arthritis (CIA) models.

Methods: CIA was induced in 7–8week-old DBA/1 mice by intradermal injection of 200 μg of bovine type II collagen (CII) in Freund's complete adjuvant on day 0, followed by a booster injection of 200 μg of CII in Freund's incomplete adjuvant on day 21. The severity of arthritis in each paw was evaluated 3 times weekly. We first analyzed the number of Gr1[+]/CD11b[+] MDSCs in the spleens of mice with CIA by flow cytometry at the onset, the peak, and the convalescence of CIA. Next, MDSCs were isolated from spleens of mice with CIA by magnetic cell separation. Carboxyfluorescein diacetate succinimidyl ester (CFSE)-labeled CD4[+] T cells were stimulated with anti-CD3/CD28 antibodies (Abs) and cultured in the presence of 30 U/ml interleukin (IL)-2 with or without MDSCs for 5 days. We investigated CD4[+] T cell proliferation using flow cytometric measurement of CFSE dye dilution. Next, MDSCs were co-cultured with CD4[+] T cells stimulated with anti-CD3/CD28 Abs for 3 days. We measured cytokines released into supernatant using specific enzyme-linked immunosorbent assay (ELISA).

Results: In a murine arthritis model, MDSCs significantly accumulated in the spleens of mice with CIA at the peak of its severity. MDSCs inhibited the proliferation of CD4[+] T cells in response to anti-CD3/CD28 Abs *in vitro*. When we co-cultured CD4[+] T cells and MDSCs interferon (IFN)-γ and IL-6 released into supernatant were significantly decreased, 97.6 ± 16.1 pg/ml to 79.8 ± 10.1 pg/ml ($p < 0.05$), 10.4 ± 2.1 pg/ml to 2.9 ± 1.0 pg/ml ($p < 0.01$), respectively.

Conclusion: MDSCs accumulated in the spleens of mice with CIA. These MDSCs inhibited CD4[+] T cell proliferation and pro-inflammatory cytokine production *in vitro*. These findings may indicate the protective roles of MDSCs against autoimmune arthritis, which could be exploited for new cell-based therapies. We are now investigating the function of MDSCs *in vivo*.

The Potent, Highly Selective and Orally Bioavailable Spleen Tyrosine Kinase Inhibitor GSK143 Demonstrates Efficacy in B Cell Receptor and Fc Receptor Signalling in Models of Inflammatory and Autoimmune Disease.

Marion C. Dickson, Nicholas Smithers, Huw Lewis, Cesar Ramirez-Molina, Scott McCleary, Mike Barker and John Liddle. GSK, Stevenage, United Kingdom

Background/Purpose: Spleen tyrosine kinase (Syk), a 72 KDa cytosolic non-receptor tyrosine kinase is a key mediator of B cell receptor (BCR) and Fc receptor (FcR) signalling in a variety of inflammatory cell types and has been implicated in the pathogenesis of a number of allergic and autoimmune diseases including Asthma, Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE). Several Syk inhibitors are currently in clinical development and here we report an extended pharmacological and biological profile of GSK143 a novel, highly selective, orally bio-available Syk inhibitor.

Methods: GSK143 inhibitory activity (dose range 10uM to 1nM) on BCR signalling was evaluated in human and murine whole blood by assessing the cell surface expression of IgM stimulated CD69 using flow cytometry. IgM antibody titres in a 7 day murine T independent immunisation model, induced by a TNP-ficol challenge, were measured after once daily dosing (5, 10, 15 and 30mg/kg) to determine in-vivo activity. The effect of GSK143 (dose range 10uM to 10nM) on TNFa production was explored in human monocytic cells, from 8 donors, differentiated to a pro-inflammatory M1 macrophage phenotype with GM-CSF. Macrophages were stimulated with Ig-conjugated sepharose beads to mimic immune complex activation of the Fc gamma receptor (FcγR).

Results: GSK143 dose dependently inhibited the IgM stimulated CD69 expression in both human and murine whole blood with IC50s of 185nM (pIC50 6.734 +/− 0.06) and 364nM (pIC50 6.44 +/−0.28) respectively. In the murine model of T cell independent immunisation, GSK143 administered orally once daily (qd) from day 1 to day 6, produced a significant reduction in the concentration of IgM antibodies (ng/mL) in comparison to that of the corresponding vehicle control group (22843.11 ± 3377.88 ng/mL) vs (15484.62 ± 1984.15 ng/mL, P < 0.01)), (11135.83 ± 2129.6 ng/mL, P < 0.001), (5919.73 ± 1539.03 ng/mL, P < 0.001) and (2877.67 ± 722.79 ng/mL, P < 0.001) at the 5, 10, 15 and 30 mg/kg doses respectively. The systemic exposure observed on day 6 increased with the administered dose with AUC$_{0-24h}$ (ng.h/mL) values of 1435.3 ± 808.2 ng.h/mL, 2457.1 ± 640.1 ng.h/mL, 5533.6 ± 2772.4 ng.h/mL and 7901.7 ± 3058.7 ng.h/mL for the 5, 10, 15 and 30 mg/kg doses, respectively. In human GM-CSF differentiated macrophages stimulated with Ig conjugated beads, GSK143 inhibited FcγR mediated TNFa release in a concentration dependent manner (IC50 = 34nM, pIC50 of 7.47 +/− 0.31).

Conclusion: GSK143, a potent, highly selective and orally bio-available Syk inhibitor blocked FcγR and BCR signalling in pre-clinical human and rodent *in-vitro* and *in-vivo* models of inflammatory and autoimmune diseases.

Background/Purpose: Bone destruction in the joints of patients with rheumatoid arthritis (RA) is the result of a combination of osteoclastic bone resorption and osteoblastic bone formation. This process is not completely understood, and especially the importance of local inflammation needs further investigation. We used 3D stereological estimators to evaluate how bone formation and bone resorption are altered in autoimmune arthritis.

Methods: Twenty one 9–12-weeks-old female SKG mice were randomised to either an arthritis group or a control group. Arthritis was scored twice weekly by an observer blinded for group distribution. The fluorescent label tetracycline was injected intraperitoneally 8 days before termination of

the study at the end of week 6. Right hind paws were fixed in alcohol and embedded undecalcified in methylmethacrylate. Seven-μm-thick sections were cut exhaustively according to the principles of vertical sectioning. Systematic sampling was used to obtain approximately10 levels each with 12 sections. Using newCAST stereological software, intercepts between a line grid and the tissue of interest were counted by an observer blinded for the group distribution. Osteoclast-covered bone surfaces (Oc.S) and eroded surfaces (ES) were estimated on sections stained for TRAP and mineralising surfaces (MS) were estimated on unstained sections using fluorescent microscopy. The absolute number of osteoclasts (N.Oc) was estimated using the physical fractionator. All parameters were assessed in the tarsus on the periosteal and endosteal surfaces, and the presence of adjacent inflammatory tissue was evaluated for each intersection and cell count. The relevant reference bone surface (BS) was estimated for all parameters. The results were expressed as relative values (MS/BS, ES/BS, Oc.S/BS, and N.Oc/BS).

Results: At the end of week 1 and until termination, the arthritis score was higher in arthritic animals ($p<0.01$). Likewise, MS/BS, ES/BS, Oc.S/BS, and N.Oc/BS were elevated in arthritic mice compared to normal mice both at the endosteal surface and the periosteal surface ($p<0.001$). On surfaces both adjacent to and not adjacent to inflammation in arthritic mice MS/BS were elevated on endosteal as well as periosteal surfaces compared to normal mice ($p<0.001$). In arthritic mice, ES/BS and Oc.S/BS were larger on endosteal as well as periosteal surfaces adjacent to inflammation compared to surfaces without inflammation ($p<0.01$). However, the difference between MS/BS at surfaces adjacent to and not adjacent to inflammation on either periosteal or endosteal surfaces did not reach the level of statistical significance.

Conclusion: Arthritis caused bone formation to occur on more bone surfaces, irrespectively of the adjacent tissue being inflamed. However, bone degradation was present almost exclusively on surfaces with adjacent inflammation. Therefore, arthritic bone loss is likely to be explained by an imbalance of erosion and formation of bone rather than a general down-regulation of bone formation. These findings may be important for the development of new bone targeting drugs in RA. The present study is the first to apply 3D stereological estimators to quantify bone formation and degradation in a model of RA.

Green Tea Epigallocatechin-3-Gallate Ameliorates Murine Arthritis by Inducing IDO Producing Dendritic Cells Via Nrf2 Antioxidant Pathway. Soyoun Min, Mei Yan, Kamala Vanarsa, Anna Bashmakov and Chandra Mohan. University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: To examine the immunomodulatory effects and mechanisms of Green Tea ($-$)-epigallocatechin-3-gallate (EGCG) on experimental arthritis in mice, we investigated whether EGCG can afford therapeutic benefit in collagen-induced arthritis (CIA) subjected mice.

Methods: EGCG (10 mg/kg body weight) was administered by oral feeding three times per week for three weeks after booster immunization, while the control mice were administered phosphate-buffered saline (PBS). The effects of EGCG were examined by assessment of joint swelling, histological changes, and immune cell populations, and the mice were sacrificed 7 weeks after the first immunization. The level of protein obtained from spleen cells and joint homogenates was examined by Western Blotting analysis. Serum levels of anti-type II collagen specific antibodies and cytokine production were measured by ELISA.

Results: EGCG treatment ameliorated clinical symptoms and reduced histological scores in arthritic mice (7.2 ± 1.2 vs 12.4 ± 2.3, P < 0.01). The serum concentrations of type-II collagen-specific IgG2a antibodies were significantly lower in EGCG-fed mice compared to PBS-treated mice (0.105 ± 0.01vs 0.283 ± 0.25 OD units, P < 0.05). EGCG significantly suppressed T cell activation by reducing [3H]-thymidine uptake and cell division as assessed by CFSE dilution. EGCG also reduced CD4 and CD8 T cells, B cells, marginal zone B cells, T1 and T2 transitional B-cells in the draining lymph node (dLN) and spleen, suggesting that down-regulation of several immune cell populations is one of the mechanisms of EGCG action. EGCG treatment increased the frequency of CD4$^+$ Foxp3$^+$ regulatory T cells ($6.4 \pm 1.25\%$ vs 1.94 ± 1.0, P < 0.05) and IDO expression within CD11b$^+$ dLN cells. The increased CD11b$^+$ DCs elicited by EGCG could induce CD4$^+$CD25$^+$ Tregs in an IDO dependent manner *in vitro*. Additionally, CD11b$^+$ DCs in spleen cells and the joint homogenates from EGCG-fed mice exhibited significantly increased NF-E2-related factor-2 (Nrf-2) and heme

oxygenase-1 (HO-1) compared with PBS-fed mice, alluding to the importance of anti-oxidants.

Conclusion: EGCG ameliorated experimental arthritis in mice eliciting IDO-producing DCs and the activation of the Nrf-2 anti-oxidant pathway. Our results also indicate that ECGC may be of potential therapeutic value for inhibiting cartilage destruction and increasing immunoregulatory cells in arthritic joints. It remains to be established whether EGCG is useful for the prevention and treatment of rheumatoid arthritis.

Combined Effects of a c-Fos/AP-1 Inhibitor T-5224 and Methotrexate On Collagen-Induced Arthritis in Mice. Tomomi Date[1], Yukihiko Aikawa[1], Tetsuya Yamamoto[1], Hirokazu Narita[1], Shuichi Hirono[2] and Shunichi Shiozawa[3]. [1]Research Laboratories, Toyama Chemical Co., Ltd, Toyama, Japan, [2]Department of Pharmaceutical Sciences, School of Pharmacy, Kitasato University, Tokyo, Japan, [3]Department of Medicine & Rheumatology, Kyushu University Beppu Hospital, Beppu, Japan

Background/Purpose: Activator protein-1 (AP-1) is an important transcription factor for cytokine production and joint destruction in rheumatoid arthritis (RA), and a potential target for the treatment of RA. We previously reported the preventive and therapeutic effects of T-5224, a small molecule inhibitor of c-Fos/AP-1, on type II collagen-induced arthritis (CIA) in mice. The purpose of this study was to investigate the effect of T-5224 in combination with or with add-on to methotrexate (MTX) on the development of arthritis and joint destruction in mice with CIA.

Methods: CIA was induced in DBA/1J mice by the immunization with bovine type II collagen twice on days 0 and 21. In a combination study, T-5224 (3 mg/kg/day) and/or MTX (0.5–5 mg/kg/day) were orally administered once daily from the day of the 2nd immunization (day 21) to day 34. In an add-on study, MTX (0.5 mg/kg/day) was administered from day 21 to day 49. The add-on treatment of T-5224 (3 mg/kg/day) to MTX (0.5 mg/kg/day) or MTX at a dose increased to 5 mg/kg/day started from day 27. In both studies, anti-rheumatic efficacy was determined by arthritis score, X-ray examination, and serum interleukin-1β (IL-1β) on days 35 and 50, respectively.

Results: In a combination study, MTX alone showed dose dependent reduction in arthritis scores by 15% to 58% at 0.5 to 5 mg/kg/day. T-5224 at 3 mg/kg/day in combination with MTX at 0.5 and 1.5 mg/kg/day decreased the arthritis scores by 57% and 62%, respectively, which was similar to that achieved by MTX alone at 5 mg/kg/day (58%). The joint destruction was suppressed by 78% and 90%, respectively, in combination of T-5224 and MTX at 0.5 and 1.5 mg/kg/day, which was more potentiated than MTX alone at 5 mg/kg/day. Elevated IL-1β level in the serum reduced by combined treatment of T-5224 and MTX, whereas MTX alone at 0.5 and 1.5 mg/kg was without effects.

Add-on treatment of T-5224 (3 mg/kg/day) with MTX (0.5 mg/kg/day) decreased the arthritis scores by 70%, which was more marked than MTX alone at a dose escalated from 0.5 to 5 mg/kg/day (29%), when started dosing from day 27 after the onset of arthritis. Add-on treatment of T-5224 with MTX reduced the joint destruction scores by 81%, while MTX alone did by 46%. Serum level of IL-1β decreased only in mice treated with T-5224 added-on to MTX.

Conclusion: These results indicate that either combined or add-on use of T-5224 and MTX with a different mode of anti-arthritic actions is expected to augment anti-rheumatic and anti-joint destructive effects in the therapy of RA.

CCR6$^+$ Foxp3$^+$ Regulatory T Cells Regulate the Development of Collagen Induced Arthritis in T Cell Specific RORγt Transgenic Mice. Yuya Kondo, Masahiro Tahara, Mana Iizuka, Hiroto Tsuboi, Satoru Takahashi, Isao Matsumoto and Takayuki Sumida. University of Tsukuba, Tsukuba, Japan

Background/Purpose: Recent studies reported that IL-17 producing Th-17 cells appear to play an important role in the generation of several autoimmune arthritis models. We previously reported that T-bet expression regulates the development of collagen induced arthritis by suppression of

antigen reactive Th17 cells differentiation via the repression of RORγt expression (Kondo Y et al. *Arthritis Rheum* 64,162-72, 2012). This observation suggested that RORγt might be pivotal on the development of autoimmune arthritis. The aim of this study is to clarify the effect of RORγt expression on T cells in the development of autoimmune arthritis.

Methods: 1) Incidence and severity of collagen induced arthritis (CIA) were assessed in C57BL/6 (B6) and T cell specific RORγt transgenic (RORγt Tg) mice under the control of CD2 promoter. 2) Histological assessment of inflamed joints was performed with hematoxilin-eosin staining. 3) Collagen type II (CII) specific antibody in sera was measured with ELISA. 4) Draining lymph node cells were harvested from B6 and RORγt Tg mice at 10 days after the immunization of CII, and cultured in the medium containing CII. Cytokine level in supernatants were analyzed by ELISA. 5) Draining lymph node cells were cultured in vitro as described in 4), transcription factors expression on CD4$^+$T cells was analyzed by FACS and real-time PCR. 6) The correlation between the expression of transcription factors and chemokine receptor 6 (CCR6) was analyzed by FACS.

Results: 1) CIA was significantly suppressed in RORγt Tg mice compared with B6 mice. 2) Histological assessments revealed that inflammation and bone destruction were milder in RORγt Tg mice than B6 mice. 3) Anti-CII antibody was significantly lower in RORγt Tg mice than B6 mice ($P < 0.05$). 4) IL-17 level in supernatant was significantly increased in RORγt Tg mice compared with B6 mice ($P < 0.05$). 5) FACS analysis showed that RORγt expression on CD4$^+$ T cells was significantly higher in RORγt Tg mice than B6 mice. Although there was no significant difference of Foxp3 expression on CD4$^+$ T cells between B6 mice and RORγt Tg mice, most of Foxp3$^+$ CD4$^+$ T cells also expressed RORγt in RORγt Tg mice. Bcl-6 expression on CD4$^+$ T cells of RORγt Tg mice was comparable to that of B6 mice. 6) The expression of CCR6 on CD4$^+$ T cells was significantly higher in RORγt Tg mice compared with B6 mice ($P < 0.01$). In particular, CCR6 was remarkably upregulated in Foxp3$^+$ CD4$^+$ T cells of RORγt Tg mice compared with that of B6 mice ($P < 0.01$).

Conclusion: CIA was significantly suppressed in RORγt Tg mice, although IL-17 production from CII reactive T cells was increased. The inhibition of arthritis might be related with the increase in CCR6$^+$ Foxp3$^+$ CD4$^+$ T cells in RORγt Tg mice.

Efficacy of the Potent PI3K-δ,γ Inhibitor IPI-145 in Rat Adjuvant Arthritis. David L. Boyle, Katharyn Topoleweski and Gary S. Firestein. UCSD School of Medicine, La Jolla, CA

Background/Purpose: Phosphoinositide 3-kinase (PI3K) is a family of intracellular signaling transducers and could be targeted to treat inflammatory diseases like rheumatoid arthritis (RA). However, blockade of the a and b isoforms could cause significant toxicity due to their ubiquitous expression. On the other hand, g and d isoform expression is restricted mainly to leukocytes and, for the latter, synovial fibroblasts. These enzymes regulate a variety of innate and adaptive immune pathways, especially through activation of AKT. In this study, IPI-145, a novel potent PI3K-δ,γ inhibitor (K$_i$'s: PI3K-d: 16 pM, PI3K-g: 244 pM, PI3K-β: 1.6 nM and PI3K-a: 25.9 nM) was tested for its activity in the rat adjuvant induced arthritis model.

Methods: Rat adjuvant arthritis was induced by immunizing Lewis rats with CFA. Then, from either Day 8 or Day 14 through Day 21 one of three treatments (vehicle, 10 or 50mg/kg/d IPI-145) was administered daily by oral gavage. Paw swelling was assessed by plethysmometry, radiographs by a semi-quantitative scoring system, ankle gene expression by qPCR (relative expression units; REU), and pAKT and AKT by Western blot. Clinical endpoints were assessed every other day from Day 0 through Day 21.

Results: Treatment with 10 or 50 mg/kg/d of IPI-145 (n=16/group) beginning on day 8 prior to onset of ankle swelling inhibited arthritis progression in a dose dependent fashion. Disease progression was significantly reduced at 50 mg/kg from Day 12 through Day 21 (see Figure; p<0.05) when initiated on Day 8. Treatment of established disease with 50 mg/kg of IPI-145 starting on Day 13 resulted in 70% less swelling relative to vehicle treated animals (see Figure; p<0.05). Synovial IL-6 and MMP3 gene expression on Day 21 were similar between groups, however MMP13 expression was substantially inhibited in the 50 mg/kg group (Vehicle, 4.5±0.9; 50 mg/kg, 1.2±0.3 p<0.05). MMP13 was reduced by over 80% in the delayed IPI-145 treated groups (Vehicle, 4.5±0,9; IPI-145 0.6±0.1 p<0.05) PI3K-δ,γ blockade significantly decreased radiographic bone destruction in both regimens (vehicle 3.5±0.4, 50 mg/kg=1.5±0.4; day 13,

2.8±4 p<0.05). AKT phosphorylation in ankles was reduced on day 21 in both regimens (pAKT/AKT ratio: Vehicle 0.57±0.02; day 8 protocol, 0.23±0.06; day 13 protocol, 0.28±0.02 p<0.05).
Conclusion: PI3K-δ,γ blockade demonstrated prominent disease-modifying effects in both pretreatment and established preclinical arthritis protocols with statistically significant reductions in ankle swelling, MMP13 gene expression, radiographic bone destruction, and AKT phosphorylation. Compared with broad spectrum or single isoform inhibitors, PI3K-δ,γ inhibitors could have a favorable therapeutic profile.

IL-6 Blockade Augments the Anti-Inflammatory Effect without Increasing the Side Effects of Steroids in Collagen-Induced Arthritis. Miho Suzuki[1], Hiroto Yoshida[1], Misato Hashizume[1], Masashi Shiina[1], Keisuke Tanaka[1] and Yoshihiro Matsumoto[2]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan, [2]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan

Background/Purpose: Steroids are the main therapy for chronic inflammatory diseases. They are very effective, but induce many side effects, such as osteoporosis, making it important that the dose steroids be reduced. However, some patients with chronic inflammatory disease may have difficulty tapering off steroids. It is thought that IL-6 might be involved in the steroid resistance because elevated levels of IL-6 are found in these patients. Here, we elucidated the role of IL-6 in several effects of steroids using a collagen-induced arthritis (CIA) mouse model to examine the possibility of combination therapy.

Methods: To prepare a CIA model, DBA/1J mice were immunized intradermally with bovine type II collagen, and 21 days later (Day 21) once again given a booster injection. Mice were treated with the steroid prednisolone (PSL) intraperitoneally from Day 21 at doses of 1, 3, and 6 mg/kg five times a week or were administered with 8 mg of rat anti-mouse IL-6R monoclonal antibody (MR16-1) intraperitoneally once on Day 21. Another group was given a combination of the two from Day 21. Clinical symptoms of arthritis were evaluated by observation and expressed as an arthritis score on a scale of 0–4 for each limb. To assess the side effects of PSL, BMD was measured with DXA, and neutrophils and lymphocytes were quantified in blood using a sysmex system. Furthermore, synovial cells from CIA mice were cultured in the presence of dexamethasone (DEX) for 3 h after IL-6 pretreatment, and then COXII mRNA was quantified by real-time PCR.

Results: PSL dose-dependently reduced the arthritis score in the CIA model on the peak (Day 33) of arthritis. At the same time, neutrophil count was increased and lymphocyte count was decreased in a dose-dependent manner. MR16-1 in combination with low doses of PSL (1, 3 mg/kg) improved clinical symptoms significantly more than the same dose of PSL alone on Day 33 even though administration of MR16-1 alone resulted in no improvement. Interestingly, neutrophil and lymphocyte counts did not change and BMD was not reduced. To explore how MR16-1 could improve the anti-inflammatory effect of PSL, we next examined the influence of IL-6 on DEX activity *in vitro*. COXII expression was clearly suppressed by DEX, but IL-6 pretreatment attenuated the inhibitory effect of DEX.

Conclusion: We demonstrated that IL-6 blockade augmented the anti-inflammatory effect of PSL without changing BMD or neutrophil and lymphocyte counts in CIA mice. IL-6 blockade might make steroid tapering possible.

Low-Density Lipoprotein Receptor Deficiency Ameliorates the Development of Inflammatory Arthritis. Shawn Rose and Harris R. Perlman. Northwestern University, Chicago, IL

Background/Purpose: Patients with rheumatoid arthritis (RA) carry a higher risk of cardiovascular disease compared to the general population. The low-density lipoprotein receptor (LDLR) and Apolipoprotein E (ApoE) have been shown to modulate atherosclerosis in mice, yet murine models of RA-like disease have yielded conflicting data regarding the development of joint disease in mice lacking ApoE. Here, we examined the effect of deleting ApoE or the LDLR on the development of the effector phase of RA-like disease and on the formation of atherosclerotic lesions in arthritic mice.

Methods: The K/BxN serum transfer-induced arthritis (STIA) model was utilized in control, LDLR$^{-/-}$, and ApoE$^{-/-}$ mice. Inflammatory arthritis severity was assessed using clinical indices and by immunohistochemical staining of ankle joint specimens. Serum cholesterol levels were determined via enzymatic assays. Serum cytokine and chemokine levels were measured utilizing luminex-based assays. Aortic atherosclerotic plaque burden was quantitated using Sudan IV staining.

Results: LDLR-deficiency resulted in a reduction in arthritis severity as compared to controls. In contrast, ApoE deficiency had no effect on arthritis intensity. LDLR$^{-/-}$ and ApoE$^{-/-}$ mice exhibited comparable serum levels of total, low-density lipoprotein, and high-density lipoprotein cholesterol. However, LDLR$^{-/-}$ STIA mice expressed lower levels of circulating IL-6 compared to ApoE$^{-/-}$ STIA mice, which correlated with diminished arthritis severity. Arthritic LDLR$^{-/-}$ and ApoE$^{-/-}$ mice displayed a similar degree of aortic atherosclerosis.

Conclusion: STIA was reduced in LDLR$^{-/-}$ mice but not ApoE$^{-/-}$ mice despite similar serum cholesterol profiles in these animals. These data suggest that factors other than altered cholesterol levels are responsible for the decreased arthritis severity observed in LDLR$^{-/-}$ mice. In contrast, atherosclerotic burden was unaffected by the presence of arthritis in either ApoE$^{-/-}$ or LDLR$^{-/-}$ mice. Thus, targeting the LDLR may be a viable strategy to reduce arthritis disease activity in RA.

Anti-Interleukin-6 Receptor Antibody Improves Systemic Osteoporosis in a Mice Model of Glucose-6-Phosphate Isomerase-Induced Arthritis. Hiroto Yoshida[1], Miho Suzuki[1], Misato Hashizume[1], Keisuke Tanaka[1], Masashi Shiina[1], Isao Matsumoto[2], Takayuki Sumida[2] and Yoshihiro Matsumoto[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan, [2]University of Tsukuba, Tsukuba City, Japan

Background/Purpose: Patients with rheumatoid arthritis (RA) have a high risk of osteoporosis and osteoporotic fracture. In addition to the primary risk factors for osteoporosis, osteoporosis in RA is characterized by a complexity of other risk factors, including inflammation, immobilization, and use of corticosteroids. Anti-human interleukin-6 (IL-6) receptor antibody and various TNF inhibitors have an excellent therapeutic effect on RA symptoms, such as inflammation, pain, and swelling of joints. However, it is not fully understood whether inhibition of IL-6 and TNF-α can improve osteoporosis in patients with RA. Here, we investigated the interaction between proinflammatory cytokines and bone loss, using glucose-6-phosphate isomerase (GPI)-induced arthritis.

Methods: GPI-induced arthritis in DBA/1J mice was triggered by intradermal injection of recombinant GPI. Mice were injected once with anti-mouse IL-6 receptor antibody (MR16-1) intraperitoneally 5 days after immunization. On the other hand, TNF receptor-Fc (TNFR-Fc) was given intraperitoneally 3 times per week from the 5th day of immunization. The femurs of mice were harvested at various time points and the lumbar spine was excised at day 35. The trabecular bone volume (BV/TV) of the femurs and the lumbar spine was analyzed by using micro-computed tomography (μCT).

Results: First, we examined the severity of bone loss in GPI-induced arthritis. In immunized mice, BV/TV of femurs had significantly declined by 32.5% on day 7 (beginning of swelling) and by 61.5% on day 14 (peak of swelling) compared with non-immunized mice. Thereafter, as the swelling decreased, BV/TV of femurs in immunized mice was gradually recovered to 61.0% of non-immunized mice by day 35. Because arthritis significantly decreased the bone volume of femurs in mice, we next examined the involvement of IL-6 and TNF-α in bone loss in GPI-induced arthritis. Both MR16-1 and TNFR-Fc significantly suppressed the development of arthritis compared with untreated immunized mice. In MR16-1-treated mice, BV/TV of femurs and lumbar spine on day 35 was significantly increased to 1.3-fold and 1.2-fold that in untreated arthritic mice. On the other hand, TNFR-Fc increased the bone volume of femurs to 1.2-fold, but it did not affect that of the lumbar spine.

Conclusion: We demonstrated that IL-6 and TNF-α play a crucial role in bone loss of femurs caused by inflammatory arthritis in mice. However, in the lumbar spine, IL-6 is involved in bone loss but TNF-α is not. This suggests that blockade of IL-6 would have a beneficial effect on systemic osteoporosis in RA patients.

IL-20 Is Not Involved in Mouse Collagen Induced Arthritis. Christina Andersson[1], Kyle Serikawa[2], Hermann Pelzer[1], Peter Thygesen[1], Patricia Smith[2], Kim Kruse[2], Shameek Biswas[2], Brian Fox[2], Anders Milner[1], Peter Kvist[1], Josephine Hebsgaard[1], Jesper Pass[1] and John Rømer[1]. [1]Biopharmaceutical Research Unit, Novo Nordisk A/S, Måløv, Denmark, [2]Biopharmaceutical Research Unit, Novo Nordisk A/S, Seattle, WA

Background/Purpose: Interleukin-20 (IL-20) is a pro-inflammatory cytokine involved in the pathogenesis of rheumatoid arthritis (RA). Clinical phase 2a testing has shown that treatment with an anti-IL-20 monoclonal antibody (NNC0109-0012) reduces disease activity in patients with RA. In order to further explore the role of IL-20 in arthritis pathogenesis we have investigated the effects of a neutralizing anti-IL-20 antibody in the collagen induced arthritis (CIA) model.

Methods: Two separate experiments in the mouse CIA model were conducted to test the effect of an anti-IL-20 antibody (5B7, human IgG4), which cross reacts with mouse IL-20. Two doses of 5B7 (1 and 10 mg/kg, 3xweek for 6 weeks) were tested in a prophylactic setting with dosing from day 0 after immunization. Three doses of 5B7 (1, 10, and 40 mg/kg, 3xweek for 3 weeks) were tested in a late prophylactic setting with dosing from day 21. Serum samples were collected for exposure analysis and to test for anti-drug antibodies and anti-collagen type II (CII) antibody levels. Paws were collected for histopathological evaluation. Overall mRNA expression profiles were assessed with RNA sequencing in paws from non-treated CIA mice with different degrees of disease.

Results: Prophylactic administration of anti-IL-20 5B7 starting from either day 0 or day 21 after immunization did not affect the clinical disease activity scores, whereas administration of a TNFα inhibitor decreased disease activity. Histopathological evaluation revealed no effects of anti-IL-20 treatment on i) the degree of synovitis based on scoring of HE stained paw tissues and ii) the number of TRAP+ osteoclasts as an indicator of bone destruction. Analysis of blood samples from CIA mice dosed from day 0 showed that anti-IL-20 treatment did not affect the levels of the pathogenic anti-CII antibodies. The pharmacokinetic profile revealed that the mice have been adequately exposed to anti-IL-20 throughout the experiments and no formation of anti-drug antibodies was detectable. IL-20 mRNA expression data from the paws and lymph nodes of non-treated CIA mouse with varying degrees of arthritis (mild, moderate, severe) showed a very low level of IL-20 mRNA expression in all analysed paws. Importantly, there was no correlation to disease activity in the individual paws. The level of mRNAs for IL-20R1 and IL-20R2 were also low and indicated a negative correlation with paw disease scores.

Conclusion: Very low expression of IL-20 locally in the diseased paws and lack of correlation with disease severity may explain the lack of efficacy of anti-IL-20 treatment in the mouse CIA model. In contrast to previous data showing that anti-IL-20 treatment decrease disease activity in the rat CIA model, our findings indicate that IL-20 does not play a pathogenic role in the mouse CIA arthritis model.

Aνβ3 Integrin Inhibition with Cilengitide Both Prevents and Treats Collagen Induced Arthritis. Despoina Sykoutri[1], Nisha Geetha[1], Silvia Hayer[1], Peter Mandl[1], Josef S. Smolen[2], Gerald Prager[1] and Kurt Redlich[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial inflammation and osteoclast (OC) mediated bone erosions. AlphaVbeta3 ($\alpha v \beta 3$) integrin is highly expressed in osteoclasts and its inhibition disturbs their function. Aνβ3 blocking antibodies can reduce bone resorption and mice lacking $\beta 3$ are osteopetrotic. However, the role of $\alpha v \beta 3$ in the development of collagen induced arthritis (CIA), a well established model for human RA, has not been examined extensively. We aimed to study the role of the $\alpha v \beta 3$ inhibitor cilengitide, a synthetic Arginine-Glycine-Asparagine amino acid peptide (RGD peptide), on osteoclastogenesis and its efficacy in preventing and treating CIA.

Methods: For *in vitro* analysis mouse bone marrow-derived cells (BMCs) were differentiated into tartrate resistant acid phosphatase positive (TRAP+) mononuclear OC precursor cells (pre-OCs) and TRAP+ multinucleated mature OCs in the presence of macrophage-colony stimulating factor (M-CSF) and receptor activator of nuclear factor kappaB ligand (RANKL). Cilengitide, was added in increasing concentrations (2nM to 20μM) to the culture. Moreover, we performed these osteoclastogenesis assays on plates coated with RGD containing matrix molecules such as osteopontin, fibronectin and fibrinogen but also on Poly-D-lysine coatings to asses for $\alpha v \beta 3$ independent adhesion.

For *in vivo* analysis CIA was induced in 6–8 week old male DBA/1 mice by immunisation with bovine type II collagen at day 1, followed by boosting at day 21. For the CIA prevention study mice were injected 1,5mg/kg cilengitide (n=15) or placebo (n=15) subcutaneously (s.c.), 5 days per week, starting 1 day prior to CIA induction until day 53. In the CIA treatment study mice with established arthritis were randomized and treated s.c. with 1,5 mg/kg (low dose, n=19) or 75 mg/kg (high dose, n=7) cilengitide or placebo (n=21) 5 days per week until day 59. The preventive and treatment effects were evaluated by investigating the clinical course of arthritis assessed by paw thickness and grip strength.

Results: *In vitro* increasing concentrations of cilengitide (IC50: 250nM) dose-dependently reduced pre-OC numbers on all plate coatings, indicating an inhibiting effect at the early stage of pre-OC proliferation. OCs were significantly reduced between 20nM and 200nM, followed by complete blockade of OC formation above 2μM. At 200nM an intriguing morphological difference was observed with reduction in OC size, suggesting that cilengitide may disrupt spreading and the fusion capacity at the early pre-OC stage. In the *in vivo* preventive experiment, cilengitide significantly reduced incidence (92,8% vs. 40%) and severity of CIA as evidenced by the reduction of the clinical disease activity scores of paw swelling and grip strength. In the *in vivo* treatment experiment, both low dose and high dose cilengitide effectively inhibited the progression of established arthritis.

Conclusion: Osteoclastogenesis requires intact $\alpha v \beta 3$ integrin function. Systemic $\alpha v \beta 3$ integrin inhibition with cilengitide potently prevents and treats experimental CIA arthritis. Therefore, cilengitide may be a novel therapeutic target in RA.

2082

Peripheral and Local Effects of Anti-C5aR Treatment in the Collagen Induced Arthritis Model. Christina Andersson. Carola Wenander, Pernille Usher, Josephine Hebsgaard and Lars Hornum, Biopharmaceutical Research Unit, Novo Nordisk A/S, Måløv, Denmark

Background/Purpose: The activated C5a-fragment of complement factor C5 is a potent pro-inflammatory effector molecule that chemo-attracts and activates myeloid cells such as neutrophils, monocytes, and macrophages. C5a levels are elevated in rheumatoid arthritis (RA) synovial fluids, and C5a receptor (C5aR)–expressing cells infiltrate RA synovial tissues. Currently, a Novo Nordisk clinical trial is investigating the potential of an anti-C5aR antibody as a treatment for RA. Because C5a and C5aR-expressing cells are found also in affected joints of collagen-induced arthritis (CIA) mice, we investigated whether a blocking anti-mC5aR antibody is efficacious in inhibiting disease progression in already established arthritis in the CIA model. Furthermore, an analysis of the mechanism of action in the therapeutic

CIA model qualified a number of peripheral and locally produced biomarkers with translational potential for future verification of anti-C5aR treatments effects in human trials.

Methods: DBA/1 mice were immunized s.c. with collagen type II in complete Freund's adjuvant at day 0 and received a boost immunization at day 21. Therapeutic s.c. treatment with an anti-mC5aR mAb was initiated in mice with already established arthritis. Mice were sacrificed after two weeks of treatment (0.5 mg/mouse three times a week) or 48 hours after one single treatment. TNFα inhibition was used as reference treatment. Blood samples were analysed by flow cytometry for cell type and activation state. Cytokine and chemokine profiles were obtained on blood samples and paw homogenates.

Results: Anti-mC5aR treatment was able to halt disease development. Histopathology and serum MMP-3 levels confirmed the clinical treatment effect. In comparison to treatment with a TNFa inhibitor or control antibody, peripheral blood neutrophils from anti-mC5aR treated mice exhibited significantly reduced CD11b expression after two weeks of treatment, indicating reduced activation. The numbers of circulating neutrophils were reduced in both the anti-TNFα and anti-mC5aR treated groups. The CD11b expression was reduced 48 hours after one single anti-mC5aR treatment. Cytokine and chemokine profiles showed significant impact on local inflammatory mediators in the paw, such as IL-6, KC, MCP-1, and MIP-2 already 48 hours after a single anti-mC5aR treatment but not after a single treatment with a TNFα inhibitor. Anti-mC5aR had no impact on the level of anti-collagen type II antibodies.

Conclusion: The data suggest that C5aR blockade has a rapid effect on joint inflammation by down-regulation of pro-inflammatory mediators. This may be due to a direct effect on infiltrating myeloid cells, as C5a induces cytokine and chemokine release by macrophages and other cells. The effect on the circulating neutrophil number and activation stage indicate also a peripheral effect on target cells, suggesting that leukocyte activation and recruitment may also be targeted by C5aR blockade. The effects on peripheral cells may be used as biomarkers in human clinical trials. In conclusion, mechanistic data from the CIA model suggest that C5aR blockade is a potential novel treatment for arthritis that may elicit rapid clinical effects on both infiltrating and peripheral leukocytes.

2083

New Treatment Approach of Rheumatoid Arthritis Based On Inhibition of Cyclin Dependent Kinase-9. Annelie Hellvard[1], Lutz Zeitlmann[2], Ulrich Heiser[3], André Niestroj[3], Hans-Ulrich Demuth[3], Jan Potempa[4] and Piotr Mydel[1]. [1]Broegelmann Research Laboratory, The Gade Institute, University of Bergen, Bergen, Norway, [2]Ingenium Pharmaceuticals GmbH, Martinsried, Germany, [3]Probiodrug AG, Halle/Saale, Germany, [4]Jagiellonian University, Krakow, Poland

Background/Purpose: Cyclin dependent kinase-9 (cdk-9) is transcription regulator of the carboxyterminal domain of RNA polymerase II. The usage of pan-cdk inhibitors such as flavopiridol has proven to be efficient in the treatment of cancer, targeting both cell cycle- and transcription-regulating cyclin dependent kinases. In this study we sought to investigate the effect of specific small molecular inhibitor of cell cycle independent cdk-9 development and progression of collagen induced arthritis.

Methods: DBA/1 mice were immunized with 100ug bovine collagen type II at day 0 and day 21. During experiment mice were treated orally with highly specific cdk-9 inhibitors (compound 1 and compound 2), either 10mg/kg daily or 10mg/kg and 30mg/kg twice a week, respectively. Clinical scoring was performed every second day during experiment and was followed by histological evaluation at end of experiment. Protein expression of Mcl-1 and survivin in spleens was determined by western immunoblotting. Flow cytometric analysis of regulatory T cells in spleens from arthritic mice following daily treatment as well as 7day treatment of healthy NMRI mice was performed.

Peripheral blood mononuclear cells were incubated with compound 1 and induction of apoptosis, as well as protein and RNA expression of Mcl-1 was investigated. Caspase-3 activity, LDH activity and Mcl-1 protein expression was assessed in human monocyte derived macrophages following incubation with compound 1.

Results: Mice treated with compound compound 1 or compound 2 showed striking delay in onset as well as significant reduction in severity of arthritis. This effect was shown, not only in daily treatment but also in bi-weekly regime. Western blot of spleens showed decreased level of Mcl-1 in a dose dependent manner, whereas survivin levels were significantly increased. Flow cytometric analysis of splenocytes in arthritic- and healthy mice treated with inhibitors showed an increase in frequency of regulatory T cells.

Cdk-9 inhibition in peripheral blood mononuclear cells resulted in loss of Mcl-1 expression both on protein and RNA level with a subsequent increase in apoptosis. Down-regulation of Mcl-1 was also observed in monocyte derived macrophages with an activation of caspase-3.

Conclusion: This study provides clear results that inhibition of cdk-9 is working in an immunomodulatory manner, independent of high survivin expression and may in the future serve as an alternative treatment, not only of cancer, but also of autoimmune- and inflammatory diseases.

ASP015K: A Novel JAK Inhibitor Demonstrated Potent Efficacy in Adjuvant-Induced Arthritis Model in Rats. Shunji Yamazaki, Masamichi Inami, Misato Ito, Yasutomo Fujii, Kaori Hanaoka, Kaoru Yamagami, Kenji Okuma, Yoshiaki Morita, Shohei Shirakami, Takayuki Inoue, Susumu Miyata and Yasuyuki Higashi. Astellas Pharma Inc., Tsukuba, Japan

Background/Purpose: The Janus kinase (JAK) family of enzymes plays a key role in cytokine signaling, which is involved in the pathogenic events of immune-mediated disorders such as rheumatoid arthritis (RA). The objectives of this study were to identify *in vitro* and *in vivo* pharmacological profiles of a novel synthesized compound, ASP015K, and to evaluate its therapeutic potential in the treatment of RA patients using an experimental animal model.

Methods: *In vitro* enzyme inhibition assays were conducted against JAKs and tyrosine kinase 2 (TYK2) enzymes. Cell-based assays were also conducted to assess the selectivity of ASP015K for signaling via JAK1/JAK3 over JAK2/JAK2. JAK1/3 activation was evaluated by interleukin (IL)-2-stimulated T cell proliferation; JAK2/2 action was evaluated by erythropoietin (EPO)-stimulated erythroleukemia cell proliferation. In order to evaluate the potential efficacy of ASP015K to reduce clinical signs and symptoms of RA as well as disease progression, the reduction of paw swelling and ankle bone destruction in adjuvant-induced arthritic (AIA) rats were assessed after both prophylactic and therapeutic dosing regimens of ASP015K. Dunnett's and Steel's multiple comparison tests were used to compare ASP015K-treated groups with the control group of the paw volume and ankle bone destruction score, respectively.

Results: ASP015K inhibited JAK1, JAK2, JAK3 and TYK2 enzyme activities with IC_{50} values of 3.9, 5.0, 0.71 and 4.8 nM, respectively. ASP015K inhibited the IL-2-induced proliferation of human T cells with an IC_{50} value of 18 nM. Moreover, ASP015K was 14-fold more potent against JAK1/3 than JAK2/2 on the basis of EPO-induced proliferation of human leukemia cells. This selectivity suggests that ASP015K has the potential to demonstrate JAK1/3-mediated immunomodulatory effects without the occurrence of JAK2-mediated hematopoietic effects. In rat AIA model, the hind paw volume gradually increased starting 10 days after adjuvant injection and ankle bone destruction was established by day 25, the end of the experiment. After once-daily oral administration of ASP015K 1 to 30 mg/kg in prophylactic dosing regimen, the increase in paw volume was significantly ($p<0.05$) decreased in a dose-dependent manner and was completely suppressed at the highest dose compared to control. Similar findings of dose-dependent reduction in ankle bone destruction score were observed. In therapeutic dosing regimens initiated after paw swelling was established, paw swelling and ankle bone destruction score was also suppressed in a dose-dependent manner.

Conclusion: Data from the current study demonstrates that ASP015K potently inhibits human JAK enzymes with moderate selectivity against JAK1/3 over JAK2/2, which may translate to less hematological side effects observed in the clinic such as anemia. In rat AIA model, ASP015K demonstrated a dose-dependent reduction in paw swelling and suppression of ankle bone destruction scores after both prophylactic and therapeutic dosing regimens. The data suggests that ASP015K has the potential to reduce clinical signs and symptoms as well as prevent disease progression in RA patients warranting further clinical investigation.

T Cell-Mediated Murine Antigen-Induced Arthritis Is Resistant to Transgenic Disruption of Glucocorticoid Signaling in Osteoblasts and Osteocytes in Vivo. Cornelia M. Spies[1], Edgar Wiebe[1], Jinwen W. Tu[2], Aiqing Li[2], Timo Gaber[1], Dörte Huscher[1], Markus J. Seibel[2], Hong Zhou[2] and Frank Buttgereit[1]. [1]Charité University Medicine, Berlin, Germany, [2]ANZAC Research Institute, The University of Sydney, Concord, Australia

Background/Purpose: The role of endogenous glucocorticoids (GC) in, and their contribution to the susceptibility and severity of rheumatoid arthritis remains inconclusive. We previously demonstrated that disruption of GC signaling in osteoblasts results in attenuation of arthritis in the antibody-mediated mouse model of K/BxN serum-induced arthritis (Buttgereit *et al.*, Arthritis Rheum 2009). The aim of this study was to test whether GC-dependent osteoblast effects have a similar impact on the T cell-mediated model of antigen-induced arthritis (AIA).

Methods: GC signaling in osteoblasts was disrupted by transgenic overexpression of 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2) under the control of a type I collagen promoter. Arthritis was induced by intra-articular injection of mBSA into one knee joint of pre-immunised 11-week old male transgenic mice (tg) and their wild-type (WT) littermates. Controls received PBS. Knee joint swelling was assessed continuously for 14 days until the mice were sacrificed. The mice were examined by histology, histomorphometry, and micro-CT. In a part of the animals, arthritis was prolonged through three weekly repeated intravenous injections of mBSA until day 28. Statistical analysis was performed by repeated measures analysis.

Results: Acute and significant arthritis developed in both 11β-HSD2-tg and WT mice with maximum knee joint swelling on day 1 and abatement thereafter, with no significant difference in knee joint swelling between tg (n=14) and WT mice (n=17). Histological indices of inflammation, cartilage damage and bone erosion of WT and tg mice, respectively, accordingly showed no differences. Bone turnover and bone volume measured at the contralateral knee remained unchanged. In the prolonged AIA model with repeated intravenous antigen boosts, a significant arthritis with flares on days 7, 14 and 21 was achieved, but also without significant differences between tg mice (n=7) and their WT littermates (n=8) and corroborating histological findings.

Conclusion: In contrast to K/BxN serum-induced arthritis, murine antigen-induced arthritis is resistant to disruption of GC signaling in osteoblasts. This suggests that osteoblasts do not modulate the T cell-mediated inflammatory response but the antibody-mediated inflammatory response (complement, Fc receptors, neutrophils, monocytes/macrophages) via a GC-dependent pathway.

PI3-Kinase Controls Inflammatory Bone Destruction by Regulating the Osteoclastogenic Potential of Myeloid Cells. Stephan Blueml[1], Gernot Schabbauer[2], Antonia Puchner[2], Emine Sahin[2], Victoria Saferding[1], Birgit Niederreiter[1], Josef S. Smolen[3] and Kurt Redlich[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University Vienna, Vienna, Austria, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Local bone destruction in rheumatoid arthritis, psoriasisarthritis or ankylosing spondylitis is a serious health burden and the major cause of disability and severely reduced quality of life in these diseases. This damage to the bony structures is exclusively mediated by a special cell type, the osteoclast (OC). Therefore, it is important to understand factors and pathways regulating the generation of OCs under inflammatory conditions. As PTEN is a lipid phosphatase and one of the main antagonists of the PI3-kinase, we analyzed the impact of the PI3-Kinase/PTEN axis on OC generation and bone biology in an animal model of inflammatory bone loss.

Methods: We induced osteoclastogenesis in wt and PTEN deficient bone marrow cells and measured the generation of OCs, their resorptive capacity and induction of OC differentiation markers *in vitro*. Moreover, we analyzed mice with a monocyte/macrophage-specific deletion of PTEN (myeloid specific PTEN$^{-/-}$) by bone histomorphometry and crossed these mice into hTNFtg animals.

Results: We show that myeloid specific PTEN$^{-/-}$ mice have increased osteoclastogenesis *in vitro* and *in vivo* when compared to wild-type animals. However, under non-inflammatory conditions, enhanced osteoclastogenesis did not result in systemic bone loss *in vivo*. However, when we crossed myeloid specific PTEN$^{-/-}$ into hTNFtg mice we found significantly decreased grip strength scores in myeloid specific PTEN$^{-/-}$/hTNFtg mice compared to wt hTNFtg mice. Joint swelling scores, however, were not different between both groups. In line, myeloid specific PTEN$^{-/-}$/hTNFtg mice displayed enhanced local bone destruction as well as OC formation in the inflamed joints, whereas the extent of synovial inflammation was not different between the groups. Analysis of the synovial membranes of wt and myeloid specific PTEN$^{-/-}$ animals revealed similar relative compositions of the cellular infiltrate including macrophages, which serve as OC precursors. This suggests that increased capacity for osteoclastogenic differentiation rather than enhanced recruitment of precursor cells is responsible for the enhanced local generation of OCs.

Conclusion: Taken together, these data demonstrate that sustained PI3-Kinase activity in myeloid cells specifically elevated the osteoclastogenic potential of these cells, leading to enhanced inflammatory local bone destruction. Therefore, targeting the PI3-Kinase pathway therapeutically may be especially useful for the prevention of structural joint damage.

Regulatory Effect of the Combination of Methotrexate and 1,25-Dihydroxyvitamin D3 On the Balance of Treg and Th17 in Collagen-Induced Arthritis. Jing Luo. the Second Hospital of Shanxi Medical University, Taiyuan, China

Background/Purpose: 1,25-dihydroxyvitamin D3 (1,25-(OH)2D3) is the physiologically active metabolite of vitamin D, and it may modulate inflammatory response, cell maturation and cell differentiation. More recently, animal and human studies have suggested that vitamin D is a potential modifier of autoimmune diseases such as rheumatoid arthritis (RA), but the mechanism is not yet clear.In this study, we aimed to determine the effect of methotrexate (MTX) and 1,25-(OH)2D3, used alone or in combination, in the balance of CD4(+) CD25(+) Tregs and Th17, in a rat model of collagen induced arthritis (CIA).

Methods: Arthritis was induced in 50 female Sprague-Dawley rats. After the clinical onset of CIA, rats were assigned to treatment with MTX (1 mg/kg/week), 1,25-(OH)2D3 (5 mg/kg twice weekly), both treatments at the same regimens, or vehicle. Arthritis score and paw thickness were recorded twice weekly.At termination of the experiment (day 56), bone mineral density (BMD) was analyzed by densitometry, and hind paws were removed for radiographic, histological and immunohistochemical analysis. mRNA expression of transcription factor and proinflammatory mediators was determined by reverse transcriptase–polymerase chain reaction (RT-PCR), and purified T cell proliferation was assessed using [3H]-thymidine incorporated assay, and T-cell phenotypes and activation were assessed by fluorescence-activated cell sorting analysis and T helper (Th) 17/Th1/Th2/Tregs type cytokine production from supernatants from spleen, lymph node and paw cultures was examined by ELISA.

Results: The combination of 1,25-(OH)2D3 with MTX was more effective than MTX alone for reducing the incidence and severity of CIA, and inhibited the production of interleukin (IL)-1β, tumor necrosis factor (TNF)-α and IL-6, IL-2, interferon (IFN)-γ, and matrix metalloproteinases (MMP)-3 and up-regulated anti-inflammatory cytokines IL-4, IL-10. Cytokine analysis indicated that the combination of 1,25-(OH)2D3 with MTX not only modulated the T-helper cell balance from Th1 to Th2 effector function but also associated with the upregulation of CD4(+) CD25(+) Tregs, downregulation of Th17 differentiation. Correspondingly, the mRNA expression of IL-17A and RORrt (a specific transcription factor for Th17) was also reduced.

Conclusion: A combination of MTX and 1,25-(OH)2D3 had beneficial effects on CIA by regulating the balance of CD4(+) CD25(+) Tregs and Th17. These two different mechanisms of action provide support for the use of a combination of these two drugs to improve the prevention of structural joint damage in RA.

Annexin A1 Receptor Agonist Suppresses Development of Inflammatory Arthritis. Yuan Hang Yang[1], Yuan Jia[2], Wenping Kao[1], Wuqi Song[3], Zhan-guo Li[2] and Eric F. Morand[1]. [1]Monash University, Melbourne, Australia, [2]Peking University People's Hospital, Beijing, China, [3]Harbin Medical University, Harbin, China

Background/Purpose: Annexin A1 (AnxA1) is recognized as an endogenous anti-inflammatory molecule. An AnxA1 receptor, formyl-peptide receptor 2 (FPR2), has been identified in human and mice. The contribution of FPR2 to rheumatoid arthritis (RA) is not well understood. We investigated the contribution of AnxA1 and FPR2 to the regulation of inflammatory arthritis.

Methods: Arthritis was induced by injection of K/B×N serum (38μl/mouse, ip) in wild-type or AnxA1−/− mice at day 0 and 2. Wild-type mice were treated with Compound 43, an agonist of FPR1/2, at 6–30μg/g on days 0–4. RA synovial like fibroblasts (FLS) were treated with FPR2 ligand or antagonist compounds, and AnxA1 was silenced using siRNA.

Results: Deficiency of AnxA1 significantly increased arthritis clinical and histopathological severity. Treatment of wild-type mice with Compound 43 dose-dependently and significantly suppressed clinical scores (Fig 1A), paw thickness (Fig 1B) and histopathologic severity. AnxA1 silencing increased RAFLS proliferation, ERK and NFKB activation. RAFLS expressed FPR2, and an FPR ligand inhibited proliferation while, blocking FPR2 significantly increased proliferation, ERK and NF-κB activation, and IL-6 release.
Figure 1. Mice were injected with KB×N serum on day 0 and 2 and Compound 43 from day 0 to 4. *P<0.05. A. Clinical scores B. Paw thickness.

Conclusion: Compound 43 was potently therapeutic in K/BxN arthritis and FPR2 regulates RAFLS activation. These data suggest that FPR2 ligands may have important beneficial actions on RA.

High Local Cathepsin Activity in a Murine Rheumatoid Arthritis Model, but Not in an Osteoarthritis Model, Explains the Difference in Cartilage Vdipen Neoepitope Formation. Eline A. Vermeij, Marije I. Koenders, Onno J. Arntz, Miranda B. Bennink. Arjen B. Blom, Peter L.E.M. van Lent, Wim B. van den Berg and Fons A.J. van de Loo, Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by joint inflammation and connective tissue destruction. On the other hand, osteoarthritis (OA) is regarded as a joint disease with cartilage destruction, but the role of inflammation in OA is still debatable. During joint inflammation and destruction, a variety of proteases are upregulated, including different cathepsins and matrix-metalloproteinases (MMPs). MMPs are a large group of enzymes known to degrade the extracellular matrix during both RA and OA, causing cartilage proteoglycan depletion and breakdown of the collagen network, leading to erosion. Cathepsins are lysosomal proteases which are abundantly found in the synovial fluid and the lining tissue of arthritic joints. In this study we investigated cathepsin and

MMP activity in the process of cartilage destruction, in both a RA and an OA model.

Methods: Collagen-induced arthritis (CIA) was induced in DBA1/J mice, mimicking a RA model. Destabilization of the medial meniscus (DMM) was induced in C57Bl6/N mice causing instability of the joint and subsequently osteoarthritic features. For the CIA model at day 30 and for the DMM model at day 56, fluorescent imaging was performed using Sense 680 probes (PerkinElmer, Massachusetts, USA) and enzyme activity was detected using the IVIS Lumina (Caliper Life Sciences). The ProSense 680 probe becomes activated upon enzymatic cleavage by cathepsins, whereas the MMPSense 680 can be activated by different MMPs. After imaging, mice were sacrificed and knee and ankle joints were dissected and processed for histology. Sections were also immunostained for VDIPEN, a neoepitope of aggrecan cleaved by MMPs.

Results: The ProSense as well as the MMPSense showed a 3 times higher fluorescent signal intensity during CIA, indicating both cathepsin and MMP activity in this model. Interestingly, on the other hand, only MMP activity (1,5 times higher), but no cathepsins activity, could be measured in the DMM model. On histological level, although different in severity, the CIA model and the DMM model both showed features of cartilage damage. In the CIA model, more VDIPEN staining was seen with increasing severity of the disease; on the other hand, in the DMM model no VDIPEN staining was seen above baseline levels.

Conclusion: In the CIA model, inflammation and destruction are correlated, while the DMM model showed MMP activity without inflammation. Mort *et al.* (1998) showed that cathepsin-B can also cleave aggrecan, and can thereby form the VDIPEN neoepitope. Because no cathepsin activity could be measured in the DMM model, this can explain the absence of the VDIPEN neoepitope. This argues for a role of cathepsins in cartilage destruction but their role in CIA remains to be determined. Combining the imaging of local enzyme activity using activatable fluorescent probes together with cartilage neoepitope immunolocalization may unravel the processes involved in joint destruction.

Orchestrating the Orchestrators: Blockade of Flt3L Signaling-Dependent Dendritic Cells Protects Against Collagen Induced Arthritis.
Maria I. Martins Ramos[1], Karpus O.N. Karpus[1], Pleun Broekstra[1], Saïda Aarrass[1], Paul P. Tak[2] and Maria C. Lebre[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Academic Medical Center, University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: Autoimmune diseases often result from inappropriate or unregulated activation of autoreactive T cells. The induction and maintenance of T cell tolerance to tissue antigens is essential to prevent autoimmunity. A key requirement for tolerance is the presentation of antigens in a correct context. Dendritic cells (DCs) are the central antigen-presenting cells (APCs) for the initiation of T cell responses. In this context, stimulation of the Flt3 via Flt3L is known to drive expansion and differentiation of DCs. Traditional approaches to treatment of autoimmune diseases through immunosuppression have focused on direct inhibition of T cells. In the present study, we examined the targeted inhibition of APCs as a mean to downregulate/prevent autoimmune disease in a mouse model for rheumatoid arthritis.

Methods: Collagen-induced arthritis (CIA) was induced in mice lacking Flt3L (Flt3L$^{-/-}$) and WT littermates (C57/BL6 background, 9–10 weeks old). The arthritis severity was assessed using an established semiquantitative scoring system (0–4). After 60 days (chronic phase) phenotypical and functional analysis of spleen and lymph nodes was performed: T and B cell markers, FoxP3 expression, activation markers, co-stimulatory markers and cytokine production. Collagen type II specific antibodies and a panel of inflammatory cytokines were measured in the serum. Histological markers for cellular infiltration, cartilage destruction and peptidoglican loss were performed, as well as immunohistochemistry stainings for cellular markers.

Results: In CIA abrogation of Flt3 signaling led to decreased disease incidence (area under the curve p<0.0005) and severity (p<0.005). CIA Flt3L−/− mice showed reduced spleen and lymph node cellularity (p< 0.0001) and reduced percentage of activated CD4$^+$CD25$^+$ T cells compared with WT (p=0.03). Flt3L−/− CD4$^+$ T cells also produce significantly less IL-17 (p=0.016) and TNF-a (p=0.010), and CD8$^+$ T cells less IFN-γ (p=0.029) compared to WT. We also observed less infiltration of inflammatory cells and less peptidoglican loss.

Conclusion: Mice lacking Flt3L are protected from CIA. We observed that Flt3L deletion influences the magnitude (cell numbers) and quality (CD25 expression and cytokine expression) of T cell responses. Stimulation of lymphocytes by different types of DC, DC at different stages of maturity and producing and responding to different growth factors might contribute for this change in T cell numbers and/or effector functions in Flt3L−/− mice. Targeting this signaling pathway might be considered as a good therapeutic strategy in RA.

The Effect of Pretreatment with Capsaicin On Measurement of Arthritis Pain by Dynamic Weight Bearing and Evoked Pain Responses in an Acute Murine Arthritis Model.
Hollis E. Krug[1], Christopher W. Dorman[2], Sandra Frizelle[2] and Maren L. Mahowald[3]. [1]VA Health Care System, Minneapolis, MN, [2]Minneapolis VA Health Care System, Minneapolis, MN, [3]University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, MN

Background/Purpose: Murine models are important to study arthritis pain and new analgesics, however measuring pain in mice is challenging. The Dynamic Weight Bearing (DWB) device measures individual limb forces during spontaneous activity and time spent bearing weight on each limb. Evoked pain behaviors in mice are sensitive to change due to arthritis pain and analgesia. We hypothesized that mice with acute arthritis would have measurable changes in DWB due to joint pain and that this could be prevented by pre-treating with intra-articular (IA) capsaicin.

Objectives: We measured DWB and Evoked Pain Scores (EPS) in acute arthritis to determine if DWB correlates with EPS and whether it is a reliable measure of spontaneous pain behavior in animals with arthritis. To test the reliability of DWB in differentiating arthritic from nonarthritic animals, some mice were pretreated with capsaicin to prevent development of arthritis.

Methods: C57Bl6 mice were used for all experiments. Acute inflammatory arthritis was produced by IA injection of $10\mu l$ 2.5% carrageenan into the left knee 2–4 hours prior to pain behavior testing. Analgesic controls were injected with 2.5% carrageenan diluted in morphine (MOR) solution (morphine dose of $0.15\mu g$/knee). Some mice were injected IA with capsaicin (0.305 mmol) 7 days before induction of arthritis. DWB was measured with a Dynamic Weight Bearing apparatus (Bioseb, Vitrolles, France). Evoked pain behavior was measured by tallying fights + vocalizations/1 min with repeated firm palpation of the knee.

Results: Arthritis pain was clearly and reproducibly indicated by increased Evoked Pain Scores (EPS) in arthritic mice. DWB was significantly reduced by acute arthritis in the affected limb measured by both % weight bearing and time on the affected limb. IA MOR improved EPS but did not improve DWB significantly. Pretreatment with capsaicin abolished the increased EPS from carrageenan arthritis and normalized DWB by all measures. IA capsaicin injection alone had no effect on DWB or EPS by day 7.

Mean (SEM)	Naive	Sham Injected	Acute Arthritis	MOR Rx Acute Arthritis	MOR Alone	Capsaicin Pre-treatment	Capsaicin Alone
EPS	1.25 (0.49)	1.67 (0.88)	*12.75 (3.41)*	*5.38 (1.34)*	1.88 (0.85)	0.33 (0.33)	*1.67 (1.67)*
DWB L/R Ratio % Weight	0.975 (0.065)	1.189 (0.134)	*0.581 (0.105)*	*0.515 (0.128)*	1.303 (0.136)	1.002 (0.134)	0.838 (0.131)
DWB L/R Ratio % Time on Limb	0.961 (0.023)	0.992 (0.027)	*0.757 (0.085)*	*0.830 (0.084)*	0.988 (0.023)	1.030 (0.017)	0.967 (0.047)

Conclusion: Pain can be quantitated in murine arthritis models using measures of DWB and EPS. EPS increased and DWB of the affected limb decreased significantly with acute inflammatory arthritis. Animals pretreated with capsaicin did not develop pain as measured by EPS or DWB. IA MOR was not effective in normalizing DWB in this small experiment, but was effective in reducing EPS in arthritic mice. DWB appears to have significant utility for measuring arthritis pain in animal models. It is sensitive to change, has good reproducibility between mice and is highly correlated with other measure of arthritis pain in mice.

No Significant Effect of Hepatitis B Virus Infection On Disease Activity, Synovitis or Joint Destruction in Rheumatoid Arthritis. Chan Juan Zou, Yan Hua Li, Ying Qian Mo, Lang Jing Zhu, Dong Hui Zheng, Jian Da Ma, Xia Ouyang and Lie Dai. Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background/Purpose: The prevalence of chronic hepatitis B virus (HBV) infection is high in China. 4% patients with HBV infection can present with polyarthritis and positive rheumatic factor similar to RA, which implied similar pathogenic mechanism.We aimed to investigate the association between HBV infection and serological, radiological or histological disease status in RA.

Methods: 223 continuous hospitalized Chinese patients with RA were enrolled retrospectively. Clinical and laboratory data including HBV detection, and hand X ray were collected. Among 133 active RA patients, synovium was obtained by closed-needle biopsy from inflamed knee joint. Serial tissue sections were stained immunohistochemically for HBV surface antigen (HBsAg), CD79a, CD20, CD38, CD68, CD3, and CD34. Densities of positive-staining cells and synovitis score were determined.

Results: According to HBV infection status, 25/223 had chronic HBV infection (including 4 chronic hepatitis B and 21 HBV carriers), 72/223 had past HBV infection and 126/223 had no HBV infection. The prevalence of HBsAg positivity and chronic hepatitis B in RA was 11.2% and 1.7%, not significantly different with age-matched general Chinese population (8.7% from 2006 Chinese national epidemiological survey and 1.0% from 2005 local survey, respectively, P>0.05). Clinical parameters, DAS28 or Sharp scores showed no significant difference among chronic HBV infection, past HBV infection and no HBV infection groups in 206 active RA or 140 active RA patients without any corticosteroid or DMARDs treatment (all P>0.05). Synovial immunohistochemical staining showed negative HBsAg in 10 HBV carriers and 10 past HBV infection patients. Except for higher sublining CD3+ cell density in past HBV infection group, Krenn's synovitis score, mean densities of sublining positive-staining cells (CD20, CD38, CD79a and CD68) and CD34+ microvessel counts showed no significant difference among RA patients with HBV carrier, past HBV infection or no HBV infection (all P>0.05).

Conclusion: The prevalence of HBV infection in RA patients was consistent with general Chinese population. Chronic HBV infection have no significant effect on disease activity, synovitis or joint destruction in RA, implying that chronic HBV infection may play neither promotive nor protective role in RA.

Rates of Opportunistic Infections Among Rheumatoid Arthritis Patients Switching Biologic Therapy. John Baddley[1], Shuo Yang[1], Klye Brizendine[2], Scott DuVall[3], Kevin L. Winthrop[4], Mary J. Burton[5], Nivedita M. Patkar[6], Elizabeth S. Delzell[1], Monika M. Safford[1], Jasvinder A. Singh[1], Iris E. Navarro[1], Grant W. Cannon[7], Ted R. Mikuls[8], Lang Chen[1], Kenneth G. Saag[6], Kimberly Alexander[9], Pavel Napalkov[9], Aaron Kamauu[10] and Jeffrey R. Curtis[6]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Birmingham, AL, [3]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [4]Oregon Health & Science University, Portland, OR, [5]VA Hospital, Jackson, [6]Univ of Alabama-Birmingham, Birmingham, AL, [7]George E. Wahlen VA Medical Center, Salt Lake City, UT, [8]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [9]Genentech, Inc., South San Francisco, CA, [10]Anolinx, Bountiful, UT

Background/Purpose: The incidence of opportunistic infections (OIs) in patients on biologics is low, but may approach several cases per 100 person-years (PY). Data on risks for OIs associated with newer biologics and in those switching biologics among rheumatoid arthritis (RA) patients are limited.

Methods: Using data from 1998–2011 from the U.S. Veteran's Health Administration we identified a cohort of rheumatologist-diagnosed RA patients

(n=36,433). Patients eligible for this analysis started anti-TNF therapy (adalimumab, infliximab, etanercept) after previous anti-TNF exposure, or rituximab (RTX) or abatacept (ABA). To minimize confounding from channeling of patients to certain biologics, those patients with a history of hematologic malignancy in the past year were excluded. Potential OIs were identified using ICD-9 codes and/or available laboratory results (cultures, serology). With the exception of zoster, where ICD-9 code alone identified a case, all other OIs were confirmed by chart review using standardized case definitions. Patients were censored at first OI event. Baseline co-morbidities were defined in the 1-year period prior to treatment initiation. Exposure was "as treated" on the basis of days supply or usual dosing intervals. Exposure was extended 60 days after the end of the day's supply; RTX exposure was assumed to be 12 months after infusion. Frequencies of OIs were calculated and crude OI incidence rates were estimated using a Poisson distribution.

Results: A total of 2917 unique RA patients contributed 3774 treatment episodes (ABA 338; RTX 511, TNFs 2925). Two-thirds of TNF use was adalimumab. Mean age of the cohort was 60.8 ± 10.7 years; 87% were male. Hypertension (55.5%), diabetes (25.6%) and COPD (14.2%) were common. Overall, 84 OIs (2.9%) in 2917 patients were identified, yielding an overall rate of 1.5 (95% CI 1.2, 1.9) OIs per 100 PY(Table). The most common OIs were zoster, rate 1.17 (0.9, 1.5) per 100 PY and tuberculosis, rate 0.05 (0.02, 1.6) per 100 PY. Crude rates of OIs per 100 PY among TNFs, ABA and RTX users were 1.5 (1.2, 1.9); 1.1 (0.4, 2.6), and 1.8 (1.0, 3.2), respectively. Among TNFs, rates per 100 PY were infliximab 0.8 (0.3, 2.1), adalimumab 1.6 (1.2, 2.2) and etanercept 1.6 (1.0. 2.5). For the 19 confirmed OIs other than zoster, 7 (37%) were identified by screening lab data and were not identified by ICD-9 codes.

Table. Frequency of Physician-Confirmed Opportunistic Infections (OIs) by Biologic Exposure

Opportunistic Infection	Abatacept N=338 PY=486	Adalimumab N=1826 PY=2727	Etanercept N=741 PY=1181	Infliximab N=358 PY=511	Rituximab N=511 PY=651	TOTAL N=3774 PY=5538
Zoster	5	38	16	2	4	65
Tuberculosis	0	0	2	0	1	3
Pneumocystosis	0	0	0	0	3	3
Legionellosis	0	3	0	0	0	3
Coccidioidomycosis	0	0	1	0	2	3
Histoplasmosis	0	1	0	1	0	2
Non-tuberculous mycobacteria	0	1	0	0	1	2
Salmonellosis	0	1	0	0	1	2
Nocardiosis	0	0	0	1	0	1
Total OIs	5	44	19	4	12	84
IR (95% CI) per 100 p-years	1.1(0.4, 2.6)	1.6 (1.2, 2.2)	1.6 (1.0, 2.5)	0.8 (0.3, 2.1)	1.8 (1.0, 3.2)	1.5 (1.2, 1.9)

OI=opportunistic infection; IR=incidence rate

Conclusion: In US veterans with RA, overall crude OI rates were low and similar among biologics. The most common OI was zoster. The availability of serologic and culture data for OI screening yielded a meaningfully higher proportion of OI cases compared to administrative data alone.

Reactivation of Hepatitis B Virus in Autoimmune Disease Patients Receiving Immunosuppressive Agents. Daisuke Kobayashi[1], Satoshi Ito[1], Megumi Unno[1], Ichiei Narita[2] and Akira Murasawa[1]. [1]Niigata Rheumatic Center, Niigata, Japan, [2]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background/Purpose: Reactivation of resolved hepatitis B in patients undergoing immunosuppressive therapy is now considered to be a complication of major clinical importance. Because this is still an emerging concept, the majority of our patients with autoimmune disease have been tested only for hepatitis B surface antigen (HBsAg), and not for hepatitis B surface antibody (anti-HBs) or hepatitis B core antibody (anti-HBc) in our country.

We evaluated the prevalence of previous infection of hepatitis B virus (HBV) in patients with autoimmune disease and the incidence of its reactivation.

Methods: We enrolled 318 patients (63 males, 255 females) with autoimmune disease, who were receiving, or were scheduled to receive, immunosuppressants at our hospital. The immunosuppressants included methotrexate (MTX), tacrolimus (TAC), mizoribine (MZR), prednisolone (PSL) at over 30 mg/day, azathioprine (AZ), cyclosporine (CyA), cyclophosphamide (CPA), etanercept (ETN), infliximab (IFX), tocilizumab (TCZ), adalimumab (ADA), and abatacept (ABA). Patients underwent HBV serological examination including HBsAg, anti-HBs, and anti-HBc. When HBsAg, anti-HBs and/or anti-HBc were positive, HBV-DNA was measured once a month using a real-time polymerase chain reaction assay. Clinical data were examined by reviewing the medical records.

Results: Among the 318 patients, 4 were HBsAg positive and the rest were HBsAg negative; 61 patients were anti-HBs positive and 70 were anti-HBc positive. Eighty patients (rheumatoid arthritis (RA) 72, systemic lupus erythematosus (SLE) 4, adult-onset Still's disease 1, polymyositis 1, polymyalgia rheumatica 1, juvenile rheumatoid arthritis 1) showed HBsAg negative and anti-HBs and/or anti-HBc positive serology, indicating previous HBV infection. Among these patients, 72 had already been treated with immunosuppressive agents as monotherapy or in combination (MTX 42, TAC 25, MZR 11, high-dose PSL 5, AZ 3, CyA 1, CPA 1, ETN 9, IFX 7, TCZ 4, ADA 1, ABA 1) for 43.9 ± 44.4 months (range 4–248 months, median 32 months) before evaluation of anti-HBs and anti-HBc without developing acute hepatitis. Another 8 patients were scheduled to begin immunosuppressive therapy. Among patients with past HBV infection, 5 were positive for viral replication (>2.1 log copies/ml). The first of these patients had SLE, and the other four had RA. Among them, a patient was treated with high-dose PSL and CPA. She was HBsAg negative at the start of immunosuppressant therapy, but 3 months later HBV-PCR increased to 7.9 log copies/ml, and HBsAg became weakly positive with elevation of the transaminase level. The second patient was treated with 3 mg/day TAC, 150 mg/day MZR and 5 mg/day PSL, and the third with 3 mg/day TAC and 5 mg/day PSL. Two patients who were treated only with sulfasalazine and bucillamine, showed reactivation of HBV in the absence of immunosuppressants.

Conclusion: Reactivation of HBV sometimes occurs without MTX or biological agents. Patients in whom hepatitis B infection has serologically been resolved, need to be monitored carefully even when receiving immunosuppressants other than MTX, or biological agents.

Identifying Arthralgia Patients At Risk for Rheumatoid Arthritis in the Rotterdam Early Arthritis Cohort. M. van der Veer[1], D. van Zeben[2], A.E.A.M. Weel[3], P.J. Barendregt[3], A.H. Gerards[4], Johanna M.W. Hazes[5] and Jolanda J. Luime[6]. [1]ErasmusMC, Rotterdam, Netherlands, [2]Sint Franciscus Gasthuis, Rotterdam, Netherlands, [3]Maasstad Hospital, Rotterdam, Netherlands, [4]Vlietland Hospital, Schiedam, Netherlands, [5]Erasmus Medical Center, Rotterdam, Netherlands, [6]Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background/Purpose: Patients with rheumatoid arthritis (RA) frequently have a high disease burden and erosions at first presentation because of the insidious nature of the disease. Previous studies showed that early recognition and initiation of therapy lowers the risk for developing erosive disease and leads to a better quality of life. Our aim is to identify predictive features in patients at risk for rheumatoid arthritis when inflammatory joint complaints are present but before synovitis is observed.

Methods: We used data from the Rotterdam Early Arthritis Cohort (REACH). Patients with two or more joints with pain or loss of movement with two or more of the following criteria: morning stiffness for more than 1 hour; unable to clench a fist in the morning; pain when shaking someone's hand; pins and needles in the fingers; difficulties wearing rings or shoes; a family history of RA; unexplained fatigue for less than 1 year were eligible. All patients did not have synovitis at baseline. Data were analyzed using simple descriptive analysis and univariate logistic regression in STATA12.

Results: 458 patients fulfilled the REACH criteria without synovitis at baseline. After 12 months 40 patients developed arthritis (8.7%), 34 out of those 40 developed arthritis within the first six months (85%). Rheumatoid arthritis was diagnosed 16 times in the arthritis group (40%). A predictor for developing arthritis was positive ACPA (OR 10.5, 95% CI 4.5–24.5). In the 28 ACPA positive patients at baseline, 12 patients developed arthritis (43%),

after 12 months 16 patients were still free from arthritis. Increasing ESR was the second predictive feature (OR 1.06 per point ESR, 95% CI 1.03–1.09). RF was a less strong predictor (OR 2.86, 95% CI 1.08–7.52). No difference was observed for age, gender, tender joint count, symmetry of joint complaints, distribution of joints in a rheumatoid arthritis pattern, smoking, education level, VAS and CRP.

Conclusion: In patients with inflammatory joint complaints, raised ESR and positive ACPA both predicted the development of arthritis within 12 months. Therefore, we advise to monitor patients with inflammatory joint complaints with positive ACPA or/and raised ESR carefully.

A Prediction Rule for the Progression to Rheumatoid Arthritis Applied in a Mexican Mestizo Cohort with Undifferentiated Arthritis. Ana Arana Guajardo, Lorena Pérez Barbosa, David Vega Morales, Janett Riega Torres, Roberto Negrete López, Jacqueline Rodríguez Amado, Jorge Esquivel Valerio, Cassandra Skinner Taylor. Diana Flores Alvarado, Dionicio Galarza Delgado, Miguel Villarreal Alarcon and Mario Garza Elizondo, Hospital Universitario, UANL, Monterrey, Mexico

Background/Purpose: A high proportion of patients who present with recent-onset arthritis have undifferentiated arthritis (UA), as these patients do not fulfill the classification criteria for a specific diagnosis. Several cohort studies in UA have used predictive score models to screen patients at risk to develop rheumatoid arthritis (RA). Our objective is to validate the Leiden Prediction Rule (LPR) in an inception cohort of patients with UA.

Methods: We included patients with UA diagnosed from 2008 to 2011, mostly from a community based epidemiological study (COPCORD), who met the following characteristics: >18 years old, at least 1 swollen joint, with a symptom duration of >1 week to 1 year. We excluded patients with pregnancy or with well-defined inflammatory disease. During one year the patients were followed every 2 months. We applied the LPR at the first visit, which includes sex, age, morning stiffness, disease distribution, painful and swollen joints, C-reactive protein (CRP), rheumatoid factor assay (RF) anti-cyclic citrullinated peptide (anti-CCP) antibodies; in each visit they were evaluated for clinical signs of inflammation including the metacarpophalangeal (MCP)/metatarsophalangeal (MTP) squeeze test (ST). Subsequently we reclassified patients a year after their diagnosis of UA. The diagnosis of RA was made according to 1987 ACR classification criteria. Statistic Analysis. The results were expressed as means and standard deviations. The groups were compared with Mann Whitney U test. Chi-Square test was applied for categorical variables. The association between MCP/MTP ST and LPR was established by relative risk (RR) with a confidence interval (CI) of 95%.

Results: We included 47 patients with UA with a mean age of 51.6 years + 9.5 SD, 98% were females. One year after diagnosis, the patients were reclassified as follows: RA 20(43%), and non-RA which included: persistent UA 12(25%), other inflammatory arthritis 9(19%) and spontaneous remission 6(13%). There were no statistical differences between the groups on the number of swollen or painful joints (p=0.576 and p =0.564, respectively) or titers of CRP, RF and anti-CCP antibodies (p=0.754, p=0.97, p=0.29, respectively). In patients who progressed to RA, LPR was ≥ 8 points in only 15% (3 patients), while 85% (17 patients) had <8 points in LPR. When we compared the score obtained from LPR between groups, we did not find any significant difference (p=0.940). We found an association between the MCP/MTP squeeze test (ST) and patients who progressed to RA, RR 1.74; 95% CI [0.92 – 3.28] on MCP ST and RR 2.99; 95% CI [1.12 – 4.70] on MTP ST.

Conclusion: A proportion of 43% of our patients with UA had progression to RA after 1 year of follow-up; 100% patients who scored >8 points in the LPR progressed to RA. These proportions are similar to the data published previously from other UA cohorts. Notably, an important difference is the 56% of patients who progressed to RA with a score <6 points on LPR compared to the Leiden cohort were it was less than 10%. We did find that the presence of pain during the MCP/MTP squeeze test is associated with the progression of RA.

2097

Adiponectin Is Associated with Pro-Inflammatory Cytokines in Autoantibody Positive First-Degree Relatives (FDRs) of Patients with Rheumatoid Arthritis. Jan M. Hughes-Austin[1], Kevin D. Deane[2], Lezlie A. Derber[3], Gary O. Zerbe[1], Dana M. Dabelea[1], Jeremy Sokolove[4], William H. Robinson[5], V. Michael Holers[2] and Jill M. Norris[6]. [1]Colorado School of Public Health / University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Colorado Anschutz Medical Campus, Aurora, CO, [4]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [5]Stanford University, Palo Alto, CA, [6]Colorado School of Public Health, Aurora, CO

Background/Purpose: While adiponectin is generally considered an anti-inflammatory adipokine, it has also been shown to participate in active RA in inflammatory, matrix-destructive and fibrotic processes leading to joint destruction. Because adiponectin's role as a pro- or anti-inflammatory adipokine has been controversial in situations of autoimmunity and chronic inflammation, we sought to determine the relationship of adiponectin to rheumatoid arthritis (RA)-related autoantibodies and markers of inflammation in a population without RA, but at increased risk for future development of the disease.

Methods: We selected all visits of 113 FDRs who were positive for rheumatoid factor (RF), RF isotypes IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2) at least once, and 100 FDRs who were never autoantibody positive. In blood obtained from these 391 visits, we measured cytokines/chemokines, high-sensitivity C-reactive protein (hsCRP), and adiponectin. As a comprehensive measure of inflammation, we calculated a Cytokine Score by summing all cytokine/chemokine levels, weighted by their regression coefficients for RA-autoantibody association. We first compared the effect of adiponectin on two autoantibody phenotypes: positivity for RF, and positivity for the high-risk autoantibody profile (HRP) (positive for anti-CCP2 and/or $\geq$ 2 RF isotypes) that we have shown in previous work to be highly specific ($>96\%$) for future RA; and then tested the interaction between autoantibodies and adiponectin on markers of inflammation using mixed models to account for multiple samples per FDR. All analyses were adjusted for age, sex, ethnicity, body mass index, pack-years of smoking, a delay in sample processing, and current use of statins.

Results: Adiponectin was not associated with either RF (p=0.44) or HRP (p=0.60) positivity. Adiponectin was inversely associated with hsCRP (β=-0.31 $\pm$ 0.10; p=0.002) and IL-5 (β=-0.21 $\pm$ 0.10; p=0.044). The relationship between adiponectin and TNF-α, GM-CSF, and the Cytokine Score differed by HRP status, where a 10% increase in adiponectin resulted in a 5% increase in TNFa and 4% increase in GM-CSF among HRP+ FDRs; whereas no association was observed among HRP- FDRs (Interaction p=0.016, p=0.028 for TNF-α and GM-CSF, respectively). Similarly, a 10% increase in adiponectin was associated with a 2% increase in Cytokine Score among HRP+ FDRs, but not in HRP- FDRs (Interaction p=0.038).

Conclusion: In a population without RA, elevations of adiponectin were associated with elevations of several pro-inflammatory cytokines as well as a marker of overall inflammation, Cytokine Score, in the setting of autoantibody positivity; and were inversely associated with elevations of another marker of inflammation, hsCRP. These findings indicate that adiponectin may have a complex role in early RA-related autoimmunity and inflammation, and that adiponectin may respond differentially according to inflammatory triggers and functions. Further study is needed to determine the role of adiponectin in early RA pathogenesis.

Patient Report Outcomes Variance Between Centers Is Much Lower Than Physician and Laboratory Assessed Measures of Rheumatoid Arthritis Activity: Results From a Multinational Study. Nasim A. Khan[1], Horace Spencer[2], Tuulikki Sokka[3] and QUEST-RA[4]. [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [4]Jyväskylä

Background/Purpose: Clinical trials and epidemiological rheumatoid arthritis (RA) studies often recruit patients from multiple centers. We studied the proportion of variance in the American College of Rheumatology (ACR) core set measure, Disease Activity Score 28 (DAS28, representative physician and laboratory measure derived composite index), and Routine Assessment of Patient Index Data 3 (RAPID3, representative PRO derived composite index) explained by between-center differences in a multinational study.

Methods: 7568 patients receiving usual care from rheumatologists in 83 centers located in 30 countries were recruited using standard protocol in the Quantitative Standard Monitoring of Patients with RA (QUEST-RA) study. Mixed-effects analyses of covariance (ANCOVA) models were used to model each ACR core set measure as functions of demographic, medical characteristics and remaining ACR core set measures. Demographic variables included age, race (white, other races), gender, and education > 12 years (yes, no); while medical characteristics included RA duration, rheumatoid factor status, patient's fatigue score (0–10), Psychological Health Assessment Questionaire score (Psych HAQ, 0–3), morning stiffness (0, 1–60, and >60 minutes), comorbidity burden, body mass index, fibromyalgia (yes, no), osteoarthritis (yes, no), and chronic back pain (yes, no). DAS28 model included patient's pain score (0–10 cm) and HAQ, while the RAPID3 model included tender joint count (TJC), swollen joint count (SJC) and erythrocyte sedimentation rate (ESR) in addition to demographic and medical characteristics. The patient recruiting center was included as a random effect to estimate the amount of the residual variance explained by it. MIXED procedure in SAS was used.

Results: Patient reported outcomes had lower proportion (3.25–6.87%) of residual variance that was explained by between recruiting center differences compared to clinician and laboratory derived measures (10.36–14.86%) of RA activity (Table). Similarly, DAS28 had a much larger proportion of variance explained by between recruiting center difference than RAPID3.

Table. Variance of RA disease activity measures accounted for by between recruiting center differences

Variable	Clinic	Residual Variance Unexplained	Total	% Residual Variance Explained by Clinic
PTGL	0.0942	2.8039	2.8981	3.25

RAPID3	0.9806	17.4026	18.3832	5.33

PTGL, patient's global assessment of RA activity; HAQ, health assessment questionnaire, MDGL, clinician's global assessment of RA activity.

Conclusion: Patient reported outcomes variance accounted for by between different centers is considerably lower than clinician and laboratory derived measures after adjusting for potential demographic, medical and RA related characteristics. This is despite patient recruitment in QUEST-RA study from several countries with widely different cultural and socio-economic differences. These results highlight the need for implementation of procedures to standardize RA activity assessment by clinicians involved in multi-center studies.

Patient Self-Assessments and Selected Patient Reported Outcomes May Reliably Identify Rheumatoid Disease Flare in Early Rheumatoid Arthritis Patients. Vivian P. Bykerk[1], CO Bingham III[2], Ernest Choy[3], Juan Xiong[4], Gilles Boire[5], Carol A. Hitchon[6], Janet E. Pope[7], J. Carter Thorne[8], Boulos Haraoui[9], Edward Keystone[10] and Susan J. Bartlett[11]. [1]Hospital for Special Surgery, New York, NY, [2]Johns Hopkins University, Baltimore, MD, [3]Cardiff University School of Medicine, Cardiff, United Kingdom, [4]Mount Sinai Hospital, Toronto, ON, [5]CHUS - Sherbrooke University, Sherbrooke, QC, [6]University of Manitoba, Winnipeg, MB, [7]Western University of Canada, St. Joseph's Health Care, London, ON, [8]Southlake Regional Health Centre, Newmarket, ON, [9]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [10]University of Toronto, Toronto, ON, [11]McGill University, Montreal, QC

Background/Purpose: Significant RA worsening or flare may predict poorer outcomes and signal a need for treatment reassessment. However, there is little agreement about how to reliably identify a flare. Candidate domains essential for assessing RA flare were identified by OMERACT patients (pts)and health care providers including pain, function, stiffness, participation, coping, patient global assessment, fatigue and self-management[1]. We aimed to determine the extent of agreement between pts

and treating rheumatologists (MD) in identifying a flare, and concordance of clinical and patient-reported outcomes (PROs) with flare status.

Methods: Pts in the Canadian early ArThritis CoHort (CATCH) completed the OMERACT preliminary flare questionnaire (PFQ). In the PFQ pts were asked if they were in a flare and to rate severity, pain, function, stiffness, participation, coping, patient global assessment and fatigue (0–10 NRS). Pts also identified tender and swollen joints (TJC and SJC)(42 joint homunculus). MDs rated if their patient (pt) was in a flare and performed a joint count. Pt-MD agreement on flare status was assessed using Cohen's kappa. Wilcoxon rank sum test was used to compare MD and pt reported joint counts. Clinical indices and PROs between flare and non-flare pts were compared using paired t-tests.

Results: 512 pts (75% female) answered PFQ: 13% at baseline, 39% at 3–12 months and 49% at 12 months+ after study entry. Pts had a mean age of 53 ± 14 yrs; 18% were smokers, 63% RF+, 51% CCP+ and 18% had erosions. 149 (29%) reported a flare at study visits. Pts and MDs agreed about flare status 72% of the time (Kappa=0.34). Changes in DAS28 and CDAI from previous visits were higher in flare vs. non flare pts(0.44 vs. −0.14) (1.67 vs.−3.20) (both p<.0001). PROs were significantly different between flare and non-flare pts and were highest when pts and MDs both agreed the pt was in a flare (p<.0001) (see Table). Pts in a flare reported higher TJC/SJCs than MDs. The differences between pt and MD TJC & SJC were 3.74 (p<.0001) and 2.31 (p<.0004). Agreement was modest (Kappa=.32) when pts/MDs agreed on flare status but poor then they didn't (Kappa=.20)

Table 1. Ratings of flare severity and PROs by Patient/MD concordance

Domain	Pt Flare/ MD Flare (n=86)	Pt Flare/ MD Non-Flare (n=63)	Pt Non Flare/ MD Flare (n=83)	Pt Non Flare/ MD Non Flare (n=280)	p-values
Flare severity	6.2 (2.4)	5.2 (2.6)	0.3 (1.5)	0.2 (0.8)	<.001
Pain	6.3 (2.4)	5.1 (2.7)	3.7 (2.6)	1.7 (1.9)	<.001
Function	6.2 (2.6)	4.1 (3.2)	3.7 (2.8)	1.3 (1.8)	<.001
Stiffness	5.8 (2.8)	4.3 (2.9)	3.7 (2.5)	1.7 (1.9)	<.001
Participation	5.6 (2.8)	3.8 (3.0)	3.4 (2.8)	1.2 (1.9)	<.001
Fatigue	5.6 (2.8)	4.7 (3.1)	4.1 (3.0)	2.0 (2.5)	<.001
Coping	4.8 (2.6)	3.2 (2.7)	3.1 (2.6)	1.1 (1.8)	<.001

Values are mean (SD)
* Domains scored 0–10 on a numerical rating score, ascending by severity.

Conclusion: Pts reporting a flare have clinical indices reflecting worsening disease activity. PROs (pain, function, stiffness, coping, participation, and fatigue) significantly discriminated between pts reporting flare vs. no flare. There is modest agreement between pts and MDs regarding flare status. Flare pts identify more swollen and tender joints than MDs. PROs and pt-joint counts may reliably identify pts in disease flares but some ratings are higher in pts than MDs. More research is needed to identify predictors of concordance and discrepancy between pts and providers in flare assessment.

Relative, Reliability-Adjusted Diagnostic Test Accuracy of Erosion Detection Between Magnetic Resonance Imaging and Radiography in Rheumatoid Arthritis. Ruben Tavares[1], Naveen Parasu[2], Karen Finlay[2], Erik Jurriaans[2], Hao Wu[1], Karen A. Beattie[1], Maggie Larche[1], Lawrence E. Hart[3], William G. Bensen[4], Raja S. Bobba[1], Alfred A. Cividino[1], Colin E. Webber[5], Jean-Eric Tarride[6] and Jonathan D. Adachi[7]. [1]McMaster University, Hamilton, ON, [2]Hamilton Health Sciences, Hamilton, [3]St. Joseph's Health Care, Hamilton, ON, [4]St. Joseph's Hospital and McMaster University, Hamilton, ON, Hamilton, ON, [5]Hamilton Health Sciences, Hamilton, ON, [6]Programs for Assessment of Technology in Health (PATH) Research Institute, Hamilton, ON, [7]Charlton Medical Centre, Hamilton, ON

Background/Purpose: In rheumatoid arthritis (RA), erosion detection on radiography (X-ray) compared to magnetic resonance imaging (MRI) is characterized by low sensitivity and high specificity. This supports the hypothesis that MRI has a lower limit of detection for erosion than X-ray. To date, however, no studies have directly assessed measurement reliability. The objective of this study was to determine the relative diagnostic test accuracy of MRI and X-ray for erosion detection while accounting for inter-rater reliability.

Methods: A paired, cross-sectional study of 65 RA patients with a range of symptom duration was conducted. For each participant, MRI scans of the bilateral metacarpophalangeal joints (MCP) 2–5 and X-ray of both hands, wrists and feet were taken. Comparisons were limited to the MCP 2–5 joints. The Outcome Measures in Rheumatology (OMERACT) rheumatoid arthritis magnetic resonance imaging score (RAMRIS) and the van der Heijde-modified Sharp (vdHSS) scores were used to evaluate the MRI and X-ray images, respectively. Data were paired at the smallest level of analysis common to both measures: the joint. A total of 488 paired joints were compared. Odds ratio (OR), sensitivity (Se), specificity (Sp), and accuracy were calculated and the smallest detectable difference (SDD)-adjusted and unadjusted evaluations were compared.

Results: The association between erosion detection on MRI and X-ray of MCP 2–5 had an OR of 1.8 (1.2–2.9), Se of 0.31±0.03, Sp of 0.80±0.03, and accuracy of 0.47. Adjusting for measurement reliability increased the OR, Sp, and accuracy to 3.2 (1.5–6.1), 0.93±0.01, and 0.79, respectively, while decreased the Se to 0.19±0.04. Reliability-adjustment decreased the number of erosions detected per joint from 67.8% to 18.6% on MRI and 27.5% to 9.8% on X-ray. Per MCP joint, 2.6- to 8.0-fold the erosions detected on X-ray were detected on MRI. Compared by affected MCP 2–5 joint set, adjustment resulted in MRI detection of 2.1-fold the erosive disease detected on X-ray. At the patient level of analysis, bilateral MRI of the MCP 2–5 joints resulted in the detection of erosive disease in 1.1-fold the number detected on X-ray of hands, wrists and feet (McNemar's test, $p = 0.83$, Cohen's k=0.17±0.13, $p=0.16$). The correlation between SDD-adjusted vdHSS erosion score and symptom duration was 0.37 ($p<0.0001$). Correlation between MRI and symptom duration was non-significant (0.10, $p=0.26$).

Conclusion: Following reliability-adjustment of evaluations at the unit of measurement, a greater proportion of erosive disease is detected on MRI compared to X-ray per joint imaged. At the patient level of analysis, the relative performance of the two imaging modalities is highly dependent on the anatomy imaged. Despite detecting similar proportions with erosive disease when bilateral MRI of MCP 2–5 and X-ray of the hands, and feet are compared, the non-significant low level of agreement indicates that the proportions detected by each modality are unique. The interaction with symptom duration suggests that MRI may detect a greater proportion of patients with erosions at earlier stages of disease progression.

2101

How Much Can Patient Reported Outcomes Improve Among Rheumatoid Arthritis Patients Who Have a Clinical Response to Biologic Therapy but Have Not Attained Low Disease Activity? Jeffrey Curtis[1], Ying Shan, Jie Zhang[1], Jeffrey D. Greenberg[3] and George W. Reed[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]New York University School of Medicine, New York, NY, [3]University of Massachusetts Medical School, Worcester, MA

Background/Purpose: Current treat-to-target (T2T) recommendations suggest that rheumatoid arthritis (RA) patients should strive for remission or low disease activity (LDA) as a goal. Treatment changes as often as every 3 months are recommended if necessary. However, it is unclear whether patients that have had a good clinical response to anti-TNF therapy by 3 months but who are not yet in LDA or remission might experience further meaningful improvement in patient reported outcomes (PROs) if they subsequently achieve these T2T disease state targets.

Methods: We used data from the Consortium of Rheumatology Researchers of North America (CORRONA) to study participants with RA (n = 31701 total) who initiating anti-TNF therapy with a subsequent follow-up visit approximately 3 months later. The analysis cohort was restricted to patients who had clinical improvement (CDAI improvement by >= 10 units) at three months. Subsequent clinical response for patients who remained on the same anti-TNF therapy was examined approximately 6 months later to assess whether PROs (global, pain, disability by mHAQ) improved more among those who improved their CDAI category (from LDA to remission, or moderate/high disease activity to low disease activity) compared to those who stayed in the same CDAI category.

Results: A total of 293 patients who initiated anti-TNF therapy and who had an improvement in CDAI of >= 10 units three months later were identified. After excluding 61 patients in CDAI remission (CDAI <=2.8) at 3 months, there were 120 individuals in LDA (CDAI 2.8 – 10) and 112 in

moderate/high CDAI (CDAI > 10) eligible for analysis. Among patients who achieved LDA at 3 months, 45 (38%) subsequently went on to achieve CDAI remission, 26 (22%) stayed in LDA; 49 (41%) worsened to moderate/high disease activity and were excluded. Among the 112 patients still in moderate/high disease activity patients at 3 months, 40 (36%) went on to achieve LDA (CDAI <= 10) and the remainder stayed in moderate/high disease activity. The mean change in PROs was compared. Patients who improved their CDAI disease activity category were significantly better for patient global and pain and no different for mHAQ versus those who stayed in the same disease CDAI activity category.

Patient Reported Outcome	Adjusted* Mean Change (95% CI) for Patients Who Improved to a Better CDAI Disease Activity Category Compared to Those Who Stayed the Same	Adjusted* p value
Patient Global (0–100 scale)	−14.7 (−20.4, −8.9)	<0.001
Patient Pain (0–100 scale)	−11.5 (−17.5, −5.6)	<0.001
Disability (mHAQ)	−0.02 (−0.10, 0.07)	0.74

* adjusted for age, gender, duration of RA, CDAI at 3 months, and baseline PRO

Conclusion: Among patients with a clinical response to anti-TNF therapy at 3 months but who have not yet attained LDA or remission, the magnitude of further change in patient reported outcomes for those who achieve these disease states 6 months later was relatively small compared to those who stayed the same. Some improvement was observed for patient global and pain but not for disability. These results suggest that patients may not experience much additional benefit in their PROs from subsequently attaining the LDA or remission targets recommended in T2T guidelines as long as they have had a good clinical response.

2102

Patient Versus Physician Global Assessments in Ethnic Patients Wtih Rheumatoid Arthritis. Gail S. Kerr[1], Yusuf Yazici[2], Christopher J. Swearingen[3], Luis R. Espinoza[4], Edward L. Treadwell[5], Yvonne R. S. Sherrer[6], Angelia D. Mosley-Williams[7], Akgun Ince[8], Raj G. Nair[9], Theresa Lawrence Ford[10], Jeffrey Huang[11] and Carl A. Nunziato[11]. [1]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [2]New York University, New York, NY, [3]University of Arkansas, Little Rock, AR, [4]Louisiana State University, New Orleans, LA, [5]East Carolina University, Greenville, NC, [6]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [7]John Dingell VAMC, Detroit, MI, [8]Saint Louis University, St. Louis, MO, [9]Washington Hospital Center, Washington DC, DC, [10]North Georgia Rheumatology, Lawrenceville, GA, [11]Howard University Hospital, Washington, DC

Background/Purpose: Patient reported outcomes in rheumatoid arthritis (RA) are validated tools that assess disease status, are easily administered and used as components of RA composite disease activity scores. Further, patient global score is a criterion for RA remission and recent data suggest a 5mm difference in patient (PT) and physician (MD) global scores significant. Ethnic Minority RA Consortium (EMRAC) is a clinical registry of disease characteristics collected in a "real-world" setting. We evaluated ethnic RA subsets for differences in and associations of PT and MD global scores.

Methods: IRB consented patients enrolled in EMRAC were evaluated. In addition to PT and MD global scores, differences in PT/MD scores (PT-MD >5mm, >10 mm), socio-demographic data, pain scores, parameters of RA disease status (MDHAQ, TJC, SJC) and composite RA disease measures (RAPID3, CDAI, DAS28) were collected. Comparisons of baseline data amongst ethnic groups were analyzed, and correlations of PT, MD global scores and differences in PT/MD scores with years of education, pain, MD-HAQ, TJC/SJC, treatments (DMRAD, biologic) and composite scores in each ethnic group were evaluated.

Results: Analyses of 625 EMRAC patients were performed [Table]. Mostly female, the mean age was 55.5 (16.2) yrs and African Americans (AA) were the majority. RAPID3 composite scores were significantly higher in Hispanics vs all ethnic groups. AA and Hispanics had significantly higher MD- HAQ, pain and PT global scores than Caucasians. Mean difference in PT-MD global scores was 1.5(2.8), but significantly greater in Hispanics and Others compared to AA and Caucasians [2.7(2.5), 2.1(2.6), vs 1.2(2.8), 1.4 (3.0), p=0.005, respectively]. Similarly, PT-MD global score differentials of >5mm and >10mm were more frequent in Hispanics (80,76%) and Others (70,60%), compared to 50% in both AA and Caucasians, (p=0.004, p=0.01,

respectively). In comparison to Caucasians, correlation of PT global scores with disease duration, pain and RAPID3 scores was significantly lower in AA. Age showed less correlation with PT global scores in AA than Hispanics, (p=0.002). Hispanics had the greatest correlation of MD global scores with TJC compared to AA (p=0.001) and Caucasians (p<0.001). While MD global scores correlated less with CDAI in Caucasians than in Hispanics, the RAPID3 showed less correlation in Caucasians vs Other, (p=0.004, p=0.006 respectively). The ESR correlated with MD global in Hispanics vs AA (p=0.004) and Other (p<0.001).

	Total	African-American	Caucasian	Hispanic	Other†	P-value
N	625	228	207	120	70	–
Age (years)	55.5 (16.2)	59.0 (13.9)	54.5 (18.5)	53.5 (15.0)	50.7 (15.7)	<0.001

† Asian and Pacific Islanders
*N (%) and Chi-square reported. Otherwise, Mean (SD) and Kruskal-Wallis reported.

Conclusion: In a diverse ethnic RA cohort, significant differences in patient and physician global scores were found. Multiple contributors and confounders may account for these findings, and may vary amongst ethnic subsets. Patient input from multiple ethnic groups is imperative to identify relevant parameters of disease function and standardize patient reported outcomes in the definition of remission.

2103

Reliability of DAS28 in Rheumatoid Arthritis When Based On Patient Self-Assessment of Tender and Swollen Joints. Ole Rintek Madsen and Cecilie Heegaard. Copenhagen University Hospital Gentofte, Hellerup, Denmark

Background/Purpose: Clinical assessment of disease activity is a routine procedure when evaluating individual rheumatoid arthritis (RA) patients in daily practice. Swollen joint count (SJC) and tender joint count (TJC) are traditionally performed by the physician (Ph) or the nurse. Patient (Pa) assessed joint count may be an advantage in the busy clinic. The reliability of DAS28 based on patient self-assessment of tender and swollen joints has not previously been reported. The objective of this study was to examine the agreement between patient and physician evaluation of SJC and TJC, to examine the agreement between physician and patient derived DAS28 and to evaluate the reproducibility of these measures when assessed by the physician and the patient, respectively.

Methods: 30 out-clinic RA patients (mean age 60±15 years) with a disease duration of at least 5 years, who were familiar with physician joint counting and who were considered to have a stable and controlled disease activity were included. 28 TJC and SJC were assessed by patient self-evaluation and by an experienced specialist in rheumatology (the same specialist for all patients) on two different days (median interval 7 days, range 4–10 days) under standardised conditions. Patient global assessment (PaGA) (range 0–100) and CRP (mg/l) were also determined on both occasions. DAS28-CRP with four variables (4V) and three variables (3V) were calculated (1). The association between the duplicate measures was expressed by Pearson's coefficient of correlation (r). Lower and upper limits of agreement (LOA) were calculated as the mean difference between scores of duplicate measurements (the bias) ± 1.96 × SD of these differences (2).

Results: The mean values for SJC, TJC, DAS(4V) and DAS(3V) based on Ph joint count versus Pa self-evaluation at the first visit was 3.7±2.4 vs.

3.6±3.2 (NS), 4.1±5.2 vs. 4.1±4.7 (NS), 3.5± 1.0 vs. 3.6±1.1 (NS) and 3.4±0.9 vs. 3.5±0.9 (NS). Mean values for CRP and PaGA were 7.9±6.5 and 33±28, respectively. Ph-DAS(4V) and Pa-DAS (4V) were highly correlated (r = 0.90, p < 0.0001), and so were corresponding DAS scores based on 3V (r = 0.85, p < 0.0001). The bias for Ph-DAS(4V) vs. Pa-DAS(4V) and associated lower and upper LOA were −0.1 (NS), −0.9 and +0.8, respectively. For DAS(3V) the corresponding results were −0.1 (NS), −1.1 and +0.9. The bias for the duplicate Pa-DAS(4V) assessments was −0.1 (NS) with lower and upper LOA of −0.9 and +0.8; and for Pa-DAS(3V) 0.0 (NS), −0.9 and +0.9. For duplicate Ph-DAS(4V) assessments the bias was 0.0 (NS), and LOA were −1.1 and +1.1. For Ph-DAS(3V) the corresponding figures were: 0.0 (NS), −1.2 and +1.2.

Conclusion: On group level, patient and physician derived DAS scores were in practical identical. Differences between patient and physician derived DAS on the individual level corresponded to the intra-rater agreement for both patients and physicians with LOA approximating ±1. Thus, patient-derived DAS seems to have suitable reliability and may therefore substitute traditional assessment by the physician, at least when the disease activity is stable.

Quantitation in Patients with Rheumatoid Arthritis of Inflammation, Joint Damage and "Unexplained Symptoms" (e.g., Fibromyalgia) in Addition to Overall Status, According to 4 Physician Global Estimates Scored 0–10. Isabel Castrejón[1], Martin J. Bergman[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Taylor Hospital, Ridley Park, PA

Background/Purpose: A physician global estimate (DOCGL) of patient clinical status in rheumatoid arthritis (RA) is scored by many rheumatologists entirely based on inflammation, but others may incorporate joint damage and chronic pain, which may affect many RA patients. To address this matter, three 0–10 physician global visual analog subscales (VAS) have been developed to estimate levels of *a)* inflammation, *b)* damage, and *c)* "unexplained symptoms" (e.g., fibromyalgia), in addition to *d)* overall status.

Methods: A random visit was analyzed of all 103 patients with RA seen between Dec 2007 and March 2011 in the private practice of one rheumatologist. All patients complete a multidimensional health assessment questionnaire (MDHAQ) at each visit, which includes 10 physical function items (MDHAQ-FN) and a query, "Are you able to deal with feelings of depression or feeling blue?" with 4 response options in the patient-friendly HAQ format: without any difficulty (=0), with some difficulty (=1), with much difficulty (=2), and unable to do (=3). A formal 28 tender and swollen joint count is performed in all patients with RA. Duration of disease, and 4 DOCGL 0–10 VAS estimates for inflammation, damage, "unexplained'" and overall status are assigned by the rheumatologist. Regression models were computed to explain variation in each of the 4 DOCGL estimates according to variables that were correlated significantly with at least one DOCGL estimate, including swollen joint count (SJC28), duration of disease, depression score and MDHAQ-FN scores.

Results: Mean age of the patients was 61.3 years, disease duration 10.3 years, MDHAQ-FN score (0–10) 1.7, RAPID3 (0–30) 8.5, SJC28 4.2, depression score (0–3) 0.37. The 4 DOCGLs were recorded in about 5 seconds. MDHAQ-FN scores were independently statistically significant to explain variation in all 4 DOCGLs (Table: 1st Models); therefore, a second set of regressions not including MDHAQ-FN was computed (Table: 2nd Models). Variation in DOCGL-Inflammation was explained significantly by SJC28, but not by disease duration or depression score, in both models. Variation in DOCGL-Joint Damage was explained significantly by disease duration, but not by SJC28 or depression score, in both models. Variation in DOCGL-"Unexplained Symptoms" was explained significantly only by MDHAQ-FN in the first model, and by depression score, but not SJC28 or disease duration, in the second model. DOCGL-

Overall Status variation was explained significantly by SJC28 (and MDHAQ-FN) in the first model, and SJC28 and depression score in the second model, but not by disease duration.

Table. Multivariate regression models to recognize significant explanatory variables for 4 physician global estimates (DOCGL) for inflammation, damage, "unexplained symptoms" and overall status in 103 patients with RA

	DOCGL: Inflammation		DOCGL: Damage		DOCGL: "Unexplained"		DOCGL: Overall status	
	Coeff	P	Coeff	P	Coeff	P	Coeff	P
First Models								
SJC28	0.09	<0.001	0.01	NS	0.01	NS	0.25	<0.001
Disease Duration	−0.006	NS	0.04	<0.001	0.01	NS		NS
Depression	−0.13	NS	−0.08	NS	0.15	NS	−0.006	NS
MDHAQ Function	0.32	<0.001	0.47	<0.001	0.30	<0.001	1.01	<0.001
Second Models								
SJC28	0.10	<0.001	0.02	NS	0.01	NS	0.26	<0.001
Disease Duration	−0.004	NS	0.04	<0.001	0.002	NS	−0.02	NS
Depression	0.01	NS	0.10	NS	0.28	<0.001	0.57	0.003

Coeff = regression coefficient; MDHAQ = multidimensional health assessment questionnaire; NS = not statistically significant; SJC28 = 28 swollen joint count.

Conclusion: Variation in DOCGLs for inflammation, damage and "unexplained symptoms" are explained significantly by MDHAQ-FN and/or only 1 of 3 other measures: SJC28, disease duration, and patient self-report depression score, respectively. The 4 DOCGLs have face validity, and are recorded in about 5 seconds.

2105

Significant Correlation Between ACR/EULAR Remission Criteria and a Simplified Measure Using RAPID3 and Careful Joint Examination without a Formal Joint Count. Martin J. Bergman[1], Isabel Castrejón[2] and Theodore Pincus[2]. [1]Taylor Hospital, Ridley Park, PA, [2]NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Definitions for the classification of "remission" have been proposed by ACR/EULAR: Boolean and SDAI<3.3. These criteria require a formal tender and swollen joint count, a patient global assessment, a C-reactive protein (CRP) and (for SDAI definition) a physician global assessment. Rheumatologists usually perform a careful joint examination, but do not perform formal joint counts at most visits, and CRP often is missing at the time of the visit. RAPID3, a patient reported disease activity measure, is correlated significantly with DAS28, CDAI, and other RA indices and can be calculated in less than 5 seconds, compared to 90 seconds to perform a formal joint count. Simply counting >1 swollen joint can be performed without interfering with usual patient interactions, unlike a full formal joint count. We sought to analyze the capacity of a novel description of remission in RA using RAPID3 and the presence or absence of greater than 1 swollen joint, and compared results to ACR/EULAR remission.

Methods: All patients (with any diagnosis) in a solo Rheumatology practice are given an MDHAQ to be completed by the patient in the waiting area and RAPID3 is calculated before the patient is seen. Patients are instructed to obtain standard laboratory tests approximately 1 week prior to the visit, including a CRP, so that CRP values will be available at the time of the visit. A formal joint count (28 tender/28 swollen) is performed in all RA patients, and, a physician global score is assigned. A random patient visit was selected which included all measures. Patients were identified as in remission or not, according to ACR/EULAR Criteria or "RAPID3RJ" defined as a RAPID3 score <=3.0 AND ≤1 swollen joint. Comparisons of the two descriptions were analyzed using Spearman correlations and kappa statistics.

Results: 191 patients with RA were identified. Complete data were available in 122 patients. ACR/EULAR remission criteria were met in 27 of 122 patients; RAPIDRJ1 in 23 patients (Table 1). 22 patients were in agreement using both measures; 5 in ACR/EULAR were not in RAPIDRJ, 1 in RAPIDRJ were not in ACR/EULAR. Spearman rho was 0.86 (p<0.0001); Kappa=0.85 (substantial agreement).

Table 1.

RAPID3≤3 + SWOLLEN JOINT COUNT ≤1 (RAPIDRJ1)	ACR/EULAR REMISSION CRITERIA		
	NO	YES	TOTAL
NO	94	5	99
YES	1	22	23
TOTAL	95	27	122

Kappa=0.85 p<10⁻⁴ Spearman rho=0.86

Kappa=0.85 $p<10^{-4}$ Spearman rho=0.86

Conclusion: The classification of remission can be made using a simple patient questionnaire and requiring only the identification of ≤1 swollen joint. Future studies are planned to determine if this new definition of remission will also predict X-ray progression, one of the criteria for the development of the ACR/EULAR criteria.

Patient Characteristics Associated with Discrepancies in Evaluator-Reported and Patient-Reported Outcomes in U.S. Veterans with Rheumatoid Arthritis. Archana Jain[1], Rebecca Belsom[1], Jeffrey Curtis[2], Shuo Yang[2], Ted R. Mikuls[3], Lang Chen[2] and Angelo L. Gaffo[4]. [1]University of Alabama, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [4]Birmingham VA Medical Center and University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Validated tools that incorporate evaluator and patient reported outcomes (PROs) are used for guiding therapy in patients with rheumatoid arthritis (RA). PROs used in RA evaluation may be influenced by co-morbidities (i.e. diabetes, coronary artery disease, congestive heart failure). We hypothesized that these co-morbidities lead to discrepancies between the tender and swollen joint counts and between patient- and evaluator-reported global assessments of RA activity.

Methods: We performed a cross-sectional analysis at baseline visit for all patients enrolled in the Veterans Affairs Rheumatoid Arthritis (VARA) registry with linkage to the VA Decision Support System (DSS). Patient global assessments (PGA) and evaluator global assessments (EGA) of disease activity distribution were divided into tertiles. PGA and EGA values in the same tertiles were defined as concordant, whereas the values in different tertiles were defined as discordant. Swollen joint count (SJC) to tender joint count (TJC) ratio of ≥ 0.8 was defined as concordant, whereas ratio < 0.4 was defined as discordant. Demographic characteristics and frequencies of DSS-derived co-morbidities in patients with concordant and discordant PGA and EGA; and TJC and SJC respectively were compared. Additionally, a longitudinal analysis of the subset of patients with at least 2 visits was performed to determine which ratio of SJC/TJC was associated with a decision to switch to a new biologic agent in patients with at least moderate disease activity (DAS28ESR > 3.2).

Results: 1305 unique patients with linkage to DSS were identified. The mean age was 68.2 years and 90.5% were males. PGA and EGA data was available for 529 patients. There were 95 (18%) patients with a discordant PGA worse than EGA, 123 (23.3%) with a discordant EGA worse than PGA, and 311 (58.8%) patients with concordant PGA and EGA. There was no significant difference in socio-demographics and prevalence of co-morbidities in patients with discordant worse PGA subgroup as compared to patients with concordant PGA and EGA. SJC and TJC data was available for all 1305 patients. There were 825 (63.2%) patients with SJC/TJC < 0.4, 326 (25%) patients with SJC/TJC ≥0.8, and 154 (11.8%) patients in-between these categories. Patients with SJC/TJC ratio < 0.4 were older than those with ratio ≥0.8 (68.8 yrs vs 67.2 yrs, p 0.02). There were no other significant differences in socio-demographic variables or prevalence of co-morbidities. Among all VARA patients treated with biologics who were in moderate or high disease activity (DAS28ESR > 3.2) at a VARA visit (n=1365 visits), approximately 7% were switched at that visit to another biologic. The likelihood of switching for patients with a SJC/TJC > 0.4 was 2.5 (1.5–4.4) fold greater compared to those with a SJC/TJC ratio ≤ 0.4.

Conclusion: There was no association of co-morbidities with discordantly high PGA or low TJC/SJC ratio. A SJC/TJC ratio < 0.4 appears useful to identify patients whose patient reported outcome data is unduly affected by factors other than RA and might be used to screen for patients not appropriate for traditional treat-to-target strategy cutpoints.

Assessing Subclinical Synovitis in Rheumatoid Arthritis: Arthrosonographic Findings in Patients with Good Response to Therapy. Matthias Witt, Felix Mueller, Axel Nigg, Christiane Reindl, Hendrik Schulze-Koops and Mathias Grunke. Division of Rheumatology and Clinical Immunology, Medizinische Klinik und Poliklinik IV, University of Munich, Munich, Germany

Background/Purpose: Treat-to-target is a key principle in rheumatoid arthritis. Composite scores such as the DAS-28 help to monitor disease activity and response to therapy. However, in patients without clinical activity, ultrasound examination may reveal subclinical synovitis. While some findings have prognostic relevance, little is known about the relevance of borderline (grade 1) ultrasound findings in asymptomatic joints of patients with good response to therapy. This study was undertaken to give a sonographic analysis of subclinical synovitis in this subset of RA patients.

Methods: Patients with newly diagnosed RA were included. At baseline, patients were assessed by clinical examination and ultrasound. Ultrasound was performed with grey scale (GSUS) and power Doppler (PDUS) in the metacarpophalangeal, proximal interphalangeal, metatarsophalangeal and wrist joints, using the dorsal approach in each joint. Synovitic findings in GSUS and PDUS were graded semiquantitatively from 0 to 3 as specified before. After the initial assessment, patients were treated with anti-rheumatic drugs according to national guidelines and were seen on a regular outpatient basis. Clinical and sonographic reevaluation together with assessment of EULAR responses was performed at month 6.

Results: Sofar, 40 patients were included into this ongoing study. Patients' characteristics are consistent with a typical RA cohort. By month 6, good, moderate and no EULAR responses were reached by 65.7%, 25.7% and 8.6% of the patients, respectively. In the group with good EULAR response, 7.2% of the joints had clinical synovitis, while 92.8% of the joints were asymptomatic. In the asymptomatic group, ultrasound detected subclinical synovitis in 11.1% in GSUS and in 3.8% in PDUS with significant differences for both modalities in comparison to the clinically apparent group. The sonographic findings in the subclinical group could be classified as grade 1, grade 2 and grade 3 in 78.9%, 19.7% and 1.3% in GSUS, and in 76.9%, 23.0% and 0% in PDUS. Grade 1 GSUS and PDUS findings were found significantly more often in the subclinical group, while non-grade 1, i.e. grade 2 and grade 3 GSUS and PDUS findings were significantly more prevalent in the clinically apparent group.

Conclusion: More than 90% of the joints were asymptomatic in the group with good response. Ultrasound of these joints revealed subclinical synovitis in 11.1% in GSUS and in 3.8% in PDUS. Concerning the pattern of ultrasound findings, grade 1 findings were most prevalent in both modalities and were found significantly more often than in the clinically apparent group. Of note, grade 1 GSUS findings are also found in healthy individuals and hence, the clinical relevance seems to be questionable. While persistent PDUS activity in general has been linked to clinical relapses in asymptomatic patients, the specific relevance of grade 1 PDUS findings needs to be further clarified. Taken together, these data indicate that the relevance of subclinical synovitis may be overestimated in asymptomatic joints of patients with a good clinical treatment response. In this situation ultrasound seems to add little to the clinical overall impression. Further analysis is underway to clarify the role of grade 1 PDUS findings.

Identification of Four Parameters That Drive the Discordance Between the Patient and Physician Global Assessment in Rheumatoid Arthritis. William Bensen[1], Denis Choquette[2], Milton F. Baker[3], Susan M. Otawa[4] and Hayssam Khalil[4]. [1]St. Joseph's Hospital and McMaster University, Hamilton, ON, [2]University of Montreal, Notre-dame Hospital, Montreal, QC, [3]University of Victoria, Victoria, BC, [4]Janssen Canada Inc, Toronto, ON

Background/Purpose: Patient (PtGA) and physician (MDGA) global assessment of disease activity are standard outcome measures used to ascertain physician and patient subjective perception of disease activity in rheumatoid arthritis (RA). Given that the PtGA and MDGA measure the same construct from two different perspectives, assessing their discordance may provide valuable insight on patient and physician differences with respect to the relative importance placed on specific disease parameters.

Methods: BioTRAC is an ongoing Canadian registry of patients initiating treatment with infliximab or golimumab as first biologics. PtGA and MDGA were measured at baseline using a 10cm VAS. Using tertiles of the baseline MDGA-PtGA distribution every patient was classified as having higher assess-

ment than the physician (range: −10.0 to −0.5), agreement (range: −0.4 to 1.1) or lower assessment than the physician (range: 1.2 to 8.0).

Results: 841 patients with baseline data for both PtGA and MDGA were included. Among these 623 (74.1%) were female, mean age was 57.0 yrs and mean disease duration was 9.8 yrs. Mean (SD) PtGA and MDGA were 6.1 (2.4) and 6.5 (2.1), respectively, and the mean (SD) PtGA – MDGA was 0.4 (2.4) with a median of 0.3; for 6.4% of the patients the PtGA-MDGA was nil.

Significant differences between patients with lower, equal or higher assessment relative to the physician assessment were identified. When compared to patients with higher PtGA relative to MDGA, patients with lower assessment of their disease activity had lower morning (AM) stiffness, pain, and HAQ-DI but higher SJC (Table 1). AM stiffness, SJC, TJC, and HAQ-DI were highest in patients with PtGA-MDGA agreement. Age, gender, and SJC/TJC ratio were not different for the three groups. Linear regression using backwards selection identified pain (P<0.001), SJC (P<0.001), and HAQ-DI (P=0.056) as independent predictors of PtGA-MDGA.

Table. Patient Baseline Characteristics by Degree of Difference Between MDGA and PtGA

Mean (SD)	Lower PtGA vs. MDGA[1]	Higher PtGA vs. MDGA[2]	P-Value[3]
Age: Years	56.9 (13.8)	57.2 (13.2)	0.815
Disease Duration: Years	9.0 (8.3)	10.0 (10.5)	0.478
AM Stiffness: min	62.0 (44.5)	70.7 (43.2)	*0.019*
Pain: VAS mm	42.0 (22.4)	67.4 (21.2)	*<0.001*
SJC-28	11.1 (7.0)	9.1 (6.4)	*<0.001*
TJC-28	12.0 (8.1)	11.4 (7.3)	0.326
SJC/TJC	1.1 (1.1)	1.1 (1.6)	0.805
HAQ-DI	1.42 (0.73)	1.69 (0.65)	*<0.001*

[1] MDGA-PtGA range: 1.2 to 8.0
[2] MDGA-PtGA range: −10.0 to −0.5
[3] P-Value was assessed with a t-test for independent samples

Conclusion: The relative importance of morning stiffness, pain, HAQ, and SJC in assessing disease activity may be different between patients and physicians. These results have implications for development of assessment tools that better represent both patient and physician perspectives of disease activity.

2109

Discrepancy Between Patient and Physician Global Assessments Over Time in Early Rheumatoid Arthritis. Pooneh Akhavan[1], Vivian P. Bykerk[2], Juan Xiong[3], Janet Pope[4], Boulos Haraoui[5], J. Carter Thorne[6], Gilles Boire[7], Carol A. Hitchon[8], Diane Tin[6], E. Keystone[3] and CATCH[9]. [1]University of Toronto, Toronto, ON, [2]Hospital for Special Surgery, New York, NY, [3]Mount Sinai Hospital, Toronto, ON, [4]Schulich School of Medicine and Dentistry, Western University, London, ON, [5]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [6]Southlake Regional Health Centre, Newmarket, ON, [7]CHUS - Sherbrooke University, Sherbrooke, QC, [8]University of Manitoba, Winnipeg, MB, [9]Toronto

Background/Purpose: Discrepancy between patient (PGA) and physician (MDGA) global assessments in RA can adversely affect therapeutic decisions in many cases. The purpose of this study is to assess whether baseline PGA-MDGA discrepancy predictors change after one year in patients with early RA.

Methods: Patients with RA were recruited from the Canadian Early Arthritis Cohort (CATCH) a prospective cohort where data is collected according to a standardized protocol. CATCH patients were considered for this analysis if they initiated DMARDs at baseline, were biologic naïve and had ≥12 months follow up. PGA and MDGA were scored out of 100. PGA-MDGA discrepancy was calculated by subtracting MDGA from PGA at baseline. A clinically meaningful discrepancy was considered a difference of ≥30 (PGA-MDGA > 30: Positive (Pos) and PGA-MDGA < −30: Negative (Neg)). Linear regression analysis was used to evaluate factors associated with the PGA-MDGA discrepancy, MDGA and PGA when adjusted for potential confounders at baseline and at 1 year separately. To address the variability of the rheumatologists' influence on the discrepancy we included CATCH recruiting "site" as one of the predictors. Sites with more than 25 patients were considered for analysis.

Results: Baseline characteristics of the 480 RA patients who met inclusion criteria for this study included: 74% female, mean (SD) age 54(14.5), disease duration 0.5(0.24) years, TJC 8.6 (6.8), SJC 8.7 (6.3) (of 28), DAS28 5.2 (1.4), ESR 28.6 (22.6), CRP 15.0 (19.6) mg/L, PGA 58.7 (29.4) and MDGA 51.6 (24.8). Discrepancy rates are shown in Table 1. At baseline significant predictors of PGA-MDGA were Pain (p<.0001), SJC (p<.0001), TJC (p=0.008), ESR (p=0.02) and "site" (p=0.0006). At 12 months significant predictors of PGA-

MDGA were Pain (<.0001), SJC (p<.0001), TJC (p=0.02), age (0.04) and "site" (p=0.0002). At baseline PGA was significantly associated with pain, HAQ, SJC, age and "site" and at 12 months with pain and "site" only. Baseline factors associated with MDGA were SJC, TJC, pain, ESR, HAQ and "site" and at 12 months ESR and HAQ were no longer significant.

Table 1. Discrepancy rates at baseline and 12 months

	No discrepancy	Positive discrepancy	Negative discrepancy
Baseline	65%*	25%	10%
12 months	73%*	23%	4%

(*P<0.05)

Conclusion: PGA-MDGA discrepancy rate decreases over time but the pattern remains the same in early RA. Pain and SJC significantly influence PGA-MDGA discrepancy at baseline and this persists after one year when the disease is better controlled. Although previous studies have emphasized the pain score as a major factor affecting the PGA-MDGA discrepancy; we have also demonstrated a significant influence of the SJC.

2110

Prospective Assessement of Bone Texture Parameters At the Hand in Rheumatoid Arthritis. Laetitia Sparsa[1], Sami Kolta[1], Karine Briot[1], Simon Paternotte[1], Rashra Masri[2], Damien Loeuille[2], Piet P. Geusens[3] and Christian Roux[1]. [1]Paris Descartes University, Cochin hospital, Paris, France, [2]CHU Brabois, Vandoeuvre les Nancy, France, [3]Maastricht University, Maastricht, Netherlands

Background/Purpose: Bone and cartilage loss and destruction is associated with rheumatoid arthritis (RA) and inflammation. There is a need for tools for prediction of potential severe patients with poor outcome. The BMA device (D3ATM Medical Systems, Orleans, France) is a high resolution X-ray technique, used to image bone and joints, and to measure bone texture parameters including the fractal dimension (Hmean). The aims of this study were to evaluate, by BMA analysis, the metacarpal bone texture in a cohort of 165 RA patients after 1 year of follow up, and to assess the relationship between these parameters and RA disease parameters at baseline and over 1 year.

Methods: Patients with RA according to ACR criteria were included. They were assessed every 6 months over 1 year, in the context of a prospective study conducted in Maastricht. For this substudy, activity of the disease was assessed by erythrocyte sedimentation rate (ESR), C reactive protein (CRP) and Disease Activity Score (DAS 28) performed at each visit. Radiographic bone damage is assessed using hand and feet conventional posterior-anterior radiographs at baseline and on a 1-year basis The bone texture parameters were evaluated on the second and third metacarpal heads of the left hand (MCP2 and MCP3) using BMA device, with standard acquisition at baseline, 6 and 12 months. A single investigator performed all the analyses, with standardized position of regions of interest in the bones. The calculated parameter was Hmean as an approach to bone roughness.

Results: 165 patients were included 57 men and 108 women, mean age 63.63 years [33–89]. The mean disease duration was 9.67 years [2–36]. Among the 138 cases where rheumatoid factor results were available, 75 were positive and among the 11 cases where anti CCP antibodies were available only 6 were positive. 53 patients were followed using BMA device and a total of 632 joints were studied. 24/53 (45.3%) patients had RA damage (erosions, joint space narrowing). The mean DAS28 score was 3.34 [0.63–7.35]. Twenty four patients were receiving bisphosphonate during the study. Hmean was similar in MCP2 and MCP3 at baseline: 0.411 ± 0.038 and 0.412 ± 0.043 respectively; H mean MCP2 was correlated with disease duration (-0.17, p=0.03). There was an increase in H mean MCP2 (+ 1.0 % p=0.0004) over 1 year. ESR and CRP were correlated with H mean MCP3 at baseline (-0,15, p=0.055; −0.15 p=0.06) and 6 months (-0.22 p=0.006, −0.25 p=0.002 respectively). DAS was correlated with H mean MCP3 at 6 months (-0.14, p=0.07) and H mean MCP2 at 12 months (-0.16 p=0.04).

Conclusion: This new high resolution digital X-ray device provides bone texture parameters of metacarpal heads in RA patients. This preliminary analysis suggests that these parameters measured at the metacarpal heads are influenced by disease duration and activity.

Diagnostic Performance of the 2010 American College of Rheumatology/European League Against Rheumatism Classification Criteria for Rheumatoid Arthritis: Systematic Literature Review and Meta-Analysis. Garifallia Sakellariou[1], Carlo Alberto Scirè[2], Roberto Caporali[1] and Carlomaurizio Montecucco[3]. [1]Division of Rheumatology, University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, [2]Epidemiology Unit, Italian Society for Rheumatology (SIR), Milano, Italy, [3]University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background/Purpose: in 2010 ACR and EULAR proposed new classification criteria for rheumatoid arthritis (RA). This new set of criteria has been tested in several external populations. The aim of the present study was to summarize the available evidence performing a systematic literature review and meta-analysis of their diagnostic accuracy.

Methods: We searched PubMed, EMBASE, Cochrane and screened the abstracts of the ACR and EULAR congresses from 2010 to 2012. The inclusion criteria were: 1) population of patients with recent onset arthritis, at least one swollen joint, no alternative diagnosis; 2) The ACR/EULAR 2010 criteria (cut-off of 6) as index test; 3) The use of methotrexate (MTX) or disease modifying antirheumatic drugs (DMARDs) as reference standard; 4) Diagnostic accuracy, case control, prospective or retrospective cohort studies; 5) Sufficient data to build a 2×2 table of diagnostic accuracy. Sensitivity (Se) and specificity (Sp) were calculated for each study, data were pooled using a hierarchical summary receiving operator characteristic curve (HSROC) with confidence and prediction intervals. Three separate meta-analysis were performed, considering MTX, DMARDs or their combination as reference standard. To test the robustness of the results, diagnostic odds ratio (DOR) was calculated and an exploratory meta-regression was performed for the analysis of MTX+DMARDs, considering as confounders symptom duration, rheumatoid factor, anti cyclic citrullinated petide antibodies and the timing of assessment of the reference standard. The risk of bias of the included studies was evaluated using the modified version of the Quality Assessment of Diagnostic Accuracy Studies (QUADAS) proposed by the Cochrane collaboration.

Results: A total of 1,257 references were retrieved, after screening title and abstract 4 full papers were included, together with 6 abstracts from the ACR and EULAR congresses. Using MTX as reference standard, the first meta-analysis showed: Se (95% confidence interval, CI) was 0.73 (0.64,0.80), Sp was 0.74 (0.68,0.79), positive likelihood ratio (LR+) (95% CI) was 2.85 (2.53,3.22), negative LR (LR-) 0.35 (0.27,0.45), DOR 8.03 (6.4,10.09). Using DMARDs as reference standard, Se 0.80 (0.74,0.85), Sp was 0.61 (0.56,0.67), LR+ 2.11 (1.92,2.32), LR− 0.31 (0.25,0.38), DOR 6.74 (5.49,8.28). Using the combination of MTX and DMARDs as reference standard, Se was 0.76 (0.71,0.81), Sp was 0.69 (0.61,0.75), LR+ 2.48 (2.08,2.95), LR− 0.33 (0.29,0.38), OR 7.38 (6.33, 8.62). Meta-regression demonstrated no influence of the possible confounders on the results. The risk of bias was low or unclear for most of the studies.

Conclusion: the new classification criteria have a good sensitivity, while specificity is lower. The development of an optimal diagnostic tool for RA is limited by the absence of a real reference standard. In fact, also the decision to start MTX or DMARDs depends on the rheumatologist and the setting. However, these results confirm the mainly classificative and not diagnostic role of the criteria.

Combination of Magnetic Resonance Imaging (MRI)-Proven Osteitis with 2010 RA Classification Criteria Improves the Diagnostic Probability of Rheumatoid Arthritis (RA). Mami Tamai[1], Yoshikazu Nakashima[1], Takahisa Suzuki[2], Yoshiro Horai[2], Akitomo Okada[2], Junko Kita[2], Shin-ya Kawashiri[2], Naoki Iwamoto[1], Kunihiro Ichinose[2], Kazuhiko Arima[1], Hideki Nakamura[1], Tomoki Origuchi[2], Masataka Uetani[2], Kiyoshi Aoyagi[2], Katsumi Eguchi[3] and Atsushi Kawakami[2]. [1]Nagasaki University, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Sasebo City General Hospital, Sasebo, Nagasaki, Japan

Background/Purpose: In the articles of 2010 rheumatoid arthritis (RA) classification criteria, it is stated that additional evidence of joint injury from other imaging techniques such as magnetic resonance imaging (MRI) may be used for confirmation of the clinical findings. Considering the impact of MRI on the clinical assessment of inflammatory arthritides, it would be desirable to address the algorithm toward earlier classification of RA by the MRI findings combining to 2010 RA classification criteria. We have tried to investigate whether MRI-proven joint injury assist the diagnostic performance of 2010 RA classification criteria toward early arthritis patients.

Methods: Two hundred patients with early arthritis patients, whose median duration of symptoms at entry is 3 months, were consecutively enrolled into this study. Patients, whose diagnoses were compatible as other rheumatic diseases than RA or obvious to plain radiographic erosion at entry, were excluded in the present study. All of the patients were examined by Japan College of Rheumatology (JCR)-certified rheumatologists and considered as RA potentially at entry. Patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. All of the subjects had been examined by physical examination, blood tests, gadolinium-diethylenetriamine pentaacetic acid (Gd-DTPA)-enhanced MRI and plain radiograph of both wrist and finger joints at the same day. Gold standard RA in the present study was defined as the patients received disease-modifying antirheumatic drugs (DMARDs) therapy during the first year. Patients were evaluated by the 2010 RA classification criteria at the initial visit. Diagnostic performance of 2010 RA criteria combined with or without the finding of MRI-proven joint injury were investigated. One hundred fifteen were diagnosed as gold standard RA whereas 85 were not.

Results: 2010 RA classification criteria classified RA at sensitivity 59.8%, specificity 80.7%, positive predictive value (PPV) 81.4%, respectively. Osteitis was the most specific MRI finding toward gold standard RA (sensitivity 45.3%, specificity 90.4%, PPV 86.9%) as compared with symmetrical synovitis and bone erosion. We have proposed the decision tree algorithm of 2010 RA classification criteria combined with MRI-proven osteitis which demonstrate initially applied 2010 RA classification criteria, and if the patients do not fulfill 2010 RA classification criteria, MRI-proven osteitis rule is introduced. The tree algorithm has shown to differentiate the patients more efficiently compared with 2010 RA classification criteria alone as sensitivity 74.4%, specificity 94.0%, PPV 94.6%, respectively.

Conclusion: The present data indicate that combination of MRI-proven osteitis with 2010 RA classification criteria improves the diagnostic probability of RA at earlier stage.

2113

Performance of the New ACR/EULAR Classification Criteria for Rheumatoid Arthritis - A Systematic Literature Review. Helga Radner[1], Josef Smolen[2] and Daniel Aletaha[3]. [1]Medical University Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [3]Medical University of Vienna, Vienna, Austria

Background/Purpose: Since introduction of the new ACR/EULAR classification criteria of rheumatoid arthritis (RA) several studies were published validating the new criteria in different cohorts using different approaches and goldstandards. Performing a systematic literature review we want to summerize published studies and assess the sensitivity and specificity of the new ACR/EULAR classification criteria in comparison to the 1987 ACR criteria using different cohorts and goldstandards.

Methods: A systematic literature review was performed in the three main databases (Medline, EMBASE and Cochrane Central). Information of all included studies were extracted and raw data of patients fulfilling different criteria and goldstandards were extracted in order to calculate sensitivity and specificity, positive and negative predictive values as well as standard deviations. Taking into consideration heterogeneity meta-analyses were performed if possible.

Results: In total 1080 articles were retrieved by the search strategy, of which 14 studies (total 6200 patients) could be included. 9 studies included early arthritis patients, 3 established RA, 1 undifferentiated arthritis (UA) and 1 patients with joint symptoms. 5 studies used initiation of MTX (range sensitivity (sens) 0.68 to 0.88 and specificity (spec) 0.3 to 0.72;pooled (95%CI): sens 0.86 (0.84–0.88); spec 0.49 (0.46–0.52)), 3 studies initiation of DMARD (range sens 0.62 to 0.85 and spec 0.38 to 0.78; pooled (95%CI): sens 0.80 (0.78–0.82); spec 0.61 (0.57–0.64)), and 6 studies used expert opinion as goldstandard, out of them 3 in early arthritis patients (range sens 0.62 to 0.91; spec 0.35 to 0.78; pooled (95%CI): sens 0.87 (0.85–0.89) spec 0.45 (0.41–0.49)); 2 in established RA (sens 0.66 to 0.78); 1 in UA (sens 0.47, spec 0.71). Two studies used expert opinion and DMARD as goldstandard (sens 0.58 to 0.74, spec 0.8 to 0.86). Considering different joint counts (JC) no differences of sens and spec could be observed (28JC 3 studies (sens 0.83 to 0.86; spec 0.37 to 0.6); 40JC 3 studies (sens 0.64 to 0.88; spec 0.53 to 0.76); 66/68JC 7 studies (sens 0.48 to 0.88; spec 0.54 to 0.83) no pooling due to different goldstandards/cohorts).

Seven studies directly compared 2010 with 1987 criteria using different goldstandards showing an slightly lower overall specificity (mean delta Sensitivity 2010 Π Sensitivity 1987 criteria = −0,05) but higher overall sensitivity (mean delta Sensitivity 2010–Sensitivity 1987 criteria =+0,13) of the new 2010 criteria compared to the 1987 criteria (**figure 1**).

STUDY	Cohort	N	Goldstandard	1987 criteria		2010 criteria	
				sens	spec	sens	spec
Van de...	early arthritis	330	DMARD use + Expert opinion	0,84	0,8	0,58	0,80
Kaarela...	juba synovcom	424	...	0,87	0,03	0,73	0,71
...	early arthritis	145	MTX use + ...	0,42	0,8	0,58	0,72
...	early arthritis	428	MTX use + ...	0,70	0,53	0,85	0,5
Naum...	early arthritis	434	MTX use + ...	0,80	0,3	0,88	0,37
Cram...	early arthritis	344	Expert opinion after 3.0 ...	0,57	0,75	0,6	0,80
... Leiden	early arthritis	338	MTX use + MTX after 1 year	0,80	0,74	0,84	0,8

◇ Difference sens of dg by 2010 – de-criteria's sens
◆ Difference of spec of dg by 2010 – Specificity's spec

Favours 1987 criteria | Favours 2010 criteria

-02   -01   0   01   02

Conclusion: The new ACR/EULAR classification criteria seems valid independent of goldstandard and cohort used. Compared to the 1987 criteria they show higher sensitivity and almost equal specificity.

Joint Damage Progression in Rheumatoid Arthritis: Role of the HLA-DRB1 Shared Epitope and Anti-CCP. Jose Felix Restrepo[1], Inmaculada del Rincon[1], Roy W. Haas[1], Daniel F. Battafarano[2] and Agustin Escalante[1]. [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Brooke Army Medical Ctr, San Antonio, TX

Background/Purpose: The HLA-DRB1 shared epitope (SE) and antibodies to cyclic citrullinated peptides (anti-CCP) are important to the susceptibility to rheumatoid arthritis (RA), and are thought to be involved in pathogenesis. Clinically, their presence identifies patients with more severe disease. Few studies have examined their combined effect on RA outcome. We studied a large cohort of RA patients focusing on the association of radiographic joint damage with the presence of the SE and anti-CCP.

Methods: A radiograph of both hands and wrists was used to measure erosions and joint-space narrowing in patients with RA, using the technique developed by Sharp et al. The SE was genotyped using sequence-specific primer amplification, and anti-CCP was measured using ELISA. An anti-CCP concentration of 20 IU or higher was considered-positive. Patients were followed over time with repeated hand radiographs. We used generalized estimating equations (GEE) with the Sharp score as a dependent variable to examine association between the SE and anti-CCP.

Results: We studied 1,328 RA patients. Of these, 1,264 (95%) had hand radiographs, as well as SE and anti-CCP results. There were 3,824 radiographs, or 3.0 films per patient, over 8,700 patient-years of observation (6.9 years per patient). The Sharp score at baseline was 47 (SD 61, range 0 to 294). The Sharp score progressed at a rate of 4.09 units per year (95% CI 3.96, 4.22) in the cohort considered as a whole. Among the 157 patients who were negative for both the SE and anti-CCP, the Sharp score progressed at a rate of 2.76 units per year (2.44, 3.08). Among 449 patients who were positive for either the SE or the anti-CCP, the Sharp progression rate was 4.02 (3.82, 4.22, P < 0.001). Among 658 patients who were positive for both the SE and anti-CCP, Sharp progression rate was 4.50 (4.34, 4.67, P < 0.001). We also examined at what point in time the mean Sharp score diverged significantly between the groups defined by SE and anti-CCP. Compared to patients who had negative SE and negative anti-CCP, patients who had positive SE and/or positive anti-CCP did not develop significantly higher Sharp score until 17 years of disease duration had passed.

Conclusion: Joint damage progressed more rapidly among RA patients who had positive SE and/or anti-CCP. However, it was not until well into the second decade of disease that the amount of damage in the patients with positive SE and/or positive anti-CCP became significantly different from those in whom these markers were negative.

Altered Serum Levels of Bone Metabolism Markers in Rheumatoid Arthritis. Lang Jing Zhu, Xia Ouyang, Lie Dai, Dong Hui Zheng, Ying Qian Mo, Xiu Ning Wei, Chan Juan Zou and Bai Yu Zhang. Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease leading to joint destruction and disability. Previous studies showed abnormal activation of osteoclasts as well as altered skeletal bone metabolism and co-morbid conditions in RA. Tumor necrosis factor receptor-associated factor (TRAF) 6 is one of the critical modulator in differentiation and resorption activity of osteoclasts. New biochemical markers of bone formation showed contradictory results in different studies, although markers of bone resorption have shown significant increase in patients with RA. This study aimed to evaluate serum levels of bone metabolism markers and their correlation with synovial TRAF6 expression, as well as clinical and biological parameters that reflect the activity and severity of RA.

Methods: Serum C-terminal telopeptide of type I collagen (CTX-I), N-terminal propeptide of type I collagen (PINP) and N-terminal midfragment of Osteocalcin (N-MID.OC) was tested by chemiluminescence in 30 patients with active RA, as well as 60 age and gender matched healthy controls. Synovial tissue samples were obtained by needle biopsy from

RA patients, and semiquantitative analysis was performed to evaluate the intensity of TRAF6+ cells. Serological and clinical parameters that reflect the activity and severity of RA, as well as radiographic joint destruction (Sharp score) were collected simultaneously.

Results: Serum CTX-I level was significantly higher in RA patients compared with healthy controls (0.56 ± 0.37 vs. 0.34 ± 0.21, p=0.004). No significant difference was found in serum PINP or N-MID.OC level. Spearman's correlation test showed serum PINP and N-MID.OC level of RA patients correlated negatively with morning stiffness (r=−0.450 and −0.267, p=0.016 and 0.046, respectively) and pain VAS (r=−0.247 and −0.354, p=0.049 and 0.045, respectively), but correlated positively with gripping power (r=0.676 and 0.621, p=0.005 and 0.006, respectively). Significant correlation was found between synovial TRAF6 expression and serum PINP level (r=0.381, p=0.038), as well as serum N-MID.OC level (r=0.345, p=0.042). Subanalysis of lining and sublining TRAF6 expression showed that PINP correlated significantly with sublining TRAF6 expression (r=0.353, p=0.046), N-MID.OC correlated significantly with lining TRAF6 expression (r=0.407, p=0.025).

Conclusion: Increased bone resorption and altered skeletal bone metabolism was found in RA. PINP and N-MID.OC may be a helpful biomarker for disease activity in RA. Synovial TRAF6 expression in RA correlated significantly with serum PINP and N-MID.OC level and maybe involved in the pathogenesis of bone metabolism disbalance in RA.

The Associations of HLA-DR Shared Epitope Alleles and Serum Cytokines Among Postmenopausal Women with Rheumatoid Factor and Anti-Citrullinated Protein Antibody-Positive Rheumatoid Arthritis.
Mehret Birru Talabi[1], Rachel Mackey[2], Larry W. Moreland[2], Jan Dorman[3], Kevin D. Deane[4], Jeremy Sokolove[5], V. Michael Holers[4], William H. Robinson[6], Brian Wallitt[7] and Lewis Kuller[2]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh School of Nursing, Pittsburgh, PA, [4]University of Colorado School of Medicine, Aurora, CO, [5]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [6]Stanford University, Palo Alto, CA, [7]Washington Hospital Center, Baltimore, MD

Background/Purpose: This study evaluates associations between HLA-DRβ1 associated shared epitope (SE) alleles and cytokines among postmenopausal women with rheumatoid arthritis (RA). Presence of 1 or 2 versus absence of SE alleles is associated with more erosive RA in a number of studies. Fewer studies have examined if the number of SE alleles is associated with markers of inflammation.

Methods: Participants (n=2877) were enrolled in a substudy of the Women's Health Initiative, and reported RA on questionnaires. Rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA), HLA- DRβ1 genotyping, and cytokines (IL-1B, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-13, IL-12, IL-17, TNFα, MCP-1, MIF-1, IFN-Y, GCSF) were measured. SEs included QKRAA, KRRAA, RRRAA. Kruskal-Wallis tests were used to evaluate median cytokine concentrations by SE allele frequencies.

Results: Women included in this analysis (n=591) were RF and ACPA-positive. N=208 had 0 SE alleles, n=288 had 1 SE, and n=95 had 2 SEs. Several cytokines showed a dose-response increase from 0 to 1 to 2 SEs (underlined in table), with IL-2 and IL-6 showing the most marked differences (p<0.05 for differences between SE categories).

Table 1. Median (Interquartile Range) Cytokine Levels by Number of Shared Epitopes in ACPA/RF+ Women

Cytokines	Shared Epitopes			p-value
	0 (n=208)	1 (n=288)	2 (n=95)	
IL-2	11.3 (4.3–35.1)	12.7 (5.6–41.6)	19.0 (6.4–60.6)	0.047
IL-6	11.8 (6.4–32.6)	15.3 (8.5–35.3)	20.3 (10.1–56.5)	0.003
IFN-Y	68.8 (39.1–171.2)	77.4 (43.8–196.8)	87.7 (48.6–214.6)	0.22
MCP1	20.2 (13.4–33.1)	21.5 (15.1–36.7)	23.6 (13.5–42.6)	0.24
IL-1b	2.2 (1.4–5.0)	2.4 (1.6–6.4)	2.6 (1.7–7.1)	0.18
IL-10	3.0 (2.0–5.3)	3.2 (2.3–5.0)	3.5 (2.4–5.7)	0.32
IL-4	2.3 (1.3–3.7)	2.32 (1.5–3.6)	2.2 (1.5–3.2)	0.80
IL-5	4.0 (2.8–5.9)	4.2 (3.0–6.6)	4.0 (2.9–6.0)	0.46
IL-7	8.4 (6.0–11.5)	8.6 (6.5–12.8)	8.4 (6.1–11.6)	0.47
IL-8	9.6 (7.4–12.8)	10.1 (7.4–13.2)	9.6 (7.3–12.7)	0.50
IL-12	22.2 (12.2–65.5)	23.3 (14.0–53.4)	21.7 (13.5–69.6)	0.82
IL-13	4.0 (2.3–10.5)	4.4 (2.7–10.2)	4.2 (2.6–11.3)	0.46
GCSF	165.8 (112.7–224.2)	175.2 (120.0–235.8)	167.4 (124.8)	0.62
MIP1b	44.2 (33.0–61.5)	47.5 (34.4–65.8)	45.9 (36.1–64.6)	0.40
TNF-α	35.3 (20.1–79.6)	38.8 (23.6–88.5)	38.5 (24.7–125.0)	0.22
IL-17	4.6 (0–11.6)	4.6 (0–13.3)	3.1 (0–8.7)	0.23

Conclusion: ACPA/RF+ women with 2 SE alleles had higher IL-2 and IL-6 levels than did women with fewer SE alleles. Studies indicate that Il-6 induces IL-2 proliferation, which in turn induces cytotoxic T cell differentiation. A pro-inflammatory milieu may explain why higher numbers of SE alleles are associated with more destructive arthropathy. IL-6 may be a particularly important therapeutic target among these women. Future work should examine whether these associations differ with use of disease-modifying anti-rheumatic drugs.

Algorithm Using Genome-Wide SNP Analysis for Prediction of Radiographic Progression Per Year in RA Patients From Multiple Medical Cohorts.
Tsukasa Matsubara[1], Satoru Koyano[2], Yoshitada Sakai[3], Keiko Funahashi[2], James E. Middleton[2], Takako Miura[1], Kosuke Okuda[1], Takeshi Nakamura[1], Akira Sagawa[4], Takeo Sakurai[5], Hiroaki Matsuno[6], Tomomaro Izumihara[7] and Eisuke Shono[8]. [1]Matsubara Mayflower Hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Kobe University Hospital, Kobe, Japan, [4]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [5]Inoue Hospital, Takasaki, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [8]Shono Rheumatology Clinic, Fukuoka, Japan

Background/Purpose: Although not yet fully possible, ideally, since patients with rapidly progressing joint destruction need tight initial control, predicting the progression of joint destruction would be pivotal in establishing a treatment strategy for individual RA patients. We developed a SNP algorithm with the aim of enabling the prediction of yearly radiographic progression by means of genome-wide SNP analysis using multiple medical cohorts.

Methods: One-hundred twenty-four RA patients whose disease duration was 5 years or less were enrolled in this study from 6 hospitals in different regions of Japan. All patients were treated with biologics after the failure of DMARDs therapy. Radiographic progression of joint destruction was estimated by Sharp score per year of disease duration. We defined three groups, rapid, intermediate, and slow radiographic progression, according to Sharp score per year of disease duration. Twenty-three patients had a yearly Sharp score of >50 (rapid radiographic progression), 76 had a yearly score of 50-10 (intermediate radiographic progression) and 25 had a yearly score of <10 (slow radiographic progression). Case-control analyses between 278,347 SNPs and radiographic progression (rapid vs. intermediate+slow or rapid+intermediate vs. slow) were examined by Fisher's exact test. We selected 10 SNPs closely associated with radiographic progression (p < 0.0001). We then scored a relationship between each SNP and radiographic progression, the estimated total score of the 10 SNPs (estimated scoring in each SNP was as follows: homo allele in the majority in rapid radiographic progression group: +1 point, hetero allele: 0 point, and homo allele in the majority of intermediate+slow radiographic progression group: −1 point), and examined relationships between the rapid and intermediate+slow group, and the total score.

Results: Accuracy ((true positive+true negative)/total), specificity (true negative/(false positive+true negative)) and sensitivity (true positive/(true positive+false negative)) of the algorithm for distinguishing the rapid progression group from the intermediate+slow progression group ranged from 93–96%. Accuracy, specificity and sensitivity of the algorithm for distinguishing the rapid+intermediate progression group from the slow progression group ranged from 88–90%. It is therefore suggested that this SNP algorithm may enable the prediction of rapidly progressing severe joint destruction.

Conclusion: This highly accurate algorithm using SNP analysis may be useful in initially diagnosing rapid radiographic progression, and, in this way, may contribute to establishing a strategy of treatment for individual RA patients.

Ritchlin[13], Dafna Gladman[14], Philip Mease[15], Dirkjan van Schaardenburg[16], Marina Backhaus[17], Bernard Combe[18], Gianfranco Ferraccioli[19] and Anthony Marotta[20]. [1]University of Alberta, Edmonton, AB, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]Univ of Ottawa Faculty of Med, Ottawa, ON, [5]Columbia University Medical Center, New York, NY, [6]Johns Hopkins University, Baltimore, MD, [7]Hospital for Special Surgery, New York, NY, [8]Copenhagen University Hospital at Glostrup, Glostrup, Denmark, [9]Diakonhjemmet Hospital, Oslo, Norway, [10]VU University Medical Center, Amsterdam, Netherlands, [11]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [12]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [13]University of Rochester Medical Center, Rochester, NY, [14]Toronto Western Hospital and University of Toronto, Toronto, ON, [15]Swedish Rheumatology Research Group, Seattle, WA, [16]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [17]Charite University Hospital, Berlin, Germany, [18]Hopital Lapeyronie, Montpellier, France, [19]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [20]Augurex Life Sciences Corp, North Vancouver, BC

Background/Purpose: The OMERACT soluble biomarker subcommittee has published validation criteria related to truth, discrimination and feasibility for biomarkers reflecting structural damage[1]. The large majority of biomarker assays assessed in RA have not undergone such validation, particularly the key performance criteria considered essential prior to clinical validation studies[2]. Extracellular 14-3-3 eta is 1) a synovial-derived novel mediator of inflammation/damage with serum levels being differentially expressed in early and established RA compared with controls, 2) modifiable with TNF therapy and 3) independently associated with joint damage in RA and PsA. With 14-3-3 eta fulfilling several OMERACT criteria, this study aimed to focus on aspects of feasibility and discrimination by testing assay reproducibility, reliability, biomarker stability, and sources of variability.

Methods: The 14-3-3 eta ELISA was evaluated for intra- and inter-assay reproducibility by running 20 duplicate measurements on 3 samples within a single assay and over 4 days by 4 operators. Possible interferents [hemoglobin, lipids, bilirubin, albumin, RF, erythrocytes, Aspirin, MTX, and anti-TNFs] were spiked into serum and 14-3-3 eta % recovery was determined. Biomarker stability was examined in 1) 3 samples over 3 freeze-thaw cycles and 2) 6 samples up to 2 years of storage at $-80°C$. Age and gender effects were assessed on 100 healthy controls, 50 males and 50 females [median age 55.0 and 57.5 years]. The effect of menopause was evaluated in the 50 females, 20 under and 30 over the age of 51. Correlations were used to evaluate the relationship of age and 14-3-3 eta concentration. 2-tailed t-tests and Mann-Whitney U-tests were performed to examine mean and median differences between genders and menopausal status.

Results: The intra- and inter assay coefficients of variation (CV%) were less than 10% [range (R)=6.0–9.2%]. Interference testing delivered a 106% median 14-3-3 eta recovery [R=100–115%] across the analytes tested demonstrating 14-3-3 eta quantification is not confounded by common RA patient serum substances. Results from sample stability testing indicate that serum 14-3-3 eta is stable over 3 freeze-thaw cycles with the median CV% being 109% [R=92–129%]. Long-term storage studies show that samples negative for 14-3-3 eta remain negative while those with levels above the upper limit of quantification of >20ng/ml have substantially equivalent levels. Stability of 14-3-3 eta was further confirmed using samples with levels in the linear range of the assay; median CV% was 104% of the original values [R=89–128%]. There was no correlation between age and 14-3-3 eta. Median 14-3-3 eta serum concentrations in healthy males and females did not differ significantly nor were there any significant differences in females aged over and under 51 years.

Conclusion: This 14-3-3 eta ELISA fulfills several key performance criteria considered essential by OMERACT. Quantification of 14-3-3 eta using this assay is reproducible and the biomarker is highly stable with no confounding of age, gender or menopause.

Interleukin-6 As a Biomarker for the Clinical and Radiological Effectiveness of Methotrexate in Rheumatoid Arthritis. Naoshi Nishina, Hideto Kameda, Yuko Kaneko, Masataka Kuwana and Tsutomu Takeuchi. Keio University School of Medicine, Tokyo, Japan

Background/Purpose: Methotrexate (MTX) is now an anchor drug in the treatment strategy of rheumatoid arthritis (RA) and its effectiveness has been established. However it is still unclear how MTX should work in the pathologically complicated cytokine network in RA including tumor necrosis factor (TNF)-α and interleukin (IL)-6. The aims of this study were to reveal the kinetics of TNF-α and IL-6 during the treatment of MTX and to assess the relationship between these cytokines and clinical and radiological states.

Methods: Sixty two RA patients were enrolled in this study whose estimated disease duration before the diagnosis of RA was less than 36 months and who received MTX treatment without biologic agents for at least 3 months. Plasma IL-6 and TNF-α level were measured by CLEIA before the start of the treatment and several months after, and the clinical characteristics were gathered at the same time. Radiography assessment was performed by means of van der Heijde modified Sharp Score (mTSS). The comparison of two continuous variables was performed by Wilcoxon signed-ranks test and the correlations with two variables were analyzed by logistic and multiple regression model.

Results: Of 62 patients, 49 (79%) were female. Mean age was 57 ± 15 years and median estimated disease duration was 3 months. The time when the cytokines were measured after the start of the treatment was at a median of 11 months (5–18). Forty six patients (74%) were positive for RF and 47 patients (76%) for anti-CCP antibody. Mean MTX dosage was 8.7 ± 2.3 mg/week. With concomitant use of MTX, steroid and synthetic DMARDs were prescribed in 20 patients (prednisolone in 6 patients, bucillamine 6, salazosulfapyridine 6, bucillamine and salazosulfapyridine 1, tacrolimus 1). Compared with the values of median DAS 28, serum CRP and plasma IL-6 before the start of the treatment, those after the use of MTX were decreased significantly from 4.42 to 2.58, 0.55 to 0.06 mg/dl and 4.72 to 1.04 pg/ml, respectively ($p<0.01$ for all), while plasma TNF-α level didn't change from 0.87 to 0.83 pg/ml (Table 1). Of those parameters, the estimated yearly progression of mTSS (ΔmTSS) was not correlated with CRP but significantly correlated with plasma IL-6 level after the use of MTX (Figure 1, R^2=0.05, 0.45, respectively). In multivariate analysis, rapid radiographic progression (ΔmTSS$\geq$5) was associated only with high plasma IL-6 level after the treatment [OR 1.15, 95%CI 1.02–1.32].

Table 1. Changes of the clinical parameters before and after the MTX treatment

	before	after	p value
DAS 28	4.42 [3.60, 5.62]	2.58 [1.93, 3.16]	<0.01
CRP (mg/dl)	0.55 [0.10, 1.43]	0.06 [0.02, 0.18]	<0.01
IL-6 (pg/ml)	4.72 [2, 11.55]	1.04 [0.58, 5.41]	<0.01
TNFα (pg/ml)	0.87 [<0.55, 1.58]	0.83 [<0.55, 1.18]	0.14

Results are expressed as median [IQR]. IL, interleukin; TNF, tumor necrosis factor
Figure 1. The correlation of ΔmTSS with plasma IL-6 level nad CRP after MTX treatment.

Conclusion: In the treatment of RA, MTX had a great effect on decreasing plasma IL-6 and the level of IL-6 after the use of MTX was the greatest impact on the radiological progression.

2120

Predictive Value of Anti-CCP Positivity On Disease Course and Response to Therapy in Early Rheumatoid Arthritis. Results From the Swedish EIRA Study. Saedis Saevarsdottir[1], Marie Holmqvist[2], Johan Askling[2], Lars Alfredsson[3] and Lars Klareskog[2]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institute, Stockholm, Sweden, [3]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Does anti-CCP-positivity predict disease course and response to therapy in early rheumatoid arthritis (RA)?

Methods: We retrieved clinical follow-up data for patients entering the EIRA cohort 1996–2009 from the Swedish Rheumatology Quality Register (1996–2010). Overall, 1,640 of the 2,567 registered RA patients were followed from diagnosis. Then, 99 received no DMARD treatment, 41 received only prednisolone, 670 only methotrexate, 476 methotrexate and prednisolone, 224 sulfasalazine, whereas 130 patients received other DMARDs or combinations. The association between anti-CCP-positivity and EULAR good response was evaluated by logistic regression and expressed as univariate p-values and multivariate odds ratios (OR) with 95% confidence intervals (CI), adjusted for gender, age, inclusion year, symptom duration, HAQ score and cigarette smoking habits.

Results: The proportion starting DMARD/methotrexate at diagnosis increased during the inclusion period (p<0.0001/<0.0001). In the subgroup receiving no DMARD, anti-CCP-positive patients were, compared to anti-CCP-negative patients, less likely to fulfil the criteria for 'good response' after 3 months (15% vs. 48%, p=0.002; adjusted odds ratio=0.24; 95%CI 0.07–0.82). A smaller, but significant difference was observed between anti-CCP-positive and anti-CCP-negative patients receiving methotrexate only (31% vs. 41%, p=0.02; adjusted odds ratio=0.65; 95%CI 0.44–0.94), whereas no difference was observed between anti-CCP-positive and anti-CCP-negative patients receiving both methotrexate and prednisolone (52% vs. 49%, p=0.5; adjusted odds ratio=1.23; 95%CI 0.78–1.92). No significant differences were observed in patients receiving sulfasalazine or in the entire cohort during 2 years follow-up.

Conclusion: Anti-CCP positivity predicts persistent disease activity in early RA patients not receiving DMARD treatment, while its predictive value for response is limited in patients treated with MTX, SSZ and prednisolone, and in the entire group of RA patients reflecting all treatment options over time. Our findings also indicate that the less chance of a favorable clinical disease course in anti-CCP positive patients may be compensated for with treatment, namely that today′s standard care with methotrexate and low dose prednisolone may have its main effects in ACPA-positive patients. This highlights the importance of performing a careful subgrouping of the RA syndrome in all controlled as well as observational studies on drug treatment.

A Multi-Biomarker Disease Activity (VECTRA™ DA Algorithm) Score Reflects Clinical Disease Activity and Structural Changes in Rheumatoid Arthritis Patients Treated with Tocilizumab. Yoshiya Tanaka[1], Kentaro Hanami[1], Hisashi Tasaka[1], Shunsuke Fukuyo[1], Douglas J. Haney[2], Nadine Defranoux[2], Rebecca Bolce[2], Guy Cavet[2], David Chernoff[2], Kunihiro Yamaoka[1], Kazuyoshi Saito[1] and Shintaro Hirata[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Crescendo Bioscience Inc., South San Francisco, CA

Background/Purpose: The multi-biomarker disease activity (MBDA) score assessed with 0.2 mL serum has been reported as a novel composite disease activity index for patients with rheumatoid arthritis (RA). We reported the correlation of MBDA score with conventional composite measures such as DAS28 in patients with RA. However, the estimation of the MBDA score in RA patients treated with anti-IL-6 receptor antibody tocilizumab (TCZ) has not been investigated. Purpose of this study is to clarify if the MBDA score could reflect disease activity and track therapeutic effect including clinical and radiographic outcomes in RA patients treated with TCZ.

Methods: Fifty two RA patients who treated with TCZ were enrolled. The MBDA algorithm combines 12 serum biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, Leptin, Resistin, CRP, SAA) into a single score from 1–100 according the Vectra™ DA algorithm. MBDA disease activity categories were defined as high (HDA>44), moderate (MDA>29≤44), low (LDA<25≤29) and remission (REM≤25). Radiographic changes were assessed by the modified total Sharp score (mTSS). For statistic analysis, Spearman's rank correlation coefficients and Pearson's chi-square test were used. All p-values are two sided and <0.05 were considered significant.

Results: At baseline (BL), patients had median age of 57 ± 18, disease duration of 12.4 ± 11.2 years, DAS28 of 5.6 ± 1.3, CDAI of 22.1 ± 12.2, HAQ-DI of 1.4 ± 0.9 and mTSS of 106 ± 112. MTX was used in 86.5% and positivity of RF was 78.8%. MBDA score at BL was 57.7 ± 19.2 and were correlated well with DAS28 and CDAI (ρ=0.63 and 0.57, respectively, p<0.0001). TCZ improved MBDA score from 57.7 to 43.7 and 42.5 at W24 and W52, respectively, DAS28 from 5.6 to 2.5 and 2.9, CDAI from 22.2 to 6.4 and 5.6, at BL, W24 and W52, respectively. Changes of MBDA from BL to 52W by TCZ were significantly correlated with those of DAS28 (r=0.471, p<0.001) and CDAI (r=0.373, p<0.01). MBDA-REM ratio at W52 was significantly correlated with DAS28-REM ratio (AUROC=0.643) and CDAI-REM ratio (0.768). Yearly progression of mTSS (ΔmTSS) was improved from 12.3 ± 14.9 to 0.5 ± 2.5 by TCZ and 77% achieved ΔmTSS<0. Interestingly, all patients who achieved MBDA-LDA (8), MBDA-REM (3) or Boolean-REM (5) at W24 showed ΔmTSS<0.5, whereas some of DAS28-REM and CDAI-REM did ΔmTSS>0.5. Patients who achieved MBDA-REM or Boolean-REM at W24 revealed higher likelihood ratio for achieving both radiographic and functional REM at W52 than those who DAS28-REM and CDAI-REM.

Conclusion: This is the first report of the MBDA estimated in RA patients treated with TCZ. TCZ efficiently improved MBDA score and BL and changes of MBDA were correlated with those of conventional composite measures. Although additional data are needed to assess the relationship between MBDA and radiographic and functional remission, The MBDA score reflects disease activity and tracks therapeutic effects and MBDA-REM might be preferable to DAS28-REM for predicting good outcome in both radiographic damage and physical function in RA patients treated with TCZ.

Plasma chemerin as a Useful Marker for Disease Activity in Patients with Rheumatoid Arthritis. Sang Tae Choi[1], You-Jung HA[2], Eun-Jin Kang[3], Kwang-Hoon Lee[4] and Jung-Soo Song[1]. [1]Chung-Ang University College of Medicine, Seoul, South Korea, [2]Kwanding University College of Medicine, Myongji Hospital, Goyang, South Korea, [3]Busan Medical Center, Busan, South Korea, [4]Dongguk University Ilsan Hospital, Goyang, South Korea

Background/Purpose: Chemerin is an adipokine that is linked to adipogenesis and chemotaxis of the innate immune system. It is expressed on macrophage, dendritic cells, and synovial lining and sublining cells. It has been reported that chemerin has both pro-inflammatory and anti-inflammatory roles, and higher level of chemerin was detected in various chronic inflammatory diseases. Recent studies have showed that its expression is increased in the synovium of patients with rheumatoid arthritis (RA), and the chemerin may play an important role in the pathogenesis of RA. However, the association between plasma chemerin level and disease activity in RA patients remains unclear. This study aims to determine whether plasma

chemerin level is elevated in patient with RA and its correlation with disease activity and other parameters.

Methods: This study includes 71 RA patients and 42 age- and sex-matched healthy controls. Plasma samples were obtained from healthy controls and patients with RA during active and inactive disease status. We assessed the clinical characteristics and laboratory parameters including body mass index (BMI), erythrocyte sedimentation rate, C-reactive protein, and disease activity score 28 (DAS28). The plasma level of chemerin and tumor necrosis factor (TNF)-α were determined using enzyme-linked immunosorbent assay (ELISA).

Results: Plasma chemerin level was significantly elevated in patients with RA than healthy control (9.074 ± 13.513 pg/mL vs 0.370 ± 0.219 pg/mL, p<0.001). In RA patients, the adjusted plasma chemerin level according to BMI was correlated with DAS28 (γ=0.340, p=0.004), but not plasma TNF-α level. The adjusted plasma chemerin level of active disease group patients (DAS28 ≥ 2.6) was significantly higher than that of remission group patients (DAS28 < 2.6) (0.591 ± 0.879 pg/mL vs 0.220 ± 0.154 pg/mL, $p = 0.015$).

Conclusion: Patients with RA showed higher plasma chemerin than that of healthy controls. The adjusted plasma chemerin level according to BMI was well correlated with RA disease activity. These findings suggest that plasma chemerin could play a role in the inflammatory process of RA, and that it may be a useful disease activity marker in RA.

Circulating Mir-223 Is Associated with Disease Activity and May Predict the Response to Therapy in Treatment naïve Patients with Early Rheumatoid Arthritis. Maria Filkova[1], Caroline Ospelt[1], Serena Vettori[1], Ladislav SĚnolt[2], Herman F. Mann[2], Beat A. Michel[3], Jiri Vencovsky[2], Karel Pavelka[2], Renate E. Gay[1], Steffen Gay[1] and Astrid Jüngel[1]. [1]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Switzerland, Zurich, Switzerland, [2]Institute of Rheumatology, Department of Clinical and Experimental Rheumatology of the 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [3]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Parameters/ predictors of treatment response in patients with early rheumatoid arthritis (ERA) are needed to optimize treatment management based on the expected disease course. miRNAs are stable in cell-free form in body fluids and have therefore a potential to serve as biomarkers for diagnosis and treatment response. Our aim was to analyze the association between the expression of miRNAs in sera of patients with ERA with disease activity and outcome.

Methods: The study included 34 patients with ERA (64.52% RF+, 51.61% ACPA+) who fulfilled 2010 ACR/EULAR classification criteria for RA with symptom duration <8 months. Total RNA was isolated using phenol-chloroform extraction from whole sera obtained at baseline and after 3 months of therapy with DMARDs. The expression of miR-146a, 155, 223, 203, 132, 124a, 16 and let-7a was analyzed using specific primers by TaqMan Real-Time PCR. Peripheral blood mononuclear cells (PBMC) were treated with methotrexate (MTX, 25ug/ml) *in vitro.*

Results: In treatment naïve ERA patients, the expression of miR-223 positively correlated with baseline DAS28 (p=0.031), with change of DAS28 (DDAS28) calculated as the difference between DAS28 at 3 months follow up and baseline (p=0.014), CRP (p=0.008) and peripheral leukocyte count (p=0.007). After treatment, the correlation of miR-223 with the leukocyte count remained significant (p=0.004). Levels of miR-223 were lower in patients with positivity of both RF and ACPA in comparison with patients that were RF+/ACPA−, RF−/ACPA+ or RF−/ACPA− (p=0.02). None of the other miRNAs analysed in our study were associated with clinical activity of ERA.

Expression of miR-223 was significantly decreased after 3 months of treatment with DMARDs in comparison with baseline (p=0.007). Further analysis revealed 2 groups of patients with opposing change in the expression of miR-223. One group ("miR-223/-", n=24; 52.4% RF+, 30.1% ACPA+) developed decreased levels of miR-223 (p<0.0001) while another group ("miR-223/+", n=10; 90% RF+, 80% ACPA+) showed an increase in miR-223 expression after treatment (p=0.002). In the miR-223/− group, the baseline levels of miR-223

correlated with DDAS28 (p=0.039) and the change in miR-223 was associated with DDAS28 (p=0.007). In contrast, no correlations between miR-223 and parameters of disease activity were found in the miR-223/+ group.

The change in expression of miR-223 in sera may be attributable to the change in number of leukocytes between 3 months and baseline concluded from the positive correlations between these variables (p=0.025). In addition, the expression of miR-223 in PBMC is downregulated by 15% (p=0.001) after treatment with MTX.

Conclusion: Our data support the potential of miR-223, known to be upregulated in T cells in RA (Sebastini GD et al. 2011), to serve as a marker of disease activity in patients with treatment naïve ERA and its association with disease outcome in a short time follow up. We hypothesize that differential expression of miR-223 in RF+/ACPA+ patients may characterize ERA patients who are at risk of more severe disease progression.

Serum Concentrations of Soluble Interferon Receptor in Patients with Rheumatoid Arthritis. Masao Sato, Masao Takemura, Ryuki Shinohe, Tsuneo Watanabe and Katsuji Shimizu. Gifu University, Gifu, Japan

Background/Purpose: Interferon (IFN) exerts antiviral and antineoplastic activities, and is involved in immunoregulatory activities. IFN probably plays an important role in the pathogenesis of rheumatoid arthritis (RA), which is a chronic and progressive inflammatory disease. IFN is eliminated from the bloodstream, with a half-life of 2 h, it is difficult to detect IFN concentrations in the sera. IFN, similar to other cytokines, exerts its biological activities by binding to cell-surface receptors. In this study, we evaluated the serum concentrations of soluble IFN α/β receptor (sIFNR) in patients with RA.

Methods: The study involved 57 patients (11 men and 46 women) with RA who met the American College of Rheumatology 1987 RA classification criteria. The patients were aged 31 – 85 y (mean age, 61.2 y). The control group consisted of 16 patients with osteoarthritis (OA) of the knee and 216 healthy subjects, (mean age, 57.1 y and 52.3 y, respectively); the sIFNR concentrations of these subjects were determined. All the subjects recruited in this study were negative for hepatitis B surface antigens and hepatitis C antibodies. Blood samples were obtained from the subjects, and serum fractions separated from the blood samples were stored at −80 degree, until the assay was performed.

Results: The serum concentrations of sIFNR in RA patients that varied from 0.7 to 5.8 ng/ml (mean, +/− SD: 2.1 +/− 1.2 ng/ml) and were significantly higher than those in the OA patients (mean, +/− SD: 1.4 +/− 0.7 ng/ml: p < 0.03) and the healthy subjects (mean, +/− SD: 1.0 +/− 0.5 ng/ml: p < 0.001). The serum levels of sIFNR in the RA patients with radiographic stage scores of II, III, and IV were 1.0 +/− 0.2 ng/ml, 1.3 +/− 0.3 ng/ml, and 2.5 +/− 1.2 ng/ml, respectively. The serum levels of sIFNR in the RA patients with activities of daily living (ADL) scores of 2, 3, and 4 were 1.2 +/− 0.2 ng/ml, 2.5 +/− 1.0 ng/ml, and 3.8 +/− 1.5 ng/ml, respectively. The serum levels of sIFNR in the RA patients were positively correlated with the disease durations (r = 0.55: p < 0.0001).

Conclusion: In this study, we observed that the serum levels of sIFNR in the RA patients were significantly higher than those in the OA patients and the healthy subjects. A significant correlation was observed between the serum levels of sIFNR in the RA patients and the RA stage scores, ADL scores, and disease durations. Therefore, serum levels of sIFNR might be a useful predictor for the prognosis of chronic conditions and RA.

Response to Methotrexate Plus Prednisone in Camera II Using a Multi-Biomarker Disease Activity (Vectra™ DA) Test and DAS28-ESR. J.W.J. Bijlsma[1], M. Verhoef-Jurgens[1], M.F. Bakker[1], J.W.G. Jacobs[1], F.P.J.G. Lafeber[1], P.M.J. Welsing[1], G. Cavet[2], D. Chernoff[2] and D.J. Haney[2]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Crescendo Bioscience, Inc., South San Francisco, CA

Background/Purpose: The CAMERA II study (Computer Assisted Management in Early RA) demonstrated that the addition of prednisone to a MTX-based tight control strategy increased effectiveness of therapy, including reductions in disease activity, disability, and joint erosion, increased likelihood of achieving sustained remission, and less frequent need for biological treatment. The purpose of this study was to evaluate changes in biomarker levels over time with MTX and MTX + prednisone treatment.

Methods: Clinical and biomarker assessments were performed for 104 patients at multiple visits between Baseline (BL) and 1 year. The average number of visits per patient was 4. Clinical assessments were used to calculate the DAS28-ESR, and 12 serum biomarker concentrations were combined to produce a score between 1 and 100 using the MBDA algorithm, which is a validated biomarker-based measure of disease activity. Association between DAS28-ESR response and Multi-Biomarker Disease Activity (MBDA) response was assessed using Spearman's correlation. Changes from BL were analyzed using the paired t-test.

Results: There was a significant association between change in DAS28-ESR from BL to 1 year and change in MBDA from BL to 1 year in both the MTX-only arm ($r = 0.57$, $p < 0.001$, $n = 31$) and in the MTX + prednisone arm ($r = 0.57$, $p = 0.002$, $n = 28$). Improvements in DAS28-ESR ($p < 0.001$) and MBDA ($p = 0.01$) were observed as early as 1 month post-BL in the MTX + prednisone arm. Significant reduction in disease activity in the MTX-only arm was first observed at 2 months for DAS28-ESR ($p = 0.02$) and at 4 months for MBDA ($p = 0.03$).

| | | DAS28-ESR | | | | | MBDA | | |
| | | MTX | | MTX + pred. | | | MTX | | MTX + pred. |
Timepoint	n	Mean Chg.	n	Mean Chg.		n	Mean Chg.	n	Mean Chg.
1 Month	16	−0.3 (p = 0.24)	11	−1.9 (p < 0.001)	18	−3 (p = 0.27)	14	−12 (p = 0.01)
2 Months	15	−0.7 (p = 0.02)	11	−2.4 (p < 0.001)	17	−3 (p = 0.25)	14	−11 (p = 0.02)
3 Months	22	−1.3 (p < 0.001)	13	−3.0 (p < 0.001)	25	−5 (p = 0.09)	17	−15 (p = 0.002)
4 Months	13	−1.8 (p < 0.001)	10	−3.9 (p < 0.001)	17	−9 (p = 0.03)	14	−19 (p = 0.003)
5 Months	15	−2.2 (p < 0.001)	10	−4.2 (p < 0.001)	18	−13 (p = 0.006)	12	−21 (p = 0.003)
6 Months	18	−2.8 (p < 0.001)	12	−3.0 (p = 0.001)	29	−20 (p < 0.001)	19	−16 (p < 0.001)
9 Months	17	−2.7 (p < 0.001)	12	−3.2 (p = 0.001)	24	−24 (p < 0.001)	17	−20 (p < 0.001)
12 Months	31	−2.8 (p < 0.001)	28	−3.1 (p < 0.001)	44	−20 (p < 0.001)	37	−16 (p < 0.001)

Conclusion: The biomarker-based MBDA test and DAS28-ESR responded quickly to combination therapy with MTX and prednisone and were correlated with one another. MBDA may be useful in combination with clinical assessment to evaluate early response to therapy with MTX or MTX + prednisone.

2126

Changes of Serological Markers in the Course of Traditional and Biological Disease Modifying Therapy of Rheumatoid Arthritis. Christoph Böhler[1], Helga Radner[1], Josef S. Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Rheumatoid factor (RF) and antibodies against citrullinated peptides (ACPA) are established markers in the diagnostic approach to rheumatoid arthritis (RA). Both auto-antibodies (AAB) also have a prognostic value, since they are associated with more aggressive, destructive disease [1]. Therefore decreases in AAB levels may be highly relevant to improve the long-term outcome of RA. We aimed to investigate the changeability of ACPA and RF levels under anti-rheumatic therapy, with special focus on the influence of treatment response.

Methods: We obtained data of outpatients from a long-term observational database with prospective data entry. We retrieved clinical and serological data of patients treated with traditional disease modifying anti-rheumatic drugs (DMARDs) and/or biological response modifiers from the treatment start and after 6 months of therapy. We used non-parametric tests to analyse changes of ACPA and RF levels between the two visits, as well as differences

between treatment responders and non-responders. SDAI50 criteria were used to define treatment response [2]. Furthermore, we investigated the trend of ACPA, RF and SDAI over a period of 18 months.

Results: 143 ACPA and RF positive patients were included. As depicted in Figure 1, the median (25th /75th percentile) relative changes after six months were −35.6% (−63.3; −8.3) for RF, and −15.2% (-40.0; 10.0) for ACPA (p<0.001 for both). The changes of RF levels were significantly greater than those seen for ACPA (p<0.001). SDAI50 response was achieved in 60 (42%) patients. As can be seen in Figure 2, the decrease of ACPA and RF was significantly higher in patients with treatment response than in those without (p=0.034 and p=0.01, respectively). After 3 months the decline of ACPA, RF, and SDAI amounted to 4.6%, 13.2%, and 23.5%, respectively; after 12 months it was 16.9%, 31.4% and 40.5, and after 18 months 23.8%, 35.2%, and 44.3%, respectively.
Figure 1. Fractional rank depiction of relative ACPA and RF changes.
Figure 2. Differences of ACPA and RF changes between responders and non responders due to SDAI 50 criteria.

Conclusion: ACPA and RF levels decreased significantly after 6 months of therapy. Reduction of both AAB were closely linked to a reduction of disease activity. RF declined faster, to a larger extent and in greater numbers of patients than ACPA. Further research is needed to investigate whether reductions of ACPA and RF levels are associated with a better radiographic outcome.

Rheumatoid Arthritis (RA) Patients Discordant for Rheumatoid Factor and Anti-CCP Positivity Have Different Clinical and Laboratory Features Than RA Patients Seropositive or Seronegative for Both Markers. Swati Modi[1], Yona Cloonan[1], Danielle Goudeau[1], Donald M. Jones[2], Christine L. Amity[3], Lynne M. Frydrych[2], Kelly A. Reckley[4], Heather Eng[3], Stephen R. Wisniewski[5], Larry W. Moreland[1] and Marc C. Levesque[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA, [5]University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA

Background/Purpose: Rheumatoid factor (RF) and anti-cyclic citrullinated peptide (CCP) positive rheumatoid arthritis (RA) patients develop more extra-articular disease manifestations and erosions, and have a worse prognosis than seronegative RA patients. Levels of RA and CCP may be regulated independently. Therefore, our aim was to identify demographic and clinical differences between RA patients grouped according to RF and CCP status.

Methods: Cross-sectional analysis of RA subjects from the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry was performed. The analysis included data from the first visit at which both RF and CCP levels were available (n=884). Patients were categorized based on clinical cut-offs: RF+CCP+, RF+CCP-, RF-CCP+, RF-CCP-. The following demographic and clinical data were compared across RF/CCP groups: age, race, gender, disease duration, CRP, RF, CCP, disease activity (DAS28, CDAI),rheumatoid nodules, morning stiffness, physician/patient global health assessment, and medication use (ever used DMARD, biologic, corticosteroid). Categorical and continuous variables were analyzed using chi-square and Kruskal-Wallis tests, respectively

Results: 60% of subjects were RF+CCP+, 12% RF+CCP-, 10% RF-CCP+ and 18% RF-CCP-. Disease duration, RF, CCP, CRP, DAS28 score, presence of rheumatoid nodules, morning stiffness, and use of biologic therapy were statistically significantly different across groups (p<0.05). RF+CCP+ patients had longer disease duration than other patients (median 143 vs 88–93 months), and higher median RF (122 vs 20–28) and CCP (118 vs 2–47). Mean CRP ranged from 2.8 (RF+CCP+) to 8.1 (RF-CCP-). Morning stiffness was most common in the RF-CCP- group (54% vs 26–40%), while rheumatoid nodules were more common in the CCP+ groups (12–15% CCP+ vs 5–6% CCP-). The proportion of patients ever having used biologic therapy ranged from 28% (RF+CCP+) to 56% (RF-CCP+). There were no statistically significant differences for the remaining demographic and clinical characteristics.

Conclusion: There were statistically significant demographic, clinical and laboratory differences between RA subjects grouped on the basis of RF and CCP positivity. RF+/CCP+ subjects had longer disease duration but were similar in age to the other groups, suggesting that earlier age of RA onset may be associated with the development of high levels of both RF and anti-CCP. The associations of disease activity measures with RF levels (and not with CCP), suggests that RF levels vary with the degree of inflammation and disease activity (as does CRP) and are likely regulated by different factors than those that govern CCP levels. The greater use of biologic therapies by CCP+ subjects suggests that these RA patients may experience greater disease severity. An understanding of the differences between RA subjects grouped on the basis of RF and CCP status may allow for individualized treatment and will form the basis for future studies of the mechanisms differentially regulating RF and CCP levels.

Matrix Metalloproteinase 3: A Biomarker of Disease Activity in Rheumatoid Arthritis. Sandra Reuter[1], Torsten Matthias[2] and Bruno Larida[3], [1]AIRA e.V., AESKU.KIPP Institute, Wendelsheim, Germany, [2]AESKU. Diagnostics GmbH & Co. KG, Wendelsheim, Germany, [3]AESKU. DIAGNOSTICS INC, Oakland, CA

Background/Purpose: New biomarkers for monitoring Rheumatoid Arthritis (RA) disease activity and prognosis of progression are urgently needed to individually optimize drug therapy and prevent joint destruction. Serum Matrix Metalloproteinase 3 (MMP-3) has been proposed to be such a marker. Thus we set out to correlate MMP-3 serum levels in Rheumatoid Arthritis patients with their individual disease activity.

Methods: 64 sera from adult patients (44 female, 20 male) with established RA and 97 control sera from adult healthy donors (48 female, 49 male) were analyzed using the AESKULISA DF MMP-3 kit. The 64 RA patients were classified as "Active" or "Inactive" according to their individual disease activity based on clinical data. Both RA groups were correlated to their individual MMP-3 serum concentrations (termed as "elevated" and "non-elevated" MMP-3 levels). The normal range of MMP-3 concentration in serum was determined by calculating the 95th percentile of the measured MMP-3 concentrations for each gender.

Results: Of the 64 RA patients, 35 were classified as "Active" and 29 as "Inactive" based on their individual disease activity. Normal MMP-3 serum concentrations were determined as: up to 60 ng/ml and up to 120 ng/ml for females and males, respectively. 89% (31/35) of "Active" patients had elevated and only 11% (4/35) had normal or borderline MMP-3 levels. 90% (26/29) of "Inactive" patients had normal and only 10% (3/29) had elevated MMP-3 levels.

Conclusion: Serum concentration of MMP-3 exhibits a high correlation with RA disease activity.

Dickkopf-1 Is Increased in Rheumatoid Arthritis of Recent Onset and Might Be a New Biomarker of Structural Progression. Data From the Espoir Cohort. Raphaèle Seror[1], Stephan Pavy[2], Thierry Schaeverbeke[3], Alain Saraux[4], Xavier Mariette[5] and Corinne Miceli-Richard[1]. [1]Université Paris Sud, Le Kremlin Bicêtre, France, [2]Hopital Bicetre, Paris, France, [3]Groupe Hospitalier Pellegrin, Bordeaux, France, [4]CHU de la Cavale Blanche, Brest Cedex, France, [5]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: Dickkopf-1 (DKK-1) is an inhibitory protein of the Wnt signalling pathway that could be involved in subchondral bone erosions occurring in rheumatoid arthritis (RA). Few studies have investigated the role of DKK1 in RA. We aimed to investigate DKK-1 serum levels in patients with recent inflammatory arthritis fulfilling ACR/EULAR criteria for RA and to investigate the parameters associated with DKK-1 increase and the relationship between DKK-1 levels and radiographic changes in RA.

Methods: The ESPOIR cohort is a prospective, multicenter French cohort of patients with early arthritis, including 813 patients between 2002 and 2008. DKK-1 serum levels were assessed at baseline on the whole cohort by sandwich ELISA (Biomedica, Vienna). DDK-1 serum levels were further analyzed at inclusion in the subgroup of patients fulfilling ACR/EULAR criteria for RA after 2 years of follow-up (N=694; 85.3%) and compared with serum levels from 70 age and sex-matched controls (without autoimmune or chronic inflammatory disease). Uni and multivariate analyses were conducted to look for parameters associated or correlated with DKK-1 serum levels. DKK-1 serum levels were also compared between patients with and without radiographic change at baseline and after 2 years of follow-up.

Results: Among the 813 patients with early arthritis, 694 of them (85%) fulfilled ACR/EULAR criteria for RA (mean age 48.5±12.3, 78.2% female, with mean baseline DAS28=5.3±1.2, 54.6% anti-CCP positive). Serum DKK-1 level was significantly increased in RA patients compared to healthy controls (28.0±13.2 vs 10.8±9.3; p<0.0001). In univariate analysis, the level of DDK-1 was significantly correlated with the level of CRP (r=0.16; p<0.0001), ESR (r=0.11; p=0.005), patient global assessment (PGA) (r=0.08; p=0.046) and DAS28 (r=0.09; p=0.02). In addition, we found that DKK-1 level was significantly higher in patients with typical erosion related to RA at baseline, compared to those without (32.4±14.0 vs 27.2±12.9; p=0.0001). In the multivariate analysis adjusted for DAS28, PGA, and smoking status, only CRP levels and the presence of typical erosions related to RA remained associated with DKK-1 levels. Last, the most interesting result was that baseline DKK-1 levels was predictive of radiological progression (defined by increase of modified Sharp score >1) (29.3±13.0 in patients with progression vs 16.7±12.1 in patients without progression; p=0.025). Nevertheless, DKK-1 was no more associated with radiological progression in a model including other main predictors of severity (erosion at baseline, and anti-CCP positivity) in the multivariate analysis.

Conclusion: This study conducted in a large cohort of patients presenting with early onset RA clearly showed an increase in DKK-1 serum levels, associated with disease activity, biological inflammation and bone erosions at baseline. More interestingly, increase in DKK-1 serum levels were predictive of structural progression at 2 years and, then might be an interesting new structural biomarker in early RA.

Studies of Disease and Therapy-Response Biomarkers in Early Rheumatoid Arthritis Treated with Methotrexate. Aase Haj Hensvold[1], Saedis Saevarsdottir*[1], Wanyiang Li*[2], Vivianne Malmström[1], Guy Cavet[3], Lars Klareskog[4] and Anca Irinel Catrina[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Crescendo Bioscience Inc. 341 Oyster Point Blvd South San Francisco, CA 94080, San Francisco, CA, [3]Crescendo Bioscience Inc., South San Francisco, CA, [4]Karolinska Institute, Stockholm, Sweden *equally contributed

Background/Purpose: To identify disease and therapy response serum biomarkers in early untreated RA patients started on methotrexate as the only DMARD.

Methods: 186 patients with early treatment naïve RA (symptom disease duration less than 1 year), started on methotrexate (MTX) monotherapy at diagnosis were included in the current study. All patients are part of a larger cohort of early RA named EIRA (epidemiology investigation of rheumatoid arthritis) and had available blood samples at baseline and a median of 3 months after treatment initiation. Concentrations of 12 serum biomarkers were measured at baseline and a median of 3 months after treatment start to calculate multi-biomarker disease activity (MBDA) scores [1]. Additionally ELISA for CCP-2 was performed at baseline. Associations between different biomarkers were calculated using Spearman's rank correlation. The ability of MBDA score in tracking and differentiating clinical response was estimated by correlation between the change of MBDA score and the change of DAS28ESR from baseline to 3-months visit, and also by calculating area under the ROC curves (AUROCs) for classifying good/moderate EULAR responders versus non-responders at 3-months visit.

Results: No differences in the baseline characteristics were observed between patients included in the current study and MTX treated patients in the original large EIRA cohort (n=873) with a median (IQR) age of 52 (42–59), % female of 72%, % anti-CCP positive of 67% and median (IQR) DAS28ESR of 5.7 (5.0–6.2). At 3 months, 29% of the patients were good EULAR responders, 37% were moderate responders and 34% were non-responders. The change of MBDA score from baseline to 3-months visit was significantly correlated with the change of DAS28ESR and able to differentiate EULAR responders and non-responders (AUROC = 0.79, p-value<0.001). The median decrease in the MBDA score was significantly greater in the anti-CCP negative group than in the positive group but correlated with DAS28ESR changes in both groups.

Conclusion: We confirm the value of MBDA as a surrogate marker for measuring clinical disease activity and differentiate clinical response in early RA patients treated with MTX whether they were anti citrullinated-protein antibodies (ACPA) negative or positive.

An Evaluation of Prognostic Factors for Orthopaedic Joint Surgery in Rheumatoid Arthritis. Results From Two Multicentre UK Inception Cohorts (1986–2011). Elena Nikiphorou[1], Lewis Carpenter[2], Sam Norton[3], David James[4], Patrick D. Kiely[5], David Walsh[6], Richard Williams[7] and Adam Young[8]. [1]ERAS, St Albans City Hospital & University College London (UCL), London, United Kingdom, [2]University of Hertfordshire, Hatfield, United Kingdom, [3]ERAS, St Albans City Hospital, St Albans, United Kingdom, [4]Diana Princess of Wales Hospital, Grimsby, United Kingdom, [5]St. Georges Hospital, London, United Kingdom, [6]City Hospital, Nottingham, United Kingdom, [7]County Hospital, Hereford, United Kingdom, [8]St Albans City Hospital, St Albans, United Kingdom

Background/Purpose: The need for orthopaedic surgery in Rheumatoid Arthritis (RA) is the result of failed medical treatment and a surrogate marker for joint destruction. Reliable prognostic markers are currently limited but have a potential role in guiding clinicians in early management decisions.

Methods: Standardised clinical, laboratory and X-ray measures were performed at baseline, prior to DMARD therapy and then yearly in both the Early RA Study (ERAS, n=1465, 1986–1998) and Early RA Network (ERAN, n=1236, 2002–2011), median follow up 18 and 6 years respectively, maximum 25 years. Treatment of patients included disease modifying, steroid and biologic therapies according to standard UK practices for management of hospital based RA patients. Source data of all orthopaedic interventions included clinical datasets (patient reports and medical records from 1986) and national data: Hospital Episode Statistics and the National Joint Registry. Length of follow up was based on the National Death Registry. For analysis, interventions were grouped into major (total large joint replacements), intermediate (mainly synovectomies, arthroplasties and fusion procedures of wrist, hand, hind/forefoot), and minor (mainly soft tissue and tendon surgery).

Results: 1602 procedures were performed in 770 out of 2701 patients (29%). 576 were large joint replacements (mainly of hips and knees) in 354 (out of 2701) patients (13%), 392 intermediate in 221 (8%), 552 minor in 361 (13%), 55 internal fixations for hip fracture in 53 (2%), 9 cervical spine fusions and the remainder were miscellaneous/not classified procedures. 232 (8.6%) patients had more than one major and/or intermediate procedure. 1255 had minimum 10 year follow up (46%) of whom 531 (42%) had orthopaedic surgery. In univariate analysis, baseline and 1 year Health Assessment Questionnaire (HAQ), Erythrocyte Sedimentation Rate (ESR), high Disease Activity Scores (DAS), erosions and low haemoglobin(HB) all predicted major and intermediate surgery with odds ratios (ORs) all significant around 1.5–2, but these variables were not predictive of minor surgery. Strongest predictors for major surgery were low HB (OR 2.6, 95% CI 2–3.3), high Body Mass Index (BMI) only for total knee replacements (OR 1.7, 95% CI 1.2–2.4), for intermediate surgery were women (OR 3.2, 95% CI 2.21–4.7), DAS (OR 3.8, 95% CI 2.1–7.0) and RA related shared epitope (SE, OR 1.6, 95% CI 1.0–2.4). For multiple surgery, strongest predictors were erosions (OR 2.7, 95% CI 1.6–4.3), HAQ (OR 2.6, 95% CI 1.6–4.2), HB (OR 3.4, 95% CI 2.3–4.9), ESR (OR 3.1, 95% CI 1.9–4.7), SE (OR 1.9, 95% CI 1.2–3.4), ESR (OR 3.3, 95% CI 2.3–4.8). In Cox regression, sex, onset age and erosions predicted intermediate surgery, and sex, onset age and HB predicted major surgery.

Conclusion: Orthopaedic surgery is an important and common outcome in RA, not often reported and difficult to predict. HB does not normally perform well as a predictor of outcome in RA, but did for orthopaedic intervention, especially major and multiple surgery.

Disease Activity and Anti-CCP Status, but Not Sociodemographic Factors or Patient Comorbidities, Affect Time to Diagnosis in Early Rheumatoid Arthritis. Cheryl Barnabe[1], Juan Xiong[2], Gilles Boire[3], Carol A. Hitchon[4], Boulos Haraoui[5], Janet E. Pope[6], J. Carter Thorne[7], Edward Keystone[8], Diane Tin[7], Vivian P. Bykerk[9] and Canadian ArThritis CoHort[10]. [1]University of Calgary, Calgary, AB, [2]University of Toronto, Toronto, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]University of Manitoba, Winnipeg, MB, [5]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [6]St. Joseph's Health Care London, London, ON, [7]Southlake Regional Health Centre, Newmarket, ON, [8]University of Toronto, Toronto, ON, [9]Hospital for Special Surgery, New York, NY, [10]Toronto

Background/Purpose: Delays in patient presentation to primary care providers, subsequent referral for rheumatology assessment, and recognition of rheumatoid arthritis (RA) by the rheumatologist increase time to diagnosis. This time period is a modifiable determinant of joint damage and affects the odds of entering remission, and factors impacting this time must be elicited. Our aim was to evaluate whether time to diagnosis is influenced by measures of disease severity or a family history of RA, sociodemographic factors affecting access to care (age, sex, socioeconomic status [SES], education level, ethnicity), or comorbidities that may influence the physical examination, such as obesity, mental health conditions, or other musculoskeletal pain conditions.

Methods: A prospective national cohort of patients with confirmed or possible RA by 2010 ACR criteria (n=1,151) was evaluated for predictors of the duration of time to diagnosis. Variables examined in univariate analysis are summarized in Table 1. Simple linear regression was applied to each variable, and significant predictors carried forward to multivariate linear regression.

Table 1. Variables Assessed in Univariate Analysis for Time to Diagnosis

Female	74%
Age, mean (SD)	54 (14.7) years
Caucasian ethnicity	83%
BMI, mean (SD)	28.6 (10.5)
DAS28, mean (SD)	5.02 (1.44)
Swollen joint count, mean (SD)	28 Joints: 7.7 (6.0); 66 Joints: 9.8 (7.9)
Tender joint count, mean (SD)	28 Joints: 8.3 (6.5); 66 Joints: 12.7 (9.4)
HAQ, mean (SD)	1.02 (0.70)
Patient Global (VAS 0-10), mean (SD)	5.7 (2.9)
Acute Phase Reactants, mean (SD)	ESR: 28.1 (22.6) mm/hr; CRP: 14.4 (17.8) mg/L
Serology	Rheumatoid factor positive 67%; Anti-CCP positive 58%
Education	Only elementary or high school 46%; College or post-secondary 51%
Annual Income	<$20,000: 12%; $20,000-$50,000: 24%; $50,000-$100,000: 18%; >$100,000: 8%
Mental Health Condition	Depression: 11%; Other: 1%
Fibromyalgia	2%
Osteoarthritis	11%
Family History of RA	22%

The mean symptom duration at the baseline rheumatology visit was 6.0 months (range 0.1–19.6). In univariate analysis, age, joint counts, DAS28, patient global, HAQ, ESR, CRP, education level and anti-CCP status were all significant predictors (p<0.05) for time to diagnosis, whereas BMI, sex, ethnicity, income, RF status, family history of RA, and history of depression, fibromyalgia or osteoarthritis had no effect. In multivariate analysis, higher swollen joint counts, higher ESR, worse patient global scores, and negative anti-CCP antibody status were significant predictors of shorter time to diagnosis (Table 2).

Results:

Table. 2. Multivariate Analysis for Predictors of Time to Diagnosis

Parameter	Estimate	95% CI	P-value
Intercept	7.789	7.257; 8.322	<.0001
Swollen Joints	−0.051	−0.089; −0.013	0.0085
ESR	−0.016	−0.026; −0.006	0.0017
Patient Global Score	−0.085	−0.161; −0.009	0.0280
Damaged joint count	−0.090	−0.204; 0.023	0.1192
Anti-CCP Positive	0.814	0.383; 1.245	0.0002

Conclusion: Recognition of RA is not affected by a family history, sociodemographic factors, body habitus, mental health conditions, or other musculoskeletal pain syndromes. Worse patient global, more swollen joints, higher ESR and anti-CCP status influence time to diagnosis. The impact of fewer swollen joints and normal laboratory parameters on delay to diagnosis merits further consideration.

2133

Relationship Between Clinical Response and Radiographic Outcomes in Patients with Moderate Rheumatoid Arthritis. Josef S. Smolen[1], Ronald F. van Vollenhoven[2], Andrew S. Koenig[3], Ronald Pedersen[3], Annette Szumski[3] and Eustratios Bananis[3]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]The Karolinska Institute, Stockholm, Sweden, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Clinical evidence has established the importance of early, intensive treatment of rheumatoid arthritis (RA) to decrease disease activity and prevent joint damage.[1] The objective of this analysis is to examine the relationships between disease activity and inhibition of radiographic progression after 36 weeks of etanercept (ETN) + methotrexate (MTX) therapy in patients with moderate RA.

Methods: In the PRESERVE trial, patients with moderately active RA (DAS28 3.2–5.1) despite stable MTX for ≥3 months received open-label ETN 50 mg once weekly + MTX for 36 weeks. Week 36 (final time point) mTSS, defined as the sum of baseline mTSS and mTSS progression rate (units/year), was analyzed in relationship to disease activity by CDAI and DAS28.

Results: 704 patients who received ≥1 dose of ETN 50 mg + MTX and had available X-rays were included in this analysis. The percentage of patients achieving CDAI and DAS28 remission was 28% and 69%, respectively, and LDA including remission was seen in 87% and 88%. Both week 36 CDAI and week 36 DAS28 remitters had lower week 36 mTSS progression rate (units/year) compared with non-remitters (P<0.05). Week 36 CDAI remitters

also had lower baseline mTSS and lower week 36 mTSS (P<0.05; Table). CDAI and DAS28 week 36 disease activity categories (remission, LDA excluding remission, and NR) had similar proportions of patients (80–87%) who achieved radiographic non-progression (mTSS Δ ≤0.5). A significant relationship (P<0.001) was observed between baseline mTSS quartiles and week 36 mTSS progression rate categories (≤0.5, >0.5≤3, >3); the lowest baseline mTSS quartile (≤5) had the highest proportion of non-progressors (≤0.5; 28%) and the highest quartile (>51) yielded the highest percentage (54%) of patients with large radiographic progression (>3). A similar, significant (P<0.01) relationship was seen between baseline mTSS quartiles and week 36 CDAI response categories, with the lowest quartile having the highest proportion of CDAI remitters (33%) and highest quartile having the largest proportion of CDAI NR (31%).

Table. Descriptive Statistics for mTSS by Week 36 Clinical Disease Response Category

		ETN + MTX mTSS		
Week 36 Response	**n**	**Baseline, Units Mean (Median)**	**Final Time Point,† Units Mean (Median)**	**Progression Rate, Units/Yr Mean (95% CI)**
CDAI Remission (≤2.8)	195	36.5 (14.5)*	36.6 (14.5)*	0.1 (−0.1, 0.4)*
CDAI LDA (>2.8≤10)	415	39.3 (17.5)	39.7 (19.5)	0.4 (0.2, 0.6)
CDAI NR (>10)	94	44.4 (22.3)	45.0 (22.3)	0.6 (−0.3, 1.4)
DAS28 Remission (≤2.6)	487	37.9 (16.5)	38.2 (18.0)	0.3 (0.2, 0.5)*
DAS28 LDA (>2.6≤3.2)	135	41.9 (19.4)	42.1 (19.5)	0.2 (−0.1, 0.6)
DAS28 NR (>3.2)	82	42.6 (16.0)	43.3 (17.0)	0.7 (−0.2, 1.6)

*P < 0.05, Kruskal Walis test for differences in distributions. †Final time point defined as the sum of baseline and progression rate. DAS28 = 28-joint Disease Activity Score; CDAI = Clinical Disease Activity Index; LDA = low disease activity; NR = no response.

Conclusion: A large proportion of patients treated with ETN+ MTX achieved remission as measured by CDAI and DAS28 which inhibited radiographic progression regardless of week 36 disease activity. Overall, patients had less radiographic progression if they also achieved remission compared to LDA or NR. These results indicate that achievement of clinical goals in moderate RA has implications for structural benefits.

The Changed Prognosis of Patients with Early Rheumatoid Arthritis. Karin Britsemmer[1] and D. van Schaardenburg[2]. [1]Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: The treatment of rheumatoid arthritis (RA) has changed greatly during the past fifteen to twenty years. Major steps in this development were the introduction of methotrexate in the early nineties, the use of combination therapies including high-dose corticosteroids in the late nineties and the introduction of biologic therapies in the past decade. These improvements resulted in a better outcome and clinical remission became an attainable goal for many patients. This study documents trends in patient outcome over the last decades.

Methods: Five-year follow-up data was used from consecutive early RA patients (according to the 2010 ACR/EULAR criteria), included in the periods 1995–1999, 2000–2004 and 2005–2009. Disease activity (DAS-28), functional status (HAQ) and employment status (hours paid work per week) were used as outcome measures.

Results: 322, 369 and 389 patients were included in the three time periods, respectively. Median follow-up was 2 years. Patients included in 1995–1999 were older compared to the patients from the other periods, while the percentage of ACPA positive patients was higher in the last period. General practitioners referred patients increasingly sooner during the last 15 years. In the periods 1995–1999, 2000–2004 and 2005–2009 new patients with RA were treated in the first year with combination therapy in 13, 45 and 59% and/or biologics in 0, 9 and 19%, respectively. The baseline values of DAS-28, but not HAQ and hours paid work, showed a slight decrease over the three periods. However, after 5 years follow-up these differences were no longer significant. The trends in HAQ did not show differences between the three groups. The hours paid work of patients included in 2005–2009 remained stable during follow-up while the other groups showed a decrease over time. Data on radiographic progression are currently being analyzed.

Table. Baseline differences between patients of the three time periods

	1995–1999	2000–2004	p-value*	2005–2009	p-value*	p-value$
Age, yr	57 (15)	53 (14)	<0.001	53 (13)	<0.001	ns
Female, %	69	72	ns	72	ns	ns
ACPA, %	59	61	ns	75	<0.001	<0.001
RF, %	57	59	ns	58	ns	ns
Disease duration, mos.	5.0 (3.4–8.0)	4.3 (2.6–7.2)	0.015	2.8 (1.6–5.9)	<0.001	<0.001
GP-delay, wk	13 (8–29)	9 (4–21)	<0.001	4 (1–13)	<0.001	<0.001
DAS-28	5.2 (1.2)	5.1 (1.3)	ns	4.9 (1.3)	0.021	*0.052*
HAQ	1.13 (0.5–1.75)	1.13 (0.75–1.75)	ns	1.13 (0.63–1.63)	ns	ns
Work, h/wk	32.9 (15.9)	30.0 (11.0)	ns	32.6 (12.8)	ns	ns

Values are expressed as mean (SD) or median (IQR) * p-value compared to period 1995-1999
$ p-value compares period 2000-2004 vs 2005–2009
Conclusion: The results document an increasingly better prognosis of early RA patients over the last 15 years. Early recognition and referral by general practitioners has led to a lower disease activity at baseline. Next, more intensive treatment resulted in improved outcomes. However, despite a favorable trend in work participation, there still remains ample opportunity for a further reduction of disease activity and improvement of function.

Trabecular Bone Texture parameters are Correlated with Magnetic Resonance Imaging (MRI) bone Edema At Hand and Wrist in Active Rheumatoid Arthritis (RA). Thao Pham[1], Sophie Trijau[1], Roland Chapurlat[2], Damien Loeuille[3], Thierry Schaeverbeke[4], Christian Roux[5], Claude-Laurent Benhamou[6], Olivier Vittecoq[7], Jean Sibilia[8], Frederic Mistretta[9] and Cécile Hacquard-Bouder[10]. [1]Sainte Marguerite Hospital, Marseille, France, [2]Hôpital Edouard Herriot, Lyon, France, [3]CHU Brabois, Vandoeuvre les Nancy, France, [4]Groupe Hospitalier Pellegrin, Bordeaux, France, [5]Paris Descartes University, Paris, France, [6]EA 4708 University Orleans, Orleans, France, [7]Rouen University Hospital & Inserm905, University of Rouen, Rouen Cedex, France, [8]CHU Hautepierre, Strasbourg, France, [9]Lyon, France, [10]Abbott France, Rungis, France

Background/Purpose: In RA, bone marrow edema (BME) is predictive of erosive progression. Bone erosions are assumed to appear through activation of local bone resorption mechanisms, reflected by periarticular osteopenia. Measurement of periarticular bone mineral density by DXA requires specific hand software limiting its application in large population, and does not assess bone texture. A new high resolution direct digital X-ray device has been recently developed to provide bone texture analysis reflecting changes in trabecular bone architecture, with a very low radiation exposure.

Objectives: To assess the correlation between MRI bone edema and trabecular bone texture parameters in active RA.

Methods: *Study design:* cross-sectional multicenter study. Comparative MRI and high resolution X-rays of the dominant hand and wrist were obtained from 55 patients with active RA according to ACR/EULAR criteria (DAS 28 ≥ 3.2). Clinical examination and radiographs of the hands and wrist were also performed. *High resolution direct digital X-ray* (BMA™, D3A Medical Systems): The fractal trabecular bone texture parameter (Hmean) was evaluated on the 2nd and 3rd metacarpal head, capitatum and lunatum. *MRI:* BME was scored according to the RA MRI score (RAMRIS) by two independent and experienced radiologists (central reading). BME was also specifically assessed on the 4 bones where Hmean was evaluated (BME4 score). *Radiographs:* plain radiographs were scored using the modified Sharp-van der Heijde method. *Analysis:* Inter-reader reliability: ICC. Correlation between BME and Hmean: Spearman test.

Results: Data from 53 patients were analyzable. The main patients characteristics were (mean ± SD): age 57 ± 14 years, 75% women, disease duration 8.6 ± 9.2 years, DAS28 5.4 ± 1.3, anti-CCP 76%, Sharp-DvdH 23.8 ± 31.3, currently treated with DMARDs 74%, biologics 47%, corticosteroids 60% (mean daily dosage 9.1 ± 6.6 mg). The mean ± SD [median] RAMRIS BME, BME4 and Hmean scores were 12.7 ± 14.6 [5.0], 2.7 ± 2.8 [1.0] and 0.60 ± 0.06 [0.61], respectively. RAMRIS BME inter-reader reliability: ICC=0.96. Correlations between Hmean and both RAMRIS BME and BME4 scores were r=-0.31 (p=0.022) and r=-0.32 (p=0.018), respectively. When evaluated only on the 2nd and 3rd metacarpal head, Hmean was significantly correlated with the total BME score r=-0.28 (p=0.038) whereas it was not when evaluated on lunatum and capitatum (r=-0.22 – p=0.120).

Conclusion: This study demonstrated trabecular bone texture parameters are correlated to MRI bone edema scores. It would be interesting to assess if bone texture impairment, measured with a high resolution digital Xray device, could predict RA radiographic progression in a wider range prospective study.

Alcohol Use and Radiographic Disease Progression in African Americans with Recent Onset Rheumatoid Arthritis. Marshall Davis[1], Kaleb Michaud[1], Harlan Sayles[1], Doyt L. Conn[2], Larry W. Moreland[3], S. Louis Bridges Jr.[4] and Ted R. Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Emory Univ School of Medicine, Atlanta, GA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Previous studies have shown that alcoholic beverage consumption can modify levels of circulating inflammatory cytokines and alter expression of innate immune system receptors. Recognizing these changes, investigators have sought to identify the association of alcohol consumption with rheumatoid arthritis (RA) risk and progression. To date, studies have primarily been limited to patients of European ancestry and have yielded conflicting results. To address this gap of knowledge we sought to investigate alcohol consumption and RA disease progression in African Americans; a historically understudied cohort. Specifically, the aim of our study was to determine if alcohol consumption, stratified by dose, is associated with radiographic disease progression in African Americans during the early stages of RA.

Methods: RA patients included in the study were participants in the Consortium for the Longitudinal Evaluation of African Americans with Early Rheumatoid Arthritis (CLEAR) registry with < 2 years disease duration from symptom onset. Patients reported the average number of alcoholic beverages consumed per month and a modified Sharp/van der Heijde score was computed to assess disease progression using joint space narrowing and erosion totals in radiographs of the wrists, hands, and

feet. Upon visual inspection, a clear natural break with an inflection in the slope was identified at 15 beverages per month. Patients were subsequently categorized into two groups: those consuming < 15 beverages per month versus those consuming ≥ 15 per month. Associations of radiographic disease progression over a one to three year period of observation with alcohol consumption was evaluated using generalized estimating equations adjusting for patient demographics, current RA therapy, anti-CCP, RF-IgM, c-reactive protein, and smoking status.

Results: There were 166 patients included in the study; 139 reported that they consumed, on average, < 15 alcoholic beverages per month and 27 reported consuming ≥ 15 per month. A "checkmark-shaped" relationship of alcohol consumption and radiographic disease progression was identified and is shown in Figure 1. In patients consuming ≥ 15 alcoholic beverages per month, alcohol intake was associated with an increased risk of radiographic disease progression ($p = 0.017$) after multivariate adjustment. There was no evidence of a relationship in those consuming < 15 beverages per month ($p = 0.802$).
Figure 1. Radiographic disease progression summarized based on the average number of alcoholic beverages consumed per month.

Conclusion: There appears to be a dose-dependent relationship between alcohol use and radiographic disease progression in African Americans with RA. Individuals who consume 15 or more alcoholic beverages per month may have accelerated rates of radiographic joint damage compared to those with lower levels of consumption.

Contribution of Disease Activity, Joint Damage and Comorbidity to Impairment (SOFI) and Disability (HAQ) in Rheumatoid Arthritis Patients Over 20 Years.
Meliha C. Kapetanovic[1], Elisabet Lindqvist[2], Jan-Åke Nilsson[3], Pierre Geborek[4], Tore Saxne[5] and Kerstin Eberhardt[2]. [1]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden, [2]Department of Clinical Sciences Lund, Section of Rheumatology, Skåne University Hospital, Lund University, Lund, Sweden, Lund, Sweden, [3]Lund University, Malmö, Sweden, [4]Sweden, [5]Dept of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden

Background/Purpose: To study the contribution of disease activity, joint damage and co-morbidity on development of impairment measured by signals of functional impairment (SOFI) and disability measured by health assessment questionnaire (HAQ) in rheumatoid arthritis (RA) patients prospectively followed over 20 years after diagnosis.

Methods: 183 RA patients diagnosed between 1985 and 1989 were prospectively monitored over 20 years. There were 116 (63 %) women, mean (SD) age was 52 (12) years and symptom duration before inclusion was 11 (7) months. Disease activity was measured by 44-joint DAS, joint damage by Larsen score of radiographs of hands and feet, comorbidity by Charlson Comorbidity Index (17 diagnoses each weighted by mortality risk), impairment by SOFI (3-parts performance based index measuring hand, arm and leg function) and disability by HAQ. Two separate multiple regression models with SOFI and HAQ as outcome variables at 0, 5, 10, 15 and 20 year follow up were created.

Results: Altogether, disease activity, radiographic joint damage and co-morbidity explained 22–38% of SOFI and 14–38 % of HAQ (figure). For SOFI, DAS contributed with 2–27% with a peak at 5 years. Radiographic damage contributed increasingly (6–35%). For HAQ, DAS contributed significantly at all follow up times (7–28%), with a peak at 5 years whereas radiographic damage had minor contribution (0–10%). Comorbidity showed minor contribution both to SOFI and HAQ.
Figure. Contribution of disease activity (DAS), joint damage (Larsen score) and comorbidity (Charlson comorbidity index) to impairment (SOFI) and disability (HAQ) in rheumatoid arthritis patients over 20 years

Conclusion: In the long-term perspective impairment is increasingly explained by radiographic damage, whereas disability is less well explained by RA related factors over time. Comorbidity contributed only to small extend to both impairment and disability.

Racial and Ethnic Disparities in Rheumatoid Arthritis Outcomes in Community-Based U.S. Rheumatology Practices: Results From the Consortium of Rheumatology Researchers of North America Registry.

Jeffrey D. Greenberg[1], Tanya Spruill[2], Gbenga Ogedebe[3], Joel M. Kremer[4], Ying Shan[5], Katherine C. Saunders[6], Yusuf Yazici[7] and Leslie R. Harrold[5]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]NYU School of Medicine, New York, NY, [3]New York University School of Medicine, New York, NY, [4]Albany Medical College and The Center for Rheumatology, Albany, NY, [5]UMass Medical School, Worcester, MA, [6]CORRONA, Inc., Southborough, MA, [7]New York University, New York, NY

Background/Purpose: Disparities in medication use and clinical outcomes have been reported in patients with rheumatoid arthritis (RA) and other chronic diseases. However, there is little information regarding whether disparities exist in RA clinical outcomes in black and Hispanic patients treated in community-based rheumatology practices in the U.S..

Methods: We examined data from RA patients (pts) participating in the Consortium of Rheumatology Researchers of North America (CORRONA) registry, an independent registry collecting patient and physician-derived data from both academic-affiliated and community-based practice sites. Among the 30,869 RA pts enrolled in the registry across 146 academic and community-based sites, we examined data from 26,640 RA pts under the care of 109 community-based rheumatology practices. We performed a cross-sectional study using data collected from the most recent registry visit as of 05/05/2012. We compared medication use and RA outcomes across race/ ethnic groups, comparing non-Hispanic white RA pts versus black and Hispanic RA pts based on self-reported race/ethnicity categories. Specifically, we compared measures of RA disease activity (DAS28 and CDAI), as well as patient-reported outcomes (pain VAS and HAQ score). Pairwise statistical comparisons were performed versus the white RA cohort.

Results: The study cohorts included 23,396 non-Hispanic whites,1,890 black and 1,354 Hispanic pts. The mean duration of RA was greater for whites (11.6 yrs) vs blacks (9.4 yrs, p<0.001) and Hispanics (10.8 yrs, p<0.001). Similar proportions of Hispanics (58.3%) and white pts (59.7%) were treated with methotrexate (MTX), and more blacks (62.4%) were treated with MTX versus whites. Prescribed MTX dosages were comparable across groups, although blacks and Hispanics reported taking significantly lower dosages. Estimated MTX adherence calculated as patient-reported dosage divided by the prescribed dosage varied from 89% in whites to 78.5% in blacks and 82.6% in Hispanics. Slightly higher rates of biologic use were observed for whites (44.9%) vs. blacks (42.8), although not significantly different (p=0.07). In comparison to whites, Hispanics actually had higher rates of biologic use (48.7%, p<0.01). Higher levels of disease activity using both the CDAI and DAS28 were observed for blacks and Hispanics vs. whites (p<0.001, see Table). Higher patient pain scores (p<0.001) and worse functional status (p<0.001) were also reported by both black and Hispanic RA pts vs. whites.

Table. Medication Use and Outcomes by Racial and Ethnic Group

	White (N=23,396)	Black (N=1,890)	Hispanic (N=1,354)
Clinical Outcomes			
Disease Activity Score (DAS28), mean	3.3	3.6***	3.6***
Clinical Disease Activity Index (CDAI)	11.2	12.5***	13.4***
MD global VAS, mean	18.3	23.0***	21.9***
Patient global VAS, mean	29.8	34.8***	33.3***
Tender joint count, mean	3.2	3.4	4.4***
Swollen joint count, mean	3.1	3.2	3.6***
Patient Pain Score (VAS), mean	32.1	37.3***	35.7***
Functional Status (HAQ Score), mean	0.69	0.82***	0.77**
RA Treatment			
Biologic prescribed currently (%)	44.9	42.8	48.7**
MTX prescribed currently (%)	59.7	62.4*	58.3
MTX dose prescribed, mean (mg/wk)	15.9	16.1	15.5
MTX dose self-reported, mean (mg/wk)	14.2	12.7*	12.8*

Note: ***p<0.001, **p<0.01, *p<0.05

Conclusion: Although some differences in RA medication prescribing were observed, both black and Hispanic pts treated in community-based practices demonstrated higher RA disease activity, higher pain scores and worse functional outcomes than white RA pts.

2139

Smoking Is Associated with Worsening Functional Status Over Time in a Diverse Cohort of Patients with Rheumatoid Arthritis.

Matthew Reimert[1], Laura Trupin[2], Patricia P. Katz[3], Edward Yelin[4], Jennifer Barton[5] and John B. Imboden[6]. [1]University of CA San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]Univercity of California San Francisco, San Francisco, CA, [4]University of California San Francisco, San Francisco, CA, [5]UCSF, San Francisco, CA, [6]University of California, San Francisco, San Francisco, CA

Background/Purpose: Although the effects of tobacco use on disease onset, severity, and response to therapy have been well studied in rheumatoid arthritis (RA), there is little data addressing the effect of smoking on the functional status of patients with RA. This study assesses the relationship between tobacco use and change in functional status over time in patients with RA.

Methods: Retrospective analysis of 121 subjects with confirmed RA in an ethnically diverse outpatient rheumatology clinic at a public hospital. Primary outcome was the difference between baseline HAQ score and repeated assessment of HAQ 2–5 years later. Primary predictor variable was current smoking at baseline. Covariates included time between HAQ assessments, age, gender, rheumatoid factor positivity, baseline HAQ and DAS28-ESR scores, synthetic DMARD use, biologic use, and disease duration. Student's t-test was used to compare the mean change in HAQ over time between smokers and non-smokers. Association between smoking and change in HAQ over time, controlling for all covariates, was assessed with multivariate linear regression. Multivariate logistic regression was then used to assess the odds of achieving the accepted clinically meaningful improvement in HAQ score of −0.22[1] during this time period.

Results: Of the 121 subjects, 14 (12%) were current smokers at baseline assessment, 108 (89%) were female, and 114 (94%) were non-Caucasian. Mean age was 53 (+13). Mean baseline HAQ score was 1.32, mean time between HAQ assessments was 3.5 years, and mean change in HAQ over time was 0.088. Individual change in HAQ score ranged from −1.88 to 2.0. Mean change in HAQ was 0.411 among smokers and 0.046 among non-smokers (p = 0.043). One of 14 smokers (7%), and 33 of 107 non-smokers (31%), achieved a clinically meaningful improvement in HAQ during this time period. Multivariate linear regression demonstrated that smoking is independently associated with a worsening HAQ over time (coefficient= 0.33, p= 0.047). Multivariate logistic regression demonstrated that smoking decreased the odds of achieving a clinically meaningful improvement in HAQ (OR 0.07, 95% CI 0.01–0.83).

Conclusion: Cigarette smoking was associated with worsening functional status among patients in this cohort over a mean time of 3.5 years. In addition, the odds of achieving a clinically meaningful improvement in functional status during this follow-up period were significantly lower in smokers as compared to non-smokers.

2140

A Longitudinal Study of Prognostic Factors in Patients with Early RA Providing Direction for Future Clinical Treatment- Predict Study.

Paul Bird[1], David Nicholls[2], Julien P. de Jager[3], Hedley Griffiths[4], Lynden Roberts[5], Kathleen Tymms[6], Jane Zochling[7], Mark H. Arnold[8], Geoffrey O. Littlejohn[9] and OPAL Consortium[10]. [1]Combined Rheumatology Practice, Sydney, Australia, [2]Coast Joint Care, Maroochydore, Australia, [3]Suite 2, Osler House, Southport, Australia, [4]Barwon Rheumatology Service, Geelong, Australia, [5]James Cook University, Townsville, Australia, [6]Canberra Rheumatology, Canberra, Australia, [7]Menzies Research Institute Tasmania, Hobart, Australia, [8]Level 2 The Gallery, Chatswood, Australia, [9]Monash Medical Center, Melbourne, Australia, [10]Melbourne, Australia

Background/Purpose: Despite the conspicuous increase in available treatment for rheumatoid arthritis [RA], and the shift to early, more aggressive management, there is a paucity of reliable prognostic markers to assist in the stratification of therapy in individual patients. As a result, individualized risk-adapted therapy for patients with RA remains a desirable, but elusive goal. The primary objective of this study was to assess the association between baseline clinical prognostic factors and subsequent DAS remission in early RA patients.

Methods: The study utilised point of care clinical software to collect data from *20* participating rheumatology treatment centres. Newly diagnosed RA patients over the age of 18 years treated at a participating clinic were eligible. Patients were required to have attended the clinic on at least two occasions in 6 months and have at least two available DAS assessments. Clinical predictors of outcome were identified and the list was refined by consensus. Data captured included baseline demographics, mode of disease onset, pattern of joint involvement at onset, smoking status, DAS, RF and CCP titre, time from onset of symptoms to presentation and disease activity at baseline. Statistical analysis utilized a univariate and multivariate logistic regression of DAS28ESR remission 12 months after the first assessment.

Results: 1,121 patients were included in the analysis (71% female, 29% male). 434 patients were RF positive, 265 CCP positive. Mean age 61.3 years (SD 13.4).

The strongest baseline predictors of DAS28ESR remission at 12 months were younger age, male and low disease activity at baseline. There was no statistically significant association between joint onset patterns, mode of onset, RF or CCP status and smoking status.

The association between DAS28ESR remission at 12 months and age was borderline significant. Odds ratio for age was 0.985 (95% CI = (0.969, 1.01)). For each additional decade of age, the odds of being in remission at 12 months decreased by 15% (p = 0.057)

For female patients the odds of being in remission at 12 months was 0.887;for male patients the odds of being in remission at 12 months was 2.00; therefore the odds of a male patient being in remission at 12 months was 2.256 times greater than those for female patients (OR 2.256, 95% CI = (1.384, 3.675), P<0.001.)).

For patients who were in remission at baseline the odds of being in remission at 12 months was 2.44; for patients who were not in remission at baseline the odds of being in remission at 12 months was 0.57; therefore the odds of a patient in remission at baseline being in remission at 12 months were 4.28 time greater than those patients not in remission at baseline (OR 4.28, 95% CI = (2.56, 7.17), P < 0.001.)).

Conclusion: The strongest baseline predictors of DAS remission at 12 months were younger age, low baseline disease activity and male gender. Traditional prognostic factors associated with outcome such as smoking and CCP status were not strong predictors of outcome at 12 months. The study identifies potential high-risk groups that may benefit from more frequent clinical assessment and therapy adjustment. The cohort will be followed over the next five years to provide data on long term outcome.

Effects of Cigarette Smoking On EARLY Arthritis (CONAART). Maria Haye Salinas[1], Ana C. Alvarez[1], Rafael Chaparro del Moral[2], Mariana Benegas[2], Christian A. Waimann[3], Rodolfo Perez Alamino[3], Rodrigo Garcia Salinas[4], Ana Lucía Barbaglia[5], Veronica Bellomio[5], Josefina Marcos[6], Adrian Salas[6], Cristian Quiroz[7], Federico Ceccato[8], Sergio Paira[8], Dora Lia Vazquez[9], Gabriela Salvatierra[10], M. Crespo[11], Edson Javier Velozo[12], Oscar L. Rillo[13], Enrique Soriano[14], Antonio Catalan Pellet[4], Alberto Berman Sr.[5], Juan Carlos Marcos[6], Gustavo Citera[15] and Francisco Caeiro[16]. [1]Hospital Privado, Córdoba, Argentina, [2]Hospital Tornu, Buenos Aires, Argentina, [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [4]Hospital Rivadavia, Buenos Aires, Argentina, [5]Hospital Padilla, Tucuman, Argentina, [6]Hospital San Martin, La Plata, Argentina, [7]Rheumatology Section, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [8]Hospital Jose Maria Cullen, Santa Fe, Argentina, [9]Centro Integral de Reumatologia, Santiago del Estero, Argentina, [10]Centro de enfermedades Reumaticas, Santiago Del Estero, Argentina, [11]Hospital Señor del Milagro, Salta, Argentina, [12]Sanatorio Adventista del Plata, Entre Rios, Argentina, [13]Hospital Tornú, Buenos Aires, Argentina, [14]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [15]Instituto de Rehabilitación Psicofísica., Buenos Aires, Argentina, [16]Hospital privado de Cordoba, Cordoba, Argentina

Background/Purpose: According to recent reports the cigarette smoking persons have 2–4 times greater risk of developing rheumatoid arthritis (RA). The cigarette smoking is associated with an early onset, a greater seropositivity, erosions and severity in patients with early arthritis. The purposes of our study was to analyze the effects of cigarette smoking on the disease activity, serology, presence of extra-articular manifestations (ExM) and radiographic damage in patients with early arthritis.

Methods: This cross-sectional study involving 1.305 patients (729 diagnosed with rheumatoid arthritis (American College of Rheumatology '87 criteria) and 576 undifferentiated arthritis) belonging to CONAART (Argentine Consortium for Early Arthritis) that includes patients older than 16 yrs with arthritis in at least 1 joint and less than two years of disease. The patients have been divided in never smokers, former smokers and current smokers and these last two were classified according the amount of pack years smoked. The following variables were assessed: ExM, joint count, Health Assessment Questionnaire (HAQ), Disease Activity Score of 28 joint (DAS28), Rheumatoid Arthritis Disease Activity Index (RADAI), The Rheumatoid Arthritis Quality of Life (RAQoL), erythrocyte sedimentation rate (ESR), C reactive protein (CRP), Rheumatoid Factor (RF) and Simple Erosion Narrowing Score (SENS) of radiographs.

Categorical variables were compared with chi square and continuous with ANOVA or Kruskal Wallis. Conditional logistic regression was used to estimate the odds ratios (ORs) and 95% confidence intervals.

Results: Mean age was 48 ± 14 years and 82% were female. Were current smokers 23.1%, former smokers 9.5% and never smokers 67.4%. Univariate analysis is showed on table one. Variables independently associated with cigarette smoking were RADAI (OR=1.18, 95% CI 1.04–1.33; $p=$ 0.007) and SENS (OR=1.04, 95% CI 1.02–1.71; $p=$ 0.003). No relationship was found between disease activity and severity and number of pack years.

Table 1. The features of arthritis according to smoking status.

	Current smokers n 302	Former smokers n 124	Never smokers n 879	p
Painful joints, M (R_Q)	10 (5–17)	7.5 (3–15.7)	8 (3–17)	**0.02**
Swollen joints, M (R_Q)	7 (3–13)	4.5 (3–10)	5 (2–10)	**0.003**
ExM, n (%)	7 (2.3)	2 (1.6)	16 (1.8)	0.83
DAS28, m ± DS	5.21 ± 1.45	5.05 ± 1.35	4.87 ± 1.41	**0.02***
HAQ, M (R_Q)	1.2 (0.5–1.8)	1.2 (0.5–1.7)	1.0 (0.5–1.6)	**0.01**
RADAI, m ± DS	5.04 ± 2.11	4.92 ± 2.21	4.39 ± 2.14	**<0.001*/0.03#**
RAQUOL, M (R_Q)	15 (9–22)	15 (9–20)	13 (6–20)	**0.008**
RF title, M (R_Q)	128 (32–282)	89.8 (19.2–226.5)	78.5 (17–180)	**0.010**
RF positive, n (%)	178 (67.7)	77 (67.5)	468 (58.8)	**0.014**
ESR, M (RQ)	25 (13–42)	25 (12.2–40)	25 (13–44.7)	0.59
CRP, M (R_Q)	2.55 (0.38–12)	1.88 (0.21–6.95)	2.47 (0.3–9.89)	0.54
SENS, M (R_Q)	11 (4–20)	13 (4.5–19)	9.5 (3–16)	**0.02**

*Current smokers compared with current smokers. # Former smokers compared with never smokers.

Conclusion: In this study, smokers exhibited higher frequency of seropositivity for RF, higher levels of disease activity, worse functional capacity and more severe radiographic damage. There was no increased frequency of ExM. In multivariable analysis the smoking was independently associated with RADAI and SENS. There was no relationship between the variables of disease activity and the magnitude of smoking. Our study reinforces the importance to quit smoking in patients with early arthritis.

Magnetic Resonance Imaging-Proven Osteitis At Baseline Predicts the Early Rheumatoid Arthritis Patients Who Will Develop Rapid Radiographic Progression: MRI Is Beneficial to Find the Window of Opportunity in Early RA. Mami Tamai[1], Yoshikazu Nakashima[2], Takahisa Suzuki[2], Yoshiro Horai[2], Akitomo Okada[2], Junko Kita[2], Shin-ya Kawashiri[2], Naoki Iwamoto[1], Kunihiro Ichinose[2], Kazuhiko Arima[1], Hideki Nakamura[1], Tomoki Origuchi[2], Masataka Uetani[2], Kiyoshi Aoyagi[2], Katsumi Eguchi[3] and Atsushi Kawakami[2]. [1]Nagasaki University, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [3]Sasebo City General Hospital, Sasebo, Nagasaki, Japan

Background/Purpose: Window of opportunity exists in the earlier phase of rheumatoid arthritis (RA), thus, early recognition of the RA patients who will develop rapid radiographic progression (RRP) is crucial. We have reported an importance of magnetic resonance imaging (MRI)-proven symmetrical synovitis, osteitis and bone erosion of wrist and finger joints toward

the early classification of RA from the prospective early arthritis cohort at Nagasaki University, Nagasaki, Japan. To investigate whether MRI assessment of joint injury at baseline predict the development of RRP at 2 years in patients with early RA by our cohort.

Methods: One hundred-eleven RA patients, who fulfilled 2010 RA classification criteria and introduced disease-modifying anti-rheumatic drugs (DMARDs) including biologics within the first 1 year, were consecutively enrolled in this study. These patients were referred to the RA patients in the present study. Patients gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. All of the subjects had been examined by gadolinium-diethylenetriamine pentaacetic acid (Gd-DTPA)-enhanced MRI and plain radiograph of both wrist and finger joints at the same day every 6 months during 2 years. MRI-proven synovitis, osteitis and bone erosion were evaluated by RAMRI scoring (RAMRIS) technique. RRP was defined as yearly progression of Genant-modified Sharp score >3.0 during 2 years. We have examined what variables at entry, including MRI features, and the therapies during 2 years predict the development of RRP at 2 years by logistic regression analysis.

Results: The mean disease duration, age, % female, prevalence or titer of rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), disease activity score (DAS) 28-CRP at entry were 4.0 months, 56.2 y.o., 66.7%, 60.4% or 95.5 ± 186.7 IU/ml, 58.6% or 160.3 ± 345.4 U/ml and 4.38, respectively. The frequency of MRI-proven symmetrical synovitis, osteitis and bone erosion at baseline was 80.7, 54.5, 37.2%. Biologics were administrated in 17.1% of the patients during 2 years. Twenty patients (18.0%) were classified as RRP at 2 years. Logistic regression analysis has shown that MRI osteitis at baseline, history of biologics use during 2 years, Genant-modified Sharp score at baseline are independent variables to predict the development of RRP at 2 years (Odds ratio = 3.88, 7.95 and 12.4, respectively. 95% confidence interval = 1.05–14.42, 2.29–27.56 and 1.03–1.50, respectively, p-value = 0.043, 0.0011 and 0.027, respectively. Akaike's information criterion = 91.50).

Conclusion: Our present data indicate that MRI-proven osteitis at baseline is a predictor toward the development of RRP in patients with early RA. MRI is beneficial to find the window of opportunity in these patients.

2143

Analysis of Factors Associated with the Health Assessment Questionnaire Score Change in Five Years. Shinji Yoshida[1], Katsunori Ikari[2], Kensuke Ochi[1], Yoshiaki Toyama[3], Atsuo Taniguchi[1], Hisashi Yamanaka[1] and Shigeki Momohara[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Institute of Rheumatology, Tokyo Women's Medical University, Shinjuku-ku, Japan, [3]Keio University, Shinjuku, Japan

Background/Purpose: The Health Assessment Questionnaire (HAQ) score is thought to be a disease specific tool for the assessment of inflammatory joint disorders including rheumatoid arthritis (RA). It is considered as the main and good functional outcome measure in RA. The purpose of this study was to find the factors associated with the magnitude of HAQ score change in five years from the baseline.

Methods: We enrolled 4408 RA patients, who participated in the IORRA (Institute of Rheumatology RA cohort) from 2000 to 2004, and from whom the HAQ score was obtained at the baseline and five years later. From the IORRA database, we collected demographic, clinical and therapeutic data: rheumatoid factor (RF) positivity, age and body mass index (BMI) at the baseline; gender; year of onset; average disease activity score with 28-joint counts (DAS28) score in five years from the baseline. The HAQ score change is calculated as the Year 5 value minus the baseline. Factors associated with the HAQ score change were analyzed by multiple linear regression analysis adjusted for baseline HAQ score.

Results: The multiple linear regression analysis adjusted for baseline HAQ score revealed that the lower levels of average DAS28 score was most significantly associated with the better HAQ change in five years (Table 1). Recent onset of the disease, older age of onset and male sex are also associated with the better HAQ change, while RF positivity and BMI at the baseline are not associated with HAQ change.

Table.

Factor	Standardized regression coefficient	P value
RF	0.01	0.42
Average DAS28	0.26	<2e-16
Gender (female)	0.03	0.002
BMI	0.008	0.40
Year of onset	−0.12	<2e-16
Age	−0.07	5.0e-12

Conclusion: The lower levels of average DAS28 score, recent onset of the disease, older age of onset and male sex are associated with the better HAQ change. The results of this study may help patients without these factors to get early and aggressive intervention.

Early RA Patients Fulfilling the New 2010 ACR/EULAR Criteria, Display Better Clinical Responses to DMARD Therapy but Have Higher Radiographic Damage Progression Than Patients with Early RA Not Fulfilling the 2010 ACR/EULAR Criteria. Ruediger Mueller[1], Toni Kaegi[1], Axel Finckh[2] and Johannes von Kempis[1]. [1]MD, St. Gallen, Switzerland, [2]Geneva University Hospitals, Geneva 14, Switzerland

Background/Purpose: New ACR/EULAR criteria for the classification of rheumatoid arthritis (RA) were recently proposed. The aim of this analysis was to examine the impact of fulfilling the 2010 ACR/EULAR criteria at the initial visit on long-term progression of disease and radiographic progression.

Methods: For this observational cohort study within the Swiss RA registry SCQM, we included patients suffering from early RA or undifferentiated arthritis (UA, disease duration ≤1 year), as defined by the treating rheumatologist, who had not received any previous DMARDs. Baseline diagnosis of RA/UA was reassessed according to the 2010 ACR/EULAR criteria at baseline. Patients were separated into 2 groups depending on whether or not they fulfilled the 2010 ACR/EULAR criteria at baseline (≥ 6 points versus < 6 points). The primary outcome measures were the DAS 28 and erosions as measured by the Ratingen score over time.

Results: A total number 592 patients was analysed. 352 of them fulfilled the 2010 ACR/EULAR at baseline, 240 were not classifiable as RA according to the new criteria at baseline. The score calculated by the new ACR/EULAR criteria correlated with disease activity at disease onset. Treatment was initiated with DMARDs, mostly MTX, in all patients. There were no significant differences in the therapeutic strategies between patients fulfilling the classification criteria or not. The patients fulfilling ACR/EULAR criteria at baseline developed a 39.1%reduction of DAS 28 scores, as compared to a 33.6%reduction in ACR/EULAR-negative patients after 6 months, independent of their respective treatments. After 1 year of follow-up no differences were found comparing the mean DAS28 scores in the 2 groups. Average radiographic progression was higher among ACR/EULAR-positive patients (progression of Ratingen score/year 0.50 vs. 0.32, resp., p=0.03) after 3 years of follow up.

Conclusion: The 2010 ACR/EULAR criteria appeared to select a subset of patients among early RA/UA patients with a favourable clinical response to conventional anti-rheumatic therapy. Despite this therapy, radiographic progression was higher in 2010 ACR/EULAR positive patients.

Age At Onset Determines Severity and choice of Treatment in Early Rheumatoid Arthritis. Lena Innala[1], Bozena Möller[2], Lotta Ljung[1], Torgny Smedby[3], Anna Södergren[1], Staffan Magnusson[4], Ewa H. Berglin[1], Solbritt M. Rantapää-Dahlqvist[1] and Solveig Wållberg-Jonsson[1]. [1]Institution of Public health and clinical medicine/ Rheumatology, University of Umeå, Umeå, Sweden, [2]Department of Rheumatology, Sunderby Hospital, Luleå, Sweden, [3]Department of Rheumatology, Östersund hospital, Östersund, Sweden, [4]Department of Internal Medicine, Sundsvall Hospital, Sundsvall, Sweden

Background/Purpose: Mortality is increased in rheumatoid arthritis (RA). Contributing factors are disease activity/severity and comorbidity. A relationship between age at onset and pharmacological treatment has been implicated. We evaluated the impact of age at onset on prognostic risk factors and given treatment during five years from disease onset.

Methods: All patients from the 4 most northern counties of Sweden diagnosed with RA (<12 months symptoms) are consecutively included in a large survey on the progress of the disease and its co-morbidities. Up till now 950 (649f, 301m) patients have been included. Median age at disease onset was 58 years (range 18–89). All patients have been followed on a regular basis; a survey of co-morbidities was made at inclusion and after 5 years, measures of disease activity (ESR, CRP, tender joints, swollen joints, VAS pain and VAS global, DAS28, HAQ) and X-ray of hands (erosions, Larsen score) were assessed regularly. Disease severity (extraarticular disease, rheumatoid nodules), co-morbidities and pharmacological treatment (DMARDs, corticosteroids, biologics, NSAIDs, COX2-inhibitors) were registered. Autoantibodies (RF, ANA, ACPAs) and genetic markers (HLA-shared epitope, PTPN22 T-variant) were analysed. Young (YORA)/late (LORA) onset of RA was defined as below/above median age (58 years) at disease onset. Data analyses were based on stratification of the patients in YORA and LORA.

Results: Patients with LORA had higher ESR (34.3 vs. 26.0 mm/h, p<0.001), VAS global (47.8 vs. 42.9, p=0.085) and HAQ (1.0 vs 0.8, p=0.075) at baseline and significantly higher accumulated disease activity (AUC for DAS28) at 6 (p=10.0), 12 (p<0.01) and 24 months (p<0.05) compared to YORA. Patients with YORA had more often ACPAs (72.4% vs 65%; p<0.01) and PTPN22 T-variant (37,8 vs 29.5, p=0.056). Presence of extraarticular disease was similar however nodules tended to be more common at young onset (p=0.069) and YORA had significantly higher Larsen score (p<0.001 at 0 and 24 mo). Patients with LORA were significantly more often treated with corticosteroids (77.5 vs. 68.8%; p<0.01), significantly less with methotrexate (81.9 vs. 90.2%; p<0.01) and with biologics (7.6 vs. 24.9%, <0.001). Patients with YORA were treated with DMARDs earlier (within 3 months from inclusion; 94.0% vs. 85.8%; p<0.01) and overall (98.9 vs. 96.7, p=0.05). NSAID was more common in the early onset group (90 vs. 75.9%, p<0.001) with no difference for COX2 inhibitors.

Conclusion: Patients with young onset of RA presented with more risk factors for poor prognosis but those with late onset had higher disease activity. YORA were treated with more DMARDs in early disease whilst those with LORA were treated more often with corticosteroids. This may have implications for development of co-morbidities.

Impact of Severity Index for Rheumatoid Arthritis On Healthcare Costs and Utilizations in Patients with Rheumatoid Arthritis. Onur Baser[1], Li Wang[2], Juan Du[3], Hai Wang[3] and Lin Xie[3]. [1]STATinMED Research/The University of Michigan, Ann Arbor, MI, [2]STATinMED Research, Dallas, TX, [3]STATinMED Research, Ann Arbor, MI

Background/Purpose: Examine the impact of a claims-based severity index for rheumatoid arthritis (RA) on healthcare costs and utilizations of RA patients using large U.S. claims data.

Methods: Adult patients with at least two RA diagnoses and 12 months of continuous health plan enrollment before and after the index date (first RA diagnosis date) were identified from a large U.S. claims database (10/1/2008 to 09/30/2009). A severity index for rheumatoid arthritis (SIFRA) was developed by calculating a weighted sum of 34 RA-related indicators including laboratory, clinical and functional status, extra-articular manifestations, surgical history, and medications as assessed by an expert Delphi panel of six rheumatologists. The relationship between SIFRA terciles and healthcare utilizations and costs was also examined using histograms. A regression model was used to examine the improvement of the model fitting by adding SIFRA.

Results: A total of 23,951 RA patients (mean SIFRA: 9.14) with laboratory information were identified. Descriptive analysis showed that patients in the upper tercile of SIFRA incurred $9,123 more all-cause healthcare costs and $1,326 more RA-related healthcare costs than patients in the lower tercile of SIFRA. The most dramatic difference between highest and lowest SIFRA terciles occurred with pharmacy costs ($6,860 vs. $1,919, p<0.001). Healthcare visits followed a similar to healthcare costs for SIFRA terciles. Patients in the highest SIFRA tercile had higher total office visits (110.14 vs. 77.16, p<0.001) and higher RA-related visits (6.72 vs. 3.93, p<0.001) compared to patients in the lowest tercile. Regression results showed that the model was more than 6-times (611%) superior in explaining the variation in outcomes after adding SIFRA into the model.

Conclusion: SIFRA demonstrated evidence of being a significant determinant of healthcare costs and utilizations for RA patients. This study suggests that SIFRA could be an important methodological tool to control for severity in RA-related outcomes research.

Risks to Visit Emergency Room in Patients with Rheumatoid Arthritis: A Two-Year Retrospective Study. Yoshiki Nagai, Naoto Yokogawa, Kota Shimada and Shoji Sugii. Tokyo Metropolitan Tama Medical Center, Tokyo, Japan

Background/Purpose: Patients with rheumatoid arthritis (RA) suffer from both physical disabilities and medical comorbidities and tend to use emergency room for many reasons. However, the detail has not been well investigated from the perspective of emergency medicine. The aim of this study is to identify the risks to visit emergency room in RA patients.

Methods: We retrospectively reviewed all emergency room visits in RA patients followed at Tokyo Metropolitan Tama Medical Center from April 2007 to March 2009 using an electric health record system. We compared the characteristics of RA patients who visited emergency room ("ER user group") to those who did not visit emergency room ("Control"). We compared the background characteristics between the two groups. A logistic regression analysis was performed to evaluate the risks of emergency room visits.

Results: "ER user group" and "Control" included 294 and 298 patients. The background characteristics of both groups were summarized in Table 1. By a logistic regression analysis, cardiovascular diseases, prednisolone>5mg/d, anti-TNF agents, age over 65, and pulmonary diseases predicted emergency room visits with odds ratio of 4.2, 3.5, 3.3, 1.7, and 1.6 respectively (Table 2).

Table 1

Background characteristics of "ER user" and "Control"

	ER user (294 pts) N (%)	Control (298 pts) N (%)	p
Age, year±SD	68.0±11.1	63.1±12.3	<0.001
Disease duration, year±SD	15.3±12.6	12.8±11.7	0.017
Female	235 (80%)	241 (81%)	NS
Diabetes mellitus	49 (17%)	27 (9%)	0.005
Pulmonary diseases[*1]	82 (28%)	49 (16%)	0.001
Cardiovascular diseases[*2]	40 (14%)	8 (3%)	<0.001
Glucocorticoids	214 (73%)	149(50%)	<0.001
Prednisolone equivalent (mg/day)	4.2±4.0	2.2±2.6	<0.001
Methotrexate	146 (50%)	143 (48%)	NS
Anti-TNF agents	28 (10%)	12 (4%)	0.007
Salazosulfapyridine	54 (18%)	55 (18%)	NS
Bucillamine	43 (15%)	32 (11%)	NS

[*1] Pulmonar diseases: interstitial lung disease, old tuberculosis, asthma, bronchiectasis, nontuberculous mycobacteriosis, chronic obstructive pulmonary disease

[*2] Cardiovascular diseases: heart failure, old myocardial infarction, angina pectoris

NS: not statistically significant

Table 2. Multivariate logistic analysis to predict emergency room visits

Variable	Odds ratio	P
Cardiovascular disease	4.2	<0.001
Prednisolone equivalent >5mg/d	3.5	<0.001
Anti-TNF agents	3.3	0.001
Age over 65	1.7	0.003
Diabetes mellitus	1.7	NS (0.051)
Pulmonary disease	1.6	0.030

[*1] Pulmonar diseases: interstitial lung disease, old tuberculosis, asthma, bronchiectasis, nontuberculous mycobacteriosis, chronic obstructive pulmonary disease
[*2] Cardiovascular diseases: heart failure, old myocardial infarction, angina pectoris
NS: not statistically significant

Conclusion: Preexisting cardiovascular disease, prednisolone>5mg/d, and anti-TNF agents were considered higher risks for emergency room visits in patients with RA.

Peer to Peer Mentoring for Individuals with Early Inflammatory Arthritis: Feasibility Pilot.
Mary J. Bell[1], Paula Veinot[2], Gayathri Embuldeniya[2], Joyce Nyhof-Young[3], Joanna Sale[4], Joan Sargeant[5], Peter Tugwell[6], Sydney Brooks[7], Susan Ross[7], Ruth Tonon[7], Sharron Sandhu[8], Dawn Richards[8], Jennifer Boyle[7], Kerry Knickle[9], Nicky Britten[10], Emma Bell[2], Fiona Webster[9] and Mary Cox-Dublanski[11], [1]Sunnybrook Health Sciences Centre and University of Toronto, Toronto, ON, [2]Sunnybrook Health Sciences Centre, Toronto, ON, [3]University Health Network, University of Toronto, Toronto, ON, [4]University of Toronto, St. Michael's Hospital, Toronto, ON, [5]Dalhousie University, Halifax, NS, [6]University of Ottawa, Ottawa General Hospital, Ottawa, ON, [7]The Arthritis Society, Ontario Division, Toronto, ON, [8]Canadian Arthritis Network Consumer Advisory Council, Toronto, ON, [9]University of Toronto, Toronto, ON, [10]University of Exeter, Exeter, United Kingdom, [11]St. Mary's General Hospital, Kitchener, ON

Background/Purpose: The goal of this research is to examine the potential benefit of early peer support to improve the health and quality of life of individuals with early inflammatory arthritis (EIA). This poster presents preliminary findings of a pilot study, as part of a complex healthcare intervention, to assess acceptability and feasibility of a peer support intervention for individuals with EIA.

Methods: Qualitative and quantitative methods were used to evaluate a feasibility pilot of a peer mentoring intervention for individuals with EIA. Individuals with IA (diagnosed at least 2 years and managing well) were recruited through a rheumatology clinic, The Arthritis Society, and research team to be trained as peer mentors A peer mentor training model was developed consisting of 18 hours of didactic and interactive sessions over 4 non-consecutive days. Individuals with EIA (mentees; disease duration 6–52 weeks) were recruited through 2 rheumatology clinics. Trained peer mentors were paired with an individual with EIA to provide one-on-one support (face-to-face or telephone) up to once a week over a 12 week period. Peer mentor *self-efficacy* was assessed at baseline, immediate post-training, immediate post-peer mentoring program and 3-months follow-up. Mentees were assessed at baseline, immediate post-program and 3-months follow-up re: *disease modifying anti-rheumatic drugs (DMARDs)/biologic treatment use, self-efficacy, self-management, health-related quality of life, anxiety, coping-efficacy, social support* and *disease activity*. Results were examined using descriptive statistics, and effect sizes were calculated to determine clinically important changes (changes >0.3 considered important). One-on-one interviews with participants were also conducted to examine acceptability and feasibility of study procedures and outcome measures and to gain perspectives on the value of peer support. Key themes were identified through constant comparison.

Results: Nine pairs participated. The training was well-received by peer mentors. Peer mentors' self-efficacy increased significantly after training completion. Mentees experienced improvement in overall arthritis impact on life, coping, and social support (effect size>0.3). Mentees perceived emotional, informational, appraisal, and instrumental support, while mentors themselves reported benefits (e.g., new self-management techniques, lifestyle changes), and learned from mentees' fortitude and self-management skills. Participants' experience of peer support was informed by the unique relationship they forged with their peer partner. All participants were unequivocal about the need for peer support for the newly diagnosed.

Conclusion: Early peer support is proposed as a way to augment current care in rheumatology. The intervention was well-received. The training process, peer support program, and outcome measurements were demon-strated to be feasible with modifications. This intervention has been expanded to a small pilot RCT study to demonstrate effectiveness of peer support in EIA management.

Atsttrin-â, an Engineered Protein Derived From Progranulin Growth Factor, Binds to TNF Receptors and Exhibits Potent Anti-Inflammatory Activity in Mice.
Yunpeng Zhao[1], Qingyun Tian[1], Haicheng Song[1], Fanhua Wei[1] and Chuanju Liu[2]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York University, New York, NY

Background/Purpose: Progranulin (PGRN) is a multifunctional growth factor. Recently, we reported that PGRN and its derived protein Atsttrin-α (referred to as "Atsttrin" in our previous publication) directly bound to TNF receptors (TNFR), blocked the binding of TNF to TNFR and inhibited TNF activity (Tang, W., et al, *Science*, 2011 Apr 22;332 (6028):478–484). It is well established that TNF family ligands bind to receptors in a heterohexameric 3:3 complex. Atsttrin-α was comprised of the three functional fragments of PGRN, thus we hypothesized that the three fragments of Atsttrin-α act independently for interacting with TNFR. If so, change of order of the three fragments would not affect binding activity to TNFRs. In this study, we created a novel engineered protein, Atsttrin-β which comprised the same fragments as Atsttrin-α but in a different order. The purpose of this project is to determine whether the novel protein Atsttrin-β is able to block the binding of TNF-α to TNFR, and has therapeutic effect in inflammatory arthritis, as does Atsttrin-α.

Methods: Yeast-two hybrid assay was used to compare the binding to TNFR between Atsttrin-α and Atsttrin-β; Solid-phase binding was performed to determine the Atsttrin-β inhibition of TNF-α binding to TNFRs; Collagen-induced arthritis(CIA) in DBA-IJ mice and TNF-α transgenic (hTNF-tg) mice that spontaneous inflammatory arthritis. Mice were divided into various groups and injected intraperitoneally with PBS, etanercept, Atsttrin-α and Atsttrin-β. Clinical assessment for arthritis scores, micro CT for bone erosion and histological analysis of joint sections were performed.

Results: Yeast-two hybrid assay showed that Atsttrin-β bound to TNFR1 and TNFR2, as did Atsttrin-α; Solid-phase binding assay revealed that Atsttrin-β inhibited TNF-α from binding to TNFRs in a dose-dependent manner. Clinical scores, Micro CT and histological analysis of joints from CIA model and hTNF-tg mice demonstrated that Atsttrin-β attenuated synovial proliferation, infiltration of inflammatory cells, cartilage destruction and bone erosion compared with vehicle-treated mice, and these effects were shown in dose-dependent manners.

Conclusion: These findings suggest the three functional fragments of Atsttrin-α worked independently in binding to TNFRs and blocking TNF-α activity, and the novel engineered protein Atsttrin-β has anti-inflammatory effect and may represent a promising alternative in treatment of rheumatoid arthritis.

Action of Tofacitinib Via Human Dendritic Cells.
Satoshi Kubo, Kunihiro Yamaoka, Shigeru Iwata and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background/Purpose: Tofacitinib, an oral Janus Kinase (JAK) inhibitor, has gathered attention in treatment of Rheumatoid arthritis (RA). Although JAKs are well known for its importance in lymphocyte development and

expressed in monocyte lineage cells, the effect of tofacitinib on the maturation and function of human dendritic cells (DCs) remains unknown.

Methods: Human monocyte-derived DCs were generated with granulocyte macrophage colony-stimulating factor and IL-4. DCs were matured with lipo-polysaccharide (LPS) in the presence of tofacitinib in vitro for 48 hours and cytokine production, cell survival and surface markers were assessed by flow cytometry. After washout of tofacitinib, DCs were co-cultured with CD4+CD45RA+ naive T cells purified from healthy donor, and allogeneic-mixed lymphocyte reaction (aMLR) performed to evaluate T-cell stimulatory capacity.

Results: When DCs were stimulated with LPS, expression of CD80, CD86 and HLA-DR were strongly induced. However, the addition of tofacitinib to DCs reduced expression of CD80 and CD86, but not HLA-DR, indicating that maturation was disturbed. Tofacitinib also inhibited the production of TNF-α (6217ng/ml to 4964ng/ml), IL-6 (43640ng/ml to 33027ng/ml) and IL-1β (22ng/ml to 13ng/ml) at 300nM, and the inhibitory effect was in a dose dependent manner. On the contrary, the production of TGF-β from DCs was not affected. Notably, tofacitinib increased the levels of indoleamine 2, 3-dioxygenase (IDO), an immunomodulatory enzyme in DCs. Co-culture of tofacitinib-treated DCs with allogeneic naive T cells resulted in reduction of T-cell proliferation and IFN-γ production. However, CD4+CD25+ FoxP3+ regulatory T cell population was not affected.

Conclusion: In addition to the previously known effect of tofacitinib on acquired immunity, our results indicate that tofacitinib could affect the innate immunity. Importantly, tofacitinib attenuated the LPS-induced upregulation of costimulatory molecules during DC maturation. This resulted in a decreased allo-reactive T cell response. Moreover, tofacitinib suppressed inflammatory cytokine production and induced IDO expression. Taken together, these data provide novel potential mechanisms of action of tofacitinib, the restoration of immunoregulation as well as anti-inflammation, in patients with rheumatoid arthritis.

2151

Inhibitory Effect of Type I Interferon On Interleukin-17 Response in Rheumatoid Arthritis Fibroblast-Like Synoviocytes.
Eva Ruzicska[1], Hannelie F. Semmelink[2], Gyula Poor[3], P. P. Tak[4] and L.G.M. van Baarsen[5]. [1]Budapest, Hungary, [2]Amsterdam, Netherlands, [3]National Inst of Rheumatology, Budapest, Hungary, [4]Academic Medical Center/University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands, [5]: Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Type I interferon (IFN) response genes are upregulated in several inflammatory diseases, including systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and multiple sclerosis (MS). Whereas in SLE this type I IFN signature is associated with disease severity, IFN-beta (IFNβ) is a beneficial treatment in two-third of the patients with MS. In RA the functional role of the type I IFN signature in disease pathogenesis is unclear. The effects of type I IFN may be dependent on the specific type of interferon, the disease and the tissue. Recent studies have shown that administration of type I IFN can confine the inflammatory response by inhibiting Th17 development. The recently discovered interleukin (IL)-17 producing Th17 cells appear to play a pro-inflammatory role in the pathogenesis of RA. IL-17 has been shown to act on several cell types in order to protect against microbial infection but can also promote and maintain inflammatory processes. Accordingly, tight regulation of the IL-17 response is required to prevent inflammation and autoimmunity.

Giving the above mentioned function of type I IFN in limiting the Th17 response, we investigated whether type IFN can modulate the pro-inflammatory effect of IL-17 on fibroblast-like synoviocytes (FLS).

Methods: Synovial tissues were obtained by arthroscopy of eight rheumatoid arthritis patients (RA), two osteoarthritis patients (OA) and four non-disease control individuals (HD). Subsequently, FLS were isolated and cultured in the presence of TNF (1 ng/ml), IFNβ (100 U/ml), IL-17A (50

ng/ml), or combinations thereof. Supernatants were collected 24 or 48 hours after treatment and levels of IL-6 and IL-8 were measured by ELISA.

Results: We examined the modulatory effect of type I IFN on IL-17A induced IL-6 and IL-8 production by FLS in the presence and absence of TNF (Table 1). A large variation in IL-17 response between different donors was observed with respect to production of IL-6 and IL-8. As expected, TNF had a synergistic effect on the IL-17 induced cytokine response. On group level, IFNβ had no inhibitory effect on the IL-17 induced IL-6 cytokine production, but there was a large variation in IFNβ sensitivity between donors. While in some donors IFNβ had no effect on the IL-17 induced cytokine response, in other donors IFNβ had a clear inhibitory effect. Interestingly the IL-17 induced IL-8 production could be inhibited by IFNβ, after both 24 and 48 hours. No differences were observed between the different diagnoses.

Table 1.

Change in IL-6 production in the presence of IFNβ (median (IQR))	RA		HD		OA	
	24h	48h	24h	48h	24h	48h
Modulation of IL-17A response (%)	144.5 (104.4–150)	124.1 (75.74–161)	123.5 (99.42–169.6)	88.72 (73.21–118)	221.4 (123.3–319.6)	98.98 (41.52–185)
Modulation of TNF response (%)	104.3 (94.39–112.8)	91.6 (71.85–108.5)	109.9 (65.76–154.9)	89.12 (76.89–137.9)	117.3 (94.84–139.8)	110 (60.37–159.1)
Modulation of IL-17A+TNF response (%)	114.4 (85.74–160.3)	79.08 (45.11–140.9)	77.99 (66.02–100.5)	102.9 (77.01–124.7)	85.32 (78.43–92.22)	110 (103.8–116.2)
Change in IL-6 production in the presence of IFNβ (median (IQR))	RA		HD		OA	
	24h	48h	24h	48h	24h	48h
Modulation of IL-17A response (%)	31.09 (0–92.26)	48.18 (28.48–561.7)	47.87 (0–65.98)	81.43 (50.72–112.1)	67.92 (35.85–100)	50 (0–100)
Modulation of TNF response (%)	28.38 (0–37.3)	47.74 (29.41–63.61)	44.03 (32.88–47.35)	34.68 (27.46–41.91)	30.05 (23.2–36.91)	14.13 (2.223–26.04)
Modulation of IL-17A+TNF response (%)	54.59 (37.41–61.82)	79.82 (45.32–102)	57.88 (42.73–66.62)	86.74 (69.15–104.3)	59.97 (49.52–70.42)	48.91 (44.72–53.1)

Conclusion: These findings suggest that in a pro- inflammatory environment IFNβ can modulate the IL-17 response by inhibiting IL-8 production in FLS, whereas the effect on IL-6 production is donor dependent. These data provide further insight into the anti-inflammatory role of IFNβ in inflammatory diseases with possible implications for treatment.

Inhibition of Fucose Incorporation Abrogates the Development of Arthritis by Suppressing the Inflammatory Macrophage Development and TNF-α Production.
Jun Li[1], Hui-Chen Hsu[2], PingAr Yang[1], Qi Wu[1], David M. Spalding[1], W. Winn Chatham[1], Robert P. Kimberly[1], S. Louis Bridges Jr.[1] and John D. Mountz[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham and Birmingham VA Medical center, Birmingham, AL

Background/Purpose: Fucosylation, catalyzed by fucosyltransferases (Futs), is an important glycosylation process involved in inflammation, cell death, and differentiation. We have observed an extremely high positive correlation between *Tnfα* and *Fucosyltransferases 1 and 3* (*Fut1* and *Fut3*, p=0.0001) in rheumatoid arthritis (RA) synovial tissues. However, the role of fucosylation in RA has not been extensively studied. The purpose of this study is to determine: *(i)* expression of *Futs* in different cell population isolated from human RA synovial fluid; *(ii)* the effect of a fucosylation inhibitor on RA effector cell differentiation; and *(iii)* the ability of a fucosylation inhibitor to suppress the development of collagen II-induced arthritis (CIA) in mice.

Methods: Twenty RA subjects were recruited in this study. Real-time PCR was used to determine the expression of *Fut1* and *Fut3* in FACS sorted cell subsets from fresh RA synovial fluids. Purified human synovial macrophages (MΦs) were cultured with GM-CSF and CD4 T cells were polarized towards Th1 and Th17 cells with and without the presence of 15 mM 6-Deoxy-L-galactose (fucose) or its analog, 2-Deoxy-D-galactose (2-D-gal) which can inhibit the fucosylation process. Cytokines in the supernatant were measured by ELISA. CIA was induced in DBA/1J mice. Fucose or 2-D-Gal

(200 mg/kg BW, every 2–3 days) was administered via I.P. initiated on Day 1. FACS, ELISA and histopathology analysis were performed on Day 40.

Results: In FACS sorted cells from fresh human RA synovial fluid, the expression of *Fut1* and *Fut3* was five-fold higher in M1 inflammatory MΦ (CD68⁺CD80⁺) compared to M2 MΦ (CD68⁺CD80⁻), with lower expression in Th1, Th17, total memory and naïve CD4 T cells. *In vitro* 2-D-gal treatment for 3 days lead to dramatic cell death of purified human MΦ and reduced levels of TNF-α (3800 pg/ml vs 450 pg/ml, p<0.001) in the supernatant. There was, however, no inhibitory effect of 2-D-gal on human Th1 or Th17 differentiation *in vitro*. *In vivo* treatment of 2-D-gal in DBA/1J mice immunized with bovine CII abrogates the development of arthritis whereas the same dose of fucose exacerbated it (arthritis scores: control, 9.5±1.7; 2-D-gal, 0.5± 0.3; Fucose, 15.3± 2.2, p<0.01). FACS analysis revealed that the percentages of inflammatory MΦ (CD11b⁺TNF-α⁺) in the draining LN were reduced by 2-D-gal but were increased by Fucose (control 1.1±0.23; 2-D-gal, 0.6±0.10; Fucose, 1.5± 0.32, p<0.05). 2-D-gal treatment also resulted in significantly decreased levels of TNF-α (130.1 vs 39.4pg/ml, p<0.05) and anti-CII total IgM and IgG in the serum. Joint histopathology showed a significantly decreased macrophage infiltration, synovial hyperplasia, cartilage damage, and bone erosion in 2-D-gal treated mice. No significant liver and renal toxicity and dysfunction was observed.

Conclusion: Our results show that *Futs* are highly expressed in inflammatory MΦ and fucosylation is a critical process regulating MΦ differentiation and TNF-α production. Inhibition of fucose incorporation by 2-D-gal significantly impairs inflammatory macrophage development and function, completely blocking development of arthritis without systematic toxicity. Our results suggest that MΦ fucosylation may be a new therapeutic target for RA.

Target-Directed Development of a Proposed Biosimilar Rituximab (GP2013): Comparability of Antibody-Dependent Cellular Cytotoxicity Activity and Pre-Clinical Pharmacokinetics and Pharmacodynamics with Originator Rituximab. Antonio da Silva, Ulrich Kronthaler, Ines Meyer, Anastassia Papandrikopoulou, Thomas Stangler and Jan Marinus Visser, Sandoz Biopharmaceuticals / HEXAL AG, Holzkirchen, Germany

Background/Purpose: Biosimilars are biologics approved by highly-regulated markets as similar to existing agents, with the aim of offering more affordable treatment and thereby increasing patient access. Development of a biosimilar involves extensive characterization of the originator product over several years and a target-directed iterative development process to ensure a product that is highly comparable to the originator with similar clinical efficacy, safety and quality. Using antibody-dependent cellular cytotoxicity (ADCC), a main mode of action of rituximab, we illustrate how functional/structural relationship can be engineered into a biosimilar to ensure comparability at the *in vitro* level. Here we present pre-clinical data confirming *in vivo* comparability for the proposed biosimilar rituximab GP2013, in terms of pharmacokinetics (PK), pharmacodynamics (PD) and efficacy.

Methods: By employing a highly sensitive glycan quantitation method, relevant post-translational glycosylation patterns were assessed for their impact on *in vitro* ADCC relative potency data using the Raji and NK3.3 cell lines as target and effector cells, respectively. Subsequently, bioactivity of GP2013 and originator rituximab were evaluated in a dose-response manner across a wide concentration range against SU-DHL-4 (diffuse large B-cell lymphoma) and Daudi (Burkitt's lymphoma) cell lines using freshly purified human NK cells. *In vivo* anti-tumor activity was assessed in two xenograft SCID mouse models of non-Hodgkin's lymphoma (SU-DHL-4 and Jeko-1 cell lines). Comparative PK and PD were assessed in single (5 mg/kg, n=14) and multiple (20 or 100 mg/kg, n=8) dose studies in cynomolgus monkeys, the pharmacologically most relevant species.

Results: GP2013 and originator rituximab showed similar ADCC potency against both SU-DHL-4 and Daudi cells, with ADCC being reflective of engineered glycosylation patterns and structure-function relationships. In both xenograft mouse models, GP2013 and originator rituximab inhibited tumor growth to a similar extent, including at the more sensitive sub-optimal dose levels that are most likely to identify any potential differences. In primates, PK analysis confirmed bioequivalence between GP2013 and originator rituximab with nearly identical AUC values and 90% CIs entirely within the standard acceptance range of 0.8–1.25. Bioequivalence of PD response (B-cell depletion) was also shown, with 95% CIs of areas under the effect-time curves (AUEC) ratios for relative change from baseline in B-cell populations within the 0.8–1.25 acceptance range. The use of different doses indicated that comparable exposure and PD response can be expected for GP2013 and originator rituximab using indication-specific dosing regimens.

Conclusion: This pre-clinical comparability exercise confirms that GP2013 and originator rituximab are pharmacologically similar with regard to ADCC potency, anti-tumor activity, PK exposure (AUC) and B-cell depletion. As such, GP2013 is anticipated to show similar efficacy and safety as the originator product in ongoing clinical trials across different clinical indications.

Regulation of Folate Pathway Related Genes in Methotrexate naïve and Methotrexate Treated Patients with Rheumatoid Arthritis. Marjolein Blits[1], Gerrit Jansen[1], Saskia Vosslamber[1], Yehuda G. Assaraf[2] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Haifa, Israel

Background/Purpose: Rheumatoid arthritis (RA) is one of the most prevalent systemic autoimmune disorders. The folate antagonist methotrexate (MTX) is an anchor drug in the treatment of RA. Here, we aim to provide insight into the pharmacological effects of MTX by gene expression analysis

Methods: Subanalysis of microarray data was performed for a set of 18 genes involved in the methotrexate/folate pathway using peripheral blood gene expression data of 10 MTX naïve RA patients (MTX-), 25 RA patients treated with MTX (MTX+), and 15 healthy controls which were age and sex-matched (test cohort). Multiplex realtime PCR of these methotrexate/folate pathway related genes was performed on second cohort consisting of 28 MTX naïve RA patients (MTX-), 180 RA patients treated with MTX (MTX+) and 24 healthy controls (validation cohort). Statistical analysis was performed using Student's t test or Mann-Whitney U test. P-values of ≤0.05 were considered to be statistically significant.

Results: Several folate/MTX-related genes were markedly and significantly altered between the three study groups in the test cohort. Metabolizing enzymes FPGS (p=0.0035) and GGH (p<0.0001) were significantly up-regulated in the MTX⁻ RA group compared to the healthy control group (HC group). For the folate dependent enzymes we found that GART (p=0.0004) expression was decreased in the MTX⁻ group compared to HC. In the efflux transporters, MRP3 (p=0.0335) was significantly higher expressed in the MTX⁻ group compared to HC. The other genes displayed no significant change in the test cohort. In the validation cohort we were able to validate most of the genes except FPGS, GART for MTX⁻ compared to HC. In both test and validation cohort the differentially altered genes in the MTX⁻ group returned to a normal range as observed in the HC.

Conclusion: Overall, these results indicate that, under inflammatory conditions basal folate metabolism is altered in blood cells of RA patients compared to HC. Treatment with MTX restores expression of these genes to the levels within the range of the HC group.

The Annualized Progression of Radiologic Damage in Placebo Arms of Rheumatoid Arthritis Trials Is Much Lower Than the Mean Annual Progression Since Disease Onset. Jean-Marie Berthelot and Celine Cozic. Nantes University Hospital, Nantes, France

Background/Purpose: A previous meta-analysis by Graudal and Jürgens (*Arthritis Rheum.* 2010;62:2852–63) challenged the belief that biologics better protect rheumatoid arthritis (RA) from joint destruction than DMARDs or glucocorticoids. Destruction rates had been expressed as percentages of the maximal scores and annualized. We aimed to re-analyse this work and: 1-seek for differences in baseline radiologic scores, and mean progression of destruction rates since the onset of RA, according to the subset of drug tested

(DMARD, combination of DMARDS, glucocorticoids, biologics); 2-compare destruction rates since RA onset and during the period of the trial, both in the *verum* arms and placebo arms.

Methods: All studies from groups II to V of this meta-analysis were retrieved and re-analysed by two independent readers. Destruction rates could be calculated both since RA onset and per-trials in 41/55 studies (41 *verum* arms, and 43 control arms).

Results: Baseline scores were higher in patients from biologic trials, but duration of RA was also longer. Consequently, destruction rates before baseline were even lower in biologic trials. In absolute values, difference between *verum* and controls were not superior in trials of biologics, but when expressed as % of reduction as compared to per-trial destruction rates in the control arms, biologics seemed more efficient (71% +/ 19, median: 78%), than DMARDs (52% +/− 41, median: 64%) and glucocorticoids (52% +/− 22, median: 48%). The per-trial mean destruction rates were (much) lower than the mean destruction rates since RA onset in the four groups, even in the placebo arms, especially in biologic trials. Only placebo arms appear in the figure below. Boxplots represent median, lower and upper quartile, and 95th percentiles.

II = single DMARDs; III = combination DMARDs
IV = glucocorticoids; V = biologics
Conclusion: 1-The difference of per-trial radiographic progression might have biased the results of the previous meta-analysis. When expressed as ratio of destruction rates between *verum* and control arms, biologics performed better, although DMARDS and glucocorticoids were also clearly effective; 2-'expected worsening' as a substitute for placebo arms is inappropriate, and should be banned.

Anti-Cyclic Citrullinated Protein Antibodies As a Predictor of Response to Tocilizumab in Patients with Rheumatoid arthritis A Prospective Study. Kensuke Kume[1], Kanzo Amano[1], Susumu Yamada[1], Kuniki Amano[2], Kazuhiko Hatta[3], Hiroyuki Ohta[4] and Noriko Kuwaba[5]. [1]Hiroshima Clinic, Hiroshima, Japan, [2]Sky Clinic, Hiroshima, Japan, [3]Hatta Clinic, Kure, Japan, [4]Hiroshima, Japan, [5]Sanki Clinical Link, Hiroshima, Japan

Background/Purpose: Tocilizumab, interleukin-6 receptor antibody is very effective in patients with rheumatoid arthritis (RA). Anti-cyclic citrullinated protein antibodies (ACPA) are highly specific and sensitive for RA. There are several reports that the correlation between the efficacy of anti-tumor necrosis factor and the titer of ACPA. There is no evidence that the correlation between the efficacy of Tocilizumab and ACPA.To investigate the Tocilizumab on ACPA, and its association with treatment response.

Methods: RA patients were eligible if they had active disease despite treatment with methotrexate (MTX). Fifty four consecutive IgM-rheumatoid factor positive patients with RA were treated with infusion of 8mg/kg tocilizumab every 4 weeks. Disease activity was assessed by DAS28 score. ACPA titer was measured by a commercial ELISA at Week 0 and Week 24.The primary outcome was correlation between clinical response to therapy and ACPA titer. Secondary outcome was the change of ACPA titer from baseline to week 24.

Results: Primary outcome: There was a significant correlation between clinical response to therapy and ACPA titer(r=0.54, p<0.02). Secondary outcome: There was no change of ACPA titer from baseline to week 24(p=0.76). No patient at baseline turned negative at week 24 for ACPA (negative cut off<4.5U/ml).

Conclusion: ACPA titer might be predictor of the efficacy of Tocilizumab in patients with RA. Tocilizumab treatment didn't affect the change of ACPA titer.

Resveratrol Counters Pro-Atherogenic Effects of Systemic Lupus Erythematosus and Rheumatoid Arthritis Plasma On Cholesterol Efflux in Human Macrophages. Allison B. Reiss, Iryna Voloshyna, Ofek Hai, Michael J. Littlefield, Elise Belilos, Kristina B. Belostocki, Lois A. Bonetti, Gary C. Rosenblum and Steven E. Carsons. Winthrop University Hospital, Mineola, NY

Background/Purpose: Our group has demonstrated that resveratrol, a plant polyphenol, possesses atheroprotective properties, enhancing expression of reverse cholesterol transport (RCT) proteins. We have reported that Systemic Lupus Erythematosus (SLE) and rheumatoid arthritis (RA) patients manifest a pattern of disturbance in expression of RCT genes that is atheroma-promoting. The cholesterol efflux proteins 27-hydroxylase, ATP binding cassette transporter (ABC) A1 and ABCG1 are suppressed by plasma from persons with these autoimmune rheumatic diseases. These proteins are crucial for efficient cholesterol efflux from macrophages, a process that prevents foam cell formation (FCF) and protects against atherosclerosis. This study examines whether resveratrol can protect macrophages from pro-atherogenic effects of SLE and RA plasma on cholesterol metabolism.

Methods: ABCA1, ABCG1 and 27-hydroxylase expression were evaluated in THP-1 human macrophages, a pertinent model of atherosclerosis. Cells were incubated for 18h in 10% pooled SLE, RA or normal human plasma (NHP) $\pm$ resveratrol (25μM). mRNA was isolated and reverse transcribed. The resulting cDNA was subjected to quantitative PCR with specific primers for each gene. Cell extracts were prepared for immunoblotting after 24h. FCF was quantified as % oil red O stained cells. Studies were done in triplicate.

Results: 10% SLE plasma suppressed ABCA1 and ABCG1 expression by $58.3 \pm 15.5\%$ (n=3, P<0.001) and $48.3 \pm 18.7\%$ (n=3, P<0.01) below NHP, respectively (NHP set as 100%). 10% RA plasma induced similar levels of ABC transporter downregulation. 27-hydroxylase message level fell by $36.2 \pm 12.8\%$ and $49.1 \pm 14.7\%$ (n=3, P<0.01) below NHP, respectively for SLE and RA plasma. When THP-1 macrophages were incubated with SLE or RA plasma + resveratrol, the resveratrol significantly negated downregulation of efflux proteins, restoring levels to that observed with NHP (Fig 1). FCF by THP-1 macrophages was significantly reduced by addition of resveratrol compared to SLE or RA plasma alone (by $22.2 \pm 5.1\%$ and $35 \pm 7.5\%$, respectively [n=3, P<0.01]).
Fig 1. *-P<0.05; ** P<0.01; *** P<0.001 vs. NHP; # P<0.05, ## P<0.01 vs. corresponding plasma without resveratrol.

Conclusion: Resveratrol is able to counteract pro-atherogenic factors in SLE and RA plasma. Resveratrol acts as an anti-atherogenic agent by preventing lipid overload via effects on cholesterol transport. Since resveratrol has a strong safety profile and is well-tolerated, low cost, and can be used in combination with multiple other therapies without contraindication, these findings provide the rationale for a novel therapeutic approach to decrease the cardiovascular consequences of RA and SLE. Administration of resveratrol in these groups of patients might restore a critical defense mechanism against atherosclerosis and cardiovascular disease progression. Further in vivo studies are indicated for this promising treatment option.

2158

Baseline Folate Related Biomarkers in Serum and erythrocytes Are Not Associated with Methotrexate Response and Adverse Events in Rheumatoid Arthritis. Maurits C.F.J. De Rotte[1], Saskia M.F. Pluijm[2], Maja Bulatovic[3], Johanna M.W. Hazes[1] and Robert De Jonge[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus Medical center, Rotterdam, Netherlands, [3]University Medical Centre Utrecht, Netherlands

Background/Purpose: Methotrexate (MTX) is the most commonly used drug in rheumatoid arthritis (RA). 30% of patients fail to respond to the drug or suffer from adverse events. Therefore, there is a need to identify determinants of MTX response and adverse events in RA. MTX is an antagonist for folate and interferes with folate homeostasis. We investigated whether folate-related biomarkers, including homocysteine (HCy), vitamin B6, B12 and folate, measured at baseline were associated with MTX response and adverse events over nine months of treatment.

Methods: The study included patients from two longitudinal cohorts who were diagnosed with RA according to the 2010 ACR criteria and were treated with MTX therapy: 285 patients from the treatment in Rotterdam Early Arthritis Cohort (tREACH) (1) and 99 from the Methotrexate in Rotterdam (MTX-R) study. Serum concentrations of HCy, B6, B12 and folate, and folate in erythrocytes were determined at baseline (t0). MTX response was assessed with the disease activity score (DAS)-28 at 0,3,6 and 9 months after MTX start and EULAR response criteria at 3,6 and 9 months. Adverse events were defined as gastro-intestinal intolerance and overall complaints at 3,6 and 9 months. Using DAS 28 as outcome measure, analysis of covariance (ANCOVA), adjusted for age, gender, DAS28 at baseline, MTX dose, MTX route of administration, other DMARDs, NSAIDs, steroids and study cohort, was used. EULAR and adverse events were analyzed with logistic regression. Biomarkers were analyzed as continuous variables, quintiles and tertiles.

Results: Concentrations at baseline (mean/SD) were: homocysteine: 12.9 μmol/l (5.9), B6: 93 nmol/l (97), B12: 322 pmol/l (131), folate in serum: 23 nmol/l (35) and folate in erythrocytes: 1007 nmol/l (450). DAS28 was 4.76 (1.26) at baseline and 3.08 (1.20), 2.91 (1.22), 2.68 (1.16) at 3,6 and 9 months. 52%,26% and 24% had gastro-intestinal complaints at 3, 6 and 9 months, respectively. 46%, 49% and 47% of the patients reported one or more adverse events at 3 6 and 9 months of follow-up.

None of the biomarkers (defined as continuous measure) were associated with DAS28 at all 3 time-points (table). For HCy we only found a positive association at 6 months (standardized-β = 0.18, p = 0.001), whereas folate in erythrocytes was only associated negatively with DAS28 at 3 months (st-β = −0.14, p = 0.017). Analyses with biomarkers divided into quintiles or tertiles showed similar results. In addition, no associations were found between any of the baseline biomarkers and EULAR response criteria or adverse events.

Table. Analysis of covariance for the association between folate related biomarkers and DAS28

Biomarkers	3 months Standardized-β (p)	6 months Standardized-β (p)	9 months Standardized-β (p)
Homocysteine	−0.06 (0.278)	0.18 (0.001)*	−0.03 (0.650)
Vitamin B6	−0.01 (0.912)	−0.03 (0.633)	−0.08 (0.197)
Vitamin B12	0.01 (0.792)	−0.08 (0.141)	0.00 (0.949)
Folate in serum	−0.04 (0.396)	−0.05 (0.415)	−0.01 (0.928)
Folate in RBC	−0.14 (0.017)*	−0.07 (0.296)	0.06 (0.394)

* = significant. All analyses are adjusted for age, gender, DAS28 at baseline, MTX dose, MTX route of administration, other DMARDs, NSAIDs, steroids and study cohort.

Conclusion: In this first longitudinal study, folate-related biomarkers were unrelated to MTX treatment outcome in RA.

Correlation of a Multi-Biomarker Disease Activity Response Assessment to Disease Activity Score 28 (C-Reactive Protein) Response Assessment and Omeract Ramris Scores in a Placebo-Controlled Rheumatoid Arthritis Clinical Trial with Abatacept (ASSET). DJ Haney[1], G. Cavet[2], P. Durez[3], R. Alten[4], G. R. Burmester[5], P. P. Tak[6], Anka. I. Catrina[7], C. Gaillez[8], M. Le Bars[8], S. Connolly[9] and R. Townsend[9]. [1]Crescendo Bioscience Inc., South San Francisco, CA, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]Université Catholique de Louvain, Brussels, Belgium, [4]Schlosspark-Klinik, University Medicine, Berlin, Germany, [5]Charité-Universitätsmedizin, Berlin, Germany, [6]Academic Medical Center/University of Amsterdam, Amsterdam, the Netherlands; GlaxoSmithKline, Stevenage, United Kingdom, [7]Karolinska Institute, Stockholm, Sweden, [8]Bristol-Myers Squibb, Rueil Malmaison, France, [9]Bristol-Myers Squibb, Princeton, NJ

Background/Purpose: A novel multi-biomarker disease activity (MBDA) score has been validated and is a tool for monitoring disease activity in RA.[1] Here, we evaluate the relationship between MBDA scores and both clinical and MRI assessments in patients (pts) from the ASSET trial (NCT00420199) who received abatacept (ABA) or placebo (pbo).

Methods: Fifty pts with active RA, baseline (BL) DAS28-CRP >3.2 or Tender Joint Count and Swollen Joint Count >6 and CRP >upper limit of normal and inadequate response to MTX were randomly assigned 1:1 to receive ABA or pbo plus MTX, administered intravenously at BL; Days 15, 29; and every 28 days up to and including Day 113.[2] Concentrations of 12 serum biomarkers including inflammatory cytokines and receptors (IL-6, TNF-RI), growth factors (EGF, VEGF-A), matrix metalloproteinases (MMP-1, MMP-3), skeletal-related protein (YKL-40), hormones (leptin, resistin), acute phase proteins, and markers of systemic inflammation (CRP and SAA1) were measured in pt serum at BL, 2 and 4 wks to calculate MBDA scores between 1 and 100. Disease activity measures (DAS28-CRP) were evaluated at BL, Wks 2 and 4, and every 4 wks until Wk 16, EULAR response was assessed at Week 16, and OMERACT RAMRIS scores (components: erosion, osteitis, and synovitis scores) were evaluated at BL and Mth 4. Associations between MBDA scores and DAS28-CRP, and between MBDA scores and OMERACT RAMRIS scores, were evaluated *post hoc* using Spearman's rank correlation. The relationships of early changes in DAS28-CRP and MBDA score with subsequent EULAR response were evaluated by two-sample *t*-test. Comparisons of changes in disease activity scores between treatment arms were evaluated by two-sample *t*-tests.

Results: Statistically significant correlations were observed between DAS28-CRP and MBDA score (r=0.47, p<0.001, n=146; all time points combined), and between change in DAS28-CRP and change in MBDA score from BL to Wk 4 (r=0.58, p<0.001, n=48). Pts in the ABA + MTX arm experienced significantly greater improvements in MBDA score and DAS28-CRP versus pbo + MTX arm at Wk 4 (p=0.003 in each case). A significant association between change in DAS28-CRP from BL to Wk 4 and EULAR good response at Wk 16 (p=0.02) was observed, as well as a marginally significant association between change in MBDA at Wk 4 and good EULAR response at Wk 16 (p=0.05). There was a significant correlation between MBDA score and OMERACT RAMRIS synovitis and osteitis scores at BL (Table).

Disease activity measure	Synovitis Correlation	P value	n	Osteitis Correlation	P value	n	Erosion Correlation	P value	n
MBDA score	0.34	0.02	47	0.36	0.01	47	0.27	0.06	47
DAS28-CRP	0.08	0.60	47	0.10	0.52	47	0.10	0.49	47

Conclusion: In the ASSET trial, pts receiving abatacept had a better improvement in both clinical disease activity and disease activity biomarkers than pts in the pbo group. The MBDA score was correlated with disease activity and the OMERACT RAMRIS synovitis and osteitis scores. Monitoring of changes in MBDA score may be useful in RA pts in combination with clinical assessment.

Fcγ Receptor IIIb Polymorphism Is Associated with Injection Reaction to Adalimumab in Patients with Rheumatoid Arthritis. Masako Tsukamoto[1], Yosuke Hashimoto[1], Tatsuhiro Ohshige[1], Keiko Yoshimoto[1], Yuko Kaneko[2], Hideto Kameda[1] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Keio Univ School of Medicine, Shinjuku-ku, Japan

Background/Purpose: Biological agents targeting a specific molecule provide an effective means for therapeutic management of rheumatoid arthritis (RA), but infusion/injection reaction is a major adverse event in patients with RA treated with biological agents. We previously reported that a high affinity Fcγ receptor (FcγR) IIIB polymorphism (NA1/NA1) is an independent risk factor for the development of infusion reaction to infliximab in RA patients (*Ann Rheum Dis 70:299,2011*). In this study, we investigated whether FcγR IIIB polymorphisms are related with injection reaction to adalimumab (ADA), a fully human anti-TNFα monoclonal antibody in patients with RA.

Methods: Consecutive patients with RA who fulfilled the 1987 revised criteria of the American College of Rheumatology (ACR) for the classification of RA or the 2010 ACR/EULAR RA Classification Criteria were invited to participate in the study after informed consent. Peripheral blood samples and clinical records were obtained from 65 RA patients (56 females and 9 males) treated with ADA between July 2008 and May 2012. The genomic DNA was extracted from peripheral blood mononuclear cells. Genetic polymorphisms for FcγR IIIB were genotyped in *FCGR3B* NA1/2 alleles by real allelic discrimination assay. Clinical records in 65 patients were collected retrospectively. Genetic polymorphisms were subjected to logistic regression analysis to evaluate the association with clinical parameters.

Results: Injection reaction to ADA was observed in 8 patients, 2 patients of those discontinued ADA due to those injection reactions. There was no significant difference in clinical background between patients with injection reaction and those without. The *FCGR3B* NA1/NA1 genotype was found in 75.0% (6/8) of the patients with injection reaction whereas in only 28.1% (16/57) of those without injection reaction, indicating that this genotype is associated with the development of infusion reactions. In contrast, the genotypes NA1/NA2 and NA2/NA2 were only observed in 12.5% and 12.5% of the patients with injection reaction while in 42.1% and 29.8% of those without injection reaction. Analyses confirmed that the distribution of the *FCGR3B* genotypes between patients with and without injection reactions was significantly different (p=0.022). On the other hand, any clinical parameters tested in this study were not associated with injection reaction.

Conclusion: The *FCGR3B* NA1/NA1 genotype may be the potential predictive marker for the development of injection reaction to ADA as well as infusion reaction to infliximab in Japanese RA patients.

Methotrexate Polyglutamate Concentrations in Erythrocytes Are a Potential Tool for Therapeutic Drug Monitoring of Methotrexate Response in Rheumatoid Arthritis. Maurits C.F.J. De Rotte[1], Ethan den Boer[2], Maja Bulatovic[3], Saskia M.F. Pluijm[4], Johanna M.W. Hazes[1] and Robert De Jonge[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Erasmus University Hospital, Rotterdam, Netherlands, [3]University Medical Centre Utrecht, Netherlands, [4]Erasmus Medical center, Rotterdam, Netherlands

Background/Purpose: Methotrexate (MTX) is the most commonly used drug in rheumatoid arthritis (RA). 30% of patients fail to respond to the drug or suffer from adverse events. Therefore, there is a need for therapeutic drug monitoring (TDM). MTX plasma concentrations decrease in a few hours, whereas MTX polyglutamates (MTX-PG) are accumulated intracellular over months inside cells, and therefore may be a tool for TDM.

Methods: The study included patients from two longitudinal cohorts who were diagnosed with RA according to the 2010 ACR criteria and were treated with MTX therapy: 285 patients from the treatment in Rotterdam Early Arthritis Cohort (tREACH) (1) and 99 from the Methotrexate in Rotterdam

(MTX-R) study. We measured MTX with a tail of 1,2,3,4 and 5 glutamates in erythrocytes at 3 months after MTX start with an LC-MS/MS assay. As outcome measure for MTX response we defined disease activity score (DAS) 28 at 0,3,6 and 9 months after MTX start and EULAR response criteria at 3,6 and 9 months. Adverse events were measured as gastro intestinal intolerance and overall complaints at 3,6 and 9 months. DAS28 was analyzed with analysis of covariance (ANCOVA). EULAR response and adverse events were analyzed with logistic regression. All MTX-PGs were analyzed as continuous variables, quintiles and tertiles. All analysis were adjusted for age, gender, DAS28 at baseline, MTX dose, MTX route of administration, other DMARDs, NSAIDs, steroids and study cohort.

Results: Concentrations at 3 months (mean/SD) were: MTX-PG1: 17.99 nmol/l (18.28), MTX-PG2: 9.25 nmol/l (4.61), MTX-PG3: 18.26 nmol/l (7.66), MTX-PG4: 7.78 nmol/l (5.95), MTX-PG5: 2.41 nmol/l (3.02) and total MTX-PG: 58.07 nmol/l (27.47). DAS28 was 4.76 (1.26) at baseline and 3.08 (1.20), 2.91 (1.22), 2.68 (1.16) at 3,6 and 9 months, respectively. At 3 months 52% had gastrointestinal complaints, at 6 months 26% and at 9 months 24%. 46%, 49% and 47% of the patients reported to have one or more adverse events at 3, 6 and 9 months. Lower DAS28 scores at 3,6 and 9 months were associated with higher MTX PG1, MTX-PG2 and total MTX-PG concentrations (table). Analysis in quintiles revealed that MTX-PG1,2 and total MTX-PG concentrations were non-linearly associated with EULAR response. As compared with patients in the lowest quintiles, patients in the highest quintiles had a higher chance to respond. No associations were found between any of the MTX-PG concentrations and adverse events.

Table. Analysis of covariance for the association between MTX-PG concentrations and DAS28

MTX-PG at 3 months	3 months Standardized-β (p)	6 months Standardized-β (p)	9 months Standardized-β (p)
MTX-PG1	−0.12 (0.022)*	−0.15 (0.015)*	−0.17 (0.012)*
MTX-PG2	−0.15 (0.003)*	−0.19 (0.001)*	−0.19 (0.003)*
MTX-PG3	−0.075 (0.196)	−0.05 (0.390)	−0.04 (0.558)
MTX-PG4	−0.04 (0.498)	−0.07 (0.281)	0.13 (0.074)
MTX-PG5	−0.03 (0.584)	0.10 (0.138)	0.20 (0.004)
MTX total PG	−0.15 (0.012)*	−0.13 (0.053)*	−0.16 (0.028)*

* = significant. All analyses are adjusted for age, gender, DAS28 at baseline, MTX dose, MTX route of administration, other DMARDs, NSAIDs, steroids and study cohort.

Conclusion: In this first longitudinal study, higher MTX-PG1,2 and total MTX-PG concentrations in erythrocytes were associated with MTX response over the first 9 months treatment and are therefore a potential tool for TDM of MTX in RA.

Correlation of A Multi-Biomarker Disease Activity (VECTRA™ DA) Score with Clinical Disease Activity and Its Components with Radiographic Progression in Rheumatoid Arthritis Patients Treated with Tofacitinib. Kunihiro Yamaoka[1], Satoshi Kubo[1], Koshiro Sonomoto[1], Shintaro Hirata[1], Guy Cavet[2], Rebecca Bolce[2], Michael W. Rowe[2], David Chernoff[2], Nadine Defranoux[2], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Crescendo Bioscience Inc., South San Francisco, CA

Background/Purpose: A multi-biomarker disease activity (MBDA) score has been developed for evaluation of disease activity of rheumatoid arthritis (RA) to complement clinical assessment and to provide information about underlying disease processes. We have reported the usefulness of MBDA as clinical measures of disease activity. However, relation of MBDA score with clinical features in RA patients treated with a JAK-inhibitor tofacitinib is unknown.

Methods: DAS28(ESR), SDAI, MBDA and modified total sharp score (mTSS) were evaluated at baseline and 1 year in 37 patients (31 women, mean age: 54.6 years, mean disease duration: 78.9 months) enrolled in phase II and III clinical trials of tofacitinib. Patients were randomized to different doses of tofacitinib or placebo for the first 3 to 6 months (8 patients with dosed tofacitinib as monotherapy and 29 patients with concomitant MTX). All patients were treated with tofacitinib 5 mg or 10 mg BID after 6 months. MBDA combines 12

serum biomarkers (VCAM-1, EGF, VEGF-A, IL-6, TNF-RI, MMP-1, MMP-3, YKL-40, Leptin, Resistin, CRP, SAA) in a pre-specified algorithm resulting in a score between 1 and 100.

Results: (1) Disease activity significantly improved: MBDA, 60.8 to 28.5 as well as SDAI 37.7 to 6.2, DAS28-ESR 6.4 to 3.0, HAQ-DI 1.4 to 0.8,. HAQ-DI $\leq$0.5 was achieved in 19 patients (51%). Yearly progression of mTSS (ΔmTSS) significantly decreased from 14.7 to 0.9 and 21 patients (56%) achieved structural remission.

(2) Significant correlation was observed between yearly ΔMBDA score and ΔDAS28(ESR), ΔSDAI or ΔCDAI (p<0.01).

(3) When clinical remission was determined as MBDA $\leq$25, remission rate was similar among measurements. (SDAI 37.8%, DAS28-ESR 35.1%, MBDA 40.5%)

(4) No correlation was observed between ΔmTSS and ΔMBDA, ΔDAS28(ESR), ΔSDAI or ΔCDAI.

(5) The proportion of radiographic progressors in remission was similar among different measurements. (38.5% (5/13) of DAS28-ESR remission, 35.7% (5/14) of SDAI remission and 33.3% (5/15) of MBDA remission)

(6) IL-6 decreased from 163.0pg/ml to 25.1pg/ml and MMP-3 decreased from 159.1ng/ml to 39.5ng/ml. The measures of IL-6 and MMP-3 at 52 weeks significantly correlated with change of mTSS (69.1 to 70.0).

(7) When patients were separated into 2 groups with median value of serum IL-6 (9.0ng/ml) at 52 weeks, 78% achieved structural remission in low concentration group, whereas 38% was achievable in high concentration group.

Conclusion: MBDA significantly correlated with cpnventional composite measures of disease activity and equally contributed to remission rate in patients with RA. Although ΔMBDA did not correlate with ΔmTSS in this study size, concentration of IL-6 and MMP-3 at 52 weeks correlated with change of mTSS. These results indicate that tofacitinib acts through the inhibition of IL-6 and is able to prevent bone destruction. Our results further support the usefulness of MBDA as an additional composite measure for RA disease activity.

Abatacept Monotherapy Effectively Reduces the Frequency of Osteoclast Precursor Cells in the Peripheral Blood of Patients with Rheumatoid Arthritis and Inhibits Their Differentiation Into Osteoclasts. Sandra Mueller-Schmucker[1]. Roland Axmann[1], Sonja Herman[2], Mario Zaiss[1], Manuela Le Bars[3], Thomas Harrer[1] and Georg A. Schett[4], [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Medical University of Vienna, Vienna, Austria, [3]Bristol-Myers Squibb, Rueil Malmaison, France, [4]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Bone resorbing osteoclasts origin from monocytes. We have recently shown that binding of abatacept (CTLA4-Ig) to CD80 and CD86 on the surface of monocytes blocks their differentiation into osteoclasts in vitro (Axmann et al, Ann Rheum Dis. 2008;67:1603-9). We thus speculated whether abatacept therapy impairs the potential of osteoclast differentiation in rheumatoid arthritis patients in vivo.

Methods: We compared the frequency of CD11b+CD115+ osteoclast precursor cells in the peripheral blood of 60 patients with rheumatoid arthritis (RA), either untreated (N= 15) or treated with methrotrexate (N=15), adalimumab (N= 15) or abatacept as monotherapies (N=25) using FACS analysis. We also performed osteoclast differentiation assays from the peripheral blood mononuclear cells from these patients to quantify osteoclast differentiation and to test for osteoclast gene expression profiles.

Results: The frequency of osteoclast precursors in the peripheral blood was significantly (p< 0.01) lower in abatacept treated patients (82,4 $\pm$ 1,8%) than in untreated controls (97,4 $\pm$ 0,6%), whereas no significant differences between controls and adalimumab and methotrexate treated patients, respectively, were found. In addition, osteoclast differentiation from peripheral blood was impaired in abatacept-treated patients (mean osteoclast number per well= 32,5) as compared to untreated controls (mean osteoclast number per well= 145,6). In addition, sequential analysis of patients before and after abatcept exposure showed reduced potential of osteoclast precursors to differentiate into osteoclasts

after the exposure to abatacept. Moreover, we found significant down regulation of essential osteoclast differentiation factors c-Fos and NFAT1c after in vitro exposure of monocytes to abatacept.

Conclusion: Abatacept treatment decreases osteoclast precursor cell frequency in RA patients as well as osteoclast differentiation potential of peripheral blood mononuclear cells. Moreover, abatcept leads to a down regulation of key osteoclast genes such as c-Fos and NFATc1. These data explain the mechanism by which abatcept may achieve bone protection during the treatment of RA patients.

Evidence for NF-Kb Intracellular Signaling Involvement Following CTLA4-Ig (Abatacept) Treatment of Human Macrophages. Renata Brizzolara[1], Paola Montagna[1], Stefano Soldano[1], Alberto Sulli[1], Bruno Seriolo[1], Barbara Villaggio[2], Pierfranco Triolo[3], Lamberto Felli[4] and Maurizio Cutolo[1]. [1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy, [2]Research Laboratory of Nephrology, Department of Internal Medicine, University of Genova, Genova, Italy, [3]Rheumatoid Arthritis Unit, Orthopedic Surgery Department, CTO Hospital, Turin, taly, Turin, Italy, [4]Orthopedic Department, University of Genova, Genova, Italy

Background/Purpose: The transcription factor NF-kB is an intracellular signaling essential for the expression of a variety of immune-response genes, including those related to pro-inflammatory cytokines [1]. Previous studies showed that a significant downregulation of TNFα, IL-1β and IL-6 was evident for cultured human macrophages treated with CTLA4-Ig [2,3]. Therefore, we investigated the involvement of the NF-kB pathway as possible intracellular signaling target during the CTLA4-Ig modulation of cytokine production in cultured human macrophages.

Methods: Human THP1 cell line cells, differentiated by phorbol myristate acetate in macrophages, were cultured with CTLA4-Ig (100 and 500 μg/ml; 3,12, 24 hours) or without CTLA4-Ig (cnt). CTLA4-Ig/CD86 binding was evaluated by fluorescence activated cell sorter (FACS) analysis. Quantitative RT-PCR analysis (qRT-PCR) of mRNA for NF-kB, its inhibitor IKBα and for TNFα, IL-1β, IL-6 was performed after 3 and 12 hours from CTLA4-Ig treatment. Western blot (WB) analysis for NF-kB and IKBα proteins was performed after 24 hours of CTLA4-Ig treatment.

Results: FACS analysis showed a reduction of B7.2 positivity on macrophages CTLA4-Ig-treated vs. cnt, due to CTLA4-Ig/B7.2 binding. The qRT-PCR analysis of NF-kB, at 3 and 12 hours from CTLA4-Ig [100, 500 μg/ml] treatment, showed a significant downregulation (both p<0.001) vs. cnt. On the contrary, IKBα showed, at 12 hours from CTLA4-Ig [500 μg/ml] treatment a significant increase (p<0.01), while after 3 hours from [100 and 500 μg/ml] CTLA4-Ig treatment vs. cnt, resulted unchanged. The qRT-PCR analysis of inflammatory cytokines, after 3 hours from treatment, showed for CTLA4-Ig [100 μg/ml] a significant decrease of TNFα and IL-6 (p<0.05), vs. cnt. CTLA4-Ig [500 μg/ml] reduced TNFα vs. cnt in a larger extent (p<0.001). After 12 hours from CTLA4-Ig [100, 500 μg/ml] treatment, it was still evident at qRT-PCR a significant downregulation (p<0.001) for all cytokine gene expression, vs. cnt. Finally, WB analysis showed that CTLA4-Ig treatment at higher concentration [500 μg/ml] was able to reduce NF-kB protein expression and to increase IKBα expression, vs. cnt.

Conclusion: CTLA4-Ig, while it reduces the inflammatory cytokine gene expression in human macrophages, seems to promote a downregulation of the intracellular signaling linked to the NF-kB pathway, including an increased expression of its cytoplasmatic inhibitor IKBα both at gene and protein level.

Utility of Vectra-DA™ On Assessment of Rheumatoid Arthritis Disease Activity and Golimumab Response: Results of a Pilot Study From a Phase 3 Trial in Patients with Active Rheumatoid Arthritis Despite Methotrexate Therapy. Sarah Lamberth, Yauheniya Cherkas, Carrie Brodmerkel and Mark Curran. Janssen Research and Development, LLC, Spring House, PA

Background/Purpose: Currently, disease activity in Rheumatoid Arthritis (RA) is measured using scoring systems that rely primarily on a collection of subjective measures from patients and clinicians. To improve care and treatment for RA patients, objective measurements of disease activity and response to treatment are desirable. Using a small cohort derived from an ongoing study of intravenously administered golimumab (GO-FURTHER), we evaluated the performance of Vectra-DA™ (Crescendo Biosciences), a multi-biomarker serum-based test designed to measure RA disease activity through correlation with DAS28-CRP and sensitive to anti-TNF therapy.[1] This analysis examines if Vectra-DA™ correlates with disease activity and golimumab response in a clinical trial setting.

Methods: 137 serum samples collected in a Phase III study of intravenously administered golimumab in patients with active RA despite methotrexate (MTX) therapy was analyzed using Vectra-DA™ (Crescendo Bioscience©; San Francisco, CA, USA). Samples were collected at weeks 0, 2, 4, and 14 from patients treated with IV placebo + MTX (PBO; n= 42) or IV golimumab 2mg/kg + MTX (GLM; n=95) who received study medications at Weeks 0, 4, and every 8 weeks thereafter. Healthy control serum samples (n=21) were obtained from Bioreclamation (Hicksville, NY).

Results: A subset of subjects was chosen for analysis with Vectra-DA™ from the GO-FURTHER study. The subset had an ACR50 response to golimumab of 35.8% (PBO 7.1%) at week 14 and 48.4% (PBO 16.7%) at week 24. Correlation of Vectra-DA™ and DAS28-CRP scores was r=0.51 (95% CI=0.45–0.57) using all four timepoints tested. Study subjects had statistically higher mean Vectra-DA™ scores (64.2 at wk 0; 45.5 at wk 2; 50.2 at wk4; 44.9 at wk14) compared to healthy controls (35.2). At baseline, there were no significant differences in GLM and PBO-treated subjects by Vectra-DA™ or DAS28-CRP scores. As early as week 2, GLM-treated subjects had a significant drop in Vectra-DA™ score of D= −18.7 (p=<2.2×10−16). The decrease in Vectra-DA™ score was maintained through week 14, whereas PBO-treated subjects did not have a significant change in Vectra-DA™ scores from baseline to weeks 2, 4 and 14. Vectra-DA™ scores were statistically different between GLM-treated subjects who achieved an ACR50 response at week 14 versus non-responders at weeks 0 (p=0.024), 4 (p=0.013), and 14 (p=0.009). Vectra-DA™ scores were not statistically different between GLM-treated subjects who achieved an ACR50 response at week 24 versus non-responders at all timepoints tested, though a trend was seen at week 14 (p= 0.054).

Conclusion: Vectra-DA™ offers a molecular measurement of RA disease activity that can discriminate between normal and RA subjects, and also PBO and GLM-treated subjects as early as week 2 post-treatment. GLM treated week 14 responders had significantly lower Vectra-DA™ scores compared with non-responders. The Vectra-DA™ score reflects a patient's disease activity before and after the treatment with intravenous golimumab.

2166

Identification of Serological Biomarker Profiles Associated with Response to IL-6 Intervention in Rheumatoid Arthritis. Morten Asser Karsdal[1], Anne C. Bay-Jensen[1], Inger Byrjalsen[2], Andrew Kenwright[3], Adam Platt[3], Thierry Sornasse[4] and Claus Christiansen[5]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark, [3]Roche, Welwyn Garden City, United Kingdom, [4]Genentech, Inc., South San Francisco, USA, San Fransisco, CA, [5]CCBR, Ballerup, Denmark

Background/Purpose: RA is characterized by poly-articular synovial inflammation, cartilage loss and erosion of subchondral bone. It is critical to diagnose and effectively treat the disease early to suppress inflammation and halt destruction of the joint. Thus, identification of the patients most likely to respond to a given intervention should be pursued for optimal benefits for both patients and payers. The objectives were i) to investigate the early changes in biomarkers of bone, cartilage, synovium and inflammation as an effect of 8mg/kg tocilizumab (TCZ) treatment, and ii) to identify profiles associated with responders and non-responders biomarker profiles.

Methods: The prospective biomarker substudy of the LITHE trial included 626 patients. The LITHE trial (Roche WA17823) was a 2-year phase III, 3-arm randomized, double-blind, placebo-controlled, parallel group, including patients with moderate/severe active RA, and with inadequate response to DMARDs. The patients were randomized: TCZ8mg/kg (TCZ8), TCZ4mg/kg or placebo. Patients received an infusion of TCZ 8mg/kg, 4mg/kg or placebo every 4 weeks. Escape patients were defined as those who experienced <20% improvement in both swollen (SJC) and tender joint counts (TJC) at week 16 (non-responders). Current analysis only considered the TCZ8 group where serum was analyzed at baseline and 4 weeks. Following biomarkers were measured: C2M (cartilage degradation), C3M (synovial inflammation), MMP3, total CRP, CRPM (MMP-degraded CRP), VICM (Citrullinated and MMP-degraded Vimentin), ICTP (MMP destroyed type I collagen), osteocalcin (bone formation) and CTX-I (Bone resorption). This analysis consisted of 102 responders and 33 escape-therapies. Data is shown as geometric mean percentage change from baseline (Mann-Whitney test) and the odds ratio (OR) for response was calculated.

Results: The general inflammatory marker serum CRP was completely blocked (<10% of baseline) by TCZ8 in both the responder and non-responder group, with no significant ability to separate these groups (OR 1.6, *ns*). The level of serum CRPM was decreased to 72% in the responder group and only to 83% in the non-responder group (OR 4.0, *0.0014*). Cartilage degradation - C2M - was reduced to 89% of baseline levels upon treatment with TCZ8 in the responder group, whereas the level of serum C2M remained unaltered or increased to 102% of baseline level in the non-responder (OR 5.8, *0.0003*). The synovial turnover measure, serum C3M, was decreased to 73% of baseline in the responder group, compared to 88% in the non-responder group (OR 9.6, *0.0004*). There were only minimal differences in the bone resorption and formation markers, as well as in serum MMP-3, ICTP and VICM.

Conclusion: Biomarkers of cartilage and synovial turnover were able to discriminate between responders and non-responders to anti-IL-6R intervention at an early time point, in contrast to traditional CRP and the standard bone markers. These responder and non-responder profiles may enable identification of the optimal treatment for the individual patients, so-called Il-6 super-responders. Whether these response profiles are specific for IL-6 interventions or other biological treatments or other novel interventions remain to be investigated.

2167

Serum Based Biomarkers of Joint Destruction Can Identify Responders and Non-Responder to Tocilizumab. Anne C. Bay-Jensen[1], Inger Byrjalsen[2], Claus Christiansen[3] and Morten Asser Karsdal[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark, [3]CCBR, Ballerup, Denmark

Background/Purpose: RA is characterized by synovial inflammation, cartilage loss and erosion of subchondral bone. It is critical to diagnose and effectively treat the disease early to suppress inflammation and stop destruction of the joints. Inflammation results in the release of tissue fragments that reflects disease activity which are measurable in serum. Identification of the patients that would most likely respond and not respond to treatment would bring optimal benefits for patients. The objective of the study was to investigate whether early changes (within 4 weeks) in serum biomarkers were predictive of ACR50 response at week 52 to 4 and 8 mg/kg tocilizumab (TCZ) treatment of RA patients.

Methods: The prospective biomarker substudy of the LITHE trial included 693 patients. The LITHE trial (Roche WA17823) was a 2-year phase

III, 3-arm randomized, double-blind, placebo-controlled, parallel group, including patients with moderate/severe active RA, and with IR to DMARDs. The patients were randomized: TCZ8mg/kg (n=244), TCZ4mg/kg (n=207) or placebo (PBO, n=242) on a background of MTX. Biomarkers were measured in serum from baseline and 4 weeks: C2M (cartilage degradation), C3M (synovial inflammation), MMP3, total CRP, CRPM (MMP-degraded CRP), VICM (Citrullinated and MMP-degraded Vimentin), and ICTP (MMP destroyed type I collagen), osteocalcin (bone formation) and CTX-I (Bone resorption). Cut-off values for dichotomized analysis of the markers and the ACR50 response was determined by ROCs by best likelihood ratio for i) the individual markers at baseline, ii) changes from 4 weeks, and iii) ratio between markers. Decision trees (CART) were constructed using the cut-offs values and the predictive values for ACR50 response were calculated by 2×2 diagnostic tests.

Results: The proportion of ACR50 responders at week 52 for TCZ4 and PBO were 29% and 8.2%, corresponding to a number need-to-treat ratio (NNT) of 3.5 and 12, respectively. CART#1 (baseline C2M/CRP and C3M/CRPM ratios): A positive test resulted in identification of 68 TCZ4 cases which led to a PPV of 40% and a NPV of 76%. PBO; 1 out 19 cases with a positive test were responder. CART#2 (baseline MMP3 and C3M/CRPM ratio); A positive test resulted in identification of 86 TCZ4 cases, which led to a PPV of 43% and a NPV of 80%. PBO; 2 out 27 cases with a positive test were responder (NNT 2.3). CART#3 (CART#2 + 4-week change in osteocalcin and CTXI/C2M ratio); A positive test resulted in identification of 30 TCZ4 cases, which led to a PPV of 63% and a NPV of 79% (NNT 1.6). No PBO cases were selected. Similar data was obtained independently for TCZ 8mg/kg.

Conclusion: We identified more than 76% of the patients that did not respond to TCZ4 treatment. This increased the response rate from 29% up to 63%. We found that measurement of baseline biomarkers the need-to-treat ratio could be reduced from 3.5 to 2.3. If early changes in biomarkers were included then this need-to-treat ratio could be further reduced to 1.6. Whether this is an IL6 pathway-specific serological profile need to be investigated in additional clinical settings.

Background/Purpose: This study aimed to compare the efficacy and the safety of Rituximab (RTX)in elderly (aged ≥ 65years) and younger patients (aged 18–64 years) with active rheumatoid arthritis (RA).

Methods: We included all the RA patients in the Auto-immunity and RTX 7-years prospective registry with 2 years follow-up and divided them in 2 main groups on the basis of their age (aged ≥ 65 and aged <65). A minor group with the very old patients (75years old or more) was studied too. The primary efficacy outcome was EULAR response (good, moderate and no response), the secondary

efficacy outcome were low disease activity and remission. The primary tolerance outcome was drug discontinuation rates due to side effects.

Results: Among the 1709 patients having at least 2 years of follow up, 608 were ≥ 65years of whom 191 were ≥ 75years old, and 1101 were <65years. At baseline, the elderly patients showed a longer disease duration, a higher rate of CRP and ESR (medians respectively 21 vs 14mg/L, p<0.001, and 35 vs 32 mm, p<0.001), lower rate of previous aTNF therapy (71% vs 79.6%, p<0.001) and lower number of aTNF previously used (medians 1 vs 2, p<0.001). Disease activity, previous DMARDs rates, rheumatoid or aCCP rates and corticotherapy (yes/no) were not statistically different between the 2 groups. At 24 months, no significant difference was showed between groups for RTX discontinuation rates for side effects: 5.8% if < 65years, 4.9% if ≥ 65 years and 4.2% if ≥ 75years old. However, death rates increased with age: 2.5% if < 65years, 7.7% if ≥ 65 years and 16.2% if ≥ 75years old, p<0.001.The EULAR response criteria were not statistically different after 2 years (n=506) in the younger (<65 years, n=354)and older groups (≥ 65years, n=152) with respectively 64.1% and 68.4% of responders including 39.5% and 48% moderate responders, and 24.6% and 20.4% good responders respectively. However, there were significant differences concerning very old patients (≥75ans). Before adjustment younger patients and patients between 65 and 75years had more chances to be good responders at one year follow-up (n=642) than patients ≥ 75years old, with respectively OR= 3.54 (95% IC= [1.2–10.47]) and OR= 4.53 (95 IC= [1.12–12.33]). After adjustment, this difference was only significant between the old (≥ 65years) and very old patients (≥ 75years): OR= 3.71, 95% IC= [1.12;12.33] (n= 475). At 24 months, these differences were no longer significant with or without adjustment. Concerning remission, there was no significant difference between the young and the elderly, either at 1 year or at 2 years, respectively 12.05% vs 13% (adjusted p=0.372), and 15.6% vs 11.04% (adjusted p= 0.410).

Conclusion: This study is the first to date to compare tolerance and effectiveness of RTX between elderly and younger patients with RA. No significant difference in efficacy or discontinuation rate after 2 years of follow-up. Increase of mortality in the oldest patients is probably due to the decrease of life expectancy with age.

Short to Medium Term Safety of Glucocorticoid Therapy in Rheumatoid Arthritis: A Systematic Review and Dose-Response Analysis of Randomized Controlled Trials.
Simon Tarp[1], Daniel E. Furst[2], John R. Kirwan[3], Maarten Boers[4], Henning Bliddal[1], Thasia Woodworth[5], Else Marie Bartels[1], Bente Danneskiold-Samsoe[1], Lars Erik Kristensen[6], Steffen Thirstrup[7], Mette Rasmussen[7], Marian Kaldas[2] and Robin Christensen[1]. [1]The Parker Institute, Copenhagen University Hospital at Frederiksberg, Copenhagen F, Denmark, [2]University of California in Los Angeles, Los Angeles, CA, [3]Bristol Royal Infirmary, Bristol, United Kingdom, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Leading Edge Clinical Research LLC, Florida, FL, [6]Lund University, Lund, Sweden, [7]University of Copenhagen, Copenhagen, Denmark

Background/Purpose: Concerns regarding Adverse Effects (AEs) often dominate decisions on applying Glucocorticoid (GC) therapy. Evidence of AEs is mainly based on observational data without proper control groups. Thus, an examination of Randomized Controlled Trials (RCTs) for short to medium term AEs from GC would be useful. Our aim was to assess the risk of selected AEs, ranked as most worrisome among patients and rheumatologists (1), in relation to dose.

Methods: A systematic search in MEDLINE, EMBASE, and CENTRAL was performed. Inclusion criteria were RCTs in patients with Rheumatoid Arthritis (RA) with any Prednisone Equivalent Dose Differences (PEDD) between trial arms, independent of type of administration, type of GC, or study duration. RCTs of GCs without a prednisone equivalent conversion factor were excluded. One reviewer extracted the data from the included trials and a second reviewer checked the extracted data. Analyses were based on differences in dose between trial arms (more vs. less) and therefore an assumption for linearity in response, e.g. 10 mg/d PEDD in trials of 10 vs. 0 mg was equal to 70 vs. 60 mg. For the meta-analyses, a random-effects (REML) model was used to estimate the pooled Risk Ratios (RR) with 95% Confidence Intervals (CI). The average daily and accumulated PEDD in mg between trial arms were estimated and categorized in following dose-groups:

low (≤7.5 mg), medium (>7.5, ≤30 mg), and high (>30 mg) for each RCT. Meta-regression and stratified analyses were conducted to explore dose-response, using daily and accumulated PEDD as covariates and dose-groups as strata for each outcome.

Results: Of 2821 references identified, 524 were reviewed in detail, and 59 RCTs (66 Randomized Comparisons with a total of 4831 patients) were eligible for inclusion. Overall, the risks of the selected AEs over 24 to 104 weeks were not increased when comparing more vs. less GC (Table). Although none of the analyses showed statistical significance, some of the meta-regression and stratified analyses suggested a trend for a dose-response for GC given up to doses of maximum 75 mg/d PEDD. There was a trend towards an increasing risk of osteoporosis (from RR 1.07 to 3.41 when applied in medium dose), cardiovascular diseases (from RR 1.19 to 2.75 when applied in high dose). Interestingly, with data for the high dose relatively limited, the dose-response pattern for both non-viral infections and diabetes showed a tendency to decreasing risk with increasing GC dose.

Outcome	No of Studies (RC)	No of Pt.	Pt. years	Overall RR 95%(CI)	Duration Median (weeks)	Daily PEDD Median (mg)	Accum. PEDD Median (mg)	Dose-Response RR (95%CI) Low dose Stratum	Medium dose stratum	High dose stratum	P-value for interaction
Diabetes	18	1880	2196	1.18 (0.56,2.49)	78	8.8	4612	1.72 (0.29,10.18)	1.03 (0.13,8.36)	1.03 (0.29,3.67)	0.84
Osteoporosis	12	1464	2166	1.31 (0.74,2.32)	104	5.0	3650	1.07 (0.51,2.25)	3.41 (0.68,7.13)	NA	0.17
Cardiovascular diseases	20	2180	2865	0.88 (0.59,1.32)	38	5	2730	1.19 (0.44,3.26)	2.41 (0.61,9.50)	2.75 (0.18,42.76)	0.27
Hypertension	21	2178	3047	1.24 (0,83,1,86)	104	5	3600	1.41 (0.85,2.35)	0.77 (0.40,1.50)	1.67 (0.35,7.84)	0.28
Infections (non-viral)	19	2107	2402	0.90 (0.78,1,04)	24	7.5	1425	0.95 (0.78,1.16)	0.82 (0.63,1.07)	0.36 (0.01,11.01)	0.53
Renal Dysfunction	15	2044	2724	1.41 (0.97,2.05)	78	5	1890	1.25 (0.64,2.43)	1.99 (0.11,35.44)	NA	0.72
Weight gain	18	1967	2626	1.19 (0.98,1.46)	78	7.3	3625	1.23 (0.83,1.83)	1.25 (0.92,1.71)	0.91 (0.49,1.70)	0.60

#PEDD: Prednisone Equivalent Dose Differences; RC: Randomized Comparisons; RR Risk Ratio; CI: Confidence Intervals; pt: patients.

Conclusion: This study presents empirical evidence, based on RCTs, that: 1) there is no statistical evidence to support concerns of an overall increased risk of the selected side effects of GCs, when the GC is used over a period of 24 to 104 weeks; 2) a tendency to a dose-dependent increased risk was noted for osteoporosis and cardiovascular side effects, while there may be decreasing risk for diabetes and non-viral infections.

Methotrexate and Interstitial Lung Disease in Rheumatoid Arthritis – A Systematic Literature Review and Meta-Analysis. Richard Conway[1], Candice Low[2]. Robert J. Coughlan[3], Martin O'Donnell[3] and John J. Carey[3], [1]St James's Hospital, Dublin, Ireland, [2]St. James Hospital, Dublin, Ireland, [3]Galway University Hospitals, Galway, Ireland

Background/Purpose: Methotrexate is commonly prescribed for a variety of diseases including rheumatoid arthritis. Methotrexate has frequently been implicated as a causative agent in interstitial lung disease. Patients with rheumatoid arthritis can develop pulmonary disease for a variety of reasons including infection and rheumatoid interstitial lung disease. Distinguishing methotrexate lung toxicity from other aetiologies is vital in the clinical setting as methotrexate is an effective treatment for rheumatoid arthritis. The aim of this study was to evaluate if methotrexate is associated with an increased risk of lung disease in rheumatoid arthritis.

Methods: We performed a systematic literature search from 1st January 1990 to 31st March 2011 using Pubmed and Cochrane databases. The inclusion criteria for study selection were (1) randomised controlled trials; (2) human patients with rheumatoid arthritis; (3) studies in English; (4) studies consisting of a minimum of two arms, at least one receiving methotrexate and at least one not receiving methotrexate; (5) studies including only adults(>18 years); (6) trials of ≥6 months duration; (7) studies of ≥100 patients; (8) studies reporting respiratory side effects for methotrexate and comparator groups individually. Random effects meta-analysis using the Mantel-Haenszel method was used to assess total respiratory events, infectious respiratory events and non-infectious respi-

ratory events. Results were expressed as relative risks (RR) with 95% confidence intervals.

Results: 21 studies with a total of 8276 participants met our study's inclusion criteria and were included in the meta-analysis. Methotrexate was not associated with an increased risk of total adverse respiratory events, RR 1.1 (95% CI 1.0–1.2, $I^2=8\%$), Figure 1. No difference was identified in the risk of adverse events when analysed separately for infectious and non-infectious outcomes, RR 1.09 (95% CI 1.0–1.19, $I^2=0\%$) and 1.11 (95% CI 0.68–1.81, $I^2=48\%$) respectively. There was no difference in the risk of pulmonary death between the 2 groups, RR 1.41 (95% CI 0.43–4.63, $I^2=0\%$). A subgroup analysis of studies specifically reporting pneumonitis revealed an increased risk in the methotrexate group, RR 6.99 (95% CI 1.57–31.05, $I^2=0\%$); however none of the publications since 2001 in our study reported any cases of pneumonitis.

Test for overall effect: Z = 1.93 (P = 0.05)

Favours methotrexate / Favours comparator

Figure 1. Total Respiratory Events.

Conclusion: Our study did not find a significant increase in the risk of lung disease in RA patients treated with methotrexate. One subgroup analysis showed a significant increased risk of pneumonitis; however publications after 2001 have not reported this association.

2171

Comparative Efficacy of Biologics As Monotherapy and in Combination with Methotrexate in Rheumatoid Arthritis Patients with an Inadequate Response to Conventional Dmards: A Network Meta-Analysis. Felicity Buckley[1], Axel Finckh[2], Tom W. J. Huizinga[3], Fred Dejonckheere[4] and Jeroen P. Jansen[1]. [1]MAPI Consultancy, Boston, MA, [2]University Hospital of Geneva, Geneva, Switzerland, [3]Leiden University Medical Center, Leiden, Netherlands, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background/Purpose: A number of meta-analyses compare the efficacy of biologics for rheumatoid arthritis (RA). However, systematic reviews comparing the efficacy of biologics as monotherapy versus combination with DMARDs are rare,[1] and none include all currently approved biologics. Our objective was to compare ACR response at 24 weeks in RA patients with an inadequate response to conventional DMARDs (DMARD-IR) receiving approved biologics as monotherapy or in combination with methotrexate (MTX).

Methods: A systematic literature review was undertaken to identify RCTs that assessed approved biologic therapies as monotherapy or in combination with MTX in DMARD-IR RA patients. 22 RCTs were identified that evaluated tocilizumab (TCZ), adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, abatacept, or anakinra. ACR responses at 24 weeks were extracted and combined by means of Bayesian network meta-analyses to obtain treatment effect estimates between all interventions included in the analysis, whether directly or indirectly compared. As shown elsewhere,[1,2] an assumption was made that the effects of anti-TNF-α agents (aTNFs) are

exchangeable. Given this, and the limited data identified for these therapies in monotherapy, aTNF data were pooled.

Results: Using random effects models, TCZ + MTX was shown to be comparable to other biologics + MTX across the ACR outcomes. A higher expected treatment effect was seen with TCZ + MTX for ACR70, in line with earlier analyses.[3] When comparing biologic monotherapies with biologics + MTX, TCZ showed a comparable likelihood of ACR20, ACR50, and ACR70 response versus TCZ + MTX ([RR 0.98 (95% credible interval [CrI]: 0.70, 1.71)], [RR 0.92 [95% CrI: 0.62, 1.56)], and [RR 1.04 (95% CrI: 0.58, 2.08)], respectively). aTNF as monotherapy was likely to be less efficacious compared to aTNFs + MTX in terms of ACR20 and ACR50 response (probability better=13% [RR 0.71 (95% CrI: 0.48, 1.64)] and probability better=5% [RR 0.52 (95% CrI: 0.31, 1.25)], respectively). Between monotherapies, the chance of ACR20, ACR50, and ACR70 response for TCZ was found likely to be greater compared to responses for aTNFs (probability better=88%, 97%, and 96%, respectively), in line with recently reported outcomes of a trial[4] comparing TCZ and adalimumab.
Figure 1. Expected ACR50 responcse at 24 weeks with combination therapy and monotherapy (random effects network meta-analysis)

Conclusion: Our network meta-analysis, involving indirect comparison of trial findings, suggests that in DMARD-IR patients, TCZ + MTX shows comparable efficacy to other biologics + MTX. In monotherapy, TCZ is likely to have a greater efficacy than aTNFs and shows comparable efficacy compared to TCZ + MTX, whereas aTNFs are likely to show lower efficacy compared to aTNFs + MTX.

An Update of Management of Coccidioidomycosis in Patients On Biologic Response Modifiers and Disease-Modifying Antirheumatic Drugs.
Susan Knowles[1], Dominick Sudano[1], Sara Taroumian[2], Neil M. Ampel[1], John Galgiani[3], Jeffrey R. Lisse[1] and Susan E. Hoover[1]. [1]University of Arizona, Tucson, AZ, [2]University of California, Los Angeles, Los Angeles, CA, [3]Valley Fever Center for Excellence, Tucson, AZ

Background/Purpose: Coccidioidomycosis (valley fever) is an endemic fungal infection in the Southwestern United States which typically causes a self-limited pulmonary illness. Patients with rheumatic disease on immunosuppressive medication, including methotrexate and tumor necrosis factor (TNF) antagonists, are at higher risk of more severe infection or dissemination. Currently, there are no guidelines for management of coccidioidomycosis in patients on disease-modifying antirheumatic drug (DMARD) or biologic response modifier (BRM) therapy.

Methods: A retrospective chart review identified patients at two centers in Tucson, Arizona, who developed coccidioidomycosis while on DMARD or BRM therapy. Review emphasized disease manifestations, antifungal therapy and duration, as well as management of BRM/DMARD therapy.

Results: Sixty-six patients who developed coccidioidomycosis while on DMARD and/or BRM therapy were identified. Forty-four of these have been previously reported, and their charts were re-reviewed for an additional 12 months of follow-up. Twenty-two new patients were identified. Rheumatologic treatment included BRM alone (18), DMARD alone (15), or combination therapy (33). Eighteen patients were on oral prednisone at the time of diagnosis, with doses ranging from 3 to 40 mg daily (median 10 mg). Manifestations of coccidioidomycosis were asymptomatic positive serologies (15), pulmonary illness (41), and dissemination (10). At the time of coccidioidomycosis diagnosis, 35 patients held all BRM and DMARD therapy, 9 patients held BRM but continued DMARD therapy, and 22 patients had no change in immunosuppressive therapy. Most patients (54) received antifungal therapy, usually for 3 months or longer.

Follow-up data were available for 56 patients. BRM and/or DMARD therapy was continued or resumed in 45 patients, of whom 17 continued concurrent antifungal therapy. Three patients with disseminated disease restarted BRM therapy. The most common reasons for continuing antifungal therapy were persistent positive serology or disseminated disease. The most common reason for stopping antifungal therapy was a negative serology. Follow-up for patients who stopped antifungal therapy or were never treated is 2 to 119 months (median 18 mos). One patient on DMARD and corticosteroid therapy died soon after diagnosis of severe disseminated coccidioidomycosis despite antifungal therapy. Another patient with coccidioidal meningitis had relapse of disease, possibly related to non-adherence to antifungal therapy. Otherwise, there have been no cases of subsequent dissemination or complications to date.

Conclusion: Continuing or restarting DMARD and/or BRM therapy after coccidioidomycosis appears to be safe in some patients with appropriate monitoring. If coccidioidomycosis is asymptomatic and rheumatic disease is active, continuation of DMARD and/or BRM can be considered. Patients with symptomatic infection should stop immunosuppressive therapy and continue antifungal therapy until the coccidioidomycosis is under control.

2173

Pharmacoeconomic Evaluation of Tocilizumab Monotherapy Vs. Adalimumab Monotherapy in Reducing Disease Activity in Patients with Rheumatoid Arthritis.
Navarro Sarabia F[1], Francisco J. Blanco[2], Alvaro Gracia JM[3], JA García Meijide[4] and Jl Poveda[5]. [1]Hospital. Virgen Macarena, Sevilla, Spain, [2]INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [3]H. Universitario La Princesa, Madrid, Spain, [4]Hospital Ntra. Sra. La Esperanza, Santiago de Compostela, Spain, [5]Hospital Universitario La Fe, Valencia, Spain

Background/Purpose: ADACTA trial (Gabay C et al EULAR June 2012) showed that tocilizumab (TCZ) monotherapy was superior to adalimumab (ADA) monotherapy in reducing signs and symptoms of adult rheumatoid arthritis (RA) patients who were either intolerant to methotrexate (MTX) or for whom continued MTX treatment was inappropriate. The aim of the current study was to develop a cost-effectiveness analysis of TCZ vs. ADA in MTX-intolerant/contraindicated patients.

Methods: An economic evaluation based on the ADACTA study was conducted to estimate the incremental cost-effectiveness ratio (ICER) of TCZ vs. ADA. Time horizon was 24 weeks. In ADACTA study, patients were randomly assigned (1:1) to TCZ 8 mg/kg IV every 4 weeks or ADA 40 mg subcutaneously every 2 weeks. Baseline characteristics were similar between the TCZ and ADA. Mean weight considered in the analysis was 68 kgs (C. Rubio-Terrés et al. Farm Hosp 2007; 31: 78–92). To estimate treatment cost for each drug it was considered 6 doses for TCZ and 12 doses for ADA treatment. Patient's response in the model was measured through ACR responses (ACR20/ACR50/ACR70) and DAS28 remission. **Results** were presented as incremental cost of TCZ vs. ADA per response. The analysis was conducted from the perspective of the Spanish National Healthcare System, considering drug costs. Unitary costs (€, 2012) were obtained from a Spanish database. Simple univariate sensitivity analyses were performed, for this analysis it was considered weight and infusion cost.

Results: ACR20 response rates were achieved in 65% and 49.4% in the TCZ and ADA groups respectively (p<0.010). ACR50 response rates were achieved in 47.2% and 27.8% in TCZ and ADA groups (p<0.010) and ACR70 response rates in 32.5% and 17.9% in TCZ and ADA groups

(p<0.010) respectively. DAS28 remission was achieved in 39.9% and 10.5% in TCZ and ADA group (p<0.001). Treatment with TCZ provided better results in cost per response than ADA over 24 weeks in terms of ACR response (ACR20 €8,105 and €11,553; ACR50 €11,162 and €20,382; ACR70 €15,965 and €31,705) and DAS 28 remission €13,509 and €54,352 respectively. TCZ was dominant over ADA in ACR response and DAS28 remission. Sensitivity analysis confirmed the stability of the results.

Conclusion: The results of this analysis suggest that TCZ monotherapy represents an efficient and cost-effective strategy vs. ADA in Spain, for treating RA patients who are MTX intolerant/contraindicated.

ACR/ARHP Poster Session C
Sjögren's Syndrome - Clinical
Tuesday, November 13, 2012, 9:00 AM–6:00 PM

2174

Natural History of Sjögren's Syndrome Phenotypic Features in the Sjögren's International Collaborative Clinical Alliance Registry. Caroline Shiboski[1], Alan N. Baer[2], Mi Y. Lam[1], Stephen Challacombe[3], Hector Lanfranchi[4], Morten Schiødt[5], Hisanori Umehara[6], Frederick B. Vivino[7], Yan Zhao[8], Yi Dong[8], Bruce W. Kirkham[9], Kenneth E. Sack[10], Susumu Sugai[6], Cristina F. Vollenweider[11], Wen Zhang[8], John S. Greenspan[1], Troy Daniels[1], Lindsey A. Criswell[1] and Sjögren's International Collaborative Clinical Alliance[12]. [1]University of California San Francisco, San Francisco, CA, [2]Johns Hopkins University, Baltimore, MD, [3]Kings College London, London, United Kingdom, [4]University of Buenos Aires, Buenos Aires, Argentina, [5]Rigshospitalet, Copenhagen, Denmark, [6]Kanazawa Medical University, Ishikawa, Japan, [7]Penn Presbyt Med Ctr, Philadelphia, PA, [8]PUMCH, Bejing, China, [9]Guys Hospital, London, United Kingdom, [10]Univ of Calif-San Francisco, San Francisco, CA, [11]German Hospital, Buenos Aires, Argentina, [12]University of California San Francisco, CA

Background/Purpose: Sjögren's syndrome (SS) is known to be a relatively stable or slowly progressing disease, however, few studies have actually followed patients over time while taking into account all its components. We explore changes in the phenotypic features (serologic/ rheumatologic, oral, and ocular) of SS, and in SS status, using the new American College of Rheumatology (ACR) classification criteria for SS, among participants in the Sjögren's International Collaborative Clinical Alliance (SICCA) registry over a 2-year time interval.

Methods: SICCA is an international registry enrolling participants with signs and/or symptoms suggestive of SS in 9 centers across 7 countries. It was created to develop new classification criteria, establish a patient data and biospecimen repository and make these available to the scientific community to explore the genotype, phenotype, pathogenesis and epidemiology of this chronic autoimmune disease. All participants found to have any objective measures of salivary hypofunction, ocular dryness, focal lymphocytic sialadenitis in a lip salivary gland (LSG) biopsy, or anti-SSA and/or B antibodies, are recalled 2 years after their baseline examinations to repeat all examinations and specimen collections. We explored change in phenotypic features and in SS status.

Results: As of September 30, 2011, 2510 participants had enrolled in SICCA, and 703, or nearly one third, presented for a 2-year follow-up visit. We found remarkable stability over time of both individual phenotypic features of SS and of SS status. For most phenotypic variables the percent unchanged exceeded 80%, ranging from 77% (for Schirmer's test) to 96% (for anti-SSA/B). The ocular staining score (OSS that may range from 0 to 12) increased from baseline (median=5) to follow-up (median=6) (p<0.0001; signed-rank test). Among 168 participants found to have SS using the 2012 ACR classification criteria, 90% again met these criteria after 2 years. Among those who did not meet the ACR classification criteria at baseline, 11% had progressed and met them at the follow-up visit. One case of mucosa-associated lymphoid tissue lymphoma was detected in a follow-up LSG biopsy. Three other cases of non-Hodgkin's lymphoma were diagnosed during the follow-up period by a study-independent physician.

Conclusion: There was remarkable stability over a 2-year time period of both individual phenotypic features of SS and of SS status. This suggests that to fully characterize longitudinal outcomes and progression,

a longer follow-up interval may be needed. Funded by NIH/NIDCR/NEI N01-DE32636.

Interstitial Lung Disease in Sjogren Syndrome: A Population-Based Study. Carlotta Nannini[1], Adlene Jebakumar[2], Jay H. Ryu[2], Cynthia S. Crowson[2] and Eric Matteson[2]. [1]Prato Hospital, Prato, Italy, [2]Mayo Clinic, Rochester, MN

Background/Purpose: The reported frequency of pulmonary involvement in primary Sjögren's Syndrome (pSS) varies widely ranging from 8 to 75% depending on the detection method employed and consists of various forms of airways disease. There is little information regarding interstitial lung disease (ILD) patterns other than lymphocytic interstitial pneumonia occurring in pSS in terms of frequency and risk factors. We aimed to assess incidence, and mortality of ILD in a well-characterized, population-based cohort of patients with pSS.

Methods: We examined a population-based incidence cohort of patients diagnosed with pSS in 1976–2005. All subjects were followed longitudinally through their complete community medical records, until death, migration or August 2011. ILD was defined using strict, validated composite criteria developed by an expert panel including pulmonologists and rheumatologists. These criteria included physician diagnosis, radiologic data, pulmonary function parameters, lung biopsy and autopsy findings. Cumulative incidence adjusted for the competing risk of death was estimated. A Cox model with a time-dependent covariate for development of ILD was used to examine the impact of ILD on survival in patients with pSS.

Results: 105 patients with pSS were identified (mean age 58.1 years; range 23–95; 91% female). Lung disease was present prior to diagnosis of pSS in 12 patients and developed after diagnosis of pSS in 35 patients with a median follow-up time of 9.2 years (1205 total person-years). Among pSS patients without prior ILD, the cumulative incidence of ILD in patients with pSS was 10% (± 3%) at 1 year after diagnosis of pSS and increased to 20% (± 4%) by 5 years after pSS. The development of lung disease in pSS was associated with poor survival with an hazard ratio of 2.16 (95%CI: 0.99, 4.74) adjusted for age, sex, and calendar year. ILD was identified as the most frequent type of lung disease detected at or after pSS diagnosis (53%) followed by emphysema (13%).

Conclusion: Our findings emphasize the high incidence of ILD and the adverse effect on survival in patients with pSS. Patients with pSS should be carefully assessed for diagnosis and treatment of ILD in order to improve the detrimental survival experience.

Pulmonary Manifestations and Treatment of Primary Sjogren's Syndrome-Associated Lung Involvement Patients: A Prospective Study. Hui Gao, Xuewu Zhang, Jing He, Min Feng, Wei Zhao, Yan Ding and Zhan-guo Li, Peking University People's Hospital, Beijing, China

Background/Purpose: Pulmonary involvement is common in primary Sjögren's syndrome (pSS). Clinicopathologic pulmonary manifestations associated with pSS have yet to be reviewed in a large series. However, the pulmonary functional and radiological characteristics of pSS-associated lung disease which are more practical in clinic were less studied. Besides, the treatment of those patients has hardly been explored before. Most studies were specifically designed to evaluate sicca features. We aimed to describe the clinical, radiologic, and pulmonary Functional characteristics in a large Chinese pSS patient with lung involvement, and to analyze efficacy and safety of corticosteroid therapy combined with hydroxychloroquine (HCQ) or intravenous cyclophosphamide (CTX) in pSS-associated lung disease.

Methods: A total of 112 hospitalized patients with pSS-associated lung disease were retrospectively analyzed. The high-resolution computed tomography (HRCT) was re-evaluated by two experienced chest radiologists. Autoantibodies, inflammation markers, arterial blood gas (ABG) and PFT results were obtained.

A total of 15 patients were recruited in the prospective study. Prednisone was prescribed initially at a dosage of 30–40mg/day, and was tapered to 7.5mg/d within 4 months. HCQ was administered at a dosage of 200mg, twice a day. CTX was administered intravenously at an initial dosage of 400mg, every 2 weeks for 6 months, and then tapered to 400mg every 4 weeks.

Results: Among the 112 pSS patients with lung involvement, 102 (91.10%) were female. The mean age was 61.74 ± 10.24 years old. The disease duration was 60 months (12.00 to 147.00 months). Elevated IgG was prominent in those patients. There were more frequent and severer of the lower lung lobes involvement. The most frequent HRCT findings were linear opacities (94.2%), ground-glass attenuation (87.0%), reticular pattern (65.2%) and pleural involvement (65.2%). Impaired diffusing capacity was the most significant (74.3%). Among the 36 patients who took ABG, 20 patients had hypoxia and 7 had Type 1 respiratory failure.

Seven patients took oral prednisone combined with HCQ and 8 patients received oral prednisone combined with intravenous CTX. One patient from CTX group withdrew from the study for stopping DMARDs to have surgery. The rest were followed up for 11.57 ± 4.91 months. There was evidence of improvement in HRCT for most of the patients, and no obvious deterioration of PFT was observed. One patient in HCQ group presented hypoleukemia, which was ameliorated after reducing to 100mg, twice a day. Two patients had pneumonia and one had herpes zoster virus (HZV) infection in CTX group.

Conclusion: The distribution of the abnormalities and severe parenchymal involvement are most pronounced in the lower lobes of pSS patients. Impaired diffusing capacity is the most significant PFT abnormalities. Hypoxia is not rare for pSS-association lung involvement patients. Corticosteroid therapy combined with hydroxychloroquine or intravenous cyclophosphamide is administered with a favorable response seen in the majority of patients. This should be further confirmed in a large cohort.

The Forced Oscillation Technique Is a Sensitive Method for Detection of Obstructive Airway Disease in Patients with Primary Sjögren's Syndrome.
Anna M. Nilsson[1], Elke Theander[2], Roger Hesselstrand[3], Per Wollmer[2] and Thomas Mandl[2]. [1]Skane University Hospital Malmo, Lund University, Malmo, Sweden, [2]Skane University Hospital Malmo, Lund University, Malmö, Sweden, [3]Skane University Hospital Lund, Lund University, Lund, Sweden

Background/Purpose: To study signs of obstructive airway disease in patients with primary Sjögren's syndrome (pSS) by the forced oscillation technique (FOT), a method that may aid in distinguishing between peripheral and central airway obstruction.

Methods: 37 female pSS patients (median age 64, range 38–77 years) without known chronic obstructive pulmonary disease (COPD), participating in a longitudinal follow-up study of pulmonary function, and 74 female population-based controls (median age 64, range 47–77 years), also without known COPD, and matched with regard to gender, age, height, weight and tobacco consumption were included in the study. The pSS patients and controls were after inhalation of beta agonist studied by the FOT, evaluating airway resistance and reactance, at different oscillation frequencies, as well as the resonance frequency. pSS patients were also assessed by spirometry according to which 14 were diagnosed with obstructive airway disease (OAD) (12 with COPD and 2 with abnormal reversibility test).

Results: pSS patients had significantly increased resistances at 5–25Hz (p<0.001), decreased reactances at 10–35Hz (p<0.001) and an increased resonance frequency (p=0.002) whilst the resistance slope between 5 and 20Hz was not significantly different (p=NS) in comparison with controls. Airway resistance was negatively correlated and airway reactance positively correlated to the vital capacity, the forced expiratory volume in 1 second and the diffusion capacity for carbon monoxide. Both pSS patients with and without OAD had significantly increased resistances at 5–25Hz (p<0.001) and decreased reactances at 10–35Hz (p<0.001) in comparison with controls respectively, whilst only the former had a significantly increased resonance frequency (p<0.001).

Conclusion: pSS patients showed FOT signs of airway obstruction, possibly due to airway sicca, impaired mucus clearance and bronchial inflammation. OAD also affect central airways in pSS. Also pSS patients without spirometric signs of OAD show clear FOT signs of airway obstruction. FOT thus seems to be a sensitive method in detecting airway obstruction in pSS patients.

18-Fludeoxyglucose Positron Emission Tomography Is a Valuable Marker of Activity of Interstitial Lung Disease in Primary Sjogren's Syndrome.
Camille Cohen[1], Arsene Mekinian[1], Michael Soussan[2], Yurdagul Uzunhan[2], Veronique Eder[2], Robin Dhote[3], Dominique Valeyre[4] and Olivier Fain[5]. [1]Jean Verdier Hospital, Bondy, France, [2]Bobigny, France, [3]Avicenne Hospital, Bobigny, France, [4]Avicenne Hospital (AP-HP), Bobigny, France, [5]Service de médecine interne, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France., Bondy, France

Background/Purpose: To assess the value of 18-Fludeoxyglucose Positron Emission Tomography (PET) in patients with primary Sjogren's Syndrome (pSS).

Methods: All patients with confirmed pSS (AECG) from 3 French university centers who underwent PET were retrospectively analysed. PET was realized to assess activity in SS-related interstitial lung disease (ILD) (n=24), lymphoma suspicion (n=10) or systematically (n=5). Positive PET was defined as FDG uptake >2.5 SUVmax. A control group was constituted of patients with PET for isolated pulmonary nodule (n=17).

Results: Thirty-nine patients with pSS were included (table 1). FDG uptake was noted in 30 cases (83%): salivary gland (n=20 (57%); median SUVmax 3.1 [2,8-4]); lymph nodes (n=24 (67%); median SUVmax 5 [4–8]); pulmonary uptake (n=13 (33%); median SUVmax 3,3 [3–6]) and thyroiditis (n=3). Salivary gland uptake was more frequent and SUVmax was higher in pSS than in the control group (median 3 [2,8-4] versus 2 [1,5-2,5]; p<0,001).

Lymph node fixation	24 (67%)	7 (50%)	18 (75%)
Lymph node SUVmax	5 [4–8]	3,8 [3–4]	5,4 [4–8]
Salivary gland fixation	20 (57%)	10 (71%)	11 (48%)
Salivary gland SUVmax	3,1 [2,8–4]	2,7 [2,7 –3]	3 [2,7–4]

* p<0,005
** p =0,006

In 24 patients with ILD, 13 (57%) had FDG pulmonary uptake (median SUVmax 3 [3–6]). Whereas there were no clinical, biological or functional respiratory test difference between ILD patients with/without FDG uptake, patients with pulmonary FDG uptake had also more lymph node uptake, and PET allowed the diagnosis of active ILD in these patients, with 100% specificity.

In 10 patients with PET for suspected lymphoma, PET confirmed diagnosis in 6 cases, and confirmed the remission in 1 case.

Lymph node FDG uptake was present in 24 (67%) cases and was significantly associated with pulmonary uptake in ILD patients. With a follow up of 2 years [0,8-4], no patient with lymph node FDG uptake developed lymphoma.

Conclusion: Whereas salivary uptake is frequent in pSS, in patients with ILD, PET could constitute an interesting tool to assess activity, and necessitate to be confirmed in prospective study.

Disclosure: **C. Cohen**, None; **A. Mekinian**, None; **M. Soussan**, None; **Y. Uzunhan**, None; **V. Eder**, None; **R. Dhote**, None; **D. Valeyre**, None; **O. Fain**, None.

High Resolution CT Findings and Concomitant Nontuberculosis Mycobacterial Infection (NTM) in Patients with the Diagnosis of Primary Sjogren's Syndrome Evaluated At a Respiratory Referral Center. Mehrnaz Maleki-Fischbach[1] and Gloria M. Russell[2]. [1]National Jewish Health, Denver, CO, [2]Pontificia Universidad Católica Madre y Maestra, Santiago, Dominican Republic

Background/Purpose: Although lung disease can occur with primary Sjogren's syndrome (pSS), far too little is known about the clinical phenotype or natural history of its lung involvement. The objective of this retrospective observational study was to characterize a cohort of subjects with pSS-associated lung disease. It also seems that there is an association between pSS and nontuberculousis mycobacterial (NTM) infection.

Methods: We identified all subjects evaluated at our center between Jan. 2008–May 2012 that fulfilled the American-European classification criteria for the diagnosis of pSS and that had respiratory symptoms along with thoracic high resolution CT (HRCT) available to review. All clinical data were extracted from the medical record by comprehensive review. We excluded patients with secondary Sjogren's syndrome.

Results: A total of 38 subjects were identified. Mean age was 63.7 years (range 50–78) and all but one of the subjects were women. A history of past smoking was reported in 14 (37%) and only one subject was an active smoker. All reported xerostomia and keratoconjunctivitis sicca Other pSS associated manifestations included the presence of Reynaud's in 5 (13%), arthritis in 8 (21.0%), arthralgias in 31 (82%), and esophageal reflux in 27 (71%). All of the subjects had positive SS-A and/or SS-B antibodies. 37 were SS-A positive, 26 were SS-B positive and 25 had both positive. (Mean SS-A & SS-B were 106.5 and 78.1 units respectively) Also all of the patients had positive ANA (titer range 1:160-1:2560) by direct immunofluorescence. ANA patterns identified; 26 (68.4%) speckled, 1 (2.6%) homogeneous, 1 (2.6%) centromere, 6 (15.7%) speckled and nucleolar, and 4 (10.5%) speckled and homogeneous. 22 were rheumatoid factor positive. All of the subjects had respiratory symptoms as manifested either by isolated cough (n=33, 87%), dyspnea (n=36, 95%) or both. 12 (31.6%) patients had proven infection with Nontuberculousis Mycobacteriosis (NTM).

High resolution CT (HRCT) of the chest showed 24 (63.1%) patients with airway disease including 1 (2.6%) with large airway disease, 3 (7.9%) with bronchiolitis, 3 (7.9%) with bronchiolitis plus bronchiectasis and 17 (44.7) with bronchiectasis out of which 11 (28.9%) had proven NTM infection as well. 4 (10.5%) patients were found to have interstitial lung disease (ILD); 3 (7.9%) patients with lymphoid interstitial pneumonia (LIP) and 1 (2.6%) patient with nonspecific interstitial pneumonia (NSIP). 10 (26.3) patients had combined ILD and airway disease including 1 (2.6%) with LIP, bronchiectasis and bronchioloitis; 4 (10.5%) with LIP and bronchiectasis; 3 (7.9%) with NSIP and bronchiolitis and 2 (5.3%) with NSIP and bronchiectasis. One (2.6%) of the patients with LIP and bronchiectasis also had concomitant NTM infection.

Conclusion: There is a myriad of pulmonary manifestations associated with pSS. In this cohort, the most common lung manifestation was airway disease. It also seems that pSS may predispose patients to NTM infection and NTM having a causative effect on worsening their lung condition. Further studies are needed to better define the natural history of pSS-associated lung disease and possible relationship with NTM infection especially among middle age and elderly women.

Coronary Flow Reserve and Asymmetric Dimethylarginine Levels: New Measurements for Identifying Subclinical Atherosclerosis in Patients with Primary Sjögren's Syndrome. F. Atzeni[1], L. Boccassini[1], M.C. Signorello[2], MA Carrideo[2], L. Gianturco[2], V. De Gennaro Colonna[3], L. Drago[4], M. Turiel[2] and P. Sarzi-Puttini[1]. [1]Rheumatology Unit, L. Sacco University Hospital of Milan, Milan, Italy, [2]IRCCS Galeazzi Orthopedic Institute, University of Milan, Department of Health Technologies, Cardiology Unit,, Milan, Italy, [3]Pharmacology Department, University of Milan, Milan, Italy, [4]Laboratory Unit, IRCCS Galeazzi Orthopedic Institute, Department of Health Technologies, University of Milan, Milan, Italy

Background/Purpose: Clinical and biochemical data suggest that autoimmune diseases are associated with endothelial dysfunction and increased atherosclerosis. We have previously shown that asymmetric dimethylarginine (ADMA) levels and coronary flow reserve (CFR) are impaired in patients with early rheumatoid arthritis, but it is not known whether the same is true of patients with primary Sjögren's syndrome (SS). We therefore investigated sub-clinical cardiovascular involvement in primary SS patients by means of ADMA and coronary flow reserve (CFR) assessments.

Methods: The study involved 15 patients who fulfilled the ACR criteria for primary SS without any documentable cardiovascular disease and 20 age- and gender-matched control subjects. Dipyridamole transthoracic stress echocardiography was used to evaluate wall motion and CFR in the distal segment of the left anterior descending coronary artery before and after dipyridamole infusion (0.86 mg/kg over six minutes). A CFR value of <2.5 was considered a sign of impaired coronary functionPlasma ADMA levels were determined using high-performance liquid chromatography. Linearity was assessed in the range of ADMA 0.1–20 μM. The mean correlation coefficient was >0.99. The ADMA limit of quantitation (LOQ) was 0.01 μM.The continuous variables were expressed as mean values and standard deviations, and the non-continuous variables as median values and interquartile ranges (IQR). The data were analysed using SAS statistical software 9.2. All tests were two-tailed, and probability (p) values of less than 0.05 were considered statistically significant.

Results: All of the patients were affected by primary SS, the majority of patients were being treated with hydroxychloroquine (HCQ) at dose of 400 mg/day, two were taking methotrexate (MTX) and four azathioprine (AZA) at a mean dose of 150 mg/day (range 50–200 mg). Only 3 patients used corticosteroids—one at a dosage of 2.5 mg and two at 5 mg/daily. All of the patients were ANA and/or RF and anti-SSB and/or anti-SSA positive. The patients' mean age and ejection fraction were respectively 62 ± 8 years and 65% ± 6% (not significant). Although within the normal range, their CFR was lower than that of the controls (median 3.0, IQR 2.5–3.5 *vs* median 3.4, IQR 3.2–3.82, P=0.02), whereas their ADMA levels were significantly higher (median 0.80 mM, IQR 0.78–0.82mM *vs* median 0.55mM, IQR 0.49–0.59mM respectively; P <0.0001) and their E/A ratios significantly lower (median 0.8, IQR 0.7–1.1 *vs* median 1.3, IQR 1.3, 1.2–1.4; P <0.0001).

Conclusion: Higher ADMA levels suggest the presence of endothelial dysfunction and sub-clinical atherosclerosis in primary SS patients, even in the case of normal CFR. Our preliminary data indicate that ADMA may be a useful marker for identifying early endothelial dysfunction in primary SS patients.

Concomitant Atheosclerosis and Impaired Bone Health in Patients with Primary Sjogren's Syndrome. Clio P. Mavragani[1], Fotini Gravani[2], Andrianos Nezos[1], Eleni Antypa[3], Kiki Maselou[3], Dimitrios Ioakeimidis[4], Michael Koutsilieris[1] and Haralampos M. Moutsopoulos[5]. [1]School of Medicine, University of Athens, Athens, Greece, Athens, Greece, [2]School of Medicine, University of Athens, Athens, Greece, M Asias st, Athens, Greece, Athens, Greece, [3]General Hospital of Athens, Greece, [4]General Hospital of Athens "G. Gennimatas", Greece, Greece, [5]School of Medicine, University of Athens, Athens, Greece

Background/Purpose: To determine the prevalence of subclinical atherosclerosis and impaired bone health in primary Sjogren's syndrome (pSS) patients and to explore whether they associate with clinical and

serological disease features, traditional risk factors for cardiovascular disease (CVD) and osteoporosis as well as with activation of the Receptor activator of nuclear factor kappa-B ligand (RANKL)-RANK system, previously implicated in the pathophysiology of both CVD and osteoporosis.

Methods: 64 consecutive pSS patients according to the American-European Classification Criteria (mean age $\pm$SD 57.19$\pm$12.4) and 39 healthy controls °f similar age and sex distribution (mean age $\pm$SD 53.6$\pm$7.04) were enrolled. Demographic data, clinical, laboratory and histopathological features were recorded and classical risk factors for atherosclerosis and osteoporosis were evaluated. Patients and controls underwent intimal-medial thickness score (IMT) and bone mineral density (BMD) levels measurements. The presence of carotid/femoral plaque and fractures was also determined by ultrasound and lateral spine radiographs respectively. Serum RANKL and osteoprotegerin levels were determined by ELISA. RANKL and osteoprotegerin mRNA levels were determined in cDNA derived from minor salivary gland (MSG) tissues from 19 pSS patients, 9 pSS patients complicated by lymphoma and 11 sicca controls by real time PCR. Determinants of IMT/BMD levels and the presence of plaque were assessed by univariate and multivariate models. Comparisons between groups were performed by Fisher's exact two tailed test and Mann Whitney test.

Results: Increased prevalence of subclinical atherosclerosis (defined as IMT >0.90mm) and osteoporosis/osteopenia was detected in pSS patients compared to controls [58.7% vs 27.5%, p=0.0071 and 61.2% vs 20.5%, p=0.0001) with fracture rates not significantly differing between the two groups. Multivariate analysis in the pSS group revealed age, BMI and periepithelial disease (defined as peribronchial, interstitial nephritis, primary biliary cirrhosis) as independent predictors of IMT, age and lymphopenia as independent determinants of carotid and/or femoral artery plaque and increased urine PH, periepithelial disease and total steroid dose as independent predictors of osteoporosis and/or osteopenia. The latter was independently associated with the presence of plaque, when independent predictors for both variables were included in the multivariate model [(OR:4.75 (1.05–21.47, p=0.043)]. Compared to the control group, pSS patients displayed increased serum RANKL levels (p=0.0003) while at MSG tissue, mRNA RANKL/osteoprotegerin ratio was significantly increased in pSS patients complicated by lymphoma compared to sicca controls.

Conclusion: pSS patients are characterized by higher levels of concomitantly occurring subclinical atherosclerosis and impaired bone health compared to their healthy counterparts, with traditional risk factors, disease related features and activation of RANKL system being potential contributors. The significance of RANKL activation in pathogenesis of SS related complications remains to be further explored.

Prevalence of Fibromyalgia Is Increased in Primary Sjögren's Syndrome Compared with SLE and Associated with Depression and Severe Vitamin D Deficiency. Byoong Yong Choi, Hye Jin Oh, Jun Won Park, Bon Seung Ku, Sung Hae Chang, Eun Young Lee, Eun Bong Lee and Yeong Wook Song. Seoul National University Hospital, Seoul, South Korea

Background/Purpose: Although clinical features of primary Sjögren's syndrome (pSS) overlap with those of fibromyalgia (FM), the relationship between FM and pSS has remained unclear. Furthermore, ACR preliminary diagnostic criteria for FM developed in 2010 do not require a tender point exam and focus on the presence of widespread pain or somatic symptoms. This cross-sectional study was conducted to investigate the prevalence and risk factors of FM in pSS.

Methods: Sixty-nine with pSS and 97 with systemic lupus erythematosus (SLE) were assessed to identify the presence of FM based on the 2010 ACR criteria. Clinical and laboratory data for pSS or SLE were collected from all patients. Additional assessments included number of tender points (TPs), visual analogue scale (VAS) of pain, fatigue, and Fibromyalgia Impact Questionnaire, Hamilton depression rating scale 17-items (HAM-D). Serum 25-hydroxy vitamin D (25-OH-D) levels were determined in patients with pSS. Disease activities in pSS were measured using EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI).

Results: The prevalence of FM was 28% [95%CI: 17.0–38.0] in pSS and 3.0% [95% CI: 0–7.0] in SLE. Primary SS patients had more frequent somatic symptoms such as myalgia (p=0.016), insomnia (p=0.048), headache (p=0.018) and cognitive dysfunction (p<0.001) compared to SLE patients. The widespread pain index (WPI) and score of somatic symptom scale (SS scale) in pSS patients were also significantly higher than those of SLE. Multiple linear stepwise regression analysis showed that HAM-D, ESSDAI and serum 25-OH-D levels were the significant determinants of WPI; HAM-D and serum 25-OH-D levels were also the significant determinants of score of SS scale in pSS patients. Depression and severe 25-OH-D deficiency (<10 ng/mL) in pSS was associated with presence of FM (OR: 34.00 [95% CI: 6.72–171.9], OR: 4.15 [95% CI: 1.09–15.83], respectively).

Conclusion: The prevalence of FM was higher in patients with pSS compared to SLE. Depressive mood and severe vitamin D deficiency in pSS patients was associated with the presence of FM.

Common Features in Lymphoproliferative Complications in the Course of Primary Sjögren's Syndrome: Results From a Multi-center Cohort of 1170 Patients. Luca Quartuccio[1], Chiara Baldini[2], Roberta Priori[3], Elena Bartoloni Bocci[4], Francesco Carubbi[5], Miriam Isola[6], Marta Maset[1], Sara Salvin[1], Nicoletta Luciano[2], Giovanna Picarelli[3], Alessia Alunno[4], Roberto Giacomelli[7], Roberto Gerli[8], Guido Valesini[9], Stefano Bombardieri[2] and Salvatore De Vita[10]. [1]Rheumatology Clinic, DSMB, University of Udine, Italy, Udine, Italy, [2]Rheumatology Unit, University of Pisa, Pisa, Italy, [3]Rheumatology Unit, Sapienza University of Rome, Rome, Italy, [4]Rheumatology Unit, Department of Clinical & Experimental Medicine, University of Perugia, Perugia, Italy, [5]Rheumatology Clinic, University of L'Aquila, L'Aquila, Italy, [6]Institute of Statistics, University of Udine, Udine, Italy, [7]Rheumatology Unit, University of Aquila, L'Aquila, Italy, [8]Rheumatology Unit, University of Perugia, Perugia, Italy, [9]Sapienza, Universita di Roma, Rome, Italy, [10]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy

Background/Purpose: To describe the prevalence of lymphoproliferative complications (defined as B-cell lymphoma or definite conditions predisposing to lymphoma, i.e, cryoglobulinemic vasculitis (CV) and major salivary gland swelling) in the course of primary Sjögren's syndrome (pSS) in a large cohort of patients followed in five Rheumatologic Centres.

Methods: Demographic, clinical, laboratory and histopathologic data in 1170 pSS were retrospectively collected according to a standard protocol. Univariate and multivariate analyses were performed.

Results: Prevalence of lymphoma in this SS cohort was 4.4% (51/1170), prevalence of CV was 3.9% (33/850), and prevalence of salivary gland swelling and/or myoepithelial syaladenitis was 30.9% (362/1170). Salivary gland swelling and/or MESA, CV and lymphoma shared many laboratory features, i.e., positive rheumatoid factor, hypocomplementemia and leucopenia, as well as a the presence of purpura as clinical hallmark of the circulating immune complexes (table 1). Interestingly, polyclonal hypergammaglobulinemia was strictly associated with salivary gland swelling, but it was not associated with CV or lymphoma; on the other hand, serum monoclonal component was significantly associated with CV or lymphoma, but not with salivary gland swelling and/or MESA (table 1). Younger age was associated with salvary gland swelling and/or MESA, while male sex with an increased risk of lymphoma (OR 5.4 95% CI 2.4–11.7) (table 1). By multivariate analyses, glandular swelling (OR 8.9 95%CI 4.0–19.9, p<0.0001), low C4 (OR 6.2 95%CI 3.0–12.8, p<0.0001), anti-La (OR 3.8 95%CI 1.8–7.9, p<0.0001), leukopenia (OR 2.8 95%CI 1.4–5.7) and monoclonal component (OR 3.2 95%CI 1.3–7.9, p=0.01) were strictly related to lymphoma, while peripheral nervous system involvement (OR 6.8 95%CI 2.1–21.6, p=0.001), low C4 (OR 7.3 95%CI 2.7–19.8, p<0.0001) and leukopenia (OR 6.5 95%CI 2.3–17.9) with CV, and, finally, younger age (OR 0.97 95%CI 0.96–0.98, p<0.0001), lymphoma (OR 7.9 95%CI 3.9–16.1, p<0.0001) and hypergammaglobulinemia (OR 1.5 95%CI 1.1–2.0, p=0.007) with salivary gland swelling and/or MESA.

Feature	SS with salivary gland swelling and/or MESA (362/1170: 30.9%) P value	SS with cryoglobulinemic vasculitis (33/850: 3.9%) P value	SS with lymphoma (5I/1170: 4.4%) P value
Age (yrs)	<0.0001 (for youngers)	ns	ns
Sex	ns	ns	<0.0001 (for males)
Salivary gland swelling and/or MESA	NA	ns	<0.0001
Cryoglobulinemic vasculitis	0.009	NA	0.001
Lymphoma	<0.0001	<0.0001	NA
Purpura	0.03	<0.0001	0.02
Peripheral nervous system	ns	<0.0001	0.04
Renal involvement	ns	0.007	ns
Fibromyalgia	ns	0.007	ns
ANA positivity	0.001	ns	ns
Anti-SSA positivity	<0.0001	ns	0.005
Anti-SSB positivity	<0.0001	ns	<0.0001
Rheumatoid factor positivity	<0.0001	<0.0001	<0.0001
Presence of serum cryoglobulins	ns	<0.0001	<0.0001
Low C3	0.003	<0.0001	0.02
Low C4	<0.0001	<0.0001	<0.0001
Leukopenia (<3000/mmc)	0.004	<0.0001	<0.0001
Hypergammaglobulinemia (>1.7 g/l)	<0.0001	ns	ns
Presence of serum M-component	ns	<0.0001	<0.0001

Conclusion: Salivary gland swelling, CV and B-cell lymphoma are consequent to B-cell deregulation in SS. B-cell clonal proliferation from polyclonal to monoclonal likely occurs in the pathologic target tissue of SS (i.e., salivary gland MALT tissue), predisposing to CV and/or to B-cell lymphoma.

Pregnancy and Fetal Outcome in Patients with an Established Diagnosis of Primary Sjögren's Syndrome.. Roberta Priori[1], Angelica Gattamelata[1], Mariagrazia Modesti[1], Serena Colafrancesco[1], Marta Maset[2], Luca Quartuccio[2], Salvatore De Vita[2], Elena Bartoloni Bocci[3], Alessia Alunno[3], Roberto Gerli[3], Francesca Strigini[4], Chiara Baldini[4], Chiari Tani[4], Marta Mosca[4], Stefano Bombardieri[4] and Guido Valesini[1]. [1]Rheumatology Unit, Sapienza University of Rome, Rome, Italy, [2]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy, [3]Rheumatology Unit, Department of Clinical & Experimental Medicine, University of Perugia, Perugia, Italy, [4]Rheumatology Unit, University of Pisa, Pisa, Italy

Background/Purpose: To investigate pregnancy and fetal outcome in patients with an established diagnosis of primary Sjögren's syndrome (pSS).

Methods: The clinical charts of 1075 women with pSS, from four Italian referral rheumatology centres were retrospectively evaluated. When a pregnancy has occurred after pSS diagnosis, the patient was personally interviewed to obtain more detailed information regarding obstetric history; obstetric clinical charts were reviewed as well. In a subgroup analysis from a single center, each delivery in patients with an established diagnosis of pSS was compared with the first 8 consecutive deliveries occurred during the same month in the referral universitary hospital. Chi square and Mann-Whitney test, SPSS release 15.00, were used for statistical analysis.

Results: Patients' mean age was 59 yr (17–89), mean age at diagnosis 51,4 yr; 139/1075 (12,8%) were diagnosed before 35 yr. Thirty-six women (31 with anti-SSA/Ro and/or anti-SSA/La antibodies) with an established diagnosis of pSS had 45 pregnancies which ended with the delivery of 40 newborns. Two miscarriages, 2 fetal death and one induced abortion were recorded. Mean age at the first pregnancy was 33,9 yr (range 27–44), mean number of pregnancy 1,25 (1–3); 18/40 (45%) cesarean sections were performed, mean pregnancy length was 38,5 week (range 32–43) with 6 preterm delivery. The mean Apgar score at 5 minute was 8,9 (range 5–10), mean birth weight was 2920 mg (range 826–4060). Congenital heart block (CHB) occurred in 2/36 newborns (5,5%) of 31

mothers with anti-SSA and/or SSB antibodies with fatal outcome. The reported rate of breastfeeding for at least one month was 60,5% (range 1–21 months), 44,7% for 3 months, During pregnancy one patient presented thrombocytopenia and another palpable purpura. In 4/40 pregnancies (10%) a flare of disease activity was observed within a year from delivery. In the case-control subgroup analysis no significant differences were found regarding age at delivery, pregnancy duration, way of delivery, baby sex. The neonates of primary SS mothers tended to have a lower weight and a lower Apgar score but the difference was not significant.

Conclusion: Even if pSS generally starts after menopause, it can appear during the childbearing age. pSS can have successful pregnancies, which might be followed by a mild relapse. CHB, a fearful complication for women with anti-SSA/Ro and or anti-SSB/La antibodies, is the only cause of death for offspring of pSS mothers.

2185

Prevalence of Severe Extra-Glandular Manifestations in a Large Cohort of Patients with Primary Sjögren's Syndrome. Chiara Baldini[1], Pasquale Pepe[1], Luca Quartuccio[2], Roberta Priori[3], Elena Bartoloni Bocci[4], Alessia Alunno[4], Serena Colafrancesco[3], Angelica Gattamelata[3], Marta Maset[2], Mariagrazia Modesti[3], Antonio Tavoni[1], Salvatore De Vita[2], Roberto Gerli[4], Guido Valesini[3] and Stefano Bombardieri[1]. [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Rheumatology Clinic, DSMB, University of Udine, Italy, Udine, Italy, [3]Rheumatology Unit, Sapienza University of Rome, Rome, Italy, [4]Rheumatology Unit, Department of Clinical & Experimental Medicine, University of Perugia, Perugia, Italy

Background/Purpose: i) to describe the clinico- serological features of a cohort of 1115 patients with primary Sjögren's syndrome (pSS); ii) to assess the prevalence of systemic extra-glandular manifestations in the cohort; iii) to estimate the impact of the serological and immunological patients' features on disease different phenotypes and on the utilization of immunosuppressive drugs

Methods: The case records of 1115 patients with a diagnosis of pSS attending four Italian reference centers were reviewed. Clinical and laboratory data of the patients enrolled were retrieved according to a standard form. Independent risk factors for glandular and extra-glandular disease manifestations were identified by logistic regression.

Results: The cohort consisted of 1115 pSS patients (1067 F: 48 M; mean age at the diagnosis of 51.6 ± 13.8 yrs; mean follow-up 5.8 ± 6.5 yrs). All the patients included fulfilled the European classification criteria for pSS, while the AECG criteria were fulfilled in 926/1115 (83%) cases. Xerostomia (93%), xerophtalmia (95%) and articular involvement (62%) were the most commonly detected clinical manifestations followed by hematological involvement (32%) and salivary gland enlargement (31%). A systemic extra-glandular involvement was diagnosed in 475/1115 (42%) patients. Severe extraglandular manifestations included: active synovitis (11%), axonal sensory-motor neuropathy (2%), diffuse purpura or ulcers (6%) renal involvement (0.7%), myositis (0.5%), cerebral vasculitis (0.5%) and transverse myelitis (0.2%). Finally, 50 cases of non-Hodgkin lymphoma were documented. Patients with a systemic disease had a lower mean age at diagnosis (p=0.002), a longer follow up (p<0.0001) and a higher frequency of serologic markers (ANA, RF, anti-Ro/SS-A antibodies, anti-LA/SS-B antibodies, cryoglobulins, hypergammaglobulinemia, low C3/C4 levels) in the univariate analysis. The adjusted multivariate analysis identified as independent serological risk factors for severe extraglandular involvement: low C3 (OR 2.6, 95% CI 1.6–4.1), low C4 (OR1.9, 95% CI 1.1–3.3), hypergammaglobulinemia (OR 2.1, 95% CI 1.5–2.9), cryoglobulins (OR 7.6, 95% CI 2.6–22.3), Rheumatoid factor (OR 2.5, 95% CI 1.5–22.9). No correlation was found among pSS extraglandular involvement and fulfillment of the AECG criteria or positive minor salivary gland biopsy at the diagnosis.

Conclusion: Although the hallmark features of pSS are represented by glandular manifestations, this study support the evidence that severe systemic manifestations may occur in about the 20% of the patients.

Patients presenting an active serological profile should be more closely monitored and may deserve more aggressive immunosuppressive drugs.

Ultrasonography of Major Salivary Glands in Primary Sjögren's syndrome. Malin V. Jonsson[1], Daniel Hammenfors[2], Johan G. Brun[2] and Roland Jonsson[1]. [1]University of Bergen, Bergen, Norway, [2]Haukeland University Hospital, Bergen, Norway

Background/Purpose: Minor salivary gland biopsy is part of the diagnostic process for primary Sjögren's syndrome (pSS), but is not suitable for repeated follow-up. Ultrasound (US) represents a non-invasive imaging method of the major salivary glands that may serve as a supplement to minor salivary gland biopsy. The aim of this study was to investigate parotid and submandibular gland ultrasound in relation to sicca symptoms, glandular function and minor salivary gland inflammation.

Methods: Patients with primary Sjögren's syndrome were recruited from Haukeland University Hospital (n=41). The parotid and submandibular glands were examined by US using a GE LogiqE9 with a linear transducer with 6–16MHz. Glandular homogeneity and presence of hypoechogenic areas was evaluated and scored (0–3) according to Hocevar et al 2005. Scores 0–1 were considered normal and scores 2–3 pathological. Sicca symptoms of the mouth and eyes were recorded. Salivary gland functional capacity was evaluated by unstimulated and stimulated sialometry. Tear secretion was evaluated by the Schirmer I-test. Minor salivary gland inflammation was evaluated by focus score.

Results: Ultrasound was performed in 40 patients, with scores ranging 0–1 (n=22) and 2–3 (n=18). Mean age of patients with normal US findings was 63 years compared to 52 years in patients with pathological US findings ($p<0.05$), and correlated with ultrasound score ($p<0.05$, r=-0.388, n=40). Oral sicca symptoms correlated with sicca symptoms of the eyes ($p<0.001$, r=592, n=41), ultrasound score ($p<0.05$, r=0.402, n=40), and saliva levels ($p<0.05$, r=-0.392, n=41) and ($p<0.05$, r=-0.363, n=41), unstimulated and stimulated saliva respectively. In patients with normal and pathological US, mean unstimulated saliva was 2.2 ml/15 min and 0.5 ml/15 min ($p<0.01$), and the stimulated saliva levels were 6.1 ml/5 min and 2.5 ml/5 min ($p<0.001$). Levels of unstimulated and stimulated saliva correlated ($p=0.001$, r=0.509, n=41). Ultrasound scores correlated with unstimulated ($p<0.001$, r=-0.531, n=40) and stimulated saliva ($p<0.01$, r=-0.454, n=40). 17/27 patients with unstimulated saliva ≤ 1.5ml/15 min had pathological ultrasound changes compared to 1/13 with normal unstimulated saliva ($p<0.01$). 13/17 patients with stimulated saliva ≤ 3.5ml/5 min had pathological ultrasound compared to 5/23 with normal stimulated saliva ($p<0.01$). Tear secretion by the Schirmer I-test correlated in the right and left eye ($p<0.001$, r=0.749, n=39). Unstimulated saliva secretion correlated with tear secretion ($p<0.001$, r=0.537, n=39) and ($p<0.05$, r=0.343, n=39), right and left eye, respectively. Focus score was available in 31/41 patients, and correlated with ultrasound score ($p<0.05$, r=0.373, n=30). Mean focus score was 2.6 in patients with ultrasound pathology and 1.3 in patients with normal ultrasound ($p=0.051$).

Conclusion: In this cohort of patients with pSS findings from non-invasive imaging method ultrasound correlate with oral sicca symptoms, glandular function and minor salivary gland inflammation. Ultrasound of major salivary glands seems to be a useful tool for diagnostics and follow-up of patients with pSS.

Safety of Minor Labial Salivary Gland Biopsy. Žiga Rotar, Alojzija Hočevar, Nataš A. Gašeršč, Branka Hostnik, Anita Antolić and Matija Tomšič. University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia

Background/Purpose: Histopathological analysis of minor salivary glands is a part of the latest classification criteria for SS proposed by the American-European Consensus Group (AECG), and the ACR.[1, 2] Recently it has been proposed that the presence of germinal center like structures in diagnostic minor salivary gland biopsies may be a highly predictive marker for NHL development in primary SS.[3] Our aim was to prospectively evaluate adverse events of minor salivary gland biopsy performed by rheumatologists in patients suspect of having Sjögren's syndrome.

Methods: At our rheumatology department we run a weekly diagnostic outpatient clinic where we see patients presenting with symptoms suggestive of Sjögren's syndrome referred to us by their rheumatologists. We evaluate them using the AECG criteria. In consenting patients who cannot be classified on the basis of history, clinical tests, and serological tests we perform the minor salivary gland biopsy.

Under aseptic conditions an assistant exposes mucosa of the lower lip. We clean it with 0.2% chlorhexidine digluconate solution, and infiltrate the lateral third of the lip with approx. 0.5–1 cm^3 of 2% lidocaine near one of the many orifices of the minor salivary gland excretory ducts identified by observation of nascent droplets of saliva. The rheumatologist makes an approx. 5 mm linear incision of the mucosa, removes all the exposed glands using a forceps, and places a single suture to close the wound using 4-0 absorbable braided polyglycolic acid. Removed glands are transported to pathology laboratory in 10% formalin.

Before the biopsy we informed each patient orally and in writing about possible adverse events and appropriate responses. Ten days to two weeks following the biopsy, a nurse phoned each patient to inquire about the pain (0–10 scale, VAS) during biopsy, and in the week following it; the survival of sutures, and whether the patient's GP or dentist had to remove them; and any other adverse events experienced by the patient.

Results: From 02/01/2007 to 12/15/2010 350 patients were referred for biopsy (89.7% females, average age 56.9±12.5 years). Incision length was measured and was on average 5.0±0.8 mm. The average volume of the obtained tissue sample was 26.5±72.8 mm^3. 322 patients responded to the follow up call by the nurse. During the biopsy 89.8%, 5.3%, and 1.5% reported pain on VAS of 0, 1–3, and 4–5, respectively, while 3.4% provided no answer. In the week following the biopsy 78.9%, 12.4%, 2.8%, 1.9%, 0.9% scored their pain on VAS 0, 1–3, 4, 5, and 6–8, respectively, while 3.1% provided no answer. 80.1% of patients report no adverse events, the rest complained about paresthesia, wound suppuration, hematoma, irritating mucosal scar, and lower lip swelling in 5.6%, 5%, 3.4%, 3.4%, and 2.5%, respectively. All the adverse events were transient and have resolved within the first three days after biopsy in 95.5% of patients.

The average suture survival was 3.7±2.1 days. In 15.5% of patients sutures were removed by their GP or dentist after on average 4.8±2.3 days.

Conclusion: Minor salivary gland biopsy is a safe outpatient procedure in the hands of rheumatologists.

Background/Purpose: The subsets of primary Sjögren's syndrome (pSS) patients justifying biological therapy (BT) remain a matter of debate. Our goal was [1] to describe which inclusion criteria have been used in all previous studies using BT in pSS and [2] to evaluate the proportion of patients who may be included in further trials evaluating a biologic according to the chosen criteria.

Methods: We performed a literature review using pubmed and clinicaltrial.gov of all studies evaluating BT in pSS to identify their inclusion criteria. Then, we evaluated in the ASSESS cohort (a French national multi-center prospective cohort set up in 2006 to identify valuable predictive factors lymphoma during a 5-year prospective follow-up in which 15 tertiary centers

included 410 patients with pSS) the proportion of pSS patients who could be included in a trial according to the chosen criteria.

Results: Our literature review identified 16 studies evaluating biologics in pSS: Two open label studies and two double blind studies have been conducted to evaluate anti TNF. Only one open label study evaluated epratuzumab, in patients with B-cell activity. Five open-label studies and 4 randomized studies evaluated or are evaluating prospectively rituximab. Two studies are ongoing with belimumab. The main frequently used inclusion criteria were AECG criteria, disease duration (less than 4, 5 or 10 years), presence of systemic involvement (ESSDAI>1), visual analogic score (VAS) for dryness, pain, and fatigue higher to 5/10 and biological markers of activity (hypergammaglobulinemia and/or cryoglobulinemia and/or β2 microglobulinemia and/or low level of C4). In the ASSESS cohort, 263 patients had all data available. **Table 1** shows a tree representing the number of patients of the ASSESS cohort which fulfil each of these criteria. Their combinations show that if we limit inclusion to patients with systemic and recent pSS (less than 4 years), with 2/3 VAS>5/10 and biological activity, only 52/263 (20%) of the patients could be included. If we consider systemic or recent pSS, 2/3 VAS>5/10 and biological activity, 166/263 (63%) could be included.

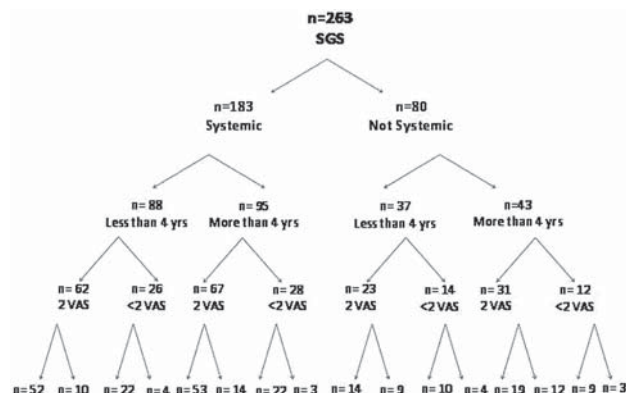
Tuesday, November 13


Figure 1. Number of patients in the ASSESS cohort fulfilling each criteria First step: AECG criteria, second step: systematic disease or not , third step: Disease of less than 4years, fourth step: visual analogic scale; fifth step: biological activity.

Conclusion: The number of patients that could be include in a trial evaluating pSS, depends highly on the inclusion criteria. Even with a slightly selective criterion of systemic involvement (ESSDAI >1), a small number of patients with very recent disease could be included. Most patients reported 2 VAS higher to 50/100 and have biological markers of activity.

Efficacy of Belimumab On Non-Malignant Parotid Swelling and Systemic Manifestations of Sjögren's Syndrome: Results of the Beliss Study. Salvatore De Vita[1], Raphaèle Seror[2], Luca Quartuccio[3], Frederic Desmoulins[4], Sara Salvin[3], Gabriel Baron[5], Martina Fabris[6], Philippe Ravaud[5], Miriam Isola[7] and Xavier Mariette[8]. [1]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy, [2]Université Paris-Sud, Le Kremlin Bicêtre, LE Kremlin-Bicetre, France, [3]Rheumatology Clinic, DSMB, University of Udine,, Udine, Italy, [4]Université Paris-Sud, Le Kremlin Bicêtre, Le Kremlin Bicetre, France, [5]Université Paris-Descartes, Paris,, Paris, France, [6]Institute of Clinical Pathology, Udine, Italy, [7]Institute of Statistics, University of Udine, Udine, Italy, [8]Université Paris-Sud, Le Kremlin Bicetre, France

Background/Purpose: to report the effects of anti-BAFF/BLyS antibody belimumab (BEL) on the different ogan manifestations of primary Sjögren's syndrome (pSS), by evaluating the ESSDAI score and the single ESSDAI domains.

Methods: Thirty patients (15+15) with pSS (positive classification criteria and positive anti-SSA/SSB antibodies) were investigated in two European Centres to assess the efficacy and safety of BEL in pSS. They were all females (49.5±16.5 years). At least one of the following items was needed for enrolment: a) parotid swelling and/or systemic involvement; b) objective

sicca with at least one laboratory sign of B-cell hyperactivation in serum (increased IgG, increased free Ig light chains, increased beta2-microglobulin, decreased C4, monoclonal gammopathy or cryoglobulinemia); c) recent onset of sicca symptoms (<5 years). Belimumab 10 mg/kg was administered intravenously on days 0, 14, 28 and then every 28 days through 48 wks, with a final evaluation at wk52, and after drug suspension. Concomitant therapies were left unchanged.

Results: 29/30 patients completed the 28 wk infusions, and 1 case with lymphoma and cryoglobulinemic vasculitis was withdrawn at w12 for worsening. Wk52 data are available in one Centre.

At wk 28, the ESSDAI score decreased from a median of 7 (1–33) to 4 (0–23) (p= 0.0001, Wilcoxon) with a decrease of $\geq$ 3 points in 14/29 (48.3%) and of $\geq$ 2 points in 18/29 (62.1%). The following domains mainly contributed to the ESSDAI score at baseline: glandular, biological, lymphadenopathy, articular, haematological and pulmonary. Activity (low-moderate-high) was present (baseline vs. wk28) in these domains as follows: glandular 15/30 vs. 7/29; biologic 27/30 vs. 20/29; lymphadenopathy 9/30 vs. 3/29; articular 9/30 vs. 3/29; haematological 5/30 vs. 3/29; pulmonary 4/30 vs. 5/29. At wk 28 the glandular domain improved in 10/13 (76.9%) patients with non-malignant parotid swelling (confirmed by biopsy, whenever possible), while no improvement occurred in 2/2 patients with parotid low-grade lymphoma (stage IE). Data available at wk52 showed persistent disappearance of swelling in 4/5 patients and further amelioration in 1/5. After BEL suspension parotid swelling relapsed in 2/5 of these responders (4 and 14 months later).

Overall, 13/15 patients completed the trial at w52 in one Centre. The median ESSDAI at wk52 was 2 (0–12) [vs. 3 (1–16) at w28 vs. 8 (2–33) at baseline; p=0.003, wk52 vs. baseline, Wilcoxon)], with activity in the ESSDAI domains (baseline vs. wk28 vs. wk52) as follows: glandular 7/15 vs. 2/14 vs. 2/13; biologic 13/15 vs. 11/14 vs. 10/13; lymphadenopathy 8/15 vs. 3/14 vs. 0/13; articular 4/15 vs. 0/14 vs. 0/13; 1/15 vs. 1/14 vs. 0/13; pulmonary 2/15 vs. 2/14 vs. 2/13. At wk52 we no additional side effects, if compared to wk28, were observed in the available cases.

Conclusion: Belimumab proved to be beneficial for non malignant glandular swelling in pSS. Recently, BAFF serum level were significantly increased in this subset of patients (Quartuccio L. et al., Rheumatology 2012, in press), supporting the rationale and the results observed. Other systemic features of pSS might also improve with BEL therapy. A controlled randomized trial is advisable.

Antimalarials for Sjogren's Syndrome Treatment in Adults, Meta-Analysis. Vibian A. Coy[1], Carlos E. Granados[2], Diana Gil[1], Alejandro Junca[1], Daniel Jaramillo[1], Antonio A. Iglesias-Gamarra[3], Jose Felix Restrepo[4] and Federico Rondon-Herrera[4]. [1]Fellow of Rheumatology Universidad Nacional de Colombia, Bogotá, Colombia, [2]Professor - Universidad Nacional de Colombia, Bogotá, Colombia, [3]Professor-Universidad Nacional de Colombia, Bogota, Colombia, [4]Professor-Universidad Nacional de Colombia, Bogota, Colombia

Background/Purpose: Sjögren's syndrome (SS) is a chronic *inflammatory autoimmune disease* that is presented with lymphocytic infiltration of exocrine glands. Its secondary secretory dysfunction may involved extraglandular or extracraneal tissues. Antimalarials have been used for treatment of sicca symptoms and inflammation. However its effectiveness remains controversial. The objective of this systematic review is to evaluate the effectiveness and toxicity of antimalarials to treat adults with SS.

Methods: Between September 2010 and May 2012 we conducted an electronic search in the following databases: MEDLINE, Embase, LILACS, ISI WEB OF KNOWLEDGE, Cochrane Central Register of Controlled Trials and International Clinical Trials Registry of the World Health Organization (WHO ICTRP). *We included experimental, quasi-experimental and uncontrolled before and after studies.* Evaluated outcomes were: improvement in xerophtalmia, xerostomia and Schirmer's test; change in inflammatory markers and adverse events. Quality assessment of the trials was done by two authors independently. I2 and Chi-square tests were performed to estimate heterogeneity. The Mantel-Haenszel random-effects method with odds ratio (OR) as association measure were used for dichotomous outcomes, and mean difference for continuous data. All Statistical analysis was performed using RevMan 5.0

Results: 22 trials were found and 6 were included in the analysis. A total of 140 patients were included, all women. There were no statistically significant differences with respect to improvement in xerophtalmia (OR 2.27; 95% CI, 0.38 to 13.34), xerostomia (OR 1.0; 95% CI, 0.02 to 5) and Schirmer′s test (MD −1.03; 95% CI, −2.38 to 0.32). We observed a tendency in favor of antimalarials for decreasing erythrocyte sedimentation rate (MD −6.98; 95% CI, −20.73 to 6.76). One trial evaluated adverse effects (ocular, hepatic, hospitalization or dead) without significant differences. It was not possible to explore publication bias.

Conclusion: Up to the moment the available evidence has poor quality. The best evidence did not identify a clear benefit of antimalarials in the reviewed outcomes. The analyzed data reported low incidence of adverse events. More and good quality research (RCT′s) are needed to answer this question.

Secretagogue Use in Patients with Primary Sjogren's Syndrome.
Ghaith Noaiseh[1], Joshua Baker[1] and Frederick B. Vivino[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]Penn Presbyt Med Ctr, Philadelphia, PA

Background/Purpose: Secretagogues are commonly used to treat xerostomia in primary Sjogren's syndrome (pSS). Side effects and/or lack of efficacy sometimes result in cessation of therapy. Our aim was to determine clinical and laboratory predictors associated with therapeutic failures.

Methods: We retrospectively reviewed use of the secretagogues, pilocarpine (PC) and cevimeline (CV), in patients with pSS who fulfilled the 2002 American European Consensus Group criteria; followed from January 2002 to June 2012. Individuals with inadequate follow up (less than two visits) were excluded. Baseline variables included age, sex, duration of xerostomia, anti Ro (SSA) and anti La (SSB) antibodies, rheumatoid factor, antinuclear antibodies (ANA), complement levels, beta 2 microglobulin, serum protein electrophoresis, smoking history, unstimulated salivary flow rate, scintigraphy scores, focus score on lip biopsy, and previous use of hydroxychloroquine. Failure of therapy was defined as the clinician or patient's decision to stop treatment either due to lack of efficacy or side effects.

Results: Among 118 patients with pSS (92.4% female, mean age 61.4 years), PC was used in 72 (59 first users, 13 second users) and CV in 91 (59 first users, 32 second users). Cevimeline was associated with lower failure rates among all users (29/91, 31.9%) than PC (44/72, 61.1%) (p<0.001). Among first-time users, CV was also associated with lower failure rates (16/59, 27.1%) versus PC (28/59, 47.5%). (p=0.02). Severe sweating was the most frequent side effect leading to cessation of therapy and occurred more frequently among patients using PC (18/72, 25%) than CV (10/91, 11%) (p=0.02). Patients who previously failed one secretagogue were less likely to discontinue treatment with the other agent: i.e. 61/118 (51.7%) of first-time users compared to 12/45 (26.7%) of second-time users (p= 0.004). Among all users, the proportion of subjects stopping medication for any documented side effect tended to be higher in the PC group (31/72, 43.1%) than CV group (23/91, 25.3%) (p=0.09). Among the various clinical and laboratory parameters studied; only ANA positivity was associated with therapeutic failure: 45/76 (59%) of ANA-positive patients vs. 15/40 (38%) of ANA-negative patients discontinued for any reason. (p=0.03)

Conclusion: Our data suggests that patients with pSS who take secretagogues for xerostomia are more likely to continue cevimeline than pilocarpine long-term. This is primarily due to a lower incidence of severe sweating (the most common side effect of therapy). However, therapeutic failure of one secretagogue did not predict similar results with the other. Second time users may be more likely to continue long-term treatment due to the lack of effective therapeutic alternatives. Among various clinical and laboratory features of pSS, only ANA positivity was associated with a higher likelihood of treatment failure. Further studies are needed to confirm these observations.

Phenotypic Features of Sjögren's Syndrome Among Patients with Low-Titer SSA/B Antibodies.
Mara McAdams DeMarco[1], Mi Y. Lam[2], Steve Shiboski[2], Lindsey A. Criswell[3], Caroline Shiboski[2] and Alan N. Baer[4]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University of California, San Francisco, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA, [4]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD

Background/Purpose: The significance of a low titer of SSA and/or SSB antibodies (SSA/B-Ab) in individuals with clinical or other laboratory findings suggestive of Sjögren's syndrome (SS) is unclear. Low titers may represent false positive immunoassay results, seropositivity in the absence of clinical disease, or true markers of a connective tissue disease, such as SS. It is unclear whether low titers represent a distinct phenotype or one more similar to those with negative titers. We sought to explore the association between SSA/B titer levels and phenotypic features of SS, including histopathological characteristics.

Methods: The Sjögren's International Collaborative Clinical Alliance (SICCA) is an NIH-funded registry of individuals with suspected or established SS. Each participant undergoes a uniform and protocol-driven evaluation for SS, including rheumatologic, oral, and ophthalmologic examinations, serologic testing, labial salivary gland biopsy, and ocular staining. SSA/B-Ab testing was performed by Quest Laboratories, using an automated multiplex flow immunoassay. Positive results were expressed in "antibody index" (AI) units and provided as continuous variables measure up to a level of 8 AI. Levels more than >8 AI were not quantified. We compared the mean and prevalence of phenotypic features of SS by category of SSA/B-Ab (High: both SSA-Ab and/or SSB-Ab>8; Low: SSA-Ab and/or SSB-Ab≥1 but both ≤8; Negative: both SSA-Ab and SSB-Ab<1).

Results: Among the SICCA participants, low titers of SSA/B-Ab were present in 277 (14.1%), high titer SSA/B-Ab in 434 (22.1%) and negative SSA/B-Ab in 1256 (63.8%). The associations between these three strata of SSA/B-Ab titers and phenotypic features of SS are shown in the Table. Mean age decreased while focus score increased as SSA/B-Ab titers increased. The percentage of participants with each phenotypic feature was greater for those with high SSA/B-Ab compared with those with low titers and greater for those with low titers compared with negative titers.

Table. Phenotypic Features of Sjögren's Syndrome by SSA/B Antibody Titer

	High		Low		Negative		
	N	Mean or %	N	Mean or %	N	Mean or %	p
Age (years)	454	50.79	287	51.33	1270	54.48	<.0001
Focus score (foci/ 4 mm^2)	367	3.32	204	2.79	527	1.50	<.0001
ANA≥1:320	455	69.5%	287	44.3%	1276	16.1%	<.0001
Rheumatoid factor ≥ 30 IU/ml	454	49.8%	287	34.2%	1275	10.0%	<.0001
IgG>1445 mg/dl	455	62.0%	285	49.5%	1273	12.1%	<.0001
C4<16 mg/dl	455	22.6%	285	17.2%	1273	10.6%	<.0001
WBC ≤ 4000/mm^3	448	27.5%	283	19.4%	1266	7.4%	<.0001
FLS or F/SLS focus score ≥ 1*	434	74.0%	277	57.4%	1256	19.1%	<.0001
Germinal centers in lip biopsy	454	23.8%	285	7.4%	1273	4.2%	<.0001
Schirmer's ≤5 mm either eye	454	46.0%	286	37.8%	1276	24.3%	<.0001
Ocular surface staining ≥ 3	454	94.1%	286	83.2%	1275	67.2%	<.0001
Unstimulated saliva ≤0.5 ml/5 min	455	64.4%	286	61.2%	1274	48.0%	<.0001

*FLS=focal lymphocytic sialadenitis; F/SLS=focal /sclerosing lymphocytic sialadenitis.

Conclusion: There is a higher prevalence of all phenotypic features of SS among those with higher SSA/B-Ab titer. Low antibody titers occur in approximately 14% of patients suspected of having SS and may represent an intermediary phenotype distinct from those with high or negative titers.

2193

Validity of Low Titers of SSA/B Antibodies in Predicting A Key Feature of Sjögren's Syndrome. Mara McAdams DeMarco[1], Mi Y. Lam[2], Steve Shiboski[2], Lindsey A. Criswell[3], Caroline Shiboski[2] and Alan N. Baer[4]. [1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University of California, San Francisco, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA, [4]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD

Background/Purpose: The validity of low titers of SSA and/or SSB (SSA/B) antibodies (Ab) in the diagnosis of Sjögren's syndrome (SS) has not been defined. We explored the validity of using varying SSA/B-ab titers to predict a "positive lip biopsy", a known objective test used in the ACR classification of SS (Arth Care Res 2012;64:375).

Methods: SICCA is an NIH-funded registry in which patients with suspected or established SS undergo a uniform evaluation, including minor salivary gland (lip) biopsy. SSA/B-Ab testing was performed by Quest Laboratories, using a multiplex flow immunoassay. Positive results were expressed in "antibody index" (AI) units and as continuous measure variables up to a level of 8 AI, beyond which the units were not quantified. We defined "low titer" SSA/B-Ab as those between 1 and 8 AI. A "positive lip biopsy" was defined as focal or focal/sclerosing lymphocytic sialadenitis with a focus score $\geq$ 1. The validity of SSA/B-Ab testing was defined by the degree to which patients were correctly classified as having or not having a positive lip biopsy, used in lieu of a gold standard. This was quantified by sensitivity and specificity across the range of AI units for 1) SSA-Ab alone, 2) SSB-Ab alone, and 3) combinations of SSA/B-Ab.

Results: Of the 1,861 SICCA patients, the mean age was 53, 91% were female and 629 (34%) had a positive lip biopsy. For SSA-Ab, 431 (23%) >8 AI and 139 (7%) had low titers. For SSB-Ab, 184 (9%) >8 AI and 168 (9%) had low titers. SSA- and SSB-Ab > 8 AI had unacceptably low sensitivity (see Table). With increasing SSA-Ab cutoff levels, the likelihood of misclassifying a patient with a negative lip biopsy decreased (specificity 84 $\rightarrow$ 91%) while the likelihood of not identifying a patient with a positive lip biopsy increased (sensitivity 60 $\rightarrow$ 51%). Use of the SSB-Ab test alone was associated with high specificity but low sensitivity. In the combined analysis, the sensitivity and specificity respectively, were, 1) SSA-Ab$\geq$1 & SSB-Ab<1: 0.35 & 0.89; 2) SSA-Ab$\geq$1 & SSB-Ab$\geq$1: 0.51 & 0.94; 3) SSA-Ab<1 & SSB-Ab$\geq$1: 0.05 & 0.98 and; 4) SSA-Ab>1 or SSB-Ab>1: 0.62 & 0.82. Results were similar when the study was restricted to those patients with an objective parameter indicative of dry eye syndrome.

Table. Sensitivity, Specificity and 95% Confidence Intervals by SSA/B Threshold

SSA/SSB Threshold	SSA test alone		SSB test alone	
	Sensitivity	Specificity	Sensitivity	Specificity
>1	0.60 (0.56, 0.64)	0.84 (0.82, 0.86)	0.41 (0.38, 0.45)	0.93 (0.91, 0.94)
>2	0.59 (0.55, 0.63)	0.86 (0.84, 0.88)	0.35 (0.31, 0.39)	0.94 (0.93, 0.96)
>3	0.58 (0.54, 0.62)	0.87 (0.85, 0.88)	0.32 (0.28, 0.36)	0.95 (0.94, 0.96)
>4	0.57 (0.53, 0.61)	0.88 (0.86, 0.89)	0.29 (0.26, 0.33)	0.96 (0.94, 0.97)
>5	0.56 (0.52, 0.60)	0.89 (0.87, 0.90)	0.28 (0.24, 0.31)	0.96 (0.95, 0.97)
>6	0.52 (0.49, 0.56)	0.90 (0.88, 0.91)	0.26 (0.23, 0.30)	0.97 (0.95, 0.98)
>7	0.52 (0.48, 0.56)	0.90 (0.89, 0.92)	0.25 (0.22, 0.29)	0.97 (0.96, 0.98)
>8	0.51 (0.47, 0.55)	0.91 (0.89, 0.93)	0.24 (0.21, 0.27)	0.97 (0.96, 0.98)

Conclusion: SSA- and SSB-Ab > 8AI had low sensitivity and the inclusion of low titers resulted in a minimal improvement in the test's moderate sensitivity and minimal decrease in specificity. This confirms the need to perform additional objective tests, such as a lip biopsy, in the diagnosis of SS.

Cathepsin S Activity in Tears As a Marker of Sjögren's Syndrome. S.E. Whitt[1], K. Renduchintala[1], S. Janga[2], M. Shah[2], J. Zhu[3], K. Silka[3], S. Bricel[3], D. Bach[3], M. Heur[4], S. Christianakis[3], J. Irvine[4], D. Arkfeld[3], W.J. Mack[3], William Stohl[3] and S.F. Hamm-Alvarez[2]. [1]University of Southern California Keck School of Medicine - These authors contributed equally to this work, Los Angeles, CA, [2]University of Southern California School of Pharmacy, Los Angeles, CA, [3]University of Southern California Keck School of Medicine, Los Angeles, CA, [4]Doheny Eye Institute, Los Angeles, CA

Background/Purpose: Currently used biomarkers for Sjögren's Syndrome (SS), such as anti-SSA/Ro or anti-SSB/La, lack sensitivity and specificity. The goal of the work presented here is to evaluate the association of elevated Cathepsin S (CATS) with SS and contrast this to CATS associations with other autoimmune or dry eye disorders.

Methods: Patients were recruited from outpatient Rheumatology and Ophthalmology clinics. Schirmer's tests were administered to patients with primary or secondary SS (n=47), rheumatoid arthritis (RA) without SS (n=41), systemic lupus erythematosus (SLE) without SS (n=18), other autoimmune diseases without SS (n=10), non-autoimmune dry eyes (n=13), and blepharitis (n=8). The Schirmer's strips were immediately placed on ice after tear collection, and tear proteins were eluted and analyzed within 4 hours for CATS activity using commercial assay kits. CATS activity was normalized to protein concentration. Serum positivity for anti-SSA and anti-SSB in autoimmune disease patients was determined by a clinical laboratory.

Results: CATS data were log-transformed prior to analysis to deemphasize outlier values. To compare log CATS activity among patient groups accounting for correlated data (correlation among eyes), generalized estimating equations were used. Median CATS activity in SS patients (median 5140) was compared to non-SS patient groups: SS vs. RA (median 1476, p=<.00001), SS vs. SLE (median 2226, p=.0008), SS vs. Blepharitis (median 1770, p=.022), SS vs. Dry Eye (median 2768, p=.003), and SS vs. Other (median 1770, p=.013). CATS activity did not significantly differ (p=0.31) between primary SS (n=11; median 5514) and secondary SS (n=36; median 4970). Anti-SSA-positive SS patients (n=30; median 3288) and anti-SSA-negative SS patients (n=8; median 1732) also did not significantly differ on CATS activity (p=0.29). The data did not demonstrate a significant difference (p=0.25) in median CATS activity between SSB-positive (n=13; median 5321) and SSB-negative (n=25; median 4456) groups.

Conclusion: Normalized CATS activity is significantly greater in the tears of SS patients than in the tears of patients with non-SS autoimmune or non-autoimmune diseases. Determination of CATS activity in tears may be clinically useful by shortening the lag time in diagnosing patients with SS, thereby promoting earlier initiation of appropriate therapy. The simplicity of the test may permit its automation and use in real-world clinical settings.

Long-Term Changes in Autoantibody Profile After Pandemic Unadjuvanted Influenza A/H1N1 Vaccine in Sjögren's Syndrome. Sandra G. Pasoto[1], Ana C. Ribeiro[1], Vilma S.T. Viana[1], Elaine P. Leon[2], Cleonice Bueno[1], Mauricio Levy Neto[1], Alexander R. Precioso[3], Maria do Carmo S. Timenetsky[4] and Eloisa Bonfa[1]. [1]Division of Rheumatology - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Fundação Butantan - Instituto Butantan, São Paulo, Brazil, [4]Instituto Adolfo Lutz - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: Despite WHO recommendations about the A/California/7/2009/H1N1-like virus vaccination, there are no studies evaluating its possible influence on clinical manifestations and autoantibody profile in (primary) Sjögren's syndrome (SS). Objectives: To evaluate short/long-term effect of influenza A/California/7/2009/H1N1-like virus vaccination on clinical manifestations and autoantibody profile in SS.

Methods: Thirty-six SS patients (The American-European Consensus Group Criteria, 2002) and 36 gender-, age-, matched-healthy controls were evaluated before and 21-days after vaccination with unadjuvanted influenza A/H1N1-like virus regarding seroprotection/seroconversion, factor increase in geometric mean titre (FI-GMT) and side effects. New onset of parotiditis, arthritis, vasculitis, pneumonitis or neurological disorders and autoantibody profile [antinuclear antibodies (ANA), rheumatoid factor (RF), anti-dsDNA, anti-Ro(SS-A)/La(SS-B), anti-alpha-fodrin, anti-RNP, anti-Sm and anticardiolipin] were assessed before, 21-days and 1-year after vaccination.

Results: Patients and controls had similar rates of seroconversion (78 vs. 69%, p= 0.42), seroprotection (83 vs. 72%, p= 0.26) and FI-GMT (p= 0.85). Pre-vaccination evaluation revealed that disease duration, glucocorticoid (mean dose 10.1 +− 5.1 mg/day), methotrexate (up to 17.5 mg/week) or azathioprine (up to 100 mg/day) did not affect seroconversion (p> 0.05). Regarding short-term analysis, no change in the frequency or levels of autoantibodies was observed (p> 0.05) and only mild side effects were

observed in comparable rates to controls (p> 0.05). At 1-year follow-up, the rate of new disease flares was similar to the previous year (11 vs. 19%, p= 0.51) and four seroconverted patients developed positivity to one of the following specificities: anti-Ro/SS-A, anti-La/SS-B, anti-alpha-fodrin, or IgM anticardiolipin. None developed other specific lupus autoantibodies. Of note, a significant increase in the mean levels of anti-Ro/SS-A (p< 0.0001) and anti-La/SS-B (p< 0.002) was detected after 1-year with no change in the other autoantibodies.

Conclusion: This is the first study to indicate that influenza A/H1N1 vaccine induces long-term changes in autoantibody profile restricted to SS spectrum without a deleterious effect in disease course. FAPESP grant: 2010/10749-0.

Decreased Expression of TSLP in Labial Salivary Glands of Patients with pSS Is Associated with Local and Systemic Disease Parameters.
M.R. Hillen, A. Bikker, A.A. Kruize, M. Wenting-van Wijk, F.P.J.G. Lafeber, C.E. Hack and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: Thymic Stromal Lymphopoietin (TSLP) is a potent immunomodulatory cytokine involved in Th2-mediated immune responses and homeostatic T-cell expansion. Reduced TSLP expression by intestinal epithelial cells was recently shown to lead to reduced Th2 responses and development of Th1-mediated experimental colitis. In addition, TSLP is described as a proinflammatory factor in rheumatoid arthritis, which is driven by Th1/Th17 responses. A Th1/Th17 polarized environment is also present in the salivary glands of patients with Primary Sjögren's syndrome (pSS).The aim of this research was to investigate TSLP expression in salivary glands of pSS patients as compared to non-SS Sicca (nSS) patients and to study the relationship to local and systemic disease parameters.

Methods: Tissue sections of minor salivary glands from 38 pSS and 18 nSS patients were stained with a monoclonal antibody (mAb) against human TSLP or an isotype control. In addition, sections were stained with a mAb against the epithelial cell marker Cytokeratin High Molecular Weight (CK HMW) or stained with alcian blue to detect mucus production. The number of cells that stained positive for TSLP was assessed. In addition, TSLP was quantified at sites where only intact (CK HMW positive), functional (alcian blue positive) structures were present. TSLP expression was correlated to local (lymphocyte focus score, LFS; %IgA positive plasma cells) and systemic (erythrocyte sedimentation rate, ESR; serum IgG levels) disease parameters.

Results: TSLP was almost exclusively expressed by acinar cells in both pSS and nSS patients. The number of TSLP-expressing cells per mm^2 was significantly decreased in pSS patients as compared to nSS patients (462 ± 42 vs. 773 ± 84, p<0.01) and correlated negatively to LFS (r= −0.48, p<0.001) ESR (r= −0.41, p<0.01), serum IgG levels (r= −0.41, p<0.01) and positively to the percentage of local IgA producing plasma cells (r= 0.35, p<0.05). At sites with intact, functional epithelium TSLP expression tended to be reduced in pSS patients as compared to nSS patients (840 ± 75 vs. 1064 ± 72, p=0.079). Furthermore, pSS patients with a LFS equal to or higher than 3 had significantly lower numbers of TSLP-producing cells per mm^2 at these sites compared to nSS patients (677 ± 105 vs. 1064 ± 72, p<0.01). Also, in intact and functional epithelium, the number of TSLP-producing cells correlated negatively to LFS (r= −0.40, p<0.01), ESR (r= −0.32, p<0.05) and serum IgG levels (r= −0.27, p<0.05)

Conclusion: TSLP expression is reduced in pSS patients, associated with local and systemic inflammatory markers including increased lymphocytic infiltration. Considering the described role of TSLP in promoting Th2 responses at mucosal sites, we hypothesize that TSLP is constitutively expressed in salivary glands and promotes a protective Th2 milieu, whereas loss of TSLP expression may contribute to Th1/Th17 associated immunopathology in pSS.

Diagnostic Value of Blood B-Cell Subset Profiling and Autoimmunity Markers in Anti-SSA-Negative Sjögren's Syndrome Patients.
Divi Cornec[1], Alain Saraux[2], Jacques-Olivier Pers[1], Sandrine Jousse-Joulin[3], Yves Renaudineau[1], Thierry Marhadour[3] and Valerie Devauchelle-Pensec[2], [1]Brest Occidentale University, Brest, France, [2]Brest Occidentale university, Brest, France, [3]CHU de la Cavale Blanche, Brest, France

Background/Purpose: Recently published ACR classification criteria for primary Sjögren's syndrome (pSS) suggest considering antinuclear antibodies (ANA) titer and rheumatoid factor (RF) positivity in patients negative for anti-Ro/SSA antibodies. The diagnostic value of these tests for pSS has to be confirmed in independant cohorts. Besides, we have shown in a previous case-control study that blood B-cell subset profiling through (Bm2+Bm2′)/(eBm5+Bm5) ratio computation is abnormal in pSS patients. Gammaglobulins and IgG titers are often increased in these patients. The aim of this study was to evaluate the diagnostic value of these B-cell markers for pSS, and to assess if they could improve American-European Consensus Group (AECG) criteria.

Methods: This cross-sectional study was conducted in a monocentric cohort of patients with suspected pSS, prospectively included between November 2006 and September 2011. Clinical examination, basic biology, immunological tests and minor labial salivary gland biopsy (SGB) were performed systematically. For blood B-cell subset profiling, the (Bm2+Bm2′)/(eBm5+Bm5) ratio (referred to as B-cell ratio) was determined using flow cytometry. The gold standard for the analysis was a clinical diagnosis of pSS performed by a group of experts, blinded to the results of B-cell profiling. The diagnostic values and the independance of the different tests were compared using logistic regression analysis.

Results: 181 patients have been included in the study (mean age 56±13 years, symptoms duration 6.0±6.9 years, 92.2% females). 77 patients had pSS diagnosed by the experts. No differences were found between the 2 groups concerning age, disease duration, and sex ratio. The sensitivity (Se) and specificity (Sp) of the different tests were respectively: 60.6% and 99.0% for anti-SSA/SSB; 81.7% and 61.1% for ANA≥1:320; 70.4% and 83.2% for ANA≥1:640; 45.5% and 79.8% for IgM-RF; 42.3% and 97.9% for IgA-RF; 46.5% and 92.6% for gammaglobulins ≥14 g/l; and 49.6% and 91.6% for IgG ≥14 g/l. The mean B-cell ratio was significantly higher in the pSS group than in the non-pSS group (7.4±6.9 vs 3.2±2.3, $P<0.001$), and a ratio ≥5 had 52.1% Se and 83.2% Sp. Logistic regression analysis selected only ANA≥1:640 and B-cell ratio ≥5, with a similar weight. The combination of these two tests (ANA and ratio) displayed 37.7% Se and 96.2% Sp in the whole population, but only 12.9% Se in anti-SSA-negative patients. The association of the two tests (ANA or ratio) displayed 85.7% Se and 67.3% Sp in the whole group, and 71.0% Se in anti-SSA-negative patients. The modification of AECG criteria including the two tests in association (ANA or ratio) increased the Se from 83.1% to 90.9%, but decreased the Sp from 97.1% to 85.6%, whereas using the tests in combination (ANA and ratio) did not modify significantly their diagnostic value.

Conclusion: Blood B-cell subset profiling using flow cytometry is a simple test which has good diagnostic properties for pSS. However, the inclusion of this test, associated or not with ANA positivity, does not improve current classification criteria. Anti-SSA/SSB antibodies remain the best serologic item for the diagnosis of pSS.

Interstitial Lung Disease in Primary Sjogren's Syndrome: Any Association with IgG4 Related Sclerosing Disease?
Adlene Jebakumar[1], Carlotta Nannini[2], Eunhee S. Yi[1], Hiroshi Sekiguchi[1], Jay H. Ryu[1], Cynthia S. Crowson[1] and Eric L. Matteson[1]. [1]Mayo Clinic, Rochester, MN, [2]Prato Hospital, Prato, Italy

Background/Purpose: Various forms of interstitial lung disease (ILD) are associated with primary Sjögren's syndrome. IgG4-related sclerosing disease (ISD) is a recently described systemic fibroinflammatory disease associated with dense lymphoplasmacytic infiltrates rich in IgG4-positive plasma cells. Sicca symptoms and ILD are two of the known manifestations of ISD, and are also characteristic of Sjögren's syndrome. We aimed to describe the lung histopathology in a series of patients with Sjögren's syndrome who underwent open lung biopsy for evaluation of ILD, and to evaluate the occurrence of IgG4 in the lung parenchyma from a subset of these patients.

Methods: The archived pathology specimens of 15 patients with primary Sjögren's syndrome related ILD who underwent lung biopsies between 1998 and 2010 were reviewed, and evaluated for the presence of IG4 by immunohistochemical staining. Diagnosis was based on 2002 American European Consensus Group criteria for primary Sjogren's syndrome. Patient demographic data and findings from high resolution computed tomography (HRCT) findings of the lungs of these patients were recorded.

Results: Among the 15 identified patients, 11 (73%) were female; mean age was 58 years. All of these patients had dry eyes and dry mouth symptoms. Anti-nuclear antibodies were present in 11 (85%) of 13 tested patients. Of 12 patients tested, 12 (100%) had anti- SSA antibodies and 9 (75%) had anti-SSB antibodies. Six (55%) of 11 tested patients were rheumatoid factor positive, and hypergammaglobulinemia was noted in 9 (75%) of 12 tested patients. Six (40%) patients had positive smoking history. Lung histopathology revealed usual interstitial pneumonia (UIP) in 6 patients; 3 patients had non-specific interstitial pneumonia (NSIP). The other patients had bronchiolitis (n=1), cryptogenic organizing pneumonia (n=1), desquamative interstitial pneumonia (n=1), follicular bronchiolitis with amyloid (n=1), obstructive pneumonitis (n=1), and lymphocytic interstitial pneumonia (n=1). Immunohistochemical staining of these lung biopsy specimens for IgG4 were negative for 7 (100%) of 7 patients. HRCT was performed in 12 of 15 patients. Linear or reticular opacities were noted in 9 patients, ground glass or non-solid opacities in 8 patients, and bronchiectasis in 8 patients. Other common HRCT findings were lymphadenopathy (n=3) honey-combing (n=3), multifocal cysts (n=3) and solid nodules (n=3).

Conclusion: The most common form of ILD in these patients with Sjögren's syndrome undergoing lung biopsy is UIP, and the majority had linear and/or ground opacities on HRCT. While there are reports that dacroadenitis and sialoadenitis is associated with IgG4 deposition, we found no evidence of IgG4 in the lung tissue of patients with primary Sjögren's syndrome suffering from ILD.

Elevated IgG4 Serum Levels Among Primary Sjogren's Syndrome Patients: Do They Unmask Underlying IgG4-Related Disease? Clio P. Mavragani[1], George Fragoulis[2], Dimitra Rontogianni[3], Maria Kanariou[4] and Haralampos M. Moutsopoulos[2]. [1]School of Medicine, University of Athens, Athens, Greece, Athens, Greece, [2]School of Medicine, University of Athens, Athens, Greece, [3]Evangelismos General Hospital, Athens, Greece, [4]"Aghia Sophia" Children's Hospital, Athens, Greece

Background/Purpose: To determine IgG4 serum levels in a cohort of patients fulfilling the classification criteria for primary Sjogren's syndrome (pSS) and to explore whether they associate with distinct clinical, serological and histopathological parameters.

Methods: IgG4 levels were measured by nephelometry in sera from 140 consecutive pSS patients and 45 healthy controls of similar age and sex distribution. Immunohistochemical IgG4 analysis was performed on paraffin-embedded salivary gland tissues from patients with high and low IgG4 serum levels.

Results: Raised IgG4 serum levels defined as higher than 135mg/dl were detected in 8 out of 81 pSS patients analyzed (9.9%) ("High-IgG4" group) and in none of controls (p=0.05). Compared to their counterparts with normal IgG4 serum levels, the "High-IgG4" subset is characterized by significantly increased prevalence of IgG4-related features such as autoimmune pancreatitis, cholangitis and interstitial nephritis (p=0.006), lower rates of ANA (p=0.05) and anti-Ro/SSA (p=0.05) positivity. Although not statistically significant, sicca features and anti-La/SSB positivity occurred less frequently in the "High-IgG4" group. Multivariate logistic regression analysis revealed interstitial nephritis (p=0.048), autoimmune cholangitis (p=0.012) or pancreatitis (p=0.027) and absence of ANA (p=0.005) as independent predictors of IgG4 serum levels. Positive staining for IgG4+ plasma cells was detected in one out of four available MSG biopsies in the "High-IgG4" group but in none of the control patients with normal IgG4 serum levels. Analysis of the whole group is in process.

Conclusion: Raised IgG4 levels occur approximately in 10% of patients with pSS and characterize a subgroup with high prevalence of IgG4-related clinical and serological features. Whether these patients represent a distinct pSS subset or a misclassified IgG4-Related (IgG4-RD) disease group remains to be defined.

IgE Autoantibodies Against SSA and SSB in Patients with Sjögren's Syndrome and Healthy Controls. Stamatina Danielides[1], Barbara Dema[2], Juan Rivera[2] and Gabor G. Illei[3]. [1]NIH, Bethesda, MD, [2]Laboratory of Molecular Immunogenetics, NIAMS, NIH, Bethesda, MD, [3]NIDCR/ NIH, Bethesda, MD

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disorder, presenting as an autoimmune exocrinopathy. Although the pathogenesis of this disease is largely unknown, evidence indicates that B cells, and hence the T helper 2 environment, may play an important role in its development. Recent evidence supports that IgE double stranded DNA (dsDNA) autoantibodies may be involved in the amplification loop of T helper 2 cells in lupus. In addition, there is a correlation between the presence of IgE autoantibodies and disease activity, measured by low complement levels. We sought to determine whether autoreactive IgE autoantibodies can be found in patients with Sjögren's syndrome.

Methods: We included 180 patients with the diagnosis of Sjögren's syndrome based on the American European consensus group criteria and 53 blood bank donors. We performed ELISA to determine the levels of IgG and IgE antibodies against SSA, SSB, dsDNA and Sm-RNP. Subjects with autoantibody levels over the mean +2SD of the controls were considered autoantibody positive. Statistical analysis was done with the Wilcoxon test.

Results: IgE autoantibodies against SSA and SSB were found in higher titers and higher frequencies in SS patients compared to blood bank donors (SSA 33.8% vs 6.81%, SSB 41.67% vs 1.85% in patients vs controls respectively, p<0.0001 for both), IgE autoantibodies to Sm-RNP and albeit less frequently anti-dsDNA were also seen more commonly in SS patients than controls (Sm RNP 25% vs 1.85%, p<0.0001 and dsDNA 15.70 vs 5.55%, p=0.0156).

The presence of IgE autoantibodies was not exclusive to the group of patients with positive IgG autoantibodies, as 29.2% of patients were discordant for SSA and 26.25% for SSB IgG and IgE antibodies.

The difference between IgG and IgE antibodies was striking for antiSm-RNP, as 7.25% of SS patients had IgG Sm-RNP and 25% had IgE Sm-RNP positivity.

No correlation was seen between IgE antibody titers and serum IgE levels or the respective IgG antibodies.

Among IgG antibodies only SSA IgG was associated with low complement levels, however several IgE autoantibodies were associated with low complements (low C3 and SSB IgE, p=0.0107; low C4 and SSB IgE p=0.0023; low C4 and SSA IgE, p=0.0316, low C4 and dsDNA IgE, p=0.0078).

There was no association between SSA or SSB IgE and focus scores.

Conclusion: IgE autoantibodies are present in a high proportion of SS patients compared to controls, and they appear independent from their respective IgG autoantibodies. Preliminary data suggest that IgE autoantibodies may be associated with hypocomplementemia, but further studies are needed to clarify their role in the cascade of events leading to disease pathogenesis.

Involvement of Interleukin-33 in the Pathogenesis of Sjögren's Syndrome. Ahmad Awada, Valérie Gangji and Muhammad S. Soyfoo. Hôpital Erasme,Université Libre de Bruxelles, Brussels, Belgium

Background/Purpose: To investigate the role of IL-33/ST2 in the pathophysiology of primary Sjögren's syndrome (pSS)

Methods: Serum levels of IL-33 and sST2 was determined by ELISA. The expression of IL-33 and ST2 was examined in the salivary glands of patients by immunohistochemistry and western blot. PBMC were isolated and stimulated with IL-33, IL-12 and IL-23 and the cytokine profile response was examined by flow cytometry. Intracellular cytokine detection of IFN-gamma and IL-17 was performed by flow cytometry. RT-PCR was performed to detect IL-33, sST2 and ST2L transcripts after PBMC stimulation by TNF-a and IL-1b with and without LPS.

Results: IL-33 and sST2 was increased in pSS patients compared to controls. Expression of IL-33 was upregulated in the salivary glands of pSS patients with Chisholm scores of 2 and 3 but comparable to controls for patients with Chisholm score of 4. sST2 expression was downregulated in pSS patients. IL-33 in a dose related fashion increased the secretion of TNF, IL-1,IL-6 and IL-10. Moreover, IL-33 acts synergistically with IL-12 and

IL-23 promoting IFN production. NK and NKT cells were identified as main producers of IFN. TNF and IL-1 increased the ST2L transcripts levels while no IL-33 expression was detected

Conclusion: IL-33 is released in pSS, favouring the secretion of pro-inflammatory cytokines.Our study reveals IL-33/ST2 axis in the pathophysiology of pSS.

Classification Criteria for Sjögren's Syndrome: Comparison of the Performance of the 2002 American-European Consensus Group Criteria (AECG) and the 2012 ACR Criteria. Elke Theander[1], Peter Olsson[2] and Thomas Mandl[3]. [1]Skane University Hospital, Lund University, Malmö, Sweden, [2]Department of Rheumatology, Skåne University Hospital, Lund University, Malmö, Sweden, [3]Skane University Hospital Malmo, Lund University, Malmö, Sweden

Background/Purpose: To assess level of agreement between 2002 AECC and 2012 ACR criteria for primary Sjögren's Syndrome syndrome (pSS) within the Malmö Sjögren's Syndrome Registry

Methods: The Malmö Sjögren's Syndrome Registry was established 1984. Patients not fulfilling the AECG criteria were after 2002 designated as having Sicca-Syndrome in contrast to pSS. To date 368 pSS according to AECG and 264 Sicca patients are registered. Here the ACR-criteria ocular staining score (OSS) ≥ 3 was substituted by van Bijsterveld score ≥ 3. An inter-criteria reliability analysis with Kappa statistic was performed to determine classification consistency.

Results: Of 264 Sicca patients not fulfilling AECG, 81% had sufficient data available to make a decision about fulfilling the ACR criteria. Seven patients (2.7%) fulfilled the ACR critiera but not AECG. All of these fulfilled the ACR criteria due to high titres of ANA and positive RF. None was positive for anti-Ro or La or had a positive salivary gland biopsy. Nor did they have signs of lymphoma risk or had developed lymphoma. Thus, in 97% of the evaluable sicca patients the two criteria sets agreed. Of 368 fulfilling AECG, 268 (73%) had information on all ACR items available, 309 (84%) had sufficient information to evaluate fulfillment of the ACR criteria set. Forty-eight (15%) of AECG positive patients were negative when applying the ACR criteria. 261 of 309 evaluable AECG positive patients were positive according to the ACR criteria, resulting in a consensus in 85%. A calculated kappa-value of 0.781 signals a substantial agreement between the two criteria sets.Amongst the patients not identified by the ACR-criteria there were several with known risk factors for development of lymphoma (table 1). One lymphoma patients (pos biopsy, low C3, high titre ANA but no SSA/SSB or RF, low OSS) was negative in the ACR criteria. Seventeen of the 46 patients not identified by the ACR criteria were previously included in an analysis of germinal center (GC) formation in salivary gland biopsies. Two of these (12%) were positive for GC. These patients with low complement levels, polyneuropathy, low salivary flow were missed applying the ACR criteria due to lack of severe eye disease and SSA/SSB.

Characteristics of 46 patients fulfilling AECG- but not ACR-criteria (n/% of available)

Pos autoimmune sialadenitis	32 (70%)
Pos SSA/SSB	13 (29%)
Low C3 (<0.8 g/l)	4 (11,4%)
Low C4 (<0.20 g/l)	8 (23%)
High IgG (>16 g/l)	7 (17%)
Parotid swelling	9 (21%)
Purpura Waldenstršm	2 (4%)
Cryoglobulinemia	2 (4%)
Low CD4/CD8 ratio	1 (2%)
Lymphoma	1 (2%)

Conclusion: The 2002 AECG and 2012 ACR criteria for SS identify mainly the same patient population (Kappa: 0.781), when applied to the Malmö SS registry containing 386 pSS and 264 sicca syndrome patients. A subgroup of patients lacking SSA/SSB antibodies can be catched only by the ACR criteria. The patients classified as Sjögren's syndrome by the ACR-criteria in our sicca-cohort had mild disease. On the other hand, several patients with high risk disease manifestations such as hypocomplementemia, GC formation or parotid swelling were missed using the ACR criteria because they lacked severe keratoconjunctivitis sicca. Sensitivity and specificity of the ACR criteria were 85% and 97% respectively.

Disclosure: **E. Theander**, None; **P. Olsson**, None; **T. Mandl**, None.

Effects of Reclassification Using the American College of Rheumatology Criteria On a Large cohort Sjögren's Syndrome Patients. Astrid Rasmussen[1], John A. Ice[1], He Li[2], Kiely Grundahl[3], Jennifer A. Kelly[1], Lida Radfar[4], Kimberly S. Hefner[5], Donald U. Stone[4], Juan-Manuel Anaya[6], Michael Rohrer[7], Glen D. Houston[4], David M. Lewis[4], James Chodosh[8], John B. Harley[9], Pamela Hughes[7], Jacen S. Maier-Moore[4], Courtney G. Montgomery[1], Nelson L. Rhodus[7], A. Darise Farris[10], Barbara M. Segal[11], Christopher J. Lessard[12], R. Hal Scofield[10] and Kathy Moser Sivils[1]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma CIty, OK, [3]Oklahoma Medical Research Foundation, oklahoma CIty, OK, [4]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [5]Hefner Eye Care and Optical Center, Oklahoma City, OK, [6]Universidad del Rosario-Corporacion para Investigaciones Biologicas, Bogota, Colombia, [7]University of Minnesota, Minneapolis, MN, [8]Harvard Clinical and Translational Science Center, Boston, MA, [9]Cincinnati Children's Hospital Medical Center; US Department of Veterans Affairs Medical Center, Cincinnati, OH, [10]Oklahoma Medical Research Foun, Oklahoma City, OK, [11]Hennepin County Medical Center, Minneapolis, MN, [12]Oklahoma Medical Research Foundation; University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background/Purpose: There is no single clinical diagnostic test for primary Sjögren's syndrome (pSS). For research purposes, multiple classification criteria have been proposed over the past decades. These include the 2002 American-European Consensus Group (AECG) criteria as well as the newly proposed (2012) American College of Rheumatology (ACR) criteria. We compared the performance of these two sets of criteria in a large carefully characterized sicca cohort.

Methods: In a multidisciplinary (eye, mouth, and medicine) clinic for the evaluation of sicca, we determined the classification of subjects under the AECG and new ACR criteria(n=584) and the mRNA expression profile in whole blood of a subset of 201 participants (pSS by both criteria sets n=127, ACR+/AECG-: n =7, ACR-/AECG +: n=29 and controls n=38). The data points recorded for each patient for classification purposes were: the answers to subjective eye and mouth symptoms (according to the AECG questionnaire), Schirmer's I test, ocular dye score (lissamine green + fluorescein staining of conjunctiva and cornea quantified either by the van Bijsterveld score or the OSS score), salivary whole unstimulated flow, histopathology of minor salivary gland biopsy, serology (antiRo, antiLa, ANA and rheumatoid factor antibodies).

Results: The initial cohort of participants evaluated at either the Sjögren's Clinic at Oklahoma Medical Research Foundation and/or the Sjögren's Clinic at the University of Minnesota consisted of 748 individuals. Of these, a complete data set was available for 584 subjects and these constitute the study cohort. The two cohorts are comparable in terms of age, sex, race and ethnicity. Among the 584 subjects with complete data, 259 were classified as pSS under AECG, and 249 were so classified under ACR criteria while 222 met both sets of criteria and they represent 78% of all pSS cases. The two sets of criteria were not significantly different (p=0.26, McNemar's test; concordance = 0.77, Kappa statistic, 95% CI=72.5–82.9); the ACR criteria had a sensitivity of 0.86 (95% CI=0.81–0.90) and a specificity of 0.92 (95% CI=0.88–0.94). Thirty seven subjects were classified as pSS by AECG only (ACR-/AECG+), of whom 29 (78%) had a minor salivary gland biopsy focal score >1, while 8 (22%) had positive anti-Ro/La. On the other hand, there were 27 ACR+/AECG- and they met ACR criteria mainly due to differences in the scoring of the corneal staining (OSS ≥ 3 for ACR; van Bijsterveld ≥ 4 for AECG). Interestingly, when attempting to correlate the subgroups generated by the classification criteria with their global gene expression profiles, we were unable to identify distinct clustering.

Conclusion: When considering any subject who would meet classification for pSS by either set of criteria, only 75% would be so classified by both. Twenty five percent would be classified by only one set, leading to heterogeneity by either. This suggests that further refinement of the criteria using molecular data is warranted.

Overall Agreement Between Sjögrens's Minor Salivary Gland Biopsy and 2002 and 2012 Classification Criteria. Laura Aline Martinez[1], Candido Flores[2], Alberto Arana Fraustro[2] and Luis H. Silveira[3]. [1]Instituto Nacional de Cardiologia Ignacion Chavez, Mexico City, Mexico, [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico, [3]Instituto Nacional Cardiología Ignacio Chávez, Mexico City, Mexico

Background/Purpose: Sjögren's syndrome (SS) is an inflammatory autoimmune disease characterized by lymphoid infiltration of exocrine glands, although extraglandular involvement is frequently observed. Prevalence is around 0.5% to 1%. There have always been difficulties for the classification and diagnosis of patients. Several criteria have been proposed. The classification criteria used in recent years where those established by the American-European Consensus Group in 2002. Recently, new classification criteria have been published by the International Collaborative Clinical Alliance Cohort; these criteria have been approved by the American College of Rheumatology. Although minor salivary gland biopsy has been used throughout the years, its findings are not highly specific.

Objectives: *Primary.* To determine the agreement between a positive minor salivary gland biopsy and having al least 4 of the 6, 2002 criteria, as well as having 2 of the 3, 2012 criteria. *Secondary:* To determine the agreement between 2002 and 2012 SS classification criteria.

Methods: This is a retrospective study consisting of clinical chart review from patients with primary SS (PSS) and secondary SS (SSS), having minor salivary gland biopsy report. Clinical chart review included patients attending the Rheumatology Clinic at the National Institute of Cardiology in Mexico City, between January 1, 2000, and May 31, 2011. Clinical manifestations, serology, and the biopsy report were obtained in all patients. Biopsies were considered positive when a focal lymphocytic sialadenitis with a focus score $\geq$ 1 focus ($>$ 50 cells)/4 mm^2 was observed. Biopsies were assessed by the same expert pathologist. The 2002 and 2012 criteria were applied according to their requirements. Descriptive statistic was used and kappa index was calculated as an agreement measure. A p value $<$ 0.05 was considered significant. SPSS version 15.0 was used for the statistical analysis.

Results: A total of 75 clinical charts with a biopsy report were reviewed; 8 patients were excluded because information was incomplete. 67 patients were included in the analysis, 62 women and 5 men. 55.2% had PSS and 44.8% had SSS. The agreement between a positive biopsy and having 4 of the 6, 2002 criteria, was weak (kappa = 0.27; p = 0.01); the agreement of a positive biopsy with having 2 of the 3, 2012 criteria, was moderate (kappa = 0.5; p $<$ 0.0001). The agreement between the 2002 criteria and the 2012 criteria was good (kappa = 0.70; p $<$ 0.0001), when all the patients were considered. In the SSS patients, the agreement decreased (kappa = 0.44; p = 0.003).

Conclusion: The agreement between a positive biopsy and having 4 of the 2002 criteria was low, and moderate when having 2 of the 20012 criteria. The agreement between the 2002 and the 2012 criteria was very good when PSS patients were included, however, it decreased when only the SSS patients were included.

Longitudinal Evaluation of the Performance of Different Classification Criteria in Patients with Primary Sjögren's Syndrome. Martina Plešivčnik Novljan[1], Žiga Rotar[1], Aleš Ambrozič[1], Gaj Vidmar[2] and Matija Tomšič[1]. [1]University Medical Centre Ljubljana, 1000 Ljubljana, Slovenia, [2]University Rehabilitation Institute, 1000 Ljubljana, Slovenia

Background/Purpose: Over the past 3 decades, 10 different classification criteria for Sjögren's syndrome (SS) had been proposed. In 2001 and 2002 222 consecutive patients suspected of having primary SS (pSS) were each evaluated for pSS using the Copenhagen (COP), Californian (CA), European (EU) and American-European consensus group (AECG) criteria. 90 patients could be classified as pSS by at least one of the criteria.(1) The purpose of our current study was to prospectively compare the longitudinal performance of different classification criteria by reassessing the diagnosis in 2009 in the group of patients classified as pSS in 2001 and 2002.

Methods: Eligible patients were invited for reassessment. In each patient we repeated diagnostic tests as required by any of the respective classification criteria. Additionally, we used the new ACR criteria (ocular stain score $\geq$3 was replaced by Rose Bengal score $\geq$ 3 following the Bijsterveld's method) to classify the patients on the data from the initial cohort and at reassessment (2).

Results: In 2009 63/90 (70%) of patients from the initial cohort consented to participate. The flow of the patients is summarized in Figure 1.

During the 7.5-year follow up period we observed a transition from pSS to secondary SS (sSS) in 9/63 (14%) patients on average after 4.0±0.9 years. While cases of transition from pSS to sSS were observed for all criteria used to make the initial diagnosis of pSS, it was significantly more common if the diagnosis of pSS was initially made using AECG (17%, p=0.008), or ACR (17%, p= 0.016) criteria.

In the 34 patients who underwent a full diagnostic reassessment the diagnosis retention rate was statistically significant for the CA, AECG, COP and ACR criteria, but not for the EU criteria (Table 1). At reassessment 3/32 (9%), and 2/26 (8%) of patients initially diagnosed as pSS using the EU, and COP criteria, respectively could not be classified as pSS by any of the criteria.

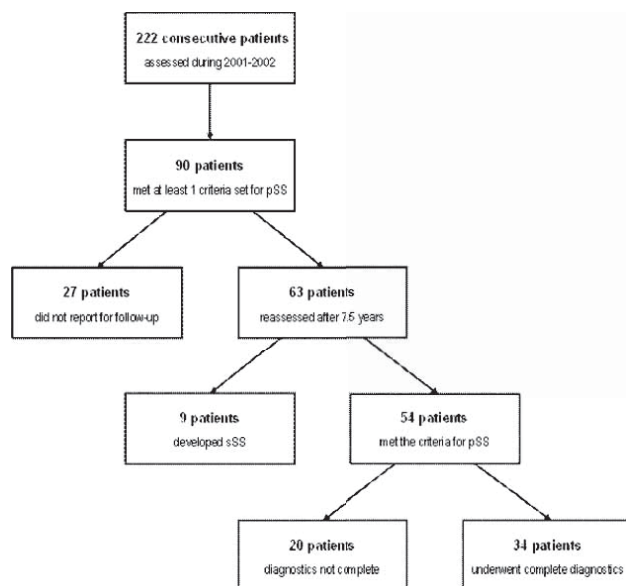
Although the difference between classification using the AECG, and new ACR criteria almost reached statistical significance for the initial 90 patients (p=0.063), the difference was lost at reassessment (p=1.000).


Figure 1.

Table 1.

Patients (100%)	Meeting the criteria for pSS				
	Copenhagen	Californian	European	AECG 2002	ACR 2012
All the 34 pts. before 7.5 years	26/34(76%)	12/34(35%)	32/34(94%)	24/34(71%)	22/34 (65%)
pSS not confirmed after 7.5 years	2/26 (8%)	0/12 (0%)	3/32 (9%)	0/24 (0%)	0/22 (0%)
pSS confirmed anew after 7.5 years	2/26 (8%)	1/12 (8%)	2/32 (6%)	1/24 (4%)	2/22 (9%)
All the 34 pts. at follow-up	26/34 (76%)	13/34 (38%)	31/34 (91%)	25/34 (74%)	24/34 (71%)
	Agreement between initial assessment and reassessment				
Cohen's Kappa (95% confidence interval; significance)	κ=0.673 (0.377, 0.969; p=0.001)	κ=0.937 (0.815, 1.000; p<0.001)	κ=−0.076 (−0.148, −0.004; p=1.000)	κ=0.927 (0.787, 1.000; p<0.001)	κ=0.866 (0.688, 1.000; p<0.001)

References
1. Novljan MP, et al. Scand J Rheumatol 2006;35:463–8.
2. Shiboski SC, et al. Arthritis Care Res 2012;64:475–87.

Conclusion: The longitudinal diagnosis retention rate is highest for the Californian and AECG criteria and lowest for the European criteria. Regardless of the classification criteria we observed that with time some patients develop sSS. When using classification criteria without mandatory positivity in immunoserology or histology there is a caveat of misclassification of patients as pSS.

Patients Fulfilling the Imaging-Arm and Patients Fulfilling the HLA-B27+ Arm of the Assessment of Spondyloarthritis International Society Axial Spondyloarthritis Classification Criteria: Are They Similar? Rosaline van den Berg, Manouk de Hooge, Floris van Gaalen, Monique Reijnierse, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: It is possible to classify patients as having spondyloarthritis (SpA) according to the ASAS axial SpA (axSpA) criteria HLA-B27+ arm without any signs of sacroiliitis on MRI or X-ray. The question arises whether patients fulfilling the HLA-B27+ arm reflect a group of patients similar to those fulfilling the imaging-arm of the ASAS axSpA criteria[1]. Therefore, we compared demographics, number of SpA-features and level of disease activity in patients fulfilling the imaging-arm to patients fulfilling the HLA-B27+ arm of the ASAS axSpA criteria.

Methods: The SPondyloArthritis Caught Early (SPACE)-cohort is set-up in the Leiden University Medical Center (LUMC) aiming to diagnose and treat patients with axSpA at an earlier stage. Patients with back pain (≥3 months, but ≤2 years, onset <45 years) visiting the rheumatology outpatient clinic were included. All patients of the SPACE-cohort (n=157) fulfilling the ASAS axSpA criteria were included in this analysis (n=60). Patients were compared on demographics, presence of SpA-features and level of disease activity.

Results: Of those 60 patients, 30 fulfilled the imaging-arm (11 patients fulfilling the modified New York (mNY) criteria; 19 patients had sacroiliitis on MRI only); 30 fulfilled the HLA-B27+ arm. Patients fulfilling the HLA-B27+ arm have significantly more often a positive family history for SpA (p=0.001), are more frequently female (p=0.04) and have a significantly shorter symptom duration (p=0.02). Moreover, there was a trend toward more uveitis (p=0.07). Patients in both arms are very similar with respect to all other SpA-features and level of disease activity (BASDAI and ASDAS). Within the imaging-arm, patients with sacroiliitis on X-ray did not differ significantly from patients with sacroiliitis on MRI in any of the tested variables including symptom duration and disease activity.

Imaging-arm, n=30

	mNY+, n=11	mNY-, n=19	Total, n=30	HLA-B27+ arm, n=30

How Useful Is Imaging of the Sacroiliac Joints (MRI and/or X-ray) in Patients with Possible Spondyloarthritis in the Diagnostic Work-up? Rosaline van den Berg, Manouk de Hooge, Victoria Navarro-Compán, Floris van Gaalen, Monique Reijnierse, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: In daily practice, the diagnostic work-up of patients with possible axial spondyloarthritis (axSpA) starts with clinical and laboratory data. In many patients MRI and/or X-rays of the sacroiliac joints (MRI-SIJ and X-SIJ) is performed to be able to diagnose patients with confidence. We investigated the contribution of imaging (MRI-SIJ and X-SIJ) in making a final diagnosis with confidence.

Methods: All patients with chronic back pain (≥3 months, but ≤2 years, onset ≤45 years) in the SPondyloArthritis Caught Early (SPACE)-cohort in our clinic underwent a diagnostic work-up according a fixed protocol. First, medical history, physical examination and laboratory assessments, including HLA-B27 typing, were performed. Based on this information, an experienced rheumatologist diagnosed all patients as either SpA or no-SpA with a level of confidence (scale 0 (not confident at all) to 10 (very confident)). Second, imaging (MRI-SIJ and X-SIJ) was performed and a diagnosis was recorded by the same rheumatologist with a new level of confidence. For the analyses, cut-off values of ≤5 (not confident) and ≥6 (confident) were used.

Results: The results are presented in the table. In 52/157 of the patients (33%), the rheumatologist was confident about the diagnosis, either SpA (n=31) or no-SpA (n=21), based on clinical and laboratory data only. Imaging was positive in 32/157 patients (20.4%). In 3/157 patients (1.9%) the rheumatologist was confident about the diagnosis no-SpA, but revised the diagnosis into confident SpA after imaging. In 9/157 patients (5.7%) the rheumatologist reduced the level of confidence about the diagnosis SpA after imaging was performed, since imaging was negative. In 105/157 of the patients (67%), the rheumatologist was not confident about the diagnosis. After performing imaging, the rheumatologist was confident about the diagnosis in 73/105 patients: SpA in 21/105 (20%) patients and no-SpA in 52/105 (50%) patients. In the remaining 32/105 patients (30%) imaging did not change confidence, nor diagnosis.

	Before imaging	After imaging	MRI pos, n	X-ray pos, n	MRI & X-ray pos, n
Confident n=52	SpA n=31	Conf SpA n=22	5	0	1
		Conf no-SpA n=0	-	-	-
		Not conf SpA n=9	0	0	0
		Not conf no-SpA n=0	-	-	-
	No-SpA n=21	Conf SpA n=3	2	0	1
		Conf no-SpA n=18	0	0	0
		Not conf SpA n=0	-	-	-
		Not conf no-SpA n=0	-	-	-
Not Confident n=105	SpA n=17	Conf SpA n=5	3	0	2
		Conf no-SpA n=1	0	0	0
		Not conf SpA n=11	0	0	0
		Not conf no-SpA n=0	-	-	-
	No-SpA n=88	Conf SpA n=16	9	4	3
		Conf no-SpA n=51	0	0	0
		Not conf SpA n=2	1	0	0
		Not conf no-SpA n=19	0	1	0

Conclusion: Imaging (MRI-SIJ and/or X-SIJ) is useful for the rheumatologist in the large majority of patients with possible axSpA, except for the patients in which the rheumatologist is confident about the diagnosis of SpA before imaging.

2208

Referral Patterns and Diagnosis of Patients with Axial Spondyloarthritis: Results of an International Survey. Désirée van der Heijde[1], Joachim Sieper[2], Dirk Elewaut[3], Aileen L. Pangan[4] and Dianne Nguyen[5]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Charité Universitätesmedizin Berlin, Berlin, Germany, [3]Ghent University Hospital, Ghent, Belgium, [4]Abbott Laboratories, Abbott Park, IL, [5]Abbott Laboratories, Singapore, Singapore

Background/Purpose: This analysis compares referral patterns and diagnostic tools for axial spondyloarthritis (axSpA) used by rheumatologists working in academic centers and in community clinical practice settings.

Methods: The MAXIMA (**M**anagement of **Axi**al SpA **I**nternational and **M**ulticentric **A**pproaches) survey asked respondents questions pertaining to referral, diagnosis, and management of patients with axSpA. The survey was completed anonymously online by participants from 42 countries in Europe, Latin America, and North America. The MAXIMA survey was funded by Abbott Laboratories and conducted by a third-party vendor with guidance and approval of the questionnaire by a steering committee of SpA experts. None of the participants were compensated for completing the survey.

Results: 500 surveys were completed by 141 rheumatologists in academic practice settings (28%) and 359 rheumatologists in community practice settings (72%). Only 58% of academic rheumatologists compared to 72% of clinical rheumatologists agreed that the concept of axial SpA is clear to the rheumatology community. However, responses to various questions about referral and diagnostic work-up for patients with axSpA were generally similar in both practice settings (table). The majority of respondents (87%) reported that primary care providers referred patients with chronic back pain for 3 months and onset <45 yrs old; 47% of respondents received referrals from other specialists such as dermatologists, gastroenterologists, and ophthalmologists. Other than chronic and inflammatory back pain, referrals from non-rheumatology specialists were triggered by the occurrence of uveitis (82%), inflammatory bowel disease (48%) and skin lesions (46%). At the time of referral to the rheumatologist, 48% of patients have symptoms for ≥3 yrs. The ASAS criteria (85%) were cited as the most common classification criteria that guide respondents in the diagnosis of axSpA in clinical practice, compared to the modified New York criteria for AS (23%), ESSG (8%), and Amor (6%). In terms of diagnostic work-up, approximately half systematically request HLA-B27 typing. MRI of the sacroiliac joints is the most commonly used imaging test, closely followed by pelvic x-rays.

Table. Response rates in MAXIMA survey regarding SpA referral patterns and diagnosis

	Rheumatology Practice Setting		
Question	Academic Center N=141	Community Clinical Practice N=359	Overall N=500
Patients with back pain ≥3 mo, <45 yrs old			
Source of referrals[a]			
Primary care provider	82	89	87
Physiotherapist	18	30	27
Private office rheumatologist	22	18	19
Other specialist[b]	50	46	47
Duration of symptoms			
<1 yr	9	10	10
1–2 yrs	36	45	42
3–4 yrs	41	30	33
>5 yrs	14	15	15
Triggers of past referrals from other specialists			
Uveitis	81	82	82
Chronic back pain	69	64	65
IBP	38	44	42
Skin lesions	47	45	46
Nail lesions	23	30	28
Inflammatory bowel disease	45	49	48
Diagnosis in daily practice			
Classification guides used for diagnosis of axSpA in practice			
ASAS	92	83	85
Modified New York criteria for AS	21	24	23
ESSG	4	10	8
HLA-B27 typing performed routinely	49	50	49
Imaging tests used			
MRI sacroiliac joint	92	93	93
Pelvic x-ray	88	85	86
Spinal x-ray	71	78	76
MRI spine	56	58	57

[a]Respondents may have indicated >1 source of referrals. [b]Other specialist = dermatologist, gastroenterologist, ophthalmologist. AS, ankylosing spondylitis; ASAS, Assessments in Spondyloarthritis International Society; axSpA, axial spondyloarthritis;; BASDAI, Bath AS Disease Activity Index; ESSG, European Spondylarthropathy Study Group; IBP, inflammatory back pain; mo, months; MRI, magnetic resonance imaging; SpA, spondyloarthritis; yr, year.

Conclusion: Results of the MAXIMA survey show general agreement in referral patterns and use of diagnostic tools by rheumatologists in academic and clinical practice settings when evaluating patients for axSpA. Half of the patients are still being seen by rheumatologists several years after onset of symptoms, which indicates the need for appropriate early referral.

2209

Assessing Active Inflammation in Sacroiliac Joints in Spondyloarthritis Patients: No Added Value of Gadolinium Compared to Short Tau Inversion Recovery Sequence. Manouk de Hooge, Rosaline van den Berg, Victoria Navarro-Compán, Floris van Gaalen, Désirée van der Heijde, Tom Huizinga and Monique Reijnierse. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: MRI is used as a diagnostic tool to detect active disease of the sacroiliac joint. T1 weighted and STIR images are generally used and ASAS definition is based on bone marrow edema (BME). However, imaging after intravenous administration of gadolinium (Gd) may improve the detection of BME, synovitis, capsulitis and/or enthesitis compared to STIR sequence[1].

The purpose of this study is to investigate the additional value of T1 fatsat after Gd (T1/Gd), compared to T1 and STIR sequence in the detection of active lesions of the SIJ typical for spondyloarthritis (SpA) and to assess its influence on final MRI diagnosis based on the ASAS definition of active sacroiliitis.

Methods: All patients included in the SpondyloArthritis Caught Early (SPACE)-project received MRI of the SIJ (MRI-SIJ). Inclusion criterion for this study was chronic back pain of short duration ≥3 months, ≤2 years, onset ≤45 years). Imaging was performed on 1.5T (Philips, Best, Netherlands). Acquired sequences were coronal oblique T1, STIR and T1/Gd. The parameters evaluated were BME, synovitis and capsulitis/enthesitis. Parameters were scored on STIR as well as T1/Gd sequence and compared in conjunction with unenhanced T1 images. A positive MRI was defined as the presence of BME on the STIR images according to the ASAS definition. Scoring was done by three blinded trained readers. If 2 out 3 readers stated positive, the MRI was considered as such.

Results: In 127 patients that were included a baseline, MRI was obtained and in 67 patients also a follow-up MRI after 3 months was obtained. 22/127 patients (17.3%) were diagnosed with active sacroiliitis according to the ASAS definition based on the STIR sequence. No additional BME was found on the T1/Gd. At baseline, in 7 patients (5.5%) in addition to present BME, synovitis and/or capsulitis/enthesitis were found. All patients with capsulitis also showed synovitis. In 1 patient (0.8%) synovitis was an isolated finding. This patient did not fulfill the ASAS, ESSG, Amor or modified New York classification criteria. These findings did not change at follow up. The patients with a positive MRI, capsulitis or synovitis at follow-up were the same patients who show this signs at baseline (table 1).

	Baseline (n=127)		Follow-up (n=67)	
	STIR	T1/Gd	STIR	T1/Gd
Positive MRI (according to ASAS)	22	22	11	11
Enthesitis/Capsulitis	0	2	0	1
Synovitis	*		*	4

* not estimated with STIR

Conclusion: STIR sequence by itself is sufficient to detect active sacroiliitis according to the ASAS definition. The additional presence of synovitis, capulitis/enthesitis observed with gadolinium, is seen in the presence of BME, except in one patient without clinical SpA. In line with the recommendations by ASAS, our data show that Gd is not needed in the MRI assessment of patients with SpA.

The Canada-Denmark Fat Spondyloarthritis Spine Score: Validation of a New Scoring Method for the Evaluation of Fat Lesions in the Spine of Patients with Axial Spondyloarthritis. Susanne Juhl Pedersen[1], Zheng Zhao[2], Robert GW Lambert[3], Mikkel Østergaard[1], Ulrich Weber[4] and Walter P. Maksymowych[3]. [1]Glostrup Hospital, Copenhagen, Denmark, [2]Department of Rheumatology, University of Alberta and PLA General Hospital, Beijing, PR China, Beijing, China, [3]University of Alberta, Edmonton, AB, [4]Balgrist University Hospital, Zurich, Switzerland

Background/Purpose: Fat metaplasia has been shown to follow resolution of inflammation in axial SpA and this may be evident within one year (1). Fat metaplasia at vertebral corners has also been shown to predict the development of new syndesmophytes (2). Consequently, the scoring of fat lesions in the spine may constitute both an important measure of treatment efficacy as well as a responsive surrogate for new bone formation. Because of this, we developed and validated a new scoring system for fat lesions in the spine, the CanDen Fat SpA Spine Score (FASSS), which addresses the localization and phenotypic diversity of fat lesions in SpA.

Methods: In 2007, the Canada-Denmark MRI working group developed anatomy-based definitions of fat lesions on T1 weighted sagittal MRI scans of the spine (3). In 2011, further definitions, a reference image module, and an online spinal unit schematic for data entry were developed, which formed the basis for a scoring method. The method comprises six different types of fat lesions defined according to their anatomical location, which are recorded dichotomously (present/absent) at each vertebral endplate from C2 lower to S1 upper (scoring range per disco-vertebral unit in C spine: 0–8, and in T and L spine: 0–18). Two rheumatologists assessed spine MRI scans obtained at two time points (mean 1.5 years (SD 0.5)) in chronological order of 66 patients with axial SpA (exercise 1). Scoring methodology and reference image set were revised based on discrepant cases in exercise 1. Then the two readers re-read 30 randomly selected pairs of MRI scans from the first exercise together with 40 new pairs of MRI scans (exercise 2) (mean 1.7 years (SD: 0.8)) (exercise 2). Inter-observer reliability were assessed by intra-class correlation coefficients (ICCs), and responsiveness as mean change per year by standardized response mean (SRM).

Results: In exercise 2, the change in fat scores ranged from −34 to 52 for reader A and from −38 to 61 for reader B. Inter-observer ICC scores were high to very high for the FASSS baseline scores, and improved substantially in change scores from exercise 1 to 2 (Table). This was particularly notable for the 30 patients evaluated in both exercises. Inter-observer ICCs for baseline scores were high for all spinal segments, and change scores improved from small to moderate (C spine), and from moderate to high (L spine) and very high (T spine). For total FASSS score the mean change/year and SRM were 2.4 and 0.34 for reader A and 3.7 and 0.26 for reader B.

Table. Interobserver ICCs for spinal segments scored according to the CanDen Fat SpA Spine Score (FASSS)

| | Inter-observer ICCs (CI95%) | | | | | |
| | Exercise 1 (n=65) | | Exercise 2 (n=70) | | Exercise 1 (n=30)* | Exercise 2 (n=30)* |
	Baseline ICC (95% CI)	Change ICC (95% CI)	Baseline ICC (95% CI)	Change ICC (95% CI)	Change ICC (95% CI)	Change ICC (95% CI)
C spine	0.76 (0.62;0.85)	0.38 (0.16;0.57)	0.82 (0.72;0.88)	0.49 (0.29;0.65)	0.27 (−0.05;0.56)	0.54 (0.23;0.75)
T spine	0.89 (0.78;0.94)	0.55 (0.32;0.71)	0.88 (0.64;0.95)	0.94 (0.87;0.97)	0.42 (0.08;0.67)	0.70 (0.46;0.85)
L spine	0.77 (0.60;0.87)	0.45 (0.22;0.63)	0.92 (0.88;0.94)	0.74 (0.64;0.82)	0.48 (0.15;0.71)	0.75 (0.48;0.88)
FASSS	0.89 (0.78;0.93)	0.53 (0.21;0.71)	0.95 (0.91;0.97)	0.84 (0.75;0.90)	0.41 (0.02;0.68)	0.64 (0.37;0.81)

*The 30 patients, that were scored two times, were a subgroup of patients in exercise 1 and 2.

Conclusion: The FASSS meets essential validation criteria for further assessment in axial SpA, and may thus be useful for follow-up of SpA in clinical trials and practice.

Is It Useful to Repeat an MRI of the Sacroiliac Joints in the Diagnostic Work-up for Spondyloarthritis? Rosaline van den Berg, Manouk de Hooge, Victoria Navarro-Compán, Floris van Gaalen, Monique Reijnierse, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: In the diagnostic work-up of spondyloarthritis (SpA), imaging of the sacroiliac joints by MRI (MRI-SIJ) is an important step. One study showed that in HLA-B27+ patients and male patients it might be useful to repeat an MRI-SIJ after one or two years[1]. It is not known if repeating an MRI-SIJ after a shorter period than 1 year is useful. Therefore, we investigated whether it is useful to repeat an MRI-SIJ after 3 months in the diagnostic process for SpA.

Methods: Patients with chronic back pain (n=157) (≥3 months, but ≤2 years, onset <45 years) included in the SPondyloArthritis Caught Early (SPACE)-cohort in the Leiden University Medical Center (LUMC) underwent an MRI-SIJ during baseline visit. All patients with SpA and possible SpA are included for follow-up (n=90) and received a second MRI-SIJ during a follow-up visit after 3 months. All MRI-SIJs of both time points were scored by 3 independent readers 'positive' or 'negative' according to the ASAS definition[2], blinded for the time-sequence. If 2/3 reads were positive, the MRI-SIJ was marked as positive.

Univariate and multivariate regression analyses were performed to investigate which variables (IBP, elevated CRP, MRI-SIJ status at baseline, gender, HLA-B27 status and age at onset) could predict a positive MRI-SIJ at 3 months.

Results: Only patients with complete MRI-SIJ data are included in this analysis (n=90). In the univariate analysis, MRI-SIJ positivity at baseline was the strongest predictor of a positive MRI-SIJ over time (OR 51.0, 95% CI 12.2–212.8, p<0.001). Regardless MRI-SIJ status, gender and HLA-B27-status (OR 7.7, 95% CI 2.6–23.1, p<0.001 and OR 2.6, 95% CI 0.9–7.0, p=0.07, respectively) are strong predictors of a positive MRI-SIJ over time. The latter 2 variables were used in a multivariate model. Groups were made based on this model (table). In the majority of the patients (90%), MRI-SIJ status, either positive (n=15) or negative (n=66), did not change over time. Of the patients with a negative MRI-SIJ at baseline (n=71), 5 (7%) developed a positive MRI-SIJ after 3 months, and in 4/19 (21.1%) lesions on MRI-SIJ disappeared over time. Two out of 5 patients in whom MRI-SIJ was positive for the first time at follow-up fulfilled the ASAS axial SpA criteria only at follow-up.

	Only baseline MRI-SIJ pos, n (%)	Only 3-months MRI-SIJ pos, n (%)	Both baseline and 3-months MRI-SIJ pos, n (%)
HLA-B27- female, n=38	1 (2.6)	1 (2.6)	2 (5.3)
HLA-B27+ female, n=21	0 (0.0)	1 (4.8)	2 (9.5)
HLA-B27- male, n=14	2 (14.3)	1 (7.1)	4 (28.6)
HLA-B27+ male, n=17	1 (5.9)	2 (11.8)	7 (41.2)

Conclusion: We confirmed that a positive MRI-SIJ at baseline is a very strong predictor for a positive MRI-SIJ after 3 months. In patients with a negative MRI-SIJ at baseline, male gender and HLA-B27+ are predictive for a later positive MRI-SIJ.

In this group of patients with short symptom duration, variation in MRI-SIJ positivity occurred in 10% of the patients over a very short period of only 3 months. A positive change of MRI-SIJ has led to a different classification in 2 patients (2.2%). More data are needed to decide if it is necessary to repeat MRI-SIJ, and if so, with what time interval.

How Much Does the Spondyloarthritis Research Consortium of Canada Score of the Sacroiliac Joints Change Over a 3-Month Period in Patients On Non-Biological Treatment? Rosaline van den Berg, Manouk de Hooge, Victoria Navarro-Compán, Floris van Gaalen, Monique Reijnierse, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: The SpondyloArthritis Research Consortium of Canada (SPARCC) score of the sacroiliac joints (SIJ) is often used in clinical trials to detect changes over time. It is important to know if the SPARCC score spontaneously change over time in patients on non-biological treatment. We investigated how much change in the SPARCC score of the SIJ can be detected over a 3-month period in patients on non-biological treatment.

Methods: Ninety patients with chronic back pain (≥3 months, but ≤2 years, onset <45 years) in the SPondyloArthritis Caught Early (SPACE)-cohort underwent a baseline and 3-month follow-up MRI of the SIJ (MRI-SIJ). All MRI-SIJs were scored according to the SPARCC score by 2 independent readers, blinded for time sequence. The mean SPARCC scores (2 readers) were used in this analysis. Delta scores in SPARCC between both time points were calculated. Patients were treated by their rheumatologist, who was unaware of the MRI scores; treatment was recorded.

Results: In 45 (50%) patients (41 patient with a SPARCC score of 0; 2 with a SPARCC score of 1; 2 with a SPARCC score ≥2), the SPARCC score did not change over the period of 3 months. In 18 (20%) patients, the SPARCC score changed 1 point (increased in 10 and decreased in 8 patients). In 27 (30%) patients the SPARCC score changed ≥2 points (13 patients showed an increase and 14 patients a decrease). In the patients that showed a change, the mean (SD) change in score was −0.7 (6.0), the median (range; IQR) change was −1 (−17 to 16; −3 to 1.3).

In the 45 patients without SPARCC score changes, 10 (11%) patients did not use any medication, 16 (18%) patients were on stable non-biological treatment, and 19 (21%) changed treatment (9 patients switched NSAIDs, 5 started NSAID treatment, 4 stopped treatment with NSAIDs, 1 patient started NSAIDs and stopped after 2 months during the follow-up period).

Of all patients (n=45) with SPARCC score changes, 10 (11%) patients did not use any medication, 22 (24%) patients were on stable non-biological treatment, and 13 (14%) patients changed treatment during the 3-month period. Eight of them switched to another NSAID (SPARCC score decreased 1 point in 3 patients, 4 points in 1 patient and 6 points in another patient, and increased 1 and 2 points in the remaining patients). Four patients started treatment with NSAIDs, and SPARCC score decreased in all of them (17 points, 3 points, 2 points and 1 point). One patient stopped NSAID treatment and SPARCC score increased 1 point.

Treatment over the 3-month period (baseline–follow-up)	No SPARCC score change, n=45	SPARCC score change, n=45	
		Decrease, n=22	Increase, n=23
No medication, n=20	10	3*	7*
Stable non-biological treatment, n=38	16	9*	13*
Switch NSAIDs, n=17	9	6*	2*
Start NSAID, n=9	5	4*	–
Stop NSAID, n=5	4	–	1†
Start and stop NSAID, n=1	1	–	–

*Range 1–17 points, †1 point

Conclusion: Over a short period of 3 months, the SPARCC score changed without the start of a TNF-blocker in 45 patients (50%) on non-biological treatment, with a range from −17 to 16 points. The observed changes in SPARCC score do not seem to be influenced by non-biologic treatment. While analyzing results of clinical trials, it is important to keep in mind that a change in SPARCC score in patients on non-biological treatment is possible. This is important information for the power calculation of a trial.

Ankylosing Spondylitis Is Strongly Related to Clinical Spine Fractures Independently of Drugs Use: A Register-Based Case-Control Study.
Daniel Prieto-Alhambra[1], Juan Muñoz-Ortego[2], Cyrus Cooper[3], Adolfo Díez-Pérez[4] and Peter Vestergaard[5]. [1]URFOA-IMIM, Parc de Salut Mar; Idiap Jordi Gol; University of Oxford; University of Southampton, Barcelona, Spain, [2]Hospital Sagrat Cor, Barcelona (Spain), Spain, [3]University of Oxford; Southampton General Hospital, Southampton, United Kingdom, [4]Hospital del Mar-IMIM, Universitat Autònoma de Barcelona, Barcelona; and RETI-CEF, ISCIII Madrid; Spain, Barcelona, Spain, [5]Aarhus University Hospital THG, Aarhus (Denmark), Aarhus, Denmark

Background/Purpose: Ankylosing Spondylitis (AS) is associated not only with systemic low bone mass, but also with locally increased fragility due to biomechanical changes in the spine. However, data on the impact of AS on clinical spine fracture risk is scarce. We used a large population-based registry from Denmark to investigate the association between AS and fractures, with a particular focus on the spine.

Methods: We carried out a case control study. From the Danish National Health Service Registers, we identified 124,655 fracture cases and 373,962 age- and gender-matched controls. Prevalence of AS in cases and controls

was estimated. Crude odds ratios (OR) and 95% confidence intervals (CI) according to AS status were calculated using conditional logistic regression. We further adjusted the analyses for: 1. use of oral corticosteroids; and 2.use of oral corticosteroids, NSAIDs and strong analgesics. Similar analyses were repeated separately for the spine, hip and forearm fracture cases and corresponding matched controls.

Results: Among 124,655 cases, 139 (0.11%) had a diagnosis of AS, while 271 (0.07%) out of 373,962 controls had AS (crude OR 1.54 [95%CI 1.26–1.89]). Similarly, 18 (0.54%) out of 3,364 spine fracture cases compared to 10 (0.10%) matched controls had AS (crude OR 5.42 [2.50–11.70]). Among 10,530 hip fracture cases 7 (0.07%) AS patients were identified, and 27 (0.09%) of 31,356 controls suffered AS (crude OR 0.78 [0.34–1.78]). Finally, 20,035 forearm fracture cases were screened for AS, and a prevalence of 0.08% (n=16) was found, compared to 0.04% (23) in the controls: unadjusted OR 2.09 [1.10–3.95]. The observed associations remained significant after adjustment for use of oral corticosteroids [see Table]. Conversely, all of them were attenuated when adjusted for use of NSAIDs and strong analgesics but the association between AS and clinical spine fracture (adjusted OR 4.41 [1.90–10.20]).

Table. Results for the association between fracture and AS status (conditional logistic regression).

Skeletal Site	Unadjusted OR (95%CI)	Adjusted for use of oral corticosteroids	Adjusted for use of oral corticosteroids, NSAIDs and strong analgesics
All clinical fractures	1.54 (1.26–1.89)	1.49 (1.22–1.83)	1.12 (0.91–1.38)
Clinical spine	5.42 (2.50–11.7)	5.19 (2.39–11.3)	4.41 (1.90–10.2)
Hip	0.78 (0.34–1.78)	0.76 (0.33–1.76)	0.60 (0.25–1.36)
Forearm	2.09 (1.10–3.95)	2.05 (1.08–3.89)	1.70 (0.89–3.22)

OR = Odds Ratio; 95%CI = 95% Confidence Interval

Conclusion: AS-affected patients are at increased risk for fractures independently of oral corticosteroid use. Clinical spine fractures are the most strongly related to AS, with a multivariate adjusted OR of almost 4.5, independent of use of drugs commonly used for the treatment of AS including oral corticosteroids and NSAIDs. Patients with AS should be fully assessed for fracture risk as part of their clinical management.

Similar Levels of Disease Activity in Patients with Oligoarticular Vs. Polyarticular Peripheral Spondyloarthritis.
Filip Van den Bosch[1], Philip Mease[2], Désirée van der Heijde[3], Martin Rudwaleit[4], Katie Obermeyer[5] and Aileen L. Pangan[5]. [1]Ghent University Hospital, Ghent, Belgium, [2]Swedish Medical Center, Seattle, WA, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Endokrinologikum Berlin, Berlin, Germany, [5]Abbott Laboratories, Abbott Park, IL

Background/Purpose: The ASAS criteria for peripheral spondyloarthritis (SpA) allow for classification of patients with SpA who present with peripheral arthritis, enthesitis and/or dactylitis.[1] ABILITY-2, a placebo-controlled trial of adalimumab (ADA) for the treatment of peripheral SpA in patients not previously diagnosed with psoriasis or psoriatic arthritis (PsA), is the first pivotal study to use the ASAS criteria to classify patients for study entry. This analysis characterizes ABILITY-2 patients based on gender and the pattern of joint involvement – oligoarticular vs. polyarticular.

Methods: ABILITY-2 is an ongoing, randomized, controlled multicenter phase 3 study. Eligible patients were age ≥18 yrs, fulfilled ASAS peripheral SpA criteria, did not have a diagnosis of psoriasis, PsA, or ankylosing spondylitis, and had inadequate response or intolerance to NSAIDs. Required baseline disease activity at study entry included patient global assessment of disease activity (PGA) and of pain (PGA-pain) ≥40mm (0–100 mm VAS), ≥2 SJC and TJC, ≥2 digits with dactylitis or enthesitis accompanied by at least 1 joint with active arthritis, or ≥2 sites with enthesitis judged to be severe by the investigator. Subgroup analyses of baseline demographics and disease activity were conducted by gender and by pattern of joint involvement (oligoarticular 2–4 vs. polyarticular >4 joints which are either tender and/or swollen).

Results: Of the 165 patients randomized, 90 (54.5%) were female and 125 (75.8%) had polyarticular disease. Females were slightly older and had a
