lower proportion with HLA-B27 positivity, but overall, had similar disease activity parameters as males (table). Predominantly lower limb involvement was observed at baseline in 57% of males, 50% of females, 59% of patients with oligoarticular disease, and 51% of patients with polyarticular disease. More patients with polyarthritis were HLA-B27+ compared to those with oligoarthritis (table). Although fewer polyarticular patients had an abnormal hs-CRP at baseline, the mean hs-CRP and the proportion of patients with accompanying enthesitis and dactylitis were greater in those with polyarticular disease. Otherwise, both patient and physician global assessments, BASDAI, HAQ-S and the physical component score of the SF-36v2 were similar between these 2 subgroups.

Table. Baseline demographics and disease characteristics in subgroups of peripheral SpA patients based on gender and pattern of joint involvement

| | Gender | | Pattern of Joint Involvement | |
Randomized Patients N=165	Male n = 75	Female n = 90	Oligoarticular n = 34	Polyarticular n = 125
Demographics				
Age, years	38.5	42.3	39.6	41.2
Female, %	–	–	55.9	55.2
SpA symptom duration[a], years	6.62	7.67	6.65	7.45
HLA-B27+, %	65.3	58.4	52.9	62.1
Disease Activity				
hs-CRP, mg/L	11.2	9.4	8.3	11.0
hs-CRP abnormal, %	46.7	41.1	52.9	42.4
TJC, 0–78	10.77	15.38	3.00	16.69
SJC, 0–76	6.21	7.11	2.12	8.24
MASES, 0–13	2.51	4.07	1.44	3.89
MASES >0, %	73.3	75.6	52.9	80.0
Leeds enthesitis index, 0–6	1.29	1.59	0.56	1.73
Leeds >0, %	65.3	60.0	44.1	68.0
SPARCC enthesitis index, 0–16	3.53	4.28	1.91	4.54
SPARCC >0, %	81.3	75.6	64.7	81.6
Dactylitis count	0.41	0.57	0.12	0.63
Dactylitis >0, %	20.0	24.7	8.8	27.4
PGA, 0–100 mm	63.71	67.59	63.97	66.50
PGA-pain, 0–100 mm	62.45	67.01	62.47	65.70
PhGA, 0–100 mm	59.29	58.18	56.12	59.72
BASDAI, 0–10	5.21	5.97	5.37	5.72
SF–36v2 PCS	35.65	33.58	36.77	33.88
HAQ-S	0.83	1.11	0.88	1.02

Values are the mean unless otherwise indicated. [a]N=73, 88, 34, 121, respectively. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; HAQ-S, Health Assessment Questionnaire modified for Spondyloarthropathies; hs-CRP, high-sensitivity C-reactive protein; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; PGA, Patient's Global Assessment of disease activity; PGA-pain, Patient's Global Assessment of pain; PhGA, Physician's Global Assessment; SF-36v2 PCS, Short Form-36 Health Status Survey version 2 physical component summary; SJC, swollen joint count; SpA, spondyloarthritis; SPARCC, Spondyloarthritis Research Consortium of Canada; TJC, tender joint count

Conclusion: In non-PsA peripheral SpA patients with inadequate response or intolerance to NSAIDs, similar levels of disease activity as measured by patient and physician global assessments were observed regardless of extent of joint involvement. Likewise, functional impairment was also comparable between patients with oligo- and polyarticular joint disease.

Assessment of Vascular Age in Psoriatic Arthritis Patients. Jl Rosales-Alexander. César Magro Checa, Juan Salvatierra, Jesús Cantero Hinojosa and Enrique Raya Álvarez, University Hospital San Cecilio, Granada, Spain

Background/Purpose: The European League Against Rheumatism (EULAR) recommends cardiovascular risk (CV) assessment using the systematic coronary risk evaluation (SCORE) chart in inflammatory arthritis patients. However, the absolute 10 years CV risk is a statistical and epidemiological concept that could be difficult to understand by our patients, resulting in a lack of adherence to treatment. The Framinghan heart study (FHS) incorporated the concept of vascular age, as the age of the arteries, a concept more easily understood by all patients. Recently, a calibrated vascular age chart (VAC) according to the SCORE scales was published for european people.

Objective: To assess vascular age (VA) in psoriatic arthritis (APs) patients without CV risk factors/ previous ischemic events using the VAC comparing it with healthy controls. To assess the correlation of several clinical and serological variables with VA in APs patients.

Methods: We included 80 consecutive APs patients, according to the CASPAR criteria without CV risk factors neither previous ischemic events and matched to 80 healthy controls according to sex, age and gender. We recorded demographic data, clinical and laboratory parameters of disease activity like ESR, CRP, tender and swollen joint counts, DAS28, patient global assessment by visual analogue scale, lipid profile and APs characteristics. We assessed VA using the VAC. Data was analyzed with the statistical software SPSS 15. Descriptive data were shown as percentages and mean±SD. To analyze data, we use simple lineal regression test with correlation and the multiple lineal regression analysis. The limit of statistical significance was located in the α error of 0,05.

Results: In APs patients, the median chronologic age (CA) was 47,8±12,4 years, VA was 52,48±12,82, disease duration was 11,09±7,8 and absolute CV risk was 1,99±3,5. Of these patients, 50% were female, 64% had axial and peripheral involvement and 37,5% was HLA-B27 positive. In controls, CA was 47,4±12,2, VA was 49,67±12,67 and absolute CV risk was 1,01±1,7. After applying lineal regression test, VA was correlated with CA (beta 0.973, p=0.000); and there were differences in VA between both groups (beta −2,46, p=0,000). Of interest, after adjusting for confounding factors, VA in APs seem to be correlated with time of disease (p=0,003) and with highest values on the score chart (p=0,000).

Conclusion: In our study, we found that APs patients without CV risk factors had higher VA than healthy controls. Also, we found a good correlation between VA and CA. Time of disease and highest values on the SCORE CV risk chart seem to predict higher VA in APs patients.

2216

Cardiovascular Risk Assessment in Spondyloarthritis Using the Score Chart and Reclassification by Presence of Plaques On Ultrasonography. Jl Rosales-Alexander, Juan Salvatierra, César Magro Checa, Jesús Cantero Hinojosa and Enrique Raya Álvarez. University Hospital San Cecilio, Granada, Spain

Background/Purpose: Increased cardiovascular (CV) risk have been described in patients with rheumatic diseases including spondyloarthritis (SpA). Besides traditional CV risk factors, disease specific factors have been suggested as possible etiologic factors for atherosclerosis. Increased carotid Intima-media thickness (IMT) has been found to be increased in rheumatic diseases. In RA and other inflammatory arthritis, EULAR recommends annual CV risk assessment according to national guidelines, but there is not a calibrated SCORE chart for SpA patients.

Objectives: To asses CV risk in SpA patients using the SCORE chart calibrated for Spain (SCOREm) and to determine the percentage of patients reclassified according to the presence of plaques by the use of common carotid artery (CCA) ultrasonography (US). To analyse the factors that predict a higher global CV risk.

Methods: All patients with SpA, fulfilling the "Assessment of SpondyloArthritis international Society" (ASAS) classification criteria, without previous ischemic events were prospectively included in a database, containing demographic and clinical information. For the study, 90 living Spanish patients were selected. Classic CV risk factors, acute phase reactants (APR), disease activity indexes and lipid profile were obtained. CV risk was calculated using the SCOREm and the presence of plaques – measure of the CCA IMT was evaluated by B-doppler US. Chi-square or McNemar's tests were used to assess differences between qualitative variables, and ANOVA with Bonferroni adjustment for comparing means. Factors predicting higher global CV risk were evaluated by multivariate lineal regression analysis.

Results: Most patients (54%) were men, 77% were HLA-B27 positive. Mean age was 46,32±14,4 years and mean disease duration was 8,8±6,8 years. Mean SCOREm was 1,3±2,7. Low CV risk was found in 64(71%) patients, intermediate, high and very high risk in 23(25,7%), 2 (2,2%) and 1(1,1%) patients respectively. After CCA US was performed, plaques were found in 10/90(11,1 %) patients. Of these, reclassification to high risk was done in 3 and 5 patients with low and intermediate risk respectively (p<0,001). Mean IMT was 0,61±0,11 mm. Higher global CV risk was predicted by hypertension (β 3,66; p=0,00), dyslipidemia (β −1,77; p=0,016), time of disease (β 0,075; p=0,040) and HLA-B7 positivity (β −1,82; p=0,002).

Conclusion: In our study most SpA patients have low and intermediate CV risk using the SCOREm chart, but after performing CCA US 8(8,9%) patients were reclassified into high risk by the presence of plaques. Besides classic CV risk factors, some disease characteristics might contribute to the expression of higher global CV risk in these patients.

2217

Even After Pretreatment with up to Three Biologics, Anti-TNFs Shows Effectiveness in Active Psoriatic Arthritis Patients. Frank Behrens[1], Michaela Koehm[1], Diamant Thaci[2], Brigitte Krummel-Lorenz[3], Gerd Greger[4], Bianca Wittig[4] and Harald Burkhardt[5]. [1]CIRI/Div. Rheumatologie, J.W. Goethe-University, Frankfurt/Main, Germany, [2]Klinik für Dermatologie, Venerologie und Allergologie, J.W. Goethe University, Frankfurt/Main, Germany, [3]CIRI/Endokrinologikum, Frankfurt/Main, Germany, [4]Abbott GmbH & Co KG, Wiesbaden, Germany, [5]CIRI/Div. Rheumatology, J.W. Goethe University, Frankfurt/Main, Germany

Background/Purpose: For the treatment of patients with psoriatic arthritis (PsA) only antiTNF biologics are licensed. Therefore, failures to anti-TNF are often switched to a different antiTNF treatment, despite the fact that only little evidence of effectiveness is available for anti TNF switch.

Methods: A multicentre, prospective observational study included patients (n=3320) with moderate to severe PsA treated with Adalimumab (ADA). Treatment response of ADA therapy when used as first-, second- or third/fourth line antiTNF-therapy regimen in patients with active psoriatic arthritis in clinical routine care in Germany was measured. Besides documentation of demographic data, disease activity assessments such as number of swollen (SJC) and tender joints (TJC), disease activity score 28 (DAS28), enthesitis, dactylitis as well as target lesion score (TLS) and body surface area (BSA) for skin involvement were calculated at baseline, month 3, 6, 12 and 24.

Results: Treatment with ADA is effective in patients with active PsA. The reduction of disease activity is clinical meaningful independently from the number of previous used antiTNF agents (0, 1, ≥ 2). The swollen joint count (SJC) was reduced from 8.7 at baseline to 1.4 after 24 months (TNFnaive). A comparable reduction was seen in patients pretreated with one (7.7 to 2.8) or two and more (8.5 to 1.9) antiTNF agents.

A higher reduction in DAS28 was seen in the group of biologic naive patients (−2.22) than in those with pretreatment of at least one TNF (−1.79). This leads to a mean DAS after two years of treatment with ADA near to remission (DAS28 2.62) while those switching to ADA from another TNF achieved a mean DAS of 2.89 (failed one antiTNF) and 3.12 (failed two or more antiTNF) respectively. Comparable reduction of percentages of patients with dactylitis was seen in all groups while enthesitis responses better in TNF naïve versus those who faile one or more antiTNF. Additionally, skin response in all groups was comparable measured by reduction in TLS.

Conclusion: ADA treatment is effective in patients with active PsA on all facets of the disease (arthritis, enthesitis, dactylitis and skin involvement). A switch from another antiTNF results in a meaningful reduction of disease activity. In contrast to rheumatoid arthritis in which previous antiTNF use leads to a significant decrease of response, in PsA the reduction in SJC is independent from a pretreatment with antiTNF agents. Nevertheless, the mean DAS after two years of treatment was significant lower in antiTNF naive patients than in those with up to 3 previous biologics.

5 Year Safety, Efficacy, and Radiographic Data in Patients with Active Psoriatic Arthritis Treated with Golimumab: Results From the Long-Term Extension of a Randomized, Placebo-Controlled Study. Arthur Kavanaugh[1], Desiree van der Heijde[2], Iain B. McInnes[3], Philip Mease[4], Gerald G. Krueger[5], Dafna Gladman[6], Yiying Zhou[7], J. D. Lu[7], Zhenhua Xu[7], Lenore Noonan[7] and Anna Beutler[7]. [1]UCSD School of Medicine, La Jolla, CA, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Glasgow, Glasgow, United Kingdom, [4]Swedish Medical Center, Seattle, WA, [5]University of Utah, Salt Lake City, UT, [6]Toronto Western Hospital and University of Toronto, Toronto, ON, [7]Janssen Research & Development, LLC, Spring House, PA

Background/Purpose: GO-REVEAL is the first study evaluating outcomes of anti-TNF tx in active PsA through 5 years. Safety and efficacy, including radiographic progression in golimumab (GLM) tx'd patients (pts) from the long-term extension of GO-REVEAL is presented.

Methods: 405 adult PsA pts (≥3 swollen, ≥3 tender joints) were randomized to SC injections of placebo (PBO, Grp1, n=113), GLM50mg (Grp2, n=146), or GLM100mg (Grp3, n=146) q4wks through wk20. Concomitant MTX at baseline was allowed but not required. Starting at wk16, PBO pts with <10% improvement in swollen and tender joints received GLM50mg, remaining PBO pts received GLM50mg starting at wk24; all pts received GLM from wk24 forward. After wk52, pts could change the dose from GLM50 mg to 100mg based on investigator judgment. The last GLM injection was at wk 252. Efficacy was assessed at wk 256 based on randomized grp and completer analyses using ACR response criteria, DAS28-CRP, PASI, HAQ, enthesitis, dactylitis, NAPSI scores, and the PsA-modified Sharp/van der Heijde Score (SHS). Safety evaluations included all pts who received at least one GLM dose through 5 years.

Results: Of 405 randomized,335 continued in the study at wk104, and 279 pts (69%) continued GLM tx through wk252. 29% of Grp2 pts dose escalated to GLM100mg; 25% of Grp3 pts decreased the dose from 100mg to 50mg. Baseline characteristics of pts who continued in the study at Wk 104 are provided in Table 1. Efficacy results are presented in Table 2. ACR and PASI responses were similar in pts tx'd with or without MTX; changes from baseline in SHS scores were minimal and numerically less in pts tx'd with GLM and MTX compared with GLM alone. Overall, 88%, and 21% GLM tx'd pts experienced AE and SAE, resp. 12% of pts discontinued GLM tx due to AE, and 5% and 4% pts experienced malignancy (including NMSC), and serious infection, resp. Antibodies to golimumab were detected in 6% of pts.

Table 1. Mean (SD) baseline characteristics

	Group 1[a]	Group 2[b]	Group 3[c]
No. of pts continued in the study at wk104	88	118	129
DAS28 score	5.0 (0.1)	4.9 (1.1)	4.8 (1.0)
PASI (in pts with ≥3%BSA)	7.7 (5.7)	9.4 (7.6)	11.2 (9.6)
HAQ-DI score (0–3)	1.1 (0.5)	1.0 (0.6)	1.1 (0.6)
Enthesitis score (0–15)	5.1 (4.0)	5.6 (3.8)	5.8 (4.1)
Dactylitis score (0–60)	2.9 (2.0)	6.8 (6.5)	5.5 (6.9)
Total SHS (0–528)	19.4 (30.2)	26.2 (36.9)	23.3 (36.7)

Table 2. Clinical and radiographic efficacy at wk 256

	Group 1[a]	Group 2[b]	Group 3[c]
No. of pts continued in the study at wk256	77	95	109
Clinical efficacy			
ACR20 (% of pts)	77.9%	76.8%	78.0%
ACR50 (% of pts)	49.4%	58.9%	56.9%
ACR70 (% of pts)	36.4%	41.1%	39.4%
DAS28-CR response (% of pts)	91.9%	94.5%	91.3%
Mean (SD) improvement in HAQ-DI	0.5 (0.6)	0.5 (0.5)	0.5 (0.6)
PASI75 (in pts with ≥3%BSA) (% of pts)	72.7%	68.6%	78.5%
Mean % improvement in enthesitis score	68.3%	73.7%	72.4%
Mean % improvement in dactylitis score	74.7%	85.8%	72.0%
Mean % improvement in NAPSI score	79.2%	75.9%	76.5%
Radiographic progression			
Estimated annual rate of progression at baseline (mean total SHS/mean PsA disease duration)	2.1	3.1	2.5
Mean annual rate of progression (change from baseline in total SHS/5yrs)	0.06	0.06	0.01
Mean (SD) change from baseline in total SHS	0.3 (3.8)	0.3 (4.1)	0.1 (2.7)

[a]Includes pts randomized to PBO who switched to GLM at wk16 or 24; after wk 52 pts could receive GLM50mg or 100mg.
[b] Includes pts randomized to GLM50 mg; after wk 52 pts could receive GLM50 mg or 100mg.
[c] Includes pts randomized to GLM100 mg; after wk 52 pts could receive GLM100mg or 50mg.

Conclusion: Pt attrition through 5yrs of GLM tx was low. GLM tx resulted in long-term maintenance of clinically meaningful responses in the arthritic and skin components of PsA, improved physical function, and arrest of radiographic progression. No apparent differences between long-term safety and efficacy of 2 GLM doses administered q4wks were observed, however the interpretation of the data is limited due the tx changes allowed across randomized grps.

2219

Patients with Ankylosing Spondylitis and Non-Radiographic Axial Spondyloarthritis Show Similar Response Rates After One Year of Treatment with Etanercept - results of the Esther Trial.

In-Ho Song[1], Kay-Geert A. Hermann[2], Hildrun Haibel[1], Christian Althoff[3], Denis Poddubnyy[1], Joachim Listing[4], Anja Weiβ[5], Ekkehard Lange[6], Bruce Freundlich[7], Martin Rudwaleit[8] and Joachim Sieper[9]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Charité Medical School, Berlin, Germany, [3]Charite Medical School, Berlin, Germany, [4]German Rheumatism Research Center, Berlin, Germany, [5]German Rheumatism Research Centre, Berlin, Germany, [6]Berlin, Germany, [7]Villanova, PA, [8]Endokrinologikum Berlin, Berlin, Germany, [9]Charité Universitätesmedizin Berlin, Berlin, Germany

Background/Purpose: In patients with early axial spondyloarthritis (SpA) with a disease duration < 5 years we assessed whether there is a difference to etanercept (ETA) treatment in patients with ankylosing spondylitis (AS) compared to non-radiographic axial SpA (nr-axSpA).

Methods: AS (n= 34) and nr-axSpA (n= 32) patients who were treated with ETA for one year were compared for differences in baseline data and treatment effect [1, 2]. Clinical, laboratory and magnetic resonance imaging of sacroiliac joints (SI-joints) and spine were analysed.

Results: At baseline there were no significant differences between the 34 AS and the 32 nr-axSpA patients regarding age (34.4 ($\pm$ 7.7) vs. 33.5 ($\pm$ 9.2) years), disease duration (4.0 ($\pm$ 2.2) vs. 3.1 ($\pm$ 1.8), male gender (55.9% vs. 56.3%), clinical disease activity in terms of BASDAI (5.0 ($\pm$2.0) vs. 5.4 ($\pm$ 1.5), CRP (7.7 ($\pm$ 8.7) vs. 11.2 ($\pm$ 13.7)), HLA-B27 (91.2% vs. 75.0%) and MRI SI-joint (6.7 ($\pm$ 6.2) vs. 5.1 ($\pm$ 5.4)) and spine scores (2.5 ($\pm$ 3.6) vs. 1.1 ($\pm$ 2.1)) in the AS compared to the nr-ax SpA group. After one year of treatment with ETA the treatment effect was similarly good in AS and nr-ax SpA (reduction of BASDAI by 2.1 (95% CI 1.5– 2.7) vs. 2.4 (95% CI 1.8– 2.9) and reduction of ASDAS by 1.3 (95% CI 1.0– 1.5) vs. 1.2 (95% CI 0.9– 1.5), respectively).

Table 1. Comparison of Efficacy Parameters between patients with AS and nr-ax SpA after one year of treatment with etanercept

Parameter	ETA, AS, (n= 34)	ETA, nr-ax SpA (n= 32)
BASDAI50, % (95% CI)	59.4 (42.0–76.3)	74.2 (56.9–87.4)
ASAS40, % (95% CI)	68.8 (50.0–83.9)	67.7 (50.0–83.3)
ASAS partial remission, % (95% CI)	28.7% (19.4–42.5%)	37.9% (27.7–51.8%)
ASAS major improvement, % (95% CI)	24.1 (10.3–42.3)	25.0 (10.7–44.1)
ASDAS inactive disease (< 1.3), % (95% CI)	27.6% (18.7–40.5%)	27.3% (18.9%–39.4%)
Change in BASDAI (95% CI)	2.1 (1.5–2.7)	2.4 (1.8–2.9)
Change in ASDAS (95% CI)	1.3 (1.0–1.5)	1.2 (0.9–1.5)
Change CRP (95% CI)	5.0 (2.3–7.6)	4.6 (1.9–7.3)
Change MRI SI-joint score (95% CI)	3.7 (3.0–4.4)	4.3 (3.6–5.0)
Change MRI spine score (95% CI)	1.1 (0.6–1.7)	0.9 (0.3–1.5)

Conclusion: The response rate to TNF-blockers does not differ between AS and nr-ax SpA if the baseline data regarding symptom duration and disease activity are similar for the two groups.

Development of the Pulsar (Program to Understand the Longterm Outcomes in Spondyloarthritis) Registry.

Andreas M. Reimold[1], Liron Caplan[2], Daniel O. Clegg[3], Gail S. Kerr[4], Elizabeth Chang[5], Lisa A. Davis[6], Prashant Kaushik[7], Vikas Majithia[8], J. Steuart Richards[9], Joel D. Taurog[10] and Jessica Walsh[11]. [1]Dallas VA and University of Texas Southwestern, Dallas, TX, [2]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [3]George E. Wahlen VA Medical Center, Salt Lake City, UT, [4]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [5]Phoenix, AZ, [6]Denver VA and Univ of Colorado School of Med, Aurora, CO, [7]Stratton VAMC, Albany, NY, [8]University of Mississippi Medical Center, Jackson, MS, [9]Washington DC VA and Georgetown University, Washington, DC, [10]UT Southwestern Medical Center, Dallas, TX, [11]University of Utah Hospital, Salt Lake City, UT

Background/Purpose: The spondyloarthritides are a group of conditions characterized by inflammation in the axial skeleton or peripheral joints. The arthritis may present as the primary manifestation (e.g. ankylosing spondylitis, reactive arthritis), or a related condition may predominate (inflammatory bowel disease (IBD), uveitis, or cutaneous psoriasis). To better characterize the clinical and pathophysiologic aspects of these diseases, a registry for veterans with spondyloarthritis and related conditions was initiated in 2007.

Methods: A set of electronic medical record templates was developed for standardizing collection of clinical information at outpatient visits for spondyloarthritis patients. Internal Review Board (IRB) approval for the PULSAR registry was obtained at 7 VA sites (Albany, NY, Dallas, TX, Denver, CO, Jackson, MS, Phoenix, AZ, Salt Lake City, UT, Washington, DC). Data collected includes demographics (age, gender, race/ethnicity, education, smoking status, comorbidities) and disease-specific features (disease classification, disease activity measures (BASDAI, BASFI, pain and global assessments, psoriasis area and global assessments), medications, laboratory and imaging results, and HLA-B27 status). Each patient's DNA, RNA, serum, and plasma are stored in a biorepository.

Results: The PULSAR registry has enrolled 513 patients, whose diagnoses are psoriatic arthritis (29.2%), ankylosing spondylitis (20.7%), reactive arthritis (6.2%), anterior uveitis (5.5%), and IBD-related arthritis (3.7%). Patients without arthritis but with IBD or cutaneous psoriasis make up the rest of the registry and are available as controls. To date, 3677 clinic visits have been recorded, representing 2246 patient years of observation. Patients are 92% male, with mean age of 58.5 years and 13 or more years of schooling in 61.7% of the cohort. Current tobacco use is present in 24% while 62% are former smokers. Of 275 patients tested to date, 58.5% are HLA-B27 positive. The most common comorbidities are hypertension, hyperlipidemia, osteoarthritis, diabetes, and obesity. Forty percent are currently on biologic medication, 39% take an analgesic or NSAID, 36% are on a traditional DMARD, and 29% take an osteoporosis medication. The five most commonly used medications are adalimumab, methotrexate, etanercept, hydrocodone, and ibuprofen (Table).

Medication Use

Current		Ever	
Adalimumab	17%	Methotrexate	28%
Methotrexate	16%	Etanercept	25%
Etanercept	15%	Adalimumab	23%
Hydrocodone	15%	Etodolac	21%
Ibuprofen	11%	Hydrocodone	20%
Tramadol	11%	Acetaminophen	18%
Etodolac	10%	Ibuprofen	17%
Acetaminophen	10%	Sulfasalazine	16%
Sulfasalazine	9%	Tramadol	15%
Infliximab	8%	Infliximab	14%

Conclusion: The PULSAR registry is a growing resource for study of spondyloarthritis and related conditions. Anti-TNFa medications are the most commonly prescribed drugs in the registry. Standardized multi-site data collection allows for improved disease characterization and assessment of

Tuesday, November 13

disease activity. As most participants receive all their medical care in the VA system, a particular strength of PULSAR is the comprehensive acquisition of pharmacy and comorbidity data.

2221

Major Adverse Cardiovascular Events Are More Common in Rheumatoid Arthritis Than in Psoriatic Arthritis and Are Associated with Different Risk Factors. Allen P. Anandarajah[1], Katherine C. Saunders[2], George W. Reed[3], Alina U. Onofrei[4], Jeffrey D. Greenberg[5] and Christopher T. Ritchlin[6]. [1]Univ of Rochester Medical Ctr, Rochester, NY, [2]CORRONA, Inc., Southborough, MA, [3]University of Massachusetts Medical School, Worcester, MA, [4]UMass Medical School, Worcester, MA, [5]NYU Hospital for Joint Diseases, New York, NY, [6]University of Rochester Medical Center, Rochester, NY

Background/Purpose: Rheumatoid Arthritis (RA) is associated with increased cardiovascular mortality and morbidity rates. Similarly several studies have reported an increased risk for cardiovascular events in patients with psoriasis. There, however, are few studies that have reported on the risk factors for major adverse cardiovascular events (MACE) in patients with psoriatic arthritis (PsA). Furthermore, no studies have compared the risk for MACE in PsA patients with RA patients.

Objective: To determine if the prevalence and risk factors for MACE in PsA patients and compare with prevalence and risk factors for MACE in RA patients.

Methods: All patients with RA and PsA with at least one follow up visit were identified from the Consortium of Rheumatology Researchers of North America (CORRONA) database. The incident rates (IR) for MACE per 100 person years of follow up were estimated. MACE was defined as myocardial infarction, stroke/transient ischemic attacks and death secondary to cardiovascular events. Follow up time was counted from enrollment in CORRONA to the first reported event or the last follow up. Cox regression models estimated the association of the following covariates with MACE rates: age, gender, body mass index (BMI), physician global assessment of disease activity (PGDA), disease duration, bone erosion status, disease modifying anti-rheumatic drugs, steroids, aspirin, smoking, diabetes, and hypertension.

Results: A total of 25,700 RA patients (81,104 person years of follow-up) and 3,909 PsA patients (11,828 person years of follow-up) were identified. Patients with RA were older, had a lower BMI, higher MD global assessment scores, longer disease duration, were less likely to have diabetes and less likely to be on biologic therapies but more likely to be on DMARDs or steroids than PsA patients. The percentage of previous and current smokers was similar between RA and PsA patients. The unadjusted IR for MACE events in RA and PsA patients were 0.65 (95% CI: 0.60–0.71) and 0.35 (CI: 0.25–0.47) respectively. The unadjusted IR for MACE events was higher in RA patients with erosions (0.71, 0.61–0.81) compared with those without erosions (0.53, 0.45–0.63) but in PsA patients the IR was slightly higher in those without erosions (0.33, 0.19–0.55) than in those with erosions (0.25, 0.10–0.51). Age, gender, history of hypertension, disease duration, steroids, diabetes and PGDA were identified as significant risk factors for MACE in the RA population. In contrast, in PsA patients, age, hypertension, gender and PGDA were the only risk factors.

Table 1. Hazard Ratios (HR) from Multivariate Cox Regression Models in RA and PsA patients

	HR for risk of MACE events	
	RA patients	**PsA patients**
Female	0.55 [0.46, 0.67]	0.41 [0.21, 0.80]
Age	1	1
<50	2.16 [1.46, 3.19]	3.32 [1.05, 10.51]
50–60	3.52 [2.41, 5.15]	8.61 [2.76, 26.91]
60–70	7.07 [4.85, 10.30]	8.75 [2.46, 31.05]
≥70		
Smoking status	1	1
Never	1.19 [0.95, 1.48]	1.74 [0.85, 3.56]
Previous	2.28 [1.81, 2.86]	2.55 [1.06, 6.11]
Current		
History of Hypertension	1.39 [1.16, 1.67]	2.08 [1.07, 4.03]
MD global assessment (risk per unit change)	1.006 [1.002, 1.010]	1.018 [1.003, 1.033]
History of diabetes	1.59 [1.22, 2.07]	1.08 [0.46, 2.51]
Duration of disease (risk per yr)	1.016 [1.008, 1.024]	
Steroid use	1.55 [1.30, 1.86]	

Conclusion: Unadjusted MACE events are more common in RA than in PsA. Only age, gender, hypertension, and PGDA were common risk factors

2222

Spinal Mobility Measures in Normal Individuals – the Mobility Study. Sofia Ramiro[1], Carmen Stolwijk[2], A.M. Van Tubergen[2], Désirée van der Heijde[3] and Robert Landewé[4]. [1]Academic Medical Center, University of Amsterdam, The Netherlands and Hospital Garcia de Orta, Almada, Portugal, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Academic Medical Center, University of Amsterdam and Atrium Medical Center, Heerlen, Netherlands

Background/Purpose: Spinal mobility is one of the core outcomes recommended by the Assessment of Spondyloarthritis international Society (ASAS) for following patients with axial SpA. It is currently unknown how these spinal mobility measures perform in healthy subjects and to what extent they are influenced by age, gender and height. We aimed to assess the effect of age, gender and height on spinal mobility measures among healthy individuals.

Methods: A cross-sectional study ("MOBILITY-study") was conducted in healthy volunteers aged 20–69 years old. Recruitment was stratified by gender, age (10-year categories) and height (10cm categories). Participants were Caucasians volunteering to be measured in the Netherlands and Portugal. Exclusion criteria were factors potentially influencing spinal mobility (such as previous back surgery, known spinal osteoarthritis or low back pain). The following measures were assessed: tragus-to-wall distance (TTW, cm), occiput-to-wall distance (OTW, cm), lateral spinal flexion (LSF, cm), cervical rotation (CR, degrees), intermalleolar distance (IMD, cm), chest expansion (CE, cm) and Schober's test. The Bath Ankylosing Spondylitis Mobility Index (BASMI) was computed. The effects of age, gender, height and weight were investigated using linear regression analyses (univariable followed by multivariable, forward selection procedure), adjusting for potential confounders and taking relevant interactions into account.

Results: 393 volunteers were included. A significant decrease in all spinal mobility measures was found by increasing age, and age was included in all multivariable models (some of the models are presented in the table). E.g. an increase of 10 years was associated with a decrease of 1.5cm in LSF or a decrease of 3.4cm in IMD. Height was associated with the following spinal mobility measures: TTW, LSF, CE, IMD and BASMI, with a higher height being associated with better mobility. E.g. every increase in height of 10cm resulted in an increase of 4.2cm in IMD, an increase of 0.3cm in LSF and an increase of 1.1cm in CE. Gender was associated with CE and CR, with women having a worse mobility. Weight was positively associated with TTW, OTW and Schober's test: An increase of 10kg resulted in an increase of 0.3cm in TTW, 0.2cm in OTW and 0.2cm in Schober's test. There was a significant interaction between the effects of age and gender on BASMI: in women, age was the only factor with a significant effect on BASMI (β 0.03, 95%CI 0.03; 0.04). In men, age (β 0.03, 95%CI 0.02; 0.04), and weight (β −0.01, 95%CI −0.01; −0.00) significantly contributed to BASMI.

Table. Effect of age, gender, height and weight on spinal mobility measures

Measure	Univariable linear regression β (95% CI)	Multivariable linear regression β (95% CI)
Lateral spinal flexion (cm)		
Age (years)	−0.15 (−0.17; −0.13)	−0.15 (−0.17; −0.13)
Gender (female vs male)	−0.50 (−1.23; 0.23)	
Height (cm)	0.03 (0.00; 0.06)	0.03 (0.00; 0.07)
Weight (kg)	−0.01 (−0.04; 0.01)	−0.01 (−0.04; 0.02)
Intermalleolar distance (cm)		
Age (years)	−0.46 (−0.42; −0.27)	−0.44 (−0.53; −0.36)
Gender (female vs male)	−1.05 (−3.92; 1.83)	
Height (cm)	0.44 (0.33; 0.55)	0.42 (0.33; 0.52)
Weight (kg)	0.14 (0.05; 0.23)	
Cervical rotation (degrees)		
Age (years)	−0.35 (−0.42; −0.27)	−0.34 (−0.42; −0.27)
Gender (female vs male)	−4.13 (−6.43; −1.82)	−3.83 (−5.89; −1.77)
Height (cm)	0.12 (0.03; 0.21)	
Weight (kg)	−0.03 (−0.10; 0.04)	
BASMI (0−10)		
Age (years)	0.03 (0.03; 0.04)	Significant interaction age X gender (see text)
Gender (female vs male)	0.21 (0.05; 0.38)	
Height (cm)	−0.01 (−0.02; −0.00)	
Weight (kg)	−0.00 (−0.01; 0.00)	

Conclusion: All spinal mobility measures decrease with increasing age. Height significantly influences some spinal mobility measures, especially IMD and LSF. These factors have to be taken into account when assessing patients' spinal mobility, and should be included in reference values for these measurements.

Dysregulation of Chromatin Modification Enzymes in Psoriatic Arthritis. Remy Pollock, Fawnda Pellett, Vinod Chandran and Dafna Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Chromatin modification enzymes regulate gene expression by altering the accessibility of promoters to transcription factors. Several of these enzymes are dysregulated in rheumatoid arthritis, suggesting a role for epigenetic factors in inflammatory arthritis. We sought to determine whether they are dysregulated in psoriatic arthritis (PsA), a seronegative inflammatory arthritis that develops in 30% of patients with cutaneous psoriasis (PsC).

Methods: Total RNA was isolated from peripheral blood of psoriatic disease (PsD) patients (PsA & PsC) and controls. Quantitative RT-PCR arrays were used to profile mRNA expression of 84 genes encoding DNA and histone modification enzymes. Significant fold changes were calculated using the ΔΔCt method and Student's t-test. Univariate regressions were performed to examine correlations between gene expression (ΔCt) and clinical data.

Results: Gene expression profiling was performed on 20 PsA patients satisfying CASPAR criteria (mean age 48 years, males 45%, age at psoriasis 25 years, age at PsA 32 years, PASI 5.0, active joint count 11, axial disease 35%, treated with methotrexate 35% and prednisone 25%), 18 PsC patients (mean age 45 years, males 50%, age at psoriasis 25 years, PASI 5.2), and 19 controls (mean age 43 years, males 53%). Significantly dysregulated genes (fold change >1.5 or <0.68, p<0.05) are summarized in Table 1. Two genes were significantly dysregulated in PsD vs. controls. In PsC vs. controls, no genes were significantly dysregulated >1.5 or <0.68-fold, but 6 genes were dysregulated >1.2 or <0.84-fold. Eleven genes were significantly dysregulated in PsA vs. controls: HAT1, RPS6KA3, AURKC, HDAC11 (upregulated), and ASH1L, KDM6B, EHMT2, SETD1A, MLL, HDAC9, MLL3 (downregulated). In PsA vs. PsC, 3 genes were significantly dysregulated: HAT1, PRMT8, and HDAC11. In PsA patients, SETD1A expression was positively correlated with methotrexate therapy (p=0.008, r=0.58) but negatively correlated with prednisone therapy (p=0.038, r=−0.47), active joint count (p=0.017, r=−0.53), and axial disease (p=0.014, r=−0.54).

Table 1. Significantly dysregulated genes (p<0.05, fold change >1.5 or <0.68).

Comparison	Gene	Description	Fold Change	95% CI	P-value
PsD vs. Controls	HAT1	Histone acetyltransferase 1	1.54	(1.03, 2.04)	0.017
	RPS6KA3	Ribosomal protein S6 kinase, 90kDa, polypeptide 3	1.50	(1.15, 1.81)	0.002
PsC vs. Controls†	AURKC	Aurora kinase C	1.39	(0.81, 1.97)	0.049
	HDAC11	Histone deacetylase 11	1.30	(0.78, 1.82)	0.022
	UBE2A	Ubiquitin-conjugating enzyme E2A	1.24	(1.01, 1.47)	0.041
	ASH1L	Ash1 (absent, small, or homeotic)-like	0.84	(0.67, 1.01)	0.022
	SETD1A	SET domain containing 1A	0.83	(0.66, 0.99)	0.035
	MLL3	Myeloid/lymphoid or mixed-lineage leukemia 3	0.82	(0.64, 0.99)	0.034
PsA vs. Controls	HAT1	Histone acetyltransferase 1	2.13	(1.38, 2.89)	1.0E-04
	RPS6KA3	Ribosomal protein S6 kinase, 90kDa, polypeptide 3	1.65	(1.24, 2.07)	3.0E-04
	ESCO1	Establishment of cohesion 1 homolog 1	1.56	(1.17, 1.94)	0.001
	USP16	Ubiquitin specific peptidase 16	1.54	(1.20, 1.89)	2.0E-04
	ASH1L	Ash1 (absent, small, or homeotic)-like	0.68	(0.52, 0.85)	0.001
	KDM6B	Lysine (K)-specific demethylase 6B	0.68	(0.49, 0.86)	0.011
	EHMT2	Euchromatic histone-lysine N-methyltransferase 2	0.68	(0.54, 0.82)	0.001
	SETD1A	SET domain containing 1A	0.63	(0.51, 0.76)	4.2E-05
	MLL	Myeloid/lymphoid or mixed-lineage leukemia	0.62	(0.46, 0.79)	0.001
	HDAC9	Histone deacetylase 9	0.61	(0.31, 0.91)	0.018
	MLL3	Myeloid/lymphoid or mixed-lineage leukemia 3	0.61	(0.47, 0.74)	6.8E-05
PsA vs. PsC	HAT1	Histone acetyltransferase 1	2.00	(1.39, 2.61)	1.0E-04
	PRMT8	Protein arginine methyltransferase 8	1.57	(1.21, 1.93)	3.0E-4
	HDAC11	Histone deacetylase 11	0.62	(0.31, 0.94)	0.017

† Fold change > 1.2 or < 0.83.

Conclusion: We identified several dysregulated chromatin modification enzymes in psoriatic disease, including histone methyltransferase complex component SETD1A which was downregulated in PsA and correlated with disease expression and therapy. SETD1A is located in a PsA susceptibility region on 16p11.2 that harbors genes involved in IL-23/IL-17/NF-κB signaling. HDAC11, a histone deacetylase involved in inflammation by influencing immune activation versus tolerance was downregulated in PsA compared with PsC. Future studies will seek to validate these results, examine the role of these enzymes in the epigenetic basis of PsA, and determine whether they can serve as biomarkers of PsA susceptibility and disease expression.

Oral Contraceptive Pill Use in Women with Ankylosing Spondylitis Is Associated with a Younger Age At Diagnosis. Dharini Mahendira[1], Arane Thavaneswaran[2], Adele Carty[3], Nigil Haroon[4], Ammepa Anton[3], Laura A. Passalent[3], Khalid A. Alnaqbi[3], Laurie M. Savage[5], Elin Aslanyan[6] and Robert D. Inman[7]. [1]St Michael's Hospital, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]Toronto Western Hospital, Toronto, ON, [4]University Health Network, Toronto Western Research Institute, University of Toronto, Toronto, ON, [5]Spondylitis Association of America, Van Nuys, CA, [6]Spondylitis Association of America, Van Nuys, [7]Toronto Western Research Institute, University Health Network and University of Toronto, Toronto, ON

Background/Purpose: While AS is traditionally recognized as a predominantly male disease, the impact of gender differences on AS pathogenesis has not been clearly established. Specifically, the potential role of sex hormones in mediating gender impact on both AS susceptibility and disease severity remains unanswered. Both exogenous and endogenous estrogens may play a key role in AS disease expression in women. Our objective is to elucidate the potential impact of exogenous estrogen on AS initiation and severity. We hypothesized that exogenous estrogen, in the form of oral contraceptive pills (OCP), may alter AS disease activity and severity in premenopausal women.

Methods: The study population consists of premenopausal women with AS seen in our longitudinal clinic, as well as members of the Spondylitis Association of America (SAA). Measures of disease severity included: use of biological agents, hip replacement surgery, and BASFI scores as a surrogate marker of disability. A patient questionnaire was created and used to obtain information on patient demographics, past and present OCP use, menstrual history, pregnancy history, AS duration, medication use, and hip replacement.

Results: A total of 655 women participated in this study. This was comprised of 516 OCP users and 139 non-OCP users. The mean age of OCP users was 42.2 (+/− 11.5) and 47.9 (+/− 12.2) years in non-OCP users. While no difference was noted with respect to initial onset of back pain, OCP users were significantly younger at the age of diagnosis of AS (35.7 years vs. 38.6 years, p=0.01). (Table) There was no significant difference in anti-TNF or opioid use, pregnancy complications, nor rates of hip surgery between OCP and non-OCP users. A trend towards higher rate of pregnancy complications was noted in all OCP users, although this was not statistically significant (45.4% vs. 36.5%, p=0.13). There was no significant difference in reported BASFI scores between the groups.

Table. Women with AS – Clinical Features in OCP Users vs Non-users

	OCP Users (n=516)	Non-OCP Users (n=139)	P-value
Age at diagnosis of AS	35.7 (11.2)	38.6 (12.2)	0.01
Age at onset of back pain	24.1 (10.2)	24.7 (10.5)	0.52
Race (% Caucasian)	457 (90.7%)	112 (83.0%)	0.02
Use of Anti-TNF agents	330 (64%)	80 (58.4%)	0.23
Use of Opioids	186 (41.5%)	56 (45.5%)	0.47
Past hip surgery	20 (4.4%)	8 (6.5%)	0.34
Past pregnancy complications	152 (45.4%)	35 (36.5%)	0.13

Conclusion: The use of exogenous estrogens in the form of oral contraceptive pills is associated with a significantly earlier diagnosis of AS in women. To date, this is the largest study investigating the potential impact of exogenous estrogens in women with AS. While exogenous estrogens are not associated with surrogate indicators of disease severity, the earlier age of diagnosis of AS amongst women taking OCP suggests hormone modulation of disease expression in the early stages of disease.

Improvement in Signs and Symptoms of Active Ankylosing Spondylitis Following Treatment with Anti-Interleukin (IL)-17A Monoclonal Antibody Secukinumab Are Paralleled by Reductions in Acute Phase Markers and Inflammatory Markers S100A8 and A9 (Calgranulin A and B).
Dominique L. Baeten[1], Stephan Bek[2], Jiawei Wei[3], Arndt Brachat[4], Joachim Sieper[5], Paul Emery[6], Jurgen Braun[7], Desiree van der Heijde[8], Iain B. McInnes[9], Jacob M. van Laar[10], R. Landewe[11], Paul Wordsworth[12], Jurgen Wollenhaupt[13], Herbert Kellner[14], Jacqueline E. Paramarta[15], Arthur Bertolino[2], Andrew Wright[4] and Hueber Wolfgang[2]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Novartis Institutes for BioMedical Research, Basel, Switzerland, [3]Beijing Novartis Pharma Co. Ltd., Shanghai,, China, [4]Novartis Pharma AG, Basel, Switzerland, [5]Charité Universitätesmedizin Berlin, Berlin, Germany, [6]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [7]Rheumazentrum Ruhrgebiet, Herne, Germany, [8]Leiden University Medical Center, Leiden, Netherlands, [9]University of Glasgow, Glasgow, United Kingdom, [10]Musculoskeletal Research Group, Newcastle, United Kingdom, [11]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [12]Nuffield Orthopaedic Centre, Oxford, United Kingdom, [13]Schoen-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, [14]Centre for Inflammatory Joint Diseases, Munich, Germany, [15]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Secukinumab has shown to be well tolerated and effective in active ankylosing spondylitis (AS) patients in a proof-of-concept trial[1]. Briefly, at Week (Wk) 6, 61% (14/23) patients on secukinumab achieved Assessment of SpondyloArthritis International Society (ASAS) 20 response vs 17% (1/6) patients on placebo and the primary endpoint was met. Here we explored the modulation of markers of inflammation following secukinumab treatment, including CRP, ESR and S100 proteins A8 and A9 (calgranulin A and B), recently postulated to play a role as markers of inflammation in inflammatory arthritis[2].

Methods: 30 patients were randomized 4:1 to either secukinumab 2×10 mg/kg or placebo (i.v. infusion, 3 wks apart). Primary endpoint was the proportion of patients achieving ASAS 20 response at Wk 6. Key secondary endpoints included safety and tolerability and ASAS responses up to Wk 24. S100 calgranulins were analyzed pre- and post-treatment using an in-house validated multiplex assay and high sensitivity (hs) CRP assay. In accordance with the protocol, descriptive statistics were applied for exploratory analyses, due to the small sample size in the placebo arm. No group comparisons were conducted between secukinumab and placebo.

Results: Measurements from pre-treatment (Wk 0) and post-treatment (Wk 6) were available from 21 (CRP) and 14 secukinumab patients (S100A8/9), respectively. Baseline mean (SD) CRP values were 13.84 mg/L (17.40) for CRP; 1819 (717) for S100A8; and 2013 (835) ng/mL for S100A9, respectively. Baseline elevations of CRP (> normal upper limit of 10 mg/L) were observed for only a minority of patients on secukinumab (N=8). Comparing Wk 0 with Wk 6, significant changes were seen for CRP (−19%, p=0.027, n=21), S100A8 (−25%, p=0.012, n=14) and S100A9 (−21%, p=0.008, n=14) (Figure 1). Baseline levels of CRP neither correlated with Wk 6 ASAS20 nor ASAS40 responses (R=0.03 for both). Likewise, DCRP

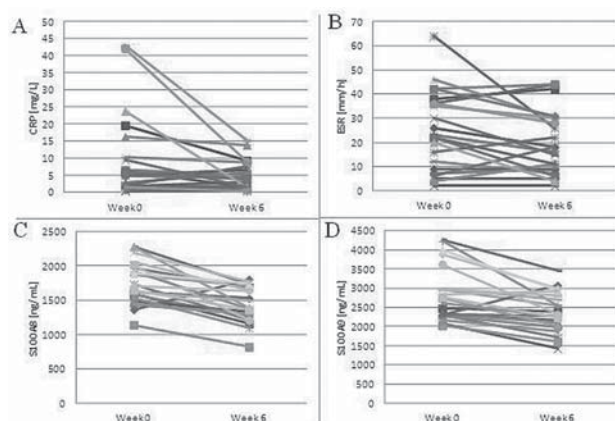
(Wk 0–6) neither correlated with Wk 6 ASAS20 (R=0.13) nor ASAS40 (R=0.15). In contrast, correlations were seen for S100A8 and A9 baseline concentrations with ASAS20 (R=0.55 and 0.39, respectively), and ASAS40 (R=0.40 and 0.59, respectively). Moreover, DS100A8 (Wk 0–6) was correlated with Wk 6 ASAS20 (R=0.43) and ASAS40 (R=0.52); and DS100A9 (Wk 0–6) with Wk 6 ASAS20 (R=0.28) and ASAS40 (R=0.64).


Figure 1. Markers of inflammation A) CRP B) ESR C) S100 A8 D) S100 A9 at baseline (Week 0) and Week 6, following secukinumab 2×10mg/kg i.v. at Week 0 and 3.

Conclusion: In this trial of secukinumab in AS, exploratory analyses of selected inflammatory markers suggest that secukinumab reduces CRP, S100A8 and S100A9, but only S100A8/9 reductions appear to correlate with clinical responses at Wk 6. Lack of correlation of CRP reductions with Wk 6 ASAS response may be attributable to the low number of patients with baseline CRP elevations. Further studies of S100 proteins in AS and their relationship with IL-17A blockade are warranted.

Application of Classification Criteria for Psoriatic Arthritis to Patients of the Rotterdam Early Arthritis Cohort.
Jos Van der Kaap[1], Johanna M.W. Hazes[2], M. Vis[3], Ilya Tchetverikov and Jolanda J. Luime[5]. [1]Rotterdam, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]VU University medical center, Amsterdam, Netherlands, [4]Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background/Purpose: Psoriatic arthritis (PsA) poses a diagnostic challenge due to lack of a clear case definition. This has led to varying reports on prevalence, which is held to be 20 to 100 per 100000 [1–3], while in the past some have even questioned whether PsA should be treated as an individual entity at all[4]. Currently, the distinction between rheumatoid arthritis (RA) and PsA is still defined on clinical grounds. We compared the number of patients clinically diagnosed with PsA with the number meeting currently used classification criteria for PsA in the REACH-population.

Methods: 1216 patients from the Rotterdam Early Arthritis Cohort were used for this analysis. Patients were eligible for REACH with confirmed arthritis in at least 1 joint or 2 painful joints and at least 2 of the following criteria: morning stiffness for more than 1 hour; inability to clench a fist in the morning; pain when shaking someone's hand; pins and

needles in the fingers; difficulties wearing rings or shoes; a family history of RA; unexplained fatigue for less than 1 year. The criteria sets considered were the Classification of Psoriatic Arthritis (CASPAR) criteria [5], the Moll & Wright (M&W) criteria[6], and the European Spondyloarthropathy Study Group (ESSG) criteria for PsA [7]. These sets were applied at baseline using descriptive statistics in STATA12. Inflammatory spinal pain was not measured in REACH and the non-specific presence of low back pain was felt to be inappropriate due to high prevalence in the REACH cohort (50%).

Results: In this cohort 45 (3.7%) patients were clinically diagnosed with PsA, similar to numbers previously reported[8]. In the remaining group, 60 (4.9%) met the CASPAR criteria, 33 (2.7%) met the M&W criteria and 2 (0.2%)met the modified ESSG criteria. Patients satisfying the CASPAR criteria and M&W criteria mainly had a negative Rheumatoid Factor and presence of current psoriasis. Among patients fulfilling the CASPAR criteria (n=60) the most frequent clinical diagnoses were oligo- or polyartritis e.c.i, (n=19), artralgia or myalgia (n=12), osteoarthritis (n=8), monoathritis e.c.i (n=6) and rheumatoid arthritis (n=5). For fulfilling the M&W criteria inflammatory arthritis is mandatory, so compared to the CASPAR criteria, patients with artralgia or myalgia did not fulfill these. The ESSG criteria for PsA were met in 2 patients with M.Bechterew and positive family history for PsA. The total number of patients meeting classification criteria was thus 62, not including patients clinically diagnosed with PsA (n=45).

Conclusion: The number of patients meeting the different classification criteria sets exceeded the total number clinically diagnosed with PsA, emphasizing the diagnostic challenge in this disease. Out of the used criteria sets, the CASPAR criteria were met in most patients.

Low dosage with Escalating Dosage of Infliximab in Psoriatic Arthritis Gives the Same Treatment Results as Standard Dosage of Adalimumab or Etanercept: Results From the Nationwide Registry ICEBIO. Bjorn Gudbjornsson[1] and Niels Steen Krogh[2]. [1]Center for Rheumatology Research, Reykjavik, Iceland, [2]ZiteLab ApS, Copenhagen, Denmark

Background/Purpose: To explore differences in response to low dosage (2.3mg/kg) regimen of infliximab with possible escalating dosage in comparison to standard dosage of etanercept and adalimumab over time in patients with psoriatic arthritis (PsA).

Methods: Patients with PsA who were all biologic naïve and initiating anti-TNF-α therapy were selected from the ICEBIO registry which is based on the DANBIO IT platform. Demographics and clinical differences at baseline, including DAS-28CRP, were compared in four treatment groups: 1) Those who responded to low dosage of infliximab ($<$ 4 mg/kg) 2) those who needed to increase the dosage of infliximab above 4 mg/kg, and those who received a standard dosage of 3) etanercept or 4) adalimumab. Follow-up data at 26 $\pm$ 6 and 52 $\pm$ 6 weeks and on the last visit (at least 13 weeks after the initiation of the treatment) were also compared. The Kruskal-Wallis rank sum test was used for comparison of the groups and the Wilcoxon test was used to compare the two infliximab dosage regimens.

Results: 185 patients, 113 women and 72 men, were identified; 84 patients received infliximab, 66 etanercept and 35 adalinmumab. Only 19% of the patients (16/84) treated with infliximab needed to escalate their dosage to exceed 4 mg/kg; thus those still on a low dosage regimen had a mean dosage of infliximab 2.9 mg/kg, but those who had escalated their dosage had a mean dosage of 4.5 mg/kg, i.e. still under the recommended 5 mg/kg. At baseline those who continued low dosage infliximab had a shorter disease duration (8 vs. 10 years), while those who needed to increase their dosage of infliximab had a higher CRP (10.4 vs 17.2 g/L), but neither value reached significant differences. No significant differences were observed at baseline in respect to numbers of swollen or tender joints, HAQ, VAS pain, VAS fatigue or in DAS28-CRP values. A similar treatment response was observed in all four treatment groups on follow-up.

Conclusion: In respect to treatment effects a low dosage of infliximab, with starting dosage of 2.3mg/kg with possible escalating dosage, is acceptable for the majority of psoriatic arthritis patients who are in need of biological treatment. This "low dosage treatment regimen" with infliximab significantly reduces the burden of drug cost for the society.

The Caspar Classification Criteria and Response to TNF Blockade in Rheumatologists Practice: A Large Observational Cohort Study. Burkhard Moller[1], Almut Scherer[2], J. Dudler[3], Bettina Weiss[4], Nikhil Yawalkar[5] and Peter M. Villiger[6]. [1]Inselspital University Hospital, Bern, Switzerland, [2]SCQM Foundation, Zurich, Switzerland, [3]Cantonal Hospital Fribourg, Fribourg, Switzerland, [4]Balgrist University Hospital, Zurich, Switzerland, [5]MD, Bern, Switzerland, [6]Inselspital-University Hospital of Bern, Bern, Switzerland

Background/Purpose: Background/Purpose: Definition of the CASPAR classification criteria and TNF blocker therapy were milestones in the area of psoriatic arthritis (PsA). We aimed to identify the 'CASPAR-positive' patients in a large patient population, and to compare the results of TNF blockade in 'CASPAR-positive' and in 'CASPAR-negative' patients with background psoriasis.

Methods: Patients in the SCQM database had a primary diagnosis of PsA on an individual decision by the treating board certified rheumatologist. Classification relevant data were in addition requested at baseline and at annual intervals. Disease activity was displayed by the physician global (PhG), patient global (PG) and pain assessment, the 66 swollen (SJC) and 68 tender joint counts (TJC), the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) serum concentrations, and numeric rating scales for skin and nail involvement.

Results: 543 female and 601 male patients were included with PsA diagnosis. Only 183 (16%) of them came from academic centers, but 231 (20%) from other hospitals and 690 (60.3%) from practice based rheumatologists. A current or a history of arthritis (81%), enthesitis (46%) or dactylitis (49.5%) was reported either alone or in combination. Axial involvement (38%) without further specification and inflammatory back pain (12%) were less frequent. Current skin psoriasis (71%) at inclusion was mild or moderate in 52% and/or obtained from the patient history in 70%. Nail involvement was registered in 9%, a positive patient's family history in 22%, positive rheumatoid factor testing in 1.8%, and PsA-typical juxta-articular osteoproliferation in 13.5% of the patients. The proportion of CASPAR-positive SCQM-PsA patients (n=625 or 54.6%) was equally distributed among the university centers and practices.

361 CASPAR-positive and 239 CASPAR-negative PsA patients were started on a TNF blocker: 223 on adalimumab (104 with background MTX), 180 on etanercept (79 plus MTX), 73 on infliximab (45 plus MTX) and 24 patients on golimumab (8 plus MTX). 302 CASPAR-positive and 188 CASPAR-negative PsA patients had at least one follow-up visit one year later, when the following parameters had improved: SJC from mean 4.5 (SD: 6.1) to 2.0 (SD: 4.6), TJC from 8.1 (SD: 11.5) to 4.4 (SD: 8.5), CRP from 11.4 (SD: 16.4) to 6.3 mg per liter (SD: 6.4), PhG from 4.2 (SD: 2.4) to 2.0 (SD: 1.9), PG from 5.1 (SD: 2.9) to 3.4 (SD: 2.7) and pain from 5.0 (SD: 2.8) to 3.5 (SD: 2.8). There were no differences in these disease activity measures between patients satisfying the CASPAR criteria and the 'CASPAR-negative' patients, neither at baseline nor at 1-year post TNF blocker initiation.

Conclusion: This study confirms that the CASPAR classification criteria could be useful in practice for affirming PsA diagnosis, but they should not stringently be used as an exclusive selection criterion for anti-TNF therapy in patients with background psoriasis.

2229

Analysis of Clinical, CRP- and MRI- Responses to TNF-Blockade in Axial Spondyloarthritis Patients with Short Vs Long Symptom Duration. Anja Weiss[1], In-Ho Song[2], Hildrun Haibel[2], Joachim Listing[3] and Joachim Sieper male[4]. [1]German Rheumatism Research Centre, Berlin, Germany, [2]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [3]German Rheumatism Research Center, Berlin, Germany, [4]Charité Universitätesmedizin Berlin, Berlin, Germany

Background/Purpose: To investigate the impact of disease duration on treatment response in patients with axial spondylarthritis (SPA) treated with etanercept (ETA) or adalimumab (ADA).

Methods: Data of 112 patients with axial SpA originally enrolled in two randomized controlled trials were pooled and analyzed. The following outcome parameters assessed after one year of treatment with ETA n=66 (1) or ADA n= 46 (2) were investigated: Bath AS disease activity index (BASDAI), functional index (BASFI), AS disease activity score (ASDAS), CRP, and active inflammation on MRI in the sacroiliac joints (SIJ) and spine. Comparisons were made between patients with a short (< 4 years) versus those with a longer (>=4 years) duration of symptoms. A mixed model approach was applied to compare the changes in the outcome parameters between baseline and end of year one between the symptom duration groups after adjustment for baseline status and gender. Partial Spearman correlation coefficients were calculated to analyse the relationship between change scores after taking their dependence from the baseline scores into account.

Results: Clinical parameters such as BASDAI, BASFI and ASDAS showed significantly better improvement in short vs longer diseased patients (Table 1). No significant differences were observed for MRI scores and for CRP. Furthermore, in short diseased patients the change in BASDAI correlated significantly with the change in SIJ score (rho=0.33, p=0.03) and the change in CRP (rho=0.40, p=0.003). In contrast, in patients with a long disease duration this correlations was poor (change in BASDAI vs change in SIJ score rho=−0.01, p=0.95, change in BASDAI vs change in CRP rho=0.22, p=0.13). We further stratified the patients into CRP positive and CRP negative patients according to their status at baseline and observed larger differences between short and longer diseased patients in the CRP negative subgroup (improvement: BASDAI: 3 [2.3, 3.7] vs. 1.31 [0.7, 1.9], BASFI: 2.42 [1.8, 3.1] vs. 0.93 [0.4, 1.5]) than in the CRP positive subgroup (improvement BASDAI: 3.34 [2.7, 4] vs. 2.41 [1.5, 3.3]), BASFI: 2.44 [1.8, 3] vs. 1.79 [0.9, 2.7]).

Table 1. Mean changes in clinical outcome parameters adjusted for the status at baseline and gender

Parameter	Baseline value (mean)	Adjusted mean changes (95% CI)		p-value
		<4 years n=58	>=4 years n=54	
BASDAI	5.4	3.2 (2.7, 3.7)	1.7 (1.1, 2.2)	<.0001
BASFI	4.4	2.4 (2, 2.9)	1.2 (0.7, 1.6)	0.0003
BASMI	1.8	0.3 (0, 0.6)	−0.1 (−0.4, 0.2)	0.09
ASDAS	3.1	1.5 (1.3, 1.8)	1.1 (0.8, 1.4)	0.04
CRP	8.0	3.8 (1.7, 5.9)	1.2 (−0.9, 3.3)	0.09
MRI spine score	1.8	0.8 (0.4, 1.3)	1.5 (0.8, 2.1)	0.10
MRI SIJ score	6.0	3.9 (3.3, 4.6)	3.7 (2.8, 4.6)	0.71

Conclusion: 1. Axial SpA patients with short symptom duration respond clearly better to TNF-blocker therapy. 2. A good correlation between improvement of patients' reported outcome parameters and objective parameters of inflammation was found in short but not in longer diseased patients. 3. CRP-negative axial SpA patients respond well in case of short symptom duration. These data indicate that patients with longer symptom duration, even in absence of significant structural damage and despite good suppression of inflammation, respond less well to TNF-blockade for reasons which have still to be defined.

The Early Clinical Response of TNF-Alpha Blockers Is a Predictor of Metrology Outcome in Ankylosing Spondylitis. Eon Jeong Nam, Jung Soo Eun, Na Ri Kim, Jong Wan Kang, Churl Hyun Im and Young Mo Kang. Kyungpook National University School of Medicine, Daegu, South Korea

Background/Purpose: TNF-α blocker is the only treatment that shows a significant effect on spinal inflammation and life quality of patients with ankylosing spondylitis (AS). However, the predicting factors for the metrology outcome in AS patients treated with TNF-α blockers have not been reported. In this study, we investigated whether the early clinical efficacy of TNF-α blockers determines the metrology outcome in AS patients.

Methods: A retrospective study was conducted in a total of 119 cases who were treated with TNF-α blockers for 21 months (85 patients with one TNF-α blocker and 17 patients with two). Patients were evaluated at baseline, after three months of TNF-α blockers, and then every six months. Clinical efficacy was evaluated using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), ASAS20, ASAS40, ASAS5/6, BASDAI50, and acute phase reactants (ESR and CRP). Metrology outcome was assessed by BASMI and chest expansion. Primary resistance was defined as a failure of improvement of at least 20% or of absolute improvement at least two units in BASDAI scores at month 3. Kaplan-Meier (KM) survival curves were plotted to determine the rates of continuation of TNF-α blockers (drug survival).

Results: Etanercept was used in 57 cases (47.9%), adalimumab in 49 (41.2%), and infliximab in 13 (10.3%). TNF-α blockers showed a similar drug survival rate and clinical efficacy. Primary resistance developed in 5 patients (4.2%). ASAS20 response rate was 90.2%, 91.7%, 92.4%, and 90% at months 3, 9, 15, and 21, respectively. TNF-α blockers showed a clinical response rate ranging 77.2 to 83.5% by ASAS40, 74.6 to 84.5% by ASAS5/6, and 74.3 to 92.1% by BASDAI50. TNF-α blockers were associated with significantly improved metrology indices including BASMI, BASMI components, and chest expansion at months 3, 9, 15, and 21. The changes in the BASMI significantly correlated with the changes in the BASDAI (r=0.260, $P < 0.001$), BASFI (r=0.726, $P < 0.001$), patient's global assessment score (r=0.479, $P < 0.001$), physician's global assessment score (r=0.517, $P < 0.001$), pain score (r=0.394, $P < 0.001$), and acute phase reactants (ESR, r=0.184, $P < 0.001$; CRP, r=0.118, $P < 0.001$). ASAS20 responders at month 3 had a significant reduction in BASMI and chest expansion, compared to those of baseline (p<0.001), while ASAS20 non-responders did not show a significant change. Reduction of metrology indices was maintained until month 21.
Conclusion: ASAS20 response at month 3 may be a valuable predictor for metrology outcome. Further studies are required to determine whether ASAS20 at month 3 is a good predictor of radiologic results along with metrology outcome in assessment of axial involvement.

Treatment of Psoriatic Arthritis with Tumour Necrosis Factor α Antagonists Successfully Maintains Work Capacity: 2 Year Results of a Prospective Cohort Study.

Leonard C. Harty[1], Alex Franciosi[2], Naomi Pettysan[2], Paul Rushe[2] and Oliver M. FitzGerald[1]. [1]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [2]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Treatment resistant psoriatic arthritis (PsA) may render a patient unwell, disabled and incapable of work with previous reports suggesting that unemployment levels among PsA patients range from 30–50%, higher than the current national unemployment level of 14.7%. It is argued that the clinical, functional and quality of life benefits of tumour necrosis factor α inhibitor drugs (TNFi) may not be sufficient to justify their significant economic cost (national cost, $>€100$ million/year in 2010). We sought to evaluate longitudinal employment levels among PsA patients treated with TNFi therapy.

Methods: A prospective cohort study of TNFi treated PsA patients between the ages of 18–65 fulfilling the ClASsification of Psoriatic ARthritis (CASPAR) criteria with active disease despite DMARD therapy was undertaken. Economic status and disease activity were recorded at baseline and following commencement of TNFi therapy. DDAS >1.2 was considered a good clinical response. Descriptive variables are presented as means (Standard Deviation) or percentages.

Results: Employment status of 114 PsA patients was reviewed at a mean of 26 months (22) after starting TNFi therapy. 51% were female, mean age 48 (11) and mean duration of disease of 13 years (8). 50% patients were treated with etanercept, 38% adalimumab, 6% golimumab and 6% infliximab with 46% also receiving DMARD therapy. 2% and 15% continued to take low dose oral steroids and PRN NSAIDs respectively. 79% of patients were judged good clinical responders. 92 patients were in full time employment at baseline. 83/92 (90%) continued in employment with 6 retiring and 3 becoming redundant. Those who retired or became redundant had a higher DAS 28 score at follow up than those who remained in employment (2.4 v 3.2 (ns)). 22 patients were unemployed upon commencing TNFi with 5 of them returning to the workforce. Of those who did not, 14 were on disability benefit prior to starting TNFi, 2 were unemployed and 1 had retired. Only 4% of all patients required home help.

Conclusion: 90% of TNFi treated PsA patients maintain their employed status with 23% of previously unemployed TNFi treated PsA patients returning to the workforce. Cumulatively, 22.8% of our TNFi treated PsA patients are unemployed, an improvement on previous published levels indicating a potential economic benefit of TNFi that may become more apparent in the future. Maintenance of an individual's work capacity likely results in societal savings that help to offset the substantial cost of TNFi treatment.

2232

Performance of Berlin Criteria in Patients with EARLY Spondyloarthritis.

Beatriz E. Joven[1], Milena Gobbo[2], Miguel A. Descalzo[2], Eugenio De Miguel[3] and Esperanza Group[4]. [1]HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, Madrid, Spain, [2]Spanish Society of Rheumatology, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Madrid

Background/Purpose: Berlin criteria are a diagnostic algorithm based on calculation of the likelihood ratio (LR) product of currently available diagnostic test for spondyloarthritis (SpA). However, these probabilities were calculated on a longstanding population, with different features from those of an early SpA cohort. ESPeranza (ESP) is a national health care multicentre program for the early diagnosis and treatment of SpA. ESP patient characteristics were collected from baseline to onset, so it permits to explore Bayesian probabilities of each feature and reproduce Berlin algorithm. OBJECTIVEs: 1. To evaluate, in an early SpA, the LR of different symptoms and signs included in Berlin criteria. 2. To evaluate the validity of Berlin algorithm for SpA diagnosis.

Methods: Patients were referred from general practitioners according with this criteria: 1) age <45years old; 2) symptom duration 3–24 months; 3) at least one of the following: inflammatory back pain (IBP), asymmetrical arthritis, SpA features associated to back pain or arthralgias (psoriasis, inflammatory bowel disease, anterior uveitis, radiographic sacroiliitis, HLA B27 positive or a family history of SpA). Patients with axial symptoms were selected (those with only arthritis were excluded) and categorized according to experts clinical diagnosis (SpA or not SpA). Data from ESP included: demographics (gender, age), clinical features (IBP characteristics, sacroiliac syndrome, enthesitis, arthritis, dactilitis, psoriasis, inflammatory bowel disease, diarrhea, urethritis, cervicitis, prostatitis, positive family history for SpA or good response to NSAIDs), HLA B27 or imaging data (sacroiliitis in x-ray or MRI, according to Omeract). Descriptive analysis was performed. Sensitivity and specificity, and LR positive were calculated. Classification according to Berlin LR product method was performed. In case of an LR product '200, a classification of axial SpA is made.

Results: From the 1179 patients referred in ESP program, only 422 fulfilled inclusion criteria with axial symptoms. 316 were diagnosed as SpA. Insidious onset and > 3months onset were the most frequent symptoms (73% and 84%, respectively). The most useful feature among IBP was the improvement with exercise (LR+ 2.2), more frequent than alternating buttock pain. Arthritis was the most useful symptom for the diagnosis (LR+ 7), apart from MRI, following by enthesitis, but heel pain (LR 5.7). Dactiyitis and uveitis and other features were less helpful, (see table). Finally, MRI was the most beneficial feature (LR+ 16), although it was not always available. Berlin criteria applied to this early SpA population showed a lower sensitivity (65%) and higher specificity (98%) than Berlin group.

	Frequent (n)	Percentage (%)	SENS %	SPE %	PPV	PNV	LR+	LR-
Inflammatory back pain	247	58.5	63.9	57.5	81.8	34.9	1.5	0.6
>3 month onset	356	84.4	83.2	12.3	73.9	19.7	0.9	1.4
Morning stiffness ^{3}30min	241	57.1	59.2	49.1	77.6	28.7	1.2	0.8
Improvement with exercise	230	54.5	63.0	70.8	86.5	39.1	2.2	0.5
No improvement with rest	262	62.1	67.7	54.7	81.7	36.3	1.5	0.6
Pain at night	195	46.2	50.9	67.9	82.6	31.7	1.6	0.7
Alternating buttock pain	126	29.9	33.9	82.1	84.9	29.4	1.9	0.8
Insidious onset	309	73.2	74.4	30.2	76.1	28.3	1.1	0.8
Arthritis	87	20.6	26.3	96.2	95.4	30.4	7.0	0.8
Heel pain	75	17.8	21.2	92.5	89.3	28.2	2.8	0.9
Enthesitis, but heel pain	18	4.3	5.4	99.1	94.4	26.0	5.7	1.0
Iritis	17	4.1	4.4	97.2	82.4	25.4	1.6	1.0
Dactylitis	18	4.3	5.7	100.0	100.0	26.2	.	0.9
Inflammatory bowel disease	16	3.8	4.4	98.1	87.5	25.6	2.4	1.0
Psoriasis	35	8.3	9.2	94.3	82.9	25.8	1.6	1.0
Uretritis/cervicitis/diarrhea	7	1.7	2.2	100.0	100.0	25.5	.	1.0
Raised CRP	97	24.6	29.8	92.4	92.8	28.6	3.9	0.8
HLA B27 positive	208	49.3	59.2	80.2	89.9	39.7	3.0	0.5
Family history	99	23.5	27.5	88.7	87.9	29.1	2.4	0.8
Sacroiliitis X-ray	203	48.1	36.8	100.0	100.0	30.0	.	0.6
Sacroiliitis RMI	99	23.5	63.0	96.2	98.0	46.6	16.7	0.4
Good response to NSAID	252	59.7	63.6	51.9	79.8	32.4	1.3	0.7
Berlin Criteria	210	49.7	65.2	96.2	98.1	48.1	17.3	0.4

Conclusion: Our data shows that MRI is a key symptom in early SpA, while HLA B27 was less useful than results from Berlin group. Berlin diagnostic algorithm should be revisited according to these data, at least in early SpA patients.

Assessing the Clinical and Economic Burden of U.S. Veteran Ankylosing Spondylitis Patients. Lin Xie[1], Onur Baser[2], Ahong Huang[3], Lu Li[3], Elyse K. Fritschel[3] and Li Wang[3]. [1]STATinMED Research, Ann Arbor, MI, [2]STATinMED Research/The University of Michigan, Ann Arbor, MI, [3]STATinMED Research, Dallas, TX

Background/Purpose: To examine the economic burden, demographic and clinical characteristics of ankylosing spondylitis (AS) in the U.S. veteran population.

Methods: A retrospective database analysis was performed using the Veterans Health Administration (VHA) Medical SAS Datasets from October 1, 2007 to September 30, 2011. Patients with AS were identified using International Classification of Disease 9th Revision Clinical Modification (ICD-9-CM) diagnosis code 720.0x. Survival was determined with the PROC LIFETEST procedure, and descriptive statistics were calculated as means ± standard deviation (SD) and percentages to measure demographics, costs and utilization distribution in the sample.

Results: In patients identified with AS (n=2,455), total survival rates in the 12-month follow-up period were 98.1% for patients age ≤39, 97.0% for those age 40–64, and 89.6% for those age ≥65. The most common comorbidities in AS patients were hypertension (62.77%), any tumor or malignancy (25.50%), and diabetes (24.11%). The percentage of patients who had follow-up inpatient visits was 14.34%, which translated into $6,240 in inpatient costs per patient. The percentage of patients who had follow-up outpatient visits was 99.88%, which translated into $6,838 outpatient costs per patient. The average number of inpatient (0.25, SD=0.79), emergency room (ER) (0.10, SD=0.58), physician office (15.99, SD=16.63) and outpatient visits (17.54, SD=17.88) were also calculated for AS patients.

Conclusion: Comorbidities may play an important role in the costs of AS treatment, since more than 20% of the study population was also diagnosed with any combination of hypertension, diabetes, and tumor or malignancy.

US Treatment Patterns of Psoriatic Arthritis Patients Newly Initiated On Etanercept or Adalimumab. Frank Zhang[1], Stan Li[1] and Jeffrey R. Curtis[2]. [1]Celgene Corporation, Warren, NJ, [2]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Etanercept (ETN) and Adalimumab (ADA) are commonly used biologic disease-modifying antirheumatic drugs (DMARDs) for psoriatic arthritis (PsA) patients (pts). However, little is known about subsequent treatment changes after the initiation of these two biologics. The objective of this study was to describe treatment patterns following the initiation of ETN and ADA in PsA patients in US in a real-world setting.

Methods: Adult PsA pts were selected from MarketScan Commercial Claims database (2005–2009). First ETN/ADA prescription date was defined as the index date. Pts were required to have continuous enrollment 6-month prior to (baseline period) and 12-month post index date (study period), no use of the index biologic treatment during baseline, have received ≥2 PsA diagnoses from physician office visits at any time over the 18-month period, with at least one PsA diagnosis during baseline period, and no diagnosis of ankylosing spondylitis. ETN/ADA combo therapy was defined as having at least 28 days of concomitant use of a non-biologic DMARD following the index date; otherwise ETN/ADA monotherapy was defined. Treatment patterns were captured over the 12-month study period and were defined as the following: complete treatment discontinuation—a treatment interruption of ≥60 consecutive days past the end of the days' supply (discontinuation date) and no other DMARD therapy between the discontinuation date and the end of the study period; a switch in therapy—the initiation of a new non-biologic/ biologic DMARD (not used during baseline) within 60 days of the discontinuation date; intermittent use of the index biologic -- ≥60 days of treatment gap of the index biologic; step-down -- discontinuation of one of the DMARD therapies among patients previously on combo therapy; step-up— adding another DMARD (not used during baseline) concomitantly with the index biologic for ≥28 consecutive days. Therapy modification was defined as any switch, intermittent use, step-down or step-up.

Results: A total of 2,037 and 2,217 PsA pts were newly initiated on ETN and ADA respectively, most on monotherapy (ETN: 69.2%, ADA: 67.5%). Over the 12-month study period, the majority of the pts had ≥ 1 therapy change (ETN: 65.3%, ADA: 69.1%), with median time to change 113 days and 112 days respectively. Among pts initiated on mono ETN/ADA, 40.7% ETN and 33.5% ADA pts remained on the index mono therapy. 12.1% ETN and 11.6% ADA pts discontinued the treatment, 18.2% ETN and 14.7% ADA pts had intermittent treatment, 7.0% ETN and 11.4% ADA pts switched to another mono therapy, and 21.9% ETN and 29.1% ADA pts step-up to combo therapy. Among pts initiated on ETN/ADA in combination with an oral DMARD, a proportion of pts remained on the original combo therapy (ETN: 21.4%, ADA: 26.8%). The majority of the patients 'stepped down' to monotherapy (ETN: 77.5%, ADA: 72.7%). Very few pts discontinued both drugs in the combo therapy (ETN: 0.5%, ADA: 0.1%) or adopting intermittent biologic therapy (ETN: 0.6%, ADA: 0.3%).

Conclusion: This study suggests that most of the PsA patients newly initiated on ETN or ADA have a therapy change over the first year. Both 'step-up' and 'step down' strategy are observed frequently.

How Important Is the Assessment of ASDAS in the Long-Term Evaluation of Disease Activity in Ankylosing Spondylitis? A Comparison with Currently Used Clinical Parameters. Xenofon Baraliakos[1], Claudia Fritz[2], Joachim Listing[3], Hildrun Haibel[4], Joachim Sieper male[5] and Jürgen Braun[1]. [1]Rheumazentrum Ruhrgebiet, Herne, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]German Rheumatism Research Center, Berlin, Germany, [4]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [5]Charité Universitätsmedizin Berlin, Berlin, Germany

Background/Purpose: Measures for disease activity (BASDAI) or response to therapy (ASAS partial remission (PR)) are widely used in the assessment of patients with ankylosing spondylitis (AS). The recently developed ASDAS is a composite score, which includes clinical measures and CRP and has a high discriminatory capacity for assessing disease activity. However, only little is known about the course of ASDAS as compared to all other clinical assessments in the long-term outcome of patients with AS. In this study we compare the performance of ASDAS-CRP vs. the BASDAI and ASAS outcomes in assessing and predicting clinical response in AS patients under longterm TNF-blocker therapy.

Methods: Initially, 69 patients were included in this first study of anti-TNF treatment with infliximab in AS, of whom 43 (63.2%) finished the 3rd, 42/69 (60.9%) the 5th and 29 (42.2%) the 10th study year (y). Low disease activity status was measured by the BASDAI (<3 units) and was compared to the ASDAS definition of low disease activity (<2.1 units), while for clinical response, the ASAS-PR was compared to ASDAS inactive disease status (ASDAS <1.3) at different time points over the 10y of follow-up.

Results: There was significant decrease in both ASDAS (BL: 4.3±0.8, 3y: 1.5±0.9, 5y: 1.6±1.0, 10y: 1.7±1.0) and BASDAI (BL: 6.4±1.4, 3y: 2.4±1.9, 5y: 2.4±2.0, 10: 2.7±2.0). Overall, a BASDAI <3 was achieved by 19/29 (65.5%), 18/29 patients (62.1%), and 17/29 patients (58.6%), while ASDAS <2.1 was achieved by 23/29 (79.3%), 20/29 (69%) and 19/29 (65.5%) patients at 3y, 5y and 10y, respectively. In comparison, ASAS-PR was found in 10/29 (34.5%) at 3y and 5y and in 5/29 (17.2%) patients at 10y while ASDAS<1.3 was found in 13/29 (44.8%) at 3y and in 12/29 (41.4%) at 5y and 10y. Clinical outcome after 12 weeks of treatment was a significant predictor for achieving ASAS-PR over the 10 years of the study: for each unit of decreasing in BASDAI status at week 12, achievement of ASAS-PR at 10y increased with an OR [95% CI] of 3.64 [1.17–11.20] (p=0.025), while the OR for each unit of decreasing in ASDAS status at week 12 in order to reach ASAS-PR at 10y was 4.76 [1.20–18.90] (p=0.027). Similar results were found for ASDAS inactive disease at the end of year 10: for each unit of decreasing in ASDAS status at week 12, achievement of ASDAS inactive disease at 10y increased with an OR [95% CI] of 2.20 [1.00–4.86] (p=0.05), while the OR for each unit of decreasing in BASDAI status at week 12 in order to reach ASDAS inactive disease at 10y was 1.64 [1.05–2.58] (p=0.029).

Conclusion: The long-term course of BASDAI and ASDAS showed similar magnitude of improvement. Interestingly the clinical outcome after 12 weeks of treatment was a significant predictor of the outcome at the end of year 10. The significant decrease of ASAS-PR rates after 10 years can be explained by the inclusion of functional assessments (BASFI) in this measure, which are not

included in the ASDAS. The higher discriminative value of ASDAS in comparison to other widely used measurements needs to be considered in clinical trials but also daily practice for assessment of long-term outcomes in patient with AS.

ACR/ARHP Poster Session C
Systemic Lupus Erythematosus: Clinical Aspects
Tuesday, November 13, 2012, 9:00 AM–6:00 PM

2236

Cross Cultural Validation of English and French Versions of a Disease Specific Patient Reported Outcome Measure for Lupus in Canada. Josiane Bourré-Tessier[1], Ann E. Clarke[2], Rachel A. Mikolaitis[3], Mark Kosinski[4], Sasha Bernatsky[5], Joel A. Block[3] and Meenakshi Jolly[3]. [1]McGill University, Montréal, QC, [2]McGill University, Montreal, QC, [3]Rush University Medical Center, Chicago, IL, [4]QualityMetric Inc, Lincoln, RI, [5]McGill, Montreal, QC

Background/Purpose: The LupusPRO, a disease targeted Patient Reported Outcome measure, was developed and validated in US patients with Systemic Lupus Erythematosus (SLE). We aimed to validate English and French versions of the LupusPRO among SLE patients in Canada.

Methods: The English version of the LupusPRO was administered to English-speaking SLE patients in Canada and the French version to French-speaking patients. Patients also completed the MOS SF-36. Physicians assessed disease activity (SELENA-SLEDAI and visual analogue scale) and damage (SLICC-ACR SDI and visual analogue scale). A mail back LupusPRO was completed within 2–3 days of the index visit. Internal consistency reliability (ICR), test-retest reliability (TRT), concurrent validity (corresponding domains of the SF-36) and criterion validity (against disease activity and damage) were tested. Confirmatory factor analysis results were available thus far only for the English version. All reported p values are two tailed.

Results: A total of 222 Canadian SLE patients participated—123 English speaking and 99 French speaking (table 1). Among the English-speaking patients, the ICR of the LupusPRO domains ranged from 0.60–0.93, while TRT ranged from 0.62–0.95. Concurrent validity with corresponding domains of the SF-36 was present and the LupusPRO domains performed well against disease activity and/or damage measures establishing its criterion validity. Confirmatory factor analysis showed a good fit.

Among the French-speaking patients, the ICR of the LupusPRO domains ranged from 0.81–0.93, except for Lupus Symptoms (0.58), Procreation (0.79) and Coping (0.44) domains. By deleting the item on religiosity/spirituality from the Coping domain, the ICR of this domain improved to 0.64. TRT ranged from 0.72–0.95. Concurrent validity with corresponding domains of the SF-36 was present. Lupus Symptoms domain correlated with disease activity as assessed by the total SLEDAI (r −0.26, p 0.01) and physician completed visual analog scale (r −0.49, p 0.001). Other domains also performed well against disease activity and/or damage.

Table 1. Description of the study cohort

	English-speaking patients N= 123	French-speaking patients N = 99
Age (Mean, SD) years	47.7 (14.8)	45.2 (14.5)
Female (%)	94	97
Ethnicity (%)	–	–
Caucasian	60.0	73.7
Asian	23.0	6.1
African-Caribbean	9.0	11.1
Other	8.0	9.1
SELENA SLEDAI (Median, IQR)	4.0 (6.0)	3.0 (6.0)
MD-Activity VAS (Median, IQR)	0.2 (0.95)	0.2 (1.00)
SDI (Median, IQR)	1.0 (3.0)	1.0 (2.0)
MD-Damage VAS (Median, IQR)	0.3 (2.8)	0.2 (3.4)

Conclusion: The English and French versions of the LupusPRO have fair psychometric properties among Canadian patients with SLE, and are now available to be included in clinical trials and in longitudinal studies for testing of responsiveness to change.

Application and Feasibility of Proposed Systemic Lupus Erythematosus Reproductive Health Care Quality Indicators At a Public Urban Rheumatology Clinic. Itziar Quinzanos[1], Angela Keniston[1], Joann Zell[2], Jinoos Yazdany[3], Alyssa Nash[1], Rebecca Fransen[1], Jennifer Stichman[1] and Joel M. Hirsh[1]. [1]Denver Health Med Ctr, Denver, CO, [2]National Jewish Health, Denver, CO, [3]University of California San Francisco, San Francisco, CA

Background/Purpose: Reproductive health quality indicators (QIs) for systemic lupus erythematosus (SLE) have recently been developed: anti-ssA, anti-ssB, and phospholipid antibody (aPL) screening prior to pregnancy; appropriate treatment of pregnancy associated anti-phospholipid antibody syndrome (PAPS); and counseling regarding risk and contraception in women taking potentially teratogenic medications (methotrexate, azathioprine, leflunomide, mycophenolate mofetil, cyclosporine, cyclophosphamide, or thalidomide). We examined performance on these QIs, their feasibility for use in a safety net rheumatology clinic, as well as sociodemographic predictors of higher performance.

Methods: Using data from the Denver Health (DH) electronic health record (EHR), we identified rheumatology clinic patients seen between July 2006 and August 2011 who had SLE, were female, and were between the ages of 18–50 years. We queried sociodemographic and other data from the EHR including age, race/ethnicity, primary language, use of interpreter services, and primary payer. Manual EHR review was conducted to determine adherence to the QIs. As a measure of feasibility, we tracked the time spent extracting the QIs. We calculated performance on each measure. For the QI regarding teratogenicity counseling, which had the largest number of eligible patients, we used either chi-square or Student's t-tests to identify the relationship between demographic characteristics and performance.

Results: 137 female SLE patients aged 18–50 years were identified. Of these, 15 were postmenopausal or status post tubal ligation or hysterectomy. Twelve pregnancies were documented during this 5-year period. Performance on the QI regarding anti-ssA, anti-ssB or aPL testing was 100%. We were unable to assess QI#2 as no pregnant patient met criteria for PAPS. 65 patients (53%) received potentially teratogenic medications. Only 30 of these patients (46%) had documented discussions about these medications' potential risk to a developing fetus upon their initiation. Age was the only sociodemographic or other variable and that predicted performance on QI#3. Patients who received teratogenicity counseling were younger on average than those who did not (29 + 8 and 35 + 10 respectively, p-value = 0.0073). The chart review time was 46 hours.

Conclusion: The new SLE reproductive health QIs allowed us to detect an important gap in counseling regarding the teratogenic risk of medications in our public health academic clinic. Greater attention to this issue is needed as only about half the patients of childbearing age received appropriate counseling, with older reproductive age women having the largest gap in care. Although extraction of the QIs was technically feasible, the time for manual EHR review was long. Electronic specification of these measures may be one way to reduce their collection burden in the future.

Alpha-Chlorofatty Acid Does Not Correlate with Baseline Subclinical Cardiovascular Disease in Systemic Lupus Erythematosus. Mary A. Mahieu[1], Camelia Guild[2], Carolyn J. Albert[2], George Kondos[3], James Carr[1], Daniel Edmundowicz[4], David A. Ford[2] and Rosalind Ramsey-Goldman[1]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Saint Louis University, Saint Louis, MO, [3]University of Illinois at Chicago, Chicago, IL, [4]Temple University School of Medicine, Philadelphia

Background/Purpose: Serum alpha-chlorofatty acid (α-ClFA) directly reflects in vivo myeloperoxidase activity, an important regulator of atherogenesis. The objective of our study was to investigate whether α-ClFA may be a biomarker for detection of subclinical cardiovascular disease (CVD) in patients with systemic lupus erythematosus (SLE).

Methods: One hundred eighty-five women with SLE and 186 controls participated in this ancillary study of the Study of Lupus Vascular and Bone Long-term Endpoints (SOLVABLE). Information on demographics, CVD risk factors, SLE risk factors, and baseline laboratory assessments were obtained at the first study visit. Using stored serum, α-ClFA was measured by liquid chromatography-electrospray ionization mass spectrometry with selected reaction monitoring detections. Each sample was run in triplicate. Coronary artery calcium (CAC) and aorta calcium (AC) were measured by either electron beam computed

tomography (EBCT) or multi-detector computed tomography (MDCT), and calcium scores were calculated with a densitometric program using the Agatston method. Outcome measures were the presence of higher risk CAC or AC scores (CAC >10 or AC >100) versus lower risk scores (CAC ≤10 or AC ≤100). Descriptive characteristics and univariate analyses were used to identify significant associations. Multivariate analyses controlled for established traditional CVD risk factors and variables found to be significant in the univariate analysis by p<0.05 between cases and controls.

Results: SLE patients had higher baseline levels of α-ClFA than controls (42.2 fmol/μl ± 19.2 vs 34.5 fmol/μl ± 10.9, p=0.014). Cases with lower risk CAC and AC scores had statistically higher levels of α-ClFA compared to controls (42.0 fmol/μl ± 17.6 vs 33.7 fmol/μl ± 10.5, p=0.010 for CAC; 40.4 fmol/μl ± 12.3 vs 33.9 fmol/μl ± 10.5, p=0.023 for AC). In contrast, cases and controls with higher risk CAC and AC scores had similar α-ClFA levels (43.3 fmol/μl ± 21.5 vs 44.0 fmol/μl ± 14.8, p=0.951 for CAC; 39.3 fmol/μl ± 7.8 vs 37.6 fmol/μl ± 13.1, p=0.743 for AC). In multivariate analyses, SLE had the strongest independent association with higher risk CAC scores (odds ratio (OR) 5.81; 95% confidence interval (CI) 2.28 to 14.83), followed by dyslipidemia (OR 5.67; 95% CI 1.50 to 21.36), and older age (OR 1.11; 95% CI 1.05 to 1.17). Dyslipidemia was defined as fasting total cholesterol >200, low-density lipoprotein >100, high-density lipoprotein <40, triglyceride >150, or use of lipid-lowering medication. SLE also had the strongest independent association with higher risk AC scores (OR 3.73; 95% CI 1.59 to 8.78), followed by history of tobacco use (OR 2.31; 95% CI 1.13 to 4.74), older age (OR 1.17; 95% CI 1.10 to 1.25), and c-reactive protein level (OR 1.05; 95% CI 1.01 to 1.11). α-ClFA was not independently associated with higher risk CAC scores (OR 1.00; 95% CI 0.99 to 1.01) or higher risk AC scores (OR 1.01; 95% CI 0.99 to 1.02).

Conclusion: SLE had the strongest association with the presence of higher risk subclinical CVD as measured by CAC and AC scores. Baseline serum α-ClFA levels were not independently associated with higher risk CAC or AC scores.

IFIMAV, Santander, Spain, [20]Hospital Universitario Carlos Haya, Málaga, Spain, [21]Hospital Marina Baixa, Villajoyosa, Spain, [22]University Hospital San Cecilio, Granada, Spain, [23]Hospital La Paz-IdiPaz, Madrid, Spain, [24]Hospital Universitario Juan Canalejo, La Coruña, Spain

Background/Purpose: Over 50% of patients with SLE develop renal involvement but only 20% of these are found to have pure membranous lupus nephritis (MLN) on biopsy. Few studies have addressed its pathogenesis and there is no big series describing its characteristics. Our aim is to establish the clinical characteristics, treatment and prognosis of MLN and to make international and intersocial comparisons.

Methods: Twenty-four Spanish centres and 1 in the US participated in the study. All SLE patients with biopsy proven MLN were included. Data on clinical and laboratory features, prescribed drugs, renal outcomes and survival were collected. Descriptive statistics were used to describe the main features of the series. Chi-squared distribution and Fisher test were used to analyse categorical variables and the U Mann-Whitney test for quantitative variable. A p value <.05 was considered significant. Multivariate models were built using variables that were significant in the previous univariate analysis.

Results: A total of 150 patients were included. Patients' characteristics are shown in the table. Spaniards (.032), patients with Public Health Coverage (.031), with a lower basal serum creatinine (BSC) (0.86 Vs 1,23 mg/dl;.014), a lower basal serum albumin (2.89 Vs 3.55 g/dl;.05), without previous venous thrombosis (.036) and those who had received chloroquine (.004) or azathioprine (AZA) (.022) for MLN were more prone to achieving a final proteinuria <.05 g. Female sex (.017), a low BSC (0.85 Vs 1.39 mg/dl;.001), low CRP (4.51 Vs 22.88 mg/l;.017), not having nephrotic syndrome at diagnosis (.028) and previous treatment with AZA (.03) were predictors of final proteinuria <1 g. Patients with final doubled creatinine had a greater initial BSC (1.92 Vs 0.86 mg/dl;.005) and a lower creatinine clearance (59.23 Vs 102.2 ml/min;.016). Moreover, male sex (.001), basal high blood pressure (<.001), chronic cardiopathy (.018) and peripheral artheriopathy (.039) were risk factors for doubling BSC. Renal failure was predicted by male sex (.001), HBP (.001), active sediment (.027), nephrotic syndrome (.008), higher BSC (1.97 Vs 0.81 mg/dl;.001), higher ESR (.043) and CRP (.013) and not having received angiotensin converting enzyme inhibitors (.036). Lastly, cardiac failure (.013), ischemic cardiopathy (.001), peripheral (.013) and cerebral (.012) artheriopathy, hemodialysis (.003) and not having received hydroxychloroquine (.03) or mophetil mycophenolate (.039) for MLN predicted death. Multivariate analysis for the different outcomes showed the type of health coverage and cardiovascular disease as the main predictors of poor outcome.

Table. Patients baseline characteristics

	All (150)	Spain (102)	NYC (48)	p
MLN Diagnosis

Death, n patients (%)	9 (6)	8 (7.8)	1 (2.1)	0.155

Abbreviations: ACEI, Angiotensin converting enzyme inhibitor; aPL, Antiphospholipidic; ARB, Angiotensin receptor blockers; CRP, C reactive protein; ESR, Erytrosedimentation rate; ESRD, End-Stage Renal Disease; HBP, High Blood Pressure; MMF, Mophetil Mycophenolate; SLE, Systemic Lupus Erythematosus.

Conclusion: MLN usually begins with nephrotic syndrome, high proteinuria and normal serum creatinine. Its prognosis is favourable in maintaining renal function although proteinuria usually persists over time. Cardiovascular disease and some socio-sanitary factors are related with poor prognosis.

Systematic Review of Skin Nontuberculous Mycobacteria Infection in Systemic Lupus Erythematosus: An Unusual Skin Infection Mimicking Lupus Vasculitis. Zahi Touma[1], Amir Haddad[1], Dafna D. Gladman[2], Elizabeth Uleryk[3] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [3]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Nontuberculous mycobacteria (NTM) have become pathogens frequently associated with skin infection in patients on immunosuppression. NTM is not unusual in lupus patients and the unawareness of this complication delays diagnosis and treatment. Studies on infections in lupus identified the common typical bacterial pathogens and little has been published on atypical pathogens in particular NTM.

We aimed to systematically review the medical literature addressing skin NTM in lupus.

Methods: We searched Ovid Medline (1946 to March 12, 2012), Embase (1980 to March 12, 2012) for relevant publications. A study was included in the review if: 1) it included lupus patients with NTM of mucocutaneous system or soft tissue 2) it was published up to March 12, 2012 and 3) it had well-documented clinical summaries and relevant information to the objective of this study. We scanned the titles and abstracts for initial selection. Selected articles were retrieved in full and two reviewers assessed them for eligibility and extracted the data. Descriptive statistics were used to report the results of the analysis.

Results: Of the 1356 retrieved abstracts, 17 publications were identified and 25 cases of skin NTM were extracted. In this review we included only patients with skin NTM and in all but 5 patients the infection was limited to the skin. The majority of the cases occurred in females (92%). The mean age at the time of the infection was 41 ± 13.3 years, with mean lupus duration of 12.9 ± 6.7 years. Skin presentations in this review were painless to mildly painful and ranged from papules, plaques, nodules to ulcerative lesions and abscesses and few patients developed constitutional symptoms in particular fever.

NTM in lupus patients occurred after relatively long period from the initial diagnosis of lupus and after the patients had been exposed to steroids and immunosuppressants. NTM occurred in the setting of active as well as inactive lupus. The pathogen species identified in this review included mainly M. Chelonae (9 patient-events [PE]), M. Haemophilum (4 PE), M. Avium (3 PE), M. Kansasii (2 PE), M. Fortuitum (2 PE), M. Scrofulaceum (1 PE), M. Marinatum (1 PE), M. Szulgai (1 PE) and M.abscessus (1 PE). In 4 PE the culture was either negative or the specific species was not identified.

Surgical intervention in particular debridement of skin lesions were considered if needed. Empirical monotherapy therapy can be initially initiated and the final choice of antibiotics should rely on the susceptibility of the culture and clinical response. The majority of the patients' lesions improved/recovered with treatment. Nevertheless, two patients developed disseminated M. Chelonae and Fortuitum respectively and this resulted in death.

The most commonly used antibiotics in this review were ciprofloxacin, clarithromycin, ethambutol, isoniazide, rifampicin, doxycyline, amikacin, ethambutol and minocycline.

Conclusion: A high index of suspicion in lupus patients is required to diagnose NTM, as the initial presentation of NTM can mimic lupus skin manifestations. NTM should be suspected in any patient with indolent deep-nodular skin lesions, especially if routine bacterial cultures are negative.

Efficacy of Belimumab in Systemic Lupus Erythematosus Patients with High Baseline Disease Activity. Ann E. Clarke[1], Susan Manzi[2], Michelle A. Petri[3], Richard Furie[4], Ronald F. van Vollenhoven[5], Simon Cooper[6], Z. John Zhong[6], William W. Freimuth[6] and Arthur Weinstein[7]. [1]MUHC, Montreal, QC, [2]West Penn Allegheny Health System, Pittsburgh, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]North Shore-LIJ Health System, Lake Success, NY, [5]Karolinska University Hospital, Stockholm, Sweden, [6]Human Genome Sciences, Inc., Rockville, MD, [7]Washington Hospital Center, Washington, DC

Background/Purpose: To assess the efficacy of belimumab in patients with SLE who had high disease activity at baseline, as defined by SELENA-SLEDAI score ≥ 10.

Methods: In 2 randomized, double-blind, multicenter phase 3 studies, 1684 SLE patients with SELENA-SLEDAI ≥ 6 at baseline were treated with placebo, or belimumab 1 or 10 mg/kg, plus standard SLE therapy (NCT00071487/NCT00583362). In a post-hoc analysis, the SLE Responder Index (SRI) at wk 52, flares, corticosteroid use, fatigue, and the SF-36 vitality domain were examined in a subgroup of patients with baseline SELENA-SLEDAI ≥ 10.

Results: 877 patients (52%) had SELENA-SLEDAI scores ≥ 10 on entry to the BLISS trials: 299, 283, and 296 were randomized to placebo, and belimumab 1 and 10 mg/kg, respectively. Mean baseline characteristics were similar across treatment groups. In patients with SELENA-SLEDAI ≥ 10 vs ≤ 9, >80% vs 56% were anti-double-stranded−DNA positive and 55%/67% vs 34%/55% had low C3/C4 levels. In patients with SELENA-SLEDAI ≥ 10 vs all patients in the BLISS trials, 89% vs 57% had >3 organ systems involved. Belimumab 1 and 10 mg/kg significantly improved SRI response, and reduced prednisone use in high disease activity patients at wk 52 (see table). Treatment with belimumab 10 mg/kg generally resulted in a greater response than with 1 mg/kg and placebo regarding reduction in severe flare risk, and improvements in SRI response, fatigue, and SF-36 vitality at wk 52.

Efficacy in Patients With SELENA-SLEDAI Scores ≥ 10 at Baseline

Response parameter[a]	Placebo (n = 299)	Belimumab 1 mg/kg (n = 283)	Belimumab 10 mg/kg (n = 296)
SRI response: wk 52, %	44.1	58	63.2
p value		<0.001	<0.001
No new BILAG A and ≤1 new B score	65.4	73.5	74.3
p value		0.024	0.017
≥4-point reduction in SELENA-SLEDAI	48	60.4	66.2
p value		0.001	<0.001
No worsening in PGA	63.1	73.1	74
p value		0.006	0.004
Patients with ≥1 severe flare, %	28.8	21.6	18.2
Severe flare risk over 52 wk: HR (95% CI)[b]		0.73 (0.52−1.01)	0.59 (0.42−0.83)
p value		0.054	0.003
Prednisone reduction ≥25% from baseline to ≤7.5mg/day: wk 40−52, n (%)[c]	12/181 (6.6)	32/182 (17.6)	31/186 (16.7)
p value		0.002	0.004
% patients with reduction in baseline prednisone from > 7.5 to ≤7.5 mg/d at week 52	16/181 (8.8)	35/182 (19.2)	41/186 (22.0)
p value		0.007	<0.001
Mean FACIT-Fatigue score improvement: wk 52	3.38	4.76	5.12
p value		0.103	0.024
Mean SF-36 vitality score change	7.82	9.69	10.76
p value		0.196	0.044

[a] p values represent comparisons of belimumab treatment with placebo; [b]Cox proportional hazards model; [c]includes only patients with baseline prednisone >7.5 mg/d.
BILAG, British Isles Lupus Assessment Group; FACIT, Functional Assessment of Chronic Illness Therapy; PGA, Physician's Global Assessment

Conclusion: Belimumab 10 mg/kg significantly reduced disease activity, flares, corticosteroid use, and fatigue in SLE patients with high disease activity, as defined by baseline SELENA-SLEDAI scores ≥10.

Clinical Manifestations and Predictive Factors for Response to Induction Therapy and Maintenance of Remission in ISN/RPS Class V Lupus Nephritis. Masanori Hanaoka[1], Takahisa Gono[1], Yasushi Kawaguchi[1], Hirotaka Kaneko[2], Kae Takagi[1], Hisae Ichida[1], Yasuhiro Katsumata[2], Yuko Okamoto[2], Yuko Ota[1], Sayuri Kataoka[1] and Hisashi Yamanaka[1]. [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: The pathophysiology and the content of treatment differ between International Society of Nephrology/Renal Pathology Society (ISN/RPS) class III/IV lupus nephritis (LN) and class V LN. However, the differences in clinical manifestations have not been revealed in detail between class III/IV LN and class V LN. Moreover, predictive factors for the response to induction therapy and the maintenance of remission have not been sufficiently investigated in class V LN. The aim of this study was to clarify the clinical manifestations and predictive factors for the response to induction therapy and the maintenance of remission in class V LN compared with class III/IV LN.

Methods: 48 patients with ISN/RPS class III/IV LN and 23 patients with class V LN were consecutively enrolled at our institute from 2001 to 2010. Clinical manifestations, autoantibodies, and treatment outcomes were analyzed and compared between two subsets. We investigated the predictive factors for the response to induction therapy and the maintenance of remission.

Results: The disease duration was significantly longer (P = 0.0024), and complement component 3 was significantly higher (P = 0.0055) in the class V LN subset. The frequency of anti-dsDNA Ab positivity did not differ between two subsets. Anti-U1snRNP Ab and anti-Sm Ab positivity were significantly higher (P = 0.0054 and P = 0.012, respectively) in the class V LN subset. Patients who were anti-dsDNA Ab-positive and anti-U1snRNP Ab-negative experienced significantly more frequent complications with class III/IV LN (odds ratio 5.1, confidence interval [CI] 1.5–17.6, P = 0.010). In contrast, patients who were anti-dsDNA Ab-negative and anti-U1snRNP Ab-positive experienced significantly more frequent complications with class V LN (odds ratio 6.5, CI 1.2–35.5, P = 0.015). The combined complete and partial remission rate exhibited no significant differentiation between two subsets (82.6% in the class V LN subset and 73.3% in the class III/IV LN subset). In the non-remission subset with class V LN, the quantification of 24-hour proteinuria on induction therapy was significantly higher (P < 0.0001) than in the remission subset with class V LN. Based on the multivariate analysis, the quantification of 24-hour proteinuria was an independent predictive factor for remission in class V LN. The relapse rate exhibited no significant differentiation between two subsets (42.1% in the class V LN subset and 30.3% in the class III/IV LN subset). In the relapse subset with class V LN, the disease duration was significantly longer and the frequency of anti-Sm Ab positivity was higher than in the maintained remission subset with class V LN. Based on the multivariate analysis, the disease duration was an independent predictive factor for the maintenance of remission in class V LN.

Conclusion: LN patients who were anti-U1snRNP/Sm Ab-positive experienced more frequent complications with class V LN. In class V LN, the increased quantification of proteinuria and the longer disease duration on induction therapy were attributed to non-responder and relapsing populations, respectively. Early intervention may improve the rate of the maintenance of remission in class V LN.

2243

A Comparison of Systemic Lupus Erythematosus (SLE) Patients Achieving Prolonged Clinical Quiescence (PCQ) On and off Corticosteroids and/or Immunosuppressive Medications. Amanda J. Steiman[1], Dafna D. Gladman[2], Dominique Ibanez[1], Anjali Papneja[3] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [3]University of Toronto, Toronto, ON

Background/Purpose: Some patients with SLE achieve PCQ. We previously described patients achieving corticosteroid- and immunosuppressive-free PCQ. As physicians attempt to minimize patients' exposure to these medications given their associated morbidities, this study's aims were to describe patients who achieve PCQ maintained on these medications and to compare them to those maintaining medication-free PCQ.

Methods: Patients followed regularly in the Lupus Clinic from July 1970– October 2011 were identified. PCQ was defined as SLEDAI-2K=0 or =2 or 4 from active serology for ≥5 consecutive years, with visits ≤18 months apart, in patients consistently maintained on corticosteroids and/or immunosuppressives ("MED"). Charts were reviewed to qualitatively characterize the PCQ period. MED demographics and clinical course before and during PCQ were then compared to patients who achieved PCQ, defined above, but without the use of corticosteroids or immunosuppressives for its duration ("NO MED"). Descriptive statistics were used. Comparisons were made using t- and McNemar's tests.

Results: 34/1613 (2.1%) MED patients were identified. Mean MED PCQ duration was 8.5±2.9 (range 5.1–16.3) years, and ended with flare in 12 patients (35.3%). In the 22 (64.7%) patients whose PCQ did not end in flare, medications were successfully discontinued in five (14.7%), being tapered in 6 (17.6%), maintained in two (5.9%) with organ transplants necessitating ongoing immunosuppression; six (17.6%) patients were maintained on a stable regimen, with no standardized drug withdrawal algorithm specified; three patients (8.8%) were lost to follow up. 38/1613 (2.4%) NO MED patients were identified, with mean PCQ duration 11.6±6.4 (range 5.1–29.4) years. When the groups were compared, MED patients were younger at diagnosis (27.9±11.7 versus 36.1±15.2; p=0.01) and required more immunosuppressives (52.9% versus 23.7%; p=0.01) and corticosteroid (100% versus 57.9%; p<0.0001) at higher cumulative doses (42.9±39.7 versus 20.7±17.2 grams (among those requiring corticosteroids; n=22); p=0.006) prior to PCQ. There was no between–group difference in ethnicity, SLEDAI at presentation, antimalarial use, time to PCQ, organ manifestations, autoantibody profile, or SLICC damage index prior to, during, or at the last PCQ visit.

Conclusion: 2.1% of our cohort achieves PCQ of ≥5 years on corticosteroids and/or immunosuppressives; however, this group appears heterogeneous: the minority who flared, representing a group whose disease activity is merely suppressed by ongoing medication use, and the majority who tolerated/were tolerating medication withdrawal, reflective of true PCQ (as in NO MED). Further comparison between these (remission versus suppression) subgroups compared to the NO MED cohort may be instructive as each may reflect unique pathophysiology.

2244

Predicting Sjögren's Syndrome At Diagnosis of Systemic Lupus Erythematosus. Gabriela Hernandez-Molina[1], Tatiana Zamora-Legoff[1], Juanita Romero-Diaz[1], Carlos Alberto Nuñez-Alvarez[1], Francisco Cárdenas-Velázquez[1], Carlos Hernández-Hernández[1], Maria Luisa Calderillo[1], Martha Marroquín[1], Claudia Recillas-Gispert[1], Carmen Avila-Casado[2] and Jorge Sánchez-Guerrero[3]. [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]University Health Network, Toronto Canada., [3]Mount Sinai Hospital, Toronto Canada.

Background/Purpose: Sjogren's syndrome (SS) overlaps with systemic lupus erythematosus (SLE) in up to 20% of patients. Attempts to identify the characteristics of the SLE patients in whom this overlap occurs have been done in prevalent patients with long disease duration.

Aim: To identify clinical variables predicting the development of SS in SLE patients.

Methods: We included all patients from a prospective cohort of lupus of recent onset (<12 months) at enrolment. At entry, and every 3–6 months a standardized evaluation including clinical assessment and laboratory tests was

done. For SS assessment, patients undertook a sequential three phase evaluation for SS as follows: screening (six-item sicca-symptoms questionnaire, Schirmer-I and wafer tests), confirmatory (fluorescein staining test, non-stimulated whole salivary flow rate) and lip biopsy. Anti-SSA/SSB and RF (ELISA) were measured at enrollment and SS screening. SS was defined by American-European Consensus Group criteria. Statistical analysis: descriptive statistics, sensitivity (SN), specificity (SP), negative predictive value (NPV), likelihood ratio positive (LR+) and negative (LR-), logistic regression. P value <0.05.

Results: At screening for SS, the cohort comprised 105 patients. Two patients were excluded (death, hepatitis C); therefore, 93 females and 10 males were screened. Median age at lupus diagnosis and SS assessment were 25 and 30 years, respectively. Lupus duration (years) was 0.48 (0–1) at enrolment, and 4.94 years (0–6.7) at SS assessment. Although the SS status could not be defined in 14 patients, 19 patients met criteria for SS, minimum prevalence 18.5% (95% C.I. 11%–23%). All SLE/SS+ patients were females, and were older at lupus diagnosis than SLE/SS-, 30 (15–49) vs. 22 (14–54) years, P=0.003. No difference between groups was observed in lupus duration, clinical manifestations, baseline and cumulative disease activity, and damage accrual. At enrollment the prevalence of anti-SSA or anti-SSB or RF was higher in SLE/SS+ (94% vs. 61%, P= 0.006); however, individually only anti-SSA was significantly different between groups [(84% vs. 55%, P=0.02), SN 0.84, SP 0.45, NPV 0.91, LR+ 1.53 (95% C.I. 1.23–1.90), LR− 0.35 (95% C.I. 0.12–1.02). Adjusting for gender, the logistic regression analyses identified age >25 at lupus diagnosis, OR 3.8 (95% C.I. 1.19–12.4, P=0.007) and anti-SSA at baseline, OR 4.4 (95% C.I. 1.04–18.27, P=0.04) as predictors for SLE/SS+. Also, the absence of anti-SSA, anti-SSB and RF at lupus diagnosis was protective, LR− 0.14 (95% C.I. 0.02–0.95).

Conclusion: The overlap of SLE and SS occurs early during the course of lupus. Even among young patients, SLE/SS+ patients are significantly older. At lupus diagnosis, age >25 years and anti-SSA antibodies predict the overlap with SS, while the absence of anti-SSA, SSB and RF identify patients at lowest risk.

Vitamin D Deficiency Is Associated with, but Does Not Predict, Change in hsCRP in Systemic Lupus Erythematosus (SLE). Adnan Kiani, Hong Fang and Michelle Petri. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: In the general population the cardioprotective effects of vitamin D are thought to be due to modulation of inflammatory cytokines. However, the effects of Vitamin D supplementation on inflammatory biomarkers in various trials have been inconsistent with some trials suggesting a decrease (Am J Clin Nutr 2006:83;754–9) and others finding no effect (Cytokines 2010:50;175–80). We used the NHANES (National Health and Nutrition Examination Survey) median cut off of Vitamin D at 21. We then investigated whether vitamin D was associated with or would predict change, in a major inflammatory biomarker, hsCRP, over 2 years in SLE.

Methods: 167 SLE patients (93% female, 63% Caucasian, 32% African-American, mean age 45 yrs) had measurement of hsCRP and 25 hydroxy vitamin D at baseline and at 2 years. Since distribution of hsCRP was markedly skewed, it was log transformed prior to calculating mean and performing inference.

Results: There was no difference in hsCRP or Vitamin D levels among patients with different age groups (18–30,31–49,50+) or 25-OH vitamin D levels (<21 and ≥21). However, Caucasian patients had higher 25 OH vitamin D levels compared to African-Americans (79% vs. 15%, p<0.0001). At baseline, those with above median Vitamin D had lower hsCRP. There was a decrease in mean hsCRP in both groups over 2 years, but the difference in change in the two groups was not statistically significant (p=0.78).

Table. Changes in $\log_e$ hsCRP levels, by 25-OH Vitamin D level

Measure	Mean at baseline	Mean after 2 years	Mean Change	p-value for change	Difference in change (95% CI)*	p-value for difference between groups§
Vitamin D <21 (n=78)	1.31	1.04	−0.29	0.011	0.08 (−0.26, 0.41)	0.78
Vitamin D ≥21 (n=89)	0.66	0.33	−0.37	0.0041		

* Difference in change: measure in vitamin D <21 group minus measure in vitamin D ≥21 group.
§ Adjusted for ethnicity.

Conclusion: Vitamin D deficiency was associated with higher hsCRP at baseline, but did not predict change of hsCRP over 2 years. In fact, in contrast to a previous study in the general population (Am J Cardiol 2012:226–30), which showed an increase in hsCRP levels over time with higher vitamin D levels, our study found a reduction in 25-OH vitamin D in this group, as well. Thus the behavior of vitamin D and hsCRP is different in SLE than in the general population.

Real World Experience with Belimumab in the Management of Systemic Lupus Erythematosus (SLE): A Single Center, Observational, Post-Marketing Study. Susan S. Kim, Tanya Pavri, Kyriakos A. Kirou, Jane Salmon and Doruk Erkan. Hospital for Special Surgery, New York, NY

Background/Purpose: With the recent FDA approval of belimumab, clinicians are faced with adjusting their SLE treatment paradigm. The purpose of this study was to examine the patterns of belimumab use, as well as its tolerability and efficacy in a "real world" tertiary clinical setting.

Methods: We identified belimumab-receiving patients from our SLE Registry. We retrieved the demographics, belimumab indications, medications, ACR SLE criteria, SELENA-SLEDAI and SLICC scores, and PGA from the registry; we performed a focused infusion chart review for prophylactic-medications (acetaminophen and diphenhydramine) and infusion reactions (during or within 24 hours of the infusion). We analyzed the baseline and 3–6–9 month data in a descriptive fashion by stratifying based on baseline SELENA-SLEDAI scores (0, 1–5, ≥6), PGA scores (0–1.49, 1.5–2, 3), and prednisone dose (≤7.5, >7.5 mg).

Results: 23 patients (female: 21; mean age 38.3±12y; mean disease duration: 11.9±7.0y; mean SLICC score: 1.3±1.3) received 134 belimumab infusions (range: 1–11) between 8/11 and 6/12. All patients except one fulfilled the ACR SLE Classification Criteria; all patients were seropositive (ANA [83%] or anti-dsDNA [57%]). Indications for belimumab were active mucocutaneous disease (MC) (3), active musculoskeletal disease (MSK) (10), active MC+MSK (3), CNS lupus under remission but requiring high dose corticosteroids (CS) (2), active serositis (1), active skin ulcers (1), cutaneous vasculitis (1), cryoglobulinemia/cytopenia (1), and gastrointestinal vasculitis (1). Concomitant medications were CS 19 (83%), hydroxychloroquine 18 (78%), azathioprine 4 (17%), mycophenolate mofetil 6 (26%), and methotrexate 1 (4%). Prophylactic-medications were given to 13 (56%) patients prior to infusions; 4 (17%) experienced transient infusion reactions (itching: 1, urticarial rash: 1, headache: 1, and URI/diarrhea: 1). Table demonstrates the baseline and follow-up SELENA-SLEDAI, PGA, CS dose, dsDNA, and C3/4. One (4%) patient discontinued the medication due to lack of clinical efficacy after 2 doses. Two (8%) patients have postponed the treatment after 3 months due to hospitalizations for unrelated events (MI, MVA).

Mean±SD (#)	BL (n:23)	3-month (n:12)	6-month (n:5)	9-month (n:4)

C4 Abnormal (n/n+)	11/17 (65%)	6/10 (60%)	1/3 (33%)	0/1 (0%)

BL: baseline; n/n+: total # of patients with positive test/total # of patients in which the test result was available. * No disease activity at BL but history of difficulty in CS tapering; mean prednisone doses were 15.8±7.2 mg and 6.25±1.7mg at BL and 3m, respectively. ** 5 patients who completed 6m follow-up had SLEDAI scores of 9.20±2.68, 4.40±2.61, and 5.20±2.28, at BL, 3m, and 6m, respectively.

Conclusion: Our study completed in a tertiary care "real world" setting demonstrates that: a) belimumab use is not limited to patients with SELENA-SLEDAI≥6; b) infusion reaction rate is comparable to clinical trial data; and c) despite relatively small number of patients and short duration of follow-up, the results are suggestive of improved disease activity.

The First Report of Desensitization to Trimethoprim/Sulfamethoxazole in Patients with Systemic Lupus Eryhtematosus. Yasuhiro Suyama[1], Mitsumasa Kishimoto[1], Hiroto Nakano[2], Ken-ichi Yamaguchi[1], Hisanori Shimizu[1], Ryo Rokutanda[1], Chisun Min[1], Yuri Ohara[1], Yoichiro Haji[1], Kazuo Matsui[2], Akira Takeda[1], Yukio Matsui[1] and Masato Okada[1]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]Kameda Medical Center, Kamogawa City, Japan

Background/Purpose: Trimethoprin-sulfamethoxazole (TMP/SMX) is the most effective and widely used prophylactic medication in immunocompromised patients. Some diseases are well-known to cause allergic reactions including human immunodeficiency virus (HIV) infection and systemic lupus erythematosus(SLE). As opposed to HIV infection, the allergic reactions in patients with SLE are often severe and result in discontinuation, which leaves the patients with high risk of serious, sometimes life-threatening infection. We examined the efficacy and safety of the TMP/SMX desensitization protocol in patients with SLE.

Methods: We conducted a retrospective cohort study in the two major urban and rural hospitals in Japan. The oral TMP/SMX desensitization protocol was applied among SLE patients who newly received TMP/SMX prophylaxis from 2009 to 2012 (Group A). The outcomes were compared with SLE patients who had been previously prescribed with usual dose of TMP/SMX prophylaxis for the first time from 1997 to 2012 (Group B). Firstly, we studied the incidence of allergic reactions to TMP/SMX prophylaxis in between Group A and B. Secondly, we assessed the risk factors for the allergic reactions using patient's demographics and laboratory data including specific antibody status. T-test and $\chi2$ test were performed to analyze these data.

Results: A total of 17 patients (2 men and 15 women, the mean age; 45.2 years old, the average dose of steroid; 160.4 mg/day of prednisone or equivalent) were enrolled for this protocol in Group A and 30 patients (3 men and 27 women, the mean age; 38.1 years old, the average dose of steroid; 26.2 mg/day of prednisone or equivalent) in Group B. Patient characteristics including sex, age, and the mean dose of steroid between groups showed no differences when compared statistically. Our analysis revealed more than half of the reduction in the incidence of allergic reactions in Group A (3/17; 17.6%) than Group B (12/30; 40%) (p = 0.114). In addition, in Group B, there was a higher positive rate of anti-SS-A/Ro antibody related to allergic reactions (83.3% in allergic reactions vs 16.7% in no allergic reactions; p = 0.019), but not with other specific antibodies. Furthermore, to compare only in SLE patients with positive anti-SS-A/Ro antibody, there were significantly fewer allergic reactions in Group A (3/13; 23.1%) than Group B (5/6; 83.3%) (p = 0.013). No patients who neither required hospitalization nor increased the dose of steroid therapy due to SLE flare related to prophylaxis were documented in both Group A and B.

Conclusion: Our findings suggested that the TMP/SMX desensitization protocol would be a simple, safe, and effective means for SLE patients to prevent allergic reactions. To our knowledge, this is the first report of attempting to desensitize allergic reactions to TMP/SMX in patients with SLE. An anti-SS-A/Ro antibody positive status might be a risk factor for allergic reactions to usual dose of TMP/SMX prophylaxis and it would also predict good candidates to initiate the desensitization protocol.

2248

Serum Phosphatidylserine-Specific Phospholipase A1 (PS-PLA1) Identified As a Novel Biomarker for Systemic Lupus Erythematosus (SLE). Tetsuji Sawada[1], Kazuhiro Nakamura[2], Ryunosuke Ohkawa[2], Aki Shoji[1], Koichiro Tahara[1], Haeru Hayashi[1], Eri Kimura[1], Koji Igarashi[3], Junken Aoki[4] and Yutaka Yatomi[5]. [1]Tokyo Medical University, Tokyo, Japan, [2]The University of Tokyo Hospital, Tokyo, Japan, [3]TOSOH Corporation, Kanagawa, Japan, [4]Graduate School of Pharmaceutical Sciences, Tohoku University, Miyagi, Japan, [5]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Background/Purpose: Lysophosphatidylserine (LPS), which is a degraded form of phosphatidylserine (PS), is an acidic lyso-glycerophospholipid, similar to lysophosphatidic acid (LPA). LPS is known to mediate a number of biological processes through G protein coupled receptors, and may act as a lipid mediator in autoimmunity. LPS and LPA are generated by lyso-glycerophospholipid producing enzymes, PS-specific phospholipase A1 (PS-PLA1) and phosphatidic acid (PA) selective PLA1, known as autotaxin (ATX), respectively. The purpose of the present study is to determine the serum levels of PS-PLA1 and ATX in sera from patients with systemic lupus erythematosus (SLE), and to investigate their relationship with disease activity.

Methods: Serum levels of PS-PLA1 and ATX of 34 patients with active SLE were quantified by enzyme-linked immunoassay. As for 26 patients with SLE, serum PS-PLA1 levels after corticosteroid treatment were also measured, and their correlation with disease activity and organ damage, as evaluated by SLE Disease Activity Index (SLEDAI) and British Isles Lupus Assessment Group (BILAG) index, were examined. Sera from 40 patients with active rheumatoid arthritis (RA), 23 patients with Sjogren syndrome (SjS), and 23 patients with systemic sclerosis (SSc) were utilized as disease controls.

Results: Serum PS-PLA1 levels were significantly higher in patients with SLE than those in disease controls, while serum levels of ATX were similar among all patients. In SLE patients, serum levels of PS-PLA1 were positively correlated with global SLE activity indices (SLEDAI and BILAG scores) and serum IgG levels, but negatively correlated with complement C3 levels. Regarding individual organ damage, serum PS-PLA1 levels were significantly correlated with the BILAG score for general constitutional symptoms, the mucocutaneous system, and vasculitis. Furthermore, serum PS-PLA1 decreased after immunosuppressive treatment in SLE patients.

Conclusion: The association of serum PS-PLA1 levels with SLE disease activity indicates that measurement of serum PS-PLA1 may be useful for the clinical evaluation of SLE as a novel biological marker. Specific elevation of PS-PLA1 in SLE suggests that lysophosphatidylserine (LPS) generated from PS-PLA1 may be involved in the pathogenesis of SLE.

Comparison of Mycophenolate Mofetil and Intravenous Cyclophosphamide As Induction Therapy in Korean Patients with Lupus Nephritis. Dong-Jin Park, Kyung-Eun Lee, Tae-Jong Kim, Yong-Wook Park and Shin-Seok Lee. Chonnam National University Medical School, Gwangju, South Korea

Background/Purpose: Although intravenous cyclophosphamide (IVC) pulses are generally accepted as standard therapy for induction treatment of active proliferative lupus nephritis (LN), several clinical trials have suggested that mycophenolate mofetil (MMF) is at least as effective as IVC. The efficacy of IVC varies among racial and ethnic groups and IVC is less effective in patients of African or Hispanic descent. In contrast, MMF seems to be consistently effective in all racial/ethnic groups. Nevertheless, it is necessary to compare these two treatment modalities among different racial or ethnic groups, particularly in Asia. This study compared the efficacy of MMF and IVC as induction treatment for LN in ethnically homogeneous Korean patients.

Methods: This study enrolled 49 LN patients with available kidney biopsy specimens. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by reviewing the patients' charts. The renal biopsy specimens were reclassified according to the ISN-RPS classification, by a renal pathologist blinded to the previous classification. The renal outcome, i.e., complete response (CR), partial response (PR), and non-response (NR), after 6 and 12 months was defined according to the ACR 2006 response criteria for proliferative and membranous renal disease in clinical trials.

Results: Of the 49 patients, 28 (57.1%) were treated with IVC and 21 (42.9%) with MMF, both in combination with prednisolone. The baseline characteristics of the two groups were comparable, except that the IVC-treated patients had lower platelet counts ($p=0.026$), lower C3 levels ($p=0.007$), and higher activity scores ($p=0.021$) in the renal biopsy compared to the MMF-treated patients. CR was seen in 9 of 21 patients (42.9%) receiving MMF and 14 of 28 patients (50.0%) receiving IVC after 6 months treatment ($p= 0.450$) and in 11 of 21 patients (52.4%) in the MMF group and 13 of 28 patients (46.4%) in the IVC group at 1 year ($p= 0.745$). The number of patients achieving PR and NR did not differ significantly at 6 and 12 months between the treatment groups.

Conclusion: These findings suggest that the efficacy of oral MMF at 1 year does not differ from that of IVC in induction treatment of LN in ethnically homogeneous Korean patients. MMF may be considered first-line induction therapy for treating LN in these patients.

A Clinical Analysis of Adult Patients with Autoimmune- and Infection-Associated Hemophagocytic Lymphohistiocytosis. Min W. So[1], Bon S. Koo[1], You J. Kim[1], Yong-G Kim[1], Wook J. Seo[2], Chang-K Lee[1] and Bin Yoo[1]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is a rare but potentially life-threatening disease. Secondary HLH is associated with various clinical conditions, including infections, malignancies, and autoimmune diseases. Although many previous studies reviewed the clinical features, treatments, and outcomes of autoimmune- or infection-associated HLH, respectively, only a few studies have evaluated the differences between autoimmune- and infection-associated HLH to these factors. The purpose of our study was to identify and compare the clinical features, treatments, and outcomes of patients with secondary HLH caused by diseases other than malignancy at a single institution.

Methods: We retrospectively collected data on 33 adult patients who were diagnosed with autoimmune- or infection-associated HLH from 1997 to 2011 at a single tertiary hospital. Patients were eligible if they were over 15 years of age and met five criteria for HLH. Patients were classified as having autoimmune- or infection-associated HLH and the medical data on each patient were reviewed.

Results: Twelve patients were diagnosed as having autoimmune-associated HLH. Among the 12 patients, nine patients had SLE and three patients had adult-onset still's disease. Steroid therapy was given to all patients. Eleven patients recovered from autoimmune associated HLH. Twenty one patients were diagnosed as having infection-associated HLH. The most common infection associated with HLH was EBV (n = 19, 90.5%) followed by hepatitis A virus (n = 1, 4.8%) and parvovirus B19 (n = 1, 4.8%). Thirteen patients were treated according to the HLH protocol. Among the 21 patients, five patients underwent allogenic HCT. Only four patients survived without disease; three of the five transplant recipients and one of the 16 patients who had received no transplants. With respect to clinical characteristics, splenomegaly was more common in patients with infection-associated HLH (p = 0.010). With respect to laboratory characteristics, the platelet count and the level of ESR were lower in the infection-associated HLH group (p = 0.009 and p = 0.020). Hyperbilirubinemia was more prominent in the infection-associated HLH group (p = 0.015). Concerning treatment, patients with infection-associated HLH received the more commonly administered cyclosporine A and etoposide therapy than patients with autoimmune-associated HLH. Patients with infection-associated HLH (19.0%) had a lower survival rate than patients with autoimmune-associated HLH (91.7%).

Conclusion: Secondary HLH is a syndrome-based diagnosis as it encompasses various heterogeneous conditions. In the present study, autoimmune-associated HLH has mild disease activity and is included mild disease entity. Although there is still considerable debate regarding the ideal initial management approach for patients with autoimmune-associated HLH, corticosteroid administration alone seems to be sufficient. In secondary HLH, an exhaustive search for an underlying cause, such as infection or autoimmune disease, is warranted as the results of such research may guide treatment regimens and help predict outcomes.

High Sensitivity C-Reactive Protein, Disease Activity and Cardiovascular Risk Factors in Systemic Lupus Erythematosus. Chi Chiu Mok[1], Daniel Birmingham[2], Ling Yin Ho[1] and Brad H. Rovin[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Ohio State University Medical Center, Columbus, OH

Background/Purpose: To study the level of high-sensitivity C-reactive protein (hsCRP) and its relationship with disease activity, damage and cardiovascular risk factors in patients with systemic lupus erythematosus (SLE).

Methods: Consecutive patients who fulfilled [3]4 ACR criteria for SLE but did not have concurrent infection were recruited. Blood was assayed for hsCRP and markers of SLE activity. Clinical activity, organ damage of SLE (SLE damage index; SDI) and cardiovascular risk factors were also assessed. Linear regression was performed for the relationship among hsCRP, SLE activity, damage and cardiovascular risk factors.

Results: 303 consecutive SLE patients were invited for this study but 14 were excluded because of evidence of active infection. Two hundred and eight-nine SLE patients were finally studied (94% women; age 39.0 ± 13.1 years; SLE duration 7.8 ± 6.7 years). The mean SLEDAI score was 4.9 ± 5.6 and clinically active SLE was present in 122(42%) patients. The mean hsCRP level was 4.87 ± 12.7mg/L, and 28(23%) patients with active SLE had undetectable hsCRP (<0.3mg/L). In contrast, 51 patients (80%) who did not have clinical or serological activity (SLEDAI score = 0; N=64) had undetectable hsCRP. Linear regression revealed a significant correlation between hsCRP and musculoskeletal (Beta=0.21), hematological (Beta=0.19), serosal (Beta=0.46) and clinical SLEDAI score (Beta=0.24), adjusting for age, sex, body mass index, creatinine and the use of various medications (p<0.005 in all). Levels of hsCRP correlated significantly with anti-dsDNA titer (Beta=0.33; p<0.001) but not with complement C3 (Beta=0.07; p=0.26). Significantly more patients with hsCRP>3.0mg/L were men and chronic smokers, and had diabetes mellitus, dyslipidemia (higher atherogenic index and total / HDL cholesterol ratio) and history of arterial thrombosis. HsCRP level correlated significantly with SDI scores in the pulmonary and endocrine system after adjustment for similar covariates.

Conclusion: hsCRP level is detectable in 77% of SLE patients with clinically active disease and correlates with SLEDAI scores, particularly serositis and in the musculoskeletal and hematological systems. Elevated hsCRP in SLE is associated with certain cardiovascular risk factors and history of arterial thromboembolism.

Epratuzumab-Treated Systemic Lupus Erythematosus Patients Report Improvements in Health-Related Quality of Life: Final Results from an Open-Label Extension Study (SL0006). V. Strand[1], K. Hobbs[2], D.J. Wallace[3], K. Kalunian[4], B. Kilgallen[5], E. Nikaï[6], W.A. Wegener[7] and D.M. Goldenberg[8]. [1]Stanford University, Palo Alto, CA, [2]Denver Arthritis Clinic, Denver, CO, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]UCSD School of Medicine, La Jolla, CA, [5]UCB Pharma, Smyrna, GA, [6]UCB Pharma, Brussels, Belgium, [7]Immunomedics Inc, Morris Plains, NJ, [8]Centre for Molecular Medicine and Immunology, Morris Plains, NJ

Background/Purpose: Epratuzumab, a monoclonal antibody targeting CD22, is in development for the treatment of systemic lupus erythematosus (SLE). Two randomized controlled trials (RCTs): ALLEVIATE 1 and 2 were prematurely terminated because of interruption of drug supply. SL0006 was an open-label extension study in which patients previously enrolled in the ALLEVIATE trials received epratuzumab.[1] Assessment of health-related quality of life (HRQoL) alongside measures of disease activity and damage is recommended in SLE RCTs and provides a comprehensive view of therapeutic responses.[2,3] This presentation reports final data from SL0006 on the effect of epratuzumab on HRQoL measured using the 36-item Short Form Health Survey (SF-36).

Methods: All patients enrolled in ALLEVIATE US sites who received randomized treatment (n = 60) and satisfied all inclusion criteria were eligible for enrollment in SL0006. Twenty-nine patients (90% female, 79% Caucasian, mean age 40 years) entered SL0006, having received placebo (n = 8), 360 (n = 17) or 720 (n = 4) mg/m^2 epratuzumab during the ALLEVIATE double-blind trials. In SL0006, all patients received 12-week cycles of 360 mg/m^2 epratuzumab; two infusions on days 1 and 8 of each cycle. SF-36 was assessed at screening and every 4 weeks thereafter. Mean changes were compared to ALLEVIATE baseline and SL0006 screening values.

Results: The table shows means and mean changes in PCS and MCS and individual SF-36 domain scores vs age- and gender-matched norms.[4] At ALLEVIATE baseline, PCS and MCS scores were approximately 2 and 1 standard deviations below normative values, respectively; domain

scores 7.9–48.5 points lower than age- and gender-matched norms, reflecting the broad impact of active SLE on HRQoL. At the SL0006 screening visit, mean changes from ALLEVIATE baseline (BL) in SF-36 PCS and 5 domain scores met or exceeded minimal clinically important differences (MCID). Throughout SL0006, these improvements were maintained or improved up to and including week 192, after which patients numbers were <50% of the screening population. Changes from ALLEVIATE baseline scores were ≥ MCID in PCS and all its domains at all timepoints, apart from RE and MH, where numerical improvements were evident and ≥ MCID at some visits. Further improvement during SL0006 was evidenced by clinically meaningful changes from the screening visit at most timepoints in PCS, RP, BP, GH, VT and SF, and at the last available visit for PCS RP, BP and SF.

Key ...

Cells shaded with this colour show <u>mean change from ALLEVIATE baseline ≥ MCID</u> (≥5.0 for SF-36 domains and ≥2.5 for PCS and MCS)

Cells shaded with this colour show <u>mean change from SL0006 screening ≥ MCID</u> (≥5.0 for SF-36 domains and ≥2.5 for PCS and MCS)

Metabolic Syndrome Is Not Only a Risk Factor for Cardiovascular Events in Systemic Lupus Erythematosus but Also Associated with Cumulative Organ Damage: A Cross-Sectional Analysis of 311 Patients. Semra Ertan-Demir[1], Bahar Artim-Esen[1], Yasemin Sahinkaya[1], Özlem Pehlivan[1], Nilüfer Alpay-Kanitez[1], Ahmet Omma[1], Burak Erer[2], Sevil Kamali[1], Ahmet Gul[1], Orhan Aral[1], Lale Ocal[1] and Murat Inanc[1]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have increased rates of cardiovascular (CV) events that are one of the major causes of mortality. In addition to the traditional CV risk factors, disease related features may contribute to accelerated atherosclerosis. The metabolic syndrome (MetS), defined by clustering of traditional CV risk factors, is reported to be increased in SLE. The aim of this study was to determine the prevalence of MetS and CV events in SLE patients and to study the link between these and SLE related factors.

Methods: Data of 311 SLE patients attending to the lupus clinic and fulfilling ACR classification criteria were collected from the records including demographic and clinical features, history of CV diseases and phenotype and characteristics of MetS as defined by the National Cholesterol Educational Programme Adult Treatment Panel III (NCEP ATP III). CV events were defined as documented coronary artery disease and cerebrovascular disease including myocardial infarction and stroke. Association with clinical features, disease duration, SLICC damage index and treatment of SLE were assessed in patients with MetS and without MetS.

Results: The mean age of the patients was 40,2± 13,4 years and (89%) were female. The mean disease duration was 112,5 ±84 months, and the mean SLICC damage score was 1,05 ± 1,5. Coronary artery disease was present in 11.1% and cerebrovascular disease was in 5.4%. The prevalence of cardiovascular events was 15.2% and of MetS was 19%. The most frequent and the least frequent criteria of MetS in SLE patients were abdominal obesity (%51,2) and hyperglycemia (%10,3) respectively. Comparing SLE patients with MetS and without MetS, age (p=0,001), cumulative damage (p<0,001), disease duration (p=0,026) and CV events (p=0,001) were associated significantly with MetS. SLE disease features and treatment modalities were not associated with MetS. CV events were related to disease duration (p=0,05), damage (p<0,001), pericarditis (p<0,001), hematologic involvement (p=0,006), lymphopenia (p<0,001), thrombocytopenia (p=0,002), neurological involvement (p<0,001) and antiphospholipid (APL) antibody positivity (p=0,008). No relationship was found between immunosuppressive drug usage or high dose corticosteroid treatment with CV events, whereas HCQ use was found protective [p= 0,005; OR: 0,32 (0,15–0,69)].

Conclusion: In SLE patients mainly consisted of young females, the prevalance of MetS was 19% and CV events was 15.2%. Mets was associated with CV events, age, disease duration and cumulative damage whereas clinical and serological features of SLE and treatment were not related to MetS. CV events was also associated with disease duration, organ damage, pericarditis, hematological involvement, neurological involvement and the presence of APL antibodies. There was a significant protective effect of HCQ from CV events in SLE. The prevention of MetS and long term use of HCQ are warranted to improve prognosis in SLE.

2254

Discoid Lupus in Patients with Systemic Lupus Erythematosus. Ghassan AlJohani, Dominique Ibanez, D. D. Gladman and Murray B. Urowitz. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Discoid lupus lesions occur in 20% of patients with SLE at some point in their disease course, and are often resistant to therapy. Atrophy, scarring, and pigmentation are often observed consequences. Recently poor response to hydroxychloroquine has been reported among SLE patients as compared with discoid lupus erythematosus (DLE) patients without SLE.

The purpose of this study was to evaluate clinical outcome of active discoid lesions in patients with SLE and examine associated features of active discoid lupus.

Methods: Patients with active discoid lupus were identified from the University of Toronto lupus clinic, a longitudinal observational cohort study of patients with SLE diagnosed on the basis of 4 ACR criteria or 3 criteria and a biopsy positive for lupus. For each patient, information on time of resolution and chronic changes of discoid lupus lesion were obtained from the database and confirmed through chart reviews. Associated features studied included demographic features, smoking, and disease activity (SLEDAI-2K). Descriptive statistics are used to describe the study population.

Results: 68 patients with active discoid lupus were identified from among 723 inception patients (9.4%). which represented 15% of the total number of patients who had any lupus rash. The age at diagnosis of SLE was 37.2 ± 11.9 years while age at diagnosis of DLE was 39.6–11.9. 59 (86.8%) were female and 41 (60.3%) were Caucasian. 30 (44.1%) patients were smokers. SLEDAI-2K was 8.66 ± 7.72 at discoid onset and adjusted mean SLEDAI was 7.51 ± 6.68. 43 (63.2%) patients were on steroid during the episode with mean steroid dose of 16.8 ± 11.6 mg/day. 56 (82.4%) were on antimalarial agents while 18 (26.5%) were on immunosuppressive agents. During their follow up 68 patients had a total of 82 episodes of DLE. Each episode lasted for 1.77 ± 2.10 years. SLE duration at discoid start is 2.3 ± 4.1 years. Pre-existing scars from previous active DLE were present in 21 (30.9%) patients while 11 (16.2%) patients developed new scars during episode and 36 (52.9%) patients never developed scars.

Conclusion: Discoid lupus is a common rash among SLE patients. SLE patients with DLE had active lupus and were taking significant doses of steroid. The duration of the discoid episode was 1.77 ± 2.10 years and 47.1% of patients developed scars.

2255

Apolipoprotein B Containing Lipoprotein Subclasses and Subclinical Atherosclerosis in Patients with Systemic Lupus Erythematosus (SLE).
Adnan Kiani[1], Hong Fang[1], Ehtisham Akhter[1], Carmen Quiroga[2], Nancy Simpson[2], Petar Alaupovic[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma, OK

Background/Purpose: Traditional classification in lipid biology using HDL, LDL and VLDL does not provide information on lipoprotein function. Apolipoproteins, (which are protein components of plasma lipoproteins including A, B, C, D, E) with their different composition, metabolic and atherogenic properties provide a much detailed insight on lipoprotein functioning. In particular ApoB/A-1 ratio is associated with atherogenic LDL and development of cardiovascular disease. Lipoprotein function Apolipoprotein C-III and its corresponding Apolipoprotein B subclasses have been shown to be independent risk factors for cardiovascular disease in the general population (Circulation. 102:1886–92;2000 and Aterioscler Thromb Vasc Biol. 23:853–858;2003)). We explored the association between these non-traditional risk factors with subclinical measures of atherosclerosis (coronary artery calcium) in SLE.

Methods: 58 SLE patients (97% female, 58% Caucasian, 40% African-American, 2% other, mean age 44±11 yrs) had measurement of apolipoprotein and lipoproteins measured by immunoturbidimetric procedures, electroimmunoassays and immunoprecipitation. Coronary artery calcium was measured by helical CT. The p-value in the table is adjusted for age, gender, and ethnicity.

Results:

Table 1. Coronary artery calcium (CAC) and Lipoprotein Subclasses

Measures Traditional CVRF	N Normal	N Abnormal	Log_e(CAC score+1) Mean (SD) Normal	Log_e(CAC score+1) Mean (SD) Abnormal	P-value (adjusted)
Total Cholesterol (mg/dl)	42	16	0.97 (1.64)	2.20 (2.46)	0.092
Triglycerides (mg/dl)	48	10	1.14 (1.57)	2.15 (3.23)	0.20
VLDL-C (mg/dl)	41	17	1.23 (1.61)	1.52 (2.65)	0.89
LDL-C (mg/dl)	40	14	1.02 (1.66)	2.41 (2.56)	0.083
HDL-C (mg/dl)	10	44	1.17 (1.30)	1.43 (2.14)	0.39
Cardioprotective					
ApoA-I	21	37	0.80 (1.26)	1.60 (2.22)	0.15
LpA-I	38	20	1.18 (1.95)	1.57 (1.99)	0.41
LpA-I:A-II	15	43	1.08 (1.40)	1.39 (2.12)	0.39
Atherogenic					
LpB:E+LpB:C:E	39	19	1.07 (1.78)	1.81 (2.25)	0.24
ApoB	46	12	1.32 (1.82)	1.28 (2.49)	0.60
LpB	55	3	1.34 (1.99)	0.80 (1.10)	0.47
LpB:C	55	3	1.38 (1.98)	0.00 (0.00)	0.24
ApoC-III	46	7	1.30 (1.90)	2.08 (2.75)	0.60
ApoC-III-HS	23	30	0.96 (1.55)	1.75 (2.28)	0.17
ApoC-III-HP	50	3	1.4 (2.0)	1.1 (1.9)	0.76
CIII-R	–	53	–	1.41 (2.02)	–
LpA-II:B:C:D:E	36	22	1.23 (1.78)	1.44 (2.25)	0.63
ApoB/ApoA-I	44	14	1.36 (1.92)	1.14 (2.12)	0.97

Conclusion: It has been shown that apoC-III containing apoB lipoproteins are risk factors for atherosclerotic progression in rheumatoid arthritis patients (Arthritis Care Res doi:10.1002.21646;2012). In our study there was no association between any of the markers with coronary artery calcium. However, we did show that cardioprotective components including LpA-1 and ApoA-I were decreased whereas atherogenic LpA-II:B:C:D:E was increased in our patient population compared to controls. Further studies with larger sample size are warranted to confirm our findings.

2256

A Population of IL-21 Producing CD4+ T Cells Correlates with Disease Damage in Systemic Lupus Erythematosus (SLE) Patients.
Babak Noamani[1], Stacey Morrison[2], Dafna Gladman[3], Jorge Sanchez-Guerrero[4], Murray B. Urowitz[3], Joan E. Wither[5] and Carolina Landolt-Marticorena[6]. [1]Toronto Western Research Institute, Toronto, ON, [2]The Toronto Western Hospital, Toronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON, [4]Mount Sinai Hospital, University Health Network, Toronto, ON, [5]Toronto Western Research Institute, University Health Network, Toronto, ON, [6]University of Toronto, Toronto, ON

Background/Purpose: SLE mice models implicate IL-21, a T cell-derived cytokine, in disease pathogenesis with cytokine over-expression promoting the development of auto-antibodies and lupus-like clinical syndromes. IL-21 dysregulation has also been noted in human SLE with a subset of patients having an increased proportion of IL-21-producing CD4+ T cells. This study aims to examine the relationship between IL-21 synthesis and distinct clinical phenotypes in human SLE.

Methods: SLE patients (n = 42) fulfilling ≥ 4 ACR criteria were recruited from an established longitudinal lupus cohort. Clinical and biochemical assessment at the time of recruitment permitted calculation of disease activity (SLEDAI-2K) and SLICC damage index. Healthy age matched controls (n = 19) were also recruited. Peripheral blood mononuclear cells were isolated over a Ficoll gradient and stimulated for 4 hours with PMA/ionomycin in the presence of GolgiStop. Cells were analyzed by flow cytometry following cell surface (anti-CD3, -CD4) and intracellular staining (anti-IL-21, -IL-17). A Mann Whitney non-parametric test was used for comparisons between groups. Elevated IL-21 expression for selected CD4+ populations was defined as values ≥ 2 standard deviations above the mean for controls.

Results: A significant proportion (26.4%) of SLE patients was found to have increased levels of CD4+ IL-21 producing T cells when compared to controls. To refine this cellular population the proportion of IL-21+, IL-17+ and double positive CD4 T cells was examined. The proportion of IL-21+IL-17^{neg}CD4+ cells was significantly elevated in SLE patients when compared to controls (p = 0.03). The IL-17+IL-21^{neg}CD4+ SLE compartment was also increased but did not reach statistical significance. No differences were noted in the double positive (IL-21+IL-17+) CD4+ T cell populations. To examine the relationship between the IL-21+IL17^{neg}CD4+ population and specific clinical phenotypes patients were segregated on the basis of the proportion of IL-21+IL17^{neg}CD4+ cells into IL-21 high patients (n = 10) with an equal number of patients with the lowest IL-21 expression selected as a comparator group. No statistically significant differences between these two groups (high vs low, mean ± SD) with regards to disease activity (5.8 ± 3.5 vs 5.7 ± 6.4), anti-dsDNA antibodies (35.6 ± 39.8 vs 44.0 ± 41.9) or complement levels (0.89 ± 0.18 vs 0.98 ± 0.38) was noted. IL-21 high patients had significantly higher disease damage index (SDI, p < 0.0001) than IL-21 low individuals. As a corollary patients were stratified into quartiles based on their SDI score. Patients with the highest SDI score had statistically significant higher proportion of IL-21+ IL17^{neg} CD4+ T cells (p = 0.02) than patients in the lowest quartile.

Conclusion: These results suggest that T cell population(s) contributing to IL-21 dysregulation in SLE reside within the IL-21+ IL-17^{neg} CD4+ T cell subset. Further, as disease damage can be viewed as a surrogate marker of disease severity, this data implies that increased IL-21 synthesis may be linked to more aggressive forms of SLE.

Association of Low Vitamin D with High Disease Activity in an Australian Systemic Lupus Erythematosus Cohort.
Kristy S. Yap[1], Alberta Y. Hoi[2] and Eric F. Morand[2]. [1]Monash Medical Centre, Clayton, Australia, [2]Monash University, Melbourne, Australia

Background/Purpose: Previous cross-sectional studies suggest that low vitamin D may be associated with higher disease activity in SLE. Vitamin D status varies with geographic location and no studies have been reported in the Southern hemisphere. The aim of this study was to determine the relationship between Vitamin D and disease activity in SLE patients in an Australian centre.

Methods: Data was collected prospectively on patients with SLE (>4 criteria) in the Monash Lupus Clinic in Melbourne Australia between January 1 2008 and January 1 2011 who had disease activity (SLEDAI-2k) and serum 25-hydroxyvitamin D concentration (VD25) measured at the same visit. Where multiple values were available, the assessment with lowest VD25 was used (n=119).

Results: Patients with VD25 in the lowest quartile had significantly higher SLEDAI (7.7±1.3) compared to those in the highest quartile (3.9±0.8, p=0.014). Accordingly, VD25 deficiency (VD25 ≤40, n=28) was associated with significantly increased SLEDAI (7.7±1.3) compared to patients with VD25 >40 (4.8±0.6, P=0.02). The relative risk of high disease activity (SLEDAI>8) for patients with VD25 deficiency was 1.6 (95% CI 1.1–2.2, P=0.002). In parallel, high disease activity was associated with significantly lower VD25 compared to patients with SLEDAI<8 (P= 0.048) or patients with inactive disease (SLEDAI<4, P=0.0073). When assessing all values, a significant negative correlation between SLEDAI and VD25 was observed (Spearman r =0.2, p =0.03). There was no association of VD25 with corticosteroid use, SLICC SLE Damage Index (SDI), or ethnicity.Vitamin D supplement use (n=53) was significantly more common among patients using corticosteroids (P=0.0001) and was associated with significantly higher VD25 (P=0.009). However, there was no association between Vitamin D supplementation and SLEDAI.

Conclusion: In a cohort of Australian patients with SLE, Vitamin D correlates negatively with disease activity. Prospective studies should examine the predictive value of Vitamin D levels and therapeutic effect of Vitamin D.

Risk Factors for Total Joint Replacement in Systemic Lupus Erythematosus Patients with Avascular Necrosis. Jennifer Lee[1], Dae-Jun Kim[1], Jae Ho Lee[1], Seung Min Jung[1], Seung-Ki Kwok[1], Ji Hyeon Ju[2], Kyung-Su Park[1], Sung-Hwan Park[1] and Ho-Youn Kim[1]. [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, Seoul, South Korea, [2]College of Medicine, The Catholic University of Korea, Stanford University, Seoul, Palo Alto, CA

Background/Purpose: Avascular necrosis (AVN) is a common manifestation in patients with systemic lupus erythematosus (SLE) and is associated with significant morbidity. A number of studies have been conducted to elucidate the risk factors for the development of AVN. However, clinical outcomes of AVN in patients with SLE have not been highlighted. We aimed to determine the clinical features predictive of the development of AVN in SLE patients and to elucidate the risk factors for the total joint replacement (TJR) of the affected joints in SLE patients with AVN.

Methods: The medical records of 938 patients with SLE admitted to a single center in Seoul, Korea from January 1990 to April 2012 were reviewed and 66 patients with AVN were identified. A hundred and one age-and sex-matched patients with SLE who didn't have apparent AVN were included as disease controls. The independent risk factors for the development of AVN were examined by univariate and multivariate logistic regression analyses. The timing and cumulative risk of TJR were identified by Kaplan-Meier methods. The independent risk factors for TJR were determined by univariate and multivariate Cox proportional hazards regression analyses.

Results: The prevalence AVN was 7.0%. Multivariate logistic regression analysis revealed that the independent risk factors for the development of AVN included discoid rash (odds ratio (OR) 7.861, p=0.022), lymphopenia (OR 12.316, p=0.003), cushingoid feature (OR 3.029, p=0.02). Among 66 patients with AVN, 61 had AVN of the hip, 10 had AVN of knee and 1 had AVN of shoulder. Thirty-eight patients underwent total joint replacement (TJR) surgery. In univariate analysis, male patients, bilateral joint involvement, neuropsychiatric lupus, renal involvement, advanced radiological stage of AVN (Association for Research on Osseous Circulation (ARCO) stage) at the time of diagnosis were included as predictive risk factors for TJR. In multivariate analysis, only advanced radiological stage of AVN at the time of diagnosis was included as an independent risk factor for TJR (hazard ratio 2.464, p=0.038).

Conclusion: Our results demonstrated that advanced radiological stage at the onset of AVN is an independent predictable risk factor for TJR in SLE patients with AVN.

Limitations of Current Treatment for Systemic Lupus Erythematosus: A Patient and Physician Survey. V. Strand[1], C. Galateanu[2], S. Lobosco[3], D.S. Pushparajah[2], J. Sayers[4] and R.F. van Vollenhoven[5]. [1]Stanford University, Portola Valley, CA, [2]UCB Pharma, Brussels, Belgium, [3]Adelphi Real World Ltd., Macclesfield, United Kingdom, [4]Adelph Real World Ltd., Macclesfield, United Kingdom, [5]The Karolinska Institute, Stockholm, Sweden

Background/Purpose: Current SLE treatment regimens follow an 'add-on' paradigm: typically, therapies are added as the activity of a patient's disease increases. Most current treatments, particularly corticosteroids (CS) and immunosuppressants (IM), frequently have severe side effects that contribute to damage in SLE. This abstract reports an analysis of data drawn from a cross-sectional survey of physicians and their consulting lupus patients.

Methods: Data were extracted from the Adelphi Real World Lupus Disease-Specific Programme (DSP), a cross-sectional survey of 233 physicians and their patients conducted between December 2009 and May 2010 in the USA, France, Germany, Italy, Spain, and the UK. Each physician completed a comprehensive patient record form for their five most recently seen SLE patients. Data collected included subjective rating of disease activity, flare occurrence, treatment satisfaction, and drug classes received. Patients were invited to fill out a self-completion questionnaire, which included EQ5D and the FACIT fatigue scale. This analysis focused on three key drug classes: CS, IM, and antimalarials (AM).

Results: The Adelphi Lupus DSP survey included 886 patients, of whom 515 completed a self-assessment questionnaire. The population was 90% female with a mean age of 42 years. A total of 618 patients (70%) were classified as having mild disease activity, compared to 247 (28%) with moderate disease activity, and 21 (2%) with severe disease activity. The numbers of patients in each disease activity group flaring in the last 12 months were 138 (22.3%), 126 (51.0%), and 12 (57.1%), respectively. The proportions of patients receiving different regimens are listed in the table. SLE treatment regimens including CS (with or without other classes) were associated with more active disease (p < 0.0001) as were regimens that included ≥ 2 drug classes (p < 0.001). Patients reporting flares were more likely to be receiving ≥ 2 vs < 2 key drug classes (p < 0.001). A greater proportion of patients reported satisfaction with their treatment regimen when it did not include CS than when it did (81% vs 68%; p < 0.01). Patients receiving CS reported lower mean EQ5D than those who were not (0.731 vs 0.792; p = 0.0002). However, those receiving CS did report better fatigue levels than those who were not (35.0 vs 38.4, p = 0.0001). A greater proportion of physicians also reported more satisfaction with their patient's treatment regimen when it did not include CS (p < 0.001).

	No classes (66)	One class only (321)	Two classes (403)	All 3 classes (95)	CS only (58)	AM only (200)	IM only or IM + AM (100)	CS + IM or CS + AM (366)
Mild (618)	57 (9.2%)	270 (43.7%)	250 (40.5%)	40 (6.5%)	40 (6.5%)	183 (29.6%)	71 (11.5%)	226 (36.6%)
Moderate (247)	9 (3.6%)	45 (18.2%)	143 (57.9%)	50 (20.2%)	15 (6.1%)	16 (6.5%)	27 (10.9%)	130 (52.6%)
Severe (21)	0 (0.0%)	6 (28.6%)	10 (47.6%)	5 (23.8%)	3 (14.3%)	1 (4.8%)	2 (9.5%)	10 (47.6%)

THERAPEUTIC CLASSES (CS, AM AND IM)

Conclusion: More active disease is associated with flare in the last 12 months, ≥ 2 classes of therapy, and use of CS specifically. Unexpectedly, physicians and patients accepted moderate or high levels of disease activity while receiving multiple medications, suggesting that they had become resigned to uncontrolled disease activity. These results support the need for new therapies for SLE, and treatment algorithms incorporating such therapies.

Serum DNAse I Anti DNAse I Antibodies, CRP and Antibodies to CRP Relation to Disease Activity in Systemic Lupus Eryhtematous: Longitudinal Studies. Ramnath Misra[1], Avadesh Pratap[2], Amit Singh[1] and Amita Aggarwal[1]. [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [2]Technician, Lucknow, India

Background/Purpose: Defective clearance of both nucleosomes and immune complexes has been suggested to intiate and perpetuate the disease.

Defects in DNAse I gene in mice have shown SLE like symptoms, also in humans the decreased levels and levels of DNAse I have been shown. There are few studies in SLE patients looking at these defects, a systemic study is lacking, thus we proposed to study these mechanisms.

Methods: One hundred sixtythree patients (Female: Male 13:1) were included in the study after written consent were obtained. Eightyfour patients were having active disease as measured by Systemic lupus erythematosus disease activity index (SLEDAI) core of more than 4. Sera samples were collected and stored in aliquots at −70 degree C till use. DNAse levels in sera both before and after heating at 56 degree C for 10 minutes to destroy the inhibitors of DNAse such as G protein and actin. DNAse I level were assayed in the sera of 132 patients and 52 normals individuals were done using Radial Enzyme Diffusion assay and the levels were measured using DNAse I as standard. C3, C4 and CRP were done by nephelometry. Antibodies to dsDNA and anti-DNAse I antibodies levels were levels in serum were quantitated by ELISA using commercial and in-house ELISA respectively. The levels of DNAse I, antibodies to DNAse I and CRP were correlated with SLEDAI and between each other statistically.

Results: In patients the median DNAse I levels for pre-heated serum was 2.9 (range 0–39) while the median levels for post heated serum (indicating the inhibitor free levels of DNAse I in serum) was 5.6 (range 3.9–39). In normal individuals the median levels in preheated serum was 8.5 (range 0–26) while median levels for post heated was 13.75 (range 0–39).The DNAse I levels was significantly higher ($p < 0.0001$) in inhbibitor depleted sera as compared to pre-heated ones in both patients and normals. Further, post heated DNAse I levels, was significantly, ($p < 0.0001$) reduced in patients as compared to normals. However, there was no correlation with activity status of patients as measured by SLEDAI. DNAse I levels significantly correlated with age ($r = 0.222$, $p < 0.05$). CRP, which also helps in clearing nucleosome levels in these patients were not significantly correlated with the levels of C3, C4 and anti-dsDNA antibodies levels. The median antibodies to DNAse I levels was 44.6 arbitrary unit (AU) (range 5.11–1522.08) as compared to healthy controls of 32.4 AU (range 7.77–133.08).The level of antibodies to DNAse I was higher in patients compared to normals although difference was not statistically different. Antibodies to DNAse correlated with $r = 0.18$, $p = 0.26$) DNAse I levels. There was no correlation between levels of anti-DNAse I antibodies with SLEDAI.

Conclusion: The levels of DNAse I are reduced in the SLE patients and the levels of inhibitor to DNAse I are high in serum of these patients. The levels of anti-DNAse I antibodies are positively correlated with the DNAse I levels. However, there was no correlation of these biomarkers with composite score of disease activity

Ovarian Reserve Markers in Reproductive Age Women with Systemic Lupus Erythematosus. Olívio B. Malheiro, Carolina P. Rezende, Gilda A. Ferreira and Fernando M. Reis. Federal University of Minas Gerais, Belo Horizonte, Brazil

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem disease, which affects mostly women at reproductive age, and can promote premature ovarian dysfunction related to factors associated to rheumatic disease or its treatment. The assessment of indicators of ovarian reserve can determine if there are differences between these patients and the general population, prior to the establishment of the climacteric. The aim of this study was to evaluate if there are differences in ovarian reserve markers in systemic lupus erythematosus (SLE) patients compared to controls, and explore the relationship of such markers with clinical and treatment features of SLE patients, in addition to inflamatory activity (SLEDAI/ACR) and damage (SLICC/ACR-DI) disease scores.

Methods: This was a controlled cross-sectional study including 27 women with SLE and 27 controls. All participants were between 18 and 40 years, were eumenorrheic and did not use hormone therapy or hormone contraceptives in the past 6 months. Clinical data were assessed at a regular follow up visit, serum concentrations of follicle stimulating hormone (FSH) and anti-mullerian hormone (AMH), and through transvaginal ultrasound antral follicle count were assessed at early follicular phase of a subsequent menstrual cycle.

Results: Mean age of SLE patients was 30.9 years (SD±4.8) and had 102.7 months (SD±66.7) of lenth disease. We found no difference between SLE group and control group at analysis of AFC [median (interquartile interval) 7 (5–13) vs. 11 (7–12), p=0.076], FSH [6.44 (4.19–7.69) vs. 7.5 (6.03–8.09) mUI/ml, p=0.135] and AMH levels [1.23 (0.24–4.63) ng/ml vs.

1.52 (1.33–1.88) ng/ml, p=0.684]. However, AMH values in SLE group were more heterogeneous compared to control group. The presence of nephritis and the cumulative dose of cyclophosphamide were factors individually related to reduced ovarian reserve, by association with lower values of AFC and AMH. At multivariate logistic regression, control group was more likely to have higher AMH values than the SLE (OR 5.2, 95% CI 1.286–20.405, p=0.021) and in the SLE group, AMH was associated with lower maximum corticosteroid doses in the follow-up (OR 0.95, 95%CI 0.894–1.000, p=0.50). AFC was associated with lower scores of SLICC/ACR-DI (OR: 0.14, 95% CI 0.025–0.841, p=0.031).
Figure. Scatters showing comparison of ovarian reserve markers in SLE patients between and controls in medians: AFC (Figure A), FSH (Figure B), and AMH (Figure C).

Conclusion: SLE patients who were eumenorrheic had average values of ovarian reserve markers similar to controls. However, AMH had a wide range of values in that group, requiring study of other markers to clarify the best clinical application for it. Ovarian function is more compromised in patients with nephritis, high cumulated dose of cyclophsphamide and higher disease damage scores.

Hypogammaglobulinemia in Pediatric Systemic Lupus Erythematosus. Emilina Lim[1] and Megan A. Cooper[2]. [1]Washington University in Saint Louis- St. Louis Children's Hospital, St. Louis, MO, [2]Washington University, Saint Louis, MO

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by B cell activation, elevated serum IgG and prominent circulating immune complexes. However, hypogammaglobulinemia in SLE patients is thought to be rare and it is unclear whether this is associated with SLE or is a transient effect of immunosuppressive treatment. Approximately 1% of patients with common variable immunodeficiency (CVID) develop symptoms or laboratory abnormalities that support the diagnosis of SLE or will manifest an SLE-like syndrome. CVID can also rarely develop in patients with established SLE. We retrospectively reviewed our pediatric SLE cases at Washington University with the goal of identifying clinical and laboratory characteristics in patients with hypogammaglobulinemia.

Methods: 115 SLE cases seen in our Pediatric Rheumatology clinic from 1997–2011 were reviewed. Eighty six patients with inclusion criteria of having an IgG level within 3 months of diagnosis and more than one IgG level during follow-up were included in this study. Excluded were patients with insufficient data for SLEDAI scoring and presence of known immunodeficiency states. Hypogammaglobulinemia was defined as an IgG level <500 mg/dl (2 SD below mean for age in pediatric population) on more than two occasions. Analysis of the different variables was done using SPSS version 10 for Windows.

Results: Seven percent (6/86) of pediatric SLE patients were found to have hypogammaglobulinemia with a median onset of 27 months (0–72 months) after SLE diagnosis. There was no significant difference in the mean age of patients with and without hypogammaglobulinemia (13.66 years and 14.41 years respectively). The risk of developing hypogammaglobulinemia was 10x higher in males than female (p=0.009). There was no significant difference in the binned SLEDAI scores (≥10 and <10) between cohorts.

However, presence of lupus nephritis (p-value=0.004) and an IgG level of <1500 mg/dl at diagnosis (RR=4.88; 95% CI=1.00 – 24.97; p = 0.05) were both associated with hypogammaglobulinemia. Rituximab treatment did not significantly increase risk of developing hypogammaglobulinemia. Using multivariate analysis, male gender and an IgG level of less than 1500 mg/dl at diagnosis continued to show significant association with hypogammaglobulinemia in SLE. Double stranded DNA antibody, complement and albumin levels did not correlate with hypogammaglobulinemia. Interestingly, two patients with SLE and hypogammaglobulinemia had IgG levels less than 500 mg/dl within three months of diagnosis, suggesting that their hypogammaglobulinemia preceded or coincided with the onset of SLE. Two other patients exhibited concomitantly low IgA levels without symptoms. Two patients had recurrent sinopulmonary infections with poor to no vaccine response and required replacement IVIG treatment.

Conclusion: Immunoglobulin deficiency can co-exist with pediatric SLE independent of biologic drug treatment. Measurement of immunoglobulin levels in SLE could help identify patients at greater risk for infection that require more aggressive follow-up to reduce morbidity.

The Association Between Prior Pregnancy Morbidity and Cardiovascular Events in Women with Systemic Lupus Erythematosus. Megan Clowse[1], Eliza F. Chakravarty[2], Jill Buyon[3] and Gerald McGwin Jr.[4]. [1]Duke University Medical Center, Durham, NC, [2]Oklahoma Medical Research Foundation, Oklahoma City, CA, [3]New York University School of Medicine, New York, NY, [4]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Adverse pregnancy outcomes have been associated with increased cardiovascular disease in healthy women. We hypothesized that women with SLE and a history of adverse pregnancy outcomes would have a higher rate of cardiovascular events.

Methods: Prior pregnancy outcomes, cardiovascular risk factors and events were collected in 2010 and 2011 through a longitudinal lupus registry. Study participants were enrolled at 17 lupus centers across North America. At enrollment, each patient reported her prior pregnancies and outcomes, including live birth, week gestation (<37 weeks indicated preterm delivery), and preeclampsia. Cardiovascular events were recorded in the SLICC-Damage Index at study entry and included prior angina or CABG, myocardial infarction, or cerebrovascular accident. Prior medical history, including a diagnosis of hypertension, diabetes, and hypercholesterolemia, current medications, and prior and current laboratory values were also reported. Univariate and multivariate analyses compared the frequency of pregnancy morbidity (a pregnancy loss, a preterm delivery, or a pregnancy with preeclampsia) among women with and without cardiovascular events. Nulliparous women were excluded from the analysis.

Results: Data are available for 602 women, of whom 316 (52.5%) had at least one prior pregnancy morbidity. The average age of SLE diagnosis and LCTC enrollment was lower for women with a pregnancy morbidity (31.2 years and 43.8 years, respectively) compared to women without a pregnancy morbidity (34.3 and 46.6 years, p<0.01). Women with a prior pregnancy morbidity were more likely to have antiphospholipid syndrome (11.1% vs 4.2%, p=0.008). The systolic blood pressure measured at enrollment, the frequency of hypertension, and the use of antihypertensive medications at LCTC enrollment were all significantly higher among women with a history of pregnancy morbidity. In contrast, the frequency of diabetes mellitus, use of anti-cholesterol medications, and hypercholesterolemia at enrollment were not significantly different between the pregnancy groups. Despite the significant increase in hypertension, the frequency of overall cardiovascular events was not significantly different between the groups: 8.23% with pregnancy morbidity vs 6.64% without pregnancy morbidity, p=0.4. A multivariate analysis demonstrated that cardiovascular events were associated with older age at LCTC enrollment, hypertension, and APS, but not race, number of pregnancies, or pregnancy morbidity.

Conclusion: Prior pregnancy morbidity is not significantly associated with cardiovascular events in this large multi-center multiethnic/racial cohort of lupus patients. This may be due to the relative young age of the cohort with the average age less than 50 years at entry. The association of pregnancy morbidity with hypertension, however, suggests that these women may be a higher risk for future cardiovascular events.

Improving Outcomes for Pregnant Lupus Patients: Is There a Geographic Link? Darneesh Thornton-Johnson[1] and Daniel Albert[2]. [1]Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH, [2]Dartmouth-Hitchcock Medical Center, Geisel School of Medicine, Lebanon, NH

Background/Purpose: Systemic lupus erythematosus (SLE) is stated to lead to miscarriages, preterm births, and other complications among pregnant women previously diagnosed with the disease. According to the LUMINA cohort study headed by Dr. Graciela Alarcon, this is especially true for young women of African-American or Hispanic origin as they may have a genetic predisposition and lack of resources to effectively manage the illness. Despite the landmark LUMINA findings, there remain few sources on geographic disparities experienced by lupus patients. The current literature shows potential uses for geographic analysis particularly through the process of geocoding patient zip codes and the development of Medically Underserved Areas.

Methods: The authors, in consultation with a statistician, performed a secondary data analysis using logistic regression on the STATA statistical software package. The author analyzed the following variables: zip code, age, race, income, education, preterm birth of fetus, miscarriage/spontaneous abortion frequency, mode of delivery (vaginal or c-section) and corticosteroid injection amount (re: dosage).

Continuous variables, such as age and dosage amounts, were analyzed via descriptive statistics whereas dichotomous variables were analyzed via logistic regression. It was in the logistic regression that the authors were able to find statistically significant results. The authors soon compared the statistically significant variables with US Census-designated, Medically-Underserved Areas to reveal stunning results.

Results: Data analysis gave 3 US Census-designated urban areas and 3 US Census-designated rural areas of interest. Urban areas were the following: Bessemer, Alabama; Houston, Texas; Pasadena, Texas.

Many of the patients from the aforementioned areas within the dataset have high dosages of corticosteroids and inconsistent physician visit dates-- leading to more complications. Women who are able to go to the doctor regularly while pregnant can effectively manage the lupus with less corticosteroids (as indicated in the dataset) and other drugs to have a relatively safe pregnancy. If they can't do that, the pregnancy may be more problematic.

Conclusion: Women who live in rural areas also exhibited higher rates of pregnancy complications in terms of miscarriages when taken into consideration one's age, race, educational level and income gains. A factor why rural women suffer from the effects of the illness disproportionately may be due to educational attainment, income, and geographic distance The results of this study can lead to better reproductive health outcomes that include full-term pregnancies, economically feasible treatment options, and a higher quality of life due to coordinated care that best serves their needs.

Clinical Manifestations of Systemic Lupus Erythematosus Vary Based On Age of Disease Onset. Flora Simmons[1], Natasha M. Ruth[1], Gary S. Gilkeson[1] and Diane L. Kamen[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease which disproportionately affects women of child-bearing age. However, onset during childhood and late adult onset can be seen. Previous studies found that age of onset may be predictive of certain clinical manifestations and childhood-onset associated with increased mortality. The purpose of our study is to compare the clinical differences between childhood, adult, and late onset SLE within a large predominantly African American cohort.

Methods: Participants enrolled in an observational database of SLE were included in this study if they met ≥4 of 11 modified ACR Classification Criteria for SLE. Data was collected prospectively from 2003 to 2012. Demographic and clinical features were collected at baseline and updated at follow-up visits. Damage was scored using the SLICC/ACR Damage Index (SDI). Age of onset was categorized in three groups: childhood onset (<18 years old), adult onset (18 – 50 years old), and late onset (>50 years old). Chi-squared or Fisher's Exact testing was used, as appropriate, to compare

characteristics between groups. All statistical testing used a two-sided $\alpha=0.05$ level.

Results: Of the 449 patients, 91.3% were female and 80.6% were African American. Age of SLE onset varied between 2.8 and 76.6 years of age (mean 30.8 ± 13.6) and year of diagnosis varied between 1973 and 2012. Data on the demographic, clinical, and laboratory characteristics between the childhood onset (n=83), adult onset (n=317), late onset (n=41) groups is presented in Table 1.

Table 1. Patient characteristics compared between groups diagnosed with SLE in childhood (<18 years), adulthood (18–50 years), or late-adulthood (>50 years).

	Childhood Onset (n=83)	Adult Onset (n=317)	Late Onset (n=41)	p-values
Age, mean ± sd in years	13.1 ± 3.8	31.3 ± 8.5	57.2 ± 6.6	
African American (%)	78.2	84.3	58.7	* p<0.01
Sex Ratio (F:M)	8.8 (70:8)	10.6 (297:28)	14.3 (43:3)	p=NS
Malar Rash (%)	55.9	53.9	40.9	p=NS
Discoid Rash (%)	23.4	29.4	26.2	p=NS
Photosensitivity (%)	42.7	58.6	47.5	* p=0.04
Mucosal Ulcers (%)	35.7	43.6	40.9	p=NS
Arthritis (%)	76.8	85.8	81.4	p=NS
Serositis (%)	40.3	44.5	24.4	p=0.05
Renal (%)	64.8	54.6	27.3	* p<0.01
Neuro Disorder(%)	28.4	14.2	11.6	* p=0.01
Heme Disorder (%)	59.7	59.5	48.8	p=NS
Immune Disorder (%)	87.1	86.6	72.5	p=NS
ANA Positivity (%)	98.6	99.0	95.6	p=NS
SDI >1 (%)	53.9	50.8	47.8	p=NS
Mortality (%)	5.1	3.7	8.7	p=NS

Late onset patients have a higher proportion of females to males compared to childhood onset, but are significantly less likely to be African American. Childhood onset patients have the highest prevalence of renal and neurologic involvement from SLE (p-values <0.01 and 0.01 respectively) and were more likely, although not statistically significant, to have irreversible damage as reflected by the SDI.

Conclusion: These results support childhood onset SLE being a more severe form of SLE, supporting the critical need for preventive interventions early in the course of disease. Patients with earlier onset of SLE were more likely to have renal and neurologic involvement, which are leading causes of morbidity and mortality in SLE.

Outcome of Renal Transplantation in Lupus Patients with Positive and Negative Serology: Survival of the Graft and Patients After Transplant. Zahi Touma, Murray B. Urowitz, Dominique Ibanez and D. D. Gladman. Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: Lupus nephritis (LN) occurs in 50–75% of adults with SLE and up to 20% of LN patients may advance to end stage renal disease over a 10-year period. The aims of this study were to provide an overview of the characteristics of lupus patients with renal transplantation (RT) followed in the Lupus Clinic between 1970–2012, and to determine the survival of the graft and patients after RT.

Methods: Patients with lupus have been followed prospectively at the lupus clinic since 1970. Patients attend the clinic at 2–6 month intervals and the standard protocol includes: complete history, physical and laboratory evaluation. Patients who underwent RT were identified from the database. RT outcomes included: a) nonfunctional graft requiring dialysis within ≤3 weeks, b) graft failure requiring permanent dialysis after 3 weeks, c) graft survival not requiring dialysis and d) death.

Descriptive analysis was used to study the characteristics of all patients. We grouped the patients into graft failure and graft survival. The duration of graft failure was defined as the time between RT and subsequent permanent dialysis. The duration of graft survival was defined as the time between RT and recipient death or the end of the study with functioning graft.

Results: 25 (20 F) of 1645 patients followed in the lupus cohort and of 780 with renal involvement were identified with RT. 10 (40%) were Caucasian, 7 (28%) Black, 4 (16%) Asian and 4 (16%) others. The age at

diagnosis of lupus and at transplant was 30.7 ± 13.8 and 38.1 ± 9.6 years respectively. Lupus duration at RT was 13.3 ± 7.6 years. 2 (8%) patients had a nonfunctional graft, 4 (16%) patients had graft failure (1 patient had failure <5 years and 3 ≥5 years) and 19 (76%) patients had graft survival (8 had S ≥5 years) (Table 1). Patients with graft survival were older and had longer lupus duration compared to patients with failure at the time of RT. 25% of the graft failures had positive lupus serology compared to 47% in the graft survival 1 year prior to RT.

Table 1. Characteristics if graft failure and graft survival patients.

	Graft Failure N=4	Graft survival N=19
Sex	F 75%	F 84%
Age at lupus diagnosis	25.4±7.3	24.4±8.3
Age at transplant	29.8±9.1	40.0±9.5
Lupus duration at 1st clinic visit	5.9±4.0	7.2±7.8
Lupus duration at transplant	4.5±2.1	15.5±7.1
Ethnicity		
Caucasian	1	7
Black	1	6
Asian	2	2
Others	0	4
Positive DNA in 1 year prior	1/4	5/18
Low complements in 1 year prior	1/4	9/19
Positive DNA and/or low complements in 1 year prior	1/4	9/19
Positive DNA and/or low complements in 1 year after transplant	2/3	8/19
SDI at transplant	4.0±0 (n=4)	4.6±1.9 (n=17)
Time (duration) on dialysis prior to transplant	3.9±2.4 (n=4)	5.8±5.6 (n=6)

The time to graft failure (n=4) was 5.75 ± 4.99y. In the failure group 3 patients died by 6 ± 5.19 years and one patient is still alive. In the graft survival group 3 patients died by 5.6 ± 4.6 years and one patient was lost of follow-up. Cause of death was not related to renal disease in 2patients and unknown in one patient.

Conclusion: 25 of 780 lupus nephritis patients followed at the Lupus Clinic underwent RT. The persistence of serological abnormalities at the time of RT was not associated with graft failure.

ACR/ARHP Poster Session C
Systemic Lupus Erythematosus - Human Etiology and Pathogenesis
Tuesday, November 13, 2012, 9:00 AM–6:00 PM

2267

Genome-Wide Pathway Analysis of Genome-Wide Association Studies On Systemic Lupus Erythematosus. Young Ho Lee[1], Sung Jae Choi[1], Jong Dae Ji[1] and Gwan Gyu Song[2]. [1]Korea University Medical Center, Seoul, South Korea, [2]Korea Univ College of Med, Seoul

Background/Purpose: Genome-wide association studies (GWASs) have been successfully used to identify novel common genetic variants that contribute to susceptibility to complex diseases, but individual GWASs are limited in terms of identifying new loci. Thus, pathway-based analysis is required to identify further new loci that contribute to susceptibility to complex diseases. The aim of this study was to explore candidate single nucleotide polymorphisms (SNPs) and candidate mechanisms of systemic lupus erythematosus (SLE).

Methods: Two SLE GWASs datasets were included in this study. Meta-analysis was conducted using 737,984 SNPs in 1,527 SLE cases and 3,421 controls of European ancestry after quality control filtering, and ICSNPathway (identify candidate causal SNPs and pathways) analysis was applied to the meta-analysis results of the SLE GWAS datasets.

Results: The most significant result of SLE GWAS meta-analysis concerned rs2051549 in the human leukocyte antigen (HLA) region ($p = 3.36E-22$). In addition, 103 SNPs had observed p-values of less than 5×10^{-8} (genome-wide significance). In the non-HLA region, meta-analysis identified 6 SNPs associated with SLE with genome-wide significance

(STAT4, TNPO3, BLK, FAM167A, and IRF5). ICSNPathway identified five candidate causal SNPs and 13 candidate causal pathways. This pathway-based analysis provides three hypotheses of the biological mechanism involved. First, rs8084 and rs7192 à HLA-DRA à bystander B cell activation. Second, rs1800629 à TNF à cytokine network. Third, rs1150752 and rs185819 à TNXB à collagen metabolic process.

Conclusion: By applying ICSNPathway to the meta-analysis results of two SLE GWAS datasets, we identified five candidate SNPs and thirteen pathways, involving bystander B cell activation, cytokine network, and collagen metabolic processing, which may contribute to SLE susceptibility.

Hyperacetylation of Histone H4 in Systemic Lupus Erythematosus.
Yiu Tak Leung[1], Lihua Shi[2], Kelly Maurer[2], Li Song[2], Zhe Zhang[3], Michelle Petri[4] and Kathleen E. Sullivan[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Bioinformatics, Children's Hospital of Philadelphia, Philadelphia, PA, [4]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Systemic lupus erythematosus (SLE) is the prototypical autoimmune disease and is characterized by multi-systemic chronic inflammation. Epigenetic processes, such as posttranslational histone modifications, can regulate gene expression without altering the underlying genomic sequence and represent important disease mechanisms that have had little attention in SLE to date. We have previously reported that histone H4 acetylation (H4ac) is globally increased across the genome in monocytes of patients with SLE as compared to in monocytes of healthy controls using a tiling array approach. In order to further characterize H4ac to determine the pathologic process responsible for the hyperacetylation, we looked for an imbalance in histone acetylatransferases (HATs) and histone deacetylases (HDACs). We further utilized flow cytometry to identify specific lysine residues hyperacetylated in SLE.

Methods: Peripheral blood monocytes (PBMCs) were obtained from 7 controls and 7 SLE patients. The patients had low SLEDAI score (mean score < 2) and were on no immune suppressive medications at the time other than low-dose prednisone. Flow cytometry for different H4 lysine acetyl groups: K5, K8, K12 and K16 were run on a FacsCalibur instrument using appropriate isotype controls. H4 acetylation was defined on both T cells and monocytes. RNA-Seq studies were performed on purified monocytes from a different set of 8 controls and 8 SLE patients to examine the differential gene expression between the groups, in order to quantify mRNA for potential HAT and HDAC enzymes responsible for histone hyperacetylation in the patients with SLE.

Results: Analysis of gene expression of HATs found that PCAF-KAT2B expression was significantly increased in SLE monocytes as compared to controls; whereas, ATF2 expression was decreased significantly in the SLE group as compared to the control group. PCAF-KAT2B can associate with IRF1 and place H4K5, H4K8, and H4K16 acetylation marks. Further examination of the RNA-Seq data revealed increased expression of genes regulated by the IRF family of transcription factors. In addition, when compared to the control group, the SLE group had significantly decreased gene expression of HDAC3, which normally functions to deacetylate all H4 lysine acetyl groups, with a preference for acetylated H4K5 and H4K12. HDAC11 expression in SLE monocytes was also significantly reduced as compared to controls. HDAC11 has been shown to negatively regulate antigen-presenting cells' production of IL-10, a cytokine that is known to have increased levels in SLE patients. Finally, using flow cytometry, we found H4K5, H4K8, and H4K16 acetylation clearly increased in SLE monocytes and H4K5 increased (but not significant statistically) in SLE T cells.

Conclusion: These data demonstrate that in addition to specific gene sets being dysregulated in SLE, global alterations to H4 acetylation occur as well. These findings parallel studies that examined CpG DNA methylation and discovered evidence of global gene demethylation. The identification of a candidate HAT provides for a potential therapeutic target.

2269

The Differences of DNA Methylome and Transcriptome Among Diverse Clinical Manifestations of Systemic Lupus Erythematosus.
Ming Zhao[1], Shuangyan Luo[1], Honglong Wu[2], Siyang Liu[2], Meini Tang[1], Wenjing Cheng[1], Qing Zhang[1], Xinhai Yu[1], Tak Mao Chan[3], Yudong Xia[2], Na Yi[2], Fei Gao[2], Li Wang[2], Ning Li[2] and Qianjin Lu[1]. [1]Second Xiangya Hospital, Central South University; Hunan Key Laboratory of Medical Epigenomics, Changsha, China, [2]Beijing Genomics Institute at Shenzhen, Shenzhen, China, Shenzhen, China, [3]Division of Nephrology, Department of Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong, China

Background/Purpose: Aberrant DNA methylation and gene expression have been observed in systemic lupus erythematosus (SLE). However, patterns of DNA methylation and gene expression associated with different clinical manifestations of SLE patients have never been reported.

Methods: DNA methylation was profiled by methylated DNA immuno-precipitation combined with high-throughput sequencing (MeDIP-seq) and the expression of genes was analyzed through transcriptome sequencing (transcriptome-seq) in CD4[+]T cells obtained from three groups [SLE with only skin lesion (S), SLE with skin lesion and renal disease (SK), Normal controls (N)] which constituted of four samples, respectively. Validations of DNA methylation status and expression levels of genes were performed with CD4[+]T cells from 15 samples from each group by bisulfite sequencing and MassArray and reverse transcription quantitative PCR (RT-qPCR), respectively.

Results: According to Different Methylated Regions (DMRs) in promoter regions of genomic DNA, we identified 3056 hypo-methylated and 1965 hyper-methylated genes in S group, and 4504 hypo-methylated and 1433 hyper-methylated genes in SK group, compared with controls. Several established autoimmune-associated genes (including ITGAM, IFI44, S1PR3 and NLRP2) were confirmed to be hypo-methylated in both S and SK groups by bisulfite sequencing and MassArray, consistent with results of MeDIP-seq. Gene Ontology (GO) analysis for "biological processes" showed a significant enrichment of 86 GO terms including "induction of apoptosis" and "response to UV" in genes with DMRs in S group. Similarly, apoptosis, adherens junction and leukocyte transendothelial migration were significantly enriched via KEGG pathway analysis. Moreover, 183 GO terms were enriched significantly in SK group, including "apoptosis" and "response to DNA damage stimulus". KEGG pathway analysis revealed a significant enrichment of "renal cell carcinoma" and several autoimmune-associated pathways such as T cell receptor signaling pathway, MAPK signaling pathway and apoptosis. For differentially expressed genes, we observed 1500 up-regulated and 309 down-regulated genes in S group, and 944 up-regulated and 1552 down-regulated genes in SK group, compared with control. Over-expression of some genes including IFI44, ITGAM, S1PR3, NLRP2, C1QC and HLADRB was validated in S and SK groups using RT-qPCR, consistent with the results of transcriptome-seq. GO analysis showed that up-regulated genes were significantly enriched in immune-mediated processes including inflammation, leukocyte or complement activation. KEGG pathway analysis showed that "renal cell carcinoma" pathway was specifically enriched in down-regulated genes in SK group, suggesting aberrant DNA methylation and gene expression in this pathway may be related to lupus nephritis.

Conclusion: We characterized DNA methylome and transcriptome profiles in CD4[+] T cells from SLE patients, and showed distinct patterns associated with different phenotypic disease manifestations.

2270

The DNA Methylome of Systemic Lupus Erythematosus (SLE) From Whole Peripheral Blood Mononuclear Cells (PBMCs).
Robert Shoemaker[1], Lou H. Bookbinder[2], David L. Boyle[3], Gary S. Firestein[3], Jonathan E. Lim[2] and David W. Anderson[1]. [1]NexDx, Inc., San Diego, CA, [2]NexDx, Inc., San Diego, [3]UCSD School of Medicine, La Jolla, CA

Background/Purpose: SLE is a disease where epigenetic mechanisms play a role. Methylation of DNA at CpG loci is known to influence the suppression or activation of genes that may be associated with disease pathogenesis. Methylation associated with SLE may define unique biomarkers that may serve as novel drug targets and diagnostic tools. Studies to date have focused on candidate genes or small subsets of functional genes. We

present the first >480,000 CpG differentiatal methylation analysis, covering >20,000 gene promoters, in PBMCs from SLE patients.

Methods: Genome-wide methylation analysis of 6 SLE, 6 Rheumatoid Arthritis (RA), and 4 Osteoarthritis (OA) whole PBMC preparations from females was performed on *Illumina HumanMethyl450* BeadChips. DNA was purified from Ficoll prepared whole PBMCs from clinically diagnosed patients. The Kolmogorov-Smirnov (KS) test determined differentially methylated loci (DML). Only loci with an average methylation difference > 0.10 between phenotypes were tested. KS p-values were converted to multiple hypothesis corrected q-values and loci with q-values < 0.15 were labeled as DM. Differentially methylated genes (DMG) contained at least one SLE/RA or SLE/OA DML in their promoter regions (−2.5 kb to 500 bp from transcription start site [TSS]). Pathway enrichment analysis of DMG was determined using Kyoto Encyclopedia of Genes and Genomes (KEGG) data and empirical p-values, based on 500,000 randomly generated background gene sets, which were converted to q-values.

Results: Genome-wide methylation analysis of >480,000 CpG loci identified 864 and 1,537 DML in SLE/RA and SLE/OA comparisons. Associating CpGs with TSS promoter regions narrowed these loci to 274 and 422 DMG. 71% and 65% of SLE/RA and SLE/OA CpGs were hypermethylated, respectively. Hypermethylation was found in *IL-23A, TNFRSF25,* and *PRIC285* (peroxisomal proliferator-activated receptor A interacting complex 285), genes known to regulate immune responses and inflammation. Hypomethylated CpG loci from SLE patients were identified in promoter regions associated with genes relevant to SLE, such as *IFI44L* (interferon-induced protein 44-like), *IFITM1* (Interferon-induced transmembrane protein 1) and *IL-10*. Combining SLE/RA and SLE/OA genes into a single group, we found: cytokine-cytokine receptor interaction (q-value = 0.004), rheumatoid arthritis (0.004), hematopoietic cell lineage (0.004), and cell adhesion molecules (0.010) were significantly enriched KEGG pathways where differential methylation was observed. These data suggest that epigenetic mechanisms may play an important role in SLE where aberrant regulation of key immune and inflammatory genes or pathways may contribute to SLE pathogenesis and progression.

Conclusion: This study demonstrates that the first genome-wide DNA methylation analysis of whole PBMC samples is informative. The differential methylation pattern for SLE has the potential for identification of novel biomarkers for diagnostic applications. Associated genes and pathways provide a greater understanding of the pathogenic mechanisms of SLE and potential novel therapeutic targets. These findings justify further exploration, including subsets of immune cells and healthy controls.

2271

Variation of Interferon-Alpha Production in Healthy Individuals and Association with Autoimmune Susceptibility Genes. Olof Berggren[1], Andrei Alexsson[1], Gunnar V. Alm[2], Ann-Christine Syvänen[3], Lars Rönnblom[1] and Maija-Leena Eloranta[1]. [1]Section of Rheumatology, Uppsala University, Uppsala, Sweden, [2]Swedish University of Agricultural Sciences, Uppsala, Sweden, [3]Molecular Medicine, Uppsala University, Uppsala, Sweden

Background/Purpose: Many autoimmune diseases, e.g. systemic lupus erythematosus (SLE), have an activated type I interferon (IFN) system and about 40 SLE susceptibility loci, many within the type I IFN pathway, have been identified. We recently showed that the IFNα production by plasmacytoid dendritic cells (pDC) is regulated by both NK and B cells, and demonstrated a large interindividual difference in IFNα producing capacity among healthy individuals. We therefore investigated whether the capacity to produce type I IFN correlates to single nucleotide polymorphisms (SNPs) associated with different autoimmune diseases.

Methods: Plasmacytoid dendritic cells (pDC) (n = 130), B cells (n = 128) and NK (n = 66) were isolated from healthy blood donor PBMC genotyped with the 200K ImmunoChip (Illumina). PDC alone or in co-cultures with NK or B cells were stimulated with U1 snRNP- and SLE-IgG-containing immune complex (RNA-IC), herpes simplex virus or a synthetic oligonucleotide (ODN2216). The IFNα levels in the cell cultures were measured with an immunoassay after 20h. The association analysis was performed with PLINK software version 1.07. A total of 67 000 SNPs with minor allele frequency ≥20% which passed quality control were included in the analysis. The 10 most associated signals per

cell type and stimuli were selected for further analysis. The IFNα production was normalized by Box-Cox transformation and the association to the genotype was analyzed by multiple linear regression with a stepwise method (SPSS 20.0).

Results: The IFNα production by the stimulated healthy donor pDC alone or in cocultures with B or NK cells varied from <1 to 100000 U/ml. We found a strong association (p < 0.001) between the level of produced IFNα and several SNPs (24 to 194) depending on the combination of cell type and IFN inducer. The 7 most significant associations between IFNα production and specific SNPs among the 9 different combinations were located in *C1orf222, MYO9B, TOX,* between *NFYAP1* and *LGMNP1,* and *IL5RA* genes (all p ≤ 0.00003).

Further analysis on the combined effect of the 10 most significant SNPs was applied on each different IFN inducer and cell type combination. For instance, the variation in IFNα production by pDC and B cells stimulated with RNA-IC could be explained to 59% by a model including SNPs located between *ID4* and *MBOAT1,* in *BLK,* in *MOBKL2B,* in *BICC1,* between *FAM86A* and *RBFOX1,* and between *IRF8* and *FOXF1* ($p < 1 \times 10^{-18}$, $r^2 = 0.59$).

Conclusion: We found that the interindividual variation in IFNα production in healthy individuals upon stimulation with RNA containing IC as well as IFN inducers of microbial origin is associated to several autoimmune susceptibility genes. Our results may contribute to the identification of functional gene variants that directly affect the type I IFN production and IFN signature in patients with systemic autoimmune diseases. We envision that our approach using genetically characterized individuals can reveal crucial immunological targets for therapeutic intervention.

2272

Gene Expression Signatures in Monocytes From Primary Antiphospholipd Syndrome, Systemic Lupus Erythematosus and Lupus with Antiphospholipid Syndrome Identify Specific Pathways Involved in the Pathogenesis of Atherosclerosis and Cardiovascular Disease. Chary Lopez-Pedrera[1], Sebastiano Messineo[2], Carlos Perez-Sanchez[1], Patricia Ruiz-Limon[1], Mª Angeles Aguirre[1], Rosario M. Carretero-Prieto[1], Antonio Rodriguez-Ariza[1], Nuria Barbarroja[3], Francisco Velasco[1], Munther A. Khamashta[4], Eduardo Collantes-Estevez[1] and Mª Jose Cuadrado[4]. [1]IMIBIC-Reina Sofia Hospital, Cordoba, Spain, [2]Dipartimento di Scienze della Salute, Universitá Magna Graecia di Catanzaro, Italy., Catanzaro, Italy, [3]IMABIS and Virgen de la Victoria Hospital, Malaga, Spain, [4]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by immune-mediated inflammation in multiple organ systems. SLE, primary Antiphospholipid syndrome (APS) and secondary APS (SAPS) share several clinical features, including atherosclerosis (AT) and cardiovascular disease (CVD), but also have some unique distinguishing characteristics. The aim of this study was to identify shared and differential molecular pathways involved in the pathogenesis of AT and CVD in that autoimmune diseases.

Methods: 127 patients (42 APS, 20 SAPS and 56 SLE) and 61 healthy donors were included. Microarray expression profiling was performed in samples of monocytes from these patients and real time RT-PCR of selected genes was used to validate microarray data. Some clinical and inflammatory parameters were also obtained.

Results: Comparing to controls, the expression of 555, 1224, and 518 genes were found significantly altered in monocytes from SLE, SAPS, and APS patients, respectively. On the other hand, 1243 genes were differentially regulated in APS vs. SLE, and 605 genes in SAPS vs. SLE. Interestingly, only 220 genes were differentially regulated when comparing APS with SAPS. Approximately 25–30% of the total number of altered genes in the three diseases were related to AT, inflammation and CVD (chemoquines/cytokines and their receptors, molecules related to angiogenesis, oxidative stress, mitochondrial dynamics and metabolism, lipid metabolism and cell to cell signalling). A specific AT/CVD/Inflammation-related gene signature was found for each disease. Thus, compared to LES, APS showed alterations in mitochondria biogenesis and function, oxidative stress and antioxidant defense. Besides the interferon signature found SAPS and SLE patients, a number of genes mediating atherosclerotic/inflammatory signalling were found further altered in SAPS. Multivariate analysis showed that IgG aCL titers, which are known risk factors for AT and CVD events in SLE,

independently predicted both atherosclerotic and thrombosis in SAPS. Moreover, a higher percentage of SAPS showed increased carotid intimate media thickness than LES patients. We further found a significant correlation of IgG-aCL titers with circulating levels of inflammatory molecules (tPA, MCP-1, TNFα, and IL-2).

Conclusion: 1) Gene expression profiling allows the segregation of APS, SAPS and SLE, with specific signatures explaining the pro-atherosclerotic, pro-thrombotic and inflammatory changes in these highly related autoimmune diseases. 2) The identification of key genes regulating specific pathophysiologic pathways will permit the development of targeted therapies for each autoimmune condition. Supported by JA0246/2009, P08-CVI-04234, and PS09/01809.

Functional Genetic Polymorphisms in Immunoglobulin-Like Transcript 3 Are Associated with Decreased Surface Expression On Dendritic Cells and Increased Serum Cytokines in Lupus Patients. Mark A. Jensen, Karen C. Patterson, Akaash A. Kumar, Marissa Kumabe, Beverly S. Franek and Timothy B. Niewold. University of Chicago, Chicago, IL

Background/Purpose: Hyperactivity of the type I interferon (IFN) pathway is involved in the pathogenesis of systemic lupus erythematosus (SLE). Immunoglobulin like transcript (ILT3) is an immunohibitory transmembrane molecule which is induced by type I IFNs. ILT3 is expressed by plasmacytoid dendritic cells (PDCs), monocytoid dendritic cells (MDCs), and monocytes/macrophages. Given the pathogenic role of IFN in SLE, we hypothesized that the IFN-induced immunosuppressive ILT3 receptor may be dysfunctional in human SLE.

Methods: 132 European-derived and 79 Hispanic-American SLE patients were genotyped for two coding-change single nucleotide polymorphisms (SNPs) predicted to interfere with protein folding in ILT3 (rs11540761 and rs1048801). 116 control DNA samples and sera from healthy controls were also studied. We detected associations between ILT3 genotype and serum cytokine profiles. ILT3 expression levels on PDCs and MDCs from 18 patients and 10 controls were studied by flow cytometry.

Results: The rs11540761 SNP in the extracellular region was associated with decreased cell surface expression of ILT3 on circulating MDCs and to a lesser extent PDCs in SLE patients. The cytoplasmically located rs1048801 SNP was not associated with a change in DC expression of ILT3. Both SNPs were significantly and independently associated with increased levels of serum type I IFN activity in SLE patients. The rs1048801 SNP was also associated with increased serum levels of TNF-α.

Conclusion: Loss-of-function polymorphisms in ILT3 are associated with increased inflammatory cytokine levels in SLE, supporting a biological role for ILT3 in SLE.

Genes Associated with Systemic Lupus Erythematosus Show Evidence of Selection in the Gullah African American Population. Paula S. Ramos[1], Satria Sajuthi[2], Yiqi Huang[3], Diane L. Kamen[4], Jasmin Divers[2], Kenneth M. Kaufman[5], John B. Harley[5], Robert P. Kimberly[6], Carl D. Langefeld[2], Michèle M. Sale[3], W. Timothy Garvey[6] and Gary S. Gilkeson[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]University of Virginia, Charlottesville, VA, [4]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [6]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: In spite of its higher prevalence and severity, little is known about the genetic etiology of systemic lupus erythematosus (SLE) in African Americans (AA). Given this greater prevalence and the increasing evidence of selection at loci associated with human diseases, identification of alleles under selection may provide insight into the susceptibility to SLE. The Gullah are an AA population with limited and well defined ancestral diversity. The shorter genetic distance between the Gullah and Sierra Leonean (SL) suggests that population genetic signals, such as regions under recent selection,

may be more easily detected in the Gullah than in other AA populations. Since population-specific selection may cause allele frequency differences, the goal of this study was to identify regions with minor allele frequency (MAF) differences between Gullah and SL that may increase the risk of SLE in AA.

Methods: We had available 120 Gullah and 400 SL samples, all unaffected, genotyped on the Illumina 1M and **Affymetrix** SNP Array 6.0, respectively. After stringent quality control was applied to each population, 185,569 SNPs common to both arrays with MAF>5% were used to compute the significance of the MAF differences between the two populations. In order to exclude spurious signals, only regions where at least two SNPs in linkage disequilibrium showed significant Bonferroni-adjusted MAF differences were considered.

Results: Amongst the regions where multiple SNPs showed significant MAF differences between the Gullah and SL (P<E-06), some are associated with SLE in Caucasians. These include the MHC, which was previously shown to be under selection in other populations, as well as PTPN22 and TNIP2. Several other regions associated with SLE in Caucasians showed suggestive MAF differences. The region showing the most significant MAF differences was that of the complement-regulatory *CSMD1* gene, which has been associated with, among other traits, emphysema, multiple sclerosis, and insulin resistance in AA. Overall, our results confirmed an enrichment of genes involved in immunity and defense (BP00148; P=0.0076).

Conclusion: We have identified several regions with significant allele frequency differences between the Gullah and SL, suggesting that population-specific selective pressures may be operating at these loci. Given the increased prevalence of SLE in AA and the homogeneity of the Gullah, identification of these regions in the Gullah has the potential to elucidate the etiology of SLE in AA.

NR1H3 (LXR alpha) Gene Polymorphisms Are Associated with Systemic Lupus Erythematosus in Koreans. Ja-Young Jeon, Hyoun-Ah Kim and Chang-Hee Suh. Ajou University School of Medicine, Suwon, South Korea

Background/Purpose: Liver X receptorsare established sensors of lipid and cholesterol homeostasis. The recent studies have reported that LXRs are involved in regulation of inflammation and immune responses. We attempted to identify single nucleotide polymorphisms (SNPs) of the NR1H3 and NR1H2 genes, associated with the susceptibility to SLE in Korean populations.

Methods: Blood samples were collected from Korean SLE patients (n=300) and normal healthy controls (NC, n=217). Also, replication samples were collected from Korean SLE patients (n=160) and NC (n=143). SNPs were genotyped using SNaPSHOT assay. The promoter activity was analyzed by luciferase reporter assay in Hep3B cells and COS-7 cells. To investigate the effects of the stimulation, we used a functional assay of transcriptional activity and B cell proliferation assay. To investigate whether the genetic polymorphism changed a transcription factor binding, we performed an electrophoretic mobility shift assay.

Results: We have identified five polymorphisms (-1851 T>C and -1830 T>C in the promoter region, -1003 G>A, -840 C>A and -115 G>A in the intron 1 region) including one novel SNPs (-1003 G>A) in the NR1H3 gene. Two SNPs in the NR1H3 gene, -840 C>A and -115 G>A, showed the complete linkage disequilibrium. There was significant difference in the -1830 T>C polymorphism (co: p=0.001), -1003 G>A polymorphism (co: p=0.002), -115 G>A polymorphism (co: p<0.001) between SLE and NC. These results were consistent with those of replication samples. Three common haplotypes for four polymorphisms were constructed: HT1 [TTGG], HT2 [CTGG] and HT3 [TCAA]. There was significant difference between SLE and NC in the observed haplotype HT1 [TTGG] (co: p=0.033) and HT3 [TCAA] (co: p=0.008). In the -1830 T>C polymorphism, arthritis was significantly more common in the SLE patients with the -1830 C allele (p=0.005). The -1003 G>A polymorphism was significantly associated with oral ulcer (p=0.039), arthritis (p=0.006), anti-dsDNA (p=0.041) and elevated triglyceride (p=0.007). The -115 G>A polymorphism was significantly associated with oral ulcer (p=0.024), arthritis (p=<0.001) and elevated triglyceride (p=0.011). Luciferase activity of the constructs containing -1830 Cand -1003 A was lower than that of the constructs containing -1830 T and -1003 G (p=0.009 and p=0.030, respectively). Moreover, promoter activity of the -1830 C and -1003 A was less enhanced when compared to that of the -1830 T and -1003 G in GW3965 and T0901317 treated cells (p=0.034 and p<0.001, respectively). Proliferation of -1830 TC type was increased when compared to that of -1830 TT type in basal,

GW3965 and T0901317 treated B cells from SLE patients (p=0.011, p= 0.040 and p=0.017, respectively). We found that transcription factor GATA-binding protein 3 (GATA3) protein preferentially bound the −1830 T promoter.

Conclusion: These results suggest that the NR1H3 gene genetic polymorphisms may be associated with disease susceptibility and clinical manifestations of SLE in Korean population. Specially, −1830 T>C polymorphism within NR1H3 promoter region may be involved in regulation of NR1H3 expression.

Signature of Circulating Micro-RNA in Systemic Lupus Erythematosus.

Anting L. Carlsen[1], Aaron J. Schetter[2], Christoffer T. Nielsen[1], Christian Lood[3], Steen Knudsen[4], Anne Voss[5], Curtis C. Harris[6], Thomas Hellmark[7], Mårten Segelmark[8], Søren Jacobsen[9], Anders A. Bengtsson[10] and Niels H. H. Heegaard[1]. [1]Statens Serum Institut, Copenhagen S, Denmark, [2]National Institutes of Health, Bethesda, MD, [3]Department of Clinical Sciences Lund, Lund, Sweden, [4]Medical Prognosis Institute, Horsholm, Denmark, [5]Odense University Hospital, Odense C, Denmark, [6]National Cancer Institute NIH, Bethesda, MD, [7]Lund, Sweden, [8]Sweden, [9]Copenhagen University Hospital, Copenhagen, Denmark, [10]Department of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by chronic inflammation sustained by a type I interferon response. The diagnostic value of circulating micro-RNA (miRNA) signatures in SLE has not been systematically evaluated and compared to healthy controls and other autoimmune conditions.

Methods: We quantified 45 mature miRNAs in 409 plasma samples from clinically well-characterized SLE patients, healthy controls, and controls with other systemic autoimmune diseases (RA and vasculitis) and immunosuppressed patients (kidney transplant recipients). SLE risk probability scores were modeled by logistic regression and validated in independent cohorts.

Results: Highly significant changes in 7 specific miRNAs were identified and validated independently. Up-regulated miRNAs were miR-142-3p and -181a and down-regulated miRNAs were miR-106a, -17, -20a, -92a, and -203. Four of five down-regulated miRNAs represent members of the polycistronic miR-17–92 family, and, together with miR-223, were significantly lower in SLE patients with active nephritis than in patients without nephritis. A predictive model for the SLE diagnosis based on 2 miRNAs discriminated SLE from controls (AUC=0.89) when validated independently (accuracy: 76%, $p<2\times10^{-9}$). Using a 4 miRNA model SLE cases was grouped statistically significantly different from disease controls except for vasculitis samples.

Conclusion: We find consistent changes of circulating miRNA profiles in SLE patients compared with healthy controls and disease controls. All 7 validated differently expressed miRNAs target genes in the TGF-b signaling pathway. Other targets imply regulation of apoptosis, cytokine-cytokine receptors, T-cell development, and cytoskeletal organization. A four-miRNA signature was diagnostic for SLE, and patients with active nephritis showed specific subset miRNA profiles. The findings highlight possible deregulated pathways in SLE and suggest that circulating miRNA signatures may potentially be used diagnostically and for monitoring purposes in SLE.

Familial Aggregation and Heritability of Systemic Lupus Erythematosus in Taiwan: A Nationwide Population Study.

Chang-Fu Kuo[1], Matthew J. Grainge[1], Lai-Chu See[2], Kuang-Hui Yu[3], Shue-Fen Luo[3], Ana M. Valdes[4], Hsiao-Chun Chang[3], I-Jun Chou[3], Weiya Zhang[1] and Michael Doherty[1]. [1]University of Nottingham, Nottingham, United Kingdom, [2]Chang Gung University, Taoyuan, Taiwan, [3]Chang Gung Memorial Hospital, Taoyuan, Taiwan, [4]St. Thomas' Hospital, King's College London, London, United Kingdom

Background/Purpose: The aims of the present study were to estimate relative risk (RR) of systemic lupus erythematosus (SLE) in individuals with affected relatives in comparison with those without family history of the disease. We also estimated the heritability of SLE in the general population in Taiwan.

Methods: Using data from the National Health Insurance Research Database in Taiwan, we conducted a nationwide cross-sectional study of data collected from 11,449,138 men and 11,800,070 women in 2010. Cases of SLE were defined as those receiving catastrophic illness certificates for SLE. The identification of first-degree relatives of each individual was determined using the NIHRD registry for beneficiaries. This specifies relationships between the insured person who paid the insurance fee and his/her dependents, allowing first-degree relatives (father, mother, son, daughter, brother, sister, twin) to be identified directly. Full siblings were identified as individuals who shared the same parents. Twins were full siblings who shared the same date of birth. The marginal Cox proportional hazard model with an equal follow-up time was used to estimate RR (95% confidence interval [CI]), accounting for shared environment and case clustering within families with robust variance, and adjusting for age and sex. Heritability (h^2) was estimated using the multifactorial polygenic model.

Results: There were 2,029 men (0.02%) and 17,200 women (0.15%) who had SLE in 2010. The prevalence of SLE was higher in individuals with affected first-degree relatives (1.16%) than those without (0.08%). The overall familial RR was 15.68 (95% CI, 13.66–18.00). The RRs (95% CIs) for an individual with an affected twin, sibling, offspring and parent were 30.00 (17.82–50.51), 24.69 (19.13–31.85), 11.26 (9.10–13.93) and 14.24 (12.07–16.80), respectively. The RR (95% CI) increased with the number of affected first-degree relatives, from 15.61 (13.59–17.93) and 36.12 (9.10–143.46) for one and two or more affected relatives. The heritability of SLE was 0.72 (95% CI, 0.66–0.79).

Conclusion: This population-based study confirms strong familial aggregation and high heritability of SLE. We provided solid evidence for the significance of genetic factor in SLE susceptibility.

Single Nucleotide Polymorphisms (SNPs) of Integrin-á-M (ITGAM) Are Associated with Susceptibility to Systemic Lupus Erythematosus (SLE) in an Asian Lupus Cohort.

Weng-Giap Law[1], Kok Ooi Kong[1], Bernard Pui Lam Leung[1], Chack-Yung Yu[2], Yeong W. Song[3], Yun Deng[4], Hiok-Hee Chng[1], Betty P. Tsao[5] and Hwee-Siew Howe[1]. [1]Tan Tock Seng Hospital, Singapore, Singapore, [2]7Center for Molecular and Human Genetics, The Research Institute at Nationwide Children's Hospital and The Ohio State University, Columbus, OH, [3]Seoul National University, Seoul, South Korea, [4]David Geffen School of Medicine University of California Los Angeles, Los Angeles, CA, [5]UCLA School of Medicine, Los Angeles, CA

Background/Purpose: SLE is a systemic autoimmune disease where lupus nephritis (LN) is a major cause of morbidity and mortality. Integrin-a-M (ITGAM) is critical for the adherence of neutrophils to stimulated endothelium and phagocytosis of complement coated particles. Recently, a variant of exon 3 (rs1143679) of ITGAM was found to be associated with susceptibility to SLE and LN in several ethnic groups including oriental Chinese and Thai populations. Our aim was to examine the potential association of ITGAM SNPs in our local SLE patients.

Methods: Custom-designed arrays were employed to study 201 SNPs covering the approximately 140kb of the ITGAM-ITGAX region in 293 Singapore SLE patients vs. 243 Asian controls. All patients satisfied the 1997 ACR revised SLE criteria. In total 147 SNPs of ITGAM-ITGAX were included in analysis. Significance difference in allelic frequencies of each SNP was examined by gPLINK 1.062 software with Bonferroni adjustment for multiple testing corrections.

Results: 13 SNPs spanning from 5' upstream of ITGAM to intron 5 of ITGAX showed significant association ($p<3.4\times10^{-4}$). The strongest association was detected at rs4561481 in the 5' upstream of ITGAM (OR=1.77 [1.34–2.32], $p=4.2\times10^{-5}$). The previously identified functional SNP of ITGAM (rs1143679, R77H) in European ancestry and African-American populations has shown a strong association for the risk allele (A). However, we observed a low frequency of the risk allele (A) in our patients (1.4% in SLE vs 0.2% in controls; p=0.039, OR=6.7 [0.83–53.42]), and its association with disease susceptibility did not remain significant after Bonferroni correction. To localize the underlying causal variant, linkage equilibrium (LD) analysis was examined among these 13 SNPs which were located in a strong LD block (r^2=0.92–1.0), and the conditional association could not be applied to further distinguish the independent association in our SLE cohort.

Signficiant Disease Association of 13/15 ITGAM SNPs from a Singapore SLE Cohort (n=293 Singapore SLE vs 243 controls)

SNP	BP	Test Allelle	Frequency SLE	Control	P value	OR (95%CI)
rs4561481	31167054	G	0.338	0.224	4.2E-05	1.77 (1.34–2.32)
rs8051304	31167513	C	0.336	0.224	5.4E-05	1.75 (1.33–2.30)
rs889551	31167923	A	0.323	0.216	1.0E-04	1.73 (1.31–2.28)

Genetic Markers for Circulating Vitamin D and the Associations with Risk of Systemic Lupus Erythematosus. Linda T. Hiraki[1], Adrienne H. Williams[2], Arun-Prasad Manoharan[3], Peter Kraft[4], Carl D. Langefeld[5], Robert R. Graham[6] and Elizabeth W. Karlson[7]. [1]Brigham and Women's Hospital, Harvard School of Public Health, Boston, MA, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Genentech, Inc., [4]Program in Molecular and Genetic Epidemiology, Harvard School of Public Health, Boston, MA, [5]Department of Biostatistical Sciences, Wake Forest University Health Sciences, Winston-Salem, NC, [6]Genentech, Inc., South San Francisco, CA, [7]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex, life threatening autoimmune disease and a presumed consequence of susceptibility genes interacting with environmental exposures. Vitamin D deficiency has been implicated as an etiologic factor in several autoimmune diseases including SLE. Studies of common single nucleotide polymorphisms (SNPs) in the genes influencing circulating 25-hydroxyvitamin D (25(OH)D) levels (eg: vitamin D receptor, the 1-alpha hydroxylase enzyme and vitamin D binding protein) have demonstrated associations with type 1 diabetes, autoimmune thyroid disease and multiple sclerosis. Few studies to date have examined these genes in predicting SLE. We hypothesized that variations in vitamin D related genes are associated with SLE susceptibility.

Methods: Vitamin D associated SNPs were identified and meta-analyzed from SLE genome wide association studies (GWAS) in two large consortia, the International Consortium on the Genetics of Systemic Lupus Erythematosus (SLEGEN) (720 cases, 2302 controls) and Genentech (1225 cases and 4683 controls). Genotyping was done using the Illumina 550K among Genentech individuals and the Illumina 317K in SLEGEN. We imputed 550K SNPs among SLEGEN individuals using Impute and retained those SNPs with a confidence score > 0.9 and an information score > 0.5. We examined individual SNP associations with SLE risk as well as a genetic risk score (GRS) comprised of four 25(OH)D GWAS associated SNPs (rs2282679, rs3829251, rs2060793, rs6013897) in *GC, DHCR7/NADSYN1, CYP2R1, CYP24A1* genes. We meta-analyzed individual study results using an inverse variance weighted approach, as implemented in the software METAL. We performed gene based tests of 29 vitamin D associated genes identified by literature review, using the versatile gene-based association study (VEGAS).

Results: We did not observe a significant association between four 25(OH)D GWAS associated SNPs and SLE or with an additive GRS comprised of those 4 SNPs (OR 0.99 (95% CI 0.93, 1.07)). Of the 29 vitamin D genes interrogated using VEGAS, *TNF* was found to be significantly associated (p<10–5), as was *CASR* (p=0.002), *SHBG* (p=0.003), *MED1* (p=0.02) and *SMAD3* (p=0.03). However the four GWAS significant 25(OH)D gene regions were not found to be statistically significantly associated with SLE.

Conclusion: We did not observe a direct association between genetic markers of vitamin D and SLE risk. Further investigation into the mechanism by which vitamin D acts on SLE disease risk would provide insight into the pathogenesis and progression of disease.

Serum Metabolomics As a Novel Diagnostic Approach for Systemic Lupus Erythematosus. Jun Saegusa[1], Yasuhiro Irino[1], Masaru Yoshida[1], Shino Tanaka[1], Yoshinori Kogata[1], Goichi Kageyama[1], Seiji Kawano[1], Goh Tsuji[2], Shunichi Kumagai[2] and Akio Morinobu[1]. [1]Kobe University Graduate School of Medicine, Kobe, Japan, [2]Shinko Hospital, Kobe, Japan

Background/Purpose: Metabolomics, or metabolome analysis, is the comprehensive study of low-molecular-weight metabolites. The metabolome represents the metabolite profiles of all the cellular processes in a cell, tissue, organ, or organism. Notably, because the metabolome is the last step in the omics cascade before the phenotype, alterations in the levels of metabolites may better reflect the physiological and pathological characteristics of a disease than changes in gene or protein expressions. It is now apparent that cell metabolism has a tremendous impact on the function of various immune cells. In this study, we evaluated the differences in the serum metabolome between systemic lupus erythematosus (SLE) patients and healthy subjects, using gas chromatography/mass spectrometry (GC/MS), and sought to identify candidates for metabolic biomarkers.

Methods: Serum samples were obtained in the morning from fasting human patients with SLE (n=26) and healthy volunteers (n=26). Serum metabolite profiling was performed by GC/MS. The metabolic profiles of the patient and control groups were compared using multivariate statistical analysis.

Results: Sixty-two metabolites were detected in the serum. The level of 24 of them was significantly different in SLE patients compared to healthy controls. The 2D-plots of the principal component analysis (PCA) scores for all 62 metabolites showed distinct clustering for the two subject groups. The corresponding 2D-PCA- and partial least squares-discriminant analysis (PLS-DA)-loading plots revealed that variations in the levels of glutamic acid, ornithine, urea, tyrosine, and glycerol greatly contributed to the observed separation of the metabolomics profiles of the SLE patients and healthy controls. Furthermore, we demonstrated that the serum levels of glutamic acid and ornithine were significantly correlated with the SLE activity index (SLEDAI) score in the patient group.

Conclusion: Our study suggests that GC/MS-based serum metabolomics can serve as a novel diagnostic and monitoring tool for SLE, and that the pattern of variation in metabolite levels may be useful for understanding the pathophysiology of SLE and establishing novel therapeutic strategies.

Tartrate-Resistant Acid Phosphatase Deficiency in the Predisposition to Systemic Lupus Erythematosus. Jie An[1], Tracy A. Briggs[2], Nalini Agrawal[1], Alice Wiedeman[1], Laurence Chaperot[3], Joel Plumas[3], Yanick J. Crow[2] and Keith B. Elkon[1]. [1]University of Washington, Seattle, WA, [2]University of Manchester, Manchester, United Kingdom, [3]Immunobiology & Immunotherapy of Cancers, La Tronche, France

Background/Purpose: The enzyme tartrate-resistant acid phosphatase (TRAP) is highly expressed in osteoclasts. One of the main substrates for TRAP in bone matrix is osteopontin (OPN). Biallelic mutations in the gene, ACP5, that encodes TRAP, result in an immuno-osseous disease called spondyloenchondrodysplasia (SPENCD). In addition to bone and neurological abnormalities, SPENCD patients also develop autoimmune disorders such as systemic lupus erythematosus (SLE). Of note, SPENCD patients demonstrate evidence of increased interferon-alpha (IFN-α) production in their

blood. Since very little is known about the function of TRAP in immune cells, the objectives of our study were to determine whether OPN is a substrate for TRAP and to define the consequences of TRAP deficiency in immune cells.

Methods: Co-localization of TRAP and OPN was determined by confocal microscopy and also by immunoprecipitation and western blot analysis (IP-western). TRAP overexpression or knockdown was performed by transfection with cDNA or shRNA, respectively. Expression of IFN-α and IFN signature genes (ISGs) were determined by enzyme-linked immunosorbent assay (ELISA) and quantitative PCR (qPCR). Phosphatase activity was quantified by Biomol Green fluorimetry.

Results: We observed that TRAP co-localized with OPN in early endosomes and the Golgi in both primary macrophages as well as in plasmacytoid dendritic cells (pDC). Co-localization was confirmed biochemically: following co-transfection of cDNAs encoding TRAP and OPN in 293 cells, we reciprocally co-immunoprecipitated TRAP and OPN as determined by western blots. Also, in macrophages, anti-TRAP antibody immunoprecipitated both TRAP and OPN, indicating that they interacted with each other in primary non-transfected cells. To confirm that OPN was indeed a substrate for TRAP, we observed that recombinant human TRAP dephosphorylated OPN by the release of free phosphate in an *in vitro* assay. To relate the functional significance of TRAP deficiency to IFN-α production, we knocked down the expression of TRAP in pDC. We observed that TRAP specific shRNA, but not scrambled shRNA, increased the expression of IFN-α and IFN signature genes (ISGs).

Conclusion: Taken together, these findings indicate that TRAP and OPN co-localize and that OPN is a substrate for TRAP in immune cells. Significantly, TRAP deficiency in pDC leads to increased IFN-α production providing an explanation for why TRAP mutations lead to a lupus-like disease in SPENCD patients.

Low Gene Copy Number for C4, C4A and C4B Is a Strong Risk Factor for Developing Systemic Lupus Erythematosus in Childhood. Luis Eduardo C. Andrade[1], Kaline M.C. Pereira[2], Atila G. A. Faria[3], Bernadete Liphaus[4], Adriana A. Jesus[5], Clovis Silva[6] and Magda Carneiro-Sampaio[5]. [1]Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo and Fleury Health and Medicine Laboratories, Sao Paulo, Brazil, [3]Sao Paulo, Brazil, [4]Instituto da Criança, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [5]Instituto da Criança da Faculdade de Medicina da Universidade de São Paulo (FMUSP), Sao Paulo, Brazil, [6]MD; PhD, São Paulo-SP, Brazil

Background/Purpose: C4 is an important component of the Complement system and plays an essential role in the activation cascade of the classical Complement pathway. Complete C4 deficiency is among the strongest genetic risk factors for systemic lupus erythematosus (SLE). There are two C4 circulating isoforms (C4A and C4B) encoded by C4A and C4B genes, respectively, that differ by only five nucleotides. C4A protein is involved in the clearance of immune complex and apoptotic debris while C4B protein is relevant in the opsonization of microbes. C4A and C4B genes are located at a gene cassette within the MHC class III region and depict gene copy-number variation (CNV). The number of C4A copies may be related to the susceptibility to SLE. This study aimed to investigate the impact of the C4A and C4B gene CNV on juvenile SLE.

Methods: We evaluated 90 children and 170 adults with SLE (meeting SLE ACR criteria) sequentially retrieved from the rheumatology outpatient clinic. Two hundred healthy individuals (HI) without evidence of autoimmune diseases were retrieved among blood bank donors. Peripheral blood leukocyte DNA was amplified by quantitative real-time PCR (qPCR) with primers for C4 gene and sequence specific TaqMan® probes for C4A (5′ FAM-ACCCCTGTCCAGTGTTAG-MGB 3′) and C4B (5′ FAM-ACCTCTCTCCAGTGATAC-MGB 3′). Gene copy number (GCN) was determined by the delta-delta cycle threshold (DDCT) method.

Results: Children with SLE had lower GCN of total C4 (mean total C4=3.1; 95% CI=2.8–3.4), C4A (mean C4A=1.7; 95% CI=1.5–1.9) and C4B (mean C4B=1.5; 95% CI=1.3–1.6) than HI (C4=4.3 with 95% CI=4.1–4.5, p<0.001; C4A=2.3 with 95% CI=2.2–2.5, p<0.001; C4B=2.0 with 95% CI=1.8–2.1; p<0.001). The frequency of SLE children with total C4 low GCN (<4 copies) was significantly higher than in HI (SLE=59% versus HI=28%; OR=3.68; 95% CI=2.19–6.20; p<0.001). The same was observed for C4A low GCN (<2 copies) (SLE=52% versus HI=18%; OR=4.98; 95% CI=2.88–8.62; p<0.001) and C4B low GCN (SLE=60% versus HI=31%; OR=3.26; CI=1.95–5.47; p<0.001). The association between adult SLE and low GCN for total C4 (OR=2.03; 95% CI=1.32–3.13; p=0.001), C4A (OR=2.36; 95% CI=1.46–3.81; p<0.001) and C4B (OR=1.13; CI=0.73–1.74; p=0.593) was less pronounced than observed in juvenile SLE. Moreover, there was an association between cardiovascular damage and low GCN for C4 and C4A. 81% of SLE children with cardiovascular damage had less than 4 copies of C4 against 51% of the children without cardiovascular manifestation (OR=4.13; CI 95%=1.02–16.68; p=0.047). The same was observed for C4A (81% of those with cardiovascular damage had <2C4A against 44% of those with no heart involvement; OR=5.54; CI 95%=1.37–22.32; p=0.016).

Conclusion: Low GCN for total C4, C4A and C4B is associated with an increased risk for developing systemic lupus erythematosus and this association is stronger in childhood than in adults. Furthermore, low GCN for C4 and C4A seems to be a risk factor of cardiovascular damage in juvenile SLE.

2283

Preferential Association of Complement Receptor 2 Variants with Anti-dsDNA Autoantibodies in Systemic Lupus Erythematosus. Brendan M. Giles[1], Jian Zhao[2], Kara M. Lough[1], Patrick M. Background/Purpose: Complement receptor 2 (CR2/CD21) is primarily expressed on B cells and follicular dendritic cells (FDC) and is required for normal humoral immune responses. We have previously identified *CR2* variants associated with systemic lupus erythematosus (SLE) susceptibility. To understand how *CR2* might contribute to disease development, we explored the association of *CR2* polymorphisms with specific clinical manifestations of SLE.

Methods: We genotyped 49 *CR2* single-nucleotide polymorphisms (SNPs) and assessed them for association with 14 clinical manifestations of SLE in 7,427 European-Americans (EA) cases and controls. We imputed genotypes for untyped SNPs, identified functional implications of associated SNPs, and evaluated haplotype-associated RNA and protein expression profiles in primary B cells from healthy control subjects.

Results: We detected a strong association between *CR2* SNPs and anti-dsDNA autoantibodies in EA SLE subjects, and identified two SNP haplotypes independently associated with the absence (H1: 7.0% vs. 10.4%, $P=1.2\times10^{-5}$) and presence (H2: 5.8% vs. 3.8%, $P=7.0\times10^{-4}$) of anti-dsDNA autoantibodies. The H1 haplotype contained imputed SNPs extending into the proximal complement receptor 1 (*CR1/CD35*) gene. Three phenotypes were found in healthy control subjects with the H1 haplotype compared to the H2 haplotype: 1) decreased mRNA levels for the *CR2* long isoform (p=0.0293), which is expressed primarily on FDC, 2) increased expression of CR1 (p=0.0353), and 3) positive correlation of surface CR2 with ligand binding capacity (H1: p=0.0311; H2: p=0.2967).

Conclusion: These data indicate that *CR2* haplotypes are preferentially associated with anti-dsDNA autoantibodies and may modify both B cell and FDC responses. The association of imputed *CR1* SNPs and altered B cell CR1 expression suggest that an extended haplotype encompassing both genes is responsible. Anti-dsDNA antibodies fluctuate with lupus disease activity, are associated with more severe disease, and are among the last autoantibodies to appear prior to the onset of clinical symptoms. Therefore, understanding the mechanisms by which they are regulated has important therapeutic implications.

Epigenetic Profiling in Monozygotic Twins Discordant for Systemic Lupus Erythematosus Reveals Prominent Hypomethylation of Interferon-Inducible Genes. Paula S. Ramos[1], Timothy D. Howard[2], Miranda C. Marion[2], Satria Sajuthi[2], Jennifer A. Kelly[3], Kathy L. Moser[3] and Carl D. Langefeld[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multisystem, autoimmune inflammatory disease. In addition to genetic and environmental influences, the discordance rate between monozygotic (MZ) twins suggests a role for epigenetic factors in disease. The analysis of MZ twins represents the ideal design to assess the role of epigenetic factors in disease etiology. Here, we report the results of a genome-wide analysis of DNA methylation on 3 MZ twin pairs discordant for SLE.

Methods: Genomic DNA was extracted from peripheral blood of 3 MZ twin pairs discordant for SLE. DNA methylation profiling was performed using the Illumina Infinium HumanMethylation450 BeadChip. Probes with a detection P-value$<$1.0E-05 were excluded. In order to identify differentially methylated genes between unaffected and affected twins, a paired *t*-test on the probe-specific β-values was computed and significance was assessed as the intersection of meeting an FDR threshold (1.06×10E-7) and mean DNA methylation difference ($\Delta\beta$)$>|0.10|$.

Results: Global hypomethylation of interferon-inducible genes was observed in the affected twins. Analysis of the top loci using Gene Ontology suggested an enrichment of epigenetic changes in genes involved in response to biotic stimulus (GO:0009607; P(Benjamini)=0.0077) and response to virus (GO:0009615; P(Benjamini)=0.021), and their functional annotation using Panther revealed an enrichment of two biological processes, immunity and defense (BP00148; P(Benjamini)=0.0044) and interferon-mediated immunity (BP00156; P(Benjamini)=0.032). The top hypomethylated sites in the affecteds were located in several interferon-inducible genes, including MX1 ($\Delta\beta = -0.47$, $P=6.59$E-13), IFI44L ($\Delta\beta = -0.29$, P=1.58E-14), and IFITM1 ($\Delta\beta = -0.25$, P=4.41E-40). Other significant loci included the polymerase PARP9 (P=6.74E-126, $\Delta\beta = -0.37$), the cytidine kinase CMPK2 ($\Delta\beta = -0.33$, P=7.98E-08), and the cyclic nucleotide phosphodiesterase PDE7A genes ($\Delta\beta = -0.35$, P=1.21E-09).

Conclusion: These data support a role for DNA methylation differences in mediating susceptibility to SLE. Furthermore, these observed hypomethylation of interferon-inducible genes offers a mechanistic explanation for the well know overexpression of interferon-inducible genes observed in patients with SLE and other autoimmune diseases.

Systemic Lupus Erythematosus RNA-Seq: Endogenous Retroviral Group K Overexpression in Monocytes. Lihua Shi[1], Zhe Zhang[2], Michelle Petri[3] and Kate Sullivan[4]. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Bioinformatics, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]THe Children's Hospital of Philadelphia, Philadelphia, PA

Background/Purpose: Gene expression studies of peripheral blood mononuclear cells in SLE have consistently shown an interferon signature. We previously examined monocytes from SLE patients to understand the impact of interferon expression on the cell that is integral to atherosclerosis and renal disease. In that study, we also found a gene expression signature consistent with interferon exposure. Various triggers of interferon expression have been identified and endogenous retroviral elements have been considered as a possible nucleic acid stimulus. Older literature on endogenous retroviruses in SLE identified intracisternal A-type particles reminiscent of retroviruses and frequent identification of anti-retroviral antibodies. Nevertheless, there has been little direct demonstration of altered expression of endogenous retroviral elements. To better understand the altered gene expression and to examine non-coding RNAs, which are poorly represented on arrays, we performed RNA-seq.

Methods: RNA-seq on the SOLiD platform was performed on RNA from monocytes from 8 SLE patients and 8 age/gender-matched controls. Reads were aligned and mapped using BioScope. The biological samples were scored to define variability by calculating the sample-sample correlation. Group comparison statistics and FDR calculation were used to identify regions with significant RPKM group-based variations. To minimize confounders, we selected patients with a low disease activity and minimal medications.

Results: Again, we saw evidence of interferon exposure. We also noted a dramatic enrichment of genes regulated by the IRF family of transcription factors. Among the most highly expressed transcripts were non-coding RNAs, anti-sense RNAs and micro-RNAs, suggesting that array studies have captured but one facet of the transcriptome. The use of RNA-seq also enabled us to look at highly repetitive transcripts such as LINE and Alu elements. Although unmappable, the total read depth was analyzed. Amongst all repetitive elements, the ERVK family was found to be 3X overexpressed in SLE monocytes relative to the controls. Other engogenous retroviral elements were expressed at comparable levels in SLE patient and controls.

Conclusion: The ERVK family of endogenous retroviruses is unusual in that it can encode gag, env, pol, reverse transcriptase and integrase proteins. Retroviruses have been implicated in murine lupus but data on human endogenous retroviruses have been limited. The recognition of the important role of TREX1 in limiting retroviral DNA induction of interferons has supported a role for retroviruses in human SLE but until the advent of next generation sequencing, it was difficult to identify specific families. This study identified many non-coding RNAs both over-expressed and under-expressed, often by 20–50-fold. Unexpectedly, the ERVK family was over-expressed out of proportion to other endogenous retroviruses, suggesting that this family may be selectively de-repressed. De-repression of ERVK elements could contribute to interferon production via accumulation of viral RNAs.

Dysregulated Discoidin Domain Receptor 2-Microrna 196a-Mediated Negative Feedback Against Excess Type I Collagen Expression in Scleroderma Dermal Fibroblasts. Katsunari Makino, Masatoshi Jinnin, Jun Aoi, Ikko Kajihara, Takamitsu Makino, Keisuke Sakai, Satoshi Fukushima, Yuji Inoue and Hironobu Ihn. Kumamoto University, Kumamoto, Japan

Background/Purpose: Systemic sclerosis (SSc) is characterized by the excess deposition of collagen in the skin, due to intrinsic transforming growth factor (TGF)-β activation. The discoidin domain receptor 2 (DDR2) is a transmembrane receptor belonging to the receptor tyrosine kinase family. DDR2 is mainly detected in mesenchymal cells and responds to collagen types I, II, III and X. This study was undertaken to clarify the expression pattern of DDR2 in SSc and the role in the pathogenesis of SSc.

Methods: DDR2 expression was evaluated by immunoblotting, immunohistochemistry and real-time PCR. The knockdown or overexpression of DDR2 was performed using siRNA or lentiviral transfection. The microRNA expression was evaluated by real-time PCR. The knockdown or overexpression of microRNA in dermal fibroblasts was performed using microRNA inhibitor or mimic.

Results: The expression of DDR2 mRNA and protein was significantly decreased in SSc cultured dermal fibroblasts, which was recovered after knockdown TGF-β. The knockdown of DDR2 in normal fibroblasts induced microRNA-196a expression, which led to type I collagen down-regulation, thus indicating that DDR2 itself has a negative effect on microRNA-196a expression and that it induces type I collagen expression. In SSc fibroblasts, however, the DDR2 knockdown did not affect TGF-β signaling and microRNA-196a expression. The microRNA-196a levels were significantly decreased in normal fibroblasts treated with TGF-β and in SSc fibroblasts. Taken together, these findings indicate that, in SSc fibroblasts, the intrinsic TGF-β stimulation induces type I collagen expression and down-regulates DDR2 expression. This probably acts as a negative feedback mechanism against excess collagen expression, since a decreased DDR2 expression is supposed to stimulate the microRNA-196a expression and further change the collagen expression. However, in SSc fibroblasts the microRNA-196a expression was down-regulated by TGF-β signaling.

Conclusion: DDR2-microRNA 196a-mediated negative feedback against excess type I collagen expression is impaired in SSc fibroblasts. Its impairment may be involved in the pathogenesis of SSc. Investigations of the overall regulatory mechanisms of fibrosis by DDR2 and microRNAs may lead to new therapeutic approaches for this disease.

Altered Regulation of Metabolic Pathways in Systemic Sclerosis Evidenced by Metabolomics. Emmanuel Chatelus, Jacques-Eric Gottenberg, François-Marie Moussallieh, Christelle Sordet, Arnaud Theulin, Alain Meyer, Jean-Francois Kleimann, Jean Sibilia and Izzie Jacques Namer. Strasbourg University Hospital, Strasbourg, France

Background/Purpose: High throughput study of metabolic pathways might help identify new biomarkers and therapeutic targets in autoimmune diseases. Systemic sclerosis (SSc) currently lacks prognostic biomarkers and efficacious and specific treatments. We therefore assessed serum levels of 40 metabolites in patients with SSc and healthy controls using high-resolution magic-angle spinning (HRMAS) proton magnetic resonance spectroscopy.

Methods: The blood samples of 38 successive patients with SSc (median age (range) 62 years (25–85); disease duration 8 years (1–22); limited cutaneous SSc: 62%; diffuse cutaneous SSc: 38%) and 39 healthy controls were analysed in this study. After cryopreservation at $-80°C$, the samples were studied with HRMAS proton magnetic resonance spectroscopy (1H-MRS). Spectra were recorded on a Bruker Avance III 500 spectrometer operating at a proton frequency of 500 MHz. The speed revolution of the tube was 3000 Hz. The 1D MR spectra were acquired during 15 min (between 0.5 and 4,7 ppm). Unsupervised clustering was performed using principal component analysis (PCA).

Results: Unsupervised clustering of the 38 samples allowed to discriminate all patients with SSc from healthy controls ($R^2Y=0.76$ and $Q^2=0.67$ (figure 1)). Interestingly, 3 metabolites were significantly more expressed in SSc blood samples than in healthy controls: acetone, acetate and formate (median 10.7 vs 8.1 μmol/l, $p<0.05$; 21.8 vs 5.4 μmol/l; $p<0.05$; 28.6 vs 7.9 μmol/l, $p<0,05$ respectively).
Figure 1. PCA scored plot based on NMR spectra of blood samples obtained from systemic sclerosis patients (red dot) and healthy controls (blue triangle).

Conclusion: This first high-throughput analysis of metabolic pathways disclosed a specific metabolomic signature of SSc allowing to discriminate all patients from controls. This new and very potent means of metabolic analysis may help to increase our knowledge on the pathogenesis of SSc, identify biomarkers, and new therapeutic targets.

The Role of TCR Vä1[+] NKT Cells in Systemic Sclerosis Patients with Interstitial Pneumonitis. Seiji Segawa, Daisuke Goto, Masanobu Horikoshi, Shinya Hagiwara, Naoto Umeda, Hiroshi Ogishima, Yuya Kondo, Hiroto Tsuboi, Makoto Sugihara, Taichi Hayashi, Yusuke Chino, Isao Matsumoto and Takayuki Sumida. University of Tsukuba, Tsukuba City, Japan

Background/Purpose: Interstitial pneumonia (IP) is one of the critical complications in patients with several autoimmune diseases. However, the exact mechanism of IP remains elusive. Recently, the pathological role of gd T cells was reported in several IP mice models. Previous our data showed that IP in Interleukin (IL)-2 plus IL-18 induced mice was similar to human IP. In this mice, $\gamma\delta$NKT cells exacerbated IL-2 plus IL-18 induced lung inflammation via the production of IFN-γ. Thus, to examine whether Vd1[+] NKT cells play a crucial role, we carried out the number and function of TCR Vδ1[+]NKT cells in systemic sclerosis patients with IP.

Methods: 1) PBMCs were isolated from healthy controls (HC, n=22) and patients with rheumatoid arthritis (RA, n=17), systemic sclerosis (SSc, n=35), and polymyositis/dermatomyositis (PM/DM, n=14). We examined the proportion of TCR Vδ1[+]NKT cells in PBMCs by flow cytometry (FCM). 2) We examined the proportion of TCR Vδ1[+]NKT cells in patients with autoimmune disease plus IP. 3) We analyzed the correlation between the proportion of TCR Vδ1[+]NKT cells in PBMCs and serum KL-6 values. 4) CD161[-] Vδ1[+] $\gamma\delta$T and CD161[+] Vδ1[+] $\gamma\delta$T cells (TCR Vδ1[+]NKT cells) in PBMCs were sorted out from HC (n=3). We performed GeneChip analysis using those two cell populations.

Results: 1) The proportion of TCR Vδ1[+]NKT cells in PBMCs from SSc patients (mean±SEM, 0.55±0.13%) was significantly higher than that of HC (0.23±0.09%, $p<0.05$), whereas RA (0.38±0.12%) and PM/DM patients (0.23±0.11%) were not. 2) In SSc patients, the proportion of TCR Vδ1[+]NKT cells in PBMCs from IP-negative subjects (1.03±0.32%) was significantly higher than that of IP-positive subjects (0.28±0.07%, $p<0.05$). In RA and PM/DM patients, there was no difference between IP-negative and IP-positive subjects. 3) In IP-positive SSc patients, results showed a negative correlation between serum KL-6 values and the proportion of TCR Vδ1[+] NKT cells ($r=-0.464$, $p<0.05$). In IP-positive PM/DM patients, there were no any correlations. 4) We found highly expressed 192 genes in TCR Vδ1[+] NKT cells compared to CD161[-] Vδ1[+] $\gamma\delta$T cells. One of 192 genes was CCL3 chemokine associating with SSc and IP. Exactly, the CCL3 mRNA was significantly increased in TCR Vδ1[+]NKT from SSc patients by real time PCR methods ($p<0.05$).

Conclusion: TCR Vδ1[+] NKT cells might play a crucial role in the generation of IP in patients with SSc.

Adiponectin Has Potent Anti-Fibrotic Effects Mediated Via AMP Kinase: Novel Target for Fibrosis Therap. Feng Fang[1], Lei Liu[2], Yang Yang[2], Jun Wei[1], Swati Bhattacharyya[1], Ross Summer[3], Boping Ye[2] and John Varga[1]. [1]Northwestern University, Chicago, IL, [2]China Pharmaceutical University, Nanjing, China, [3]Boston University, Boston, MA

Background/Purpose: Fibrosis in scleroderma is associated with transforming growth factor-β (TGF-β) signaling activation, collagen deposition and myofibroblast accumulation. Peroxisome proliferator activated receptor gamma (PPAR-γ) inhibits profibrotic responses, while regulates adiponectin production. Our recent studies demonstrated that adiponectin levels were reduced in patients with diffuse cutaneous scleroderma, and inversely correlated with disease activity, severity and duration. However, the function and molecular signaling of adiponectin during fibrogenesis are still unknown.

Methods: Collagen and α-smooth muscle actin (α-SMA) gene expression and TGF-β signaling by recombinant adiponectin, AICAR and metformin were examined by real-time qPCR, Western blot, immunofluorescence microscopy and transient transfection assays. AdipoR1 expression on skin fibroblasts was determined by real-time qPCR. Gene expression changes were examined using microarrays.

Results: In skin fibroblasts, recombinant adiponectin inhibited the basal and TGF-β-stimulated collagen and alpha-smooth muscle actin mRNA and protein expression at dose-depend manner, while RNAi knockdown of adiponectin sensitized TGF-β-stimulated fibrotic responses. Similarly, metformin and AICAR, two agonists of 5' adenosine monophosphate (AMP)-activated protein kinase, inhibited fibrotic responses. AMPK antagonist compound C impaired the anti-fibrotic effects of adiponectin. In adiponectin-null fibroblasts, PPAR-γ ligand PGJ$_2$ failed to inhibit TGF-β-stimulated fibrotic responses. In addition, adiponectin completely abrogated the profibrotic effects of lipopolysaccharide (LPS, a potent ligand of Toll-like receptor 4 (TLR4) with profibrotic effects). Furthermore, the adiponectin receptor 1 showed reduced expression in scleroderma skin biopsies, suggesting the defective adiponectin signaling in scleroderma.

Conclusion: Our results indicate adiponectin plays an important homeostatic role in negative regulation of collagen deposition and myofibroblast accumulation. The anti-fibrotic effects associated with pharmacological PPAR-γ ligands are at least in part due to the activation of the adiponectin signaling pathway. Restoring the adiponectin signaling axis in fibroblasts might represent a novel pharmacological approach to controlling fibrosis.

Type I Interferon Associated Gene *IRF7* in the Pathogenesis of Fibrosis in Systemic Sclerosis (SSc). Minghua Wu[1], Michael R. Blackburn[2], Shervin Assassi[1], Xiaochun Liu[1], John D. Reveille[1], Filemon K. Tan[1], Sandeep K. Agarwal[3] and Maureen D. Mayes[1]. [1]University of Texas Health Science Center at Houston, Houston, TX, [2]The University of Texas Medical School at Houston, Houston, TX, [3]Baylor College of Medicine, Houston, TX

Background/Purpose: Fibrosis in Systemic Sclerosis is characterized by excessive collagen production and accumulation in the skin and lungs. It has been increasingly appreciated that a substantial number of SSc patients display a type I interferon (IFN) signature. Microarray studies support a pivotal role of type I IFN in the pathophysiology of connective tissue diseases. Type I IFN and associated gene signatures might serve as a marker for more severe disease. Interferon regulatory factors (IRFs) are characterized as transcriptional regulators of type I IFNs and IFN-inducible genes. Interferon regulatory factor 7 (IRF7) polymorphisms are associated with many autoimmune diseases including SSc. However, no specific mechanism for its involvement in SSc has been identified.

Methods: Healthy adult dermal fibroblasts and SSc fibroblasts were studied in parallel. Scleroderma and normal skin biopsies (61 SSc patients and 36 healthy controls) were used for microarray studies to quantitate IRF7 levels and for immunohistochemistry (IHC) analyses (6 SSc patients and 5 healthy controls) to determine expression pattern of IRF7. In addition to patient samples, IRF7 was examined in bleomycin induced scleroderma mouse model. Lesional murine skin tissues were examined by microarray and immunohistochemistry analysis.

Results: IRF7 protein levels were significantly elevated in explanted SSc skin fibroblasts and skin tissues from patients with SSc compared to healthy controls. Microarray studies showed that IRF7 mRNA levels were up-regulated in skin and monocytes from SSc patients. TGF-β, PolyI(c) and IFN-α caused a time- and dose-dependent increase in IRF7 protein and mRNA expression in normal and SSc skin fibroblasts. IRF7 protein and mRNA levels were found to be up-regulated in skin from the bleomycin induced mouse model of scleroderma.

Conclusion: Up-regulation of IRF7 in SSc might contribute to amplification or persistence of the IFN driven inflammatory response and TGF-β-driven fibrotic response. Blocking IRF-7 may therefore represent a novel therapeutic strategy in SSc.

Enhanced Release of S100A9 and Hepatocyte Growth Factor by the Epidermis in Systemic Sclerosis. Joanna Nikitorowicz Buniak[1], Christopher P. Denton[2], David J. Abraham[1] and Richard J. Stratton[1]. [1]UCL Medical School, London, United Kingdom, [2]UCL, London, United Kingdom

Background/Purpose: Systemic sclerosis (SSc) is a severe disease of unknown aetiology characterised by cellular injury and activation in early stage, followed by autoimmunity and fibrosis. Much of the work is focused on the fibroblasts however, keratinocytes are known to be able to secrete chemo-attracting agents, as well as growth factors influencing phenotype and proliferation rate of fibroblasts. We have recently shown that SSc epithelial cells exhibit an activated phenotype similar to wound healing. Data from hypertrophic scaring and keloids demonstrate that epidermis can promote dermal fibrosis. Therefore, we decided to look for evidence that in SSc injured epidermal cells are releasing chemokines and cytokines capable of recruiting immune cells to the skin and promoting fibrosis.

Methods: Forearm biopsies were taken from 12 healthy controls and 12 SSc patients. Dermis and epidermis were separated using trypsin/EDTA and the explants incubated overnight in serum free media. The conditioned media were then collected and analysed using Legend PLEX (BioLegend) for presence of G-CSF, GM-CSF, VEGF, PDGF-AA, PDGF-BB, MCP-1, FGF-2, IL-8, IL-6, IL-1α, IL-1β, and IL-1ra. Additionally, HGF, CCL20 and S100A9 were measure by ELISA (R&D Systems). Moreover, immunohistochemistry was performed on skin biopsies of 6 dcSSc and 6 healthy controls using antibodies against S100A9, S100A8, loricrin and involucrin. The epidermal thickness and cell area were also measured. The statistical analysis was performed using Wilcoxon rank-sum test.

Results: The conditioned media analysis revealed significantly higher levels of HGF ($p<0.005$) and S100A9 ($p<0.05$) released by SSc epidermis. Also increased levels of FGF-2, VEGF-A and PDGF-AA and IL-8 found in the SSc epidermis conditioned media showed a trend towards significance. Staining of skin sections confirmed much higher levels of S100A9 in SSc present throughout the epidermis, compared to positive staining in the healthy skin only around epidermal appendages. The SSc epidermis showed significant increase in thickness ($p<0.05$) and hypertrophic cells in basal ($p<0.005$) and spinous layers ($p<0.005$). The expression of involucrin and loricrin was also altered.

Conclusion: The epidermis provides a potential source of chemokines in SSc. High levels of pro-inflammatory S100A9 released by SSc dermis might contribute to the inflammation and therefore skin fibrosis. The abnormal thickness, hypertrophic keratinocytes and altered expression of differentiation markers in SSc epidermis suggest changes in terminal differentiation and signalling. The increase in HGF release by SSc epidermis is consistent with our previous report of enhanced c-Met activation in SSc epidermis and, indicates autocrine stimulation that could be responsible for the changes observed. However, more investigations are required to fully explore the mechanisms underlying S100A9 and c-Met/HGF signaling and they role of in skin fibrosis.

Increased Synthesis of Leukotrienes by Peripheral Blood Mononuclear Cells Is Associated with More Severe Disease and Worse Prognosis in Patients with Systemic Sclerosis. Otylia M. Kowal-Bielecka[1], Anna Lapinska[2], Marek Bielecki[3], Oliver Distler[4], Izabela Domyslawska[1], Lech Chyczewski[2], Stanislaw Sierakowski[1], Steffen Gay[5] and Krzysztof Kowal[6]. [1]Department of Rheumatology and Internal Medicine, Medical University in Bialystok, Bialystok, Poland, [2]Department of Medical Pathomorphology, Medical University in Bialystok, Bialystok, Poland, [3]Department of Orthopedics and Traumatology, Medical University in Bialystok, Bialystok, Poland, [4]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [5]Center of Experimental Rheumatology, University Hospital Zurich and Zurich Center of Integrative Human Physiology (ZIHP), Switzerland, Zurich, Switzerland, [6]Department of Allergology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland

Background/Purpose: Eicosanoids are a group of arachidonic acid-derived lipid mediators which play a key role in the regulation of inflammatory response and connective tissue remodeling. Different classes of eicosanoids exert different, often opposing roles. Leukotrienes (LTs), synthesized

through the action of 5-lipoxygenase, are considered pro-inflammatory and pro-fibrotic mediators, while 15-lipoxygenase-derived products, 15-hydroxyeicosatetraenoic acid (15-HETE) and lipoxins, possess anti-inflammatory and anti-fibrotic properties, in part due to antagonizing action of LTs.

We undertook this study to investigate the role of eicosanoids in the pathogenesis of SSc trough evaluation of 1). the profile of eicosanoids synthesized by peripheral blood mononuclear cells (PBMC) and 2). relationships between eicosanoid profile of PBMC and clinical features and progression of the disease in patients with SSc.

Methods: Leukotriene B4 (LTB4), cysteinyl leukotrienes (CysLTs), and 15-HETE were measured by ELISA in the supernatants from ionophore-stimulated PBMC of 39 patients with SSc and 24 age- and sex-matched healthy controls (HC). Only patients, who had not received immunosuppressive drugs, aspirin or other NSAIDs before the study, were included. Follow-up data were available in 25 SSc patients (mean $+/-$ SD follow-up time: 34 $+/-$ 18 months). Disease progression was defined as death due to SSc-related organ complication, development of a new or progression of pre-existing SSc-related organ involvement.

Results: Concentration of LTB4 was significantly higher in PBMC cultures from patients with SSc (640 $+/-$ 518 pg/mL/10^5cells) as compared with HC (353 $+/-$ 216 pg/mL/10^5cells, p<0.05). Higher LTB4 levels were associated with the presence of diffuse SSc and pulmonary fibrosis. No significant differences could be found in the concentrations of CysLTs or 15-HETE between SSc patients and HC (data not shown). The 15-HETE/LTB4 and 15-HETE/CysLTs ratios were lower in SSc patients (13 $+/-$ 11 and 20 $+/-$ 19, respectively) as compared with HC (26 $+/-$ 28, p<0.05, and 26 $+/-$ 17, p=0.08, respectively),

In 7 SSc patients who experienced subsequent progression of the disease baseline concentration of CysLTs was significantly higher (452$+/-$ 197 pg/mL/10^5cells) while 15-HETE/LTB4 (6.9 $+/-$ 9.3) and 15-HETE/CysLTs (8.1 $+/-$ 6.0) ratios – significantly lower as compared with the remaining 18 with stable disease (276$+/-$ 139 pg/mL/10^5cells, 13.2$+/-$ 10.7, and 18.9$+/-$ 11.6, respectively, p<0.05 for all). Although LTB4 concentration was higher in patients who progressed over time (918$+/-$ 665 pg/mL/10^5cells) as compared with those with stable disease (569$+/-$ 549 pg/mL/10^5cells), the difference was not significant (p=0.1).

Conclusion: The results of our study indicate that increased synthesis of LTs, which is not balanced by sufficient synthesis of 15-lipoxygenase derived eicosanoids, might be involved in the pathogenesis and progression of SSc. Consequently, inhibition of LTs synthesis or action might represent a new, promising target in the treatment of SSc.

Interleukin-17A Positive Cells Are Increased in Systemic Sclerosis Skin and Their Number Is Inversely Correlated to Skin Thickness.
Marie-Elise Truchetet[1], Nicolò Costantino Brembilla[1], Elisa Montanari[1], Paola Lonati[2], Pier Luigi Meroni[3] and Carlo Chizzolini[1]. [1]University hospital of Geneva, Geneva, Switzerland, [2]Istituto G. Pini, University of Milan, Milan, Italy, [3]Istituto G. Pini, University of Milan, Milano, Italy

Background/Purpose: T cell producing IL-17A are increased in the peripheral blood of individuals affected by systemic sclerosis (SSc). We asked the question whether IL-17A-producing cells are present in affected SSc skin and whether they exert any role in myofibroblasts induction.

Methods: Bioptic material was obtained from the involved skin of 8 SSc and 8 healthy donors (HD) undergoing plastic surgery. We adopted an immunohistochemistry and multicolor immunofluorescence approach to identify and quantify in vivo IL-17A+, IL-4+, CD3+, tryptase+, alpha-smooth muscle (aSMA)+, myeloperoxidase+, CD1a+ cells. Dermal fibroblasts cell lines were generated from all biopsies. Quantitative PCR, western-blot, and solid phase assays used to quantify aSMA, and matrix metalloproteinase-1 (MMP1) production by cultured fibroblasts.

Results: IL-17A+ cells were significantly more numerous in SSc than HD skin (p=0.004) and present in both superficial and deep dermis. Most of these cells (>60%) were tryptase+ mast cells and between 10 to 20% Th17 cells. Some IL-17A+, but no IL-4+ cells were found adjacent to aSMA+ cells.

fibroblasts. However, IL-17A did not induce aSMA-expression in cultured fibroblasts and decreased aSMA-expression induced by transforming growth factor-beta, while directly enhancing MMP-1 production. Furthermore, the frequency of IL-17A+ cells was higher in the skin of SSc individuals with lower global skin thickness score.

Conclusion: IL-17A+ cells belonging to the innate and adaptive immune system are numerous in SSc skin where IL-17A participates to inflammation and exerts an inhibitory activity on myofibroblast differentiation. These data are consistent with a direct negative regulatory role for IL-17A in the development of dermal fibrosis in humans.

The Histone Deacetylase SIRT1 Is Anti-Fibrotic and Mediates Resveratrol Effects.
Roberta G. Marangoni[1], Archit Ghosh[1], Jun Wei[2] and John Varga[3]. [1]Northwestern University, Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern University Medical School, Chicago, IL

Background/Purpose: Fibrosis in scleroderma is associated with increased collagen synthesis driven by TGF-β and associated epigenetic modifications. The Class III histone deacetylase SIRT1 has anticancer and anti-inflammatory properties in vitro and in vivo, and its expression and activation are induced by the natural phytoalexin resveratrol. We investigated SIRT1 function and regulation by resveratrol during fibrogenesis.

Methods: *SIRT1* expression in scleroderma skin biopsies was analyzed in published microarray dataset. The effects of resveratrol on fibrotic responses were evaluated by real-time qPCR, Western analysis, immunefluorescence, transient transfection, collagen gel contraction and cell migration assays. SIRT1 modulation of TGF-β signaling was examined using the pharmacological SIRT1 inhibitors splitomicin and nicotinamide.

Results: Analysis of published microarray datasets revealed significant reduction of *SIRT1* mRNA levels in skin biopsies from patients with diffuse cutaneous scleroderma n=11, p<0.001). Resveratrol induced the activity of SIRT1 in explanted normal skin fibroblasts. Moreover, resveratrol blocked the stimulation of collagen gel contraction and cell migration induced by TGF-β, and abrogated TGF-β–induced collagen and α-smooth muscle actin expression, and Smad2/3-dependent transcriptional activity, in a dose-dependent manner. Ectopic SIRT1 by itself was sufficient to abrogate TGF-β stimulated collagen expression, whereas pharmacological inhibition of SIRT prevented the anti-fibrotic activities of resveratrol.

Conclusion: Resveratrol abrogates canonical TGF-β signaling and suppresses fibrotic responses via the histone deacetylase and essential metabolic regulator SIRT1. Reduction of *SIRT1* in scleroderma skin biopsies suggests its role in regulating fibrogenesis. Accordingly, we propose that SIRT1 is a novel target for anti-fibrotic therapy, and pharmacological enhancement of the SIRT1 expression or activity might have a therapeutic potential in scleroderma.

Caveolin-1 Deficiency Induces Spontaneous Endothelial-to-Mesenchymal Transition (EndoMT) in Murine Pulmonary Endothelial Cells *in Vitro*.
Zhaodong Li[1], Peter J. Wermuth[1], Bryan Benn[1], Michael P. Lisanti[2] and Sergio A. Jimenez[1]. [1]Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center, Thomas Jefferson University, Philadelphia, PA, [2]Jefferson Stem Cell Biology and Regenerative Medicine Center, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Recent studies demonstrated that the phenotypic transition of endothelial cells (EC) into activated mesenchymal cells, a process known an endothelial-to-mesenchymal transition (EndoMT), may be crucial in the development of tissue and organ fibrosis in fibrotic diseases such as Pulmonary Fibrosis and Systemic Sclerosis (SSc). Furthermore, it was previously demonstrated that TGF-β induces EndoMT in murine lung EC in vitro. Owing to the important role of caveolin-1 (cav-1) in TGF-β receptor internalization and TGF-β signaling

the role of cav-1 in induction of EndoMT in murine lung EC was investigated.

Methods: Pulmonary EC were isolated from wild-type (WT) and cav-1 knockout (cav-1 KO) mice employing sequential immunomagnetic selection with anti-CD31 and anti-CD102 antibodies followed by in vitro culture and treatment with TGF-β1. EndoMT was assessed by immuno-fluorescence for α-smooth muscle actin (α-SMA) and by Western blot analysis for α-SMA and type I collagen. Induction of the transcriptional repressor, Snail 1, was assessed by real time PCR. The same studies were performed in cav-1 KO pulmonary EC following restoration of functional cav-1 domains employing a cell permeable cav-1 scaffolding domain peptide.

Results: Pulmonary EC from cav-1 KO mice displayed high levels of spontaneous α-SMA and type I collagen expression which increased following TGF-β treatment. There was a remarkable increase in sponta-neous Snail 1 expression. Spontaneous and TGF-β1-stimulated EndoMT were abrogated by restoration of functional cav-1 domains.
Spontaneous and TGF-β1 stimulated EndoMT in cav-1 KO primary pulmonary EC. **A.** Pulmonary EC from WT and cav-1 KO mice were cultured in media alone (control) or with 10 ng/ml TGF-β1 for 72h, protein from cell lysates was electrophoresed and probed in Western blots for α-SMA. **B.** Culture media from the same samples were analyzed by Western blot for type I collagen.

Conclusion: Cav-1 plays an important role in the regulation of EndoMT by abrogating spontaneous and TGF-β-induced EndoMT and EndoMT-mediated generation of activated myofibroblasts. Since reduc-tion of cav-1 expression is an important molecular abnormality present in SSc lung and dermal fibroblasts the results indicate that exaggerated spontaneous and TGF-β induced EndoMT caused by cav-1 deficiency may play a crucial role in the pathogenesis of SSc tissue fibrosis and vasculopathy.

Platelet Release Products Mediate Endothelial Apoptosis: A Possible Role for Thrombospondin 1- CD36 Pathway in SSc-Endothelial Apoptosis. Bashar Kahaleh and Yongqing Wang. University of Toledo, Toledo, OH

Background/Purpose: Sequential pathologic observations in the early stages of SSc demonstrated evidence for platelet aggregation and binding to blood vessels that is generally followed by vascular effacement and the development of SSc vasculopathy. In this study we thought to investigate the effects of platelet constituents on microvascular endothelial cells (MVEC) apoptosis. We particularly investigated the role of thrombospon-din 1 (TSP1) as a possible platelet derived signal since it is a potent angiogenic inhibiter, it can mediate endothelial apoptosis and activate TGF-β and is reported to be overexpressed in SSc. Furthermore, we investigated the role of CD36 in MVEC apoptosis since TSP1 vascular effects are known to results from its binding to CD 36 receptors.

Methods: MVEC were isolated from involved SSc skin and from match healthy control subjects. Platelets were collected from healthy subjects, sonicated, ultracentrifuged and the resulting supernatant (PLSN) was used in MVEC cultures. MVEC apoptosis was evaluated by *TUNEL* and active caspases-3 staining. CD 36 expression in MVEC was measured by quantitative RT-PCR and CD36 expression was knocked down using CD36 *specific siRNA.*

Results: The following results were observed in this study:

1. Addition of PLSN to MVEC cultured in 0.5% serum concentration resulted in a dose dependent apoptosis of MVEC. SSc-MVEC were more susceptible to apoptosis than control MVEC, thus at 20%

PLSN concentration, MVEC apoptosis was 20% $\pm$ 5 and 48% $\pm$ 8 in control vs SSc MVEC respectively (mean $\pm$ SD of three cell lines).

2. Addition of TSP1 neutralizing antibody to PLSN significantly reduced PLSN induced MVEC apoptosis, suggesting that TSP1 in PLSN mediate MVEC apoptosis.

3. CD 36 expression levels were significantly higher in SSc MVEC than in control MVEC (7.4 $\pm$ 2.3 folds, mean $\pm$ SD of 3 cell lines)

4. CD36 knock down using CD36 specific *siRNA* but not ir-*siRNA* resulted in > 90% decrease in CD36 expression and the inhibition of TSP1 and PLSN induced MVEC apoptosis.

Conclusion: Platelets interaction with MVEC results in MVEC apoptosis. This effect is largely mediated by interaction of TSP1 with CD36. SSc-MVEC are more susceptible to this effect possibly because of an upregulated CD36 expression in SSc-MVEC. The data propose the platelet as a possible source for the initial MVEC apoptotic signal in the early stages of SSc vasculopathy and suggest TSP1 as a crucial player in SSc pathogenesis in view of its abundance in SSc and its documented role in the genesis of vasculopathy and tissue fibrosis

Disclosure: B. Kahaleh, None; **Y. Wang**, None.

Decrease Activity of DNA Demethylase in SSc Fibroblast and Micro-vascular Endothelial Cells: A Possible Mechanism for Persistence of SSc Phenotype. Bashar Kahaleh and Yongqing Wang. University of Toledo, Toledo, OH

Background/Purpose: DNA methylation is one of the best-characterized epigenetic modifications that have been implicated in numerous biologic and pathologic processes. It is initiated by DNA methyltransferases (DNMT) 3a and 3b and maintained in subsequent cellular generations by the maintenance enzyme DNMT1. Despite its role in long-term gene silencing, DNA methylation is now believed to be a dynamic process as active DNA demethylation has been observed in certain experimental systems. Thus, during cellular division a competition between DNMT1 and DNA demethylase determine the maintenance or the reversal of DNA methylation in the daughter cells. The molecular identity of DNA demethylase remains elusive but its activity can be measured by functional assay. DNMT1 expression is upregulated in SSc microvascular endothelial cells (MVEC) and fibroblasts (FB) in associa-tion with persistence of DNA methylation of the NCpG islands in the promoter region of key underexpressed genes (i.e. *Fli1* and *NOS3*). Thus we thought in this study to examine the activity of DNA demethylase in SSc and control cells and the role of microRNA (miRNA) in the regulation of DNA demethylase activities.

Methods: MVEC and FB were isolated from involved SSc skin and control subjects. DNMT1 expression levels were determined by qRT-PCR and by western blot analysis. DNA demethylase activity was measured in nuclear extracts using the EPI Quik™ DNA Demethylase Activity/ Inhibition Assay Kit. Small RNA molecules including miRNA were isolated from SSc and control MVEC and FB using PureLink miRNA isolation kit. The effects of miRNA on DNA demethylase activity was examined in SSc and control cells by transfecting the cells with SSc and control miRNA.

Results: The following results were observed in this study:

1. DNMT1 expression levels were significantly upregulated in SSc cells (mean 3.2 and 2.8 folds in MVEC and FB respectively vs control cells, mean 3 cell lines each).

2. DNA demethylase activity was significantly reduced in SSc cells (42% and 51 % in MVEC and FB respectively vs control cells, mean 3 cell lines each)

3. The knockdown of DNMT1 using DNMT1 specific *siRNA* did not affect demethylase activity.

4. Transfection of SSc cells with control miRNA results in decrease expression of DNMT1 and increase activity of DNA demethylase, while the transfection of control cells with SSc miRNA resulted in upregulation of DNMT1 and reduced DNA demethylase activity.

5. SSc MVEC and FB transfection with control miRNA normalized abnormal gene expression profile.

Conclusion: This study demonstrates upregulation of DNMT1 and diminished activities of DNA demethylase in SSc MVEC and FB and that

DNA demethylase activity is regulated by miRNA. The characterization of the molecular mechanisms that target both DNA methylation and demethylation is essential for understanding the emergence and persistence of the pathologic phenotype exhibited by SSc cells.

Background/Purpose: Systemic sclerosis (SSc, scleroderma) is an autoimmune disease characterized by chronic inflammation, vascular injury and profound fibrosis of the skin and internal organ. Leukotrienes (LTs) are a family of arachidonic acid-derived lipid mediators which play a key role in the regulation of inflammation, vascular function and connective tissue remodeling. Studies in humans have shown that increased synthesis of LTs takes places in SSc. However, the mechanisms responsible for overproduction of LTs in SSc remain unclear. The arachidonate 5-lipoxygenase activating protein (ALOX5AP) plays a key role in the regulation of synthesis of LTs through presenting arachidonic acid to 5-lipoxygenase.

In the present study we hypothesized that single nucleotide polymorphisms (SNPs) of *ALOX5AP* might confer risk of SSc and/or SSc-related organ involvement.

Methods: Seven SNPs of *ALOX5AP* (rs17222814, rs17216473, rs10507391, rs4769874, rs9551963, rs9315050, and rs7222842) were genotyped in a cohort of 977 patients with SSc and 539 healthy controls from European centers collaborating within the EULAR Scleroderma Trials and Research (EUSTAR) group. SSc patients were classified as having diffuse or limited SSc, according to the Medsger and LeRoy criteria. Clinical characteristics of SSc patients included the presence of SSc-related interstitial lung disease (SSc-ILD, based on chest X-ray/HRCT), pulmonary hypertension (SPAP > 45 mmHg in echocardiography), scleroderma renal crisis and digital ulcers.

In 14 SSc patients concentrations of cysteinyl leukotrienes and leukotriene B4 were measured in the supernatants of ionophore-stimulated peripheral blood mononuclear cells (PBMC) by means of commercially available EIA kits (Cayman Chemicals, MI, USA).

Results: Significant association was found between rs10507391 polymorphism (T/A) of the *ALOX5AP* and the risk of SSc (Odds Ratio; 95%CI: 1.26; 1.0655–1.49, p=0.0078) and SSc-ILD (OR;95%CI: 1.4224; 1.1621– 1.7412, p=0.0007). However, only the latter association remained significant when corrected for multiple testing (p=0.005).

PBMC from SSc carriers of rs10507391 allele A (N=5) synthesized greater amounts of cysteinyl leukotrienes (433 +/− 215 pg/mL/10^5 cells) as compared with PBMC from SSc patients with rs10507391 TT genotype (N=9, 261 +/− 99 pg/mL/10^5 cells, p<0.05). Synthesis of leukotriene B4 was comparable between the two groups (995 +/− 547 pg/mL/10^5 cells vs 790 +/− 756 pg/mL/10^5 cells, p=0.9).

No significant associations could be found between the remaining SNPs of *ALOX5AP* and the presence of SSc or SSc-related internal organ involvement.

Conclusion: The results of our study indicate, for the first time, that the genetic variants of *ALOX5AP* might play a role in the development of SSc-related pulmonary fibrosis. Moreover, our results might raise the possibility of developing genotype-specific therapy for SSc-related lung involvement. This appears particularly attractive since antileukotriene therapies are already in use in humans.

2299

Acroosteolysis Is Associated with Increased Propensity for Osteoclast Formation and Higher VEGF Levels in the Peripheral Blood of Systemic Sclerosis Patients.

Jin Kyun Park[1], Andrea Fava[2], Antony Rosen[3] and Francesco Boin[2]. [1]Seoul National University Hospital, Seoul, South Korea, [2]Johns Hopkins University, Baltimore, MD, [3]The Johns Hopkins University, Baltimore, MD

Background/Purpose: Acroosteolysis (AO) secondary to bone resorption of distal phalanges affects up to 20% of systemic sclerosis (SSc) patients leading to shortening of the digits, impaired hand function, and disability. AO pathophysiology is not known, but chronic hypoxia secondary to SSc vasculopathy may be a contributing factor. In this study, we sought to define whether the propensity for osteoclast formation is increased in peripheral blood mononuclear cells (PBMCs) of SSc patients with AO compared to controls, and whether this may be associated with levels of the hypoxia-driven vascular endothelial growth factor (VEGF).

Methods: PBMCs obtained from 26 SSc patients (11 with and 15 without AO) and 14 healthy controls were cultured in 96- well plates in the presence of receptor activator of nuclear factor-kappaB ligand (RANKL) and M-CSF. After 9 days, osteoclast-like tartrate resistant acid phosphatase (TRAP)-positive multinucleated giant cells (MNGs) were counted. MNGs formation was also assessed after VEGF (10 ng/ml) priming for 24 hours. Plasma VEGF levels were measured using an electrochemiluminescence platform (Meso Scale Discovery).

Results: SSc patients with AO formed significantly more TRAP+ MNGs at day 9 than SSc patients without AO (142.4 ± 69.6 vs. 27.2 ± 17.6 MNG/well, P < 0.01), whereas no difference was noted between SSc without AO and controls (27.2 ± 17.6 MNG/well vs. 18.7 ± 27.0 MNGs/well, P=NS). Priming with VEGF at 10 ng/ml for 24 hours significantly increased TRAP+MNGs formation by 5.3 fold (P=0.002). In plasma of SSc patients with AO, VEGF levels were significantly higher than in SSc patients without AO (165.3 ± 80.2 vs. 88.1 ± 38.1 pg/ml, P<0.05). Strikingly, plasma VEGF levels correlated with TRAP+MNG formation (Spearman rho=0.386, P=0.05).

Conclusion: AO is associated with an increased propensity of peripheral blood cells to form osteoclasts and this seems to be partly driven by higher VEGF plasma levels. Effective control of hypoxia and inhibition of terminal mediators of osteoclastogenesis may be an effective strategy to prevent and treat AO in SSc patients.

The Effects of Salvianolic Acid B in Fibrotic Models *in Vivo* and *in Vitro*.

Qingmei Liu[1], Wenyu Wu[2], Wenzheng Tu[3], Haiyan Chu[1], Yanyun Ma[1], Hejian Zou[2], Xiaodong Zhou[4] and Jiu-Cun Wang[1]. [1]Ministry of Education Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan University, Shanghai, China, [2]Huashan Hospital, Shanghai, China, [3]Shanghai Traditional Chinese Medicine-Integrated Hospital, Shanghai, China, [4]University of Texas-Houston Medical School, Houston, TX

Background/Purpose: Scleroderma or systemic sclerosis (SSc) is characterized by the fibrosis of skin and visceral organs. Salvianolic acid B (SAB) is an important water-soluble ingredient extracted from Danshen, a kind of Chinese medicinal herbs. Clinical data showed there were good curative effects and low side-effects on SSc with a compound prescription of traditional Chinese medicine including Danshen. Furthermore, SAB has been

proved its efficacy in treating chronic liver fibrosis. Our aim is to examine whether SAB can attenuate fibrosis in the activated fibroblasts from SSc patients and fibrotic mouse models.

Methods: For *in vitro* studies, dermal fibroblasts trains were cultured from skin biopsies of SSc patients which constitutively over-expressed collagen genes. Cell growth was measured with the xCELLigence system to evaluate the effects of SAB on fibroblasts. Real-time quantitative RT-PCR was used to examine the transcript levels of collagen. The levels of Smad3 and p-Smad3 were assayed by Western blot. For *in vivo* studies, C57BL/6 female mice of 6–8 weeks (n = 5 for each treatment) were injected with bleomycin through tracheal cutting to induce pulmonary fibrosis. SAB was feed daily for 10 or 24 days from the third day before bleomycin (BLM) instillation for the Group of Prevention Study (P) or the Group of Prevention &Treatment Study (P&T), respectively. The total cell counts in BALF (broncho alveolar lavage fluid) were used to evaluate the inflammatory status. HE and Masson's trichrome stains, gene expression analysis and Sircol assay were used to assess the effects of drug treatments on inflammatory and fibrotic changes. Immunohistochemistry was also performed to examine the α-SMA positive cells.

Results: ≤°For *in vitro* studies, SAB suppressed fibroblasts proliferation and decreased the synthesis of collagen mRNA in SSc dermal fibroblasts efficiently. Additionally, SAB attenuated TGF-β1-induced Smad3 phosphorylation in normal dermal fibroblasts. In the mouse model of pulmonary fibrosis, SAB significantly reduced the total cell counts in BALF in the P group, indicating the amelioration of inflammation. Furthermore, SAB potently reduced the number of myofibroblasts, the mRNA level of collagen and the collagen content in both the P group and P&T group. HE stain of mouse lung tissues further showed a significant disruption of the alveolar units and infiltration of inflammatory cells in the lungs induced by BLM, while SAB treatment improved the disruption of the alveoli with less infiltrating inflammatory cells in the P group [Figure 1].

Conclusion: SAB inhibited fibroblasts proliferation and collagen gene expression in a Smad3 dependent signaling pathway. Administration of SAB could reduce inflammation and fibrosis in mouse lungs induced by BLM. Therefore, SAB is a promising candidate for the treatment of SSc.
Figure 1. Examination of lung tissues from mice with different treatments. SS: tissues injected with saline and fed with saline; BS: tissues injected with BLM and fed with saline; B&SAB: tissues injected with BLM and fed with SAB; B&CYC: tissues injected with BLM and fed with CYC (Cyclophosphamide, being used as a positive control). Compared with negative control(A-C), mice showed increased collagen content, a disruption of the alveolar units and infiltration of inflammatory cells in the lungs induced by BLM by Masson's trichrome (D) and HE staining (E). Immunochemistry analysis with α-SMA antibody revealed increased numbers of myofibroblasts (F). Administration of SAB (G-I) or CYC (J-L) could reduce the inflammation and fibrosis induced by BLM.

The Interferon Type I Signature Is Increased in Monocytes From Systemic Sclerosis Patients. Zana Brkic[1], Lenny van Bon[2], Cornelia G. van Helden-Meeuwsen[1], Madelon C. Vonk[3], Hanneke Knaapen[3], Wim van den Berg[3], Paul L. Van Daele[1], Virgil A. Dalm[1], Timothy Radstake[2] and Marjan A. Versnel[1]. [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]University Medical Center Utrecht/Radboud University Nijmegen Medical Center, Utrecht/Nijmegen, Netherlands, [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

Background/Purpose: Systemic sclerosis (SSc) is a complex fibrosing disease of unknown etiology. The past decade clear indications for an aberrant immune system have been revealed. SSc is classified either as limited (lSSc) or diffuse cutaneous (dSSc), of which the latter is more severe with excessive involvement of the skin. Although the pathogenesis of SSc is largely unknown, the past few years it has been appreciated that a substantial part of the SSc patients display an Interferon (IFN) type I signature. In this study we assessed the prevalence of such an IFN type I signature in monocytes in a cohort of SSc patients from two clinics in the Netherlands and correlated the IFN type I signature with disease manifestations.

Methods: 41 patients with SSc were included and 25 healthy controls (HC). Patients were stratified as having lSSc (n=25) or dSSc (n=16), and further divided into patients with late (> 3 years) or early disease (<3 years). Expression levels of 11 IFN type I inducible genes, which were previously detected by us in CD14+ monocytes from Sjögren patients, were assessed using real time quantitative PCR. Expression levels were next submitted to a principal component analysis to identify correlated groups of genes.

Results: of factor analysis showed that 4 genes (IFI44L, IFITM1, IFIT1 and MX1) explained 95% of the total variance of the 11 genes, and we therefore adopted overexpression of these 4 genes as our operational definition of positivity for an IFN type I signature. Expression levels of these 4 genes were used to calculate IFN type I scores for each subject. SSc patients positive for the IFN type I signature (IFN score≥10) and patients negative for the signature (IFN score< 10) were then compared for clinical disease manifestations.

Results: IFN type I signature was present in 29% of SSc patients compared with 0% of HC. Stratifying the patients in lSSc and dSSc, we found the IFN type I signature to be present in 24% of lSSc patients and 38% of dSSc. Further dividing the patients into early and late SSc, we observed a statistically significant increase in IFN scores in the early diffuse SSc group compared with HC (P<0.001). SSc patients positive for the IFN type I signature were also significantly younger compared with the patients negative for the signature (p=0.008). Moreover SSc patients with the presence of anti-RNP had significantly higher IFN scores compared to patients without anti-RNP antibodies (P=0.003). In contrast to the presence of anti-RNP antibodies, SSc patients positive for anticentromere antibodies (9 out of 38 patients) were all negative for the IFN type I signature. Studying anti-topoisomerase and anti-SSA antibodies, we observed a trend of higher IFN scores in the patients with these autoantibodies, however no significant differences were detected. When stratifying patients according to the presence of digital ulcers, lung fibrosis, pulmonary hypertension or Raynauds's phenomenon, no differences in IFN scores were observed.

Conclusion: The monocyte IFN type I signature is present in about 1/3 of SSc patients and mainly in the early diffuse SSc group with anti-RNP autoantibodies. Such patients might benefit from treatment blocking the IFN type I production or activity.

Secreted Frizzled-Related Protein 4 Induces a Profibrotic Phenotype in Systemic Sclerosis Fibroblasts by Activating a Non-Canonical WNT Signaling Pathway. Justin Gillespie[1], Paul Emery[2] and Francesco Del Galdo[3]. [1]University of Leeds, Leeds, United Kingdom, [2]Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [3]University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom

Background/Purpose: Systemic Sclerosis (SSc) is a chronic fibrotic disease involving autoimmune activation, fibroproliferative vasculopathy and tissue fibrosis of skin and multiple internal organs. Several studies have indicated that activation of WNT/β-catenin signaling pathway plays an important role in the pathogenesis of tissue fibrosis. Intriguingly, tissue expression studies on SSc skin show both upregulation of canonical WNT ligands[1,2] and consistent upregulation of a putative WNT antagonist, Secreted Frizzled-Related Protein 4 (SFRP4) both at mRNA at protein level[3,4].

Objectives: To determine the role of SFRP4 in modulating WNT signaling and the profibrotic phenotype of SSc fibroblasts.

Methods: Immortalized primary control and SSc fibroblasts were cultured in 10% DMEM and starved in 0.5% DMEM for 24hrs prior to stimulation with recombinant WNT-3a, WNT-5a (100ng/ml) and/or SFRP4 (70ng/ml). Gene expression was quantified by SYBR green QPCR. Canonical WNT signaling activation was assessed by TOPflash TCF/LEF luciferase

reporter activity. Whole cell lysates were used to assess protein expression by Western Blot and c-Jun phosphorylation by Phospho-c-Jun ELISA (Cell Signaling Technology, UK). Mean ± SEM of 4 independent experiments were analyzed using Graph Prism 5.0.

Results: Basal SFRP4 gene expression in SSc fibroblasts was increased on average by 264% compared to normal controls [$P<0.0001$]. Stimulation with WNT-3a upregulated *SFRP4* expression by 56% [$P<0.001$]. WNT-3a upregualted *COL1A1 and α-SMA* gene expression by 160% [$P<0.001$] and 230% [$P<0.0001$] in SSc fibroblasts, in contrast to 18% [$P<0.05$] and 72% [$P<0.01$] in normal fibroblasts, respectively. Consistent with canonical WNT signaling activation, WNT-3a caused an upregulation of *axin-2* by 200% [$P<0.0001$] in SSc and 90% [$P<0.001$] in normal fibroblasts. TOPflash activity was also increased [$P<0.0001$] by 44% and 38%, respectively. Co-stimulation with SFRP4 showed no inhibitory activity of the WNT-3a effects. However, SFRP4 treatment alone was able to induce both *COL1A1* by 43% [$P<0.01$] and *α-SMA by* 46% [$P<0.001$] only in SSc fibroblasts without any significant changes in either *axin-2* expression or TOPflash activity. Similarly, stimulation with WNT-5a, a classic non-canonical WNT ligand, increased *COL1A1* in SSc fibroblasts by 42% [$P<0.0001$] without any increase in *axin-2* expression or TOPflash activity. Additionally, SSc fibroblasts treated with SFRP4 showed an increase in c-Jun phosphorylation reaching maximum levels at 10min by 167% [$P<0.001$] and again at 24hrs by 184% [$P<0.0001$].

Conclusion: Increased SFRP4 in SSc may contribute to the fibrotic process through non-canonical WNT activation instead of functioning as a WNT inhibitor. The molecular events underlying this paradox response of SSc fibroblasts may reveal insightful mechanisms in the pathogenesis and perpetuation of the fibrotic response in SSc.

Background/Purpose: Systemic sclerosis or scleroderma (SSc) is a complex autoimmune disorder that affects the connective tissue causing fibrosis in the skin and different internal organs. A recent genome-wide association study (GWAS) in European SSc patients identified three *loci* as novel genetic risk factors for the disease (*RHOB, PSORS1C1* and *TNIP1*). The latter two have a well-known role in autoimmune disease genetic susceptibility. *PSORS1C1* (Psoriasis susceptibility 1 candidate 1) is located in the vicinity of HLA class I region and has been identified as a psoriasis genetic risk factor. Polymorphisms in *TNIP1* (TNFAIP3 interacting protein 1) have been related to a number of autoimmune disorders and the protein encoded by this gene is involved in the NF-$\kappa\beta$ signaling pathway. The aim of our study was to replicate the previously mentioned findings in a large multicentre independent SSc cohort of Caucasian ancestry.

Methods: 4,389 SSc patients and 7,611 healthy controls from different European countries and the US were included in this study. Six single nucleotide polymorphisms (SNPs): rs342070, rs13021401 (*RHOB*), rs2233287, rs4958881, rs3792783 (*TNIP1*) and rs3130573 (*PSORS1C1*) were analyzed. Plink was used for the statistical analyses. Overall significance was calculated by pooled-analysis of all the cohorts. Haplotype analyses and conditional logistic regression analyses were carried out to further explore the genetic structure of the tested *loci*.

Results: Pooled-analyses of all the analyzed SNPs in *TNIP1* revealed significant association with the whole disease (rs2233287 $P_{MH}=1.94\times10^{-4}$ OR $= 1.19$; rs4958881 $P_{MH}= 3.26\times10^{-5}$ OR $= 1.19$; rs3792783 $P_{MH}= 2.16\times10^{-4}$ OR $= 1.19$). These associations were maintained in all the considered subgroups. *PSORS1C1* comparison showed association with the complete set of patients and all the subsets except for the ACA+ patients. However, the association was dependent on different HLA class II alleles. The variants in the *RHOB* gene were not associated with SSc or any of its subsets.

Conclusion: Our data confirmed the influence of *TNIP1* on an increased susceptibility to SSc and reinforced this *locus* as a common autoimmunity risk factor.

Background/Purpose: Systemic sclerosis (SSc) is a fibrotic autoimmune disease that represents a clear example of a sex biased immune disorder. The X-chromosome gene *IRAK1* has been associated with SSc and systemic lupus erythematosus (SLE), being an interesting candidate to explain this sexual dimorphism. However, *IRAK1* is in the same haplotypic block as *MECP2* on Xq28, and recent studies suggest that functional genetic variants of the latter locus may explain the association signals with SLE observed in *IRAK1*. We aimed to evaluate whether the SSc-associated *IRAK1* polymorphism rs1059702 (Phe196Ser) is the causal variant of the Xq28 association or whether it reflects another association signal from the nearby *MECP2*.

Methods: Only women were included in the study. We analysed a total of 3065 SSc patients and 2630 healthy controls from five independent Caucasian cohorts (Spain, USA, Germany, The Netherlands, and UK). A tagging strategy was used to select four taggers that cover all the common genetic variation within *MECP2* (r2≥0.8) in the CEU population of the HapMap database (rs3027935, rs17435, rs5987201 and rs5945175). We also included the SSc-associated *IRAK1* genetic variant rs1059702. The genotyping was performed with predesigned TaqMan assays. Plink was used for the statistical analyses. *P*-values were corrected for multiple testing using FDR.

Results: *IRAK1* rs1059702 was associated with diffuse cutaneous SSc (dcSSc; P_{FDR}=4.12×10−3, OR=1.27), and trends of association were evident in the global SSc/control (P_{FDR}=0.070, OR=1.13) and anti-topoisomerase positive (ATA+)/control (P_{FDR}=0.087, OR=1.23) comparisons, consistent with previously published data. Similarly, the *MECP2* rs17435 variant reached statistical significance after comparing the global disease group and dcSSc subgroup with the control population (P_{FDR}=2.68×10−3, OR=1.19, and P_{FDR}=5.26×10−4, OR=1.30, respectively). Conditional logistic regression analyses showed that the association of *IRAK1* rs1059702 with dcSSc was explained by that of *MECP2* rs17435, because only the latter remained significant after conditioned to each other (rs1059702 conditioned P=0.786; rs17435 conditioned P=0.049). However, the analysis of pulmonary fibrosis (PF) data suggested that *IRAK1* rs1059702 was consistently associated with this feature, since statistical significance was observed when comparing PF+ vs controls (P_{FDR}=0.039, OR=1.30) and PF+ vs PF- (P=0.025, OR=1.26), but not PF- vs controls (P=0.574, OR=1.04).

Conclusion: Our data suggest the existence of two independent signals within the Xq28 region, one located in *IRAK1* associated with PF, and another in *MECP2* associated with dcSSc.

A Putative Role for the TGFβ Accessory Receptors Betaglycan and Endoglin in pulmonary Complications of Scleroderma. Sarah L. Trinder, Adrian Gilbane, Markella Ponticos, Johanna Donovan, Christopher P. Denton, David J. Abraham and Alan M. Holmes. UCL, London, United Kingdom

Background/Purpose: In scleroderma (SSc) pulmonary complications such as fibrosis and pulmonary hypertension represents a significant cause of mortality. The ability of TGFβ1 to act as a potent pro-fibrotic mediator is well established, potently inducing the expression of numerous fibrogenic genes including type I collagen and CCN2. Cellular responses to TGFβs are markedly regulated by the accessory receptors betaglycan and endoglin. Here we sought to investigate the expression and cellular effects of these accessory receptors in SSc pulmonary fibroblast function.

Methods: Pulmonary fibroblasts explant cultured from SSc patient with lung complications were assessed for the expression of the TGFβ accessory receptors betaglycan/TGFβRIII and endoglin by Q-PCR and western blot. TGFβ accessory receptor expression was further determined by immunohistochemistry on pulmonary lung sections. The cellular effect of altered expression of these receptors on fibrogenic genes through transient over-expression in pulmonary fibroblasts were assessed by Q-PCR and western blot.

Results: SSc lung fibroblasts exhibited a marked elevated expression in betaglycan and endoglin. Immunohistochemical analysis demonstrated a similar elevated expression of these receptors. Consistent with a pathological role of betaglycan and endoglin, over-expression of these accessory receptors led to altered cellular responses to TGFβ, as assessed by the expression of the fibrogenic genes CCN2, collagen type I and aSMA.

Conclusion: These data demonstrate elevated expression of the TGFβ accessory receptors betaglycan and endoglin on SSc pulmonary fibroblasts. An altered accessory receptor repertoire led to a marked change in the expression of known pro-fibrotic genes, including collagen type I and CCN2. Thus altered expression of TGFβ accessory receptors may play a significant role in the pro-fibrotic phenotype exhibited by SSc pulmonary fibroblasts.

Intratracheal Instillation of Omniscan in an Adenine-Induced Model of Chronic Renal Failure: A New Model of Nephrogenic Systemic Fibrosis. Peter J. Wermuth and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center-,Thomas Jefferson University, Philadelphia, PA

Background/Purpose: Nephrogenic Systemic Fibrosis (NSF), a generalized progressive fibrotic disorder, occurs in some patients with renal insufficiency exposed to various gadolinium based contrast agents (Gd-

BCA). Currently, there is no animal model for human NSF. Some studies using subtotal nephrectomized rats described cutaneous lesions characterized by slight dermal fibrosis and increased infiltration of CD34+ cells following systemic GdBCA administration. These lesions, however, failed to reproduce the severe dermal and tissue fibrosis and other histomorphological changes characteristic of human NSF. One possible reason for this is that although subtotal nephrectomy replicates the decreased filtering capacity of human chronic renal failure, it fails to induce numerous other features that may be necessary for NSF development. In this study, we treated mice with adenine-induced renal failure by intratracheal instillation of the GdBCA Omniscan to develop a more relevant model of NSF.

Methods: Chronic renal failure was induced in C57BL6/J mice by ad libitum feeding of standard rodent diet supplemented with 3% adenine for 30 days. A single dose of either the GdBCA Omniscan (25 μL of a 0.5 M solution) or an equal volume of normal saline was administered to mice with normal renal function (controls) or with chronic renal failure by intratracheal instillation. Mice were sacrificed 28 days post-instillation and tissues were isolated for analysis by histological examination (hematoxyllin/eosin and Masson's trichrome stains. Assays of collagen content to assess the severity of tissue fibrosis were performed employing a standard hydroxyproline assay of hydrolyzed tissue samples.

Results: Histopathology studies showed mononuclear cell infiltration and fibrosis in lungs isolated from adenine-fed mice instilled with Omniscan but not in lungs from mice with normal renal function instilled with Omniscan nor in mice with either normal or ablated renal function instilled with saline. The pattern of fibrosis was predominantly peribronchial although substantial diffuse interstitial fibrosis was also observed. Hydroxyproline content was increased ~3 fold in the lungs of renal failure mice treated with Omniscan compared to mice in all other treatment groups.

Conclusion: The present study demonstrates for the first time the ability to induce significant tissue fibrosis and increased collagen deposition in mice with adenine induced renal failure exposed to the gadolinium contrast agent Omniscan. This inducible model of tissue fibrosis will be a valuable tool in studying the pathogenesis of NSF and other chemically-induced fibrotic disorders.

Role of Endosomal and Cell Membrane Toll-Like Receptors in Keratinocyte Activation by Systemic Sclerosis Autoantibodies. James M. Watson[1], Joanna Nikitorowicz Buniak[1], Xu Shiwen[2], David J. Abraham[1], Christopher P. Denton[3] and Richard J. Stratton[1]. [1]UCL Medical School, London, United Kingdom, [2]Royal Free Hospital, London, United Kingdom, [3]Royal Free and University College Medical School, London, United Kingdom

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune rare connective tissue disorder of unknown aetiology, heterogeneous clinical manifestations and an often progressive course which includes skin changes which are partly mediated by keratinocytes. It is proposed that immunoglobulin from patients with SSc causes activation of toll like receptors (TLR) 2 and 3.

Methods: Initially, patient IgG samples which had previously been shown to up-regulate interleukins in HaCat immortalised keratinocytes were studied. More patient samples of IgG were then purified using a protein A column and TLR2 and TLR3 activation was measured using the HEK cell line which was co-transfected with either the hTLR2 or hTLR3 gene, and a secreted embryonic alkaline phosphatase (SEAP) gene. Concentrations of IgG used were 1000, 100, 10, 1 and 0.1 μg/mL.

Results: Initial assessment of signalling downstream of TLRs gave variable results but some SSc samples induced nuclear translocation of NFκB (RelA)..

A total of 21 diffuse and limited SSc samples with 5 control samples were used. 13 SSc samples showed an increase in TLR2 signalling, whilst 3 SSC samples showed an increase in TLR3 signalling. No healthy control samples showed an increase in expression of TLR 2 or 3. On statistical analysis the data was grouped by disease type. At all concentrations studied p values were statistically significant showing an increase in TLR activity compared to healthy samples except for one, see figure 1 and 2.
Figure 1. Induction of TLR2 Signalling by Diffuse & Limited SSc IgG and Healthy Control IgG

HEK2 cells were exposed to Diffuse & Limited SSc (n = 21 patient samples) and control IgG (n = 5 control samples) at various concentrations for 24 hours. Treatment with Diffuse & Limited SSc IgG lead to induction of SEAP greater than healthy control IgG. Student's t-test p values for Diffuse & Limited SSc vs control values shown.
Figure 2. Induction of TLR3 Signalling by Diffuse & Limited SSc IgG and Healthy Control IgG

HEK3 cells were exposed to Diffuse & Limited SSc (n = 21 patient samples) and control IgG (n = 5 control samples) at various concentrations for 20 hours. Treatment with Diffuse & Limited SSc IgG lead to induction of SEAP greater than healthy control IgG. Student's t-test p values for Diffuse & Limited SSc vs control values shown.

Conclusion: In conclusion SSc IgG induces TLR2 and TLR3 far more than healthy control IgG which may dampen the TLR2 and TLR3 response somewhat. The autoantibody component in SSc IgG that causes this is unknown. Further work will attempt to confirm the mechanism of TLR 2 and 3 activation.

CD11c[+] Cells Are Necessary for Myofibroblast Maintenance in Bleomycin-Induced Cutaneous Fibrosis. Jennifer J. Chia[1], Sha Tian[2] and Theresa T. Lu[2]. [1]Weill Cornell/Rockefeller/Sloan-Kettering Tri-Institutional MD-PhD Program, New York, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: Systemic sclerosis (SSc) is a heterogeneous connective tissue disease that has significant mortality and morbidity secondary to internal and cutaneous fibrosis. Though the exact pathogenesis remains poorly understood, fibroblast and myofibroblast activation are thought to be key contributors to the fibrotic process. Dendritic cells (DCs) can modulate mesenchymal cell activity in lymph nodes, and we hypothesized that they may also have a role in modulating the fibroblasts activity in skin fibrosis.

Methods: We induced fibrosis by injecting bleomycin (BLM, $20\mu g$) subcutaneously into 3 adjacent points on shaved back skin for 17 or 28 days. After sacrifice, we took 3x 8mm biopsy punches of affected tissue for histology, flow cytometry and RNA extraction. Primary fibroblasts were derived from wild type, untreated mouse ears and used at passage 1. Bone marrow-derived DCs (BMDCs) were isolated from wild type, untreated bone marrow cultured in the presence of GM-CSF.

Results: By immunohistochemistry, we observe the association of CD11c[hi] cells and alpha-smooth muscle actin[+] (SMA[+]) myofibroblasts after BLM treatment. Using CD11c-DTR transgenic mice that allow for inducible depletion of CD11c[+] cells, we depleted CD11c[hi] cells after 15 days of BLM treatment. CD11c[hi] cell depletion resulted in disappearance of SMA[+] cells and over 2-fold decrease in TGFb1 transcription in total skin, suggesting that dendritic cells are required to maintain myofibroblasts and TGFb1 levels in fibrotic skin. Culturing BMDCs with primary fibroblasts resulted in increased SMA[+] and SMA[−] fibroblast numbers, as well as increased SMA expression in SMA[+] cells, suggesting that dendritic cells are sufficient to promote fibroblast and myofibroblast proliferation and activation.

Conclusion: These results suggest a scenario whereby dendritic cells in fibrotic skin contribute to fibrosis in part by promoting the proliferation and activation of fibroblasts and myofibroblasts, perhaps via their expression of TGFb1.

Increased Levels of Ser 181 Phosphorylated SOX9 in SSc Dermal Fibroblasts: A Novel Participant in the Pathogenesis of SSc Fibrotic Process. Sonsoles Piera-Velazquez, Jolanta Fertala and Sergio A. Jimenez. Jefferson Institute of Molecular Medicine, Division of Connective Tissue Diseases and Scleroderma Center,Thomas Jefferson University, Philadelphia, PA

Background/Purpose: SOX9, a high mobility group (HMG) transcription factor is a master regulator of chondrogenesis and is essential for the maintenance of the chondrocyte-specific phenotype regulating the expression of various chondrocyte-specific gene products including type II collagen and COMP. We recently performed an analysis of the kinome of human dermal fibroblasts and demonstrated that these cells contained high levels of SOX9 phosphorylated at serine residue 181 (Ser181 phosphoSOX9). Recent studies on liver fibrosis and segmental glomerulosclerosis have suggested that SOX9 may participate in tissue fibrosis. Therefore, we explored here the involvement of Ser181 phosphoSOX9 in the fibrotic process of Systemic Sclerosis (SSc) employing cultured SSc dermal fibroblasts in vitro.

Methods: Dermal fibroblasts were obtained from skin samples from normal individuals and from clinically affected and non-affected forearm skin from patients with diffuse SSc of recent onset. Ser181 phosphoSOX9 levels were assessed by Western blot analysis of cell lysates of confluent dermal fibroblast cultures employing a phospho-specific antibody that recognizes a SOX9 epitope containing a phosphorylated Ser 181 residue. Gene expression analyses were performed by real time PCR employing specific primers. Collagen production was assessed by Western blots of fibroblast culture media. The effects of TGF-β treatment on Ser181 phosphoSOX9 were assessed in confluent cultures in the presence or absence of TGF-β1 (10ng/mL) for 24h. The intracellular kinases responsible for SOX9 phosphorylation were examined by inhibition with specific small molecule kinase inhibitors.

Results: Dermal fibroblasts from SSc patients displayed marked elevation of Ser181 phosphoSOX9 levels in comparison with normal fibroblasts. Furthermore, fibroblasts cultured from clinically affected SSc skin had significantly greater levels of Ser 181 phosphoSOX9 than fibroblasts cultured from clinically non-affected skin from the same patients. TGF-β caused a potent stimulation of SOX9 phosphorylation in normal fibroblasts but only minor stimulation in SSc fibroblasts. The stimulation of SOX9 phosphorylation by TGF-β was inhibited by small molecule inhibitors targeting PKC-delta and Rho Kinase. Inhibitors of PI3 Kinase and other kinases were not effective. The levels of the Type I collagen production changed in parallel with the changes in Ser181 phosphoSOX9 levels.

Conclusion: The results indicate that Ser181 phosphoSOX9 may participate in the molecular mechanisms responsible for the exaggerated fibrotic process in SSc and suggest that PKC-delta and Rho Kinase, the specific kinases responsible for SOX9 phosphorylation, may provide novel therapeutic targets for SSc and other fibrotic disorders involving Ser181 phosphoSOX9.

Enhancement of CRACM1 Expression in Functionally Aberrant Naïve CD4[+] T Cells in Active Rheumatoid Arthritis. Shuang Liu[1], Shohei Watanabe[2], Miyuki Kuno[3], Hiromasa Miura[2] and Kazutaka Maeyama[1]. [1]Informational Biomedicine, Ehime University Graduate School of Medicine, Toon-shi, Ehime, Japan, [2]Ehime University Graduate School of Medicine, Toon, Japan, [3]Osaka City University Graduate School of Medicine, Osaka, Japan

Background/Purpose: Lymphocytes from rheumatoid arthritis (RA) patients have been reported to exhibit increased basal intracellular Ca^{2+} concentrations compared with the lymphocytes of healthy controls. A precise molecular explanation for the enhanced Ca^{2+} influx in T cells has not yet been established. To explore the molecular basis of the irregular Ca^{2+} influx in RA T cells, we performed a cross-sectional study to characterise the expression levels and functional status of Ca^{2+} release-activated Ca^{2+} (CRAC) channels in peripheral naïve CD4[+] T cells from 50 RA patients, 50 osteoarthritis (OA) patients and 15 healthy donors.

Methods: To determine whether CRACM1 channels contribute to the abnormal behavior of T cells in RA, CRACM1 expression was evaluated by western blotting and immunofluorescence analysis. We also measured Ca^{2+} influx and CRAC currents in naïve CD4[+] T cells, as well as cytokine release by activated naïve CD4[+] T cells, for each of the three groups.

Results: 1.Intracellular Ca^{2+} influx is up-regulated in naïve CD4[+] T cells from RA patients and is associated with RA disease activity.2.CRACM1 channel function is increased in T cells from active RA patients. 3.CRACM1 expression in naïve CD4[+] T cells is higher in active RA patients than in OA patients and healthy donors.

Conclusion: Functionally aberrant naïve CD4[+] T cells from active RA patients exhibited an increase in Ca^{2+} influx, as well as up-regulated CRACM1 protein expression and function, indicating that CRACM1 might represent a new molecular target for novel RA therapies.

Total Glucosides of Paeony Th1 and Th17 Cell Differentiation by Blocking STAT1 and STAT3 Activation *in Vivo*. Ningli Li[1] and JP Lin[2]. [1]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Shanghai, China

Background/Purpose: Th1 and Th17 cells play very importent role in the lesions of human rheumatoid arthritis (RA). Total glucoside of paeony (TGP), an active compound extracted from Paeony root, has been used in therapy for RA and other autoimmune diseases. However the molecular mechanism of TGP in prevention of Th1 and Th17 differentiation remains unclear.

Methods: Collagen-induced arthritis (CIA) mice were used as the RA animal model to test the therapeutic effect of TGP as well as its effect on Th1 and Th17 differentiation *in vivo*. Expression of cytokines was measured by ELISA, real-time PCR. Th1 and Th17 population were identified by flow cytometry, STATs activation was analyzed by western blotting.

Results: In this study, we found that TGP treatment significantly decreased clinical inflammatory score of CIA. Percentage and number of Th1 and Th17 cells in TGP-treated CIA CD4+ T cells decreased signifi-

cantly compared with that of without TGP treatment. Moreover, investigation revealed that CIA-treated with TGP decreased expression of T-bet and RORgt in CD4+ T cells. But we did not found regulatory T cells (Treg) was altered in TGP treatment CIA mice. Furthermore, we found that TGP treatment inhibited IL-12 and IL-6 expression, meanwhile, activation of STAT1 and STAT3 was inhibited in TGP-treated CIA mice consistently.

Conclusion: Taken together, these findings indicate that TGP inhibits inflammation and autoimmunity in RA patients possibly by reducing Th1 and Th17 cell differentiation.

Senescent T Cells Promote Bone Loss in Rheumatoid Arthritis. Johannes Fessler, Rusmir Husic, Elisabeth Lerchbaum, Verena Schwetz, Claudia Stiegler, Barbara Obermayer-Pietsch, Winfried B. Graninger and Christian Dejaco. Medical University Graz, Graz, Austria

Background/Purpose: To study the influence of aged CD28[−] T cells on systemic osteoporosis in rheumatoid arthritis (RA) patients.

Methods: Prospective, cross-sectional study on 100 patients with RA [mean age 61.9 ($\pm$SD 11.2), 75% female, median time since diagnosis 162.4 (range 0–552) months, SDAI 12.7 ($\pm$SD9.3), 81% and 50% received synthetic and/or biologic DMARDs, respectively; 24% used corticosteroids, 16% were treated with bisphosphonates]. Bone mineral density (BMD) was determined by lumbar spine (LS) and total hip DEXA and laboratory markers of bone metabolism included bone specific alkaline phosphatase, osteocalcin, osteoprotegerin, β-crosslaps and soluble RANKL. PBMCs were retrieved at the same day of BMD measurement and were stained with anti-RANKL, CD3, CD4, CD8, CD45RA, CD45RO and/or CD28 mAbs to measure surface expression of RANKL on T cells and to determine the prevalence of T cell subsets by flow cytometry. *In vitro*RANKL regulation assays were performed using human TNF-α (100ng/ml), IL-6 (100ng/ml), IL-15 (100ng/ml) or solid-phase anti-CD3 (10ng/ml).

Results: A reduced BMD as determined by DEXA was found in 63% of RA patients (13% with osteoporosis, 50% with osteopenia). The prevalences of aged CD4[+]CD28[−] and CD8[+]CD28[−] T cells inversely correlated with T-scores of LS (corr$_{coeff}$=−0.235, p=0.028 and corr$_{coeff}$=−0.266, p=0.012, respectively) and hip (corr$_{coeff}$=−0.235, p=0.025, corr$_{coeff=}$−0.253, p=0.016 respectively). Patients with a T-score below −1.0 tended to have higher prevalences of circulating CD4[+]CD28[−] (2.2% [0.1–41.2] vs. 0.5% (0–17.6), p=0.065) and CD8[+]CD28[−]T cells [44.8% $\pm$ 20.7 vs. 37.4% $\pm$ 20.1, p=0.134] than patients with normal bone mass. No association was found between frequencies of aged T cells and blood parameters of bone metabolism.

RANKL expression was higher in CD4[+]CD28[−] T cells (3.8% [0.2–57.9]) compared to naïve CD4[+]CD28[+]CD45RA[+] (2.2% [0.2–30.5], p<0.001) and memory CD4[+]CD28[+]CD45RO[+] (2.8% [0.2–38], p=0.009) T cells. In the CD8[+]T cell population surface expression of RANKL was higher on memory (4.4% [0.5–44.5]) compared to naïve (3.3% [0.5–41.3], p<0.001) and aged T cells (2.2% [0–20.1], p<0.001).

In cell culture experiments IL-15 and anti-CD3 stimulation increased RANKL expression on all T cell subsets. IL-15 stimulation showed largest effects on memory CD4[+] and CD8[+] T cells [4.5-fold and 6-fold higher expression, respectively compared to unstimulated cells, p<0.05] compared to aged [3.9-fold and 5-fold, respectively, p<0.05] and naïve T cells [1.5-fold and 3.8-fold, respectively, p<0.05]. Also, activation by anti-CD3 had the largest effect on RANKL expression on memory CD4[+] and CD8[+]T cells [7.8-fold and 7.5-fold, respectively, p<0.05] compared to naïve [5.2-fold and 4.7-fold, respectively, p<0.05] and aged cell subsets [2.9-fold and 3.2-fold, respectively, p<0.05]. IL-6 and TNF-α had no effect on RANKL.

Conclusion: Aged CD28[−] T cells are linked with the occurrence of systemic bone loss in RA. Increased expression of RANKL on CD4[+]CD28[−] T cells compared to other T cell subsets is compatible with direct stimulation of osteoclastogenesis by aged T cells in RA.

The Autoantibody-Inducing CD4 T Cell (*ai*CD4 T cell) Belongs to CCR4[+]CD45RB[lo]122[lo] CD4 Subpopulation: A Novel 'Self-Organized Criticality Theory' Explains the Cause of Systemic Lupus Erythematosus (SLE). Yumi Miyazaki[1], Ken Tsumiyama[2] and Shunichi Shiozawa[2]. [1]Kyushu University Beppu Hospital/Kobe University Graduate School of Health Sciences, Beppu/Kobe, Japan, [2]Kyushu University Beppu Hospital, Beppu, Japan

Background/Purpose: We found that systemic lupus erythematosus (SLE) was induced experimentally by repeatedly immunizing the mice normally not prone to autoimmune diseases by any exogenous antigen so far examined (Tsumiyama K. *et al.* PLoS ONE 4(12):e8382, 2009). We have then proposed a novel 'self-organized criticality theory' that takes place when host's immune system is overstimulated by repeated exposure to antigen to levels that surpass the immune system's stability limit, i.e., self-organized criticality. The autoreactive lymphocyte clones, which we name autoantibody-inducing CD4 cells (*ai*CD4 T cells) are newly generated *via de novo* T cell receptor (TCR) revision from thymus-passed non-autoreactive clones at peripheral lymphoid organs. They not only stimulated B cells to generate varieties of autoantibodies but also helped final differentiation of CD8 T cell into cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation to induce tissue injuries identical to SLE. We here tried to identify the phenotype of *ai*CD4 T cell, and show that *ai*CD4 T cell belongs to CCR4[+]CD45RB[lo]122[lo] CD4 subpopulation.

Methods: BALB/c were repeatedly immunized with ovalbumin (OVA), keyhole limpet hemocyanin (KLH) or staphylococcal enterotoxin B (SEB). RF, anti-Sm and anti-dsDNA antibodies were measured using ELISA. To assign CD number on the *ai*CD4 T cell, expression of effector/memory markers were studied in the CD4 T cell of repeatedly immunized mice. These CD4 T cells were isolated referring to CD45RB, CD27 and CD122 markers, and fractionated cells were adoptively transferred into naïve recipients. Autoantibodies in sera of recipient mice were measured 2 weeks after cell transfer. Further, we performed microarray analysis (Whole Mouse Genome Microarray; Agilent Technologies) to investigate gene expression of CD45RB[lo]122[lo] CD4 T cell, and flow cytometry of CD45RB[lo]122[lo] CD4 T cell to study protein expression profiles of *ai*CD4 T cell in the mice immunized 12x with OVA.

Results: Upon repeated immunization 12x with OVA, KLH or SEB, varieties of autoantibodies including RF, anti-Sm and anti-dsDNA antibodies were generated. Simultaneously, CD45RB[lo], CD27[lo] and CD122[hi] CD4 T cells were significantly expanded as compared with control mice upon repeated immunization with either OVA, KLH or SEB. Adoptive transfer of fractionated CD4 cells with either CD45RB, CD27 or CD122 markers of the mice immunized 12x with OVA showed that both CD45RB[lo] CD4 T cell and CD122[lo] CD4 T cells were capable of inducing autoantibodies in the naïve recipients. However, CD27 marker was irrelevant for inducing autoantibodies. Consequently, we transferred CD45RB[lo]122[lo] CD4 T cells into naïve mice and found that both RF and anti-dsDNA antibody were indeed significantly increased. In microarray analyses, we compared the gene expression profile between CD45RB[lo]122[lo] CD4 T cell and the rest of CD4 T cell subsets after immunization 12x with OVA. We found that chemokine (C-C motif) receptor 4 (Ccr4) was increased $\times$ 4 in the CD45RB[lo]122[lo] CD4 subsets. Surface expression of CCR4 protein was also similarly significantly increased in this subset.

Conclusion: The *ai*CD4 T cell that induces SLE belongs to a CCR4[+]CD45RB[lo]122[lo] CD4 subpopulation.

Correlation Between Abatacept and Rheumatoid Factor – Can Rheumatoid Factor Be a Predictive Factor for Abatacept? Tomonori Kobayakawa[1], Masatoshi Hayashi[1], Toshihisa Kanamono[1], Atsushi Kaneko[2], Toshihisa Kojima[3] and Naoki Ishiguro[4]. [1]Nagano Red Cross Hospital, Nagano, Japan, [2]Nagoya Medical Center, Nagoya, Japan, [3]Nagoya University, School of Medicine, Nagoya, Japan, [4]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan

Background/Purpose: Abatacept (ABT), a T-cell selective costimulatory regulator, went on the market in Japan in September 2010, with a number of reports issued on its effectiveness since. However, no report has been made on the correlation between ABT and rheumatoid factor (RF). We examined the correlation between ABT and RF.

Methods: Among the 143 patients with rheumatoid arthritis who were given ABT at Tsurumai Biologics Communication between September 2010 and August 2011, 89 cases whose RF was measured before and after the ABT administration with week 24 follow-up observation. The subjects were sorted into two groups according to the Simplified Disease Activity Index at week 24 after ABT administration: a good response (GR) group (n=35) that exhibited remission and low disease activity and a poor response (PR) group (n=54) that exhibited moderate and high disease activity. The correlation between the ABT responsiveness and the RF was examined for these groups. In addition, the cases with high disease activity at week zero were selected for a sub-analysis to determine the correlation between the change in disease activity and RF at 24 weeks and the correlation between the effect of ABT and RF at week 24 in terms of the duration of disease, whether or not methotrexate was concurrently used, and the history of pre-biologics administration.

Results: The percentage of men was higher and the disease activity tended to be lower at week zero in the GR group. The RF was 148.5 mg/dl and 341.1 mg/dl at week zero for the GR group and the PR group and 126.8 mg/dl and 194 mg/dl at the 24th week, respectively. In the group consisting only of subjects with high disease activity, the subjects whose disease activity had improved low at week 24 displayed significantly lower RF values at both week zero and week 24 than those whose disease activity had not improved at week 24. The sub-analysis revealed that the bio naive patients who had experienced a crisis less than two years earlier had a significantly lower RF value at week zero and maintained the low level through to week 24. No significant difference was observed in RF change over time between those with and without concurrent methotrexate administration.

Table 1. Baseline characteristics of two groups that the RA patients treated with ABT who were enrolled in the present study

	GR group (n = 35)	PR group (n = 54)	P value
Age, years (mean ± SD)	64.5 ± 9.6	63.9 ± 11.2	0.9376
Female, (%)	23 (67%)	46 (85%)	0.0316
RA duration, years (mean ± SD)	11.4 ± 12.1	12.0 ± 11.1	0.3545
Stage (I/II/III/IV)	9/7/10/9	2/14/26/12	0.0131
Class (1/2/3/4)	7/14/13/1	2/26/25/1	0.0936
MTX use (%)	21/35 (60%)	32/54 (59%)	0.9446
MTX dose, mg/w (mean ± SD)	7.3 ± 2.6	7.1 ± 1.9	0.8807
PSL use (%)	20/35 (57%)	31/54 (57%)	0.9803
PSL dose, mg/day (mean ± SD)	4.1 ± 2.2	4.8 ± 3.1	0.7962
Bio naïve/2nd/3rd/4th/5th	23/5/6/1/0	21/14/13/4/2	0.1361
DAS28ESR	4.68 ± 1.30	5.65 ± 1.30	0.0006
SDAI	18.6 ± 11.7	28.9 ± 14.2	0.0001
MMP-3	161.3 ± 117.2	258.2 ± 311.4	0.0319

GR Good response, PR poor response, RA Rheumatoid arthritis, MTX methotrexate, PSL prednisolone, DAS28ESR 28 joint disease activity score and erythrocyte sedimentation rate, SDAI simplified disease activity index, MMP-3 matrix metalloproteinase-3

# P<0.05 Un-Paired t test * VS. Baseline P<0.05 Paired t test
Conclusion: We conclude that the lower the RF was at the time of ABT administration, the more effective it was. The RF tended to be lower for the bio naive subjects who had experienced a crisis less than two years earlier. The RF can be a predictive factor for ABT.

Foxp3[+] Treg Cells Decreased in Overexpression of T-Bet in PD-1 Deficient Mice. Masahiro Tahara[1], Yuya Kondo[1], Hiroto Tsuboi[1], Satoru Takahashi[2], Isao Matsumoto[1] and Takayuki Sumida[1]. [1]Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Department of Anatomy and Embryology, Faculty of Medicine, University of Tsukuba, Tsukuba city, Ibaraki, Japan

Background/Purpose: Programmed cell Death-1 (PD-1) plays an important role in peripheral T cell tolerance, therefore PD-1 deficient (PD-1 KO) mice develop strain-specific autoimmune phenotypes. C57BL/6 (B6) background PD-1 KO mice develop glomerulonephritis after 24–48 weeks of age, which is similar to human endocapillary proliferative glomerulonehiritis observed in lupus nephritis. The differentiation of Th cells in PD-1 KO mice was not fully elucidated. The purpose of this study is to clarify the effect of T cell specific T-bet overexpression on autoimmune disease in PD-1 KO mice.

Methods: 1) T-bet overexpressing PD-1 KO mice were generated by crossing T-bet transgenic (T-bet Tg) mice under the promoter of CD2 gene with PD-1 KO mice (PD-1 KO × T-bet Tg mice; P/T mice). 2) In wild-type (WT) mice, PD-1 KO mice, T-bet Tg mice and P/T mice, the pathological evaluation of the kidneys was performed with H·E, PAS and PAM staining at 6–8 weeks of age. Deposition of IgG and C3 in kidneys was analyzed with immunofluorescence staining. 3) The histological analyses were evaluated on the heart, spleen, mesenteric LN, lung, liver, pancreas, salivary gland and lacrimal gland with H·E staining and immunofluorescence staining in WT mice, PD-1 KO mice, T-bet Tg mice and P/T mice. 4) Proportion of lymphocytes subset and cytokine production by CD4[+] T cells in spleen was analyzed by FACS. 5) FACS analysis was performed to evaluate transcription factor expression on CD4[+] T cells in spleen.

Results: 1) Most of P/T mice died within 10 weeks. 2) Glomerulonephritis was not observed in WT mice, PD-1 KO mice, T-bet Tg mice and P/T mice. Deposition of IgG and C3 was observed in glomeruli in PD-1 KO mice, but not in WT mice, T-bet Tg mice and P/T mice. 3) Splenomegaly and infiltration of mononuclear cells in liver were observed only in P/T mice. Immunofluorescence staining revealed that infiltrating cells were CD3[+] T cells. 4) FACS analysis showed that the total cell number was increased in P/T mice ($15.3 \pm 3.11 \times 10^7$cells), compared with WT mice ($6.41 \pm 0.81 \times 10^7$cells, $P<0.05$ by Mann-Whitney U-test), PD-1 KO mice ($8.46 \pm 1.77 \times 10^7$cells, $P=0.086$) and T-bet Tg mice ($7.12 \pm 2.32 \times 10^7$cells, $P=0.086$), and IFN-γ production on CD4[+] T cells observed in P/T mice ($20.5 \pm 3.42\%$) was higher than that in WT mice ($3.56 \pm 0.63\%$, $P<0.05$) and PD-1 KO mice($6.85 \pm 1.17\%$, $P<0.05$). 5) Percentage of Foxp3[+] cells in CD4[+] Treg cells was significantly decreased in P/T mice ($2.47 \pm 1.31\%$), compared with WT mice ($13.4 \pm 1.39\%$), PD-1 KO mice ($16.9 \pm 2.15\%$) and T-bet Tg mice ($19.1 \pm 2.55\%$) ($P<0.05$).

Conclusion: In P/T mice, the reduced percentage of Foxp3[+]CD4[+] Treg cells induced systemic inflammation, resulting in short-life span.

2316

Generation of CD4[+] Follicular Helper T cells by Complement and Immune Complexes. Anil K. Chauhan[1], Richard DiPaolo[2] and Terry L. Moore[1]. [1]Saint Louis University, St. Louis, MO, [2]Saint Louis, MO

Background/Purpose: Complement opsonized immune complexes (ICs) are key players of disease pathology. We showed in systemic lupus erythematosus (SLE), ICs and complement (C′) drive activation and differentiation of naïve CD4[+] cells into the T effector population. We also established activation-induced expression of FcγRIIIA in naïve CD4[+] population that is partly responsible for this activation. To further understand the role IC and C′ mediated activation in the development of autoantibody secreting plasma cells, we examined the development of Bcl6[+]PD1[+]CXCR5[+] follicular helper cells (T$_{FH}$). We asked whether ICs play a role in cognate contact between T$_{FH}$ cells and naïve B cells in pre germinal centers (GC) and/or in secondary GC that could lead to the formation B memory and/or plasma cells.

Methods: Peripheral human naïve CD4[+] T cells were stimulated in vitro using ICs and the late complement complex C5b-9. They were grown in the presence of IL-6 and IL-21. Post 72 h, cells were analyzed by flow for the expression of Bcl6, PD1, and CXCR5. RNA expression was quantified using QT-PCR. To analyze whether ICs facilitate the contact among CD4[+]T cells, we used an autoimmune gastritis mouse model (TxA23 TCR-Tg). In this model, the T and B cells association was analyzed by flow staining for a cell specific marker in the presence of Alexa Fluor 647 labeled ICs and GC reaction by staining with anti-GL-7.

Results: Antigen-specific B cell memory progressively develops under the cognate guidance of T$_{FH}$ cells, following initial priming and secondary antigenic challenge. Cognate contact of naïve B cells with T$_{FH}$ initiates immunoglobulin class switching and naïve B cell differentiation into plasma cells outside the GC. Such cell contacts also induce GC reaction. Our previous work established the presence of FcγRIIIA on CD4[+] T cells, which upon ICs engagement produced IFN-g. It also, showed T cell activation. The naïve CD4[+] T cell activation by ICs and C5b-9 showed three-fold increase in expression CXCR5[+]Bcl6[+] T cell population. This was comparable to anti-CD3 and anti-CD28 stimulation. However, CD4[+]IC[+] gated population showed 52% cells that were CXCR5[+]PD1[+]Bc6[+], in response to ICs and C5b-9 activation compared to 20% using anti-CD3 and anti-CD28. These results suggest that naïve CD4[+] cells upon activation with ICs and C5b-9 express T$_{FH}$ markers and receptors that bound to ICs. To further establish the role of these cells in starting the formation of GC reaction, we used TxA23 TCR-Tg mice that demonstrate formation of ectopic GCs. Cells obtained from spleen/lymph nodes of these mice with disease activity upon staining with anti-CD4, anti-CD19, and labeled ICs showed 39% of CD4[+]; 34.8 % of CD19[+] and 6.2 % of cells that were CD4[+]CD19[+]. The CD4[+]CD19[+] showed a very high percentage of cells (83.9%) that bound to ICs, compared to 4% CD4[+] cells and 43% CD19[+] B cells. The side scatter of CD4[+]CD19[+]was two fold higher suggesting a large size. This suggests the formation of T and B cell conjugates by ICs.

Conclusion: These results thus suggest an important role for ICs and complement in generation of T$_{FH}$ cells and formation of secondary GCs.

Protein Phosphatase 5 (PP5) Regulates Methylation Sensitive Gene Expression in CD4+ T Cells. Dipak R. Patel, Gabriela Gorelik and Bruce C. Richardson. University of Michigan, Ann Arbor, MI

Background/Purpose: CD4+CD28- T cells are enriched in chronic inflammatory diseases like rheumatoid arthritis (RA) and lupus. They are cytotoxic and resistant to apoptosis. Compared to CD28+ cells, CD28- CD4 T cells over-express killer immunoglobulin-like receptors (KIRs), perforin, and other molecules that are expected to contribute to their pro-inflammatory phenotype. These genes are regulated by DNA methylation, so they are over-expressed by CD4 T cells that are demethylated in vitro. This is a result of decreased signaling through the ERK and JNK pathways. This consequently decreases activity of the DNA methyltransferase enzymes (DNMTs) responsible for DNA methylation. Protein phosphatase 5 (PP5) is a stress induced regulator of gene expression in multiple signaling pathways, including ERK, JNK, and those involved in aging. It is expressed in CD4+CD28-, but not CD4+CD28+ T cells. We hypothesized that PP5 is over-expressed in CD4+ T cells in patients with RA and lupus, and that over-expressing PP5 in CD4 T cells from healthy donors will induce expression of methylation sensitive genes unique to CD4+CD28- T cells.

Methods: CD4+ T cells were isolated from healthy controls and patients with RA and lupus, and PP5 mRNA expression was measured by RT-PCR. To study the effects of PP5 on methylation sensitive genes, PBMCs from healthy donors were stimulated with phytohemagglutinin (PHA) and cultured for 3 days with IL-2. CD4+ T cells were then isolated by negative selection, transfected (Amaxa Nucleofector) with constructs encoding GFP and PP5 or GFP alone, and cultured an additional 24–72 hours. Expression of DNMT1, KIR, and perforin was assessed by RT-PCR in sorted CD4+GFP+ T cells. DNMT1 expression was measured 24 hours after transfection, and KIR and perforin were analyzed 72 hours after transfection. KIR protein expression was also measured by flow cytometry with unsorted cells 72 hours after transfection.

Results: Compared to CD4+ T cells from healthy controls, PP5 mRNA is over-expressed in CD4+ T cells from patients with lupus (1.97 fold change ± 0.18 SEM, $p=0.03$) and RA (1.6 ± 0.2, $p=0.06$). When transfected into CD4+ T cells from healthy donors, PP5 increased KIR mRNA expression (2DL4 gene, 2.4 ± 0.7, $n=3$, $p=0.04$) and CD70 mRNA expression (1.38 ± 0.07, $n=3$, $p=0.03$). PP5 transfection also increased the percentage of cells expressing KIR proteins on their surface ($33 \pm 7\%$ with control vs. $62 \pm 7\%$ with PP5, $n=7$, $p<0.01$). Finally, PP5 caused a corresponding $20 \pm 8\%$ decrease ($n=3$, $p=0.05$) in DNMT1 mRNA expression.

Conclusion: CD4+CD28− T cells, which are enriched in RA and lupus, over-express methylation sensitive genes that contribute to their pro-inflammatory phenotype. These data demonstrate, for the first time, that protein phosphatase 5 (PP5) contributes to the regulation of methylation sensitive genes in CD4+ T cells. Specifically, PP5 increases expression of KIR and perforin, and it decreases expression of DNMT1. Its effects on other methylation sensitive genes, including CD70 and IFN-g, are currently being studied. PP5 has not been studied in T cells before, and it potentially links aging and DNA methylation with the pathogenesis of multiple rheumatologic disorders.

Reduced Thymus Function and Accelerated T-Cell Aging in Patients with Axial Spondylarthritis. Christian Dejaco[1], Wolfgang Schwinger[1], Andrea Raicht[1], Rusmir Husic[1], Johannes Fessler[1], Christoph G. Ammann[2], Christina Duftner[3], Winfried B. Graninger[1] and Michael Schirmer[4]. [1]Medical University Graz, Graz, Austria, [2]Medical Uiversity Innsbruck, Innsbruck, Austria, [3]Hopital Elisabethinen, Klagenfurt, Austria, [4]Innsbruck Medical University, Innsbruck, Austria

Background/Purpose: To investigate thymic T-cell output, senescence of circulating T-cell subsets and changes of T cell subsets in patients with axial spondylarthritis (aSpA). **Results** are compared with data from rheumatoid arthritis (RA) patients and healthy controls (HC).

Methods: Patients with aSpA (n=26; 26.9% female, mean BASDAI 3.2 ±2.1), RA (n=20; 60.0%, mean SDAI 10.2 ±10.2) and HC (n=24; 70.8%) were prospectively enrolled. Naïve and memory CD4+ and CD8+ T-cell subsets were isolated by MACS-technology. DNA was extracted by QIAamp DNA isolation Kit. TREC Analysis was performed with LC 480 Probes Master using established oligonucleotides as primers. Telomere length analysis was performed using LightCycler FastStart DNA Master SYBR Green I with published oligonucleotides as primers for telomere length or for the single copy gene 36B4 as normalizing sequence. The telomere length was calculated by comparison of sample result with a positive control with known telomere length (HEK293 with 5 kbp). FACS analyses were performed on fresh PBMCs in a separate cohort of 25 patients and 24 HC.

Results: aSpA (median age 37.0, range 21.8–69.7 years) and RA (37.0, 21.4–73.6 years) patients did not differ from HC (35.3, 23.3–54.3 years) regarding age and disease duration (aSpA: mean 7.7±6.8, RA 6.4±5.1 years, each with p>0.2). Percentages of circulating TH17, naïve CD45RA+ and memory CD45RO+ CD4+/CD8+ T-cells as well as CD4+FOXP3+ Treg cells did not differ between aSpA patients and healthy controls.

Reduced thymus function as indicated by a lower TREC content in naïve CD3+CD4+CD45RA+ and CD3+CD8+CD45RA+ T-cells was found in aSpA (median 483 copies/ng DNA, range 33–5033 and 462, 15–4467, respectively) and RA patients (355, 0–162800 and 296, 0–71800, respectively) compared to HC (2304, 0–64444 and 2558, 0–103091, respectively; p<0.05 for comparisons between aSpA or RA patients and HC). Trends for an inverse correlation between TREC content in naïve CD4+ or CD8+ T-cells and age were found among RA patients and HC (corr$_{coeffs}$ ranging from −0.30 to −0.53, p<0.2 for each analysis) but not among aSpA patients (corr$_{coeffs}$ −0.01–0.07). Shortened telomeres were found in naïve CD45RA+CD4+ and CD8+ (6.24, 5.76–8.13 and 6.15, 5.33–7.56, respectively) as well as memory CD45RO+CD4+ and CD8+ T-cell subsets (5.99, 5.51–8.46 and 6.21, 5.50–7.79, respectively) from aSpA patients compared to HC (CD4+CD45RA+: 7.17, 3.65–8.67, CD8+CD45RA+: 6.99, 3.83–8.47; CD4+CD45RO+: 6.99, 3.70–8.32 and CD8+CD45RO+: 7.20, 3.87–8.06; p<0.05 for each comparison) whereas differences between RA patients and HC concerning telomere length of T-cell subsets did not reach statistical significance.

Conclusion: Thymic T-cell renewal is impaired in aSpA patients. Consequently, increased peripheral T-cell turnover compensates for failing thymus to maintain T-cell homeostasis leading to accelerated telomere erosion and the accumulation of early aged T-cells.

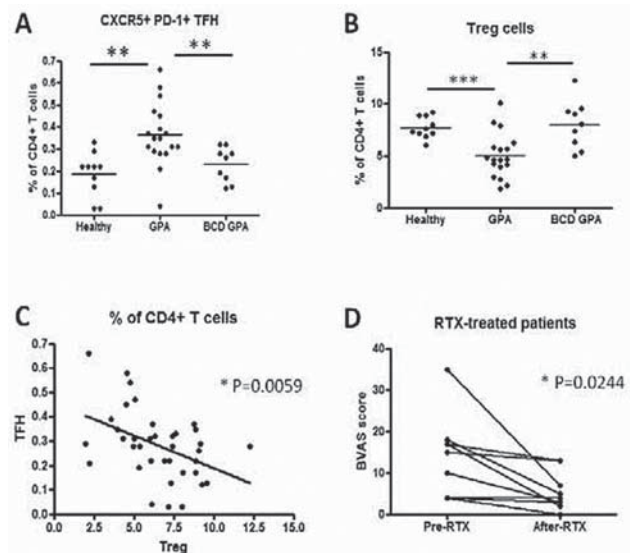
T Follicular Helper Cell and Regulatory T Cell Frequencies Are Affected by B Cell Depletion in Patients with Granulomatosis with Polyangiitis. Yuan Zhao[1], Jessica Thomas[1], Shirish Sangle[2], Pamela M.K Lutalo[3], Lee Meng Choong[4], Jennifer R. Tyler[1], Jo Spencer[1], Timothy Tree[1] and David P. D'Cruz[2]. [1]School of Medicine, King's College London, London, United Kingdom, [2]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom, [3]Louise Coote Lupus Unit, St Thomas Hospital, London, United Kingdom, [4]St Thomas' Hospital, London, United Kingdom

Background/Purpose: Granulomatosis with polyangiitis (GPA, formerly known as Wegener's granulomatosis) is a rare and sometimes fatal systemic autoimmune disease. Anti-neutrophil cytoplasmic antibodies (ANCAs) specific for proteinase 3 (PR3) are associated with GPA. Remissions in GPA can be achieved through B cell depletion therapy. However, the mechanism is not yet clear.

Methods: The frequencies of T follicular helper cells (TFH) and regulatory T cells (Treg) from 27 GPA patients including 9 rituximab treated patients and 10 healthy controls were studied by flow cytometry. Disease activity was assessed by the Birmingham Vasculitis Activity Score (BVAS) and clinical data was collected in all patients. The functional capacity of Tregs was assessed by in vitro co-culture assays.

Results: The average (range) age was 51 (25–83), and disease duration was from less than 1 year up to 25 years. The mean BVAS scores in rituximab treated patients and those on conventional therapy were 5.56 and 9.67 respectively. We observed an increased frequency of TFH (P=0.0013) and a reduced frequency of antigen experienced Treg (P<0.0001) in peripheral blood from GPA patients on conventional therapies but not in those treated with rituximab compared to healthy controls (figure A & B). The frequencies of TFH and Treg were significantly inversely correlated (P=0.0059, figure C). Furthermore, the ratio of TFH to Treg was significantly higher in GPA patients on conventional therapies (average 9.07) than in GPA patients treated with rituximab (average 2.43; P=0.0002), who were clinically improved or controls (figure D). Whereas Tregs were numerically reduced in individuals with GPA on conventional therapy (average 5.03%, P=0.0009), the suppressive capacity of Tregs on a per cell basis is not significantly altered in these individuals compared to healthy controls (P=0.23).


Conclusion: Our study demonstrates increased TFH cells and decreased antigen experienced Treg cells in GPA patients on conventional therapies compared to controls. Patients undergoing B cell depletion therapy were indistinguishable from controls. The negative correlation between TFH and Treg cells implies that the balance between T cell subsets and its B cell dependence impact on disease activity in GPA.

Superantigen Induces IL-17 Production From Extremely Polarized Th1 Clones. Kentaro Yomogida[1], Yuan K. Chou[1] and Cong-Qiu Chu[2]. [1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science Univ and Portland VA Medical Center, Portland, OR

Background/Purpose: Differentiation of naïve CD4[+] T cells is considered to be an irreversible event and, in particular, the plasticity is thought to be completely lost in Th1 subset *in vitro* after multiple stimulations. Superantigens produced by different types of pathogens have been linked to autoimmune diseases. Superantigen-stimulation does not prime an adaptive immune response but causes a massive production of cytokines by CD4[+] T cells. We hypothesized that superantigens are capable of stimulating Th1 cells to produce inflammatory cytokine, IL-17.

Methods: MOG$_{35-55}$-specific and herpes simplex virus (HSV)-specific CD4[+] T cell clones were established from PBMC of healthy individuals. These CD4[+] T cell clones were stimulated by each antigen respectively under Th17 polarizing conditions (with addition of IL-1, IL-6, TGF-beta, anti-IL-12 and anti-IFN-*f*ngamma) or cultured with bacterial superantigens, SEB or TSST-1. IL-17 and IFN-gamma production was determined by ELISA, double-color ELISPOT and intracellular cytokine staining.

Results: Upon repeated Ag-specific stimulation, Th1 clones proliferated specifically to MOG$_{35-55}$ and HSV respectively and produced IFN-gamma and IL-2, but did not produce IL-17. Various Th17-polarization conditions including co-stimulation with IL-1, TNF, IL-6, IL-23, TGF-beta in combination with anti-IL-12 and anti-IFN-gamma antibodies did not induce measurable IL-17 from these Th1 clones. However, superantigen-stimulation promoted both clones to produce IL-17 at a range of $0.5 - 1$ ng/1×10^5 cells. Combination of SEB and TSST-1 showed additive effect on IL-17 production by Th1 clone cells where IL-17 level was greater than 2 ng/1×10^5 cells. Using double-color ELISPOT assay, we found 30% of IFN-gamma-producing cells were positive for IL-17, suggests that superantigens promoted IL-17 production from highly polarized Th1 cloned cells. Interestingly, IL-17 production by these Th1 clones was blocked by anti-HLA class II or anti-TCR alpha/beta chain antibodies.

Conclusion: We have demonstrated that highly polarized Th1 clones can produce a significant amount of IL-17 in response to superantigen stimulation. Infections have been linked to exacerbation of autoimmune diseases such as rheumatoid arthritis and multiple sclerosis. Stimulating Th1 cells to produce IL-17 by superantigens of infecting pathogens may be responsible.

Interleukin 12 Is Involved in an Interferon Type I Signature Through Crosstalk of CD4[+] T Cells and Plasmacytoid Dendritic Cells. Corinne Miceli-Richard[1], Nicolas Gestermann[2], Federico Simoneta[2], Saida Boudaoud[2], Gaetane Nocturne[3], Yann Lecluze[4], Christine Bourgeois[2] and Xavier Mariette[3]. [1]Université Paris-Sud, Le Kremlin Bicêtre, France, [2]INSERM U1012, Le Kremlin Bicêtre, France, [3]Université Paris-Sud, Le Kremlin Bicetre, France, [4]Villejuif, France

Background/Purpose: STAT4 is a transcription factor involved in T_H1 polarization characterized by type II interferon (IFN) (or IFN-g) secretion and specifically activated by interleukin 12 (IL-12) binding on its receptor. Polymorphisms of STAT4 have been associated with rheumatoid arthritis, in which IFN-g may play a key role, but also with primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE), which are characterized by a type I IFN (IFN-a and IFN-β) signature. Moreover, a strong correlation was found between *STAT4* mRNA and type I IFN-induced gene mRNA expression in pSS. We aimed to elucidate the extent to which STAT4 could be involved in the type I IFN signalling pathway by investigating the effect of CD4[+] T cells stimulation with IL-12 on the type 1 IFN signature.

Methods: CD4[+] T cells (isolated by magnetic beads or cell sorting) from healthy controls were activated with anti-CD3 and anti-CD28 +/− IL-12, and then mRNA was extracted. CD4[+] T cells and plasmacytoid dendritic cells (pDCs) were cultured with supernatants from CD4[+] T cells under various conditions. mRNA expression of interferon-induced protein with tetratricopeptide repeats 1 (IFIT-1), interferon-induced transmembrane protein 1 (IFITM1), and protein kinase R (PKR), reflecting type I IFN signature, was analysed by quantitative PCR. Profiles of cytokines secretion by unstimulated CD4[+] T cells compared with IL-12 stimulated CD4[+] T cells was assessed using a 27-plex LUMINEX technology.

Results: CD4[+] T cells isolated by magnetic beads showed upregulated type I IFN-induced genes after IL-12 stimulation in healthy controls: IFIT-1

(n=13) (p=0.0007), IFITM1 (n=6) (p=0.06) and PKR (n=6) (p=0.035). This effect was mediated by the secretion of type 1 IFN since it was abrogated by anti-IFNAR antibodies. Highly purified cell-sorted CD4[+] T cells did not show any type I IFN signature under the same culture conditions, which suggests that a CD4[+] cellular partner was excluded by cell sorting. This cellular partner was demonstrated to be pDCs, which express a low level of CD4. IL-12 alone did not induce a type I IFN signature in pDCs. CD4[+] T cells–pDC crosstalk was necessary to induce this type I IFN signature after IL-12 stimulation of CD4[+] T cells. GMCSF was highly induced in the supernatant of IL12-stimulated CD4[+] T cells compared with unstimulated CD4[+] T cells. Thus, IL-12-induced GM-CSF secretion by T cells might be a good candidate to induce the secretion of type 1 IFN by pDC.

Conclusion: IL-12 specifically induces type 1 IFN and a type I IFN signature through CD4[+] T-cell–pDC crosstalk possibly via GM-CSF induction. These results could explain the implications of *STAT4* polymorphisms in type I IFN-dependent autoimmune diseases. Our data confirm that type I and II IFN-mediated autoimmune diseases are not in opposition and emphasizes the important role of IL-12. Thus, RA in one hand and SLE and pSS in another hand might be the "yin" and "yang" of activation by IL-12, which can stimulate both type I and type II IFN pathways pathways.

Dynamic Regulation of T Follicular Helper Cell Differentiation Through STAT Signaling. Shingo Nakayamada[1], Yuka Kanno[2], Golnaz Vahedi[2], John J. O'Shea[2] and Yoshiya Tanaka[1]. [1]First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD

Background/Purpose: T follicular helper (Tfh) cells are a new subset of T cells that regulate B cell function and exert an important role in the pathogenesis of *autoimmune diseases*. However, their relationship with other helper lineages and the mechanisms that direct their specification are incompletely understood. As STAT family transcription factors play pivotal roles in specifying T cell lineages, we investigated the roles of STAT proteins in Tfh cell differentiation.

Methods: Naive CD4+ T cells isolated from wild type and STAT deficient mice were activated and cultured with various cytokines. Cytokine production and expression of cell surface molecules and transcription factors were assessed by flow cytometry and qPCR. Genome-wide targets of STATs and epigenetic modifications in Tfh-like cells were evaluated by chromatin immunoprecipitation sequencing (ChIP-seq) and DNaseI hypersensitivity sequencing (DNase-seq). Expression levels of mRNA were determined by microarray analysis.

Results: IL-12 acting STAT4 directly induced IL-21- and IFN-γ-producing cells, which share features of both Tfh and Th1 cells. Although IL-4 acting STAT6 had no effect for induction of IL-21 and IFN-g, IL-6 acting STAT3 generated cells that express IL-21 and not IFN-g. STAT4-indued IL-21 in turn acted through STAT3 in a positive feedback loop to maximize IL-21 production. Using ChIP-seq and DNase-seq, we found that both STAT3 and STAT4 directly bound to multiple genes involved in Tfh cell development including *Il21* and *Bcl6*, regulating gene expression and epigenetic modifications. Thus, STAT3 and STAT4 redundantly serve to induce IL-21, Bcl6 and other Tfh cell molecules. However, STAT4 also induced the transcription factor T-bet that repressed *Bcl6,* thereby attenuating the Tfh-like phenotype. IFN-γ-dependent activation of STAT1 induced T-bet, which produced a biphasic effect: early on it promotes, but later it inhibits, Tfh-like phenotype. Finally, the *Bcl6* locus remained accessible in fully polarized effector T cells, suggesting that although Bcl6 expression can vary with different states of differentiation; this locus remains poised for transcription even in the absence of active transcription.

Conclusion: These results highlight the importance of STAT-mediated gene regulation, which underlies plasticity of Tfh cells. Like Th17 cells, Tfh cells are a fluid subset and their differentiation represents a dynamic balance of signals mediated by STATs. Thus, modulation of STAT-mediated gene regulation in Tfh cells should offer opportunities for the treatment of autoimmune diseases.

A Genetic Polymorphism on New Zealand Black Chromosome 1 Is Associated with Abnormal Dendritic Cell Function Leading to Expansion of T_H1, T_H17 and T Follicular Helper (T_{FH}) Cells. Nafiseh Talaei[1], Carolina Landolt-Marticorena[2], Babak Noamani[1], Evelyn Pau[1], Nan-Hua Chang[1] and Joan E. Wither[1]. [1]Toronto Western Research Institute, University Health Network, Toronto, ON, [2]University Health Network, Toronto, ON

Background/Purpose: We have previously shown that B6 mice with an introgressed homozygous New Zealand Black chromosome (c) 1 interval (70 to 100 cM) develop high titres of antinuclear antibodies and severe glomerulonephritis (GN), with approximately 40% of the mice dying by 8 months age. Using subcongenic mice with shorter intervals in this region we found that expansion of T_H1, T_H17, and T_{FH} cell populations was closely associated with the severity of GN. We further showed, using ovalbumin (OVA) as an exogenous antigen, that this was an intrinsic aspect of their immune system, resulting from a combination of T and non-T cell defects. In this report, we have investigated the role of dendritic cells (DC) in this expansion.

Methods: OVA-specific T cells from B6 or c1(70–100), c1(88–100), or c1(96–100) congenic OT-II TCR transgenic mice were adoptively transferred into B6.Thy1.1 or c1(70–100).Thy1.1 mice. Mice were immunized with OVA emulsified in CFA, sacrificed 2 weeks later, and the proportion of various splenic T cell subsets determined by flow cytometry, gating separately on Thy1.1[+] (recipient) and Thy1.2[+](transferred) T cells. Bone marrow-derived dendritic cells (DC) isolated from 8wk old c1(70–100), c1(88–100) and c1(96–100) congenic, and B6 control mice were cultured in the presence of LPS, imiquimod or CpG, or pulsed with OVA and co-cultured with naïve OT-II T cells. Production of cytokines (IL-12, IL-23, IL-6) by stimulated DC was analyzed by ELISA or flow cytometry.

Results: Adoptive transfer experiments revealed that the increased IFN-γ and IL-17 secreting cell differentiation in c1(70–100) congenic mice arises in part from intrinsic T cell defects localizing to the NZB c1 96–100 cM and 88–96 cM intervals, respectively. However, OT-II T cells from all mouse strains examined demonstrated enhanced differentiation to T_H1, T_H17, and T_{FH}populations when transferred into c1(70–100).Thy1.1 as compared to B6.Thy1.1 mice. This finding suggested that the increased differentiation of these T cell subsets in c1 congenic mice was also dependent upon cellular and/or cytokine cues provided by the c1(70–100) environment. Since, DC play an important role in the antigen presentation and cytokine secretion that directs T cell responses, DC function was contrasted in the various mouse strains. Following TLR stimulation, DC from c1(70–100) mice expressed significantly higher levels of MHC and co-stimulatory molecules, and secreted higher amounts of pro-inflammatory cytokines such as IL-6 and IL-12. Consistent with altered DC function, OVA-pulsed DC from c1(70–100) mice induced significantly increased differentiation of naïve OT-II cells to IFN-γ, IL-17 or IL-21 secreting cells as compared to B6 DC.

Conclusion: Our results suggest that a genetic polymorphism in the 70–88 cM interval of NZB c1 congenic mice alters DC function and acts together with intrinsic T cell defects to promote the expansion of T_H1, T_H17 and T_{FH} cells in c1(70–100) mice, resulting in severe GN.

An Essential Role for TNF and PD-L1 in the Generation of Human CD8+CD25+Foxp3+ Regulatory T Cells That Are More Protective *in Vivo* Than CD4regs. David A. Horwitz, Stephanie Pan, Julie Wang and Song G. Zheng. Keck School of Medicine of USC, Los Angeles, CA

Background/Purpose: In addition to rare thymus-derived CD8+ regulatory/suppressor cells (CD8regs), several subsets of peripherally derived CD8regs have been described. We have recently induced ex-vivo a human CD8 subset that displays TNFR2 and PD-L1 and here consider whether these receptors are important in the generation and function of these CD8regs.

Methods: Naïve CD8+ cells were stimulated with anti-CD3/28 coated beads + IL-2 and TGF-β for 6 days. CD8regs were sorted into separated into TNFR2+, PD-L1+, double + and double - cells, and the suppressive activity of each subset assessed. In some experiments TNFR2 signaling was blocked by neutralizing TNF with TNFR-Fc (Enbrel), and effects of ligating PD-L1 with anti-PD-L1 were assessed. *In vivo* CD8reg activity was assessed by protection of NOD SCID CD8 chain−/− (NOG) mice from GVHD caused by human PBMC.

Results: The CD8regs expressed Foxp3, CD25[high], CD122[high], TNFR2 and CD103, and displayed the negative co-stimulatory receptors PD-1, PD-L1, Tim-3 and CTLA-4. TGF-β enhanced expression of. Foxp3, PD-1 and CD103, and inhibited CD80, CD86 and granzymes. Most remained naïve CD45RA+ cells. CD8regs produced both IL-2 and TNF. CD8regs preferentially targeted allogeneic cells both *in vitro* and *in vivo*. While we and others reported that both expanded natural and induced CD4regs doubled survival of NOG mice from GVHD, protection by CD8regs was 2 fold greater.

Sorted TNFR2+ PD-L1+ cells suppressed the proliferation of CD4+CD25- cells markedly greater than sham sorted cells. Single positive cells had activity similar to controls, but double negative cells lacked activity. Studies with TNFR-Fc and anti-PD-L1 suggested TNF significantly enhanced CD8 cell PD-L1 expression. Both agents inhibited Foxp3 expression. Neither affected activation (CD25 expression), but adding TNFR-Fc doubled the expansion of CD8 cells while anti-PD-L1 completely blocked expansion. Blocking TNF signaling resulted in a dose-related decrease in suppressive function of the CD8regs generated. By contrast, ligating PD-L1 with anti-PD-L1 doubled the suppressive activity of the CD8regs induced, and also doubled activity when added to the suppressor cell assay. Treating CD8regs with anti-IL-10R or a TGF-βR1 signaling inhibitor decreased GVHD protection *in vivo*, but both TNF-Fc and anti-PD-L1 lacked this effect.

Conclusion: These polyclonal CD8regs have a unique phenotype associated with remarkable *in vivo* suppressive activity. They display the negative co-stimulatory marker profile characteristic of chronically stimulated, "exhausted" CD8 cells, but differ in that they also express bright IL-2R, TNF-R2, CD103 and remain naive. Although anti-PD-L1 blocks the inhibitory co-stimulatory effects of PD-L1 expressed by APC and tumor cells, we found that anti-PD-L1 had the opposite effect on PD-L1 expressed CD8regs by enhancing both generation and suppressive function. Enhancement of CD8 PD-L1 expression by TNF via TNFR2 can be considered compensatory to this cytokine's pro-inflammatory effects. The inhibitory effects of TNFR-Fc on CD8reg generation, and the opposite effect of anti-PD-L1 may affect the clinical outcome of these agents when they are used in autoimmune diseases or cancer.

PD-1 Signaling Promotes Suppressive Function of CD4[+] Regulatory T Cells in (New Zealand Black × New Zealand White) F_1 Lupus-Prone Mice in a Dose-Dependent Manner. Maida Wong, Antonio La Cava and Bevra H. Hahn. University of California, Los Angeles, Los Angeles, CA

Background/Purpose: Programmed death-1 (PD-1) has been regarded as a negative regulatory signal in T cells. Our laboratory has shown that PD-1 is important in T cell regulation of autoimmunity, as treatment with neutralizing anti-PD1 Ab increased regulatory T cell function and dramatically delayed SLE onset in young BWF_1 females. We hypothesized that tight regulation of PD-1 signaling is required for maintenance of functional $CD4^+T_{reg}$ and subsequent control of autoimmunity in BWF_1 mice, and that regulatory capacity of the cells is sustained at least in part by resistance to apoptosis, resulting in $CD4^+T_{reg}$ survival, when PD-1 is expressed at a certain level – neither absent nor high.

Methods: A neutralizing Ab against PD-1 or control isotype-matched IgG were injected i.p. into BWF_1 mice. Foxp3 and PD-1 expression were assessed by flow cytometry. Splenocytes from these animals were isolated for *in vitro* culture, and anti-PD-1 Ab at various concentrations were added *in vitro* to test for B cell apoptosis by Annexin V and 7-AAD, and $CD4^+CD25^-$ helper T cell (T_h) proliferation by CFSE. AutoAb production of anti-dsDNA and total IgG was tested by ELISA in the supernatant.

Results: Blocking the full expression of PD-1 *in vivo* resulted in induction of $CD4^+CD25^+Foxp3^+T_{reg}$ with reduced, but not absent, PD-1 expression. These PD-1[lo]$CD4^+T_{reg}$, compared to $CD4^+T_{reg}$ with PD-1[hi] expression, had increased ability to induce B cell apoptosis and to suppress T_h proliferation. The PD-1[lo]$CD4^+T_{reg}$ suppressed syngeneic B cells production of anti-dsDNA and IgG. Apoptosis was significantly lower in the PD-1[lo]$CD4^+T_{reg}$. *In vitro* PD-1 blockade confirmed that tight regulation of PD-1 expression is important in maintaining $CD4^+T_{reg}$ suppressivity. By adding anti-PD-1 Ab >25 hg/ml *in vitro*, PD-1[lo]$CD4^+T_{reg}$ from mice with *in vivo* PD-1 blockade lost their ability to induce B cell apoptosis and suppress T_h proliferation. On the other hand, PD-1[hi]$CD4^+T_{reg}$ from the isotype controls became more suppressive with the presence of anti-PD-1 Ab *in vitro*, until its concentration was > 75hg/ml. The concentration of anti-PD-1 Ab did not affect the survival of $CD4^+T_{reg}$.

Conclusion: PD-1 expression is central in the ability of $CD4^+T_{reg}$ to suppress autoimmunity; their PD-1 expression has to be finely tuned to permit $CD4^+T_{reg}$ to survive and retain suppressive capacities. One mechanism by which PD-1 sustains $CD4^+T_{reg}$ is by reducing their susceptibility to apoptosis.

Discovery of a Highly Potent, Selective Reversible Covalent Inhibitor of JAK3 Kinase. Ronald J. Hill[1], Angelina Bisconte[1], J. Michael Bradshaw[1], Ken Brameld[2], Eun Ok Kim[1], Xiaoyan Li[2], Tim Owens[2], Erik Verner[2] and David M. Goldstein[2]. [1]Principia Biopharma, South San Francisco, CA, [2]Principia Biopharma

Background/Purpose: Targeting of the JAK-STAT pathway has been shown to be efficacious for treatment of patients with rheumatoid arthritis through the successful use of pan-JAK inhibitors in clinical trials. To date, lack of selective JAK3 inhibitors has hindered the assessment of the role of JAK3 in autoimmune disorders. A JAK3 inhibitor has the potential benefit of alleviating undesirable side effects of JAK1 and JAK2 inhibition such as dyslipidemia and suppression of hematopoiesis, respectively. A new approach is presented to achieve potent, selective and durable inhibition of JAK3 by application of Principia's reversible covalent platform targeting a cysteine residue in the active site of JAK3 that is absent from other JAK family members. Ability of these inhibitors to block IL-2 and IL-4 signaling is presented.

Methods: Enzyme potencies were measured using the Caliper platform at Nanosyn Inc. (Santa Clara, CA). IL-2 stimulated phospho-STAT5 was measured in Ficoll separated human peripheral blood mononuclear cells (PBMCs) by flow cytometry. IL-4 stimulated STAT6 activation was measured in Ramos B cells based on a STAT6 reporter assay (Invitrogen, Madison, WI). Kinase profiling was performed at DiscoveRx (San Diego, CA).

Results: We have developed a series of molecules that are highly potent and selective for JAK3. Compound 1 inhibited JAK3 enzymatic activity with an IC_{50} of 0.5 ± 0.3 nM, but not JAK1, JAK2, or TYK2 up to a concentration of 5 uM. The selectivity among other kinases within the Cys sub-family was also high with no inhibition exceeding 60% at 1 uM. Profiling against a panel of 442 kinases confirmed the exceptional selectivity of the series. Compound 1 forms a durable yet reversible Cys interaction with JAK3 in biochemical assays with a dissociation half-life of 9 hours.

In cell-based assays, Compound 1 completely inhibited IL-2 stimulated STAT5 phosphorylation ($IC_{50} = 206 \pm 11$ nM) in hPBMCs, IL-4 stimulated STAT6 phosphorylation ($IC_{50} = 58 \pm 10$ nM) in Ramos B cells and IL-2 driven IFNgamma secretion ($IC_{50} = 248 \pm 8$ nM) in hPBMCs. IL-6 stimulated STAT3 phosphorylation was not inhibited up to 5 uM indicating complete cellular selectivity for JAK3 over JAK1. In addition, NFAT activation downstream of TCR stimulation in Jurkat T cells was not blocked.

Conclusion: Compound 1 is a potent, selective and durable inhibitor of JAK3 and has the potential to be an efficacious treatment for rheumatoid arthritis or other T cell driven diseases with a potential for differentiation from pan-JAK inhibitors.

CGEN-15001, a Novel Negative Costimulatory Fusion Protein Is Effective in the Collagen-Induced Arthritis Mouse Model of Rheumatoid Arthritis. Iris Hecht[1], Kay McNamee[2], Ilan Vaknin[1], Anat Oren[1], Joseph R. Podojil[3], Galit Rotman[1], Eyal Neria[1], Stephen D. Miller[3] and Richard O. Williams[2]. [1]Compugen Ltd., Tel Aviv, Israel, [2]Oxford University, London, United Kingdom, [3]Northwestern University, Chicago, IL

Background/Purpose: CGEN-15001 is a recombinant Fc fusion protein consisting of the extracellular domain of CGEN-15001T, a protein predicted to be a member of the B7/CD28 costimulatory family. CGEN-15001T was identified using a proprietary discovery platform based on shared bioinformatic characteristics with known members of this family. The immunomodu-

latory effect of CGEN-15001 on T cell activity and its efficacy in the murine collagen-induced arthritis (CIA) model were evaluated.

Methods: Murine naïve CD4+ T cells were activated with plate bound anti-CD3 and either CGEN-15001 or control proteins. The effect of CGEN-15001 on activation marker expression and cytokine secretion was evaluated after 48hrs of incubation, while effects on cell division and apoptosis were evaluated after 96hrs. The effect of CGEN-15001T was studied using a similar experimental system utilizing HEK-293 transfected cells expressing CGEN-15001T or empty vector.

To study the effects of CGEN-15001 on T cell proliferation and differentiation, CD4+ T cells from DO11.10 mice were activated with $OVA_{323-339}$ plus irradiated APCs in the presence of Th driving conditions and either CGEN-15001 or control Ig. Proliferation was evaluated after 72hrs and cytokine secretion after 96hrs.

To study the effect of CGEN-15001 in the CIA model, DBA/1 mice (n=7–10/group) were immunized with type II bovine collagen in complete Freund's adjuvant. Mice were injected intraperitoneally with CGEN-15001, TNFR-Ig, CTLA4-Ig or Ig control at 100ug/mouse, three times/week for 10 days. Treatment started at onset of clinical arthritis and mice were scored daily for arthritis severity. On day 10 of arthritis, mice were sacrificed and paws were removed for histological analysis.

Results: CGEN-15001 as well as stably expressed CGEN-15001T, inhibited T cell activation demonstrated by inhibition of proliferation, inflammatory cytokine secretion and expression of early activation markers. CGEN-15001 elicited its immunomodulatory activity by skewing immune response from Th1/Th17 to Th2.

In the CIA model, CGEN-15001 demonstrated potent therapeutic efficacy when administered to mice with existing disease. Treatment with CGEN-15001 resulted in significant inhibition of clinical symptoms including joint swelling, erythema, and stiffness compared to mice treated with Ig control. Histological analysis of the diseased joints showed reduced inflammation and joint erosion compared to the control.
Conclusion: These results as well as data showing long term efficacy of CGEN-15001 in murine models of multiple sclerosis, support the therapeutic potential of CGEN-15001 in the treatment of rheumatoid arthritis and other autoimmune diseases. The therapeutic use of negative co-stimulators to keep the immune system in check promises to provide an efficacious and safe approach to the treatment of autoimmune diseases.

A Novel Method for Quantitative and Functional Analysis of Autophagy Using Flow Cytometry in Activated Human Primary T Cells. Ryu Watanabe, Hiroshi Fujii, Yukiko Kamogawa, Kyohei Nakamura, Tsuyoshi Shirai, Yumi Tajima, Shinichiro Saito, Tomonori Ishii and Hideo Harigae. Tohoku University, Sendai, Japan

Background/Purpose: Autophagy is an evolutionally conserved self-degradation system. In this process, an isolation membrane engulfs cytoplasmic materials and organelles to form an autophagosome. The autophagosome then fuses with the lysosome, leading to the degradation of the enclosed materials to recycle or energy production. Autophagy is considered to play important roles in activated T cells to counteract various cellular stresses, and it would

be a potential therapeutic target in chronic inflammatory diseases. Although several methods to measure autophagy were developed, it is not easy to quantify autophagic activity in small number of human primary cells. The aim of this study is to develop a high sensitive and high throughput method for quantitative and functional analysis of autophagy in human primary T cells using flow cytometry.

Methods: Human naïve and effector memory CD4+ T cells were isolated from peripheral blood and stimulated with anti-CD3 and anti-CD28 antibody. Two days after stimulation, GFP-LC3 fusion protein which can function as an autophagy sensor was overexpressed in human activated T cells using retroviral vector system. To inhibit autophagy, dominant negative form of ULK1 (ULK1-DN) was overexpressed in human activated T cells. Autophagic activity and cell death were quantified in naïve and effector memory CD4+ T cells.

Results: Using Western blotting and electron microscopy, we confirmed that autophagy was induced in activated T cells and the reduction of fluorescence intensity of GFP-LC3 correlated with autophagy (Fig.1). Compared to naïve T cells, effector memory T cells had significantly lower autophagic activity (p=0.025) and were susceptible to apoptotic cell death (p=0.01). Overexpression of ULK1-DN inhibited autophagic flux and induced more apoptotic cell death in naïve and effector memory T cells. In these autophagy-defective naïve CD4+ T cells, mitochondria volumes and reactive oxygen species were increased. In contrast, enhancement of autophagy by rapamycin reduced apoptotic cell death in naïve and effector memory CD4+ T cells.
Fig 1. The GFP-LC3 fluorescence intensity was reduced in activated T cells, indicating that autophagy was induced in activated human primary T cells.

Conclusion: We established a novel method for measuring autophagic flux in activated human primary T cells. Using this assay, we first identified that effector memory CD4+ T cells had lower autophagic activity than naïve CD4+ T cells and this lower autophagic activity may contribute to more apoptotic cell death in effector memory CD4+ T cells. This novel method is helpful to examine pathological roles of autophagy and investigate autophagy as a potential therapeutic target in collagen diseases.

Increase of CD4$^+$CD25$^+$FoxP$_3$$^+$ T Cell in Patients with Systemic Sclerosis Could Secret IL-17 with Dysfunction of Immunosuppression. Xinjuan Liu[1], Na Gao[1], Mengtao Li[1], Dong Xu[1], Yong Hou[1], Qian Wang[1], Guohua Zhang[1], Qiuning Sun[1], Henghui Zhang[2] and Xiaofeng Zeng[1]. [1]Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China, [2]Peking University, People's Hospital, Beijing, China

Background/Purpose: Immune unbalance between Th17 and regulatory T cells (Treg) is a characteristic of systemic sclerosis (SSc). The functional heterogeneity and differentiation dynamics can be clearly shown by separating Treg cells into three subsets based on the expression of FoxP$_3$ and CD45RA. The aim of this study was to investigate subsets levels of Treg from the patients with naive SSc and assess their roles in the immune balance between Treg and Th17.

Methods: Peripheral blood from 31 patients with SSc and 33 health controls were collected. Peripheral blood mononuclear cells (PBMCs) were prepared and analyzed for the expression of CD4, CD25, CD45RA, CTLA-4, CD69, CD279, GITR, FoxP3 and IL-17 with flow cytometry. Measuring Treg suppressive capacity against proliferation of CD4$^+$CD25$^-$ T cells in

coculture experiments by a CFSE based. The expression of FoxP$_3$, CTLA-4, IL-17A and RORC mRNA were studied with real-time PCR.

Results: (1)The frequency of CD4$^+$CD25$^+$FoxP$_3$$^+$Treg cells were significantly elevated in patients with SSc (3.62±1.14) compared with controls (1.97±0.75, P<0.001), but the expression of CTLA-4 and its mRNA were lower in Treg cells of SSc patients compared with control with diminished immunosuppression capacity.

(2) In the patients with SSc, the frequency of CD45RA$^-$FoxP$_3$^{high} activated Treg cells (aTreg,FrII) were lower than control (0.25±0.16 vs 0.66±0.41 among CD4+, P<0.001; 12.42±5.23 vs 30.01±1.74 among Treg, P<0.001),CD45RA$^-$FoxP3^{lo} T cell (FrIII) were higher than control(6.23±2.29 vs 2.90±0.91 among CD4+, P<0.001; 73.71±9.62 vs 57.96±9.90 among Treg, P<0.001),There were no significant difference in two groups with CD45RA$^+$FoxP3^{lo}Treg cells (rTreg,FrI),which were relatively lower in Treg cells (1.87±0.94 vs 1.63±0.97 among CD4+, P=0.320; 23.19±10.60 vs 29.63±11.77 among Treg, P=0.025).

(3)In the patients with SSc, immunosuppressive capacity of aTreg and rTreg cells were diminished,FrIII cells had no immunosuppressive capacity neither in the patients with SSc nor with control; in the patients with SSc, the expression of CTLA-4 in the surface of FrII and FrIII cells were decreased significantly (P<0.001,respectively), and CTLA-4 mRNA expression in FrII were decreased.

(4) The expression of IL-17 were higher in FrIII cells than FrI and FrII cells in both groups (P<0.001,respectively),but there were no difference of FrIII between these two groups; Th17 cells were increased in the patients with SSc (P<0.001); in the patients with SSc, CD25$^+$FoxP$_3$$^+$IL17$^+$cells among CD4$^+$ cells were increased(0.075±0.032 vs 0.049±0.027, P=0.029),but no difference of CD25$^+$FoxP3$^+$IL17$^-$with control; the expression of IL-17A and RORC mRNA were increased in the FrIII cells of SSc patients(P<0.001,respectively).

Conclusion: Decreased aTreg with functional deficiency and increased CD45RA$^-$FoxP$_3$^{lo} T cells could explain increased Treg with dysfunction in the patients with SSc, which were the reasons of unbalance of Treg and Th17 cells in the patients with SSc too. Increased Treg cells were not the real regulatory T cells, but non-suppressive CD45RA$^-$FoxP$_3$^{lo} cells, which is the main provider for FoxP$_3$$^+$IL-17$^+$ cells without immunosuppressive capacity.

Mucosal-Associated Invariant T Cells Are Inactivated by IFNα and Reduced in Systemic Lupus Erythematosus. Asako Chiba[1], Naoto Tamura[2], Ran Matsudaira[2], Takashi Yamamura[1], Yoshinari Takasaki[2] and Sachiko Miyake[1]. [1]National Institute of Neuroscience, National Center of Neurology and Psychiatry, Tokyo, Japan, [2]Juntendo University School of Medicine, Tokyo, Japan

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are a subset of innate-like lymphocytes which are restricted by the MHC-related molecule-1 (MR1) and express an invariant TCRα chain:Vα7.2-Jα33 in humans and Vα19-Jα33 in mice with a limited set of Vβ chains. Although the function of MAIT cells is not well known, like other innate-like lymphocytes, MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune models. We previously demonstrated that MAIT cells exerted a suppressive activity on T cells and the frequency of MAIT cells was reduced in patients with multiple sclerosis. In this study, we sought to investigate mechanisms by which MAIT cells are activated/inactivated and whether MAIT cells are relevant to other human autoimmune diseases including systemic lupus erythematosus(SLE).

Methods: Whole blood samples or peripheral blood mononuclear cells (PBMC) of SLE patients as well as healthy volunteers were stained with anti-human monoclonal antibodies(mAb) against CD3, $\gamma\delta$TCR, invariant Vα7.2TCR, and CD161 and analyzed by FACS. MAIT cells were identified as CD3$^+$$\gamma\delta$TCR$^-V\alpha$7.2TCR$^+$CD161^{high}cells. PBMC or FACS sorted MAIT cells were labeled with CellTrace Violet dye and stimulated with anti-CD3mAb and anti-CD28mAb or various types of cytokines. 6–7 days later, the cell proliferation was analyzed by FACS.

Results: As previously demonstrated, the frequency of MAIT cells of healthy controls was about 5% among T cells. The percentages of MAIT cells of SLE patients were 10-fold lower compared with those of healthy subjects. MAIT cells proliferated upon TCR stimulation when cultured with other PBMC. However, sorted MAIT cells failed to respond to anti-CD3mAb and anti-CD28mAb stimulation. MAIT cells and $\gamma\delta$T cells were activated and proliferated by IL-15 even without exogenous TCR stimuli. MAIT cell

proliferation was markedly suppressed by IFNα, but IFNα had little effect on TCR-stimulated γδT cell proliferation.

Conclusion: This study demonstrates that MAIT cell activation greatly depends on cytokines. As IFNα is known to be related to the pathogenesis of SLE, the abnormal balance of cytokines may be responsible to the reduced frequency of MAIT cells in SLE.

The Effects of Anti–Tumor Necrosis Factor Agents On the Expansion of T Helper-Type 17 Cells Driven by Lipopolysaccharide-Stimulated Monocytes. Gianluca Fossati[1], Louise Healy[1] and Andrew Nesbitt[2]. [1]UCB Pharma, Slough, United Kingdom, [2]UCB Pharma, SLough, United Kingdom

Background/Purpose: T helper-type 17 (Th17) cells are proinflammatory CD4+ cells characterized by the production of Interleukin-17 (IL-17).There is evidence that IL-17 and other cytokines which Th17s produce such as IL-21 are involved in the pathogenesis of RA.[1] Lipopolysaccharide (LPS)-stimulated monocytes can promote differentiation of CD4+ cells into Th17 cells and produce IL-17 in vitro.[2] This study examined the effect of 4 anti–tumor necrosis factor (TNF) agents (adalimumab, etanercept, infliximab, and certolizumab pegol) on the expansion of CD4+CD45RO+ memory T cells into Th17 cells driven by LPS-stimulated monocytes.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from healthy volunteers. Monocytes and CD4 + T cells were purified from the PBMC by positive and negative selection, respectively. CD4+CD45RO+ memory T cells were enriched from the CD4+ T cell fraction by positive selection. Purified monocytes and memory T cells were co-cultured at a 1:1 ratio for 7 days with CD3/CD28 Human T-Activator Dynabeads with and without 1 μg/mL LPS. Cells were cultured in the presence and absence of the 4 anti-TNF agents at 10 μg/mL. After 7 days the CD4+ T cells were stained for intracellular Interferon γ (IFNγ) and IL-17A and analyzed by flow cytometry. IL-17A and IL-17F secretion into the supernatant was determined by ELISA.

Results: CD4+ T cells positive for IL-17A were increased from 5.7% in the control co-cultures without LPS to 20.5% with LPS (mean of 2 experiments). The frequency of IFNγ-positive CD4+ T cells showed a smaller increase from 4.4% to 10.6% when LPS was added. IL-17A and IFN-γ were expressed largely by different cells, suggesting the expansion of both Th17 and Th1 T-helper subsets. The frequency of IL-17A-producing CD4+ T cells in co-cultures of monocytes and memory T cells plus LPS in the presence of the 4 anti-TNF agents were roughly 2.5 -fold lower than the LPS-positive control cultures generated in the absence of anti-TNF agents (mean of 4 experiments). Cells exposed to the 4 anti-TNF agents showed a similar level of CD4+ cells producing IL-17A and IFNγ. The level of IL-17A secreted into the supernatant decreased from 580 pg/mL in the LPS positive control to 180 pg/mL in co-cultures generated in the presence of the 4 anti-TNF agents. IL-17F decreased from approximately 8 ng/mL to 2 ng/mL in the LPS control and the anti-TNF exposed cultures, respectively (mean of 4 experiments). There were no significant differences in the concentration of IL-17A or IL-17F from co-cultures exposed to the 4 different anti-TNF agents.

Conclusion: The increased frequency of IL-17+ T cells and secretion of IL-17A and IL-17F suggest that LPS-activated monocytes support the expansion of Th17 cells present within the memory pool. Exposure to anti-TNF agents inhibited Th17 expansion and IL-17A production. This suggests that part of the mode of action of anti-TNF agents may be to reduce Th17 expansion and, as a consequence, IL-17A and IL-17F concentration. It is unclear whether soluble TNF or membrane TNF is responsible for this activity.

Suppression of PP2Ac Causes DNA Hypermethylation Through Enhanced Pmek/Perk Activity in T Cells. Katsue S. Watanabe[1], Kamalpreet Nagpal[2] and George C. Tsokos[2]. [1]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Background/Purpose: Although many reports have focused on the impaired MEK-ERK signaling pathway in T cells from systemic lupus erythematosus (SLE) patients which results in suppression of DNA methyltransferase (DNMTs) expression and induction of gene transcription of methylation-sensitive genes, the involved mechanisms are still unclear. Here we investigated whether the catalytic subunit of protein phosphatase 2A (PP2Ac) which is overexpressed in SLE T cells contributes to inhibition of MEK-ERK signaling and DNA methylation.

Methods: Human peripheral CD3 positive T cells from normal subjects were treated with the selective chemical inhibitor, okadaic acid (OA) or transfected with siPP2Ac to achieve sufficient suppression of the PP2Ac enzymatic activity. After stimulation with PMA and ionomycin, DNA, RNA and protein were extracted. The ratio of phosphorylated over total MEK and ERK protein were determined by western blotting. The enzyme activity of DNMTs and the level of global DNA methylation status were calculated by ELISA. The transcription level of two methylation sensitive genes, CD70 and CD11a was quantified by real time RT-PCR.

Results: Chemical suppression or siRNA silencing of PP2Ac in T cells resulted in sustained phosphorylation of MEK and ERK following stimulation with PMA and ionomycin compared to T cells in which PP2Ac was not manipulated. PP2Ac suppression resulted in increased DNMT enzymatic activity of DNMT, DNA hypermethylation and decreased expression of methylation-sensitive genes.

Conclusion: Our results demonstrate that PP2A regulates DNA methylation levels by influencing the phosphorylation levels of the MEK/ERK pathway. We propose that enhanced PP2Ac in SLE T cells may dephosphorylate and activate the upstream signaling pathway of DNMT and disturb the tight control of methylation-sensitive genes such as CD70 and CD11a which are involved in SLE pathogenesis. In addition, based on our previous report that PP2Ac itself is regulated though DNA methylation around a cAMP response element (CRE) binding site located in the proximal promoter, and therefore PP2A may represent a potent accelerator of DNA demethylation through an additional positive feedback mechanism.

2333

A Novel Subset of CD4 T Cells That Provides Help for Human Memory B Cell Responses. Sang T. Kim, Jin Young Choi, Begona Lainez and Joseph E. Craft. Yale University School of Medicine, New Haven, CT

Background/Purpose: Follicular helper T (Tfh) cells provide help to B cells in germinal centers (GCs) of secondary lymphoid organs (SLOs) following primary antigen (Ag) challenge, with formation of memory B and long-lived plasma cells. Memory B cells can be recalled in secondary responses upon Ag rechallenge, with generation of short-lived plasmablast or secondary GCs with further rounds of B cell maturation. Human memory B cells function better *in vitro* with T cell help; however, the nature of the T cells that provide such help is unclear, with the role of Tfh cells, if any, not known. Our goal is to identify and characterize human memory B helper T cells.

Methods: Tonsils were obtained from tonsillectomies (2–18 y) done at Yale New Haven Hospital, with cells used for flow cytometry, qPCR, and cytokine analyses. Autologous CD4 T cell and B cells were co-cultured for immunoglobulin (Ig) production, as a readout for T dependent B cell maturation. Confocal microscopy was performed to localize memory B cells and helper T cells.

Results: We found that human Tfh cells, as defined by classical flow cytometry markers (CXCR5hi PD-1hi), can be subdivided into two groups based upon expression of P-selectin glycoprotein ligand-1 (PSGL-1), a cell surface protein that in synergy with the T cell homing marker (CCR7) dictates residence in the T cell zone of SLOs. PSGL-1lo CXCR5hi PD-1hi cells reside in B cell follicles as Tfh cells, whereas we found by confocal microscopy that PSGL-1hi CXCR5hi PD-1hi cells reside in T cell zones outside B cell follicles. We defined the latter PSGL-1hi CXCR5hi PD-1hi cells as triple hi cells (Thi), finding that except for their location in T cell zones and PSGL-1 expression, they shared with GC-resident Tfh cells a similar surface marker profile. Yet, by contrast to Tfh cells, Thi cells expressed more CCR7 with lower expression of the follicular homing marker CXCR5, findings consistent with their T zone location. Bcl6, the master transcriptional regulator for Tfh cells, was expressed in both populations at equivalent levels, but expression of Blimp1, a regulator of effector T cell development, was higher in Thi cells. Tfh cells and Thi cells produced comparable levels of IL-21; however, Tfh cells produced more IL-4 while Thi cells exclusively produced IL-10, with the latter important in provision of B cell help. Memory B cells produced more Ig when co-cultured with Thi cells than other CD4 subsets, with such help

contact dependent and reliant upon CD40L, IL-21, and IL-10; moreover, Thi cells preferentially associated with memory B cells as T-B cell couplets in flow cytometry compared to Tfh cells. Confocal microscopy showed co-localization of Thi cells and memory B cells at the T-B border. Thi cells were also found in human spleens.

Conclusion: We have identified a population of B T helper T cells in SLOs that promote maturation of memory B cells in a cytokine- and contact-dependent manner, with localization at the border of the T cell zone and B cell follicles in SLOs. They are distinct from classical GC-resident Tfh cells, and are likely critical for antibody recall responses. Their further characterization should pave the way for new understanding of human immune memory responses in normal and autoimmune subjects.

T-Cell Cross Reactivity with Citrullinated Antigen and *P. Gingivalis* Membrane Antigen Following Infection with *P. Gingavalis* and/or Injection of Citrullinated Mouse Type II Collagen in DBA/1J Mice. Michael J. Duryee[1], Anand Dusad[1], Carlos D. Hunter[1], Ke Ren[1], Dong Wang[2], James R. O'Dell[3], Lynell W. Klassen[3], Ted R. Mikuls[4] and Geoffrey M. Thiele[3]. [1]University of Nebraska Medical Center, Omaha, NE, [2]Univ of Nebraska Medical Ctr, Omaha, NE, [3]Univ of Nebraska Med Ctr, Omaha, NE, [4]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Recently, periodontal disease (PD) has been associated with the risk and progression of RA. Patients with RA complicated by PD have been shown to have higher anti-citrullinated protein antibody (ACPA) levels, which have also become predictive markers of the disease and its severity. Previous studies have demonstrated that RA can be induced in mice following oral infection with *P. gingivalis (P. ging)*, a major cause of PD. However, these studies never demonstrated antibody or T-cell responses to citrullinated antigens. Therefore, it was the purpose of this study to determine whether infection with *P. ging* can induce RA and if these responses induce antibodies and/or T-cell responses to select citrullinated antigens in DBA/1J mice.

Methods: DBA/1J mice were subjected to sulpha-methoxazole in their water for 10 days and then gavaged with *P. ging* 3 times over a 1 week period. Control mice were subjected to antibiotics in the absence of *P. ging* and injected with mouse type II collagen collagen (Col). Also, mice were immunized with citrullinated Col (Cit-Col) in parallel as previously published. Animals were evaluated weekly for inflammation of the joints for 6 weeks and sacrificed followed by serum and spleen collection. The $CD4^+$ T cells were then isolated and proliferated against Col, Cit-Col or *P. ging* outer membrane antigen (PGMA). Serum was tested for the presence of antibody to PGMA and ACPA, the latter using a second generation anti-CCP assay.

Results: At week 6, mice gavaged with *P. ging* had a significant increase in inflammation as assessed by paw thickness (2.883 mm) and scoring (3.25) compared to the respective controls (2.543 mm) and (1.6); P≤0.01 between groups. Similar results were demonstrated for the Cit-Col groups, 2.868 mm and 3.25 (P≤0.001vs. controls). There was nearly a 2-fold increase in serum ACPA in the *P. ging* infected mice (11.2 U/ml) compared to no infection (6.89 U/ml) (p=0.002). The Cit-Col injected animals showed an ACPA response of 10.8 U/ml which was significantly different from controls (P=0.02). Antibody to PGMA was significantly higher in both the *P. ging* infected animals (4.101 µg/ml) and the Cit-Col (2.714 µg/ml) injected mice compared to controls (1.201 µg/ml) (P≤0.01 for both groups). $CD4^+$ T-cells from *P. ging* infected mice proliferated to both Cit-Col (5.34 stimulation index (SI)) and to PGMA (16.68 SI) compared to controls which had SI's of (0.160) and (0.704) respectively P≤0.001. T-cells from mice immunized with Cit-Col proliferated to Cit-Col at (3.950 SI) and to PGMA at (4.829 SI). This proliferative response was not observed with exposure of T-cells from both *P.ging* or Cit-Col injected mice to *P.intermedia* (an alternative cause of PD) membrane antigen.

Conclusion: These data show that following infection with *P. ging*, DBA/1J mice develop an inflammatory arthritis that is characterized by the expression of ACPA. Furthermore, T-cells from mice immunized with Cit-Col or infected with *P. ging* showed increased proliferation to both Cit-Col and PGMA. This suggests a cross reactivity between the PGMA and the citrullinated antigen. These studies begin to provide some insight into mechanisms linking *P. ging* with RA pathogenesis.

Increased TSLP Expression in Joints of Rheumatoid Arthritis Patients Causes Increased Activation of Intra-Articular Myeloid Dendritic Cells with Enhanced Th1 and Th17 Cell Activity. F.M. Moret, C.E. Hack, T.R.D.J. Radstake, J.W.J. Bijlsma, F.P.J.G. Lafeber and J.A.G. van Roon. University Medical Center Utrecht, Utrecht, Netherlands

Background/Purpose: Thymic stromal lymphopoietin (TSLP) is well known for its potent activation of myeloid dendritic cells (mDCs) to induce Th2-mediated immune responses. Administration of TSLP in a collagen-induced arthritis model was expected to inhibit Th1 and Th17-driven arthritis by the induction of Th2 activity. However, this resulted in an enhanced severity of inflammation and joint destruction. Additionally, prevention of TSLPR signalling strongly reduced Th17-driven experimental arthritis and immunopathology. The present study determined the levels of TSLP and numbers of TSLPR-expressing mDCs in joints of rheumatoid arthritis (RA) patients as compared to peripheral blood (PB) and studied the capacity of TSLP to induce mDC-dependent T-cell activation.

Methods: TSLP was measured in synovial fluid (SF) of patients with RA (n=50) and osteoarthritis (OA, n=24) by ELISA. CD1c mDC numbers and TSLPR expression on these cells were assessed by FACS analysis in paired samples of SF and PB from RA patients (n=9). CD1c mDCs, isolated from PB as well as SF of RA patients (n=6), were stimulated with TSLP for 20 hours and cytokine production was measured by multiplex immunoassay (measuring 51 cytokines). Washed TSLP-activated CD1c mDCs from PB (n=11) and SF (n=5) were added to autologous CD4 T cells in the absence of additional stimuli, cultured for 6 days and subsequently proliferation was measured. Additionally, T-cell cytokine production was measured (by ELISA) upon restimulation with ionomycin/PMA.

Results: TSLP levels in SF of RA patients were significantly increased compared to OA patients (mean 297 vs. 80 pg/ml, resp., p<0.01). mDCs numbers from SF were significantly increased compared to PB (5.0% vs. 0.6%, resp., p<0.01) and expressed increased levels of TSLPR (MFI 24 vs. 15, resp., p<0.01). TSLP significantly stimulated the production of chemokines TARC and MIP1α by mDCs from PB and SF (TARC: PB from 1 to 42 pg/ml, p<0.05 and SF from 26 to 186 pg/ml, p<0.05; MIP1α: PB from 1268 to 5486 pg/ml, p<0.05 and SF from 2776 to 3733 pg/ml, p<0.05). Upon incubation with TSLP, TSLPR-expressing mDCs from PB potently stimulated proliferation of autologous CD4 T cells as compared to unstimulated mDCs (ratio T cell:DC 5:1, from 1503 to 16036 cpm, p<0.01). However, TSLP-mDCs from SF had a strongly increased capacity to activate CD4 T cells (ratio T cell:DC 5:1, from 26395 to 57387 cpm, p<0.05). Enhanced proliferation was associated with increased production of IFNγ (ratio T cell:DC 5:1, PB from 179 to 655 pg/ml, p<0.01 and SF from 601 to 1867 pg/ml, p<0.05), IL-17 (PB from 39 to 353 pg/ml, p<0.05 and SF from 363 to 1382 pg/ml, p<0.05), and IL-4 (PB from 17 to 246 pg/ml, p<0.01 and SF from 193 to 775 pg/ml, n.s.).

Conclusion: Our data indicate that increased intra-articular TSLP concentrations in RA potently activate TSLPR-expressing mDCs from SF to secrete enhanced levels of proinflammatory mediators causing T cell chemotaxis and to potently increase arthritogenic T cell activation. This suggests that TSLP and TSLPR-expressing mDCs could both play an essential role in the immunopathology of RA.

Elevated Frequency of Synovial Interleukin-21$^+$ CD4$^+$ T Cells Co-Expressing Tumor Necrosis Factor-a in Rheumatoid Arthritis. Maria C. Lebre[1], Pedro L. Vieira[2], Saïda Aarrass[1], Thomas Newsom-Davis[2], Paul P. Tak[3] and Gavin R. Screaton[2]. [1]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam The Netherlands, Amsterdam, Netherlands, [2]Imperial College London, London, United Kingdom, [3]Academic Medical Center, University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting synovial tissue in multiple joints. The inflammatory process in RA is regulated by several cytokines, especially TNF, which is produced not only by macrophages and dendritic cells (DC) but also by activated antigen-specific CD4$^+$ T helper cells. IL-21 is a T cell-derived cytokine that has been implicated in several autoimmune diseases, including RA. Both activated CD4$^+$ T cells and T follicular helper cells (TFh) secrete

this inflammatory cytokine. IL-21 regulates T helper 17 cells and antibody production by B cells and induces osteoclastogenesis, mechanisms that contribute to RA pathology. In addition IL-21R blockade ameliorates arthritis in mice. Taking into account the recent literature we investigated whether IL-21 might play a role in RA.

Methods: Expression of surface markers and cytokine production at the single cell level in peripheral blood (PB) and matched synovial fluid (SF) from RA (n=13) and psoriatic arthritis (PsA, n=6) patients, as compared to PB of healthy control (HC) subjects (n=17), was evaluated by flow cytometry following PMA/ionomycin stimulation ex-vivo. IL-21 concentrations were assessed by ELISA in cell-free SF samples of RA (n=15), PsA (n=14) and OA (n=5) patients and in 6 days supernatants of RA (n=6) and spondyloarthropathy (SpA, n=5) synovial biopsy cultures. In addition we dissected the in vitro requirements for the differentiation of human IL-21-secreting CD4+ T cells from naive T cells.

Results: We observed significant expansions of $CD4^+$ T cells secreting IL-21 in RA SF compared to matched PB (p<0.0001). Interestingly, while the % of IL-21$^+$ CD4$^+$ T cells in PB did not differ between RA, PsA and HC, the % of both total IL-21$^+$ and IL-21$^+$TNF-a$^+$ CD4$^+$ T cells in RA SF were significantly increased compared to PsA (p=0.0140 and p=0.0038, respectively). The % of IL-21$^+$ CD4$^+$ T cells in RA PB was positively correlated with DAS28 (r=0.592, p=0.033), serum anti-cyclic citrullinated peptide (anti-CCP) antibodies (r=0.788, p=0.001) and rheumatoid factor (RF; r=0.691, p=0.009). In addition, the % of IL-21$^+$ CD4$^+$ T cells in anti-anti-CCP$^+$ or RF$^+$ patients was significantly higher compared to anti-CCP$^-$ (p=0.03) and RF$^-$ (p=0.01) patients respectively. The levels of IL-21 present in SF did not differ between RA and PsA but there was trend towards elevated levels of this cytokine in RA SF compared to OA SF (p=0.06). RA synovial biopsies released significantly higher levels of IL-21 compared to SpA (p=0.03). Synovial IL-21-secreting CD4$^+$ T cells did not phenotypically fit the TFh cell paradigm in that they did not express CXCR5. In humans, differentiation of naive CD4$^+$ T cells into IL-21-secreting cells in vitro was preferentially driven by IL-21 and/or IL-6 in the additional presence of transforming growth factor-β.

Conclusion: IL-21 and IL-21 blocking therapy is now being tested in a number of diseases. The results of this study enhance the rationale for a trial of IL-21 blockade in RA where it may provide a useful adjunct in those patients refractory to or unable to tolerate anti-TNF therapy.

Therapeutic Promotion of CD8 CTL by CpG Oligodeoxynucleotides (ODN) in an Induced Model of Lupus. Maksym Puliaiev, Kateryna Soloviova and Charles S. Via. Uniformed Services University of Health Sciences, Bethesda, MD

Background/Purpose: In addition to TcR signaling and costimulation, CD8 T cells require a third signal to mature into effector cytotoxic T lymphocytes (CTL). In pathogen models, interferon alpha (IFN-a) and IL-12 can serve as signal 3. In the parent-into-F1 (P->F1) model, there are no exogenous pathogens yet B6->B6D2F1 mice exhibit robust donor anti-host CD8 CTL resulting in >90% elimination of host splenocytes i.e. acute graft-vs.-host disease (GVHD). Transfer of the DBA parent (DBA->F1) results in DBA CD4-driven host B cell expansion and lupus (chronic GVHD) due to a failure of CD8 CTL supporting the idea that promoting CD8 CTL by enhancing signal 3 molecules may be beneficial in lupus.

Methods: Following donor cell transfer, host splenocytes were analyzed by real time PCR and flow cytometry. To promote signal 3 molecules, three TLR-9 simulating CpG ODNs (2006, 1826 or 2336) were administered to DBA->F1 mice (100 micrograms i.p.) during the first 5 days after transfer.

Results: For untreated DBA->F1 mice, there was no significant elevation of IL-12 gene expression and transient, low level (5–10 fold) elevations of IFN-a inducible (IFI) genes (MX-1, OAS-1) during the first two weeks after donor transfer. Long term, IFI gene expression in the setting of severe lupus renal disease was similarly low level for DBA->F1 mice. DBA->F1 mice receiving CpG ODN s exhibited a robust donor anti-host CD8 CTL response and profound host B cell elimination at two weeks for CpGs 2006 and 1826. CpG 2336 prevented chronic GVHD associated host B cell expansion but did

not significantly reduce B cells below normal F1 values. Only CpGs 2006 and 1826 induced strong (30–60 fold) IL-12 and IFI-gene expression at 6 hours after administration to normal F1 mice supporting the idea that the ability of a TLR9 CpG ODN to induce CTL is related to its ability to induce signal 3 molecules IL-12 and/or IFN-a. Surprisingly, we found no evidence that either IL-12 or IFN-a are critical for the robust CD8 CTL response in B6->F1 mice. Acute GVHD phenotype was not significantly altered in BDF1 mice by transferring B6 donor T cells deficient in either IFN-a receptor or IL-12 receptor beta nor by treating with anti-IL-12 mAb however disease could be blocked by transferring B6 donor T cells deficient in TNF receptor 2 (TNFR2) but not TNFR1.

Conclusion: These results support the conclusion that in the absence of pathogens, failure of down regulatory CD8 CTL permits CD4 T cell driven lupus. Conversely, induction of IL-12 and/or IFN-a can rescue defective CD8 CTL in DBA->F1 mice and abort lupus raising the possibility that CTL promotion may be worthy of further study as a potential lupus treatment. Our results demonstrating a critical role for TNF in CD8 CTL responses in the absence of pathogens raise concerns that therapeutic TNF blockade in humans may impair CD8 CTL responses to non-pathogens (tumors, autoantigens) and raise the risk of certain tumors and humoral autoimmunity as described for some TNF-blocking agents.

1,25(OH)$_2$D$_3$ Modulates the Migration Pattern of Th17 Cells From Patients with Rheumatoid Arthritis. Wendy Dankers[1], Jan Piet van Hamburg[2], Patrick S. Asmawidjaja[1], Nadine Davelaar[3], Hoyan Wen[1], Anne-Marie Mus[1], Edgar Colin[2], Johannes van Leeuwen[1], Johanna M.W. Hazes[4] and Erik Lubberts[1]. [1]Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Erasmus MC, Rotterdam, Netherlands, [3]Erasmus MC, University Medical Center, Rotterdam, Rotterdam, Netherlands, [4]Erasmus Medical Center, Rotterdam, Netherlands

Background/Purpose: Vitamin D has suppressive effects on autoimmune diseases, such as rheumatoid arthritis (RA). Within these diseases, T-helper-17 (Th17) cells have been implicated to play a crucial role in the development and progression of persistent inflammation. Recently, we have shown that Th17 cells are able to activate synovial fibroblasts of patients with RA (RASF) resulting in a pro-inflammatory feedback loop. This leads to increased production of pro-inflammatory cytokines and tissue-degrading enzymes. We have found that the active vitamin D compound, 1,25(OH)$_2$D$_3$, has direct suppressive effects on Th17 cells from patients with early RA. In addition 1,25(OH)$_2$D$_3$ is capable of inhibiting the pro-inflammatory feedback loop between Th17 cells and RASF. The objective of this study is to identify molecular targets of 1,25(OH)$_2$D$_3$ signaling underlying this suppressive action of 1,25(OH)$_2$D$_3$ in Th17 cells.

Methods: Primary Th17 cells were sorted from peripheral blood of treatment naïve patients with early RA. They were cultured with or without 1,25(OH)$_2$D$_3$ alone or together with RASF. From these cultures gene-expression profiles were generated. Expression of genes of interest was confirmed by Q-PCR and/or specific ELISA.

Results: In the presence of 1,25(OH)$_2$D$_3$, protein expression of Th17 associated cytokines IL-17A and IL-22 was inhibited, while in contrast the anti-inflammatory cytokine IL-10 was induced. These findings were supported by the gene-expression profiles from these cultures. Furthermore, 1,25(OH)$_2$D$_3$ inhibited transcription of the cytokine receptors IL-23R and IL-7R, which are involved in Th17 survival and proliferation. Chemokines CCL20 and CXCL10 were down-regulated and chemokine receptors CCR2, CXCR6, CXCR3 and CCR10 were up-regulated. Importantly, Rorγt, which is critically involved in Th17 differentiation and function and the cell-size regulator and oncogene c-Myc were down-regulated by 1,25(OH)$_2$D$_3$.

Conclusion: From these findings, we concluded that 1,25(OH)$_2$D$_3$ modulates the expression of genes involved in cytokine production, proliferation, and migration of Th17 cells. These data indicate that 1,25(OH)$_2$D$_3$ not only suppresses Th17 cell activity but also regulates Th17 phenotype stability and migration of these cells to sites of tissue inflammation in RA.

Lowering Fli1 Levels Decreases the Levels of Lipid Mediators in the Kidneys and T Cells of MRL/Lpr Lupus Prone Mice. Marlene Bunni[1], Zainab Amani[1], Andrew Mather[1], Jennifer Berglind Schepp[1], Leah Siskind[1] and Tamara K. Nowling[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina and Ralph H. Johnson VA Medical Center, Charleston, SC

Background/Purpose: The Ets factor Fli1 is implicated as a key modulator of lupus disease expression. Over-expressing Fli1 in healthy mice, results in the development of an autoimmune kidney disease similar to that observed in lupus. Lowering the global levels of Fli1 in two lupus mouse models significantly improved kidney disease and prolonged survival. Lowering the levels of Fli1 in hematopoietic cells in MRL/lpr lupus mice resulted in significantly improved kidney disease. The mechanism(s) by which Fli1 exerts this protective effect is unknown. The glycosphingolipid lactosylceramide (LacCer) is a ganglioside precursor to which sialic acid (SA) residues are added by ganglioside synthases or removed by sialidases. Loss of SA residues from gangliosides on the surface of podocytes is linked to proteinuria in glomerulonephritis and lipids with distinct chain lengths are thought to possess distinct biological activities. We demonstrate that lowering Fli1 levels decreases the levels of LacCer and the sialidase Neu1 in the kidney cortex and in T cells of MRL/lpr lupus prone mice. We present additional data demonstrating that Fli1 regulates Neu1 promoter activity in T cells.

Methods: Kidney and/or spleen were harvested from 17–19 week-old MRL/MpJ mice and MRL/lpr Fli1+/+ and Fli1+/− mice. T cells were isolated by negative selection from spleen and left unstimulated or stimulated with anti-CD3/CD28. Supercritical Fluid Chromatography coupled with tandem mass spectrometry was performed on kidney cortex homogenates and isolated T cells to quantify LacCer. Gene expression was analyzed by real-time RTPCR on RNA isolated from kidney cortex and T cells. Immunohistochemistry for LacCer was performed on frozen kidney sections. Neu1 promoter activity was examined by co-transfection of Neu1 promoter/reporter constructs and a Fli1 expression construct in human and mouse T cell lines.

Results: Diseased MRL/lpr mice express a significant 2.5-fold increase in the major LacCer species C16 in the kidney compared to age-matched MRL/MpJ, which do not exhibit kidney disease. MRL/lpr mice that are heterozygote for Fli1 (Fli1+/−) express a significant 2-fold decrease in LacCer C16 in the kidney compared to wild-type age-matched MRL/lpr mice. Similarly, a significant reduction in LacCer staining in cells of the glomeruli is observed by immunohistochemistry. Neu1 expression is significantly elevated 40-fold in the MRL/lpr compared to the MRL/MpJ kidney cortex, but is not significantly different in the MRL/lpr Fli1+/− compared to the wild-type MRL/lpr kidney cortex. Interestingly, Neu1 is reduced 3–4-fold and LacCer levels are significantly reduced 2.5-fold in T cells isolated from Fli1+/− compared to Fli1+/+ MRL/lpr mice. Over-expression of Fli1 results in a dose-dependent increase in Neu1 promoter activity in activated T cells.

Conclusion: Our results demonstrate that one mechanism by which reducing Fli1 levels may be protective in lupus kidney disease is to decrease LacCer levels through the regulation of Neu1 expression. We speculate that Fli1 regulates Neu1 expression in T cells that may act on gangliosides intra- (within the T cell) and inter- (on neighboring kidney cells upon infiltration in the kidney) ceullarly.

A Numeric Expansion of Invariant Natural Killer T Cells Protects Against the Progression of Fatal Autoimmunity in Lupus-Prone Mice. Yuriy Baglaenko[1], Nan-Hua Chang[1], Evelyn Pau[2], Christina Loh[1] and Joan E. Wither[1]. [1]Toronto Western Research Institute, University Health Network, Toronto, ON, [2]Toronto Western Hospital, University Health Network, Toronto, ON

Background/Purpose: Previous studies from our lab have shown that the introgression of a NZB chromosome 1 (c1) interval extending from 135 to 179 Mb onto the non-autoimmune C57BL/6 (B6) background results in increased B and T cell activation, elevated anti-nuclear antibodies (ANA), and fatal kidney disease. Similar introgression of a NZB c4 interval with mapped susceptibility loci extending from 30 to 150Mb onto the B6 background

resulted in the expansion of splenic invariant Natural Killer T (iNKT) and CD5[+] B cells in the absence of autoimmunity. To define the role of NZB c4 in autoimmunity, bicongenic (c1c4) mice were produced with both NZB c4 and c1 intervals. Despite the presence of c1 autoimmune augmenting genes, c1c4 mice had reduced renal disease, increased survival, and a shift towards less pathogenic IgG1 autoantibodies. Interestingly, bicongenic mice had retained an expansion of splenic iNKT cells. Recent studies have shown that activated iNKT cells can rapidly secrete large quantities of Th1 or Th2 cytokines, thereby altering the progression and initiation of autoimmunity. In this study we sought to define the role of iNKT cells in the suppression of spontaneous autoimmunity.

Methods: NKT cells were stimulated *in vivo* by intravenous injection with 2μg of α-GalCer. Cellular phenotypes were examined by flow cytometry of de novo splenocytes. Intracellular production of IFNγ, IL-17, and IL-4 was measured by flow cytometry following 4 to 5 hour stimulation with PMA and Ionomycin.

Results: The functional capacity of NKT cells was examined by *in vivo* stimulation with α-GalCer. Following activation, there was a significant decrease in the frequency of IFNγ and IL-4 producing splenic iNKT cells in c1 and c1c4 mice when compared to B6 and c4 controls. However, the expansion of splenic iNKT cells normalized the total number of IFNγ and IL-4 producing iNKT cells in c1c4 mice to B6 levels. In order to more conclusively define the role of iNKT cells in initiation and progression of spontaneous autoimmunity, CD1d knockout mice were bred onto the suppressed bicongenic background. Characterization of aged CD1d knockout bicongenic mice, that lack NKT cells, revealed an increase in germinal center B cells, memory/effector T cells, and IL-17 or IFNγ producing T cells when compared to bicongenic mice. The CD1d knockout had no impact on the number of IL-10 producing CD5[+]B cells.

Conclusion: These data suggest that suppressed bicongenic mice have a normalization of iNKT cell cytokine production through a numeric expansion. Furthermore, knockout of NKT cells on the suppressed background resulted in an increase in cellular activation suggesting a protective role for iNKT cells in the pathogenesis of spontaneous autoimmunity.

Exacerbation of Collagen-Induced Arthritis by an Anti-CD3 Antibody Targeting Aminoterminal-Deficient CD3ε. María J. Pérez-Lorenzo[1], Elena Gonzalo[1], José M. Rojo[2], María Galindo[1], Jose L. Pablos[1] and Gabriel Criado[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Centro de Investigaciones Biológicas-CSIC, Madrid, Spain

Background/Purpose: We have previously characterized naturally occurring forms of CD3e that lack the aminoterminal region (DNH2-CD3e) and are bound with high avidity by the YCD3-1 antibody (Criado et al., Eur J. Immunol 30, 1469). The presence of high levels of DNH2-CD3e results in weaker TCR-CD3 interactions and increased TCR mediated signalling and functional responses. To understand the potential contribution of DNH2-CD3e to arthritis development, we have evaluated disease progression and functional responses in collagen-induced arthritis after treatment with YCD3-1 antibody.

Methods: Arthritis was induced in 8–10 weeks old male and female DBA/1 mice by intradermal immunization with 200 mcg of chicken type II collagen (CII) in Complete Freund Adjuvant (CFA). Mice were treated on the day of arthritis onset with YCD3-1 or control rat IgG2$_b$ (50 mcg/mouse) and arthritis severity was evaluated daily during ten days. Effect of anti-CD3 treatment in vivo was assessed by flow cytometry to detect Treg (FoxP3[+]), Th1 (IFNg[+]) and Th17 (IL17[+]) CD4 T cells in lymph nodes. To analyze T cell responses in vitro, lymph node cells were stimulated with CII, proliferation was measured by incorporation of the colorimetric reagent WST-1 and IFNg and IL17 levels were quantified by ELISA. Serum levels of anti-CII antibodies were determined by ELISA. Statistical differences were analyzed by ANOVA and Mann-Whitney U-test using GraphPad Prism software. P values < 0.05 were considered significant.

Results: Treatment of CIA mice with YCD3-1 increased disease severity in female DBA/1 mice compared to control-treated mice. Differences appeared the first day after treatment and reached statistical significance on day five and later (Figure 1). A similar trend was observed in arthritic males, although differences did not reach statistical significance. Levels of anti-CII antibodies were not affected by YCD3-1 treatment.
Figure 1. Severity of CIA in male and female DBA/1 mice treated with YCD3-1 anti-CD3 antibody.

Analysis of CD4 T cell populations in YCD3-1 treated mice showed an enrichment in FoxP3[+] Treg cells (16.85 ± 4.7 % vs 10.25 ± 2.57% in control mice, **P= 0.003). IFNg and IL17 producing cells were also increased (IFNg: 2.77 ± 2.07 % vs 0.79 ± 0.25 %, **P= 0.003; IL17: 1.74 ± 1.01 % vs 0.64 ± 0.23 %, ***P= 0.0003). Ratio of Treg to Th17 cells was reduced (10.91 ± 3.18 % vs 17.95 ± 7.21 %, P= 0.04). No significant differences were observed in Treg/Th1 ratio. In vitro stimulation with CII caused higher proliferation and production of IFNg and IL17 in lymph node cells from anti-CD3 treated mice.

Conclusion: Targeting DNH2-CD3e in vivo reduces Treg/Th17 ratio and exacerbates collagen induced arthritis. Our results suggest that DNH2-CD3e can contribute to arthritis progression.

Synovial Tissue Analysis in the Pre-Clinical Phase of Arthritis: T-Cell Infiltration Preceding the Development of Arthritis. Maria J. H. de Hair[1], Marleen G. H. van de Sande[1], Tamara H. Ramwadhdoebe[2], Robert B. M. Landewé[3], Christiaan van der Leij[4], Mario Maas[4], D. van Schaardenburg[5], Danielle Marie Gerlag[1], Lisa G.M. van Baarsen[2] and Paul P. Tak[6]. [1]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Division of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [3]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam & Atrium Medical Center, Amsterdam, Netherlands, [4]Department of Radiology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [5]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [6]Division of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: We have previously shown in a pilot study that there is no evident synovial inflammation in autoantibody-positive individuals who are at risk of developing rheumatoid arthritis (RA), compared to healthy controls. Here, we investigated in a larger, prospective cohort whether subtle changes in the synovium are associated with the development of clinically manifest arthritis in RA-prone individuals.

Methods: Fifty-five IgM rheumatoid factor (RF) and/or anti-citrullinated protein antibody (ACPA) positive individuals, without evidence of arthritis upon physical examination who are at risk for developing RA, were included in the study. All individuals underwent MRI and arthroscopic synovial biopsy sampling of a knee joint at inclusion, and were prospectively followed for arthritis development. Biopsies were analysed by immunohistochemistry using antibodies for T cells (CD3, CD4, and CD8), B cells (CD22), fibroblast-like-synoviocytes (CD55), plasma cells (CD138), von Willebrand Factor and citrullinated fibrinogen. Proportional hazard regression analysis was performed to investigate associations of (combinations of) variables with onset of arthritis over time.

Results: After a median follow-up time of 13 (IQR 6–27, range 1–47) months, 15 individuals (27%) developed arthritis. Synovial expression of CD3+ T cells was associated with arthritis development (Hazard ratio: 2.8; 95% confidence interval: (0.9 to 9.1; p=0.088)), although not statistically significant. Combined with ACPA-positivity CD3 expression was highly associated with arthritis development (double-positive vs. single-positive or double-negative (HR (95%CI): 4.0

(1.4 to 11.4); p=0.010)). The expression of other inflammatory cell markers as well as MRI-findings were not associated with arthritis development.

Conclusion: The results presented here suggest that synovial T cell infiltration might play a role in arthritis development in autoantibody-positive individuals who are at risk of developing RA.

The Therapeutic Antibody Tregalizumab (BT-061) Induces Activation of Regulatory T Cells by Engaging a Unique CD4 Mediated Signaling That Strongly Differs From Signaling Events Induced by Standard Anti-CD4 Antibodies. Bianca Helling[1], Benjamin Daelken[1], Holger Wallmeier[2], Silke Aigner[1], Chantal Zuber[1], Martin Koenig[1], Andre Engling[1], Frank Osterroth[1], Niklas Czeloth[1] and Christoph Uherek[1]. [1]Biotest AG, Dreieich, Germany, [2]Condor Scientific Computing & Consulting, Sulzbach, Germany

Background/Purpose: The humanized CD4 specific monoclonal antibody (mAb) tregalizumab is currently being tested in phase II clinical trials in Rheumatoid Arthritis. In contrast to other anti-CD4 antibodies, tregalizumab is able to activate the suppressive properties of regulatory T cells (Tregs). Since tregalizumab was the first and only humanized anti-CD4 antibody described to be able to activate Tregs we asked for the underlying reason for this specific and unique functionality. To elucidate on the mode of action of this mAb, we focused on the signaling pathways engaged by tregalizumab.

Methods: Signaling events after cross-linking of tregalizumab, other anti-CD4 antibodies (RPA-T4, MT310, QS4120 or B-A1) or anti-CD3 (OKT-3) treatment were analyzed using intracellular staining of phosphorylated proteins (Lck, ZAP-70, LAT, SLP-76, PLC-gamma, MEK, Itk, ERK, PKC, MAPK and NF-kappaB). Furthermore, the ability of tregalizumab to induce suppressive properties in Tregs was evaluated using a mixed lymphocyte reaction system. Other CD4 antibodies were included as controls. Additionally, the binding mode of tregalizumab to soluble CD4 was resolved by co-crystallization and subsequent x-ray crystallography with a resolution of 2.9 angstrom.

Results: Upon binding of tregalizumab to the CD4 molecule on T cells and subsequent cross-linking, an intracellular signal was induced. As described for anti-CD3 or other anti-CD4 antibodies, phosphorylation of the CD4 associated kinase Lck was observed. Nonetheless, significant signaling strength differences were observed between the different antibodies. Although tregalizumab induced the lowest phosphorylation signal on Lck, further downstream molecules were also activated. Tregalizumab mediated signaling additionally led to phosphorylation of ZAP-70, LAT, SLP-76, PLC-gamma and MEK, thus engaging several components of the T cell receptor pathway. However, tregalizumab induced no phosphorylation of Itk, ERK, PKC, MAPK and NF-kappaB as observed for anti-CD3 treatment or other anti-CD4 antibodies tested. Although inducing the weakest signal of all anti-CD4 antibodies, only tregalizumab was able to induce full functional activation of Tregs via CD4.

The new mode of action of tregalizumab may be explained by the special binding epitope. While all other tested anti-CD4 antibodies bound to domain 1 of CD4, the crystal structure of tregalizumab in complex with CD4 revealed binding to domain 2.

Conclusion: In summary, we hypothesize that binding to domain 2 of CD4 may be the underlying reason for inducing weak but unique signaling in CD4 T cells that is sufficient to activate the function of Tregs without activation of T effector cells. Thus, tregalizumab represents a unique and novel mode of action for treatment of autoimmune diseases with insufficient Treg activity. A phase IIb clinical trial is currently ongoing in Rheumatoid Arthritis in european countries to further evaluate clinical use of tregalizumab (Biotest Study 979).

Transcriptional Regulation of Garp Expression. Sonja Haupt, Qihui Zhou, Johannes Thomas Kreuzer, Simon Herrmann, Hendrik Schulze-Koops and Alla Skapenko. University of Munich, Munich, Germany

Background/Purpose: Regulatory T cells (Tregs) contribute to immune tolerance and play a pivotal role in the prevention of autoimmune diseases such as rheumatoid arthritis (RA). In active RA, the suppressive function of Tregs is markedly reduced. Recently, a membrane-associated molecule, glycoprotein A repetitions predominant (GARP), has been identified to be specifically expressed on Tregs in response to activation. While the function of GARP is not completely understood, diminution of GARP expression attenuates the suppressive capacity of Tregs. Therefore, we hypothesized that diminished expression of GARP on the surface of Tregs in RA patients might be responsible for their reduced suppressive function. To provide insight, we investigated in detail the molecular mechanisms of GARP transcription and analyzed GARP expression on Tregs from RA patients.

Methods: To delineate transcriptional mechanisms of GARP expression, human GARP promoter sequences and several CNS regions were cloned into reporter vectors. Their transcriptional activity in response to different stimuli was assessed. To analyze the chromatin configuration state in primary Tregs, chromatin immunoprecipitation of GARP promoters and CNS regions in activated and non-activated Tregs was performed. In order to investigate GARP expression, CD25$^+$ and CD25$^-$ CD4 T cells were purified from peripheral blood, and GARP expression was compared between eight RA patients with early active disease (disease duration 3.0 ± 2.4 months, DAS28 5.2 ± 1.2) and an age- and gender-matched healthy cohort.

Results: Two different transcript variants under the control of different promoters (denoted as promoter 1 and 2) are encoded by the GARP gene. Whereas GARP promoter 1 activity was dependent on TCR stimulation and the presence of Forkhead box protein 3 (Foxp3), the master transcription factor of Tregs, Foxp3 and retinoic acid synergistically induced transcription from GARP promoter 2 in a concentration dependent manner. Histone modifications in both promoter regions and in an upstream located CNS changed towards a more accessible chromatin configuration upon T cell activation. When GARP expression was analyzed in primary T cells, only CD25$^+$ Foxp3-expressing CD4 T cells upregulated GARP, confirming Treg specificity of GARP expression and its Foxp3 dependency. The upregulation of GARP expression upon stimulation was however less pronounced on Tregs from RA patients as compared to healthy controls.

Conclusion: Thus, GARP expression is attenuated in RA patients. As transcriptional activity of the GARP gene is initiated by coordinate action of TCR stimulation, Foxp3 and retinoic acid on two promoters and one CNS region, alterations of these control mechanisms in RA might cause diminished GARP expression and subsequently might result in the reduced suppressive capacity of Tregs in RA.

HRES-1/RAB4-Mediated Loss of DRP1 Inhibits Mitophagy, Promotes Accumulation of Mitochondria and Serves As Target for Treatment in SLE. Tiffany Telarico[1], David Fernandez[1], Zachary A. Oaks[2], Gergely Talaber[2], Mark Haas[3], Michael P. Madaio[4] and Andras Perl[5]. [1]SUNY Upstate Medical University, Syracuse, NY, [2]SUNY, Syracuse, NY, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]Medical College of Georgia, Augusta, GA, [5]Upstate Medical University, Syracuse, NY

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) exhibit accumulation of mitochondria and activation of the mammalian target of rapamycin (mTOR). Although mTOR has been implicated in blocking of autophagy and may account for increased mitochondrial mass, paradoxically, blockade of mTOR with rapamycin failed to reduce mitochondrial mass in lupus T cells. mTOR interacts and co-localizes with the small GTPase HRES-1/Rab4 on endosomes that carry autophagocytic cargo, including mitochondria, to lysosomes. Therefore, we investigated whether HRES-1/Rab4, that is over-expressed in lupus T cells, may mediate the accumulation of mitochondria and whether its inhibition by geranylgeranyl transferase inhibitor, 2-[3-pyridinyl]-1-hydroxyethylidene-1,1-

phosphonocarboxylic acid (3-PEHPC) can influence the development of disease in lupus-prone mice.

Methods: Microarray and confirmatory western blot as well as glutathione-S-transferase pull-down assays were used to map the interactome of HRES-1/Rab4 in human peripheral blood lymphocytes. Expression of Rab4, the murine homolog of HRES-1/Rab4, and its interacting partners were assessed with respect to mitochondrial mass and mTOR activity in the thymus and spleen cell subsets of lupus-prone MRL/lpr and C57BL/6, MRL/MpJ, and Black 6/lpr control mice at ages of 4 and 8 weeks. MRL/lpr mice were treated with 125 μg/kg 3-PEHPC or 1 mg/kg rapamycin in comparison to solvent controls for 10 weeks, beginning at 4 weeks of age. Disease development was monitored by antinuclear antibody (ANA) production and proteinuria. At the time of sacrifice, nephritis was assessed by histopathology, serum cytokine levels were measured by ELISA, gene expression in splenocyte subsets was measured by western blot, and mitochondrial homeostasis was evaluated by flow cytometry. Statistical analyses were done by t-tests and ANOVA, with $p<0.05$ considered significant.

Results: HRES-1/Rab4 was found to directly interact with Drp1and its overexpression caused the depletion of Drp1 in human Jurkat cells ($p=0.01$) and mouse splenocytes ($p=0.03$). Rab4A was over-expressed in MRL/lpr thymocytes at 4 weeks ($p=0.0002$). Drp1 is reduced in MRL/lpr T cells at 4 weeks ($p=0.007$). MRL/lpr mice exhibited increased mitochondrial mass in thymocytes ($p=0.02$) at 4 weeks and in splenocytes ($p=0.01$) at 8 weeks of age. At 14 weeks of age, treatment with 3-PEHPC increased Drp1 ($p=0.03$) and reduced mitochondrial mass in MRL/lpr T cells ($p=0.02$), reduced ANA production ($p=0.021$), reduced proteinuria ($p=0.00004$), and reduced nephritis scores in MRL/lpr mice ($p<0.001$). Unlike 3-PEHPC, rapamycin reduced mTOR activity ($p<0.05$) but failed to affect mitochondrial mass. IL-10 production was reduced by 3-PEHPC ($p=0.04$), while rapamycin reduced production of IFN-γ ($p=1 \times 10^{-5}$) and IL-17A ($p=0.01$).

Conclusion: These data reveal a pathogenic role of Drp1 depletion and identify the regulation of mitophagy by HRES-1/Rab4 as a promising target for treatment in SLE.

MHC II-Independent Regulation of Intestinal Tregs. Lisa L. Korn and Terri M. Laufer. University of Pennsylvania, Philadelphia, PA

Background/Purpose: Regulatory T cells (Tregs) are critical to prevent autoimmune diseases such as inflammatory bowel disease and rheumatoid arthritis. Like all CD4+ T cells, CD4+ Tregs expressing the transcription factor Foxp3 develop in the thymus, though Tregs also are generated in the periphery from naïve CD4+ T cells. T cell receptor (TCR)-major histocompatibility complex class II (MHC II) signals are necessary for thymic Treg generation and provide antigen-specific signals in the periphery. Yet the role of MHC II signals in peripheral Treg maintenance has remained unclear, or in cases of tissue sites such as intestine, unstudied.

Methods: To dissect the role of MHC II in intestinal Treg maintenance, we examined K14/Abb (K14) mice that have MHC II restricted to cortical thymic epithelium but lack peripheral TCR-MHC II interactions.

Results: Intestinal Treg frequency was increased in mice lacking peripheral expression of MHCII. Treg proliferation was equivalent in the intestinal lamina propria of young K14 and wild type mice; however, proliferation of conventional T cells was MHC II-dependent. The initial MHC II-independent Treg accumulation was not due to increased homing directly from the thymus, as intestinal Tregs in young K14 mice were not enriched for recent thymic emigrants (RTEs). Intestinal Tregs were maintained in adult K14 mice when, in contrast to young mice, Treg and Tconv proliferation and turnover were similar to wild type. In all adult mice the intestine contained no Treg RTEs. However, depletion of microbial gut flora by antibiotics in adult K14 mice partially restored the Treg frequency to wild type levels.

Conclusion: These data suggest that the intestine specifically contains a niche for regulatory T cells that does not require MHC II signals to be filled, but may rely on MHC II-independent, intestinal flora-derived signals to be subsequently maintained. These cells may represent a tissue-specific mechanism to prevent autoimmunity.

Specificity of the New American College of Rheumatology/European League Against Rheumatism Classification Criteria for Polymyalgia Rheumatica in Comparison with the Former Ones: A Single Centre Study. Pierluigi Macchioni[1], Luigi Boiardi[2], Mariagrazia Catanoso[2], Giulia Pazzola[2] and Carlo Salvarani[3]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [3]Arcispedale S Maria Nuova. IRCCS, Reggio Emilia, Italy

Background/Purpose: To evaluate the specificity of the new ACR/EULAR classification criteria for PMR in a consecutive series of outpatients attending an early arthritis clinic (EAC).

Methods: All patients attending our outpatients EAC are followed according to a standardized protocol which include clinical examination, determination of laboratory parameters, quality of life questionnaires and ultrasound (US) examination of shoulders, hips, hands and feet. In this 3-year prospective study we included consecutive patients aged > 50 years followed for at least 12 months. Patients entered the study if they had a definite diagnosis of non-PMR inflammatory joint condition confirmed at 12 month follow-up period according to rheumatologist opinion (PM). The PMR group consisted of 136 recent onset, consecutive patients seen in our rheumatological centre during a 5 year period. C statistic were utilized to compare the new ACR/EULAR classification criteria with some of the former diagnostic/classification criteria (Hunder's, Jones's, Bird's, Healey's criteria).

Results: One hundred and twenty-eight non PMR patients entered the study (mean age 64.2+9.9y, female 70.3%, mean disease duration at first visit 12.47+9.0 w, mean ESR 35.13+25.3 mm/1sth, mean CRP 2.04+2.48 mg/dl). After one year of follow up their diagnosis was: rheumatoid arthritis (RA) 96 pts, spondyloarthropaty 32 pts.

Table 1 shows the specificity and area under the curve (AUC) of the receiver operating characteristic curves when conditions were met in the total group and in the RA patients group(*).

Specificity and AUC in the total group and in the rheumatoid arthritis patients group(*)

PMR diagnostic/ classification criteria	Specificity (128 total cases)	AUC (SE)	Specificity* (96 RA patients)	AUC* (SE)
ACR/EULAR	81.5	0.872 (.029)	79.7	0.863 (.031)
US-ACR/EULAR	91.4	0.917 (.023)	89.9	0.910 (.025)
HEALEY	80.2	0.799 (.033)	78.3	0.773 (.035)
HUNDER	79.0	0.777 (.034)	78.3	0.789 (.036)
BIRD	72.8	0.742 (.036)	72.5	0.740 (.038)
JONES	96.7	0.810 (.030)	98.6	0.816 (.030)

Conclusion: In a series of outpatients attending our EAC the new ACR/EULAR PMR classification criteria have a better specificity as compared to the previous criteria (except for Jones's one). US shoulders and hips examination increases the specificity of the new ACR/EULAR criteria.

Plasma Fibrinogen Better Identifies Persistent Disease Activity in Polymyalgia Rheumatica Than Either ESR or CRP. EM McCarthy[1], Paul A. MacMullan[1], S. Al-Mudhaffer[1], Anne M. Madigan[1], S. Donnelly[1], C. J. McCarthy[1], Dermot Kenny[2], Eamonn S. Molloy[3] and G M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland, [3]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: In PMR careful tailoring of the glucocorticoid dosage to the patients needs is crucial to avoid the risk of treatment-related adverse effects and the disability associated with uncontrolled inflammation. The ESR and CRP are standard assays used to guide assessment of disease activity. Studies have demonstrated a discordance between ESR and CRP of 28% making assessment of disease activity a diagnostic challenge. Any biomarker that accurately reflects disease activity in PMR, thereby facilitating appropriate adjustment of glucocorticoid dose would be welcomed. Previously we have demonstrated that plasma fibrinogen is more specific for the confirmation of response to treatment than either ESR or CRP. Here we prospectively compare the ability of the biomarkers ESR, CRP and fibrinogen to distinguish between disease remission and disease activity in PMR.

Methods: 25 patients with newly diagnosed PMR and 35 patients with a known diagnosis were assessed at baseline and 6 weeks. Patients were divided into disease remission(Group 1) or persistent disease activity(Group 2),based on the Polymyalgia Rheumatica Activity Score (PMR-AS). A PMR-AS < 1.5 indicates disease remission with a PMR-AS >1.5 reflecting persistent disease activity. Plasma fibrinogen, CRP and ESR were assayed. An ESR value of 20mm/hr and CRP of 6mg/L(lab normal <5mg/l) were considered the upper limit for detection for remission. The upper limit of the lab normal for Fibrinogen(4g/L) was used. Sensitivity, specificity, positive predictive values and likelihood ratios was calculated for all biomarkers.

Results: Data was available from 120 patient visits. Mean age was 71.8 years.Demographic data was similar between groups. A significant difference was observed in steroid dose between groups(10mg v 3.5mg p<.001).

All biomarkers were significantly higher in those with persistent disease activity(Group 2) compared to those in remission(Group 1)(p<.0001).

Overall 24 patients were defined as being in remission as per the PMR-AS. Of these 23/24 had a normal plasma fibrinogen with 18/24 having a normal ESR and 16/24 a CRP < 6mg/L. The specificity, sensitivity, positive predictive values and likelihood ratios for the different biomarkers are shown in the table below.

	Specificity	Sensitivity	PPV	Likelihood Ratio	Fischers Exact Test
Fibrinogen	96%	34%	.97	8.2	P=.002
CRP	67%	68%	.88	2.04	P=.004
ESR	75%	43%	.87	1.7	P=.16

Plasma fibrinogen was more specific than ESR and CRP for differentiating between disease remission and disease activity. It also demonstrated a superior positive predictive value and likelihood ratio than ESR and CRP for identifying patients with persistent disease. The ESR showed no significant ability to distinguish between disease remission and activity (p=.16).

Conclusion: Elevated plasma fibrinogen more accurately indicates that patients have persistent disease activity than either the ESR or CRP. Measurement of fibrinogen may therefore help treating physicians more accurately identify patients' disease status and guide decisions with regards to glucocorticoid dosage.

Corticosterois Therapy Restored Treg/Th17 Balance in Patients with Polimyalgia Rheumatica. Lorena Alvarez-Rodriguez[1], Marcos Lopez-Hoyos[1], Jaime Calvo-Alen[2], Elena Aurrecoechea[3], Teresa Ruiz Jimeno[3], Ignacio Villa[3], Carmen Gonzalez-Vela[1] and Victor M. Martinez-Taboada[1]. [1]Hospital Universitario Marques de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Universitario Sierrallana, Torrelavega, Spain, [3]Hospital de Sierrallana, Torrelavega, Spain

Background/Purpose: To characterize the levels of circulating T regulatory cells (Tregs) and Th17 cells in polymyalgia rheumatica (PMR).

Methods: The study included 46 patients with active untreated PMR and 12 age-matched healthy controls (HC). Thirty one PMR patients were also studied after disease control with corticosteroid (CS) therapy. As disease controls, 9 patients with giant cell arteritis (GCA) and 14 with elderly onset rheumatoid arthritis (EORA) were also included. Analysis of circulating regulatory T cells and TH17 cells were performed by flow cytometry. The suppressive capacity of peripheral Tregs was assessed by CFSE at a 1:1/Teffector ratio after polyclonal activation with anti-CD3 and anti-CD28.

Results: The frequency of $CD4^+CD25^{hi}FoxP3^+CD127^{-/low}CD27^+$ in the peripheral blood of active PMR was not significantly different from HC. However, patients with EORA showed marginally significant lower levels than HC ($p=0.048$) and GCA ($p=0.048$) patients. Therapy with CS showed no significant effect on the frequency of Tregs during the course of disease. The frequency of $CD4^+IL17^+IFN^+$ and $CD8^+CD28^-CD27^+$ cells was similar in all the study groups. The frequency of Th17 cells ($CD4^+IL17^+IFN^-$ and $CD4^+IL17^+CCR6^+$) was significantly higher in the peripheral blood of patients with PMR compared to HC ($p=0.037$) and

decreased after disease control with CS therapy ($p=0.031$). No significant differences between PMR and the other disease controls were found. Consequently, the ratio Tregs/Th17 was significantly decreased in patients with active PMR ($p=0.024$) and restored to normal after disease control. Moreover, the suppressive capacity of Tregs was slightly increase in PMR patients compared to HC ($p=0.047$).

Conclusion: Active PMR is associated with increased frequency of Th17 cells that is corrected after CS therapy. The frequency of Tregs does not change in PMR. Thus, the onset of PMR seems to be associated with increased inflammatory cells with not counterbalance by regulatory cells.

Similarities Exceeds Differences in the Pattern of Joint and Vascular Positron Emission/Computed Tomography Uptake in Polymyalgia Rheumatica and Giant Cell Arteritis.

Dario Camellino[1], Silvia Morbelli[2], Francesco Paparo[3], Michela Massollo[2], Gianmario Sambuceti[2] and Marco A. Cimmino[1]. [1]Clinica Reumatologica, Genova, Italy, [2]Medicina Nucleare, Genova, Italy, [3]E.O. Ospedali Galliera, Genoa, Italy

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are two frequent overlapping diseases. The purpose of this work is to examine the relationship between these conditions by analysis of CT/PET findings.

Methods: Eighty consecutive patients (64 PMR diagnosed according to Bird's criteria, 16 GCA diagnosed according to the ACR criteria, of whom 10 also had PMR) underwent simultaneous FDG-PET and CT imaging from the skull base to the knee using an integrated PET/CT scanner (Hirez; Siemens Medical Solutions, Knoxville TN, USA), after recording demographic, clinical and laboratory data. Arterial and joint uptake were scored relative to liver uptake as 0=no uptake present, 1=lower than liver uptake, 2=similar to liver uptake, 3=higher than liver uptake. All the values were further subdivided into "positive" (scores 2 and 3) and "negative" (scores 0 and 1). Fifty-five patients were women, median age was 74 years (range 50–90 years), median disease duration was 3 months (range 0.5–11 months), median morning stiffness was 52 minutes (range 0–420 minutes), median C-reactive protein (CRP) was 36 mg/L (range 2–106 mg/L). Eighty age-matched controls were enrolled, who underwent PET/CT for suspected neoplastic disease, but without autoimmune conditions or previous chemiotherapy, radiotheraphy, and glucocorticoid treatment.

Results: Shoulders showed more frequently increased uptake (65 patients or 81.3%, bilateral in 57) (table 1), followed by the trochanteric bursae (60 patients or 75%, bilateral in 50). Among the studied arteries, an increased uptake was seen at the aortic arch and in the ascending aorta in 35 patients (43.8%). Patients had more frequently increased uptake than controls in all arterial and joint sites, except the coxofemoral joints. Among patients groups, a significant difference in uptake frequency was seen in trochanteric bursae (PMR>GCA, p=0.05), in carotid arteries (GCA>PMR, p=0.001), and in abdominal aorta (PMR+GCA>PMR, p=0.04)

Table 1. Distribution of uptake sites in patients groups and controls

	PMR n (%)	PMR+GCA n (%)	GCA n (%)	Controls n (%)	p (PMR vs. PMR+GCA vs. GCA)	p (patients vs. controls)
Patients	64	10	6	80		
Shoulders	55 (86)	8 (80)	2 (33)	14 (17)	0.07	<0.0001

Femoral arteries	20 (31)	3 (30)	3 (50)	0	0.6	<0.0001

*=PMR>GCA; **=GCA>PMR; ***=PMR+GCA>PMR.

Conclusion: With the limitation of the small number of GCA patients included and of the absence of histological data on the temporal arteries of PMR patients, our study suggests that in PMR and GCA similarities exceed differences. These conditions could be different forms of the same disease. PET/CT, a minimally invasive technique, is an effective and objective method to evaluate inflammation in PMR/GCA, optimally discriminating patients with PMR/GCA complex from controls.

Correlation Between Hypoechoic Halo of the Temporal Arteries and Clinical, Laboratory, and Temporal Artery Biopsy Findings in Patients with Giant Cell Arteritis.

Luigi Boiardi[1], Giulia Pazzola[1], Alberto Cavazza[1], Francesco Muratore[1], Giovanna Restuccia[1], Alberto Nicolini[1], Giuseppe Germanò[2], Nicolo Pipitone[1], Pierluigi Macchioni[1], Niccolò Possemato[1], Gianluigi Bajocchi[3], Ilaria Padovano[1], Olga Addimanda[1], Alberto Lo Gullo[1], Maria Grazia Catanoso[1] and Carlo Salvarani[3]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [3]Arcispedale S Maria Nuova. IRCCS, Reggio Emilia, Italy

Background/Purpose: The presence of a hypoechoic halo of the temporal arteries on Color-Doppler sonography (CDS) has high specificity and acceptable sensitivity for the diagnosis of giant cell arteritis (GCA). However, it is unclear whether patients with a positive halo sign differ from those without such a sign. The aim of our study was to evaluate the correlations between the presence of a hypoechoic halo, on the one hand, and clinical, laboratory, and histological parameters, on the other, in patients with biopsy-proven GCA.

Methods: We analyzed the clinical records of 105 consecutive patients with biopsy-proven GCA (including those with transmural cell infiltration, small-vessel vasculitis and vasa vasorum vasculitis of the temporal arteries) who underwent CDS of the temporal arteries before temporal artery. Mean age was 74 ± 8 years, while females were 72.4%. A hypoechoic halo larger than 0.4 mm around the temporal artery lumen on CDS was considered positive. Correlations were sought by chi-square test or Fisher's exact test as appropriate using SPSS version 18.0.

Results: The presence of a hypoechoic halo significantly correlated with jaw claudication (58.8% vs 25.9%; p=0.001, odds ratio [OR] 4.1, 95% confidence interval [CI] 1.8–9.3), abnormalities of temporal artery on clinical examination (67.3% vs 46,9; p=0.041, OR 2.3 [CI 1.0–5.3]), elevated erythrocyte sedimentation rate [91.5% vs 59.2%; p=0.001, OR 7.4 [CI 2.3–23.94], and the presence of giant cells on temporal artery biopsy [66.7% vs 29.4%; p=0.0001, OR 4.8 [CI 2.0–11.4]. In addition, patients with a hypoechoic halo had higher levels of blood platelets (396875 +116274 vs 327954 + 103181; p= 0.005, unpaired two-tailed t-test). However, no correlation was found between the presence of a ultrasonographic halo and visual loss.

Conclusion: These provide evidence for a close correlation between the presence of a hypoechoic halo on CDS of the temporal arteries and jaw claudication, giant cells on temporal artery biopsies, and elevated levels of erythrocyte sedimentation rate in patients with GCA. In contrast, a positive halo sign did not predict visual loss.

Temporal Artery Biopsy Culture in Tridimensional Matrix. *in Vitro* **Model for Functional Studies in Giant-Cell Arteritis.** Marc Corbera Bellalta[1], Ester Planas Rigol[1], Ester Lozano[1], Marco A. Alba[2], Itziar Tavera-Bahillo[1], Sergio Prieto-González[1], Georgina Espígol Frigolé[1], Montserrat Butjosa[1], José Hernández-Rodríguez[1], Ana García-Martínez[2] and Maria C. Cid[2]. [1]Hospital Clinic University Barcelona, Barcelona, Spain, [2]Vasculitis Research Unit. Hospital Clínic. University of Barcelona. IDI-BAPS, Barcelona, Spain

Background/Purpose: GCA is the most frequent systemic vasculitis in Europe and North America. In spite of the initial response to glucocorticoid treatment more than 60% of patients relapse when glucocorticoids are tapered indicating the need for more effective therapies. Search for therapeutic targets in GCA is hampered by the lack of an animal model to assess the consequences of therapeutic intervention. Subcutaneous engraftment of temporal artery fragments into the SCID mice is the only existing functional system (Brack et al, J Clin Invest 1997) to assess the effects of intervention. However it is costly, complex and only a limited number of conditions can be evaluated. We previously described a temporal artery culture model (Arthritis Rheum 2008 (suppl) 58:9; S929-S929), and the effects of the some cytokine blockade on cultured GCA arteries. Our purpose is to explore changes induced by corticosteroids on the expression of inflammatory mediators between control arteries, treatment naïve GCA arteries and GCA arteries treated with dexamethasone

Methods: Fresh temporal artery sections surgically removed for diagnoses purposes from 20 GCA patients and 18 controls were embedded in the reconstituted basement membrane Matrigel™ and cultured for 10 days as described (Arthritis Rheum 2008 (suppl) 58:9; S929-S929). Cultured sections were treated with medium alone or with medium supplemented with 0.5mg/ml of dexamethasone. IFNg, TNFα, IL-1β, IL-6, CD3, CD20 and CD68 mRNA were measured in recovered sections by quantitative real-time PCR (Applied Biosystems). Proinflammatory cytokine secretion was also measured in the supernatant fluid by immunoassay (R&D Systems)

Results: As expected, cultured inflamed arteries produced remarkable amounts of proinflammatory cytokine mRNAs (IFNg, TNFα, IL-1β, and IL-6) compared with control biopsies. Moreover, mRNA expression of CD3, CD20 and CD68 cell markers was significantly increased in biopsies from patients compared with controls. Glucocorticoid treatment of the GCA biopsies for 10 days markedly reduced mRNA expression of all cytokines and cell markers. At the protein level we found a significant decrease in IL-1β, TNFα and IL-6 which was less marked for IFNg. Our model reproduces previous results obtained in other functional systems or in cross-sectional or serial comparison of biopsies obtained from patient naïve versus treated patiens (Visvanathan S, Rheumatology 2011)

Conclusion: Our temporal artery culture system in tridimenional matrix is viable and is a suitable model to evaluate functional changes in biomarker expression and secretion after intervention. This model has several advantages compared with the SCID mice engraftment: it is simpler and cheaper, it allows continuous assessment of viability, the analysis of more conditions per specimen and the assessment of proteins in the supernatant fluid. Unfortunately, as in the SCID mice, disease outcomes cannot be assessed in our model.

TLR2 Activation by Acute Serum Amyloid A Induces Pro-Inflammatory Mechanisms in a Novel Ex Vivo Temporal Artery Explant Culture/ Model of Giant Cell Arteritis. Peadar Rooney[1], Danielle Molloy[1], Jennifer McCormick[1], Mary Connolly[1], Sinead M. Miggin[2], Ashwini Maratha[2], Douglas J. Veale[3], Conor Murphy[4], Eamonn S. Molloy[3] and Ursula Fearon[5]. [1]Dublin Academic Medical Centre, Dublin, Ireland, [2]Immune Signalling Laboratory, Maynooth, Ireland, [3]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland, [4]Royal Victoria Eye and Ear Hospital, Dublin, Ireland, [5]Translation Research Group, Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Giant cell arteritis (GCA) is the most common form of primary vasculitis. The pathogenesis of this disease is characterised by disregulated angiogenesis and inflammatory infiltration, however the causative mechanisms involved in regulating these processes have yet to be elucidated. This study examines the role of acute serum amyloid A (A-SAA), TLR2 activation and the downstream Notch signalling pathway in mediating the pro-inflammatory response in GCA.

Methods: A-SAA expression in Temporal artery (TA) sections from GCA patients was assessed by immunohistology. *Ex vivo* TA explant cultures were established from GCA patients, and the effect of pro-inflammatory stimuli A-SAA (10μg/ml) and a TLR2 agonist Pam3CYSK4 (1μg/ml) on Ang2, MMP2, MMP9, IL-6 and IL-8 was quantified by ELISA and gelatin zymography. Spontaneous release of A-SAA from *ex vivo* TA explant cultures was quantified by ELISA. Furthermore, myofibroblast outgrowth from TA explants was assessed using matrigel assays over a time course of 1–15 days. A-SAA induced TA explant and microvascular endothelial cell function in the presence of Notch-1 inhibition (γ-secretase inhibitor (DAPT)) or anti-TLR2 was assessed by gelatine zymography, angiogenic assays and ELISA. The effect of conditioned media from TA explants on Human embryonic kidney (HEK) -TLR2 cells was quantified by NFkb luciferase reporter assays.

Results: A-SAA expression was demonstrated in the advential and intimal regions, particularly localised to endothelial cells. High A-SAA levels (386 +/− 191 pg/ml) were spontaneously released from TA explants cultures. *Ex-vivo* TA explant cultures spontaneously released pro-inflammatory mediators, maintained cell viability and histological morphology, reflecting the *in vivo* microenvironment. A-SAA and Pam3CSK4 induced expression of instability growth factor Ang2 (p<0.05), IL-8 (p<0.05), IL-6 (p<0.05) and MMP2 and MMP 9. A-SAA and Pam3CSK4 induced myofibroblast outgrowths from TA explants embedded in matrigel over a time course of 1–15 days. In parallel, Ang2, MMP2/9 and pro-inflammatory chemokine IL-8 were induced in myofibroblast outgrowth cultures in response to A-SAA, and to a lesser extent Pam3CSK4. A-SAA induced Ang2, IL-8, IL-6 were significantly decreased in the presence of Notch inhibitor DAPT. Furthermore anti-TLR2 inhibited the effects of A-SAA on endothelial cell function. Finally conditioned media from TA explants significantly induced TLR2 activation through induction of NFκb activation, suggesting the presence of a TLR2 ligand in the inflamed microenvironment.

Conclusion: A-SAA-induced pro-inflammatory events in GAC are mediated through Notch signaling and the TLR2 activation. A better understanding of A-SAA/TLR2-mediated inflammatory pathways may lead to novel treatment strategies for RA.

The Prevalence of Low Bone Mineral Density in Patients with New Onset Giant Cell Arteritis. Do They Get Appropriate Bone Protective Treatment? Andreas P. Diamantopoulos and Glenn Haugeberg. Hospital of Southern Norway HF, Kristiansand, Norway

Background/Purpose: Giant cell arteritis (GCA) is a common form of vasculitis mainly affecting individuals older than 50 years with a mean onset age of 69 years. The prevalence of osteoporosis in postmenopausal women is high and increases with age. The recommended standard treatment for GCA is high doses of glucocorticosteroids which over weeks are reduced to lower maintenance doses. The aim of this study was to examine the prevalence of reduced bone mineral density (BMD) in patients with a new onset GCA and to examine if these patients were treated adequately according to the American College of Rheumatology (ACR) 2010 recommendations for the prevention and treatment of glucocorticoid-induced osteoporosis.

Methods: Patients diagnosed at our outpatient clinic with GCA from January 2010 to May 2012 were retrospectively assessed. The majority of patients were examined by dual energy X-ray absorptiometry (DXA) in spine and hips. The WHO definition was applied to define osteoporosis (T-score ≤−2.5 SD at femoral neck and/or lumbar spine L1–4) and osteopenia (T-score <-1 and >-2.5 SD). Treatment data were also recorded.

Results: A total of 36 patients were diagnosed with GCA (27 females, 9 males). Two patients were excluded due to known osteoporosis. From the 34 remaining patients (25 females and 9 males) DXA measurement was performed in 27 (23 females and 4 males) patients at the time of the

initial evaluation. A total of 21 patients (78%) had reduced BMD (osteoporosis in 13 females and osteopenia in 3 males and 5 females). Treatment with bisphosphonates was initiated in 14 out the 21 patients (67%) with reduced BMD (11 patients with osteoporosis and 3 patients with osteopenia) who according to the ACR guidelines were recommended treatment. All patients with osteoporosis and osteopenia received calcium and vitamin D supplementation.

Conclusion: More than 75% of the DXA examined patients had reduced BMD and thus were in need for osteoporosis treatment with bisphosphonates according to the ACR 2010 recommendations for glucocorticoid-induced osteoporosis. Despite the clear guidelines 1 out of 3 GCA patients were in our patient cohort not treated properly. Our data emphasizes the need for increased awareness of osteoporosis and osteopenia in these patients which are at high risk for future fractures.

Increase in Duration and Cumulative Dose of Glucocorticoid Therapy in Recent Decades: Observations From a Population-Based Cohort of Patients with Giant Cell Arteritis. P. Deepak Udayakumar, Tanaz A. Kermani, Kenneth J. Warrington, Cynthia S. Crowson and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Systemic glucocorticoid (GC) therapy is the first line treatment for giant cell arteritis (GCA). Patients with GCA are often counseled that therapy will be needed for 1 to 2 years, but in recent years it has been recognized that GCA is a chronic disease requiring long-term therapy and monitoring. We sought to evaluate the duration and cumulative dose of GC therapy in a population based cohort of patients with GCA diagnosed 1980–2004 compared with 1950–1979.

Methods: We retrospectively reviewed a population-based incidence cohort of GCA patients diagnosed between 1950 and 2004. All subjects were longitudinally followed through all available community medical records until death, migration or December 31, 2009. Data was collected regarding dosing and duration of GC use. Kaplan-Meier methods were used to estimate the time to discontinuation of GC and log rank tests were used for comparisons between time periods.

Results: The study population included 204 patients. Mean age was 76 years and 163 (80%) were female. Median follow-up was 8.8 years with 1,996 total person-years. Mean erythrocyte sedimentation rate at diagnosis was 79.2 mm/hr. Temporal artery biopsy was positive in 176 (86%) patients.

The mean starting dose of prednisone was 53.2mg/day in 1980–2004 and 54.8 mg/day in 1950–1979 (p=0.79). Prednisone dose of <10 mg/day for 6 months was reached in 34%, 81% and 98% patients by 1, 2 and 5 years from GCA incidence date respectively in patients diagnosed between 1980–2004 compared to 52%, 88% and 100% respectively among patients in the 1950–1979 cohort (p=0.003). In the 1980–2004 cohort, only 14% permanently discontinued GC use by 1 year from GCA incidence date, 41% by 2 years and 75% by 5 years compared to 40%, 64% and 76% respectively in the 1950–1979 cohort (p=0.032).

The median time to reach a prednisone dose of <10mg/day was about 6.5 months in 1980–2004 versus 3.2 months in 1950–1979 (p <0.001). The mean cumulative dose of prednisone by 1 year after incidence of GCA was 6.1 gm in 1980–2004 versus 4.1 gm in 1950–1979 (p < 0.001). Mean cumulative dose by 5 years was 10.3 gm in 1980–2004 versus 7.8 gm in 1950–1979 (p=0.007).

Conclusion: Patients diagnosed with GCA in recent decades were on GC for a longer duration and received higher cumulative doses. As well, a significantly higher proportion of patients remain on GC therapy even beyond 5 years following diagnosis. The reasons for the secular trend in longer duration and higher doses of GC for treating GCA are unclear, but may relate to recognition that GCA a more chronic disease with late sequelae such as large vessel disease than previously recognized, increasing the concern for GC associated adverse effects in these patients.

Visual Manifestations in Giant Cell Arteritis: Trend Over Five Decades. Abha G. Singh[1], Cynthia S. Crowson[1], Tanaz A. Kermani[2], Cornelia M. Weyand[3], Eric L. Matteson[1] and Kenneth J. Warrington[1]. [1]Mayo Clinic, Rochester, MN, [2]University of California Los Angeles, Los Angeles, [3]Stanford University School of Medicine, Stanford, CA

Background/Purpose: Cranial ischemic complications, particularly permanent visual loss, are catastrophic complications of giant cell arteritis (GCA). Corticosteroids have been used to decrease the risk of vision loss but it is unclear if the rate of visual complications has changed in recent decades. We examined trends in visual manifestations in GCA over the last 5 decades.

Methods: We reviewed the medical records of a population-based cohort of patients with GCA meeting ACR classification criteria, diagnosed between 1950 and 2004. We characterized the clinical, ophthalmological and laboratory features of patients with visual manifestations and compared them with patients who did not develop visual complications. Trends of visual manifestations in GCA over time were examined using logistic regression model adjusted for age and sex.

Results: 204 cases of GCA were identified (mean age 76.0 ± 8.2 years, 80% female) of which 47 had visual manifestations attributable to GCA at presentation. Blurred vision (15%) and diplopia (5%) were the most common visual symptoms. Ischemic optic neuropathy (ION) was the predominant ophthalmologic diagnosis (17/204, 8%). Nine patients (4.4%) suffered complete loss of vision. As compared to patients with GCA without visual manifestations at presentation, patients with visual manifestations were more likely to have associated jaw claudication (59/157 v.s 26/47, p =0.04), but were similar with regard to other clinical (age, smoking status, headache, scalp tenderness, constitutional symptoms, frequency of polymyalgia rheumatica) and laboratory features.

Recovery from visual symptoms was less likely in patients with complete vision loss as compared to those with blurred vision alone [Hazard ratio, 95% Confidence Interval (HR, 95% CI): 0.20 (0.06–0.63), p<0.01], and in patients with ION or central retinal artery occlusion as compared to other diagnoses [HR (95% CI): 0.22(0.10–0.49), p<0.001].

Over a period of 55 years, there has been a significant decline in the incidence of visual symptoms (figure) and ION [1950–1979 vs 1980–2004: 9/61 (15%) vs 8/143 (6%), p=0.03] with time. Additionally, patients diagnosed more recently were more likely to have recovery from visual symptoms than patients diagnosed in earlier years [HR (95% CI): 1.34 (1.06–1.71) per 10 year increase in calendar year, p=0.016].
Figure. Incidence of visual manifestations (adjusted for age and sex) among 204 patients with giant cell arteritis declined over time (p=0.02). Point estimate and 95% confidence interval for each 5 year time period are displayed.

Conclusion: In this population-based cohort study of patients with GCA we found that the incidence of visual symptoms and ION has declined over the past 5 decades, and chances of recovery from visual symptoms have improved. Reasons for this improvement are unclear but may relate to increased disease awareness, earlier diagnosis and timely initiation of treatment.

Relapses in Patients with Giant-Cell Arteritis: Prevalence, Characteristics and Associated Clinical Findings in a Prospectively Followed Cohort of 106 Patients. Marco A. Alba[1], Ana García-Martínez[1], Itziar Tavera-Bahillo[1], Sergio Prieto-González[1], Montserrat Butjosa[2], Georgina Espígol[3], Marc Corbera[3], Ester Planas[3], Jose Hernandez-Rodriguez[4] and Maria C. Cid[1]. [1]Vasculitis Research Unit. Hospital Clínic. University of Barcelona. IDI-BAPS, Barcelona, Spain, [2]Hospital Clinic University Barcelona, Barcelona, Spain, [3]Vasculitis research unit. Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain, [4]Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain

Background/Purpose: In spite of the satisfactory initial response to glucocorticoid treatment, patients with giant cell arteritis (GCA) frequently experience relapses during follow-up. The objectives of this study were 1) To investigate the prevalence and characteristics of relapses in a prospectively followed cohort of patients with GCA. 2) To determine whether clinical or analytical findings at presentation may predict relapses and 3) To analyze whether a relapsing course is associated with higher cumulated GC doses and more prolonged treatment periods.

Methods: Between 1995 and 2007, 187 patients were diagnosed with biopsy-proven GCA at our institution. Among them, 106 patients fulfilled the following inclusion criteria: prospective treatment by the authors according to uniform criteria and prospective follow-up for at least 4 years. GCA features and blood tests at diagnosis (acute phase reactants, blood cell counts and liver function tests), ischemic complications, relapses, and prednisone doses for at least 4 years. Relapses were defined as reappearance of disease related symptoms accompanied by elevation of acute-phase reactants that required treatment adjustment. Type of relapse was defined as PMR, cranial symptoms, severe cranial ischemic complications or systemic disease (anemia, fever and/or weight loss). Chi-square test, student T test and Kaplan-Meyer survival analysis/log-rank test were used for statistical comparison.

Results: During the follow-up period (mean 7.6 ± 3.3 years), 66 (62%) patients experienced at least 1 relapse and 38 (36%) 2 or more. Relapses consisted of PMR in 33 (50%), cranial symptoms in 19 (29%), systemic complaints in 13 (19.5%) and cranial ischemic complications in 1 (1.5%). Mean time (in weeks) to first relapse was 72 ± 71 (11–339). There were no differences in clinical findings or blood test results at presentation between patients who relapsed and those who achieved sustained remission. However, 23 (60.5%) of patients with ≥ 2 relapses had a strong systemic inflammatory response at presentation (defined as at least 3 of the following fever >38°C, weight loss >5 kg, hemoglobin < 11 gr/L or ESR >85 mm/hour) which was present in only 5 (18%) of the remaining patients (p=0.001). Patients with ≥ 2 relapses presented significantly higher levels of ESR and C-reactive protein at 6 months and lower concentrations of hemoglobin at baseline, at 6 months (all p<0.01) and at 24 months (p=0.045). Patients with relapses required longer periods of time to reach a stable maintenance dose of prednisone <10mg/day (67±58 weeks vs 31±21, p<0.001), <5mg/day (159±106 vs 89±42, p<0.001) and to completely discontinue GC treatment (237±124 vs 157±59 p=0.005). In addition, cumulative prednisone dose at one year was significantly different between both groups (6.2±1.7 gr vs 5.4±0.7, p=0.01).

Conclusion: More than 60% of patients with GCA experience at least one relapse and 36% have multiple relapses. Relapses usually consist of PMR. Those with multiple relapses have stronger systemic inflammatory response at presentation. A relapsing course is associated with higher and prolonged GC requirements underlining the need for more effective treatments for GCA.

Large Vessel Giant Cell Arteritis: A Cohort Study. Francesco Muratore[1], Tanaz A. Kermani[2], Cynthia S. Crowson[3], Abigail B. Green[3], Eric L. Matteson[3] and Kenneth J. Warrington[3]. [1]Arcispedale S Maria Nuova, Reggio Emilia, Italy, [2]University of California Los Angeles, Los Angeles, [3]Mayo Clinic, Rochester, MN

Background/Purpose: A subset of patients with giant cell arteritis (GCA) has large vessel (LV) involvement. We sought to identify baseline variables that distinguish patients with GCA with subclavian artery involvement (LV-GCA) from those with cranial disease (C-GCA), and to compare treatment, long term follow-up and prognosis of these two subtypes of GCA.

Methods: All patients over age 50 years with radiographic evidence of subclavian LV-GCA diagnosed between January 1, 1999 and December 31, 2008 were identified in this retrospective study. These were compared to a cohort of patients with biopsy-positive C-GCA diagnosed in the same period.

Results: The study included 120 patients with radiographic evidence of LV-GCA and 212 patients with C-GCA. LV-GCA was noted at GCA diagnosis in 90 patients, and after GCA in 30 patients (mean time 2.6 years from diagnosis of GCA). Temporal artery biopsy (TAB) was performed in 79 patients with LV-GCA, and was positive in 41 (52%). In addition to subclavian vasculitis, 56% of LV-GCA cases had radiographic evidence of thoracic aortic involvement (thickening or aneurysm/ectasia).

Compared to patients with C-GCA, patients with LV-GCA were younger (mean age 68.2 + 7.5 years vs 75.7 + 7.4, p <0.001), more likely to have a prior history of PMR (26% vs 15%, p = 0.01) and had longer duration of symptoms at GCA diagnosis (median 3.5 months vs 2.2 months p <0.001). Cranial symptoms (41% vs 83%, p <0.001) and vision loss (4% vs 11%, p = 0.04) were less frequent in LV-GCA compared with C-GCA. Upper extremity claudication (52% vs 0%, p <0.001), Raynaud's phenomenon (11% vs 0%, p <0.001), vascular bruits (38% vs 9%, p <0.001) and abnormal pulse exam (60% vs 14%, p <0.001) were more frequent in LV-GCA compared to C-GCA. There were no differences in cardiovascular risk factors, sex distribution and ESR/CRP between the 2 cohorts. ACR classification criteria for GCA were satisfied in 39.2% of LV-GCA and in 95.3% of C-GCA patients (p <0.001). Patients in the C-GCA cohort met a median of 4.0 ACR criteria for GCA, while the LV-GCA patients met only a median of 2.0 criteria (p <0.001).

103 patients with LV-GCA and 167 patients with C-GCA had a follow-up period longer than 6 months (median follow up 3.6 and 4.6 years respectively). Relapse rate was significantly higher (48.6 vs 29.8/100 person-yrs, p <0.001) and time to first relapse was shorter (median 0.8 vs 1.2 yrs, p = 0.005) for LV-GCA compared with C-GCA. The cumulative corticosteroid (CS) dose at 1 year was higher (11.4 + 5.9 grms vs 9.1 + 3.7, p <0.001) and the time to discontinuation of CS therapy was longer (median 4.5 vs 2.2 yrs, p <0.001) in LV-GCA. At 5 years of follow-up, the rate of incident aortic aneurysm was higher in LV-GCA (1.5% vs 0.3%, p = 0.005) compared with C-GCA. Rate of incident stroke was similar in the 2 GCA cohorts.

Conclusion: In this large study, patients with LV-GCA presented less often with cranial symptoms and more often with findings of large-vessel insufficiency. Although patients with LV-GCA had a lower rate of vision loss, they had a higher relapse rate, greater CS requirements and an increased incidence of aortic aneurysm compared with C-GCA. The ACR criteria for GCA are inadequate for the classification of patients with LV-GCA.

2359

Outcome of Aortic Involvement in GIANT CELL Arteritis (GCA) After 1-Year Follow-up: Prospective Study in 35 Patients Using Computed Tompography Angiography (CTA). Sergio Prieto-González, Pedro Arguis, Ana García-Martínez, Itziar Tavera-Bahillo, Marc Corbera-Bellalta, Marco A. Alba, Georgina Espígol-Frigolé, Ester Planas-Rigol, José Hernández-Rodríguez and Maria C. Cid. Vasculitis Research Unit. Hospital Clínic. University of Barcelona. IDIBAPS, Barcelona, Spain

Background/Purpose: 65% of patients with newly diagnosed, biopsy-proven GCA showed radiologic finding of aortitis using CTA in a prospective study of 40 patients.

By segments, the involvement was as follows: ascending aorta 30%, aortic arch 57,5%, descending thoracic aorta 57,5%, and abdominal aorta 47,5%. Moreover, 15% of patients already had aortic dilation at the time of diagnosis.

The objective of our study was to prospectively evaluate the outcome of aortic involvement by comparing CTA findings at the time of diagnosis and those obtained after 1 year of treatment in the same patient cohort.

Methods: All the patients included in the first study were prospectively treated and followed by the investigators according to a defined protocol, and a new CTA were performed after 1 year of treatment. Vessel wall thickness

and vessel diameter at the aforementioned four aortic segments were evaluated. Aortitis was defined as circumferential aortic wall thickness ≥2 mm with or without contrast enhancement of the vessel wall observed in zones without adjacent atheroma.

Results: Five out of the 40 patients were lost to follow-up or declined a new CTA, so follow-up CTA has been completed in the remaining 35 patients. CTA findings of aortitis were still present in 16 (72% of the patients who initially had aortitis). Nevertheless, significant reduction in mean wall thickening was detected in all of the aortic segments: ascending aorta (1,51±0,81 vs 1,22±0,59 mm, p=0,018), aortic arch (2,31±1,02 vs 1,77± 0,87 mm; p=0,002), descending thoracic aorta (2,74±1,06 vs 2,02±0,95 mm; p<0,001), and abdominal aorta (1,68±0,8 vs 1,31±0,6 mm; p=0,012). None of the 35 patients evaluated developed new lesions in previously unaffected areas and no patients lacking aortitis in the first CTA developed new aortic involvement. Similar to the first evaluation, aortic arch and descending thoracic aorta were the most affected segments, followed by the abdominal aorta and ascending aorta, respectively. Interestingly, aortic diameters remained stable, and no patients developed new aortic dilation or increase in previous dilations.

Conclusion: CTA signs of aortitis persisted in 72% of the patients who presented initial aortic inflammation after one year of steroid treatment. Nevertheless, aortic thickening significantly decreased and there were no changes in aortic diameters during this period of time. In order to rule out clinical significance of these inflammatory findings and their possible relationship with dilatation longer follow-up is mandatory.

Prevalence, Management and Outcomes of PET Positive Large Vessel Vasculitis in Difficult to Treat PMR and GCA Patients. Pravin Patil[1], Shaifali Jain[1], Katerina Achilleos[1], Tochukwu Adizie[1], Mark Williams[1], Matthew Tam[1] and Bhaskar Dasgupta[2]. [1]Southend University Hospital, Westcliff on sea, United Kingdom, [2]Southend University Hospital, Westcliff-on-Sea, United Kingdom

Background/Purpose: Management of PMR and GCA can be challenging in patients with persistently elevated inflammatory markers, prominent constitutional symptoms and inadequate steroid response. We undertook an audit in such difficult to treat cases of the utility of FDG-PET CT scanning and outcomes of therapeutic decisions subsequently made.

Methods: We report a retrospective case notes review of 52 rheumatology patients with active PMR, GCA despite optimal steroid/ methotrexate therapy or patients with an unexplained systemic illness who had PET-CT from 2008–2012. FDG uptake was graded on a 4-point scale and grade 2 or more was accepted as positive.

Results: Of the 52, 68 % were female (median age 70, range 57–89), 23 PMR and 20 had GCA (12 biopsy positive). 63 % PMR and GCA patients were on steroids. The average dose of Prednisolone prior to PET scan was 6mg daily in PET positives compared to 21mg daily in PET negative patients.

Large vessel vasculitis (LVV): 15 had avid FDG uptake in the subclavian, aortic and axillary arteries, suggesting presence of LVV. All had constitutional symptoms notably night sweats, weight loss and lethargy. The average CRP in patients with LVV was 112mg/dl (range 13–403). Where PET scans were negative, the average CRP was 19 (1–48). There was no significant difference in gender, incidence of PMR, GCA, and resistance to treatment in both groups. 8 out of 9 with LVV who had abdominal CT scan were found to have inflammatory aortitis (soft tissue vascular cuffing) on retrospective CT review. All patients with LVV had successful clinical response to escalation of immunosuppression with 4–6 weeks post treatment mean CRP of 7 (1–26). 78% were treated with high dose Predinisolone and Leflunomide (53%). 4 patients required treatment with Tocilizumab (TCZ). 1 patient with retroperitoneal fibrosis and LVV associated with pan aortitis was treated with Rituximab. All patients on TCZ showed reversal of FDG avidity, normalized CRP, reduction of prednisolone to < 90% pre TCZ dose and 1 showed re-vascularisation of axillary artery stenosis on follow up CT angiography and ultrasound.

Non LVV findings on FDG PET: 2 patients had uptake in sterno-clavicular and sacroiliac joints suggestive of SpA. One patient with connective tissue disease overlap had symmetrical uptake in shoulders consistent with inflammatory arthritis. In 2 patients with atypical clinical presentation the diagnosis of PMR was confirmed with bursal & entheseal uptake in the shoulder/hips. In 3 cases FDG PET revealed cancer (pancreas 2, metastatic breast 1).

Conclusion: LVV is a common finding in both PMR and GCA exhibiting lack of steroid response, constitutional symptoms and raised inflammatory markers. Abdominal CT scan may provide important diagnostic clues of aortitis which can be confirmed on FDG-PET scan. Scan results are influenced by dose of steroid intake and we suggest prednisolone no higher than 7.5 –10mg daily a week prior to the scan. Patients on higher doses may have false negative scans. FDG PET can also reveal occult malignancies or confirm the PMR diagnosis. Novel agents like leflunomide and tocilizumab provide targeted and effective therapy in refractory patients with reversal of FDG avidity on and re-vascularisation on repeat scans.

Misdiagnosis of Giant Cell Arteritis Presenting As Fever of Unknown Origin. Chiara Stagnaro, Rosaria Talarico, Claudia Ferrari, Anna d'Ascanio and Stefano Bombardieri. Rheumatology Unit, University of Pisa, Pisa, Italy

Background/Purpose: Giant cell arteritis (GCA) represents the most common primary vasculitis of the elderly, that usually involves large and medium sized arteries. The wide spectrum of clinical manifestations can extensively vary, from cranial symptoms, such as headache, jaw claudication or visual alterations, to constitutional symptoms, like fever, weight loss or asthenia. Fever of unknown origin (FUO) may sometimes represent the initial symptom of GCA and when it is not associated with other typical GCA features, unfortunately the diagnosis can be delayed. The primary aim of this study was to evaluate the prevalence of GCA presenting as FUO. The secondary aims were: to identify delays in recognizing patients with GCA presenting as FUO and to explore any potential differences between the subset of GCA patients characterised by the presence of FUO at the onset, and the other patients of the cohort.

Methods: Epidemiological and clinical data of 180 GCA patients followed in the last 15 years in our Unit were analysed. We quantified the latency period between the onset of signs and symptoms and the final diagnosis of GCA in terms of months.

Results: One hundred and thirty-five patients (13 males and 122 females, mean ± SD age at the onset 75±6 years, mean follow-up 8 years) had shown at the onset signs and symptoms suggestive of GCA (new onset headache and/or scalp pain 78%, jaw claudication 36%, vision loss 33%, abnormal temporal artery on examination 32%, dizziness 29%) while 45 patients (9 males and 36 females, mean age at the onset 67±2 years, mean follow-up 6 years) were sent to our attention because of FUO onset and an increase of erythrocyte sedimentation rate and C-reactive protein not otherwise justified. After an extensive work-up aimed at excluding any kind of infection, malignancy or hematological disorder, we performed temporal artery biopsy (TAB) in all patients presenting as FUO, that resulted positive in 52% of cases. Moreover, (18)F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) was performed in 29 cases and was positive in 27. The main PET alterations reported were characterized by a (18)FDG uptake of the aortic arch and its major branches, including the carotid, subclavian, thoracic aorta and, less frequently, the abdominal aorta. The mean latency period between the onset of FUO and the diagnosis of GCA was 7±2 months, which was significantly higher compared with the mean latency period between the onset of signs and symptoms suggestive of GCA and the definitive diagnosis (3±1 months) in the other patients of the cohort. No difference was noted between the 2 groups, except for the mean age at the onset, which seems to be earlier in GCA patients presenting with FUO.

Conclusion: GCA patients presenting with constitutional symptoms may sometimes represents a diagnostic challenge and our results confirm that FUO must to be carefully investigated in elderly patients. In fact, there are major delays in the recognition of GCA patients presenting with FUO, and it partially seems to be due to the long diagnostic work-up before performing a rheumatologic evaluation.

Evaluation of Disease Activity Using FDG PET-CT in Patients with Large Vessel Vasculitis. Giulia Pazzola[1], Luca Magnani[1], Luigi Boiardi[1], Nicolo Pipitone[1], Annibale Versari[1], Debora Formisano[1], Olga Addimanda[1], Riccardo Meliconi[2], Lia Pulsatelli[3], Gianluigi Bajocchi[1], Pierluigi Macchioni[1], Maria Grazia Catanoso[1], Niccolò Possemato[1], Ilaria Padovano[1], Alberto Lo Gullo[1] and Carlo Salvarani[1]. [1]Arcispedale S Maria Nuova, IRCCS, Reggio Emilia, Italy, [2]Istituto Ortopedico Rizzoli, University of Bologna, Bologna, Italy, [3]Istituto Ortopedico Rizzoli, Bologna, Italy

Background/Purpose: 18F-Fluorodeoxyglucose (FDG) positron emission tomography (PET)/computerized tomography (CT) [PET/CT] has been proposed as a useful tool to diagnose and monitor activity of large vessel vasculitis (LVV), but its precise role remains debated. The objective of this study was to determine the value of PET-CT in the assessment of disease activity in LVV. To this end, PET/CT findings were correlated with clinical indices including ITAS (Indian Takayasu activity score) and Kerr/National Institute of Health, serum acute-phase reactants (ESR, CRP) levels as well as interleukin-6 (IL-6) and the soluble IL-6 receptor (sIL-6R).

Methods: 78 patients with LVV (giant cell arteritis, Takayasu arteritis or idiopatic aortitis) underwent a total of 204 PET/CT scans. PET/CT scans were reviewed by a nuclear medicine physician without knowledge of clinical information. Vascular uptake was graded using a 4-point semiquantitative scale where grade 0=no uptake, grade 1=less than liver uptake, grade 2=similar to liver uptake, grade 3=higher than liver uptake. Visual analysis was performed on 14 vessel segments. PET/CT scans were considered negative if vascular FDG uptake was grade 0–1, moderately positive if vascular uptake was grade 2, and markedly positive if vascular uptake was grade 3 in at least one vessel. ITAS, Kerr/NIH scores, ESR, CRP, IL-6 and sIL-6R values were obtained within 20 days of PET/CT scans.

Results: 43% of 204 PET-CT were negative, 31% were moderately positive, and 26% were markedly positive. We found a significant association between the intensity of the uptake and both ESR and CRP levels. Significantly higher ESR values were observed in the patients with markedly positive PET/CT (49.4 + 36.5 mm/1st h) compared with those with moderately positive (27+ 21 mm/1st h, p = 0.0001) and inactive scans (22.7 + 15.9 mm/1st h, p=0.0001), respectively. CRP levels were 0.8+1.0 mg/dL in patients with inactive scans, 1.3+ 2.2 mg/dL in patients with moderately positive (p=0.001) and 3.0 + 3.6 in patients with markedly positive scans (p = 0.0001). Significantly higher levels of IL-6 were measures in patients with markedly positive scans (10.0 + 8.9 pg/ml) compared to those with inactive scans (8.1+18.5 pg/ml, p=0.013). No association was found between sIL-6R levels and intensity of vascular FDG uptake. However, there was a significant association between the intensity of vascular FDG uptake and both ITAS and Kerr/NIH scores.

Patients with markedly positive scans had more frequently (50%) active vasculitis according to the ITAS compared with those with moderately active (31.7%) and inactive scans (28.1%) (p=0.003). Likewise, vasculitis was judged to be active according to the Kerr/NIH index in 50% of patients with markedly positive scans, 22% of those with moderately positive scans, and 14.6% with inactive scans (p=0.0001).

Conclusion: Our findings show a strong association between vascular FDG uptake and clinical activity and traditional inflammatory markers. A weaker association was found between vascular FDG uptake and IL-6 levels. These data suggest that PET/CT may be a useful tool for evaluating disease activity in patients with LVV.

2363

Assessment of Disease Activity in Large Vessel Vasculitis: Initial Results of an International Delphi Exercise. Sibel Z. Aydin[1], Haner Direskeneli[2], Eric L. Matteson[3] and Peter A. Merkel[4]. [1]Medeniyet University, Goztepe Training and Research Hospital, Istanbul, Turkey, [2]Marmara University, School of Medicine, Istanbul, Turkey, [3]Mayo Clinic, Rochester, MN, [4]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Assessment of disease activity in large vessel vasculitis (LVV) is challenging. The lack of specific, validated outcome measurements for both Takayasu's (TAK) and giant cell arteritis (GCA) affects clinical care and research in these diseases.

Methods: The Delphi survey was sent out to >300 experts by e-mail. Experts were chosen from different specialties based on their interest in LVV and previous involvement in vasculitis clinical research. Experts from countries with high prevalence of either TAK or GCA were especially recruited. The first round included 99 items on a 5-point scale aiming to cover all potential disease manifestations. Items accepted or rejected by >70% of the voters are not advanced to subsequent rounds.

Results: 116 experts completed the survey and included physicians from 23 countries in Asia, Australia, Europe and North and South America. Most of the vascular/cardiovascular items (e.g. bruits, new loss of pulse, claudication) were accepted by >70% of experts for TAK; ocular findings (e.g. visual loss, blurred vision, retinal vasculitis) were considered high-priority outcomes for GCA. Vascular imaging (CT, MRI, PET, or ultrasound) was accepted for both TAK and GCA. SF36 and patient global assessment were widely accepted as tools for patient-reported outcomes in both diseases. Disease Extent Index-Tak (DEI.Tak) was the only composite index accepted by the majority for TAK. Only ESR and CRP were suggested as biomarkers in TAK, whereas hemoglobin level was also supported in GCA. Findings rejected by >70 % of the experts were erythema nodosum for TAK and pulmonary assessments for GCA. Many items were endorsed by a majority of experts but did not reach the 70% threshold for final acceptance; it is expected that additional items will reach the 70% threshold in subsequent Delphi rounds. Several new items were proposed by participants (e.g. IL-6 levels and novel patient reported outcome measures) that will be considered in subsequent rounds.

The majority of experts (63%) voted for aiming to have a common tool for both TAK and GCA but also develop additional tools specific for each disease. 25% felt the two diseases were unsuitable for common outcome measures.

Conclusion: This exercise points out the similarities and differences from experts' perspective for assessing clinical activity in TAK and GCA. The completion of the Delphi will produce a consensus-driven set of outcomes to study prospectively with the long-term goal of developing a core set of validated outcomes for LVV. Based on these data it is anticipated that such a set of outcomes will include many data elements common to both diseases, supplemented by disease-specific items for TAK and GCA. Continued international collaborative work will be required to advance this research for these diseases.

CROSS-Sectional Assessment of Damage in Takayasu Arteritis with A Validated Tool. Ahmet Omma[1], Burak Erer[1], Omer Karadag[2], Neslihan Yilmaz[3], Fatma Alibaz-Oner[3], Fatih Yildiz[4], Melike Kalfa[5], Gezmis Kimyon[6], Sedat Kiraz[2], Haner Direskeneli[3], Eren Erken[4], Kenan Aksu[5], Ahmet Mesut Onat[6], Ahmet Gul[1], Lale Ocal[1], Murat Inanc[1] and Sevil Kamali[1]. [1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Hacettepe University, Faculty of Medicine, Ankara, Turkey, [3]Marmara University, Faculty of Medicine, Istanbul, Turkey, [4]Cukurova University, Faculty of Medicine, Adana, Turkey, [5]Ege University, Faculty of Medicine, Izmir, Turkey, [6]Gaziantep University, Faculty of Medicine, Gaziantep, Turkey

Background/Purpose: Takayasu arteritis (TA) is a large vessel vasculitis with a chronic course, usually causing damage by the time of diagnosis. To our knowledge, there is no reported study assessing the damage related to TA itself or treatment. We aimed to evaluate the damage cross-sectionally in TA patients with Vasculitis Damage Index (VDI), a generic tool developed for systemic vasculitides.

Methods: A collection of 165 TA patients (146 female) fulfilling ACR criteria and followed-up more than 6 mo from 6 centers in Turkey, were enrolled into the study. All patients underwent detailed examination including eye, vascular imaging, echocardiography and bone dansitometry. Clinical, angiographical and treatment characteristics and damage items of VDI were recorded using a standardized protocol. Disease activity and quality of life (QoL) were evaluated by Kerr criteria and SF-36, respectively. TA patients with persistant disease activity ≥6 mo were considered as resistant. The correlation between VDI scores and disease duration, cumulative glucocorticoid (GC), cyclophosphamide (CYC) duration and doses, and mental (MCS) and physical (PCS) component summary scores of SF-36 were analysed by Pearson correlation test. VDI scores according to the disease resistance and

poor QoL (MCS and PCS scores <50) were compared by Mann Whitney U test.

Results: The mean age, follow-up time and disease duration were 40 ± 12 years, 74 ± 73 mo and 95 ± 91 mo, respectively. Type I (51%) was the most common type of vascular involvement. Cumulative doses / duration of GC and CYC were $10,6 \pm 9,6$ g / 64 ± 60 mo and $2 \pm 5,5$ g / $2,3 \pm 6,5$ mo, respectively; 39% of them had resistant course. Major vessel stenosis, absent pulses, claudication were demonstrated in ≥50% of TA patients, as damage items. Osteoporosis (22%) and cataract (12%) were the main treatment related damages. Cumulative VDI scores in TA cohort were found to be 4.3 ± 2.2, mainly (3.8 ± 1.9) due to disease itself. MCS and PCS scores were calculated as 43 ± 10 and 38 ± 11, respectively. Poor SF-36 MCS scores were demonstrated in 70% and PCS scores in 80% of the patients. VDI scores were found to be correlated with disease duration ($p<0.01$, $r= 0.27$), cumulative doses of GC ($p<0.01$, $r= 0.29$) and CYC ($p=0.02$, $r= 0.20$) and duration of GC ($p<0.01$ $r= 0.37$). A negative correlation was observed between the VDI and both MCS ($p=0.007$, $r=-0,21$) and PCS scores ($p<0.001$, $r=-0.36$). The higher VDI scores were detected in the subgroup of patients PCS <50 ($4,8 \pm 2,2$ vs $2,9 \pm 1,5$, $p<0.001$).

Conclusion: Cross-sectional analysis of this TA cohort with a long disease duration revealed vascular damage scores comparable to the scores of severe systemic necrotizing vasculitides. Majority of TA patients had disease related damage, characterized by peripheral vascular involvement. The longer disease duration and higher GC and CYC exposure were significantly associated with the damage. The severe damage scores (≥5) were observed in TA patients with poor health quality.

Asymptomatic Myocardial Ischemic Disease in Takayasu's Arteritis.
Chloe Comarmond[1], Odile Dessault[2], jean-Yves Devaux[2], Nathalie Costedoat-Chalumeau[3], Mathieu Resche Rigon[4], Richard Isnard[5], Fabien Koskas[6], Patrice Cacoub Sr.[7] and David Saadoun[3]. [1]Hôpital Pitié Salpétrière, Paris, France, [2]Groupe Hospitalier Saint-Antoine, Paris, France, [3]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpêtrière, Paris, France, [4]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [5]Department of Cardiology, CHU Pitié-Salpêtrière, 47–83 Boulevard de l'hôpital, 75651 Paris Cedex 13, Paris, France, Paris, France, [6]Department of Internal Medicine and 2Laboratory I3 ≪ Immunology, Immunopathology, Immunotherapy ≫, UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [7]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Cardiac involvement in Takayasu's arteritis (TA) is a leading cause of death. Previous studies reported a high incidence of myocardial involvement using exercise thallium-201 scintigraphy whereas macrovascular coronary lesions are not frequent in coronary angiography.

Objective: The aim of the present study is to evaluate coronary microvascular dysfunction in TA using dipyridamole thallium-201 myocardial scintigraphy.

Methods: Twenty five consecutive patients with TA [median (IQR) age 48 (36–60) years, with 18 (72%) females, and median duration of disease between diagnosis and enrollment 7 (3–11) years] were prospectively examined by 201Tl myocardial scintigraphy at rest and after dipyridamole induced stress.

Results: Among 25 TA patients, 21 (84%) had abnormal scintigraphic findings and 4 (16%) had normal myocardial perfusion. Using 17-segments model for quantitative image analysis, dipyridamole significantly improved resting 201Tl myocardial perfusion in 14/23 patients (60.9% with reversible defects in at least 3 segments) versus 9/23 (39.1% with permanent defects or reversible defects in less than 3 segments). We were able to examine coronary artery stenoses in 11 patients including 10 patients with thallium perfusion abnormalities. Among patients with thallium perfusion abnormalities, significant coronary artery stenoses were present in only 2/11 (18.2%) patients. No significant difference was found between TA patients with normal and abnormal myocardial perfusion scintigraphy in terms of cardiovascular risk factors or characteristics of TA.

Conclusion: Our results demonstrate a high incidence of myocardial involvement in TA patients mainly related to microcirculation impairment. This clearly demonstrate that this large vessel vasculitis, also affect vessels of small size. Systematic cardiac evaluation including dipyridamole thallium-201 stress myocardial scintigraphy is required to properly identify TA patients with asymptomatic myocardial involvement. Further studies are needed to determine whether myocardial findings using dipyridamole thallium-201 stress myocardial scintigraphy have an impact on the prognosis and treatment strategy.

2366

Aortic and Coronary Calcifications in Takayasu Arteritis.
Emire Seyahi[1], Ayca Ucgul[2], Serdal Ugurlu[1], Canan Akman[3], Deniz Cebi Olgun[3], Sebahattin Yurdakul[1] and Hasan Yazici[1]. [1]Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey, [2]University of Istanbul, Cerrahpasa Medical Faculty, Istanbul, Turkey, [3]Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

Background/Purpose: We had previously shown, similar to patients with systemic lupus erythematosus (SLE), patients with Takayasu arteritis (TAK) had significantly more atherosclerotic plaques in the carotid arteries compared to the healthy controls (1). Moreover, we had observed that atherosclerotic plaques were more common in areas where arteritis was more prominent, implying that atherosclerosis in TAK might be mainly due to local inflammation.

In this study, we aimed to investigate the presence of coronary artery (CAC) and thoracic aorta calcifications (ToAC) using multi-detector computed tomography (MDCT) in a larger cohort of TAK patients and controls. We again investigated the frequency of atherosclerotic plaques in the carotid arteries. These investigations enabled us to compare atherosclerotic lesions in different vessel beds in patients with TAK and controls and thus to test the hypothesis that atherosclerosis observed in TAK is primarily due to local factors.

Methods: We studied 47 female with TAK (mean age: 37.4 ± 8.0 SD years), 43 patients with SLE (mean age: 39.3 ± 8.1 years) and 70 healthy controls (mean age: 40.2 ± 5.2 years). Calcification in the coronary arteries and thoracic aorta was measured using MDCT. Carotid artery plaques (CAP) were assessed using B-Mode ultrasonography.

Results: Table 1 demonstrates the odds ratios for the surrogate markers of atherosclerosis among the study groups with healthy controls being the reference group. The OR for having atherosclerotic plaques was considerably higher (9 vs 4) among the SLE patients as compared to the TAK patients while the frequency of CAC was significantly increased only among patients with SLE compared to the healthy controls. However, ToAC and CAP were significantly more common among both TAK and SLE patients compared to the healthy controls. Calcification in the thoracic aorta was present in 45 % of TAK patients and its morphology was different than that observed in SLE. It was mostly circumferential in TAK, whereas punctuate or linear in SLE. As reported previously, similar to SLE patients, TAK patients were found to have increased risk for CAP. Moreover, among TAK patients CAC, ToAC and CAP were more likely to be seen in places where primary vasculitic lesions were frequent (coronary artery involvement: 67% vs 7 %, CAC (+) vs CAC (−), respectively, p =0.027; thoracic aorta involvement: 52 % vs 19 %, ToAC (+) vs ToAC (−), respectively, P= 0.029, and carotid artery involvement: 92 % vs 69 %, CAP (+) vs CAP (−), respectively, P=0.146).

Table. Prevalence and the odds ratios of CAC, ToAC and CAP

	Study groups	Patients with, n (%)	OR (95 % CI)	P value
CAC	TAK, n =47	5 (11)	4.0 (0.8–21.8)	0.104
	SLE, n =43	9 (21)	9.0 (1.8–44.0)	0.007
	HC, n =70	2 (3)	−	−
ToAC	TAK, n =47	21 (45)	27.5 (6.0–125.5)	<0.001
	SLE, n =43	10 (23)	10.3 (2.1–49.7)	0.004
	HC, n =70	2 (3)	−	−
CAP	TAK, n =47	12 (23)	3.1 (1.1–8.6)	0.030
	SLE, n =43	12 (28)	3.5 (1.2–9.7)	0.017
	HC, n =70	7 (10)	−	−

Conclusion: Unlike what is observed in SLE, atherosclerosis in TAK seems to be influenced by local rather than systemic factors.

Presence of Fibromyalgia and Fatigue Is Not Increased in Patients with Takayasu's Arteritis. Fatma Alibaz-Oner, Meryem Can, Birkan Ilhan, Ozge Polat and Haner Direskeneli. Marmara University, School of Medicine, Istanbul, Turkey

Background/Purpose: Takayasu's arteritis (TAK) is a large-vessel vasculitis of the aorta and its major branches. To our knowledge, no data is reported about the frequency of Fibromyalgia Syndrome (FM), in TAK. We aimed to investigate the frequency of FM in TAK, defined according to the new 2010 ACR Preliminary Diagnostic Criteria for Fibromyalgia. The correlation between ACR-1990 and 2010 FM criterias and the effect of patient-reported outcomes (PROs) such as Health Assessment Questionnaire (HAQ), Multidimensional Assessment of Fatigue Scale (MAF), *Short-Form 36*-item survey (*SF-36) and hospital* anxiety and depression scales (HADS) on FM were analyzed.

Methods: We studied 51 patients with TAK (F/M: 47/4, mean age: 42.3 years), 50 (F/M: 35/15, mean age: 40.89 years) healthy controls (HC). All patients were examined for FM tender points by two observers (kappa: 0.648) and asked to complete new ACR 2010 FM questionnaire for FM (ref1). *SF-36, MAF* and HADS were used to assess quality of life together with HAQ. Seventeen patients were re-evaluated 6 months later.

Results: Six(11,7%) patients with TAK and 5 HC (10%) met the ACR-2010 FM criteria, whereas only 3(5,8%) TAK patients and no controls (0%) met the 1990 Criteria. No significant differences regarding the FM frequency were present according to both ACR-2010 and 1990 FM criterias between TAK and HC. No differences were also observed for the 2 subscales of 2010 criteria, the Widespread Pain Index(WPI) and the Symptom Severity scale (SSS) scale among the groups. Fourteen patients (33,3%) were clinically active. FM presence was also similar between active and inactive patients (p=0,188). The results of PROs were showed in Table 1. WPI correlate significantly with tender points (r=0,477, p<0,001), MAF (r=0,623, p<0,001), HAQ (r=0,477, p<0,001), anxiety (r=0,458, p<0,001), depression (r=0,378, p<0,001), PCS (r=−0,586, p<0,001) and MCS (r=−0, 335, p<0,001). SSS correlate significantly with tender points (r=0,477, p<0,001), MAF (r=0,775, p<0,001), HAQ (r=0,437, p<0,001), anxiety (r=0,557, p<0,001), depression (r=0,438, p<0,001), PCS (r= −0,593, p<0,001) and MCS (r=−0,531, p<0,001). During follow-up, no significant differences between baseline and 6.month were observed in terms of frequency of FM, MAF, HAQ, HADS, PCS and MCS.

Table 1. Results of the patient-reported outcomes in TAK and controls

	Takayasu'sarteritis (n=51)	Healthy controls (n=50)	P values
MAF	18,5 (0–49,7)	17,5 (0–38,6)	0,282
Anxiety scale score	5 (0–21)	5 (0–18)	0,533
Depression scale score	3 (0–21)	3 (0–14	0,529
HAQ	0,15 (0–2,35)	0 (0–0,8)	**<0,001**
PCS	46,9 (17,5–61,7)	53,4 (30,4–100)	**0,003**
MCS	46 (22,4–65,4)	49,9 (20,8–100)	0,350

Conclusion: The frequency of FM is similar to general population in patients with Takayasu arteritis. However, although other PROs also does not differ from HC, the new FM criteria subscales WPI and SSS significantly correlated with scales such as SF-36, MAF, anxiety and depression scale and HAQ in TA, suggesting that in a minority of patients with FM and TA, PROs are affected with FM presence.

Tocilizumab in Refractory Takayasu's Arteritis: 7 Patients Followed At a Single Italian Centre. Enrico Tombetti, Elena Baldissera, Stefano Franchini, Patrizia Aiello, Francesca Motta, Barbara Gulgielmi and Maria Grazia Sabbadini. Vita-Salute San Raffaele University, Milan, Italy

Background/Purpose: Takayasu arteritis (TA) is a rare chronic-relapsing vasculitis involving primarily the aorta and its major branches.TA is associated with considerable morbidity and mortality. Therapy is based on corticosteroids (CS) but steroid-sparing immunosuppressive drugs are required in most patients to minimize CS adverse events and to control progressive vascular disease. However, about 25% of patients relapse when CS are tapered. In this setting, previous works showed that tocilizumab (TCZ), an humanized anti-IL6 receptor antibody may be useful.

Objectives: To evaluate the safety and efficacy of TCZ in the treatment of refractory TA.

Methods: We retrospectively studied 7 TA patients (pts) treated with TCZ (8 mg/kg monthly) between 2010 and 2012 at a single academic Italian center. All pts satisfied ACR criteria for TA classification and had active refractory TA. Treatment efficacy was evaluated as: i) reduction of signs and symptoms of active disease, ii) steroid sparing activity (assessed as reduction in the average daily dose measured within the 12 month period preceding each medical evaluation, iii) angio-MRI assessment of vascular lesions evolution, iv) decrease in CRP and ESR.

Results: All 7 pts were female, with a median age at the beginning of TCZ therapy of 35 years (range 32–46), median duration of disease 66 months (range 17–101). Before TCZ therapy, they were taking a median of 4 (range 1–8) immunosuppressive agents. Four pts had been previously treated with anti-TNF agents. Median FU on TCZ therapy was 14 months (range 9–24). Mean duration of CS therapy before TCZ was 37 months. Two pts did not show signs or symptoms of active disease during FU while in 3 pts satisfied NIH criteria of active disease. During FU, average prednisone daily dose decreased from a median value of 8.3 mg (range 5.9–29) to 8.0 mg (range 5.0–16): however, the dose could be reduced more than 3 mg/day in 4 patients. The median number of vascular lesions was unchanged (8, range 4–12) at baseline and at the end of FU. In one pt vascular lesions improved during FU and in another did not progress, while in the other 5 pts there was worsening of at least one vascular lesion. Median values of ESR and CRP decreased from 34 (range 8.0–76) to 4.0 (range 2.0–45) mm/h and from 13 (range 10–35) to 2.0 (range 1.0–44) mg/l, respectively. TCZ was stopped in 4 pts because of suboptimal disease control. During FU one pt had severe pneumonia, requiring TCZ interruption, another had relapsing upper respiratory infections and a third developed pytiriasis rosea, that subsided after TCZ interruption.

Conclusion: In this study of refractory TA, TCZ showed efficacy only in a minority of pts. Our data do not confirm the positive results of TCZ therapy reported in previous studies. However, our pts may have had more severe disease, as suggested by the higher number of immunosuppressive agents at baseline compared to previous reports. Finally, it should be noted that ESR and CRP do not appear to correlate reliably with disease activity during TCZ therapy. Further studies are necessary to better define the role of TCZ in TA therapy.

Aspects of Innate Immunity in Behçet′s Disease: A Model of Auto-inflammatory Disease? Sandro F. Perazzio[1], Paulo Vitor Soeiro Pereira[2], Alexandre Wagner S. de Souza[3], Antonio Condino-Neto[2] and Luis Eduardo C. Andrade[4]. [1]Federal University of Sao Paulo, Sao Paulo, Brazil, [2]USP, São Paulo, Brazil, [3]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [4]Universidade Federal de São Paulo, Sao Paulo, Brazil

Background/Purpose: Behçet's disease (BD) is a systemic vasculitis of unknown etiopathogenesis. Increased neutrophil activation has been previously shown in BD patients and it is unclear whether neutrophil activation occurs constitutively or if it is secondary to a yet unknown stimulus or some serum or tissue soluble factor. The hypersensitivity to *Streptococcus sanguinis* antigens suggests that infectious agents may play a role in BD pathogenesis. Recently, it has been postulated that BD may be a form of auto-inflammatory disease. The present study investigated several aspects of

cellular activation in neutrophils and peripheral blood mononuclear cells (PBMC) of patients with active and inactive BD.

Methods: four study groups were analyzed: active BD (aBD; n=17), inactive BD (iBD; n=26); septic patients (SP; n=10); healthy controls (HC; n=10). BD activity was established as Behçet's Disease Current Activity Form simplified (BDCAFs) score[3]2. Flow cytometry analysis evaluated phagocytosis (zymosan particles, *Stretococcus pneumoniae* and *Candida albicans)* and the oxidative metabolism before and after stimulation with phorbol myristate acetate (PMA). The shedding of CD62L was determined after stimulation of TLR-2, -3, -4, -5, -7. Microbicidal activity against *Streptococcus* and *Candida* was determined by means of 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) reduction and absorbance read by ELISA. The supernatant of PBMC cultures under TLR or microbial stimuli were used for determination of TNFa, IFNg, IL-12p70, IL-23, IL-6 and IL-10 by ELISA. The supernatant of neutrophil cultures under PMA, LPS or microbial stimuli were used for determination of IL-1$_\beta$ and IL-8.

Results: There was no difference in medication use between aBD and iBD. Phagocytosis, microbial killing activity and oxidative burst assays in PMN and monocytes showed no difference among the four groups. The activated monocyte index of shedding assay showed higher activation by TLR3 in iBD (31±28%, p=0.022) and aBD (27±20%, p=0.029) than in SP (3.4±25%). In contrast, the activation by TLR7 was lower in iBD (27±23%, p=0.022) and aBD (32±27%, p=0.029) than in SP (74±39%). BD monocytes did not differ from HC monocytes regarding activation via TLR stimuli. Neutrophils from aBD produced less IL-1β after stimulus with *S. pneumoniae* (68±61 pg/mL) than HC (273±174 pg/mL, p=0.05) and showed a trend for lower values comparing to iBD (175±93 pg/mL, p=0.076). There was no difference in the production rate of other cytokines.

Conclusion: These results showed that phagocytes in BD are not constitutively activated. This negative evidence suggests that the marked involvement of neutrophils in BD pathophysiology may be caused by some kind of stimuli produced by other cells at or close to the target tissues. Thence, further studies should address proteomic analyses of the serum and samples from target tissues in BD in an attempt to identify possible metabolic pathways involved in neutrophil activation in BD.

A Genome-Wide DNA Methylation Study Identifies Significant Epigenetic Changes Across the Genome and in Multiple HLA Loci in Behçet's Disease.

Haner Direskeneli[1], Patrick S. Coit[2], Filiz Ture-Ozdemir[1], Fatma Alibaz-Oner[1], Guher Saruhan-Direskeneli[3], Matlock A. Jeffries[4] and Amr H. Sawalha[2]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]University of Michigan, Ann Arbor, MI, [3]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [4]University of Oklahoma and Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Behcet's disease (BD) is a systemic vasculitis of poorly understood etiology. Herein, we study the DNA methylome in BD for the first time and identify significant DNA methylation changes in this disease.

Methods: We studied six untreated newly diagnosed male patients with BD and six age-, sex-, and race-matched controls. Monocytes and CD4+ T cells were purified using magnetic bead separation from PBMCs. DNA was extracted from each cell subset and treated with sodium bisulfite. Genome-wide DNA methylation changes were assessed using the Illumina Infinium HumanMethylation450 BeadChip arrays. This platform allows for the interrogation of over 485,000 CpG sites within the entire genome. Percent methylation of each CpG site and differential methylation between patients and controls were determined using GenomeStudio. False discovery rate of ≤5% was applied to correct for multiple testing. Further, only CpG sites with a differential methylation score between patients and controls ≥75 ($P \leq 5\times10^{-8}$), and a methylation difference of at least 1.2-fold were included in the analysis. Pathway and gene ontology analysis was performed using Ingenuity.

Results: A total of 343 hypomethylated and 337 hypermethylated CpG sites, and 232 hypomethylated and 254 hypermethylated CpG sites, were identified in BD monocytes and CD4+ T cells, respectively. The most significant DNA methylation change detected was hypomethylation in multiple CpG sites located within the *HLA-C* gene in both monocytes (7.9-fold) and CD4+ T cells (8.2-fold) in patients compared to controls. Differential

DNA methylation between patients and controls, consistent in the two cell subsets, was also observed in *HLA-DPB1, HLA-DPB2, HLA-DQA1, HLA-DQA2, HLA-DRB1, HLA-DRB6,* and *HLA-G.* Other hypomethyled loci in BD include *NOP10* (monocytes, 3.2-fold; CD4+ T cells, 4.2-fold), and *SPDEF* (monocytes, 2.3-fold; CD4+ T cells, 2.2-fold). Hypermethylated loci include *IL17RA* (monocytes, 4.0-fold; CD4+ T cells, 2.2-fold), *MMP27* (monocytes, 3.8-fold; CD4+ T cells, 2.0-fold), *MRPL1* (monocytes, 2.1-fold; CD4+ T cells, 5.7 fold), and *SLC37A1* (monocytes, 2.0-fold; CD4+ T cells, 1.9-fold). Canonical pathway analysis of differentially methylated genes highlights the antigen-presentation pathway (monocytes, $P=1.1\times10^{-6}$; CD4+ T cells, $P=4.02\times10^{-11}$). Indeed, transcription factor binding site analysis demonstrates enrichment of CIITA binding sites in differentially methylated genes (monocytes, $P=1.22\times10^{-3}$; CD4+ T cells, $P=4.52\times10^{-4}$). Cytotoxic T cell-mediated apoptosis, allograft rejection signaling, graft-versus-host disease signaling, and OX40 signaling, are also enriched pathways. Network analysis also highlights type-I interferon and NFkB signaling.

Conclusion: We performed a genome-wide DNA methylaltion study in BD using two distinct cell populations. Our data demonstrate significant genome-wide epigenetic differences between BD patients and healthy age-, sex-, and race-matched controls. We identified differential DNA methylation in the HLA locus in BD, and hypothesize that BD-associated risk alleles in the HLA might induce disease susceptibility, at least in part, by tagging a DNA methylation change.

The Unmet Need in Behcet's Disease: Most Patients Are Not in Complete Remission in the Long-Term Follow-up.

Fatma Alibaz-Oner[1], Gonca Mumcu[2], Gülsen Ozen[3], Zeynep Kubilay[1], Meryem Can[1], Sibel Yýlmaz Oner[1], Tülin Ergun[4] and Haner Direskeneli[1]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]Marmara University,Faculty of Health Sciences, Department of Health Informatics and Technologies, Istanbul, Turkey, [3]Marmara University, School of Medicine., Istanbul, Turkey, [4]Marmara University School of Medicine, Istanbul, Turkey

Background/Purpose: The nature of Behcet's disease (BD) as a multisystemic disorder with a remitting-relapsing course is unsufficiently explored. As complete remission should be aimed in all inflammatory diseases, we investigated the frequency of complete remission in routine practice in BD.

Methods: In this retrospective study, 130 patients with BD (F/M: 67/63, mean age: 43.23±11,7 years) classified according to ISG criteria were included. The demographic and clinical data for active organ manifestations and treatment protocols were evaluated, both for the current visit and in the last month. Patients having at least one of any disease manifestations were categorized as active.

Results: A total of 857 visits of 130 patients were overviewed**.** Mean visit number was 6,5± 2,7 (range:1–10) and mean follow-up duration was 53,54±41,79 months (3–162). Sixty-one patients (46,9%) were of mucocutaneus type, whereas 69 patients (53,1%) had major organ involvement. When all visits combined, 16–49% of the patients were using immunosuppressives (IS), whereas 30–62,3% was under non-IS therapies such as colchicine or NSAIDs. There was also a group of noncompliant patients (6–53,8%) without any treatment. Patients were clinically active in 67% (n=575) of the total visits (n=857). Mean frequency of clinical activity was 61,9% (53,7–87,7), which increased to 77,2% (64,2– 90) when the month before the visit was also included. The major cause of the activity was aphthous ulcers (44,1–74,6%) with other mucocutaneous manifestations also commonly present (Genital ulcer: 4,5–33,8 %, erythema nodosum: 7,5–30%, papulopustular lesions: 16,3–39,2%, arthritis: 19,9–33,3%, uveitis: 0–7,7% and vascular involvement: 2,3–12,3%). No difference was observed between the frequency of activity of patients having ISs or non-IS therapies.

Conclusion: Although complete remission is the current, primary target in inflammatory rheumatological diseases such as rheumatoid arthritis or vasculitides, it is fairly difficult to achieve complete remission in BD with current therapeutic regimens. The reluctance of the clinician to be aggressive for some manifestations with low morbidity, such as mucocutaneous lesions, might be influencing the continuous, low-disease activity state in BD patients.

Disclosure: F. Alibaz-Oner, None; G. Mumcu, None; G. Ozen, None; Z. Kubilay, None; M. Can, None; S. Yýlmaz Oner, None; T. Ergun, None; H. Direskeneli, None.

Efficacy of Quantitative Analysis of Brainstem Atrophy On Magnetic Resonance Imaging for Diagnosis of Chronic Progressive Neuro-Behçet's Disease. Hirotoshi Kikuchi[1], Maki Takayama[2], Yoshitaka Kimura[2], Kurumi Asako[2], Hajime Kono[2], Yasuo Ono[1] and Shunsei Hirohata[3]. [1]Teikyo University Shool of Medicine, Tokyo, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan, [3]Kitasato University School of Medicine, Sagamihara, Japan

Background/Purpose: CNS involvement in Behçet's disease, usually called neuro-Behçet's disease (NB), can be classified into acute NB (ANB) and chronic progressive NB (CPNB) based upon the differences in clinical courses and responses to corticosteroid treatment. Previous studies demonstrated that brainstem atrophy was significantly more frequently observed in CPNB than in ANB or non-NB. Since the presence of brainstem atrophy depends on the anecdotal judgment by expert radiologists, more objective definition of brainstem atrophy is required. The present study was designed to examine whether quantitative analysis of the brainstem areas on magnetic resonance imaging (MRI) scans might be useful for early diagnosis as well as for evaluation of the disease activity of CPNB.

Methods: MRI scans recorded at the diagnosis and at various periods thereafter were evaluated in patients with ANB (n=10), CPNB (n=10), non-NB (n=8), and NPSLE (n=8). MRI scans of age- and sex- matched control patients for CPNB (non-inflammatory CNS diseases [NID]) (n=10) were also studied. The areas of midbrain tegmentum and pons were measured on mid-sagittal sections of T1-weightened images of brain MRI using image analysis software Image J (ver.1.45, National Institutes of Health: NIH, U.S. [http://imagej.nih.gov/ij/download.html]).

Results: The areas of midbrain tegmentum (ANB: 145.9 ± 20.1 mm^2 [mean $\pm$ SD], CPNB: 125.6 ± 18.0 mm^2, non-NB: 133.0 ± 16.4 mm^2, NPSLE: 133.4 ± 19.7 mm^2, NID: 151.1 ± 11.8 mm^2) as well as those of pons (ANB: 540.1 ± 87.2 mm^2, CPNB: 482.0 ± 91.3 mm^2, non-NB: 540.3 ± 40.2 mm^2, NPSLE: 517.3 ± 47.1 mm^2, NID: 574.1 ± 43.4 mm^2) were found to be lower in CPNB than those in the other 4 groups. On receiver operating characteristic (ROC) analysis, the sensitivity / specificity of the areas of midbrain tegmentum, pons and brainstem (midbrain tegmentum + pons) for diagnosis of CPNB against non-CPNB (ANB + non-NB) were 80.6% / 66.7% at cut-off value of 134.0 mm^2, 70.0% / 77.8% at cut-off value of 483.7 mm^2 and 70.0% / 94.4% at cut-off value of 614.9 mm^2 respectively (figure). The time kinetics analysis demonstrated that brainstem atrophy progressed most markedly during the first 2 years from the initial diagnosis of CPNB. Finally, brainstem atrophy progressed at significantly greater degree in CPNB patients with continuous elevation of cerebrospinal fluid (CSF) IL-6 (>20 pg/ml) compared with those in whom CSF IL-6 levels were kept bellow 20 pg/ml.

The area of brainstem for CPNB vs non-CPNB

Sensitivity 70.0%
Specificity 94.4%
at 614.9 mm^2
AUC: 0.75
p=0.03
Conclusion: These results confirm that brainstem atrophy is one of the characteristic features of CPNB. Moreover, the data suggest that quantitative analysis of the brainstem areas on MRI scans might be effective for early diagnosis as well as for evaluation of the disease activity of CPNB. Finally, it is also suggested that brainstem atrophy might progress due to CNS inflammation mediated by IL-6 during the early phase of CPNB.

The Clinical Course of the Acute Deep Vein Thrombosis of the Legs in Behçet's Syndrome. Yesim Ozguler[1], Melike Melikoglu[2], Firat Cetinkaya[3], Serdal Ugurlu[4], Emire Seyahi[5], Koray Tascilar[4] and Hasan Yazici[2]. [1]Istanbul University, Cerrahpasa Medical School, Rheumatology, Istanbul, Turkey, [2]Rheumatology, Istanbul, Turkey, [3]Istanbul, Turkey, [4]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey, [5]Cerrahpasa Faculty of Medicine, Istanbul University, İstanbul, Turkey

Background/Purpose: 15-50% of patients with Behçet's syndrome have vascular involvement (BS). Deep vein thrombosis is the most common form with lower extremity deep vein thrombosis (LEDVT) making up 70% of all vascular involvement. The aim of this study was to determine the clinical course of LEDVT about which there has been little data.

Methods: Consecutive BS patients attending our multidisciplinary BS outpatient clinic were included after an acute or subacute first episode of LEDVT in one leg. They might have had a previous episode of LEDVT in the contralateral extremity. The same radiologist performed a structured and detailed lower extremity Doppler ultrasonography (US). All deep veins, VCI and major superficial veins were examined at 1, 3, 6, 18 and 24 months after the index event. Nodular lesions that evolved during the follow-up were also examined for their US structure to differentiate between the presence of superficial vein thrombosis and erythema nodosum.

Results: Within a course of 20 months 31 patients (4F, 27M) with LEDVT in a previously uninvolved leg were seen and included in the study. 10 patients had had a previous episode of LEDVT in the opposite leg. Mean age was 29.5 ± 7, mean disease duration since disease onset was 49.5 ± 34.6, and the mean follow-up duration during the study was 13.4 ± 6.2 months. Veins involved in order of frequency were popliteal vein (42%), superficial femoral vein (31%), crural veins (29%) and common femoral vein (27%). VCI was involved in 3 (5%) patients. 14 patients (45%) relapsed during follow-up. 11 patients relapsed with a superficial thrombophlebitis and 5 patients relapsed with a new deep vein thrombosis. Mean time to relapse was 2.83 ± 1.99 months when the relapse was a superficial thrombophlebitis and 6.0 ± 2.3 months when the relapse was a LEDVT (P=0.001). Only 3 out of 19 patients who had a recanalization ($\geq$50%) at month 3 follow-up had a relapse. On the other hand, a relapse was observed in 11 of the 12 patients with poor recanalization(<50%) (P=0.001). All 3 patients with VCI involvement had venous skin ulcers in the lower extremity and these 3 patients were also the only patients with skin ulcers in the whole group. 17/31 (55%) patients developed nodular lesions during the study. 13/17 had had previous episodes of nodular lesions while in 4 patients these appeared for the first time. Doppler ultrasonographic examination of these nodules revealed superficial thrombophlebitis in 12 (70%) and like lesions in 5 patients (29%).

Conclusion: The more common vascular relapse after an episode of LEDVT is superficial thrombophlebitis. Relapses of a superficial thrombophlebitis occur earlier than relapses with a LEDVT. Poor recanalization of the index LEDVT at 3 months is associated with relapses. The presence of skin ulcers seems to go along with inferior vena caval thrombosis. As expected, LEDVT in BS is associated more with superficial thrombophlebitis than with erythema nodosum lesions.

Characteristics, Treatment and Outcome of Gastrointestinal Involvement in Behçet's Syndrome: Experience in A Dedicated Center. Ibrahim Hatemi[1], Gulen Hatemi[2], Yusuf Erzin[1], Aykut Ferhat Celik[1] and Hasan Yazici[3]. [1]Istanbul University, Cerrahpasa Medical School, Gastroenterology, Istanbul, Turkey, [2]Istanbul University, Cerrahpasa Medical Faculty, Rheumatology, Istanbul, Turkey, [3]Istanbul University, Cerrahpasa Medical School, Rheumatology, Istanbul, Turkey

Background/Purpose: Gastrointestinal involvement can be a severe complication resulting in perforation and massive bleeding. Controlled data regarding treatment is lacking and long term prognosis is not well known.

Methods: We retrospectively reviewed the charts of all BS patients evaluated with a suspicion of gastrointestinal involvement. We identified those with GIBS and surveyed their demographic features, other BS manifestations, clinical, endoscopic and histologic gastrointestinal findings, and treatment modalities. Patients were evaluated either in the outpatient clinic or if not possible by phone calls to assess their outcome.

Results: Among the 8058 recorded BS patients in our multidisciplinary outpatient clinic, 69 had symptoms suggesting gastrointestinal involvement and lesions on endoscopy. Among these, 18 patients had other reasons for their gastrointestinal symptomes and endoscopic lessions. The remaining 51 patients had GIBS (Table). The presenting symptoms were acute abdomen caused by perforations in 4/51 patients, massive bleeding in 8/51 patients and abdominal pain and/or diarrhea in 39/51 patients. Surgery had to be performed in 20/51 patients, and 4 of them had to be re-operated for development of stricture, progressive disease, relapse, and corrective surgery, 1 patient each. The most commonly used drugs for initial management were azathioprine 2–2.5 mg/kg/day (n=33) and 5 ASA compounds 3–4 g/day (n=13). Remission was observed and there were no relapses during a mean follow-up of 44.3±46.9 months in 22/33 (67%) patients who had initially been prescribed azathioprine (2.5 mg/kg) and during 45.0±50.1 months in 9/13 (68%) patients who had been prescribed 5 ASA compounds. Other than the 33 patients who used azathioprine as their initial treatment, remission was also obtained with azathioprine in 3/4 patients who were resistant to 5 ASA compounds. Among the 10 patients who had relatively severe symptoms and persistent large ulcers despite at least 6 months of azathioprine treatment, endoscopic and symptomatic remission could be obtained with thalidomide in 4 patients, infliximab in 4 patients and adalimumab in 2 patients. After a mean follow-up of 7.1±4.8 years (range 0.25–17 years), 42 (84%) patients were in remission and 14 (28%) of these were off treatment. Four (8%) patients were still active, 3 (6%) patients had died due to non-GI releated reasons and 2 (4%) were lost to follow-up. The reasons for death were pulmonary artery thrombosis, infection and acute renal failure due to amyloidosis in 1 patient each.

Patients with GI involvement of BS (n)	51
Men:women	27:24
Mean age ± SD (years)	38.5 ± 9.3
Mean age at diagnosis of GIBS ± SD (years)	31.2 ± 7.1
Oral ulcers	51/51
Genital ulcers	43/51 (86%)
Positive pathergy reaction	27/51 (54%)
Papulopustular lesions	34/51 (68%)
Erythema nodosum	24/51 (48)
Arthritis	17/51 (33%)
Uveitis	10/51 (20%)
Deep vein thrombosis	4/51 (8%)
Superficial thrombophlebitis	4/51 (8%)
Pulmonary artery thrombosis	1/51 (2%)
Neurologic parenchymal involvement	3/51 (6%)
Dural sinus thrombosis	3/51 (6%)
Ileocecal region involvement	20/51 (40%)
Colonic involvement	14/51 (28%)
Terminal ileum involvement	12/51 (24%)
Iliocolonic involvement	4/51 (8%)
Duodenal bulbus involvement	1/51 (2%)

Conclusion: 84% of patients with GIBS were in remission after a mean of 7 years of follow-up. Surgery was required in 40% of patients with GIBS. 5 ASA compounds or azathioprine provided remission and prevented relapses in two thirds of the patients. The latter was also beneficial in some patients resistant to 5 ASA compounds. Resistant and relapsing cases could be managed with thalidomide or TNF-alpha antagonists.

What Affects the Quality of Life in Patients with BEHCET'S Disease?
Mehmet Melikoglu[1] and Meltem Alkan Melikoglu[2]. [1]Health Ministry Erzurum Regional Training and Research Hospital, Erzurum, Turkey, [2]Ataturk University School of Medicine, Erzurum, Turkey

Background/Purpose: The aim of this study was to evaluate the possible associations between quality of life (QoL) and sociodemographic features, disease characteristics and the Behcet's Disease (BD) disease activity.

Methods: One hundred and seven patients with BD were included in this study. Sociodemographic features including age, gender, education level of the patients and the disease characteristics including disease duration, disease onset age, the history BD clinical involvements were recorded. In patients with BD, the BD Current Activity Form was used for the evaluation of disease activity. The short form-36 (SF-36) QoL scale was used to evaluate the QoL in patients with BD. The Student t test, analysis of variance and Spearman's correlation matrix were used for the statistical analysis.

Results: Men showed higher mean scores of role-physical and bodily pain domains of SF-36 than women did (p <0.000 and 0.001). Patients over 41 years of age had higher mean general health scores and university graduates had higher mean mental health scores than the other groups (p <0,01). Patients with a disease duration more than 5 years and patients have a younger disease onset age showed lower general health score than the others (p<0,01). Also patients with an anamnesis of uveitis, genital ulceration, erythema nodosum, thrombophlebitis, joint and gastrointestinal system involvement showed lower QoL than the patients without these complaints (p <0,05 and p <0,01). In the analysis of disease activity physical subscores of SF-36 were found to be correlated with fatigue, oral ulceration and joint involvement (p<0, 01). Bodily pain showed a correlation with fatigue, headache and more highly with joint involvement (p<0,01 and p<0,001 respectively). General health was correlated with GIS and eye involvement and vitality was found to be correlated with fatigue, patient's and doctor's impression of disease activity (p<0,01). Mental and emotional scores were correlated with oral- genital ulceration, eye and joint involvements (p<0,01).

Conclusion: In addition to demografic features and clinical involvements, BD disease activity can affect QoL in patients with BD. These results highlight the importance of managing the symptoms and the disease activity effectively in order to improve QoL in BD.

Behcet's Disease: Combination of Pulse Cyclophosphamide, Azathioprine, and Prednisolone for the Treatment of Retinal Vasculitis; Longitudinal Study On 10 Years.
Fereydoun Davatchi, Farhad Shahram, Bahar Sadeghi Abdollahi, Hormoz Shams, Abdolhadi Nadji, Massoomeh Akhlaghi, Tahereh Faezi and Farimah Ashofteh. Shariati Hospital-Tehran Univ, Tehran, Iran

Background/Purpose: Ocular lesions of Behcet's Disease (BD), need aggressive treatment to prevent severe loss of vision or blindness. Cytotoxic drugs are the main therapeutic agents and the first line treatment for it. Retinal vasculitis is the most aggressive lesion of ocular manifestations. It has the worse outcome. We present here the outcome with a combination of pulse cyclophosphamide, azathioprine, and prednisolone, on long-term usage up to 10 years on 291 patients (17286 eyes-months of follow-up).

Methods: Cyclophosphamide was used as one gram as monthly pulse for 6 months and then every 2 to 3 months as necessary. Azathioprine was used as 2 to 3 mg/kg/weight/daily. Prednisolone was associated as 0.5 mg/kg/ daily. Upon the suppression of the inflammatory reaction, prednisolone was tapered gradually. Inclusion Criteria: 1- Fulfilling the International criteria, the ICBD. 2- Having active posterior uveitis (PU) and/or retinal vasculitis (RV). Visual acuity (VA): was calculated by the Snellen chart on a scale of 10 (best vision 10/10). An activity index was calculated for PU and RV. A Total Adjusted Disease Activity Index (TADAI) was calculated for both eyes taking in account all parameters. Results were assessed at 3, 6, 9 months, then at 1, 1.5, 2, 2.5, 3, 4, 5, 6, 7, 8, 9, and 10 years.

Results: The mean improvement for Visual Acuity (p value) was: 0.9 (<0.001), 0.9 (<0.001), 0.9 (<0.001), 1.0 (<0.001), 0.8 (<0.001), 0.9 (<0.001), 0.9 (<0.001), 0.9 (<0.001), 1.1 (0.005), 0.1 (0.9), −0.5 (0.3), −0.5 (0.35), +2.0 (0.2), +2.9 (0.2), +0.3 (0.9). The mean improvement for Posterior Uveitis was: 1 (<0.001), 1.2 (<0.001), 1.5 (<0.001), 1.4 (<0.001), 1.4 (<0.001), 1.6 (<0.001), 1.6 (<0.001), 1.7 (<0.001), 1.9 (<0.001), 1.9 (<0.001), 1.9 (<0.001), 2 (<0.001), 2 (0.01), 2.8 (0.08), 1 (0.9). The mean improvement for Retinal Vasculitis was: 1.1 (<0.001), 1.7 (<0.001), 1.6 (<0.001), 1.6 (<0.001), 1.8 (<0.001), 1.7 (<0.001), 1.9 (<0.001), 1.8 (<0.001), 2.1 (<0.001), 2.2 (<0.001), 2.2 (<0.001), 1.8 (0.004), 6 (0.11), 4 (0), 2 (0). The mean improvement for TADAI was: 9.1 (<0.001), 11.7 (<0.001), 12.7 (<0.001), 11.9 (<0.001), 13 (<0.001), 13.8 (<0.001), 14.2 (<0.001), 14.6 (<0.001), 13.5 (<0.001), 16.3 (<0.001), 19.6 (<0.001), 17.1 (<0.001), 16.2 (0.6), 5.4 (0.2), 4 (0.6). Overall results (from baseline to the last evaluation): The mean VA improvement was 0.8 (<001), PU 1.4 (<0.001), RV 1.6 (<0.001), and TADAI 11 (<0.001). VA improved in 45.4% of eyes, PU in 75.6% of eyes, RV in 71.5% of eyes, and TADAI in 74.9% of patients. VA aggravated in 33% of eyes, PU in 14% of eyes, RV in 16.9% of eyes, and TADAI in 18.9% of patients. The remaining kept their baseline values.

Conclusion: All parameters improved significantly. The improvement in VA was the least. It was mainly due to cataract. The non-significance of p values in the last years of follow-up was due to the low number of patients.

Combination of pulse cyclophosphamide and azathioprine is the best treatment choice for retinal vasculitis before opting for biologic agents.

2377

Impaired Endothelial Function in Patients with Takayasu's Arteritis.
Fatma Alibaz-Oner[1], Selen Yurdakul[2], Yelda Tayyareci[2], Saide Aytekin[2] and Haner Direskeneli[1]. [1]Marmara University, School of Medicine, Istanbul, Turkey, [2]ISTANBUL FLORENCE NIGHTINGALE HOSPITAL, Istanbul, Turkey

Background/Purpose: Takayasu' s arteritis (TAK) is a chronic, inflammatory, large-vessel vasculitis. In the present study we aimed to evaluate vascular endothelial function in patients with TAK compared to systemic lupus erythematosus (SLE), another inflammatory, autoimmune disorder.

Methods: We studied 33 patients with TAK, 18 patients with SLE and 20, age and sex-matched healthy controls. Brachial artery Doppler ultrasonography (USG) and bilateral carotid artery intima-media thickness (CIMT) measurements were performed.

Results: Basal diameter and nitrate- induced dilatation (NID) values of the brachial artery were similar between the three groups. However, flow-mediated dilation (FMD) was markedly reduced in patients with TAK (Table 1). Carotid artery intima-media thickness (CIMT) was also significantly increased in TAK group, compared to the controls (0.11 ± 0.03 vs to 0.07 ± 0.009 cm, respectively, p=0.0001). Presence of hypertension had no association with FMD and CIMT measurements. In the SLE group, a marked impairment in FMD % was obtained (8.85 ± 2.8, p=0.0001). % NID and CIMT measurements was observed to be similar between the patients with SLE and the healthy controls (p=0.60 and p=0.05, respectively).

Table 1. Brachial artery Doppler ultrasonography measurements in patients with Takayasu's Arteritis and SLE as compared controls

	Basal diameter (cm)	FMD (%)	NID (%)
TAK patients (N=33)	0.28 ± 0.06	**6.96 ± 4.5***	16.28 ± 9.8
SLE patients(N=18)	0.29 ± 0.04	**8.85 ± 2.8****	15.67 ± 4.5
Controls (N=20)	0.29 ± 0.02	15.6 ± 2.2	16.07 ± 2.36

*P:0.0001, **P:0.0001
TAK: Takayasu' s arteritis, FMD: Flow mediated dilatation, NID: Nitrate induced dilatation.

Conclusion: In the present study, we detected significantly decreased FMD and increased CIMT in TAK patients, suggesting a marked endothelial dysfunction. Chronic inflammation and vascular fibrosis might lead to increased atherosclerosis in TAK.

2378

Evaluation of the EULAR/ACR 2012 Classification Criteria for Polymyalgia Rheumatica: Comparison of the New Algorithms with and without Ultrasound to the Formerly Used Criteria. Sandra Balser[1], Wolfgang Hartung[1], Emmanuelle LeBras[1], Boris P. Ehrenstein[1], Martina Müller[2] and Martin Fleck[1]. [1]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany, [2]University Clinic Regensburg, Regensburg

Background/Purpose: The purpose of this study was to compare the sensitivity of the algorithms with and without ultrasound of the EULAR/ACR 2012 Classification Criteria for Polymyalgia rheumatica (PMR) to the former criteria in a retrospective single center study.

Methods: All patients newly diagnosed with PMR at our tertiary rheumatology center between 01/2011 to 06/2012 were included in this retrospective study and analyzed whether the EULAR/ACR 2012 Classification Criteria for PMR with and without ultrasound as well as the formerly used PMR criteria (Bird & Wood's, Chuang & Hunder's, Healey's, Jones & Hazelman's) were fulfilled. All patients with suspected PMR underwent physical examination, questionaires, laboratory analysis, ultrasound examination of joints and an organ staging to exclude other conditions mimicking PMR (mostly laboratory analysis, chest X-ray and abdominal ultrasound examination).

Results: PMR was established as a new diagnosis by a rheumatologist of our center in 35 patients between 01/2011 to 06/2012. The average age was 66.4 +/- 8.8 (mean +/- standard-deviation) years. 60.0% of those 35 patients were female. The average ESR before treatment was 43.0 +/- 24.6 mm/1h, the average CRP 43.8 +/- 31.6 mg/l, the average duration of morning stiffness 88.7 +/- 59.0 min. 82.9 % had hip pain or limited range of motion, 91.4 % had normal values for RF and ACPA and 34.3 % had no other joint involvement. We found that the sensitivity of the EULAR/ACR 2012 classification criteria for PMR without ultrasound was 88.6 %, the sensitivity of the algorithm with ultrasound was 82.9 %. We did not detect any patient fulfilling the classification criteria with ultrasound but not the criteria without ultrasound. The sensitivity of the formerly used criteria was 82.9 % for Bird & Wood's, 40.0 % for Chuang & Hunder's, 77.1 % for Healey's and 82.9 % for Jones & Hazelman's criteria.

Conclusion: The results demonstrate a higher sensitivity of the novel EULAR/ACR criteria compared to the previous PMR classification criteria. However, ultrasound findings did not contribute to the higher sensitivity observed in our cohort of recent onset PMR patients.

Successful Treatment of Churg-Strauss Syndrome with Rituximab. Christin Dubrau[1], Fabian Arndt[2], Wolfgang L. Gross and Frank Moosig[2]. [1]University Hospital Schleswig-Holstein, Campus Luebeck and Klinikum Bad Bramstedt, Bad Bramstedt, Germany, [2]University Hospital Schleswig Holstein and Klinikum Bad Bramstedt, Bad Bramstedt, Germany

Background/Purpose: Rituximab has recently been shown to be equipotent to cyclophosphamide for induction of remission in generalized ANCA-associated vasculitis. A substantial number of observational pro- and retrospective studies also investigate the efficacy of RTX in refractory ANCA-assiciated vasculitis. However, there are only few data regarding the effectiveness of rituximab in Churg-Stauss syndrome.

Objective: To investigate the overall efficacy and safety of rituximab in Churg-Strauss syndrome at a tertiary vasculitis referral center.

Methods: This study represents a retrospective, standardized data collection from all Churg-Strauss syndrome patients treated with rituximab from 06/2007 to 06/2012. Patients were assessed in a standardized diagnostic procedure (ANCA, CRP, B cell levels, immunoglobulin levels, Eosinophil count, Birmingham Vasculitis Activity Score, glucocorticoid demand etc.) before and after receiving rituximab. After achieving complete remission or a response under rituximab, patients were switched on maintenance therapy with methotrexat or azathioprine or leflunomide.

Results: 11 patients were included in the study. Five were ANCA positive. Five were refractory tostandard cyclophophamide treatment, three were relapsers and three patients could not be treated with cyclophosphamide in order to preserve fertility (2) or because of hemorrhagic cystitis (1). Manifestations prior to rituximab were sinusitis (7), alveolitis (7), polyneuropathy/mononeuritis (4), myositis (2), glomerulonephritis (1), cardiac involvement (1), skleritis (1), gastrointestinal involvement (1), purpura (2) and arthritis (2). Eight patients had more than one manifestation before the start of RTX. The median BVAS was 7 (range 1–27).

Regarding overall efficacy eight patients had a response (1 remission, 7 response), one patient was refractory. In two patients follow-up was pending. Birmingham Vasculitis Activity Score version 3 (BVAS 3), glucocorticoid demand, Eosinophil count, CRP and immunoglobulin levels decreased in all patients (table 1). ANCA and peripheral blood lymphocyte counts became undetectable after rituximab treatment. After a median follow-up of eight months (1–54) there was no increase in disease activity. Three infections occurred during follow-up: one pneumonia, two bronchopulmonary infection.

Table 1.

	Before rituximab Median (range)	After rituximab Median (range)
BVAS 3	7 (1–27)	4 (1–8)
glucocorticoid demand (mg)	30 (5–80)	9 (4–12)
Eosinophil count (Eosinophils/μl)	300 (0–3300)	200 (0–1600)
CRP (mg/dl)	0,6 (0,1–5,5)	0,2 (0–8)
immunoglobulin G (g/l)	7,4 (0,3–11)	5,3 (5–7,7)

Conclusion: The overall response rate of Churg-Strauss syndrome to RTX was high (1 remission, 7 respond). There was no increase in disease activity in all patients until the end of follow-up.

2380

High Frequency of Ferritin Autoantibodies in Takayasu Arteritis.
Niklas T. Baerlecken[1], Katherina Große[2], Frank Moosig[3], Wolfgang L. Gross[4], Reinhold E. Schmidt[5] and Torsten Witte[6]. [1]MD, Hannover, Germany, [2]Student, Hannover, Germany, [3]Stormarnzing 156, Bad Bramstedt, Germany, [4]Medical University at Lubeck, Lubeck, Germany, [5]Hannover Medical School, Hannover, Germany, [6]Hannover Medical School, Hanover, Germany

Background/Purpose: Takayasu arteritis (TA) may be difficult to diagnose since diagnostic biomarkers have not been established so far. In a previous study, we could show the presence of autoantibodies against the human ferritin heavy chain protein (HFC) in sera of patients with giant cell arteritis (GCA) and/or polymyalgia rheumatica (PMR). Therefore, we studied the presence of autoantibodies against HFC in TA.

Methods: We established 7 ELISAs for the detection of autoantibodies against HFC. As autoantigen we used the full recombinant HFC expressed by E. coli or one of six different peptides of the HFC: 1–18Aa (purity 98.8%), 19–45Aa (purity 98.8%), 52–78Aa purity 98.3%), 79–104Aa (purity 98.8%), 105–143Aa (purity 98.4%), 145–183Aa (purity 98.5%). We collected sera of 43 patients with TA, 36 patients with systemic lupus erythematosus (SLE), 77 patients age >65yrs, 35 patients with arteriosclerosis, 118 sera of fever patients with underlying chronic infectious and malignant diseases, which are known for having unspecific autoantibodies, and 50 blood donors' sera served as controls.

Results: The best results were obtained by using ferritin pedtides as antigens. By combining different ELISAs detecting autoantibodies against HFC peptide 19–44A, 79–104A and 105–144A, we were able to detect ferritin peptide antibodies in 27/43 (63%) TA patients. For early TA, the frequency was lower than in early GCA and PMR (previous study up to 92%). In the controls, 0/100 (0%) of the *blood donors*, 10/36 (28%) of the patients with SLE, 7/77 (9%) of the patients with age >65yrs, 4/35 (11%) of the patients with arteriosclerosis and 24/118 (20%) of the fever patients were positive.

Conclusion: Considering the lack of biomarkers for TA, autoantibodies against peptides of HFC could be helpful as a marker for TA.

2381

Serum Level of IL-33 and Soluble ST2 and Their Association with Disease Activity in Patients with Behcet's Disease.
Dae-Jun Kim[1], Jae-Ho Lee[1], Ji Hyeon Ju[1], Sung-Hwan Park[2], Ho-Youn Kim[1] and Seung-Ki Kwok[1]. [1]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, South Korea, [2]Catholic University of Korea, Seoul, South Korea

Background/Purpose: Interleukin-33 (IL-33) is a new member of the IL-1 family of cytokines which signals via receptor, ST2(IL-33R), and has an important role in Neutrophil migrations, Th2 responses and mast cell responses. This study aims to measure the serum levels of IL-33 and soluble ST2 (sST2) in patients with Behcet's disease (BD) and to examine their association with disease activity.

Methods: Fifty three BD patients were evaluated for disease activity, determined by BDCAF, IBDDAM, ESR/CRP levels. IL-33 and sST2 were measured by sandwich ELISA in the 53 BD serum samples and compared with 31 age- and sex-matched healthy controls. The cutaneous expressions of IL-33 and sST2 in BD patients with erythema nodosum(EN) or EN-like lesion was compared with normal control skin tissues by immunohistochemical stains

Results: Serum IL-33 level was significantly higher in active BD patients [594.48 pg/ml] compared with normal controls [224.23 pg/ml] (P<0.05), and soluble ST2(sST2) level was also significantly higher in active BD patients [99.01 pg/ml] compared with normal controls [23.56 pg/ml]. The tissue expressions of IL-33 and sST2, shown by immunohistochemistry, were higher in BD compared with the controls. Serum sST2 level correlated significantly with BDCAF, IBDDAM, ESR and CRP. Multiple linear regression showed that both serum CRP and serum sST2 were independent

predictive factor for IBDDAM (regression coefficient: 0.519; P = 0.000, regression coefficient: 0.300; P = 0.016, respectively).

Conclusion: These results suggest that IL-33 and sST2 area increased in Behcet's disease and The level of sST2 are correlated with Behcet's disease activity index (IBDDAM) and acute phase reactant (ESR, CRP) and also a independent predictive factor of IBDDAM, suggesting a potential role of sST2 as a surrogate marker of disease activity of BD.

2382

Plasma Fibrinogen is an Accurate Marker of Disease Activity in Patients with Polymyalgia Rheumatica.
E.M. McCarthy[1], Paul A. MacMullan[1], S. Al-Mudhaffer[1], Anne M. Madigan[1], S. Donnelly[1], C. J. McCarthy[1], Dermot Kenny[2], Eamonn S. Molloy[3] and G M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland, [3]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Accurate determination of disease activity in polymyalgia rheumatica(PMR) is challenging due to the subjective nature of symptoms and concurrent musculoskeletal complaints in an elderly population.Any biomarker than assists physicians in more accurately determining patients disease state, thereby enabling safe adjustment of steroid dose would be welcomed. Previously we have demonstrated the enhanced specificity of plasma fibrinogen over both ESR and CRP for the detection of response to treatment in patients with active PMR. We sought to prospectively evaluate the utility of the biomarkers ESR, CRP and Fibrinogen for identifying different disease states in patients with known PMR.

Methods: Patients with PMR were divided into high/moderate disease activity(Group 1) or low disease activity(Group 2) according to the Polymyalgia Rheumatica Activity Score(PMR-AS) as per Bird and Leeb. PMR-AS =CRP(mg/dl)+ VAS pain(0–10 scale)+ VASphysician (0–10scale)+ Morning stiffness([min]x.1)+ Upper Limb Elevation(0–3 scale). A PMR-AS > 7 indicates medium/high disease activity with a PMR-AS < 7 indicating low disease activity. Plasma fibrinogen, CRP and ESR were also assayed. An ESR value of 30mm/hr(lab normal<20mm/hr) and CRP of 6mg/L (lab normal<5mg/l) were considered the upper limit for detection of low disease activity. The upper limit of the lab normal for Fibrinogen (4g/L) was used. Sensitivity, specificity, positive predictive values and likelihood ratios were calculated for all biomarkers.

Results: Data was available from 120 patient visits. Demographic data was similar in both groups. Mean age was 71.8 years. All patients were receiving glucocorticoids with a median steroid dose of 10mg in Group 1 and 5mg in Group 2.There were significant differences in steroid dose between the two groups(p<.001). 70 patients were defined as having low disease activity as per the PMR-AS. Of these 64/70 had a normal plasma fibrinogen with 56/70 having an ESR <30mm/hr and 45/70 a CRP < 6mg/L. Table 1 shows the specificity, sensitivity, positive predictive values and likelihood ratios for the biomarkers as calculated for all 120 patient visits.

	Specificity	Sensitivity	PPV	Likelihood Ratio	Fischers Exact Test
Fibrinogen	91%	52%	.81	6.06	P<.001
CRP	80%	90%	.66	2.68	P<.001
ESR	64%	50%	.64	2.5	P<.001

Overall plasma fibrinogen was more specific than either ESR or CRP for differentiating between low disease activity and moderate/high disease activity in PMR. It also demonstrated a better positive predictive value and likelihood ratio than the standard biomarkers ESR and CRP for identifying patients with moderate/high disease activity.

Conclusion: Plasma fibrinogen can aid treating physicians in determining disease activity in PMR. An elevated plasma fibrinogen level more accurately indicates that patients are in a moderate or highly active disease state than either the ESR or CRP alone. Measurement of fibrinogen as an adjunct to ESR and CRP in patients with PMR can help treating physicians more accurately identify patients' disease status and guide decisions with regards glucocorticoid dosage.

2383

Rituximab As Induction and Maintenance Therapies for ANCA-Associated Vasculitis: A Multicenter Retrospective Study On 80 Patients.

Pierre Charles[1], Antoine Néel[2], Nathalie Tieulié[3], Arnaud Hot Sr.[4], Grégory Pugnet[5], Olivier Decaux[6], Isabelle Marie[7], Mehdi Khellaf[8], Jean-Emmanuel Kahn[9], Alexandre Karras[10], Jean-Marc Ziza[11], Christophe Deligny[12], Colas Tchérakian[13] and Loic Guillevin[1]. [1]Department of Internal Medicine, Referral Center for Rare Autoimmune and Systemic Diseases, Hôpital Cochin, AP–HP, Université Paris Descartes, Paris, France, Paris, France, [2]Internal Medicine, Nantes University Hospital, Nantes, France, [3]Service de Médecine onterne, CHU Nice, Nice, France, [4]Lyon hospital, Lyon, France, [5]Toulouse University Hospital, University of Toulouse, INSERM UMR 1027, Toulouse, France, [6]Hôpital Sud, Rennes, France, [7]Service de médecine interne, CHU de Rouen, Rouen, France., Rouen, France, [8]Service de médecine interne, Université Paris Est Créteil, AP-HP, Hôpital Mondor Créteil, France, Creteil, France, [9]Internal Medicine, Foch Hospital, Suresnes, France, [10]Hôpital Européen Georges Pompidou, APHP, Paris, France, [11]Hopital Croix Saint Simon, Paris, France, [12]Centre hospitalier Universitaire de Fort de France, Fort de France, Martinique, [13]Service de pneumologie, hôpital Foch, Suresnes, France

Background/Purpose: Rituximab has been shown to induce remission of ANCA-associated vasculitis (AAV). Our study was undertaken to 1) describe the clinical response of AAV to rituximab used for remission-induction and/or maintenance therapy, 2) assess rituximab's safety profile, and 3) evaluate French clinical practices (choice of rituximab, modalities of its use and monitoring).

Methods: This retrospective cohort study concerned AAV patients who had received at least 1 rituximab infusion, between 2002 and January 2011, and all patients had at least 12 months of follow-up.

Results: Eighty patients were included, most had refractory or relapsing AAV: 70 (88%) had granulomatosis with polyangiitis (GPA), 9 (11%) had microscopic polyangiitis (MPA), 1 (1%) had eosinophilic granulomatosis with polyangiitis (EGPA). Rituximab was first prescribed to induce remission in 73 patients. The 2 most commonly administered regimens were: 1 infusion of 375 mg/m2/week for 4 weeks (55 patients) and 1 infusion of 1 g every 2 weeks for a month (17 patients). Rituximab was first prescribed to maintain remission in 7 patients, usually at a dose of 500 mg every 6 months. Relapse-free survival rates at 1, 2 and 3 years after the first rituximab infusion were, respectively, 80% (95% CI 72–89), 63% (95% CI 51–77) and 52% (95% CI 39–70). A trend towards rituximab superiority as maintenance therapy was observed: 9/45 (20%) patients given rituximab relapsed vs 7/14 (50%) prescribed various other therapies (p = 0.13). Twenty-two (27.5%) rituximab-treated patients experienced a severe adverse event. Among them, 12 (15%) had infectious complications leading to 4 (5%) deaths. Only 15 (19%) patients had received anti-pneumococcal vaccine before the first rituximab infusion.

Conclusion: Rituximab was able to induce AAV remission in already immunodepressed patients and seems to be superior to other therapies at maintaining remission. However, caution is needed concerning its safety, especially bacterial infections, in this immunosuppressant-treated population.

2384

Giant Cell Arteritis and Cardiovascular Events in the French Apogee Cohort. A Population-Based Study Using the French Health Insurance System Database.

Grégory Pugnet[1], Laurent Sailler[2], Robert Bourrel[3], Jean-Louis Montastruc[4] and Maryse Lapeyre-Mestre[4]. [1]Toulouse University Hospital, University of Toulouse, INSERM UMR 1027, Toulouse, France, [2]Toulouse University Hospital, University of Toulouse, INSERM UR 1027, Toulouse, France, [3]Caisse Nationale de l'Assurance Maladie échelon régional, Midi-Pyrénées, Toulouse, France, [4]Toulouse University Hospital, INSERM U1027, University of Toulouse, France, Toulouse, France

Background/Purpose: The risk of cardiovascular events (CVE) during giant cell arteritis (GCA) has rarely been quantified in population-based studies. Our objective was to quantify the risk of CVE during GCA in a population-based GCA cohort and to compare it to controls using the French Health Insurance system reimbursement database.

Methods: The APOGEE cohort includes most incident GCA patients of the Midi-Pyrénées County, south of France from January 2005 to December 2008. GCA patients are identified in the French Health Insurance System database by their international classification of diseases code, 10th version (M31.5: "GCA with polymyalgia rheumatica (PMR)" or M31.6: "GCA without PMR"). Incident cases are defined by a continuous glucocorticosteroids (GCs) course lasting for at least 6 months, and no previous exposure to GCs during the 6 preceding months. For each case two controls matched on gender and age were randomly selected in the FIHS database. The cardiovascular risk factors (CVRF) were identified through the exposure to drugs prescribed to treat diabetes mellitus, hypertension or dyslipidaemia CVE were cerebrovascular disease (CVD), coronary disease (CD), peripheral arterial disease (PAD) congestive heart failure and atrial fibrillation. New CVE were identified by analysing comprehensive data on drugs' reimbursement, diagnostic procedures, hospital stays and new cardiovascular diseases registered in the database. Serious CVE were defined as CVE leading to hospitalization > 24 hours or death. Follow-up ended in April 2011. We compared the occurrence of the first CVE in cases and controls by a log-rank test. The analysis was then stratified on exposure to statins or anti-platelets drugs (APD). We did not perform a multivariate analysis because of the limited number of events.

Results: The cohort included 103 patients (80 women (77.7%); mean age 74.8 ($\pm$9) years; mean follow-up 48.9 ($\pm$14.8) months). The mean initial GC dosage was 54 ($\pm$ 27) mg/d. At study entry, there was no difference between cases and controls for CVRF except for diabetes mellitus, which was more prevalent in controls (p<0.01). CVE all combined as well as serious CVE occurred more frequently in GCA patients (respectively, 33% vs. 19%, RR= 1.8 [1.25–2.53], p= 0.0011 and 15.5% vs. 7.8%, RR= 2.0 [1.15–3.49], p= 0.014). The mortality rate among GCA patients was not different from matched-controls (8/103 vs. 18/206, p> 0.05).

Conclusion: In the general population, the probabilities of first non-serious and serious CVE are significantly increased among incident GCA patients. Further studies are necessary to measure the protective effects of statins and anti-platelets drugs in these patients.

Prognostic Impact of *HLA-B* 51* and *HLA-A* 26:01* On Ocular Behcet's Disease.

Jun Won Park[1], Eun Ha Kang[2], Hye Won Kim[1], Chaerin Park[1], Hyeong Gon Yu[1], Eun Young Lee[1], Yun Jong Lee[2], Eun Bong Lee[1] and Yeong Wook Song[1]. [1]Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Bundang Hospital, Seongnam-si, South Korea

Background/Purpose: To investigate the prognostic implication of *HLA-B*51* and *HLA-A*26:01*on visual outcome in Korean Behcet's disease (BD) patients with uveitis.

Methods: Seventy-seven Korean BD patients with uveitis (F:M=29;48) who met the classification criteria by the International Study Group were enrolled. The presence of *HLA-B*51* was determined by polymerase chain reaction (PCR) using sequence specific primers. Genotyping for *HLA-A* locus was performed with PCR-Luminex typing method. Patient visual acuity (VA) was measured using Snellen chart at every visit to ophthalmology clinic. Loss of useful vision (LUV) was defined as VA worse than 20/200 for more than 6 months and near blindness (NB) was defined as VA of light perception or worse.

Results: The onset of uveitis was 36.6 $\pm$ 10.8 (mean $\pm$ standard deviation) years of age and the duration of uveitis was 10.8 $\pm$ 7.2 years. Posterior uveitis was found in 64.9% (50/77) of patients. Forty-seven (61.0%) patients were treated with one or more systemic immunosuppressants other than steroids; azathioprine (n=38), cyclosporine (n=24), methotrexate (n=7), mycophenolate mofetil (n=7), cyclophosphamide (n=6), tacrolimus (n=2), or anti-TNF-a agents (n=2). *HLA-B*51* was positive in 44.2% (34/77) while *HLA-A*26:01* in 18.2% (14/77) of patients. In multivariate analyses, LUV was associated with male gender (p=0.032), duration of uveitis (p = 0.016), and posterior uveitis (p=0.010). *HLA-A*26:01* was not directly associated with LUV but with posterior involvement (p<0.001). *HLA-B*51* did not show any significant associations with LUV or posterior involvement. NB was associated with duration of uveitis (p=0.022) and glaucoma (p=0.026) in multivariate analysis. When patients with posterior uveitis were analyzed, the single most important factor for LUV was duration of uveitis

(p=0.036) in multivariate analysis. NB in posterior uveitis patients was associated with the presence of *HLA-B[*]51* (p = 0.025 in univariate analysis, p=0.062 in multivariate analysis).

Conclusion: *HLA-A[*]26:01* was found to be associated with posterior involvement of uveitis in BD patients while *HLA-B[*]51* tended to be associated with NB in those who develop posterior uveitis.

2386

Disability and Mortality Related to Cerebrovascular Disease in Systemic Vasculitis. Jamal Mikdashi and Marcia Wozniak. University of Maryland School of Medicine, Baltimore, MD

Background/Purpose: Despite improved therapeutic strategies, patients with systemic vasculitis (SV) continue to experience serious morbidity and mortality from persistent low grade disease activity and permanent damage, particularly cardiovascular diseases. Nonetheless, the outcome of cerebrovascular disease (CVD) in patients with SV during the first-ever stroke remains unclear when compared to patient with other causes for their first-ever stroke. Purpose: To examine the clinical outcome related to CVD in SV, and determine whether disability and mortality are related to the disease itself, or associated comorbidities.

Methods: Disability and mortality were examined in 24 SV patients (large vessel vasculitis n = 8, medium vessel vasculitis n = 10, and small vessel vasculitis n = 6; with mean age of 55.7 years, 55% men) admitted to a tertiary care stroke center with validated first-ever stroke between January 2000 and January 2012. Disability rated according with modified Rankin Scale (mRS> 3), and mortality defined as all-cause fatal event were measured the day of first-ever stroke and at 90 days of follow up. Demographics and clinical manifestations were compared between those with SV and age- and gender –matched non SV controls with their first-ever stroke (n = 24) from the same tertiary stroke center. Significant variables in these analyses and the National Institute of Health Stroke Severity Scale (NIHSS) were entered into the multivariate analyses and Cox proportional hazards analyses to determine their contribution to disability and mortality related to CVD.

Results: Patients from the SV and non SV groups had comparable ethnic distribution, socioeconomic features, smoking, and their stroke type (ischemic, hemorrhagic) and Charlson comorbidity scores were similar. Disability was more frequent among SV patients as compared to controls (odds ratio= 4.2, 95% Confidence interval: 1.2–14.4, p value = 0.04). Within the SV patients 18 were disabled (mRS > 3), and 6 were not. Intractable disease activity and cumulative damage involving the pulmonary and renal organs were higher in disabled than the non disabled SV patients, although the difference was not statistically significant. Four patients died among SV group as compared to one patient among the controls. Death due to infection was more frequent among SV patients compared to controls (odds ratio = 2.0; 95% CI: 0.2–21.4, p value = 0.50).

Table 1. Proportional Cox hazard analyses of factors associated with disability related to first-ever CVD in patients with SV

Proportional Hazard Model

Factors	Hazard Ratio (95 % Confidence interval)
BVAS2	7.2 (1.1–47.9)
VDI	10.0 (1.4–69.3)
ANCA PR 3	0.7 (0.03–12.57)
ANCA MPO	5.0 (0.5–51.7)
C Reactive Protein	1.6 (0.4–11.1)
Long -term Prednisone use	8.5(1.3–54.9)

Birmingham Vasculitis Activity Score (BVAS2), Vasculitis Damage Index (VDI)

Conclusion: SV patients are at an increased risk for disability and mortality after the first –ever CVD event. Intractable disease activity, cumulative damage and long-term prednisone use are independently associated with disability related to CVD after adjustment for stroke severity. Death due to infection is frequent.

2387

Takayasu's Arteritis: Features and Management of 216 Patients in China. Xia Liu[1], Tao Zhang[2], Xiaofeng Zhuang[3], Kai Yuan[1], Xiaoming Shu[1] and Guochun Wang[1]. [1]China-Japan Friendship Hospital, Beijing, China, [2]Chinese PLA General Hospital, Beijing, China, [3]FuWai Hospital and Cardiovascular Institute, Beijing, China

Background/Purpose: Takayasu's arteritis (TA) is a rare vasculitis. Although it appears to be most common in Asia countries, research on Chinese TA patients with large sample size was still deficient in recent years. This study on Chinese TA patients aimed to not only evaluate demographic, clinical, laboratory, and radiological features but also the responses to treatments.

Methods: 216 patients in China diagnosed as TA between the year 2000 and 2011 were retrospectively evaluated.

Results: The mean age of all patients was 27 years (14–65) and 84.2% were female. Vascular bruit, headache, diminished or absent pulse, malaise, hypertension, and dizziness were presented in 75%, 60.2%, 56.5%, 51.9%, 49.5%, and 48.1% of the patients, respectively. The active TA patients had more frequent involvement of the fever, claudication, hypertension, retinopathy, dyslipidemia, and heart failure than did the inactive group. According to the angiographic findings, the distribution of all patients was as follows, 45.4% Type I, 14.4% Type IIa, 5.1% Type IIb, 2.3% Type III, 6.5% Type IV, and 26.4% Type V arteritis. Most patients (61.1%) were treated with pharmacotherapy, while the others received interventional therapy (26.4%) or surgical operation (12.5%). And in those patients treated by medicine, 76.7% showed effective improvement. Especially, in patients received prednisone joint with immunosuppressive agents, 84.2% responded well.

Table 1. Characteristics of TA patients

Characteristics	All patients n=216		Inactive patients n=53		Active patients n=163		p
Sex Female no. (%)	182	(84.2)	44	(83.0)	138	(84.6)

Anti-TNFα+MTX	1/132	(0.8)	1/1	(100)
Others	6/132	(4.5)	3/6	(50.0)
Total	132/132	(100)	101/132	(76.5)

Pred: prednisone, CTX:Cyclophosphamide, MTX:Methotrexate, HCQ:Hydroxychloroquine; AZA:Azathioprine, CysA:Cyclosporine-A, TGV:Thunder god vine

Conclusion: Our study indicated that TA could non-accidentally happen in people over 40 years old. It also revealed that, in all expressions, vascular symptoms occurred more frequently than systemic symptoms. Moreover, fever, claudication, hypertension, and retinopathy were more typical in active TA patients. When monitoring disease activity, erythrocyte sedimentation rate and C-reactive protein were useful. Most of our patients received medicine treatments after definite diagnosis. And the outcome revealed that glucocorticoids and immunosuppressive agents were notably effective.

Urticarial Vasculitis: Clinical Study. Javier Loricera[1], Vanesa Calvo-Rio[1], Francisco Ortiz Sanjuan[1], Marcos Antonio Gonzalez-Lopez[1], Hector Fernandez-Llaca[1], Javier Rueda-Gotor[1], Carmen Gonzalez-Vela[1], Cristina Mata-Arnaiz[2], Jose Luis Peña-Sagredo[1], Miguel A. Gonzalez-Gay[1] and Ricardo Blanco[1]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Laredo, Santander, Spain

Background/Purpose: Urticarial vasculitis is an infrequent subset of vasculitis described by McDuffy et al, in 1973, characterized clinically by urticarial skin lesions of more than 24 hours duration and histologically by vasculitis. Our aim was to evaluate the frequency, clinical and pathological features and treatment of UV from a large series of patients with cutaneous vasculitis.

Methods: Retrospective study of UV from a series of 877 patients with cutaneous vasculitis of a University Hospital. For the diagnosis of UV, besides urticarial lesions persisting more than 24 hours, a skin biopsy showing necrotizing vasculitis of small vessels was required.

Results: UV was observed in 19 (2.17%) of 877 patients with cutaneous vasculitis. There were 8 men and 11women, with a mean age of 33.21 ± 26.08 years. Precipitating factors and/or possible causes identified were upper respiratory tract infections (4 cases), drugs (4 cases), malignancy (megakaryocytic leukemia, 1 case) and 1 patient had a Schnitzler syndrome. Besides urticarial lesions, other features such as palpable purpura (7 patients), arthralgias (5 patients), arthritis (7 patients), abdominal pain (2 patients), and nephropathy (2 patients) were observed. Hypocomplementemia (low C4) was observed in 2 of the 19 patients. These patients also had low C1q. Other abnormal laboratory data

observed were increase of ESR (6 cases), leukocytosis (7 cases), anemia (4 cases), positive ANA (2 cases), and positive Rheumatoid Factor (1 case). Neither of the patients with positive ANA or Rheumatoid Factor developed systemic lupus erythematosus, rheumatoid arthritis or any other connective-tissue disease. The main histological findings were vascular and perivascular infiltration, endothelial swelling and fibrinoid necrosis. The cellular infiltrate was composed mainly of neutrophils, lymphocytes and eosinophils. The most common treatments were corticosteroids (10 cases), antihistaminic drugs (6 cases), chloroquine (4 cases), colchicine (2 cases) and NSAIDs (1 case). The patient with Schnitzler syndrome needed cytotoxic agents. After a mean follow-up of 16.68 ± 27.78 months (median 4 months) recurrences were observed in 4 patients. A patient died because of an underlying malignancy while the remaining had full recovery without complications.

Conclusion: UV is a rare subtype of cutaneous vasculitis. In addition to urticarial skin lesions, joint involvement was the most common clinical manifestation. Corticosteroids and antihistaminic drugs are the drugs more commonly used. The prognosis depends on the underlying disease but is usually good.

Cutaneous Leukocytoclastic Angiitis: Study of 173 Patients. Javier Loricera, Vanesa Calvo-Rio, Francisco Ortiz-Sanjuan, Marcos Antonio Gonzalez-Lopez, Hector Fernandez-Llaca, Javier Rueda-Gotor, Carmen Gonzalez-Vela, Miguel A. Gonzalez-Gay and Ricardo Blanco. Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain

Background/Purpose: Cutaneous leukocytoclastic angiitis (CLA) was defined by the International Consensus Conference for the Nomenclature of the Vasculitis (Chapel Hill, A&R 1994) as an isolated cutaneous vasculitis without systemic vasculitis or glomerulonephritis. Our objective was to evaluate the clinical features, treatment and outcome of patients with CLA.

Methods: From a large series of patients with cutaneous vasculitis those diagnosed as having cutaneous vasculitis in the setting of connective tissue diseases, malignancies, infections, primary systemic necrotizing vasculitis and other entities such as Henoch-Schönlein Purpura and Essential Mixed Cryoglobulinemia were excluded from this analysis. Patients with systemic involvement including gastro-intestinal or renal involvement (glomerulonephritis) were also excluded. The remaining patients were classified as having CLA.

Results: According to the above mentioned methodology, 173 patients (91 men and 82 women), with a mean age of 46.29 ± 24.37 years (range, 1 to 95 years) were diagnosed as having CLA.

Precipitating events were found in 146 (84.39%) patients. A history of drug intake before the onset of the vasculitis was found in 82 (47.40%) patients and a previous history of upper respiratory tract infection in 48 (27.74%) patients. The most frequent drugs taken shortly before the onset of the cutaneous vasculitis were Beta-lactam antibiotics (38 cases), NSAIDS (20 cases) and diuretics (8 cases). The most frequent clinical manifestations were cutaneous (100%), joint manifestations (41.51%) and fever (17.92%). The main laboratory data were elevated ESR (46.82%), leukocytosis (28.90%), anemia (10.98%), positive Rheumatoid Factor (13.87%), positive ANA (16.18%), hypocomplementemia (C3 and/or C4) (2.89%), cryoglobulins (2.31%) and positive ANCA (0.58%).

Treatment included NSAIDS (17.34%), Corticosteroids (16.18%), Colchicine (2.89%) and Azathioprine (1.73%). After a mean follow-up of 12.42 ± 30.31 months (median, 3 months), relapses were observed in 19.65% of patients.

Conclusion: CLA is usually a benign syndrome, often secondary to drugs or infections, or both. Its main clinical features are skin and joint manifestations. Its prognosis is very good.

2390

Color Doppler Ultrasonography an Alternative to CT/MR Angiography for Identifying Large Vessel Involvement in Giant Cell Arteritis? Andreas P. Diamantopoulos[1], Glenn Haugeberg[1] and Geirmund Myklebust[2]. [1]Hospital of Southern Norway HF, Kristiansand, Norway, [2]Hospital of Southern Norway, Kristiansand, Norway

Background/Purpose: Large vessel involvement has been reported to be present in 20–50% of patients with giant cell arteritis (GCA). Computed tomography (CT) and magnetic resonance (MR) angiography are used for assessment of large vessel involvement in patients with GCA. Our aim was to compare color Doppler ultrasonography (CDUS) to CT/ MR angiography for identifying large vessel involvement in patients with GCA at the time of initial evaluation.

Methods: Consecutive GCA patients with large vessel involvement assessed by CDUS underwent CT/MR angiography between January 2010 and May 2012. The aorta and supraaortic vessels were assessed by CT/MR angiography, while the carotid and axillary arteries were assessed by CDUS. The patients were diagnosed by CDUS with large vessel vasculitis (LVV) when intima-media complex thickness was homogenous and more than 1.5 mm in the carotid artery and more than 1 mm in the axillary artery.

Results: A total of 13 GCA patients (7 females, 6 males, mean age 70 years) were identified with LVV using CDUS. In these 13 patients aortic involvement was observed in 5 patients (38%) by CT/MR angiography. In all of these 5 patients, involvement of axillary arteries (4 patients) or carotid arteries (3 patients) were found by CDUS. In the other 8 patients axillary arteritis was visible on CDUS whereas only 2 these patients revealed large vessel vasculitis on CT/MR. Interestingly, inflammation in large vessels was retrospectively identified by CT/MR angiography in 6 of 13 patients and this after reevaluating the images after the positive CDUS examination.

Conclusion: CDUS seems to be a valuable tool for assessment of large vessel vasculitis. The data from our pilot study suggest that CDUS is comparable and even better than CT/MR angiography to detect large vessel involvement in GCA. In the future CDUS may become the gold standard for first line evaluation of large vessel involvement. However further validation of the method is warranted.

New Disease Manifestations After Diagnosis in Six Types of Vasculitis. Peter C. Grayson[1], David Cuthbertson[2], Simon Carette[3], Gary S. Hoffman[4], Nader A. Khalidi[5], Curry L. Koening[6], Carol A. Langford[4], Kathleen Maksimowicz-McKinnon[7], Paul A. Monach[8], Philip Seo[9], Ulrich Specks[10], Steven R. Ytterberg[10] and Peter A. Merkel[11]. [1]Boston University Medical Center, Boston, MA, [2]University of South Florida, Tampa, FL, [3]UHN/MSH, Toronto, ON, [4]Cleveland Clinic, Cleveland, OH, [5]McMaster University, Hamilton, ON, [6]Salt Lake City Veterans Administration, Salt Lake City, UT, [7]University of Pittsburgh, Pittsburgh, PA, [8]Boston University, Boston, MA, [9]Johns Hopkins Vasculitis Center, Baltimore, MD, [10]Mayo Clinic, Rochester, MN, [11]University of Pennsylvania, Philadelphia, PA

Background/Purpose: The proportion of patients who experience new manifestations of vasculitis after diagnosis is unknown. Our objectives were to quantify the occurrence of new features of vasculitis after diagnosis in 6 types of vasculitis and to compare patterns of disease activity over time.

Methods: Standardized data collection on 98 disease manifestations in 6 vasculitides, including granulomatosis with polyangiitis (Wegener's, GPA), microscopic polyangiitis (MPA), Churg-Strauss syndrome (CSS), polyarteritis nodosa (PAN), giant cell arteritis (GCA), and Takayasu's arteritis (TAK), was performed within a set of multicenter, longitudinal cohorts. For each form of vasculitis, the frequency of disease-specific manifestations at diagnosis was compared to the cumulative frequency of each manifestation. The percentage of patients who developed new "severe" manifestations after diagnosis, defined as organ-threatening or life-threatening in the small and medium vessel vasculitides and as ischemic/vascular in the large vessel vasculitides, was described.

Results: The number of patients and median length of follow-up (years) for the vasculitides was: GPA 341, 7.2; MPA 26, 3.7; CSS 117, 5.1; PAN 55, 4.3; GCA 191, 2.8; TAK 132, 6.8. On average, patients with vasculitis experienced 1.3 new disease manifestations after diagnosis (GPA - 1.9, MPA - 1.2, CSS - 1.5, PAN - 1.2, GCA - 0.7, TAK - 1.0). Depending on the type of vasculitis, at least 1 new disease manifestation occurred after diagnosis in

44%–69% of patients **(Figure)**, most notably in GPA and CSS. A subset of patients (7–28%) with each type of vasculitis experienced ≥ 3 new manifestations after diagnosis. The 3 most frequent new manifestations after diagnosis for each type of vasculitis are listed in the **Table**. New severe manifestations occurred after diagnosis in GPA - 30%, MPA - 27%, CSS - 23%, PAN - 29%, GCA - 26%, and TAK - 45%. Mean time from diagnosis to initial flare in disease activity did not significantly differ among those who experienced a new manifestation versus a recurrence of prior disease (1.15 vs 1.18 years, p=0.8).

Frequency of New Manifestations After Diagnosis
Three Most Frequent New Manifestations After Diagnosis

Type of Vasculitis	New Manifestation
Granulomatosis with polyangiitis (Wegener's)	Arthralgias (11%)
	Rhinitis (9%)
	Glomerular disease (9%)
Microscopic polyangiitis	Venous thromboembolic event (12%)
	Glomerular disease (11%)
	Arthalgias (8%)
Churg-Strauss syndrome	Nasal polyp (10%)
	Eosinophilic pulmonary infiltrate (9%)
	Purpura (8%)
Polyarteritis nodosa	Motor mononeuritis multiplex (12%)
	Arthralgias (12%)
	Venous thromboembolic event (10%)
Giant cell arteritis	Polymyalgia rheumatica (11%)
	Headache (7%)
	Arthralgias (7%)
Takayasu's arteritis	Upper extremity claudication (14%)
	Lightheadedness (8%)
	Carotidynia (7%)

Conclusion: A majority of patients with vasculitis develop new features of disease after diagnosis, including a substantial number of new, severe manifestations. New manifestations after diagnosis, although more frequent among the small-vessel vasculitides, are also common in patients with medium- or large-vessel vasculitis. Patterns of disease recurrence after diagnosis are not related to disease duration. Ongoing clinical assessment of patients with all types of established vasculitis should remain broad in scope.

2392

Blood Vessel Instability and Oxidative Damage in Giant Cell Arteritis. Danielle Molloy[1], Jennifer McCormick[1], Mary Connolly[1], Muhammad Haroon[1], Douglas J. Veale[1], Conor Murphy[2], Ursula Fearon[1] and Eamonn S. Molloy[1]. [1]Dublin Academic Medical Center, St. Vincent's University Hospital, Dublin, Ireland, [2]Royal Victoria Eye and Ear Hospital, Dublin, Ireland

Background/Purpose: Giant cell arteritis (GCA) is the most common form of primary vasculitis. The pathogenesis is incompletely understood, but involves neoangiogenesis and inflammatory infiltration of the arterial wall. The aim of the present study was to assess blood vessel stability and oxidative damage in patients with the condition and correlate with disease activity.

Methods: 20 patients with a clinical diagnosis of GCA were included, 16 of whom had a positive temporal artery biopsy. Temporal artery (TA) sections were assessed for blood vessel maturity (%BVM) by dual-immunofluorescent staining for Factor VIII/αSMA. Oxidative DNA damage (8-oxo-7,8-dihydro-2′-deoxyguanosine; 8-oxo-dG), lipid peroxidation (4-hydroxy-2-nonenal; 4-HNE), angiogenic growth factor Angiopoietin 2 (Ang2) and it receptor Tie-2 were assessed by immunohistochemistry. *Ex vivo* TA explant cultures were established directly from fresh biopsy specimens (n=4) and spontaneous release of pro-angiogenic factors were examined by ELISA and gelatine zymography. Patients were categorised into low disease (CRP<50) vs high disease activity (CRP>50).

Results: Strong expression of 8-oxo-dG, 4HNE, Ang2 and Tie2 were demonstrated in the adventitial and intimal regions. 8-oxo-dG and 4HNE correlated with disease activity marker ESR (r=.568, p<0.017: r=.451, p<0.05 respectively). Expression of 8-oxodG significantly correlated with Tie2 (r=0.538, p<0.017) and that of 4HNE significantly correlated with Ang2 (r=0.0529, p<0.02). A mixture of immature and mature blood vessels was demonstrated in all GCA patients, with a lower number of vessels expressing α-SMA in patients with high disease activity (41% ± 13.4) compared to low disease activity (66% ± 8.2) suggesting a more unstable vascular microenvironment is associated with high disease activity. This was further supported when we demonstrated spontaneous release of pro-inflammatory mediators Ang2, MMP-2, MMP-9, IL-6 and IL-8 from *ex vivo* TA explants in culture. Furthermore conditioned media from TA explants significantly induced angiogenic tube formation (p<0.05).

Conclusion: This is the first study directly demonstrating that vessels in the inflamed temporal arteries from patients with GCA are unstable and are associated with incomplete EC/pericyte interactions, expression of Ang2 and oxidative damage markers.

High Mobility Group Box 1 Levels Are Not Associated with Subclinical Carotid Atherosclerosis in Patients with Granulomatosis with Polyangiitis but Are Reduced by Glucocorticoids and Statins. Alexandre Wagner S. de Souza[1], Karina de Leeuw[1], Johanna Westra[2], Andries J. Smit[1], Anne Marijn van der Graaf[2], Hans L. A. Nienhuis[1], Johan Bijzet[1], Pieter C. Limburg[2], Coen A. Stegeman[2], Marc Bijl[3] and Cees G.M. Kallenberg[2]. [1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands, [3]Martini Hospital, Groningen, Netherlands

Background/Purpose: High mobility group box 1 (HMGB1) is a non-histone DNA binding protein that is passively released by dying cells or actively secreted by immunocompetent cells and the receptor for advanced glycation end-products (RAGE) is one of its receptors. Higher levels of HMGB1 have been found in patients with granulomatosis with polyangiitis (GPA) with active disease whereas higher HMGB1 and lower soluble (sRAGE) levels have been found in patients with acute atherosclerotic events suggesting sRAGE acts as a decoy receptor. This study aims to evaluate HMGB1 levels in relation to subclinical carotid atherosclerosis in GPA, and the impact of therapy on HMGB1 levels.

Methods: A cross-sectional study was performed on 23 GPA patients during a quiescent phase of the disease in comparison to 20 matched controls. All study participants underwent carotid ultrasound to assess atherosclerotic plaques and intima-media thickness (IMT) and were tested for traditional risk factors for atherosclerosis, serum HMGB1 levels (ELISA–Shino Test, Kanagawa, Japan), and sRAGE levels (ELISA R&D Systems, Minneapolis, Minnesota, USA).

Results: GPA patients and controls had similar mean levels of total cholesterol (4.99±0.78 vs. 4.98±0.82 mmol/L; $P = 0.978$), HDL-cholesterol (1.41 ± 0.37 vs. 1.51±0.33 mmol/L; $P = 0.359$), LDL-cholesterol (3.01±0.79 vs. 3.29±0.82 mmol/L; $P = 0.267$), and a similar frequency of smoking (8.7% vs. 5.0%; $P = 0.635$), family history of premature coronary artery disease (CAD) (39.1% vs. 40.0%; $P = 0.954$), and obesity (4.3% vs. 10.0%; $P = 0.446$). Hypertension was only found in GPA patients (39.1% vs. 0.0%; $P = 0.002$) while no study participants

had diabetes. Overt cardiovascular disease was found only in 13.0% of GPA patients. Statins were prescribed for 21.7% of GPA patients and 5.0% of controls ($P = 0.127$). Among GPA patients, prednisolone was being used by 34.8% with a median daily dose of 5.0mg (2.5–15.0) and azathioprine by 34.8%. Only two GPA patients used statins and prednisolone concomitantly. Carotid plaques were found in 30.4% of GPA patients and in 15.0% of controls ($P = 0.203$) and the overall IMT was similar in GPA patients and in controls (0.833±0.256 vs. 0.765±0.133mm; $P = 0.861$). Median serum HMGB1 levels were similar between GPA patients and controls [2.13ng/mL (1.11–7.22) vs. 2.42ng/mL (0.38–6.75); $P = 0.827$] as well as mean sRAGE levels (1256.1±559.6 vs. 1483.3±399.8pg/mL; $P = 0.155$). No correlations were found between HMGB1 and sRAGE ($\rho = 0.068$; $P = 0.681$) and between HMGB1 and maximum IMT in carotid arteries ($\rho = -0.067$; $P = 0.720$). GPA patients on prednisolone (1.77±0.76 vs. 3.53±2.06ng/mL; P = 0.017) and statins (1.39±0.28 vs. 3.34±1.94ng/mL; $P = 0.001$) presented significantly lower serum HMGB1 levels whereas no difference in mean HMGB1 levels was found regarding azathioprine use (2.89±2.28 vs. 2.93±1.75; $P = 0.970$).

Conclusion: No association was found between subclinical atherosclerosis in carotid arteries and HMGB1 levels in GPA patients. Furthermore, the use of either prednisone or statins was associated with lower HMGB1 levels in GPA patients. These findings suggest that the anti-inflammatory properties of statins include effects on serum HMGB1 levels in GPA.

2394

Fibromyalgia in Behçet's Disease Is Associated with Disease Activity. Meryem Can[1], Fatma Alibaz-Öner[2], Sibel Yılmaz-Öner[1], Birkan İlhan[1], Tülin Ergun[1], Gonca Mumcu[3] and Haner Direskeneli[1]. [1]Marmara University School of Medicine, Istanbul, Turkey, [2]Marmara University School of Medicine, Turkey, [3]Marmara University,Faculty of Health Sciences, Department of Health Informatics and Technologies, Istanbul, Turkey

Background/Purpose: Studies on the relationship between Fibromyalgia (FM), a generalized pain disorder with up to 2% prevalence and Behcet's Disease (BD), a systemic, inflammatory vasculitis, is limited. We conducted the present study to assess the prevalance of FM in BD diagnosed according to 2010 American College of Rheumatology (ACR) criteria and to evaluate the association of FM with disease activity, disability, depression, anxiety and quality of life (QoL) in BD patients.

Methods: One hundred-two patients followed as BD (F/M:56/46, mean age: 40.4 years) fullfilling the International Study Group Criteria (ISG,1990), 85 patients with systemic lupus erythematosus (SLE) (F/M:81/4, mean age: 41.4 years) and 51 healthy controls (HC) (F/M: 30/21, mean age: 40.9 years) were enrolled to the study. All patients were examined for FM tender points (according to ACR 1990 criteria for the classification of FM) by two observers (kappa=0.8) and asked to complete new ACR 2010 FM questionnaire for FM (ref1). The clinical activity score in BD was determined by Behcet's Syndrome Activity Scale (BSAS) and SLE by SLEDAI. *SF-36* and hospital anxiety and depression scales were also used to assess QoL together with health assessment questionnaire (HAQ).

Results: Twenty-four (23.5%) BD patients met the ACR 2010 criteria for FM, compared to 18 (21.2%) in SLE and 5 (9.8%) in HC (p=0.1). When we analysed according to 1990 ACR FM criteria, 13(12.7%) in BD group, 6 (7.1%) in SLE and one (2.7%) in HC were classified as FM.

BSAS score correlated with FM (r=0.5, p=0.002), whereas FM and SLEDAI had no correlation (r=0.2,p=0.1). While mean anxiety scores were similar between groups (7.1±4.3, 7.01±4.3 and 5.8±4.6 in BD, SLE and HC, respectively)(p>0.05), mean depression scores were significantly different (5.8±3.4, 6.4±4.8 and 3.9±3.5 in BD, SLE and HC respectively)(p>0.05) between the groups. When anxiety and depression scores were analyzed as possible contibuting factors for FM presence, correlation was observed between anxiety and depression scores with FM (r=0.3, p=0.002 vs r=0.3, p=0.002, respectively) in BD.

Mean SF-36 physical component scores (PCS) were observed significantly lower in BD and SLE patients [41.7(11.3), 41.6(12.2) and 49.9(8.5) in BD, SLE and HC, respectively] (p<0.01). Also, SF36-mental components (MCS) were different between BD and HC groups [42.3(9.8), 46.6(10.3) in

BD and HC, respectively] (p=0.05). There were negative correlations between SF36 –PCS and -MCS with FM (r=−0.4 and r=−0.1).

BSAS score (median) was 20 (0–79) in BD and %53.2 (n=50) of the BD group had a mucocutaneous and %46.8 (n=44) had major disease. The presence of FM did not differ significantly between the patients with mucocutenous and major organ involvement (p=0.6). No significant difference were also observed between SF36 parameters, HAQ scores, BSAS score and anxiety-depression scores between the two subsets.

Conclusion: Fibromyalgia, with new diagnostic criteria, seem to be more prevalent in BD compared to previous studies. Association of BSAS and SF-36 with FM in our study group suggests that disease activity and QoL status seems to influence FM presence in BD.

2395

Body Composition, Strength, and Function in Elderly Patients with Giant Cell Arteritis. Rebecca L. Manno[1], Allan C. Gelber[1], Philip Seo[2], Stuart M. Levine[1], Sharon R. Ghazarian[3], Po-Han Chen[3], Kerry J. Stewart[1], Jeffrey Metter[4], Luigi Ferrucci[4] and Kevin R. Fontaine[5]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Vasculitis Center, Baltimore, MD, [3]Baltimore, MD, [4]National Institute on Aging, Baltimore, MD, [5]The University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Loss of muscle and strength typically occur with advanced age. Chronic inflammatory diseases, such as rheumatoid arthritis, have reported similar deficits. Giant cell arteritis (GCA) is an inflammatory systemic vasculitis that occurs almost exclusively in the elderly. We sought to determine the body composition, strength, and functional disability in a cross-sectional sample of GCA patients (pts) and compare these parameters to age-matched community dwelling non-GCA controls.

Methods: Pts were recruited from a tertiary academic center. Body composition was evaluated by dual energy x-ray absorptiometry (DEXA, GE Lunar Prodigy Software V13); strength was assessed by hand grip dynamometry and lower extremity isokinetic testing (Biodex System 3 dynamometer); and functional disability by the short physical performance battery (SPPB). The SPPB includes: chair stands, semitandem, tandem, one-leg stand, and gait speed (6 meter walk). GCA pts were matched (1:2 ratio) by age (within 1 year), gender, and race to eligible controls randomly selected from the Baltimore Longitudinal Study of Aging (BLSA). The BLSA prospectively follows a cohort of healthy volunteers who undergo comprehensive evaluation every 1–2 years. Continuous and categorical variables were compared using student's t-test and chi-square analyses respectively.

Results: GCA pts (N=18) had a mean ± SD age of 74 ± 7 yrs (range 59–86). They were mostly female (83%), white (83%) and had a positive temporal artery biopsy (89%). Mean disease duration was 2.7 ± 4.1 yrs (range 0.1–16); 7 (39%) were diagnosed >2 years prior to their study visit. Most (78%) were on daily prednisone (11 ± 13 mg/d) with a mean duration of steroid exposure at the study visit of 11 ± 13 months. GCA pts were significantly weaker on all measures of strength compared to BLSA controls (Table 1). GCA pts also had marked slowness as indicated by longer time to complete chair stands and slower gait speed. Body composition was similar between the two groups without a corresponding decrease in lean mass among the GCA group despite their decreased strength.

Table 1.

	GCA N=18	BLSA N=36	p-value
Age, mean ± SD (years)	75 ± 7	74 ± 7	0.672
Gender (% women)	83	78	0.633
Race (% Caucasian)	83	83	1.000
Strength Measures			
Grip strength (kg)	21 ± 6	27 ± 9	0.015
Leg extension 180d/s peak torque (Nm)			
Left quadriceps	46 ± 17	89 ± 2 (n=23)	<0.001
Right quadriceps	49 ± 20	69 ± 16 (n=31)	0.001
Leg flexion 180d/s peak torque (Nm)			
Left hamstrings	21 ± 10	66 ± 22 (n=23)	<0.001
Right hamstrings	23 ± 10	49 ± 15 (n=31)	<0.001
Functional Measures (Short Physical Performance Battery)			
Completes 10 chair stands (%)	83	94	0.184
Time to complete (seconds)	32 ± 8	23 ± 5	<0.001
Holds semi tandem stand 30 seconds (%)	94	97	0.610
Holds tandem stand 30 seconds (%)	83	83	0.149
Holds one leg stand 30 seconds (%)	17	100	<0.001
Gait Speed (m/s)	0.86	1.06	0.005
Body Composition by DEXA			
BMI (kg/m²)	28 ± 6	25 ± 4	0.079
Bilateral arms			
Total fat mass (g)	3177 ± 1155	2559 ± 989	0.046
Total lean mass (g)	4262 ± 1070	4337 ± 1315	0.836
Bilateral legs			
Total fat mass (g)	10334 ± 4352	8965 ± 3830	0.242
Total lean mass (g)	13141 ± 2853	13600 ± 3242	0.538
Trunk			
Total fat mass (g)	16360 ± 3834	13603 ± 5915	0.079
Total lean mass (g)	19235 ± 2533	20889 ± 4311	0.140
Total Body			
Total fat mass (g)	30915 ± 8614	25942 ± 9772	0.073
Total lean mass (g)	39995 ± 6065	42216 ± 8898	0.346

Conclusion: GCA pts in this small cross-sectional study were significantly weaker and slower than age-matched controls in the absence of significant differences in body composition. Slow gait speed (<0.8 m/s) is associated with disability, morbidity, and mortality among elderly adults. The preservation of lean mass in elderly GCA pts, in the presence of clinically significant weakness, suggests that impairment/dysfunction in muscle quality rather than muscle quantity may be the culprit. Prednisone use may be a significant contributor to weakness and slowness in elderly GCA pts. However, prednisone is unavoidable in the treatment of this potentially catastrophic illness and future investigation should focus on methods to improve strength and function in GCA pts regardless of their need for steroid therapy.

2396

Higher Homocysteine Levels Are Associated with Ischemic Arterial Events Rather Than Disease Activity and the Extension of Arterial Involvement in Takayasu Arteritis. Alexandre W.S. Souza[1], Carla S. Lima[2], Ana Cecilia D. Oliveira[3], Luiz Samuel G. Machado[3], Frederico A. G. Pinheiro[3], Sonia Hix[4] and Vânia D'Almeida[5]. [1]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina - Universidade Federal de São Paulo, São Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil, [4]Universidade Federal de São Paulo - Escola Paulista de Medicina, São Paulo, Brazil, [5]Universidade Federal de São Paulo- Escola Paulista de Medicina, São Paulo, Brazil

Background/Purpose: High plasma homocysteine is an independent risk factor for arterial ischemic events. The objective of this study is to evaluate plasma homocysteine levels in patients with Takayasu arteritis (TA) and in controls, and to analyze the association between homocysteine levels and paraoxonase 1 (PON1) activity, methotrexate and folate use, disease activity, extension of arterial involvement and with ischemic arterial events in TA.

Methods: A cross-sectional study was performed with 29 TA patients and 30 control subjects. Plasma homocysteine levels were determined by high performance liquid chromatography using fluorimetric detection and isocratic elution. PON1 activity was evaluated by spectrophotometry using paraoxon as substrate with 1M sodium chloride. Disease activity was ascertained by the National Institutes of Healthy criteria and the extension of arterial involvement by the angiographic classification of the International TA conference in Tokyo 1994.

Results: Active disease was observed in 9 (31.0%) and previous arterial ischemic events in 10 (34.5%) TA patients. Nine (31.0%) TA patients were on methotrexate therapy with a mean dose of 20.5 ± 3.9 mg/week and it was associated to folic acid in 8 cases. Median homocysteine levels were significantly higher in TA patients in comparison to control subjects [10.9 (8.5–24.7) vs. 6.9 μmol/L (2.8–15.1); $P < 0.001$]. TA patients with active

disease presented lower homocysteine (10.4 ± 2.1 vs. 13.1 ± 4.2 μmol/L; $P = 0.034$) when compared to patients in remission. Median homocysteine levels were higher in patients with previous ischemic events [13.2 (9.6–24.4) vs. 9.8 (8.5–17.9) μmol/L; $P = 0.027$]. In a multivariate model that included age, disease duration and homocysteine levels, age (OR: 1.13; 95% CI: 1.01–1.25; $P = 0.022$) and 1 μmol/L increase in homocysteine plasma levels (OR: 1.31; 95% CI: 1.01–1.71; $P = 0.041$) were independently associated with ischemic events in TA. Mean homocysteine levels were similar in TA patients on methotrexate and in those being treated with other immunosuppressive agents (12.8 ± 5.3 vs. 12.1 ± 3.2 μmol/L; $P = 0.662$) and regarding the extension of arterial involvement, no differences in homocysteine levels were found in TA patients with angiographic type V in comparison to other angiographic types (12.7 ± 4.2 vs. 11.0 ± 2.6 μmol/L; $P = 0.342$). No differences in PON1 activity were found in TA patients with active disease in than those in remission (386.7 ± 251.2 vs. 323.7 ± 264.1 U/mL; $P = 0.552$) and between TA patients with and without previous ischemic events (411.4 ± 232.3 vs. 307.4 ± 268.6 U/mL; $P = 0.310$). No correlation was found between plasma homocysteine and PON1 activity ($\rho = 0.214$; $P = 0.265$).

Conclusion: Patients with TA presented higher homocysteine levels than control subjects and homocysteine levels were independently associated with acute arterial ischemic events in TA. Higher homocysteine levels were not observed in TA patients with active disease or with extensive vascular involvement and folate use associated to methotrexate seemed to prevent higher homocysteine levels in TA. No associations were found between PON1 activity with homocysteine levels, active disease or ischemic events.

Urinary Biomarkers in Vasculitis Associated with Anti-Neutrophil Cytoplasmic Antibodies. Jason G. Lieberthal[1], David Cuthbertson[2], Simon Carette[3], Gary S. Hoffman[4], Nader A. Khalidi[5], Curry L. Koening[6], Carol A. Langford[4], Kathleen Maksimowicz-McKinnon[7], Philip Seo[8], Ulrich Specks[9], Steven R. Ytterberg[9], Peter A. Merkel[10] and Paul A. Monach[11]. [1]Boston University School of Medicine, Boston, MA, [2]University of South Florida, Tampa, FL, [3]UHN/MSH, Toronto, ON, [4]Cleveland Clinic, Cleveland, OH, [5]McMaster University, Hamilton, ON, [6]Salt Lake City Veterans Administration, Salt Lake City, UT, [7]University of Pittsburgh, Pittsburgh, PA, [8]Johns Hopkins Vasculitis Center, Baltimore, MD, [9]Mayo Clinic, Rochester, MN, [10]University of Pennsylvania, Philadelphia, PA, [11]Boston University, Boston, MA

Background/Purpose: Glomerulonephritis is common in ANCA-associated vasculitis (AAV), but non-invasive tools for early detection of renal involvement suffer from low sensitivity (red blood cell casts) or low specificity (hematuria). We investigated four urinary proteins as potential markers of active renal AAV: alpha-1 acid glycoprotein (AGP), kidney injury molecule-1 (KIM-1), monocyte chemoattractant protein-1 (MCP-1), and neutrophil gelatinase-associated lipocalin (NGAL).

Methods: Patients with active renal AAV (n=20), active non-renal AAV (n=16), and AAV in long-term remission (n=14) were identified within a longitudinal cohort, in which detailed clinical assessment and urinalysis results had been recorded at every visit. Biomarker concentrations were measured by ELISA and normalized for urine creatinine. Marker levels during active AAV were compared to baseline remission levels determined from 1–4 remission visits for each patient. Areas under receiver-operating characteristic curves (AUC), sensitivities, specificities, and likelihood ratios (LR) comparing disease states were calculated. Generalized linear models were used to assess the effects of proteinuria, treatment, and other variables on marker levels.

Results: Baseline biomarker levels varied among patients. All four markers increased during renal flares (P<0.05). MCP-1 discriminated best between active renal disease and remission: a 1.3-fold increase in MCP-1 per mg creatinine had 94% sensitivity and 89% specificity for active renal disease (AUC=0.93, positive LR 8.5, negative LR 0.07; see Figure 1). However, increased MCP-1 also characterized 50% of apparently non-renal flares. Changes in non-specific proteinuria did not account for the association of MCP-1 with active renal disease, nor did changes in treatment. Change in AGP, KIM-1, or NGAL showed more modest ability to distinguish active renal disease from remission (AUC 0.71–0.75). Hematuria was noted during 63% of active renal episodes, but also during 38% of non-renal flares and 25%

of remission visits.
Figure 1. Fold-changes above baseline in urinary MCP-1/Cr in individual samples from patients with active renal AAV, active AAV thought to be lacking renal involvement (Non-renal), from the same patients during remission (Rem), and from other patients in long-term remission.

Conclusion: An increase in urinary MCP-1 may signal renal involvement in AAV. In contrast to a previous report, MCP-1 was imperfect in distinguishing active renal AAV from remission and was also elevated in cases in which renal involvement was thought to be absent. Either MCP-1 showed poor specificity for renal disease, or it improved sensitivity for detecting it, and urinalyses indicated that non-invasive assessment of active renal disease might be challenging in this cohort. AGP, KIM-1, and NGAL, despite being among the most promising markers in other kidney diseases, have lower prospects for clinical use in AAV.

Pauci-Immune Glomerulonephritis in the Elderly: Disease Severity and Outcomes. Rebecca L. Manno[1], Duvuru Geetha[1], Stuart M. Levine[1], Philip Seo[2] and Allan C. Gelber[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Vasculitis Center, Baltimore, MD

Background/Purpose: Incident cases of pauci-immune glomerulonephritis affect adults at the older end of the age spectrum though relevant published data are limited. We sought to determine whether the clinical expression of disease differed in adults older than 70 years of age.

Methods: Between January 1, 1995 and June 22, 2012, a total of 55 patients (pts) $\geq$ age 60 years with histologic evidence of pauci-immune glomerulonephritis were evaluated at a single university center. The association of demographic and clinical parameters with age category was assessed using student's t and chi-square tests for continuous and categorical variables, respectively. The association of age category (vasculitis onset age 60–69 vs $\geq$70 yrs) with several outcome measures was examined using logistic regression in univariate analyses.

Results: 33 pts were age 60–69 yrs at presentation; 22 were $\geq$70 yrs. This cohort was 87% Caucasian, 44% female, and 89% ANCA-positive; the proportion pANCA and cANCA positive did not differ by age group. There were no differences in mean BVAS/WG scores at diagnosis between the 2 groups (8.2 ± 4.4 vs 9.5 ± 3.4, p=0.25). Peak serum creatinine at the time of renal biopsy was 4.6 mg/dl $\pm$ 2.4 among the older vs 3.4 ± 2.3 (p=0.085) among the younger age group with a mean GFR 15.9 ± 8.4 vs 26.8 ± 21.6 (p=0.035), respectively. Combination therapy with steroids and cyclophosphamide was the most frequently employed first vasculitis treatment regardless of age group (n=15; 68% older vs. n=26; 79% younger; p=0.53). There were 4 total deaths in the cohort, 2 in each age group. Ultimately, 5 renal transplants were performed among the younger vs. none in the older patient group (p=0.056). Further associations of key clinical features of disease differed between the two age groups, as follows:

Outcome	Univariate Odds Ratio (95%CI) (older vs younger)
Hospitalization at Presentation	5.0 (1.0,25.4)
Hemodialysis-dependent at diagnosis	3.1 (1.0,9.9)
Severe infection (hospitalization) during initial therapy	5.7 (1.3–24.9)
Leukopenia during initial therapy	1.1 (0.4–3.5)

Conclusion: There is relatively little information on the clinical features and outcomes regarding pauci-immune glomerulonephritis in the elderly. This single center experience, limited by retrospective design and small sample size, suggests that patients ≥70 years of age have worse renal outcomes associated with a higher serum creatinine and lower GFR at time of diagnosis, and an increased risk of progression to hemodialysis (borderline statistically significant) despite similar BVAS/WG scores. Elderly patients may be diagnosed later in their disease course, which may reflect a delay in initiating effective therapy. Our experience also suggests that elderly patients are more likely to experience treatment complications such as severe infection; although this did not correlate with an increased rate of leukopenia. These data imply that older pates may require a different treatment paradigm with more aggressive surveillance for both incipient renal disease and treatment complications.

Exercise On Prescription: Barriers to Participation in Community Based Exercise Programmes. Dr Nicola E. Walsh[1] and Professor Mike Hurley[2]. [1]University of the West of England, Bristol, United Kingdom, [2]St George's University of London, London, United Kingdom

Background/Purpose: Osteoarthritis (OA) is highly prevalent, disabling and incurs considerable healthcare costs. Symptoms of pain and functional impairment can be ameliorated through participation in regular exercise, and this is encouraged as a long-term self-management strategy. Community based, instructor-led 'exercise on referral' schemes are common but infrequently assessed to determine their effectiveness; furthermore, participant and instructor views on these services are rarely reported. The aims of this study were to audit a 12-week local authority subsidised exercise programme and to report on participant and instructor views of this scheme.

Methods: Pre-existing databases were analysed to determine participation and health outcomes, an on-line survey and semi-structured interviews recorded instructor beliefs, whilst focus groups were used to collect data regarding participant views of community-based exercise. (Ethical approval references IRAS 11/SW/0084 and UREC HSC/11/02/27).

Results: In a two-year period 2101 people, age 45 and over with chronic joint pain/OA were referred for exercise. 36% of individuals completed the 12-week scheme; 22% of individuals did not start the programme; the remainder started but did not finish. Improvements were seen in BMI, blood pressure and self-reported activity levels for those that did complete all 12 sessions. Qualitative interviews (n=14) suggested people with OA were sceptical regarding the ability of gym instructors to manage their condition appropriately when exercising, and they feared their condition may worsen in this environment. Feedback from instructors (n=88) demonstrated a reduced specialist knowledge regarding the management of rheumatological conditions, and a recogntion that they required further specialist training to manage OA effectively. Instructors did however consider themselves appropriately trained to manage psychosocial issues, and to motivate individuals to exercise.

Conclusion: Community based exercise schemes are common, but there is an apparent reluctance amongst people with OA to engage with these schemes. Reasons for non-engagement include a perception that instructors are not appropriately qualified to manage their condition safely, and that symptoms may worsen. These beliefs may be vindicated as instructors reported a lack of specialised knowledge to support exercise programmes in people with rheumatological conditions. Although only 36% of individuals referred onto a 12-week exercise scheme completed the programme, these individuals demonstrated physiological improvements and an increase in self-reported activity levels. Future success of these programmes is likely to be dependant on exercise instructors gaining further qualifications in managing rheumatological conditions.

Hospital for Special Surgery Osteoarthritis Wellness Initiative: the Impact of a Hospital-Based Exercise Program On Osteoarthritis. Sandra Goldsmith, Dana Friedman, Linda Roberts, Dana Sperber and Laura Robbins. Hospital for Special Surgery, New York, NY

Background/Purpose: The Centers for Disease Control and Prevention (CDC) reports that about 27 million adults were affected by osteoarthritis (OA) in 2005. OA is characterized by degeneration of cartilage and bone within a joint, leading to pain and joint stiffness. Its effects are not just physical; lifestyle also declines (NIAMS). Research has shown that physical activity reduces pain, improves physical function, and delays disability in people with OA. Among older adults with knee OA, engaging in moderate physical activity at least 3 times per week can reduce the risk of arthritis related disability by 47%. However, almost 44% of adults with doctor-diagnosed arthritis report no leisure time physical activity compared with 36% of adults without arthritis (CDC). This specialty orthopedic hospital developed its Osteoarthritis Wellness Initiative, comprised of educational and exercise programs, to raise awareness, educate and reduce the impact of OA. This study attempts to support the efficacy of hospital-based exercise programs in increasing physical activity and improving quality of life (QOL) through pain reduction in the older adult community.

Methods: This prospective cohort study assesses the impact of participation in exercise classes on self-reported pain, balance, falls and level of physical activity, based on responses to a pre/post-test survey of 120 participants conducted in the Fall of 2011. The 11-point Numeric Pain Intensity Scale was used to quantify the intensity of muscle or joint pain. Pain interference on aspects of QOL (general activity, mood, walking ability, sleep, enjoyment of life etc.) was measured using items from the 10-point Brief Pain Inventory. Participants were asked to rate their balance on a 6-point rating scale, while self-reported number of falls and fall severity was assessed on a 5-point scale. Independent sample t-tests were performed to measure changes in mean pain intensity, pain interference scores, physical activity and fall severity scores from pre- to post test. Chi square tests were conducted to ascertain whether reports of pain, balance ratings and physical activity significantly changed from pre- to post test. Demographics such as age, gender and race/ethnicity were also collected.

Results: Most respondents were female (88.6%) with the majority ages 65+ (77.3%). The proportion of respondents who reported pain decreased from pre- to post test (73.4% to 56.5%). Statistically significant differences (p < 0.001) were found in mean pain intensity ratings between pre- and post test (pre-test = 5.1; post-test = 2.8). Significant differences in pain interference scores were found with regard to mood, walking ability and enjoyment of life (p < 0.05). Balance ratings improved, number and severity of falls diminished and vigorous physical activity increased.

Conclusion: Preliminary results indicate that providing low cost exercise programs to the community can play an important role in fighting OA with minimal resources. Data indicate that hospital-based exercise classes are associated with positive changes in pain, fitness and QOL, suggesting these exercise programs may play an important role in alleviating and/or minimizing symptoms of OA.

An International Framework for Chronic Condition Self Management Support: Results from an International Electronic Consultation Process. Teresa J. Brady[1], Sue Mills[2], Peter Sargious[3] and Shabnam Ziabakhsh[4]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]University of British Columbia, Vancouver, BC, [3]Alberta Health Services, Calgary, AB, [4]BC Women's Hospital & Health Centre, Vancouver, BC

Background/Purpose: Self-management support (SMS)—a grouping of policies, programs, services, and structures that extend across health care, social sectors and communities to support and improve the way individuals manage their chronic conditions—is important in both health care delivery and population-based public health approaches, in the United States and internationally. However, SMS initiatives have evolved differently in differ-

ent professional disciplines, service systems and countries, with very limited cross-fertilization among them. The purpose of this project was to establish a framework of SMS (definitions, guiding principles, and strategic directions) to guide the development of self-management support initiatives locally, regionally, nationally and internationally. The purpose of this paper is to report on the international framework that emerged from an international electronic consultation process.

Methods: The British Columbia Center of Excellence for Women's Health hosted a three day roundtable discussion among twenty-three opinion-leaders from five English-speaking countries to explore SMS from a broad system perspective encompassing health care delivery, public health, and the social services sectors; a wide variety of funding sources supported the initiative. Roundtable participants were selected to represent a balance of policy, practice, and research perspectives across the US, Canada, Australia, the UK, and New Zealand. A preliminary draft framework was developed using a thematic analysis of the roundtable proceeding; the draft framework was refined through two rounds of a modified Delphi process among roundtable participants.

International electronic consultation was conducted using an online survey tool. A snowball sampling technique was used to gather international responses to the key elements of the draft framework. Data was collected using an on-line survey tool.

Results: A total of 204 reviewers from 16 countries responded to the electronic consultation. Representation by country ranged from 31% (Canada) to 1% (9 countries including Austria, Brazil, Denmark, Germany). 24% of respondents were researchers, 18% health care providers, 7% policy-makers, 6% consumers or patient advocates. 96% of respondents agreed or strongly agreed with the definitions of self management and self management support. The final draft framework contained eight guiding principles and seven strategic directions, with international agreement ranging from 94–96% and 98–99% respectively.

Conclusion: The international electronic consultation demonstrated strong international agreement with the definitions, guiding principles, and strategic directions that emerged from the modified Delphi process. While the original draft framework was developed by opinion-leaders in 5 English-speaking countries, the framework also resonated with respondents from 11 other countries where English is not the national language. While SMS developments need to reflect local, regional, and national needs, this international framework provides an emerging consensus on strategies to move the field forward across multiple perspectives and countries.

Clinical Utility of the Hospital Anxiety and Depression Scale for an Outpatient Fibromyalgia Education Program. Diane Tin[1], Lorna J. Bain[1], J. Carter Thorne[1], Seungree Nam[2] and Liane Ginsburg[2]. [1]Southlake Regional Health Centre, Newmarket, ON, [2]York University, Toronto, ON

Background/Purpose: The Arthritis Program (TAP) at Southlake Regional Health Centre has offered an inter-professional, patient centered Fibromyalgia (FM) education program for nearly two decades. This program currently consists of seven weekly group sessions covering topics such as: medications options, exercise techniques, problem solving skills to attain empowerment, self-management and increased emotional well- being. For many years, TAP has been using the Fibromyalgia Impact Questionnaire (FIQ) and Arthritis Self-Efficacy (ASE) Scale to measure patient outcomes Recently, TAP added the Hospital Anxiety and Depression Scale (HADS). The objective of this study was to examine the clinical utility of adopting HADS in measuring effectiveness of the outpatient FM education program in helping patients to manage anxiety and depression.

Methods: A retrospective chart review was performed on 232 outpatients who attended fibromyalgia education program between November 2011 and March 2012. These patients completed HADS, FIQ and ASE just prior to attending the first class. Post-program questionnaires were completed during the final class. Paired t-tests were performed on the 59 cases with complete pre and post program data. Results for the ASE and HADS scales are presented. Large sections of the FIQ were not applicable for this population.

Results: There was significant improvement in the ASE Pain subscale (mean±SD) (N=59) (35.14±15.52 vs. 45.04±17.65, p=0.00) and the ASE Other Symptoms subscale (N=57) (40.02±18.10 vs. 49.44±17.61, p=0.00). ASE Daily Activity subscale did not see significant change (N=59) (63.05±22.47 vs. 61.75±21.20, p=0.521). There was no significant differ-

ence between the overall pre and post HADS score, HADS-A (N=61) (11.97±4.04 vs. 11.90±4.16, p=0.866) and HADS-D (N=60) (9.98±3.76 vs. 9.33±3.87, p=0.074). In order to further explore our HADS data, HADS paired pretest and posttest scores were examined for two subsets of patients: (1) those taking one or more neuropathic pain reliever (SNRI, antiepileptics, TCA) and/or mood stabilizer (SSRI, Bupropion) at the beginning of program and (2) those who were not taking any of these drugs at the beginning of the program. There was a significant improvement in their HADS depression scale score and HADS anxiety scale score in the pre-post period for the group not taking any neuropathic pain reliever or mood stabilizer at baseline (HADS-A (N=19) (10.99±4.29 vs. 9.79±4.17, p=0.043) and HADS-D (N=19) (9.53±4.03 vs. 8.16±3.53, p=0.008)).

Conclusion: HADS is a sensitive outcome measure tool for detecting changes in level of anxiety and depression for certain subsets of fibromyalgia patients. Those who are not taking any neuropathic pain relievers or mood stabilizers at baseline show improvement in level of anxiety and depression measured by HADS upon completion of a seven week outpatient FM education program. Furthermore, improvement in the pain and other symptoms subscales of the ASE were demonstrated in the full sample of patients who completed the outpatient FM education program.

The Effect of a Rheumatoid Arthritis Peer Support Program On Clinical Outcomes. Rebecca Thrower[1], Christine K. Iannaccone[1], Hsun Tsao[2], Michael Weinblatt[3], Jing Cui[4] and Nancy A. Shadick[5]. [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [4]Brigham and Womens Hospital, Boston, MA, [5]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

Background/Purpose: To evaluate the effect of a rheumatoid arthritis (RA) peer support program on fatigue, functional status (pain, SF-12 PCS), self-efficacy, emotional health (SF-12 MCS) and medication adherence (ASK-20).

Methods: RA patients enrolled at a tertiary hospital arthritis center were recommended for peer support (mentees) by their rheumatologist. Peer support mentors received a three hour training to learn how to help other patients with concerns, coping strategies and medical decision-making. Mentors contacted mentees by phone once a week for 6 months, with optional email. Mentees were compared with controls who were not receiving peer support. They were matched on disease duration (years), age (years), and gender. Both groups filled out questionnaires at baseline and six month follow-up, assessing VAS fatigue and pain, arthritis self-efficacy, functional status (SF-12 PCS), emotional health (SF-12 MCS), and medication adherence (ASK20). A linear regression model with and without adjustment for baseline outcome differences was used to assess outcomes at 6 months.

Results: 20 mentees and 22 controls completed the baseline and 6 month questionnaires. Only 2 participants dropped out of the program. There were no differences in baseline demographics or disease duration between groups. The mean age was 49.7 years (SD, 12.3), 88.1% were female, and the mean disease duration was 8.5 years (SD, 10.2). Mentees entered the study with worse pain, fatigue, health status, and self-efficacy, but with similar medication adherence scores compared to controls. In linear regression analyses, the mentees had a significant improvement in self-efficacy (p=0.01) and physical function (p=0.007) compared to controls (see Table 1) and physical function improvement persisted after adjusting for baseline clinical outcome differences (p=0.02).

	Mentees (N=19)* Change (SD)	Controls (N=22) Change (SD)	P-Value	P-Value†
VAS Pain (0–100)	−9.7 (33.1)	1.4 (36.0)	0.31	0.86
VAS Fatigue (0–100)	−9.2 (34.3)	4.3 (27.1)	0.17	0.59
Arthritis Self-Efficacy	13.1 (21.0)	−3.6 (10.6)	0.01	0.72
SF-12 (MCS)	3.4 (9.2)	1.7 (8.8)	0.61	0.29
SF-12 (PCS)	5.8 (7.7)	−2.0 (8.2)	0.007	0.02
ASK-20 Scale (20–100)	−3.6 (11.5)	−0.5 (7.0)	0.33	0.69

*Outlier removed;
† Adjusted for baseline outcome differences

Conclusion: This pilot study suggests that RA patients who have active disease and receive peer support show improvement in self-efficacy and physical function. Peer support programs may be effective in enhancing patients' coping skills. Further analyses on a larger number of participants are needed to demonstrate the impact of the program on patient self-reported outcomes of fatigue, pain and medical adherence.

2404

Cardiovascular Disease Prevention Counseling Program for Systemic Lupus Erythematosus and/or Antiphospholipid Antibody Positive Patients: Two-Year Preliminary Analysis of Diet and Exercise Habits. Virginia Haiduc, Monica C. Richey, Sotiria Everett, Aeshita Dwivedi, Lisa Konstantellis, Hassan Ghomrawi and Doruk Erkan. Hospital for Special Surgery, New York, NY

Background/Purpose: SLE patients have high rate of cardiovascular events due to increased prevalence of traditional cardiovascular disease (CVD)- and other lupus-related thrombosis risk factors. In addition, antiphospholipid antibody (aPL)- positive patients are at increased risk for thrombosis. We have developed a free-of-charge CVD prevention counseling program (PCP) for SLE and/or aPL-positive patients that provides a basic assessment of and education about the CVD and thrombosis risk factors (Arthritis Rheum 2009;60;S743). We report two-year patient reported outcomes in our ongoing CVD-PCP.

Methods: The CVD PCP consists of two phases: "*assessment*" (blood pressure, blood glucose, cholesterol profile, waist circumference, body mass index, family history of CVD, smoking status, Framingham 10-year CVD risk calculation, aPL-profile, and medications) and "*education*" (counseling about the above mentioned risk factors). Patients are followed every 3–6 months for a maximum of 3 years; they are questioned about their diet and exercise habits during each visit. In addition, patients are offered to fill out baseline and follow-up surveys during each visit. We analyzed diet and exercise habits in a descriptive fashion (Likert Scale; 1–5, 5 is best). Repeated measures analysis was utilized to assess the change of the need for counseling on dietary and exercise habits over time. Our hypothesis was that over time there will be less need for counseling as a result of the program.

Results: Between 3/2009 and 12/2011, 115 SLE and/or aPL-positive patients received baseline counseling and 102/115 (89%) completed the baseline surveys. The mean (+ SD) scores for the baseline surveys were: a) improvement in patient's knowledge about CVD risk factors: 4.3 ± 0.9; b) likelihood of the counseling program improving patients' diet: 4.1 ± 1.1; and c) likelihood of the counseling program improving patients' exercise pattern: 4.0 ± 1.1. Patients completed surveys during 268/429 (63%) of follow-up visits (range: 3–33 months); some-to-significant improvement in the diet and exercise habits were reported during 251 (94%) and 225 (84%) of the visits, respectively. Repeated measures analysis showed that there was a significant decrease over time of the need for counseling on all dietary habits investigated (fruits, vegetables, whole-grain, fiber, fish) and 30 min/day exercise habits mostly starting at 9–12 months, continuing up to 2 years (Table).

Variable	3 or 6m Visit OR (95%CI)	9 or 12m Visit OR (95%CI)	15 or 18m Visit OR (95%CI)	21 or 24m Visit OR (95%CI)
Need for counseling on Fruits & Vegetables	0.63 (0.32–1.26)	0.44 (0.22–0.88)*	0.24 (0.1–0.54)*	0.20 (0.08–0.51)*
Need for counseling on Whole-Grain & High-fiber	0.62 (0.31–1.22)	0.4 (0.3–0.8)*	0.48 (0.23–0.99)*	0.22 (0.09–0.52)*
Need for counseling on Fish	0.51 (0.3–1.02)	0.4 (0.54–0.8)*	0.41 (0.2–0.86)*	0.33 (0.15–0.73)*
Need for counseling on Cholesterol Free Diet	0.50 (0.21–1.15)	0.70 (0.29–1.66)	0.95 (0.27–1.09)	0.72 (0.27–1.93)
Need for counseling on exercise at least 30 min/day	0.33 (0.15–0.71)*	0.23 (0.11–0.5)*	0.28 (0.13–0.63)*	0.19 (0.08–0.44)*

Conclusion: Two year preliminary analysis of our ongoing CVD prevention counseling program demonstrates our patients' belief that the program is helping them make healthful lifestyle choices in terms of diet and physical exercise. These findings are supported by the significant reported improvement in their diet and exercise. The three-year longitudinal analysis of clinical outcomes will determine the true effectiveness of the program with respect to decreasing the prevalence of cardiovascular disease risk factors.

A Proof-of-Concept Study of an Animated, Web-Based Methotrexate Decision Aid for Patients with Rheumatoid Arthritis. Linda C. Li[1], Paul M. Adam[2], Catherine L. Backman[1], Sydney Brooks[3], Gwen A. Ellert[4], Allyson Jones[5], Otto Kamensek[6], Cheryl Koehn[7], Diane Lacaille[6], Colleen Maloney[6], Anne F. Townsend[6], Elaine Yacyshyn[5], Charlene Yousefi[6] and Dawn Stacey[8]. [1]University of British Columbia, Vancouver, BC, [2]Mary Pack Arthritis Centre, Vancouver, BC, [3]The Arthritis Society, Ontario Division, Toronto, [4]Trelle Enterprises Inc, Vancouver, BC, [5]University of Alberta, Edmonton, AB, [6]Arthritis Research Centre of Canada, Vancouver, BC, [7]Vancouver, BC, [8]University of Ottawa, Ottawa, ON

Background/Purpose: Patient decision aids are designed to present the potential benefits and harm of treatment options, clarify individuals' preferences, and guide discussion at a clinic visit. The majority of decision aids on arthritis treatments are in printed formats. Although informative, they tend to be less engaging for users. We applied the concept of edutainment (i.e., education that engages through entertainment) to develop a web-based decision aid called ANSWER. Designed for patients with rheumatoid arthritis (RA), ANSWER presents information on methotrexate (MTX) in print, voice recording, and animated stories created with Adobe Photoshop. The current study aims to assess the extent to which ANSWER reduces patient's decisional conflict, and improves their medication knowledge and skills of being 'effective healthcare consumers'.

Methods: We used a pre-post study design. Participants were recruited from rheumatologists' clinics, patient groups and social networking sites (Facebook, Twitter, Craigslist, Kijiji). Eligible participants were those who: 1) had a physician diagnosis of RA, 2) had been prescribed MTX but were unsure about starting it, 3) had access to the internet. Password access to the ANSWER was provided immediately after enrollment. Participants completed a questionnaire before and within 48 hours after using the ANSWER. Outcome measures included: 1) Decisional Conflict Scale (DCS, primary outcome; 0–100, scores <25 are associated with follow-through with decisions), 2) MTX in RA Knowledge Test (MiRAK; 0–60, higher=better), and 3) Effective Consumer Scale (EC-17; 0–100, higher=better). Paired t-test was used to assess differences before and after the intervention.

Results: 30 participants were recruited between November 2010 and April 2012. The majority were women (n=23, 76.7%) with a mean age of 54.90 years (SD=14.91). 73.3% (n=22) attended/graduated from university. The median disease duration was 1 year (IRQ=0.3; 5.0), and the mean Health Assessment Questionnaire score was 1.16 (SD=0.68). The mean DCS was 49.50 (SD=23.17) pre-intervention and 21.83 (SD=24.12) post-intervention (change= -27.67, 95% CI= -15.44, -39.89; p<0.001). Before using the ANSWER, 13.3% of participants scored <25, compared to 70% after the intervention. Similar results were observed in MiRAK (pre: 30.62, SD=9.26; post: 41.67, SD=6.81; change: 11.03, 95% CI=6.73, 15.34; p<0.001), but not in EC-17 (pre: 68.24, SD=12.46; post: 72.94, SD=12.74; change: 4.71; 95% CI= -1.81, 11.22; p=0.15). After using the ANSWER, 20 participants (66.6%) were able to make a decision (14 would take MTX, 6 would decline MTX and talk to their doctor about other treatment options). 10 participants (33.3%) remained unsure about their preferred choice.

Conclusion: Patients' decisional conflict and MTX knowledge improved after using the ANSWER. Our results show similar changes to other studies evaluating decision aids in chronic diseases. The lack of a statistically significant change in the EC-17 might reflect the fact that it takes time to develop effective consumer attributes, such as how to find resources. Further research into the application of edutainment in developing patient decision aids and education programs is warranted.

Tuesday, November 13

2406

Implementation of a Pilot Nutrition Education Intervention for Culturally Diverse Teens with Lupus and Their Families in Hospital for Special Surgery's Charla De Lupus/Lupus Chat® Teen and Parent Support Group. Jillian A. Rose[1], Roberta Horton[1], Dariana M. Pichardo[2], Dana Friedman[1], Robyn Wiesel[1], Sandra Goldsmith[1], Sotiria Everett[1] and Lisa F. Imundo[3]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital For Special Surgery, New York, NY, [3]Morgan Stanely Children's Hospital of New York-Presbyterian, Columbia University Medical Center, New York, NY

Background/Purpose: Based on results of our previously reported needs assessment, the hospital's national lupus support and education program worked with our Public and Patient Education Department to adapt their existing culturally sensitive nutrition program to the needs of predominantly Hispanic teens with lupus and their families. This community service plan initiative was affiliated with an urban medical center's pediatric rheumatology department. The 5 session curriculum focused on whole grains/fiber, calcium/vit D, fruits/vegetables, protein foods, and snacks/fast foods. Portion control, food labels, sodium and culturally appropriate recipe examples were included throughout. "Lupus Links" were provided by a Registered Dietitian to address bone and cardiac health, hypertension, renal disease, and obesity. The program's goal was to provide practical strategies to initiate/sustain healthy nutrition practices in this community.

Methods: A bilingual (English/Spanish) 68 item pre-test was administered at the 1st session and a 78 item post-test at the 5th session to assess the program's impact on knowledge and behavior. True/false, multiple choice, Likert-type, and open ended questions were included. Program satisfaction was also assessed. A 3 month follow-up was conducted.

Results: Pre/post tests were completed by all 19 participants (8 teens, 11 parents), a total of 7 households. 80% of participants were female; ages ranged from 12–50; >70% were Hispanic; 66% indicated household incomes of 10,000–29,999 per year. 94% reported the program led them to include more nutritious foods in their diet. Results indicated a statistically significant increase ($p \leq 0.05$) cooking with canola oil (41% to 76%); weekly frequency of reported consumption of fish, chicken (turkey)and hot cereals increased, as did consumption of whole or rye bread($p \leq 0.05$).Positive behavioral changes occurred in most households along every nutritional item.

Although mean knowledge scores > from pre to post-test (64% to 70%), this was not statistically significant. The most knowledge gained (11%) related to whole grains/fiber. Overall, teens and their parents didn't always agree on how often they cooked or ate healthy at pre-test, but more congruent behavioral responses were reported from most households at post test.

The program was well -received by participants: 94% rated overall content as excellent; 88% rated the program excellent in terms of organization, clarity, and level of presentation; 93% rated the instructor's knowledge of the subject, and ability to keep the group engaged as excellent.

Seven participants completed the 3-month follow up survey (3 teens, 4 parents); all reported eating healthier. The use of canola oil for cooking < to 66.7% at follow-up, though still higher than baseline. There were slight reductions in several knowledge items.

Conclusion: Overall this program, limited by our small sample size, helped families implement healthy dietary changes. A consideration for future planning is building in follow-up communications (nutritional tips, facts and strategies) using texting/social media to reinforce knowledge and engage participants in sustaining healthy nutritional choices.

Perceptions of the Chronic Disease Self-Management Program Among Low Income African American Women with Lupus. Charmayne M. Dunlop-Thomas, Terrika Barham, Natasha DeVeauuse Brown and Cristina Drenkard. Emory University, Atlanta, GA

Background/Purpose: Chronic illnesses have emerged as major health concerns of Americans in recent decades. African Americans with lupus are at high risk for poor disease outcomes and may face challenges in effectively self-managing multiple health problems, par-

ticularly among patients of low income. The Chronic Disease Self-Management Program (CDSMP) is a skill-building group-based, evidence-based intervention that improves the health of people with chronic illnesses. It is important to assess the perceptions of this program as success is regarded as dependent on its value to the targeted group. This study assessed the perceived acceptability, relevance and value of the program among a group of low-income African American (AA) female patients with lupus.

Methods: The CDSMP consisted of six weekly sessions led by two African American instructors and conducted in a small group (10–15 participants) workshop. Contents of the CDSMP are emotion and fatigue management, better communication, exercise, healthy eating, medication management, working with healthcare professionals, and cognitive techniques for relaxation and symptom management. Twenty-seven of the 45 study participants who completed the CDSMP workshops participated in 4 focus groups. A moderator led each focus group discussion using a guide. Participants' perceptions on the acceptability to general elements and settings of the program, relevance of contents and tools of the CDSMP, and beneficial value of the intervention to participants' disease experience were assessed. Semi-structured interviews were conducted with the two CDSMP instructors to supplement findings from the focus groups.

Data Analysis: Audio recordings of the focus groups and instructor semi-structured interviews were transcribed verbatim and thematically analyzed. Three research coders independently reviewed and coded each transcript to identify common themes. Two or more quotes were used to develop a theme.

Results: Participants were empowered by the group and program environment. They had a positive experience and were accepting of the program's locations and times. The program tools (CD on relaxation, textbook topics, action plan), as well as curricular contents were deemed as relevant and relatable to their disease experience. Participants felt empowered to use skills learned to make behavioral changes and manage their health. They valued the group peer interactions and relationships that were established. The instructors' perspectives were consistent with the participants' viewpoints.

Conclusion: This study suggests that the CDSMP was well received by low-income African American women with lupus. The education and social support provided as part of the program dynamics appear to be especially important for this targeted group. This overall acceptability was demonstrated through the expressed value and motivation in this sample. Further study is needed to examine long-term implications of participating in the CDSMP as an AA lupus patient, and the best community-based venues for implementation.

Effects of Ground and Joint Reaction Force Exercise On Bone Mineral Density in Postmenopausal Women: A Meta-Analysis of Randomized Controlled Trials. George A. Kelley[1], Kristi S. Kelley[1] and Wendy M. Kohrt[2]. [1]West Virginia University, Morgantown, WV, [2]University of Colorado @ Denver, Aurora, CO

Background/Purpose: Previous randomized controlled trials have led to conflicting findings regarding the effects of ground and/or joint reaction force exercise on femoral neck (FN) and lumbar spine (LS) bone mineral density (BMD) in postmenopausal women. The purpose of this study was to use the aggregate data meta-analytic approach to resolve these discrepancies.

Methods: The *a priori* inclusion criteria were: (1) randomized controlled trials, (2) ground and/or joint reaction force exercise > 24 weeks, (3) comparative control group, (4) postmenopausal women, (5) participants not regularly active, (6) published and unpublished studies in any language since January 1, 1989, (7) BMD data available at the FN and/or LS. Studies were located by searching six electronic databases, cross-referencing, hand searching and expert review. Dual selection of studies and data abstraction were performed. Hedge's standardized effect size (g)

was calculated for each FN and LS BMD result and pooled using random-effects models. Z-score alpha values, 95% confidence intervals (CI) and number-needed-to-treat (NNT) were calculated for pooled results. Heterogeneity was examined using Q and I^2. Mixed-effects ANOVA and simple meta-regression were used to examine changes in FN and LS BMD according to selected categorical and continuous variables. Statistical significance was set at an alpha value ≤ 0.05 and a trend at >0.05 to ≤ 0.10.

Results: Statistically significant exercise minus control group improvements were found for both FN (28 g's, 1632 participants, $g = 0.288$, 95% CI = 0.102, 0.474, $p = 0.002$, Q = 90.5, $p<0.0001$, $I^2 = 70.1\%$, NNT = 6) and LS (28 g's, 1504 participants, $g = 0.179$, 95% CI = -0.003, 0.361, $p = 0.05$, Q = 77.7, $p<0.0001$, $I^2 = 65.3\%$, NNT = 6) BMD. None of the mixed-effects ANOVA analyses were statistically significant. For both FN and LS BMD, statistically significant, or a trend for statistically significant and positive associations were observed for intensity of training and compliance (joint reaction force exercise only) as well as changes in static balance. Inverse associations were observed for compliance (combined ground and joint reaction force exercise) as well as changes in body mass index, body weight and percent body fat. When limited to the LS, statistically significant, or a trend for statistically significant and positive associations were found for age, years postmenopausal and changes in lean body mass while inverse associations were observed for duration of training (minutes per session, ground reaction force exercise only), total minutes of training per week (ground reaction force exercise only), compliance (combined ground and joint reaction force exercise) and changes in aerobic fitness.

Conclusion: Exercise benefits FN and LS BMD in postmenopausal women. Several of the observed associations appear worthy of further investigation in well-designed randomized controlled trials.

Work Productivity in a Population Based Cohort of Patients with Spondyloarthritis. Emma Haglund[1], Ann B. I. Bremander[2], Stefan Bergman, Lennart TH Jacobsson[3], Britta Strömbeck[4] and Ingemar F. Petersson[4]. [1]R&D Center Spenshult, Oskarstrom, Sweden, [2]Halmstad University School of Business and Engineering,, Halmstad, Sweden, [3]Department of Rheumatology, Clinical sciences, Skane University Hospital, Malmö, Sweden, [4]Musculoskeletal Sciences, Department of Orthopedics, Clinical Sciences, Lund, Sweden

Background/Purpose: Spondyloarthritis (SpA) often causes impaired function, activity limitations, affected health related quality of life and work disability. Work disability has been shown to be affected both in terms of absenteeism and in impaired productivity while working (presenteeism). In this group with increased socioeconomic costs there is also an increase in the use of expensive pharmacotherapies. Thus, it is important to study factors related to the ability to stay productive while at work. The aim was to study factors associated with presenteeism in patients with SpA. Also to analyse possible differences in age, gender and SpA subtypes (ankylosing spondylitis, psoriatic arthritis and undifferentiated SpA).

Methods: The analysis was based on 1773 patients seeking health care for SpA aged 18–67 years from southern Sweden, identified by a health care register. A questionnaire survey in 2009 included questions concerning self-reported presenteeism, defined as the percentage of impairment due to SpA while working 0–100, (0=no impact), was answered by 1447 individuals. Patients' characteristics: disease duration, disease activity (BASDAI), physical function (BASFI), health related quality of life (EQ-5D), anxiety (HAD-a), depression (HAD-d), self-efficacy pain and symptom (ASES) and register based sick leave. The Pearson's correlation coefficient and univariate analyses with ANOVA were used to study factors associated with presenteeism and t-test was used for group comparisons.

Results: Fifty-five percent (n=802/1447) reported no impact on work presenteeism, while mean impairment was 20 (95% CI 18–21) (n=1447). Women reported higher impact on work presenteeism than men (mean impairment 23 vs. 17, p<0.001) but no statistically significant differences were found between the SpA subtype groups. Twenty-eight percent (n=504/1773) were registered for any sick leave (absenteeism > 14 days). Worse outcome in quality of life (EQ-5D), disease activity (BASDAI) and physical function (BASFI) all correlated to higher impact on work presenteeism (r >0.5, p <0.001), while sick leave (absenteeism) did not. In the univariate

analyses experiencing worse outcome in EQ-5D (β-est -9.6, p<0.001) BASDAI (β-est 7.8, p<0.001) and BASFI (β-est 7.3, p<0.001) were all associated to higher impact on presenteeism regardless of age, gender and disease subtype. Worse outcome of EQ-5D was associated to a higher degree impact on presenteeism in the younger women (18–52 yrs). Self-efficacy, anxiety, depression, disease duration and education level <12 years were all associated to higher impact on presenteeism but were not significant in all strata for age, gender and disease subtype.

Conclusion: Quality of life, disease activity and physical function all affect work presenteeism in patients with SpA, regardless of age, gender and disease subtype. The results indicate that work presenteeism is affected in patients with all types of SpA and more affected in women. We also find that presenteeism and register based sick leave (absenteeism) may be related to different dimensions of the individuals and their disease.

The Impact of Severe Hip and Knee Joint Disease On Paid and Unpaid Work Participation in Australia. Ilana N. Ackerman[1], Zanfina Ademi[1], Richard H. Osborne[2] and Danny Liew[1]. [1]The University of Melbourne, Melbourne, Australia, [2]Deakin University, Melbourne, Australia

Background/Purpose: Severe hip and knee joint disease are common and disabling conditions which represent a growing public health problem internationally. Although people of working age are commonly affected, the impact of severe hip and knee joint disease on work participation is not well understood. Using a national approach, this study aimed to evaluate participation in paid and unpaid work according to the severity of hip and knee joint disease.

Methods: A sample of 5000 people was randomly selected from the Australian electoral roll and invited to complete a questionnaire to screen for doctor-diagnosed hip arthritis, hip osteoarthritis (OA), knee arthritis and knee OA, and evaluate the severity and burden of these conditions. Joint disease severity was classified using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores (range 0–100): <7=asymptomatic, 7–38=mild to moderate and $\geq$39=severe. Self-reported data were collected on paid and unpaid work status, premature exit from the workforce, and changes to work due to hip or knee arthritis or OA.

Results: Data were available for 1157 participants, with 237 (20%) reporting hip or knee joint disease. Of these, 16% (n=37) were classified as asymptomatic, 51% (n=120) as mild-moderate and 27% (n=64) were classified as severe. Neither age nor gender was associated with severity (p>0.05). Only 25% of the severe group was in paid employment, compared with 40% of the mild to moderate group and 54% of the asymptomatic group (p<0.01). Nine per cent of the severe group had stopped work due to their hip or knee, while no participant from the asymptomatic or mild to moderate groups had stopped work for this reason. After adjustment for age and gender, the severe group was over 3 times less likely to be in paid employment (adjusted odds ratio (AOR) 0.28, 95%CI 0.09–0.88), and over 4 times less likely to undertake unpaid work (AOR 0.24, 95%CI 0.10–0.62), compared with the asymptomatic group. Mild to moderate joint disease was not associated with a reduced likelihood of either being in paid employment or of undertaking unpaid work (p>0.05). Increasing severity was associated with greater difficulty in undertaking work; the proportion of participants who reported having to change the way they worked due to arthritis or OA rose with increasing disease severity (5% for asymptomatic group, 20% for mild to moderate group, and 59% for severe group; p<0.01). The proportion who reported having to change the number of hours worked due to arthritis or OA also increased with greater disease severity (3% for asymptomatic group, 15% for mild to moderate group, and 33% for severe group; p<0.01).

Conclusion: This study has generated new information on the relationship between severity of joint disease and work. Compared with those who had milder disease, individuals with severe joint disease reported markedly reduced paid and unpaid work participation, and greater difficulty in undertaking work. These data provide further evidence of the personal burden of severe joint disease and highlight the need for timely access to care.

Obesity Is Associated with Higher Levels of Fatigue in RA. Patricia P. Katz[1], Vladimir Chernitskiy[2] and Mary Margaretten[3]. [1]Univercity of California San Francisco, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA, [3]UCSF, San Francisco, CA

Background/Purpose: Fatigue is recognized as a major problem for individuals with rheumatoid arthritis (RA), yet the causes of fatigue are not well defined. Obesity appears to be common in RA, and studies outside RA have linked obesity with fatigue. This analysis examined the association of obesity with fatigue in RA.

Methods: Subjects are participants in an on-going study of RA fatigue (current n=136). Home visits are made to individuals with documented RA to assess a number of factors, including the following variables used to estimate body composition: height, weight, waist circumference, and bioelectrical impedance analysis (BIA). Height and weight were used to calculate body mass index (BMI). Obesity was defined by standard definitions of BMI (≥ 30 kg/m^2) and waist circumference (women: ≥ 88cm; men: ≥ 102cm). Revised definitions of obesity from BMI (≥ 26 kg/m^2) and waist circumference (women: ≥ 83 cm; men: ≥ 96 cm)* were also examined. Total percent body fat was calculated from BIA. Fatigue was measured with the Fatigue Severity Index, and used the rating of average fatigue severity over the past week (range 0–10, no fatigue to severe fatigue). Subjects also completed questionnaires to measure RA disease activity (RA Disease Activity Index [RADAI]), sleep quality (Pittsburgh Sleep Quality Index [PSQI]), depression (PHQ), and functioning (HAQ). Multiple linear regression analyses were used to identify the association of each measure of obesity with fatigue severity. Covariates included RADAI, PHQ, HAQ, sleep quality, age, sex, and RA duration.

Results: Mean ($\pm$SD) age was 59 ($\pm$12) years, 87% were female, and 77% were white. Mean fatigue severity rating was 3.8 ($\pm$2.1; range 0–10). Proportion defined as obese ranged from 27% (BMI≥ 30) to 61% (waist circumference, revised), and mean percent fat was 35.6% ($\pm$09.0). In unadjusted analyses, all measure of obesity and body fatness were significantly associated with fatigue (Table). Adjustment for covariates attenuated the relationship of body composition measures with fatigue, but the association persisted.

Table. Associations of body composition measures with fatigue severity

	% (n) obese	Unadjusted		Adjusted[1]	
		Beta (95% CI)	p	Beta (95% CI)	p
BMI obese (30 kg/m^2)	27% (37)	1.2 (0.4, 1.9)	.003	0.5 (-0.2, 1.1)	.18
BMI obese (revised; 26 kg/m^2)	51% (70)	1.6 (1.0, 2.3)	<.0001	0.7 (0.1, 1.3)	.02
Waist obese (women $\geq$ 88cm, men $\geq$ 102 cm)	47% (63)	1.3 (0.6, 2.0)	.0002	0.5 (-0. 1, 1.1)	.11
Waist obese (revised; Women $\geq$ 83cm, Men $\geq$ 96 cm)	61% (82)	1.3 (0.6, 2.0)	.0004	0.6 (-0.02, 1.2)	.06
Total % fat (per 10% increment)		1.4 (0.7, 2.1)	.0002	0.3 (-0.06, 0.7)	.10

[1]Adjusted for RADAI, PHQ, HAQ, self-reported sleep quality, age, sex, RA duration.
* Katz, presented at ACR/ARHP, 2011.

Conclusion: Obesity appears to play a role in RA fatigue, even after controlling for important covariates such as disease activity, sleep, and depression. Associations found using the revised obesity definitions, which increased the number of individuals classified as obese by 89% (BMI) and 30% (waist circumference), were not substantially different from those found with the standard definitions. Addressing obesity in RA may be part of effective interventions for RA fatigue.

Valdiation of a Diagnosis of Gout in the Epiccare Electronic Medical Records. Neera Narang[1] and Eswar Krishnan[2]. [1]Stanford Univ Medical Center, Stanford, CA, [2]Stanford University, Stanford, CA

Background/Purpose: Electronic Medical Records (EMR) offer great opportunities for pharmacoepidemiologic, health outcome and health services research. However, the critical limiting factor in the widespread use of these data is the accuracy, precision and validity of diagnoses. EpicCare is a large and growing proprietary EMR software system that has been adopted by several large tertiary care facilities.The goal of this FDA funded project was to assess the validity of an ICD code of 274.* to identify patients meeting a clinical diagnosis of gout from among those who have ever been prescribed colchicine.

Methods: We identified 143 patients in the Stanford EpicCare system in the past 6 years that met our case definition for gout -at least one prescription of colchicine and one instance of ICD-9 code of 274.*. The records of these patients were individually reviewed and data on the following aspects were abstracted: physician diagnosis (notes), performance of arthrocentesis, use of urate lowering therapy, and documentation of each of the American College of Rheumatology (ACR) criteria for diagnosis/classification of gout. Data were analyzed quantitatively and qualitatively.

Results: Overall 143 case records were reviewed, of which 3 did not have any physician authored clinical documents. A physician diagnosis of gout was documented in 114 (80%). Three charts revealed a diagnosis of pseudogout and 31 did not have any physician documentation of gout. Among those records with a physician diagnosis of gout, 35 records documented intra-articular urate crystals, 36 records had documentation that met the ACR criteria, and 19 records had documentation of ACR criteria and urate crystals. The median number of ACR criteria met in the 114 charts was 4, with an interquartile range of 2 to 6. Among those records with a positive crystal identification, only 48% had documentation that met the ACR criteria. Among those records where arthrocentesis was performed and found to be negative for crystals, physician diagnosis was documented in 90%, and ACR criteria were met in 40%. In the case records that did not show documentation of arthrocentesis or any relevant laboratory evaluation, 75% had physician diagnosis and about 13% met the American College of Rheumatology criteria.

Conclusion: This study showed that in the setting of a tertiary medical center, Electronic Medical Records are an excellent resource for gout research. Documentation of the individual ACR criteria and performance of arthrocentesis is infrequent and hence these may not be useful gold standards for validation studies of gout in the EMR. From our qualitative review, documentation of physician diagnosis may be considered a useful benchmark for assessing the utility of case definitions for gout.

The Impact of Asymptomatic Vertebral Fractures On Quality of Life in Community-Dwelling Older Women: The Sao Paulo Ageing & Health Study (SPAH). Jaqueline B. Lopes[1], Leandro Fung[2], Carolina C. Cha[2], Camille P. Figueiredo[2], Liliam Takayama[2], Valéria Caparbo[2] and Rosa M.R. Pereira[2]. [1]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: Health-related Quality of life (HRQL) has been used as a complementary measure of bone mineral density to evaluate the burden of osteoporosis on a patient's daily life. There are few epidemiological studies evaluate HRQL and vertebral fractures in non-ambulatory or non-institutionalized elderly individuals. The aim of this study was to investigate the impact of asymptomatic vertebral fractures on quality of life in community-dwelling older women.

Methods: This cross-sectional study is nested within the larger epidemiological project of prevalence vertebral fractures in older living in Sao Paulo, Brazil. A random sample of 180 women with 65 years of age or over was evaluated. The Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO) was applied to all subjects. The QUALEFFO is a specific questionnaire designed to be used by patients with vertebral fractures attributed to osteoporosis. A low domain score indicates worse health and a high score indicates better health. Anthropometric data was obtained by physical examination and body mass index (BMI) was calculated. A lateral thoracic and lumbar spine X-ray was performed to identify asymptomatic vertebral fractures using Genant semi-quantitative method. A generalized linear model (GLM) with gamma distribution and logarithmic link function was used in the final statistical analysis.

Results: Women with asymptomatic vertebral fractures had lower QUALEFFO total score [61.4(15.3) *vs.* 67.1(14.2), p=0.03] and worse QUALEFFO-physical-function domain [69.5(20.1) *vs.* 77.3(17.1), p=0.02] compared to those without fractures. QUALEFFO total score was also worse in women classified as obese, compare those classified as overweight and normal. High physical activity was related with better QUALEFFO total score (p=0.01). Likewise, lower QUALEFFO-physical-function score was observed in women with higher BMI (p<0.05) and lower physical activity (p<0.05). GLM with gamma distribution and logarithmic link function,

adjusted to age, showed that impair QUALLEFFO-total score and QUALEFFO-physical-function domain was related with high BMI, lower physical activity and vertebral fractures (p<0.05).

Conclusion: Vertebral fractures are associated to decrease QOL in community-dwelling older women regardless of age, BMI, and physical activity. Therefore, our results highlight the importance of preventing and controlling asymptomatic vertebral fractures in order to reduce their impact on QOL among older women.

Multisite Joint Pain and Fatigue: the Role of Pain Severity and Sleep Problems in Adults with Arthritis. Mayilee Canizares[1] and E.M. Badley[2]. [1]Division of Health Care and Outcomes Research. Toronto Western Research Institute, Toronto, ON, [2]Division of Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: Little is known about the severity and determinants of fatigue in adults with arthritis. We hypothesize that the number of joint sites affected is associated with fatigue through pain severity and sleep problems.

Methods: Data source: a representative sample of people reporting arthritis, the 2009 Survey on Living with Chronic Diseases in Canada—Arthritis Component (age 20+: n=4,565). Variables: frequency and severity of fatigue and of pain, sleep difficulties (a lot, a little, not at all), sites of joint pain (up to 18 joint sites), other chronic conditions, arthritis type (most frequently unknown type or osteoarthritis), and personal characteristics (age, sex, education, income, obesity). The number of joint sites affected were grouped: no pain, single site, 2–3 sites, 4–7 sites, and 8+ sites (widespread). For multivariate analysis, the frequency and severity of fatigue were combined into a continuous score (0 = no fatigue to 100 = always and as bad as it could be). A similar score was calculated for pain. Sequential multivariate linear regression models, controlling for personal and health characteristics were fitted to investigate the relationship of joint site groups, pain severity, and sleep problems with fatigue.

Results: 91.7% reported fatigue with a mean score of 50.4. The average joint site count was 5.1 (95% CI: 4.9–5.3). Over 80% reported multisite joint pain (24.3% 2–3 sites, 25.2% 4–7 sites, 30.4% 8+ sites). There was a significant gradient of higher pain severity and more sleep problems with increasing joint site count. Women, obese individuals and those with comorbidities had higher levels of fatigue. No differences were seen by arthritis type. In the model adjusting only for personal and health characteristics having 2–3 sites or more was significantly associated with higher levels of fatigue. When pain severity was added to the model the coefficients for 2–3 and 4–7 sites were no longer significant, and for the 8+ sites group was decreased by 67.4% (β=5.7, 95% CI: 0.5–9.1) suggesting that the effect of joint count on fatigue was fully mediated by pain severity for <8 joints and partially mediated for 8+ joint sites group. Adding sleep problems to the model, further decreased the coefficient for 8+ sites by 15.8% (β=4.8, 95% CI: 0.5–9.1).

Conclusion: The results underscore the high frequency of multiple joint site involvement among people with arthritis, as well as the importance of joint site count for pain severity, sleep problems, and fatigue. The findings confirm that the effect of number of joint sites on fatigue is mediated through pain severity and sleep problems, and indicate at least some direct effect of widespread joint involvement on fatigue. These findings together with the similarities for the different types of arthritis point to the need to pay attention to the number of joint sites affected for all types of arthritis in strategies aiming to reduce the impact of fatigue.

Does Interleukin-6 Mediate the Relation Between Estrogen and Bone? an Epidemiologic Approach in the Framingham Osteoporosis Study. Robert R. McLean[1], Xiaochun Zhang[2], Andrea D. Coviello[3], Joao D.T. Fontes[4], L. Adrienne Cupples[5], Douglas P. Kiel[1] and Marian T. Hannan[1]. [1]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [2]Hebrew Senior Life, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Framingham Heart Study and Boston University, Framingham, MA, [5]Boston University School of Public Health, Boston, MA

Background/Purpose: Laboratory and animal studies suggest that lower sex hormone levels promote production and activity of pro-inflammatory cytokines that trigger bone resorption. This paradigm is a hypothesized mechanism for accelerated bone loss following menopause, and may influence bone loss in men and premenopausal women as cytokine levels may vary across the range of endogenous hormones within these groups. Confirmation of these hypotheses in epidemiologic studies could inform the development of interventions to prevent bone loss. We examined whether interleukin-6 (IL-6) concentration is a mediator of the cross-sectional relation between total estradiol concentration and hip bone mineral density (BMD), separately among men, premenopausal women and postmenopausal women in the Framingham Osteoporosis Study. We hypothesized that a direct association between total estradiol and BMD would be attenuated after adjusting for IL-6, suggesting IL-6 as a potential mediator.

Methods: Fasting blood samples and BMD measures were obtained (1996–2001) from 1,230 men, 215 premenopausal and 1,300 women. Serum total estradiol (pg/mL) and IL-6 (pg/mL) concentrations were measured via LC-MS/MS and ELISA, respectively. Femoral neck BMD (g/cm²) was measured with a Lunar DPX-L. Separately for men, premenopausal and postmenopausal women, total estradiol was categorized into quartiles and analysis of covariance was used to calculate least squares-adjusted mean BMD for each quartile and test for a linear trend, adjusting for age, BMI, height, physical activity, current smoking and in postmenopausal women, use of hormone replacement therapy (HRT). To examine potential effect modification by HRT in postmenopausal women analyses were also stratified by HRT use. Models were additionally adjusted for IL-6 and if an association between total estradiol and BMD was consequently attenuated, IL-6 was considered a mediator.

Results: Mean age was 61 y (range 29–86 y). There was a statistically significant positive association between total estradiol and BMD among men and a similar, though not statistically significant, relation in postmenopausal women (Table). There was no association in premenopausal women. In postmenopausal women the relation was similar for HRT users and non-users (data not shown). Associations were nearly identical after adjusting for IL-6, suggesting no mediation by IL-6.

Least squares-adjusted mean femoral neck BMD (g/cm²) for quartiles of serum total estradiol, with and without adjustment for IL-6, among men and women in the Framingham Osteoporosis Study.

	Estradiol quartile (range, pg/mL)	N	Median IL-6 (pg/mL)	LS Mean BMD (SE) Model 1*	Model 1 + IL-6
Men	1 (1.1, 19.6)	307	2.53	0.960 (0.007)	0.960 (0.007)

Postmenopausal women	1 (3.0, 6.0)	323	2.59	0.846 (0.007)	0.846 (0.007)
	2 (7.0, 11.0)	347	2.70	0.849 (0.006)	0.850 (0.006)
	3 (12.0, 22.0)	317	3.06	0.854 (0.007)	0.855 (0.007)
	4 (23.0, 459)	313	2.63	0.862 (0.007)	0.862 (0.007)
			P for trend	0.15	

*Adjusted for age, BMI, height, physical activity, current smoking, and, in postmenopausal women, current HRT use.

Conclusion: These cross-sectional findings suggest that while lower estrogen status was associated with lower hip BMD in men and postmenopausal women, these relations are not influenced by IL-6. Subsequent analyses should examine additional markers of estrogen status (free estradiol, estrone, sex hormone-binding globulin) and pro-inflammatory cytokines (CRP, TNF-α), the role of hormonal contraceptive use and phase of menstrual cycle in premenopausal women, and prospective changes in BMD.

Arthritis-Attributable Interference in Routine Life Activities. Kristina A. Theis[1], Teresa J. Brady[1], Charles G. Helmick[1], Louise Murphy[2] and Kamil E. Barbour[1]. [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]CDC, Atlanta, GA

Background/Purpose: Arthritis-attributable interference (AAI) in routine life activities are indicators of quality-of-life (QOL) that have not often been studied in a population-based sample of U.S. adults with arthritis. The purpose of this study is to estimate, among people with arthritis, the proportion and number with AAI in four routine life activity domains (1. recreation, leisure, and hobbies; 2. household chores; 3. errands and shopping; and 4. normal social activities), as well as the proportion affected among those with select characteristics.

Methods: Data were from ACHES, a cross-sectional, random digit dialed national telephone survey of non-institutionalized U.S. adults ≥ 45 years with self-reported doctor-diagnosed arthritis conducted in 2005–06. All respondents (n=1,793) confirmed a diagnosis of arthritis from a health professional. AAI for the first 3 life activity domains was asked by: "During the past 7 days, how much did your arthritis or joint symptoms interfere with the following activities?" AAI in the fourth domain used a 30-day recall; responses for all 4 questions were: a lot, a little, or not at all. For analysis across the 4 activity domains, a composite measure of AAI was created with three mutually exclusive subgroups: substantial ("a lot" in ≥1 domain), modest ("a little" in ≥1 domain), and none (no interference in any domain). The proportion of adults in each of these subgroups was examined overall and by demographics, clinical measures, and psychological factors. Weighted proportions and 95% confidence intervals (CI) were calculated accounting for the complex sample design (SAS 9.2).

Results: AAI (a lot, a little) was reported by more than half of respondents in each of the 4 life activity domains and was highest for household chores (68%) and recreation/leisure/hobbies (65%). The proportion of U.S. adults ≥45 years with arthritis who reported any degree of composite AAI in routine life activities was 79% (29.9 million) (substantial AAI = 38% (14.3 million); modest AAI = 41% (15.6 million)). Only 21% (7.8 million) reported no AAI. Substantial AAI was significantly higher in women compared with men (42% vs. 31%) but similar by age and race/ethnicity. Substantial AAI was significantly lower among those with high confidence in ability to manage arthritis symptoms. The proportion with substantial AAI by select characteristics was > 50% for those with: severe fatigue (74%), severe joint stiffness (69%), severe joint pain (68%), anxiety (61%), depression (68%), low confidence in managing arthritis symptoms (65%), and those currently seeing a doctor or healthcare provider (51%).

Conclusion: Severe arthritis symptoms identify patients with substantial interference in routine life activities, but other characteristics (above) may identify additional patients who can benefit from interventions to preserve QOL. Controlling arthritis symptoms medically, in combination with referrals for evidence-based self-management education and physical activity programs, may reduce AAI in these important life activity domains and help address the large and growing public health problem of arthritis and its related QOL impacts.

2417

Transitioning to Adulthood: Employment Experiences of Young Adults with Lupus and Juvenile Arthritis. Arif Jetha[1], E. M. Badley[2], Dorcas Beaton[3], Paul R. Fortin[4], Natalie J. Shiff[5], Alan M. Rosenberg[6], Lori B. Tucker[7], Dianne P. Mosher[8] and M. A. Gignac[9]. [1]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [2]Division of Health Care and Outcomes Research,Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [3]Institute for Work & Health; Mobility Program, Clinical Research Unit, St. Michaels Hospital, Toronto, ON, [4]Division of Rheumatology, Centre de recherche du centre hospitalier universitaire de Québec, Faculté de médecine de L'université Laval, Quebec City, QC, [5]University of Saskatchewan, Saskatoon, SK, [6]Royal University Hospital, Saskatoon, SK, [7]BC Childrens Hospital, Vancouver, BC, [8]University of Calgary, Calgary, AB, [9]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto; Institute for Work & Health, Toronto, ON

Background/Purpose: A considerable body of evidence highlights the negative impact of rheumatic disease on employment. However, most research examines middle- and older-aged adults. We lack information on the employment experiences of young adults with rheumatic diseases who are transitioning to adulthood.

Objectives: To describe the working experiences of young adults (ages 18 to 30 years) with systemic lupus erythematosus (SLE) and juvenile arthritis (JA) in terms of: 1) employment status 2) disease-related job absenteeism and disruptions and 3) demographic, health, psychological and work factors associated with job disruptions.

Methods: 143 participants (mean age=23.3 years, SD=3.5, 80%= female) with SLE (n=78) and JA (n=65) were recruited from rheumatology clinics in four Canadian provinces (Ontario, Saskatchewan, British Columbia and Alberta). All completed an online questionnaire asking about demographic (age, gender, education), health (diagnosis, pain, fatigue, disease activity), work context (job sector, hours worked), absenteeism, job stress, and psychosocial factors (perceived independence, disclosure of disease). The number of disease-related job disruptions (work interruptions, arriving late/leaving early, missed meetings) were also asked (1=yes; 0=no). A multivariate linear regression analysis examining the association of demographic, health, work context, and psychological factors with disease-related job disruptions was conducted.

Results: 61% of the sample were employed, 26% were students and 13% were not working. Participants mostly reported a well controlled disease with low pain (mean=3.5 SD=3.0), fatigue (mean=4.2, SD=3.1) and disease activity (mean=3.1, SD=3.0). 56% had attended post-secondary school. Among those employed, half worked full-time (54%) and about a third of participants worked in sales and service jobs (36%). Over half of employed participants (53%) reported at least one disease-related job disruption (mean=1.5, SD=2.3; range: 0–7) and 56.5% reported a job absence because of their disease in the previous 6 months. The most common disease-related job disruptions in the past 6 months were work interruptions of 20 minutes or more (33%), lost time because of arriving late/leaving early (22%) and being unable to work requested schedules (20%). Greater job disruptions were significantly associated with older age, greater job stress, workplace activity limitations, and having disclosed arthritis to one's manager. Increased fatigue and perceiving that one would be able to remain employed were significantly associated with fewer job disruptions.

Conclusion: Similar to their healthy peers, the majority of young adults with SLE and JA in this sample were employed or pursuing an education. However, many experienced disease-related absenteeism or job disruptions that were associated with having discussed their disease with an employer, higher work stress and workplace limitations, signaling the need for intervention. Flextime or workplace self-management are examples of interventions, in this age group, that may improve long-term success in employment.

2418

The Everyday Challenge of Living with Lupus. Brenda L. Frie. St. Catherine University, St. Paul, MN

Background/Purpose: The purpose of this study was; 1) to assess the unmet needs of adults with lupus; 2) to explore their future interest in attending community based educational programing.

Systemic Lupus Erythematosus (SLE) is an arthritis related chronic autoimmune disease. SLE is the most common and most severe form of lupus involving multiple body systems including the blood, muscles, joints, organs and the nervous system (Wallace, 2009). It is estimated that 161,000 to 322,000 adults with SLE live in the United States (Helmick, et al., 2008). The rising costs of health care, increasing incidence and the impact of SLE on quality of life provides rationale for this study. This research can be used to support the future design of community based services.

Methods: This research proposal was reviewed and approved by the University Institutional Review Board and the Lupus Foundation of Minnesota (LFM). Adult members of LFM were invited to participate in the survey. The survey was conducted in Minneapolis and St. Paul, Minnesota. Items for the needs assessment survey were selected by the researcher in collaboration with the Lupus Foundation of Minnesota. The survey included 23 items listed

on the Systemic Lupus Erythematosus Needs Questionnaire (SNLEQ) (Moses, Wiggers, Nicholas, & Cockburn, 2007) and 25 items from categories listed on the World Health Organization Quality of Life Assessment (1995) and the Healthcare Assessment Questionnaire developed by Fries, Spitz, Kraines, & Holman (1980). Survey items were ranked on a 5 point rating scale based on level of difficulty participating in daily life tasks, managing physical symptoms and emotional concerns. Demographic information, access to services, and interest in community based programing was assessed through open ended and multiple choice questions. The data was analyzed descriptively.

Results: Ninety six participants completed the survey. The majority of the study participants were women (95%), with an average age of 49 years old. Over half of the respondents (52%) reported that they were not working at the time of the survey. Three percent of those surveyed received occupational therapy services within the past year. Most participants were Caucasian (82%). Fifty percent of participants reported moderate or higher level difficulty doing the daily tasks of sports, climbing, outdoor work, and managing the physical symptoms of pain and fatigue. Thirty percent of those surveyed reported difficulty coping with emotional concerns of depression, stress and anxiety. Management of fatigue was the most prevalent area of concern. Eighty seven percent of participants reported that they may be interested in attending a community based educational program addressing the areas of fatigue, pain, stress, strength and conditioning, coping skills and life balance.

Conclusion: This study is important in that it identifies there is a need for and interest in community based educational programing for those living with lupus. Community based services can play a key role in improving the quality of life of those with SLE through providing services to help adapt or modify their environments and manage the disease symptoms.

Novel Candidate Genes for Structural Foot Disorders: A Genome-Wide Association Study in an Older Caucasian Population. Marian T. Hannan[1], Yi-Hsiang Hsu[2], Chia Ho Cheng[2], Youfang Liu[3] and Joanne M. Jordan[4]. [1]Hebrew SeniorLife & Harvard Medical School, Boston, MA, [2]Hebrew SeniorLife & Harvard Med Sch, Boston, MA, [3]University of North Carolina, Chapel Hill, NC, [4]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

Background/Purpose: Structural foot disorders, such as hallux valgus, deformities of the lesser toes (toes 2–5) and plantar soft-tissue atrophy, commonly affect 60% of older adults at the population level and are often linked with foot pain, chronic mobility limitations, and disability. Although, body weight and other environmental factors are considered possible causes of these foot conditions, the importance of genetics is commonly suspected in clinical observations of family aggregation. Previously, we reported strong heritability (h^2) for lesser-toe deformity (61% in men; 85% in women) and moderate h^2 for hallux valgus (35%) and plantar soft-tissue atrophy (20%) in older men and women, suggesting potential genetic predisposition to structural foot disorders. To identify their genetic determinants, we have undertaken a GWAS using 2.5M imputed SNPs (HapMapII CEU reference panel) to localize susceptible genes in the population-based Framingham Foot Study.

Methods: Structural foot disorders were indicated as present or absent and were assessed based on an atlas of pictorial depictions. Plantar soft tissue atrophy was determined by palpating the plantar fat pad at the forefoot and heel during a validated foot examination. Among 2,446 Framingham participants (mean age 66 yrs; 57% women; Caucasian), we identified 753 (31%), 764 (31%) and 665 (27%) participants with deformities of the lesser-toes, hallux valgus and plantar soft-tissue atrophy, respectively. A mixed-effect regression model was performed and adjusted for age, sex, weight and principal components of ancestral genetic background. A kinship covariance matrix was used to take into account within-family correlations among siblings. We filtered out SNPs with low imputation quality (O/E variance ratio of allele frequency $<$ 0.3) and SNPs with MAF $<$ 1%. In addition, p-values were also adjusted for λGC.

Results: We found several associations achieved genome-wide significance ($p < 5 \times 10^{-8}$), i.e. SNPs on *TBC1D22A* and *OR5D13* gene for lesser-toe deformity. For hallux valgus, the most significant SNP (p=4.9×10^{-7}) is located in *GATAD2B* gene. For plantar soft-tissue atrophy, the most significant SNP (p=4.76×10–7) is located near *ADAMTS16* gene. Pathway and gene-set analyses for the genome-wide significant and suggestive genes suggested significant clustering of genes involved in

connective tissue disorders (such as oligoarticular arthritis, osteoarthritis and osteosclerosis). Of note, a few SNPs were reported to associate with longevity. These results are undergoing replication in independent samples.

Conclusion: In conclusion, our results identify novel candidate genes to further elucidate the etiology of structural foot disorders.

Frequent Self-Reported Pain and Disease Symptoms in Juvenile Idiopathic Arthritis Persist Despite Advances in Medication Therapies: An Electronic Diary Study. Maggie H. Bromberg[1], Mark Connelly[2], Kelly K. Anthony[3], Karen M. Gil[1] and Laura E. Schanberg[3]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Children's Mercy Hospitals and Clinics, Kansas City, MO, [3]Duke University Medical Center, Durham, NC

Background/Purpose: Previous research has demonstrated that children with Juvenile Idiopathic Arthritis (JIA) experience frequent pain that interferes with performing tasks at home and at school. However, it is unclear whether pain and associated functional limitations persist despite recent advances in the understanding and medical treatment of the disease. The present study used electronic (e-) diaries to determine whether pain, stiffness, and fatigue continue to be common, disabling symptoms in children with JIA despite aggressive contemporary medical management.

Methods: Fifty-nine children with JIA (44 girls, 73% Caucasian, mean age 13.3 years) were recruited during routine pediatric rheumatology clinic visits. Most had mild (42%) or moderate (43%) physician-rated disease activity (minimal 11%, severe 4%). Participants provided current ratings of pain, stiffness, and fatigue intensity; number of painful locations; and functional limitations using a Smartphone e-diary three times each day for one month. Medication information was collected via parent report and checked for accuracy by chart review. Descriptive analyses were conducted to determine typical symptom intensity, frequency, and variability for the sample. Multilevel modeling was then used to analyze associations between symptoms and functional outcomes and between medication use and symptom intensity.

Results: Across 3258 completed e-diary entries, the average pain intensity rating was 26.3/100 (SD = 27.5), average stiffness intensity 24.4/100 (SD =25.2), and average fatigue intensity 42.7/100 (SD = 28.19). Children reported pain ($>$1/100) on 69% of e-diary entries. No children were entirely pain-free across the reporting period. Children endorsed high pain ($> 40/100$) on 31% of all e-diaries with 86% reporting high pain at least once in study period. The majority of children in this sample were prescribed DMARDS (chart review 79%, caregiver report 54%). Biologics were the next most commonly prescribed medication (chart review 47%, caregiver report 32%). Few children were taking opioids (chart review 1%, caregiver report 3%). Medication type did not reliably predict differences in symptom intensity. Momentary pain intensity ($t(3040) = 19.76$, $p <.01$), number of painful locations ($t(3039)= 8.44$, $p <.01$), and stiffness intensity ($t(3038)= 2.60$, $p <.01$) uniquely predicted functional limitations, but fatigue intensity did not ($t(3037)= -1.71$, $p=.09$).

Conclusion: Self-reported pain, stiffness, and fatigue continue to be common in children with JIA despite contemporary treatment advances including biologics. Prescribed medication class did not have a significant effect on reported symptoms. The findings are surprisingly consistent with previous results from paper daily diary research in the pre-biologic era. There remains a pressing ongoing need to optimize pain and symptom management in JIA.

2421

The Pediatric Rheumatology Nursing Network: An International Email MANAGED COMMUNICATION System. Norma L. Liburd. All Children's Hospital, St. Petersburg, FL

Background/Purpose: The Pediatric Rheumatology Nursing (PRN) Network is an electronic listserv linking 190 pediatric rheumatology nurses in 8 countries. Pediatric rheumatology nurses often have a sense of isolation because the closest nurse in this specialty could be 1000 miles away. However, this communication system makes consultation with another pediatric rheumatology nurse as close as one click away.

The purpose of the PRN Network is to promote communication, networking and to enhance practice knowledge, thereby improving patient care in pediatric rheumatology. The listserv goals are to exchange best pediatric rheumatology nursing practices; discuss difficult treatment issues such as patient adherence; share family educational and support products, activities, and materials; and exchange disease information, resources, school forms, treatment protocols, and procedures.

Methods: The PRN Network began in 1988 with a quarterly newsletter disseminated to pediatric rheumatology nurses in the United States (US). The nurses who initially received the newsletter were part of 11 multidisciplinary pediatric rheumatology teams from SPRANS Grant Programs (Special Programs of Regional and National Significance) through the US Division of Maternal & Child Health. The newsletter was published from 1988 to 1996. Grants totaling $3,000 were obtained from Astra USA to underwrite the newsletter. By 1997, the newsletter reached pediatric rheumatology nurses throughout the United States and Canada. The number of nurses on the mailing list increased from 20 to 60 nurses, primarily through word of mouth.

In 1998, the PRN Network listserv was initiated. Some nurses were participating on the well-established pediatric rheumatology (physician) listserv run by Peter Dent, MD, through McMaster Children's Hospital in Ontario, Canada. However, the pediatric rheumatology nurses felt that a nurse-only listserv would enable them to discuss issues relevant to their profession. This listserv was launched on a trial basis with 7 nurses. By 2002 there were 31 nurses on the listserv. By 2004 subscribers had grown to 82. In 2010, there were 146 nurses.

Lack of funding required startup from a home computer. Eventually the listserv transitioned to the server at All Children's Hospital in St. Petersburg, Florida. The listserv coordination is done from a home laptop and the database is maintained on gmail. Twice a year listserv members receive a copy of the updated member list.

Results: There are currently 190 nurses on the Listserv—from the United States, Canada, United Kingdom, Germany, Spain, Australia, New Zealand, and Singapore. Benefits of the listserv include increased knowledge of timely issues, management of medication shortages, sharing of difficult cases, promotion of patient adherence, conference planning, and sharing of educational materials.

Conclusion: There is no cost to participate on the PRN Network listserv. Once a year, an email is sent to the physicians' pediatric rheumatology listserv to recruit nurses for the PRN Network. All pediatric rheumatology nurses are welcome to join. For more information, contact Norma Liburd at norma.liburd@allkids.org.

Sexual Activity and Sexual Functioning Among Women with Systemic Sclerosis Compared to Women From a Population Sample. Brooke Levis[1], Andrea Burri[2], Marie Hudson[1], Murray Baron[3] and Brett D. Thombs[1]. [1]McGill University, Montreal, QC, [2]King's College, London, United Kingdom, [3]Jewish General Hospital, Montreal, QC

Background/Purpose: Systemic sclerosis (SSc), or scleroderma, is a chronic, multi-system, connective tissue disorder characterized by thickening and fibrosis of the skin and internal organ involvement. Approximately 80% of patients are women, with highest onset rates between ages 30–60. Common problems include pain, fatigue, pruritus, body image distress, depressive symptoms, and general disability. Reduced sexual activity and impaired sexual functioning are also common among women with SSc and, in addition to age and marital status, are associated with disease severity and symptoms. To date, however, no studies have compared the rates of sexual activity and impairment of women with chronic medical disease to general population data. Thus, the objectives of this study were to 1) determine the rates of sexual activity and sexual impairment, stratified by age and marital status, for a SSc sample and a female population sample, 2) identify the odds of sexual activity and sexual impairment for women with SSc compared to the population sample, controlling for age and marital status, 3) identify the domains of sexual function (desire, arousal, lubrication, orgasm, and pain) most closely related to impairment in SSc compared to the general population, and 4) assess the association between sexual domain scores and sexual satisfaction in SSc versus the general population.

Methods: Female SSc patients from the Canadian Scleroderma Research Group Registry were compared to females from a UK population sample. SSc patients were asked whether they had engaged in sexual activities with a partner in the past 4 weeks. Sexually active patients completed a 9-item version of the Female Sexual Function Index (FSFI) and an item on sexual satisfaction. Women from the UK completed the FSFI as part of a study on female sexual dysfunction. Multivariate logistic regression analyses were used to assess the independent association of sample group with sexual activity and impairment status. Analysis of covariance was used to assess differences in sexual domain scores in both samples, controlling for total FSFI scores. Pearson's correlations were used to assess the association between sexual domain scores and sexual satisfaction.

Results: Among 730 women with SSc, 296 (41%) were sexually active, 181 (61%) of whom were sexually impaired. Among 1,498 women in the population sample, 956 (64%) were sexually active, 420 (44%) of whom were impaired. Adjusting for age and marital status, women with SSc were significantly less likely to be sexually active (OR=0.34, 95%CI=0.28–0.42) and significantly more likely to be sexually impaired (OR=1.88, 95%CI=1.42–2.49), compared to women from the general population. Adjusting for total FSFI scores, women with SSc had significantly worse lubrication and pain scores than women in the general population. All domains were substantially more highly correlated with satisfaction among women with SSc compared to population sample women.

Conclusion: This study highlights that sexual functioning is a problem for many women living with scleroderma and that it is associated with pain and poor lubrication, two known problems for women with SSc.

2423

Perceptions Regarding Cardiovascular Risk Factors and Barriers to Risk Reduction Among African American Women with Lupus. Barron Mia[1], Lynne Nemeth[1], Diane L. Kamen[2] and Youlanda C. Gibbs[1]. [1]Medical University of South Carolina, Charleston, SC, [2]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC

Background/Purpose: Cardiovascular disease (CVD) is highly prevalent among African American (AA) women diagnosed with systemic lupus erythematosus (SLE). Studies have suggested that CVD risk factors in AA women are different from that experience by other ethnic groups. However little is known regarding the perceptions or barriers and facilitators in reducing CVD risk factors among this population. The objective of this study was to assess perceptions of modifiable risk factors for CVD and to evaluate the barriers and facilitators to implementing any lifestyle changes needed to reduce CVD risk.

Methods: Eight AA women with SLE participating in a longitudinal observational registry (SLE in Gullah Health (SLEIGH) were invited to participate in this study. After informed consent was obtained, a formative, qualitative study using a focus group format was conducted, audio taped, transcribed verbatim and entered into a qualitative text management software program (NVIVO) to facilitate analysis. Transcript content was evaluated in relation to perception of CVD risk factors with a diagnosis of lupus and barriers to lifestyle changes in reducing CVD risk factors. Participants completed questionnaires on sociodemographics and CVD risk factors. Duration of SLE and disease activity was obtained as part of the SLEIGH registry.

Results: Participant characteristics are displayed in Table 1. The total prevalence of CVD risk factors among this population was 86%, 50% accounting for family history of CVD before age 55. Significant themes (Table 2) included lack of education and awareness along with ineffective patient-clinician communication. Barriers included physical and psychosocial limitations in adopting healthier behaviors.

Table 1. Patient demographics and disease characteristics

Number of participants (% female)	8 (100%)
Mean age in years	45 (range 19–65)
Highest Education (>12 years)	8 (100%)
Yearly Income (under 10,000)	4 (50%)
Family history of CVD before age 55	4 (50%)
Personal History of CVD with SLE	3 (37.5%)
Disease duration of SLE in years	20.6 (range 12–39)
Median Disease Severity (SLICC scores)	2 (range 0–4)

Table 2. Five key themes identified with examples

THEMES	QUOTES
A need for more information and awareness about CVD risk	"Yes. I think it would be real beneficial. You would have the awareness and the knowledge to know what to look for."
A desire for healthcare providers time, attention and communication regarding CVD risk factors	"Because when you get a diagnosis like lupus, you already think your life is over and I just think that they have to know how to present the information in order for the patient to really understand yes you are at risk but I mean you can do things to prevent this and as it stands right now, in my experience and I don't know what kind of experience you guys have had but like my doctor basically told me my life was over."
Physical and psychosocial limitations related to the impact of lupus	"Doing things that I used to do is limited now, very, very limited"
The need for effective prevention and disease management approaches	"Well I've never been offered screening so if it was offered to me, [crosstalk], then I would go through the process but I mean it's never been offered to me."
Adoption of healthier living habits (activity and diet)	"I can add to what she's saying. You eat more whole food. If you can pick it off a tree or pull it out of the ground eat that." "Aquatic therapy. I've been doing that for about maybe four or five years. Aquatic therapy seems to help."

Conclusion: This study provides additional data illustrating the importance of patient-clinician communication and the obstacles of effective management in reducing CVD risk. These findings suggest the need for further exploration of interventions used to eliminate barriers and foster facilitation in reducing CVD risk factors in the presence of SLE.

2424

Sleep Disturbances in Systemic Sclerosis: Evidence for the Role of Gastrointestinal Symptoms, Pain, and Pruritus. Katherine Milette[1], Marie Hudson[1], Annett Koerner[1], Murray Baron[2] and Brett D. Thombs[1]. [1]McGill University, Montreal, QC, [2]Jewish General Hospital, Montreal, QC

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune connective tissue disorder characterized by thickening and fibrosis of the skin and internal organs. There is significant mortality and morbidity in SSc, considerable functional disability, and no known cure. Therefore, appropriate symptom management is critical in improving patient quality of life. SSc patients experience numerous problems contributing to reduced quality of life, including fatigue, pain, depression, sexual dysfunction, body image distress, and itching. In SSc, as well as other rheumatic diseases, sleep disturbances also appear to be common. However, to date, there has been very little research in this area. In fact, only 3 relatively small studies have investigated sleep disturbance in SSc. This study's objective was therefore to investigate the association of factors potentially associated with sleep disturbance in the general population (gender, age, marital status, education, income, current medications, and medical diagnoses), in SSc (shortness of breath, gastrointestinal symptoms, pain, and pruritus), and across rheumatic diseases (pain) with sleep disturbance in a large Canadian sample of SSc patients.

Methods: The sample included patients enrolled in the Canadian Scleroderma Research Group's (CSRG) 15-center, pan-Canadian Registry. To be eligible for the Registry, patients must have a diagnosis of SSc, be >18 years of age, and be fluent in English or French. Pearson correlations were used to assess bivariate associations of sociodemographic and medical variables with PROMIS sleep disturbance scores (range 8–40). Multivariate linear regression was used to assess the association of factors associated with sleep disturbance in the general population, in SSc, and across rheumatic diseases with PROMIS sleep disturbance scores.

Results: There were 397 patients in the study. The mean (SD) sleep disturbance score was 22.8 (8.0). More gastrointestinal (GI) symptoms (standardized β = 0.19, p = 0.001), pain severity (standardized β = 0.21, p < 0.001), and pruritus severity (standardized β = 0.13, p = 0.024) were associated with more severe sleep disturbance in multivariate regression.

Conclusion: The number of GI symptoms, pain severity, and pruritus severity are medical factors that are associated with increased sleep disturbance in SSc. This is consistent with previous studies that identified GI involvement and pain as independent predictors of sleep disturbance in SSc. Previous studies did not include pruritus, however. This is the first study to do so and findings support the need for further research into pruritus, as well as possible interactions between the itch- and pain-processing pathways of the neuronal system. Important sociodemographic and medical factors related to sleep disturbance in the general population were also investigated. However, none of these factors were related to sleep disturbance in SSc, possibly because of the strong influence of disease-specific factors. Overall, better management of GI symptoms, pain, and pruritus, which are key medical factors in SSc, may have important ramifications for quality of life in SSc, including sleep quality.

2425

A Qualitative Study of Self-Image and Body Image in Individuals with Systemic Lupus Erythematosus. Afton L. Hassett[1], Diane C. Radvanski[2] and Elizabeth Hale[3]. [1]University of Michigan, Ann Arbor, MI, [2]Robert Wood Johnson Medical School, NJ, [3]Dudley Group NHS Foundation Trust, Dudley, United Kingdom

Background/Purpose: Symptoms and treatment related to SLE are often outwardly evident. Patients with SLE cope with such external manifestations as joint swelling, rashes, scarring, loss of skin pigmentation, alopecia, facial changes (Cushingoid appearance) and overall weight gain. Despite findings that side effects affecting appearance are associated with poor medication adherence, body-image and self-image in general have received very little attention in the SLE scientific literature. The primary objective of this qualitative study was to learn more about the role of self-image and body image in SLE.

Methods: 15 patients with SLE underwent semi-structured interviews that were approximately one hour long. Interviews were audio recorded, transcribed verbatim and analyzed using Interpretive Phenomenological Analysis (IPA). IPA is a qualitative method that takes an idiographic approach, trying to understand the experience from an individual account, then building up to commonalities and differences when looking across cases. Themes for these interviews were identified and collected under major thematic headings.

Results: Our participants included 14 females and 1 male all between the ages of 22 and 57. Patients were ethnically and racially diverse (e.g., 53.3% African American, 13.3% Caucasian) and just over half were married (53.3%). Running throughout the interviews were the themes of the changed self, the battle for normality and being attacked by an unwanted physical enemy. It also became clear that it is the outward "cosmetic" effects of SLE that can cause the most distress for participants, quite apart from the internal effects with which they were coping. We found that the concepts of body-image and self-image were inextricably linked; body-image impacts self-image and when feeling negative about one, it's hard to feel positive about the other. This was the daily challenge our participants faced. Often highlighted was how much they felt they had changed when talking about their body image, particularly in outward appearance. This was a topic that caused great distress as individuals remembered how they used to be. Sometimes this was expressed as

looking in the mirror and not recognizing the person looking back, which suggests that not only did individuals experience a distancing from other people and valued social roles, they experienced a disembodiment from their own selves as well.

Conclusion: Patients reported that self-image and body image are adversely affected by SLE and these changes in perception can impact quality of life. Weight gain, Cushingoid appearance, hair loss and rashes were the most troubling manifestations.

Prevalence and Characteristics of Sleep Problems in Rheumatoid Arthritis: A Systematic Review of the Literature. Cassandra Coleman and Yvonne C. Lee. Brigham and Women's Hospital, Boston, MA

Background/Purpose: Rheumatoid arthritis (RA) patients commonly complain of sleep problems. Difficulties with sleep may be associated with increased fatigue, greater pain and worse quality of life. We aimed to establish the prevalence of sleep problems among RA patients and to characterize these sleep problems based on survey and polysomnographic measurements.

Methods: We conducted a systematic literature review to identify studies reporting the prevalence and characteristics of sleep problems in RA. Pubmed searches were conducted using MESH keywords for "Arthritis, Rheumatoid," "Sleep," Sleep Disorders", and "Fatigue", for studies published worldwide in English between August 1989 and April 2012. Further articles were obtained from the reference lists of these articles. Articles were selected based on title, abstract and manuscript review. Inclusion criteria included studies focusing on sleep problems in adult-onset RA patients. Review articles, case reports, and qualitative studies were excluded. One author (CC) screened titles and abstracts. Both authors independently extracted data from the articles. Data regarding the prevalence of sleep problems and specific types of sleep problems were extracted, and ranges of values and median of means are reported.

Results: The literature search identified 1410 articles of which 23 were included in the review. Of these articles, 8 had specific measures of the prevalence of sleep problems, and 18 used survey and/or polysomnograph methods to characterize these problems based on sleep duration, sleep efficiency and sleep disturbance. Only 5 articles had data comparing RA patients to controls (**Table**). Methods and scales for evaluating prevalence and characteristics of sleep disturbances varied greatly among these articles. The prevalence of sleep problems ranged from 60–97% by self-report questionnaires. The Pittsburgh Sleep Quality Index score, reflecting sleep quality, sleep latency, sleep efficiency, sleep disturbance, and sleep duration, was markedly higher, signifying poorer sleep, in RA patients compared to control patients. Polysomnograph studies also indicated lower sleep efficiency, increased number of awakenings, and longer sleep latency among RA patients compared to control subjects. However, mean hours of sleep, measured by polysomnograph, were similar among RA patients compared to controls.

Table. Median of means and ranges of reported values for survey and polysomnograph measures among RA patients and controls

Clinical Characteristics	Median of Means (Range of Values) Rheumatoid Arthritis	Controls	Number of Studies
Survey Measures			
Pittsburgh Sleep Quality Index [1]	8.5 (7.6–9.5)	2.6 (2.4–2.8)	2
Polysomnograph Measures			
Mean Hours of Sleep (hrs)	6.3 (5–7.2)	6.9 (6–7.6)	4
Sleep Efficiency (%)	80.9 (61–93.6)	90.8 (85–94)	4
Number of Awakenings	67.6 (3.1–194)	7.4 (2.6–112)	4
Sleep Latency (min)	25.1 (21.8–30.5)	13.7 (12.1–25.2)	4

[1]Range = 0–21, PSQI score < 5 = "good sleeper", PSQI > 5 = "poor sleeper"

Conclusion: Sleep disturbances, notably increased awakenings, were reported by the majority of RA patients, while sleep duration was similar among RA patients compared to controls. These results suggest that widespread sleep problems among RA patients may be a result of disturbed sleep rather than an overall lack of sleep. Future studies are needed using uniform sleep measures in large cohorts of well-characterized RA patients with appropriately selected controls.

Health-Related Quality of Life in Adolescents with Rheumatic Disease. Sandra J. Watcher[1], Maggie Sepkowitz[1], Suhas M. Radhakrishna[2], Anusha Ramanathan[3], Elizabeth Morasso[3], Jennifer Chang[3] and Jeffrey I. Gold[4]. [1]Children's Hospital of LA, Los Angeles, CA, [2]Kaiser Permananete Medical Group, Oakland, CA, [3]Childrens Hospital Los Angeles, Los Angeles, CA, [4]Keck School of Medicine, University of Southern California - Children's Hospital Los Angeles, Los Angeles, CA

Background/Purpose: Adolescents with chronic health disease face a variety of physical and psychological challenges. Adolescents with rheumatologic conditions vary with regard to their physical, emotional, and functional health outcomes, such as quality of life. The purpose of this project was to evaluate health-related quality of life (HRQOL) in adolescents with rheumatic disease. In addition, an examination of agreement between adolescent and parent-report of HRQOL was completed.

Methods: Adolescents and their parents participated in concurrent rheumatology support groups focused on psychoeducation, medical management, and quality of life. The sample consists of 38 adolescent (11–20 years)/parent pairs. Prior to attending the support/education group one parent and their adolescent completed self-reports of HRQOL. Measures of interest included a demographic questionnaire and the Simple Measure of Impact of Illness or Lupus Erythematous in Youngsters© (SMI-ILY© - SMILEY©) for parents and adolescents. This tool evaluates perception of overall quality of life, current illness and four individual domains: effect on self, burden of illness, social impact, and limitations of illness. Scores are calculated into a percentile score for each domain, with a higher score indicating greater HRQOL.

Results: 65.8% were Latino/Hispanic and 34.3% reported other (Asian, Asian/pacific, Asian pacific-islander black or white/non-Latino). Mothers represented 69.4%, fathers 22.2% and other 8.3%. Gender of the adolescent was 82.4% female.

Adolescents reported functioning above average quality of life in the domains of effect on self (61.26%) and social impact (73.02%). Two domains demonstrated a moderate impact on HRQOL in the domains of burden of illness (51.73%) and limitations (54.27%). Parent-report reflected similar responses being slightly lower in all domains reflecting the effect on self (58%), social impact (66.97%), burden of illness (47.59%) and limitations (52.76%).

The Wilks' Lambda distribution was used and no significant differences were found between adolescent and parent ratings. Additionally, there was no significant corelation between the parent and adolescent-reports on all domains and total score of the SMI-ILY© - SMILEY©.

Conclusion: Adolescents and their parents enrolled in a support/education program reported moderate to moderately high levels of self and social support. Of interest is the consistent burden of illness and limitations reported by adolescent with rheumatic disease and their parents. The findings are consistent with other literature supporting the effects of pediatric chronic health disease on HRQOL. While similar trends were reported across all domains of HRQOL, measures of agreement were not statistically significant. Information regarding the effects of rheumatic disease on the four domains lend further support for interventions focused on the direct burden of illness and limitations caused by the patient's disease. Future investigations should focus on maintaining the impact of rheumatic disease on self and social support and focus on interventions for specific aspects of burden of illness and disease specific limitations.

Disclosure: **S. J. Watcher**, None; **M. Sepkowitz**, None; **S. M. Radhakrishna**, None; **A. Ramanathan**, None; **E. Morasso**, None; **J. Chang**, None; **J. I. Gold**, None.

Causal Beliefs of Disease Among Patients with Systemic Vasculitis. Peter C. Grayson[1], Naomi Amudala[1], Carol McAlear[2], Renée Leduc[3], Denise Shereff[3], Rachel Richesson[3], Liana Fraenkel[4] and Peter A. Merkel[5]. [1]Boston University Medical Center, Boston, MA, [2]Vasculitis Clinical Research Consortium, University of Pennsylvania, Philadelphia, [3]University of South Florida, Tampa, FL, [4]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [5]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Patients vary in their beliefs related to the cause of serious illness. The impact of these beliefs among patients with systemic vasculitis is not known. This study aimed to describe patient beliefs related to the cause of systemic vasculitis and to examine whether casual beliefs are associated with psychological impact of disease and functional impairment.

Methods: Participants were recruited online from a patient contact registry in vasculitis. Causal beliefs were measured using two approaches. Using an open-ended question, participants were asked to list the three most

important causal beliefs about disease-onset. Responses were categorized and weighted by rank to determine the relative frequency of beliefs. Participants also rated 18 specified causal beliefs (obtained from the well-validated revised Illness Perception Questionnaire, IPQ-R) on a 5-point scale, with higher scores indicating stronger agreement. Response scores to the specified items were summed into a *belief score* which defined strength of causal beliefs. Psychological impact was measured using a scale from the IPQ-R assessing the negative emotional impact of vasculitis. The Medical Outcomes Study General Health Survey was used to assess functional impairment (*physical*, *role*, and *social*). Pearson correlation coefficients were calculated between belief scores, psychological, and functional impairment.

Results: 692 participants with 9 forms of vasculitis were included. There was considerable variability of causal beliefs among participants and beliefs differed by type of vasculitis (**Table**). The most common beliefs listed by participants using the open-ended approach were environmental exposures (16%), stress (15%), hereditary factors (15%), and infection (15%). For the 18 specified items (scored 1–5), altered immunity (3.6 ± 1.1) and stress (3.2 ± 1.3) were the most agreed upon causal items for each type of vasculitis. Negative emotional impact of illness, role, and social function were significantly correlated with belief score (r= 0.26, 0.12, 0.12; p<0.01). Physical function was not significantly associated with belief score (r=0.07, p=0.09).

Table. Frequency (%) of Disease-Onset Causal Beliefs in Systemic Vasculitis

Causal Belief	Total n=692	BD n=48	CNS n=12	CSS n=121	GCA n=32	HSP n=12	MPA n=42	PAN n=36	TAK n=57	GPA n=332
Environmental Exposure	16	9	3	18	12	11	15	1	3	20
Stress	15	12	14	11	17	11	15	13	17	17
Hereditary	15	**29**	9	11	10	0	13	11	**19**	15
Infectious	15	23	**17**	8	6	**40**	22	18	17	15
Altered Immunity	11	11	13	16	15	13	8	7	17	10
Other Risk Factors*	7	6	11	9	**16**	7	9	**20**	7	4
Medications and Vaccines	6	3	0	11	9	18	7	8	3	3
Psychological Factors#	6	3	2	3	5	0	5	6	8	6
Chance	5	2	9	4	2	0	3	7	2	6
Past Medical Problems	4	3	14	7	5	0	2	5	5	3

The most common beliefs per column are highlighted in bold. * Other Risk Factors = diet or eating habits, poor medical care, my own behavior, ageing, alcohol, smoking, accident or injury. # Psychological Factors = my mental attitude, family problems, my emotional state, overwork, my personality. BD= Behçet's disease; CNS= central nervous system vasculitis; CSS= Churg-Strauss syndrome; GCA= giant cell arteritis; HSP= Henoch-Schönlein purpura; MPA= microscopic polyangiitis; PAN= polyarteritis nodosa; TAK= Takayasu's arteritis; GPA= granulomatosis with polyangiitis (Wegener's).

Conclusion: Patient beliefs related to the cause of systemic vasculitis are highly variable. Patients with strongly-held causal beliefs report that their illness has greater negative impact on their psychological well-being and their ability to perform role and social functions. Clinicians who care for patients with vasculitis should be mindful of these associations and consider asking patients about their causal beliefs.

2429

Balancing Work and Health: Do Younger Workers Experience More Work-Health Conflict Than Middle- and Older-Aged Workers with Rheumatic Diseases? Arif Jetha[1], Xingshan Cao[2] and Monique A. Gignac[3]. [1]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [2]Arthritis Community Research and Evaluation Unit, Toronto Western Research Institute, Toronto, ON, [3]Arthritis Community Research and Evaluation Unit, Toronto Western Research Institute, University of Toronto and Institute for Work and Health, Toronto, ON

Background/Purpose: Research on work-life balance with healthy adults finds that difficulties balancing roles is related to negative employment outcomes. Yet, little is known about work-health balance among those with rheumatic diseases, especially in different age groups or career stages.

Objective: To compare perceptions of work-health balance/conflict in younger (18 to 30 years of age) and older (greater than 30 years of age) workers, as well as demographic, health, and job context factors associated with work-health balance/conflict.

Methods: Data from two separate studies were combined: an online survey of 143 young adults (mean age=23.3, SD=3.5, range: 18–30 years) with juvenile arthritis and systemic lupus erythematosus; and a telephone survey of 350 workers (mean age =54.2, SD = 8.9; range: 26–69 years) with inflammatory arthritis and osteoarthritis. Respondents completed the Arthritis-Work Spillover Scale (AWS), a 6-item measure of perceived rheumatic disease-related work-health conflict (1 = "strongly disagree"; 5 = "strongly agree"). Participants also completed information on demographics, health (e.g. diagnosis, pain), and work context factors (e.g. work hours, work activity limitations). Descriptive analyses and separate multivariate linear regression analyses by age group (18 to 30 years of age; greater than 30 years) examined factors associated with AWS.

Results: Younger workers reported working significantly fewer hours (30.7 vs. 34.8) and were more likely to work in sales and service jobs (36% vs. 21%) than workers aged 30 years or older (p<.05). AWS was significantly lower among younger workers (mean=2.5, SD= 1.1 versus mean=2.9, SD=1.0, p <.05). Although health and work context factors were associated with AWS for all workers, R-squared values indicated that health factors explained more of the variance in younger workers and work context factors were more important for older workers. Specifically, pain was related to more AWS in younger adults and work hours, job disruptions (e.g., missed meetings), and disclosing one's disease to an employer were associated with higher AWS in workers older than 30 years of age. Workplace activity limitations was related to increased AWS for all workers.

Conclusion: Younger workers with rheumatic diseases reported less work-health conflict which can be related to differences in the type and hours of their work. In reducing work-health conflict, pain management may be particularly important for younger workers and workplace accommodations may be important for older workers. Future research needs to examine age differences in greater detail, as well as health care management and work context factors.

2430

Using the Internet in Help-Seeking As Illness Develops in Early Rheumatoid Arthritis. Anne F. Townsend[1], Jenny Leese[2], Catherine L. Backman[3], Paul M. Adam[4] and Linda C. Li[5]. [1]Arthritis Research Centre of Canada, Vancouver, BC, [2]Arthritis Research Centre, Vancouver, BC, [3]University of British Columbia, Vancouver, BC, [4]Mary Pack Arthritis Centre, Vancouver, BC, [5]Arthritis Centre of Canada and Department of Physical Therapy, University of British Columbia, Vancouver, BC

Background/Purpose: Patients' Internet use for health purposes is regarded as potentially transformational. Using on-line resources is associated with the emergence of the e-patient; broadly defined as someone who is an involved and empowered partner in care and is engaged in informed decision-making. We know little however, about how Internet use influences help seeking, the patient-clinician consultation and informed decision-making in early rheumatoid arthritis (RA). This qualitative study examines patient accounts of their Internet use during the 12 months following their diagnosis of RA, how it impacted patient help seeking and how Internet use evolved over time.

Methods: Twenty-two participants (17 women, 5 men), age range 30s–70s, were recruited, within 12 months of an RA diagnosis, from rheumatologist and family physician offices and online patient advocacy groups. A series of 3–4 in-depth interviews were conducted over twelve months to track illness experiences and behaviors over time. The interview guide is based on 3 areas: 1) Pre-diagnosis symptoms, impact and management; 2) Experiences with health professionals leading to the diagnosis; 3) Post-diagnosis experience of symptoms, management and the health care system. Analysis is informed by grounded theory. Early analysis was concurrent with data collection enabling new and salient questions to be introduced to the interview schedule. Internet use as impacting illness behaviors emerged as an early theme and was subsequently included as a topic for inquiry in all interviews.

Results: Preliminary analysis identified that online patients' experiences affected help seeking in a range of ways. Three early themes emerged: 1) Assessing trustworthiness: participants compared different sites to validate information and favored institutional sites offering factual information over personal blogs, which could heighten their anxieties; 2) Help-seeking support: the Internet provided participants with information which some discussed with their family doctor e.g. to gain a specialist referral, while others used it to gain a 'second opinion' to compare with their doctor's advice; 3) Evolving strategies: Over time participants changed the way they used the Internet; e.g. some used it less as they secured knowledge and support from their doctors, and others used it in a more targeted or selective way.

Conclusion: Our findings show how our participants used the Internet in a range of ways, which impacted their help seeking, and had the potential for both positive and negative impacts. As Internet use becomes a key feature of help seeking, it influences patients' experiences. This has implications for both the patient's and clinician's role in managing RA. More research is needed to identify the ways in which health professionals can best support patient Internet use for optimum outcome, and encourage patients to become more informed partners in care.

ARHP Concurrent Abstract Session
Physical/Occupational Therapy and Exercise in Patients with Rhematologic Disease
Tuesday, November 13, 2012, 9:00 AM–10:30 PM

2431

Are Occupational Therapy Interventions Included in the Most Commonly Used European Clinical-Practice Guidelines for the Management of Osteoarthritis? Michaela Stoffer[1], Doris Taurok[2], Birgit Prodinger[3], Josef S. Smolen[4], Anthony D. Woolf[5] and Tanja A. Stamm[6]. [1]Medical University of Vienna, A–1090 Vienna, Austria, [2]Orthopaedic Hospital Vienna Speising, 1130 Wien, Austria, [3]University of Western Ontario, London, ON, [4]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [5]Royal Cornwall Hospital, Truro Cornwall, United Kingdom, [6]Medical University of Vienna, Vienna, Austria

Background/Purpose: The EUMUSC.net project facilitates cooperation between EU Member States and promotes a comprehensive European strategy to optimise musculoskeletal health.

Part of the EUMUSC.net project was devoted to retrieving clinical practice guidelines (CPG) for Osteoarthritis (OA) and to appraise them critically. The purpose of this study was to identify the relevance given to occupational therapy interventions.

Methods: National rheumatological scientific societies, social leagues and health professional associations were contacted and asked to provide relevant documents. Furthermore, a systematic review of the respective literature was conducted in Medline, CINAHL and the Internet. Documents fulfilling pre-defined inclusion and exclusion criteria have been critically appraised by two independent assessors using the AGREE II Instrument. The appraised documents were examined for occupational therapy interventions/occupational therapy (OT).

Results: Six guidelines/recommendations have been included into this study and appraised using the AGREE II Instrument. All six CPGs obtained the highest scores in the domain "Scope and Purpose" followed by remarkably high scores in the domain "Rigor of Development".

Four CPGs had low scores in the domain "Stakeholder Involvement" and five in the domain "Applicability". We identified ten interventions relevant to occupational therapy: adapting the environment, assistive devices for activities of daily living, hand exercise, joint protection, comprehensive occupational therapy, patient education, self management, splinting/orthoses, thermotherapy and walking assistive devices. Only "patient education" was recommended in all CPGs. "Adapting the environment" in one.

Inclusion Criteria for the documents	Exclusion Criteria for the documents
Published after 1/2002 till 3/2011	Non-European origin
Dealing with hand, hip and knee OA	Full text not available
Denoting themselves as a guideline or as recommendations	Full text neither German nor English
Non-pharmacological approach included	Pharmacological approach only
Last Version (if the CPG was updated)	Guidelines dealing with back pain/OA of the spine

Conclusion: All six guidelines/recommendations addressed occupational therapy interventions. Two CPGs were referring to the term occupational therapy while the others did not. In all appraised documents no occupational therapist could be identified to be a member of an OA Guideline development group.

2432

Arthritis Foundation's Tai Chi Program for People with Arthritis: One Year Follow-up. My-Linh Luong[1], Rebecca J. Cleveland[1], Betsy Hackney[1] and Leigh F. Callahan[2]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill, NC

Background/Purpose: To evaluate program adherence and whether the improvements seen after completing the Arthritis Foundation's 8-week Tai Chi course remained for reduction of symptoms, increased function, and improved psychosocial status in participants with arthritis one year after program completion.

Methods: At one year after the end of the intervention, individuals who completed the 8-week follow-up (n=144) were mailed a self-report questionnaire designed to assess continuation of the Tai Chi program as well as evaluate pain, fatigue and stiffness visual analog scales (VAS), Health Assessment Questionnaire (HAQ), general health, Rheumatology Attitudes Index (RAI, helplessness), and Arthritis self-efficacy (ASE) for pain and symptoms. Participants also completed the PROMIS™ (PR) Short Form instruments for sleep disturbance and satisfaction with social roles. Regression analyses evaluated the change in scores from baseline assessment to 1-year follow-up, with adjustment for baseline score, age, gender, and BMI.

Results: The follow-up rate for the 1-year evaluation was 78% (n=113) and 31% reported that they continued participation in the Tai Chi Program (n=35) after completion of the 8-week follow up. Overall, those who participated in the Tai Chi program at baseline reported improvements in several self-reported health status measures one year after completion of the program. Modest improvements were seen for pain and stiffness VAS (effect size [ES] =0.30 and 0.25, respectively). Participants also reported statistically significant improvements for helplessness, pain impact and pain behavior (ES=0.23, 0.21, and 0.32, respectively). However, when comparing those who continued to practice Tai Chi at one year with those who did not, there were no statistically significant differences in improvements from baseline in self-reported measures for those who continued with the Tai Chi program except for helplessness (RAI, ES=0.49 vs. ES=.11, p=0.03). The most frequently cited reasons for not continuing the Tai Chi program were that participants did not feel comfortable doing Tai Chi outside of a class setting (41%) and that there were no classes convenient to them (37%). 95% of participants said they would recommend the program to others.

Conclusion: Participants in the AF Tai Chi program showed continued modest improvements in pain, and stiffness. The HAQ measure of physical function did not indicate significant change; however those who continued practicing Tai Chi saw improvements in feelings of helplessness. While we did not observe sustained effects of the Tai Chi program, those who participated enjoyed the program and many did not continue with the program due to lack of availability in their area.

Integration of a Healthy Aging Program Into the Arthritis Foundation Exercise Program: Six-Month Results. Elizabeth A. Schlenk[1], Joni Vander Bilt[1], Wei-Hsuan Lo-Ciganic[1], Sarah E. Woody[1], Janice C. Zgibor[1], Molly B. Conroy[2], C. Kent Kwoh[3] and Anne B. Newman[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, PIttsburgh, PA, [3]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA

Background/Purpose: In 2001, the University of Pittsburgh Prevention Research Center (PRC) developed the "10 Keys"™ to Healthy Aging program in response to the need to promote healthy aging. The "10 Keys"™ focus on systolic blood pressure (BP), smoking cessation, cancer screenings (breast, cervical, prostate, and colon), immunizations (influenza and pneumonia), blood glucose, LDL cholesterol, physical activity, musculoskeletal health (bone density test and BMI), social contact, and combat of depression. Primary objectives of the program were collaboration and dissemination. In 2010, the PRC partnered with the Arthritis Foundation (AF) of Western Pennsylvania and targeted older adults with arthritis or joint pain for a

community-based, group-delivered intervention. We hypothesized that the integrated program would improve preventive behaviors and outcomes targeting both arthritis and clinical assessments of preventive health goals.

Methods: A quasi-experimental design was used for this pilot study ($N=51$). A 10-week curriculum that integrated the "10 Keys"™ program into the AF Exercise Program was developed, instructors were recruited and trained, and host sites and participants were recruited. Classes were held twice weekly in three sites and once weekly in one site. Data were collected at baseline, post-intervention, and six months post-intervention and included BP, BMI, cholesterol and glucose levels, questionnaires [preventive behaviors; WOMAC scales: pain (range 0–20), stiffness, and function (range 0–68); Loneliness subscale of the Perceived Isolation scale (range 0–12); and Stanford Arthritis self-efficacy scale (range 0–30)], and Short Physical Performance Battery (SPPB, range 0–12).

Results: Participants were on average 75.5 ($SD=9.3$) years of age and primarily white (92%, $n=47$) women (88%, $n=44$) who reported an arthritis diagnosis (73%, $n=37$). Thirty-eight (75%) participants attended >50% of the classes. At six months, 50% ($n=18$) performed the AF Exercise Program exercises 1–2 days/week, and 28% ($n=10$) did so 3–7 days/week. Baseline to six-month results demonstrated significant improvements in WOMAC function in worst knee/hip (Ms 23.0 to 17.7, $p=.01$), loneliness (Ms 4.3 to 3.6, $p=.002$), self-efficacy for communication with physician ($Mdns$ 28.5 to 30.0, $p=.006$), and SPPB ($Mdns$ 10.0 to 11.0, $p=.02$). Trends in improvements from baseline to six months were seen in diastolic BP (Ms 72.4 to 69.3 mm HG, $p=.07$), influenza vaccinations (Ms 54% to 69%, $p=.06$), and WOMAC pain in worst knee/hip (Ms 7.4 to 6.2, $p=.09$). Participants (92%, $n=34$) rated the program overall as excellent or very good.

Conclusion: Our results indicate that this pilot program was feasible, was successful in engaging community partners, and improved participant behaviors and outcomes six months post-intervention. A clustered randomized trial comparing the integrated community program to the AF Exercise Program is underway.

Disclosure: E. A. Schlenk, None; **J. Vander Bilt**, None; **W. H. Lo-Ciganic**, None; **S. E. Woody**, None; **J. C. Zgibor**, None; **M. B. Conroy**, None; **C. K. Kwoh**, None; **A. B. Newman**, None.

Effects of Interventions That Aim to Increase Exercise Adherence in People with Arthritis: A Best Evidence Synthesis. Katie, E. MacPherson[1], Allison M. Ezzat[2], Jenny Leese[3] and Linda C. Li[2]. [1]New Westminster, BC, [2]University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre, Vancouver, BC

Background/Purpose: Exercise is a central component in treatment and rehabilitation for chronic musculoskeletal conditions. Current literature supports the use of therapeutic exercise to reduce pain, improve function, and enhance quality of life in people with arthritis. Due to an estimated 30–60% of patients not following prescribed exercises, studies have investigated barriers and predictors of exercise adherence, as well as interventions that aim to increase it. The objective of this best evidence synthesis was to determine the effectiveness of interventions aiming to increase exercise adherence to prescribed exercise programs in adults living with arthritis.

Methods: This study is part of a larger systematic review on the effectiveness of exericse adherence in people with a variety of chronic diseases. A literature search was conducted from 1947 to December 2010 using MEDLINE, EMBASE, PubMed, CINAHL, Academic Search Complete, IS Web of Science, PSYCInfo, SPORTDiscus, and Cochrane Database of Systematic Reviews using search terms related to chronic diseases and exercise adherence. Eligible studies for the current review included: participants 18 years and older with a diagnosis of arthritis; intervention(s) that aimed to improve adherence to a prescribed exercise regimen; a control or comparison group; and, measured exercise adherence as an outcome. Four independent assessors scanned titles and abstracts, performed data extraction and assessed study quality using the Pedro scale. The relative difference of exercise adherence was calculated for each study.

Results: The search strategy revealed 12,085 articles. Of the 68 eligible articles on exercise adherence interventions in chronic diseases, 13 articles from 12 studies involved patients with arthritis. Interventions varied from knowledge-based programs (ie. educational brochure) to motivational-based strategies (ie. social cognitive model). Of the 12 studies, 7 had a Pedro score >6, indicating high quality. Of the 4 studies in rheumatoid arthritis (RA), 3 were of high quality reporting a statistically significant difference in exercise adherence between the intervention and control groups (relative difference = 20.9%–66.7%). Six studies involved patients with osteoarthritis (OA), 4 of which were rated high quality,

with only 1 reporting a statistically significant difference between groups (relative difference = 32.2%–106.3%). Two low quality studies included a mix of patients with OA and inflammatory arthritis; one reported a statistically significant result while the other did not provide sufficient data to determine statistical significance (relative difference = 42.1%–104.8%).

Conclusion: Based on three high quality studies in RA, there is strong evidence supporting the effectiveness of exercise adherence interventions in this population. The evidence for OA neither supports nor disproves the effectiveness of interventions for this population as results among 4 high quality studies were mixed. The evidence was also unclear in mixed types of arthritis due to poor quality of the studies. Our results suggest that future research efforts on exercise adherence interventions should target those with OA.

Lumbrical Splinting and Stretching Versus Standard Treatment On Grip, Pinch, and Dexterity in People with Carpal Tunnel Syndrome. Nancy A. Baker[1], Krissy Moehling[2], Elaine Rubinstein[3], Norman Gustafson[1] and Mark Baratz[4]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, [4]Alleghancy General Hospital, Pittsburgh, PA

Background/Purpose: Carpal tunnel syndrome (CTS) is a prevalent peripheral upper extremity neuropathy. Splinting and exercise is often recommended for those with mild to moderate symptoms. Lumbrical muscles of the hand appear to affect carpal tunnel canal pressure and CTS symptoms. We hypothesized that a lumbrical intensive treatment of nocturnal splinting and stretching exercises would provide greater improvements in impairments than less lumbrical intensive treatments.

Methods: A randomized controlled 2×2 factorial design study was conducted with four groups: Lumbrical splint/Lumbrical stretch (Lsp/Lst); General splint/Lumbrical stretch (Gsp/Lst); Lumbrical splint/General stretch (Lsp/Gst); General splint/General stretch (Gsp/Gst). Appropriate patients with mild/moderate CTS were recruited by 2 hand surgeons.

Assessments were obtained at baseline and 4 weeks after completion of an at-home regimen of splinting and exercise. Grip strength and lateral and palmar pinch were measured using standardized assessment tools. Fine motor dexterity was evaluated using the Purdue Pegboard.

Results: The average age of this cohort (N=103) was 53.3 ± 11.8 years. The majority were female (71.8%), with chronic carpal tunnel symptoms ≥ 3 months (85.7%). As CTS was most prevalent for the right (43.7%) or bilateral hand (38.8%) and the majority were right handed (91.3%), only right-sided results are provided for strength measurements (Table 1). There were no significant differences in demographics between groups.

Table 1. Results of 2-way ANOVA between Baseline and 4 week follow-up

(n)	4 wk	29.9 ± 8.9 (0.52)	28.8 ± 7.2 (0.06)	26.8 ± 9.7 (0.17)	31.5 ± 8.7 (0.23)

[a](lumbrical splint, lumbrical stretch); [b](general splint, lumbrical stretch); [c](lumbrical splint, general stretch);
[d](General splint, general stretch)
* effect of time significant; †effect of group×time significant

2-way ANOVAs were performed using SPSS 18 with group as the between-subjects factor and time as the within-subjects factor. Post hoc analyses used pairwise comparisons on difference scores for significant between-group outcomes with alpha set at.05. We calculated a Cohen's D to identify the clinical effect of the intervention.

The main effect of time was significant for all but Purdue - both hands. When analyzing group by time interactions the only outcomes with significant changes were right lateral pinch (p=.03) with greatest improvement in the Gsp/Gst group, and Purdue - left hand only (p=.03) with greatest improvement in the Lsp/Lst group. Overall the group using the GSP/GST demonstrated the greatest clinical improvements (small to moderate D).

Conclusion: All groups showed significant improvements over time regardless of treatment. Intensive lumbrical treatment was significantly better only for Purdue left hand, however, dexterity tasks such as Purdue both hands and Purdue assembly also showed greater improvement for this group (D scores were small to moderate). It appears that a more intensive lumbrical treatment may affect dexterity more than strength at 4 weeks follow-up. Future CTS research should examine the effects of more intensive lumbrical treatments on impairments over a longer follow-up period.

Clinical Effectiveness and Costs of an Integrated Rehabilitation Programme Compared with Outpatient Physiotherapy for Chronic Knee Pain. Mike Hurley[1], Dr Nicola E. Walsh[2] and Sally Jessep[3]. [1]St George's University of London, London, United Kingdom, [2]University of the West of England Bristol, Bristol, United Kingdom, [3]Kent, United Kingdom

Background/Purpose: Chronic knee pain is a major cause of disability. Management guidelines recommend exercise and self-management interventions. We previously described a rehabilitation programme that integrates exercise and self-management *(Enabling Self-Management and Coping with Arthritic Knee Pain through Exercise, ESCAPE-knee pain)* that produced short term improvements in pain and physical function. Sustaining these improvements is problematic. In addition, the programme is untried in the community where it is most likely to be delivered. This study evaluated the feasibility of delivering *ESCAPE-knee pain* in a community setting, and compared its clinical effectiveness and costs with Out-Patient Physiotherapy.

Methods: This was a pragmatic, randomised controlled trial. 64 people with chronic knee pain were randomised to receive Out-Patient Physiotherapy or the *ESCAPE-knee pain* programme in a Local Adult Education Community Centre. Primary outcome was physical function assessed using the Western Ontario and McMaster Universities Osteoarthritis Index. Secondary outcomes included pain, objective functional performance, anxiety, depression, exercise-related health beliefs, exercise self-efficacy and healthcare utilisation. All outcomes were assessed at baseline and 12 months after completing the interventions (primary endpoint). ANCOVA investigated between-group differences.

Results: Both groups demonstrated similar improvements in clinical outcomes, except health beliefs and self-efficacy where imporvements were greater in *ESCAPE-knee pain* participants. Out-Patient Physiotherapy cost £130 per person and its participants had healthcare utilisation costs over one year of £583, the *ESCAPE-knee pain* programme cost £64 per person and participant's healthcare utilisation was £320.

Conclusion: *ESCAPE-knee pain* and Out-Patient Physiotherapy produced sustained physical and psychosocial benefits, but *ESCAPE-knee pain* cost less and was more cost-effective. Greater improvements in beliefs about the role of exercise in the management of knee pain, and their confidence in their abilty to perform exercise that will help their knee pain (exercise self-efficacy), may make *ESCAPE-knee pain* participants more self-reliant and utilise less healthcare resources, thereby accounting for the better cost-effectiveness of *ESCAPE-knee pain*.

Initiating an Innovative Training Programme to Improve Access to Musculoskeletal Health Care in Kenya. Anthony D. Woolf[1], Jo Erwin[2], Omondi G. Oyoo[3], Lillian Mwaniki[4], Ingrid Cederlund[5], Paul Etau[6] and Katie Edwards[7]. [1]Royal Cornwall Hospital, Truro Cornwall, United Kingdom, [2]Royal Cornwall Hospital, Teliske, United Kingdom, [3]University of Nairobi, Nairobi, Kenya, [4]Association for Arthritis & Rheumatic Diseases of Kenya, Nairobi, Kenya, [5]Reumatikerforbundet, Stockholm, Sweden, [6]University of Nairobi, Nairobi, Kuwait, [7]Royal Cornwall Hospital, Truro, United Kingdom

Background/Purpose: Musculoskeletal conditions (MSC) are common in Kenya yet the training of primary care physicians in MSC is minimal and there are only 2 full time rheumatologists for a population of 41 million. The aim of this project, supported by ILAR, is to enable early access to appropriate health care for MSC in Kenyan communities. In a collaboration between colleagues in Kenya, UK and Sweden an innovative sustainable training programme has been developed to raise the knowledge and skills of health professionals working in the community in the early detection, diagnosis and management of MSC.

Methods: A programme was developed to train a cohort of mid-grade physicians and patients as trainers in musculoskeletal health. These trainers teach health providers that are the first point of contact for patients in the community e.g. clinical officers. The training emphasises history and examination to identify the musculoskeletal syndrome; the use of basic investigations, diagnosis, management and referral. The trainers work as a physician/patient team with the patients playing a key role in teaching history taking and examination skills and in making health providers aware of the impact of MSC on patient's lives.

Results: A train the trainer session was held in March 2012. 10 physicians and 9 patients were trained to become trainers in a 2.5 day session followed by a one-day demonstration training session which was videoed as a resource for the trainers. The trainers have gone on to deliver training to 150 first contact providers in 4 regions across Kenya. The content and delivery of the trainer and health provider courses were rated by participants as very good or excellent. After the first round of health provider training 75% of participants felt they were well prepared to use the skills in MSC diagnosis and 68% felt they were well prepared to use the skills in MSC management in their daily work. A 6 month post training evaluation is to be completed.

Training patients to be educators has started empowering them in advocacy and self-management. The project recognises the need to work with patients to develop an appropriate self management programme for Kenya and plans to address this in the future.

Conclusion: This sustainable programme has developed a system and resources for delivering effective and appropriate musculoskeletal health care training to first contact health providers across Kenya. It has also raised the level of knowledge and competency of mid-grade physicians so they can fill the gap between first contact providers and hospital specialists. Should the project evaluation show it to be effective in changing practice and improving care for MSC this may provide a template for a programme of MSC training which could be implemented in other low income countries globally.

The Effect of a Systematic, Personalized Computer Workstation Redesign On Musculoskeletal Symptoms. Nancy A. Baker and Krissy Moehling. University of Pittsburgh, Pittsburgh, PA

Background/Purpose: Musculoskeletal symptoms (MSS), such as pain, numbness or cold, are common and distressing occurrences during computer use. One commonly used method to reduce MSS is workstation redesign which aims to "fit the workstation to the worker" and thereby reduce awkward postures. However, recent systematic reviews have reported that this method may not be effective [1]. This pilot study tested if a systematic method of workstation redesign which focused on 19 areas where mismatch could occur combined with active involvement of the worker in the development of the workstation redesign intervention plan (personalized ergonomics) would reduce or eliminate MSS one month after intervention.

Methods: This was a single group pretest/posttest study that examined 26 computer operators with self-reported computer related MSS of at least 2 in one body area (neck/shoulder, arm/wrist, hand) on a scale of 0 to 10 (with 0 being no pain and 10 the worst possible). Workers completed an MSS survey, as well as a self-assessment of their workstation set-up, the Computer Ergonomic Survey (CES), and were photographed in their computer workstations. An expert in workstation redesign used the results of the CES and photographs to identify in which of the 19 areas mismatch occurred. The expert and the computer operator then developed an intervention plan to rectify these mismatches. Workers implemented this plan over a one month period. Workers then completed the MSS survey again. They also rated their satisfaction with the workstation redesign process.

Results: The 26 computer operators mean age was 46.4 ($\pm$10.5). They were primarily female (92%) and used a computer, on average, 6.0 ($\pm$1.2)

hours per day. There were significant reductions in MSS for all body areas on both the left and right sides. Reductions in MSS achieved clinically important levels of at least 1 point for the neck/shoulder (left -1.23; right - 1.08), and right hand (1.01). Many subjects reported complete elimination of MSS at follow-up: neck/shoulder – left 35%, right 31%; arm/wrist – left 27%, right 46%; hand – left 27%, right 35%. This change was significant for the left arm/wrist and both hands. The changes reported to have the greatest effect on MSS were: adjusting the chair height to ensure that the feet were well supported (29%), adjusting the monitor height to reduce head tilt (18%), and adjusting the arm support height to support the arm during computer use (18%). Ninety-five percent of subjects reported that they were satisfied with the recommended changes, and 100% reported that they found the process to be helpful and they felt empowered to be able to continue to adjust their workstation to continue reducing MSS.

Conclusion: This study suggests that a systematic method of computer workstation redesign combined with worker involvement lead to significant improvements in computer-related MSS.

A Brief Exercise and Self Management Programme Improves Upper Limb Disability in People with Early Rheumatoid Arthritis.
Lindsay M. Bearne[1], Victoria L. Manning[1], David L. Scott[2], Ernest Choy[3] and Michael V. Hurley[4]. [1]Kings College London, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]Cardiff University School of Medicine, Cardiff, United Kingdom, [4]St George's University of London, London, United Kingdom

Background/Purpose: Upper limb dysfunction occurs early in people with rheumatoid arthritis (RA) and deteriorates as the disease progresses, impacting on independence and work capacity. Exercise is a important component in the management of upper limb disability, however, studies focus on the hand in isolation and do not address potential proximal motor deficits. Individually tailored, home exercise regimens are required to address global upper limb dysfunction which, if completed in the long term, could encourage self management. This study evaluated the efficacy of a gobal, upper limb home exercise programme supplemented with a brief supervised exercise, education and self management (Education and eXercise Training in early Rheumatoid Arthritis (EXTRA)) programme.

Methods: 108 adults with RA of less than 5 years duration (26 males, age mean (SD) 55 (15) years, disease duration 20 (19) months) were randomized to receive either Usual Care (n= 52) or the EXTRA programme (n=56). This progamme is a tailored home exercise regimen, focused on improving upper limb function, which is supplemented with 4 group supervised exercise, education and self management sessions, aimed at improving self efficacy and disease self management (2 sessions per week for the first 2 weeks, each session lasting approximately 1 hour, with 4–6 participants per group). Upper limb disability (Disability of Arm, Shoulder, Hand questionnaire (DASH)), grip strength, function (Grip Ability Test (GAT)), self efficacy (Arthritis Self Efficacy Scale - pain subscale (PSE)) and disease activity (Disease Activity Score (DAS 28)) were assessed at baseline, 3 months (primary end point) and 9 months. Intention to treat analysis using full factorial mixed Analysis of Variance (ANOVA) (treatment, time and treatment × time interaction) adjusted for baseline disease duration, disease activity and disability, and corrected for multiple comparisons, were used to determine between group differences,. Significance was accepted at $P<0.05$.

Results: Compared to a usual care control group, participants who completed the EXTRA programme demonstrated improved disability, function, non dominant grip strength and self efficacy with no adverse effects on disease activity (Table).

Table. Changes in disability, grip strength, function, self efficacy and disease activity following the EXTRA programme or Usual Care

Mean (95% Confidence intervals)	EXTRA programme	Usual Care	Between Group Differences	Effect size (95% CI)(P value)
Disability (DASH)				
Baseline	44.6 (37.2,52.0)	40.8 (33.6,48.0)	3.8 (-6.6,14.1)	
change at 3 months	-5.3 (-10.4,-0.2)†	1.5 (-3.5, 6.5)	-6.8 (-12.6,-1.0)†	0.5 (-2.3,3.3) **(0.022)**†

Decisional Conflict Among Vulnerable Patient Populations with Rheumatoid Arthritis Is Associated with Limited Health Literacy and Non-English Language.
Laura Trupin, Jennifer Barton, Gina Evans-Young, John B. Imboden, Andrew J. Gross. Dean Schillinger and Edward H. Yelin, UCSF, San Francisco, CA

Background/Purpose: Suboptimal communication in shared decision-making among vulnerable populations has been reported in rheumatoid arthritis (RA). National and international recommendations for quality health care highlight the importance of patient-centered care and involvement of patients in decision-making. The concept of decisional conflict captures the extent to which patients lack adequate information and support to make an informed health care decision. The objective of this study was to identify patient-level factors associated with high decisional conflict in RA treatment decisions among vulnerable populations who are at highest risk for poor health outcomes.

Methods: Data derive from a subset of participants in the RA Cohort Study, which enrolls adult RA patients from university-affiliated rheumatology clinics at an urban county hospital and a tertiary care facility. Enrollment for the present study occurred from September 2011 to May 2012; eligibility included having moderate to high disease activity, defined as a RAPID-3 score >6, and being a member of a vulnerable population based on the following criteria: immigrant, ethnic/racial minority, non-English speaker, age >65, or limited health literacy. Eligible patients completed a questionnaire in English, Spanish, or Chinese immediately after their clinic appointment. The questionnaire included a screening measure of health literacy, a series of true-false questions about RA and its treatments, and a low-literacy version of the 10-item Decisional Conflict Scale (DCS), given to patients who reported discussing a medication change with their doctor. DCS scores were compared by gender, race/ethnicity, age, and language using non-parametric ANOVA (Kruskal-Wallis) tests. Correlations among DCS, RA knowledge, and health literacy were assessed with Spearman correlation coefficients.

Results: Of 163 cohort members screened, 97 had active disease according to their RAPID-3 score and were enrolled in the study; 48 of those patients reported receiving a new prescription or discussing a medication change and were included in this analysis. Mean age was 59 (±12), 75% were women, 58% immigrants, 82% ethnic minorities, 35% Spanish or Chinese speakers, 61% had limited health literacy. DCS scores ranged from 0 to 80 (higher scores indicate more decisional conflict). Scores were significantly higher ($p<0.01$) among Chinese (45 ± 7) and Spanish speakers (23 ± 6) compared with African Americans (14 ± 7) and Whites (12 ± 8), but did not

differ by age or gender. Higher decisional conflict was associated with lower levels of health literacy (Spearman's r=-0.35, p=0.01) and poorer RA knowledge (Spearman's r=-0.36, p=0.01).

Conclusion: Limited health literacy and non-English language were associated with greater levels of decisional conflict about a real-time RA treatment decision. Providing low literacy decision aid tools to reduce decisional conflict and promote shared decision-making may lead to more patient-centered care, treatment decisions that align with patient preferences, and ultimately, improved health outcomes among vulnerable populations with RA.

Readability and Suitability Assessment of Patient Education Materials in Rheumatic Diseases. Rennie L. Rhee[1], Joan Marie Von Feldt[2], H. Ralph Schumacher[3] and Peter A. Merkel[1]. [1]University of Pennsylvania, Philadelphia, PA, [2]Univ of Pennsylvania/Philadelphia VAMC, Philadelphia, PA, [3]University of Pennsylvania and VA Medical Center, Philadelphia, PA

Background/Purpose: Comprehension of health resources may be challenging for patients particularly those with limited health literacy. The objective of this study was to examine the readability and suitability of commonly used patient education materials for systemic lupus erythematosus (SLE), vasculitis, rheumatoid arthritis (RA), and osteoarthritis (OA) and to determine whether readability and suitability vary among diseases of different complexities.

Methods: Several highly popular web-based patient resources were chosen for evaluation: American College of Rheumatology (ACR), Arthritis Foundation (AF), Mayo Clinic Health Information, National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), UpToDate Basics, UpToDate Beyond the Basics, Vasculitis Clinical Research Consortium (VCRC), and Vasculitis Foundation. Readability was measured using the Flesch-Kincaid Reading Ease and Grade Level and computed after the removal of illustrations, tables, captions, disease and medication names, all forms of "rheumatology," and defined terms. Suitability was determined by the Suitability Assessment of Materials (SAM), a score that considers characteristics such as content, graphics, layout/topography, and cultural appropriateness. Three different reviewers rated the SAM score and means were used in the analysis. Scores were then converted into a percentage by dividing the given score by the total possible score. A score of 0–39% was considered not suitable, 40–69% adequate, 70–100% superior.

Results: The education material for all four diseases studied had readability above the 8th grade level and readability did not differ among the diseases. The mean grade level for each resource ranged from 4.8 to 12.5 with a median grade level of 9.6. Only 5 of the 23 resources received superior suitability scores (ACR for SLE, ACR for OA, AF for RA, AF for OA, UpToDate Basics for OA). Suitability scores among the four diseases were similar and again did not differ based on disease complexity.

Readability by Grade Level

Resource	SLE	Vasculitis	RA	OA	Mean
ACR	10.0	10.5	7.3	8.8	**9.2**
AF	9.0	—	9.7	8.4	**9.0**
Mayo Clinic	8.0	7.8	7.6	7.0	**7.6**
NIAMS	11.4	—	11.6	9.8	**10.9**
UpToDate Basics	5.1	—	4.5	4.8	**4.8**
UpToDate Beyond Basics	9.9	8.5	11.1	10.3	**10.0**
VCRC	—	10.6	—	—	**10.6**
Vasculitis Foundation	—	12.5	—	—	**12.5**
Mean	**8.9**	**10.0**	**8.6**	**8.2**	

Suitability by mean SAM score (in percentage)

	SLE	Vasculitis	RA	OA	Mean
ACR	76%*	48%	56%	79%*	**65%**
AF	67%	—	71%*	78%*	**72%**
Mayo Clinic	61%	61%	63%	69%	**64%**
NIAMS	26%	—	40%	47%	**38%**
UpToDate Basics	58%	—	60%	76%*	**65%**
UpToDate Beyond Basics	52%	52%	46%	57%	**52%**
VCRC	—	32%	—	—	**32%**
Vasculitis Foundation	—	33%	—	—	**33%**
Mean	**57%**	**45%**	**56%**	**68%**	

*SAM score considered superior

Conclusion: Patient education materials for rheumatic diseases other than UpToDate Basics are written at readability levels above the recommended sixth-grade reading level for the general public. Most resources were considered to have only adequate suitability. Scores were similar among the four diseases which suggest that disease complexity does not explain poor readability and suitability indices. Most educational resources for patients with rheumatic diseases should be revised to more appropriately communicate information about these diseases.

Screening of Osteoporosis in Men Age 70 and Older: A Need for Increased Awareness. Sian Yik Lim, Kenneth Nugent, Joon Hee Lim, Hoda Mojazi Amiri, Rie Okamura and Dan Nguyen. Texas Tech University Health Sciences Center, Lubbock, TX

Background/Purpose: The National Osteoporosis Foundation (NOF) currently recommends osteoporosis screening with bone mineral density (BMD) testing in men age 70 and older, regardless of clinical risk factors. Despite these recommendations being published initially in 2008, data regarding BMD testing rates in men age 70 and older in a primary care setting in the United States are lacking. We hypothesize that BMD testing rates using Dual-energy X-ray absorptiometry (DEXA) scan in men age 70 and older remains low despite recommendations by the NOF.

Methods: We performed a retrospective chart review of male patients age 70 and older who were seen at the Internal Medicine Clinic at Texas Tech University Health Science Center, a major primary care setting in West Texas. We reviewed charts of patients seen between January 1st, 2011 and January 1st, 2012. We identified patients who had established the Internal Medicine Clinic as their primary care provider. We included patients who had been seen at least twice over a 3 year period. We excluded patients who were one time hospital discharge follow-ups and those who visited the internal medicine clinic for preoperative evaluations. Demographic information and BMD testing status were determined from electronic medical records. 10-year osteoporotic and hip fracture probabilities of individual patients were calculated using the World Health Organization Fracture Risk Assessment Tool. Analysis of the effect of increasing age on BMD testing was performed using chi square test for trend with patients divided into age groups of 70–74, 75–79, 80–84, 85–89, 90–94 and 95–99. The Pearson's correlation was used to analyze correlation of age with 10-year osteoporotic and hip fracture probabilities.

Results: The median age of our patients was 76 years (range 70–98 years). There were 341 male patients age 70 and older who were seen at the clinic during the study period. 310 patients were included in the study. 35 patients, which is 11.4% (95%CI [7.9–15.7]) of the study population received BMD testing using DEXA scans. BMD testing indicated that 8 patients (22.9%) were osteoporotic, 22 patients (62.9%) were osteopenic, and 5 patients (14.3%) had normal BMD. No significant association was found between increasing age and BMD testing (p=0.299). The medians of the 10-year osteoporotic and hip fracture probabilities in the 70–74 age group were 5.6% (range 2.0–14.0%) and 1.4% (range 0.2–5.3%). The medians of the 10-year osteoporotic and hip fracture probabilities peaked in the 90–94 age group at 9.4% (range 5.7–10.0%) and 6.1% (range 3.0–7.9%) respectively. Age was positively correlated with 10-year hip fracture probability (r=0.68, p<0.0001) and 10-year osteoporotic fracture probability (r= 0.53, p<0.0001).

Conclusion: Osteoporosis in men age 70 and older is still underscreened and underrecognized. Despite recommendations by the NOF for BMD testing using DEXA scan in men age 70 and older since 2008, BMD testing rates remain low. Although there was an increase in both the 10-year osteoporotic and hip fracture probabilities with age, no association was found between increased age and BMD testing. In view of the aging society in the United States, more has to be done to increase awareness of this major public health problem.

Pain and Function Outcomes in Systemic Lupus Erythematosus Hip and Knee Arthroplasty. Ummara Shah[1], Lisa A. Mandl[2], Mark P. Figgie[2], Michael Alexiades[2] and Susan M. Goodman[2]. [1]New York University School of Medicine, NYC, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: There is little information on Systemic Lupus Erythematosus (SLE) patients undergoing total joint arthroplasty (TJA). The purposes of this study were to determine the patterns of TJA in a contemporary SLE cohort and to determine if SLE is a risk factor for worse outcomes compared with similar osteoarthritis (OA) patients.

Methods: Patients with SLE who underwent hip or knee arthroplasty between May 2007 and June 2011 and enrolled in our institution's arthroplasty registry were eligible for this study. SLE cases were identified by ICD-9 code 710 and confirmed if they met 3/14 ACR criteria, were on immunosuppressant therapy, or had the diagnosis confirmed by a rheumatologist. Validated SLE cases were matched to two OA controls by age ($+/- 2.5$ years), gender, procedure, and presence of osteonecrosis (ON). ON was confirmed in cases and controls by pathology or radiology review. Pain and function were measured by WOMAC and the validated Lower Extremity Activity Scale (LEAS). Administrative and self-report data were collected at baseline and 2 years. Standard univariate comparisons were performed to compare SLE with matched OA cases at baseline and at two years post-op. Multivariate regressions were performed to analyze the relationship between diagnosis, presence of ON, and WOMAC pain and function at 2 years. TKA patients' pre-operative expectations were measured with the validated TKR Expectations Survey.

Results: 101 SLE cases were identified, 56 hip (THR) and 45 knee (TKR). 5 cases could only be matched to 1 control. Pre-operatively, SLE THR cases had statistically and clinically significantly worse WOMAC pain, stiffness, and function than matched OA hips, (see Table). Renal failure, hypertension, pulmonary, and valvular disease were also more common in SLE THA patients. Both SLE THA and TKA has statistically significantly worse SF-36 PCS pre-operatively, and, despite significant improvements, they remained statistically significantly worse compared to matched OA controls post-operatively. Two-years post-operatively, there were no differences in pain and function scores between SLE and OA controls. In multivariate regressions controlling for type of surgery, disease type, and ON, neither SLE nor ON predicted worse pain or function at 2 years. There were no differences in expectations of surgery between SLE TKA and OA TKA.

Table.

	SLE THA +/− SD n= 56	OA THA +/− SD n=108	p-value	SLE TKA +/− SD n= 45	OA TKA +/− SD n=89	p-value

LEAS 2 yr	10.4+/−3.9	12.2+/−2.9	0.06	9.9+/−2.5	11.6+/−2.9	0.05
Elix-hauser Co-morbidities						
Valvular disease	10 (17.9%)	2 (1.9%)	0.0004	4(8.9%)	3 (3.4%)	0.22
Renal failure	8(14.3%)	1 (0.9%)	0.0009	5(11.1%)	2 (2.2%)	0.04
Hypertension	29 (51.8%)	32 (29.6%)	0.007	25 (55.6%)	53 (59.6%)	0.7
Pulmonary circulation disease	3 (5.4%)	0 (0.0%)	0.04	0 (0.0%)	0 (0.0%)	—
corticosteroids	9 (16.1%)	0 (0.0%)	—	3 (6.7%)	0 (0.0%)	—
immunosuppressants	40 (71.4%)	0 (0.0%)	—	34 (75.6%)	0 (0.0%)	—

* 5 patients have no controls so prevalence of ON is different between SLE and OA; this imbalance was addressed by including ON in the multivariate regressions

Conclusion: SLE THA and TKA patients have similar pain and functional outcomes at 2 years compared with matched OA controls. Although PCS scores improved after arthroplasty, they remained lower in SLE patients than OA

controls. To our knowledge, this is the first study to demonstrate that neither SLE nor ON should be considered risk factors for poor post-operative outcomes.

Restricting Back Pain Is Associated with Disability in Community-Living Older Persons. Una E. Makris[1], Liana Fraenkel[2], Ling Han[3], Linda Leo-Summers[3] and Thomas M. Gill[4]. [1]UT Southwestern Medical Center, Dallas, TX, [2]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [3]Department of Medicine, New Haven, CT, [4]Yale University, New Haven

Background/Purpose: Although back pain is common and costly, few longitudinal studies have evaluated the association between back pain, severe enough to restrict activity (hereafter referred to as restricting back pain), and the development of disability in mobility. Older persons who lose independent mobility have higher rates of morbidity and mortality, and experience a poorer quality of life. We hypothesized that restricting back pain would be strongly associated with mobility disability over the $13+$ years of follow-up.

Methods: We evaluated the 555 participants (mean age 77.5 years, 56% women) of the Precipitating Events Project, a prospective study of community-living persons, aged 70+ years, all non-disabled at baseline, who completed monthly telephone assessments of restricting back pain and who were at risk for developing mobility disability for up to 159 months. Restricting back pain was defined as staying in bed for at least half a day and/or cutting down on one's usual activities due to back pain. Mobility disability (hereafter referred to as disability) was defined as needing help with or inability to complete any of the following four tasks in any given month: walking a 1/4 mile, climbing a flight of stairs, lifting or carrying 10 pounds, or driving a car. The event rate for disability was estimated using a Generalized Estimation Equation Poisson model. A recurrent events Cox model was used to evaluate the associations between the occurrence of restricting back pain (yes/no) and subsequent (within one month) disability. The model was adjusted for fixed-in-time (sex, education, ethnicity) and time-varying covariates (age, chronic conditions, BMI, depressive symptoms, cognitive impairment, and physical frailty defined by slow gait speed) that were updated every 18 months. We tested potential interactions of restricting back pain with sex, BMI, depressive symptoms, and physical frailty.

Results: The event rate for disability was 8.47 per 100-person months (95% CI 8.08,8.88) with a median duration of 2 (interquartile range: 1–5) months. The frequency of each of the four disability items at baseline was 13.2% for walking a 1/4 mile, 3.6% for climbing stairs, 10.5% for lifting/carrying 10 pounds, and 11.2% for driving a car. After adjusting for covariates, restricting back pain was strongly associated with subsequent disability, with a hazard ratio (95% CI, p-value) of 3.35 (2.91,3.86, <0.001). Only the interaction with physical frailty was statistically significant (p = <0.001). Subgroup analyses suggest that restricting back pain is associated with disability among participants with and without physical frailty at baseline assessment 2.10 (1.67,2.63) and 4.06 (3.42,4.81), respectively.

Conclusion: In this longitudinal study, restricting back pain was independently associated with disability among older persons. It is possible that individuals who are not physically frail may be more active and therefore at higher risk for developing subsequent disability. Calculating absolute risk differences may help to clarify the results of our subgroup analysis. Interventions implemented to decrease or prevent restricting back pain are likely to decrease disability.

Ipsilateral Lower Extremity Joint Involvement Increases the Risk of Poor Pain and Function Outcomes After Hip or Knee Arthroplasty. Jasvinder A. Singh[1] and David Lewallen[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Mayo Clinic college of medicine, Rochester

Background/Purpose: Persistent pain and functional limitation are unfavorable outcomes after knee and hip replacement, which are getting increasing attention due to a dramatic increase in rates of knee and hip replacements. Our objective was to assess the association of ipsilateral knee/hip pain on short- and mid-term pain and function outcomes after total hip or knee arthroplasty (THA/TKA).

Methods: We used the prospectively collected data from the Mayo Clinic Total Joint Registry to assess the association of ipsilateral knee or hip joint

Tuesday, November 13

involvement with moderate-severe pain and moderate-severe functional limitation at 2- and 5-year follow-up after primary and revision THA and TKA using multivariable-adjusted logistic regression analyses. Analyses were adjusted for patient characteristics (unmodifiable—age and gender; and modifiable—BMI, comorbidity, depression and anxiety), implant fixation (cemented/hybrid versus not cemented) and health care access as assessed by the distance from medical center.

Results: At 2-year, 3,823 primary THA, 4,701 primary TKA, 1,218 revision THA and 725 revision TKA were studied. After adjusting for multiple covariates, ipsilateral knee pain was significantly associated with outcomes after primary THA (all p-values <0.01): (1) moderate-severe pain: at 2-years, odds ratio (OR), 2.3 [95% confidence interval (CI), 1.5, 3.6]; at 5-years, OR 1.8 [95% CI:1.1, 2.7]; (2) moderate-severe functional limitation: at 2-years, OR 3.1 [95% CI:2.3, 4.3]; at 5-years, OR 3.6 [95% CI:2.6, 5.0]. Ipsilateral hip pain was significantly associated with outcomes after primary TKA (all p-values <0.01): (1) moderate-severe pain: at 2-years, OR 3.3 [95% CI:2.3, 4.7]]; at 5-years, OR 1.8 [95% CI:1.1, 2.7]; (2) moderate-severe functional limitation: at 2-years, OR 3.6 [95% CI:2.6, 4.9]; at 5-years, OR 2.2 [95% CI:1.6, 3.2]. Similar associations were noted for revision THA and TKA patients.

Conclusion: Presence of ipsilateral joint involvement after primary and revision THA and TKA is a poor prognostic factor for pain and function outcomes. A potential way to improve outcomes may be to address ipsilateral lower extremity joint involvement.

Activity Limitations Experienced by People with Rheumatoid Arthritis On Biologic Medications and Their Use of Ergonomic Methods. Alison Hammond[1] and Sarah Tyson[2]. [1]University of Salford, Salford, United Kingdom, [2]University of Salford, Manchester, United Kingdom

Background/Purpose: People with rheumatoid arthritis (RA) commonly have daily activity difficulties. Whilst biologics significantly improve ability, ergonomic methods (e.g. altered working methods, ergonomic equipment, activity and environment modification) may still improve ability further. The aim of this study was to investigate activity limitations of people with RA on biologics and their use of ergonomic methods.

Methods: Participants on biologics completed the Evaluation of Daily Activity Questionnaire (EDAQ): measuring ability performing 138 activities (grouped in 14 domains: Table 1). Activities are scored as 0 (no difficulty) to 3 (unable to do). Each is scored twice: Section A = ability without ergonomic methods or help; Section B (completed if difficulty) =ability with ergonomic methods (if used). Percentages of participants experiencing difficulties per activity (Section A) were calculated. Score differences between sections A and B were analysed using paired t-tests.

Results: Participants were recruited from 14 Rheumatology units (n=198: 156 women; 42 men). Mean age = 59.16 (SD 10.46) years; RA duration 13.83 (SD 9.24) years. Biologics prescribed were: etanercept (n=75); adalimumab (57); rituximab (44), infliximab (16), golimumab (3), certolizumab (1) and abatacept (1). Average pain was 4.69 (SD2.57) and fatigue 5.47 (SD2.47). Average HAQ score was 1.21 (SD 0.83).Participants rated their health as: very good (9%); good (29%); fair (42%); poor (16%) and very poor (4%). Average EDAQ scores without ergonomic methods were at or below the lower tertile in all domains (Table 1). Common difficulties included: opening jars (88%); carrying pans (82%); preparing vegetables (76%); using a kettle (68%); vacuuming (67%); turning taps (56%); preparing meals (49%). Average ability using ergonomic methods (section B) was significantly better for all domains, except Caring (as many had few childcare responsibilities due to their age). Ergonomic methods were used more by those rating health as fair, poor or very poor.

Table 1. EDAQ domain scores for people with RA on biologic drugs (n=198)

EDAQ Domain score	Domain score range	n	Section A Mean (SD)	Section B Mean (SD)	p
1. Eating/Drinking	0–30	187	10.47 (6.70)	8.21 (6.12)	<0.001
2. Bathroom	0–36	184	5.83 (5.80)	5.24 (5.49)	<0.001
3. Dressing	0–33	190	8.65 (7.30)	8.25 (7.10)	<0.001
4. Bathing	0–33	192	9.85 (8.36)	8.95 (7.86)	<0.001
5. Cooking	0–42	182	12.26 (9.69)	11.26 (9.63)	<0.001
6. Moving Indoors	0–36	180	10.38 (7.78)	9.81 (7.62)	<0.001
7. Cleaning	0–27	194	9.66 (7.15)	9.43 (7.19)	<0.001
8. Laundry	0–27	191	8.41 (7.31)	7.92 (7.17)	<0.001
9. Transfers	0–18	196	4.68 (3.71)	4.44 (3.64)	<0.001
10. Communication	0–18	192	3.15 (3.13)	2.83 (2.98)	<0.001
11. Moving Outdoors	0–39	182	11.86 (9.32)	11.12 (9.14)	<0.001
12. House/Garden maintenance	0–21	194	10.30 (7.08)	10.21 (7.08)	<0.001
13. Caring	0–27	189	3.99 (7.16)	3.97 (7.12)	0.1
14. Leisure	0–27	184	6.43 (6.26)	6.24 (6.29)	<0.001

Conclusion: People with RA on biologics continued using ergonomic methods, reporting significantly better ability as a result. Section B scores indicated scope for greater use of ergonomic methods to further reduce limitations. Many on biologics might benefit from occupational therapy assessment and ergonomic advice to help further reduce limitations.

Accuracy of Sensewear Mini[TM] and Actigraph GT3X[TM] Accelerometers for Differentiating Sedentary and Light Physical Activities in a Controlled Laboratory Setting. April Y. F. Leung[1], Lynne M. Feehan[2], Cynthia Macdonald[1], Jenny Leese[3], Erin Carruthers[3] and Linda C. Li[1]. [1]University of British Columbia, Vancouver, BC, [2]Arthritis Research Centre of Canada and University of British Columbia, Vancouver, BC, [3]Arthritis Research Centre of Canada, Vancouver, BC

Background/Purpose: People living with inflammatory arthritis are likely to be less physically active due to pain and fatigue. To understand the relationship between physical inactivity and poor health outcomes in inflammatory arthritis, it is necessary to accurately identify and quantify lower levels of physical activity. Accelerometers are small activity monitors used to measure moderate and higher levels of physical activity. However, it is unclear how accurately different monitors capture sedentary and light physical activities. The purpose of this study was to compare the accuracy of the SenseWear Mini™ (SW) and Actigraph GT3X™ (AG) accelerometers for differentiating between sedentary and non-sedentary/light physical activities in a controlled laboratory setting.

Methods: 22 adults (F=15, M=7, mean age 35.7, range 19 to 72) volunteered to participate. Both monitors were synchronized with Greenwich Mean Time and were set to collect data at 1-minute intervals. Participants were randomly assigned to perform 9 activities for 5 minutes each. All activities were observed and timed. The activities were performed in: 1) standing (**slow treadmill, **wash dishes, *text messaging), 2) sitting (**slow cycling, *watch television, **computer typing), and 3) lying down (*rest with music, *read book, *knee ROM exercise in lying). According to the 2011 Compendium of Physical Activities (CPA), 5 activities were defined as *sedentary (<1.6 METs) and 4 were defined as **non-sedentary/light (1.6 to 3 METs). The middle 3-minute interval from each 5-minute time period was analyzed. Each SW activity was categorized as sedentary (< 1.6 METs) or non-sedentary (≥ 1.6 METs) based on the SW proprietary MET data. Each AG activity was categorized as sedentary or non-sedentary, based on 2 different sedentary cut-points (< 100 and < 589 activity counts/minute) for the AG vertical axis data.

Percentage of activities correctly identified as sedentary (sensitivity) and non-sedentary (specificity), proportion of all activities identified as sedentary or non-sedentary that were in fact sedentary (positive predictive value – PPV) or non-sedentary (negative predictive value – NPV), as well as, the positive (LR+) and negative (LR-) likelihood ratios were calculated for both accelerometers.

Results: Compared against derived values from the 2011 Compendium of Physical Activities, SW performed notably better than AG in differentiating between sedentary and non-sedentary/light physical activities under controlled laboratory settings (Table 1). Accuracy of AG was not affected by the cut-point chosen.

Table 1. Summary of measurement accuracy of SenseWear Mini and Actigraph GTX3 compared with the Compendium of Physical Activities

	SenseWear Mini	Actigraph GTX3 (<100 activity counts/minute)	Actigraph GTX3 (<589 activity counts/minute)
Sensitivity (Sedentary)	0.98	1.00	1.00
Specificity (Non-Sedentary)	0.70	0.27	0.11
PPV (Sedentary)	0.81	0.63	0.59
NPV (Non-Sedentary)	0.97	1.00	1.00
LR+ (Sedentary)	3.32	1.38	1.13
LR− (Non-Sedentary)	0.03	0.00	0.00

Conclusion: Our results suggest that SenseWear Mini may be a better accelerometer for objective measurements of low physical activity in people

with inflammatory arthritis. Further studies are needed to examine the accuracy of SenseWear Mini for measuring physical activity under free-living conditions.

Sustained Improvement Physical Function Following an Integrated Rehabilitation Programme for Chronic Knee Pain. Mike Hurley[1] and Dr Nicola E. Walsh[2]. [1]St George's University of London, London, United Kingdom, [2]University of the West of England Bristol, Bristol, United Kingdom

Background/Purpose: Chronic knee pain causes personal suffering and impairs physical function and quality of life. Usual primary care involves prolonged drug therapy in spite of growing concerns about effectiveness and side-effects. Exercise and self-management interventions can have good short-medium term (up to 6 months) benefits, but whether short term benefits are sustained is largely unknown. Since chronic knee pain is a long term problem establishing long term outcome is important. We devised a rehabilitation programme that integrates exercise and self-management (*Enabling Self-management and Coping with Arthritic knee Pain through Exercise, ESCAPE-knee pain*), that produced short-medium term (6-months) improvements in physical functioning. To measure long term effects of the programme we continued to follow participants for 30 months after completing the programme.

Methods: 418 people from 54 primary care surgeries were (cluster) randomised to receive i) usual care, or *ESCAPE-knee pain* delivered to ii) individual or iii) groups of 8 participants. As there no differences in the baseline or post-rehabilitation data between participants who received the programme individually or in groups these data were combined. Subjective physical function was measured by the Western Ontario and McMasters University Osteoarthritis Index function sub-scale (WOMAC-func) was assessed at baseline, immediately post-rehabilitation, 6-months, 18-months and 30-months after completing the *ESCAPE-knee pain* programme. Multilevel Modelling was performed to adjust for clustering, baseline WOMAC-func and missing data.

Results: At baseline physical function in both groups were similar. Immediately after the intervention, participants who undertook *ESCAPE-knee pain* reported better physical function than participants who remained on usual primary care. In the following 30 months, physical function of participants who remained on usual care remained unchanged. Physical function of participants who undertook the *ESCAPE-knee pain* programme improved at each assessment compared to baseline value, i.e. mean WOMAC-func decreased, (post-rehabilitation WOMAC-func -5.49 (95%CI -7.78, -3.19; p<0.0001); 6-month WOMAC-func -4.44 (-6.54, -2.33; p<0.0001); 18-month WOMAC-func -3.10 (-5.44, -0.76; p<0.0095) 30-month WOMAC-func -2.78 (-5.32, -0.23; p<0.0323)), but declined over time becoming more similar to the usual care values.

Conclusion: *ESCAPE-knee pain* is an exercise-based rehabilitation programme for chronic knee pain that has sustained improvement in physical function for up to 2½ years after completing the programme. Models of care should be developed that will sustain for longer the large initial improvement in physical functioning.

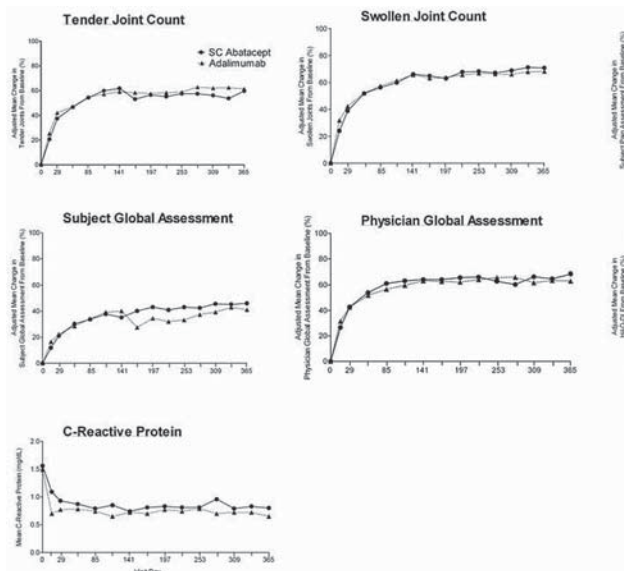
Head to Head Comparison of Subcutaneous Abatacept Versus Adalimumab in the Treatment of Rheumatoid Arthritis: Key Efficacy and Safety Results From the Ample (Abatacept Versus Adalimumab Comparison in Biologic-Naive RA Subjects with Background Methotrexate) Trial. Michael E. Weinblatt[1], Michael H. Schiff[2], Roy Fleischmann[3], Robert Valente[4], Désirée van der Heijde[5], Gustavo Citera[6], Cathy Zhao[7] and Michael A. Maldonado[7]. [1]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [2]University of Colorado, Denver, CO, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]Arthritis Center of Nebraska, Lincoln, NE, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [7]Bristol-Myers Squibb, Princeton, NJ

Background/Purpose: The availability of multiple biologic agents to treat rheumatoid arthritis (RA) has created a need for comparative assessment. AMPLE (**A**batacept Versus Adali**m**umab Com**p**arison in Bio**l**ogic-Naiv**e** RA Subjects with Background Methotrexate) is the first head-to-head study powered to compare SC abatacept (ABA) and adalimumab (ADA) on a background of methotrexate (MTX). Here, we report key 1 year data from AMPLE including ACR core component data.

Methods: AMPLE is an ongoing, phase IIIb, randomized, investigator-blinded study of 24 months duration with a 12 month primary efficacy endpoint. Biologic-naïve RA patients with an inadequate response to MTX were randomized to 125 mg ABA weekly or 40 mg ADA bi-weekly, in combination with MTX. The primary end point was non-inferiority (NI) of ABA to ADA based on ACR 20 at 12 months; key secondary endpoints were rates of radiographic non-progression, safety, injection site reactions and retention. ACR core component data were also analyzed.

Results: A total of 646 patients were randomized and treated; 86.2% of ABA patients and 82.0% of ADA patients completed 12 months. Baseline characteristics were balanced across both arms (mean DAS28-CRP of 5.5 and disease duration 1.8 yrs). At 1 year, 64.8% of ABA patients and 63.4% of ADA patients achieved an ACR 20 response, with an estimated difference between the two arms (95% CI) of 1.8 (-5.6, 9.2) supporting NI of ABA to ADA. The kinetics of response across ACR scores were comparable overall, with an ACR50 of 46.2% and 46% and ACR70 of 29.2% and 26.2% for ABA and ADA, respectively, at 1 year. Similar responses over time were seen in some ACR core components (Figure). At 1 year, the rates of radiographic non-progression were comparable, as were mean changes in van der Heijde-modified total Sharp scores (0.58 vs. 0.38, for ABA vs. ADA respectively). The rates of AEs, SAEs, serious infections and malignancies were comparable. There were more patients with autoimmune AEs (3.1% vs. 0.9%) in the ABA arm; however, none were serious. One patient discontinued in each arm due to an autoimmune event. There were fewer discontinuations with ABA due to AEs (3.5% vs. 6.1%) and due to serious infections (0% vs. 1.5%). Injection site reactions occurred in significantly fewer ABA-treated patients (3.8% vs. 9.1% [p=0.006]).


Conclusion: This first head-to-head study in RA patients comparing biologic agents on background MTX demonstrated that subcutaneous abatacept is comparable to adalimumab by most efficacy measures, including radiographic progression. Safety was generally similar with fewer discontinuations and injection site reactions observed with abatacept.

Evoked Pain Brain Response Is Associated with Reduced μ-Opioid Receptor Binding in Fibromyalgia. Heng Wang[1], Daniel J. Clauw[2], Jon-Kar Zubieta[1] and Richard E. Harris[2]. [1]University of Michigan, Ann Arbor, [2]University of Michigan, Ann Arbor, MI

Background/Purpose: Previous studies indicate that fibromyalgia (FM) patients have augmented clinical and brain responses to painful stimuli (i.e. hyperalgesia/allodynia), as well as increased production of endogenous opioids, and reduced μ-opioid receptor (MOR) binding. However, it is not known if these factors co-occur within the same individual or if these factors act independently. We performed a longitudinal investigation using functional magnetic resonance imaging (fMRI) and positron emission tomography (PET) in chronic pain patients diagnosed with FM to address this question. If these factors operate in the same individual, we expected an inverse correlation between changes in fMRI evoked pain activity and MOR binding potential (BP).

Methods: fMRI and PET imaging sessions were performed on 18 female opioid-naïve FM patients (age $45.4+/- 13.0$). Each participant underwent 4 weeks of non-pharmacological treatment. Before and after treatment, each patient underwent an fMRI scan with varying levels of pressure pain applied to the thumb as well as a 90-minute [11C]carfentanil PET scan under resting conditions. After quantification of the PET data with Logan plots, fMRI images and preprocessing of PET data were performed with statistical parametric mapping (SPM5). fMRI and PET scans were normalized to the same template. Difference images before and after treatment were calculated for both the fMRI contrast and PET images. A whole-brain voxel-by-voxel correlation analysis between the fMRI and PET difference images were carried out using the Biological Parametric Mapping toolbox. Activation clusters were defined based on a correlation coefficient, with $R >= 0.6$ uncorrected. Clinical pain was assessed with Short Form McGill Pain Questionnaire (SFMPQ).

Results: Negative correlations between the change in the fMRI blood oxygenation level dependent (BOLD) signal and MOR BP were observed in multiple regions involved in pain processing and modulation: right posterior insula $R=-0.82, P=0.0004$; left medial insula $R=-0.82$, $P=0.0003$; left orbital frontal cortex $R=-0.75$, $P=0.0004$; right amygdala $R=-0.68$, $P=0.002$; brainstem $R=-0.71$, $P=0.0009$. Positive correlations were observed in right DLPFC $R=0.66$, $P=0.003$; posterior cingulate $R=0.62$, $P=0.006$; right putamen $R=0.72$, $P=0.0008$. Changes in both functional imaging outcomes were negatively associated with changes in clinical pain: BOLD in right DLPFC and clinical pain SFMPQ $R=-0.52$, $P=0.03$; MOR BP in left medial insula and SFMPQ present pain $R=-0.51$, $P=0.03$.

Conclusion: We find strong longitudinal associations between evoked pain activations suggestive of hyperalgesia, and μ-opioid receptor availability (binding potential, BP) within the same brain regions, in individual FM patients. Positive associations were also observed between BOLD responses, and μ-opioid receptor BP (in opposite directions) with respect to clinical pain. These data suggest that the μ-opioid system is somehow involved in the pathogenesis of FM, and may even help explain why these patients are generally not felt to respond to narcotic analgesics, and may even be made worse when these drugs are used therapeutically.

Laquinimod (LAQ) Is Equivalent to Mycophenolate Mofetil (MMF) in Preventing and Suppressing Murine Lupus Nephritis and Has Greater Effects On Myeloid/Monocyte/Macrophage Cells. Bevra H. Hahn, Maida Wong, Elaine Lourenco and Brian Skaggs. UCLA David Geffen School of Medicine, Los Angeles, CA

Background/Purpose: Lupus nephritis (LN) depends on autoAb deposition and activation of multiple cell types that infiltrate kidneys and promote inflammation—monocytes/macrophages (MM), DCs, T and B cells. Laquinimod (LAQ) administered to humans downregulates Ag presentation, decreases chemokine production, decreases MHC expression on MM, and induces apoptotic pathways in PBMC (Gurevich M et al 2010). LAQ reduces progression of relapsing remitting multiple sclerosis (Comi G et al NEJM 2012); it is currently in clinical trials in SLE. MMF targets primarily lymphocytes; it is effective in many LN patients.

Methods: We compared clinical and immune cell changes in groups of 10–12 BWF1 female mice treated orally 3 times a week for 24 weeks with a)

water; b) LAQ 1 mg/kg; c) LAQ 25 mg/kg; d) MMF 30 mg/kg; e) MMF100 mg/kg.

Results: Survival was better in both LAQ groups and the MMF100 group vs controls ($p=0.028$). LAQ at both doses was equivalent to MMF100 in preventing proteinuria in mice treated before disease appeared. At 32 wks of age 50% of mice on water had proteinuria vs zero in LAQ and MMF100 groups ($p<0.0001$) Renal histology mirrored proteinuria: mean total histologic scores were 7.8 on water, 1.0 on LAQ and 0.9 on MMF100 ($p<0.01$ both treatment groups compared to controls). Glomerular deposition of Ig and C3 were in the normal range in LAQ and MMF, but significantly increased in the water group ($p<0.001$).

Mice treated after clinical nephritis appeared ($\geq 3+$ proteinuria) improved on LAQ: after 3 wks of treatment proteinuria was present in 100% on water vs 25% on LAQ ($p<0.001$). Survival was also better in mice treated with LAQ ($p<0.0001$).

Effects on splenic PBMC differed between LAQ and MMF. Neither treatment changed total numbers of B cells. MMF decreased CD4+ and CD8+ T cell percents; LAQ did not. LAQ compared to MMF increased numbers of two putative regulatory cells, CD4+CD25+Foxp3+ Treg and CD11b+Ly6^{int}GR-1+ myeloid MM. Most interesting was the observation that LAQ, but not MMF, significantly reduced numbers of MM.

Conclusion: LAQ was highly effective in preventing and suppressing proteinuria and glomerular immune disease in BWF1 mice. Responses to MMF in high dose were similarly good. However, LAQ reduced numbers of MM, and MMF did not. In addition, LAQ induced different types of regulatory cells, distinguishing it from MMF. Since suppression of MM is likely to reduce renal inflammation and damage, future development of LAQ as a therapeutic for lupus nephritis is especially promising.

Rheumatoid Arthritis-Associated PTPN22 Modulates Toll-Like Receptor-Mediated, Type 1 Interferon-Dependent Innate Immunoregulation. Yaya Wang[1], Stephanie Stanford[2], Wenbo Zhou[1], Jennifer L. Auger[1], Genhong Cheng[3], Amanda Campbell[2], Fernanda M. Shoyama[1], Henry H. Balfour Jr.[4], Andrew C. Chan[5], Bryce A. Binstadt[1], Nunzio Bottini[2] and Erik J. Peterson[1]. [1]University of Minnesota, Minneapolis, MN, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA, [3]University of California, Los Angeles, Los Angeles, CA, [4]University of Minnesota, Minneapolis, [5]Genentech Inc, South San Francisco, CA

Background/Purpose: A coding polymorphism (C1858T) in *PTPN22* is strongly associated with risk of Rheumatoid Arthritis (RA) and other autoimmune diseases. *PTPN22* encodes Lymphoid Phosphatase (Lyp); the Lyp disease variant bears an R620W substitution ("LypW"). The mechanism by which LypW increases disease susceptibility remains unclear. *PTPN22*-expressing dendritic cells (DC) and macrophages have been implicated in RA pathology. Such myeloid cells produce type 1 interferons (IFN) and proinflammatory cytokines in response to Toll-like receptor (TLR) engagement. We hypothesized that *PTPN22* might modulate TLR signaling and attendant innate immune responses.

Methods: We studied TLR signaling and type 1 IFN-mediated antiviral responses and immunoregulation in *Ptpn22*-deficient myeloid cells and mice, in transgenic mice harboring human LypW or LypR (major allele protein product), and in human LypW carrier peripheral blood mononuclear cells (PBMC).

Results: We found markedly decreased induction of type 1 IFN after TLR3/4/7/9 activation in *Ptpn22*$^{-/-}$ macrophages, DC, and plasmacytoid DC. Interestingly, *Ptpn22* was dispensable for induction of proinflammatory cytokines, including TNFα, IL-6, and IL-1β, after TLR2/3/4/7/9 stimulation. The selective TLR signalling defect in *Ptpn22*$^{-/-}$ cells was associated with impaired type 1 IFN-dependent immunity, manifested by reduced serum type 1 IFN, impaired dendritic cell activation, and diminished T cell responses after lymphocytic choriomeningitis virus (LCMV) infection of *Ptpn22*$^{-/-}$ mice. In the K/BxN serum transfer model of rheumatoid arthritis, treatment with type 1 IFN-inducing TLR ligands suppresses disease. However, we observed significantly decreased TLR ligand-mediated suppression of inflammatory arthritis in *Ptpn22*$^{-/-}$ mice. RA-associated LypW carrier human PBMC and myeloid cells derived from LypW transgenic mice displayed defective induction of type 1 IFN after TLR stimulation. LypR directly associated with TNF receptor-associated factor 3 (TRAF3), a key TLR signaling mediator upstream of type 1 IFN induction. LypR, but not LypW promoted TRAF3 K63-linked polyubiquitinylation, which is required for TLR-induced type 1 IFN production.

Conclusion: *PTPN22* is a key positive regulator of TLR-driven upregulation of type 1 IFN. LypW, product of the RA-associated *PTPN22* allele, exhibits "loss of function" in type 1 IFN dependent processes, including antiviral host defense and amelioration of inflammatory arthritis. Our findings strongly suggest that *PTPN22* could regulate severity of joint inflammation in RA through modulation of TLR signaling in innate immune cells.

The Role of Bob1 in Rheumatoid Arthritis: Potential Implications for Autoimmunity. Nataliya Yeremenko[1], Tineke Cantaert[1], Melissa N. van Tok[1], Ioana Gofita[1], Juan D. Canete[2], Paul P. Tak[1], Hergen Spits[3] and Dominique L. Baeten[1]. [1]Division of Clinical Immunology and Rheumatology and Department of Experimental Immunology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [2]Rheumatology Department, Hospital Clinic, Barcelona, Spain, [3]Tytgat Institute for Liver and Intestinal Research, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a prototypic autoimmune disease characterized by a prominent humoral autoimmunity. Of particular relevance is the local production of autoantibodies such as rheumatoid factor and anti-citrullinated protein antibodies in the inflamed synovial tissue. The mechanisms underlying break of B cell tolerance and local autoantibody production remains poorly understood. This study was conducted in order to identify cellular and molecular pathways implicated in RA-specific humoral autoimmunity.

Methods: Synovial tissue samples were obtained by arthroscopy from untreated individuals with RA (n=33) and inflammation matched SpA controls (n=58). Gene expression profiling was performed on tissue samples of patients with established arthritis using 44K Whole Genome Human microarrays (Agilent). Top differentially expressed genes were validated on three independent cohorts by Taqman based RT-qPCR and immunohistochemistry. Collagen-induced arthritis (CIA) and Experimental autoimmune encephalomyelitis (EAE) experiments were conducted using Bob1 knockout mice and their littermate controls.

Results: Microarray screening for genes differentially expressed in the inflamed synovium, the key target of the disease process in RA, revealed a prominent and disease-specific B cell/plasma cell signature with the B cell-specific transcriptional co-activator Bob1 and its transcriptional target BCMA among the most upregulated genes. Validation by RT-qPCR on two independent cohorts representing early and established arthritis confirmed microarray data and demonstrated elevated expression of Bob1 and BCMA not only in established RA, but also at the early phase of the disease. Quantitative evaluation of immunohistochemical stainings of synovial tissue with monoclonal antibody for Bob1 revealed significant increase in Bob1 positive cells in RA synovium (p<0.01). Next we determined whether lack of functional Bob1 modifies disease onset or severity in CIA. Interestingly, the results showed that Bob1$^{-/-}$ mice were fully resistant to CIA induction compared to their wild-type littermates. This remarkable protection from CIA is explained by failure to produce pathogenic anti-collagen autoantibodies in the absence of Bob1. In contrast, Bob1$^{-/-}$ mice were susceptible to MOG protein induced EAE and incidence and severity of clinical disease were not altered in these mice comparing to wild-type littermates, suggesting that absence of Bob1 does not impact on antigen-presentation/costimulatory capacity of B cells.

Conclusion: The specific increase in Bob1 expressing cells in RA synovitis and the resistance of Bob1-defecient mice to development of CIA indicate that Bob1/BCMA axis may contribute to humoral autoimmunity in RA. The relationship between an aberrant Bob1 expression and the break of peripheral tolerance in RA is currently under investigation.

Expression of TLR5 Strongly Correlates with Levels of TNF-a and DAS28 in RA Monocytes and Ligation of TLR5 Induces Angiogenesis in RA. Nathan D. Chamberlain[1], Michael Volin[2], Olga M. Vila[1], Shiva Arami[1], Suncica Volkov[1] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL

Background/Purpose: This study was performed to determine whether expression of TLR5 is associated with Rheumatoid Arthritis (RA) disease activity as well as to examine the role of TLR5 ligation in the pathogenesis of RA.

Methods: Expression of TLR5 was determined in RA and normal (NL) PB monocytes and *in vitro* differentiated macrophages by real-time RT-PCR and/or flow cytometry. Next, linear regression analysis was employed to correlate expression of TLR5 with levels of TNF-a and DAS28 score in RA monocytes from 43–48 patients. Finally, the mechanism by which TLR5 ligation mediates RA pathogenesis was determined by endothelial chemotaxis and tube formation.

Results: We performed microarray studies to identify differentially regulated genes in RA synovial fluid macrophages from active patients and identified Toll like receptor (TLR)5 as one of the most highly upregulated genes in RA synovial fluid macrophages compared to normal macrophages. Using real-time RT-PCR and FACS analysis we confirmed that expression of TLR5 is significantly elevated in RA synovial fluid macrophages (35 fold) and RA monocytes (7 fold) compared to normal counterpart cells. Interestingly, we found that blockade of TLR5 on RA peripheral blood (PB) monocytes greatly reduces RA synovial fluid mediated TNF-a transcription by 80% suggesting that there are endogenous TLR5 ligands expressed in the RA synovial fluid that are crucial for joint TNF-a modulation. Since TNF-a stimulation is also capable of upregulating TLR5 levels there is a positive feedback modulation in RA monocytes between TNF-a and TLR5 ligation and expression. We found that patients with higher expression of TNF-a expressed elevated levels of TLR5 (R^2=0.79, p=3.6×10^{-7}) in RA monocytes and the concentrations of TLR5 and TNF-a strongly correlated with increased disease activity as determined by examination of 28 defined joints (DAS28) (correlation of TLR5 with DAS28; R^2=0.75) (correlation of TNF-a with DAS28; R^2=0.58). Since our previous studies demonstrated that TLR5 expression is elevated on RA synovial tissue endothelial cells compared to control tissue we asked whether ligation of this receptor induces angiogenesis and if TLR5 endogenous ligands present in RA synovial fluid play a role in this process. We found that when endothelial cells were exposed to a dose response of flagellin, a TLR5 agonist, migration of endothelial cells was induced at concentrations ranging from 0.1 to 100 ng/ml (p<0.05). Further, incubation of endothelial cells with neutralizing antibody to TLR5 significantly suppressed RA synovial fluid endothelial migration and tube formation suggesting that the RA synovial fluid contains TLR5 endogenous ligands that are chemotactic for TLR5+ endothelial cells.

Conclusion: Our observations highlight that there is a strong correlation between TNF-a and TLR5 expression with disease activity in RA monocytes suggesting that TLR5 may be a TNF-a responsive gene that is linked to RA progression through induction of angiogenesis.

Buckner[14], Fernando S. Cavalcanti[12] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Lab of immunology, IRCCS Istituto Auxologico Italiano, Milano, Italy, [3]INOVA Diagnostics, Inc., San Diego, CA, [4]Division of Rheumatology - Istituto G. Pini, University of Milan, Milano, Italy, [5]Corgenix Inc, Broomfield, CO, [6]Theratest Laboratories Inc, Lombard, IL, [7]TheraTest Laboratories Inc, Lombard, IL, [8]Phadia Thermofisher, Freiburg, Germany, [9]Bio-Rad Laboratories, Benicia, CA, [10]Bio-Rad Laboratories, Hercules, CA, [11]Bio-Rad Laboratories, Hercules, [12]Biokit, Barcelona, Spain, [13]Instrumentation Laboratories, Bedford, MA, [14]Corgenix, Broomfield, CO

Background/Purpose: Despite numerous efforts aimed at the standardization of assays for detection of anti-β_2Glycoprotein I (aβ_2GPI) antibodies, there are still concerns, including the type and source of properly validated calibrant and reference material and the lack of universal units of measurement. Based on recommendations of an international task force at the 13th Congress on Antiphospholipid Antibodies, a project was started with the goals of establishing a

reference preparation (RP) and international consensus units (IU) for the measurement for IgG aβ_2GPI antibodies.

Methods: Whole IgG fractions were affinity-purified (AP) from sera of 2 primary Antiphospholipid syndrome patients with high IgG ab$_2$GPI levels using a Protein G Sepharose column. Pooled IgG fractions were further AP using an affinity column coupled to β_2-GPI, and the protein concentration of the AP material was determined using two methods, and a value based on the definition that 1 IU/ml equates to 1 μg/ml of AP aβ_2GPI, was assigned. A reference preparation (RP) serum created from sera taken from the 2 original PAPS patients was then assigned an IU value based on repeated testing using original AP material as a calibrator. RP was sent to six commercial companies for testing in their respective kits (eight total) according to an approved protocol to enable evaluation of linearity and unit equivalency, along with a set of 30 samples (APS samples and healthy controls) to allow for commutability studies to be done. Companies (and kits) included INOVA Diagnostics (QUANTA Lite® β_2GPI IgG ELISA, QUANTA Flash® β_2GPI IgG chemiluminescent assay), Bio-Rad Laboratories (BioPlex® 2200 APLS IgG Kit, Anti-β_2Glycoprotein I IgG EIA Test Kit) TheraTest (EL-b$_2$GPI IgG kit), Corgenix (IgG Anti-Beta 2 Glycoprotein I Test Kit), Phadia (EliA β2-Glycoprotein I IgG on Phadia® 250) and Instrumentation Laboratory (HemosIL® AcuStar anti-β_2Glycoprotein-I IgG).

Results: The pooled AP material had a protein concentration of 103.1 μg/ml (OD280nm) and 108.8 μg/ml (Bradford) and was assigned a value of 100 IgG aβ_2GPI IU/ml. RP had a value of 270 IgG aβ_2GPI IU/ml. The R^2 values of the regression lines of the RP for all kits were >0.95. The value of the RP in the various kit units ranged from 115 to 9993.1. Results of correlations between kits with commutability samples are shown in Table 1 (kit units and international units).

Table 1. Correlation of commutability sample values among various ab$_2$GPI assays

		IL AcuStar	INOVA BIO-FLASH	INOVA ELISA	Bio-Rad ELISA	Bio-Rad BioPlex	Theratest	Corgenix	Phadia	
	IL AcuStar		.996	.961	.940	.990	.978	.966	.950	
	INOVA BIO-FLASH	0.996		.959	.935	.988	.971	.961	.939	
CORRELATIONS OF COMMUTABILTY SAMPLES IN INTERNATIONAL UNITS	INOVA ELISA	0.938	0.933		.896	.942	.987	.925	.956	CORRELATIONS OF COMMUTABILITY SAMPLES IN KIT UNITS
	BioRad ELISA	0.972	0.963	0.897		.929	.914	.915	.846	
	Bio-Rad BioPlex	0.948	0.945	0.810	0.920		.960	.963	.933	
	Theratest	0.964	0.958	0.978	0.936	0.891		.949	.958	
	Corgenix	0.974	0.968	0.911	0.993	0.907	0.939		.905	
	Phadia	0.953	0.944	0.944	0.898	0.878	0.958	0.903		

For values in table: p<0.001

Conclusion: Establishment of equivalency between kit units and IU value of RP was successful. The RP demonstrated excellent linearity and was commutable in the various aβ_2GPI IgG assays and is therefore adequate to be used as a reference material. Expressing results in the new IU instead of arbitrary kit units illustrated the comparability of the results obtained in the different kits. These studies contribute significantly to the much-needed standardization of aβ_2GPI immunoassays.

2456

Pro-Inflammatory and Pro-Thrombotic Markers in Persistently Antiphospholipid Antibody-Positive Patients with/without Systemic Lupus Erythematosus. Gurjot Basra[1], Doruk Erkan[2], Rohan Willis[1], JoAnn Vega[2], Ana Laura Carrera Marin[1], Patricia Ruiz Limon[1], Vijaya L. Murthy[1], Shraddha Jatwani[1], Neha Dang[1], Emilio B. Gonzalez[1] and Silvia S. Pierangeli[1]. [1]University of Texas Medical Branch, Galveston, TX, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: Pro-inflammatory/thrombotic biomarkers (BMR), which are associated with aPL-mediated pathogenic effects in vitro/vivo, are also increased in aPL-positive patients. Here we examined whether those BMR are differentially upregulated in persistently aPL-positive patients with or without systemic lupus erythematosus (SLE).

Methods: In this cross-sectional study, persistently aPL-positive patients (aCL IgG/M≥40 GPL/MPL, aβ_2GPI≥20U IgG/M, and/or positive lupus anticoagulant [LA] test on 2 occasions at least 12w apart) were identified from our open-label prospective mechanistic pilot study of fluvastatin (selected exclusion criteria for this trial were pregnancy, prior statin use, prednisone

>10 mg/day, and immunosuppressive use [except hydroxychloroquine]). Control samples (age/sex matched) were identified from our databank of healthy people. Interferon (IFN)-α, Interleukin (IL)1b, IL6, IL8, inducible protein (IP)10, tumor necrosis factor (TNF)-α, vascular endothelial growth factor (VEGF), and soluble CD40 ligand (sCD40L) levels were determined by the MILLIPLEXMAP human cytokine/chemokine assay (Millipore, Billerica, MA) in the serum of patients and controls. Plasma samples were used to detect sTF using a chromogenic assay. aCL (IgG, IgM and IgA), aβ_2GPI (IgG, IgM and IgA), soluble intercellular cell adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1, and E-selectin (E-sel) were evaluated by ELISA. Mann-Whitney Rank Sum test was used to analyze the data for differences between patient subgroups and controls; Kruskal-Walllis One Way Analysis of Variance was used to compare medians of BMR among groups.

Results: 41 persistently aPL-positive patients (mean age: 44.6±13.6 y; female: 70%; primary APS; 18, SLE/APS: 7; Primary aPL [no history of thrombosis or pregnancy morbidity]: 9; and SLE/aPL: 7) and 30 healthy controls were included in this analysis. All APS patients had history of thrombosis except two SLE/APS patients who had only obstetric APS. Median levels of: a) all BMR except IL-8, sVCAM-1, and sE-sel was significantly higher in all groups combined when compared to the controls; b) IL-8, TNF-α, and IP-10, were significantly higher in Primary APS, SLE/APS and SLE/aPL when compared to primary aPL; c) VEGF, sICAM-1, and sVCAM-1 were significantly higher in Primary APS when compared to the other groups; and d) sTF was elevated in all subgroups (Table). There was no difference in aCL/aβ_2GPI titers among the groups.

Biomarkers (median)	Controls n: 30	Combined n:41	Primary APS n:18	SLE/APS n:7	Primary aPL n:9	SLE/aPL n:7

# of BMR elevated		9/12	9/12	7/12	3/12	4/12

* significantly different from the median of controls (p<0.05)

Conclusion: Our study suggests that the pro-inflammatory and prothrombotic markers are differentially upregulated in persistently aPL-positive patients with or without vascular events and/or SLE. These findings have implications in the pathophysiology of APS and the risk-stratification of aPL-positive patients.

An Open-Label Prospective Pilot Mechanistic Study of Fluvastatin in Persistently Antiphospholipid Antibody-Positive Patients. Doruk Erkan[1], Rohan Willis[2], JoAnn Vega[1], Vijaya L. Murthy[2], Ana Laura Carrera Marin[2], Gurjot Basra[2], Patricia Ruiz Limon[2], Emilio B. Gonzalez[2] and Silvia S. Pierangeli[2]. [1]Hospital for Special Surgery, New York, NY, [2]University of Texas Medical Branch, Galveston, TX

Background/Purpose: Antiphospholipid antibodies (aPL) induce a pro-inflammatory and pro-thrombotic state by upregulating various cytokines, chemokines, and tissue factor (TF). Fluvastatin reduces TF expression and decrease thrombogenic effects of aPL in vitro and in mice. The purpose of this prospective pilot study was to examine the effects of fluvastatin on pro-inflammatory and pro-thrombotic biomarkers (BMR) in persistently aPL-positive patients.

Methods: Persistently aPL-positive patients (IgG/M aCL≥40 GPL/MPL, IgG/M aβ_2GPI≥20U, and/or positive lupus anticoagulant (LA) test on 2 occasions at least 12w apart) received fluvastatin 40 mg daily for at least 3 months. At 3 months, patients were instructed to stop fluvastatin and they were followed for another 3 months. Serum samples were collected at baseline and monthly thereafter for 6 months. Selected exclusion criteria were pregnancy, statin use, prednisone >10 mg/day, and immunosuppressive use (except hydroxychloroquine [HCQ]). Interferon (IFN)-α, Interleukin (IL)1b,

IL6, IL8, inducible protein (IP)10, tumor necrosis factor (TNF)-α, vascular endothelial growth factor (VEGF), and soluble CD40 ligand (sCD40L) levels were determined by the MILLIPLEXMAP human cytokine/chemokine assay (Millipore, Billerica,MA) in serum of patients and controls. Plasma samples were used to detect sTF using a chromogenic assay. aCL IgG/M/A, aβ_2GPI IgG/M/A, soluble intercellular cell adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM)-1, and E-selectin (E-sel) were evaluated by ELISA. We used Spearman test to analyze the significance of monthly changes in BMR levels.

Results: Of 41 patients recruited, 24 completed the study (mean age: 44.6 + 13.6y; female: 70%; Primary APS: 8, SLE/APS: 7, Primary aPL: 5; SLE/aPL: 4; HCQ: 61%; and Anticoagulation: 43%). The early withdrawal reasons for 15/41 patients were: 6 lost to follow-up or refused further treatment without adverse events; 4 stopped treatment due to myalgia (normal muscle/liver enzymes); 3 wanted to continue fluvastatin after 3 months; 1 screen failure after the baseline visit; and i stopped treatment due to insomnia. The table shows the number of patients with elevated BMR (above the assay cut-off) at baseline as well as follow-up BMR levels during and after fluvastatin. The levels of 6/12 (50%) BMR (IL-6, IL-1b, VEGF, TNF-α, IP-10, sCD40L, and sTF) significantly decreased with fluvastatin, followed by significant increases after stopping the treatment. Of note, aCL/aβ_2GPI and LA tests remained unchanged throughout the study.

Biomarker (BMR)	# of Patients with Elevated BMR at BL	# of Patients with Decreased BMR after Fluvastatin	Mean+SD Maximum BMR reduction with fluvastatin	# of Patients with Increased BMR After Stopping Fluvastatin	Mean+SD maximum BMR Increase After Stopping Fluvastatin

* p<0.05

Conclusion: Our pilot study demonstrating that fluvastatin can reversibly reduce the pro-inflammatory and prothrombotic biomarkers in persistently aPL-positive patients with or without SLE provide the basis for future larger randomized-control trials to examine the effects of the statins on the aPL-induced biomarkers as well as on the aPL-related clinical manifestations.

The Estimated Prevalence of Antiphospholipid Antibodies in General Population Patients with Pregnancy Loss, Stroke, Myocardial Infarction, and Deep Vein Thrombosis. Laura Andreoli[1], Alessandra Banzato[2], Cecilia B. Chighizola[3], Guillermo J. Pons-Estel[4], Guilherme Ramires de Jesus[5], Michael D. Lockshin[6], Doruk Erkan[6] and On Behalf of APS Action[7]. [1]Rheumatology and Clinical Immunology, University of Brescia, Brescia, Italy, [2]Department of Cardiac Thoracic and Vascular Sciences, University of Padua, Padua, Italy, [3]Istituto Auxologico Italiano, University of Milan, Milan, Italy, [4]Department of Autoimmune Diseases, Institut Clìnic de Medicina i Dermatologia, Hospital Clìnic, Barcelona, Spain, [5]Department of Obstetrics, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [6]Hospital for Special Surgery, New York, NY[7].

Background/Purpose: Anti**P**hospholipid **S**yndrome **A**lliance For **C**linical **T**rials and Internati**O**nal **N**etworking (APS ACTION) is an international research network that has been created specifically to design and conduct well-designed, large-scale, multi-center clinical trials in persistently antiphospholipid antibody (aPL)-positive patients. One of the first needs of APS ACTION was to know the true prevalence of aPL in the general population with pregnancy loss (PrL), stroke (ST), myocardial infarction (MI) and deep venous thrombosis (DVT).

Methods: The search for "aPL" and multiple keywords regarding the outcomes of interest was completed in PubMed; additionally, review articles were searched. A total of 108 full-text papers were collected and analyzed for the type of outcome, the aPL tests used (criteria tests *vs.* non criteria), the definition of "positive aPL" (low, medium, high, other), the confirmation of aPL (at least 6–12w apart), and the prevalence of positive aPL in the study population (defined by sex and age range). The mean, median, and range of the aPL prevalence were calculated separately for papers with and without aPL confirmation. The incidence of PrL, ST, MI and DVT in the general US population was retrieved from official sources.

Results: Of 108 papers, the outcome of interest was early/late PrL in 32, ST in 31, MI in 24, and DVT in 21. Despite the limitations of the literature, the table demonstrates the estimated prevalence and incidence of aPL-related events. These limitations were: a) approximately 60% of the papers were published between 1984 and 2000; b) the number of aPL criteria tests used was single test in 45 (36.6%), two tests in 65 (52.8%), and 3 tests in 13 (10.6%); c) anticardiolipin and/or anti-β2glycoprotein-I ELISA cut-off was not available in 10% of the papers and "low titer" (<20U) was used in 36% of the papers; d) the method of reporting the cut-off for anti-β2GPI was quite heterogeneous, reflecting the lack of international reference units; e) the confirmation of aPL was performed only in 24 papers (19.5%); and f) half of the studies were not designed to answer our research question (case-control:30%; retrospective cohort/case series:20%).

	Estimated aPL Prevalence (%) (Literature Review) Mean, Median (Range)			US Incidence/y*	Estimated US Incidence/y
	aPL Confirmation (−)	aPL Confirmation (+)	Average (median)	All Events	aPL-associated Events
PrL	12, 9 (0–48)	14, 14 (0–25)	12%	526,000	~ 60,000
ST	23, 21 (0–49)	10, 6 (0–53)	14%	795,000	~ 120,000
MI	14, 8 (3–39)	17, 17 (14–21)	13%	935,000	~ 120,000
DVT	14, 11 (0–35)	10, 9 (5–19)	10%	300,000	~ 30,000

* Source: **PrL:** Macklon N, Hum Reprod Update 2002;8:333; Stephenson MD. Fertil Steril 1996;66:24; National Vital Statistics for the year 2009. **ST, MI, DVT:** "Heart Disease and Stroke Statistics -2012 Update", Circulation 2012;125:e12; White RH. Circulation 2003;107:I4; 2010 US Census.

Conclusion: It is difficult to determine the prevalence of a "clinically significant aPL profile" in the general population patients with pregnancy loss and thrombosis due to the lack of robust data. Pending more rigorous data collection, our best estimates of the incidence of aPL-associated events should be confirmed with appropriately sampled and designed population studies. One of the goals of APS ACTION is to improve upon existing aPL prevalence studies.

Efficacy of Aspirin for the Prevention of the First Thrombo-Embolic Events in Patients with Antiphospholipid Antibodies: A Meta-nalysis of Literature Data. Laurent Arnaud[1], Alexis Mathian[1], Amelia Ruffatti[2], Maria Tecktonidou[3], Ricard Cervera[4], Ricardo Forastiero[5], Vittorio Pengo[6], Marc Lambert[7], Stephane Zuily[8], Denis Wahl[8] and Zahir Amoura[1]. [1]Hôpital Pitié-Salpêtrière, AP-HP, UPMC Univ Paris 06 & French National Reference Center For Systemic Lupus and Antiphospholipid Syndrome, Paris, France, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Padua, Padua, Italy, [3]First Department of Internal Medicine, School of Medicine, National University of Athens, Athens, Greece, [4]Hospital Clínic of Barcelona, Barcelona, Spain, [5]Favaloro University, Argentina, [6]Clinical Cardiology, Department of Cardiac Thoracic and Vascular Sciences, University of Padova, Padova, Italy, [7]Internal Medicine Department, Universitary hospital, Lille, France, [8]Nancy University Hospital, Université de Lorraine & INSERM U961, Vandoeuvre-Les-Nancy, France

Background/Purpose: Whether aspirin is needed in patients with antiphospholipid antibodies (aPL+) for prevention of a first thrombotic event is controversial. The aim of this metaanalysis was to determine whether aspirin had a protective effect in aPL+ patients with no history of thrombosis.

Methods: Both observational (either prospective or retrospective) and interventional studies were selected if they assessed the incidence of the

first thrombosis in patients with aPL, either treated with aspirin or not, were included. Data sources were MEDLINE, Embase, Cochrane Library, hand search, contact with investigators, and reference lists of studies, without language restrictions. Data on study and patient characteristics, risk estimates, and study quality were independently extracted by 2 investigators. Pooled effect estimates were obtained by using random-effect models according to the DerSimonian and Laird method.

Results: Of 342 identified abstracts, 9 primary studies (8 observational and 1 interventional) met inclusion criteria, including 1136 aPL patients and 133 thrombotic events. Compared with aPL+ patients without aspirin (n=556), the overall pooled odds ratio for the risk of first thrombosis in aPL+ patients treated with aspirin (n=580) was 0.48 (95%CI: 0.24 to 0.93), with significant heterogeneity across studies (I^2=53%, p=0.03). Subgroup analysis according to the type of study suggested a protective effect of aspirin when considering only retrospective (OR: 0.25 [0.15–0.43]) but not prospective (OR: 0.84 [0.46–1.54]) studies. Subgroup analysis according to the type of thrombotic event suggested a protective effect of aspirin when considering only arterial (OR: 0.48 [0.28–0.83]) but not venous (OR: 0.52 [0.24–1.14]) thrombosis.

Conclusion: This metaanalysis suggests that aspirin has a protective effect for the risk of first thrombosis among aPL+ patients. Significant heterogeneity was found across included studies, with subgroup analyses showing a protective effect in retrospective but not in prospective studies, as well as for arterial but not venous first thrombotic events. A collaborative metaanalysis of individual patient data is currently underway to clarify these findings at patient level by taking into account the various pathogenic backgrounds as well as potential confounding factors.

Dual Antiplatelet Therapy As Prophylaxis of Recurrent Arterial Thrombosis in Patients with antiphospholipid Syndrome. Yuichiro Fujieda, Olga Amengual, Toshiyuki Watanabe, Michihito Kono, Yusaku Kanetsuka, Takashi Kurita, Toshio Odani, Kotaro Otomo, Toshiyuki Bohgaki, Tetsuya Horita, Shinsuke Yasuda and Tatsuya Atsumi. Hokkaido University, Sapporo, Japan

Background/Purpose: Arterial thrombosis (AT) is a major clinicalmanifestation of the antiphospholipid syndrome (APS). A number of studies have evaluated the rate of recurrent thromboembolism, including arterial and venous thrombosis, after an initial event in patients with APS. Regardless of the presence of warfarin therapy, recurrent events were seen in >11% of APS patients-year. Therefore, the optimal treatment for recurrent AT in patients with APS remains unclear. The purpose of this study is to clarify the efficacy of prophylaxis for recurrent AT in patients with APS.

Methods: This study comprised 82 unselected consecutive APS patients with AT recruited at one single center. Patients were included in this observation study at the initial arterial thrombotic event and followed up. We retrospectively assessed the efficacy and safety of several therapies for the secondary prevention of AT in those patients.The recurrence rate of AT was analyzed as the efficacy outcome and the occurrence of major bleeding event and overall mortality as the safety outcome. The evaluated therapies include warfarin monotherapy (Group1), antiplatelet monotherapy (Group2), combination therapy with warfarin and antiplatelet agent (Group3), and dual antiplatelet therapy (Group4).

Results: Among all the patients, 67 (76%) were females, the mean age was 44 years (range 15–74 years) and 51 (62%) were diagnosed as systemic lupus erythematosus. The mean follow up period was 8.5 years (range 2–22 years). Thirteen (16%) patients were in Group1, 35 (43%) in Group2, 21 (26%) in Group3, and 13 (16%) in Group4. Antiplatlet therapy consisted on aspirin, ticlopidine, clopidogrel, cilostazol, or others such as dipyridamole, beraprost and sarpogrelate hydrochloride. Distribution of antiplatelet agents in each group is shown in Table. Dual antiplatelet treatment comprised 7 (54%) patients on aspirin and ticlopidine/clopidogrel, 3 (23%) on aspirin and others, 2 (15%) on aspirin and cilostazol, 1 (8%) on cilostazol andticlopidine.

Thrombotic events recurred in 25 patients (3.4 100 patient-year). No recurrences were observed in the Group 4. However, a high incidence of recurrences rate observed in Groups 1, 2, 3 (Log-rank p=0.01) (Fig).There was no statistically significant difference in the bleeding events nor in the mortality rate between the study groups.

Table. Distribution of anti-platelet agents in each treatment groups

	Total N = 82	Warfarin monotherapy N = 13	Antiplatelet monotherapy N = 35	Warfarin Antiplatelet combination N = 21	Dual antiplatelet N = 13
aspirin	55 (67%)	-	26 (74%)	17 (81%)	12 (92%)
ticlopridin/clopidogrel	12 (15%)	-	3 (9%)	1 (5%)	8 (62%)
cilostazol	8 (10%)	-	3 (9%)	2 (10%)	3 (23%)
others*	7 (9%)	-	3 (9%)	1 (5%)	3 (23%)

others*: dipyridamole, beraprost and sarpogrelate hydrochloride.
Fig. Kaplan-Meier analysis shows that the treatment with dual antiplatelet therapy was more effective for the prevention of thrombotic recurrences than other therapies (Log-rank p=0.01).

Conclusion: Dual antiplatelet therapy may be an effective therapy for prevention of recurrent arterial thrombosis in patients with APS.

Cost-Effectiveness of Systemic Therapies for Acute Gouty Arthritis. Kimberly Reiter[1], Jeremy Goldhaber-Fiebert[2] and Eswar Krishnan[3]. [1]Stanford University School of Medicine, Palo Alto, CA, [2]Stanford, Stanford, CA, [3]Stanford University, Stanford, CA

Background/Purpose: Rising prevalence has led to increased demand for newer and potentially costly treatments for acute gouty arthritis, but few studies comparing effectiveness and costs of both older and novel treatments exist to guide best clinical practice. We aimed to assess the effectiveness and cost-effectiveness of currently available drug classes (non-selective and COX-2 selective non-steroidal anti-inflammatory drugs, colchicine, and systemic corticosteroids), as well as a long-acting biologic agent for the treatment of acute gout flare.

Methods: We modeled acute gout flare in 50 year old adult men with definite gout and no contraindications to considered therapies. Our decision analytic model incorporated quality of life impact of the flare, and costs and health effects of drugs and drug-related adverse events. The perspective was that of a third party payer, with an 8 week time horizon. Probabilities of response to therapies and adverse events, health state utilities, and costs in 2010 U.S. dollars were informed by published literature, U.S. hospital statistics, and payment algorithms that may be employed by a third party payer. We utilized published data for canakinumab (Ilaris®, Novartis) as representative of a long-acting biologic drug, although this drug is not approved for use in gout. Outcomes were measured in quality-adjusted-life-days (QALDs) and quality-adjusted-life-years (QALYs).

Results: Literature review revealed relatively small differences in overall effectiveness between treatments, in spite of a wide range of costs. Steroids provided 47.17 QALDs, colchicine 47.39 QALDs, and biologic 47.57

QALDs. After accounting for toxicities and for the cost of COX-2 selective NSAIDs, both NSAID sub-classes were more expensive and less effective than other non-biologics. Intramuscular steroid cost $11,935 per QALY over no treatment, and branded colchicine cost $18,234 per QALY compared to steroid. The biologic drug cost over $22 million per QALY gained. Results were sensitive to untreated flare duration, probability of first-day drug response, and drug costs. When priced as an unbranded product, colchicine offered greater benefits at a lower cost than all other non-biologic drugs. A scenario analysis assuming equivalent efficacy of oral prednisone to intramuscular steroid showed prednisone to cost less than $3,000 per QALY, in which case branded colchicine exceeded a traditional willingness-to-pay threshold of $50,000 per QALY.

Conclusion: Compared to moderate dose intramuscular corticosteroid, colchicine provides reasonable value for money in the treatment of acute gout flare. When priced as an unbranded product, it is more effective and less expensive than all other options. If oral prednisone is similar in effectiveness to intramuscular steroid, then it is most cost-effective and branded colchicine costs much more for its incremental benefits. At current prices, biologic therapy does not provide additional benefits commensurate with its higher cost.

Limitations: These results apply only to uncomplicated gout among men in outpatient settings. Non-canakinumab biologics may have a different cost-effectiveness profile.

2462

Projecting the Direct Cost Burden of Osteoarthritis in Canada Using a Population-Based Microsimulation Model From [2010–2031]. Behnam Sharif[1], Jacek A. Kopec[1], Mushfiqur Rahman[1], Nick Bansback[2], Eric C. Sayre[1], Philippe Finès[3], Hubert Wong[2] and Aslam H. Anis[2]. [1]Arthritis Research Centre of Canada, Vancouver, BC, [2]St Paul's Hospital, University of British Columbia, Vancouver, V6Z 1Y6, Canada, Vancouver, BC, [3]Statistics Canada, 150 Tunney's Pasture Driveway, Ottawa, ON, Canada, Ottawa, ON

Background/Purpose: POHEM-OA (Population Health Model-Osteoarthritis) is a population-based microsimulation model that uses Canadian Community Health Survey-2001 to generate the initial population and models every individual's life history in terms of osteoarthritis (OA) diagnosis and treatment for the entire Canadian population. The objective of this study was to incorporate treatment and other costs of OA into POHEM-OA to project the future direct cost burden of OA in Canada for the years 2010 to 2031.

Methods: Average healthcare treatment costs were estimated from the British Columbia (BC) linked health administrative database spanning 1986/87–2003/03 that included physician visits, surgical procedures, medication, and all hospital admissions covered by the Medical Services Plan (MSP) of BC. Surgical procedures related to OA were micro-costed based on unit costs available from the fully allocated St. Paul's hospital (Vancouver) cost model. Since the number of hip and knee replacements almost doubled in the last 10 years, replacement rates were recalibrated and a time trend was introduced based on the Canadian Joint Registry database from 1997–2007. Average drug costs (both over-the-counter and prescription drugs) were estimated from the PharmaNet (BC) database in 2003 and the National Population Health Survey for four main types of OA-related drugs (acetaminophen, NSAID, coxibs and opioids). Each patient was assigned a cost variable based on sex, age category, OA stage (defined by OA diagnosis, orthopedic surgeon visit, primary replacement surgery, and revision), and time in each stage. All costs were implemented in POHEM according to two categories: "ongoing costs" as they accumulated based on the person-years of each individual staying in a given OA stage and "event-based costs" for hip and knee replacement surgeries. A 5% annual discount rate was applied.

Results: The total direct costs of OA in Canada were estimated to rise from $1.8 billion dollars in 2010 ($0.7 and $1.1 billion dollars for males and females, respectively) to $8.1 billion dollars in 2031 ($3.3 and $4.8 billion dollars for males and females, respectively) (Figure 1). This rise is in part attributable to an increase in the number of persons living with OA, due to increasing OA incidence and general longevity. OA prevalence is projected to increase from 3 million (14%) in 2010 to 5.8 million (18%) in 2031 (Figure 1). Other contributing factors are the increasing number of total knee/hip replacements, greater use of services by patients treated surgically, and the aging of the OA population.

Figure 1. Sex-specific direct costs and prevalence of OA in [2010,2031]
Conclusion: This population simulation model predicts a 350% increase in the total costs of OA over the next 20 years. The model will be helpful in the estimation of the economic consequences of potential changes in the prevailing model of care for persons with OA.

2463

Cost-Effectiveness of Tocilizumab Monotherapy Vs. Adalimumab Monotherapy in the Treatment of Severe Active Rheumatoid Arthritis. Josh J. Carlson[1], Sarika Ogale[2], Fred Dejonckheere[3] and Sean Sullivan[1]. [1]University of Washington, Seattle, WA, [2]Genentech, South San Francisco, CA, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background/Purpose: The ADACTA trial found that biologic naïve patients with severe active RA who are methotrexate (MTX) intolerant or in whom continued MTX treatment is inappropriate, achieved a significant benefit after 24 weeks on tocilizumab (TCZ) 8mg/kg IV every 4 weeks monotherapy vs. 40mg adalimumab (ADA) every 2 weeks monotherapy. The objective of our study was to estimate the cost-effectiveness of TCZ vs. ADA used as monotherapy (mono) for RA from the U.S. payer perspective.

Methods: We compared treatment initiation with TCZ (8mg/kg every 4 weeks) mono vs. two different dose regimens of ADA mono: 1) 40mg weekly, 2) 40mg every 2 weeks. Efficacy for TCZ and ADA every 2 weeks was obtained from ADACTA. Efficacy for ADA weekly was estimated by adjusting upward the ADA response in ADACTA, using a ratio of response rates for ADA weekly:ADA every 2 weeks derived from the 2004 van de Putte et al. study, which evaluated both doses of ADA mono. For the 6-month trial period, we calculated the incremental cost per additional ACR20, 50, 70 responder, and low disease activity score (LDAS) achieved for TCZ vs. ADA ("6-month model"). We also used a patient-level simulation model (10,000 patients, 2,000 simulations) to estimate the lifetime incremental cost per quality-adjusted life year (QALY) of initiating treatment with TCZ vs. ADA mono ("life-time model"). In this model, both drugs are followed by an etanercept-certolizumab-palliative care sequence. Non-responders discontinue at 6 months; responders experience a constant probability of discontinuation thereafter. Discontinued patients go to the next treatment in the sequence. Trial-based ACR responses are linked to changes in HAQ scores at 6 months. HAQ remains constant while on biologics and is mapped to utility to estimate QALYs using pooled data from TCZ trials (Diamantopoulos 2012). Costs are derived from published sources and include drug treatment, monitoring, and direct medical resource utilization (derived from HAQ score; Kobelt 1999). Costs and QALYs were discounted at 3%. Sensitivity analyses were performed to test the robustness of the model results.

Results: In the 6-month and lifetime models, TCZ 8mg/kg mono had higher ACR response rates and QALYs, respectively, and lower costs

compared with ADA mono 40mg weekly (Table). Compared with ADA 40mg every 2 weeks, the 6-month incremental cost for TCZ ranged from $2,077 per additional LDAS achiever to $4,509 per additional ACR70 responder; in the lifetime model the incremental cost-effectiveness ratio was $49,195/QALY. Based on one-way sensitivity analyses, model results were most sensitive to changes in drug costs and ACR response rates.

	TCZ Monotherapy	ADA Monotherapy	Difference: TCZ Mono-ADA mono	Incremental Cost-effectiveness Ratio (ICER)
Comparison 1: Life-time Cost/QALY for TCZ Mono 8mg/kg every 4 weeks vs. ADA Mono 40mg every week				
Costs	$202,707	$270,779	($68,072)	
Life-years	16.13	16.09	0.04	
QALYs	7.49	7.35	0.14	**TCZ Dominates ADA weekly (more effective, less costly)**
Comparison 1a: 24-week ICERs for clinical outcomes- TCZ Mono 8mg/kg every 4 weeks vs. ADA Mono 40mg every week				
Costs	$13,758	$25,512	($11,754)	
ACR20	65%	57%	8%	**TCZ Dominates ADA weekly (more effective, less costly)**
ACR50	47%	44%	3%	
ACR70	33%	27%	6%	
Comparison 2: Life-time Cost/QALY for TCZ Mono 8mg/kg every 4 weeks vs. ADA Mono 40mg every 2 weeks				
Costs	$202,707	$186,064	$16,643	
Life-years	16.13	16.05	0.08	
QALYs	7.49	7.15	0.34	**$49,195/QALY**
Comparison 2a: 24-week ICERs for clinical outcomes- TCZ Mono 8mg/kg every 4 weeks vs. ADA Mono 40mg every 2 weeks				
Costs	$13,758	$13,100	$658	
ACR20	65%	49%	16%	**$4,220/ACR20 resp**
ACR50	47%	28%	19%	**$3,393/ACR50 resp**
ACR70	33%	18%	15%	**$4,509/ACR70 resp**
LDAS	52%	20%	32%	**$2,077/LDAS**

Conclusion: TCZ (8mg/kg every 4 weeks) mono dominates (more effective and less costly) ADA (40mg weekly) mono and is cost-effective compared to ADA (40mg every 2 weeks) mono, from a US payer perspective, in patients with severe RA for whom methotrexate treatment is not appropriate.

2464

Cost-Sharing and Utilization of Biologic and Non-Biologic Dmards Among U.S. Medicare Beneficiaries with Rheumatoid Arthritis. Chris Tonner, Gabriela Schmajuk and Jinoos Yazdany. University of California, San Francisco, San Francisco, CA

Background/Purpose: While Medicare's Part D prescription drug benefit expanded access to drugs for many patients, it also includes a controversial provision called the "coverage gap" during which beneficiaries are fully responsible for drug costs. As an initial step in understanding the potential impact of cost-sharing for beneficiaries with rheumatoid arthritis (RA), we compared drug utilization and out-of-pocket (OOP) costs for biologic and non-biologic disease-modifying anti-rheumatic drugs (DMARDs) for two groups of patients: those with a coverage gap and those who were not subject to cost-sharing because they were fully eligible for the low-income subsidy program.

Methods: Data derive from Medicare fee-for-service claims files for 2009 for a 5% random sample of beneficiaries linked to the Medicare Part D prescription drug event file. We included 5,808 individuals age ≥ 65 years with ≥ 2 face-to-face encounters for RA who were continuously enrolled in a Part D drug plan and had at least one prescription DMARD event. We compared patients who had no, partial or full coverage during the gap phase to those who were fully eligible for the low-income subsidy program, which is intended to reduce OOP costs for those with low socioeconomic status. We calculated mean annual RA drug OOP costs per patient for the deductible, initial, gap, and catastrophic phases of Part D coverage in two mutually exclusive groups: 1) those using biologic DMARDs (with or without non-biologic DMARDs) and 2) those using only non-biologic DMARDs.

Results: Among the 5,808 RA beneficiaries with Part D drug events for DMARDs in 2009, 679 (12%) were classified as biologic DMARD users, 5,129 (88%) as non-biologic DMARD users and 1,414 (24%) received a low-income subsidy. 44% of biologic DMARD users received a low-income subsidy compared to 22% of non-biologic users. For the low-income subsidy group, OOP annual costs for biologic and non-biologics were low as expected ($26, $11, respectively) and varied little over the benefit phases (range $2–13; see **Figure**). The non-subsidized group's annual OOP costs for biologics and non-biologics were $3,009 and $85, respectively; larger variations in OOP

cost existed for biologics ($21 to $1,805) compared to non-biologics ($21 to $75) across the benefit phases (**Figure**) with the highest costs incurred during the gap phase.

Figure 1. Medicare FFS Beneficiaries Out-of-pocket Costs, by DMARD Type and Part D Benefit Phase
Conclusion: We found that a significantly larger proportion of biologic DMARD users were enrolled in the low-income subsidy program compared to non-biologic DMARD users. Whether the low rates of biologic DMARD use among Medicare beneficiaries who are not eligible for financial subsidies is a consequence of substantial cost-sharing warrants further investigation.

Seroresponse Rates After Influenza Vaccination in Rheumatoid Arthritis Patients Treated with Biological Agents During the 2011–2012 Flu Season. Masatoshi Hayashi[1], Toshihisa Kojima[2], Naoki Ishiguro[3], Tomonori Kobayakawa[1] and Toshihisa Kanamono[1]. [1]Nagano Red Cross Hospital, Nagano, Japan, [2]Nagoya Univeristy, School of Medicine, Nagoya, Japan, [3]Nagoya University, Graduate School & Faculty of Medicine, Nagoya, Aichi, Japan

Background/Purpose: At present, annual vaccination against influenza is recommended for rheumatoid arthritis (RA) patients. However, whether humoral responses to influenza vaccine are impaired in RA patients treated with biological agents remains controversial. This study aimed to compare seroresponse rates after influenza vaccination in RA patients treated with five biological agents.

Methods: Trivalent influenza subunit vaccines containing A/H1N1, A/H3N2, and B-1 were administered subcutaneously once to 64 RA patients treated with methotrexate (MTX, control, n = 15), infliximab (IFX, n = 12), etanercept (ETN, n = 11), adalimumab (ADA, n = 3), tocilizumab (TCZ, n = 12), or abatacept (ABT, n = 11). We measured antibody titers using hemagglutination inhibition (HI) test at baseline and 4–8 weeks after vaccination. The immunogenicity end points were the proportion of patients with antibody titers of 1:40 or more on HT test and the proportion of patients with either seroconversion or a significant increase in antibody titer.

Results: Table 1 shows baseline characteristics of all the 64 RA patients. Seroconversion and seropositive rates (%) after subcutaneous vaccination were 54.3 and 64.4, respectively, in MTX; 46.2 and 61.1, respectively, in IFX; 73.3 and 87.9, respectively, in ETN; 62.5 and 66.7, respectively, in ADA; 48.3 and 58.3, respectively, in TCZ; and 21.4 and 33.3, respectively, in ABT. Seronegative rates (%) were 45.7 in MTX, 53.8 in IFX, 26.7 in ETN, 37.5 in ADA, 51.7 in TCZ, and 78.6 in ABT (Table 2). Both the decrease in the seroresponse rate after influenza vaccination in the ABT group and increase in the seropositive rate in the ETN group were significant compared with those in the MTX control group ($P < 0.01$) (Table 2). Of the 64 RA patients, only one patient in the MTX group was infected by influenza during this season.

Table 1. Baseline characteristics of 64 RA patients

Agents	Number of patients	Males (%)	Mean age ± SD (years)	PSL rate (%)	Mean usage of PSL ± SD (mg/day)
MTX	15	6.7	68.3 ± 9.8	33.3	4.1 ± 2.2
IFX	12	16.7	61.6 ± 10.8	66.7	3.9 ± 2.1
ETN	11	9.1	58.6 ± 15.6	54.5	3.5 ± 2.4
ADA	3	33.3	69.3 ± 7.0	33.3	5.0 ± 0.0
TCZ	12	25.0	67.7 ± 12.8	58.3	3.6 ± 1.7
ABT	11	27.3	62.0 ± 9.8	81.8	3.8 ± 2.8

RA, rheumatoid arthritis; *SD*, standard deviation; *PSL*, prednisolone; *MTX*, methotrexate; *IFX*, infliximab; *ETN*, etanercept; *ADA*, adalimumab; *TCZ*, tocilizumab; *ABT*, abatacept

Table 2. Seroresponse rates to influenza vaccination in 64 RA patients treated with MTX or five biological agents (192 vaccines)

Agents	Number of vaccinations	Seroconversion (%)	Seropositive (%)	Seronegative (%)
MTX	45	54.3	64.4	45.7
IFX	36	46.2	61.1	53.8
ETN	33	73.3	87.9**	26.7
ADA	9	62.5	66.7	37.5
TCZ	36	48.3	58.3	51.7
ABT	33	21.4**	33.3**	78.6**

**significant difference from MTX (control). **: $P < 0.01$.
RA, rheumatoid arthritis; *MTX*, methotrexate; *IFX*, infliximab; *ETN*, etanercept; *ADA*, adalimumab; *TCZ*, tocilizumab; *ABT*, abatacept

Conclusion: RA patients treated with ABT exhibited compromised immune responses to influenza vaccine compared with those treated with MTX or other biological agents. Therefore, RA patients treated with ABT would benefit from repeated influenza vaccinations.

2466

Pregnancy Outcome in Women Treated with Adalimumab for the Treatment of Rheumatoid Arthritis: The OTIS Autoimmune Diseases in Pregnancy Project. Christina D. Chambers[1], Diana L. Johnson[1], Yunjun Luo[1], Janina L. Jimenez[1], Nicole Mirrasoul[1], Elizabeth Salas[1], Kenneth Lyons Jones[1] and OTIS Research Group[2]. [1]University of California, San Diego, La Jolla, CA, [2]La Jolla

Background/Purpose: The fully human, anti-tumor necrosis factor monoclonal antibody, adalimumab (ADA), is approved for the treatment of rheumatoid arthritis (RA), psoriatic arthritis, ankylosing spondylitis, juvenile idiopathic arthritis, Crohn's disease and psoriasis in the United States and elsewhere. The effect of ADA during human pregnancy is unknown. Outcome data collected by the Organization of Teratology Information Specialists (OTIS) provides some information on the safety of ADA when used by pregnant patients with RA.

Methods: In this ongoing, prospective cohort study, women with RA in the U.S. or Canada exposed to ADA during the first trimester of pregnancy were enrolled, followed for 1-year postpartum, and medical records are obtained. Additionally, live born infants receive a dysmorphology exam for both major and minor structural anomalies. Outcomes in the ADA-exposed group are primarily compared with those in a disease-matched group of women without ADA exposure during pregnancy, and secondarily compared to those in a group of pregnant women who neither have autoimmune disease nor have been treated with ADA, all followed in the same manner.

Results: Between November 2004 and May 2012, pregnancy outcomes were collected on 312 women in the ADA RA cohort study. Of these, 69 were in the ADA-exposed cohort, 80 in the disease-matched comparison group, and 163 in the healthy comparison group (Table 1). Spontaneous abortion (SAB) occurred in 10.1% of ADA-exposed, compared to 7.5% and 2.5% of the disease-matched and healthy comparison women respectively. After adjustment for gestational age at enrollment, the relative risk (RR) for SAB in the ADA-exposed group compared to the disease-matched group was not statistically significant (RR 1.33, 95% CI, 0.42, 4.28, p = 0.62). Among all births with known outcome, major birth defects were reported in 4.5% of the ADA-exposed pregnancies, 5.2% of the disease-matched pregnancies, and 6.6% of the healthy comparison pregnancies (p = 1.0 for ADA-exposed vs. disease-matched group). There was no evidence of a pattern of either major or minor structural defects in the ADA-exposed group, nor were

there any statistically significant differences between the ADA-exposed group and the disease-matched comparison group for preterm delivery (p = 0.49), birth weight in full-term infants (p = 0.59) or serious infections (p = 1.0) (Table 1).

Table 1.

Outcome	ADA-Exposed n=69	RA Comparison n=80	p – value ADA-Exposed vs. RA Comparison	Healthy Comparison n=163
Live born - n (%)	60 (87.0)	71 (88.8)	0.80	148 (90.8)
Spontaneous Abortion - n (%)	7 (10.1)	6 (7.5)	0.62**	4 (2.5)
Therapeutic Termination – n (%)	0	0	—	0
Stillbirth - n (%)	0	0	—	0
Lost to follow-up - n (%)	2 (2.9)	3 (3.8)	1.0	11 (6.7)
Preterm live born infants – n (%)	8/59 (13.6)	13/71 (18.3)	0.49	8/148 (5.4)
Birth Weight full term infants – gm (SD)	3292 (489)	3342 (460)	0.59	3468 (503)
Number of infants with major birth defects among live born infants – n/N (%)	3/60 (5.0)	3/71 (4.2)	1.0	10/148 (6.8)
Number of infants with major birth defects among all pregnancies – n/N (%)	3/67 (4.5)	4/77 (5.2)	1.0	10/152 (6.6)
Serious infections in live born infants up to 1 yr of age – n (%)	2 (3.3)	2 (2.8)	1.0	3 (2.0)

* Excludes lost-to follow-up, **After adjustment for gestational age at enrollment

Conclusion: Based on these findings, there are no significant differences for any adverse pregnancy outcome studied in the ADA-exposed group vs. the primary comparison group of women with RA and no ADA exposure. Additionally, there is no evidence of a specific pattern of major or minor malformations in infants born to women with ADA-exposure.

ACR Concurrent Abstract Session
Osteoarthritis - Clinical Aspects II: Structural Risks for Osteoarthritis End-points and Potential Treatments
Tuesday, November 13, 2012, 2:30 PM–4:00 PM

Tissue Lesions in Osteoarthritis Initiative Participants with Normal X-Rays and Risk Factors for Incident Cartilage Damage. Leena Sharma[1], Ali Guermazi[2], Orit Almagor[1], Michel Crema[3], Dorothy D. Dunlop[1], Frank Roemer[4], Marc C. Hochberg[5], Charles Eaton[6], Joan M. Bathon[7], Rebecca D. Jackson[8], W.J. Mysiw[8], C. Kent Kwoh[9], Michael C. Nevitt[10] and Joan S. Chmiel[1]. [1]Northwestern University, Chicago, IL, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, MA, [4]Klinikum Augsburg, Augsburg, Germany, [5]University of Maryland, Baltimore, MD, [6]Warren Alpert Medical School at Brown University, RI, [7]Columbia University Medical Center, New York, NY, [8]Ohio State University, Columbus, OH, [9]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [10]University of California-San Francisco, San Francisco, CA

Background/Purpose: Understanding factors underlying initial development of knee OA is crucial to effective prevention strategy design. Our goals were to: 1) determine extent of tissue damage on MRI in knees of persons at higher risk for knee OA and in whom both knee x-rays were normal (KL 0); and 2) evaluate whether presence of any bone marrow lesions (BML), meniscal tears (MT), meniscal extrusion (ME), or hand OA is associated with risk of incident cartilage damage.

Methods: The Osteoarthritis Initiative (OAI) is a cohort study of men

and women, 45–79 years, all with or at increased risk to develop knee OA. 850 participants had had bilateral KL 0 at 12 months (baseline for this study) by centralized reading. On their right knee MRIs, we undertook assessment of cartilage morphology, BML, MT, and ME using a modified MOAKS scoring system. Readers were blinded to hypotheses, clinical data, and KL grade. The definition of hand OA relied upon number of bony enlargements. 12 and 48 month image assessments occurred within an ancillary study; in addition, OAI clinical data V6.2.1 and BU x-ray reading data V1.5 were used. Mulitiple logistic regression models were used to evaluate associations between baseline data and incident cartilage damage by 3 year follow-up; results are reported as adjusted odds ratios (aORs) with 95% CIs.

Results: 850 persons met criteria for inclusion [mean age 59.6 years (8.8, SD), mean BMI 26.7 kg/m^2(4.2), 475 (56%) women]. Among the 850 KL 0 knees, the number with abnormal tissue in one or more subregions at baseline was: 483 (57%) with cartilage damage (full-thickness in 67); 353 (42%) with BML; 180 (21%) with MT; and 117 (14%) with ME. In only 56 (7%) knees were all of these tissues normal. 367 persons [age 58.5 (8.8), BMI 26.4 (4.2), 226 (62%) women] contributed 367 knees with normal cartilage morphology in all regions at baseline. Of the 367, 80 had BML, 45 had MT (32 horizontal, 9 vertical, 4 partial maceration), and 25 had ME. Lesions coexisted in some knees (11 with BML+MT, 7 with BML+ME, and 10 with MT+ME). In separate models, each adjusting for age, gender, BMI, and hand OA, BML [aOR 2.24, 95% CI (1.15, 4.34)] and ME [aOR 2.83, 95% CI (1.03, 7.79)] were each associated with incident cartilage damage. In a model including all covariates, BML continued to be significant [aOR 2.19, 95% CI (1.12, 4.28)], while ME was not quite significant [aOR 2.71, 95% CI (0.97, 7.58)]. Of note, hand OA presence was consistently associated with incident cartilage damage, e.g., in the fully adjusted model, aOR 2.30, 95% CI (1.15, 4.60) for this variable.

Conclusion: Cartilage damage was already present in 57% of right knees from persons without OA in either knee by protocolized x-ray, but at higher risk, suggesting that radiographic studies of incident OA in this population, even restricted to KL 0, are frequently evaluating not incidence but early progression. Among knees with normal cartilage morphology, hand OA, BML, and ME were each associated with an increased risk of incident cartilage damage. While MRI is superior to x-ray, the optimal window for cohort studies to capture the onset of knee OA by MRI may fall earlier in the lifetime of individuals at higher risk than is being evaluated in many current studies. Prevention strategies may be most powerful at this time point.

Incident Symptomatic Hip Osteoarthritis Is Associated with Differences in Hip Shape by Active Shape Modeling: The Johnston County Osteoarthritis Project. Amanda E. Nelson[1], Felix Liu[2], John A. Lynch[2], Jordan B. Renner[3], Todd A. Schwartz[4], Nancy E. Lane[5] and Joanne M. Jordan[1]. [1]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC, [2]University of California at San Francisco, San Francisco, CA, [3]University of North Carolina at Chapel Hill Dept of Radiology, Chapel Hill, NC, [4]University of North Carolina Gillings School of Global Public Health, Dept of Biostatistics, Chapel Hill, NC, [5]UC Davis School of Medicine, Sacramento, CA

Background/Purpose: We investigated hip shape by active shape modeling (ASM) as a potential predictor of incident radiographic and symptomatic hip OA (rHOA and srHOA) in a community-based study that includes African American and Caucasian men and women.

Methods: All hips developing rHOA from baseline (Kellgren-Lawrence grade [KLG] 0 or 1, 1991–7) to follow up (KLG >=2, 1999–2004, mean 6 years follow up, 190 hips), and 1:1 control hips (KLG 0 or 1 at both timepoints, 192 hips) were selected in approximately equal numbers from 4 race-by-gender strata. The shape of the proximal femur was defined on a baseline AP pelvis radiograph for all hips by a trained reader (AEN), and 60 landmark points were input into an ASM. The ASM produced a mean shape, plus continuous variables representing independent modes of variation in that shape. The scores for modes which together explained 95% of shape variance (n=14) were simultaneously included in logistic regression models as

independent predictors, with incident 1) rHOA and 2) srHOA (defined as rHOA plus symptoms in the case hip at follow up) as the dependent variables, and adjusted for intra-person correlations. Analyses were adjusted for sex, race, body mass index (BMI), and baseline KLG and/or symptoms. Stratified analyses for sex, baseline KLG and symptoms were performed.

Results: We evaluated 382 hips (Figure) from 342 individuals: 61% women, 83% Caucasians, with a mean age of 62 years and BMI of 29 kg/m^2. No ASM modes were associated with incident rHOA in the sample, or in stratified analyses among women. However, among men only, modes 1 and 2 (53% of total shape variance) were significantly associated (for a 1-SD *decrease* in mode 1 score, OR 1.7 [95% CI 1.1, 2.5], and for a 1-SD *increase* in mode 2 score, OR 1.5 [95% CI 1.0, 2.2]) with incident rHOA (Figure, left).

Figure. Numbers of hips by demographic group and selected modes associated with incident rHOA and srHOA [± 2 SD]
For incident srHOA, modes 2 and 3 (representing 16 and 13% of total shape variance, respectively) were significantly associated, with a 1-SD *decrease* in either of these modes increasing the odds of srHOA by 50% (mode 2: OR 1.5 [95% CI 1.0, 2.1], mode 3: figure, right). The presence of baseline hip symptoms increased the odds (OR 3.2 [95% CI 1.7, 5.9]) of incident srHOA, while African Americans compared to Caucasians had 70% lower odds of incident srHOA (OR 0.3, [95% CI 0.1, 0.8]); no other covariates were associated. Analyses stratified by the presence of baseline symptoms showed a consistent association between mode 3 and srHOA. However, among those *without* baseline symptoms, an *increase* in mode 6 (3% of variance) was associated with srHOA (OR 1.9 [95% CI 1.2, 3.1]), while among those *with* symptoms the association was with a *decrease* in mode 6 (OR 2.1 [95% CI 1.3, 3.5]).

Conclusion: Variations in shape modes 1 and 2, derived from the ASM, were associated with incident rHOA in men only. Shape modes 2 and 3 were associated with srHOA overall, and mode 6 with srHOA depending upon baseline symptom presence. Such shape variations may contribute to hip OA risk.

2469

A Virtual Knee Joint Replacement Clinical Endpoint Based On Longitudinal Trends and Thresholds in Koos Knee Pain and Function in Osteoarthritis Initiative Participants. Robert M. Boudreau[1], David J. Hunter[2], Zhijie Wang[3], Frank Roemer[4], Felix Eckstein[5], Michael J. Hannon[3], Ali Guermazi[4] and C. Kent Kwoh[6]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Sydney, Sydney, Australia, [3]University of Pittsburgh School of Medicine, Pittsburgh, PA, [4]Boston University School of Medicine, Boston, MA, [5]Paracelsus Medical University, Salzburg, Austria, [6]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA

Background/Purpose: Knee joint replacement (KR) is a cost-effective procedure with good long-term outcomes, but has limitations as an endpoint in OA intervention trials. A definition of virtual total joint replacement (vTKR) based on clinical measures may be a more useful, efficient and practical outcome measure. The aim of this study was therefore to develop and evaluate a potential vTKR definition based on clinical measures in the OAI.

Methods: The sample included 8204 knees from 4143 individuals (42% male, age 61.6 ± 9.2) in the Progression, Incident and Control cohorts. A total of 187 individuals underwent KR (216 knees) over the five years after baseline. Individuals with continuous health care coverage during the five years were included, except for individuals who underwent KR. Clinical measures individually predictive of KR, thus considered for inclusion in the model, were: WOMAC Knee Pain, Stiffness, Disability and Total scores; KOOS Knee Pain (KOOSKP), Symptoms, ADL, Quality of Life (QOL) and Total scores; Knee pain severity in past 30 days and PASE. Several other clinical measures were excluded as not predictive. At each annual visit, logistic regression models were developed predicting actual KR during the following year. Baseline, the two timepoints prior to KR (and changes between them) entered models with up to three clinical measures. Sensitivity, specificity, ROCs and AUCs were evaluated. Adapting a propensity-score approach, the 5% of non-KR knees with the highest predicted probability of being a KR were eligible vTKR knees. We then further

required that clinical measures at the incident vTKR timepoint be as poor or worse than baseline and also did not improve through year 5.

Results: A combination of KOOS Knee Pain and QOL scores was identified as the best KR-predicting vTKR model. vTKR criterion was based on three factors that increased the predicted odds of KR: crossing a threshold of severe knee pain (KOOS), a threshold of sufficiently poor quality of life, a weighted combination of these two, and/or a marked increase in knee pain over the year prior. Cross-validated AUCs, distinguishing between KR and non-KR knees across annual visits ranged from 0.867 to 0.921. A parity-inducing probability cutpoint correctly separated KR from non-KR knees with sensitivity and specificity of 0.85. A total of 399 knees maintained or got worse after their vTKR. Of these, 143 were as bad or worse than baseline.

Final clinical variable vTKR prediction model Odds-ratios* (95% C.I.'s) for KOOSKP and KOOSQOL (during preceding two periods) Predicting Actual KR

vTKR month	KOOSKP Threshold (OR per 1 unit lower)	KOOSQOL Threshold (OR per 1 unit lower)	Additional effect if KOOSKP got worse during preceding two periods (OR per 1 unit worsening)
24†	1.047 (1.028,1.065)	1.032 (1.013,1.051)	1.018 (0.997,1.039)**
36	1.043 (1.025,1.062)	1.028 (1.011,1.044)	1.054 (1.035,1.073)
48	1.053 (1.035,1.072)	1.027 (1.010,1.044)	1.060 (1.041,1.079)
60	1.048 (1.030,1.066)	1.023 (1.008,1.039)	1.048 (1.029,1.067)

† vTKR month 24: Model predicting KRs during year following 12 month OAI contact * All OR's were statistically significant at p < 0.003, except KOOSKP worsening at 24m ** KOOSKP worsening at 24m: p=0.0903

Conclusion: We have developed a promising vTKR criterion based on a combination of threshold KOOS Knee Pain and QOL scores, and/or worsening KOOS Knee Pain. This vTKR criterion may be a useful outcome measure for OA intervention trials.

Does Structural Progression of Knee Osteoarthritis Measured with Magnetic Resonance Imaging or Radiography Predict Knee Replacement?—Data From the Osteoarthritis Initiative. Felix Eckstein[1], C. Kent Kwoh[2], Robert M. Boudreau[3], Zhijie Wang[4], Michael J. Hannon[4], Wolfgang Wirth[1], Ali Guermazi[5], Frank Roemer[6], Michael C. Nevitt[7], Markus R. John[8], Leena Sharma[9], Jeffrey W. Duryea[10], David J. Hunter[11] and Osteoarthritis Initiative Investigators[12]. [1]Paracelsus Medical University, Salzburg, Austria, [2]University of Pittsburgh and VA Healthcare System, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh School of Medicine, Pittsburgh, PA, [5]Boston University, Boston, MA, [6]Klinikum Augsburg, Augsburg, Germany, [7]University of California-San Francisco, San Francisco, CA, [8]Novartis Pharma AG, Basel, Switzerland, [9]Northwestern University, Chicago, IL, [10]Brigham & Women, Boston, MA, [11]University of Sydney, Sydney, Australia, [12]San Francisco

Background/Purpose: Imaging biomarkers that predict relevant clinical endpoints, such as knee replacement (KR), are valuable tools for knee osteoarthritis prognosis. Currently, measurement of minimum radiographic joint space width (mJSW) is the accepted standard for testing the efficacy of disease modifying drugs (DMOADs) in clinical trials. The purpose of this study was to compare the predictive power of magnetic resonance imaging (MRI)-based longitudinal measures of cartilage loss and mJSW for KR.

Methods: We studied knees from Osteoarthritis Initiative (OAI) participants who received a KR between 24 and 60 month (M) follow-up (confirmed by radiography and/or review of hospital records). A matched control knee that did not receive a KR during this period was selected for each case, with the same sex, similar age (within 5 years), and the same baseline Kellgren Lawrence (KL) grade (central X-ray readings; strata 0–1, 2, 3, 4). Knees were not discordant for medial vs. lateral semi-quantitative joint space narrowing (JSN). Medial femorotibial compartment (MFTC) cartilage thickness change was determined from a sagittal 3 Tesla double echo steady state water excitation (DESSwe) MRI sequence, and, mJSW from fixed flexion radiography. The time points prior to KR (T0) and that 12 months earlier (T-1) were analyzed in case knees (i.e. in a knee with KR between 24M and 36M: 24M=T0;12M=T-1), and the same time points in control knees, with blinding to acquisition order. P-values for differences in longitudinal change between case/control pairs were assessed using the Wilcoxon signed rank test, and the area (AUC) under the receiver operation curve (ROC).

Results: 261 knees of 225 OAI participants received a KR (between 24M and 60M). Of these, 93 had central X-ray readings, JSW, and MRI readings available

at both T0 and T-1, and a matched control based on the above criteria (38 men, 55 women, age 63.4±9.3, BMI 30.2±4.9). Medial (MFTC) cartilage loss (over a 12 month period prior to KR), measured with MRI, was significantly greater in KR case than in control knees (-0.13±0.29 vs. -0.04±0.15mm; p=0.038, AUC=0.57). The differences in longitudinal change was borderline significant for the central MFTC (-0.24±0.57 vs. -0.07±0.23 mm; p=0.079, AUC=0.57) and was not significant for the change in radiographic mJSW (-0.19±0.91 vs. 0.01±0.58mm; p=0.397, AUC=0.55). The difference in cartilage loss (MRI) between KR case and control knees was particularly strong in knees with early radiographic OA (KLG2: n=22; MFTC p=0.008; AUC=0.72), whereas no difference in mJSW change was detectable in KLG2 case/control pairs (p=0.126; AUC=0.58).

Conclusion: Medial compartment longitudinal cartilage thickness loss, measured with MRI, predicts knee replacement as a clinical endpoint. In contrast, no significant difference in the 12 month change of radiographic mJSW was detected between case and control knees in the above sample. Given the relationship with an important clinical endpoint (i.e. knee replacement), MRI-based measures of cartilage thickness change are useful imaging biomarkers for clinical trials, for instance to demonstrate the efficacy of a DMOAD. The current findings also support the concept that treatments that slow cartilage loss may delay or prevent KR.

Oral Glucosamine Sulphate for the Prevention of Knee Osteoarthritis in Overweight Females; The First Ever Preventive Randomized Controlled Trial. Jos Runhaar[1], Marienke van Middelkoop[1], Max Reijman[1], Edwin Oei[1], Dammis Vroegindeweij[2], Gerjo van Osch[1], Bart Koes[1] and Sita Bierma-Zeinstra[1]. [1]Erasmus MC, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands

Background/Purpose: Previous studies showed the largest effects of glucosamine on osteoarthritis (OA) symptoms of the knee joint and when used in an early phase of the disease. The present study evaluates the effect of a tailor made diet and exercise program (DEP) and of oral glucosamine sulphate, in a 2×2 factorial design, on the incidence of knee OA over 2.5 years in a high risk group of overweight, middle-aged females; free of clinical knee OA at baseline (ISRCTN 42823086; financed by The Netherlands Organisation for Health Research and Development). Worldwide, this is the first large RCT on prevention of knee OA. Here we present the results of the glucosamine intervention and the interaction with DEP.

Methods: 50 general practitioners contacted all registered women between 50 and 60 years. In total, 407 women met all inclusion criteria (BMI ≥ 27, no clinical knee OA (ACR criteria), no contraindications to MRI, no rheumatic diseases, no recent glucosamine usage), were invited for baseline measurements and were randomised. All subjects were instructed to dissolve and consume 1500 mg of the distributed study drug (crystalline glucosamine sulphate and placebo) each day, for 2.5 years. Pre-specified primary outcome was incidence of knee OA, defined by incidence of either K&L ≥ 2, joint space narrowing of ≥ 1.0 mm or incident clinical knee OA (ACR criteria).

Results: After 2.5 years of follow-up, forty-three women (11%) were lost to follow-up. Twenty-nine percent of all subjects reported one or more adverse events throughout the study; without difference in frequency between groups (p = 0.23). The interaction term between both interventions on the primary outcome proved to be significant (p = 0.04). Adjusted Generalized Estimated Equations showed no significant effect of glucosamine sulphate within the DEP control group (OR 0.59; 95%CI 0.31–1.12) or within the DEP intervention group (OR 1.44; 95%CI 0.83–2.48), for the Intention To Treat population (see table). The difference in direction of the association, however, is notable. Within subjects compliant to the study drug (≥75% of study drug, N = 250), also no significant effects of glucosamine sulphate over placebo were found (OR 0.69, 95%CI 0.32–1.52 and OR 1.32, 95%CI 0.70–2.51 respectively). Interestingly, among subjects compliant to DEP the interaction effect became stronger (p = 0.01) and, hence, the contrast

of the effects in the placebo and glucosamine group more distinct (see table).

Baseline characteristics and incident OA figures for Intention To Treat and Per Protocol analyses

| | Diet & Exercise Program | | | |
| | Control group | | Intervention group | |
	Placebo	Glucosamine	Placebo	Glucosamine
Baseline characteristics				
N - subjects	102	102	101	102
Age (yr)	55.7 ± 3.3	55.7 ± 3.1	55.7 ± 3.2	55.7 ± 3.1
BMI (kg/m2)	32.6 ± 4.3	32.4 ± 4.6	32.3 ± 4.5	32.1 ± 3.7
Heberden nodes				
uni-lateral	15%	16%	12%	12%
bi-lateral	10%	14%	20%	9%
Postmenopausal status	70%	68%	66%	67%
N - knees	204	204	202	204
K&L				
grade 0	53%	47%	53%	50%
grade ≥ 1	46%	53%	46%	50%
Varus	46%	38%	38%	37%
Mild symptoms	17%	20%	27%	19%
Past injury	14%	12%	10%	13%
Incident knee OA (after 2.5 years)				
ITT	19%	13%	15%	20%
PP glucosamine	21%	17%	18%	24%
PP DEP	19%	13%	9%	23%
PP glucosamine and DEP	21%	17%	7%	24%

ITT: Intention To Treat population (all randomized subjects). PP: Per Protocol population (compliant to intervention). DEP: diet and exercise program

Conclusion: Although safe compared to placebo, crystalline glucosamine sulphate was ineffective for the prevention of knee OA in overweight females over 2.5 years of follow-up.

Background/Purpose: Hand osteoarthritis (HOA) is a frequent painful polyarticular disease which often does not respond to any classical therapeutics. TNF a is involved in the osteoarthritic process both in disease progression and in pain perception.

Objective: To evaluate TNF blockers in patients with painful OA refractory to analgesics and NSAIDs.

Methods: The digital osteoarthritis in refractory hand OA study (DORA), is a phase 3 randomized superiority, double-blind (patients and assessors of outcomes), parallel, placebo controlled, 26 weeks, multicenter trial (conducted in 16 French clinical sites), using TNF blocker adalimumab (2 sub cutaneous injections at week 0 and week 2). Patients meeting the American College of Rheumatology criteria for hand OA with pain above 40 mm on a 100 mm visual analogue scale (VAS), involving at least 3 painful interphalangeal joints and at least 3 OA joints at Kellgren Lawrence (KL) grade > 2 on a recent radiograph, who did not respond to analgesics and NSAIDs, were recruited. Randomization and allocation to trial group were carried out by a central computer system. The primary endpoint was change in pain score after 6 weeks. Secondary outcomes at 6 weeks were change in the number of spontaneous painful joints, in number of painful joints on pressure, in number of swollen joints, in morning stiffness, in patient' and practitioner' global assessments, in functional index for hand OA (FIHOA) and Cochin hand functional index. Consumption of analgesics was recorded (acetaminophen up to 3g/D was the only rescue medication allowed until week 6). Serum markers (COMP, PIIANP, HA, usCRP, cytokines level of TNF a, IL-6, IL-1) and urine level of CTX-II (corrected by creatinine) were measured at W0 and W6.

Results: On the 99 patients selected, 85 were randomized (42 in the placebo group, 41 in the adalimumab group). 35 patients in the placebo group and 38 in the adalimumab group received the two injections. 78 patients with at least one injection were analyzed (37 placebo and 41 adalimumab) (mITT). Mean (SD) age was 62.5 (6.9), 85 % of women, mean (SD) level of pain was 65.4 (12.9) mm; mean (SD) number of painful IP joints: 11 (6), mean number of joints with clinical synovitis was 5.9(4.4), mean FIHOA score 15.6 (6.3). The difference in the mean change in pain score on VAS (0–100 mm) over 6 weeks between adalimumab and placebo (primary end point) was: -2.5 mm (95% CI, -14.0 to 9.0), p: 0.67, non significant. No statistically significant differences were found for any of the secondary outcomes, except for a decrease in the number of swollen joints between week 0 and week 26 which favoured adalimumab group: mean difference: -1.9 (95% CI, -3.2 to - 0.6), p: 0.006. Analgesics use was similar between groups. There were no safety concerns. There was none variations of any biological markers between the 2 groups. TNF alpha serum level was not correlated with clinical outcome in the group of patients treated with adalimumab.

Conclusion: In a group of patients with refractory hand OA, TNFa blockers (adalimumab, 2 sc injections) failed to demonstrate any clinical improvement.

A Randomized Trial in New Onset Juvenile Dermatomyositis: Prednisone Versus Prednisone Plus Cyclosporine Versus Prednisone Plus Methotrexate. Nicolino Ruperto, Angela Pistorio, Sheila Oliveira, Rubén J. Cuttica, Angelo Ravelli, Michel Fischbach, Stefan Hagelberg, Tadej Avcin, Emanuel Cheuret, Fabrizia Corona, Gerard Couillault, Frank Dressler, Valeria Gerloni, Gary Sterba, Francesco Zulian, Maria Teresa Apaz, Adriana Cespedes-Cruz, Rolando Cimaz, Fabrizio De Benedetti, Pierre Quartier, Ricardo Russo, Nico Wulffraat, Simona Angioloni and Alberto Martini. Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Data regarding the safety and efficacy of treatment regimens for juvenile dermatomyositis(JDM) tends to be from anecdotal, small, uncontrolled, non-randomized case series. This randomized trial was aimed to find out the treatment regimen associated with the lowest occurrence of flare and the lowest drug related toxicity.

Methods: Children with newly diagnosed JDM were randomized in an open fashion to receive one of 3 different therapeutic approaches: prednisone (PDN) versus PDN plus methotrexate (MTX) versus PDN plus Cyclosporine A. The overall hypothesis to be tested in this trial was that the early introduction of combination therapy of corticosteroids and either MTX or CsA will prove more effective and safe than corticosteroids alone in the treatment of JDM.

Primary outcome measures after 6 months of treatment: response rate according to the PRINTO provisional definition of improvement in the 3 arms (20% improvement in at least 3 core set variables with no more than 1 of the remaining variables, (muscle strength excluded), worsened by > 30%). The PRINTO JDM core set variables are: 1) muscle strength by the mean of the Childhood Myositis Assessment Scale (CMAS); 2) physician's global assessment of disease activity on a 10 cm VAS; 3) global

disease activity assessment by the mean of the Disease Activity Index (DAS); 4) parent's/patient's global assessment of overall well-being on a 10 cm VAS; 5) functional ability assessment by the mean of the Childhood Health Assessment Questionnaire (CHAQ); 6) health-related quality of life assessment.

Primary outcome measures after 24 months of treatment: a) time to inactive disease; b) time to major therapeutic changes because of inefficacy/flare/adverse events.

Results: 138/139 randomized patients were included in the efficacy dataset. There were 81/138 females (59%) with a median age at onset of 7.4 years (1st–3rd quartiles 1.1–15.4) and a median disease duration of 2.8 months (1.4–5.3). Frequency of response at 6 months was for 24/46 (52.2%) for PDN, 31/46 (67.4%) for PDN+CSA and 34/46 (73.9%) for PDN+MTX (p 0.082). Time to inactive disease (Figure) in the combination group (PDN+CSA or PDN+MTX) was significantly shorter than that of PDN alone (p 0.031). Time to major therapeutic changes in the combination group (PDN+CSA or PDN+MTX) was significantly longer than that of PDN alone (p 0.006). Total number of adverse events were 57/276 (20.7%) in the PDN group, 141/276 (51.1%) in PDN+CSA and 78//276 (28.3%) in PDN+MTX (p < 0.0001). Skin and subcutaneous tissue disorders, and nervous system disorders were statistically more frequent in PDN+CSA (p 0.0015, p 0.039 respectively).

Time to inactive disease in the 3 randomized groups

Log-Rank test; P=0.031
Conclusion: combined therapy with PDN and either CSA or MTX was more effective than with PDN alone. However the safety profile favour the combination with MTX toward that with CSA.

Urine Biomarkers Distinguish Between Proliferative and Membranous Lupus Nephritis in Childhood Onset Systemic Lupus Erythematosus.
Rina Mina[1], Michael Bennett[2], Lining Qi[3], Shannen Nelson[4], Jessica Hummel[5], Pavel Shiyanov[3], John Schlager[3], Prasad Devarajan[2] and Hermine I. Brunner[4]. [1]Cincinnati Children's Hospital Medical Center/University of Cincinnati, Cincinnati, OH, [2]Cincinnati Children's Med Ctr, Cincinnati, OH, [3]US Air Force Research Lab, Wright-Patterson Air Force Base, OH, [4]Cincinnati Children's Hospital, Cincinnati, OH, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: The ISN/RPS Morphologic Classification of Lupus Nephritis (LN) reports on histological features that differentiate among various forms of LN, most notably between proliferative and membranous classes which have different renal outcomes. There is a lack of non-invasive biomarkers that can discriminate among LN subtypes which are important so that appropriate therapies can be planned. We aim to investigate candidate urine biomarkers that will distinguish between proliferative and membranous LN in childhood onset systemic lupus erythematosus (cSLE).

Methods: Using liquid chromatography tandem mass spectrometry proteomics, we isolated Vitamin-D Binding Protein (VDBP) and Prostaglandin D synthase (PGDS) from urine collected from 53 patients with LN. Levels of VDBP were measured using a commercially available ELISA assay and these were standardized to urine creatinine (UCr). Differences in the levels of VDBP between proliferative and membranous LN were analyzed using Mann-Whitney rank sum analysis. For PGDS, we performed spectral counting through ProteoIQ and validated the results with western blot.

Results: There were 27 renal biopsies classified as proliferative LN and 26 were classified as membranous LN. Median levels in ng/ml (range) of urinary VDBP levels were significantly higher in proliferative LN compared to membranous LN [90.9 (IQR 28.9–948.4) versus 33.5 (IQR 21.3–124.1), p-value=0.046]. The results remained significant when VDBP levels were corrected for UCr [median in ng/mg (range) = 22.2 (29.0–1822.9) versus 44.1 (14.8–139.5), p-value=0.045]. PGDS was overexpressed in the urine of patients with membranous LN compared to proliferative LN with an average spectral count of 13 versus 4, respectively, and a ratio of 3.25 (p-value < 0.05). This difference was confirmed by western blot.

Conclusion: We isolated two candidate urine biomarkers, Vitamin-D Binding Protein and Prostaglandin D synthase, and thereafter validated our proteomic finding that these can distinguish between proliferative LN and membranous LN. The discovery of these non-invasive biomarkers and its application in a clinically usable platform could lead to a substantial impact on management strategies for LN in cSLE.

Background/Purpose: Compared to adults with SLE, relatively little is known about cancer risk in pediatric-onset SLE. We assessed cancer incidence in a multi-centre pediatric-onset SLE cohort, compared to general population cancer rates.

Methods: We ascertained cancers within SLE clinic registries at 10 pediatric centers, located in Birmingham AL; Cincinnati OH, Durham NC; Hackensack NJ; Oklahoma OK; San Francisco CA; Montreal QC; Toronto ON; Saskatoon SK; and Winnipeg MB. Subjects were linked to state or provincial cancer registries for the observational interval, spanning 1974–2009. In-situ cancers were excluded. Follow-up was calculated from the date first seen at the clinic, and the first of 3 possible events: death, cancer, or end of study interval (Dec. 2009). We pooled observed cancers and person-years of observation. The cancers expected to occur were calculated by multiplying the person-years in the cohort by the geographically matched age, sex, and calendar year-specific cancer rates. The ratio of observed to expected cancers represents the SIR, or relative cancer risk in pediatric SLE, versus the general population. We provided estimates for total cancer and for hematological cancers, and also results stratified on sex, age group, and SLE duration.

Results: There were 999 patients aged <18 at cohort entry. Most (82%) were female; mean age at cohort entry was 12.9 years (SD=3.6).The majority were Caucasian. Subjects were observed for a total of 7,986 patient-years (average 8.0 years). Within this interval, only 3.0 invasive cancers were expected, however, 14 invasive cancers occurred, for an SIR of 4.7, 95%

confidence interval, CI 2.6, 7.8. Three hematologic cancers were found (2 non-Hodgkin's lymphoma, 1 leukemia), for an SIR of 5.2 (95% CI 1.1, 15.2). The non-hematologic cancers included one cancer each of bladder, brain, breast, and thyroid, 3 head and neck cancers, and 4 unspecified cancers. At time of cancer diagnosis, mean SLE duration was 12.3 years (range 0.1, 25.2 years). Excluding cancers that occurred within the first year of cohort entry, the over-all cancer SIR was 3.0 (95% CI 2.3, 7.8). The SIRs stratified by age group and sex, were similar across strata (though more precise for females than males, due to relatively small numbers of males). Though not definitive, there was a trend for heightened relative risk in the period 10–19 years after SLE diagnosis. However, in absolute terms, this stratum experienced only 8 cancers.

Conclusion: These up-dated results suggest an increased cancer risk in pediatric onset SLE versus the general population. However, in absolute terms, this still translates into few events, which is somewhat re-assuring. A limitation is that some patients may have developed a cancer after relocating to another state or province, thus under-representing the true cancer incidence. Of note, risk may be highest in the period 10–19 years after SLE diagnosis, at a time when patients will have transferred to an adult provider. Further work will assess other potential factors of interest, such as race/ethnicity and calendar effects. Our work highlights the importance of continuity as adolescents transition to adult care, and a need for collaborations to allow longitudinal assessment of long-term risks.

2476

Role of Whole-Body Magnetic Resonance Imaging in the Assessment of Disease Activity in Juvenile Dermatomyositis. A Pilot Study. Clara Malattia[1], Annalisa Madeo[1], Silvia Pederzoli[1], Anna Providenti[2], Marta Mazzoni[1], Agnese Beltramo[1], Alessandro Consolaro[1], Stefania Viola[1], Antonella Buoncompagni[1] and A. Martini[1]. [1]Istituto G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [2]Istituto G Gaslini, Genova, UO Fisioterapia, Genova, Italy

Background/Purpose: Musculoskeletal MRI represents a valuable non-invasive technique for dectecting muscle inflammation in idiopathic inflammatory myopathies (IIM). So far, all MRI studies in juvenile dermatomyosis (JDM) have focused on the thighs muscles. Whole-body MRI (WB-MRI) is a new technique which allows to screen the entire muscular-skeletal system and gives a complete assessment of the total inflammatory burden in patients with IIM. However, its potential in children with JDM has never been explored so far.

Purpose: to evaluate the contribution of WB-MRI examination in the clinical assessment of JDM patients and to investigate its feasibility and validity in the assessment of disease activity.

Methods: WB-MR images were obtained from 30 JDM patients (12M;18F, median age 8.6 years) and from 30 children (13M; 17F, median age 10.4 years) without inflammatory myopathies (control group), using a 1.5 Tesla and Short Tau Inversion Recovery (STIR) sequences. Signal intensity was scored using a 0–2 point scale in 42 muscular groups; myofascial and subcutaneous tissue inflammation were assessed on the upper and lower extremities using a 0–1 point scale. Validation procedures included the analysis of reliability, construct validity, discriminant validity and sensitivity to change.

Results: in addition to a symptomatic proximal distribution of inflammation, WB-MRI revealed asymptomatic distal legs muscle inflammation in 19 out of 30 patients (70%) and asymptomatic forearms inflammation in 15 out of 30 patients (50%). Twenty-three patients showed a typical patchy and heterogeneous distribution of muscular inflammation. In 3 patients the abnormal hyperintense areas tended to be diffusely and homogeneously distributed within the muscles. WB-MRI showed inactive disease in 4 patients. Fascial and subcutaneous tissue inflammation were detected in 9 out of 30 (30%) and 18 out of 30 (60%) patients, respectively. WB-MRI scores were significantly increased in active JDM when compared with the inactive JDM group (p=0.02) and the control group (p<0.0001), indicating an excellent discriminant validity of the WB-MRI. The inter- and intra-reader agreement for the muscular,

subcutaneous and fascial WB-MRI scores were excellent (intra-class correlation coefficient >0.8). The muscular WB-MRI score showed moderate to excellent correlations with indicators of disease activity such as the Manual Muscle Test (MMT; rs=0.86), the Childhood Myositis Assessment Scale (CMAS; rs=0.85) and physician's assessment of disease activity (VAS Phys; rs=0.75). WB-MRI score showed a higher responsiveness to change (standardized response mean=0.86) compared to MMT (SRM=0.51), CMAS (SRM=0.28), VAS Phys (SRM=0.63) and CPK (SRM=0.17).

Conclusion: WB-MRI provides additional information to the clinical assessment by revealing a wider involvement of muscle groups and different patterns of distribution of muscle inflammation. WB-MRI score allows to reliably visualize the extent of the inflammatory process and therefore it represents a promising non-invasive tool to estimate the total disease burden, to adjust treatment to disease severity and to monitor treatment efficacy in JDM.

The Comparison of Childhood Polyarteritis Nodosa and Cutaneous Polyarteritis Nodosa and a New Set of Diagnostic Criteria for Cut-Polyarteritis Nodosa. Erkan Demirkaya, Seza Ozen, Turker Turker, Rubén J. Cuttica, Paul Brogan, Pierre Quartier, Jordi Anton, Nuray Aktay Ayaz, Stella Maris Garay, Graciela Espada, Raju Khubchandani. Francesco Zulian, Arvind Bagga, Alexandre Belot, Clovis Artur Silva, Sulaiman Al-Mayouf, Amparo Ibanez Estrella, Sheila Oliveira, Cengizhan Acikel, Claudia Saad-Magalhães, Alberto Martini and Nicolino Ruperto, Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Systemic polyarteritis nodosa (PAN) is a predominantly medium size vasculitis characterized by non granulomatous necrotizing vasculitis. We aimed to evaluate clinical, laboratory and imaging features of cutaneous (cut-) PAN and the PAN form and to develop a new set of diagnostic criteria for cut-PAN in a large international pediatric vasculitis registry available on the PRINTO database.

Methods: We extracted from the PRINTO database all the patients who fulfilled the Ankara 2008-EULAR/PRES/PRINTO criteria for PAN. The cut-PAN patients as per the treating physician diagnosis were also extracted. To define clinical and laboratory characteristics who could help to differentiate cut-PAN from PAN and univariate logistic regression analysis was performed.

Developing a new set of diagnostic criteria for cut-PAN: Principle component analysis were performed to detect best representative factors of cutaneous symptoms in cut-PAN patients. The one with the highest sensitivity and specificity in the generated models were accepted as diagnostic criteria in our study.

Results: There were 109 and 45 patients classified as PAN, and cut-PAN respectively with a mean age at diagnosis of 9.47±3.59 years; and 9.12±3.83 years; respectively. The female/male ratio and ethnicity did not differ in the 2 subtypes. The cutaneous group had significantly less constitutional features and less acute phase reactant levels, as expected. The median values (IQR 25–75%) for the ESR and CRP for PAN were 78 (48–108) mm/h and 7.36 (2.76–15.03) mg/dL. Musculoskeletal features such as myalgia was present in 82 (75.2 %) patients with PAN and 18 (40.9%) patients with cut-PAN (p<0.001) both groups. As differentiating features skin infarcts were observed in PAN only and constitutional features, angiographic abnormalities, and organ involvement was not seen in any of the cut-PAN patients. Malaise, fever, severe headache, motor mononeuritis multiplex, sensory peripheral neuropathy, abdominal pain, and hematuria were the most statistically significant clinical characteristics able to differentiate these two entities.

New set of diagnostic criteria for cut-PAN is the absence of any organ involvement (constitutional and musculo skeletal symptoms are acceptable) and presence of any of 4 cutaneous findings (Livedo reticularis, skin nodules, polymorphous exanthema, panniculitis). Sensitivity of proposed diagnostic criteria obtained from the existing database for cut-PAN was calculated as 88.8%, specificity 97.8%, positive predictive value 83.3% and negative predictive value 98.6%.
Conclusion: The large number of patients with other vasculitides and cutaneous PAN has enabled us to have a significant specificity and sensitivity for the suggested criteria. Furhter biological studies are needed to effectively differentiate the two entities.

Identification of Disease-Specific Neuroimaging Phenotypes in Childhood Inflammatory Brain Diseases. Tania Cellucci, Pascal N. Tyrrell, Shehla Sheikh, Suzanne Laughlin and Susanne M. Benseler. The Hospital for Sick Children, Toronto, ON

Background/Purpose: Magnetic resonance imaging (MRI) is a key diagnostic modality of childhood inflammatory brain diseases (IBrainD). While overlapping clinical features contribute to significant diagnostic uncertainty, neuroimaging characteristics may provide guidance for a targeted diagnostic approach. The aim of this study was to identify specific MRI patterns at diagnosis of distinct childhood IBrainD.

Methods: This single centre cohort study included children less than 18 years old who were diagnosed with an IBrainD between June 1989 and December 2010 and were enrolled in the BrainWorks cohort at SickKids Hospital. All patients also had a high-quality brain MRI based on institutional protocol at diagnosis. Demographic, clinical, laboratory, neuroimaging and histologic data at diagnosis were collected. Correspondence analysis was performed to obtain a multidimensional representation of the relationship between MRI findings and IBrainD diagnoses. Pearson residuals (PR) were calculated to estimate the strength of associations.

Results: A total of 142 children (51% females, median age 8.8 years) with IBrainD were identified: 104 primary angiitis of the CNS (cPACNS), 11 secondary CNS vasculitis, 8 neuronal antibody syndromes, 6 post-infectious IBrainD and 13 unclassified IBrainD. Children with angiography-positive non-progressive cPACNS were likely to have unilateral, unifocal and ischemic lesions (PR 4.2, 3.4, and 3.0, respectively). Common sites for lesions were the basal ganglia (PR 3.5), middle cerebral artery territory (PR 1.8), and internal capsule (PR 1.3). Angiography-negative cPACNS was grouped together with multifocal lesions (PR 1.64) and involvement of the leptomeninges (PR 2.3), parietal or temporal lobes (PR 1.5, 2.8), and subcortical or deep white matter (PR 2.8, 1.5). Optic neuritis (PR 2.9), volume loss (PR 1.8) and frontal lobe lesions (PR 1.5) were more likely in neuronal antibody syndromes. Frontal lobe involvement was also seen in post-infectious IBrainD (PR 1.6). Symmetric lesions were grouped with secondary CNS vasculitis (PR 2.0) and unclassified IBrainD (PR 2.7).

Conclusion: Childhood inflammatory brain diseases are characterized by distinct patterns of neuroimaging findings with respect to location and type of lesion. Identifying these patterns requires a standardized approach involving high-quality MRI for any child with suspected IBrainD. The neuroimaging phenotype may guide further diagnostic work-up and should be incorporated into diagnostic algorithms for childhood IBrainD in the future.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects IV:
Non-biologic Drugs for Rheumatoid Arthritis:
New Insights on Comorbidities and Adverse Events
Tuesday, November 13, 2012, 2:30 PM–4:00 PM

2479

Rheumatoid Arthritis Does Not Increase Risk of Short Term Total Knee Replacement (TKR) Adverse Events (AE). Zachary J. LoVerde[1], Lisa A. Mandl[2], Beverly K. Johnson[2], Mark P. Figgie[2], Friedrich Boettner[2] and Susan M. Goodman[2]. [1]New York Medical College, Valhalla, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: TKR is commonly performed for rheumatoid arthritis (RA) and osteoarthritis (OA). Historically, RA patients were at higher risk of post-operative AEs. The purpose of this study was to evaluate whether this is true in the era of widespread DMARD and biologic use.

Methods: Patients participating in the institution's TKR registry between 2007 and 2010 were screened for RA by ICD-9 code or self report, and the diagnosis confirmed by chart review. AEs were identified by 6 month questionnaire, and review of office and hospital notes. Self-reported AEs were validated by chart review or phone call. Infection was defined as any surgical site infection as well as systemic infections. Each RA patient was matched to 2 controls by age ($+/-$ 5 years), gender, and primary vs. revision surgery. Baseline characteristics of RA and OA patients were compared by standard statistics and bivariate relationships to AE calculated.

Results: 159 RA TKA patients were identified, and matched to 318 OA controls. Mean age: 63 years (range 22–93), 88% female. 20% of RA were on corticosteroids, and 67% were on DMARDS. Assessment of co-morbidities using Charlson co-morbidity scores did not reveal a significant difference between groups. RA had significantly worse baseline WOMAC pain (47.1 vs. 53.7; p-value < 0.01) and function scores (43.8 vs. 54.2; p-value < 0.01), and lower perceived health status on the EQ-5D (0.59 vs. 0.65; p-value < 0.01), and SF-36 PCS (29.3 vs. 33.3; p-value < 0.01). Operative time (144 minutes RA vs. 146 minutes OA; p-value = 0.66) and length of stay (5 days for both) were no different between groups. There were no deep joint infections in either group, and there was no significant difference between OA and RA rates of superficial infection, i.e. cellulitis or stitch abscesses (9.4% RA vs. 10.1%; p-value = 0.82) or thromboembolism (1.3% RA vs. 0.6%; p-value = 0.60). Re-operation was more common in OA (2.5% vs. 8.8% p-value =.015), largely due to manipulations.

Adverse Events	RA cases (N=159)	OA controls (N=318)	P-Value
In hospital (post-op, prior to discharge)			
Surgical Site Infection (SSI), N (%)	2 (1.3%)	3 (0.9%)	0.99
Other infection, N (%)	2 (1.3%)	7 (2.2%)	0.72
DVT, N (%)	1 (0.6%)	4 (1.3%)	0.67
PE, N (%)	0	1 (0.3%)	0.99
Pneumonia, N (%)	1 (0.6%)	1 (0.3%)	0.99
In office (post-op, within 6 months)			
SSI, N (%)	6 (3.8%)	19 (6.0%)	0.39
Other infection, N (%)	3 (1.9%)	4 (1.3%)	0.69
DVT, N (%)	0	1 (0.3%)	0.99
PE, N (%)	1 (0.6%)	1 (0.3%)	0.99
Pneumonia, N (%)	0	0	—
REOP, N (%)	4 (2.5%)	28 (8.8%)	**0.02**
REOP manipulation	2 (1.3%)	25 (7.9%)	**<0.01**
REOP revision	1 (0.6%)	3 (0.9%)	0.99
REOP other	1 (0.6%)	0	0.33
Self-report (at 6 months)			
Infection, N (%)	1 (0.72%)	6 (2.0%)	0.44
DVT, N (%)	0	8 (2.6%)	0.06
PE, N (%)	1 (0.72%)	1 (0.3%)	0.52
Pneumonia, N (%)	2 (1.5%)	1 (0.3%)	0.23
6-month Totals*			
Infection (SSI and other Infection), N (%)	15 (9.4%)	32 (10.1%)	0.83
DVT, N (%)	1 (0.6%)	10 (3.1%)	0.11
PE, N (%)	2 (1.3%)	2 (0.6%)	0.60
Pneumonia, N (%)	3 (1.9%)	2 (0.6%)	0.34
REOP (manipulation, revision, and other), N (%)	4 (2.5%)	28 (8.8%)	**0.02**

The same AE identified by multiple sources was counted only once

Conclusion: The belief that RA increases post-operative AEs may be outdated. In spite of worse pre-operative function, and high steroid and DMARD use, infection and wound healing complications were not increased in RA in a high volume orthopedic hospital. RA patients additionally had

lower rates of re-operation. These data are reassuring, but further study is needed to see if these trends continue and are generalizable.

Disease-Modifying Antirheumatic Drug Use and Toxicities Among Elderly Patients with Rheumatoid Arthritis.
Rebecca L. Manno[1], Dimitrios A. Pappas[2], Katherine C. Saunders[3], George Reed[4], Shannon Grant[5] and Clifton O. Bingham III[1]. [1]Johns Hopkins University, Baltimore, MD, [2]Columbia University, College of Physicians & Surge, New York, NY, [3]CORRONA, Inc., Southborough, MA, [4]UMass Medical School, Worcester, MA, [5]Axio Research LLC, Seattle, WA

Background/Purpose: The aging population has resulted in large numbers of *older* individuals requiring treatment for rheumatoid arthritis (RA). We sought to describe the clinical characteristics of elderly (≥70 yrs) RA pts in a large prospective cohort and determine the frequency of DMARD use and factors associated with drug toxicities among elderly RA pts.

Methods: Data were obtained from the Consortium of Rheumatology Researchers of North America (CORRONA) registry; an independent prospective observational cohort with >30,000 RA patients from over 100 US academic and private practices. We evaluated RA pts aged ≥ 70 yrs with ≥1 post-enrollment follow up (f/u) visit after age 70 [the 'index visit' (IV)]. Pts were classified as either aging with RA (RA onset <70) or older-age onset RA (RA onset ≥70). A subset of older RA patients with > 12 mo f/u beyond the IV was also identified. Demographic, clinical, and DMARD data were obtained. Unadjusted ORs were calculated to determine characteristics associated with DMARD or biologic exposure and drug-associated toxicities at IV and 12 mo f/u.

Results: 5801 RA pts age ≥70 yrs were identified with the following clinical features: 44% erosive, 30.8% joint deformities, mHAQ 0.7 ± 0.6. 4017 elderly RA patients were aging with RA (RA onset 56 ± 10.9 yrs) and 1784 had older-age onset RA (RA onset 75 ± 4.6 yrs). Mean age at IV was 74.9 ± 5.1 yrs with disease duration 13 ±11.6 yrs. 88.6% were on DMARD treatment (68.8% MTX, 34.8% biologic). Among those with 12 mo f/u (n=4077), 93.8% were on DMARD therapy (73.6% MTX, 42.8% biologic) with 16.1% adding a DMARD during f/u. Drug toxicity with non-biologic (1.6%) and biologic DMARDs (0.4%) was overall low. Among those with 12 mo f/u, 3.9% reported toxicity associated with non-biologic DMARD and 0.9% with biologic DMARD. The most commonly reported infection was URI (9%). Factors associated with DMARD, biologic use, or adverse events at the IV or 12 mo f/u are reported in *Table 1*.

Table 1.

Outcome	Parameter	OR (95% CI) at index visit	OR (95% CI) at 12 mo follow up
DMARD use	N (%)	5141 (88.6%)	3825 (93.8%)
	RA onset ≥70 yo	0.961 (0.807, 1.144)	1.140 (0.857, 1.517)

* p <0.05

Conclusion: Most elderly (≥70) RA pts in this large cohort received DMARD therapy, but DMARD and biologic toxicities were very low (<5%). Age of RA onset and age at f/u were not associated with increased biologic side effects. Greater RA severity and longer RA duration influenced if elderly RA patients were on DMARD or biologic therapy. Disability was strongly associated with risk of serious infection in this older age group. Limitations of this study include limited data on co-morbid conditions and precise medication timing. These data confirm that elderly RA patients tolerate DMARD and biologic therapy well with low rates of side effects and emphasize that treatment decisions for RA should never be based on age alone. However, disabled elderly RA patients are at high risk for serious infections. This vulnerable population should be the focus of future studies to determine strategies to improve outcomes beyond measures of RA activity alone.

2481

Time Trends in Corticosteroid Use in Rheumatoid Arthritis: Results From a Population Based Inception Cohort 1980–1994 Vs. 1995–2007.
Ashima Makol, John M. Davis III, Cynthia S. Crowson, Terry M. Therneau, Sherine E. Gabriel and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Corticosteroids (CS) are a double edged sword in rheumatoid arthritis (RA) treatment. Low doses may have disease modifying effects but long-term use risks detrimental side-effects. Treat-to-target strategies with intense use of disease-modifying anti-rheumatic drugs (DMARDs) and biologic response modifiers as steroid-sparing agents have impacted RA management in recent years, but it is unknown whether this has actually resulted in less CS use. The purpose of this study was to examine trends in CS use among patients diagnosed with RA in 1995–2007 compared to 1980–1994.

Methods: A population-based inception cohort of patients with RA who fulfilled 1987 ACR criteria for RA in 1980–2007 was assembled. All subjects were followed longitudinally through their complete medical records until death, migration or 12/31/2008. RA disease characteristics, DMARD use, and CS doses were ascertained by medical record review, including the use of oral, intravenous and intramuscular CS, their start date, stop date and number of weeks to taper. Cumulative incidence of CS initiation and discontinuation was computed with adjustment for competing risk of death. The current prevalence of CS use was estimated as the fraction of subjects on CS from among those under observation during each month of RA duration.

Results: The study population comprised 349 (68% female) diagnosed in 1980–1994 and 464 (69% female) diagnosed in 1995–2007, with mean followup of 15.3 and 5.7 years, respectively. Mean age was 55 years and 66% were rheumatoid factor positive in both cohorts. Those in 1995–2007 had a higher BMI (28.6 vs 26.8, p<0.001) and lower mean ESR at diagnosis (23.0 vs 27.2 mm/hr, p<0.001) than in 1980–1994. More patients started DMARDs in the 1st year of disease in 1995–2007 than in 1980–1994 (83% vs. 52%, p<0.001). A higher proportion of patients started CS in their 1st year of disease in 1995–2007 (68% vs 36%, p<0.001), but the starting dose (mean 8.7 vs 10.3 mg, p=0.08) and cumulative dose in the 1st year of use (mean 1.8 g vs 2.1 g, p=0.48) were not different than in 1980–1994. Differences in CS initiation in 1995–2007 vs 1980–1994 persisted throughout followup (81% vs 50% at 5y, 89% vs 62% at 10y; p<0.001). Discontinuing CS for at least 90 days was also more common in the 1995–2007 cohort than in the 1980–1994 cohort (41% vs 31% at 1 year after CS start, 78% vs 51% at 5y, 94% vs 69% at 10y; p<0.001). Current prevalence of CS use according to RA duration is displayed in the figure.
Conclusion: A higher proportion of patients are starting CS early in their disease course now compared to previously. Although more patients are also discontinuing CS now compared to previously, the proportion of patients on CS at any given time point of disease duration is higher now than previously.

Hydroxychloroquine Has Lipid-Lowering Effects in US Veterans with Rheumatoid Arthritis. Nicole A. Kieffer[1], Gail S. Kerr[2], J. Steuart Richards[3], Lisa A. Davis[4], Liron Caplan[5], Jeffrey Huang[6], Grant W. Cannon[7], Harlan Sayles[8] and Kaleb Michaud[9]. [1]Georgetown University, Washington, DC, [2]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [3]Washington DC VA and Georgetown University, Washington, DC, [4]Denver VA and Univ of Colorado School of Med, Aurora, CO, [5]Denver VA and Univ of Colorado School of Medicine, Aurora, CO, [6]Washington DC VA and Howard University Hospital, Washington, DC, [7]George E. Wahlen VA Medical Center, Salt Lake City, UT, [8]University of Nebraska Medical School, Omaha, NE, [9]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Recent data report significant decreases in low-density lipoprotein (LDL) and total cholesterol (TC) levels in predominantly female Caucasian rheumatoid arthritis (RA) patients treated with hydroxy-chloroquine (HCQ). We evaluated the association of HCQ use with lipid profiles in Veterans Affairs registry (VARA) patients; a predominantly male cohort with multiple comorbidities.

Methods: VARA patients that had post-enrollment lipid profiles available were evaluated. [LDL, TC, high-density lipoprotein (HDL), triglycerides (TG)] values and HCQ status were extracted through links to national VA administrative and pharmacy databases. HCQ user was defined as at least 3 consecutive months of prescription prior to the index lipid value. Patient data included socio-demographics, MDHAQ, RA disease activity measures (TJC, SJC, ESR, CRP, 3vDAS28), treatment [DMARD (excluding HCQ), anti-TNF], statin and prednisone use, and presence of diabetes mellitus (DM). HCQ users and HCQ non-users were compared using chi-square tests for categorical variables and t-tests for continuous variables. Multivariate analysis was performed, controlling for age, gender, race, 3vDAS28, prednisone, DMARD, statin use and DM.

Results: A total of 1012 VARA patients had at least one lipid profile following enrollment; 208 were excluded (< 3 consecutive months of HCQ use). Of 804 patients, the mean age was 62.5 yrs, predominantly male (91.7%) and Caucasian (79.6%), with established disease (10.6 yrs, SD12.2). Seventy-five percent received DMARDS, 24.6% biologic therapy. One hundred and sixty-six patients (20.7%) were HCQ users and 638 (79.3%) were HCQ non-users. Significant differences in HCQ-users versus non-users were age

(64.4 vs 62.1 yrs, p<0.009), disease duration (13.0 vs 10.0 yrs, p=0.003), TJC (3.9 vs. 5.8, p < 0.001), SJC (3.5 vs. 5.0, p =0.001), 3vDAS28 (3.4 vs 3.8, p=0.001), and DMARD use (94.6 vs 70.5%, p<0.001).

HCQ users had statistically significant lower levels of TC, TC/HDL and LDL compared to HCQ non-users that persisted after multivariate analyses (Table). Despite no ethnic differences in HCQ use vs non-user status, prednisone, DMARD, and statin use or 3vDAS28 scores, multivariate analyses found significantly better lipid profiles in Caucasian but not African-American HCQ users versus non-users.

Table. Univariate and Multivariate Associations of Lipid values in HCQ Users vs Non-Users in RA patients

	HCQ Usage				Multivariate Analysis Model Coefficients (p value)

[a] Controlling for Age, Race, Gender, Prednisone Use, Statin Use, 3vDAS28, and Diabetes
[b] Controlling for Age, Race, Prednisone Use, Statin Use, 3vDAS28, and Diabetes
[c] Controlling for Age, Gender, Prednisone Use, Statin Use, 3vDAS28, and Diabetes

Conclusion: In a cohort of US Veterans, RA patients taking HCQ had more optimal lipid profiles than those not using the drug. However, African Americans on HCQ did not demonstrate similar benefits as Caucasian patients. For a relatively inexpensive, low-risk drug, there may be a potential lipid lowering role for HCQ in some RA patients.

Folic Acid Pathway Single Neucelotide Polymorphisms Associated with Methotrexate-Related Significant Adverse Events. Lisa A. Davis[1], Brooke Ivan Polk[2], Alyse D. Mann[3], Roger K. Wolff[4], Gail S. Kerr[5], Andreas M. Reimold[6], Grant W. Cannon[7], Ted R. Mikuls[8] and Liron Caplan[9]. [1]Univ of Colorado School of Med, Aurora, CO, [2]University of Colorado Medical School, Aurora, CO, [3]Denver VA Medical Center, Denver, CO, [4]University of Utah, Salt Lake City, UT, [5]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [6]Dallas VA and University of Texas Southwestern, Dallas, TX, [7]George E. Wahlen VA Medical Center, Salt Lake City, UT, [8]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [9]Denver VA and University of Colorado School of Medicine, Aurora, CO

Background/Purpose: Methotrexate (MTX) is the cornerstone medication in the treatment of rheumatoid arthritis (RA). While MTX has been associated with a number of adverse events (AE), most are insignificant, and do not result in cessation of MTX. We examined whether single nucleotide polymorphisms (SNPs) in enzymes that participate in the folic acid pathway (folypoly-gamma-glutamate synthetase [FPGS], gamma-glutamyl hydrolase [GGH], and methylenetetrahydrofolate reductase [MTHFR]) are associated with significant adverse events (SigAE) complicating MTX treatment.

Methods: Patients (n=319) enrolled in the prospective Veterans Affairs RA (VARA) registry and who were taking MTX were genotyped for multiple SNPs with DNA samples derived from whole blood. Genes and associated SNPs included: FPGS (rs7033913, rs10760503, rs10106), GGH (12548933, rs7010484, rs4617146, rs719235, rs11988534), MTHFR (rs1801131, rs1801133). Patients were also genotyped for HLA-DRB1 polymorphisms. Covariates included: age, gender, Charlson-Deyo comorbidity index at VARA enrollment, glucocorticoid use concomitant with MTX, and mean 4-variable disease activity score. SigAE was defined as an AE leading to MTX discontinuation (operationalized as an AE occurring within 120 days prior to MTX cessation). Multivariate backward stepwise logistic and Cox regression were performed to determine factors associated with the presence of SigAE and time to SigAE, respectively. SNPs were modeled as a categorical variable comparing no minor alleles (homozygous major allele) and ≥ 1 copy of minor allele. A p-value <0.005 was deemed significant in the final model.

Results: The SNP associated with an increased odds of SigAE by logistic regression was the minor allele of GGH rs12548933 (OR 3.43, 95% CI 1.58–7.48) (see Table). This same variable was also associated with an increased hazard ratio (HR) of SigAE (HR 2.42, 95% CI 1.32–4.41) (see Figure).

Table. Final Regression results for logistic and Cox models

		Logistic				Cox		
	OR	95% CI		p-value	HR	95% CI		p-value
GGH, rs12548933, ≥1 copy of minor allele	3.43	1.58	7.43	0.002	2.42	1.32	4.41	0.004
GGH, rs7010484, ≥ 1 copy of minor allele	2.86	1.31	6.27	0.009				
MTHFR, rs1801131, ≥ 1 copy of minor allele					2.67	1.33	5.36	0.006

Figure: Significant MTX AE, by rs12548933 status
Conclusion: RA subjects on MTX may be at increased risk of AE leading to cessation of MTX if they have ≥ 1 copy of the minor allele in GGH rs12548933. Further investigation is warranted, as this SNP may indicate a susceptibility to MTX toxicity.

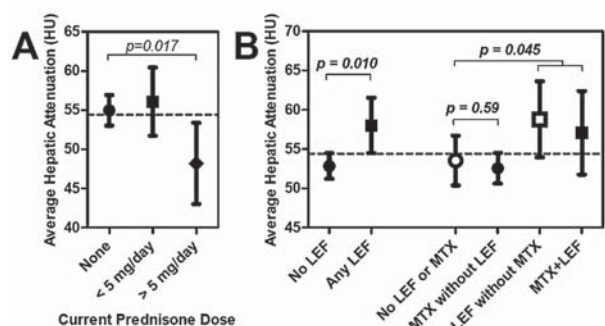
Hepatic Steatosis in Rheumatoid Arthritis: Associations with Disease Characteristics, Pharmacotherapies, and Atherosclerosis. Jon T. Giles and Joan M. Bathon. Columbia University Medical Center, New York, NY

Background/Purpose: Ectopic deposition of liver fat (steatosis) is associated with insulin resistance (IR), cardiovascular disease (CVD), and is a potent risk factor for cirrhosis. RA patients are at risk for IR and CVD, and cirrhosis risk is a concern with several RA pharmacotherapies.

Methods: RA patients underwent abdominal computed tomography (CT). Liver images were analyzed using Slice-o-Matic software, with the average radiographic attenuation [in Hounsfield units (HU)] for five (250 pixels each) sites of liver parenchyma, selected away from hepatic vasculature. Attenuation was corrected using a tissue phantom of known density. Steatosis was defined as average hepatic attenuation <48 HU (a standard definition that correlates histologically to ≥30% fatty deposition).

Results: A total of 113 RA patients were studied [mean age 64 ± 8 years, 70% female, median RA duration=13 years, median DAS28=3.1]. Mean hepatic attenuation was 54 ± 9 HU and steatosis was detected in 20 (18%). Steatosis was unrelated to age, gender, or ethnicity. Those with steatosis reported fewer minutes of exercise and more minutes of daily television watching, had significantly higher IR and serum triglyceride levels, and lower HDL levels. All measures of adiposity were higher among those with steatosis. Current alcohol use, and average and maximum number of alcoholic drinks consumed were not significantly associated with steatosis. Among RA patients, liver HU was, on average, 5 HU lower for those seropositive for RF vs. negative (p=0.003). CRP was strongly inversely correlated with liver HU, but DAS28 was unassociated. Current prednisone use>5 mg/day was associated with, on average, 7 HU lower liver density compared to no prednisone use, an association that was maintained after adjustment (Fig A). Among non-biologics, leflunomide was associated with a higher adjusted liver HU (Fig B), an association not modified by concomitant methotrexate use. Methotrexate use was only significantly associated with lower liver HU among the group with trunk fat above the median (14.7 kg). Likewise, the magnitude of the associations of RF, prednisone, CRP, leflunomide, and lean mass with liver HU was greater in the group with higher trunk fat. Biologics

were not associated with liver density in any analysis. Liver HU was not associated with coronary calcium score, ultrasound measures of carotid atherosclerosis, or ankle brachial index.

Figure: Adjusted Average Radiographic Hepatic Attenuation [in Hounsfield Units (HU)] According to Medication Use


Adjusted for age, exercise, rheumatoid factor, leflunomide use (A), current prednisone dose (B), trunk fat, and fat free mass index (FFMI). Adjusted means and 95% confidence intervals are depicted. The dotted horizontal line is at the population mean HU for liver attenuation (54.4 HU).

Conclusion: No prior studies have explored hepatic attenuation in RA. The findings of this cross-sectional investigation link body composition, systemic inflammation, immunologic characteristics, and pharmacotherapies to the degree of steatosis. For most associations, the effects were accentuated in the setting of increased adiposity, suggesting a biologic interaction. Although strongly associated with insulin resistance, steatosis was unassociated with measures of atherosclerosis.

Rheumatoid Arthritis Treatment - Small Molecules, Biologics and Gene Therapy: Safety & Efficacy of Janus Activated-Kinase (JAK) Inhibitors
Tuesday, November 13, 2012, 2:30 PM–4:00 PM

2485

Tofacitinib, an Oral Janus Kinase Inhibitor: Analyses of Efficacy and Safety of 10 versus 5mg Twice Daily in a Pooled Phase 3 and Long-Term Extension Rheumatoid Arthritis Population. S. Cohen[1], S. Krishnaswami[2], B. Benda[3], R. Riese[2], M.G. Boy[2], D. Gruben[2], G. Wallenstein[2], C. A. Mebus[2], S. H. Zwillich[2] and J. D. Bradley[2]. [1]Metroplex Clinical Research Centre, Dallas, TX, [2]Pfizer Inc., Groton, CT, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. Phase (P) 3 studies demonstrated tofacitinib is effective and has a manageable safety profile at both 5 and 10 mg twice daily (BID) doses. These post-hoc analyses of pooled P3 and long-term extension (LTE) data assessed whether there are relative differences in efficacy or safety between the two doses.

Methods: Data from patients (pts) receiving tofacitinib 5 or 10 mg BID were pooled from five randomized P3 and two open-label LTE studies. Pooling was justified by similarity of demographic and baseline (BL) disease characteristics of pts across the studies. For efficacy comparisons, pooled P3 data were assessed for signs and symptoms (rates of ACR response, rates of DAS28-4[ESR] (DAS) ≤3.2 and <2.6), physical function (rates of HAQ-DI improvement ≥0.3), and fatigue (rates of FACIT improvement ≥4) (all at Month 3). For safety comparisons, pooled P3 and LTE incidence rates (IR) (events/100 pt-y) were assessed for all-cause mortality, serious infection events (SIE), malignancies (excluding non-melanoma skin cancer), lung cancers, major adverse cardiovascular events, GI perforations and herpes zoster. Results were expressed as probability (proportion of responders for efficacy) or risk (IR for safety) ratios, respectively, for 10 mg BID divided by that of 5 mg BID, with 95% confidence intervals (CIs).

Results: In the efficacy analysis, the robust group sizes (approximately 1100 pts each) allowed demonstration of statistical separation (95% CIs excluding 1) of 10 mg BID from 5 mg BID for each of the efficacy

endpoints except fatigue. Point estimates for the 10 mg BID/5 mg BID ratios were between 1.11 and 1.15 for ACR20 responses, ACR50 responses and HAQ-DI improvement ≥0.3, and between 1.30 and 1.43 for ACR70 responses and rates of DAS28 ≤3.2 and <2.6, indicating a greater likelihood of achieving the more stringent outcomes with the 10 mg BID dose compared with 5 mg BID. In the safety analyses, all the CIs for important safety events included 1, indicating similar rates between doses, with the exception of increases in SIEs for 10 mg BID in LTE (risk ratio 1.74 [95% CI 1.24, 2.45]). In contrast to LTE, SIE risk ratio was 0.92 (95% CI 0.55, 1.56) in P3. Malignancy risk ratios were 1.59 (95% CI 0.52, 4.86) in P3 and 1.17 (95% CI 0.67, 2.05) in LTE. As patients from P2 received 5 mg BID in LTE, and pts from P3 received 10 mg BID in LTE, there were more pts receiving 10 (N=2415) compared with 5 mg BID (N=1370) in LTE but the exposure was greater for 5 than 10 mg BID (2700 vs 1700 pt-y).

Conclusion: Both doses of tofacitinib, 5 and 10 mg BID, are efficacious across multiple domains of efficacy. Pooled analyses show statistical separation of 10 mg BID vs 5 mg BID on most efficacy parameters except fatigue. Event rates for safety are generally similar between the two doses but differences were noted in SIE rates in LTE, favoring 5 mg BID. Importantly, event rates for the tofacitinib 5 and 10 mg BID dose groups in both the P3 and LTE studies are well within the ranges observed with biologic therapies approved for treatment of RA.

Radiographic, Clinical and Functional Comparison of Tofacitinib Monotherapy Versus Methotrexate in Methotrexate-Naïve Patients with Rheumatoid Arthritis. Eun Bong Lee[1], Roy M. Fleischmann[2], Stephen Hall[3], Ronald F. van Vollenhoven[4], John Bradley[5], David Gruben[5], Tamas Koncz[6], Sriram Krishnaswami[5], Gene Wallenstein[5], Samuel H. Zwillich[5], Bethanie E. Wilkinson[5] and the ORAL Start Investigators[7]. [1]Seoul National University, Seoul, South Korea, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Cabrini Health and Monash University, Melbourne, Australia, [4]Karolinska Institute, Stockholm, Sweden, [5]Pfizer Inc., Groton, CT, [6]Pfizer Inc., New York, NY, [7]Groton, CT

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. This Phase 3, 24-mo study (ORAL Start; NCT01039688) compared efficacy, inhibition of structural damage, and safety of tofacitinib vs methotrexate (MTX, 10–20 mg/wk) in MTX-naïve patients (pts) with active RA.

Methods: Pts were randomized 2:2:1 (double-dummy, double-blind) to: tofacitinib 5 mg twice daily (BID); tofacitinib 10 mg BID; or MTX 10 mg/wk with 5 mg/wk increments every 4 wks to 20 mg/wk. Predetermined primary endpoints (Mo 6) compared tofacitinib vs MTX for: 1) mean changes from baseline (BL) in van der Heijde modified Total Sharp Score (mTSS); 2) ACR70 response. Evaluation of safety and tolerability was also a primary objective. **Results** are from planned 12-mo interim analyses.

Results: Overall, 952 pts were randomized and treated with tofacitinib 5 mg BID (N=371), 10 mg BID (N=395), and MTX (N=186). Demographic and BL RA disease characteristics, including radiographic scores (mTSS: 20.30, 18.85, and 16.51 for 5 mg BID, 10 mg BID, and MTX, respectively), were similar across groups. Mean changes from BL in mTSS and ACR70 rates at Mo 6 were statistically superior for both doses of tofacitinib vs MTX (Table). There was a statistically significant difference in ACR70 response for both doses of tofacitinib vs MTX by Mo 1 (first post-BL visit) with increasing efficacy over time. Secondary radiographic endpoints were also significantly different for tofacitinib vs MTX: smaller changes in erosion and joint space narrowing scores and greater proportions of pts with no progression from BL (mTSS change ≤0.5) at Mo 6. Other secondary endpoints, including ACR20 and ACR50 responses, mean change in DAS28-4(ESR), DAS28-4(ESR) <2.6 rates, and mean change in HAQ-DI, were significantly better with tofacitinib vs MTX at all timepoints.

The incidence of adverse events (AEs) and serious AEs was similar across groups (Table). Most AEs were mild or moderate; the most frequently reported AEs in all groups were infections. Herpes zoster occurred in 2.2%, 2.5%, and 1.1% of tofacitinib 5 mg BID, 10 mg BID, and MTX pts, respectively; 1 pt had bone tuberculosis (10 mg BID) and 1 had cytomega-

lovirus infection (MTX); 2 tofacitinib pts died later in the same trial. Decreases in mean neutrophil counts and small increases in mean serum creatinine were seen in all groups. Increases were seen in mean LDL- and HDL-cholesterol levels with tofacitinib. The incidence of aspartate and alanine aminotransferase elevations ≥3x the upper limit of normal was low.

Table. Primary and selected secondary efficacy endpoints and safety data

	Tofacitinib 5 mg BID (N = 371)	Tofacitinib 10 mg BID (N = 395)	Methotrexate (N = 186)
Efficacy (Month 6)			
LS mean change from BL in mTSS[a,b]	0.18**	0.04***	0.84
Pts with no radiographic progression (mTSS change from BL ≤0.5) (%)[b]	83.5*	89.7***	70.5

24-Week Results of a Blinded Phase 2b Dose-Ranging Study of Baricitinib, an Oral Janus Kinase 1/Januse Kinase 2 Inhibitor, in Combination with Traditional Disease Modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis. Mark C. Genovese[1], Edward Keystone[2], Peter Taylor[3], Edit Drescher[4], Pierre-Yves Berclaz[5], Chin H. Lee[5], Douglas E. Schlichting[5], Scott D. Beattie[5], Rosanne K. Fidelus-Gort[6], Monica E. Luchi[6] and William Macias[5]. [1]Stanford University Medical Center, Palo Alto, CA, [2]University of Toronto, Toronto, ON, [3]University of Oxford, Oxford, United Kingdom, [4]Veszprém Csolnoky Ferenc County Hospital, Department of Rheumatology and Physical Rehabilitation, Veszprém, Hungary, [5]Eli Lilly and Company, Indianapolis, IN, [6]Incyte Corporation, Wilmington, DE

Background/Purpose: Baricitinib (formerly LY3009104/INCB028050), a novel, oral inhibitor of JAK1 and JAK2 in the JAK-STAT signaling pathway, has been evaluated in a 24 week blinded phase 2b study in patients (pts) with moderate to severe RA with inadequate response to methotrexate (MTX).The primary endpoint after 12 weeks of treatment was met[1]. The 24 week safety and efficacy findings are reported here.

Methods: Pts with active RA (defined as at least 8 swollen and 8 tender joints based on the 66/68 joint assessment) on stable MTX were randomized 2:1:1:1:1 to receive placebo (PBO) or 1of 4 once-daily baricitinib doses (1, 2, 4, or 8 mg) for 12 wks. Pts assigned to 2 mg, 4 mg or 8 mg continued blinded treatment for an additional 12 weeks. Patients assigned to placebo or 1 mg were reassigned to an exploratory 4 mg daily or 2 mg twice daily group between weeks 12–24 and were excluded from the primary 24-week analysis.

Results: Three hundred one pts entered the study. After 12 weeks of treatment, significant differences versus placebo (p<0.05) were observed in the proportion of patients achieving ACR20, ACR50 and ACR70, DAS28CRP<2.6 and CDAI≤2.8, and for DAS28CRP, HAQ-DI and CDAI (Table1). At week 24, patients receiving 2 mg, 4 mg or 8 mg baricitinib

maintained or improved in all measures. Over 12 weeks in the PBO and combined baricitinib groups, there were similar incidence rates of TEAEs (44% vs 41%), infections (12% vs 14%) and SAEs (2% vs 2%, respectively) over 12 weeks. Over 24 weeks in the combined 2 mg, 4 mg and 8 mg groups, the rate of TEAEs was 64% (36% mild, 23% moderate, 5% severe), the rate of infections was 27% (16% mild, 9% moderate, 1% severe), and the rate of SAEs was 5%. There were no opportunistic infections and no deaths. Decreases in hemoglobin and small increases in serum creatinine were seen. Increases were seen in LDL and HDL (Table 2).

Table 1. Primary and Selected Secondary Efficacy Endpoints at 12-and 24 weeks

	PBO (N=98)	1 mg QD (N=49)	2mg QD (N=52)	4 mg QD (N=52)	8 mg QD (N=50)

Table 2. Summary of Laboratory Data at Week 24: Change from Baseline

Mean (SD)	2 mg QD	4 mg QD	8 mg QD
Hemoglobin (g/dL)	−0.28 (1.1)	−0.24 (0.9)	−0.44 (1.0)
Neutrophil count (10^3/mm^3)	−0.25 (2.2)	−0.21 (2.0)	−1.37 (2.3)
Creatinine (mg/dL)	0.04 (0.10)	0.05 (0.08)	0.07 (0.13)
HDL cholesterol (mg/dL)	5.63 (12.21)	5.40 (10.62)	8.24 (13.05)
LDL cholesterol (mg/dL)	11.52 (22.80)	8.75 (32.60)	13.98 (30.87)

Conclusion: Significant improvements in the signs and symptoms of RA versus placebo were observed over 12 weeks. These responses were maintained or improved for an additional 12 weeks of blinded treatment with 2 mg, 4 mg and 8 mg. In addition, safety signals observed over 12 and 24 weeks were consistent with previously conducted studies of baricitinib.

Magnetic Resonance Imaging Substudy in a Phase 2b Dose-Ranging Study of Baricitinib, an Oral Janus Kinase 1/Janus Kinase 2 Inhibitor, in Combination with Traditional Disease-Modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis. Charles G. Peterfy[1], Paul Emery[2], Mark C. Genovese[3], Edward Keystone[4], Peter Taylor[5], Pierre-Yves Berclaz[6], Julie C. DiCarlo[1], Chin H. Lee[6], Douglas E. Schlichting[6], Scott D. Beattie[6], Monica E. Luchi[7] and William Macias[6]. [1]Spire Sciences LLC, Kentfield, CA, [2]University of Leeds, Leeds, United Kingdom, [3]Stanford University Medical Center, Palo Alto, CA, [4]University of Toronto, Toronto, ON, [5]University of Oxford, Oxford, United Kingdom, [6]Eli Lilly and Company, Indianapolis, IN, [7]Incyte Corporation, Wilmington, DE

Background/Purpose: Baricitinib (formerly, LY3009104/INCB028050) is a novel, oral inhibitor of JAK1 and JAK2 in the JAK-STAT pathway. Primary results of this phase 2b study have already been reported and show that baricitinib reduces signs and symptoms of rheumatoid arthritis (RA) with no unexpected safety signals[1]. MRI was used in this study to examine dose dependency of baricitinib on joint changes in a subgroup of patients (pts) with erosive RA and inadequate response to methotrexate (MTX).

Methods: In this phase 2b randomized, double-blind, placebo-controlled trial, 301 pts with active, established RA (≥ 8 swollen and 8 tender joints) on stable MTX were randomized 2:1:1:1:1 to placebo or 1 of 4 once-daily LY doses (1, 2, 4 or 8 mg) for up to 24 weeks. 208 pts (placebo [n=68], 1 mg [n=34], 2 mg [n=40], 4 mg [n=33], 8 mg [n=33]) with definitive radiographic erosion had MRI of the dominant hand/wrist at baseline, week 12 and week 24. Pts assigned to placebo or 1 mg were reassigned to an exploratory 4 mg or 2 mg twice daily group at week 12 and excluded from the 24-week analysis. Fat-suppressed, T1-weighted 3D gradient-echo and STIR images were obtained with and without gadolinium contrast using 1.5T MRI and a hand frame to ensure reproducible positioning. MR images were read independently by 2 expert radiologists blinded to treatment and visit order. Images were scored using RAMRIS and a validated 9-point cartilage loss scale. Total inflammation (osteitis + 3x synovitis) and total joint damage (erosion + 2.5x cartilage loss) scores were calculated. ANCOVA adjusting for baseline score and dose group was used for analysis. Due to the exploratory nature of the substudy, 1-sided p-values less than 0.1 were considered indicative of possible MRI difference (trends) vs placebo.

Results: There was a significant (≥ smallest detectable change) decrease in osteitis over 12 weeks in 15% of pts on placebo vs 29% and 29% on baricitinib 4 and 8 mg, respectively. Similarly, synovitis decreased in 18% of pts on placebo vs 33% and 29% of pts on 4 or 8 mg baricitinib. Significant decreases in bone erosion did not progress in 80% of placebo vs 96% and 88% of pts on 4 or 8 mg baricitinib. Significant decreases in adjusted mean synovitis, osteitis and total inflammation scores were observed in the 4 mg and 8 mg groups compared to placebo at week 12 that persisted to week 24 (table 1). A trend in improvement in total joint damage was also observed for the 4 mg group. These MRI improvements correlated with significant improvements in tender and swollen joints in the 4 mg and 8 mg groups and with numeric decreases in median CRP.

Table 1. MRI and Clinical Changes Over 12 and 24 weeks

MRI and Clinical Parameters	Placebo	1-mg	2-mg	4-mg	8-mg
			Baricitinib Treatment Groups		
Synovitis					
12-week LS Mean change	−0.6	−1.2	−0.6	−1.6	−1.5
p-value[a]	−	NS	NS	0.036	0.047
24-week mean change	−	−	−0.8	−1.7	−2.1
Osteitis					
12-week LS Mean change	−0.4	−1.3	−0.8	−3.6	−2.2
p-value[a]	−	NS	NS	<.001	0.037
24-week mean change	−	−	−1	−3.7	−2.1
Total Inflammation					
12-week LS Mean change	−2.1	−4.9	−2.7	−8.6	−6.6
p-value[a]	−	NS	NS	0.003	0.027
24-week mean change	−	−	−3.5	−8.7	−8.3
Bone Erosion					
12-week LS Mean change	0.8	0.1	0.1	0.3	0.5
p-value[a]	−	0.071	0.051	NS	NS
24-week mean change	−	−	0.5	−0.5	0.2
Cartilage Loss					
12-week LS Mean change	−0.2	0	−0.2	−0.4	−0.2
p-value[a]	−	NS	NS	NS	NS
24-week mean change	−	−	0.2	−0.3	−0.1
Total Joint Damage					
12-week LS Mean change	0.4	0.1	−0.3	−0.8	−0.1
p-value[a]	−	NS	NS	0.068	NS
24-week mean change	−	−	0.9	−1.3	0
CRP (mg/L)					
12-week median	4.6	3.1	2.4	2.3	2.6
24-week median	−	−	3.4	2.5	2.5
Tender joints (of 68)					
12-week LS Mean change	−7.5	−8.8	−10.8	−13.7	−13.4
p-value[b]	−	NS	0.064	<.001	0.001
24-week mean change	−	−	−12.4	−14	−17.5
Swollen joints (of 66)					
12-week LS Mean change	−6.7	−8.4	−8	−10.5	−10.1
p-value[b]	−	NS	NS	<.001	0.002
24-week mean change	−	−	−10	−10.5	−12.2

a 1-sided comparison vs Placebo; b 2-sided comparison vs Placebo; NS=non-significant

Conclusion: MRI findings in this subgroup of pts with active erosive RA suggest dose-dependent suppression of synovitis, osteitis and total inflammation by baricitinib for the 4-mg and 8-mg groups at 12 and 24 weeks. These findings corroborate previously demonstrated clinical efficacy of bariticinib.

Selective JAK1 Inhibition in the Treatment of Rheumatoid Arthritis: Proof of Concept with GLPG0634. Frédéric Vanhoutte[1], Minodora Mazur[2], Annegret Van der Aa[1], Piet Wigerinck[1] and Gerben van 't Klooster[1]. [1]Galapagos NV, Mechelen, Belgium, [2]State Medical and Pharmaceutical University "Nicolae Testemitanu", Chisinau, Moldova

Background/Purpose: Janus kinases (JAKs) are critical components in signaling pathways for a number of cytokines and growth factors, including those involved in the disease process of rheumatoid arthritis (RA). Non-selective JAK inhibitors have shown long-term efficacy in RA trials with an early onset of action, but doses and thereby efficacy are limited by side effects. By specifically targeting JAK1, we hypothesize that selective inhibition of JAK1 will result in a cleaner safety profile while maintaining high levels of clinical efficacy and a rapid onset of action. We have therefore developed GLPG0634, an orally-available, selective inhibitor of JAK1.

Objectives: Evaluate the short-term efficacy and safety of GLPG0634 in RA patients with insufficient response to methotrexate (MTX) alone.

Methods: A double-blind, placebo-controlled Proof-of-Concept trial in patients with active RA, showing an insufficient response to MTX, was conducted. Twenty-four patients with moderate to severe disease received GLPG0634 200 mg daily, half as once-daily regimen (200 mg QD) and half as twice-daily regimen (100 mg BID), and 12 patients received a matching placebo for a period of four weeks, while continuing to take their stable background therapy of MTX.

Results: Patient and disease characteristics were comparable for all three dose groups, with DAS28 (CRP) disease activity scores between 6.3 and 6.6. In each dose group, 11 out of 12 patients were female. Across the groups the mean background MTX dose was 11 mg/week.

GLPG0634 was found to be well tolerated and safe with a rapid onset and high level of efficacy. Considering the small sample size, no clinically relevant differences were observed among the 100 mg BID and the 200 mg QD dose regimens. GLPG0634 met the primary endpoint of significant improvement in ACR20 response rate. Overall ACR20 responses were observed in 83% of patients receiving GLPG0634 vs. 33% of patients receiving placebo (p<0.01). GLPG0634 showed impressive results in secondary efficacy endpoints, such as the DAS28 (-2.5), and in reductions of serum C-reactive protein levels (-24.4 mg/L), both significant changes vs. placebo (p<0.0001). All patients completed the trial, and no treatment-emergent safety signals were reported. No severe adverse events were reported in patients receiving GLPG0634. Instead of anemia, a modest improvement in hemoglobin was observed. In contrast to observations with JAK inhibitors with other selectivity profiles, no increases in LDL/cholesterol, no liver effects (ALT/AST) and no effect on creatinine were observed in this trial.

Conclusion: These early clinical results are the first to demonstrate that selective inhibition of JAK1 is efficacious and safe for the treatment of RA. Consistent with the lack of inhibition of JAK2, no anemia was observed. Encouraging results include the high level of response within 4 weeks and the absence of effects on LDL/lipid. An extended GLPG0634 dose-range finding trial is now being conducted to further define the optimal doses for efficacy and safety for longer term studies.

Herpes Zoster and Tofacitinib Therapy in Patients with Rheumatoid Arthritis. K. L. Winthrop[1], H. Valdez[2], E. Mortensen[3], R. Chew[4], S. Krishnaswami[4], T. Kawabata[4] and R. Riese[4]. [1]Division of Infectious Diseases, Oregon Health and Science University, Portland, OR, [2]Pfizer Inc., New York, NY, [3]Pfizer Inc., Collegeville, PA, [4]Pfizer Inc., Groton, CT

Background/Purpose: Patients (pts) with RA are at increased risk for herpes zoster (HZ) i.e. 'shingles'. Tofacitinib, a novel oral Janus kinase inhibitor investigated as a targeted immunomodulator and disease-modifying therapy for RA, down-regulates cytokine-induced signalling that is potentially important to HZ immunity. It has been reported previously that HZ incidence rates (IRs) in the tofacitinib RA program are higher than those reported with biologic and non-biologic DMARDs,[1–4] however the reasons are unknown.

Methods: Adverse events of HZ were identified in the randomized controlled Phase 2, 3, and open-label long-term extension (LTE) tofacitinib RA studies (data cut March 29, 2011). HZ IRs (per 100 pt-years [pt-yrs] [95% CI]) were calculated and logistic regression was used to evaluate potential risk factors for HZ.

Results: In the tofacitinib RA program Phase 2, 3, and LTE studies (4789 pts with 5651 pt-yrs of tofacitinib treatment), 239 tofacitinib-treated pts experienced HZ. One case (0.4%) was multidermatomal, and none involved visceral dissemination or death. Twenty-five pts with HZ (10.5%) permanently discontinued tofacitinib and 16 (6.7%) were hospitalized or received intravenous antiviral drugs. In Phase 3 studies the number of HZ cases and IRs per 100 pt-yrs (95% CI) for each treatment were: tofacitinib 90 cases, IR 4.4 (3.5, 5.4); placebo 3 cases, IR 1.5 (0.5, 4.6); and adalimumab (included as active control in one study) 5 cases, IR 2.8 (1.2, 6.8). In LTE studies, 134 HZ cases were identified in tofacitinib recipients, with an IR of 4.5 (3.8, 5.3). Tofacitinib-associated HZ IRs varied widely across countries of enrollment and were significantly higher among Asians (7.6 [6.3, 9.2]) vs whites (3.3 [2.8, 4.0]), blacks (2.3 [0.7, 7.1]), and others (3.0 [1.8, 4.9]). For tofacitinib-treated pts, those aged ≥65 years (odds ratio [OR] 1.26 [95% CI 0.91, 1.75]), females (OR 1.31 [95% CI 0.89, 1.92]), those using glucocorticoids (OR 1.24 [95% CI 0.95, 1.61]), and those with a longer disease duration (OR 1.02 for each extra year of RA [95% CI 1.00, 1.03]) were more likely to develop HZ. There was no association between HZ risk and background non-biologic DMARD use (i.e. tofacitinib monotherapy or in combination with DMARD), neutrophil or lymphocyte count, or baseline RA severity. In Phase 3 studies, patients treated with tofacitinib 5 mg BID were no more likely to develop HZ than those treated with 10 mg BID (OR 0.96 [95% CI 0.62, 1.51]).

Conclusion: In the tofacitinib RA program, rates of HZ observed among placebo, adalimumab, and tofacitinib-treated pts (particularly in pts of Asian race) were higher than those reported in the literature for patients with RA treated with biologic and non-biologic DMARDs (IRs 0.56–1.32 events per 100 pt-yrs).[2–4] HZ was more common among tofacitinib-treated pts compared with placebo-treated subjects, although confidence intervals were overlapping, with similar rates between tofacitinib 5 mg and 10 mg BID dose groups. Complicated HZ was rare in tofacitinib-treated pts.

IL-17 Expression Is Low in Psoriatic Arthritis Synovium Compared to Expression in Matched Skin Lesions. Jennifer Belasco[1], Hiroshi Mitsui[1], Mayte Suarez-Farinas[1], James S. Louie[2], Nathan Wei[3], Nicholas Gulati[1] and James G. Krueger[1]. [1]The Rockefeller University, New York, NY, [2]UCLA School of Medicine, Los Angeles, CA, [3]Arthritis Treatment Center, Frederick, MD

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory joint disease associated with psoriasis. It is known that treatment modalities are not equally effective for both skin and joint disease, indicating that there are different pathomechanisms driving each component. For example, TNF antagonists are relatively effective treatments for both psoriasis vulgaris and skin/joint manifestations of PsA. However, results from the set of emerging IL-17 antagonists for psoriasis show marked psoriatic lesional skin improvement, but less robust results for PsA joint symptoms. The purpose of this study was to determine differential gene expression between matched lesional skin and affected synovial tissue in patients with psoriatic arthritis to better define the inflammatory pathways of PsA in both skin and joint pathogenesis.

Methods: Matched lesional psoriatic skin samples and synovial samples from inflamed joints were obtained from subjects with PsA (n=13). Gene expression analysis was conducted using Affymetrix HGU133 2.0 plus arrays. The gene expression profile of each diseased tissue was then compared to that of corresponding normal tissue. We considered differentially expressed genes (DEGs) with a cut-off of fold change >2.0 and false discovery rate <0.01. Results were confirmed using RT-PCR with coupled directed pre-amplification. Ingenuity Pathway Analysis (IPA) was utilized to identify canonical pathways among differentially expressed genes.

Results: Principal components analysis demonstrates that there is a clear difference between gene expression patterns of skin and synovium from psoriatic arthritis patients even when adjusted for tissue specificity. The total number of DEGs after adjustment for tissue specificity in both skin and synovium was 2532. The number of genes shared by both was 518. The number of genes unique to the skin was 686 and to synovium was 1328. IPA revealed that the role of IL17A in psoriasis was significant in lesional skin but not in synovial tissue. RT-PCR confirmed the marked expression of IL17A, IL17F, and IL22 in lesional skin compared to inflamed synovium (p<0.05). TNF was present in both tissues without any significant difference between the two. There was no correlation at the messenger level of IL17A, IL17F, IL22 and TNF between pairs of skin and synovium from the same subject.

Conclusion: These results demonstrate that gene expression differs greatly between matched pairs of lesional psoriatic skin and synovium from inflamed joints in patients with PsA. Our results support clinical trial data that indicate psoriatic arthritis skin and joint disease are both responsive to TNF antagonists whereas skin shows better results when compared to joints with IL17 antagonists. Genes selectively expressed in PsA synovium might direct future therapies for this condition.

Protective and Pathogenic Effects of the IL-23 Family of Cytokines in Spondyloarthropathy in SKG Mice. Helen Benham[1], Linda Rehaume[1], Merja Ruutu[1], Jared Velasco[1], Kristine Kikly[2], Geoffrey Strutton[3], Michael McGuckin[4] and Ranjeny Thomas[1]. [1]Diamantina Institute University of Queensland, Brisbane, Australia, [2]Biotechnology Discovery Research, Eli Lilly and Co., Indianapolis, [3]Department of Pathology, Princess Alexandra Hospital, Brisbane, Australia, [4]Mater Medical Research Institute, Brisbane, Australia

Background/Purpose: IL-23 is required for the expansion and maintenance of T cells and innate cells secreting IL-17 and IL-22. These cytokines are important for control of fungal infections. Genetic studies implicate IL-23 receptor signalling in the pathogenesis of spondyloarthropathies. Spondyloarthritis and Crohn's-like ileitis develop in an IL-23-dependent fashion in ZAP70-mutant SKG mice, which have deficient T cell receptor signalling. Our aim was to determine the role of IL-23, IL-17 and IL-22 in pathogenesis of spondyloarthritis and ileitis in this model.

Methods: SKG mice or IL-17A deficient SKG mice were injected intraperitoneally with curdlan (1,3-D β-glucan) to induce disease. Anti-mouse IL-22, anti-IL-23 or isotype control antibodies were given i.p one day before curdlan, and weekly until sacrifice and anti-mouse IL-23 and IL-17A or isotype control antibodies were given in weekly doses commencing three weeks after i.p curdlan in a treatment regime. Outcomes were measured by clinical and histological scoring. Cytokines were measured by quantitative RT-PCR and in supernatants of cultured tissue explants.

Results: Curdlan induced spondyloarthritis in 100% and ileitis in 60% of SKG mice. Weekly anti-IL-23 treatment of SKG mice from induction suppressed development of spondyloarthritis and decreased the severity of ileitis. In curdlan-treated IL-17A deficient SKG mice, or SKG mice treated with anti-IL-17 from induction, spondyloarthritis and ileitis were less severe than control treated mice. In absence of IL-17A, peripheral enthesitis was particularly spared. Treatment with anti-IL-23 or anti-IL-17 three weeks after induction improved spondyloarthritis and ileitis, and anti-IL-23 was significantly more beneficial than anti-IL17. In contrast, anti-IL-22 modestly suppressed arthritis, increased anti-proteoglycan auto antibodies, and exacerbated ileitis. IL-23 mRNA and protein were expressed within days of induction, and increased over time in the ileum, but not in serum, lymph nodes or joint.

Conclusion: In curdlan-treated SKG mice, initiation and perpetuation of spondyloarthritis is dependent on IL-23, likely derived from the gut. IL-17A is particularly associated with enthesitis. Ileal inflammation is dependent on IL-23 and IL-17A and protected by IL-22. The data suggest that beta-glucan promotes IL-23 secretion, with protective and pathogenic consequences in different tissues through T cell cytokines downstream. Defective T cell signalling in SKG mice not only hinders negative selection of self-reactive T cells but also microbial defence, potentially enhancing the requirement for innate immune mechanisms, including IL-23, IL-17 and IL-22 for host protection.

The Presence of HLA-B27 Shapes Gut Microbiome Composition in Rats. Mary H. Bach[1], Russell N. Van Gelder[1], Joel D. Taurog[2] and James T. Rosenbaum[3]. [1]University of Washington Medical Center, Seattle, WA, [2]UT Southwestern Medical Center, Dallas, TX, [3]Oregon Health & Science University, Portland, OR

Background/Purpose: The association of spondyloarthropathies (SpA) with HLA-B27 was first described in 1973. However, the mechanism remains unknown. The HLA-B27-human beta2 microglobulin (B27/hβ2m) transgenic (TG) rat model has been used to study SpAs. It is known that the gut microbiome affects the immune response. Previous studies characterized the gut microbiome of TG and wild type (WT) animals using standard culture media or limited 16S rRNA sequencing from denaturing gradient electrophoresis gels. In this study we tested the hypothesis that B27 shapes the cecal microbiome by utilizing a deep DNA sequencing technique called biome representational in silico karyotyping (BRiSK). This technique has the potential for more complete microbiome analysis.

Methods: We studied (21–3×283–2)F1 B27/hβ2m TG rats on the LEW background, which develop arthritis but not colitis (*A&R* 54:1317, 2006), and WT LEW controls. Sixteen rat cecum and content samples (7 TG co-housed with WT, 6 WT co-housed with TG, 3 WT housed separately) underwent DNA digestion and were subjected to BRiSK for high throughput DNA sequencing. Quantitative PCR (qPCR) normalized to 16S was used to confirm the BRiSK results. Statistical analysis was done with Graphpad Prism.

Results: Over 900 bacterial and bacteriophage species were identified using BRiSK. Heat map analysis indicated quantitative differences of 4 bacteria between separately housed WT and TG rats. Two differences were identified by BRiSK and confirmed independently by qPCR (p<0.05 for comparison of non-cohoused wild type to other groups) for the microorganisms *Akkermansia muciniphila* and *Bacteroides vulgatus*. Consistent with other recent reports, co-housing tended to obscure differences in microbiota.

A muciniphila BRiSK
Relative Expression of A muciniphila with Normalization to 16S (qPCR)

B vulgatus BRiSK
Conclusion: B27/hβ2m TG rats showed altered abundance of certain bacteria in the cecum, compared with WT rats housed apart. Differences were also seen in WT rats housed with the TG rats. *B. vulgatus* has been implicated in the pathogenesis of colitis (*J Clin Invest* 1996;98:945),and *A. muciniphila* is reduced in inflammatory bowel disease (*Am J Gastroenterol* 2010;105:2420). This study suggests that the increase in *B. vulgatus* and reduction of *A. muciniphila* in the TG rats are effects of B27 that may be related to the pathogenesis of SpA.

Incidence and Severity of Spondyloarthritis and Crohn's Ileitis Are Determined by Interaction Between the Microbiota and Genetic Susceptibility in Beta-Glucan-Treated SKG Mice.

Ranjeny Thomas[1], Linda Rehaume[1], Daniel Aguirre de Cárcer[2], Stan Mondot[2], Jared Velasco[1], Helen Benham[1], Merja Ruutu[1], Mark Morrison[2] and Michael McGuckin[3]. [1]University of Queensland Diamantina Institute, Brisbane, Australia, [2]CSIRO Livestock Industries, Brisbane, Australia, [3]Mater Medical Research Institute, Brisbane, Australia

Background/Purpose: Spondyloarthritis and inflammatory bowel disease (IBD) or microscopic gut inflammation co-exist in many patients. These conditions share genetic associations in the *IL23R* signaling pathway. Rodent models of spondyloarthritis or IBD typically improve in germ free (GF) conditions and intestinal microbial diversity is reduced in Crohn's disease, with enrichment in Gram negative rods. Thus resident microbiota are implicated in pathogenesis. We hypothesized that microbiota directly affect incidence and severity of spondyloarthritis and ileitis in SKG mice, where the ZAP-70[W163C] mutation of the BALB/c strain reduces T cell receptor signaling.

Methods: SKG and BALB/c mice were housed in SPF or rederived to GF conditions then injected i.p. with 1,3-D beta-glucan (curdlan). Paw width was scored for 8 weeks. Joint, tail and small intestinal histological sections were scored at sacrifice. The fecal microbiota of BALB/c and SKG mice was assessed by 454 pyrosequencing 0, 3, 7, 10 and 14 days after curdlan treatment. Double principal components analysis (DPCA) and other methods were used to compare phylogenetic groups across samples.

Results: In SPF conditions, i.p. curdlan triggered IL-23-dependent severe spondyloarthritis and Crohn's-like ileitis in 100% and 70% of female SKG mice respectively. BALB/c control mice developed mild peripheral arthritis without ileitis. In GF conditions, the incidence of spondyloarthritis in SKG mice was 10% and ileitis 0%. No priming of anti-proteoglycan autoantibodies occurred without spondyloarthritis. Spondyloarthritis and ileitis incidence and severity, and anti-proteoglycan antibodies were restored when GF mice were reconstituted with a limited bacterial consortium. Within days after curdlan under SPF but not GF conditions, IL-23 and Grp-78 mRNA increased in the ileum, and activated dendritic cells (DC) were recruited to the mesenteric lymph nodes, where IL-17 mRNA expression increased. By DPCA of fecal and cecal microbiota, a large shift in community structure occurred in SKG but not BALB/c mice 3 days after curdlan, related to increased *Bacteroides*-affiliated sequences. Segmented filamentous bacteria were absent. When BALB/c and SKG mice were cohoused after weaning and injected with curdlan at 6 weeks of age, arthritis and ileitis severity was similar in BALB/c and SKG mice cohoused in each cage.

Conclusion: Microbiota are necessary and sufficient for priming spondyloarthritis and Crohn's-like ileitis by DC in gut draining lymph nodes in SKG mice. The SKG mutation predisposes to lack of control of particular transmissable microbial species triggered by systemic delivery of curdlan, which enhance susceptibility to spondyloarthritis and Crohn's-like ileitis.

Dense Genotyping of Candidate Genes Identifies 16 New Susceptibility Loci in Ankylosing Spondylitis.

Adrian Cortes[1], Philip Robinson[1], International Spondyloarthritis Genetics Consortium[2] and Matthew A. Brown[1]. [1]The University of Queensland Diamantina Insititute, Brisbane, Australia, [2]Brisbane, Australia

Background/Purpose: Ankylosing spondylitis (AS) is a highly heritable inflammatory arthritis common in both Asian and European populations. Thus far genes identified include the HLA-B*27 allele, and 13 non-MHC loci identified in European populations. In this study we aimed to better characterize the genetic architecture of AS and to fine-map known susceptibility loci.

Methods: We successfully genotyped 129,030 polymorphic SNPs in 10,624 AS affected and 15,174 healthy individuals of European and Asian descent using the Illumina Immunochip microarray, which designed for immunogenetic studies.

Results: In this study we identified 16 new AS risk loci reaching genome-wide significance ($P < 5 \times 10^{-8}$), bringing the number of known non-MHC loci to 27. All attempted genome-wide significant loci reported in European populations were replicated. We found multiple independent association signals in 8 of these loci, caused by both common and low frequency variants, suggesting that multiple genetic variants within a gene can affect disease susceptibility. Three AS-loci encoding four aminopeptidases were identified which are involved in peptide handling prior to MHC Class I presentation; protective variants at two of these are associated with both reduced aminopeptidase function and MHC Class I cell surface expression. European and Asian specific signals were observed in *IL23R* and *PTGER4*. Identified loci implicate microbial sensing (*NOS2, NKX2–3, SH2B3* and *ICOSLG*), intracellular antigenic peptide handling (*ERAP1, ERAP2, LNPEP, NPEPPS*) and CD8+ T cells (*EOMES* and *IL7R*) pathways as important in AS etiology as well as increase the number of susceptibility genes in the TH17 pathway (*TYK2* and *IL6R*). A second MHC association with the classical HLA-A*0201 was observed in both HLA-B*27 positive and negative disease (OR=1.2; P= 4.5×10^{-9}).

Conclusion: This increased characterization of the genetic architecture of AS aids greatly in explaining the currently poorly understood high observed heritability and familiality in AS. This data also guides functional studies towards uncovering how these genes cause disease and in the development of new therapeutics**.**

Disclosure: **A. Cortes**, None; **P. Robinson**, None; **M. A. Brown**, None.

Elevated Serum Level of the Vascular Endothelial Growth Factor Is Highly Predictive for New Syndesmophytes Formation in Patients with Ankylosing Spondylitis. Denis Poddubnyy[1], Kristina Conrad[1], Uta Syrbe[1], Hildrun Haibel[1], Heiner Appel[1], Martin Rudwaleit[2] and Joachim Sieper[3]. [1]Charité Medical University, Campus Benjamin Franklin, Berlin, Germany, [2]Endokrinologikum Berlin, Berlin, Germany, [3]Charité Universitätesmedizin Berlin, Berlin, Germany

Background/Purpose: In the recent years several predictors of radiographic spinal progression/syndesmophyte formation in ankylosing spondylitis (AS) were identified: syndesmophytes at baseline (the strongest predictor so far), smoking, elevated level of the C-reactive protein [1]. Furthermore, a number of predictive biomarkers (such as matrix metalloproteinase 3, procollagen II N-terminal propeptide, Wnt-antagonists) were identified, all, however, with a rather modest predictive value. Vascular endothelial growth factor (VEGF) is an essential mediator of the enchondral ossification and, therefore, might play a role in the process of syndesmophyte formation in AS.

The aim of the study was to investigate the predictive role of serum VEGF regarding radiographic spinal progression (new syndesmophytes formation) in patients with AS.

Methods: Altogether 54 patients with AS from the German Spondyloarthritis Inception Cohort (GESPIC) were included in this analysis. Radiographs of the lumbar (lateral and anteroposterior views) and cervical spine (lateral view) performed at baseline and after 2 years of follow-up were centrally collected, digitized, and subsequently scored independently by two trained readers. Syndesmophytes were considered to be present if both readers agreed on it. Serum VEGF levels were detected at baseline.

Results: At baseline, syndesmophytes were present in 25 patients (46%), after 2 years of follow-up new syndesmophytes developed in 6 patients (11%). Mean baseline VEGF value was significantly higher in patients who developed new syndesmophytes in comparison to those without radiographic progression: 544±167 vs 296±159 pg/ml, p=0.004. Receiver operating characteristic (ROC) analysis demonstrated a good performance of VEGF as a predictor of radiographic progression: area under the curve (AUC) = 0.851, p=0.005—figure. A threshold of 494 (rounded for further analysis to 500) pg/ml demonstrated both high sensitivity (83%) and specificity (92%). Elevated VEGF had a positive predictive value of 56%, negative predictive value of 98%, positive likelihood ratio (LR) = 10, negative LR = 0.18, and an odds ratio (OR) = 55.0 (95% CI 5.1–593.4), p=0.001, as a predictor of new syndesmophytes development. This association remained statistically significant also after adjustment for the baseline level of CRP, presence of syndesmophytes at baseline (or mSASSS at baseline), and smoking status.
Figure. ROC analysis of the association between VEGF serum level at baseline and development of new syndesmophytes after 2 years in AS.

Conclusion: High serum level of VEGF (>500 pg/ml) seems to be highly predictive for development of new syndesmophytes in patients with AS.

ACR Concurrent Abstract Session
Systemic Lupus Erythematosus - Human Etiology and Pathogenesis II
Tuesday, November 13, 2012, 2:30 PM–4:00 PM

2497

Altered Circulating Follicular Helper T Cell Phenotype and Subset Composition Are Associated with Disease Activity in Patients with Systemic Lupus Erythematosus. Hsi-en Ho[1], Jin Young Choi[2], Viviane M. Bunin[2], Sandra G. Pasoto[3], Solange Carrasco[3], Eduardo F. Borba[3], Celio R. Goncalves[3], Priscila R. Costa[4], Esper G. Kallas[4], Eloisa Bonfa[3] and Joseph E. Craft[2]. [1]Yale University School of Medicine, New Haven, CT, [2]Yale University School of Medicine, Internal Medicine, Section of Rheumatology, New Haven, CT, [3]Universidade de São Paulo, Division of Rheumatology, Faculdade de Medicina, Sao Paulo, Brazil, [4]Universidade de São Paulo, Division of Immunology, Faculdade de Medicina, Sao Paulo, Brazil

Background/Purpose: Autoreactive B cells in SLE undergo autoantigen selection, suggesting a requirement for germinal center follicular helper T (Tfh) cells in their maturation. However, evidence for dysregulation of Tfh cells in SLE and their potential contribution to disease remains unclear. Recently, blood CXCR5+ CD4 T cells, a heterogeneous pool consisting of functionally distinct Th1-, Th2-, and Th17-like subsets, have been proposed to be the circulating counterpart of Tfh (cTfh) cells. We now ask if changes in cTfh markers or subset composition within blood CXCR5+ cells are found in SLE patients, and the extent to which such alterations are associated with B cell and disease activity.

Methods: Blood samples from 49 clinically well-characterized SLE patients, 28 Behçet's disease (BD) patients, and 16 healthy controls were included. Expression of Tfh surface markers (CXCR5; ICOS, inducible T-cell costimulator; PD-1, programmed cell death protein-1), composition of blood CXCR5+ subsets, and frequency of plasmablasts were enumerated by flow cytometry. The phenotype of blood CXCR5+ subsets was

correlated with disease activity, clinical history, and plasmablast expansion.

Results: SLE patients had significant expansion of CXCR5+ ICOS+PD-1+ CD4 T cells compared to controls (p < 0.001). PD-1, but not ICOS or CXCR5, expression was markedly elevated in CD4 T cells of SLE patients compared to BD patients and healthy controls (p < 0.001). PD-1 MFI in CXCR5+ cells correlated with SLE disease activity index (SLEDAI; Spearman r = 0.43, p = 0.03). PD-1 MFI also correlated with expansion of plasmablasts (Spearman r = 0.34, p = 0.02). In SLE patients with high anti-dsDNA antibody titers, PD-1 expression in CXCR5+ cells was also significantly elevated compared to patients with no detectable titers (p = 0.004). Enhanced PD-1 expression was neither a function of disease duration nor past activity; rather, it reflected current disease activity. Compared to BD patients, SLE patients also had an increase in the CXCR5+ Th2 (p < 0.05) and a decrease in the Th17 (p < 0.001) subsets. Concurrently, PD-1 expression in SLE patients was significantly higher in CXCR5+ Th2 cells compared to Th17 cells (p < 0.01). The expansion of the CXCR5+ Th2 subset was also positively associated with SLEDAI scores.

Conclusion: Our results demonstrate that dysregulation of cTfh cells is strongly correlated with disease activity in SLE, supporting a potential causal relationship. The altered composition of blood CXCR5+ cells also appeared to be a fundamental cellular defect in SLE, with our results revealing a novel dimension of Tfh dysregulation that may be central to disease pathogenesis.

Biomarkers of Mitochondrial Dysfunction Correlate with Disease Activity in SLE. Zhi-Wei Lai[1], Tiffany Telarico[2], Robert Hanczko[1], Adam Bartos[1], Lisa Francis[3], Hajra I. Tily[4], Ricardo Garcia[1], Maha M. Dawood[5], Jianghong Yu[2], Ashwini Shadakshari[2], Paul E. Phillips[6] and Andras Perl[7]. [1]SUNY, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY, [3]SUNY upstate medical university, Syracuse, NY, [4]SUNY, NY, [5]SUNY Upstate, Syracuse, NY, [6]SUNY-Upstate Medical Univ, Syracuse, NY, [7]Upstate Medical University, Syracuse, NY

Background/Purpose: Systemic lupus erythematosus (SLE) patients' T cells exhibit mitochondrial dysfunction, characterized by the persistent elevation of the mitochondrial transmembrane potential ($\Delta\Psi_m$) or mitochondrial hyperpolarization (MHP), that predisposes to oxidative stress, activation of the mammalian target of rapamycin (mTOR), and pro-inflammatory death via necrosis. Here, we evaluated metabolic checkpoints of mitochondrial dysfunction as biomarkers of disease activity in patients with SLE.

Methods: 49 female SLE patients and 41 female healthy controls were matched for 209 independent study visits. SLE disease activity was assessed by using the British Isles Lupus Assessment Group (BILAG), SLE Disease Activity Index (SLEDAI), and Fatigue Assessment Scale (FAS). Peripheral blood lymphocytes (PBL) and untouched T cells (using Dynal negative T-cell isolation kit) were freshly isolated on the same morning from patients and controls matched for ethnicity and age within 10 years and investigated in parallel for $\Delta\Psi_m$, mitochondrial mass, glutathione, NO and ROI production, cytosolic ($[Ca^{2+}]_c$) and mitochondrial calcium levels ($[Ca^{2+}]_m$), T and B cell subset distribution, and mTOR activity by flow cytometry with or without CD3/CD28 co-stimulation.

Results: The SLEDAI (9.8 ± 0.5), BILAG (25.0 ±0.7) and FAS (26.3 ±0.4) scores showed significant correlations (SLEDAI and BILAG scores: r = 0.5138; p = 0.0014;. FAS and SLEDAI: r = 0.3570; p = 0.0326; FAS and BILAG, r = 0.4341; p = 0.0082). SLEDAI positively correlated with necrotic T cells (r = 0.383; p=0.007), necrotic CD4+ T cells (r = 0.418; p=0.003), and necrotic CD4-/CD8- double negative (DN) T cells (r = 0.347; p=0.016). SLEDAI negatively correlated with Foxp3+/CD25+/CD4+ Tregs (r = -0.293; p=0.043) and CD3/CD28-induced mTOR activation in CD4+ (r = -0.310; p=0.032) and CD8+ T cells (r = -0.410; p=0.004). Among the immunological biomarkers of SLEDAI, C3 negatively correlated with viable CD8+ T cells (r = -0.388; p=0.008) and positively correlated with viable CD4+ T cells (r = 0.405; p=0.005). C4 negatively correlated with MHP of T cells (r = -0.370; p=0.011) and DN T cells by TMRM fluorescence (r = -0.428; p=0.003). C4 positively correlated with viable CD4+ T cells (r = 0.302; p=0.041) and necrotic CD8+ T cells (r = 0.307; p=0.038). Anti-DNA positively correlated with the increased mitochondrial mass in DN T cells (r = 0.438; p=0.002), increased H_2O_2 levels in

CD8+ T cells (r = 0.447; p=0.002), and increased $[Ca^{2+}]_c$ in T cells (r = 0.480; p=0.001), CD4+ T cells (r = 0.467; p=0.001), CD8+ T cells (r = 0.487; p=0.001), DN T cells (r = 0.456; p=0.001), and CD19+ B cells (r = 0.432; p=0.003).

Conclusion: MHP, necrosis rate, and $[Ca^{2+}]_c$, particularly in DN T cells, represent biomarkers of disease activity in patients with SLE.

The Peroxisome-Proliferator Activated Receptor-γ Agonist Pioglitazone Modulates Aberrant T-Cell Responses in Systemic Lupus Erythematosus. Wenpu Zhao[1], Celine C. Berthier[1], Matthias Kretzler[2] and Mariana J. Kaplan[1]. [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, MI

Background/Purpose: Previous studies indicate that PPAR-γ agonists, including pioglitazone (PIO), down-regulate autoimmune responses and renal inflammation in murine SLE. However, the mechanisms implicated in this process remain unclear. We tested the effect of PIO in human SLE and control PBMCs with regards to gene regulation and various functional assays.

Methods: RNA from PIO-treated or untreated SLE and control PBMCs (4–5/group) was extracted and processed on microarrays (Affymetrix Human U133 Plus 2.0). Confirmation of modulation of specific genes was performed by real-time PCR in lupus and control CD3+, CD4+ or CD8+ T cells isolated by magnetic beads.

T cell proliferation was quantified by flow cytometry with CFSE. Numbers and function of peripheral blood T regulatory cells were quantified by flow cytometry, IL10 synthesis and by suppression assays of effector T cells.

Results: Several T cell-related pathways were highlighted in the analysis of the 1362 transcripts altered by PIO-treated vs. unteated SLE PBMCs. In contrast, only 215 mRNAs were modified in the PIO-treated vs. untreated controls. Resulting network analysis showed Interferon-γ as a major regulatory node, with PIO treatment downregulating various genes implicated in T-cell responses. These suppressive effects of PIO were confirmed in in purified CD4+ and CD8+ T cells by real-time PCR, with significative induction of downregulation of *IFN-gamma, CCL4, CCR5, CXCL10* and *HES1*, among others. PIO downregulated lupus CD4+ T cell proliferation, while it significantly increased numbers and function of lupus T regulatory cells, as assessed by IL-10 synthesis and suppression assays of T effector cells. These effects of PIO were not observed in control T cells.

Conclusion: These results indicate that PPAR-γ agonists selectively modulate T cell function in SLE. Given their beneficial effect in murine lupus, these results support the concept that PIO and related-agents should be further explored as potential therapies in this disease.

Podocyte Injury in Membranous and Proliferative Lupus Nephritis: Distinct Underlying Mechanisms? Gabriela M. Rezende[1], Vilma S. T. Viana[1], Denise M. Malheiros[2], Elaine P. Leon[3], Eduardo F. Borba[1], Neila AS Silva[2], Irene L. Noronha[4], Cleonice Silva[4] and Eloisa Bonfá[5]. [1]Division of Rheumatology - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Division of AnatomoPathology - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Division of Nephrology - Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [5]University of Sao Paulo, São Paulo, Brazil

Background/Purpose: Lupus nephritis (LN) is a major cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE) with proteinuria being the predominant common manifestation and may therefore reflect podocyte injury. Podocytes are highly specialized cells that have a relevant role in the glomerular filtration barrier and alteration in the expression of their biomarkers has been shown to be associated with podocyte dysfunction in some glomerulopathies.

A systematic analysis of podocyte-associated molecules encom-

passing different subcellular compartments was performed in a large series of LN biopsies. Expression of Wilms′ tumor protein (WT1), Synaptopodin (Synpo) and glomerular epithelial protein 1 (GLEPP1) with nuclear, cytoplasmic and membrane distribution respectively, were evaluated attempting to identify if podocyte phenotype is distinct in proliferative and membranous nephritis. Possible association of molecular expression alterations with long term proteinuria severity and outcome in lupus was also investigated.

Methods: Immunohistochemistry analysis was performed using monoclonal antibodies to WT1, Synpo and GLEPP1 proteins in 52 biopsies from patients with lupus nephritis fulfilling the revised ACR criteria for SLE. Demographic, clinical and laboratorial data at the time of biopsy were analyzed.

Results: Thirty-nine (75%) biopsies were classified as proliferative LN and thirteen (25%) as pure membranous class V. Immunohistochemistry analysis in normal kidney revealed preserved staining of WT1, Synpo and GLEPP1 podocyte biomarkers along the capillary walls. Preserved and concomitant WT1 and Synpo staining was observed in a significant higher frequency in pure class V biopsies than in proliferative LN (69.23 *vs*. 2.56%, *p*<0.0001). Likewise, preserved GLEPP1 expression was also more frequent in pure class V LN (53.85 vs. 2.86%, *p*=0.0002). Proteinuria and serum albumin levels at the time of biopsy did not statistically differ in the two groups (*p*=0.87 and *p*=0.41) whereas in the mean long-term follow-up of four years a tendency of lower proteinuria (*p*=0.050) was observed in those patients with biopsies expressing preserved WT1/Synpo staining.

Conclusion: This is the first study comparing proliferative and membranous lupus nephritis which evaluated simultaneously the expression of proteins in different subcellular podocyte compartments and provided novel evidence of preserved podocyte structural architecture predominantly in membranous lesions which may account for a better long term outcome of patients with this LN histological class. These findings suggest possible different underlying mechanisms for proteinuria in both conditions.

Mirorna Mir-150 Contributes to Chronic Kidney Injury in Lupus Nephritis by Increasing the Synthesis of Fibrotic Proteins Via Down-regulation of SOCS1. Hua Zhou[1], Sarfaraz A. Hasni[2], Mayank Tandon[1], Shyh-Ing Jang[1], Howard A. Austin[3], James E. Balow[3], Ilias Alevizos[1] and Gabor G. Illei[1]. [1]NIDCR/NIH, Bethesda, MD, [2]NIAMS/NIH, Bethesda, MD, [3]NIDDK/NIH, Bethesda, MD

Background/Purpose: We have previously shown that renal expression of miR-150 correlates with chronicity index (CI) in lupus nephritis. Since fibrosis is a major histologic feature of the CI we explored the potential role of miR-150 in renal fibrosis. Our data showed a positive correlation between fibrosis and miR-150 expression, therefore we assumed that miR-150 increases the production of pro-fibrotic molecules by downregulating a regulator of fibrotic proteins. The European Bioinformatic Institute (EBI) database identified SOCS-1 (suppressor of cytokine signaling-1) as such a target of miR-150. SOCS-1 has previously been shown to decrease fibronectin in mesangial cells as well as reduce fibronectin and collagen 1 in renal tubular fibroblast. SOCS1−/− mice developed lupus nephritis-like disease. We hypothesized that miR-150 increases the synthesis of profibrotic molecules by down regulating SOCS1.

Methods: The localization of miR-150 in kidney was identified by in situ hybridization in 6 kidney needle biopsies from patients with lupus nephritis (3 from patients with high renal miR-150 and 3 from patients with low renal miR150) and 2 kidneys from autopsies without known kidney diseases. Renal collagen 1(COL1) immunofluorescent staining was performed on the same samples. Primary human renal proximal tubular epithelial cells (RPTEC) and primary human mesangial cells (MC) were used for transfection with miR-150. To confirm SOCS1 as a mir-150 target a luciferase gene linked with the 3'UTR of SOCS1 was cotransfected with miR-150 in RPTEC cells and the luciferase activity was measured 48hrs after the cotransfection. Protein expression of SOCS1 and fibrotic proteins, COL1, collagen 3 (COL3) and fibronectin (FN) were analyzed by western blot in these cultured cells 48hr after miR-150 transfection.

Results: miR-150 predominantly localized in renal cortical proximal tubular cells. Moderate staining was seen in podocytes in kidney biopsies

with high but not in those with low renal miR-150 expression. Immunofluorescent staining showed significantly increased COL1 in kidney biopsies with high renal miR-150 and high CI compared to the kidneys with low renal miR-150 and low CI. Luciferase activity linked to the 3'UTR of SOCS1 was downregulated to 68.5% (p<0.01) of control cells by miR-150 in RPTEC, confirming SOCS1 as a direct target of miR-150. miR-150 transfection significantly decreased SOCS1 signal and increased expression of FN in both RPTEC and MC whereas it led to increased levels of COL3 in RPTEC and COL1 levels in mesangial cells.

Conclusion: miR-150 transfection increased the synthesis of pro-fibrotic molecules in two primary human renal cells by downregulating the expression of SOCS1, a negative regulator of fibrosis. These data together with the previously described observavtion that miR-150 expression in lupus nephritis correlates with chronicity index suggest that miR-150 plays an important role in chronic kidney injury in lupus nephritis.

Neutrophil Extracellular Trap-Associated Protein Activation of the Inflammasome Is Enhanced in Lupus M1 Macrophages. J. Michelle Kahlenberg, Carolyne K. Smith, Carmelo Carmona-Rivera and Mariana J. Kaplan. University of Michigan, Ann Arbor, MI

Background/Purpose: Neutrophil extracellular traps (NETs) contain numerous bactericidal proteins and are an important defense mechanism against microorganisms. Clearance of NETs is impaired in a subset of patients with systemic lupus erythematosus (SLE), which may contribute to disease pathogenesis. Additionally, we recently described that NETs are vigorously and spontaneously released from low density granulocytes (LDGs) isolated from lupus patients and that these lattices are toxic to the endothelium, expose immunostimulatory molecules and may participate in organ damage through incompletely characterized pathways. We propose that in antigen presenting cells, NETs may act as strong activators of inflammatory pathways, such as the inflammasome, contributing to organ damage. We have examined the role of NETs in inflammasome activation and have specifically characterized the ability of one NET-associated antibacterial peptide, LL37, in stimulating this process.

Methods: Primary human macrophages were derived from monocytes isolated from control and lupus patients. Murine macrophages were cultured from bone marrow. M1 and M2 differentiation were promoted by growth in GM-CSF or M-CSF, respectively, and confirmed by FACs. Spontaneously-induced NETs from LDGs were isolated by micrococcal nuclease incubation to allow their release into the supernatant. Macrophages were primed for 4 hours with 100 ng/ml LPS, prior to stimulation with LL37 peptide or NETs for 2 hours. Active IL-1beta and IL-18 release was determined by ELISA. Quantification of caspase-1 activation was determined by incubating macrophages with a specific fluorogenic marker, followed by fluorescent microscopy.

Results: Stimulation of human macrophages with NETs resulted in activation of caspase-1 and in IL-1beta and IL-18 activation and secretion. Incubation of macrophages with the NET-associated peptide LL37 resulted in robust activation of caspase-1 and release of IL-1beta and IL-18; this activation was enhanced in M1 versus M2 macrophages. Caspase-1 activation required the NLRP3 inflammasome, as murine macrophages deficient in NLRP3, ASC or caspase-1 did not respond to the murine LL37 analog mCRAMP, whereas wild-type macrophages demonstrated caspase-1 activation and IL-1beta release. Comparison of control versus lupus macrophage dose responses to LL37 revealed a lower threshold for inflammasome activation in lupus macrophages, suggesting that exposure to this molecule in vivo may trigger enhanced inflammatory responses. Exposure of lupus macrophages to NETs also led to a significant increase in caspase-1 activation when compared to control macrophages.

Conclusion: Macrophages isolated from lupus patients have enhanced activation of the inflammasome in response to NETs or to the NET-associated peptide LL37. As NETs are increased in SLE, these results suggest that these structures could be an important trigger for inflammasome activation and the resultant downstream inflammatory pathways in SLE patients.

CD8+Foxp3-CD103+ Regulatory T Cells Generated Ex Vivo with TGF-β Suppress Autoimmunity Through IL-10-Dependet Mechanism. Ya Liu[1], An-Ping Xu[2], David A. Horwitz[3] and Song G. Zheng[3]. [1]USC Keck School of Medicine, Los Angeles, CA, [2]2nd Affiliated Hospital of Sun Yat-sen University, [3]Keck School of Medicine of USC, Los Angeles, CA

Background/Purpose: TGF-β is crucial for induction of CD4+Foxp3+ Tregs and maintenance of immunologic tolerance. It is, however, unclear if TGF-β also induces the similar CD8+ Tregs.

Methods: CD8+Foxp3- cells isolated from Foxp3-GFP knock-in mice were stimulated with anti-CD3/28 antibodies and IL-2 with (Tregs) or without TGF-β (Tcon cells). After 3–4 days, Granzyme A/B, Perforin and other Tregs related markers were examined by FACS staining. GFP+, GFP-, GFP+CD103+, GFP+CD103-, and GFP-CD103- were sorted. Suppressive activity in vitro was examined by adding various ratios of CD8+ subsets to responder T cells. Anti-TGF-β, anti-IL-10R, or the TGF-β receptor I (ALK5) inhibitor was added to some cultures. The effect of CD8+ Tregs in vivo was tested following iv injection with 5×10^5 C57BL/6 CD4+CD45RB^{high} cells to Rag2-/- mice. CD8+ iTregs were also injected to Experimental Allergic Encephalomyelitis (EAE) model and lupus-like chronic Graft-versus-host disease (GVHD) model.

Results: While CD8+ iTregs displayed much low Foxp3 expression compared with compartment CD4+ cells, their suppression activity in vitro and in vivo was equivalent or even better. These cells did not express Granzyme A, B or Perforin A and lacked cytotoxic activity on T response cells. CD8+ iTregs generated from Granzyme B and Perforn A KO mice still suppressed autoimmunity. Transwell experiments revealed that cell-contact is required for their suppression. CD8+ iTregs infusion markedly suppressed experimental colitis, EAE and cGVHD. Both Foxp3- and Foxp3+ subsets from TGF-primed CD8+ cells had suppressive activities. Among CD8+Foxp3- cells, CD103 is crucial for their generation and function since CD8+ but not CD4+ iTreg production decreased on CD103 KO mice. CD4+CD103+Foxp3- subset suppressed colitis through IL-10 signal.

Results: While CD8+ cells primed with TGF-β (CD8+ iTregs) displayed much low Foxp3 expression compared with compartment CD4+ cells, their suppression activity in vitro and in vivo was equivalent or even better than CD4+ Tregs. These cells did not express Granzyme A, Granzyme B or Perforin A and lacked cytotoxic activity on T response cells. Additionally, CD8+ iTregs generated from Granzyme B and Perforn A KO mice still suppressed autoimmunity. Transwell experiments revealed that cell-contact is required for their suppressive activity. Adoptive transfer of the CD8+ iTregs markedly suppressed experimental colitis, EAE and cGVHD. We further found both Foxp3- and Foxp3+ subsets from TGF-primed CD8+ cells had suppressive activities. Among CD8+Foxp3- cells, we identified CD103 expression is crucial for their generation and function since CD8+ but not CD4+ iTreg production decreased on CD103 KO mice. Adoptive transfer of CD4+CD103+Foxp3- subset suppressed colitis and EAE and IL-10 signal seems to be crucial for this therapeutic effect.

Conclusion: TGF-β can induce CD8+Foxp3- and CD8+Foxp3+ iTreg subsets that displayed suppressive activity in cell contact-dependent, non-cytotoxic manner and have protective effects on autoimmune diseases. Generation of CD8+ iTregs may have considerable therapeutic potential on patients with autoimmune diseases.

SOCS1 Is One of the Key Molecules to Prevent the Plasticity of Regulatory T Cells and the Development of Autoimmunity. Reiko Takahashi[1], Kenji Itoh[1], Fumihiko Kimura[1] and Akihiko Yoshimura[2]. [1]National Defense Medical College, Tokorozawa, Japan, [2]Keio University School of Medicine, Tokyo, Japan

Background/Purpose: Suppression of autoimmunity or inflamation by regulatory T cells (Tregs) is now well established, recently, natural Foxp3+ T cells have been shown to be a heterogeneous population consisting of a committed Treg lineage and an uncommitted subpopulation with develop-

mental plasticity. Tregs have been reported to convert into Th1- or Th17-like cells (exFoxp3 cells) under lymphopenic or inflammatory conditions, which might be one of causes of autoimmunity. SOCS1 is defined as an important mechanism for the negative regulation of the cytokine-JAK-STAT pathway. SOCS1-deletion specifically in T cells (LckCre-SOCS1-flox mice) or Tregs (Foxp3Cre-SOCS1-flox mice) induced lupus-like phenomenon such as dermatitis, splenomegaly and lymphoadenopathy, suggesting a defective Treg function in these mice.

We examined the role of SOCS1 to maintain the Foxp3 expression or suppressive functions in natural Tregs.

Methods: Natural Tregs (CD3$^+$CD4$^+$CD25$^+$Foxp3^{GFP}) from LN of wild type (WT), LckCre-SOCS1-flox, or Foxp3Cre-SOCS1-flox mice sorted by flowcytometry

Transfer of Treg cells with naïve T cells into $Rag2^{-/-}$ mice

Single transfer of Tregs into $Rag2^{-/-}$ mice

Tregs cultured with CD3/CD28 or antigen presenting cells in vitro

Results: 1) SOCS1$^{+/+}$Tregs from WT mice efficiently suppressed colitis induced by naive CD4$^+$ T cell transfer into $Rag2^{-/-}$ mice, however, SOCS1$^{-/-}$ Tregs from LckCre-SOCS1-flox mice could not prevent it (n=3). Only SOCS1$^{-/-}$ Tregs transferred into $Rag2^{-/-}$ mice caused colitis, lost Foxp3 expression more rapidly, and converted into IFNγ-producing cells accompanying with hyperactivation of STAT1 (n=3). Foxp3 was stable in IFN$\gamma^{-/-}$ SOCS1$^{-/-}$Tregs (n=3).

2) Because Tregs from LckCre-SOCS1-flox mice were constantly exposed to inflammatory cytokines from non-Treg cells in vivo, we then analyzed Treg specific SOCS1 deficient mice (Foxp3Cre-SOCS1-flox). Tregs from Foxp3Cre-SOCS1-flox mice maintained Foxp3 expression transferred into $Rag2^{-/-}$ mice, on the contrary, those from LckCre-SOCS1-flox mice (n=3).

3) Tregs from LckCre-SOCS1-flox mice produced IFNγ after culture with CD3/CD28 in vitro, however, Tregs from Foxp3Cre-SOCS1-flox mice did not (n=3). When Tregs from Foxp3Cre-SOCS1-flox mice were cultured with antigen presenting cells (APCs) from LckCre-SOCS1-flox mice, they produced IFNγ, which was blocked by anti-IL-12 antibodies (n=3).

Conclusion: SOCS1 plays important roles in maintaining Foxp3 expression and is necessary for suppression activity of Tregs by regulating STAT1 under inflammatory conditions in which APCs are highly activated.

Involvment of CD4$^+$ FoxP3$^+$ Regulatory T Cells in Interleukin-6 Receptor Targeted Treatment in Murine Arthritis and Rheumatoid Arthritis. Allan Thiolat[1], Jerome Biton[1], Luca Semerano[1], Yves-Marie Pers[2], Pierre Portales[2], Delphine Lemeiter[1], Patrice Decker[1], Christian Jorgensen[2], Pascale Louis-Plence[2], Natacha Bessis[1] and Marie-Christophe Boissier[1]. [1]EA4222, Li2P, University Paris 13, Sorbonne Paris Cité and Rheumatology Department, Avicenne Hospital, Assistance Publique-Hôpitaux de Paris (AP-HP), Bobigny, 93009, France, Bobigny, France, [2]Inserm U844, CHU saint-Eloi, Université Montpellier 1, CHU Lapeyronie, Montpellier, France

Background/Purpose: Studies have demonstrated the clinical efficacy of tocilizumab, a humanized anti-IL-6 receptor (R) antibody (Ab), in patients with rheumatoid arthritis (RA). The rational for blocking IL-6 in this disease mainly lays on the pro-inflammatory role of this cytokine in the disease. However, only few works have studied the consequences of anti-IL-6R treatment on Tregs cells and mainly focuses on their frequency. Our objective was thus to elucidate anti-IL-6R mode of action, by studying the consequences of this treatment on Tregs phenotype and biological activity. in RA patients treated with tocilizumab and in a RA model, namely collagen-induced arthritis (CIA).

Methods: Mice with CIA were treated at day 0 by MR16-1 (a rat anti-mouse IL-6 receptor monoclonal Ab provided by Chugai Pharmaceutical Co. LTD, Japan) and the evolution of Tregs (defined as CD4$^+$ FoxP3$^+$) during arthritis course was assessed at key time points (day 8–18–28 and 42 after CIA induction) by studying their number, frequency and phenotype (expression of GITR, ICOS, Helios, CD62L, CTLA-4 and CD39) in lymph nodes (LN), thymus and spleen by flow cytometry. The immunosuppressive activity of the Treg cells on CFSE-labeled CD4+ CD25- T effector (Teff) cells proliferation was also studied. Numerical analysis of Th17 and Th1 cells was also performed at the same times by flow cytometry.

Twenty patients with severe and active RA, refractory to methotrexate or anti-TNF therapies were recruited and treated with 8mg/kg of tocili-

zumab monthly. Peripheral blood was recovered for each patient at day 0, as well as 1 and 3 month, and Th17and Tregs were analyzed by flow cytometry.

Results: In mice, clinical and histological evaluation of arthritides in mice treated with anti-mouse IL-6R mAb showed, as expected, a less severe disease as compared to control Ig treated mice. Th17 frequency was unchanged, but Tregs frequency was enhanced in the LN of MR16-1 treated mice. In the thymus, we observed an enhanced frequency of Tregs $CD4^+CD8^-FoxP3^+$. Tregs phenotype was also modified in treated mice, with an increased frequency of $CD39^+$ Tregs (LN and spleen), suggesting an enhanced ATP hydrolysis immunosuppressive activity of Tregs. In contrast, the immunosuppressive activity of the Treg cells on Teff cells proliferation was not modified.

In RA patients, we also shown that tocilizumab did not changed Th17 frequency but rather acted on Tregs. Indeed, in responder patients to tocilizumab, $CD4^+CD25^+FoxP3^+$ staining was confined to $CD127^{low}$, suggesting the induction of induced Tregs following treatment.

Conclusion: Tregs, but not Th17, are modified by anti-IL-6R treatment in RA, that could result in an enhanced central and peripheral generation of Tregs. These results highlight the benefit of therapeutic approaches based on Treg promotion in RA, and stress the relevance of the monitoring of cell populations in arthritis following cytokine blockade.

Expression of Helios Facilitates Distinction Between FoxP3$^+$ Treg and FoxP3$^+$ Activated T Conventional Cells in Patients with Systemic Lupus Erythematosus. Amit Golding[1], Sarfaraz A. Hasni[2], Gabor G. Illei[3] and Ethan M. Shevach[4]. [1]NIAID/National Institutes of Health, Bethesda, MD, [2]National Institutes of Health, Bethesda, MD, [3]NIDCR/NIH, Bethesda, MD, [4]NIAID/NIH, Bethesda, MD

Background/Purpose: FoxP3 is not a reliable marker for distinguishing regulatory T (Treg) cells in humans due to the fact that FoxP3 may be up-regulated in activated, conventional T (Tconv) cells. Recently, the marker CD45RA has been added to distinguish RA^+, "resting" FoxP3$^+$ Tregs from RA^- "activated" FoxP3^{hi} Tregs (Miyara et al, 2009). This scheme has also included a third "non-Treg" group that is RA^- and expresses lower levels of FoxP3 similar to that seen in RA^+ Tregs. Previous data demonstrated that in normal individuals as well as in patients with systemic lupus erythematosus (SLE), the largest subset of FoxP3$^+$cells is, in fact, the "non-Treg" group. The transcription factor Helios has recently been defined as a marker of thymus-derived Tregs in both mouse and man (J. Immunol. 2010). The goal of this study was to determine if expression of Helios could reliably indicate what fraction of FoxP3$^+$cells are true Tregs in healthy controls and in SLE patients.

Methods: Samples included 35 healthy donors and 52 SLE patients (23 SLEDAI 0; 19 SLEDAI 2–4; 10 SLEDAI 6–20). Ficoll-purified PBMCs were surface stained followed by fixation/pemeabilization and intracellular staining prior to FACS analysis. When appropriate, cells were pre-stimulated for 4–5 hours with PMA/ionomycin/golgistop. CpG methylation analysis of sorted cells was performed using the Qiagen EpiTect platform.

Results: We found that $CD4^+$ T cells in SLE patients contain both resting (RA^+) and activated (RA^-/FoxP3^{hi}) Tregs and that the majority of cells in each group were Helios$^+$, (3/4 and 4/5, respectively). Surprisingly, even within the sub-group defined as "non-Tregs", the majority of the cells in both healthy controls (2/3) and SLE patients (3/4) were Helios$^+$. All FoxP3$^+$ Helios$^+$ cells, including those within the "non-Treg" RA^- subset, were found to be demethylated at the FoxP3 locus (a gold standard epigenetic mark of the Treg lineage), as compared to Helios$^-$cells. In pre-stimulated cells, FoxP3$^+$ Helios$^-$ cells consistently produced significantly high amounts of cytokines (IFN-gamma and IL-2), whereas FoxP3$^+$Helios$^+$ cells produced essentially no cytokines, which is characteristic of Tregs. In SLE patients with mild and highly active disease, there was a significant increase in both the % Foxp3$^+$Helios$^+$ and % FoxP3$^+$Helios$^-$ relative to both healthy controls and inactive patients (p<0.05, Mann-Whitney test). There was not a significant difference for *absolute* numbers of either Helios$^+$ or Helios$^-$ cells, likely due to the significant reduction in total CD4 counts in more active patients (p<0.05, Mann-Whitney test).

Conclusion: Expression of Helios is a highly useful tool for distinguishing true Tregs from FoxP3$^+$ cells that include activated Tconvs. The use of Helios has allowed us to de-convolute the largest subset of CD45RA-based grouping of FoxP3 cells. Furthermore, we have also shown that active SLE patients *do* have a higher frequency of FoxP3$^+$Helios$^+$ Tregs, but that in active SLE patients these are counter-balanced with a higher frequency of Foxp3$^+$Helios$^-$ cells that contain cytokine-producing Tconvs. Future studies may make use of Helios to reliably monitor both true Tregs and activated Tconvs in SLE and other autoimmune diseases.

Activated Cullin-Ring Ubiquitin Ligases (CRLs) Dampen T Cell Signaling and Inactivation of Crls Arrests the Progression of Inflammatory Arthritis. Leonard L. Dragone[1], Lisa K. Peterson[1], Allison Berger[2] and Samantha F. Friend[1]. [1]National Jewish Health, Denver, CO, [2]Millennium Pharmaceuticals, Inc, Cambridge, MA

Background/Purpose: The role of Cullin-Ring ubiquitin ligase (CRL) activity in regulating T cell function is largely unexplored. Thus, we sought to determine if cullin neddylation and CRL activity regulates signaling initiated through the T-cell receptor (TCR) complex to modulate T cell activation and effector functions.

Methods: To determine if TCR complex signaling affects CRL activity, we treated T cells *in vitro*, with a specific neddylation inhibitor (MLN4924), a drug currently undergoing clinical trials for several malignancies, that prevents CRL activation in combination with CD3 activation and measured IL-2 production. We then assessed CRL activity during TCR complex signaling by examining the neddylation status of the cullin subunit of the CRL. In addition, we knocked down the cullin subunit of the CRLs in T cell lines and examined T cell function. Further we treated arthritis prone mice that have a TCR signaling defect with MLN4924 *in vivo* to assess the impact of CRL inactivation on T cell activation and effector function.

Results: Treating T cells with MLN4924 lowers the threshold for TCR signaling, as evidenced by enhanced IL-2 production and regulatory T cell (Treg) development upon suboptimal TCR stimulation. Moreover, MLN4924 treatment of the arthritis-prone SKG mouse, arrests arthritis progression and decreases the numbers of IL-17 producing T cell effectors *in vivo*. We found that strong TCR complex signaling results in cullin deneddylation, which renders the CRL inactive. After knocking down cullins in T cell lines, we found that IL-2 production is increased compared to the parental cell line, but some individual cullin knockdowns do not achieve the same enhancement of IL-2 production as MLN4924 treatment, suggesting that multiple CRLs contribute to regulating TCR complex signaling and IL-2 production.

Conclusion: Thus, we propose that strong TCR complex signaling normally triggers cullin deneddylation to shut off CRL activity and the otherwise tonic ubiquitination and degradation of proteins essential for TCR complex signaling and IL-2 production. Ongoing studies are elucidating the specific CRL targets that contribute to the phenotype seen.

Significance: These findings represent the first step in understanding the interplay between neddylation, CRL-mediated ubiquitination and TCR complex signaling. Expanding our knowledge of how CRLs neddylation regulates TCR complex signaling and T cell function will create opportunities for developing drugs to modulate T cell function to treat immune-mediated diseases.

miR142-3p Interfers with T Cell Proliferation by Targeting the Expression of Garp in Patients with Rheumatoid Arthritis. Qihui Zhou, Sonja Haupt, Johannes Thomas Kreuzer, Hendrik Schulze-Koops and Alla Skapenko. University of Munich, Munich, Germany

Background/Purpose: Rheumatoid arthritis (RA) is a systematic chronic inflammatory disorder, characterized by severe joint destruction. Regulatory T cells (Tregs) have been implicated to be important for maintaining peripheral tolerance and controlling disease development. A novel surface protein, Glycoprotein A repetitions predominant (GARP), was recently identified to be specifically expressed on human Tregs and important for the suppressive capacity of Tregs. Several studies suggest that GARP expression in Tregs is post-transcriptionally regulated. In this study, we investigated in detail miRNA regulation of GARP expression, and dissected

the functional outcome of miRNA:GARP-mRNA interaction and its resulting effects in patients with RA.

Methods: *In silico* analysis was performed to predict putative miRNA binding sites (MRE) in the 3'UTR of the GARP mRNA. Luciferase reporter vectors were used to identify specific GARP 3'UTR-recognizing MREs. Ribonucleoprotein immunoprecipitation (RNP-IP) was performed using antibodies against the Ago1- or Ago2-asscociated RISC complex. For cell proliferation and GARP expression, CD25+ and CD25- CD4 T cells were isolated from the peripheral blood. Cells were transfected with miRNA mimics or antagomirs and labeled with CFSE. The proliferating capacity was accessed by FACS. For Treg function assays, CD25+ T cells were transfected with miRNA mimics and co-cultured with CFSE-labeled CD25- T cells. Eight patients with early treatment naive RA (disease duration 3.0±2.4 months, DAS28 5.2±1.2) and 20 age and gender-matched healthy individuals were analyzed for GARP surface expression as accessed by FACS, or GARP mRNA and miRNA expression as measured by RT-PCR.

Results: The distal part of the GARP 3'UTR was capable to down-modulate reporter protein expression. Within this region, one MRE was recognized by its miRNA, miR142-3p. Mutation of this site abrogated the respective miRNA recognition confirming the specificity of the binding to the GARP 3'UTR. GARP mRNAs and miR142-3p were both immunoprecipitated in the Ago2-associated RISC complex by RNP-IP using an antibody against Ago2. Co-transfection with the antagomir of miR142-3p prevented GARP mRNA loading into the Ago2-associated RNP complex. CD25+ CD4 T cells treated with the antagomir showed a higher proliferating capacity upon stimulation. Complementary, treatment of cells with miRNA mimics lead to reduction of proliferation. CD25+ CD4 T cells treated with miRNA mimics showed a reduced suppressive capacity. The up-regulation of miR-142-3p was more prominent in RA patients than in healthy individuals resulting in consequentially diminished up-regulation of GARP.

Conclusion: We identified and characterized miR-142-3p regulation of GARP expression in Tregs. miR142-3p is critical for high GARP expression on Tregs and therefore for Treg function. Delineation of miR-142-3p expression and the linked GARP expression in RA provides an important hint for the reduced Treg function in RA.

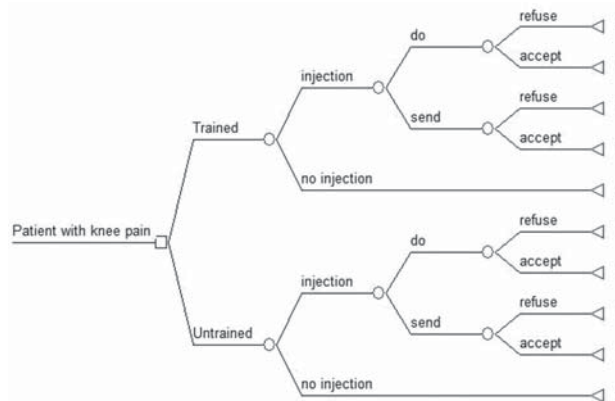
Cost-Effectiveness of Training Rural Providers to Perform Joint Injections. Michael J. Battistone, Richard E. Nelson, William D. Ashworth, Andrea Barker. Marissa Grotzke, Timothy A. Huhtala, Robert Z. Tashjian and Grant W. Cannon, Salt Lake City VA and University of Utah, Salt Lake City, UT

Background/Purpose: Community based outpatient clinics (CBOCs) have been established by the Department of Veteran Affairs (VA) to provide primary care services to veterans living in remote and rural regions. While CBOCs provide excellent primary care services, the current model does not allow providers in CBOCs to develop and deliver specialty services. The objective of this study was to evaluate the cost-effectiveness of training rural primary care providers to perform knee injections in CBOCs, rather than referring the patient to an urban medical center with rheumatology and orthopaedic specialists. Referral often involves significant travel for patients in rural areas.

Methods: We developed a decision analytic model to compare costs and outcomes between rural providers who are trained to perform knee injections and those who are not trained. In the model, each type of provider is presented with a hypothetical patient who has knee pain and should receive an injection. Costs included in the model (including medical management for patients who do not receive an injection, training of the rural provider to perform injections, travel reimbursement for patients who are sent to an urban medical center) were from the perspective of the VHA. The effectiveness outcome was quality-adjusted life years (QALYs). In our primary analysis, a range of values were used for 2 key inputs: the number of patients with knee pain presenting to the rural clinic in 1 year period (range:10–100) and the average distance from the patients' home address to the urban medical center (range:50–500). Probabilistic sensitivity analyses were performed using

1,000 2nd order Monte Carlo simulations and the benefits of knee injection were assumed to last 90 days.


Results: In our base case analyses (which assumed 30 patients per year presenting with knee pain that could benefit from an injection and an average distance of 100 miles from the patient's home adders to the urban medical center), the incremental cost-effectiveness ratio (ICER) for trained rural providers was $27,692/QALY. ICERs were more sensitive to the number of patients than to distance Table 1. Training rural providers was cost-effective in 68.6% of 1,000 Monte Carlo simulations at a willingness to pay threshold of $50,000/QALY.

Incremental cost effectiveness ratios for range of values for average distance and number of patients per year (US dollars/QALY)

	Number of patients			
Distance	10	30	50	100
50	$70,732	$27,888	$19,319	$12,893
100	$70,536	$27,692	$19,124	$12,697
200	$70,145	$27,301	$18,732	$12,305
500	$68,970	$26,126	$17,557	$11,130

Conclusion: Training rural providers to perform knee injections for patients with knee pain appears cost-effective at the commonly used threshold of $50,000/QALY if sufficient numbers of such patients are seen at rural primary care clinics. We are currently implementing such a training program to test the validity of these projections.

2510

Patient and Provider Factors Associated with Compliance with Rheumatoid Arthritis Treatment Recommendations. Leslie R. Harrold[1], George W. Reed[2], Katherine C. Saunders[3], Ying Shan[1], Tanya Spruill[4] and Jeffrey D. Greenberg[5]. [1]UMass Medical School, Worcester, MA, [2]University of Massachusetts Medical School, Worcester, MA, [3]CORRONA, Inc., Southborough, MA, [4]NYU School of Medicine, New York, NY, [5]New York University School of Medicine, New York, NY

Background/Purpose: Only approximately 50% of rheumatoid arthritis (RA) patient with active disease receive care consistent with the American College of Rheumatology (ACR) recommendations for the use of biologic and nonbiologic disease modifying anti-rheumatic drugs (DMARDs). Therefore we examined patient and provider factors associated with receipt of the recommended care using data from a multi-center observational registry within the United States (the Consortium of Rheumatology Researchers of North America: CORRONA).

Methods: We identified biologic naïve RA patients cared for within the CORRONA network between 12/08 and 12/11. Initiation or dose escalation of biologic and nonbiologic DMARDs in response to active disease (using the Clinical Disease Activity Index) was assessed in comparison to the ACR recommendations. The population was divided into two mutually exclusive cohorts: 1) methotrexate (MTX) only users; and 2) multiple non-biologic DMARD users. We compared the characteristics of patients (age, gender, race/ethnicity, working status, insurance

and RA disease characteristics) who received care consistent with the ACR recommendations and their treating providers (gender, years since medical school graduation, academic vs. private practice and region of the country [Northeast, South, Midwest and West]) to those who did not in the two cohorts with active disease using logistic regression adjusting for clustering of physicians and patients.

Results: There were 5,196 patients who met inclusion criteria cared for by 191 providers at 86 practice sites. Of the 991 MTX only users with active disease (moderate disease activity with a poor prognosis or high disease activity), 44% received care consistent with the treatment recommendations. In adjusted analyses, patient characteristics including age 65 and older (OR 0.70; 95% CI 0.54–0.91), female gender (OR 1.47, 95% CI 1.10–1.98) and prednisone dose (OR 1.37, 95%CI 1.05–1.79) were associated with care practices while physician characteristics were not. Among the 1209 multiple nonbiologic DMARD users with moderate or high disease activity, 48% received care consistent with the recommendations. Patient age 65 and older (OR 0.73, 95% 0.57–0.94), residence in the South (OR 0.69, 95% CI 0.50–0.94) or Midwest (OR 0.73, 95% CI 0.54–0.99) and care by a private practice rheumatologist (OR 0.56, 95% CI 0.37–0.83) were associated with a reduced likelihood of receiving care consistent with the recommendations.

Conclusion: Compliance with the ACR treatment recommendations is influenced by both patient and provider characteristics. Identification of these characteristics will help us identify which patients and providers to target for interventions to improve care.

2511

Potential Barriers That Limit Access to Rheumatologists Among Patients with Early Rheumatoid Arthritis in a Universal Access Health Care System. Jessica Widdifield[1], J. Michael Paterson[2], Sasha Bernatsky[3], Karen Tu[2], Nadia Gunraj[2], Noah Ivers[1], Debra Butt[2], R. Liisa Jaakkimainen[1], J. Carter Thorne[4], Vandana Ahluwalia[5] and Claire Bombardier[1]. [1]University of Toronto, Toronto, ON, [2]Institute for Clinical Evaluative Sciences, Toronto, ON, [3]Research Institute of the McGill University Health Ctre, Montreal, QC, [4]Southlake Regional Health Centre, Newmarket, ON, [5]William Osler Health Center, Mississauga, ON

Background/Purpose: Current guidelines for the optimal care of rheumatoid arthritis (RA) recommend prompt referral to a rheumatologist. In the province of Ontario, Canada all 13 million residents are covered by universal public health insurance. However, almost 2 million residents do no have a regular family physician. Previous research has shown that sustained continuity of primary care plays a positive role in patient health outcomes for other chronic diseases. However, the impact of sustained continuity of primary care on access to rheumatologists remains unstudied. This is particularly concerning since family physicians function as gatekeepers for access to rheumatologists. Our objective was to estimate the percent of incident RA patients who see a rheumatologist within 1 year of diagnosis, and to identify determinants of contact with a rheumatologist within 1 year of RA diagnosis.

Methods: We assembled an incident RA cohort aged >65 years from Ontario health administrative data across 1997–2008. We used a validated algorithm to identify 27,127 seniors with early RA. We followed patients for 1 year, assessing if they had a visit to a rheumatologist. We assessed secular trends and differences for patients who saw a rheumatologist versus those who had not. We performed multilevel logistic regression analyses to determine whether receipt of rheumatology care was associated with: patient characteristics, primary care physician characteristics and provider continuity, and geographic characteristics.

Results: Overall, 17830 (66%) seniors with early RA identified over 1997–2008 saw a rheumatologist within 1 year of diagnosis. This increased from 50% in 1997 to 78% in 2008. The majority of patients (67%) were female. Few patients (16%) resided in rural areas. Factors associated with a rheumatologist encounter included increasing continuity of primary care, [adjusted Odds Ratio (aOR)=1.30 95% CI 1.11, 1.53], patients of highest socioeconomic status (SES) [aOR=1.24 95% CI 1.13–1.36], and having more rheumatologists in the area (Rheumatology supply per 100,000 adults aOR=1.20 95% CI 1.16, 1.24). Less contact with rheumatologists occurred among patients with increasing age (aOR= 0.97 95% CI 0.97, 0.98), patients

who had male primary care physicians (aOR=0.73 95% CI 0.66, 0.80), residing in a rural area (aOR=0.74 95% CI 0.68, 0.81) and at a remote distance (≥100 km) to the closest rheumatologist (aOR=0.37 95% CI 0.31, 0.44).

Conclusion: Improvements in access to rheumatologists for RA care have occurred over time but more efforts are needed. Potential barriers that limit timely access to rheumatologists include increasing age, lower SES, and having a male primary care physician. Measures of poor access (poor continuity of primary care, density and proximity to rheumatologists) negatively impacted rates of encounters with a rheumatologist. Proactive, tailored approaches are needed to provide rheumatology care to such populations.

2512

Changes in Bone Marrow Lesion Volume Relate to Changes in Knee Pain. Data From the Osteoarthritis Initiative. Jeffrey B. Driban[1], Lori Lyn Price[1], Grace H. Lo[2], Jincheng Pang[3], Eric Miller[3], Charles Eaton[4], John A. Lynch[5] and Timothy E. McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX, [3]Tufts University, Medford, MA, [4]Warren Alpert Medical School at Brown University, RI, [5]University of California at San Francisco, San Francisco, CA

Background/Purpose: Changes in bone marrow lesions (BMLs), common magnetic resonance (MR) imaging findings in osteoarthritis (OA), are predictive of OA progression. However, it is unclear if quantitative measurements of BML volume change are related to knee pain. Therefore, the purpose of this study was to determine whether quantitative measures of BML volume change are positively associated with knee pain change.

Methods: The sample comprised 404 participants in the Osteoarthritis Initiative (OAI) progression cohort who had sagittal intermediate-weighted, turbo spin echo, fat-suppressed MR images at the 24- and 48-month OAI visits. The right knee was assessed unless contraindicated. BML volume was determined on the sagittal fat-suppressed MR images by one rater using a semi-automated segmentation method (ICC [3,1 model] = 0.95). BML volumes were calculated for each knee region and then summed to form a total knee BML volume (cm^3). Knee pain was defined based on WOMAC pain score at the 24- and 48-month OAI visits. Multiple linear regressions were used to evaluate the association between the WOMAC pain, as an outcome, and BML volume while controlling for sex, weight, height, and age. To further explore these associations we assessed the associations stratified among tertiles based on baseline BML volume. Based on diagnostic tests (e.g., DFFITs, Cook's D) for the linear regression models among tertiles we opted to perform robust regression models. WOMAC scores and participant characteristics are available at http://oai.epi-ucsf.org.

Results: The cohort included 199 (49%) females and were 64.9 ± 9.2 years old, 85.3 ± 16.2 kg, and 1.7 ± 0.1 m. The average baseline total knee BML volume was 2.6 ± 2.7 cm^3(range =0.1 to 10.2 cm^3). Total knee BML volume change was -0.2 ± 2.1 cm^3(range =-12.7 to 10.2 cm^3; see Figure). Larger BML volumes are associated with greater knee pain and larger BML volume changes are associated with worsening knee pain (see Table). Stratified analyses by baseline BML volume (tertiles) indicated that only in the first tertile (no BMLs or BMLs < 1.0 cm^3) was BML volume change and WOMAC pain change significantly related (estimate = 0.65, standard error =0.25, p = 0.009).

Table. Cross-sectional and Longitudinal Association between BML Volume and WOMAC Pain

Outcome Variable Stratified by Baseline BML Volume Tertile	Descriptives Mean ± SD	Models* with Baseline BML Volume B (p-value)	Models* with BML Volume Change B (p-value)
Full Cohort (n = 404)			
WOMAC pain (baseline)	3.3 ± 3.4	0.16 (0.01)	n/a
WOMAC pain (change)	0.0 ± 3.0	−0.01 (0.87)	0.21 (0.004)

* All models adjusted for sex, weight, height, and age. SD = standard deviation, BML = bone marrow lesion, B = parameter estimate, n/a = not assessed.
Figure. Scatter plot of WOMAC Pain Change by BML Volume Change Stratified by Tertiles (colors). Tertiles, based on baseline BML volume, had average baseline total knee BML volumes of 0.6 ± 0.2 cm^3, 1.6 ± 0.5 cm^3, and 5.5 ± 2.9 cm^3; respectively.

Conclusion: Change in BML volume is associated with change in knee pain severity. This association may primarily be driven by knees that are progressing from no or small BML volumes to larger BML volumes.

Association of Arthritis and Joint Pain with Accelerometer-Measured Physical Activity in Adults Aged 50 and Older in the United States: Findings From the National Health and Nutrition Examination Survey (2003–2004). Kathryn Remmes Martin[1], Dane Van Domelen[1], Matthew Pantell[1], Ming-yang Hung[1], Tamara B. Harris[1] and Kushang Patel[2]. [1]NIA/NIH, Bethesda, MD, [2]University of Washington, Seattle, WA

Background/Purpose: To compare the prevalence of meeting current public health physical activity (PA) guidelines by arthritis and knee/hip joint pain status, and to examine the relationship between arthritis, joint pain and accelerometer-measured PA in US older adults.

Methods: Data are a sample of 1680 men and women from the 2003–2004 NHANES aged $\geq$50 years who had 4+ valid days ($\geq$ 10 hrs $\cdot$ d^{-1}) of hip-worn accelerometer wear-time. PA was examined 2 ways: 1) adherence to PA guidelines of accumulated 10-minute bouts of moderate/vigorous physical activity (MVPA) (inactive: no bouts; insufficient <150 min $\cdot$ wk^{-1}; recommended: $\geq$150 min $\cdot$ wk^{-1}) using average daily minutes; and 2) average counts per minute (CPM) during wear-time and min $\cdot$ d^{-1}spent in sedentary, light, lifestyle, and MVPA. Participants self-reported doctor-diagnosed arthritis and knee and/or hip joint pain, and were categorized as follows: 1) no arthritis or joint pain (NEITHER); 2) arthritis only (ARTH); 3) joint pain only (JP); and 4) arthritis and joint pain (BOTH). Regression analyses adjusted for age, education, race, occupation, BMI, smoking status, self-rated health, self-reported functional limitations, arthritis-attributable limitations, and current pain medication use. All analyses were stratified by gender and accounted for NHANES PA monitor sampling weights.

Results: Age-adjusted prevalence of arthritis and joint pain (knee and/or hip) was 44% and 47%, respectively. These conditions co-occurred in 33% of participants (BOTH); 42% had NEITHER condition, 11% had ARTH only, and 14% had JP only. Having BOTH was more common among women (40%) than in men (24%).

The proportions of women meeting PA guidelines in the NEITHER (5%) and JP (6%) groups were similar. Women with ARTH and BOTH had the lowest proportion of recommended PA (<1%; 2%). Only 7% of men without either condition (NEITHER) achieved recommended PA, which was similar to men with ARTH (7%); however, the proportion meeting recommended PA was substantially lower in men with JP or BOTH (2%; 3%).

Regression models adjusted for demographics showed that women with ARTH, JP, or BOTH had lower CPM and lower levels of PA by various measures, which remained significant, though attenuated, after further adjustment for health conditions and functional limitations. Rela-

tive to the NEITHER group, women with ARTH had fewer CPM (B=-23.6, p=0.027) and fewer min $\cdot$ d^{-1} of MVPA (B=-3.2, p$\leq$0.001), and women with BOTH had 2.4 fewer min $\cdot$ d^{-1}of MVPA (p=0.013). Among men, only those with BOTH had fewer min $\cdot$ d^{-1}of MVPA compared to men in the NEITHER group (B=-12.2, p=0.004); however further adjustment for health conditions and functional limitations yielded unexpectedly higher CPM, fewer sedentary min $\cdot$ d^{-1}, and greater time in lifestyle-intensity activity in men with ARTH and BOTH compared to men in the NEITHER group.

Conclusion: Adherence to PA guidelines was low across all groups. Our data suggests gender differences in the relationship between arthritis, joint pain and PA. Women with ARTH and BOTH were generally less active, whereas men with ARTH and BOTH were more active than those with NEITHER. Continued PA promotion and pain management should be intensively targeted to US older adults with arthritis and joint pain.

Racial/Ethnic Trends in Incidence and Prevalence of Rheumatoid Arthritis in a Large Multi-Ethnic Managed Care Population. Aniket A. Kawatkar[1], Cecilia Portugal[1], Li-Hao Chu[2] and Rajan Iyer[1]. [1]Kaiser Permanente Southern California, Pasadena, CA, [2]Kaiser Permanente Southern California, Pasadena

Background/Purpose: As epidemiologic studies throughout the world have shown significant variations, we sought to characterize racial differences in longitudinal epidemiologic trends of adult rheumatoid arthritis (RA) in a large, racially diverse, managed care organization. The study objective was to estimate racial/ethnic differences in incidence density (ID) and prevalence rates (PR) of RA over time, while adjusting for age, and gender.

Methods: This was a retrospective population based study using active members from a large managed care health plan, during 01/01/2002 and 12/31/2010. RA patients were identified using a diagnosis code for RA in combination with the use of a disease modifying antirheumatic treatment within a year of the diagnosis code date. Subjects were required to be between the ages of 18 years and 100 years at the time of diagnosis. Non-RA adult health plan members informed the denominator for the ID and PR rates which were calculated on an annual basis. The longitudinal trend of ID and PR across 2002 to 2010, was further stratified by race/ethnic groups (Caucasian; Hispanic; African American; Asian and Other race); age (18–34; 35–44; 45–54; 55–64; and >= 65), and gender. Negative binomial regression models were used to estimate age, gender and race, adjusted rate ratios, for incidence density (aIDr) and prevalence (aPRr). The negative binomial models also included yearly dummy indicators to evaluate the statistical significance (alpha 0.05) in changes of these rates overtime.

Results: During the study period, a total of 8,108 incident cases and 58,644 prevalent cases of RA were identified. The majority of incident (76.9%) and prevalent (77.8%) cases were females. The major race/ethnic group was Caucasians, in the incident (55.8%) as well as the prevalent (64.2%) cases. Due to the predominance of females, the negative binomial models were stratified by gender. For females, the aIDr (mean (95% CI) with Caucasians as reference category) was as follows: Asian 0.7 (0.51–0.89); African Americans 1.0 (0.77–1.35); Hispanics 0.6 (0.45–0.78) and other race 0.9 (0.72–1.25). The aPRr in females (with Caucasians as reference category) was as follows: Asian 0.69 (0.56–0.83); African Americans 1.02 (0.84–1.24); Hispanics 0.45 (0.37–0.55) and other race 0.88 (0.73–1.07). Additionally, as compared to the 18–34 year age group, all other age groups had significantly higher aIDr and aPRr in both genders. Lastly, as compared to reference year 2002, the time trend for aPRr confirmed a statistically significant increase in prevalence rates in both genders.

Conclusion: We find evidence of racial differences in epidemiologic trends in RA with Asians and Hispanics having significantly lower incidence density and prevalence rates as compared to Caucasians. We also find evidence on increase in incidence and prevalence of RA with increasing age and also increase in prevalence rates over time.

Low Density Lipoprotein Receptor Deficiency Results in Osteophyte Formation During Experimental Osteoarthritis Which Is Enhanced Under High Cholesterol Conditions. Wouter de Munter, Birgitte Walgreen, Monique M. Helsen, Annet W. Sloëtjes, Wim B. van den Berg and Peter L.E.M. van Lent. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Synovial macrophages are involved in osteophyte formation during experimental collagenase-induced osteoarthritis (OA). Accumulated LDL can be oxidized in an inflammatory environment such as OA and be taken up by scavenger receptors of macrophages, changing the macrophage fenotype. The effect of LDLr deficiency and cholesterol accumulation on OA pathology was investigated using an experimental OA model.

Methods: LDLr deficient (LDLr$^{-/-}$) mice and their wild type (WT) controls received either a high cholesterol or control diet for 120 days. Experimental OA was induced by intra-articular injection of collagenase on day 84 and 86. Paraffin sections of total knee joints were stained with safranin O – fast green or haematoxylin – eosin to determine OA development. Thickening of the synovial lining layer was measured using an arbitrary scale (0 to 3). Cartilage destruction was determined in four cartilage surfaces of the knee joint (lateral and media femur and tibia) using the OA score developed by Pritzker *et al.*(2006), adapted by us for mice (0 to 30). Size of osteophyte formation was determined using image analysis by measuring osteophyte surface areas at the margins of the tibial plateau and femoral condyles. Data are depicted as mean ± SD.

Results: WT mice receiving a normal diet developed moderate cartilage destruction (6.1 ± 2.6), synovial thickening (1.4 ± 0.6), and osteophyte formation (56.5 μm^2 ± 94.6). Both LDLr$^{-/-}$ groups showed comparable cartilage destruction and showed no change in bodyweight (23.99 g ± 1.85). WT mice receiving a cholesterol-rich diet showed increased bodyweight compared to the other three groups (28.82 g ± 4.81; p<0.0001), however, no significantly increased cartilage destruction was observed. No differences between the four groups were found regarding synovial thickening. LDL levels were significantly higher in LDLr$^{-/-}$ mice compared to WT mice (7.33 mmol/L ± 1.44 and 0.54 mmol/L ± 0.11 respectively; p<0.0001), which was additionally increased by a cholesterol-rich diet (38.73 mmol/L ± 9.84; p<0.0001). At the tibial plateau, LDL$^{-/-}$ mice showed almost a 4 times increase of osteophyte formation compared to WT mice (206.3 μm^2 ± 196.3; p<0.05). When receiving a cholesterol-rich diet, osteophyte formation at the lateral side of the tibial plateau in LDLr$^{-/-}$ mice further increased from 107.0 μm^2 ± 156.0 to 309.4 μm^2± 132.0 (p<0.05).

Conclusion: Enhanced LDL levels correlate with increased osteophyte formation in LDLr$^{-/-}$ mice, suggesting a pathologic role of LDL accumulation during OA.

Adenosine Receptors Stimulate Bone Regeneration by Targeting Osteoclasts. Aranzazu Mediero[1], Tuere Wilder[1] and Bruce N. Cronstein[2]. [1]NYU School of Medicine, New York, NY, [2]NYU School of Medicine, Division of Rheumatology, New York, NY

Background/Purpose: Various types of orthopedic procedures, including spinal fusion and repair of bone defects due to trauma, infection or metastatic disease, require formation of new bone. Adenosine, generated from the catabolism of adenine nucleotides, modulates cell function by interacting with specific cell-surface receptors (A$_1$R, A$_{2A}$R, A$_{2B}$R, A$_3$R). We have previously reported that A$_1$R receptor blockade and A$_{2A}$R stimulation inhibit osteoclast (OC) differentiation but only A$_{2B}$R stimulation affects osteoblast (OB) differentiation or function. We determined whether A$_1$R blockade, A$_{2A}$R stimulation or enhancing adenosine concentrations via blockade of purine transport into cells via ent1 with dipyridamole regulates bone formation in a murine calvarial model.

Methods: Male C57Bl/6 mice were anesthetized, a 3mm trephine defect

was formed and covered with a collagen scaffold soaked in saline or 1mM adenosine receptor agonists/antagonists. Animals received appropriate treatment daily until sacrifice. At 0, 2, 4, 6 and 8 weeks calvarias were harvested and prepared for microCT and histology. XenoLight Rediject Bone Probe 680 was injected intravenously at different time points.

Results: 8 weeks after surgery microCT examination of mouse calvaria demonstrate that an A$_1$R antagonist (DPCPX), A$_{2A}$R agonist (CGS21680M) or dipyridamole markedly enhances bone regeneration (77±0.2%, 60±2% and 79±2% bone regeneration, respectively, vs. 32±4% in control, p<0.001, n=5 mice per condition) whereas an A$_3$R agonist (IB-MECA) had no effect (32±3% regeneration, n=5). In DPCPX-, CGS21680- and dipyridamole-treated mice there is increased immunostaining for osteoblast or bone formation markers (Alkaline Phosphatase, Osteocalcin and Osteonectin) in the bony defects (Alkaline Phosphatase positive cells/hpf increased from 15±1 for control to 22±1 for DPCPX, 21±1 for CGS21680 and 24±1 for Dipyridamole, p<0.001), and diminished inmunostaining for macrophages (CD163, TNfa) and osteoclasts (RANKL, RANK) in treated defects when compared to control. TRAP staining revealed fewer OCs in DPCPX-, CGS21680- and Dipyridamole-treated defects (14±1, 17±1 and 16±1 OC/hpf respectively vs. 24±1 Osteoclast/hpf for control, p<0.001) 8 weeks after defect formation. In vivo imaging with XenoLight Rediject Bone Probe 680 (a marker of bone formation) reveals a strong fluorescent signal in treated animals (DPCPX, CGS21680 and Dipyridamole) compared to control as soon as one week after bone defect formation and lasting for at least 7 weeks.

Conclusion: Inhibition of OC formation via A$_{2A}$R stimulation, A$_1$R blockade or increasing local adenosine concentration stimulates new bone formation and represents a novel approach to stimulating bone regeneration.

Inhibition of Notch Signaling Increases the Severity of Experimental Osteoarthritis. Neng-Yu Lin[1], Alfiya Distler[2], Christian Beyer[2], Clara Dees[2], Jingang Huang[3], Francesco Dell'Accio[4], Oliver Distler[5], Georg A. Schett[1] and Joerg HW Distler[1]. [1]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [3]University of Erlangen-Nuremberg, Erlangen, Germany, [4]William Harvey Research Institute, Barts and the London Queen Mary's School of Medicine and Dentistry, Centre for Experimental Medicine and Rheumatology, London, United Kingdom, [5]Department of Rheumatology and Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland

Background/Purpose: Notch signaling is triggered by binding of ligands such as Jagged-1 (Jag-1) to Notch receptors, which results in cleavage of Notch receptors by the γ-secretase complex and subsequent release of the active Notch intracellular domain (NICD). The NICD is the central regulator of the pathway, which translocation to nucleus where it interacts with the DNA binding factor RBP-J. Aberrant Notch signaling has been implicated into the pathogenesis of various diseases including cancer, Alzheimer's disease and fibrosis. Of note, increased expression of Notch signaling pathway has recently been observed in OA chondrocytes. However, the implications of the findings for the pathogenesis of OA and potential therapeutic implications have not been investigated so far.

Here, we aimed to further elucidate the role of Notch signaling pathway in OA using genetic and pharmacological inhibition of Notch signaling in the mouse model of destabilization of the medial meniscus (DMM) induced OA.

Methods: To analyze the activation status of the Notch cascade, we quantified the mRNA expression of Notch receptor family by real-time PCR and also analyzed the expression of NICD and Jag-1 protein by immunohistochemistry. To characterize the effects of Notch inhibition on osteoarthritis development *in vivo*, we evaluated the outcome of Notch anti-sense transgenic mice or mice treated with the γ-secretase inhibitor DAPT in the DMM (destabilization of the medial meniscus) model of OA. We used a modified Mankin score to analyze the histological changes. Hypertrophic differentiation of chondrocytes was analyzed by staining for Collagen X. We also analyzed the mRNA level of Epas1 and Aggrecanase-1 by real-time PCR.

Results: We demonstrated that the mRNA levels of Notch1 are increased by 200 ± 79 % in human OA cartilage (p<0.05). Moreover, the protein levels of Jag-1 and of the NICD are upregulated in human OA cartilage. Similar results were also obtained in murine OA induced by DMM.

However, genetic or pharmacologic inhibition of Notch signaling exacerbated the osteoarthritic changes in the DMM model. The modified Mankin score upon surgical DMM was significantly increased in mice expressing a Notch-1 anti-sense construct or upon treatment with DAPT ($56 \pm 6\%$ increase in Notch as tg and $60\% \pm 5$ increase in DAPT treated mice compared to non-transgenic or sham-treated DMM controls, respectively, p<0.01 for both). Immunostaining for Col X was also strongly increased upon inhibition of Notch signaling indicating increased differentiation into hypertrophic chondrocytes. Genetic or pharmacologic inactivation of Notch signaling also enhanced the mRNA expression of OA markers, such as Epas1 (increases by up to $94 \pm 10\%$ (p<0.05)), Aggrecanase-1 (increases by up to $150 \pm 20\%$ (p<0.01)).

Conclusion: We demonstrate that Notch signaling is hyperactivated in chondrocytes of OA patients. However, inhibition of Notch signaling pathway enhances chondrocyte hypertrophy and exacerbates osteoarthritis in the DMM model, indicating that the activation of Notch signaling in OA is a counter-regulatory mechanism to ameliorate chondrocyte dedifferentiation and cartilage damage.

The Sphingosine-1-Phosphate Pathway Is a Key Regulator of Bone Substrate-Mediated Osteoclast Differentiation in Inflammatory Arthritis. P. Edward Purdue[1], Jon Hill[2], Steven R. Goldring[3], Nikolaus B. Binder[3], Jennifer L. Swantek[4], Zhenxin Shen[5], Tania N. Crotti[5], Gerald H. Nabozny[4] and Kevin P. McHugh[5]. [1]Hospital for Special Surgery, Weill Cornell Medical Center, New York, NY, [2]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT, [3]Hospital for Special Surgery, New York, NY, [4]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT, [5]Center for Advanced Orthopedic Studies, Beth Israel Deaconess Medical Center, Boston, MA

Background/Purpose: Multiple lines of evidence have established that osteoclasts are required for physiologic bone resorption and pathological bone loss in inflammatory disorders. Isolation of differentiated osteoclasts from bone is technically challenging, but with the discovery that M-CSF and RANKL are sufficient for osteoclast differentiation came the ability to generate multinucleated osteoclasts from myeloid precursor cells *in vitro* with high efficiency. *In vivo,* analysis of osteoclasts at sites of bone resorption reveals that functionally activated osteoclasts are almost exclusively localized to the immediate bone surface, indicating that cell-substrate interactions contribute to terminal osteoclast differentiation. In this study, we have employed a unique *in vitro* osteoclastogenesis system using authentic bone substrates and expression profiling and pathway analysis to identify critical bone substrate-mediated pathways of osteoclast formation and activation. We have further validated the sphingosine-1-phosphate (S1P) generation, transport and signaling pathway as a key component of the bone-substrate regulated osteoclast differentiation program *in vitro* and *in vivo*.

Methods: Murine bone marrow derived macrophages were cultured in the presence or absence of RANKL on plastic, hydroxyapatite, or calvarial bone discs. RNA was isolated at different stages of osteoclast generation and subjected to microarray analysis. Pathway analysis was performed using GSEA and Ingenuity pathway analysis. SphK inhibitors were used to validate involvement of S1P signaling in osteoclastogenesis *in vitro*. Immunohistochemical analysis of the RA bone-pannus interface was used assess activation of this pathway in osteoclasts *in vivo*.

Results: Microarray analysis revealed unique clusters of RANKL induced and bone substrate-modulated osteoclast genes. Of 1490 genes upregulated by RANKL in differentiated osteoclasts, 5.4% were further upregulated by culture on the bone substrate; an additional 8.5% were downregulated. Pathway analysis identified the S1P pathway as significantly regulated by both RANKL and bone substrate, and that this regulation was dependent upon the presence of integrin beta 3, a key mediator of osteoclast attachment to bone. SphK inhibitors dose-dependently blocked RANKL-induced human and mouse osteoclastogenesis *in vitro*. Furthermore, SphK1 was highly induced in osteoclasts at sites of RA bone erosions.

Conclusion: Interaction of osteoclasts with the bone surface regulates multiple critical pathways of osteoclast formation and activation. Pathway analysis and *in vitro/in vivo* validation identifies the S1P pathway as a critical regulator of RANKL-bone-dependent osteoclastogenesis. This pathway represents a novel therapeutic target for preventing osteoclast-mediated bone destruction in inflammatory bone loss disorders.

IL-1β and TNF-α Regulate the Global and Locus-Specific hydroxymethylation of Genomic DNA by Modulating the Expression and Activity of Tet-1 in Human OA Chondrocytes. Abdul Haseeb[1] and Tariq M. Haqqi[2]. [1]Case Western Reserve University, Cleveland, OH, [2]Metro Health Medical Center, Cleveland, OH

Background/Purpose: 5-hydroxymethylcytosine (5-hmC), which is formed by the oxidation of 5-methylcytosine (5-mC), is a recently discovered epigenetic mark and is highest in brain and in embryonic stem cells. There have been reports supporting the notion that generation of 5-hmC may be a mechanism of DNA demethylation and thus important in the regulation of gene expression. In the present study we investigated the global and locus-specific 5-hmC content in the promoter region of MMP-3 gene and its expression in human OA chondrocytes. We also investigated the effect of IL-1β and TNF-α on the level of 5-hmC, expression and activity of the enzymes responsible for hydroxylation of 5-mC to generate 5-hmC and MMP-3 in human chondrocytes.

Methods: Primary human chondrocytes were isolated from the deep zone of the cartilage obtained from OA patients who underwent total joint replacement (n=8) and were treated with IL-1β and TNF-α for 48 hr. Global 5-hmC content in genomic DNA was quantified using a 5-hmC-specific ELISA (Epigentek, Farmingdale, NY). Total TET methylcytosine dioxygenase (Tet) activity was determined by an ELISA based activity assay kit (Epigentek). Tet-1, Tet-2 and Tet-3 and MMP-3 mRNA levels were quantitated by using the TaqMan assays (Applied Biosystems, Carlsbad, CA). Locus specific 5-mC and 5-hmC content in the MMP-3 promoter was examined by using EpiMark 5-mC and 5-hmC analysis kit (NEB, Ipswich, MA), which uses methylation sensitive HpaII and glucosylation sensitive enzyme MspI following the treatment of genomic DNA with T4-β-glucosyl transferase, and PCR using specific primers. Data were derived using Origin 6.1 software and $P<0.05$ was considered significant.

Results: The global content of 5-hmC in human chondrocytes was found to be 0.1–0.2% of the total genome. There was approximately 70% decrease (P<0.05) in the 5-hmC content upon treatment with IL-1β in combination with TNF-α for 48 hrs. This correlated with the reduction of Tet enzyme activity in chondrocytes after treatment with IL-1β and IL-1β + TNF-α. There was a significant (upto 20 fold) reduction in the level of Tet-1 mRNA expression while expression of Tet-3 mRNA was increased slightly (2–3 fold). The level of Tet-2 mRNA expression did not change upon treatment with the cytokines. MMP-3 promoter contained a high percentage (70%) of 5-hmC at HpaII locus in deep zone chondrocytes and these chondrocytes showed a dramatic (40 fold) increase in the expression level of MMP-3 upon treatment with IL-1β and TNF-α.

Conclusion: Our results demonstrate for the first time the presence of a significant amount of 5-hmC in human chondrocyte DNA. We also for the first time show that the 5-hmC content of the genomic DNA can be modulated by treatment with proinflammatory cytokines IL-1β and TNF-α in a short span of 48 hrs. The changes in 5-hmC levels correlated with the Tet-1 gene expression level and Tet enzyme activity in chondrocytes stimulated with IL-1β + TNF-α. Our data also demonstrate that the expression of MMP-3 was significantly (P<0.005) increased in chondrocytes with high content of 5-hmC in its promoter region. Taken together our novel data identify an important role for DNA hydroxymethylation in cartilage and may be important in understanding the mechanism and pathogenesis of OA.

Suppressor of Cytokine Signaling 3 Is Reduced in Obese Patients with Osteoarthritis and Regulates Leptin Responses in Chondrocytes. Anna Koskinen[1], Katriina Vuolteenaho[1], Riku Korhonen[1], Teemu Moilanen[2] and Eeva Moilanen[1]. [1]The Immunopharmacology Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland, [2]Coxa Hospital for Joint Replacement, Tampere, Finland

Background/Purpose: Leptin is an adipokine whose concentrations in circulation are proportional to body fat stores and body mass index (BMI). Initially leptin was discovered to regulate energy metabolism and body weight. More recently it has been recognized as effector and regulator in inflammation and arthritis. Leptin has been shown to have detrimental effects on cartilage metabolism including upregulation of proinflammatory and catabolic factors.

Suppressor of cytokine signaling 3 (SOCS-3) is an intracellular regulator of inflammatory response and a negative regulator of leptin's effects in hypothalamus. It has also been shown to be expressed in chondrocytes and overexpression of SOCS-3 has been reported to reduce severity of arthritis in mice models.

The aim of the present study was to explore how SOCS-3 expression in osteoarthritic (OA) cartilage is related to obesity and synovial fluid levels of matrix metalloproteinases (MMPs) 1 and 3 and leptin in OA patients. We also studied the role of SOCS-3 in regulating leptin-induced inflammatory responses in chondrocyte cultures.

Methods: We collected synovial fluid and cartilage samples from 91 OA patients [age 70.2 (9.6) years, BMI 30.8 (5.8) kg/m^2; mean (sd); females 66%] undergoing knee replacement surgery. Leptin, MMP-1 and MMP-3 in synovial fluid were measured by immunoassay. SOCS-3 expression in cartilage (from a subgroup of the patients, n = 28) was determined by Western blotting. The results were analyzed in the whole group and in two subroups divided by BMI (non-obese, BMI < 30 kg/m^2, n = 45; obese, BMI > 30 kg/m^2, n = 46). In addition, H4 chondrocytes and OA cartilage were used in the cell culture experiments. Interleukin-6 (IL-6), MMP-1 and MMP-3 were measured in the culture media by ELISA, and inducible nitric oxide synthase (iNOS) expression was determined by RT-PCR and Western blotting.

Results: Leptin concentrations in synovial fluid were higher (p < 0.001) and SOCS-3 expression in cartilage samples was lower (p = 0.032) in obese than in non-obese patients. Leptin correlated positively with MMP-1 and MMP-3 levels in synovial fluid from obese (r = 0.49, p = 0.001; r = 0.48, p = 0.001, respectively) but not from non-obese patients. SOCS-3 levels in the cartilage correlated negatively with synovial fluid MMP-1 and MMP-3 (r=-0.49, p=0.013; r=-0.44, p=0.024, respectively). Leptin enhanced MMP-1, MMP-3, IL-6 and iNOS expression in chondrocyte cultures. Interestingly, when SOCS-3 was down-regulated by small interfering RNA, chondrocytes' response to leptin was enhanced.

Conclusion: The results show, for the first time, that SOCS-3 is associated with and regulates leptin-induced responses in cartilage; When SOCS-3 expression was down-regulated, leptin-induced effects were enhanced. In OA patients high leptin levels and low SOCS-3 levels were associated with cartilage degradation (high MMP levels) and obesity. Assuming that SOCS-3 is a factor that inhibits the effects of leptin in cartilage, obese patients are possibly more susceptible to detrimental effects of leptin not only because of its elevated levels in joint, but also because of the disturbed regulation mechanism.

Immunoglobulin G Fc Receptor Activity *in Vivo* Is Under Complement Control. Eveline Y. Wu, Haixiang Jiang, C. Garren Hester and Michael M. Frank. Duke Univ Med Ctr, Durham, NC

Background/Purpose: Immunoglobulin G receptors (FcγR) are critical in the development of autoimmunity and pathogenesis of immune complex (IC) diseases. Although ICs activate complement, contributing to tissue damage, it is reported complement does not affect IC interaction with FcγR. We have re-explored this issue and find complement has a major impact on IC interaction with FcγR. Specifically, the classical pathway (CP) down-regulates and the alternative pathway (AP) promotes IC binding to FcγR. We performed reverse passive Arthus reactions, a model of IC-mediated cutaneous vasculitis, in normal C57Bl/6 mice and mice genetically deficient in complement proteins C1q, C4 and Factor B. It is also reported that complement does not contribute to Arthus reactions in mice, unlike in other animals. We hypothesized the CP, rather than contributing to vasculitis, down-regulates tissue injury caused by IC interaction with activating FcγR; therefore, its absence (C1q−/− and C4−/−) would enhance cutaneous vasculitis, while absence of the AP (Factor B−/−) would diminish cutaneous vasculitis.

Methods: Sedated and shaved mice (normal, C1q−/−, C4−/−, and Factor B−/−) were injected intradermally with 20 μl of PBS alone on one side and affinity purified rabbit anti-bovine serum albumin (BSA) IgG 5 μg in PBS on the opposite side. Immediately following, BSA 100 μg and ^{125}Iodine-labeled BSA 1.25 μg in PBS containing 1% Evans blue was injected intravenously. After 4 hours, mice were sacrificed and the extravasated blue spot and control injection spot were dissected and weighed. Radioactivity per specimen weight (cpm/gm) of treated skin was divided by that of control skin to determine an Arthus index (AI) for each mouse. Arthus indices were first analyzed by Kruskal-Wallis ranked test, followed by Mann-Whitney U test to evaluate for significant differences in median AI. P values less than 0.05 were considered significant.

Results: Complement activation strongly influenced the degree of cutaneous vasculitis in mice (Fig. 1, p=0.0013). C1q−/− (mean AI 3.8±0.7, p=0.0125) and C4−/− (mean AI 4.7±2.3, p=0.0504) mice exhibited more extensive vasculitis than normal animals (mean AI 2.6±1.2). Conversely, Factor B deficient (mean AI 1.4±0.5, p=0.0553) mice trended towards significantly reduced vasculitis compared to normal animals.
Fig 1. Reverse Passive Arthus Reactions

Conclusion: Cutaneous vasculitis is significantly greater in mice deficient in CP complement proteins and appeared reduced in mice deficient in AP complement proteins. Our results are the first to provide physiologic evidence *in vivo* that complement critically influences IC and FcγR mediated inflammation. They also refute previous data suggesting complement possesses no role in Arthus-induced vasculitis in mice. They may further our understanding of why individuals with CP defects are noted to have frequent signs of autoimmune pathology.

M-Ficolin, an Activator of the Complement System, Is the Strongest Predictor of Both DAS28 Remission and Low Disease Activity in a Cohort of 180 Early DMARD Naïve Rheumatoid Arthritis Patients Followed in the Opera-Study. Christian G. Ammitzbøll[1], Jens Christian Jensenius[2], Torkell Ellingsen[3], Steffen Thiel[2], Kim Hørslev-Petersen[4], Merete L. Hetland[5], Peter Junker[6], Julia Johansen[7], Mikkel Østergaard[8], Jan Pødenphant[9] and Kristian Stengaard-Pedersen[1]. [1]Arhus University Hospital, Aarhus, Denmark, [2]Aarhus University, Aarhus, Denmark, [3]Silkeborg Regional Hospital, Silkeborg, Denmark, [4]University of Southern Denmark, Graasten, Denmark, [5]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark, [6]Odense University Hospital, Odense, Denmark, [7]Glostrup Hospital, Glostrup, Denmark, [8]Copenhagen University Hospital Glostrup, Glostrup, Denmark, [9]Gentofte Hospital

Background/Purpose: M-ficolin is a soluble pattern recognition molecule that activates the complement system. We recently reported a factor 300 difference in the synovial fluid M-ficolin concentration between rheumatoid arthritis (RA) and osteoarthritis, suggesting a pathogenic role of M-ficolin (1). We assessed M-ficolin in DMARD naïve early RA patients, investigated correlations between M-ficolin and disease activity markers, and analyzed the predictive value of M-ficolin.

Methods: 180 DMARD naïve RA patients with disease duration <6 months were included in a randomized double blind placebo-controlled trial (OPERA) of methotrexate, intraarticular glucucorticoids + either adalimumab(ADA)orplacebo(PLA).Asandwich-typetime-resolvedimmunofluorometric assay using monoclonal antibodies was used for quantification of M-ficolin in the OPERA cohort, 101 healthy adults and 51 chronic RA patients in remission. Concentrations are reported as medians. Spearman test, Students T-test and one-way analysis of variance were used. Logistic regression analyses were performed and adjusted for CRP, treatment group (ADA/PLA), x-ray erosions, anti-CCP, IgM-RF, neutrophils and monocytes.

Results: The highest M-ficolin levels were measured in the OPERA cohort at baseline ($2.84\mu g/ml$, CI 2.63–3.09), and during treatment the level decreased 24% (CI 18–31%, $p<0.001$) at year one ($2.31\mu g/ml$, CI 2.14–2.50). The healthy adults had significantly lower concentrations ($1.88\mu g/ml$, CI 1.72–2.06) than the OPERA cohort at baseline ($p<0.001$) and year one ($p<0.001$), and the chronic RA patients ($2.17\mu g/ml$, CI 1.94–2.42) ($p=0.03$). At baseline M-ficolin correlated to DAS28 (rho=0.29, $p<0.001$) and the four variables constituting DAS28 ($0.001< p \leq 0.04$). At year one M-ficolin correlated to DAS28 (rho=0.36, $p<0.001$) and 3 of the 4 variables constituting DAS28 ($0.001< p \leq 0.05$), except tender joint count 28 ($p=0.23$). Furthermore M-ficolin correlated to HAQ at debut (rho=0.25, $p=0.003$) and year one (rho=0.23, $p<0.001$).

Logistic regression analysis determined M-ficolin as the strongest predictor of DAS28<2.6 at year one (coefficient=1.42, $p=0.0001$) followed by treatment group (PLA/ADA) (coefficient=1.23, $p=0.001$) and erosions on baseline x-ray (coefficient=1.19, $p=0.02$), but M-ficolin was the only variable able to predict DAS28<3.2 at year one (coefficient=0.89, $p=0.02$). Low baseline M-ficolin level was the only variable associated with low disease activity at year one, and this was further analyzed by comparing the group with the 25% lowest baseline M-ficolin levels with the remaining 75% of patients (cutoff 2.00 $\mu g/ml$). This resulted in a sensitivity of 29%, a specificity of 96%, and a positive predictive value of 98% in determining a DAS28 score <3.2 at year one.

Conclusion: The elevated baseline M-ficolin levels in early RA correlated consistently to disease activity markers, most notably DAS28 and HAQ, thus reflecting essential parts of the disease activity. Low M-ficolin level at baseline was the strongest predictor of a favorable DAS28 level after one year, and has a positive predictive value of 98% of a DAS28<3.2 after one year irrespective of treatment and well-known prognostic factors.

Periodontal Pathogens Directly Promote Autoimmune Experimental Arthritis by Inducing a Toll-Like Receptor 2 and Interleukin-1 Driven Th17 Response. Shahla Abdollahi-Roodsaz[1], Sabrina Garcia de Aquino[2], Marije I. Koenders[1], Fons A. van de Loo[1], Ger J. Pruijn[3], Mario J. Avila Campos[4], Fernando Q. Cunha[5], Joni A. Cirelli[2] and Wim B. van den Berg[1]. [1]Rheumatology Research and Advanced Therapeutics, Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Department of Diagnosis and Oral Surgery, Periodontic Division, Araraquara Dental School, Sao Paolo, Brazil, [3]Radboud University Nijmegen, Nijmegen, Netherlands, [4]Department of Microbiology, Institute of Biomedical Sciences—ICB/USP, Sao Paulo, Brazil, [5]Department of Pharmacology, School of Medicine of Ribeirao Preto, Sao Paolo, Brazil

Background/Purpose: The periodontal pathogen *Porphyromonas gingivalis* has been associated with the pathogenesis of rheumatoid arthritis (RA) because of its ability to citrullinate mammalian proteins and to induce disease-specific anti-citrullinated peptide antibodies (ACPA). The aim of this study was to investigate the influence of periodontal pathogens on the development of experimental arthritis and the T helper cell balance as a possible underlying mechanism for disease modulation.

Methods: The effect of *P. gingivalis* and *Prevotella nigrescens,* the latter lacking citrullinating enzymes, on T cell differentiation and the involvement of Toll-like receptors (TLRs) was studied *in vitro* using either wild-type or TLR deficient antigen-presenting cells (APCs) and CD4[+] T cells in co-culture. *In vivo*, mice with collagen-induced arthritis received five oral inoculations of either *P. gingivalis* or *P. nigrescens*every other day starting from day 14 after immunization. Joint histopathology, synovial gene expression, collagen-specific T cell phenotype and presence of ACPA were analyzed on day 30.

Results: *P. gingivalis*strongly induced an interleukin-1 driven Th17 differentiation in the co-culture of APCs with CD4[+] T cells, as measured by FACS and IL-17 production. This Th17 induction strongly depended on TLR2 expression on APCs and was substantially increased in the absence of IL-1 receptor antagonist. Remarkably, the Th17 inducing capacity was shared by another major periodontal pathogen, *Prevotella nigrescens*, lacking citrullination capability. In addition, both bacteria were weak inducers of Th1 and interferon γ production, which was dependent on TLR2 expression directly on T cells.

When applied in collagen-induced arthritis model through repeated oral inoculations, both *P. gingivalis* and *P. nigrescens* promoted antigen-specific Th17 response *in vivo* and aggravated the severity of arthritis. This occurred under conditions where ACPA against major citrullinated peptide candidates such as α-enolase and vimentin were undetectable. Instead, the levels of IL-17 induced by periodontal pathogens directly correlated with the intensity of arthritic bone erosions. In addition, while *P. gingivalis* induced local joint-destructive factors such as cathepsin K and matrix metalloproteinase 9 in synovial tissue, *P. nigrescens* suppressed the anti-inflammatory IL-4 production by T cells.

Conclusion: Our data reveal a novel mechanism, besides citrullination capability, by which periodontal pathogens influence autoimmune arthritis through direct modulation of the T cell phenotype, with a remarkable impact on bone erosion. This study further supports the relevance of periodontal pathogens in the pathogenesis of RA.

Snapin Is Critical for the Maturation of Autophagosome and Phagosome in Macrophages. Bo Shi, Qiquan Huang, Robert Birkett, Renee E. Koessler, Andrea Dorfleutner, Christian Stehlik and Richard M. Pope, Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: We found that Snapin, a SNARE complex protein required for synaptic vesicle docking and fusion, was significantly increased in rheumatoid arthritis (RA) synovial tissue compared to control synovial tissues. Snapin was highly expressed in CD68 positive macrophages (MΦs) in the sublining, which correlated with inflammation. Snapin expression in MΦs co-localized with Rab7, a marker of late endosomes. Therefore, studies were performed to determine the role of Snapin in the formation of autophagosomes and their fusion with lysosomes.

Methods: The forced reduction of Snapin in primary human MΦs was performed using siRNA. Snapin, Lamp1, 2 and LC3 protein levels were determined by Western blot analysis. MΦ phagocytosis of living bacteria was performed by infection of *Staphylococcus aureus* and intracellular bacteria number was determined by counting the bacterial colonies on LB-agar plates with MΦ lysates. Forced reduction of Snapin in Raw 264.7 macrophage cell line was performed by infection with a lentiviral vector expressing Snapin shRNA, followed by puromycin selection. Phagocytosis of fluorescent pHrodo-labeled dead *S. aureus* by Raw stable cell lines was performed and the amount of intracellular bacteria was determined either by mean fluorescence with flow cytometry or by cell fluorescence microscopy.

Results: The expression of Snapin progressively increased during human monocyte to MΦ differentiation. The forced reduction of Snapin in MΦs (documented by immunoblot analysis) resulted in elevated levels of LC3-II, a marker for autophagosomes, and Lamp-1, Lamp-2, two lysosomal markers. Snapin siRNA combined with cell starvation by FBS deprivation to promote autophagy, further increased LC3-II. However, the reduction of Snapin in MΦs co-treated with chloroquine, an autophagy efflux blocker, did not affect LC3-II levels, suggesting that the reduction of Snapin does not affect autophagy formation but leads to accumulation of autophagosomes by impaired autolysosome formation.

Phagocytosis of pHrodo fluorescent labeled dead *S. aureus* by Raw 264.7 stably expressing Snapin shRNA demonstrated a 25% increase in mean fluorescence intensity (MFI) by flow cytometry compared to control shRNA infected Raw cells. Following the forced reduction of Snapin in primary human MΦs, phagocytized *S.aureus* numbers at 1 hour after infection did not show differences, compared to non-targeting siRNA transfected MΦs. However, after 5 hours of infection, there were significantly increased numbers of *S aureus* remaining intracellularly in Snapin siRNA transfected MΦs compared to control siRNA treated MΦs (2.6 verses 1.7 colony formation units per cell, p<0.05). These data suggested Snapin is important for phagosomal fusion with lysosomes and the clearance of bacteria in MΦs.

Conclusion: Reduction of Snapin in MΦs resulted in the blockage of the fusion of autophagosmes and phagosomes with lysosomes. By promoting autophagy, the increased expression of Snapin in the RA joint may contribute to the long term survival of MΦs which contribute to the disease pathogenesis and joint destruction.

Bruton's Tyrosine Kinase Inhibition Suppresses Inflammatory Cytokine Production and Affects Gene Expression in Human Macrophages and RA Synovial Tissue Explants. Linda M. Hartkamp[1], Inge E. van Es[1], Jay S. Fine[2], Michael Smith[2], John Woods[2], Satwant Narula[2], Julie DeMartino[2], Paul P. Tak[3] and Kris A. Reedquist[1]. [1]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Hoffmann-La Roche, Nutley, NJ, [3]Academic Medical Center/University of Amsterdam and GlaxoSmithKline, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and progressive autoinflammatory disorder characterized by the infiltration of inflammatory cells, including B-cells, T-cells and macrophages, in the synovial membrane ultimately leading to cartilage destruction and bone erosion. Clinical disease activity in RA correlates strongly with macrophage numbers in synovial tissue and expression of macrophage-derived cytokines. Bruton's tyrosine kinase (Btk), a downstream target of phosphatidylinositol 3-kinase, is important not only in B cell activation, but also mediates immune complex-dependent activation of monocytes. Pharmacological inhibition of Btk effectively suppresses pathology in murine models of arthritis, but potential roles for Btk in the pathology of RA have not been examined.

Methods: Expression of Btk was detected by immunohistochemistry combined with digital image analysis in synovial tissue from 19 RA and 15 PsA patients, naïve to treatment with biologicals. Immunofluorescent double labelling confocal microscopy was performed to identify which cell types express Btk in RA synovial tissue, and validating qRT-PCR and immunoblotting experiments were performed on isolated relevant cell populations. Effects of a specific Btk inhibitor, RN486, on activation-dependent IL-6 production by human macrophages (n=8) and RA synovial tissue explant cultures (n=6) were assessed by ELISA. The influence of RN486 on macrophage expression of genes related to angiogenesis, cellular adhesion, tissue remodelling and innate immune responses was determined using low density qPCR arrays.

Results: Btk was expressed at equivalent levels in patients with RA and PsA, and no relationship was observed between expression levels and patient clinical characteristics (CRP, ESR, DAS28, RF-positivity). In RA, but not PsA, there was a significant relationship between Btk expression and numbers of synovial macrophages (R= 0.57, p< 0.01), T cells (R= 0.64, p< 0.005) and fibroblast-like synoviocytes (FLS) (R= 0.56, p< 0.05) but not B cells, plasma cells, or endothelial cells. qPCR and immunoblotting experiments confirmed that Btk was expressed in B cells, monocytes, and macrophages, but not T cells or RA FLS. RN486 (1μM) inhibited macrophage IL-6 production in response to Fc receptor stimulation (40% inhibition, p< 0.01) and anti-CD40 antibodies (50%, p< 0.05), but not TNFα or LPS stimulation. qPCR analysis of human macrophages demonstrated that RN486 inhibited by more than 2-fold 12 of 21 genes induced by IgG, 11 of 52 genes induced by CD40 stimulation, and 6 of 25 genes induced by RA SF in 3 independent experiments. RN486 also inhibited spontaneous IL-6 production by cultured RA synovial explants (65%, p< 0.01).

Conclusion: Our data demonstrate that Btk is expressed in RA synovial tissue and suggest that macrophages would be the prominent synovial targets of strategies aimed at inhibiting Btk in RA. As Btk activity is needed to drive macrophage activation in response to multiple stimuli relevant to RA, and drives IL-6 production in RA synovial tissue, pharmacological targeting of Btk may be of therapeutic benefit in the treatment of RA.

Bruton's Tyrosine Kinase and Calreticulin: A Novel Interaction with Implications for Inflammatory and Autoimmune Disease. Jennifer C. Byrne[1], Joan Ní Gabhann[1], Kevin Stacey[1], Barbara M. Coffey[1], Eoghan M. McCarthy[2], Warren Thomas[3], Eamonn S. Molloy[4], Grainne M. Kearns[2] and Caroline Jefferies[1]. [1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Beaumont Hospital, Dublin 9, Ireland, [3]Royal College of Surgeons in Ireland, Dublin 9, Ireland, [4]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Bruton's Tyrosine Kinase (Btk) regulates innate immune responses downstream of multiple Toll-like receptors (TLRs), including TLR7. Given the role of TLR7 in driving type I interferon and inflammatory cytokine production in the autoimmune condition systemic lupus erythematosus (SLE), pharmacological inhibition of the tyrosine kinase Btk has been proposed as a potential therapeutic. Given this interest it is essential that the role of Btk downstream of TLR7 activation be thoroughly explored.

Methods: Primary WT and Btk deficient murine macrophage were used to carry out a 2D proteomic study to identify differences downstream of TLR7 stimulation. Immunoprecipitation studies were carried out in macrophages and the human monocytic cell line THP-1. Confocal analysis was used to investigate localisation of proteins as well as uptake of apoptotic cells by primary macrophages.

Results: Our data describes a novel role for Btk as a regulator of the molecular chaperone calreticulin (CRT). Studies in primary macrophages demonstrate that CRT undergoes TLR7-induced tyrosine phosphorylation in a Btk-dependent manner. In addition Btk can directly interact with and phosphorylate CRT. Given the key role CRT in apoptotic cell uptake, we observe that in the absence of Btk, CRT fails to localise to the cell membrane or interact with the transmembrane receptor CD91, also known to be required for apoptotic cell uptake. Also, Btk-deficient macrophages show an impaired uptake of human apoptotic neutrophils in a phagocytosis assay as well as reduced staining for CRT within the phagocytic cup. In a preliminary study, pharmacological inhibition of Btk in monocytes derived from healthy controls demonstrated a reduction in apoptotic cell uptake following Btk inhibition, an effect that was exacerbated in monocytes derived from SLE patients.

Conclusion: Overall our data has revealed a novel regulatory role for the tyrosine kinase Btk with regard to CRT. Loss of Btk results in an alteration in the cellular trafficking of CRT downstream of TLR7 stimulation in myeloid cells as well as a reduction in their ability clear apoptotic cells. Given the interest in the use of pharmacological inhibitors of Btk for the treatment of

SLE, our data indicates that further investigation into the effect of Btk inhibition with regard to myeloid cell function is warranted.

Prozone Phenomenon Leads to Low IgG4 Concentrations in IgG4-Related Disease. Arezou Khosroshahi[1], Lynn A. Cheryk[2], Mollie Carruthers[1], Judith A. Edwards[2], Donald B. Bloch[1] and John H. Stone[1]. [1]Massachusetts General Hospital, Boston, MA, [2]Mayo Medical Laboratories, Andover

Background/Purpose: IgG4-related disease (IgG4-RD) is frequently associated with elevations in serum IgG4 concentration. However, the frequency of serum IgG4 elevation varies in published series from 44%–100%. The prozone effect, also known as the "hook" effect, occurs when antigen excess interferes with antibody-based assay methods that require immune complex formation for detection, and can lead to spuriously low results. Additional sample dilutions are the solution to the prozone effect. After identifying the prozone effect in one patient with IgG4-RD whose serum IgG4 corrected following appropriate dilutions from 17 to 1850 mg/dL (nl: 2.4–121 mg/dL), we examined additional samples to determine the frequency of this problem.

Methods: We re-tested 38 serum samples from patients with the diagnosis of IgG4-RD whose original serum IgG4 results had been reported earlier. The IgG subclasses were measured by nephelometry in dilutions up to 1:160,000, using two different commercially-available reagents (Siemens; The Binding Site). The testing laboratory was blinded to the patients' clinical history and previous values. The serum IgG4 concentrations from these assays were compared to the original results.

Results: Falsely low IgG4 values were reported in 10/38 patients (26%) using The Binding Site assay (Table). The prozone effect was identified as the cause of 8 incorrect values (21% of all samples tested). Correction of the prozone effect by sample dilution until the concentration reported was stable, led to a revision of the mean IgG4 result from 21.6 to 2440. In contrast, samples measured by the Siemens reagent were checked automatically for antigen excess as part of the testing method; the appropriate numbers of dilutions were performed either automatically by the instrument or manually as the result of a flag associated with the value, thereby avoiding the prozone effect. The Binding Site assay gave no indication that antigen excess might be present.

Table. Characteristics of patients with IgG4-RD with significant differences in their retested IgG4 results

Case #	* Original reported IgG4 values (mg/dL)	** Retested IgG4 values (mg/dL)	X-fold increase after dilution	Number of affected organs	Active disease	Presence of prozone effect
1	10.3	2470	247	1	Yes	Yes
2	28.4	941	33	3	Yes	Yes
3	29.3	219	7.5	1	Yes	No
4	59.8	337	5.6	1	Yes	No
5	12.7	5340	420	3	Yes	Yes
6	17.6	1850	105	4	Yes	Yes
7	8.0	5160	645	7	Yes	Yes
8	43.9	1030	23	4	Yes	Yes
9	14.4	1910	132	7	Yes	Yes
10	37.5	819	22	1	Yes	Yes

* The Binding Site reagent was used for the assay
** Siemens reagent was used for the assay

All 8 patients whose samples were affected by the prozone effect had active IgG4-RD, and 6 had multi-organ disease. Medical record review indicated that the original clinical decision regarding further evaluation (e.g.,

tissue biopsy) or treatment might have been different had the correct value been known to the clinician.

Conclusion: We have identified a major issue in the serological measurement of IgG4 concentrations. The prozone effect which led to substantial underestimations of IgG4 concentrations in 21% of the samples, offers potential explanations for the poor correlation observed between disease activity and serum IgG4 level in some patients. This phenomenon should be considered when the serum IgG4 measurement appears discordant with the clinician's assessment of disease activity.

Hypertrophic Pachymeningitis: IgG4-Related Disease Is A Common Etiology. Zachary S. Wallace, Mollie Carruthers, Arezou Khosroshahi, Robert Carruthers, Shweta Shinagare, Anat Stemmer-Rachamimov, Vikram Deshpande and John H. Stone. Massachusetts General Hospital, Boston, MA

Background/Purpose: Hypertrophic pachymeningitis (HP) is an inflammatory condition in which the dura mater of the cranium or spine becomes thickened, leading to symptoms that result from mass effect, nerve compression, or vascular compromise. The differential diagnosis of HP includes immune-mediated conditions such as rheumatoid arthritis and vasculitis, malignancies, and infections. Many times, no diagnosis is reached; in such cases, the disease has been described as idiopathic HP. IgG4-related disease (IgG4-RD) is a recently described inflammatory condition known to cause tumefactive lesions at myriad anatomical locations. Both IgG4-RD and idiopathic HP share similar demographics, histopathology, and natural history. We hypothesized that IgG4-RD is a common cause of idiopathic HP.

Methods: To investigate this hypothesis, we identified all pathology specimens diagnosed as HP in a 25-year time span at our institution. Fourteen cases had extant stained slides and cell blocks to permit review of the original hematoxylin and eosin (H&E) stained slides was well as immunostaining of cell blocks. Recently published consensus guidelines describing characteristic histopathology and the necessary quantity of IgG4+ plasma cell infiltrate were used to diagnose IgG4-RD.

Results: Four cases (29%) that had been regarded previously as representing idiopathic HP were diagnosed as IgG4-RD (Table 1). Of the remaining cases, there were three cases associated with granulomatosis with polyangiitis (GPA), two with lymphoma, and one each with rheumatoid arthritis, giant cell arteritis, and sarcoidosis. Two of the cases could not be diagnosed more precisely and were classified as undifferentiated HP.

Table 1.

Case	Diagnosis	Site	Age	Gender	Symptoms	Lympho-plasmacytic Infiltrate	Storiform Fibrosis	Phlebitis	Eos	Granulomas	Giant Cells
1	IgG4-Related Disease	Intracranial dura	50	Female	Seizures	Y	Y	N	N	N	Y
2	IgG4-related Disease	Intracranial dura	52	Female	Headache	Y	Y	Y	Y	Y (few)	N
3	IgG4-related Disease	Intracranial dura	39	Male	Headache & arm numbness	Y	Y	N	N	N	N
4	IgG4-related Disease	L5 nerve root dura	32	Male	Weakness	Y	Y	Y	Y	N	N
5	Granulomatosis with Polyangiitis	T2-T8 dura	59	Female	Sensory abnormalities & urinary retention	Y	N	N	Y	Y	Y
6	Granulomatosis with Polyangiitis	Intracranial dura	75	Female	Gait instability	N	Y	N	N	N	Y
7	Granulomatosis with Polyangiitis	Intracranial dura	55	Male	Painful diplopia	Y	Y	N	N	Y	Y
8	Rheumatoid Arthritis	Intracranial dura	58	Female	Ataxia, numbness & visual loss	Y	N	N	N	Y	Y
9	Giant Cell Arteritis	Intracranial dura	59	Male	Central DI	N	N	N	N	N	N
10	Sarcoidosis	Intracranial dura	67	Male	Nausea, vomiting & ataxia	Y	N	N	N	Y	N
11	Lymphoma	Intracranial dura	52	Male	Headache & dizziness	Y	N	N	N	N	N
12	Lymphoma	Intracranial dura	61	Female	CN III Palsy	Y	N	N	N	N	N
13	Undifferentiated	Intracranial dura	44	Female	Headaches & thrombosis	Y	N	N	N	N	Y
14	Undifferentiated	Intracranial dura	75	Male	FUO, gait instability & eye pain	N	N	N	N	N	N

Conclusion: This case series demonstrates that IgG4-RD may be the most common etiology of non-infectious HP and highlights the necessity of biopsy for accurate diagnosis. Clinical history, serologic tests, cerebrospinal fluid studies, and radiology alone could not identify the cause of HP. Rather, biopsy with histopathology and immunostaining was necessary to reach an accurate diagnosis. Significant IgG4+ plasma cell infiltrates were observed in rheumatoid arthritis, granulomatosis with polyangiitis, and lymphoma, underscoring the importance of histopathology in making the diagnosis of IgG4-RD.

Molecular Mechanism of IgG4 Class Switch Recombination in IgG4-Related Disease. Hiroto Tsuboi[1], Mana Iizuka[1], Hiromitsu Asashima[1], Sayaka Tsuzuki[1], Yuya Kondo[1], Akihiko Tanaka[2], Masafumi Moriyama[2], Isao Matsumoto[1], Seiji Nakamura[2] and Takayuki Sumida[1]. [1]University of Tsukuba, Tsukuba, Japan, [2]Kyushu University, Fukuoka, Japan

Background/Purpose: IgG4-related disease (IgG4-RD) is a new disease entity characterized by high serum IgG4 levels, IgG4-positive plasmacytic infiltration and fibrosis in various organs. Although the clinical features including serum abnormalities, organ involvement, diagnosis, and the therapeutic approach have been reported recently, the molecular mechanism of this disease remains unclear. The purpose of this study was to determine the mechanism of up-regulation of IgG4 class switch recombination in IgG4-RD.

Methods: 1) We extracted RNA from PBMC of patients with IgG4-RD (n=6), Sjögren's syndrome (SS) (n=6), and healthy control (HC) (n=8), from CD3 positive T cells and CD20 positive B cell sorted from PBMC of patients with IgG4-RD (n=3), SS (n=4), and HC (n=4). The RNAs were also prepared from labial salivary glands (LSG) of patients with IgG4-RD (n=11), SS (n=13), and HC (n=3).

2) The mRNA expression levels of IgG4-specific class switch-related molecules such as Th2 cytokines (IL-4 and IL-13), Treg cytokines (IL-10 and TGFβ), transcriptional factors (GATA3 and Foxp3) were examined by quantitative PCR assay.

3) IgG4-non-specific class switch related molecules such as CD40, CD154, BAFF, APRIL, IRF4, and AID were also examined by quantitative PCR assay.

Results: 1) IgG4-specific class switch-related molecules. The mRNA expression level of IL-4 was significantly higher in LSG of IgG4-RD than HC (P<0.05). Treg cytokines (IL-10 and TGFβ) were significantly higher in LSG of IgG4-RD than SS and HC (P<0.05, each). There were no significant differences in the PBMC expression levels of various cytokines, among the three groups. In LSG, the expression of GATA3 was significantly lower in IgG4-RD than in SS, Foxp3 was significantly higher in IgG4-RD and SS than in HC (P<0.05, each).

2) IgG4-non-specific class switch-related molecules. The mRNA expression levels of CD40 and CD154 were significantly lower in PBMC of IgG4-RD than SS (P<0.05, each). However, the expression of CD40 in CD20 positive B cells and that of CD154 in CD3 positive T cells were comparable in the three groups. The expression of BAFF was significantly higher in LSG of IgG4-RD than HC (P<0.05). The expression of APRIL was significantly lower in PBMC of IgG4-RD than HC (P<0.05). The expression of AID was significantly higher in LSG of IgG4-RD than SS and HC (P<0.05, each).

Conclusion: In LSG of IgG4-RD, increased Treg cytokines (IL-10 and TGFβ) might play important roles in IgG4-specific class switch recombination and fibrosis, which are characteristic features of IgG4-RD. High expression of AID could also contribute to up-regulation of IgG4-specific class switch recombination along with IL-10 in LSG of IgG4-RD. Thus overexpression of IL-10, TGFβ, and AID in LSG might play important pathogenic roles in IgG4-RD. This study showed different expression levels of IgG4 class switch-related molecules in LSG than in PBMC of IgG4-RD, which suggested that IgG4 class switch recombination seem be mainly up-regulated in affected organs.

Anti-Ribosomal P Antibodies in a Large Cohort of Autoimmune Hepatitis with No Evidence of Lupus: A Common Underlying Mechanism Targeting Liver? Ana Luisa Calich[1], Vilma S. T. Viana[1], Eduardo L. Cançado[1], Débora R. Terrabuio[1], Francisco Tustumi[1], Elaine P. Leon[1], Clovis Artur Silva[2], Eduardo F. Borba Neto[1] and Eloisa Bonfa[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Anti-ribosomal P proteins antibody (anti-rib P) is a highly specific marker for systemic lupus erythematosus (SLE) and it is associated with liver involvement in this disease. Similarities between autoimmune hepatitis (AIH) and SLE-associated hepatitis raised the possibility that anti-rib P antibodies may also have relevance in AIH. This study was therefore undertaken to evaluate the frequency and clinical significance of anti-rib P antibodies in a large AIH cohort before treatment.

Methods: Ninety-six patients with AIH diagnosed according to the Revised Original Pretreatment Scoring System of the International Autoimmune Hepatitis Group were studied. Charts were reviewed for demographic, clinical, treatment and laboratorial parameters. 82 healthy individuals were included as control. Available frozen sera samples from AIH patients obtained at diagnosis were tested for IgG anti-rib P by ELISA using a commercial kit employing synthetic 22 amino acid C-terminal peptide as antigen and reactivity was confirmed by immunoblotting using rat liver ribosomal fraction. All sera were screened for other lupus specific autoantibodies, anti-dsDNA and anti-Sm. Three patients positive for anti-dsDNA (n=1) and anti-Sm (n=2) were excluded.

Results: Moderate to high titers (>40U) of anti-rib P antibody were found in 9.7% (9/93) AIH patients and in none of the controls (p=0.003).Mean antibody titer was 93.6 ± 33.1 units. Positive results by ELISA were confirmed by immunoblotting. Patients with positive results for anti-rib P were referred to the Rheumatology Outpatient Clinic for a more detailed clinical evaluation. No sign of lupus was found in all of them. At presentation, AIH patients with and without anti-rib P antibodies had similar demographic/clinical features, including the frequency of cirrhosis (44% vs. 28%, p=0.44), hepatic laboratorial findings (p>0.05), corticosteroid and azathioprine therapy frequencies (100% vs. 99%, p=0.17 and 78% vs. 92%, p=0.17, respectively). The long follow up period was also comparable in those with and without anti-rib P antibodies (10.7± 5.1 vs. 10.3 ± 5.2 years, p=0.68). Importantly, at the final observation AIH patients with anti-rib P had a significantly higher frequency of cirrhosis compared to negative group (100% vs. 60%, p=0.04) despite no difference in the frequency of drugs at the last visit (p>0.05).

Conclusion: The novel demonstration of anti-rib P in AIH patients without clinical and laboratorial evidence of SLE suggests a common underlying mechanism targeting liver in these two diseases. In addition, this antibody seems to predict a group of patients with worse AIH prognosis.

The Relapsing Polychondritis Disease Activity Index: International Development and Initial Validation of the First Disease Activity Score for Relapsing Polychondritis. Laurent Arnaud[1], Hervé Devilliers[2], Stanford L. Peng[3], Zahir Amoura[4] and the RPDAI study group[5]. [1]Assistance Publique-Hôpitaux de Paris, Hopital Pitié-Salpétrière, Paris, France, [2]CHU Dijon, Dijon, France, [3]Virginia Mason Medical Center, Seattle, WA, [4]CHU Pitié-Salpêtrière, Paris, France, [5]Paris

Background/Purpose: Relapsing polychondritis (RP) is a rare multisystemic disorder characterized by recurrent, destructive, inflammatory lesions of the auricular, nasal, and laryngo-tracheo-bronchial cartilages. Additional clinical features include ocular inflammation, audio-vestibular impairment, vasculitis, skin involvement, valvular insufficiency, and non-erosive arthritis. The rarity of the disease makes it difficult to provide a standardized approach for treatment and follow-up of RP patients, and there is no consensus agreement on any outcome measures in this dis-

ease. Here, we describe the development of a score for assessing disease activity in RP, the Relapsing Polychondritis Disease Activity Index (RPDAI).

Methods: This study reflects a multi-center, international and inter-disciplinary collaboration of experts involved in the management of RP. Selection and definition of items for disease activity were established by consensus between 27 experts during a 4-round internet-based Delphi survey. Then, twenty-six experts assessed the Physician's Global Assessment (PGA) of disease activity of 43 test cases on a 0–100 scale. The weight of each item was estimated by multivariate regression models with generalized estimating equation, using PGA as the dependent variable.

Results: Experts decided in consensus that the RPDAI should consider the 28-day period before each scoring. Twenty-seven items were selected using the Delphi survey and a glossary defining each item was derived by consensus. Then, item weighting was performed by 26 experts, who assessed the Physician's Global Assessment (PGA) of disease activity of 43 test cases on a 0–100 scale. Inter-rater reliability assessed by the intra-class correlation coefficient for these PGA ratings was 0.51 (CI95%: 0.41–0.64). Multivariate analysis revealed that the individual weigh of items ranged from 1 to 24. The final RPDAI score therefore comprised 27 items with a maximum theoretical score of 265. Correlation between the RPDAI scores calculated for all test cases based on the weights derived from the final multivariate model, and the PGA of these cases was good (r=0.56, p<0.0001).

Conclusion: We have developed a consensus scoring system to measure disease activity in relapsing polychondritis (see www.RPDAI.org for online scoring). We believe this tool will be valuable for improving the care of patients with this rare disease.

Whole Transcriptome Analysis in Relapsing Polychondritis: A Single-Center Analysis of 35 Patients. Laurent Arnaud[1], Alexis Mathian[1], Bruno Faivre[2], Karim Dorgham[2], Julien Haroche[1], Nathalie Costedoat-Chalumeau[1], Jean-Charles Piette[1], Guy Gorochov[2] and Zahir Amoura[1]. [1]Hôpital Pitié-Salpêtrière, AP-HP & UPMC Univ Paris 06, Paris, France, [2]Institut National de la Santé et de la Recherche Médicale, INSERM UMR-S 945, Paris, France

Background/Purpose: Relapsing polychondritis (RP) is a severe and episodic inflammatory condition involving cartilaginous structures, predom-inantly those of the ears, nose, and laryngotracheobronchial tree. Other affected structures may include the eyes, cardiovascular system, peripheral joints, skin, middle and inner ear, and CNS. To date, gene expression profiling has not been performed in RP. The aim of this study was to analyze the transcriptome of RP compared to healthy individuals, as a manner to identify new pathways involved in the pathogenesis of the disease as well as new therapeutic targets.

Methods: Total RNA was extracted from peripheral blood mononuclear cell (PBMC) obtained in 35 patients with RP (according to Michet criteria) and 36 healthy individuals. Complementary DNA (cDNA) was hybridized in Illumina Human HT-12® v4 Expression Bead Chips. Statistical analysis of Microarray (SAM) algorithm with Benjamini and Hochberg multiple testing correction was used to determine the statistical significance of the differences in gene expression while controlling the false-discovery rate. Cluster analysis was also performed with JMP8 software. Differentially expressed genes were analyzed to identify potential functional pathways using Ingenuity®Pathway Analysis (IPA).

Results: Gene expression analysis using SAM showed 165 significantly down- or up-regulated transcripts between RP patients and controls. Cluster analysis of these transcripts by similarity on gene expression patterns identified several clusters containing only RP patients, healthy individuals, or both, underlining the strong heterogeneity of the disease. The set of genes statistically different between RP and healthy individuals was further ana-lyzed with IPA Analysis, which revealed a role for genes related to growth factor and cytokine activities, control of the cell-cycle, and kinase-phosphorylation.

Conclusion: This transcriptome analysis of 35 patients with relapsing polychondritis reveals that complex gene expression patterns are involved in the pathogenesis of the disease. This may be seen as a significant advance in this under researched disease with complex clinical presentation and non-formally codified therapeutic management.

ACR Concurrent Abstract Session
Osteoarthritis - Clinical Aspects I:
Weight, Activity, and Metabolic Effects on Osteoarthritis
Tuesday, November 13, 2012, 4:30 PM–6:00 PM

2533

Weight Loss Is Associated with Structure Modification in Subjects with Radiographic Osteoarthritis of the Knee: Data From the Osteo-arthritis Initiative. Marc C. Hochberg[1], Danuta I. Bujak[1], Jeffrey W. Duryea[2], Knachelle Favors[3] and John D. Sorkin[4]. [1]University of Mary-land, Baltimore, MD, [2]Brigham & Women, Boston, MA, [3]VA Maryland Health Care System, Baltimore, [4]VA Maryland Health Care System, Baltimore, MD

Background/Purpose: Obesity is a risk factor for the development and progression of knee osteoarthritis (OA) and weight loss is recom-mended as part of the management of patients with knee OA. We tested the hypothesis that weight loss is associated with structural progression, as measured by the rate of decline in joint space width (JSW), in subjects with radiographic knee OA.

Methods: Data for this analysis were obtained from the Osteoarthritis Initiative (OAI) public access database (http://www.oai.ucsf.edu). At each visit, subjects completed an extensive battery of questionnaires; weight was measured with a balance beam scale; and fixed flexion, weight-bearing PA radiographs of both knees were obtained using a standard protocol and the Synaflexer platform. We examined data from the baseline, 12-, 24-, 36- and 48-month follow-up visits for subjects with radiographic knee OA. Medial compartment JSW was determined using digitized images and a software tool; all images from a subject were analyzed together blinded to time sequence (see http://oai.epi-ucsf.org/datarelease/SASDocs/kXR_QJSW_Duryea_descrip.pdf for documenta-tion). Mean change in both minimum (mJSW) and JSW0.25 were examined using multiple variable random effects (random slope and random intercept) models including weight, age, WOMAC pain score and use of analgesic and/or anti-inflammatory medications at each visit along with sex, race/ethnicity, and study site from baseline.

Results: Data from 2683 subjects with radiographic OA in one or both knees (Kellgren-Lawrence grade >=2 on baseline radiograph), with measurement of mJSW and JSW0.25 at one or more time points (median = 3) were included in the analysis. If both knees were affected by radiographic OA, data for the right knee were arbitrarily used in the analysis. Mean (SD) age was 62.1 (9.1) years, weight was 83.9 (16.0) kg, mJSW was 3.97 (1.46) mm and JSW0.25 was 5.36 (1.54) mm at baseline. The mean rate of decline in JSW was more rapid for JSW0.25 than mJSW (0.110 [0.0055] mm vs. 0.088 [0.0055] mm; difference = 0.021 mm/year [95% CI 0.006, 0.037], P = 0.006). Heavier weight was significantly associated with narrower joint space at both mJSW and JSW0.25 at all visits (P < 0.0001). There was a significant inverse association between change in weight and change in both mJSW and JSW0,25 in the multiple variable adjusted models such that subjects with a decline in weight over time had a smaller adjusted rate of decline in both mJSW and JSW0.25 that those who had an increase in weight. The rate of decline in JSW per unit change in weight did not differ, however, for JSW0.25 and mJSW. Sensitivity analyses performed after ex-cluding subjects with isolated lateral compartment disease (OARSI medial compartment JSN grade = 0 and lateral compartment JSN grade >=1) did not alter the results. Finally, higher WOMAC pain scores and use of analgesic and/or anti-inflammatory medications were both inde-pendently associated with the rate of decline in JSW in multiple variable models.

Conclusion: These data demonstrate an association between weight loss and a reduction in the rate of decline in both mJSW and JSW0.25 in subjects with radiographic knee OA. Weight loss should be recommended as an approach for both symptom and structure modification in knee OA.

The Intensive Diet and Exercise for Arthritis Trial (IDEA): 18-Month Radiographic and MRI Outcomes. David J. Hunter[1], D. Beavers[2], Felix Eckstein[3], Ali Guermazi[4], Richard F. Loeser[5], Barbara J. Nicklas[6], Shannon Mihalko[7], Gary D. Miller[7], Mary Lyles[8], Paul DeVita[9], Claudine Legault[8], J. Jeffery Carr[8], Jeff D. Williamson[8] and Stephen P. Messier[7]. [1]University of Sydney, Sydney, Australia, [2]Winston Salem, NC, [3]Paracelsus Medical University, Salzburg, Austria, [4]Boston University, Boston, MA, [5]Wake Forest School of Medicine, Winston-Salem, NC, [6]Winston-Salem, NC, [7]Wake Forest University, Winston-Salem, NC, [8]Wake Forest University School of Medicine, Winston-Salem, NC, [9]East Carolina University, Greenville, NC

Background/Purpose: Dietary induced weight loss is a proven non-pharmacologic intervention for osteoarthritis. Based upon current literature it is unclear if weight loss modifies structural progression. We report the radiographic and MRI structural outcomes of an 18 month study of intensive weight loss, with or without exercise compared to exercise alone in older, overweight and obese adults with symptomatic knee osteoarthritis.

Methods: The Intensive Diet and Exercise for Arthritis trial (IDEA) was a prospective, single-blind, randomized controlled trial that enrolled 454 overweight and obese (BMI = 27–42 kg/m2) older (age ≥ 55 yrs) adults with pain and radiographic evidence of tibiofemoral osteoarthritis (KL = 2–3). Participants were randomized to one of three 18-month interventions: intensive dietary weight loss-only (D); intensive dietary weight loss-plus-exercise (D+E); or exercise-only control (E). X-rays and MRIs were acquired at baseline and 18 months of follow-up. Standardized weight bearing x-rays (N = 325) were acquired and joint space width (JSW) was measured (blinded to time point) using an automated algorithm for minimum JSW and JSW at 4 fixed locations in the medial compartment. MRIs were obtained on a subsample of study participants (N = 105) and tibiofemoral cartilage thickness measured and semi-quantitative (SQ) MRI scoring performed using BLOKS. We used an intention to treat analysis to compare change between groups at 18 month follow-up. X-ray and MRI results were analyzed using ANCOVA adjusted for baseline values, BMI, and gender. X-ray was also adjusted for inter-rim distance. Ordinal logistic regression was used for the ordinal SQ analyses, adjusting for baseline values, BMI and gender.

Results: Mean baseline descriptive characteristics of the cohort included: age, 65.6 yrs.; BMI 33.6 kg/m[2]; 72% female; 81% white. A total of 399 (88%) participants completed the study and returned for FU18mth testing. Mean weight loss was: D, -9.5%; D+E, -11.4%; E, -2.2%. There were no baseline differences between groups in JSWx (0.225) 4.5 (1.9)mm or for cartilage thickness of the medial tibia and central medial femur combined 2.90 (0.08)mm. All 3 groups demonstrated continued progression of JSW loss with no significant difference between groups D -0.07(0.22)mm, D+E -0.27(0.22)mm and E -0.16(0.24)mm (p=0.79). All 3 groups demonstrated continued progression of MRI cartilage loss with no significant difference between groups D -0.10(0.05) mm, D+E -0.13(0.04)mm and E -0.05(0.04)mm (p=0.42). Maximal bone marrow lesion (BML) size showed a trend to improvement for the D+E OR 0.70 (0.25–1.95) and D OR 0.44 (0.16 – 1.23) groups.

Conclusion: Despite the potent effects of weight loss on symptoms, there does not appear to be any amelioration in the rate of structural progression either on x-ray or MRI cartilage measurement. The evidence of a trend towards improvements in BML suggests that this may be one mechanism for the symptom improvements related to weight loss.

Childhood Physical Fitness Predicts Adulthood Knee Cartilage Volume and Bone Area: A 25-Year Cohort Study. Benny Samuel Eathakkattu Antony[1], Graeme Jones[1], Alison Venn[1], Leigh Blizzard[2], Flavia Cicuttini[3], L. March[4], Terry Dwyer[5] and Changhai Ding[6]. [1]Menzies Research Institute Tasmania, Hobart, Australia, [2]Hobart, Australia, [3]Monash University, Central and Eastern Clinical School, Melbourne, Australia, [4]University of Sydney, Insitute of Bone and Joint Research, Royal North Shore Hospital, St Leonards - Sydney, Australia, [5]Murdoch Children's Research Institute, Melbourne, Australia, [6]Menzies research institute & Monash University, Hobart, Australia

Background/Purpose: Physical activity interventions are often advised for management of osteoarthritis patients, despite contradictory findings regarding its effect on knee structure. In particular, there is little evidence relating childhood physical performance measures to adult joint structure. The aim of this cohort study was to determine the associations between childhood physical performance measures and knee cartilage volume and tibial bone area in adults 25 years later.

Methods: Subjects broadly representative of the Australian population (n=298, aged 31–41 years, female 48.7%) were selected from the Childhood Determinants of Adult Health study. They underwent T1-weighted fat-suppressed magnetic resonance imaging of their dominant knee and cartilage volume and tibial bone area were measured. Childhood measures including physical work capacity at 170 beats per minute (PWC_{170}), leg and hand muscle strength, sit-ups, long-run, and short-run were measured by standard protocols 25 years prior.

Results: There were consistent and significant associations of all childhood measures including PWC_{170}(β: 0.48 cm[2]per 100 mW, 95% CI: 0.22, 0.73), hand muscle strength (β: 1.49 cm[2]per 100g, 95% CI: 0.79, 2.19), leg muscle strength (β: 0.29 cm[2]per 100g, 95% CI: 0.09, 0.50), short-run (β: -0.71 cm[2]per second, 95% CI: -1.21, -0.21) and sit-ups (β: 0.28 cm[2]per count/10, 95% CI: 0.13, 0.43) with adult tibial bone area in multivariable linear regression, after adjustment for sex, childhood age, duration of follow-up and childhood and adulthood measures (body mass index and knee injury). In addition, these associations were independent of the corresponding adulthood fitness measures and tibial cartilage volume.

Similarly, there was a significant positive association between childhood PWC_{170} and adult medial tibial cartilage volume (β: 0.1 mm[3]per 100 mW, 95% CI: 0.03, 0.17) after adjustment for covariates including adult PWC_{170}. The magnitude of the association decreased by 33% but remained significant after further adjustment for tibial bone area. Other childhood measures such as hand muscle strength (β: 0.21 mm[3]per 100g, 95% CI: 0.04, 0.37) and sit-ups (β: 0.04 mm[3]per count/10, 95% CI: 0.01, 0.08) were significantly associated with medial tibial cartilage volume, but these became non-significant after further adjustment for medial tibial bone area.

Conclusion: A number of childhood physical performance measures are significantly associated with knee bone area and cartilage volume in adulthood. The associations with cartilage volume appear to be mediated by tibial bone area. This suggests physical activity in childhood can independently influence adult knee joint health possibly through adaptive mechanisms during growth.

The Effects of Intensive Diet and Exercise On Bone Density in Older Adults with Knee Osteoarthritis: The Intensive Diet and Exercise for Arthritis (IDEA) Trial. Nicole R. Walton[1], Richard F. Loeser[2], Daniel Beavers[3], Barbara J. Nicklas[4], Mary Lyles[3] and Stephen P. Messier[5]. [1]Wake Forest University School of Medicine, Winston Salem, NC, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Wake Forest University School of Medicine, Winston-Salem, NC, [4]Winston-Salem, NC, [5]Wake Forest University, Winston-Salem, NC

Background/Purpose: Previous studies on the effects of weight loss and exercise on bone mass show conflicting results and there are no studies of older adults with knee OA. We examined change in bone mineral density (BMD) in response to weight loss, with and without exercise, and to exercise alone in older adults enrolled in the IDEA trial and determined whether BMD changes were related to the magnitude of fat mass loss and to changes in leptin.

Methods: 454 overweight and obese (avg BMI 34) adults (avg age 66yrs, 72% female) with symptomatic knee OA were randomized to 18 months of intensive dietary induced weight loss (D); intensive weight loss plus exercise (D+E); or exercise control (E). The weight loss goal for the two diet groups was ≥ 10% of baseline body weight. The exercise intervention consisted of low to moderate intensity walking and resistance training 3 d/wk for 1 hr/d. A total of 399 (88%) participants completed the study. BMD at the hip (total hip=thip and femoral neck=FN) and spine, as well as total body fat mass, were measured by DXA and vitamin D levels (baseline only) were assessed in 392 subjects. Osteoporosis (OP) and osteopenia (OPE) were defined as location-specific t-scores <-2.5 and between -2.5 and -1, respectively. A subset of 162 subjects had serum leptin levels measured. Treatment group means were compared using ANCOVA, adjusted for baseline dependent variable values, BMI, and gender. Corrections for multiple comparisons used

Tukey's method. Linear associations of change measures used a general model, adjusted for baseline values, BMI, gender, and treatment arm.

Results: Mean weight loss was: D+E, 11.4%; D, 9.5%; E, 2.2%. BMD declined at the hip but not the spine in both weight loss groups (D= -0.024g/cm^2 thip; -.013 FN; both p<.0001 and D+E =-0.020 thip; -.012 FN; both p<.0001) but not the E group (-0.002;p=0.54 thip; -0.001; p=0.8 FN). At baseline 10 subjects (2.5%) had OP (4 hip and 6 spine) and 45% had OPE in at least 1 site. Following intervention, 9 subjects had OP and no subjects with OPE became OP. The mean serum vitamin D level at baseline was 29 ng/mL and baseline BMD values were not related to vitamin D levels. The D and D+E groups but not the E group had significant declines in fat mass and leptin. Changes in hip (but not spine) BMD correlated positively with changes in fat mass (b=.003 g/cm^2/kg, p<.0001) (Fig 1) and changes in leptin (b=.001ng/ml/kg, p<.0001).
Conclusion: To our knowledge, this is the longest study to date that analyzed change in BMD with intentional weight loss and the first in older adults with knee OA. Weight loss and the associated reduction in fat mass resulted in a decrease in total hip and femoral neck, but not spine, BMD. The addition of exercise did not prevent these declines. The bone loss was not severe enough to result in osteoporosis but the findings suggest patients with low BMD should be monitored when starting a weight loss interevention.

Cross-Sectional and Longitudinal Associations Between Circulating Leptin and Knee Cartilage Thickness in Older Adults. Oliver Stannus[1], Yuelong Cao[2], Benny Samuel Eathakkattu Antony[1], Graeme Jones[3] and Changhai Ding[4]. [1]Menzies Research Institute Tasmania, Hobart, Australia, [2]Menzies Research Institute Tasmania, Research Institute of Orthopaedics, Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine,, Hobart, Australia, [3]Menzies Research institute Tasmania, University of Tasmania, Hobart, 7000, Australia, [4]Menzies research institute & Monash University, Hobart, Australia

Background/Purpose: To investigate cross-sectional and longitudinal associations between serum leptin levels and knee cartilage thickness in older adults.

Methods: A prospective cohort of 163 randomly selected subjects (mean 63 years, range 52–78, 46% female) were studied. Knee cartilage thickness at medial tibial, lateral tibial, femoral and patellar sites was determined using T1-weighted fat suppressed magnetic resonance imaging (MRI) using custom semi-automated segmentation software written in MAT-LAB. Serum leptin levels were measured by radioimmunoassay. Radiographic osteoarthritic changes including joint space narrowing and osteophytes were assessed according to Osteoarthritis Research Society International (OARSI) atlas. Fat mass and lean mass (kg) were measured using a Hologic dual energy x-ray absorptiometry (DXA) scanner. Weight and height were measured, and body mass index (BMI) was calculated.

Results: Knee cartilage thickness was negatively and significantly associated with age, female sex and BMI in multivariable analyses. It was also associated with joint space narrowing at medial tibial, lateral tibial and patellar sites (β: -0.08 to -0.12 mm per grade, all P<0.05) and osteophytes.

Cross-sectionally, serum levels of leptin were negatively associated with femoral (β: -0.012 mm per pg/ml, 95% CI: -0.021, -0.003), medial tibial (β: -0.008 mm per pg/ml, 95% CI: -0.016, 0.001), lateral tibial (β: -0.010 mm per pg/ml, 95% CI: -0.019, -0.001) and patellar (β: -0.015 mm per pg/ml, 95% CI: -0.026, -0.003) cartilage thickness after adjustment for covariates including BMI and radiographic OA. Moreover, BMI, trunk fat and total fat were negatively associated with cartilage thickness at various sites, and the significant associations disappeared after further adjustment for leptin.

Longitudinally, both baseline leptin and change in leptin were associated with greater deleterious changes in medial tibial cartilage thickness (β; -0.004 mm per pg/ml, 95% CI: -0.007, -0.001 and β: -0.009 mm per pg/ml, 95% CI: -0.018, -0.001, respectively) in multivariable analyses.

Conclusion: This is the first study to examine the cross-sectional and longitudinal associations between serum levels of leptin and cartilage thickness in older adults. Serum levels of leptin are independently and consistently associated with reduced cartilage thickness cross-sectionally and over time. In addition, the associations between adiposity measures and cartilage thickness are mediated by leptin suggesting leptin may play a key role in cartilage loss.

The Association of Fat Mass and Skeletal Muscle Mass with Clinical and Structural Knee Osteoarthritis: The Netherlands Epidemiology of Obesity Study. A. Willemien Visser, Marieke Loef, Martin den Heijer, Monique Reijnierse, Frits R. Rosendaal and Margreet Kloppenburg. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Body mass index (BMI) is an important risk factor for knee osteoarthritis (OA), but BMI depends only upon height and weight and gives no insight in underlying causal pathways. The objective of this study was to investigate whether the association of BMI with clinical and structural OA can be explained by the amount of fat mass (FM) and/or skeletal muscle mass (SMM).

Methods: Participants of the NEO (Netherlands Epidemiology of Obesity) study, a population-based cohort of individuals aged 45–65 years with a BMI ≥ 27 kg/m^2 and a control group with a BMI < 27 kg/m^2, were used. BMI was assessed by measured weight and length. FM and SMM were assessed using bioelectrical impedance analysis. Clinical OA was defined according to the ACR criteria; based on self-reported knee complaints and physical examination of the knees. Structural OA was defined based on MR imaging of the right knee, performed on 1.5T (Philips, Best, The Netherlands) using a standard knee protocol. Osteophytes were scored according to the Knee Osteoarthritis Score System in nine compartments. Osteophytes were graded from 0 (absent) to 3 (severe). A total score was calculated for each individual, a score of ≥ 6 was considered as structural OA. Odds ratios (OR) with 95% confidence intervals (CI) were calculated to associate BMI, FM, SMM and the FM/SMM ratio with OA using logistic regression analyses, stratified for sex and adjusted for age.

Results: In 4562 participants (mean age 56 years, 52% women) median (IQR) BMI was 30.3 kg/m^2 (28.4–33.1), FM 33.5 kg (27.5–40.8) kg and SMM 28.3 (23.0–33.8) kg. Clinical OA was present in 24% of women and 12% of men. MRI data were available in 1134 participants; structural OA was present in 34% of women and 35% of men. In women and men, BMI was associated with clinical and structural OA. Both FM and SMM were associated with clinical OA, in women ORs were 1.02 (1.01–1.03) and OR 1.05 (1.02–1.08) respectively, and in men; ORs 1.02 (1.01–1.04) and 1.04 (1.01–1.07), respectively. Comparable associations were found with structural OA. Remarkably, in clinical OA the FM/SMM ratio was positively associated with OA (ORs 1.48 (1.13–1.94) and 1.92 (1.20–3.06) in women and men respectively), meaning that a higher FM relative to SMM is unfavorable. In structural OA we found that in multivariate analysis including BMI and FM, the association between BMI and OA disappeared, but the association between FM and OA was unchanged, suggesting that FM is mediating the association of BMI with OA. In multivariate analysis including BMI and SMM, the association of both BMI and SMM with structural OA decreased, suggesting that SMM acts as a partial mediator.

Conclusion: BMI, FM and SMM were associated with structural and clinical OA in both women and men. Further analyses suggest that both FM and SMM are involved in the underlying mechanisms of developing knee OA and associated complaints.

Fine-Specificity of Anti-Citrullinated Peptide Auto-Antibodies: Associations with Cardiac Structure and Function in Rheumatoid Arthritis.

Laura Geraldino-Pardilla[1], Jon T. Giles[1], Jeremy Sokolove[2], William H. Robinson[3] and Joan M. Bathon[1]. [1]Columbia University Medical Center, New York, NY, [2]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [3]Stanford University, Palo Alto, CA

Background/Purpose: Despite advancements in rheumatoid arthritis (RA) treatment, standardized mortality rates remain up to 3 times higher than in the general population. Cardiovascular disease (CVD) is the leading cause of excess deaths in RA. Our group has recently found lower left ventricular (LV) mass in RA patients which was associated with anti-CCP antibody levels. Although anti-CCP Abs have been associated with increased CVD and mortality in RA, little is known about the underlying pathophysiology and whether specific anti-citrullinated peptide antibodies (ACPAs) play a role in altering cardiac function or structure. Our objective was to test the association of autoreactivity of a selected panel of ACPAs with myocardial function and structure parameters in RA patients.

Methods: This study was nested in an RA cohort without known CVD. A cross-sectional analysis was performed using clinical data and collected serum from a subset of participants who underwent cardiac magnetic resonance (CMR) imaging at baseline. With a custom multiplex bead based antigen array using the BioPlex platform and ran on the Luminex 200 instrument, the autoreactivity against a panel of 17 ACPAs was tested. The association of each ACPA with CMR-derived cardiac measures was tested by linear regression analyses, adjusting for potential confounders.

Results: A total of 76 RA patients underwent CMR [mean age 59 ± 9 years, 49% male, mean disease duration 12 ± 11 years, mean DAS28$=3.5 \pm 1.1$]. At an established level of significance of <0.05, categories of anti-citrullinated vimentin (epitopes 58–77), anti-citrullinated histone2b (epitopes 62–81) and anti-citrullinated enolase antibodies were associated with a decrease in LV end diastolic mass. A decrease in LV mass index was associated with categories of anti-citrullinated histone2b, anti-citrullinated histone2b (epitopes 62–81), anti-citrullinated fibrinogen (epitopes 211–230, 556–575), anti-citrullinated histone2a (epitopes 1–20) and anti-citrullinated enolase antibodies. These and additional associations with other tested cardiac parameters are shown in table 1.

Table 1. Summary of Linear Regression Analysis of the Associations between Specific ACPAs and statistically significant directional changes in each individual left ventricular measure

ACPA categories-per quartile	EDM	MI	EDVI	HR	ESV	EF	SV	CO	ESVI
Anti-cit-vimentin			↓						
Anti-cit-fibrinogen									
Anti-cit-histone2b*		↓							
Anti-citfibrinogen (616–635)				↑					
Anti-cit-vimentin (58–77)	↓			↑					
Anti-cit-fibrinogen (41–60)									↓
Anti-cit-fillagrin (48–65)									
Anti-cit-biglycan (247–266)				↑	↓				↓
Anti-cit-clusterin (231–250)				↑					↓
Anti-cit-histone2b (62–81)	↓	↓	↓	↑	↓		↓		
Anti-cit-fibrinogen (211–230)		↓	↓	↑	↓				↓
Anti-cit-fibrinogen (556–575)		↓	↓	↑	↓				
Anti-cit-histone2a (1–20)		↓	↓	↑					
Anti-cit-apo E (277–296)									
Anti-cit-apo A				↑			↑		
Anti-cit-apo E				↑			↑		
Anti-cit-enolase	↓	↓	↓	↑	↓				↓

EDM=LV end diastolic mass, MI= LV mass index, EDVI= LV end diastolic volume index, HR= heart rate, ESV= end systolic volume, EF=ejection fraction, SV=stroke volume, CO=cardiac output, ESVI= end systolic volume index. ↑ =increase, ↓ =decrease. *Adjusted for Framingham score. Statistical significance: p-value <0.05.

Conclusion: Our results suggest that categories of specific ACPAs are associated with alterations in cardiac parameters in RA patients. Identifying the specific peptide(s) against which the anti-CCP reactivity is directed represents an indirect, but important, advance in understanding the pathophysiology of accelerated CVD in RA.

2540

Prescription of Tumour Necrosis Factor α Antagonists Is Strongly Associated with a Reduction in Hospital Admissions and in Musculoskeletal Surgical Procedures for Rheumatoid Arthritis Based On a 16 Year Analysis of Nationwide Data.

Leonard C. Harty[1], Gary O'Toole[2], Kathleen Bennett[3] and Oliver M. FitzGerald[4]. [1]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland, [2]Department of Orthopaedic Surgery, St. Vincent's University Hospital, Dublin, Ireland, [3]2. Department of Pharmacology & Therapeutics, Trinity centre for Health Sciences, St James's Hospital, Dublin, Ireland, [4]Dublin Academic Medical Centre, St. Vincent's University Hospital, Dublin, Ireland

Background/Purpose: Comorbidities, joint destruction leading to orthopaedic intervention and physical disability are predictable outcomes of uncontrolled Rheumatoid Arthritis (RA). Synthetic DMARDS have a slow mechanism of action and used as monotherapy induce remission in <20% of RA patients. Tumour Necrosis Factor inhibitors (TNFi) were first prescribed in 1999, have a faster mechanism of action and in combination with methotrexate in early RA induce remission in up to 50%. It is argued that the clinical, functional and quality of life benefits of TNFi may not be sufficient to justify their significant economic cost (National expense, >€100 million/year in 2010). We thus sought to evaluate the number of hospital inpatient days and of musculoskeletal surgical procedures (MSKSPs) in RA patients from 1995 to 2010 and to assess whether there is any association with TNFi usage.

Methods: The Hospital In-Patient Enquiry system (HIPE), which is a national system recording information on hospital bed utilization, was evaluated from 57 hospitals from 1995–2010 for patients admitted with a diagnosis of RA. Age group, number of inpatient days, gender and reason for admission (ICD codes) were also recorded. Annual prescription data for TNFi usage nationally was separately analysed from 2000 to 2010. Descriptive analyses are presented as totals, mean (standard deviation (SD)) and mean % change. Correlations were examined by Spearman's rho; p<0.05 was considered statistically significant.

Results: 57,774 inpatient records in RA patients were reviewed from 1995–2010; F: M 2:1, mean age 66 (16). Annual TNFi prescribing has increased by 156% per annum (pa) from 2389 units in 2000 to 116,747 in 2010. An increase in TNFi prescribing coincided with a decrease in RA inpatient days for any reason: 49,000 (4880) pa pre-2002, reducing by 13% pa thereafter to 31000 pa in 2010 (r= -0.78, p=0.0055), likely contributing significantly to savings of approximately €16,000,000 pa based on current inpatient hospital costing. 550 (51) pa MSKSPs were recorded on RA in-patients pre-2002 with a subsequent reduction of 10% pa to 291 in 2010 (overall 47% decrease) and correlating significantly but negatively with number of TNFi prescriptions (r= -0.96, p<0.0001). 71 (27) pa elective hip procedures (64 replacements) were recorded pre-2002 with a subsequent reduction of 8% pa to 40 in 2010 (r= -0.88, p=0.0007), a 44% decrease on pre 2002. 79 (12) pa elective knee procedures (64 replacements) were recorded pre-2004 with a subsequent 7% pa reduction to 37 in 2010 (r= -0.96, p=0.003), a 53% decrease on pre-2004.

Conclusion: Increased prescription of TNFi drugs for RA patients negatively correlates with reduction in RA hospital inpatient bed days and likely contributed significantly to estimated €16,000,000 pa savings. TNFi usage also correlates negatively with a reduction in all MSKSPs and specifically with both elective hip and knee procedures. It is recognised that factors other than TNFi usage, such as improved use of non-biologic disease-modifying treatments and prevention of comorbidities, may also have contributed to these improved patient outcomes. Further analysis of these data including the economic impact is underway.

High Risk of Intensive Care Unit Admission in Rheumatoid Arthritis Patients: A Population Based Study. Christine Peschken, Carol A. Hitchon, Allan Garland, Charles N. Bernstein, Randy Fransoo and Ruth Ann Marrie. University of Manitoba, Winnipeg, MB

Background/Purpose: Comorbidity in Rheumatoid arthritis (RA) has been a focus of intensive research in recent years, but little is known about the incidence of critical illness in RA, as defined by admissions to Intensive Care Units (ICU). While hospital care is the largest component of health resource use in Canada, admissions to ICU consume a disproportionate share of costs. Using a large, population-based dataset we determined the incidence of ICU admissions in RA patients.

Methods: In a stable population of over 900,000 adults, we used hospital claims from a large administrative database linked to a population based ICU database to determine the incidence of ICU admissions from 2000–2010. RA patients were compared to a cohort from the general population, matched on sex, year of birth and region of residence, with up to 5 controls for each case. Individuals with any diagnostic codes (ICD-9/10) for autoimmune inflammatory disease were excluded from the general population cohort. We estimated the annual incidence rates by age group, sex, and geographic region by stratification; (number of persons in each cohort who had at least one ICU admission/number of persons alive in that cohort at year-end). The results were age and sex standardized to the general Canadian population. The incidence of ICU admission between the RA cohorts and matched cohorts were compared using incidence rate ratios (RR). We compared the 10 year cumulative incidence of ICU admission for the period 2000–2010: (number of persons with disease who had at least one episode of critical illness/person-years at risk).

Results: The age and sex standardized annual incidence of ICU admission was relatively stable over the 10 year period, at 0.82–1.18% for RA patients compared to 0.32–0.59% for the matched cohort, RR 1.53–3.14. The risk of ICU admission increased with age (age 18–39, 0.38% for RA vs. 0.10% for controls; age 40–59, 0.81% vs. 0.31%; age 60+ 1.74% vs. 1.09%) in a similar pattern to that seen in the general population. The 10 year cumulative incidence rate for RA patients was7.68% compared to 4.73% in the general population, with a RR of 1.62 (95% CI 1.46–1.80).
Conclusion: The risk of ICU admission is significantly increased in RA patients compared to the general population, with more than 1% of adults with RA developing critical illness each year, and a 10 year risk near 8%. This represents a substantial disease burden and cost to the healthcare system. Further work is ongoing to determine causes and predictors of ICU admission.

The Association Between Inflammatory Markers and Hyperlipidemia and the Risk of Myocardial Infarction in Patients with Rheumatoid Arthritis. Jie Zhang[1], Lang Chen[1], Elizabeth S. Delzell[1], Paul M. Muntner[1], William B. Hillegass[2], Monika M. Safford[1], Iris E. Navarro[1] and Jeffrey R. Curtis[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Birmingham, AL, [3]Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of developing myocardial infarction (MI) which is not explained by Framingham CHD risk factors. We examined the association between RA-related inflammatory markers, hyperlipidemia and the risk of MI in RA patients.

Methods: We conducted a retrospective cohort study of RA patients using administrative claims data from a large U.S. commercial health plan from 2005 to 2010. Eligible patients were required to have two or more RA diagnoses from physician visits that were between 7 and 365 days apart, a baseline period of 6 months with continuous enrollment with medical and pharmacy benefits, and have results for at least one of the three lab tests occurring either during baseline or follow-up. Labs of interest included erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and low density lipoprotein cholesterol (LDL-C) and were available for a subset of RA patients from electronic records of tests performed by a national laboratory chain ordered during routine clinical care. We identified the first hospitalized MI event by inpatient primary ICD9 diagnosis codes '41001', '41011', '41021', '41031', '41041', '41051', '41061', '41071', '41081', or '41091' with at least a 3 day length of stay (or expired as the discharge status of the hospitalization). We examined the association between ESR, CRP and LDL-C quartiles (to avoid assumptions of linearity) and hospitalized MI, controlling for age and sex; and stratified by sex, controlling for age, using proportional hazard regression to estimate hazard ratios (HRs).

Results: We identified 116,181 RA patients, 74.8% of whom were women. Mean age was 48.2 ± 15.2 SD years and 74.8% were female. Depending on lab tests of interest, the numbers patients who had MI during follow-up ranged from 85 to 110 (table). The overall and sex-specific crude incidence rates of MI were 2.7 cases per 1,000 person-years, 2.1 among women, and 4.8 among men. After controlling for age and sex, higher CRP (highest compared to the lowest CRP quartile) was associated with a 3.0 (95% CI: 1.5–5.9) and higher ESR (highest compared to the lowest quartile of ESR) had an HR = 2.5 (95% CI: 1.5–4.3) for MI, but higher LDL-C was not significantly associated with increased MI risk (table). The observed association between CRP and MI appeared greater for women.

Table. Hazard Ratios (95% CI) for Factors Associated with Myocardial Infarction

	Overall[a]			Men[b]			Women[b]		
C-Reactive Protein quartile (mg/dL)									
Events, N	85			42			43		
1st (<=1.2) [referent]	1.00			1.00					
2nd (>1.2 and <=3.1)	1.09	(0.48	2.48)	0.88	(0.32	2.44)	1.64	(0.39	6.89)
3rd (>3.1 and <=8.1)	2.56	(1.28	5.15)	2.02	(0.85	4.82)	4.06	(1.16	14.19)
4th (>8.1)	2.97	(1.49	5.93)	1.51	(0.61	3.77)	6.76	(2.00	22.89)
Erythrocyte sedimentation rate quartile (mm/hr)									
Events, N	95			40			55		
1st (<=4) [referent]	1.00			1.00			1.00		
2nd (>4 and <=9)	0.85	(0.40	1.77)	0.95	(0.34	2.72)	0.81	(0.29	2.27)
3rd (>9 and <=20)	1.52	(0.81	2.83)	2.00	(0.82	4.88)	1.30	(0.55	3.11)
4th (>20)	2.52	(1.46	4.34)	2.77	(1.24	6.19)	2.40	(1.12	5.11)
Low density lipoprotein cholesterol quartile (mg/dL)									
Events, N	110			59			51		
1st (<=83) [referent]	1.00			1.00			1.00		
2nd (>83 and <=105)	1.09	(0.66	1.81)	0.97	(0.50	1.90)	1.29	(0.59	2.86)
3rd (>105 and <=130)	0.81	(0.46	1.40)	0.72	(0.34	1.52)	0.94	(0.40	2.18)
4th (>130)	1.03	(0.60	1.78)	0.97	(0.46	2.04)	1.15	(0.50	2.64)

a. Adjusting for age and gender; b. Adjusting for age.

Conclusion: Among this large national sample of RA patients, inflammatory markers (both CRP and ESR) were significantly associated with increased MI risk but LDL-C was not.

Hospitalized Bacterial Infections Among U.S. Veterans with Rheumatoid Arthritis Initiating TNF Antagonist and Newer Biologic Agents. Jeffrey Curtis[1], Shuo Yang[1], Nivedita M. Patkar[2], Lang Chen[1], Jasvinder A. Singh[1], Grant W. Cannon[3], Ted R. Mikuls[4], Elizabeth S. Delzell[1], Kenneth G. Saag[2], Monika M. Safford[1], Scott DuVall[5], Kimberly Alexander[6], Pavel Napalkov[6], Aaron Kamauu[7] and John Baddley[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]George E. Wahlen VA Medical Center, Salt Lake City, UT, [4]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [5]VA Salt Lake City Health Care System and University of Utah School of Medicine, Salt Lake City, UT, [6]Genentech, Inc., South San Francisco, CA, [7]Anolinx, Bountiful, UT

Background/Purpose: Risks of hospitalized infections for newer biologic agents have not been well characterized compared to risks for anti-TNF therapy. **Purpose:** To compare the risk of hospitalized bacterial infections among RA patients starting rituximab (RTX), abatacept (ABA) or a new anti-TNF after failure of at least one previous anti-TNF

Methods: Using data from 1998–2011 from the U.S. Veteran's Health Administration, we identified 3872 patients who started RTX, ABA, or anti-TNF therapy after prior exposure to another anti-TNF agent. *To minimize confounding from channeling of cancer patients to certain biologics, the 720 patients with a history of cancer between 1998 and 2011 were excluded, leaving a final sample of 3152 patients. Baseline characteristics were defined in the year prior to treatment initiation. For each subject, exposure episodes were defined based upon days supply (injections) or usual dosing intervals (infusions), with 9 months assumed for RTX exposure. Current exposure was extended by 90 days for all biologics. The outcome was hospitalization with a primary diagnosis of bacterial infection. The hazard ratio (HR, 95% CI) for hospitalized infection for RTX and ABA vs. anti-TNFs was calculated, adjusting for confounders as in the Table.*

Table 1. Multivariable Adjusted* Hazard Ratios for Risks of Hospitalized infections Among RA Patients Switching to Abatacept or Rituximab Compared to Patients Switching to Another Anti-TNF (Analysis Restricted to Patients Without Prior Cancer)

Infection-Related Risk Factor	Hazard Ratio (95% CI)
Medication Exposure (referent to anti-TNF therapy)	
Abatacept	0.72 (0.41–1.26)
Rituximab	1.14 (0.70–1.87)
Age Group (years) (referent to <50)	
50–60	1.82 (0.86–3.86)
60–70	1.78 (0.82–3.86)
70–80	2.11 (0.92–4.80)
≥ 80	2.40 (0.80–7.15)
Comorbidities	
COPD	1.77 (1.20–2.59)
Diabetes	1.06 (0.75–1.51)
Prednisone-equivalent steroid dose (referent to no use)	
1 – 7 mg/day	1.33 (0.88–2.02)
7 – 10mg/day	1.31 (0.83–2.08)
> 10mg/day	1.71 (1.10–2.68)

* adjusted for variables included in the table and additionally for heart failure, recent biologic switch in last 90 days, number of biologic switches and calendar year; none were significantly associated with the outcome

Results: A total of 596 RTX, 451 ABA and 3111 anti-TNF (61% adalimumab) switcher treatment episodes (first initiation of the biologic),were identified among the eligible patients. Mean age was 60.2 +10.6 years, 87% were male; 25% had diabetes, 14% had COPD, and 44% used oral glucocorticoids. Two-thirds of anti-TNF exposure episodes were adalimumab. The mean ± SD follow-up time for each treatment episode was 11±12 months. The most common types of hospitalized infections were pneumonia (37%), skin/soft tissue infections (22%), urinary tract infections (9%), and bacteremia/sepsis (7%).

Crude hospitalized infection rates/100 person years (95% CI) were: RTX=4.4 (3.1, 6.4), ABA=2.8 (1.7, 4.7), anti-TNF=3.0 (2.8, 3.9). Results were similar for a less restrictive cohort of RA patients excluding only hematologic cancer in the prior 12 months (4927 episodes, 3727 RA patients).

Conclusion: In older, predominantly male US veterans with RA and a high comorbidity burden, risk of hospitalized bacterial infections for patients treated with RTX or ABA were comparable to patients switching to a different anti-TNF therapy (mostly adalimumab).

2544

Widening Gap Between Cardiovascular Specific Mortality in Patients with Inflammatory Polyarthritis Compared to the General Population? Alexander J. Warner[1], Jh Humphreys[2], Mark Lunt[3], Tarnya Marshall[4], Deborah P. M. Symmons[1] and Suzanne Verstappen[5]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK Epidemiology Unit,, Manchester, United Kingdom, [3]University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [4]Norfolk and Norwich University Hospitals Trust, Norwich, United Kingdom, [5]University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom

Background/Purpose: Cardiovascular (CVD) mortality rates are raised in patients with inflammatory polyarthritis (IP) but have been shown to be falling in the general population. This study aims to examine CVD mortality over time in a cohort of recent onset IP patients compared to the general population in Norfolk, UK.

Methods: Between 1990–2004, patients >16 years with ≥2 swollen joints for >4 weeks were registered to an inception cohort, the Norfolk Arthritis Register (NOAR), in Norfolk, UK. Three cohorts (limited to symptom onset <2 years before baseline assessment) were defined by year of baseline assessment: cohort 1 (1990–1994); cohort 2 (1995–1999); cohort 3 (2000–2004). Rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA) status (+/−) were determined from blood samples obtained at baseline assessment. The 1987 ACR criteria for RA were also applied. Patients were tracked via Office for National Statistics (ONS) for notification of death. CVD as underlying cause of death was defined according to ICD-10 (Chapter "I"). ONS also provided CVD death rates for the Norfolk general population. For all cohorts, standardised mortality ratios (SMRs) for CVD were calculated over 5 years from baseline as well as for subgroups who fulfilled the 1987 ACR criteria for RA; those RF+ or ACPA+ at baseline. To ensure adequate statistical power, analyses were performed only for sub-groups with at least 10 observed CVD deaths over the 5 year follow up.

Results: Cohort 1 comprised 1006 patients, cohort 2: 880 patients and cohort 3: 638 patients. Approximately two-thirds were women in each cohort and median age at symptom onset was 54 (IQR 42–67); 55 (IQR 44–67); 58 (IQR 47–70) years in each respective cohort. The percentages RF+ were 28% (249/877), 29% (225/788) and 36% (203/559) and ACPA+ were 23% (174/745), 26% (191/730) and 31% (160/517) in each respective cohort.

By 5 years from baseline there were 96 (3.8% of the total cohort) CVD deaths: 36 (3.6%); 34 (3.9%); 26 (4.1%) in each respective cohort. The overall crude CVD death rate in adults >16 years in Norfolk decreased over time: 3.3% (1990–1994); 3.0% (1990–1994) and 2.7% (2000–2004). Five year CVD SMRs were raised in all cohorts but only significant statistically in cohort 3: cohort 1: 1.13 [95% CI 0.82–1.57]; cohort 2: 1.29 [95% CI 0.92–1.81] and cohort 3: 1.51 [95% CI 1.03–2.22]. RF+ patients had significantly raised 5 year CVD SMRs (1.74 [95%CI 1.05–2.88]) as did ACPA+ patients (2.17 [95%CI 1.23–3.80]) in cohort 1; more recent cohorts were excluded as <10 CVD deaths were observed. CVD SMRs were not statistically significantly increased in the subgroup of patients who met the ACR 1987 criteria for RA at baseline. No consistent differences in CVD SMRs between men and women were observed across the cohorts.

Conclusion: Raised SMRs for IP patients in advancing cohort years may be due to the declining CVD deaths observed in the general population over the same time period. The status of RF+ and ACPA+ may also contribute to excess early CVD mortality in IP patients.

2545

A Randomized, Double-Blind, Parallel Group Study of the Safety and Efficacy of Tocilizumab SC Versus Tocilizumab IV, in Combination with Traditional Dmards in Patients with Moderate to Severe RA. G. R. Burmester[1], Andrea Rubbert-Roth[2], Alain G. Cantagrel[3], Stephen Hall[4], Piotr Leszczynski[5], Daniel Feldman[6], Madura J. Rangaraj[7], Georgia Roane[8], Charles L. Ludivico[9], Francesco Ramirez[10] and Min Bao[11]. [1]Charité-Universitätsmedizin Berlin, Berlin, Germany, [2]Klinikum der Universität zu Köln, Köln, Germany, [3]Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [4]Cabrini Medical Centre, Malvern, Australia, [5]Hospital J. Strusia, Poznan, Poland, [6]Universidade Federal de de São Paulo, Sao Paulo, Brazil, [7]Arthritis & Diabetes Clinic, Monroe, LA, [8]Rheumatology Associates, P.A., Charleston, SC, [9]East Penn Rheumatology Assoc, Bethlehem, PA, [10]Roche Products Limited, Welwyn, United Kingdom, [11]Genentech, South San Francisco, CA

Background/Purpose: The objective of this study was to compare the efficacy and safety of tocilizumab (TCZ) subcutaneous (SC) and TCZ intravenous (IV) regimen in patients with adult rheumatoid arthritis (RA) who had an inadequate response to DMARDs (up to 20% may have failed one or more anti-TNF agents).

Methods: This 2-year Phase 3 trial is a randomized, active controlled, parallel group, study including a 24-week double-blind (DB) period, followed by a 72-week open-label phase. TCZ SC dose was based on previous pharmacological studies. During the DB period, patients (pts) received TCZ SC 162 mg qw + placebo IV q4w or TCZ IV 8mg/kg q4w + placebo SC qw, in combination with traditional DMARDs. The primary end point to demonstrate the non-inferiority of TCZ SC to TCZ IV was the proportion of patients in each group meeting the ACR20 improvement criteria at Week 24. Additional clinical efficacy, immunogenicity and safety assessments were evaluated as secondary outcomes. Pts were stratified by body weight and regions at baseline. The hypothesis of non-inferiority of TCZ SC with respect to TCZ IV regarding ACR20 response was tested by means of 95% confidence interval (CI) and with a 12% non-inferiority margin (NIM).

Results: A total of 1262 pts were enrolled globally. Mean baseline characteristics were similar between TCZ SC and TCZ IV groups: age 53 years; RA duration 9 years; DAS28-ESR 6.6 and 6.7, respectively. At Week 24, 69.4% (95% CI: 65.5, 73.2) of TCZ SC-treated pts versus 73.4% (95% CI: 69.6, 77.1) of TCZ IV-treated pts achieved an ACR20 response (weighted difference between groups 4.0% [95% CI: -9.2, 1.2]); a 12% NIM was met. ACR50/70 responses, disease activity and physical function improvements were also comparable between TCZ SC and TCZ IV groups. Up to Week 24, the proportions of pts with at least one adverse event (AE) and serious AE were 76.2% and 4.6%, respectively in the TCZ SC group compared with 77.0% and 5.2%, respectively in the TCZ IV group. The most common AEs in both groups were infections. Injection site reactions occurred more frequently in the TCZ SC (placebo IV) group than the TCZ IV (placebo SC) group (10.1% vs 2.3%, respectively); most were grade 1 severity. No anaphylaxis was reported over the 24-week period.

Conclusion: TCZ SC 162mg qw demonstrated comparable efficacy and safety to TCZ IV 8mg/kg q4w. No new clinically meaningful safety signals were identified in TCZ SC-treated pts.

Tofacitinib Inhibits Radiographic Progression in Patients with Rheumatoid Arthritis Prone to Develop Structural Damage: A Post-Hoc Analysis of a Phase 3 Trial. Désirée van der Heijde[1], Robert B. M. Landewé[2] and David Gruben[3]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center/University of Amsterdam & Atrium Medical Center, Amsterdam, Netherlands, [3]Pfizer Inc., Groton, CT

Background/Purpose: Tofacitinib is a novel, oral Janus kinase inhibitor being investigated as a targeted immunomodulator and disease-modifying therapy for RA. In the ORAL Scan trial [NCT00847613] progression in radiographic scores (mean change from baseline [BL] in modified Total Sharp Scores [mTSS] at Month 6) was a primary analysis using an Analysis of Covariance (ANCOVA). ANCOVA demonstrated statistically significant inhibition of structural damage progression for tofacitinib 10 mg but not 5 mg twice daily (BID) doses, versus placebo (PBO).[1] Rank analysis of change from BL values performed as a sensitivity analysis demonstrated borderline evidence of inhibition by both doses. Mean change from BL in mTSS with PBO was <0.50 at Month 6 and also 77.7% of PBO patients showed no progression (mTSS change from BL ≤0.5). There is a trend towards less PBO progression in recent radiographic studies[2] driven, in part, by the early rescue of PBO patients. In ORAL Scan, PBO treatment was only 3 months for non-responders (<20% improvement from baseline in swollen/tender joint counts, approximately 50% of patients receiving PBO) and 6 months for all others. Thus analyses focusing on prognostically-relevant characteristics of patients at particular risk of damage progression may be informative.

Methods: Literature was reviewed for factors identified as predicting higher risk of structural progression.[3,4] BL data were used to subset the patients by these high-risk factors, regardless of treatment group assignment. ANCOVA was then applied to each high-risk subset.

Results: Factors reported to predict increased risk of damage progression included: anti-CCP+; BL DAS28-4(ESR) ≥5.1; both seropositive (either RF+ or anti-CCP+) and BL erosion score ≥3; and >median BL mTSS (Figure). The primary analysis of the whole data set is displayed for reference. Each of these high-risk subsets showed maintained or increased differentiation between tofacitinib and PBO treatments. We further evaluated the predictive power of BL mTSS by tertiles, ie across three evenly divided groups irrespective of treatment assignment. In the first tertile, inhibition could not be demonstrated because of lack of progression in the PBO group. In the 2nd and 3rd tertiles, PBO progression led to large mean differences between both tofacitinib doses and PBO (Figure).
Figure. Dots = means; Bars = confidence intervals

Conclusion: In prognostically relevant subsets of patients with RA, especially in patients at increased risk of radiographic progression, both tofacitinib 5 and 10 mg BID demonstrated inhibition of damage progression compared to PBO. These analyses support the conclusion of the primary analysis that tofacitinib inhibits progression of structural damage.

Weekly Subcutaneous Abatacept Confers Comparable Onset of Treatment Response and Magnitude of Efficacy Improvement Over 6 Months When Administered with or without an Intravenous Abatacept Loading Dose. M. Schiff[1], R. Alten[2], M. Weinblatt[3], P. Nash[4], R. Fleischmann[5], P. Durez[6], J. Kaine[7], I. Delaet[8], S. Kelly[8], M. Maldonado[8], S. Patel[8] and M. C. Genovese[9]. [1]University of Colorado, Denver, CO, [2]Schlosspark-Klinik, University Medicine, Berlin, Germany, [3]Rheumatology & Immunology, Brigham & Women's Hospital, Boston, MA, [4]University of Queensland, Brisbane, Australia, [5]University of Texas Southwestern Medical Center, Dallas, TX, [6]Université Catholique de Louvain, Brussels, Belgium, [7]Sarasota Arthritis Research Center, Sarasota, FL, [8]Bristol-Myers Squibb, Princeton, NJ, [9]Stanford University, Palo Alto, CA

Background/Purpose: To compare clinical and functional responses with SC abatacept administered with or without an IV loading dose, in pts with active RA and inadequate response to methotrexate (MTX).

Methods: Pts from the intent-to-treat (ITT) populations of the ACQUIRE[1] and AMPLE[2] studies randomized to SC abatacept plus MTX were included in this analysis. All pts received fixed-dose SC abatacept 125 mg/week; in ACQUIRE, pts also received an IV loading dose (10 mg/kg based on weight range) on Day 1; no IV loading dose was administered in AMPLE. For this *post-hoc* analysis, assessments included ACR 20 and Health Assessment Questionnaire-Disability Index (HAQ-DI) response (improvement of ≥0.3) over 6 months, with pts who discontinued considered non-responders. Mean changes from baseline over 6 months in Disease Activity Score (DAS) 28 (C-reactive protein; CRP) were assessed in pts with DAS28 >5.1 at baseline (last observation carried forward), to account for differences in baseline disease activity between the two studies.

Results: A total of 736 pts from ACQUIRE (IV loading dose) and 318 pts from AMPLE (no IV loading dose) were included. All pts were biologic-naïve at baseline, with mean disease duration of 7.6 and 1.8 years, DAS28 (CRP) 6.2 and 5.5, and HAQ-DI 1.72 and 1.5 in ACQUIRE and AMPLE, respectively. Efficacy was compared at Days 15, 29, 57, 85, 113, 141 and 169. For pts treated with SC abatacept with an IV loading dose, ACR 20 response rates were 24.6, 44.5, 58.0, 66.6, 69.3, 72.4 and 74.8%, respectively. For pts treated without an IV loading dose, ACR 20 response rates were similar: 27.4, 42.5, 58.5, 60.1, 66.0, 70.1 and 66.0%, respectively. HAQ-DI response rates were also similar: 31.7, 45.1, 53.5, 59.5, 63.2, 64.4 and 68.3%, respectively, with the IV loading dose, and 31.8, 42.8, 54.4, 58.5, 60.1, 61.9 and 61.0%, respectively, without. For the overall populations, mean (SD) changes from baseline to Day 169 in DAS28 were –2.57 (1.30) and –2.09 (1.38) in ACQUIRE and AMPLE, respectively. For pts with baseline DAS28 >5.1, mean changes in DAS28 over time were also comparable for both studies (Figure).

DAS28 (CRP) mean change from baseline in patients with baseline DAS28 >5.1
Patients, N	15	29	57	85	113	141	169
ACQUIRE (IV loading)	644	655	655	655	655	655	655
AMPLE (no IV loading)	193	197	199	199	199	199	199

Conclusion: Time to onset and magnitude of ACR 20 and HAQ-DI responses and DAS28 improvements were similar for pts treated with SC abatacept with or without IV loading in patients with RA and an inadequate response to MTX. Previous pharmacokinetic data show that in the absence of IV loading, target therapeutic concentrations are achieved in the majority of pts by Week 2 of SC abatacept treatment.[3] The findings from this post-hoc analysis suggest that SC abatacept can be given effectively without an IV abatacept loading dose.

Global Molecular Effects of Tocilizumab Therapy in Synovial Biopsies of Early Rheumatoid Arthritis Patients. Julie Ducreux, Adrien Nzeusseu Toukap, Frédéric A. Houssiau, Patrick Durez and Bernard Lauwerys. Université catholique de Louvain, Brussels, Belgium

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, systemic autoimmune inflammatory disease that is characterized by the presence of inflammatory cytokines, including interleukin-6 (IL-6). Here, we investigated the global molecular effects of Tocilizumab, an approved humanized anti-IL6 Receptor antibody, versus Methotrexate therapy, in synovial biopsy samples collected prospectively in early RA before and 12 weeks after administration of the drug. The results were compared with our previous data, generated in prospective cohorts of Adalimumab- and Rituximab-treated (Methotrexate- and anti-TNF-resistant, respectively) RA patients.

Methods: Paired synovial biopsy samples were obtained from the affected knee of early RA patients before and 12 weeks after initiation of Tocilizumab (n=12) or Methotrexate (n=8) therapy. SDAI remission criteria were computed prospectively before, 3 months and 6 months after administration of the drugs and patients' responses were defined according to their SDAI remission status at 6 months. Gene expression studies were performed using GeneChip Human Genome U133 Plus 2.0 arrays. Quantitative real-time reverse transcriptase-polymerase chain reaction (qPCR) experiments were performed to confirm the differential expression of selected transcripts.

Results: We found that Tocilizumab induces a significant down-regulation of genes included in specific pathways: cytokines & chemokines (e.g. IL-6, IL-7, IL-22, CCL8, CCL11, CCL13, CCL19, CCL20), and T cell activation. By contrast, Tocilizumab induces a significant up-regulation of genes associated with healing processes. These effects are significantly more pronounced as compared to Methotrexate, Rituximab, or Adalimumab therapies. By opposition to the effects of Adalimumab, Tocilizumab therapy does not induce a decreased expression of genes involved in cell proliferation. Real-time qPCR experiments confirmed the differential expression of several transcripts belonging to these pathways.

Gene expression studies further identified genes differentially expressed at baseline according to SDAI remission status at 6 months. In Methotrexate-treated patients, genes involved in myeloid cell function predict remission, whereas the presence of a mesenchymal cell development signature predicts absence of remission. By opposition, in Tocilizumab-treated patients, genes involved in myeloid cell differentiation predict absence of remission, whereas genes involved in ras-dependent cell proliferation predict remission at 6 months.

Conclusion: Tocilizumab displays distinct molecular effects on synovial biopsies of RA patients. These results open perspectives for the individualization of therapeutic decisions, based on the identification of specific molecular profiles in individual patients.

Induction of Remission in Patients with up to 12 Months of Moderate-to-Severe Rheumatoid Arthritis Symptoms Treated with Etanercept Plus Methotrexate Over 52 Weeks.

Paul Emery[1], Mohammed Hamoudeh[2], Oliver M. FitzGerald[3], Bernard Combe[4], Stefanie Gaylord[5], Theresa Williams[5], Jack Bukowski[5], Ronald Pedersen[5], Andrew S. Koenig[5] and Bonnie Vlahos[5]. [1]Leeds General Infirmary, Leeds, United Kingdom, [2]Hamad Medical Corporation, Doha, Qatar, [3]St. Vincent's University Hospital, Dublin, Ireland, [4]Lapeyronie Hospital, Montpellier, France, [5]Pfizer Inc., Collegeville, PA

Background/Purpose: In the COMET study, etanercept (ETN) plus methotrexate (MTX) therapy in patients with early rheumatoid arthritis (RA) yielded high clinical remission rates,[1] but whether remission can be maintained after dose reduction or withdrawal (biologic-free) is unknown. The PRIZE trial is an ongoing, prospective,121-wk, 3-period study to evaluate the efficacy of ETN/MTX as first-line therapy in patients with early, active moderate-to-severe RA and to assess whether efficacy can be maintained with reduced-dose or biologic-free therapy (Period 2) or drug free (Period 3). The main objective of Period 1, reported here, was to achieve DAS28 remission at wks 39 and 52 in patients treated with ETN 50 mg QW plus MTX (ETN50/MTX); responders (DAS28 ≤3.2 at wk 39 + DAS28 <2.6 at wk 52) qualified for Period 2 enrollment.

Methods: MTX- and biologic-naïve RA patients (symptom onset ≤12 mo from enrollment; DAS28 >3.2) received ETN50/MTX for 52 wks. At the discretion of the investigator, the initial 10 mg/wk MTX dose was titrated up to a maximum of 25 mg/wk to achieve remission. Patients not achieving low disease activity (LDA; DAS28 ≤3.2) received corticosteroid boosts at wks 13 and/or 26; those not achieving LDA at wk 39 (non-responders) were withdrawn from the study. In addition to DAS28 and SDAI remission and LDA, other standard clinical outcomes were assessed. Efficacy and safety analyses were conducted in all patients who received ≥1 ETN/MTX dose (mITT).

Results: A total of 306 patients (female, 70%; Caucasian, 94%; mean age, 50 y; disease duration from symptom onset, 6.5 mo) were enrolled; 222 (72.6%) completed Period 1 (reasons for not completing Period 1 are listed in the table). No patient was excluded from the mITT population. Efficacy results are summarized in the table. Significant changes from baseline were observed in all clinical assessments and endpoints (P<0.0001). LDA was achieved in >75% of patients and DAS28 and SDAI remission in >60% of patients. Twenty-nine percent of patients achieved DAS28 <2.6 + HAQ ≤0.5 + no radiographic progression. The most common treatment-emergent AEs were nausea and nasopharyngitis (13%, each). No unexpected safety or tolerability findings were reported.

Table. Summary of ETN50/MTX efficacy in Period 1 of the PRIZE trial (N = 306)[a]

Efficacy Assessment[b]	Baseline Mean (SD)	Final on Therapy Visit Mean (SD)	Δ from Baseline Mean (SD)
DAS28	6.0 (1.1)	2.6* (1.5)	−3.5 (1.5)
SDAI	38.3 (14.0)	7.2* (11.9)	−31.1 (14.8)
Patient global assessment	58.9 (23.6)	16.3* (21.9)	−42.8 (28.4)
Tender/swollen joint count (28 joints)	14.1 (7.1)/11.1 (5.9)	2.5* (5.4)/1.4* (3.7)	−11.6 (7.6)/−9.7 (5.7)
HAQ DI	1.3 (0.7)	0.5* (0.6)	−0.8 (0.7)

Efficacy Endpoint[c]	% Patients (95% CI), Final on Therapy Visit
DAS28 LDA (≤3.2)/remission (<2.6)	78.0* (73.0, 82.6)/70.5* (65.0, 75.6)
SDAI LDA (≤11)/remission (≤3.3)	81.3* (76.4, 85.5)/60.9* (55.1, 66.4)
ACR Boolean remission	51.5* (45.7, 57.2)
ACR 20/50/70/90 responses	85.7* (81.2, 89.5)/ 76.1* (70.9, 80.8)/ 65.8* (60.1, 71.1)/ 34.9* (29.5, 40.6)
Complete response†	29.1* (24.1, 34.5)

[a]A total of 84 (27.4%) patients did not complete Period 1; due to non-response (30 patients); adverse events (20 patients); patient request (13 patients); protocol violation (10 patients); unsatisfactory response per investigator assessment (7 patients); sponsor's decision and lost to follow-up (2 patients each).
[b]Paired *t*-test.
[c]binomial test-value tests the null hypothesis that % = significantly different from 0; mITT population.
*P < 0.0001 vs baseline.
†Patients who discontinued treatment prior to week 52 were not included in this analysis.
DAS28 = Disease Activity Score based on a 28-joint count; SDAI = Simplified Disease Activity Index; HAQ DI = Health Assessment Questionnaire disability index; ACR = American College of Rheumatology; Complete response = patients achieving DAS28 <2.6, HAQ ≤0.5 at 39 and 52 wks, and no radiographic progression (mTSS ≤0.5) over 52 wks.

Conclusion: In Period 1 of the PRIZE trial, the majority of patients with early, moderate-to-severe RA who received ETN50/MTX for 52 wks achieved remission. ETN/MTX was well tolerated, with no unexpected safety issues. Forthcoming results from Periods 2 and 3 will address whether this initial response to combination therapy will be maintained with ETN dose reduction, biologic-free, or drug-free.

Clinical, Radiographic, and Immunogenic Effects After 1 Year of Tocilizumab-Based Treatment Strategy with and without Methotrexate in Rheumatoid Arthritis: The ACT-RAY Study.

Maxime Dougados[1], Karsten Kissel[2], Philip G. Conaghan[3], Emilio Martin-Mola[4], Georg A. Schett[5], Howard Amital[6], Ricardo M. Xavier[7], OM Troum[8], Corrado Bernasconi[9] and T.W.J. Huizinga[10]. [1]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [3]University of Leeds, Leeds, United Kingdom, [4]Hospital Universitario La Paz, Madrid, Spain, [5]Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany, [6]Center for Autoimmune Diseases, Sheba Medical Center, Tel-hashomer, Israel, Tel-hashomer, Israel, [7]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [8]USC Keck School of Medicine, Santa Monica, CA, [9]Roche, Basel, Switzerland, [10]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: 24-week data from ACT-RAY comparing an add-on strategy (tocilizumab [TCZ] + methotrexate [MTX]) with a switch strategy (TCZ + placebo [PBO]) in MTX-IR patients have been previously reported, demonstrating relevant clinical and radiographic benefit without a statistically significant difference between the 2 groups for most endpoints. Longer-term data are needed to assess the switch and add-on strategies over time and the effect of the protocol-specified treat-to-target strategy in patients who started on TCZ monotherapy or combination with MTX after Week 24. Therefore, the objective here is to assess the 52 week efficacy and safety of a TCZ-based treat-to-target strategy in patients who started treatment with and without MTX in adult patients with moderate to severe RA and an inadequate response to MTX.

Methods: ACT-RAY is a phase 3b clinical trial. Patients on stable doses of MTX were randomized to either add TCZ 8 mg/kg IV every 4 weeks to their existing MTX (add-on group) or switch to TCZ 8 mg/kg IV every 4 weeks with oral PBO (switch group). The protocol instituted the addition of open-label conventional DMARDs other than MTX at Week 24 or later in patients with DAS28 > 3.2, maintaining the blinding of MTX/PBO.

Results: 556 patients were randomized, with 85% completing 52 weeks of treatment. Baseline data were similar between the 2 groups (disease duration 8.2 yrs, DAS28-ESR 6.3, HAQ-DI 1.47 [all mean values]) except for Genant-modified Sharp Score (GSS), which was higher in the switch group. Efficacy results are shown in the table. Between Weeks 24 and 52, the proportion of patients receiving DMARD intensification was comparable in the add-on and switch arms (29% vs 33%). Clinical improvements at Week 24 in both groups were maintained or further improved up to Week 52 with a trend in favor of the add-on strategy for some endpoints. While the vast majority of patients did not experience a change from baseline, significantly more switch patients experienced radiographic progression (14.5% versus 7.6% in the add-on group). In a preliminary analysis in patients with samples available, 3.7% of patients developed antidrug antibodies (ADAs) up to week 52: 10/272 in the add-on group and 11/271 in the switch group. Neutralizing ADAs were developed by 3.3% of patients (9/272) in the add-on group and 4.1% (11/271) in the switch group. Rates of SAEs and serious infections per 100 PY were 14.2 and 4.9 in the add-on group and 17.7 and 6.3 in the switch group, respectively. In patients with normal baseline values, ALT elevations >3x the upper limit of normal were observed in 11% of add-on and 3% of switch patients.

Table. Week 24 and 52 Efficacy Results (ITT Population)

Clinical Parameter	Week 24 Add-on n = 277	Week 24 Switch n = 276	P value	Week 52 Add-on n = 277	Week 52 Switch n = 276	P value
DAS28, mean change from baseline	−3.43	−3.21	0.06[a]	−3.74	−3.66	0.67[a]
DAS28 remission (DAS28 <2.6), %	40.4	34.8	0.21	45.5	36.6	0.03
Low disease activity (DAS28 ≤3.2),%	61.7	51.4	0.031	62.5	57.2	0.12
ACR20/50/70/90,%	71.5/45.5/24.5/5.8	70.3/40.2/25.4/5.1	0.87/0.30/0.68/0.84	70.8/50.2/31.4/12.6	69.2/55.4/31.2/11.2	0.62/0.22/0.99/0.65
SJC (66)/TJC (68), mean change from baseline	−11.3/−17.3	−11.8/−17.0	0.8/0.9	−12.3/−19.4	−12.2/−18.9	0.9/0.7
GSS, mean change from baseline	0.27	0.40	0.33[b]	0.40	0.63	0.44[b]
Patients w/o radiographic progression,[c] %	90.6	87.3	0.18	92.4	85.5	0.007

[a] P values adjusted for baseline DAS28 and region.
[b] Estimates and Pvalues adjusted for baseline DAS28 and baseline GSS.
[c] No progression defined as GSS of ≤ 1.5 (SDC) (patients with missing observations classified as progressors). Not adjusted by GSS at baseline.

Conclusion: This one year analysis suggests that TCZ monotherapy might be an acceptable therapeutic strategy in patients with a contraindication for or intolerance to MTX.

ACR Concurrent Abstract Session
Sjögren's Syndrome II - Clinical
Tuesday, November 13, 2012, 4:30 PM–6:00 PM

2551

Validation of EULAR Primary Sjögren's Syndrome Disease Activity and Patient Indexes. Raphaèle Seror[1], Elke Theander[2], Johan G. Brun[3], Manel Ramos-Casals[4], Valeria Valim[5], T. Matteo Foundation, Pavia, Italy, [20]Rheumatology Unit, Sapienza University of Rome, Rome, Italy, [21]Oklahoma Medical Research Foundation, Oklahoma City, OK, [22]University Medical Center Utrecht, Utrecht, Netherlands, [23]German Hospital, Buenos Aires, Argentina, [24]Casa di Cura di Lecco, Lecco, Italy, [25]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

Background/Purpose: To validate the EULAR scores for assessment of primary Sjögren's Syndrome (SS): the EULAR SS Disease Activity Index (ESSDAI), the EULAR SS Patient Reported Index (ESSPRI).

Methods: Prospective international validation study with 2 visits: baseline and 6 months. At each physicians completed ESSDAI, SS disease activity index (SSDAI), Sjögren's Systemic Clinical Activity Index (SCAI) and physician global assessment (PhGA); and patients completed ESSPRI, Sicca

Symptoms Inventory (SSI), Profile of Fatigue and Discomfort (PROFAD) and patient global assessment (PGA). Construct validity (using correlations with gold standard), responsiveness (using standardized response mean [SRM]) and reliability (intraclass correlation coefficient [ICC]) were evaluated and compared between each scores.

Results: 395 patients (96% women, mean age 55.4 ± 13.7 years, 79% with anti-SSA and/or anti-SSB antibodies) from 15 countries have been included. At enrollment, 145 (37%) and 251 (64%) had, respectively, current or either current or past systemic manifestations. EULAR scores had higher correlation with gold standard than other scores (ESSDAI with PhGA: rho=0.59; ESSRPI with PGA: rho=0.70). Correlations between patient and systemic scores were very low (rho ranging from 0.07 to 0.29). All systemic scores had similar large responsiveness in improved patients. Responsiveness of patients scores was low in patient experiencing improvement of their symptoms but was significantly higher for ESSPRI compared to SSI and PROFAD (p=0.006 and 0.049 for SRM comparisons) Reliability was assessed in a subgroup of 47 and 62 patients, for systemic and patients scores, respectively. Reliability was very good for all scores.

	Construct validity Correlation with PhGA or PGA	Reliability ICC [95% IC]	Responsiveness SRM for improved patients	Responsiveness SRM for stable patients	Responsiveness SRM for worsened patients
Physician outcome measures		N = 62	N = 62	N = 198	N = 50
ESSDAI	0.59	0.96	−0.72	−0.17	+0.26
SSDAI	0.34	0.83	−0.82	−0.26	+0.43
SCAI	0.32	0.95	−0.69	−0.22	+0.37
Patient-centered measures		N = 62	N = 95	N = 151	N = 72
ESSPRI	0.70	0.94	−0.37	+0.08	+0.37
SSI	0.55	0.86	−0.04	+0.07	+0.34
PROFAD	0.58	0.92	−0.16	+0.15	+0.32

Conclusion: ESSDAI and ESSPRI had good construct validity, better than other scores. All scores were reliable. Systemic scores were sensitive to change in patient whose disease activity improves. Patient scores had a small sensitivity to change. However, ESSPRI was significantly better than SSI and PROFAD. The poor correlation between systemic and patients scores confirms that these 2 components are different and should be evaluated separately.

Clinically Significant and Biopsy-Documented Renal Involvement in Primary Sjögren's Syndrome: Clinical Presentation and Outcome. Andreas V. Goules[1], Ioanna P. Tatouli[1], Alexandros A. Drosos[2], Fotini N. Skopouli[3], Haralampos M. Moutsopoulos[4] and Athanasios G. Tzioufas[5]. [1]National University of Athens, Athens, Greece, [2]Professor of Medicine/Rheumatology, Ioannina, Greece, [3]Harokopion University, Athens, Greece, [4]School of Medicine, University of Athens, Athens, Greece, [5]School of Medicine, National University of Athens, Athens, Greece

Background/Purpose: Primary Sjögren's syndrome (pSS) may affect kidneys, causing either interstitial nephritis (IN) or glomerulonephritis (GMN). However, overt renal disease in pSS is rare and does not exceed 5% of patients. The aim of this study was to estimate the prevalence and investigate the clinical features and the outcome of clinically significant and biopsy documented renal involvement in a large cohort of pSS patients.

Methods: From a cohort of 715 patients who met the American-European criteria for pSS, those with clinically significant and biopsy documented renal involvement were identified and their clinical features were recorded. The primary outcomes included death, hemodialysis, lymphoma and chronic renal failure (CRF). Statistical analysis was performed to estimate the primary outcomes per 100 person-years.

Results: Thirty five (4.9 %) pSS patients had biopsy documented renal involvement, representing a total follow up time after renal diagnosis of 271.8 person-years. Twelve patients (34.3%) had IN, 18 (51.4%) had GMN and 5 (14.2%) developed both entities. Nine patients (25.7%) presented chronic renal failure (including 4 requiring chronic hemodialysis) and 9 (25.7%) developed malignant lymphoma. Seven out of 11 (63.6%) patients with CRF had IN while the remaining 4 patients (36.4%) had GMN. The corresponding rates for lymphoma, chronic renal failure and hemodialysis were estimated at 3.30

(95%CI, 1.72–6.35), 4.04 (95%CI, 2.24–7.29), and 1.47 (95%CI, 0.55–3.91) per 100 person-years, respectively.

Overall 5-year survival was 0.82 (0.62–0.92) with median not reached. Interestingly, eight out of nine (89%) reported deaths and eight out of nine malignant lymhomas (89%) were among the GMN group. After adjusting for age, type of renal involvement (IN vs GMN), lymphoma, CRF and hemodialysis, lymphoma remained the sole significant adverse predictor for survival (adjusted Hazard Ratio, 5.96, 95% CI 1.14–21.5) for survival. Causes of death included lymphoma (33.3%), cardiac arrest (22.2%) related to hemodialysis or CRF, infection (11.1%) related to CRF, stroke (11.1%) and cerebral haemorrhage (11.1%).

Conclusion: The long term prognosis of clinically significant and biopsy documented renal involvement in pSS varies. Patients with IN display a favorable prognosis while patients with GMN are in high risk to develop lymphoma and have poor survival.

Histological, Serological and Clinical Changes in Response to Abatacept Treatment of Sjögren's Syndrome. Sabine Adler[1], Meike Koerner[1], Frauke Foerger[2], Marco-Domenico Caversaccio[3] and Peter M. Villiger[4]. [1]University Hospital Bern, Bern, Switzerland, [2]Inselspital-University Hospital, Bern, Switzerland, [3]University Hospital Bern, Inselspital, Bern, Switzerland, [4]Inselspital-University Hospital of Bern, Bern, Switzerland

Background/Purpose: To prospectively evaluate histopathologic, blood and clinical responses to abatacept treatment in patients with primary Sjögren's syndrome (pSS).

Methods: Blood, saliva and minor salivary gland biopsies were obtained prior to and after the last of 8 doses of abatacept in 11 pSS patients. Histology evaluated the number of lymphocytic foci and of B- and T-cell subtypes ($CD20^+$, $CD3^+$, $CD4^+$, $CD8^+$). The numbers of $FoxP3^+$ regulatory T-cells and the FoxP3/CD 3 ratio was calculated. The histologic data were compared with results from peripheral blood and with changes in saliva secretion.

Results: The numbers of lymphocytic foci decreased (p=0.09) with a corresponding reduction of $CD20^+$, $CD3^+$, $CD4^+$ and $CD8^+$ T-cells. Numbers of local $FoxP3^+$ T-cells decreased in 9 of 10 samples (p=0.022). In peripheral blood $CD3^+$ cells did not change in numbers while $CD20^+$ B cells increased (p=0.038). This increase was due to an expansion of the naïve B cell pool (p=0.012). The slight decrease in gamma globulins and IgG did not reach significance (P=0.09 and 0.169, respectively). Overall, saliva secretion did not change, however 7 of 11 patients showed an increase in saliva secretion (p=0.018 for the 7 responders).

Conclusion: Inhibition of T cell co-stimulation using CTLA4-Ig leads to a reduced inflammation in glandular tissue with a 50% decrease in $FoxP3^+$ cells, to an expansion of peripheral naïve B cells and to an increase in saliva secretion in 70% of pSS patients. In conclusion, abatacept bears the potential of a disease-modifying biologic agent in pSS.

Background/Purpose: There is evidence for a critical role of B cells in the pathogenesis of pSS. Both open labelled and small controlled studies suggested the efficacy of Rituximab (RTX) in specific subgroups of pSS (early or systemic).We conducted a multicenter, randomized, double-blind, placebo-controlled trial to evaluate the efficacy of RTX in a large group of patients with active recent and/or systemic pSS.

Methods: 122 Patients were assigned to receive either RTX infusions (1g) or placebo (P) at weeks 0 and 2. They were followed up for 24 weeks. All patients fulfilled the new American-European Consensus Group criteria for pSS, had an active disease as assessed by mean values of the 2 highest visual analog scales (VAS) '50 evaluating dryness, pain, fatigue and global, and had either a recent (less than 10 years since first clinical sign) and a biologically active pSS [Auto antibodies (SSA or RF) or cryoglobulinaemia, or hypergammaglobulinaemia, or high level of beta 2-microglobulinemia or hypo-complementaemia] or at least one extra-glandular manifestation. The primary end point was an improvement of at least a 30 mm on 2 of 4 VAS between weeks 0 and 24. Secondary end points included delta of improvement of all VAS separately, the ESSDAI score, the number of swollen joints, the basal salivary flow rate, results of the Schirmer test, the schirmer score, biological and extra glandular improvement, evaluated from week 0 to week 24.

Results: 24 of 122 patients (19.5%) had a recent pSS, 31 (25.4%) had systemic pSS and 67 (54.9%) had both. 33 (28%) had pulmonary manifestations, 63 (53%) an articular involvement and 33 (28%) a parotidomegaly. 113 patients were evaluated at week 24. For primary end point, 11/53 (20.7%) patients receiving placebo and 13/60 (21.7%) treated with RTX had a favourable overall response (P = 0.9). Similarly, the 30 points improvement for each VAS separately did not reach significance, although the delta of improvement of sicca and fatigue VAS were statistically improved in RTX group (P<0.05). Delta improvement between W24 and W0 was significant for the salivary flow rate (p:0.009) but not for other objectives variables (Schirmer, focus score, Chisholm score). Concerning systemic manifestations, the ESSDAI score (total and each domain) was not significantly improved in the RTX group. For synovitis, only 2/24 patients of the P group and 4/25 of the RTX group were improved. The difference between RTX and P group at W24 did not differ in terms of primary end point or ESSDAI in the recent and systemic subgroups evaluated separately. Tolerance was similar in both groups excepted for reaction to infusion, more frequent in the RTX group.

Conclusion: In this randomized, double blind, placebo controlled study, the efficacy of RTX, was not sufficient enough to allow its prescription in both recent and systemic pSS. Studies in specific unfrequent manifestations (thrombopenia, neurological disorders) or using more specific measurement tools (parotid ultrasound) are warranted.

Results of the Beliss Study, the First Open Phase 2 Study of Belimumab in Primary Sjogren's Syndrome. Xavier Mariette[1], Luca Quartuccio[2], Raphaèle Seror[3], Sara Salvin[2], Frederic Desmoulins[1], Martina Fabris[4], Sara Villeneuve[5], Philippe Ravaud[6] and Salvatore De Vita[7]. [1]Université Paris-Sud, Le Kremlin Bicetre, France, [2]Rheumatology Clinic, DSMB, University of Udine, Italy, Udine, Italy, [3]Bicetre university hospital, LE Kremlin-Bicetre, France, [4]Institute of Clinical Pathology, Udine, Italy, [5]Hospital Hotel dieu, Paris, France, [6]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [7]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy

Background/Purpose: The BAFF (or BLyS) cytokine plays a key role in pathogenesis of primary Sjogren's syndrome (pSS). Belimumab, the first biological treatment inhibiting soluble BAFF, has proved its effectiveness and has been recently approved in systemic lupus. Lupus and pSS share a lot of pathogenic mechanism including interferon signature and BAFF involvement. Thus we run the first open label study of belimumab in pSS patients.

Methods: Patients were included in 2 simultaneous and identical studies in 2 European Centres. Patients had to fulfill AECG criteria, to be anti-SSA/SSB positive and had to have at the time of inclusion either systemic complications, early disease ($\leq$ 5 years), or the presence of at least one other biomarker of B-cell activation (increase in IgG, free light chains or of beta2-microglobulin, decrease of C4, presence of cryoglobulinemia or monoclonal component).The patients were treated with belimumab 10 mg/kg W0, W2, W4 and then every four weeks until W24.

The primary end-point was evaluated at W28 and consisted of improvement

of 2 of the 5 following items: 1- ≥ 30% reduction of patient's dryness VAS, 2- ≥ 30% reduction of patient's fatigue VAS, 3- ≥ 30% reduction of patient's musculoskeletal pain VAS, 4- ≥ 30% reduction of physician's systemic activity VAS, 5- ≥ 25% reduction of any of the following B cell activation biomarkers (free light chains of immunogobulins, beta2-microglobulin, monoclonal component, cryoglobulinemia, IgG) or ≥ 25% C4 increase.

Results: Thirty patients were included, 15 in each center (all female, mean age = 49.5 yrs ±16.5, mean disease duration = 5.7 yrs ± 5.6). 15 patients had systemic complications, 11 had early disease and 20 had at least one other biomarker of B-cell activation. 19/30 (63%) reached the primary end-point. For each individual component the response was as follows: VAS dryness: 10 (33%), VAS fatigue: 7 (23%), VAS pain: 7 (23%), VAS physician's systemic activity: 12 (40%), biological component: 18 (60%). The percentage of responders was 8/11 (73%) in early disease and 7/15 (47%) in systemic disease.

The ESSDAI (EULAR Sjögren's Syndrome Disease Activity Index) score decreased from 8.8±7.39 to 5.59±5.49 (p<0.0001). The ESSPRI (EULAR Sjögren's Syndrome Patients Reported Index) score decreased from 6.44 ±1.11 to 5.56 (p=0.01). There was no significant change of salivary flow (0.62±1.23 to 0.75±1.23;p=0.43) and Schirmer test (4.09±7.23 to 4.72±8.08; p=0.17).

The treatment induced significant changes of some biological data: serum IgG from 20.92±10.25 to 18.53 ±7.21 (p<0.0001); serum IgA from 4.08 ±3.02 to 3.23 ±1.87 (p=0.001), kappa free light chain from 33.15±24.65 to 25.59 ±23.42 (p<0.0001), lambda free light chain from 28.31 ±16.59 to 20.85 ±12.24 (p<0.0001), rheumatoid factor from 146 ±174 to 97 ±91 (p<0.0001).

Concerning safety, we observed 1 severe adverse event which was a pneumococcus meningitis after 6 infusions of the drug. This patient, who was responder to belimumab, recovered completely without any sequellae.

Conclusion: Results of this first open phase 2 study of belimumab in pSS patients are very encouraging and justify the realization of randomized control trials with the drug in selected populations of patients with pSS.

Allogenic Mesenchymal Stem Cells Transplantation Alleviates Clinical Sjögren's Syndrome. Lingyun Sun[1], Dandan Wang[1], Junji Xu[2] and Songlin Wang[2]. [1]Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China, [2]Salivary Gland Disease Center and Molecular Laboratory for Gene Therapy & Tooth Regeneration, Beijing Key Laboratory of Tooth Regeneration and Function Reconstruction, Capital Medical University School of Stomatology, Beijing, China

Background/Purpose: Sjögren's syndrome (SS) is a systemic autoimmune disease that is characterized by dry mouth and dry eyes. Currently, treatment of SS is difficult and challenging. This study is undertaken to determine the safety and efficacy of allogenic mesenchymal stem cells (MSCs) transplantation in SS patients.

Methods: Twenty-four patients with primary SS (23 females and 1 male; age from 27 to 68 years old, mean 45 years old) refractory to standard treatments were enrolled. Fresh umbilical cords (UC) were obtained from informed healthy mothers after normal deliveries. UC MSCs were expanded and infused intravenously (one million cells per kilogram of bodyweight per infusion). The clinical manifestations and laboratory parameters were compared pre- and post- MSCs transplantation (MSCT), with all patients completed 12 months follow up. Side effects were monitored during and post-MSCT.

Results: All patients tolerated well with allogenic UCMSCT, and no adverse events occurred during or after MSCs infusion. Mean SS disease activity index (SSDAI) scores for all 24 patients decreased from 5.63 ± 1.44 (baseline) to 4.33 ± 1.79 at 1 month, 4.08 ± 1.44 at 3 months, 3.46±1.18 at 6 months, and 3.08 ± 1.21 at 12 months (all *P*<0.05). Global assessment by visual analog scale (VAS) also improved at 1 month, and showed further ameliorations at 3, 6, and 12 months after UCMSCT. Unstimulated salivary flow rate increased significantly 2 weeks after UCMSCT (1.00 ± 0.78 ml/10 min at 2 weeks *vs.* 0.63 ± 0.73 ml/10min at baseline, *P*<0.001, n=11) and showed a 2-fold increase at 1 month (1.26 ± 1.02, *P*<0.001 *vs.*baseline, n=11). This flow rate continued to increase on subsequent follow-up visits. Stimulated salivary flow rate also significantly increased after MSCT (*P*=0.008 at 2 weeks, *P* = 0.043 at 1 month, *P* = 0.016 at 3 months, *P*=0.017 at 6 months and *P* = 0.016 at 12 months *vs.*

baseline, n=11). The determination of modified treatment emergent symptom scale (TESS) score decreased at 2 weeks visit, and was maintained at this low level on subsequent visits. Furthermore, punctate sialectasias in the parotid gland declined, dilation of main duct was improved 1 year after UCMSCT, and excretory function was also partially restored. Serum levels of anti-SSA/Ro and anti-SSB/La decreased 1 month post-MSCT (*P*<0.001, n = 5). The mechanism studies showed that the frequency of Th17 cells decreased while Treg cells increased (*P*<0.05) after MSCT. Serum levels TGF-β increased and IL-17 decreased 1 month post-MSCT (*P*<0.05).

Conclusion: Allogenic UC MSCT is safe and results in amelioration of disease activity. These data provide a foundation for conducting allogenic UC MSCT for SS patients.

Ustekinumab in Active Psoriatic Arthritis Including Patients Previously Treated with Anti-TNF Agents: Results of a Phase 3, Multicenter, Double-Blind, Placebo-Controlled Study. Christopher T. Ritchlin[1], Alice B. Gottlieb[2], Iain B. McInnes[3], Lluis Puig[4], Proton Rahman[5], Shu Li[6], Yuhua Wang[6], Mittie K. Doyle[7], Alan Mendelsohn[8] and Arthur Kavanaugh[9]. [1]University of Rochester Medical Center, Rochester, NY, [2]Tufts Medical Center, Boston, MA, [3]University of Glasgow, Glasgow, United Kingdom, [4]Universitat Autònoma de Barcelona, [5]Memorial University, St. Johns, NF, [6]Janssen Research and Development, LLC, PA, [7]Janssen Research and Development, LLC/U of Penn, Spring House/Phila, PA, [8]Janssen Research & Development, LLC, Spring House, PA, [9]UCSD School of Medicine, La Jolla, CA

Background/Purpose: Assess efficacy & safety of UST in reducing signs & symptoms of active PsA, including pts with & without previous anti-TNF experience, in PSUMMIT 2.

Methods: Adult PsA pts (n=312) with active disease (≥5 SJC & ≥5 TJC;CRP≥0.3mg/dL) despite DMARD &/or NSAID &/or exposure to anti-TNF's (≥8 wks of exposure to etanercept, golimumab, adalimumab or certolizumab pegol, or 14 wks exposure to infliximab, &/or documented evidence of anti-TNF intolerance/toxicity with exposure <8–14wks;n=180/312) were randomized to UST45mg, UST90mg, or PBO at wks 0, 4, & q12wks. At wk16, pts with <5% improvement in TJC & SJC entered blinded EE (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). Stable MTX was permitted but not mandated. Primary endpt was ACR20 at wk24. Secondary endpts at wk24 included: ACR 50/70 & DAS28-CRP responses, change from BL in HAQ-DI, PASI75 (in pts with ≥3% BSA psoriatic involvement at BL), & % change from BL in enthesitis & dactylitis scores. Stat testing adjusted for BL MTX status. AEs reported through PBO-controlled period (wk16) & wk24.

Results: BL disease characteristics were generally comparable across grps. Median BL disease characteristics among all pts were: PsA duration 5.08 yrs, CRP 9.32mg/L, SJC/TJC 11/22, pain VAS 6.8, pt global assessment VAS 6.2, PGA 7.1, HAQ-DI 1.3. BL disease characteristics among anti-TNF experienced pts: PsA duration 6.7 yrs, CRP 10.6 mg/L, SJC/TJC 12/24, pain VAS 7.2, pt global assessment VAS 6.4, PGA 7.4, HAQ-DI 1.4. Sig greater prop of UST vs PBO pts had ACR20 response at wk24. Sig improvements were also observed in DAS28-CRP response at wk12 & wk24 for both UST grps vs PBO. Clinically meaningful change from BL in HAQ-DI (≥0.3) was observed in 34.0%, 38.1%, & 16.3% of UST45mg, 90mg, & PBO pts, resp (p=0.003, p<0.001). Nearly half used MTX; ACR responses were greater with UST vs PBO regardless of MTX. Among pts with enthesitis (n=221), median % improvements in the enthesitis score (MASES) were 33.3%, 48.3%, & 0.0% for the UST45mg (p=0.098), 90mg (p=0.008), & PBO grps, resp. Among pts with dactylitis at BL (n=117), median % improvements in dactylitis scores were 0.0%, 65.0%, & 0.0% of pts in the UST 45mg, 90mg, & PBO grps (not stat sig).Through wk16, pts with ≥1 AE were 63.1%, 60.6% & 54.8% for the UST 45mg, UST 90mg, & PBO grps, resp, with infections being most common AE (28.2%, 26.0%, & 23.1%). Serious AEs were reported in 0.0%, 1.0%, & 4.8%, resp. Through wk24, no deaths, opportunistic infections, TB, or major adverse CV events were reported. 1 serious infection (interstitial lung disease, PBO) & 1 malignancy [squamous cell Ca in situ of skin (uncovered from cleared PsO plaque), UST90mg] were reported.

Patients Achieving Endpoint at Week 24 (n/N [%] or Median [Min, Max]): Overall randomized population and Sub-groups (anti-TNF-naïve [no prior anti-TNF use] and previous anti-TNF use)

		p=0.034	p=0.018

*Among patients with ≥3% BSA psoriasis involvement at baseline

Conclusion: UST reduced signs & symptoms, improved physical fxn, enthesitis & improved plaque PsO. Safety profiles were similar between UST & PBO.

Clinical Response, Drug Survival and Predictors Thereof Among 548 Switchers of Tumor Necrosis Factor Alpha Inhibitor Therapy in Psoriatic Arthritis. Results From the Danish Nationwide Danbio Registry. Bente Glintborg[1], Mikkel Østergaard[2], Niels Steen Krogh[3], Martin Dehn Andersen[4], Ulrik Tarp[4], Anne Gitte Loft[4], Hanne M. Lindegaard[4], Mette Holland-Fischer[4], Henrik Nordin[4], Dorte Vendelbo Jensen[4] and Merete L. Hetland[5]. [1]Copenhagen University Hospital Gentofte, Copenhagen, Denmark, [2]Glostrup Hospital, Copenhagen, Denmark, [3]ZiteLab ApS, Copenhagen, Denmark, [4]DANBIO, On behalf of Depts of Rheumatology, North, South, Central, Zealand and Capital Region, Copenhagen, Denmark, [5]Copenhagen University and Glostrup Hospital, Copenhagen, Denmark

Background/Purpose: Treatment with tumor-necrosis-factor-alpha inhibitors (TNFi) has improved the outcome in patients with psoriatic arthritis (PsA) who have failed treatment with synthetic disease modifying antirheumatic drugs (DMARDs). Failure may be due to insufficient effect or adverse events. However, knowledge on the effect of switching is scarce. We aimed to investigate frequencies and reasons for switching, treatment responses, drug survivals and predictors in patients with PsA who switched TNFi treatment in routine clinical care.

Methods: PsA patients were identified in the Danish nationwide DANBIO registry. Disease activity, treatment responses (ACR20/50/70 and EULAR good response at 3 and 6 months), drug survival and predictors thereof were studied in patients receiving ≥2 different biological drugs.

Results: Of 1,422 PsA patients starting TNFi treatment, 548 patients (39%) switched to a second and 189 (13%) to a third biological drug during up to 10

years of follow-up. Compared to non-switchers, switchers were more frequently women (56%/45%), had shorter disease duration (3 years/4 years), higher Health Assessment Questionnaire (HAQ) (1.1 (0.6–1.6)/0.9 (0.5–1.4) (median (interquartile-range))), higher 28-joint Disease Activity Score (DAS28) (4.8 (4.0–5.7)/4.4 (3.6–5.2)) and higher visual-analogue-scale (VAS) pain (65 (46–77)/62 (40–75) mm) and fatigue scores (67 (50–83)/64 (42–80) mm) when they started the first TNFi (all p<0.05). Main reason for switching was lack of response (57%). During the first, second and third treatment course HAQ, DAS28, CRP and VAS scores had decreased after 6 months' treatment (all p<0.05). Median drug survivals were 2.2, 1.3 and 1.1 years respectively (Figure, p<0.001). Drug survivals were similar regardless of the reason for switching to the second TNFi. All response rates were lower during the second treatment course (all p<0.01 compared to the first treatment) and the proportion of patients achieving sustained ACR20, ACR50, ACR70 and EULAR good response between 3–6 months treatment was 22% (number needed to treat, NNT 4.5), 13%(7.9), 5%(20) and 19%(5.3), respectively. Male gender, fewer tender joints and lower VAS fatigue increased drug survival of the second TNFi.
Figure. Drug adherences by treatment course number. Kaplan Meyer drug survival curves.

Conclusion: Nearly 40% of PsA patients in clinical practice switched biological treatment. Response rates and drug survivals decreased after switching and only one fifth of patients achieved ACR20 or EULAR good response within 6 months after switching to a second biological.

Mortality in Patients with Psoriatic Arthritis Compared to Patients with Rheumatoid Arthritis, Psoriasis Alone, and the General Population. Alexis Ogdie[1], Kevin Haynes[2], Andrea Troxel[2], Thorvardur Love[3], Hyon K. Choi[4] and Joel Gelfand[2]. [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania., Philadelphia, PA, [3]Labspitali University Hospital, Reykjavik, Iceland, [4]Boston University School of Medicine, University of British Columbia, Arthritis Research Centre of Canada, Boston, MA

Background/Purpose: Conflicting reports of the mortality risk among patients with psoriatic arthritis (PsA) exist in the literature, however excess mortality has been presumed given the elevated mortality rates in rheumatoid arthritis and psoriasis. Previous studies have been small, lacked internal compar-

ison groups, and were mostly performed in rheumatology clinics rather than the general population. The objective of this study was to examine the risk of mortality in patients with PsA as compared to matched controls as well as patients with psoriasis and rheumatoid arthritis (RA).

Methods: A longitudinal cohort study was performed. Patients aged 18–89 were selected from The Health Improvement Network (THIN), a large primary care medical record database in the United Kingdom, if they had a diagnosis of PsA, RA, or psoriasis. PsA and psoriasis diagnoses have been validated in THIN (positive predictive value 85% and 90% respectively). Up to 10 unexposed controls were matched on practice and start date within the practice for each patient with PsA. Data from 1994–2010 were included. Hazard ratios (HRs) were calculated using Cox proportional hazards models. A priori we hypothesized an interaction between disease status and Disease Modifying Antirheumatic Drug (DMARD) use. We used a purposeful selection modeling approach, including in the final model only confounders which changed the main effects by >15% and had a p-value of <0.1.

Results: Patients with PsA (N=8,706), RA (N=41,752), psoriasis (N=138,424) and controls (N=82,258) had mean age 50.7, 61.4, 47.6, and 49.9 years respectively. The average follow up time was 5.3 years, and 1,442,357 person-years were observed during which 21,825 deaths occurred. There was a significant interaction between disease and DMARD use and thus, stratified results are presented. Compared with population controls, patients with PsA did not have an increased risk of mortality after adjusting for age and sex and did not significantly differ by DMARD use (DMARD users: HR 0.94, 95%CI: 0.80–1.10, DMARD non-users: HR 1.06, 95%CI: 0.94–1.19). RA patients had increased mortality when compared to population controls (DMARD users HR 1.59, 95%CI: 1.52–1.66, DMARD non-users HR 1.54, 95%CI: 1.47–1.60). Similarly, patients with psoriasis who have not been prescribed a DMARD had a small increased risk of mortality compared to population controls (HR 1.08, 95%CI: 1.04–1.12) while those who had been prescribed a DMARD had greater risk (HR 1.75, 95%CI: 1.56–1.95). These findings were unchanged after adjustment for baseline comorbidities including Charlson comorbidity index, cardiovascular disease, renal disease, diabetes, body mass index, depression and smoking status. Adjusting for start year in the cohort did not change the results.

Conclusion: Patients with RA and psoriasis had increased mortality compared to the general population, a finding corroborated by previous studies. Despite increased mortality in these related conditions, however, patients with PsA did not have a statistically significant increased risk of mortality in this study.

Response and Drug Survival of 1st TNF-Inhibitor in 440 Patients with Psoriatic Arthritis - What Is the Role of Co-Medication with Methotrexate?

Karen M. Fagerli[1], Elisabeth Lie[1], Désirée van der Heijde[2], Marte S. Heiberg[3], Erik Rødevand[4], Åse S. Lexberg[5], Synnøve Kalstad[6], Knut Mikkelsen[7] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Diakonhjemmet hospital, Oslo, Norway, [4]St. Olavs Hospital, Trondheim, Norway, [5]Drammen Hospital, Drammen, Norway, [6]Tromsø, Norway, [7]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway

Background/Purpose: It is well established that methotrexate (MTX) co-medication improves efficacy of TNF-inhibitors (TNFi) in rheumatoid arthritis, while in ankylosing spondylitis it is widely accepted that it does not. The role of MTX co-medication in psoriatic arthritis (PsA) is still unclear. Our objective was to investigate if patients receiving concomitant MTX have better responses and drug survival to their 1st TNFi.

Methods: Data are from NOR-DMARD, an observational study of adult patients with inflammatory arthropathies starting DMARD-treatment. Patients with PsA receiving their 1st TNFi, either combined with MTX or in monotherapy, were selected. Due to heterogeneity in clinical presentation, the selected outcome measures were patient and physician global assessments, MHAQ and SF-6D. Baseline characteristics and state and change at 3, 6 and 12 months were compared by two-sample t-test and Chi^2 test, as appropriate. Drug survival at 1, 2 and 3 years was compared using Kaplan-Meier analysis with log-rank test, and sub-analyses were done for patients receiving Infliximab (IFX), Etanercept (ETN) and Adalimumab (ADA).

Results: 440 patients were included. We found significant baseline group differences in no. of swollen joints, physician global and SF6D scores (table 1). Three-month states and responses were similar between the groups, with signif-

icant differences only for physician global (table 1). Similar results were seen at 6 and 12 months. We did, however, find improved drug survival in the combination group (fig. 1) reaching statistical significance at 1 and 2 years. This was most prominent for IFX (p=0.01) and negligible for ETN (p= 0.79), with a trend for ADA (p=0.12).

Table 1.

	Overall	No co-medication	MTX co-medication	P-value
	Baseline characteristics			
	N=440	N=170	N=270	
Age (years)	46.5 (11.6)	47.0 (11.4)	46.1 (11.7)	0.46
Females (%)	46.4	47.6	45.6	0.70
Disease duration (yrs)*	5.2 (1.5–12.5)	5.1 (1.1–11.7)	5.5 (1.6–12.7)	0.44
No of prev. DMARDs	1.49 (1.09)	1.49 (1.20)	1.48 (1.02)	0.30
Swollen joints *	3 (1–6)	2 (0–5)	3 (1–7)	0.004
CRP mg/l *	9 (5–20)	7 (5–22)	9 (5–20)	0.44
Physician global (0–100)	37.4 (17.9)	39.6 (19.2)	36.0 (16.9)	0.04
Patient global (0–100)	54.6 (23.7)	56.5 (22.8)	53.4 (22.5)	0.17
MHAQ score (0–3)	0.70 (0.46)	0.72 (0.47)	0.69 (0.46)	0.41
SF6D score (0–1)	0.59 (0.12)	0.57 (0.12)	0.60 (0.12)	0.01
	3-month responses			
	N=328	N=123	N=205	
Physician global (0–100)	15.9 (15.0)	18.5 (17.1)	14.4 (13.5)	0.02
Δ Physician global	−21.7 (22.1)	−20.0 (23.0)	−22.6 (21.7)	0.32
Patient global (0–100)	29.2 (23.9)	32.4 (26.1)	27.3 (22.3)	0.07
Δ Patient global	−24.8 (26.4)	−22.0 (29.1)	−26.3 (24.7)	0.17
MHAQ score (0–3)	0.39 (0.41)	0.42 (0.43)	0.37 (0.40)	0.30
Δ MHAQ score	−0.31 (0.44)	−0.30 (0.50)	−0.32 (0.39)	0.67
SF-6D (0–1)	0.70 (0.15)	0.68 (0.15)	0.70 (0.14)	0.15
Δ SF-6D	0.10 (0.13)	0.10 (0.14)	0.10 (0.13)	0.92

Values are expressed as mean (SD) unless otherwise stated
MHAQ = Modified health assessment questionnaire
SF-6D = Short form – 6 dimensions
* Median(IQR)

N in figure = patients still observed at the end of the interval
•P-value by log-rank test
Conclusion: We found similar responses at 3 months in PsA patients receiving their first TNFi with and without MTX co-medication. However, drug survival was better in patients receiving concomitant MTX, and this was most prominent in patients receiving IFX.

Switching Between TNF-Inhibitors in Psoriatic Arthritis: Data From the NOR-DMARD Study.

Karen M. Fagerli[1], Elisabeth Lie[1], Désirée van der Heijde[2], Marte S. Heiberg[3], Åse S. Lexberg[4], Knut Mikkelsen[5], Erik Rødevand[6], Synnøve Kalstad[7] and Tore K. Kvien[1]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Diakonhjemmet hospital, Oslo, Norway, [4]Vestre Viken, Drammen, Norway, [5]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [6]St. Olavs Hospital, Trondheim, Norway, [7]Tromsø, Norway

Background/Purpose: Although TNF-inhibitors (TNFi) have proven efficacy in psoriatic arthritis (PsA), some patients do not respond to or do not tolerate their first TNFi. The efficacy of a second TNFi in this group is not well established. Our objective was to investigate the efficacy of switching to a second TNFi in PsA patients.

Methods: Patients were selected from NOR-DMARD – a longitudinal observational study (LOS) in which patients with inflammatory arthropathies are included when starting a new disease-modifying anti-rheumatic drug (DMARD). Patients with PsA receiving their 1st TNFi were selected, and among these patients a subgroup who later switched to a 2nd TNFi was identified (switchers). Three-month response and one year drug-survival were assessed for non-switchers and for the 1st and 2nd TNFi of the switchers. Selected outcome measures were ACR20/50/70 and EULAR responses, DAS28 remission and low disease activity rates, patient and physician global, MHAQ and SF6D. Both state and change from baseline were assessed, and compared statistically between switchers and non-switchers using Chi^2 and independent t-tests. Drug survival was compared by log-rank test. The overall response and drug survival to the first TNFi (switchers + non-switchers) was also assessed.

Results: Baseline characteristics are shown in table 1. There were no significant differences between switchers and non-switchers at baseline. There were significant differences in response between non-switchers and switchers receiving their 1st TNFi for several outcome measures, and these differences were more pronounced for the 2nd TNFi of the switchers with highly significant p-values for most outcome measures (table 2).One-year drug survival for the 2nd TNFi in switchers and non-switchers was 0.56 vs. 0.83 (p-value<0.001).

Table 1. Baseline characteristics

	Non-switchers N=344	Switchers 1st TNFi (N=95)	2nd TNFi (N=95)
Age	46.8 (11.7)	46.1 (11.6)	47.7 (11.5)
Males sex(%)	55.2	48.4	48.4
Type of TNFi(%)			
Etanercept	49.4	52.6	32.6
Infliximab	10.5	13.7	16.8

Physician global	36.5 (17.5)	39.5 (18.4)	34.7 (18.6)
Patient global	53.2 (22.9)	57.4 (21.2)	55.3 (22.7)
MHAQ score	0.68 (0.45)	0.77 (0.47)	0.74 (0.48)
SF6D	0.59 (0.12)	0.58 (0.11)	0.59 (0.13)

Mean (SD) unless otherwise indicated. VAS (0–100), MHAQ = Modified health assessment questionnaire (0–3), SF-6D = Short form -6 dimensions (0–1).

Table 2. 3-month response

	Non-switchers N=259	Switchers 1st TNFi N=74	2nd TNFi N=63	P-value Non-switcher vs. 1st TNFi (switchers)	Non-switchers vs. 2nd TNFi (switchers)
ACR20 (%)	63.0	49.3	40.7	0.05	0.003
ACR50 (%)	40.0	30.4	24.1	0.16	0.03
ACR70 (%)	31.5	23.2	13.0	0.23	0.007
EULAR response (%)	53.4	49.0	19.5	0.63	<0.001
DAS28 <2.6 (%)	61.6	39.0	31.1	0.003	<0.001
DAS28 ≤3.2 (%)	74.7	57.6	37.8	0.014	<0.001
DAS28	2.4 (1.3)	3.2 (1.6)	3.5 (1.6)	<0.001	<0.001
DAS28 Δ	-1.7 (1.3)	-1.4 (1.5)	-0.6 (1.4)	0.17	<0.001
Physician global(0–100)	13.8 (12.9)	23.5 (18.9)	22.0 (17.3)	<0.001	<0.001
Physician global Δ	-22.7 (19.9)	-16.9 (27.3)	-14.3 (23.6)	0.05	0.01
Patient global (0–100)	27.8 (23.7)	34.2 (22.9)	38.2 (23.9)	0.04	0.003
Patient global Δ	-25.5 (25.5)	-20.8 (28.5)	-14.9 (27.6)	0.19	0.006
MHAQ (0–3)	0.36 (0.39)	0.50 (0.44)	0.50 (0.45)	0.01	0.017
MHAQ Δ	-0.32 (0.42)	-0.27 (0.45)	-0.23 (0.42)	0.40	0.15
SF6D (0–1)	0.71 (0.15)	0.66 (0.13)	0.65 (0.12)	0.01	0.002
SF6D Δ	0.11 (0.14)	0.07 (0.12)	0.06 (0.13)	0.02	0.003

Mean (SD) unless otherwise indicated. MHAQ = Modified health assessment questionnaire SF-6D = Short form -6 dimensions.

The overall ACR 20/50/70 responses for the 1st TNFi (n=439) were 59.9/37.8/29.6%, and the estimated 1-year drug survival was 0.74 – hence clearly superior to the 2nd TNFi (table 2).

There was no difference in response to second TNFi when comparing those who discontinued due to lack of efficacy (n=45) to those who discontinued due to adverse events (n=33).

Conclusion: Among patients with PsA who switched to a second TNFi after having failed their first TNFi, less than half achieved a clinical response at 3 months in this LOS. This observation highlights the need for treatments for PsA with other mechanisms of action.

Ustekinumab in Patients with Active Psoriatic Arthritis: Results of the Phase 3, Multicenter, Double-Blind, Placebo-Controlled Psummit I Study.

Arthur Kavanaugh[1], Iain B. McInnes[2], Alice B. Gottlieb[3], Lluis Puig[4], Proton Rahman[5], Christopher T. Ritchlin[6], Shu Li[7], Yuhua Wang[7], Alan Mendelsohn[7] and Mittie K. Doyle[7]. [1]UCSD School of Medicine, La Jolla, CA, [2]University of Glasgow, Glasgow, United Kingdom, [3]Tufts Medical Center, Boston, MA, [4]Universitat Autònoma de Barcelona, [5]Memorial University, St. Johns, NF, [6]University of Rochester Medical Center, Rochester, NY, [7]Janssen Research & Development, LLC, Spring House, PA

Background/Purpose: To assess efficacy and safety of ustekinumab (UST) in reducing signs and symptoms of active psoriatic arthritis (PsA) in a large, multicenter, double-blind, placebo (PBO)-controlled, Phase 3 trial.

Methods: Adult PsA pts (n=615) with active disease (≥5 SJC and ≥5 TJC; CRP≥0.3mg/dL) despite DMARD and/or NSAID therapy were randomized to receive UST45mg, 90mg, or PBO at wks 0, 4, and q12wks, thereafter. At wk16, pts with <5% improvement in TJC & SJC entered blinded early escape (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). Stable concomitant MTX use was permitted but not mandated. Pts treated with prior anti-TNF agents were excluded. Primary endpoint was ACR20 response at wk24. Secondary endpoints at wk24 included: ACR 50/70, DAS28-CRP response, change from baseline (BL) in HAQ-DI, PASI75 response (in pts w/≥3% BSA involvement), and percent change from baseline in enthesitis and dactylitis scores (in pts affected at baseline). Adverse events (AE) are reported through the PBO-controlled period (wk16) and through wk24.

Results: Significantly greater proportions of UST-treated vs PBO–treated pts had ACR20 response at wk24 (Table). Significant improvements were also observed with UST45mg and 90mg for ACR50/70 responses and DAS28-CRP responses at wk24 vs PBO. The changes from baseline in HAQ-DI at wk24 were significantly greater in the UST than PBO grp, and significantly greater proportions of UST-treated pts had a clinically meaningful change from baseline in HAQ-DI (≥0.3). Nearly half used concomitant MTX at baseline; this did not alter the likelihood of benefit of UST vs PBO. While ACR responses were greater with UST than PBO regardless of MTX use, differences were numerically larger among pts not taking MTX. Of 440pts with ≥3% BSA involvement at baseline, significantly larger proportion of UST pts achieved PASI 75 at wk24. Among pts affected with enthesitis (n=425) or dactylitis (n=286) at baseline, significantly greater improvements in enthesitis and dactylitis were observed at wk24 in the UST grp than PBO. Through wk16, the proportion of pts with ≥1 AE was similar between pts receiving UST(41.8%) and PBO (42.0%), with infections being the most common AE; 1.7% (UST) and 2.0% (PBO) had ≥1 serious AE. No

malignancies, serious infections, TB, opportunistic infections, or deaths occurred through wk24.

Table. PSUMMIT efficacy results at Wk 24

	PBO (n=206)	UST 45mg (n=205)	UST 90mg (n=204)
ACR20, %	22.8	42.4	49.5
ACR50, %	8.7	24.9	27.9
ACR70, %	2.4	12.2	14.2
DAS28-CRP response, %	34.5	65.9	67.6
Median HAQ-DI change from baseline	0	-0.3	-0.3
Pts with ≥0.3 reduction, %	28.2	47.8	47.5
PASI75*, %	11	57.2	62.4
Median % change in enthesitis score*	0	-42.9	-50
Median % change in dactylitis score*	0	-75	-70.8

* Among pts affected at baseline.; p<0.001 for all parameters vs PBO

Conclusion: In pts with active PsA, UST significantly reduced the signs and symptoms of arthritis, improved physical function, enthesitis and dactylitis, and improved plaque psoriasis vs PBO-treated pts at wk24. Safety profiles were similar between UST-and PBO-treated pts.

Factors Associated with Major Cardiovascular Events in Patients with Primary Systemic Necrotizing Vasculitides: Results of a Longitudinal Long-Term Follow-up Study. Benjamin Terrier Sr.[1], Christian Pagnoux[2], Gilles Chironi[3], Alain Simon[3], Luc Mouthon Sr.[4], Loic Guillevin[5] and French Vasculitis Study Group (FVSG)[6]. [1]Cochin Hospital, Paris, France, [2]Mount Sinai Hospital, Toronto, ON, [3]HEGP, Paris, France, [4]Hopital Cochin, Paris, France, [5]Division of Internal Medicine, Hôpital Cochin, University Paris Descartes, Paris, France, [6]Paris

Background/Purpose: Primary systemic necrotizing vasculitides (SNV) were shown to be associated with more frequent subclinical atherosclerosis, independently of cardiovascular (CV) risk factors and C-reactive protein (CRP) level, suggesting that SNV might be associated with a higher risk of major CV events (MCVE).
Objective: To identify factors predictive of MCVE in SNV patients.
Methods: Consecutive patients in SNV remission were assessed for CV risk factors, body mass index (BMI), CRP levels and subclinical atherosclerosis [ultrasound detection of plaque in peripheral vessels and measurement of carotid intima–media thickness (IMT)], and prospectively followed in the same center. High-risk status, defined according to the National Cholesterol Education Program Adult Treatment Panel III (NCEP/ATP III), was a known history of CV disease, diabetes or 10-yr Framingham Risk Score ≥20%. MCVE, defined as myocardial infarction, stroke, arterial revascularization, hospitalization for unstable angina and/or death from CV causes, were recorded. Kaplan–Meier MCVE-free survival curves were plotted and compared with the log-rank test.
Results: Thirty-seven patients (24 males, age 54 ± 15 yr) were followed for 7.0 ± 2.6 yr. SNV diagnoses were: granulomatosis with polyangiitis, 19; eosinophilic granulomatosis with polyangiitis, 8; microscopic polyangiitis, 7; and polyarteritis nodosa, 3. Seven (18.9%) patients suffered MCVE, including myocardial infarction or hospitalization for unstable angina (n=4), arterial revascularization (n=2), and CV cause of death (n=1). The respective 5- and 10-yr MCVE rates were 10.8% and 25.7%.
Univariate analysis selected NCEP/ATP III-defined high-risk status [hazard ratio (HR) 5.02 (95% CI 1.17–27.4), P=0.03], BMI >30 kg/m^2 [HR 4.84 (95% CI 1.46–116), P=0.02] and plaque detection in the abdominal aorta (P=0.01) as being significantly associated with MCVE. In contrast,

SNV characteristics, corticosteroid maintenance therapy, CRP >5 mg/L, and plaque detection in the carotid and femoral arteries were not associated with MCVE. Plaque in the aorta was significantly (χ^2 test) associated with high-risk status (P<0.001), while BMI and high-risk status were independent variables (P=0.64). Thus, a BMI >30 kg/m^2 and/or a high-risk status were strongly associated with MCVE (P=0.003).
Finally, although IMT was not associated with MCVE, it distinguished between patients with early or late MCVE: 30% of patients with IMT >0.60 mm (vs none of those with IMT ≤0.60 mm) experienced MCVE within the first 3 yr of follow-up, while 23% of patients with IMT ≤0.60 mm (vs none of those with IMT >0.60 mm) experienced a 1st MCVE after 7–10 yr of follow-up. IMT was correlated with the time to MCVE (r^2=0.78, P=0.008).
Conclusion: These results suggest that factors associated with a higher MCVE risk in SNV patients are NCEP/ATP III-defined high-risk status and BMI >30 kg/m^2. Carotid IMT measurement in SNV patients could help identify those at risk of early MCVE.

A Risk Score for Predicting Short-Term Incidence of Death or Relapse in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis. Carla Maldini[1], Matthieu Resche-Rigon[1], David Jayne[2], Kerstin Westman[3] and Alfred Mahr[1]. [1]Hospital Saint-Louis, Paris, France, [2]Addenbrookes Hospital University of Cambridge, Cambridge, United Kingdom, [3]Skåne University Hospital Malmö, Lund University, Malmö, Sweden

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), combining granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), is associated with a substantial risk of relapse or death. Particularly, the first year after diagnosis is characterized by a marked excess of vasculitis-related deaths. The factors determining risk of death or relapse in the long term have been widely investigated, but those determining short-term outcome are not well known. Accurate prediction of short-term prognosis is crucial to identify patients at highest risk of an adverse event. We aimed to develop a risk score to predict the 1-year risk of death or relapse in newly diagnosed AAV.
Methods: We studied patients with incident AAV enrolled in 4 international, randomized, multicenter clinical trials focusing on various subgroups with AAV. An initial set of 22 candidate variables, including the main demographic, clinical and laboratory data, all assessed at diagnosis, and GPA or MPA diagnoses, were considered for predicting 1-year survival or relapse risk. A stepwise approach using univariate and multivariate logistic regression models in 2,000 bootstrap samples was used to identify variables that consistently predicted death or relapse at 1 year. The regression coefficients computed in the final multivariate model were used to derive weights for each of the identified predictors of the composite outcome. The discriminative ability of the final score was evaluated by analysis of the area under the receiver operating characteristic curve (AUC). A sensitivity analysis was performed with multiple imputation methods to account for missing data and calculate an AUC for the complete dataset.
Results: Among the 535 subjects, we had complete data for all 22 analyzed variables for 441 subjects (244 GPA, 197 MPA). At 1-year follow-up, we recorded 44 deaths (10.0%) and 12 relapses (3.3%). We retained 9 variables, assigned weights of 1 to 3, for the final risk score model: age > 60 yr (1 point); female sex (1); ear, nose and throat involvement (1); serum creatinine level > 300 μmol/l (3); ANCAs directed against proteinase 3 (PR3-ANCA) (1) and myeloperoxidase (MPO-ANCA) (3); peripheral neutrophil count > 7,000/mm^3(2); hemoglobin level < 10 g/dl (1) and C-reactive protein level > 10 mg/l (2). Each patient was assigned a risk score between 0 and 15. Accordingly, the 1-year risk for death or relapse was low (<5%) for 32% of patients, medium (5–20%) for 50%, and high (>20%) for 18%. The AUC for the prediction model was 0.79 (95% confidence interval 0.73–0.85) and 0.78 for the whole dataset of 535 subjects after missing-data imputation.
Conclusion: This integrative AAV-risk prediction score may be useful in predicting a patient's risk of death or relapse on short-term follow-up and may contribute to better risk-stratified characterization and management of AAV. Further validation in other AAV populations is required.

Prevalence of Anti-Neutrophil Cytoplasmic Antibodies in Infective Endocarditis: An Analysis of 109 Cases. Alfred Mahr[1], Frédéric Batteux[2], Sarah Tubiana[3], Michel Wolff[3], Claire Goulvestre[2], Thomas Papo[3], François Vrtovsnik[3], Isabelle Klein[3], Bernard Iung[3] and Xavier Duval[3]. [1]Hospital Saint-Louis, Paris, France, [2]Hospital Cochin, Paris, France, [3]Hospital Bichat, Paris, France

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCAs), particularly those directed against proteinase 3 (anti-PR3) or myeloperoxidase (anti-MPO), are considered a highly specific hallmark of ANCA-associated vasculitis. Thus, false-positive ANCA tests have been reported in the context of drug exposure or infection, and several small case studies suggested that ANCAs can be detected in infective endocarditis (IE). This situation, combined with the multisystem protean presentation of IE, may lead to inappropriate diagnosis and therapy. Because the frequency of ANCAs in IE is unknown, we assessed the prevalence of ANCAs in a relatively large number of cases with IE.

Methods: The study was conducted in the framework of a prospective cohort study of consecutive cases with IE launched in 2005 in a single university hospital. Data on the principal demographic, clinical, laboratory (including serum creatinin and hematuria) and microbiological features were collected by a standardized questionnaire. Sera were stored for all patients who gave informed consent for blood sampling. Among the patients for whom sera were stored, we selected those with blood sampled not later than 30 days after the initiation of antibiotic therapy. All selected sera were tested for ANCAs in a central laboratory using indirect immunofluorescence (IIF) assays, and positive results were confirmed by ELISA. IIF involved ethanol-fixed neutrophils and categorized positive tests for C-ANCA (cytoplasmic pattern) or P-ANCA (perinuclear pattern). ELISA for anti-PR3 and anti-MPO specificities involved use of commercially available kits. In addition, we tested all sera for antinuclear antibodies by use of a commercially available indirect immunofluorescence test.

Results: Sera from 109 patients (81 [74%] men, mean age: 57.4 yrs [SD: 15.3]) were tested. All patients fulfilled Duke's criteria for definite or probable endocarditis, and 33 (30%) had prosthetic valves. The major causative pathogens were *Staphylococcus aureus* (n = 30), Streptococci (n = 23), *Streptococcus bovis* (n = 10) and Enterococci (n = 7). C-ANCAs were found in 13 patients (12%), P-ANCAs in 11 (10%) and 1 case (1%) showed both patterns. ELISA revealed anti-PR3 in 4 cases (3%) and anti-MPO in 4 (3%), some with very high titers. The 8 anti-PR3/anti-MPO–positive IE cases involved various pathogens and both native and prosthetic valves. Testing for antinuclear antibodies was positive (titer > 1:160) in 17 (16%) cases.

Conclusion: This study is the first to assess the prevalence of ANCAs in IE and suggests that ANCAs, including those with anti-PR3 or anti-MPO specificities, occur in a significant subset of cases. These observations considerably substantiate the consideration of IE as a potential cause of false ANCA positivity.

Aβ-Related Angiitis: Comparison with Patients with Amyloid Cerebral Angiopathy without Inflammation. Carlo Salvarani[1], Caterina Giannini[2], Robert D. Brown Jr.[2], Teresa J. H. Christianson[2] and Gene G. Hunder[2]. [1]Arcispedale S Maria Nuova. IRCCS, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN

Background/Purpose: Coexistence of sporadic cerebral amyloid angiopathy (CAA) and primary central nervous system vasculitis (PCNSV) has been reported, particularly in patients with granulomatous vasculitis. This condition was termed Aβ–related angiitis (ABRA). We analyzed the clinical, radiographic, and pathological findings in a series of consecutive patients with pathologically diagnosed CAA. We describe the clinical characteristics of the patients with ABRA and compare them with the characteristics of patients with CAA without inflammation. Furthermore, we compare the features of patients with ABRA with those of PCNSV.

Methods: We reviewed all patients seen at the Mayo Clinic, Rochester, MN over the 25 year period of 1987 to 2011, who were diagnosed pathologically with CAA. Biopsy specimens were reviewed by one pathologist (CG) without knowledge of clinical information. Patients with changes of Alzheimer's disease were excluded. Of 74 identified patients, 46 did not show inflammation, 23 had ABRA, and 5 CAA-related inflammation (perivascular only). We also utilized our updated cohort of 131 consecutive patients with

PCNSV seen over a 25 year period of 1983 to 2007 at Mayo Clinic, Rochester, MN. The diagnosis of PCNSV was based on brain/spinal cord biopsy or cerebral angiography, or both. 14/131 patients had ABRA. 9 additional patients with ABRA were identified between 2008 and 2011.

Results: The 23 patients with ABRA were compared with the 46 cases with CAA without inflammation. The presence of altered cognition (15/23 or 65.2% vs 41/46 or 89.1%. p = 0.017), hemiparesis (3/23 or 13% vs 18/46 or 39.1%, p = 0.026), persistent neurologic deficit or stroke (5/23 or 21.7% vs 25/46 or 54.3%, p = 0.010), and intracranial hemorrhage (2/23 or 8.7% vs 31/46 or 67.4%, p < 0.001) at presentation were significantly less frequent in patients with ABRA than in the others. More patients with ABRA showed meningeal gadolinium enhancing lesions at MRI (13/23 or 56.5% vs 7/26 or 26.9%, p = 0.035). No differences in the demographics and cerebrospinal fluid (CSF) findings were observed in the two groups. Survival of the patients with CAA without inflammation was significantly lower compared to that of those with ABRA. The 23 patients with ABRA were compared to the other 117 patients with PCNSV (excluding the 14 patients with ABRA). The median age of patients with ABRA was significantly higher at diagnosis (67 years vs 47 years, p < 0.001). In ABRA patients, hemiparesis occurred less frequently at presentation (3/23 or 13% vs 51/117 or 43.6%, p =0.006), while gadolinium enhanced meningeal lesions occurred more frequently (13/23 or 56.5% vs 12/104 or 11.5%, p < 0.001). CSF abnormalities (a protein level > 700 mg/L) were observed more frequently in patients with ABRA (15/20 or 75% vs 40/90 or 47.1%, p = 0.024). The median protein CSF levels were higher in patients with ABRA (995 mg/L vs 660 mg/L, p = 0.009). No differences in the survival were observed between these 2 groups.

Conclusion: ABRA appears to represent a condition clinically distinct from CAA and PCNSV. However, the vasculitis seems to influence the clinical findings to a greater degree than the presence of amyloid deposits in the vessels.

Predictive Value of Selected Markers of Inflammation and Platelet Activation for Complete Remission in ANCA–Associated Vasculitis. Gunnar Tomasson[1], Paul A. Monach[2], Kahraman Tanriverdi[3], Ulrich Specks[4], John H. Stone[5], Linna Ding[6], Fernando Fervenza[4], Gary S. Hoffman[7], Cees G.M. Kallenberg[8], Carol A. Langford[7], Deborah J. Phippard[9], Philip Seo[10], Robert F. Spiera[11], E. William St. Clair[12], Nadia Tchao[9], Jane E. Freedman[3] and Peter A. Merkel[13]. [1]University of Iceland, Reykjavik, Iceland, [2]Boston University, Boston, MA, [3]University of Massachusetts, Wochester, [4]Mayo Clinic, Rochester, MN, [5]Massachusetts General Hospital, Boston, MA, [6]NIAID, Bethesda, MD, [7]Cleveland Clinic, Cleveland, OH, [8]University Medical Center Groningen, Groningen, Netherlands, [9]Immune Tolerance Network, Bethesda, MD, [10]Johns Hopkins Vasculitis Center, Baltimore, MD, [11]Hospital for Special Surgery, New York, NY, [12]Duke University Medical Center, Durham, NC, [13]University of Pennsylvania, Philadelphia, PA

Background/Purpose: Most subjects with ANCA –associated vasculitis (AAV) respond to treatment for remission induction, but predictors for complete disease remission are lacking. We have previously demonstrated that selected markers of inflammation and platelet activation (C-reactive protein (CRP), CD40 ligand (CD40L) interleukins (IL) 6 and 8, monocyte chemoattractant protein 1 (MCP-1), P-selectin and vascular endothelial growth factor (VEGF) are associated with disease activity in AAV. The aim of this study was to explore if levels of marker predict future complete remission in AAV.

Methods: Subjects were participants in the Rituximab versus cyclophosphamide for AAV clinical trial (RAVE). Subjects with active disease were randomized to either rituximab or cyclophosphamide in addition to treatment with glucocorticoids. Data from the baseline, 2-month, 4-month, and 6-month study visits were used for this analysis. Disease activity was assessed with Birmingham Vasculitis Score for Wegener's Granulomatosis (BVAS/WG). Complete remission was defined as BVAS=0 at the 6-month visit on no prednisone and without preceding severe flare or treatment failure since enrollment. CRP, CD40L, IL-6, IL-8, MCP-1, P-selectin, and VEGF were measured by ELISA. To explore if marker levels at baseline, 2 months and 4 months predicted complete remission at 6 months, logistic regression was used with complete remission as the outcome variable and marker-tertiles as independent variables. In additional analyses, the raw marker levels and log-transformed marker levels were used as independent variables in the models. The associations of the change in marker levels at the 2 4-month visits (compared to the baseline visit), with complete remission at the 6-month visit were tested with logistic regression. All analyses were adjusted for the BVAS/WG score at the baseline, 2-month, or 4-month visits, as appropriate.

Results: 197 subjects participated in the RAVE trial. The mean BVAS/WG score at baseline was 8.37 (sd 3.13). At the 6-month visit, 115 subjects achieved complete remission. Subjects with CRP levels in the third tertile at the 2-month and 4-month visits had lower odds of achieving complete remission at 6 months and subjects with IL-8 levels in the third tertile at the baseline, 2-month, and 4-month visits had lower odds of achieving complete remission at the 6-month visit compared to subjects in the lowest tertile (**Table**). In analyses using the raw or log-transformed marker levels, no marker was significantly associated with future remission, nor were changes in marker levels from the baseline visit associated with future complete remission.

Odds ratios and 95% confidence interval for achieving complete remission at 6 months, according to marker level

	Baseline (n=197)	Month 2 (n=184)	Month 4 (n=180)
CRP			
lowest tertile	reference	reference	reference
middle tertile	0.67 (0.31–1.44)	0.81 (0.36–1.81)	0.52 (0.21–1.29)

highest tertile	1.45 (0.7–2.98)	1.16 (0.54–2.46)	0.61 (0.25–1.45)
P-selectin			
lowest tertile	reference	reference	reference
middle tertile	0.86 (0.41–1.81)	1.41 (0.63–3.16)	1.46 (0.58–3.63)
highest tertile	0.81 (0.39–1.68)	0.60 (0.28–1.28)	0.46 (0.2–1.07)
VEGF			
lowest tertile	reference	reference	reference
middle tertile	2.08 (0.97–4.47)	1.28 (0.58–2.84)	0.88 (0.35–2.22)
highest tertile	1.14 (0.55–2.36)	0.89 (0.41–1.93)	0.53 (0.22–1.27)

Conclusion: High CRP and IL-8 levels measured during treatment for remission induction of AAV are inversely associated with achieving future complete remission. These markers may be of prognostic value AAV.

2568

The Risk of Pulmonary Embolism and Deep Vein Thrombosis in Giant Cell Arteritis: A Population-Based Cohort Study. J. Antonio Avina-Zubieta[1], Diane Lacaille[1], Eric C. Sayre[1], Jacek A. Kopec[1] and Hyon K. Choi[2]. [1]Arthritis Research Centre of Canada/University of British Columbia, Richmond, BC, [2]Boston University School of Medicine, Arthritis Research Centre of Canada/University of British Columbia, Boston, MA

Background/Purpose: A recent hospital-based study has suggested an 8 fold increased risk of pulmonary embolism (PE) in individuals with polymyalgia rheumatica in the year following admission. It is unknown whether a similar risk exists among individuals with giant cell arteritis (GCA). We estimated the risk of incident PE and deep venous thrombosis (DVT) events, and associated time trend among incident cases with GCA compared to controls from the general population using physician billing and hospitalization databases that cover the entire province ($\sim$ million).

Methods: Our data included all visits to health professionals and hospital admissions covered by the comprehensive provincial medical services plan from January 1, 1990 until December 31, 2007 for all individuals > 18 years of age. We conducted a matched cohort study among patients meeting the following criteria: **a)** ≥ 40 years of age; **b)** new diagnosis of GCA on at least 2 visits within a two-year period between January 1996 and December 2007; and **c)**use of oral glucocorticoids between 1 month before and 6 months after the second GCA visit (or first if hospital or rheumatologist). Ten controls were matched by birth year, sex and calendar year of exposure from the general population for each case. A patient was considered to be a PE or DVT case

when he or she had a recorded code of PE (hospitalization) or DVT (outpatient or hospitalization). We estimated relative risks (RRs) of PE and DVT compared with a matched non-RA comparison cohort, adjusting for age, sex, comorbidities, trauma, fracture, surgery, and hospitalizations.

Results: Among 1,175 individuals with GCA (74% female, mean age of 75 years), 22 developed PE and 24 developed DVT. Compared with non-GCA individuals, the age-, sex-, and entry-time-matched RRs were 3.6 (95% CI, 2.1–5.8) for PE and 2.7 (95 % CI 1.74–4.32) for DVT (Table). These RRs were attenuated slightly after adjusting for covariates, but remained significant. The time-specific, age-, sex-, and entry-time-matched RRs during the first year were 15.1 (95%CI, 6.6–36.2) for PE and 5.9 (2.9–11.4) for DVT.

Table. Relative Risk of Incident PE and DVT According to GCA Status

	GCA	Non-GCA
PE Cases, N	22	65
Incidence Rate/1000 Person-Years	5.2	1.5
Age-, Sex-, Entry time Matched RR (95% CI)	3.6 (2.1–5.8)	1.0
Multivariable RR (95% CI)	3.1 (1.9–5.1)	1.0
DVT		
Cases, N	24	93
Incidence Rate/1000 Person-Years	5.8	2.1
Age-, Sex-, Entry time Matched RR (95% CI)	2.7 (1.7–4.3)	1.0
Multivariable RR (95% CI)	2.4 (1.5–3.9)	1.0
PE or DVT		
Cases, N	36	142
Incidence Rate/1000 Person-Years	8.8	3.3
Age-, Sex-, Entry time Matched RR (95% CI)	2.7 (1.8–3.9)	1.0
Multivariable RR (95% CI)	2.4 (1.6–3.5)	1

Conclusion: This large population-based study provides the first evidence for a substantially increased risk of PE and DVT in GCA and shed light on corresponding risk trends over the duration of GCA among primarily outpatients. These findings support increased monitoring of venous-thromboembolic complications and risk factors in GCA at the population level.

Edmond L. Dubois, MD Memorial Lectureship:
Hydroxychloroquine Reduces Thrombosis in Systemic Lupus Erythematosus, Particularly in Antiphospholipid Positive Patients
Tuesday, November 13, 2012, 4:30 PM–6:00 PM

2569

Hydroxychloroquine Reduces Thrombosis (BOTH ARTERIAL AND VENOUS) in Systemic LUPUS Erythematosus, Particularly in Antiphospholipid Positive Patients. Genevieve Law[1], Laurence S. Magder[2], Hong Fang[3] and Michelle Petri[3]. [1]University of British Columbia, Vancouver, BC, [2]University of Maryland, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Past studies, mostly cross-sectional, have found a reduction in thrombosis in systemic lupus erythematosus (SLE) patients taking hydroxychloroquine (HCQ). We examined the relationship between hydroxychloroquine and other medications with thrombosis in a large prospective SLE cohort.

Methods: We studied 1795 SLE patients (56% Caucasian, 37% African American, 93.3% female, mean age 37.0 ± 12.5) with no previous thrombosis prior to entry in the cohort. The primary outcome was first thrombotic event (arterial or venous). Univariate analysis and multivariable modeling were used to examine associations between prednisone, hydroxycholoquine, and NSAID use with the risk of thrombosis.

Results: A total of 193 thrombotic events were observed over 10,508 person-years of follow-up (rate 18.4/1000 person-years). In the multivariable model controlling for age, traditional cardiovascular risk factors, and SLE disease activity, significant predictors for thrombosis included current prednisone dose (>20 mg/day, HR 4.4, p$<$0.0001) and Aspirin use (HR 1.8, p$=$0.0026). Hydroxychloroquine use remained protective for thrombosis (HR 0.6, p$=$0.0075). Subgroup analysis revealed that the protective effect of hydroxychloroquine was stronger in antiphospholipid antibody positive patients (HR 0.6, p$=$0.0090) than among antiphospholipid antibody negative patients (HR 0.8, p$=$0.57).

Subgroup		Thrombotic events	Rate of events/ 1000 person-yrs	Rate Ratios (95% CI)	P-value
Current Prednisone	None	52	10.6	1.0 (Ref. Gp)	
	1-9 mg/d	40	16.4	1.6 (1.1-2.4)	0.025
	10-19 mg/d	49	34.3	3.3 (2.2-4.8)	<0.0001
	20+ mg/d	43	71.8	6.5(4.3-9.8)	<0.0001
Cummulative Prednisone dose	None	29	13.1	1.0 (Ref. Gp)	
	<1 yr (10 mg/d)	37	23.8	1.6 (1.0-2.6)	0.075
	1-3 yrs (10 mg/d)	30	19.0	1.8 (1.1-3.1)	0.026
	3-10 yrs (10 mg/d)	45	25.5	3.0 (1.8-5.2)	<0.0001
	>10 yrs (10 mg/d)	9	24.3	3.7 (1.5-9.4)	0.0056
Current HCQ	No	95	29.0	1.0 (Ref. Gp)	
	Yes	90	14.6	0.5 (0.4-0.7)	<0.0001
HCQ use	Never	57	32.2	1.0 (Ref. Gp)	
	Past (not current)	27	27.6	0.9 (0.6-1.5)	0.81
	<6 consecutive mo	16	20.0	0.6 (0.3-1.0)	0.056
	>6 consecutive mo	64	13.8	0.5 (0.3-0.7)	0.0003
NSAID use	No	146	21.6	1.0 (Ref. Gp)	
	Yes	37	13.9	0.6 (0.4-0.9)	0.017
Aspirin use	No	137	17.9	1.0 (Ref. Gp)	
	Yes	49	28.0	1.6 (1.2-2.3)	0.0038

Conclusion: Current prednisone dose was found to be a significant independant predictor of thrombosis in SLE, after adjustment for disease activity. Current hydroxychloroquine use decreased the risk of thrombosis in this prospective cohort, particularly in those with positive antiphospholipid antibodies. Aspirin use was not protective, likely due to the bias of indication.

Background/Purpose: In systemic lupus (SLE), concern exists about immunosuppressive drugs and lymphoma risk, Yet, the relative influence of disease activity vs treatment, is unknown. Our objective was to determine, in SLE, the relative importance of disease activity vs drugs.

Methods: We performed case-cohort analyses within a multi-site SLE cohort. Cancers were ascertained by cancer registry linkage. Adjusted hazard ratios (HRs) for lymphoma were generated in multivariate regression models, for time-dependent exposures to immunomodulators (cyclophosphamide, azathioprine, methotrexate, mycophenolate, anti-malarials, glucocorticoids) demographics, calendar year, Sjogren's syndrome, SLE duration, and disease activity(mean adjusted SLEDAI-2k). Partially adjusted models were also performed, using only covariates whose HR confidence interval excluded the null value. Sensitivity analyses were performed, lagging cyclophosphamide exposures by 5 years. We used average mean SLE disease activity scores over

time, and medications were treated both categorically (ever/never) and as cumulative doses.

Results: We studied 64 lymphomas (61 non-Hodgkin's, 3 Hodgkin's) and 4,739 cancer-free controls. As is seen in the general population, lymphoma risk in SLE was higher in males versus females, and increased with age. Lymphoma cases occurred a mean of 13.1 years (standard deviation 9.8, median 12.3) after SLE diagnosis. Univariate analyses suggested a decreased lymphoma risk within the highest tertile of disease activity (relative to those with the lowest activity) but in fully adjusted models (using all variables listed above), the confidence interval widened to include the null value. Sensitivity analyses, lagging cyclophosphamide exposures, showed similar results to that portrayed in the table below. In a partially adjusted model (retaining age and highest tertile of disease activity), the HR suggested a two-fold lymphoma risk after cyclophosphamide. Despite a trend towards greater cyclophosphamide use in cases versus cancer-free controls, in fully adjusted models, no drug exposure was estimated to be an independent risk factor. Still, due to correlation, it remains difficult to differentiate the effects of medications from disease activity.

Results of the univariate and multivariate models to assess the hazard ratio (HR) of exposures on lymphoma development in patients with SLE

Variable	Univariate HR (95% CI)*	Partially adjusted model (95% CI)	Multivarate HR (95% CI)
Outside North America	1.04 (0.53, 2.05)	-	1.06 (0.45, 2.50)
Calendar year	1.01 (0.98, 1.05)	-	0.98 (0.94, 1.02)
Male	2.47 (1.24, 4.92)	-	2.21 (1.05, 4.66)
Age	1.05 (1.03, 1.07)	1.04 (1.03, 1.06)	1.05 (1.03, 1.07)
White race/ethnicity	0.97 (0.55, 1.71)	-	0.86 (0.46, 1.59)
Sjogren's syndrome	1.29 (0.66, 2.54)	-	1.21 (0.53, 2.78)
Glucocorticosteroids (GC) ever	1.39 (0.75, 2.56)	-	1.03 (0.40, 2.64)
Cumulative GC**> 3.5 gm	1.27 (0.75, 2.17)	-	1.59 (0.69, 3.67)
Cyclophosphamide (CY) ever	1.73 (0.90, 3.33)	1.99 (1.00, 3.96)	1.95 (0.61, 6.22)
Cumulative CY > 6 gm	1.51 (0.63, 3.62)	-	0.79 (0.18, 3.54)
Azathioprine (AZA) ever	0.82 (0.45, 1.52)	-	1.28 (0.53, 3.07)
Cumulative AZA > 36.5 gm	0.49 (0.19, 1.25)	-	0.46 (0.14, 1.54)
Methotrexate ever used	0.99 (0.45, 2.16)	-	0.79 (0.30, 2.05)
Mycophenolate ever used	1.38 (0.58, 3.29)	-	1.74 (0.70 4.34)
Antimalarials ever used	1.47 (0.80, 2.69)	-	1.39 (0.69, 2.78)
Disease activity (2nd tertile)***	1.00 (0.55, 1.82)	-	1.10 (0.56, 2.14)
Disease activity (3rd tertile)	0.43 (0.22, 0.84)	0.49 (0.27, 0.90)	0.52 (0.24, 1.12)

* CI=confidence interval**Systemic glucocorticosteroids, considered in prednisone equivalent doses.***Mean adjusted SLE Disease Activity-2K (SLEDAI-2k)

Conclusion: We did not definitively demonstrate an increased risk for any medications, despite a trend to greater cyclophosphamide use in the lymphoma cases. If anything, we noted a protective effect for very high SLE disease activity. Further work will focus on genetic profiles that might interact with medication exposures to influence lymphoma risk in SLE.

Lack of Control of Hypertension in Systemic Lupus Erythematosus.
Hong Fang[1], Raheel Ahmad[1], Laurence S. Magder[2] and Michelle Petri[1]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland, Baltimore, MD

Background/Purpose: Hypertension is an independent risk factor for both actual cardiovascular events and also subclinical atherosclerosis (coronary calcium, carotid IMT) in SLE. We examined the factors that predict poorly controlled hypertension in SLE.

Methods: There were 2,182 patients with SLE (92% female, 56% Caucasian, and 37% African-American). Ninety-five percent met revised American College of Rheumatology criteria for SLE. Patients were diagnosed

as having hypertension if they had systolic blood pressure ≥140 mm Hg or diastolic blood pressure ≥90 mm Hg or if receiving any anti-hypertensive medications. Patients who had ever had hypertensive episodes during cohort follow-up were compared with patients who had never had hypertension with respect to clinical and demographic characteristics. Multivariate regression modeling using generalized estimating equations was used to assess of the association between various factors and mean systolic blood pressure over cohort follow-up among patients with hypertension.

Results: There were a total 1630 (74%) patients with hypertension (91% female, 53% Caucasian, 42% African-American). Compared to non-hypertensive patients, those with hypertension were more likely to be African-American (p<0.0001), male (p=0.0004), smokers (p<0.0001), alcoholic (p<0.0001), older (p<0.0001), lower education (p<0.0001), lower household income (p<0.0001), higher disease activity (p<0.0001), higher body mass index (p<0.0001), higher prednisone dose (p<0.0001),higher urine protein to creatinine ratio (p<0.0001) and higher serum creatinine (p<0.0001).

We next examined, in just the patients with hypertension, the association between clinical variables and systolic blood pressure over followup. In the table, a negative number indicates better control of hypertension.

Variable	Effect on Mean Systolic Blood Pressure	p-value
Age at assessment (per year)	0.22 ± 0.03	<0.0001
Gender (female)	-4.56 ± 1.14	<0.0001
Ethnicity		
African-American vs Caucasian	3.24 ± 0.91	0.0004
Other ethnicity vs Caucasian	-3.64 ± 1.45	0.012
Years of education (per year)	-0.11 ± 0.14	0.45
Family income (per $1,000)	0.002 ± 0.004	0.63
Smoking	1.19 ± 0.86	0.17
Body mass index (per kg/m^2)	0.56 ± 0.05	<0.0001
Number of anti-hypertensives	-3.08 ± 0.35	<0.0001
Prednisone (per mg/d)	0.13 ± 0.02	<0.0001
SELENA-SLEDAI	0.15 ± 0.06	0.017
Urine dipstick protein	0.85 ± 0.40	0.033
Urine protein/cr ratio	2.62 ± 0.41	<0.0001
Serum creatinine	-1.94 ± 0.79	0.014

In the multivariate model, age, male sex, African-American, BMI, prednisone, disease activity, and measures of renal lupus remained independent prediction of poor blood pressure control.

Conclusion: Hypertension remains an independent risk factor for cardiovascular events in SLE. As in the general population, older age, male gender, and African-American ethnicity are associated with both hypertension and poor control of hypertension. In SLE, body mass index, prednisone, disease activity, and urine protein to creatinine ratio remain independent predictors of poor blood pressure control. These modifiable risk factors are potential "treat to target" goals. In SLE, use of more than one anti-hypertensive was superior in blood pressure control.

Molecular Signatures in SLE: Flare Vs. Infection. Meggan Mackay[1], Michaela Oswald[1], Jorge Sanchez-Guerrero[2], Juan J. Lichuaco[3], Cynthia Aranow[1], Sean Kotkin[1], Peter K. Gregersen[1] and Betty Diamond[1]. [1]The Feinstein Institute for Medical Research, Manhasset, NY, [2]Mount Sinai Hospital, University Health Network, Toronto, ON, [3]St. Luke's Medical Center, Quezon City, Philippines

Background/Purpose: Inability to distinguish between infection and the inflammatory response related to SLE disease activity using clinical judgment often compromises timely and effective treatment. Gene expression profiling of circulating leukocytes has been used to differentiate between malignancy subtypes and between sepsis and sterile inflammation. The "IFN signature" in SLE has been linked to disease pathogenesis and disease activity. A biomarker that precisely and rapidly distinguishes between active disease and infection would allow for more directed therapy, resulting in improved outcomes. RNA microarray analysis of peripheral blood leukocytes in acutely ill SLE patients was used to identify gene expression profiles that distinguish the host response to infection from inflammation related to active disease.

Methods: 37 SLE patients with suspected infection or active SLE were recruited from 3 centers in New York, Mexico and the Philippines. Subjects

were excluded for pregnancy, a history of infection with Hepatitis B, C, HIV or if treatment had been initiated for the current illness. Whole blood was collected in Tempus™ Blood RNA Tubes and disease activity (SELENA SLEDAI) was measured at the time of enrollment. Infection determination was based on results of cultures, viral antibodies or PCR analyses. Microarray analyses were performed on the Illumina HT12v4 platform. Gene expression data were grouped using a modular analysis framework for blood genomics that has been applied to SLE previously (Immunity.2008; 29:150). Clinical characteristics were summarized using appropriate descriptive statistics with correction for multiple comparisons. Statistical significance for microarray modules was determined using a hypergeometric test.

Results: 31 subjects had adequate RNA for analysis; 19 met criteria for infection and subjects were grouped as either infection or flare as the cause of acute illness. There were no significant group differences in age, disease duration, ethnicity, co-morbid states, history of prior CNS or renal disease or current medication use. Presence of low serum complement or high anti-dsDNA antibody titers did not distinguish between groups, however, SLE-DAI scores were significantly higher with disease activity (p=0.002). Flare subjects exhibited significant over expression of genes encoding immunoglobulin chains and CD38 (plasma cell module; p=0.001) and IFN inducible genes (p<.000). Subjects with infection demonstrated significant over expression of genes encoding molecules expressed by cells of myeloid lineage (p=0.018) and molecules inducible by or inducing inflammation (inflammation II module; p=.012).

Conclusion: We have identified gene expression signatures that associate significantly with either infection or disease activity. Not surprisingly, genes over expressed in flare are those associated with plasma cells or are IFN inducible. Genes expressed in response to infection encode molecules such as FcγRIIA, CD86, CD163 and others associated with pattern recognition such as CD14, TLR2, MYD88, TNFR2 and BAFF. While SLEDAI scores correlate with disease activity, identification of a "sepsis signature" provides a more objective and reliable premise for treatment.

Arthoplasty Rates Increased Among US Patients with Systemic Lupus Erythematosus: 1991–2005. Christina Mertelsmann-Voss[1], Ting Jung Pan[2], Huong Do[2], Mark P. Figgie[2] and Lisa A. Mandl[2]. [1]Hospital for Special Surgery, Cornell University, New York, NY, [2]Hospital for Special Surgery, New York, NY

Background/Purpose: There is little data regarding patterns of arthroplasty use in patients with Systemic Lupus Erythematosus (SLE). This study evaluates trends in total joint replacement (TJR) for SLE from 1991–2005. Comparisons are made to patients with non-inflammatory conditions.

Methods: Administrative hospital discharge databases from 10 states (AZ, CA, CO, FL, IA, MA, NJ, NY, WA, WI) and census data annual population estimates were used to compute annual rates per 100,000 population of knee arthroplasty, total and partial hip arthroplasty, and total and partial shoulder arthroplasty for the years 1991 to 2005 in patients with SLE and those with no inflammatory or autoimmune diseases. ICD-9-CM codes were used to identify specific diseases.

Results: During the 15 year study period, 4253 TJR were performed for patients with SLE and 2,762,660 TJR for patients with no inflammatory or autoimmune disease. SLE patients were younger (54 +/− 16 years vs 70.5 +/− 12.1 years) and much more likely to be female (90.2% vs 63.5%). Hip arthroplasty was the most frequent procedure in SLE patients (50.1% vs. 31.1%), whereas knee arthroplasty was most common in the non-inflammatory group (33.7% for SLE patients vs. 47.4%); TJR rates for patients with non-inflammatory conditions almost doubled from 1991 to 2005 (124.5/100,000 in 1991 vs. 247.5/100,000 in 2005, p-value <0.001). A similar trend was observed for SLE; (0.17/100,000 vs. 0.38/100,000, p<0.001). In particular, the proportion of total knee replacements among SLE patients increased from 15% in 1991 to 45% in 2005. The mean age of patients undergoing TJR with non- inflammatory conditions decreased (71.5±11.8 yrs in 1991, 69.0±12.0 yrs in 2005, p-value <0.001). In contrast, the mean age of SLE TJR increased (47.3+/−17.0 vs 56.8+/−16.0, p-value<0.001). When stratified by age and gender, TJRs in SLE patients increased in all groups except for women with SLE <44 years of age. In this group rates decreased from 0.073/100000 to 0.067/100000 (p-value=0.009).

Conclusion: To our knowledge this is the first evaluation of TJR rates in SLE patients. From 1991–2005 arthroplasty rates increased in patients with SLE in similar proportions to overall TJR rates. This was surprising, as we had expected a decrease in TJR mirroring improved SLE mortality rates and decreases in end stage renal disease. However, the decrease in TJR among women < 44 years suggests treatment may be preventing early damage from severe active disease. In addition, while the mean age of non-inflammatory TJR fell, the age at time of SLE TJR increased. We speculate that improvements in SLE therapy may allow patients to live long enough to suffer both the osteonecrotic effects of steroids, possibly develop degenerative changes and also be healthy enough to receive an elective TJR. Increases in knee arthroplasty among SLE patients may also reflect lower SLE morbidity, and mortality, with SLE patients living long enough to develop age/obesity related knee OA. Further study is needed to see if these trends continue with ongoing improvements in SLE clinical care.

Disclosure: C. Mertelsmann-Voss, None; **T. J. Pan**, None; **H. Do**, None; **M. P. Figgie**, None; **L. A. Mandl**, None.

Smoking, Autoantibodies and Vascular Events in Systemic Lupus Erythematosus. Johanna Gustafsson[1], Iva Gunnarsson[2], Susanne Pettersson[3], Agneta Zickert[1], Anna Vikerfors[4], Erik Hellbacher[4], Sonia Möller[3], Kerstin Elvin[4], Henrik Källberg[4], Julia F. Simard[5] and Elisabet Svenungsson[1]. [1]Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden, [2]Department of Medicine, Rheumatology Unit, Karolinska Institute, Stockholm, Sweden, [3]Karolinska University Hospital, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Smoking is a risk factor for several autoimmune diseases including rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Smoking is also a major risk factor for cardiovascular disease (CVD), both in the general population and in SLE. Smoking has furthermore been specifically associated with the occurrence of autoantibodies in RA, SLE and also in animal studies of autoimmune diseases.

We investigated the associations between patients smoking history and a set of autoantibodies in SLE. We also studied the potential interaction between smoking and autoantibodies for the occurrence of previous vascular events.

Methods: 367 prevalent SLE patients from a single center were included. Clinical evaluation, history of previous vascular events and data on smoking habits and estimated number of smoked cigarettes were recorded at inclusion. Autoantibodies: anti(a)dsDNA, aSm, aRo52, a Ro60, aSSB and antiphospholipid (aPL) antibodies (anticardiolipin antibodies (aCL) IgG/IgM/IgA, anti-b_2 glycoprotein-1 (ab$_2$GP1) IgG/IgM/IgA) and the lupus anticoagulant (LAC) were measured using ELISA and multiplex methods. Association analyses between smoking status (ever, former, current) at inclusion and antibody status were performed through logistic regression. These variables were also investigated in relation to history of CVD through interaction analysis. Never smokers were used as reference.

Results: In a first screening we noted that ever smoking was positively associated with aCL IgG (p=0.007), ab$_2$GP1 (p=0.002) and a positive LAC test (p=0.001) while the other investigated antibodies were not associated. Further analyses of the observed associations between aPL and smoking in multivariable models (including age, sex, age at disease onset, current smoking and former smoking) demonstrated that specifically former smoking was associated with LAC positivity OR 3.1(95% CI 1.6–5.9), ab$_2$GP1 IgG OR 3.1(95% CI 1.6–6.1) and aCL IgG OR 2.9(95% CI 1.6–5.8). The amount of cigarettes smoked did not affect aPL status. Interaction analysis demonstrated an interaction between occurrence of any aPL and ever smoking for the risk of venous thromboembolism (VTE), OR 2.8 (95% CI 1.3 – 5.9), attributable proportion due to interaction (AP)=0.66, p<0.05.

Conclusion: We demonstrate that among SLE patients ever smoking, and in particular former smoking, is associated with pro-thrombotic aPL. Furthermore, the combination of smoking and aPL positivity seems to interact and enhance the risk of vascular events. Our results demonstrate associations between smoking, an environmental exposure, humoral immunity and vascular events in SLE. Further studies are needed to investigate the directions and mechanisms behind these associations. Our results further underscore the importance of advocating a smoke free lifestyle among SLE patients.

Inhibition of Pathogenic Autoantibodies by Accelerating the Exit of Germinal Center B Cells Via Manipulation of Regulator of G-Protein Signaling. John D. Mountz[1], John H. Wang[2], James S. New[3], PingAr Yang[3], Qi Wu[3], Bao Luo[3], Jun Li[3], Kirk M. Druey[4] and Hui-Chen Hsu[3]. [1]Univ of Alabama at Birmingham and Birmingham VA Medical Center, Birmingham, AL, [2]Cedars Sinai Medical Center, Los Angeles, CA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]National Institute of Allergy and Infectious Diseases, Bethesda, MD

Background/Purpose: Regulator of G-protein Signaling (RGS) plays a key role in inhibiting chemokine signaling by desensitizing G-protein coupled receptor signals. RGS13 and RGS16 are two major regulators of B cell migration and regulate responses to CXCL12 and CXCL13 during development of germinal centers (GCs). We previously showed that IL-17 increased *Rgs13* and *Rgs16* in GC B cells, leading to high levels of activation-induced cytidine deaminase (AICDA), somatic hypermutation (SHM) and enabled development of pathogenic autoantibodies that cause immune complex nephritis and erosive arthritis. The objective of this work is to use BXD2-*Rgs13*[−/−] and BXD2-*Rgs16*[−/−] mice to determine if loss of RGS regulation suppressed the development of pathogenic autoantibodies.

Methods: BXD2-*Rgs13*[−/−] and BXD2-*Rgs16*[−/−] mice were produced by backcrossing BXD2 with B6-*Rgs13*[−/−] and B6-*Rgs16*[−/−] mice for > 7 generations. Confocal imaging was used to determine the location of RGS13, RGS16, AID, and GC B cells in the spleen. Immunohistochemistry staining of spleen and kidney was used to determine the presence of plasmablasts and immune complex deposition. ELISA was used to determine serum levels of autoantibodies. The levels of GC B cell (*Aicda*, *Pax5* and *Bach2*) and plasma cell (*Irf4*, *Blimp1* and *Xbp1*) program transcripts in FACS purified GC B cells were determined by quantitative real-time PCR. T-B conjugates were analyzed by sorting CD19[+]/CD4[+] doublets followed by EDTA dissociation and FACS identification of B-cell subsets.

Results: In spleens of wild-type (WT) BXD2 mice, RGS13 was mainly expressed by GC B cells with light zone (LZ) B cells expressed slightly higher levels of *Rgs13* compared to dark zone (DZ) B cells. RGS16 was expressed by LZ GC and marginal zone precursor (MZP) B cells in the LZ border. BXD2-*Rgs13*[−/−] mice exhibited higher IgM antibody titers at early age compared to WT mice; though smaller GCs, lower GC B-CD4 conjugates, and lower AID levels suggested a lesser extent of SHM and affinity maturation. RGS16 deficiency led to reduced aggregation of CD86[hi] MZP B cells in GC LZ vicinity, reduced MZP-T conjugates, and significantly fewer GCs, suggesting its role in MZP stabilization in GC LZ. Despite smaller GCs, there was increased IgM[bright] plasmablasts, upregulation of *Irf4*, *Blimp1* and *Xbp1* and down regulation of *Aicda*, *Pax5* and *Bach2* in GC B cells of BXD2-*Rgs13*[−/−] and BXD2-*Rgs16*[−/−] mice. At older ages, BXD2-*Rgs13*[−/−] and BXD2-*Rgs16*[−/−] mice showed lower titers of IgG autoantibodies and IgG deposits in the glomeruli, suggesting reduced autoantibody pathogenicity.

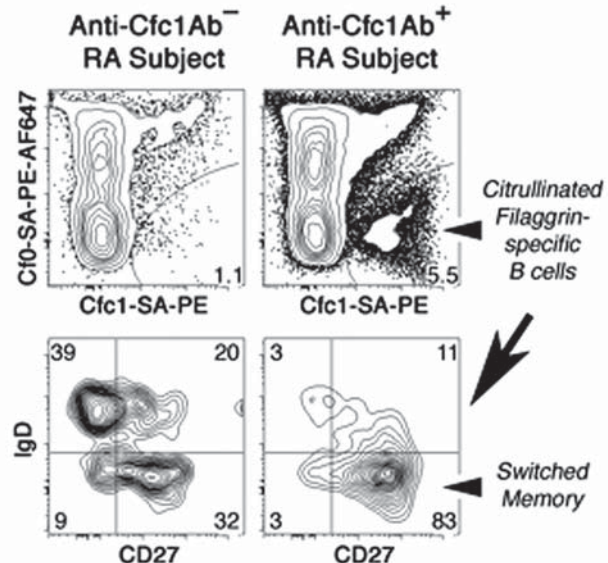
Conclusion: Lack of either RGS13 or RGS16 signal is associated with reduction in GC program genes and premature exit of less pathogenic IgM plasmablasts. Our results suggest that, in autoimmune mice, prolonged B-T interactions in the GC light zone, mediated by upregulation RGS13 or RGS16, enhanced the selection and generation of high affinity pathogenic autoantibody producing B cells. Redirection of B cell migration within different GC compartments via regulation of RGS13 and RGS16 and their associated signaling pathways may be a novel strategy to abrogate development of autoreactive B cells that produce pathogenic autoantibodies.

2576

Production of Citrullinated Filaggrin-Specific IgG in Rheumatoid Arthritis Patients Is Associated with an Expansion of Citrullinated Filaggrin Tetramer-Binding Switched Memory Blood B Cells. Philip Titcombe, Laura O. Barsness, Lauren Giacobbe, Emily Baechler Gillespie, Erik J. Peterson and Daniel L. Mueller. University of Minnesota Medical School, Minneapolis, MN

Background/Purpose: Rheumatoid Arthritis (RA) is highly associated with the production of autoantibodies, including rheumatoid factors and anti-citrullinated protein antibodies (ACPA). It remains uncertain whether production of autoantibodies in RA results from a failure of peripheral B cell deletion or anergy, or from augmented T helper cell-induced differentiation. Unfortunately, our ability to directly study pathogenic B cells in RA has been hampered by their relatively low numbers in peripheral blood and our inability to directly monitor their antigen specificity.

Methods: We now report the development of a B cell "antigen tetramer" system for use with multiparameter flow cytometry that can accurately detect and phenotype self antigen-specific B cells in RA patients. Arginine-312 —> Citrulline substituted filaggrin cyclic peptide 306–324 (Cfc1) was biotinylated and multimerized using streptavidin (SA)-phycoerythrin (PE) conjugates. A "decoy tetramer" was also created using SA-PE-Alexa Fluor 647 (AF647) conjugates and biotinylated native filaggrin cyclic peptide (Cf0) to facilitate exclusion gating of B cells that bind native filaggrin, biotin, SA, or PE.

Results: 46% of tested subjects in our University of Minnesota ACPA+ RA cohort demonstrated IgG anti-Cfc1 antibodies by ELISA (>95% specificity threshold). Using a combination of the Cfc1 and Cf0 antigen tetramers and flow cytometry, we observed in RA patients that lack Cfc1 Ab (n=22) a low number of Cfc1-specific PBMC B cells (49±31 per million) that was similar to healthy controls (HC) (51±29, n=9). Nevertheless, Cfc1-binding B cells in anti-Cfc1 Ab- RA subjects more frequently demonstrated a CD19+CD20+IgD-CD27+ phenotype consistent with isotype switching and memory cell differentiation (35±15%) as compared to either randomly selected PBMC B cells from the same patient (18±8%; p<0.01) or Cfc1-binding B cells in HC (16±11%; p=0.02). Anti-Cfc1 Ab+ RA subjects (n=21) demonstrated both an increased frequency of Cfc1-binding B cells (125±85 per million; p=0.02 vs. HC, p=0.01 vs. anti-Cfc1 Ab- RA) and increased proportion having a switched memory phenotype (55±18%; p<0.01 vs. both HC and anti-Cfc1 Ab- RA). Among all ACPA+ RA subjects tested, the level of anti-Cfc1 Ab predicted the frequency of switched memory Cfc1-binding B cells in PBMC ($r^2=0.38$).


Conclusion: The loss of B cell tolerance to citrullinated filaggrin and production of anti-Cfc1 autoantibodies in RA is associated with an expanded population of Cfc1 tetramer-binding switched memory B cells in the PBMC. Use of antigen tetramers to positively identify and characterize antigen-specific B cells will accelerate the investigation of pathogenic B cells in autoimmune disease and holds promise as a valuable biomarker system for use in human therapeutic trials.

2577

Characterization of Circulating Human B Cells That Bind Cyclic Citrullinated Peptide Antigens in Clinically Active Rheumatoid Arthritis. Gregg J. Silverman[1], John Jung[2], Jeffrey D. Greenberg[3], Adam J. Pelzek[1], Caroline Gronwall[1] and Jaya Vas[1]. [1]NYU School of Medicine, New York, NY, [2]NYU, New York, NY, [3]New York University School of Medicine, New York, NY

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) were first identified based on their high specificity for RA and now are commonly used

as a diagnostic tool. Yet, despite the success of B cell targeted therapy, and evidence that ACPA may arise long before overt inflammatory arthritis, the roles of human B cells autoreactive for citrullinated protein antigens have been little explored.

Methods: For comprehensive B cell profiling, we developed a 12-color flow cytometry panel that assesses diverse B-cell subset specific markers, with live/dead discrimination and myeloid/T-cell exclusions. Fluorochrome-labeled tetrameric forms were made with cyclic citrullinated peptide (CCP) used in clinical testing, as well as a panel of self-protein derived peptides implicated in RA, and control peptides with a single amino acid type substitution. ACPA labeled beads were included for internal calibration. Multivariate methods were used to identify natural divisions within B cell data sets, and Spearman coefficients to assess for correlations between cytometric data and clinical/laboratory data.

Results: During panel development, we performed cross-sectional studies of a total of 30 RA and 16 healthy adults. Pilot surveys demonstrated only a low background levels of CD19+ B-cell binding to control CQP tetramer in RA and healthy adults (< 0.3% mean). While levels of B cell binding to CCP were overlapping between the groups, as some RA were indistinguishable from healthy controls, B cells from RA pts displayed significantly higher binding to CCP (7.46%+/−6.8, mean +/− SD) compared to binding of a control tetramer (p<0.0001, 2-tailed Mann-Whitney test). In RA, we found expansions of CCP-reactive B cells in diverse cellular subsets, which varied between subjects, and which included naïve mature B cells (IgD+ CD27−) and both CD27+IgD− and CD27− IgD− memory subsets. In each sample, CCP-binding by B-cell subsets was independent of relative BCR levels, as assessed by MFI. There were no significant relationships between levels of CCP-binding B cells and IgG, IgA or IgM anti-CCP or IgG to panel of peptide-specific ACPAs. Importantly, our surveys demonstrated a significant correlation between levels of CCP-binding by naïve mature (CD27− IgD+) B cells and DAS28 score (n=18, p=0.04, r=0.48). We also found correlations between CD95 expression (an activation marker) on CCP-binding B cells and DAS28 score (p=0.03, r=0.56) that was improved by exclusion of pts on biologic agents (n=7, p=0.01, r=0.89).

Conclusion: These studies have provided the first direct measurements of trafficking disease-specific B cells to citrullinated self-antigens. Our initial surveys found no relationship between levels of circulating CCP-reactive B cells with levels of serum ACPA, which therefore may reflect the contribution of sources no longer linked to synovial disease. However, we did find evidence of an association between levels of CCP-reactive B cells, and especially activated B cells, and overall disease activity by DAS28 score. Our investigative approach may therefore help to better stratify patients and identify those in whom autoantigen-specific lymphocytes are direct drivers of pathogenesis.

Monoclonal IgG Antibodies (ACPAs) From Synovial Fluid B Cells of Rheumatoid Arthritis Patients – Antigen-Driven Affinity Maturation and Cross Reactivity.

Khaled Amara[1], Johanna Steen[1], Fiona Murray[1], Henner Morbach[2], Blanca Fernandez-Rodriguez[3], Vijay Balasingh[1], Marianne Engström[1], Omri Snir[1], Lena Israelsson[1], Anca. I. Catrina[1], Hedda Wardemann[4], Davide Corti[3], Eric Meffre Sr.[2], Lars Klareskog[1] and Vivianne Malmström[1]. [1]Rheumatology unit, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [2]Yale University School of Medicine, New Haven, CT, [3]Institute for Research in Biomedicine, Bellinzona, Switzerland, [4]Max Planck Institute for Infection Biology, Berlin, Germany

Background/Purpose: Antibodies targeting citrullinated proteins (ACPA) are commonly found in patients with Rheumatoid Arthritis (RA), strongly associate with distinct HLA-DR alleles and predict a more aggressive disease course as compared to seronegative patients. Still, many features of these antibodies, including their site of production and the extent of MHC class II driven T-cell help remain unclarified. In this study we have assessed the specificity and the immunoglobulin gene characteristics of B cells derived from RA synovial fluid of RA by utilizing a method that allows in vitro production of monoclonal antibodies derived from single human memory B cells.

Methods: Recombinant monoclonal antibodies (n=204) were generated from single flow cytometry purified synovial CD19+IgG+ B cells from active RA patients (n=5). Antigen specificity and affinity were determined by ELISA and Biacore respectively. Frozen tissue sections from active RA synovial inflammation were evaluated by immunohistochemistry for presence of citrullinated antigens using the generated recombinant antibodies.

Results: Our results demonstrate that approximately 25% of synovial IgG-expressing B-cells are specific for citrullinated autoantigens in ACPA-positive RA patients, while such antibodies were not found in seronegative patients. These citrulline-reactive antibodies did not react with the unmodified arginine peptides. Surprisingly, several antibodies displayed cross reactivity to several citrullinated antigens but with variable binding affinities. Overall, KD values ranged from $1.35 \times 10^{-06} - 5.94 \times 10^{-10}$ for CEP-1, from $3.84 \times 10^{-05} - 3.1 \times 10^{-09}$ for cit-fib, and from $2.8 \times 10^{-06} - 1.05 \times 10^{-10}$ for cit-vim. Positive staining has been observed in biopsies of two RA patients. On the molecular level, striking differences were found between the monoclonal recognizing citrullinated antigens and those that did not. Based on DNA sequences, we could demonstrate that the citrulline-specific antibodies displayed fewer overall mutations but, yet displayed more replacement mutations in their CDRs regions as compared to the citrulline-negative clones. Interestingly, the reversion of citrulline-specific antibodies to their germline sequences led to a loss of reactivity to all the autoantigens.

Conclusion: A role for active antigen selection of the citrulline-reactive synovial B-cells was supported by the strong bias towards amino acid replacement mutations in ACPA+ antibodies and by their loss of reactivity to citrullinated autoantigens when somatic mutations were reverted to the corresponding germline sequences. The observed cross reactivity suggests that multiple antigens could participate in driving these clones.

Novel Autoantibodies to 14-3-3 Eta Are Highly Specific for Rheumatoid Arthritis.

Walter P. Maksymowych[1], Désirée van der Heijde[2], R. Landewe[3], Vivian P. Bykerk[4] and Anthony Marotta[5]. [1]University of Alberta, Edmonton, AB, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, [4]Hospital for Special Surgery, New York, NY, [5]Augurex Life Sciences Corp, North Vancouver, BC

Background/Purpose: Serum 14-3-3 eta, a protein biomarker that is differentially expressed in rheumatoid arthritis (RA), has been reported to add incrementally to rheumatoid factor (RF) and anti-cyclic citrullinated protein (anti-CCP) in diagnosing both early and established RA. We recently reported that extracellular 14-3-3 eta behaves as a novel mediator of RA pathogenesis, inducing factors involved in driving both inflammation (TNFα) and joint re-modeling (MMP-9) and that serum 14-3-3 eta is an independent predictor of damage in patients with RA and psoriatic arthritis (PsA). Since 14-3-3 eta is normally an intracellular chaperone that is externalized through an exosomal-mediated process by a disease-specific trigger, we investigated whether its extracellular presence elicits an autoantibody response that may be measured for clinical utility.

Methods: Detection of 14-3-3 eta autoantibodies was evaluated by examining immunoreactivity towards human recombinant 14-3-3 eta by immunoblot analysis using serum from healthy subjects and those with RA. Epitope mapping and *in silico* modeling was performed to identify putative epitopes of which 11 peptide regions were selected. To further specify high-priority regions, the serum expression levels of 14-3-3 eta autoantibodies were evaluated in 30 healthy individuals and 58 RA patients. Individual sequences were selected based on their absolute specificity for RA, of which 4 of 11 met this criteria with sensitivities ranging from 34–62%. A composite score was generated by combining the fluorescence intensity (FI) measurements for these 4 peptides, each of which were equally weighted and expressed in units (U). T-tests and Mann-Whitney U-tests were used to determine group differences. The area under the ROC curve (AUC) was generated for diagnostic utility estimates and likelihood ratios (LR) for various 14-3-3 eta autoantibody composite cut-offs.

Results: Immunoblot analysis reveals that patients with RA possess autoantibodies directed towards 14-3-3 eta. This prototype 14-3-3 eta autoantibody assay exhibits high specificity for RA versus healthy controls with means (SD) and medians (min-max) of 828U (1292U) and 681U (340U–10386U) for RA and 385U (74U) and 371U (289U-568U) for healthy controls, p-value <0.0001. The ROC AUC was 0.93 (95% CI 0.88–0.98; p<0.0001). At the best cut-off of 476U, the specificity and sensitivity were 90% and 80%, respectively with a likelihood ratio positive of 7.9 increasing to 18 at 580U. These prioritized sequences will be further specified based on their differential expression in RA versus disease controls to develop an anti-14-3-3 eta ELISA for clinical diagnosis.

Conclusion: 14-3-3 eta is an RA biomarker whose extracellular expression elicits an autoantibody response that is highly specific for RA compared to healthy individuals.

Marginal Zone Defects in Wiskott-Aldrich Syndrome Are Dependent On B Cell Intrinsic Toll-Like Receptor Signals. Shaun W. Jackson[1], Nikita Kolhatkar[2], Marc A. Schwartz[2], Socheath Khim[3] and David J. Rawlings[4]. [1]Seattle Children's Hospital, Seattle, WA, [2]Department of Immunology, University of Washington, Seattle, WA, [3]Seattle Children's Research Institute, Seattle, WA, [4]Washington, Seattle, WA

Background/Purpose: Patients with the primary immunodeficiency Wiskott-Aldrich syndrome (WAS) have severe abnormalities in splenic marginal zone (MZ) anatomy and function. Consistent with this, WAS patients fail to develop T-independent antibody responses to polysaccharide antigens and are susceptible to *Streptococcus pneumoniae* infections. We previously showed that B cell entry into the MZ is unperturbed in WAS−/− mice, but that retention within the MZ is defective. However, the factors promoting WAS−/− B cell exit from the MZ have not been determined.

Methods: Proliferation of sorted wild-type (WT) and WAS−/− MZ B cells was quantified after stimulation with LPS (TLR4 agonist), CL294 (TLR7 agonist) or CPG (TLR9 agonist) for 72 hours. To study the impact of B cell intrinsic TLR signaling on WAS MZ homeostasis, mixed bone marrow chimeras were generated in which deficiency of WAS, WAS × Myd88, WAS × TLR7 or WAS × TLR9 was limited to the B cell lineage. Splenic MZ reconstitution was then analyzed by flow-cytometry and immunohistochemistry. *In vivo* labeling of MZ cells at the vascular interface was performed by PE-labeled anti-CD19 antibody injection 5 minutes prior to sacrifice.

Results: In addition to markedly decreased MZ size, we demonstrate by *in vivo* labeling that WAS−/− MZ B cells are not normally positioned at the MZ vascular interface. Unmanipulated WAS−/− mice also exhibit increased peripheral blood MZ B cells consistent with the idea that WAS−/− B cells are not appropriately retained within the MZ. Further, we show that sorted WAS−/− MZ B cells are hyper-responsive to multiple Toll-like receptor (TLR) ligands, including TLR4, TLR7 and TLR9. These combined findings suggested that TLR-mediated activation might directly promote WAS−/− B cell exit from the MZ.

To test this idea, we generated chimeras with B cells deficient in both WAS protein and the key TLR signaling adaptor, MyD88. Strikingly, the MZ B cell compartment was restored to WT levels in WAS−/− × MyD88−/− chimeras. WAS−/− × MyD88−/− B cells were also appropriately positioned within the MZ both by *in vivo* labeling and immunohistochemistry. To address the impact of individual TLRs, we generated WAS−/− × TLR7−/− and WAS−/− × TLR9−/− chimeras. Although increased compared with WAS−/− controls, WAS−/− × TLR7−/− MZ size was reduced 50% compared with WT chimeras, suggesting a partial role for endogenous TLR7 ligands in driving WAS−/− B cells out of the MZ. In contrast, no rescue of MZ B cell numbers was noted in WAS−/− × TLR9−/− chimeras, implicating TLR9 in negatively regulating B cell activation and MZ retention, perhaps via downregulation of TLR7 signaling.

Conclusion: Our data demonstrate that activation by endogenous TLR ligands is sufficient to drive WAS−/− MZ B cells from the MZ and that B cell-intrinsic TLR7 and TLR9 signals have opposing impacts on MZ homeostasis. These data imply a previously unappreciated role for B cell intrinsic TLR signals in MZ B cell function; and have important implications regarding altered immune responses to blood-borne pathogens in WAS patients and for development of autoimmune disease in WAS and other clinical settings.

ACR Concurrent Abstract Session
Imaging of Rheumatic Diseases III: Computed Tomography
Wednesday, November 14, 2012, 9:00 AM–10:30 AM

Anti-Citrullinated Protein Antibodies but Not Rheumatoid Factor Are Associated with Larger Bone Erosions in rheumatoid arthritis patients— a Cross-Sectional Micro Computed Tomography Study. Carolin Hecht[1], Stephanie Finzel[1], Matthias Englbrecht[1], Sarah Schmidt[1], Juergen Rech[1], Elizabeth Araujo[1] and Georg Schett[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Anti- citrullinated protein antibodies (ACPA) are known to be associated with joint destruction and a more severe disease course in

rheumatoid arthritis (RA) patients. Recently, ACPA have been identified to directly induce bone loss (1). No study, however, has yet compared ACPA-positive and ACPA-negative RA patients with respect to their periarticular bone structure using high-resolution imaging of bone.

Methods: Cross-sectional analysis of 234 RA-patients fulfilling the new ACR/EULAR criteria. All patients received micro-computed tomography (2) of the MCP II, II and IV joints of the dominantly affected hand. Age, gender, disease activity (DAS28), disease duration, rheumatoid factor, ACPA (by anti-CCP2 ELISA) and anti-rheumatic therapy were recorded.

Number, width, depth and volume of bone erosion were assessed by 2 independent readers, one of them reading the images twice to test for intrareader-reliability. For calculation of volumes, a semi-ellipsoid formula was used (3).

Results: 137 patients were ACPA positive (RF+: N =108, RF-: N =29), 97 patients ACPA negative (RF+. N =28, RF-: N =69). All 4 groups were comparable for age, gender, disease activity, disease duration and anti-rheumatic therapy (Tab. 1). 15 patients were excluded from further evaluation due to movement artefacts. RF+/ACPA+ RA patients had significantly more severe erosions (width: 2.00mm; depth: 2.25mm; volume: 13.86mm^3) as compared to RF−/ACPA− RA patients (1.25mm; 2.02mm; 4.60mm^3; all p<0.0001). Furthermore, when comparing only those patients without RF, we observed that bone erosions in RF−/ACPA+ RA patients were significantly larger in dimension than bone erosions in RF−/ACPA− RA patients (w−+/+−: p=0,0012; w−+/−−: p<0.0001; d: −+/+− p=0,0095 and d: −+/−− p=0,0347; vol−+/+−: p= 0,0133; vol−+/−−: p=0,0055). Intra-observer reproducibility (CH) for erosion counts, width, depth and volumes was high (Spearman's rho between 0.93–0.99; p < 0.001). Interobserver reproducibility (SF; CH) was also very high (cts: 0.99, p < 0.001; w/d: 0.98, p < 0.001; vol.: 0.996, p < 0.001).

Table 1. Details of erosions and demographic data

Group	Age	no/female/ total	disease duration	DAS28	no/erosions (total)	no/erosions (mean)	width (mm)	depth (mm)	Volume (mm3)
RF+/CCP+	55,57	77/108	6,50 ± 7,06	3,67 ± 1,70	345	4,54 ± 8,55	2,00 ± 1,18	2,25 ± 1,51	13,86 ± 69,78
RF+/CCP−	53,00	24/29	4,14 ± 5,51	4,54 ± 1,45	41	1,80 ± 1,80	1,48 ± 0,71	1,70 ± 1,06	2,40 ± 3,30
RF−/CCP+	54,38	25/29	4,52 ± 5,63	3,19 ± 1,24	40	1,74 ± 3,02	2,06 ± 1,37	3,04 ± 2,99	13,81 ± 28,15
RF/−CCP−	56,28	54/69	4,0 ± 6,06	4,03 ± 1,81	79	1,55 ± 1,90	1,25 ± 0,56	2,03 ± 1,64	3,50 ± 8,17

Means +/− standard deviation are shown if not highlighted otherwise

Conclusion: These data show that ACPA-positivity is associated with larger bone erosions in patients with RA. They also support the notion that ACPA essentially contribute to bone loss in RA by enhancing osteoclast activity, which is the key prerequisite for bone erosion. Moreover, ACPA impact bone erosion independent from the presence or absence of RF.

Bone Anabolic Changes Progress in Psa Patients Despite Treatment with Methotrexate or Tumour Necrosis Factor Inhibitors. Stephanie Finzel[1], Sebastian Kraus[1], Sarah Schmidt[1], Axel J. Hueber[1], Juergen Rech[1], Klaus Engelke[1], Matthias Englbrecht[1] and Georg Schett[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: To investigate whether methotrexate (MTX) or tumour necrosis factor inhibition (TNFi) affect osteophyte formation in patients with psoriatic arthritis (PsA).

Methods: 41 patients with PsA were examined for the presence of osteophytes and erosions at the metacarpophalangeal joints by high-resolution μCT imaging. The size of each individual lesion was quantified at baseline and 1-year follow-up in PsA patients treated with TNFi (N=28) or methotrexate (N=13). Groups were comparable for age, sex, disease duration and activity and baseline burden of osteophytes.

Results: In total, 415 osteophytes (TNFi: N= 284, MTX: N= 131) were detected. Osteophyte size increased significantly from baseline to follow-up in the TNFi group (mean ± SEM change: +0.23 ± 0.02 mm; p<0.0001) and the MTX group (+0.27 ± 0.03 mm, p<0.0001). In both treatment groups, the majority of osteophytes showed progression (TNFi: 54.3% MTX: 61.1%), whereas regression of lesions was rare (less than 10%). In contrast to osteophytes, clinical disease

activity decreased in both groups of PsA patients and erosions showed an arrest of progression in both groups.

Conclusion: Osteophytes progress in PsA patients treated with either MTX or TNFi. These data provide first evidence that pathologic bone formation in the appendicular skeleton of patients with PsA is not affected by current anti-rheumatic treatment strategies.

Bone Structure and Perfusion Quantification of Bone Marrow Edema and Pannus Tissue Areas in the Wrist of Patients with RA. Jose R. Teruel Antolin, Andrew J. Burghardt, Julien Rivoire, Waraporn Srikhum, Susan M. Noworolski, Thomas M. Link, John B. Imboden and Xiaojuan Li. University of California, San Francisco, San Francisco, CA

Background/Purpose: Bone marrow edema (BME) has been suggested as a strong predictor for erosive progression in RA joints, however, no previous studies examined the bone structure within BME. This study aimed to quantify bone structure and perfusion properties of BME, normal bone marrow (NBM) and pannus tissue areas in wrists affected by RA using 3T MRI and high resolution peripheral quantitative CT (HR-pQCT).

Methods: Sixteen patients (52.9 ± 12.7 years) fulfilling ACR classification were imaged in a HR-pQCT system (82μm isotropic voxel) and in a 3T MRI scanner using an 8-channel wrist coil. Coronal T2-weighted fast spin-echo IDEAL and 3D dynamic contrast enhanced (Gd-DTPA injection, temporal resolution 12 s, 32 time points) images were acquired. BME and pannus tissue areas were segmented semi-automatically in T2-w images. NBM areas were placed 1 to 3 mm far from BME regions and with similar distance to joint space. T2-w images were register to reformatted HR-pQCT and registration was applied to the segmented ROIs that were placed on original HR-pQCT images after upsampling (Fig 1). Perfusion parameters were calculated based on the signal-time curve obtained from DCE-MRI.
Figure 1. a: BME and pannus in T2w IDEAL image. b: HR-pQCT showing erosion and BME ROI superimposed.

Results: Eleven out of 16 RA patients presented at least one BME region. Eighteen BME areas were segmented, 13 of them were presented around areas evidently affected by pannus tissue. The regions with pannus tissue in MRI always correspond to regions with erosion in HR-pQCT images (Fig 1). Two BME areas were presented next to early stage of pannus tissue (very small quantity of pannus penetrating the bone). For 3 of the BME regions, no pannus tissue were observed. Significant increases in bone density and trabecular thickness were evidenced in all BME regions (Fig 2).
Figure 2. Percentage increase of bone parameters in regions presenting BME with regard to NBM areas (P < 0.05).

BME and pannus tissue areas show significantly increased perfusion. The maximum signal enhancement in BME was 20.33 ± 14.33 (% over NBM) within the carpal bones and 21.32 ± 10.52 within the distal radius/ulna. In pannus tissue areas was 16.48 ± 11.34 (% over NBM) within the carpal bones and 32.93 ± 16.71 within the radius/ulna.

Conclusion: BME regions show a thickening in the trabecular structure that suggests a bone regeneration before pannus tissue produces erosion. Trabecular thickening within BME is higher when pannus tissue is already presented in the patient. This higher thickening suggests sclerosis occurring to protect the bone structure from pannus tissue and kinematic re-adaptation. Combining MRI and HR-pQCT provides a powerful multi-modality approach for better understanding BME and erosion, and potentially identifying novel imaging markers for disease progression in RA.

Quantitative and Semi-Quantitative Bone Erosion Assessment On High-Resolution Peripheral Quantitative Computed Tomography in Rheumatoid Arthritis. Waraporn Srikhum, Warapat Virayavanich, Andrew J. Burghardt, Andrew Yu, Thomas M. Link, John B. Imboden and Xiaojuan Li. University of California, San Francisco, San Francisco, CA

Background/Purpose: The goals of this project were (i) to develop novel quantitative and semiquantitative measures of bone erosions at the metacarpophalangeal (MCP) and wrist joints in patients with rheumatoid arthritis (RA) using high-resolution peripheral quantitative computed tomography (HR-pQCT), and (ii) to correlate these measurements with disease duration and bone marrow edema (BME) pattern from MRI.

Methods: 16 RA patients (54.1±12.7 years, 13 females) underwent hand and wrist HR-pQCT and 3 Tesla MRI. Bone erosions of the 2nd and 3rd MCPs and distal radius were evaluated by measuring maximal erosion dimension on axial slices by two radiologists. Measurements were performed twice. Intraclass correlation coefficient (ICC) values were calculated for the inter- and intra-reader reliability. Bone erosions in each MCP and distal radius were graded (grades 0–3) based on the maximal dimension and number of erosions (Figure1A). The volume of bone marrow edema (BME) pattern was quantified on coronal T2-weighted fast spin-echo (FSE) MRI images using in-house software. Spearman correlation coefficients were calculated between 1) sum maximal dimensions, highest grades and sum grades of bone erosions; 2) erosion measures and the clinical evaluation (duration of disease, DAS28, ESR, and CRP); 3) erosion measures and BME pattern volume in distal radius.

Results: The mean maximal dimension of erosions at MCP2, MCP3 and distal radius were 0.39±0.21 cm, 0.32±0.21 cm and 0.46±0.31 cm, respectively. The inter- and intra-reader agreements of maximal erosion dimensions were excellent (ICC 0.89 and 0.99, respectively). Correlations between highest grades and sum grades, vs. sum maximal dimensions of all erosions were r=0.96 and 0.94 (p<0.01), respectively. Number of erosions, sum maximal erosion dimensions, highest grades and sum grades significantly correlated with duration of the disease (p<0.01), but not with DAS28, ESR and CRP, which reflected accumulation of the structural damage during the course of RA. Number of erosions, sum

maximal dimensions and erosion grading of the distal radius also correlated significantly with BME volume (p<0.01) (Figure 1B and C).
Figure 1. A, Axial HR-pQCT images (82μm isotropic resolution) of the metacarpal heads and distal radius of rheumatoid arthritis patients with different stage of erosions and definitions of the semi-quantitative grades for evaluating bone erosions at each region. B and C, Comparative axial HR-pQCT (B) and axial T2-weighted fast-spin echo (FSE) MRI using interative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) sequences (C) of the distal radius from a rheumatoid arthritis patient show extensive erosive change at medial aspect, which is seen as a clearly demarcated zone of hyperintense signal within normal hypointense marrow on MR image. Axial T2-weighted IDEAL FSE MR image (C) also demonstrates significant patchy hyperintense signal intensity of bone marrow edema.

Conclusion: HR-pQCT provides sensitive and highly reproducible evaluation of structural bone damage in RA. The good correlation between erosion measures with duration of the disease as well as BME volume suggests that they could become feasible measures of erosions in RA, if very detailed disease course evaluation are required.

Magnetic Resonance Imaging Versus Dual Energy Computed Tomography for Detection of Joint Pathology in Gout.
Fiona M. McQueen[1], Anthony Doyle[1], Quentin Reeves[2], Angela Gao[2], Amy Tsai[2], Gregory Gamble[1], Barbara Curteis[1], Megan Williams[2] and Nicola Dalbeth[1]. [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand

Background/Purpose: Magnetic resonance imaging (MRI) captures joint inflammation and damage in gouty arthropathy and can also reveal tophi. We have investigated reader reliability for scoring the MRI features of gout and have explored the association between erosions and tophi. We have also compared MRI with Dual Energy Computed Tomography (DECT) scans of the same region, to define sensitivity and specificity of MRI for tophi.

Methods: 3T MRI scans of the dominant wrist were obtained in 40 patients with severe, longstanding gout. The median/range patient age was 55.5 years (29–70), disease duration 17 years (1–42), serum urate 0.39mmol/L (0.2–0.69), 70% were of Polynesian/Maori ethnicity, and 85% had a history of tophi. All scans were scored separately (blinded) by 2 radiologist readers, for synovitis, bone oedema, erosions and tophi at 15 carpal sites including the bases of 1–5 metacarpals using RAMRIS criteria. Inter-reader reliability for scoring all features was determined. In a subgroup of 10 patients, DECT scans were obtained of the same region and scored by a separate reader for tophi at the same sites (or in adjacent soft tissue).

Results: Reliability was high between MRI readers for bone erosion and tophus size (ICCs 0.77 [95%CI: 0.71–0.87] and 0.71 [0.52, 0.83] respectively); and was moderate for synovitis and bone oedema (ICCs 0.62 [95%CI: 0.34–0.80] and 0.60 [0.36, 0.77] respectively). Concordance between readers for erosions was 82%, for all tophi was 85% and for tophi > 5mm was 93%. When a stringent analysis was performed (features were only counted if scored by both observers = "2-reader MRI"), 63% of patients were positive for bone erosions, 30% for bone oedema, 28% for tophi, 25% for tophi > 5mm and 61% for synovitis. The Odds ratio (OR) for tophus coexisting with erosion on MRI was 13.0 [95% CI: 1.5–113] when all sites were treated as independent and 2.9 [95% CI: 1.6–4.2] when the patient effect was factored in. When MRI and DECT scans from a subgroup of 10 patients were compared, using DECT as a gold standard, 2-reader MRI had a specificity of 0.98 [95% CI: 0.93–0.99], sensitivity of 0.63 [95% CI: 0.48–0.76], positive predictive value (PPV) of 94% and negative predictive value (NPV) of 84% for detecting tophi. There were only 2 instances in one patient where both MRI readers separately recorded tophus at a bone site where it was negative on DECT.
Figure. A) Coronal T1w MRI scan revealing extensive tophi dorsally at the radioscaphoid joint (circle). B) volume rendered DECT scan shows same tophus (circle) C) axial T1w MRI - tophus extends ventrally (arrow) D) axial DECT image shows same tophus (arrow) at level of the scaphoid and E) adjacent to the radius.

Conclusion: MRI has moderate to high reproducibility for assessment of gouty arthropathy and strong construct validity for detecting tophi when compared with DECT.

Tendon and Ligament Involvement in Gout: A Dual Energy Computed Tomography Study. Nicola Dalbeth[1], Ramanamma Kalluru[2], Opetaia Aati[1], Fiona M. McQueen[1] and Anthony Doyle[1]. [1]University of Auckland, Auckland, New Zealand, [2]Department of Rheumatology, Auckland District Health Board, Auckland, New Zealand

Background/Purpose: The involvement of bone and joints is widely recognized in gout. However, soft tissue involvement is less well defined. Dual energy computed tomography (DECT) is a recently developed technology that enables detection of urate deposits. The aim of this study was to examine the frequency and patterns of tendon and ligament involvement in patients with gout using DECT.

Methods: Ninety-two patients with tophaceous gout had a study visit including DECT scan of both feet. Two readers scored the DECT scans for urate deposition at 20 tendon/ligament sites and 42 bone sites (total 1,840 tendon/ligament sites and 3,864 bone sites). For affected tendons and ligaments, involvement was recorded as entheseal and/or non-entheseal (entheseal involvement was defined as urate deposition at the point of tendon/ligament insertion into bone). Inter-reader agreement for involvement at tendon/ligament sites was 88.0% and Cohen's kappa was 0.58, and at bone sites was 94.7% and Cohen's kappa was 0.77. For a stringent analysis, urate deposition was considered present at each site only if reported by both readers.

Results: Urate deposition was observed in 199/1840 (10.8%) tendon/ligament sites and in 399/3864 (10.3%) bone sites (p=0.60). The Achilles tendon was the most frequently involved tendon/ligament site (39.1% all Achilles tendons), followed by the peroneal tendons (18.1%) (Figure). Tibialis anterior and the extensor tendons were involved less frequently (7.6–10.3%), and the flexor tendons, plantar fascia and deltoid ligaments were involved infrequently (<5%) (p<0.0001 between sites). In those 72 Achilles tendons with urate deposition, 27 (38%) had only non-entheseal involvement, 29 (40%) had both entheseal and non-entheseal involvement, and 16 (22%) had only entheseal involvement. In contrast, entheseal involvement was less frequent at the other 127 affected tendon/ligament sites; 102 (80.3%) had only non-entheseal involvement, 25 (19.9%) had both entheseal and non-entheseal involvement, and 0 (0%) had only entheseal involvement (p<0.0001 compared with Achilles tendon site).
Figure. Volume rendered DECT image demonstrating urate deposition in the Achilles and peroneal tendons. Large adjacent tophi are present. Note normal tibialis anterior tendon.

Conclusion: Urate deposition is observed in tendon and ligament sites in patients with gout using DECT. The Achilles tendon and enthesis are major sites of involvement in gout. The patterns of urate deposition at certain tendon/ligament sites suggest that biomechanical strain or other local factors may contribute to formation of urate crystals.

2587

Practice Makes Perfect: Assessment of Proficiency of Rheumatology Fellows in Specific Joint Procedural Skills. Tara J. Rizvi, Min Xu and Nancy Searle. Baylor College of Medicine, Houston, TX

Background/Purpose: Rheumatology training programs require fellows to be proficient in joint procedural skills as a requirement for graduation. However, specific procedures required to attain proficiency in are not clearly defined. A minimum number required for performance of specific procedures to attain proficiency is also not established.

The purpose of our study is two-fold:

1. To gather rheumatology fellow's opinions about the number of times a joint procedure needs to be performed to attain proficiency.

2. To assess whether proficiency is attained by graduating fellows in 25 specific procedures generally performed by practicing rheumatologists.

Methods: An online survey was sent to junior and senior fellows enrolled in adult rheumatology programs in the United States. The survey was sent in April and May 2011, in order to obtain data from fellows near completion of their first or final year or fellowship. The survey included questions pertaining to: year of fellowship training, fellow's opinion of "average number of times a joint or soft tissue procedure should be performed in order to attain proficiency," and reported number of times fellows had performed 25 specific procedures during the course of fellowship training.

Results: Data was collected from senior fellows (n=76) near completion of fellowship training. 57/76 (75%) of graduating fellows felt individual joint procedures be performed 5 or more times to attain proficiency; 14/76 (18%) reported "3 times"; 5/76 (7%) answered "other" and felt it depended on the joint.

Based on the majority of fellow's views, we used "5" as the minimum number needed to attain proficiency. We identified that 6/25 procedures were performed 5 or more times by greater than 50% of graduating fellows (Table 1):): knee joint (98%), glenohumeral joint (57%), wrist joint (62%), ankle joint (60%), subacromial / subdeltoid bursa (74%) and trochanteric bursa (72%).

Table 1. Graduating rheumatology fellows having performed individual joint or soft tissue procedure 5 or more times

INDIVIDUAL JOINT PROCEDURE	PERFORMED >5 TIMES (n = 76)
Knee joint	74 (97%)*
Shoulder glenohumeral joint	43 (56%)*
Elbow joint	28 (37%)
Wrist joint	47 (62%)*
Ankle joint	46 (61%)*
Subtalar joint	7 (9%)
First MTP joint	24 (31%)
First carpometacarpal joint	16 (21%)
Finger Joint: DIP/PIP/MCP	15 (20%)
Hip joint	2 (3%)
Sacroiliac joint	0
Acromioclavicular joint	11 (14%)
Bicipital tendon	10 (13%)
Subacromial/ subdeltoid bursa	56 (73%)*
Trochanteric bursa	54 (71%)*
Ischigluteal bursa	2 (3%)
Olecranon bursa	26 (34%)
Pesanserine bursa	22 (29%)
Prepatellar bursa	13 (17%)
Lateral epicondylitis	17 (22%)
Medial epicondylitis	13 (17%)
Trigger finger	28 (37%)
DeQuervan's tenosynovitis	9 (12%)
Carpal tunnel	10 (13%)
Plantar fasciitis	3 (4%)

Conclusion: A substantial number of graduating fellows have not achieved the number needed to perform that most fellows themselves consider necessary to attain proficiency, in procedures commonly performed by practicing rheumatologists. The inadequacy of procedural exposure, and hence proficiency, can be circumvented by training authorities establishing specific, standardized criteria for rheumatology fellowship programs nationwide.

Standardized Patient Simulation Improves Internal Medicine Resident Musculoskeletal Examination Skills. Floranne C. Ernste[1], Uma Thanarajasingam[1], Courtney Shourt[2], Andrew Halvorsen[3] and Furman S. McDonald[3]. [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, [3]Mayo Clinic, Rochester

Background/Purpose: Few studies have addressed use of simulation-based education (SBE) to teach musculoskeletal (MSK) medicine to Internal Medicine (IM) residents. Our purpose was to obtain IM resident confidence levels in ability to diagnose MSK disorders and observe MSK performance skills with use of SBE at a single, large academic center.

Methods: Participants were 68 first and third-year IM residents. Surveys were completed before and after SBE using a 9-point Likert scale, ranging from $1 =$ poor, $5 =$ average, and $9 =$ very good, to assess ability to confidently perform MSK exams and diagnose shoulder, hand/wrist, hip, and knee disorders. Baseline exams were performed on two standardized patients (SPs) and videotaped. These were scored using a three-point scale ($0 =$ not done; $1 =$ done, but not correctly; $2 =$ done correctly). An interactive lecture, self-demonstration of MSK exam, and participation with SPs in one or more scripted scenarios was provided. A debriefing session critiqued MSK exam skills. Post-SBE exams were performed with SPs and scored. Six month follow-up surveys assessed retention of confidence in MSK exam skills.

Results: Before intervention, mean (SD) rating of ability ranged from 4.4 (1.8) for pes anserine bursitis to 5.9 (1.6) for trochanteric bursitis, while confidence to perform MSK exams ranged from 4.3 (1.4) on the hand/wrist to 5.0 (1.5) on the knee. Following SBE, ratings of ability significantly improved, ranging from $+1.7$ (1.4) for trochanteric bursitis to $+2.6$ (1.5) for pes anserine bursitis and $+2.0$ (1.4) to $+2.3$ (1.5) for knee and hand/wrist exam, respectively (all p<.0001). Hip exams improved on inspection, gait, palpation, passive and active range of motion (ROM), strength testing, and provocative maneuvers (PM) (all p<.001). Hand/wrist exams improved on inspection, palpation, active ROM, strength testing, and PM (all p<.004), while passive ROM was unchanged (p=.31). Shoulder exams improved on palpation, passive and active ROM, strength testing, and PM (all p<.005), while inspection was unchanged (p=.02). Knee exams improved on inspection, gait assessment, palpation, active ROM, and strength testing (all p<.001), while passive ROM (p=.60) and PM (p=.07) were unchanged. Follow-up surveys completed 6 months post intervention by 32 eligible residents indicate durable ratings of ability, ranging from $+1.5$ (1.7) for patellofemoral pain syndrome to $+2.5$ (2.2) for de Quervain's tenosynovitis and $+2.0$ (1.4) to 2.3 (1.5) for knee and hand/wrist examination, respectively (all p<.0001).

Conclusion: Use of SBE significantly improved IM resident confidence in ability to perform MSK exams and diagnose common MSK disorders. Resident performance of MSK exams as judged by a trained evaluator also improved. Improved confidence in ability to diagnose common disorders and perform MSK exams were durable 6 months after intervention. Therefore, use of SBE is an effective way to teach MSK medicine to IM residents.

From Novice to Expert: Competency Milestones for Musculoskeletal Ultrasound. Karina D. Torralba[1], Jay B. Higgs[2], Amy C. Cannella[3] and Gurjit S. Kaeley[4]. [1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]San Antonio Military Medical Center, Fort Sam Houston, TX, [3]University of Nebraska Med Ctr, Omaha, NE, [4]University of Florida, Ponte Vedra Beach, FL

Background/Purpose: The Accreditation Council for Graduate Medical Education and the American Board of Internal Medicine have initiated the development of milestones for internal medicine (IM) residency training that would facilitate objective documentation of resident achievement of competence in six dimensions of practice. Milestones for IM subspecialties are now in development. Musculoskeletal ultrasound (MSUS) in Rheumatology is at its infancy, and not yet a fellowship requirement. However educators and fellows are encouraged to undergo training to acquire knowledge, skills and attitudes (KSA) in this field. The American College of Rheumatology has recently approved initiation of MSUS certification examination. The objective of this study was to develop milestones in the six dimensions of general practice in relation to usage of MSUS in Rheumatology.

Methods: A core group of educators (3 program directors, 1 associate program director) who are members of the Ultrasound School of North American Rheumatologists (USSONAR) adopted the 5-level Dreyfus model of skill acquisition as a framework for defining milestones and to describe progression of a learner: novice (level 1), advanced beginner (2), competent (3), proficient (4), expert (5). Level 3 is the minimum level considered competent to independently practice MSUS. A search of the medical and educational literature was done in order to define competency-specific KSA needing assessment, and to characterize for each level a behaviorally-based narrative description. The milestones were vetted by the group every two weeks by Skype and email over a period of six weeks. Consensus was reached so that each narrative description represented a continuum of training and practice that logically progressed in acquisition of KSA.

Results: Frameworks for the competencies of Medical Knowledge (MK) and Patient Care (PC) have been developed. While still related to general IM milestones, the milestones defined were more focused on MSUS-related KSA. The content areas content for each competency were clarified. For MK, core knowledge related to correlations between anatomy, pathology and MSUS image acquisition and interpretation were emphasized along with basic principles on usage of MSUS in general, performance of MSUS-guided procedures, and documentation of findings. For PC, the area of concern was the incorporation of MSUS as a tool to aid clinical skills and reasoning, and to assist in the delivery of patient-centered care. Using the 5-level Dreyfus model, a sequence of behavioral descriptions were provided that describe the development of a learner from a novice stage (level 1) to that of an expert (level 5). A review and summary of relevant literature and references were also developed.

Conclusion: The MSUS in Rheumatology milestones in the dimensions of MK and PC provide an initial and significant step towards a meaningful assessment of outcomes for rheumatologists who want to achieve minimum through higher levels of competency in MSUS. The core group hopes to soon develop milestones for the other competencies and subcompetencies, with further plans to validate these milestones across different training programs.

Consolidating Knowledge, Comprehension, Application and Analysis in Rheumatology Education by Use of an in-House Electronic Module (Web-based Rheumatology Case Scenarios). David A. Kandiah, Diana Jonas-Dwyer and Astrid Davine. University of Western Australia, Crawley, Australia

Background/Purpose: The teaching and learning resource "Rheumatology Case Scenarios" was created as a web-based module. This electronic module was produced to maximise the interactive learning opportunities for medical students.

The key educational outcomes of this module are the:
1. Recognition of common Rheumatic conditions
2. Utilisation of systematic pattern recognition to compare and contrast these rheumatic diseases
3. Organisation and interpretation of the most appropriate investigations.
4. Planning and implementation of the most appropriate treatment strategies
5. Systematic evaluation of a patient with joint pain
6. Evaluation of their learning by pre and post-test questionnaires

Methods: A questionnaire was developed that would test the outcomes above in a Multiple Choice Question format. Human Research Ethics approval was obtained prior to commencement of the study.

Results: 131 students completed the pre-test questionnaire in 2011. Their mean score for the module (maximum score 26) was 14.3 (SD 2.9, range 6–21). A histogram showed that the student scores were in a normal distribution. Students who had completed all 8 cases were then given a follow-up questionnaire with the same questions but randomised differently. The students who completed this questionnaire had a mean score of 17.4 (SD 3.5, range 11–22) Paired samples t-test of the students who had completed the 2 questionnaires confirmed a statistically significant improvement of the scores of each student (range 2–4 points, p<0.001). The answers for the questionnaire were only provided to the students after they had completed the second questionnaire. To test their retention of knowledge, students were also given the option of completing the same questionnaire 3 months later. Questions were randomised differently again and the mean score rose to 23. This was statistically significant for these students when compared to their

scores at both previous levels suggesting that there was retention of their knowledge.

Conclusion: Web-based resources can consolidate learning in the clinical arena. Student feedback was also positive. An educational blog was activated to highlight certain management issues.

Assessment of Examination Skills of 4th Year Medical Students Using a Novel Objective Structured Clinical Examination. Seetha U. Monrad, Lisa DiPonio, Cliff Craig, John Zeller and R. Brent Stansfield. Univ of Michigan Med Ctr, Ann Arbor, MI

Background/Purpose: University of Michigan (UM) medical students participate in integrated musculoskeletal sequences during their preclinical years, but subsequently there are few opportunities for assessment of their diagnostic and physical examination skills. The purpose of this study was to evaluate the effectiveness of the longitudinal UM musculoskeletal curriculum in preparing graduates to evaluate patients with musculoskeletal disorders.

Methods: IRB exemption was obtained for this project. A multidisciplinary group of musculoskeletal specialists developed a three station objective structured clinical exam (OSCE) based on the "Hypothesis-Driven Physical Exam" (Yudkowsky, et al.) focusing on the shoulder, back and knee. 4[th]year students from the class of 2012 were invited to participate in the OSCE. For each station, students were provided a clinical vignette with three plausible diagnoses to consider, and were instructed to anticipate physical examination maneuvers or findings that would discriminate between the different diagnoses. They then examined a professional patient simulating findings associated with only one of the diagnoses. Trained faculty members directly observed students and scored performance of discriminatory physical examination maneuvers for each station. Each encounter was videotaped and independently scored by another faculty member. Inter-rater reliability for each maneuver was estimated using type-2 intra-class correlations. Percentages of perfect scores for anticipation (A) and performance (P) of each maneuver were calculated. Pearson's correlation between A and P scores was computed for each maneuver.

Results: 30% of the graduating class of 2012 participated. Inter-rater reliability was good to excellent for scoring of 6 exam maneuvers: herniated disc (disc ICC =.81), sacroiliac dysfunction (sac. ICC =.85), shoulder impingement (imp. ICC =.69), glenohumeral arthritis (arth. ICC =.76), anterior cruciate ligament tear (acl. ICC =.87), and knee osteoarthritis (ost. ICC =.87). Rater scores were averaged for each student. For the shoulder and knee stations, students could anticipate the necessary discriminatory exam maneuver for each diagnosis more frequently than they could actually perform the maneuver: (disc r =.45, p <.005, sac. r =.67, p <.0001; imp. r =.38, p <.025; arth. r =.32, p <.05; ost. r =.33, p <.05). A notable exception was the ability to perform maneuvers needed to diagnose a torn anterior cruciate ligament (ACL r =.05, n.s.).

Conclusion: A substantial percentage of graduating UM M4s are not able to perform core examination skills needed to diagnose common disorders of the shoulder, back and knee. Accurate anticipation of a discriminatory exam maneuver correlates with ability to perform the maneuver; however, students were more able to anticipate maneuvers than to actually perform them. Thus, direct observation is critical to ensure competence of students in evaluating musculoskeletal disorders.

2592

Musculoskeletal Ultrasound Objective Structured Clinical Examination: An Assessment of the Test. Eugene Y. Kissin[1], Peter C. Grayson[2], Amy C. Cannella[3], Amy M. Evangelisto[4], Janak R. Goyal[5], Rany Al Haj[6], Jay B. Higgs[7], Daniel G. Malone[8], Midori Jane Nishio[9], Darren Tabechian[10] and Gurjit S. Kaeley[11]. [1]Boston University, Boston, MA, [2]Boston University Medical Center, Boston, MA, [3]University of Nebraska Med Ctr, Omaha, NE, [4]Arthritis, Rheumatic and Back Disease Associates, Voorhees, NJ, [5]Raritan Bay Medical Center, Perth Amboy, NJ, [6]Jersey Shore Arthritis & Rheumatism A, Ocean, NJ, [7]San Antonio Military Medical Center, Fort Sam Houston, TX, [8]Family & Sports Orthopaedic Center, Beaver Dam, WI, [9]Adjunct Assistant Professor of Medicine/ Stanford University, Walnut Creek, CA, [10]Univ of Rochester Schl of Med, Rochester, NY, [11]University of Florida, Ponte Vedra Beach, FL

Background/Purpose: There is debate about whether an objective structured clinical examination (OSCE) should be part of musculoskeletal ultrasound (MSUS) competency testing in MSUS, and the reliability and validity of this approach has not been established. We aim to determine the reliability and validity of an OSCE for MSUS.

Methods: A 9-station OSCE was administered to a group of 35 rheumatology fellows, following an 8 month training program in MSUS, and to 3 expert faculty members as a control group. The participants were unaware of whether the joints were abnormal (n=5; wrist, ankle, elbow, finger, toe) or normal (n=4; wrist, ankle, knee, shoulder). Expert faculty in MSUS (n=9) graded image quality at OSCE stations using a predefined checklist and global rating (0–5 scale where 2 is barely passing) as both **proctors** and **assessors**. At each station a **proctor witnessed and graded** the studies being performed. Later, each resulting ultrasound image was also graded by two **assessors blinded to who performed the study.** Identical assessors graded the normal and abnormal wrist and ankle stations. Inter-rater reliability for assessors and proctors was estimated using the intraclass correlation coefficient (ICC). The borderline group method was used to set the overall passing score. A summative, 76 item multiple choice test (MCQ) assessed fellow knowledge necessary to interpret ultrasound images. Correlation between MCQ and OSCE performance (concurrent validity) was assessed using the Pearson correlation coefficient. Construct validity was established by comparing fellow OSCE results with that of the faculty (gold standard).

Results:
Reliability

Inter-rater reliability was good (ICC=0.7) between the assessors, but was poor (ICC=0.3) between the assessors and the proctors. Reliability of the assessor scores was good in the normal wrist and ankle stations (ICC=0.7), and moderate in the abnormal wrist and ankle stations (ICC=0.4).

Validity

MCQ grades correlated strongly with OSCE grades from both the assessors (r=0.52; p=<0.01) and from the proctors (r=0.58; p<0.01). The average MCQ score for the 5 fellows who failed the OSCE was less than that for the 30 who passed (60% vs. 71%, p= 0.04, Wilcoxon rank sum).

The fellows in the bottom quartile of the MCQ scored 3.07 on the OSCE, significantly worse than the top quartile fellows (3.32), and the faculty (3.29) (p<0.01, Wilcoxon signed rank). Scores also significantly discriminated bottom quartile fellows from faculty in the normal wrist and ankle stations (3.38 vs. 3.78, p<0.01), but not in the abnormal stations (3.37 vs. 3.49, p=0.08).

Conclusion: MSUS OSCE is a reliable and valid method for evaluation of MSUS skill when assessed by blinded examiners. Proctor grading is less reliable and adds to the cost of a practical MSUS examination. Normal joint assessment stations are more reliable than abnormal joint assessment stations and better discriminate poorly performing fellows from faculty, likely because assessors are less certain about the optimal appearance of abnormal joints and have more difficulty accurately scoring the resulting images.

Predictive Markers of Therapeutical Outcome and Their Role in the Ethiopathology of Juvenile Idiopathic Arthritis. Maura Rossetti[1], Roberto Spreafico[1], Hong Zhang[1], Maryam Moshref[1], Nora G. Singer[2], D. J. Lovell[3], Carol A. Wallace[4] and Salvatore Albani[1]. [1]Sanford-Burnham Medical Research Institute, La Jolla, CA, [2]MetroHealth Medical Center, Cleveland, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Seattle Childrens Hospital, Seattle, WA

Background/Purpose: Currently, juvenile idiopathic arthritis (JIA) is treated with methotrexate (MTX) as a first-line agent. If children fail to respond, a biologic (e.g. anti-TNF) is usually added. However, a consistent fraction of patients fail to respond even to the combination treatment. The identification of predictive markers of responsiveness to the therapy, together with the elucidation of the underlying mechanism, is therefore a dramatic unmet clinical need. Our approach is based on the premise that complex

diseases like JIA can be stratified based on the presence of multi-parametric signatures which characterize an immune function.

Methods: We have developed a multidimensional technology platform for identifying immune signatures, which includes phenotypical and functional data on a variety of blood cell types (T and B cells, APCs, NK and NKT cells, gdT cells). These tests operate in semi-high throughput (sHT) mode and can be combined with other HT "omics". This platform has been applied to a homogenous cohort of patients from the Trial of Aggressive Therapy (TREAT), including patients treated with the same iTNF (Etanercept) and MTX, sampled before (T0) and after (Tend) the therapy, and subsequently stratified in patients reaching inactive disease state, and patients not achieving ID.

Results: When Teff and Treg functions (proliferation and suppression assays) were analyzed as a whole, we could not find significant changes between ID and NO ID. However, in depth characterization of the two cell subsets led to the identification of specific phenotypical differences at both time points analyzed. When a principal component analysis was applied to the entire set of parameters analyzed, the group of responding (ID, inactive disease) patients clustered and was clearly distinct from non-responding (NO ID) patients. Three different statistical models were applied to test whether selected candidate biomarkers could segregate patients according to their clinical outcome. Strikingly, although most parameters, taken singularly, were not effective in differentiating between the two disease states, the combination of a restricted set of CD4$^+$ T cell markers was able to segregate ID and NO ID patients with up to 90% accuracy in both time points, thus providing both predictive and confirmatory value to the study. Moreover, our analysis identified a population of cells characterized by an activated phenotype which is significantly more represented in the NO ID patients. This subset selectively expressed pro-inflammatory markers and chemokine receptors targeting to inflammatory sites, and bore signs of recent antigen recognition (based on Ki67 expression), possibly indicating their direct involvement in autoimmunity.

Conclusion: We have identified a cluster of immune functions with high predictive and prognostic power for discriminating the responsiveness to treatment with MTX/iTNF in JIA, which may be developed as a theragnostic tool. Importantly, our approach has also identified a subset of experienced T cells, significantly more represented in clinical failures, which may comprise a potentially pathogenic population responsible for the resistance to treatment.

2594

Epigenetic Signature of the Response to Anti-TNF in Juvenile Idiopathic Arthritis. Roberto Spreafico[1], Maura Rossetti[1], Hong Zhang[1], Maryam Moshref[1], Carol Wallace[2], D. J. Lovell[3] and Salvatore Albani[1]. [1]Sanford-Burnham Medical Research Institute, La Jolla, CA, [2]Childrens Hosp & Regional Med, Seattle, WA, [3]Cincinnati Children's Hospital, Cincinnati, OH

Background/Purpose: The identification of prognostic markers of responsiveness to the therapy in JIA would not only radically improve clinical management, but also shed light on the immune mechanisms underlying clinical outcomes, with the potential of improving and eventually personalizing clinical care. In this context, adaptive immunity plays a central role. Indeed, it is well known that CD4$^+$ T cells are implicated in the pathogenesis of different subtypes of arthritis, including JIA. Many studies have relied on the use of whole transcriptome analysis to identify new biomarkers and get insights into the disease mechanisms. However, transcriptomes are volatile, quickly fluctuating in response to multiple factors, often clinically irrelevant. By contrast, epigenetics is more stable, possibly capturing only those changes slowly introduced by regular and consistent events such as therapy. As such, here we aimed at investigating the DNA methylation profile of JIA patients responding or not to therapy.

Methods: Patients treated with MTX+Etanercept+Prednisolone from the TREAT study were stratified based on the response to the therapy. Total CD4$^+$ T cells were sorted from PBMCs at baseline (T0) and at end of study (Tend). DNA was extracted and bisulfite converted to analyze the cytosine methylation pattern. Converted DNA was analyzed using Illumina Infinium HumanMethylation450 BeadChip, yielding the methylation percentage of more than 485,000 CpG sites across the genome.

Results: Both hypothesis-driven and hypothesis-agnostic approaches were pursued. In hypothesis-driven approaches, DNA methylation of genes governing immune functions, which our group has identified as correlated to clinical outcome, was investigated. In hypothesis-agnostic approaches, no assumptions were made and the most relevant sites were selected by computational methods. In both scenarios, descriptive and predictive models were built to test the diagnostic value of the identified epigenetic signature, which, in some cases, could reach an accuracy close to 100%. In preliminary analyses, we found that, regardless of the approach taken, the HLA-DRB1 gene is differentially metilated between responders and non responders. This finding is striking in correspondence with our recent data obtained though an high-throughput Immunomics approach, which also evidenced higher HLA-DR expression on CD4$^+$ T cells in clinical non-responders at phenotypical level (manuscript in preparation).

Conclusion: In summary, we have identified a set of genes with high predictive and prognostic power for discriminating the responsiveness to treatment, which may be developed as a screening tool. Importantly, some of the differentially methylated genes identified through whole genome DNA methylation analysis correlate with phenotypical and functional changes previously described by our group, strongly putting forward further investigation of the functional role of HLA-DRB1 expression on CD4$^+$ T cells.

S100A12 At Baseline May Be Useful for Predicting Inactive Disease within 12 Months in Polyarticular Juvenile Idiopathic Arthritis. Gali Malul[1], Joy M. Whitbred[1], MaryAnn O'Riordan[2], Sarah Ringold[3], Susan D. Thompson[4], Carol Wallace[5], Salvatore Albani[6] and Nora G. Singer[7]. [1]MetroHealth Medical Center, Cleveland, OH, [2]Case Medical Center, Cleveland, OH, [3]Seattle Children's Hospital, Seattle, WA, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Childrens Hosp & Regional Med, Seattle, WA, [6]Sanford-Burnham Medical Research Institute, La Jolla, CA, [7]Director, Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH

Background/Purpose: Achieving clinically inactive disease (ID) is a therapeutic goal in JIA. ID is defined as: no active arthritis; no fever, rash, serositis, splenomegaly or generalized lymphadenopathy due to JIA; no active uveitis; normal ESR; and physician global assessment=0. The laboratory parameters routinely used to describe patients' JIA category include antibody status (RF, anti-CCP). ESR or CRP are frequently used to assess disease activity. The S100 proteins have been implicated as biomarkers of JIA and in disease pathogenesis. The pro-inflammatory ligand S100A12 binds to RAGE and studies suggest a relationship between S100A12 and both sJIA and RA disease activity. The S100A12 gene is rapidly up-regulated in monocytes and PMNs in inflammation and may be a biomarker for poly JIA activity as well.

The objectives of this study were to evaluate the utility of baseline S100A12 levels in as a predictor of ID in poly JIA ID within 12 months, and to determine association between S100A12, RF, CCP and ESR.

Methods: S100A12 level was measured by ELISA in biospecimens from the Trial of Aggressive Therapy in JIA (TREAT) for whom baseline samples were available.The distribution of S100A12 in healthy children without JIA was determined on the log scale. The 95thpercentile was estimated. This value was used as a cut-point: below the values were classified as "low" and above as "high". The baseline values of the JIA cohort were then dichotomized the same way. RF, anti-CCP, and ESR were dichotomized as "Positive" or "Negative": RF/CCP-<20 negative and ≥20 positive, ESR ≥20 was considered elevated;. Disease status (ID or no ID) was compared to S100A12 levels and positive and negative predictive values (PPV and NPV respectively) are reported. The relationship of levels S100A12 and of ID status with the levels of the other variables was tested using Chi squared analysis with levels of other markers and p values for association reported.

Results: 53 children from TREAT had baseline S100A12 values. 44 achieved ID and 9 did not within the first 12 months of treatment. S100A12 95thpct of the control population was estimated as 6.2 on the log scale (anitlog 493). 21 children had "High" S100A12 values, all of which were in the ID group (PPV 100%). 32 children had low values, 9 were in the no ID group (NPV 28%).

53 had baseline S100A12 measurement and known RF status, 21 had elevated and 32 had low S100A12: 11/21 and 3/32 had positive RF (p<0.001).

53 had ESR measured, 21 had high and 32 had low S100A12. 18/21 and 14/32 also had high ESR (p=0.002).

50 children had baseline S100A12 measurement and known CCP ab status. 18 had elevated and 32 had low S100A12 values: 9/18 and 4/32 had anti-CCP ab detected (p=0.004).

Conclusion: The PPV value of an elevated baseline S100A12 value for the probability of achieving ID in the first 12 months in TREAT was 100%. Elevation in S100A12 was highly associated with the presence of anti-CCP ab, RF positivity and elevated ESR. Since even polyJIA is a heterogenous disease, the data suggest that measurement of S100A12 may help guide understanding and treatment of disease.

This study was supported a NIAMS award to SA and NGS, the TREAT trial was supported by an NIAMS award to CW.

Rituximab Treatment for Antineutrophil Cytoplasmic Antibody - Associated Vasculitis in Children. Katharine F. Moore[1], Leonard L. Dragone[2], Jennifer B. Soep[3] and J. Roger Hollister[3]. [1]Seattle Children's Hospital/University of Washington, Seattle, WA, [2]National Jewish Health, Denver, CO, [3]Children's Hospital Colorado, Aurora, CO

Background/Purpose: The purpose of this study was to report the experience of a tertiary-care children's hospital using rituximab in the treatment of pediatric antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), including immediate and long-term outcomes as well as adverse effects.

Methods: This was a single-center retrospective case series of 15 children with AAV treated with rituximab between March 2001 and March 2011. The majority of patients presented with severe disease, including acute pulmonary hemorrhage, and were treated with cyclophosphamide (CYC) and high-dose glucocorticoids (GC) concomitantly with rituximab (n=11); of these patients, six also required plasma exchange. Other treatment regimens given with rituximab included CYC alone (n=1), methotrexate (MTX) with GC (n=2) and MTX alone (n=1). Outcome measures included time to negative ANCA, the length of CYC therapy after starting rituximab, total cumulative CYC dose, scores on the modified Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG) as well as the Vasculitis Damage Index (VDI).

Results: Of the 15 identified patients, the median age at diagnosis was 13 (range 8–15). Seven were female. At the time of treatment with rituximab, the mean score on the BVAS/WG was 7.8 (range 1–12), with 11 patients (73%) classified as having severe disease. Three months after treatment with rituximab, the mean score dropped to 0.4 (range 0–2). Every one of the patients in this series ultimately achieved remission, defined as a BVAS/WG of zero along with a reduction in steroid dosage. Nine patients (60%) received only one course of rituximab and did not experience any relapses over a mean follow-up of 2.3 years. Following treatment with rituximab, the mean duration of CYC therapy was 11.3 weeks (range 4–28 weeks), with a mean cumulative CYC dose of 11g. The mean cumulative CYC dose received by patients who were initially treated without rituximab was 44 g prior to the addition of rituximab and was 62 g over the entire duration of illness captured by this study. In contrast, the cumulative CYC dose received by patients who received rituximab with CYC and GC for initial induction was only 8.6 g. The average length of patient follow-up after treatment with rituximab was 2.5 years (range 3 months–5.1 years); during this time, five patients were re-treated with rituximab due to a flare in disease activity occurring at a mean of 21.8 months after the last rituximab treatment. Adverse effects from rituximab included six mild infusion reactions. There were no deaths. There were no documented infectious complications.

Conclusion: This is the largest described series of pediatric patients with AAV treated with rituximab and includes a significant duration of follow-up. Our data show that rituximab can be a safe and effective therapy, even in combination with other immunosuppressive medications such as CYC and GC. This regimen allows patients to have decreased cumulative dose of CYC, thus minimizing the potential for long-term adverse effects of CYC.

Degree of Initial Intracellular Folate Depletion May Predict Methotrexate Response in Juvenile Idiopathic Arthritis. Leon van Haandel[1], Ryan S. Funk[1], Maria F. Ibarra[1], Mark F. Hoeltzel[1], Andrew Lasky[2], Daisy Dai[1], Rodger Gaedigk[1], J. Steven Leeder[1] and Mara L. Becker[1]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Childrens Mercy Hospital, Kansas City, MO

Background/Purpose: Despite widespread use, there are no predictors of methotrexate (MTX) response or toxicity. The objective of this study is to test the hypothesis that the variability in response to MTX is a function of inter-individual differences in folate homeostasis.

Methods: This is a single center prospective cohort study at a tertiary care children's hospital evaluating newly treated JIA patients on standardized doses and routes of MTX ($15mg/m^2$ PO) and folic acid (1mg/day). After obtaining informed consent, samples are collected prior to, and after 3 and 6 months of MTX. Concentrations of tetrahydrofolate (THF), 5-methylTHF (5-MTHF), 5,10-methenylTHF (5,10-METHF), folic acid (FA), and MTX polyglutamates ($MTXGlu_n$) are determined in plasma, whole blood and erythrocytes by UPLC-tandem mass spectrometry. Clinical data are recorded from chart review and forms provided to the treating physician and patient/parent (CHAQ, MD VAS, PT VAS). Clinical outcomes at 3 months were measured via ACR pediatric 30, 50, 70 criteria and the JADAS71. We report preliminary 3 month data on the first 20 patients recruited to the study.

Results: The study consisted of 12 females and 8 males with JIA. The mean ($\pm$ SD) age at study entry was 135.2 ($\pm$ 49.5) months. After 3 months on standardized MTX therapy, paired t-test revealed an overall statistically significant decline in MD VAS ($p < 0.0001$), PT VAS ($p < 0.001$), active joint count ($p = 0.002$), JADAS71 ($p < 0.001$), and 5-MTHF concentrations ($p= 0.004$). There were no statistically significant differences in CHAQ, ESR, CRP, or 5,10-METHF from 0–3 months on therapy. These results were confirmed with additional nonparametric testing. At 3 months, 8 (40%) subjects failed to reach ACR Ped 30 ("non-responders"), while 10 (50%) subjects reached ACR Ped 30 or 50, and 2 (10%) reached ACR Ped 70 ("responders").

The mean decline from baseline of 5-MTHF concentrations at 3 months was found to be significantly greater in boys (-420.8 nmol/L), compared to girls (-122.9 nmol/L) ($p=0.03$), and negatively correlated with age ($\rho=-0.7$, $p=0.0006$). A trend towards greater changes in 5-MTHF concentrations from baseline were observed in responders (-333.3 nmol/L) compared to non-responders (-105.1 nmol/L) ($p=0.07$). No statistically significant differences were seen in absolute 5-MTHF concentrations at 0 or 3 months and ACR outcomes, although responders had comparatively higher 5-MTHF concentrations (885.3 nmol/L vs. 666.2 nmol/L, p NS) at baseline. Multivariate testing supported an association between change in 5-MTHF and response ($p=0.05$) controlling for gender and age. Two subjects had exceptionally high 5,10-METHF concentrations ($>4\times$ IQR). Omitting the outliers revealed a pronounced change in 5-MTHF in responders ($p=0.04$). No association between long chain MTXGlu and outcomes or change in folate concentrations has been observed to date.

Conclusion: These preliminary data suggest that an initial decline in 5-MTHF concentrations may be correlated to MTX response, and might provide clinicians with a more effective biomarker than intra-cellular concentrations of the drug itself in JIA. Future work will investigate factors that contribute to 5-MTHF depletion.

Anti-Drug Antibodies Are Associated with Diminished Drug Levels and Treatment Failure. Miha Kosmac[1], Natasa Toplak[2], Gabriele Simonini[3], Ilaria Pagnini[3], Rolando Cimaz[4], Vladka Curin Serbec[1] and Tadej Avcin[4]. [1]Blood Transfusion Centre of Slovenia, Ljubljana, Slovenia, [2]University Children's Hospital Ljubljana Slovenia, Ljubljana, Slovenia, [3]Anna Meyer Children's Hospital, Department of Pediatrics, University of Florence, Florence, Italy, [4]Paediatric Rheumatology International Trials Organization (PRINTO), Istituto Giannina Gaslini, Genova, Italy

Background/Purpose: Due to their proteinaceus character biologics can often induce an unwanted immune response that results in the formation of anti-drug antibodies in patients receiving biologic therapy. We therefore analyzed the sera of juvenile idiopathic arthritis patients receiving either

infliximab (IFX), adalimumab (ADA) or etanercept (ETA) for the presence of anti-IFX, anti-ADA and anti-ETA antibodies.

Methods: We determined the serum drug levels and anti-drug antibody levels in the sera of 26 patients on IFX, 12 patients on ADA and 19 patients on ETA therapy. In the cases where we detected the presence of anti-drug antibodies we also investigated whether these antibodies bind the Fab or Fc fragments and compared laboratory findings with the clinical response to therapy.

Results: We detected anti-drug antibodies in 11 out of 26 (42%) patients on IFX and 4 out of 12 (33%) patients on ADA therapy, but found no anti-ETA antibodies in any of the 19 patients treated with ETA. Anti-drug antibodies were in all cases associated with decreased serum drug levels, which in the majority of cases were below the limit of detection. For the two monoclonal antibody drugs (IFX and ADA) we observed that the anti-drug antibodies bound the Fab fragments, i.e. the regions responsible for TNF binding.

Conclusion: The level of immunogenicity for patients receiving biologic therapy closely followed the degree of foreignness of the biologic drugs, with IFX inducing the formation of anti-IFX antibodies in the highest proportion of patients, followed by ADA, while ETA did not induce the formation of anti-ETA antibodies in any of the patients included in our study. Once anti-drug antibodies had developed they were in all cases associated with decreased serum drug levels, however not all non-responders showed low serum drug levels or tested positive for anti-drug antibodies, indicating a different disease mechanism. Monitoring of serum drug levels and the detection of anti-drug antibodies may therefore be important for determining the best personalized treatment strategy and enabling a more cost effective treatment.

Quality of Care for Medicare Recipients with Rheumatoid Arthritis: Vulnerable Populations More Likely to Receive Therapy with Glucocorticoids Alone. Chris Tonner[1], Gabriela Schmajuk[1], Amal N. Trivedi[2], Grace Lin[3] and Jinoos Yazdany[3]. [1]UCSF, San Francisco, CA, [2]Brown University, Providence, RI, [3]University of California San Francisco, San Francisco, CA

Background/Purpose: Use of disease-modifying anti-rheumatic drugs (DMARDs) is a nationally endorsed quality measure, yet recent studies suggest that only 60% of Medicare recipients with rheumatoid arthritis (RA) use DMARDs. We investigated the prevalence and predictors of receiving glucocorticoids alone for the treatment of RA in a nationwide sample of Medicare beneficiaries.

Methods: Data derive from a 5% random sample of U.S. Medicare fee-for-service beneficiaries. We included individuals ≥65 years with at least two face-to-face clinical encounters for RA and Part D drug claims for either a DMARD anytime during the year or sustained glucocorticoid monotherapy, defined as an annual dispensed glucocorticoid supply of ≥180 days or an annual dispensed dosage of ≥900 mg of prednisone (or steroid equivalent). Using multivariate logistic regression, we examined predictors of sustained glucocorticoid monotherapy including sociodemographic characteristics, income (low-income defined as Medicare eligible for reduced cost sharing or state buy-in), health service utilization (number of inpatient and outpatient encounters and prescribing physician specialty) and medical co-morbidities. In addition, we used the Area Resource File to examine area level predictors of socio-economic status, health care shortage areas, and Census geographic divisions. From the regression models, we calculated adjusted group proportions and 95% confidence intervals.

Results: Of the 8,062 beneficiaries, 10% (n = 830) were classified as receiving glucocorticoid monotherapy. In adjusted analyses, we found that glucocorticoid monotherapy was higher among those with advanced age (18% among those ≥85 years compared to 11% in those 74–79 years), Blacks (12% versus 10% in Whites), and among low-income beneficiaries (12% versus 10% in those with higher incomes). Having a rheumatologist prescribe one or more medications during the measurement year was associated with significantly lower rates of glucocorticoid monotherapy (7%

versus 16%). More inpatient admissions and medical co-morbidities were also positively associated with glucocorticoid monotherapy. There was little variation across the nation, with marginally higher rates of glucocorticoid monotherapy in the Middle Atlantic region (13%) compared to the Pacific region (8%).

Table 1. Proportion of U.S. Medicare Fee-for-Service Beneficiaries Receiving Sustained Glucocorticoid Monotherapy for Rheumatoid Arthritis in 2009

C statistic				0.71	

* Multivariable model adjusted for all variables in the model as well as gender, number of physician visits, number of inpatient admissions, area poverty, and health professional area shortages.

Conclusion: Approximately 10% of Medicare recipients with RA were treated with sustained courses of glucocorticoids alone in 2009. Compared to DMARD users, glucocorticoid monotherapy users were older, more likely to be Black, had lower income, had more medical comorbidities and hospitalizations, and were less likely to have a rheumatologist prescribing their RA medication. Although advanced age and accompanying medical co-morbidities may appropriately limit the use of DMARDs, differences by race, income and geographic region suggest disparities in quality of care.

Assessment of Quality of Care for Incident Lupus Nephritis in the U.S. Medicaid Population. Jinoos Yazdany[1], Candace H. Feldman[2], Jun Liu[3], Michael M. Ward[4], Michael A. Fischer[2] and Karen H. Costenbader[5]. [1]University of California San Francisco, San Francisco, CA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA, [4]NIAMS/NIH, Bethesda, MD, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: The contribution of uneven health care quality to racial/ethnic and socioeconomic disparities in lupus nephritis outcomes is unknown. We aimed to assess performance on two health care quality

measures in a nationwide cohort of Medicaid recipients with incident lupus nephritis.

Methods: We used Medicaid analytic extract (MAX) data from 2000–2004 containing person-level files on Medicaid eligibility, utilization and payments. We identified patients meeting a validated administrative data definition of incident lupus nephritis, and used this group as the denominator population for both quality metrics (QMs). Numerator components included:

QM1: Induction therapy with glucocorticoids and another immunosuppressant (azathioprine, mycophenolate mofetil, mycophenolic acid, cyclophosphamide, cyclosporine A, or tacrolimus) within 30 days of lupus nephritis onset.

QM2: Use of angiotensin-converting enzyme (ACE) inhibitors or angiotensin-receptor blockers (ARB) within 90 days of lupus nephritis onset.

We used multivariate logistic regression models to examine sociodemographic (age, sex, race/ethnicity), geographic (U.S. region), and health care (health professional shortage areas, HPSAs, from the Area Resource File) predictors of higher performance. In additional analyses, we extended the time period for both QMs to 365 days to assess whether performance improved with time.

Results: 974 Medicaid recipients met the definition of incident lupus nephritis. Mean age was 39 years (SD 12, range 18–64), 93% were female, and most were African American (African American 48%, White 27%, Hispanic 13%, Asian 6%). Individuals were geographically dispersed (20% Midwest, 22% Northeast, 34% South, 24% West), and 41% resided in partial or complete HPSAs. Only 19.5% received care consistent with all numerator components of QM1; 25% of individuals received only steroids, and 13% received immunosuppressants alone. When the timeframe for QM1 was extended to one year, performance rose to 30%. For QM2, 30% of individuals received an ACE/ARB within 90 days. When this timeframe was extended to one year, performance rose to 58%. In multivariate logistic regression models, those living in the South were less likely to receive recommended therapy for lupus nephritis (QM1; OR 0.53, CI 0.28–0.99), while younger individuals were more likely to receive treatment (OR for 18–34 years versus referent 51–64 years 3.5, CI 1.6–7.6). Individuals in the Midwest were less likely to receive an ACE/ARB (QM2; OR 0.52, CI 0.34–0.80), while African Americans were more likely (OR 1.7, CI 1.2–2.4).

Conclusion: These data suggest substantial gaps and delays in care for U.S. Medicaid patients with incident lupus nephritis. A large number received steroid monotherapy or no immunosuppressant within one month, although performance improved by one year. Use of ACE/ARBs was low in the first 90 days, but rose to 58% by one year. Geographic differences were observed, with individuals in the South and Midwest being less likely to receive recommended care. The contribution of state Medicaid policies, specialty care access, and drug coverage policies to these observed geographic differences warrants investigation.

Improving Delivery of Care for JIA Across a Multi-Center Network Using a Shared Data Registry and Quality Improvement Science: The Pediatric Rheumatology Care and Outcomes Improvement Network.
Catherine A. Bingham[1], Lynn M. Darbie[2], Keith Marsolo[2], Jennifer E. Weiss[3], Stacy P. Ardoin[4], Ronald M. Laxer[5], D. J. Lovell[2], Murray H. Passo[6], Sheetal Vora[7], Beth S. Gottlieb[8], Timothy Beukelman[9], Nancy Griffin[10], Jason A. Stock[11], Michael L. Miller[12], Karen Onel[13], Tova Ronis[14], Peter Margolis[2] and Esi M. Morgan DeWitt[11]. [1]Hershey Medical Center, Hershey, PA, [2]Cincinnati Children's Hospital, Cincinnati, OH, [3]Joseph M. Sanzari Children's Hospital, Hackensack University Medical Center, Hackensack, NJ, [4]Ohio State University, Columbus, OH, [5]The Hospital for Sick Children, Toronto, ON, [6]Medical University of South Carolina, Charleston, SC, [7]Medical College of Wisconsin, Milwaukee, WI, [8]Cohen Children's Medical Center of New York, New Hyde Park, NY, [9]Univ of Alabama-Birmingham, Birmingham, AL, [10]Cincinnati Children's Hospital Medical Center, Cincinnati, [11]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [12]Childrens Memorial Hospital, Chicago, IL, [13]University of Chicago, Chicago, IL, [14]Stanford University Hospital, Palo Alto, CA

Background/Purpose: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a quality improvement (QI) multi-center "learning network" that performs QI and research while tracking progress through data collection, analysis, and display. The mission is to optimize processes of care and improve outcomes in juvenile idiopathic arthritis (JIA). PR-COIN began operating in the spring of 2011 and currently has 12 participating sites in the United States and Canada. This is the first report of our data.

Methods: Our approach is based on the Institute for Healthcare Improvement Breakthrough Series Collaborative Model with planned interventions to improve outcomes based on the Chronic Illness Care Model. Conference calls, web-based information exchange, and face-to-face learning sessions are forums for teams to gain expertise in QI science, share knowledge, and develop new strategies to improve care. Teams conduct "Plan-Do-Study-Act" cycles to enact improvement and submit data and progress reports monthly. After informed consent/assent is obtained, site patient data are entered into the ACR's Rheumatology Clinical Registry in order to track progress of the network over time. Design of data collection forms allows assessment of performance on published proposed JIA quality measures (QM) (Arthritis Care Res 2011 Jan;63(1):10–6) and monitoring of clinical outcomes. 13 processes of care QMs and 4 clinical outcomes QMs are tracked. Site specific and aggregate data are analyzed monthly and provided with transparency as feedback to the sites. Benchmarking is possible through analysis of the data submitted by participating practices, and shared information can accelerate improvement throughout the network.

Results: As of May 2012, 516 patients from 7 sites have been entered into the registry for longitudinal assessment. Performance exceeded goal on 2 process of care QM: measurement at clinic visits of complete joint count (mean 100%, goal 90%) and pain assessment (mean 96%, goal 90). Examples of process QM requiring improvement work include: uveitis screening per Heiligenhaus guidelines (mean 72%, goal 90%); toxicity labs for DMARDs per guidelines (mean 72%, goal 90%); measurement every 180 days of: functional ability (mean 81%, goal 90%), and HRQOL (mean 3%, goal 90%). Our baseline outcome measures showed: 77% of patients have a pain score < 3; 58% patients have an optimal CHAQ score of 0; and 33% of patients on JIA medication and 60% patients off JIA medication could be defined as having clinical inactive disease.

Conclusion: PR-COIN is a growing international QI learning network. Our baseline data demonstrate mixed performance on measures of processes of care. As we reach target performance goals for our measures over time, we will continue to raise the bar for performance. The next phase of our project is to use interventions including implementation of an already developed population management tool, creation of a pre-visit planning tool to facilitate measurable improvement in meeting benchmarks for process of care, and orchestrated testing of which QI interventions most positively impact clinical outcomes.

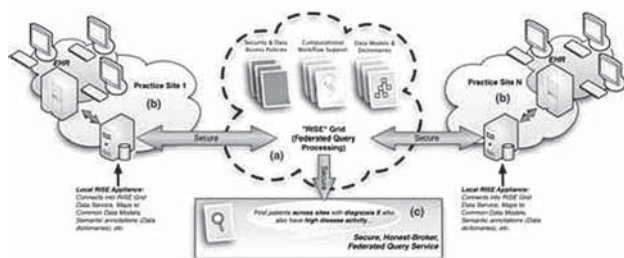
The Rheumatology Informatics System for Effectiveness (RISE): Enabling Data Access Across Disparate Sites for Quality Improvement and Research.
Peter J. Embi[1], Itara Barnes[2], Rachel Myslinski[2], David Ervin[1], William Stevens[1], Tara Borlawsky[1] and Philip R.O. Payne[1]. [1]The Ohio State University, Columbus, OH, [2]American College of Rheumatology, Atlanta, GA

Background/Purpose: Rheumatology quality improvement efforts and clinical research are often challenged by the need to access and integrate data across diverse patient populations and disparate information systems. We report on our use of a service-oriented architecture (SOA) to link disparate clinical data resources across multiple clinical sites and systems in support of rheumatology practice and research. The central aim of this technology is to provide a reliable and cost-effective means of connecting data from multiple EHR systems, and using these data for quality improvement and research querying for the rheumatology community.

Methods: The design and execution of effective quality improvement projects and clinical studies requires access to high quality, longitudinal data. In most instances, such data are collected, formalized, stored and retrieved using project- or organization-specific disease registries or data warehouses. It is increasingly desirable to access data across multiple clinical sites for quality improvement and clinical research purposes, but disparate EHR systems remain difficult to connect for data interchange. Furthermore, in these types of settings, organizational and policy barriers

often preclude the use of centralized repositories. To address this need, we developed a lightweight, SOA-based approach to create a network of clinical sites that could serve as a federated data repository. The ACR is piloting this system—called the Rheumatology Informatics System for Effectiveness (RISE)—to enhance registry efforts to benefit rheumatic disease research and quality reporting efforts. Because RISE will collect data directly from EHR systems, it will eliminate the need for manual and redundant data entry into the registry.

Results: The model employed by RISE uses an approach to enable the federated query of geographically distributed data sources in order to create a virtual data repository. This platform uses the TRIAD middleware (1), and is currently being implemented at two pilot sites in the US, with more planned in the near future. A novel feature is the use of TRIAD-enabled data sharing "virtual appliances" (**Figure 1**). The systems was designed to reduce the overhead of deploying a data sharing service, while simultaneously allowing sites to maintain full control of the type and nature of data being shared. Through deployment of a simple, menu-driven query construction and data discovery portal, RISE allows end-users with appropriate privileges to quickly and easily discover and query distributed data sets.


Conclusion: The design, deployment and initial use of the RISE Network addresses the need for data access across disparate sites using otherwise non-interoperable information systems. We believe that such an approach to distributed data sharing in rheumatology will help advance science and improve clinical practice.

Moving Into the Electronic Age: Validation of Rheumatology Self-Assessment Questionnaires On Tablet Computers. Jessica M. Sage[1], Arshia Ali[2], Jennifer Farrell[1], Jennifer L. Huggins[1], Kara Covert[1], Diane Eskra[1], Rina Mina[3], Shweta Srivastava[1], Janalee Taylor[1], Tracy V. Ting[1], Esi M. Morgan DeWitt[1] and Hermine I. Brunner[1]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center/University of Cincinnati, Cincinnati, OH

Background/Purpose: The medical field is increasingly relying on electronic health records (EHR). Many children's hospitals are converting from paper-pencil questionnaires to electronic versions. The purpose of this study was to compare correlation of results of paper-pencil versus electronically administered versions of two self-report questionnaires: 1) Rheumatology module of the Pediatric Quality of Life Inventory (RHE-PedsQL) and 2) Review of Systems (ROS) symptom checklist.

Methods: Patients (8–28 years old) with rheumatologic conditions, or their parents, completed the RHE-PedsQL (n=76) and ROS checklist (n=100) as a paper-pencil form and electronically through a tablet computer within the same office visit. Interclass correlations (ICC) and weighted-kappa statistics were computed using SAS 9.3 to compare questionnaire modes of administration. Repeated measures analysis of variance was used to determine between and within subject effects for the following covariates: age, gender, race, diagnosis, subtype, and ethnicity. Concurrently, a sample of patients/parents (n=22) was given a qualitative survey about the use of the tablet computer and preference for paper-pencil vs. electronic modes.

Results: Overall, no significant differences were found between the paper-pencil and tablet questionnaires in total score (RHE-PedsQL p=0.16; ROS p=0.56), as well as for any of the identified covariates considered.

Moderate agreement was found for each domain of the RHE-PedsQL (range: ICC= 0.46–0.61). Consistency, at the individual item level, between paper-pencil and electronic capture ranged from poor to moderate (range: kappa = 0.14–0.58), with the treatment domain having the highest correlations (kappa = 0.58) and the worry domain having the lowest (kappa = 0.14).

The ROS checklist yielded substantial agreement for "average pain" (ICC= 0.87) and "overall status" items (ICC= 0.76). Moderate to excellent agreement was found for each of the 60 individual items of the ROS questionnaire (kappa= 0.3–1.0), with questions regarding the nervous system (e.g., depression, tingling/numbness) showing the best consistency (all kappa > 0.70) and items regarding skin problems (e.g., tightening, discoloring) showing the most discrepancies (kappa = 0.32–0.95).

Qualitative analysis revealed many patients/parents found the tablet simpler, easier and faster than paper-pencil forms. Ten respondents preferred the tablet, eleven had no preference and only one patient preferred the paper-pencil.

Conclusion: There were no significant differences found, for both the ROS checklist and the RHE-PedsQL, in overall score and individual item values, when switching from paper-pencil application to electronic data capture. Furthermore, moderate to substantial agreement was found between modes of administration for the RHE-PedsQL and ROS checklist. The use of electronic questionnaires can increase efficiency of office visits, improve data collection, and patient monitoring, as well as satisfy patient preferences. The ability to integrate electronic patient-reported data into EHR has the potential to improve health care delivery.

Ask a Doc—Rheumatologic Care Delivered Just in Time. Eric D. Newman[1], Chelsea Cedeno[1], Thomas M. Harrington[1], Thomas P. Olenginski[1], Alfred E. Denio[1], Androniki Bili[1], Brian DelVecchio[1], Carolyn Houk[2] and Paul F. Simonelli[1]. [1]Geisinger Medical Center, Danville, PA, [2]Geisinger Health System, Frackville, PA

Background/Purpose: Specialty care is traditionally delivered as face to face consults. These encounters range from consult not needed to consult needed quickly. Our care systems are not designed to distinguish these different needs, creating excess visits that delay access. This delay results in overutilization and unnecessary expense (consult not needed), underutilization of needed care and worsening disease (consult needed quickly), and potential harm and patient anxiety (both). To provide specialty care just when it is needed, we developed Ask-a-Doc, a web-based tool accessed from within the electronic health record (EPIC).

Methods: Ask-a-Doc was developed using process redesign methodology. Ask-a-Doc allows the Primary Care Physician (PCP) to ask a question and the specialist to answer it through electronic chart review, phone call, or video call. Ask-a-Doc consists of 3 steps: Step 1 - ask a question (PCP). Step 2 - connect to the specialist (Scheduler). Step 3 - answer the question and complete the documentation (Specialist). 23 PCPs, 7 schedulers, and 11 specialists (6 rheumatologists, 5 pulmonologists) were trained to use Ask-a-Doc. Redesign measures included service excellence, work effort, process reliability, and clinical outcome.

Results: Step 1 - The PCP selected a specialty or specialist, turn-around time (now, today, within 3 days), preferred mode of communication (electronic messaging, phone call, instant video), and asked a question. The question could be patient-specific or not patient-specific. The request was submitted electronically to the Ask-a-Doc scheduler. Step 2 - The scheduler identified the correct specialist and sent the form to that specialist's Ask-a-Doc inbasket folder. If the request was to communicate by phone or video, the scheduler connected the specialist back to the PCP. Step 3 – the specialist reviewed the EPIC record, answered the question, and provided structured electronic documentation. Analysis of the first 74 Ask-a-Doc questions showed the following (Table 1): Service excellence - Primary care satisfaction of 4.5 (range 0–5), mean turnaround time of 3 hours, met or exceeded requested timeframe 100%. Work effort – 12 minutes average per message. Process – 100% response rate. Outcome – 57 consults saved (77%).

Category	Measure	Definition	Result
Service Excellence	Primary Care Satisfaction	Satisfaction survey results from PCP perspective (Scale 0–5; 0 = "Impossible", 5 = "Very Easy")	4.5
	Time to Completion	Timeframe from message initiation to response sent	Mean Specialty turn-around time = 3 hours; Mean PCP requested time = 21 hours
	Request Met	% Requested Response Timeframe met or exceeded	100%
Work Effort	Volume	Number of Ask a Doc messages created/started	74
	Time Spent	Average amount of time spent by Specialist to complete (min/message)	12
Process	Response Rate	% of messages responded to	100%
	Response Accuracy	% of patient specific messages converted to encounters for proper documentation	95%
Outcome	Consults Saved	Number of consults saved by using Ask a Doc	57 (77%)

Conclusion: Using process redesign methodology, we developed Ask-a-Doc to improve care delivery between PCPs and specialists. The results demonstrate excellence in service, a highly reliable process, and significant reduction in waste. Ask-a-Doc provides specialty care "just-in-time", so patients that don't need to be seen are not, and those that do can be seen promptly – by design, not by accident. As reimbursement for care delivery moves towards bundled payments, Ask-a-Doc is a value-added service that rheumatologists can provide.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects VI:
Remission and Flare in Rheumatoid Arthritis
Wednesday, November 14, 2012, 9:00 AM–10:30 AM

2605

Exploration of Possible Preliminary Descriptions of Remission Based On RAPID3, without Laboratory Tests or Formal Joints Counts but with Careful Joint Examinations, in the Etude Et Suivi Des Polyarthrites Indifférenciées Récentes (ESPOIR) Cohort of Early Rheumatoid Arthritis Patients. Isabel Castrejón[1], Maxime Dougados[2], Bernard Combe[3], Bruno Fautrel[4] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [3]Hopital Lapeyronie, Montpellier, France, [4]APHP-Pitie Salpetriere Hospital / UPMC, Paris, France

Background/Purpose: Criteria for remission in rheumatoid arthritis (RA) have been developed according to DAS28 (disease activity score), CDAI (clinical disease activity index), and two recent proposals by an American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) committee: "Boolean" with 4 measures—tender joint count (TJC28), swollen joint count (SJC28), C-reactive protein (CRP), and patient global estimate (PATGL), all ≤1; and SDAI (simplified disease activity index). All require formal joint counts, which are not performed at most visits in usual care, and all but CDAI require a laboratory test, which often is not available. Therefore, we explored 4 descriptions of remission for usual care, based on RAPID3 (routine assessment of patient index data), a composite index including function, pain and PATGL—without a laboratory test or formal joint count, but with a careful joint examination and physician global estimate (DOCGL; 0–10 scale).

Methods: The ESPOIR cohort includes 756 patients recruited between Dec 2002 and March 2005. Post hoc analyses were performed to identify the number of patients in remission 6 months after enrollment according to 4 descriptions requiring a formal joint count (and 3 a laboratory test): DAS28 ≤2.6, CDAI ≤2.8, and the two proposed by the ACR/EULAR committee –

Boolean ≤1 for TJC28, SJC28, CRP and PATGL; and SDAI ≤3.3. Four descriptions based on RAPID3 that require neither a laboratory test nor formal joint count, but a careful joint examination and DOCGL were evaluated, "RAPID3R" (RAPID3 ≤3.0), and three more stringent descriptions: "RAPID3R+J1" (RAPID3 ≤3.0 and ≤1 swollen joint; if >1 swollen joint, the criterion is not met); "RAPID3R+J1D1" (RAPID3 ≤3.0 and ≤1 swollen joint and DOCGL ≤1); and "RAPID3R+J0D1" (RAPID3 ≤3.0 and no swollen joint and DOCGL ≤1). Agreement of all 7 descriptions with the ACR Boolean definition was assessed using kappa statistics.

Results: Among the 756 ESPOIR patients, 734 had complete 6-month data to calculate all 8 descriptions. The highest percentage of patients in remission was seen with DAS28 and RAPID3R, the least stringent descriptions, and the lowest percentage with the Boolean definition. Good agreement with the Boolean ACR/EULAR definition was seen for SDAI, CDAI, RAPID3R+J1, RAPID3R+J1D1 and RAPID3R+J0D1 (92.6%–94.7%, kappa 0.70–0.79), versus only moderate agreement for DAS28 and RAPID3R (79.9%–85.8%, kappa 0.46–0.55) (Table).

Table. Proportion of 734 patients in the ESPOIR cohort who were in remission 6 months after baseline according to 8 descriptions of remission

Remission descriptions	Patients in remission by each description: Number (%)	Kappa (95% CI) vs ACR/EULAR Boolean	% Patients in remission agreement with ACR/EULAR Boolean
Indices requiring lab tests and formal joint counts:			
ACR/EULAR Boolean	96 (13%)	NA	NA
SDAI (0–86) ≤3.3	127 (17.3%)	0.79 (0.76–0.86)	94.7%
DAS28 (0–10) ≤2.6	238 (32%)	0.46 (0.39–0.52)	79.9%
Indices without lab tests:			
CDAI (0–76) ≤2.8	134 (18.2%)	0.75 (0.69–0.82)	93.5%
RAPID3 versions for remission without lab tests or formal joint counts (but with careful joint exam):			
"RAPID3R"[RAPID3 (0–30) ≤3.0]	186 (25.3%)	0.55 (0.48–0.63)	85.8%
"RAPID3R + J1"[RAPID3 ≤3.0 and ≤1 swollen joint]	136 (18.6%)	0.73 (0.66–0.79)	92.6%
"RAPID3R + J1D1"[RAPID3 ≤3.0; ≤1 swollen joint; DOCGL ≤1]	117 (16%)	0.74 (0.67–0.81)	93.6%
"RAPID3R+J0D1"[RAPID3 ≤3.0; no swollen joint; DOCGL ≤1]	97 (13.2%)	0.70 (0.62–0.77)	93.0%

NA, not applicable; DOCGL, physician global estimate of status

Conclusion: Description of remission according to SDAI, CDAI, RAPID3R+J1, RAPID3R+J1D1 and RAPID3R+J0D1 is similar to Boolean ACR/EULAR, while DAS28 and RAPID3R are less stringent. The more stringent RAPID3-based indices may be useful in usual clinical care, as they require neither laboratory tests nor formal joint counts, but do require a DOCGL and careful joint examination.

Patient Reported Outcomes in Early Arthritis Patients. L. Heimans[1], K.V.C. Wevers-de Boer[1], K. Visser[1], R. Goekoop[2], T.H.E. Molenaar[3], B.A. Grillet[4], Tom Huizinga[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, [3]Groene Hart Hospital, Netherlands, [4]Zorgsaam hospital, Terneuzen, Netherlands

Background/Purpose: To investigate patient reported outcomes (PROs) of functioning and health related quality of life (HRQOL) after 1 year remission (DAS<1.6)-steered treatment in early arthritis patients.

Methods: In the IMPROVED-study 610 patients with early rheumatoid and undifferentiated arthritis were treated with methotrexate (MTX) 25mg/week and 60mg/day of prednisone, tapered to 7.5mg/day in 7 weeks. Patients who did not achieve early remission after 4 months were randomized either to hydroxychloroquine 400mg/day, sulphasalazine 2000mg/day, MTX 25mg/week plus prednisone 7.5mg/day (arm 1) or to adalimumab (ADA) 40mg/2weeks plus MTX 25mg/week (arm 2). Every 4 months, patients filled out the Health Assessment Questionnaire (HAQ) to measure functional ability, the

Short Form 36 (SF-36) and visual analogue scales (VAS) for global health (VASgh), pain (VASp), disability (VASdis) and morning stiffness (VASms). Mean scores of HAQ, SF-36 and VAS over 1 year were compared between patients in the randomization arms using linear mixed models. HAQ- and VAS scores and changes over 1 year were compared between the treatment groups (early remission, arm 1, arm 2 and 'outside protocol treatment'). SF-36 scores (higher=better HRQOL) were compared with the Dutch population norm matched for age and sex. Predictors of significant change in PCS and MCS over 1 year were identified using linear regression analyses.

Results: After 4 months 375/610 patients achieved early remission, 83 patients were randomized to arm 1 and 78 to arm 2, and 62 did not follow the protocol; 12 were lost to follow up. Mean (sd) HAQ after 1 year was 0.4 (0.5) in the early remission group, 0.9 (0.7) and 0.8 (0.7) in arm 1 and 2, respectively, and 0.7 (0.6) in the 'outside protocol' group (p<0.001; early remission group vs either arm 1 or 2: p<0.001, early remission vs 'outside protocol': p=0.001, arm 1 vs arm 2 and 'outside protocol' vs both arms: p=1.0). Mean HAQ reduction in year 1 was 0.6 in all groups (p=0.7). Mean HAQ, PCS, MCS and VAS-scores over 1 year treatment were better in the early remission group. There was no significant difference between randomization arms 1 and 2. VAS improvements over 1 year were similar in all groups except VASdis, which improved significantly more in arm 2 than in arm 1 (36 versus 24 points; p=0.02). At baseline and after 1 year, all groups scored below the Dutch population average in PCS, MCS and all subscales (all p<0.001). Early remission was a predictor for significant improvement in PCS but not MCS after 1 year. For the MCS only baseline MCS was a predictor.

Conclusion: In patients with early arthritis, functional ability and patient reported outcomes after 1 year are significantly better in patients who achieved early remission. In patients who did not achieve early remission, treatment with polyDMARD+prednisone or adalimumab+MTX results in comparable improvements. All patients with early arthritis have significantly lower HRQOL than the Dutch general population, both at baseline and after 1 year of remission steered treatment.

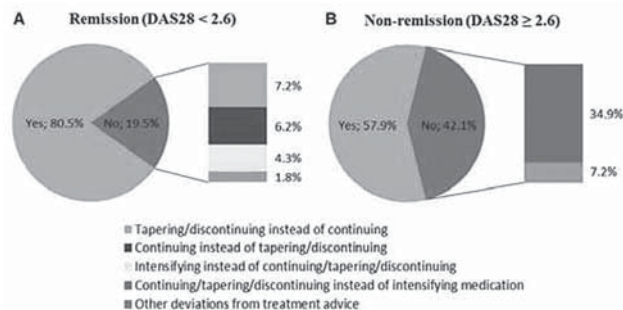
2607

Adherence to a Treat-to-Target Strategy in Early Rheumatoid Arthritis: Results of the Dutch Rheumatoid Arthritis Monitoring Remission Induction Cohort.
Marloes Vermeer[1], Ina H. Kuper[2], Hein J. Bernelot Moens[3], Monique Hoekstra[4], Marcel D. Posthumus[5], Piet L.C.M. van Riel[6] and Mart A.F.J. van de Laar[1]. [1]University of Twente & Medisch Spectrum Twente, Enschede, Netherlands, [2]Medisch Spectrum Twente, Enschede, Netherlands, [3]Ziekenhuisgroep Twente, Hengelo, Netherlands, [4]Isala Klinieken, Zwolle, Netherlands, [5]University Medical Center Groningen, Groningen, Netherlands, [6]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: A treat-to-target (T2T) approach has proven to be more effective in reaching remission in early rheumatoid arthritis (RA) than usual care [1]. However, T2T has not been fully implemented in all rheumatology clinics. In 2006, six hospitals participating in the Dutch Rheumatoid Arthritis Monitoring (DREAM) registry implemented a T2T strategy. In this DREAM remission induction cohort, early RA patients are treated according to a T2T strategy aiming at remission (Disease Activity Score in 28 joints (DAS28) < 2.6) [2]. The recommendations regarding T2T included regular assessment of the DAS28 and an advice regarding subsequent DAS28-driven treatment. The objective of this study was to evaluate the adherence to this T2T strategy.

Methods: A medical chart review was performed among a random sample of 100 RA patients of the DREAM remission induction cohort. At all scheduled visits, it was determined whether the clinical decisions were compliant to the T2T recommendations. Reasons for deviating from the recommendations were explored.

Results: The 100 patients contributed to a total of 1115 visits. The mean (standard deviation, SD) follow-up time was 28 (10) months and the mean (SD) number of visits was 11 (4) per patient. The DAS28 was available in 97.9% (1092/1115) of the visits, of which the DAS28 was assessed at a frequency of at least every three months in 88.3% (964/1092). Adherence to the treatment advice was observed in 69.3% (757/1092) of the visits. In case of non-adherence when remission was present (19.5%, 108/553), most frequently medication was tapered or discontinued when it should have been continued (7.2%, 40/553) or treatment was continued when it should have

been tapered or discontinued (6.2%, 34/553) (Figure 1A). In case of non-adherence when remission was absent (42.1%, 227/539), most frequently medication was not intensified when an intensification step should have been taken (34.9%, 188/539) (Figure 1B). In almost half of these cases, low disease activity was observed (DAS28 ≤ 3.2). The main reason for non-adherence was discordance between disease activity status according to the rheumatologist and DAS28. Other frequently observed reasons were: side effects, patient wish and unknown.


Conclusion: The recommendations regarding T2T were successfully implemented and high adherence was observed. This demonstrates that the implementation of T2T is feasible in RA in daily clinical practice.

2608

Time in Remission Is Important for Improvement of Physical Function in Patients with Rheumatoid Arthritis (RA).
Helga Radner[1], Farideh Alasti[2], Josef S. Smolen[3] and Daniel Aletaha[2]. [1]Medical University Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Physical function is one of the major outcomes in RA as it predicts work disability, quality of life, health care resource utilisation and mortality. It is currently still unclear what the minimum duration of remission is that would improve functional capacity to the best possible degree.

To investigate the course of functional status assessed by health assessment questionnaire (HAQ) in RA patients with sustained clinical remission for at least 6 months.

Methods: We were provided a random 80–90% data sample of RA patients enrolled in recent clinical trials (ASPIRE, ATTRACT, DE019, ERA, Leflunomide, PREMIER, and TEMPO; n=4863) by the respective sponsors. We identified patients, who at some point during the trials achieved sustained remission in consecutive visits of at least 6 months by the DAS28-CRP ≤ 2.6 or SDAI ≤ 3.3. We obtained HAQ scores during these 6 month remission periods, and were thus able to investigate the course of physical function over time in sustained remission using the Wilcoxon test. Furthermore we explored the proportion of patients achieving full function (HAQ = 0 over time period investigated).

Results: Out of 4362 patients we identified 605 patients in sustained remission by DAS28-CRP, and 385 patients by SDAI. No significant differences of baseline characteristics were found between these two groups. We found a significant decrease of mean HAQ values over time within the first 6 months in remission by DAS28-CRP (mean±SD HAQ monthly from baseline to month 6: 0.25±0.4 to 0.22±0.38 to 0.22±0.39 to 0.21±0.38 to 0.20±0.37 to 0.18±0.31 to 0.16±0.32) as well as SDAI (0.17±0.3 to 0.16±0.32 to 0.15±0.3 to 0.14±0.29 to 0.13±0.29 to 0.13±0.26 to 0.11±0.27) with significantly (p<0.05) lower levels of HAQ in remission by SDAI compared to DAS28-CRP at remission entry until month 4 in sustained remission. Achievement of full function (HAQ=0 over course of remission) was observed in 42.5% of patients in DAS28-CRP and 50.1 % of patients in SDAI remission at beginning of sustained remission, and in more patients with early RA (DAS28-CRP: 47.6%; SDAI: 52.6%) compared to late RA patients (DAS28-CRP: 33.3%; SDAI: 44.1%). Further, at remission entry

only 57.4% of patients in DAS28-CRP REM fulfilled SDAI remission; this percentage increased over time to 71.9% at 3 months and 76.9% at 6 months of sustained remission; thus, the improvement of HAQ in DAS28 remission went at least partly in parallel with the increasing frequency of SDAI remission in DAS28 remitters over time.
Fig. 1. Course of HAQ in DAS-CRP and SDAI sustained remission over time

Conclusion: Physical function continuous to improve over time in sustained remission. The stringency of the remission criteria determines how quickly patients in remission achieve their best possible functional improvement.

2609

Construct and Criterion Validity of Several Proposed DAS28 Based Rheumatoid Arthritis Flare Criteria: A Cohort Validation Study. Aatke van der Maas[1], Elisabeth Lie[2], Robin Christensen[3], Ernest Choy[4], Yaël A. de Man[5], Piet L.C.M. van Riel[6], Thasia G. Woodworth[7] and Alfons A. den Broeder[1]. [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Musculoskeletal Statistics Unit, The Parker Institute, Copenhagen University Hospital, Copenhagen, Denmark, [4]Cardiff University School of Medicine, Cardiff, United Kingdom, [5]Erasmus Medical Centre, Rotterdam, Netherlands, [6]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [7]Visiting Clinical Researcher, Geffen School of Medicine, UCLA, Los Angeles, CA

Background/Purpose: To enable consistent assessment of impact of tapering, withdrawal and dose optimization strategies, there is an increasing need for validated measures of flare in rheumatoid arthritis (RA) clinical studies. Several DAS28 based flare criteria have been described, but none validated

Methods: We used 3 longitudinal observational databases that included treatment withdrawal or change in relation to RA worsening to test 6 previously published DAS28 based flare criteria on fulfilment of 5 hypotheses concerning criterion and construct validity. Published DAS28 based flare criteria were: 1] an increase in DAS28>1.2, or >0.6 if current DAS28>5.1, 2] an increase in DAS28>1.2, or >0.6 if DAS28≥3.2, 3] an increase>0.6 or DAS28>3.2, 4] an increase in DAS28>1.2, 5] DAS28 >3.2, 6] DAS28 >2.6. The 5 hypotheses used to assess validity were: A+B) Sensitivity and specificity >70% compared to patient's/physician's judgment of RA worsening assessed with a transition question, and C) difference in proportion with DMARD/corticosteroid initiation/increase >0.2, D) difference in mean CRP change >10mg/L, and E) no statistical difference in SF36 Mental Health (MH) subscale change in patients fulfilling versus not fulfilling the flare criteria. Sensitivity/specificity, Chi square and two sample student's T test were done

Results: Analyses included 51, 147 and 744 RA patients in the 3 studies. Two studies included patients treated with infliximab and the larger study (NOR-DMARD) included patients initiating a new synthetic or biologic DMARD. Baseline characteristics are described in Table 1. Criterion 2 (an increase in DAS28>1.2, or >0.6 if DAS28≥3.2) fulfilled most predefined

hypotheses (4 out of 5, Table 2). Sensitivity and specificity for criterion 2 varied between 63–78% and 84 –92%, respectively. Construct validity was demonstrated with 23% more treatment change, a higher mean ΔCRP (11.4 mg/L) and a difference in ΔSF-36 MH of only -5. Criteria 3, 5 and 6 tended to be more sensitive, criteria 1, 2 and 4 more specific

Table 1. Baseline characteristics - mean (SD) unless otherwise noted

Database	1	2	3
Number of patients	51	147	744
Age, years	59 (11.2)	58 (12)	56 (13.5)

Table 2. Fulfilment of DAS28 based flare criteria on 5 hypotheses regarding construct and criterion validity

	Criterion validity: databases 1 and 2				Construct validity: database 3		
Flare criteria	Hypothesis 1		Hypothesis 2		Hypothesis 3	Hypothesis 4	Hypothesis 5
In patients classified as a having a flare:	Sens/spec patient >70% compared to transition scale		Sens/spec physician >70% compared to transition scale		Higher proportion of DMARD/ corticosteroid change (>0.2)	Higher CRP (>10 mg/L)	No change in depression (≤5 points in MH scale)
	Sens* %	Spec* %	Sens* %	Spec* %	Proportion difference**	CRP difference mg/L (SE)***	MH difference (SE)
1) ΔDAS28 > 1.2 or > 0.6 if DAS28>5.1	46/56	95/92	53/78	95/92	0.28	13.1 (2.2)	−6.1 (1.4)
2) ΔDAS28> 1.2 or > 0.6 if DAS28>3.2	69/63	92/84	73/78	92/86	0.23	11.4 (1.7)	−5.0 (1.2)
3) ΔDAS28> 0.6 or a DAS28>3.2	98/94	70/61	100/89	67/60	0.16	3.7 (1.2)	−2.8 (1.0)
4) ΔDAS28>1.2	46/56	96/93	51/78	95/92	0.27	13.0 (2.3)	−6.6 (1.4)
5) reaching DAS28>3.2	91/88	78/67	91/89	76/68	0.18	3.1 (1.2)	−2.6 (1.0)
6) reaching DAS28 > 2.6	98/94	55/46	100/89	53/47	0.13	2.4 (1.0)	−3.2 (1.1)

*Sens=sensitivity, Spec= specificity. Results from database1 / database2 are represented on sensitivity and specificity. ** All proportion differences are statistically significant, with p<0.0001.*** All differences in CRP are statistically significant, with at least p<0.05

Conclusion: An increase in DAS28>1.2, or >0.6 if DAS28≥3.2 appears most discriminating and valid by our predefined criteria. The differences in sensitivity and specificity between the various DAS28-based flare criteria may be of importance for selection of flare criteria for specific studies. Further assessment, with evaluation of impact relative to levels of worsening, in additional databases may refine criteria

2610

Predictors of Sustained Clinical Remissionin Early Rheumatoid Arthritis - Results From the Canadian Early Arthritis Cohort. Bindee Kuriya[1], Juan Xiong[2], Gilles Boire[3], Boulos Haraoui[4], Carol A. Hitchon[5], Janet E. Pope[6], J. Carter Thorne[7], Diane Tin[7], Edward Keystone[1], Vivian P. Bykerk[8] and CATCH[9]. [1]University of Toronto, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, [5]University of Manitoba, Winnipeg, MB, [6]St. Joseph's Health Care London, London, ON, [7]Southlake Regional Health Centre, Newmarket, ON, [8]Hospital for Special Surgery, New York, NY, [9]Toronto, ON

Background/Purpose: Rapid time-to-remission has been associated with sustained remission in established rheumatoid arthritis (RA)[1]. However, the prevalence and predictive factors of sustained remission in early RA is poorly understood, especially in the context of stringent remission definitions.

Methods: We used data from the Canadian early ArThritis CoHort (CATCH) and included patients with probable or confirmed RA. Remission was defined according to the ACR/EULAR clinical practice definition (TJC ≤1, SJC ≤1 and patient global ≤ 1) and SDAI ≤ 3.3. Patients in CATCH are seen q3months in year 1 and q6montly thereafter. Sustainability was defined as ≥6 months or 2 consecutive visits with ACR/EULAR or SDAI remission-.Predictors for sustained remission were identified by logistic regression analysis, adjusted for clinical confounders.

Results: 1244 patients were included. 83% were Caucasian and 73% were female, with mean age (SD) of 53.6 (14.6) years, and mean symptom duration (SD) of 6.0 (3.1) months. Initial treatment within the 1st 3 months included: methotrexate monotherapy in 392 (32%), combination DMARDs in 548 (44%), and biologics in 27 (2%). 522 (42%) achieved ACR/EULAR and 484/1205 (40%) SDAI remission with a median time-to-remission of 23.9 months for each. In those ever achieving sustained remission, 309 (59.2%) and 273 (56.4%) did so for sustained ACR/EULAR and SDAI remission. Factors associated with increased probability of sustained remission were younger age, low baseline pain scores and earlier time-to-first remission (Table). Baseline RF, CCP, patient global, smoking status, symptom duration, DAS28, HAQ, fatigue, AM stiffness and erosions had no effect on sustained remission. No initial treatment strategy predicted sustained remission, nor did biologic use within the first 6 months (8%).

Table. Multivariate analysis of baseline predictors and time-to-remission as a predictor for sustained ACR/EULAR or SDAI remission

Characteristic	ACR/EULAR Clinical Practice Remission		SDAI Remission	
	OR (95% CI)	p-value	OR (95% CI)	p-value
Age*, years	0.98 (0.96, 0.99)	0.002	0.98 (0.96, 0.99)	0.006
Female sex	0.62 (0.39, 0.99)	0.04	0.78 (0.48, 1.26)	0.31
Pain score*	0.99 (0.98, 0.99)	0.04	0.98 (0.98, 0.99)	0.03
Methotrexate monotherapy	0.95 (0.55, 1.66)	0.86	0.68 (0.37, 1.23)	0.20
Combination DMARD therapy	1.49 (0.88, 2.51)	0.14	1.42 (0.80, 2.51)	0.23
Biologic DMARD within 6 months	1.68 (0.75, 3.74)	0.21	0.85 (0.39, 1.85)	0.69
Time-to-remission	0.997 (0.996, 0.998)	<0.0001	0.997 (0.996, 0.998)	<0.0001

* Treated as continuous variables

Conclusion: Even when stringent definitions of remission are considered, sustained remission is possible within two years for ERA patients initially treated with conventional DMARDs. The time to reach sustained remission may be falsely long as after year 1, data is collected only every 6 months. Gender influenced the chance of remission only in ACR/EULAR remission. Demographic characteristics and pain are important predictors of sustained remission. Shorter time-to-remission is also related to sustainability and supports striving for early remission in patients with ERA. The optimal treatment approach for sustained remission in this cohort could not be determined.

Do Patients with Psoriatic Arthritis Fall Into Distinct Clinical Sub-Groups—a Cluster Analysis? Arane Thavaneswaran[1], Vinod Chandran[2] and Dafna Gladman[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: To determine if demographic and disease characteristics of patients with PsA at presentation to a PsA clinic cluster into distinct groups.

Methods: 1058 patients with Psoriatic Arthritis (PsA) were included from an observational cohort. Cluster analysis using Ward's method was conducted to identify groups of patients based on the following characteristics at baseline: gender, type of psoriasis (type I or II), duration of PsA, race, family history of psoriasis, ESR, severe PASI, psoriasis vulgaris, nail disease, dactylitis, swollen joint count, damage joint count, axial disease, and presence of arthritis prior to psoriasis. 7 clusters were formed and matched to non-overlapping arthritis patterns (as described previously) at first clinic visit: distal arthritis, oligoarthritis, polyarthritis, axial only, distal arthritis and axial, oligoarthritis & axial, and polyarthritis & axial. Comparisons between the clusters and arthritis patterns were conducted using t-tests and Chi-square analysis.

Results: The baseline characteristics of the 1058 patients were as follows: 613 (56.5%) males, mean age at diagnosis of PsA 37.1 (13.5) years, mean age at first visit 44 (13.1) years, mean duration of PsA 6.8 (8.2) years, mean active joint count 11.0 (9.8), mean PASI 5.8 (8.3), mean Steinbrocker score 12.9 (25.5), HLA-B*27 116(17.7%)] with an average follow-up of 8.4 (8.4) years. Two main clusters of patients were identified. One consisted of distal arthritis, oligoarthritis and polyarthritis and the other of axial only, distal and axial, oligoarthritis & axial, and polyarthritis & axial, thus clearly identifying patients into peripheral and axial disease. Comparison of the two clusters showed a longer duration of PsA at baseline, more patients with a family history of psoriasis, and more dactylitis in patients with peripheral disease. Patients falling into the axial disease cluster had a higher prevalence of males, more Caucasians, more psoriasis vulgaris, worse PASI score), higher damage joint count and more patients who developed arthritis first.

Table. Comparison of two clusters

Variable	Frequency (%) or Mean (sd)		p-value
	Cluster I	Cluster II	
Age at diagnosis of Ps (>40 vs. <=40)	63 (14.5%)	47 (20.4%)	0.06
Duration of PsA	8.6 (7.6)	5.0 (6.5)	<0.0001
Gender (Males)	259 (59.4%)	175 (76.1%)	<0.0001
Race (Caucasian vs. others)	365 (84.1%)	208 (90.8%)	0.02
Family history of Psoriasis	124 (28.6%)	33 (14.4%)	<0.0001
Nail disease	214 (69.7%)	120 (78.4%)	0.06
Dactylitis	236 (54.4%)	80 (34.8%)	<0.0001
Abnormal skin	352 (82.4%)	213 (94.3%)	<0.0001
Severe PASI (>=10)	35 (12.9%)	40 (27.2%)	0.0003
ESR	21.7 (18.9)	28.5 (22.1)	0.0002
Swollen joint count	3.3 (4.2)	2.8 (3.9)	0.12
Damage joint count	1.1 (2.9)	7.6 (11.8)	<0.0001
Axial disease	67 (15.5%)	208 (90.4%)	<0.0001
Arthritis first	20 (4.6%)	21 (9.1%)	0.02

Conclusion: Based on patients' characteristics at baseline, cluster analysis separated PsA patients into two main arthritis patterns- axial and peripheral. The study provides further evidence to classify patients into just two groups based on the presence or absence of axial arthritis.

Localisation of Bone Marrow Edema in Sacroiliac Joints in Spondyloarthritis Patients: Does the Site of Lesions Change Over a 3-Month Period? Manouk de Hooge, Rosaline van den Berg, Monique Reijnierse, Victoria Navarro-Compán, Floris van Gaalen, Tom Huizinga and Désirée van der Heijde. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: A positive MRI at baseline is a strong predictor for a positive follow-up MRI[1]. But many questions about the volatility of the lesions over short follow-up periods remain unsolved. Is it possible for lesions to disappear, occur or move localisation? Or is their location rather consistent over time?

Objectives: To describe if and how the location of active inflammatory lesions change and if lesions can occur or disappear after 3 months without changing treatment.

Methods: 90 patients with chronic back pain (≥3 months, ≤2 years, onset ≤45 years) who were included in the SPondyloArthritis Caught Early (SPACE)-cohort underwent a MRI of the SI joints (MRI-SIJ) at baseline and after 3 months follow-up.

Results: Out of all the patients 66/90 (73.3%) did not show any lesions at any of the time points. In 12 patients no difference was found between baseline and follow-up MRI with respect to the SI joint (only left side affected in 7 patients, only right side in 2 and in 3 patients both SIJ were affected). In 5 patients without lesions at baseline new inflammation occurred (4 times only in the right SIJ and once in both SIJs). In 4 patients with inflammation at baseline the inflammation was no longer present at follow-up. In 3 out of 6 patients with inflammation in both SIJ at baseline, the inflammation was only present in the left SIJ after 3 months. The other 3 patients presented

inflammation in both SIJ at baseline as well as follow-up. 24/90 (26.7%) patients had a positive MRI at baseline or follow-up, or both. The quadrant in which the lesion was present did not change over time in 6 patients. Lesions disappeared from quadrants in 9 patients (lesion disappeared in only 1 quadrant in 7 patients and in 3 quadrants in 2 patients) and occurred in 7 patients (MRI changed from negative to positive in 5 and remained positive in 2 patients). The lesions moved between quadrants in 2 patients. In these 2 patients lesions disappeared from one quadrant and occurred in another. In 20/24 patients the medication between baseline MRI and follow-up did not change (18 patients used NSAIDs and 2 of them did not use any medication) and 4 patients changed medication (2 patients switched NSAID type and the other 2 started NSAID treatment in that period). Out of the patients that changed from a negative to positive MRI (n=5) or visa versa (n=4), only 1 patient also changed medication, by switching to another NSAID.

No. of patients Baseline	3-month follow-up				
	No lesions	Only left	Only right	Both sides	
No lesions	66	0	4	1	71
Only left	3	7	0	0	10
Only right	1	0	2	0	3
Both sides	0	3	0	3	6
	70	10	6	4	90

Conclusion: BME lesions on MRI occur or disappear at SIJ level in 9% of the patients with chronic back pain after 3 months. From all patients with a positive MRI at baseline, lesions did not change location in 50% of them at SIJ level while, at quadrant level, less than 30% of the patients showed stability in the location of lesions. So, there is quite some volatility of lesions over a short follow-up period of 3 months only.

Effect of Certolizumab Pegol On Signs and Symptoms in Patients with Psoriatic Arthritis with and without Prior Anti-TNF Exposure: 24 Week Results of a Phase 3 Double-Blind Randomized Placebo-Controlled Study. Philip Mease[1], Roy M. Fleischmann[2], Jürgen Wollenhaupt[3], Atul A. Deodhar[4], Danuta Kielar[5], Franz Woltering[6], Christian Stach[6], Bengt Hoepken[6], Terri Arledge[7] and Désirée van der Heijde[8]. [1]Seattle Rheumatology Associates, Seattle, WA, [2]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [3]Schön-Klinik, Hamburg, Germany, [4]Oregon Health & Science University, Portland, OR, [5]UCB Pharma, Brussels, Belgium, [6]UCB Pharma, Monheim am Rheim, Germany, [7]UCB Pharma, Rtp, NC, [8]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, has shown efficacy in reducing signs and symptoms of psoriatic arthritis (PsA).[1] RAPID-PsA (NCT01087788) is the first report of a biologic in PsA to include patients (pts) with prior anti-TNF exposure.

Methods: The ongoing 158 week (Wk) RAPID-PsA trial is double-blind and placebo (PBO) controlled to Wk24, dose-blind to Wk48 and then open label to Wk158. Recruited pts had active PsA and had failed ≥1 DMARD. Pts could have experienced secondary failure to 1 previous anti-TNF. Pts were randomized 1:1:1 to PBO, or 400mg CZP at Wk 0, 2 and 4 (loading dose, LD) followed by either 200mg CZP every 2 wks (Q2W) or 400mg CZP every 4 wks (Q4W). Pts receiving PBO who failed to achieve a ≥10% decrease in tender and swollen joint counts at both Wks14 and 16 were rescued and randomized at Wk16 to receive CZP 200mg Q2W or CZP 400mg Q4W following LD. The clinical primary endpoint was ACR20 response at Wk12. Secondary outcomes measured in the study include PASI75, Leeds Enthesitis Index (LEI), Leeds Dactylitis Index (LDI) and Modified Nail Psoriasis Severity Index (mNAPSI). Non-responder imputation was used for ACR and PASI75; Last observation carried forward was used for LEI, LDI and mNAPSI.

Results: 409 pts were randomized. Baseline (BL) demographics were similar between groups. 19.1% and 19.8% of PBO and CZP (combined dose) pts received prior anti-TNF. ACR20 response at Wk12 was significantly higher in the CZP 200 mg Q2W and CZP 400 mg Q4W arms vs. PBO (58.0% and 51.9% vs. 24.3% [p<0.001 for both]) and was observed as early as Wk1 (21.0% [p=0.001] and 23.0% [p<0.001] vs.7.4%).[1] PASI75 response at Wk24 for pts with ≥3% psoriasis body surface area at BL (61.6% randomized set [RS]) was 62.2% with CZP 200mg Q2W and 60.5% with CZP 400mg Q4W vs 15.1% PBO (p<0.001 for both). In pts with BL enthesitis

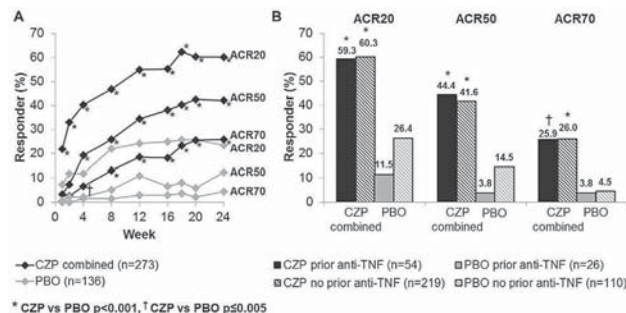
(64.3% RS) LEI change from BL at Wk24 was −2.0 with CZP 200mg Q2W (p<0.001) and −1.8 with CZP 400mg Q4W (p=0.003) vs −1.1 PBO. For pts with BL nail disease (73.3% RS) mNAPSI change from BL at Wk24 was −1.6 with CZP 200mg Q2W and −2.0 with CZP 400mg Q4W vs −1.1 PBO. No differences in LDI change from BL were observed in pts with BL dactylitis. At Wk24, ACR response rates were similar between CZP arms and greater vs. PBO irrespective of prior anti-TNF exposure (Figure). Adverse events (AEs) occurred in 62% vs 68% and SAEs in 7% vs. 4% in CZP vs PBO pts (combined dose), respectively. Two deaths occurred up to Wk24, one sudden death of unknown cause (CZP 400mg Q4W) and one myocardial infarct (CZP 200mg Q2W). No new safety signals were observed.


Figure. ACR 20/50/70 response in overall population to Wk24 (A) and pts with and without prior anti-TNF exposure at Wk24 (B) in RAPID-PsA.

Conclusion: Rapid improvements in the signs and symptoms of PsA, as well as skin manifestations and nail disease of psoriasis, were observed across both CZP dosing regimens. Similar ACR response rates with CZP were observed in pts with and without prior anti-TNF exposure.

The Risk of Diabetes in Psoriatic Arthritis and Rheumatoid Arthritis. Maureen Dubreuil[1], Young Hee Rho[1], Ada Man[2], Yanyan Zhu[3], Yuqing Zhang[2], Thorvardur Love[4], Alexis Ogdie[5], Joel Gelfand[6] and Hyon Choi[1]. [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, MA, [3]Department of Biostatistics, Boston University School of Public Health, Boston, MA, [4]Labspitali University Hospital, Reykjavik, Iceland, [5]University of Pennsylvania, Philadelphia, PA, [6]University of Pennsylvania., Philadelphia, PA

Background/Purpose: The potential impact of psoriatic arthritis (PsA) and rheumatoid arthritis (RA) on the risk of incident diabetes remains unclear. Studies have shown that patients with psoriasis have an increased risk of incident diabetes; however, no published data are available specific to patients with psoriatic arthritis. Furthermore, there is a scarcity of data on the risk of diabetes among patients with rheumatoid arthritis, and the available data in RA are conflicting. We aimed to evaluate the risk of incident diabetes in PsA and RA in the general population, with adjustment for body mass index (BMI) and lifestyle factors.

Methods: We conducted a cohort study using data from an electronic medical records database representative of the UK general population, collected between 1986 and 2010. We used previously published definitions of PsA, psoriasis, RA (exposures) and diabetes (outcome) in the same cohort context. We estimated hazard ratios (HR) for incident diabetes compared with age- and sex-matched comparison cohorts without any known rheumatic conditions, after adjusting for body mass index, smoking, alcohol, comorbidities, and glucocorticoids use.

Results: Diabetes developed in 179 of 4,196 individuals with PsA (50% female, mean age 49 years, mean BMI 27.6), in 2,202 of 59,281 persons with psoriasis (51% female, mean age 49 years, mean BMI 26.7), and in 383 of 11,158 individuals with RA (68% female, mean age 58 years, mean BMI 26.8). Age- and sex-matched HRs for diabetes were 1.72 (1.46–2.02) in PsA, 1.39 (1.32–1.45) in psoriasis, and 1.12 (1.01–1.25) in RA relative to the

comparison cohorts. After adjustment for BMI, smoking, and alcohol use, these HRs were attenuated substantially (1.43, 1.24, and 1.00, respectively). With further adjustment for glucocorticoid use and comorbidity index, the HRs were 1.33 (1.09–1.61) in PsA, 1.21 (1.15–1.27) in psoriasis, and 0.94 (0.84–1.06) in RA.

Table 1. Baseline Characteristics of the Study Populations.

		PsA (n = 4196)	No PsA (n = 41794)	P Value	Psoriasis (n = 59281)	No Psoriasis (n = 581248)	P Value	RA (n = 11158)	No RA (n = 110375)	P Value

PY = person-years

Conclusion: This large general population study suggests that the overall risk of diabetes is increased in PsA, which can be substantially explained by increased adiposity, lifestyle factors, and other covariates. In contrast, risk of diabetes among patients with RA is significantly elevated only due to increased BMI and smoking. Overall, these findings suggest that diabetes risk should not be ascribed only to the presence of inflammatory disease. Important opportunities exist for future interventions directed at weight loss and smoking cessation to reduce risk of diabetes in these populations, and to determine how psoriatic disease contributes to the risk of developing diabetes.

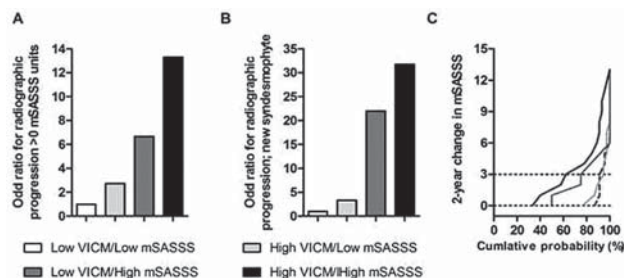
2615

Circulating Levels of Citrullinated Vimentin Fragments Are Diagnostic and Prognostic in Ankylosing Spondylitis; Evidence for Disease-Related Citrullination. Anne C. Bay-Jensen[1], Morten Asser Karsdal[1], Efstathios Vassiliadis[2], Stephanie Wichuk[3], Zheng Zhao[4], Robert GW Lambert[3], Rik Lories[5], Claus Christiansen[6] and Walter P. Maksymowych[3]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark, [3]University of Alberta, Edmonton, AB, [4]Department of Rheumatology, University of Alberta and PLA General Hospital, Beijing, PR China, Beijing, China, [5]KU Leuven, Leuven, Belgium, [6]CCBR, Ballerup, Denmark

Background/Purpose: Rheumatoid arthritis (RA) is considered an anti-CCP positive disease whereas ankylosing spondylitis (AS) is considered an anti-CCP negative disease. Anti-CCP has prognostic capacity in RA. Assessment of metalloproteinases (MMP) may also add prognostic information in both diseases. We evaluated whether a citrullinated and MMP degraded

fragment of vimentin (VICM) could be used as an in vitro diagnostic and prognostic biomarker in AS.

Methods: Serum VICM was measured in samples of controls (n=35), RA (n=47) and AS (n=201) patients. Optimal cut-off for diagnostic sensitivity and specificity was determined by ROC analysis. Baseline and 2-year spinal radiographs were available on 118 AS patients and radiographic progression was scored using the mSASSS. Correlations with patient demographics (age, disease duration), disease activity (BASDAI, CRP, SPARCC MRI Spine 23-DVU score), and severity (mSASSS), were determined. The independent association of VICM with 2-year radiographic progression, defined as mSASSS change>0 or the development of a new syndesmophyte, was analyzed by multivariate regression adjusting for baseline mSASSS.

Results: Both RA and AS had significantly higher levels of VICM than controls ($p < 0.001$). AS patients with the highest level of VICM had the largest burden of disease i.e. highest mSASSS score and disease activity (BASDAI) ($p < 0.001$). VICM correlated significantly with SPARCC MRI Spine 23DVU score ($p = 0.046$). VICM was significantly and independently associated with radiographic progression after 2 years ($\beta = 0.69$, $p=0.0005$). Patients with both high VICM and a high baseline mSASSS had the highest risk for radiographic progression (OR for mSASSS change = 13, new syndesmophyte = 32) and 67% of these had progression (figure).


Conclusion: Serum VICM is a diagnostic and prognostic marker for AS. Moreover, our data challenges the paradigm that AS is an Anti-CCP negative disease.

2616

The Transition From Psoriasis (Ps) to Psoriatic Arthritis (PsA) Is Associated with Elevated Circulating Osteoclast Precursors (OCP) and Increased Expression of DC-STAMP. Ya-Hui Chiu[1], Edward M. Schwarz[1], Dafna Gladman[2], Sharon Moorehead[1], Michelle Smith[1], Rick Barrett[1] and Christopher T. Ritchlin[3]. [1]University of Rochester, Rochester, NY, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]University of Rochester Medical Center, Rochester, NY

Background/Purpose: Approximately 20% of psoriasis (Ps) patients (pts) develop psoriatic arthritis (PsA). Early diagnosis and therapy of PsA can limit bone and joint damage; however, biomarkers to detect subclinical joint inflammation are not available. Osteoclasts (OC) are specialized cells circulating in the blood and responsible for bone erosion in erosive arthritis. We previously showed that osteoclast precursors (OCP) are elevated in a subset of Ps pts and that DC-STAMP (Dendritic Cell-Specific Transmembrane protein), a protein expressed on the surface of monocytes, is a reliable OCP marker. To examine if the transition from Ps to PsA is associated with a change in OCP frequency and the percentage of monocytes that express DC-STAMP, we monitored these 2 parameters on Ps patients before and after the onset of arthritis.

Methods: We follow over 132 Ps patients at the Rochester site in the International Psoriatic Arthritis Research Team (IPART) registry. Ps was confirmed by a dermatologist and PsA was diagnosed by a rheumatologist based on the CASPAR criteria. Blood samples were collected at baseline and after Ps pts developed PsA. To analyze DC-STAMP expression, cells were purified from blood by Ficoll gradient, stained with anti-DC-STAMP and anti-CD14 antibodies, and analyzed by flow cytometry. To enumerate OCP, cells were cultured in OC-promoting media and TRAP-stained. Cells with ≥3 nuclei were counted as OC.

Results: Over the past year, 6 Ps pts at our site developed PsA. The average Ps duration year was 28.7±17.9, Tender Joint Counts were 8.3±6.7 (prior) and 16±15 (after), Swollen Joint Counts were 3.9±4.1 (prior) and 7.1±9.6 (after), PASI scores were 4.7 ± 3.5 (prior) and 2.0 ± 1.1 (after). Of the 6 pts who developed PsA, 5 had scalp psoriasis, 4 had nail disease, 4 had a family history of psoriatic disease and a history of prior trauma. Two of these patients had baseline radiographic erosions. A significant increase in the frequency of OCP was observed at the time of arthritis onset in all patients (Fig 1), whereas an increase in the percentage of DC-STAMP+ monocytes was detected in 4 of 6 pts (Fig 2).
Figure 1. The frequency of circulating OC increases after Ps to PsA transition.
Figure 2. The frequency of circulating DCSTAMP+ monocytes increases after Ps to PsA transition.

Conclusion: The progression of Ps to PsA was associated with a dramatic increase in circulating OCP numbers accompanied with an elevated DC-STAMP+CD14+ monocyte frequency. Collectively, our results suggest that the OCP numbers as well as the frequency of circulating DC-STAMP+ monocytes in the blood are potential arthritis susceptible biomarkers in Ps patients.

2617

Outcomes Associated with Belimumab in Black/African American Patients with Systemic Lupus Erythematous in Clinical Practice Settings in the United States.
Christopher E. Collins[1], Siva Narayanan[2], Maria Dall'Era[3], Greg Dennis[2], Alan Oglesby[4], Mark B. McGuire[5], Ramesh Pappu[6], Charles T. Molta[7] and Greg Keenan[2]. [1]Washington Hospital Ctr, Washington, DC, [2]Human Genome Sciences, Inc., Rockville, MD, [3]University of California, San Francisco, San Francisco, CA, [4]GlaxoSmithKline, Research Triangle Park, NC, [5]Medical Data Analytics, Parsippany, NJ, [6]GlaxoSmithKline, USA, Philadelphia, PA, [7]GlaxoSmithKline, Philadelphia, PA

Background/Purpose: Effectiveness of belimumab in black/African American (AA) patients (pts) with Systemic Lupus Erythematous (SLE) is yet to be adequately demonstrated. The objective of this analysis is to describe the clinical outcomes associated with belimumab therapy in black/AA SLE pts in community practice settings in the United States (U.S).

Methods: This is a multi-center cohort study adult SLE pts in the U.S recruited by a nationally representative random sample of rheumatologists who were treating >10 SLE pts annually and had >5 yrs of practice experience. Physicians are randomly identifying SLE pts in their practices who had received at least 8 infusions of belimumab as part of usual care and assessed the following data corresponding to the 6 months prior to belimumab initiation (baseline: BL) and the first 6 months after belimumab initiation: demographics, comorbidities, SLE disease characteristics, clinical outcomes and resource utilization (including medications). The percentage change in disease manifestations was assessed in pts based on physician judgment at 6 months post belimumab initiation in comparison to baseline. Black/AA pts were included in this interim subset analysis.

Results: Analysis included 58 black/AA SLE pts (from 31 rheumatologists from 18 states) with available data; mean pt age was 40.3 years; 93% female; and 50% diagnosed with SLE for ≥ 5 yrs. At BL, 76% had high anti-dsDNA, 59% had low C3 or C4; and 2%, 71% and 28% had mild, moderate and severe disease respectively. The top 3 reasons for initiating belimumab (10mg/kg) were ineffective previous treatment regimens, decrease the use of steroids (steroid sparing) and worsening patient condition; 83%, 69% and 67% of pts concomitantly used oral steroids, antimalarials and immunosuppressants respectively. After 6 months of belimumab therapy, 90%, 41% and 14% of pts had an overall clinical improvement of ≥20%, ≥50%, and ≥80% respectively. Changes in manifestations by organ system (top-5) are shown in the table. The mean reduction in steroid dose was 14.2 mg/day; 10% discontinued steroids and among those still taking steroids, 93% decreased their doses.

	Musculoskeletal	Immunologic	Mucocutaneous	Constitutional	Hematologic
# of manifestations (pts)	55 (49)	52 (33)	44 (32)	36 (35)	25 (20)
Worsened	0%	0%	0%	0%	0%
No change	6%	21%	7%	8%	24%
% improvement					
<20%	9%	15%	14%	14%	8%
≥20%	85%	63%	80%	78%	68%
≥50%	38%	38%	43%s	39%	40%
≥80%	15%	8%	23%	8%	24%

Conclusion: In this analysis of black/AA pts receiving at least 6 months of belimumab therapy in clinical practices, clinical improvements were observed in a majority of pts with SLE across multiple manifestations. Steroid sparing effects were observed in most of the pts. Additional studies assessing belimumab effectiveness in black/AA pts with SLE are warranted.

Lupus Disease Activity Severely Impairs Pandemic Influenza A/H1N1 Vaccine Immune Response in Patients without Therapy.
Eduardo F. Borba[1], Sandra G. Pasoto[1], Ana L. Calich[1], Ricardo Fuller[1], Vilma S.T. Viana[1], Margareth Vendramini[1], Joao Miraglia[2], Maria A. Ishida[3] and Eloisa Bonfa[4]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Fundação Butantan, São Paulo, Brazil, [3]Adolfo Lutz Institute, Sao Paulo, Brazil, [4]University of São Paulo, São Paulo, Brazil

Background/Purpose: To determine the influence of disease activity without the effect of drugs in pandemic 2009 influenza A (H1N1) vaccine immune response in untreated systemic lupus erythematosus (SLE).

Methods: SLE patients without therapy [n=75] and healthy controls [n=170] were vaccinated with a single dose of a nonadjuvanted A/California/7/2009/H1N1 vaccine. Clinical and laboratorial data, including disease activity scores (SLEDAI), were monitored prevaccination and 21 days postvaccination. Anti-H1N1 titres, percentages of seroprotection (SP), and seroconversion (SC) were evaluated.

Results: After immunisation, untreated patients with SLEDAI=0 [n=22] had comparable SP (86.4%; 95%CI 72.0–100.7; p=1.0) and SC (86.4%; 95%CI 72.0–100.7; p=0.57) to controls whereas untreated patients with any level of disease activity (SLEDAI>0) [n=53] had lower SP (69.8%; 95%CI 57.4–84.4 vs. 84.1%; 95%CI 78.6–89.6; p=0.028) and SC rates (66.0%; 95%CI 53.2–78.7 vs. 80.0%; 95%CI 74.0–86.0; p=0.041) compared to controls. Reinforcing this finding, a significant lower SP (37.5%; 95%CI 13.8–61.2 vs. 79.6%; 95%CI 69.3–89.9; p=0.008) and SC rates (37.5%; 95%CI 13.8–61.2 vs. 77.9%; 95%CI 67.3–88.5; p=0.016) were observed in untreated SLE patients with SLEDAI>6 [n=16] compared with those with SLEDAI<6 [n=59], in spite of a similar mean lymphocyte count (1,260 ± 625 vs. 1,480 ± 840/mm³; p=0.33). Untreated SLE patients with low lymphocytes (<1,000/mm³) [n=21] had similar SP (61.9%; 95%CI 41.1–82.4 vs. 72.2%; 95%CI 60.2–84.1; p=0.41) and SC rates (57.1%; 95%CI 35.9–78.3 vs. 72.2%; 95%CI 60.2–84.1; p=0.27) compared to untreated SLE patients with levels within normal range (>1,000/mm³) [n=54]. SLE patients with anti-dsDNA+ [n=42] had lower postvaccine SP (59.5%; 95% CI 44.6

to 74.3 vs. 81.8%; 95% CI 68.6 to 94.9; p=0.046) and SC rates (57.1%; 95% CI 42.1 to 72.1 vs. 81.8%; 95% CI 68.6 to 94.9; p=0.027) compared to SLE patients without this antibody (anti-dsDNA-) [n=33].

Conclusion: This study provides clear evidence that SLE disease activity severely impairs pandemic influenza H1N1 vaccine immune response independent of lymphocyte counts or drugs.

2619

A Double-Blind Randomized Placebo-Controlled Trial of the Effect of Vitamin D3 On the Interferon Signature in Patients with Systemic Lupus Erythematosus. Cynthia Aranow[1], Maria Dall'Era[2], Elena M. Massarotti[3], Meggan C. Mackay[4], Andreea Coca[5], Fotios Koumpouras[6], Marc C. Levesque[7], W. Winn Chatham[8], Megan E. B. Clowse[9], Lisa G. Criscione-Schreiber[9], Sherri Callahan[10], Ellen A. Goldmuntz[10], Lynette Keyes-Elstein[11], Betty Diamond[12] and Diane L. Kamen[13]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]University of California, San Francisco, San Francisco, CA, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]The Feinstein Institute, Manhasset, NY, [5]University of Rochester, Rochester, NY, [6]West Penn Hospital, Pittsburgh, PA, [7]University of Pittsburgh, Pittsburgh, PA, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Duke University Medical Center, Durham, NC, [10]NIAID/NIH Rm 6807, Bethesda, MD, [11]Rho Federal Systems, Inc., Chapel Hill, NC, [12]Feinstein Institute Med Rsch, Manhasset, NY, [13]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC

Background/Purpose: Exposure of normal PBMCs to 1,25 OH vitamin D reverses the stimulatory effects of activating SLE sera on the interferon signature. Given that IFN is made by activated plasmacytoid dendritic cells (pDCs), vitamin D maintains pDC quiescence, and vitamin D deficiency has a high prevalence in SLE, we investigated the effect of vitamin D supplementation on the IFN signature in SLE patients. Secondary aims included determination of the effect of vitamin D on disease activity and the safety/tolerability of vitamin D in deficient SLE patients.

Methods: 57 anti-DNA antibody positive SLE patients from 8 centers with stable, inactive (SLEDAI ≤4) disease, serum 25-OH vitamin D ≤20ng/ml and an IFN signature were randomized (1:1:1) into a 12 week double-blind placebo controlled trial of daily oral vitamin D3. A IFN signature was defined to be present if expression of 1 of 3 IFN responsive genes (Mx1, Ifit1, or Ifi44) determined using RT-PCR of whole blood mRNA was expressed at a level ≥ 4 SD above the mean of normal controls, or if 2 of the 3 genes were expressed > 2 SD above the mean of normal controls. Immunosuppressive medications were required to be stable at baseline with no expectation of change during the 12 week treatment period. Subjects received 0, 2000 or 4000 IU vitamin D3 daily. A IFN signature response was defined as a 50% reduction in the expression of 1 gene or a 25% decrease in 2 genes compared to baseline provided that expression of the remaining genes did not increase >25%. Measures of disease activity, safety, tolerability and endocrine effects (PTH, urinary calcium/creatinine) were collected.

Results: Baseline characteristics of the 3 treatment groups were similar. Mean (SD) 25 OH D levels (ng/mL) were comparable across treatment groups at entry: 14.5 (4.65), 12.6 (3.76) and 15.3 (3.08) for placebo, low dose and high dose, respectively. No subjects receiving placebo achieved levels associated with endocrine repletion (25 OH D ≥ 30ng/ml) while 11 of 18 subjects receiving 4000 IU daily and 5 of 15 receiving 2000 IU daily exceeded that threshold. The percent of subjects with an IFN signature response was not significantly different among treatment groups at Week 12 (36.8, 23.5, 27.8; placebo, 2000 IU/day dose, 4000 IU/day dose respectively). At Week 12, 36% of deficient subjects and 31% of subjects with 25 OH D values ≥ 30 ng/ mL had an IFN signature response (NS). Furthermore, there was no significant difference in 25 OH D levels between subjects with and without an IFN signature response. Results did not differ significantly whether analyzed per protocol or by intent-to-treat. Vitamin D3 was well tolerated with no safety concerns and no treatment related serious adverse events.

Conclusion: These results suggest that vitamin D3 at doses up to 4000 IU daily was safe and well-tolerated in SLE patients. However, daily doses of vitamin D3 for 12 weeks failed to diminish the IFN signature in vitamin D deficient SLE patients, although repletion of 25 OH D to levels associated with bone health (≥ 30ng/ml) was only achieved in a minority of trial participants. Higher levels of 25 OH D sustained for longer duration may be required for affecting the anticipated immunological outcomes.

2620

Randomized, Double-Blind, Placebo-Controlled Studies of P140 Peptide in Mannitol (Lupuzor) and Trehalose (Forigerimod) in Patients with SLE. Robert Zimmer[1], Daniel J. Wallace[2] and Sylviane Muller[3]. [1]Immu-Pharma France, Mulhouse, France, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]CNRS, Strasbourg, France

Background/Purpose: Advances in the understanding of autoimmune diseases pathogenesis have led to the development of peptide-based therapies that aim to potentially reinstate tolerance to self without the need for immunosuppression. P140 peptide is a 21-mer linear peptide (sequence 131–151) that is issued from the small nuclear ribonucleoprotein U1-70K and that is phosphorylated at the Ser[140] position. Following a promising open phase IIa clinical trial in patients with SLE, two Phase IIb clinical trials were undertaken to evaluate the effect of peptide P140 administrated either in mannitol (Lupuzor) or in trehalose (Forigerimod) as excipient. Data obtained independently with Benlysta are used for comparison (Furie et al. 2011 Arthritis Rheum. 63, 3918–30).

Methods: Two multicenter, randomized, placebo-controlled phase IIb studies were run separately with similar "standard" protocols: 200μg P140/individual/month in addition to standard of care, inclusion of patients with clinical SLEDAI-2K scores >6 and no Bilag A score. The demographic characteristics of the study populations were similar in all three studies as well as in each treatment group. Drop-out rates were recorded irrespective of their reason and considered as treatment failure. Efficacy was evaluated using the SRI score.

Results: Clinical studies results:

	P140 mannitol	P140 trehalose	Benlysta (BLISS-76)
Duration of treatment	3 months	6 months	12 months
Number of patients × arms	50 × 3	92 × 2	273 × 3
SAE active/placebo	6%/6%	10%/14%	19%/20%
Drop-out rate active	5%	22%	23%
Drop-out rate placebo	16%	23%	25%
Responder rate active	62%	34%	43%
Responder rate placebo	37%	40%	33%

Conclusion: Lupuzor (P140 in mannitol) is safe and met its primary efficacy end point in lupus patients. Data suggest that P140 may restore tolerance by acting as an altered peptide ligand of the T cell receptor. P140 also reduces autophagic process, which has been shown recently to be abnormally enhanced in T lymphocytes from lupus mice and patients. The potential reduction by Lupuzor of the enhanced autophagy process (as seen in mouse models) led to a very short onset of action, which is supported by the efficacy data. Trehalose is a known inducer of autophagy and as anticipated, it interferes with the beneficial effect of P140. Its use together with P140 peptide is therefore inappropriate in the treatment of lupus patients.

Sustained Disease Improvement and Safety Profile Over 1745 Patient-Year Experience (7 years) with Belimumab in Systemic Lupus Erythematosus Patients. Joan T. Merrill[1], Richard A. Furie[2], Daniel J. Wallace[3], William Stohl[4], W. Winn Chatham[5], Arthur Weinstein[6], James D. McKay, Ellen M. Ginzler[8], Z. John Zhong[9], William W. Freimuth[9] and Michelle A. Petri[10]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]North Shore-LIJ Health System, Lake Success, NY, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of Southern California Keck School of Medicine, Los Angeles, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Washington Hospital Center, Washington, DC, [7]SUNY-Downstate Medical Center, Brooklyn, NY, [8]Human Genome Sciences, Inc., Rockville, MD, [9]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: To update belimumab safety and efficacy data over 7 y in patients with active SLE.

Methods: 449 SLE patients with SELENA-SLEDAI scores ≥4 were enrolled in a phase 2 study of belimumab 1, 4, or 10 mg/kg vs placebo, plus standard therapy, for 52 wk (NCT00071487). At wk 56, placebo patients switched to belimumab 10 mg/kg and belimumab-treated patients maintained their dose or switched to 10 mg/kg. From wk 80, all patients entering a continuation study received belimumab 10 mg/kg (NCT00583362). AEs were assessed at each study visit. Analyses of disease activity included SLE Responder Index (SRI; post-hoc analysis), British Isles Lupus Assessment Group (BILAG) A/B flares, SELENA-SLEDAI Flare Index (SFI), and biomarker changes. Efficacy assessments were limited to patients who were autoantibody positive (antinuclear antibody titer ≥1:80 or anti-double−stranded DNA ≥30 IU/mL) at baseline.

Results: Of the original 449 patients, 296 (66%) entered the continuation trial. At end of 7 y, 190 patients remained. Total belimumab exposure was >1745 patient-y. Belimumab was well tolerated, with AEs/100 patient-y stable or decreasing over 7 y (see table). Seven patients died over 7 y; no cause predominated. Etiologies included aspiration pneumonia, infection, cardiovascular disease, suicide, osteomyelitis, and B-cell lymphoma. The SRI rate with belimumab was 46% at wk 52 (vs 29% with placebo; p <0.05), increasing to 55%–65.2% through the 7-y open-label treatment. The frequency of 1 new BILAG A or 2 new B flares with belimumab (all treatment arms combined) was 38% at 1 y (vs 44% with placebo), decreasing to 7.7% at 7 y. The frequency of all SFI flares was 84% (severe 17%) at 1 y (vs 85% [19%] with placebo), decreasing to 40.4% (2.1%) at 7 y. During the study, many patients with anti-double−stranded DNA at baseline became negative (45.8% at 7 y) and normalized complement (C3 66.0%; C4 71.4%). Of the 118 remaining patients on corticosteroids at baseline, corticosteroid use decreased (median reduction 55%; absolute reduction 3.7 mg/d at 7 y).

AE Incidence (rate per 100 patient-y) in Patients Treated With Belimumab[a]

	1 (0–1 y)	2 (1–2 y)	3 (2–3 y)	4 (3–4 y)	5 (4–5 y)	6 (5–6 y)	7 (6-7y)
				Interval[b]			
Patients, n (patient-y)	336 (320.1)	339 (299.1)	274 (258.1)	248 (234.2)	223 (215.8)	208 (197.6)	190 (167.0)
Overall AEs	326 (101.8)	322 (107.7)	260 (100.8)	237 (101.2)	211 (97.8)	191 (96.7)	172 (103.0)
Serious AEs	55 (17.2)	52 (17.4)	49 (19.0)	31 (13.2)	41 (19.0)	32 (16.2)	30 (18.0)
Overall infections	254 (79.4)	237 (79.2)	192 (74.4)	181 (77.3)	145 (67.2)	126 (63.8)	128 (76.6)
Serious infections	17 (5.3)	14 (4.7)	8 (3.1)	8 (3.4)	6 (2.8)	8 (4.0)	5 (3.0)
Malignancies[c]	0	3 (1.0)	2 (0.8)	1 (0.4)	3 (1.4)	2 (1.0)	1 (0.6)
Mortality	3 (0.8)	0	1 (0.4)	1 (0.4)	0	0	2 (1.2)

[a]Data presented as no. of patients with AE (no./100 patient-y) unless specified; [b]interval 1 includes only patients treated with belimumab (and not placebo) during the 52-wk, double-blind study (except mortality data includes 2 deaths during the 52-wk, double-blind period and 1 during the extension period); intervals 2–7 (and interval-1 mortality data; n = 424; 374.0 patient-y) include all belimumab-treated patients, including those originally randomized to placebo who subsequently switched to belimumab; [c]excluding nonmelanoma skin cancer and including unspecified malignancy of lungs.

Conclusion: Belimumab plus standard SLE therapy was well tolerated in SLE patients for 7 y in an open-label study. Seven patients died; no cause predominated. Autoantibody-positive patients treated with belimumab had sustained improvement in disease activity and decreased flares over 7 y, accompanied by reductions in autoantibody levels and corticosteroid requirements.

Efficacy and Safety of Rontalizumab (Anti-Interferon Alpha) in SLE Subjects with Restricted Immunosuppressant Use: Results of A Randomized, Double-Blind, Placebo-Controlled Phase 2 Study. K. Kalunian[1], Joan T. Merrill[2], R. Maciuca[3], Wenjun Ouyang[3], J. M. McBride[3], Michael J. Townsend[3], E. Park[3], J. Li[3], X. Wei[3], A. Morimoto[3], R. Boismenu[3], John C. Davis Jr.[3] and William P. Kennedy[3]. [1]UCSD School of Medicine, La Jolla, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Genentech, Inc, South San Francisco, CA

Background/Purpose: Dysregulation of interferon alpha (IFN) activity and/or signaling is implicated in systemic lupus (SLE). This randomized, double-blind, placebo-controlled, two part Phase 2 study (ROSE) evaluated the efficacy and safety of intravenous (IV) and subcutaneous (SC) rontalizumab, a humanized IgG1 antibody against all anti-interferon alpha isoforms, in adults with moderate to severe extrarenal SLE.

Methods: Subjects were randomized 2:1 in sequential cohorts to: 750 mg IV q4wk rontalizumab or placebo (pbo) (part 1) and 300 mg SC q2wk rontalizumab or pbo (part 2). Immunosuppressants were stopped at randomization, and steroids were to be tapered to ≤10mg/day by Week 8. Rescue therapy was allowed for worsening of disease but defined as treatment failure. Efficacy endpoints included reduction in disease activity by the BILAG (primary), and the SLE Response index (SRI, secondary) at week 24. Exploratory measures included the **I**nterferon **S**ignature gene expression as **M**etric (ISM) at baseline. Pharmacokinetics (PK) and immunogenicity of rontalizumab were assessed.

Results: 159 subjects received rontalizumab (81 IV and 78 SC) and 79 received pbo. Subjects were 94% female with mean age of 39 years. At baseline, the mean SELENA-SLEDAI (SS) was 9.8, and the most common disease manifestations involved musculoskeletal and mucocutanenous systems. 76% of subjects were ISM-High. Baseline disease activity was comparable in ISM-High and ISM–Low subjects except for higher likelihood of autoantibodies and low complement in ISM-High subjects vs ISM-Low: (anti-dsDNA 71% vs 34%, anti-ENA 73% vs 19% and low C3 43% vs 16%, respectively). Overall, response rates by BILAG and SRI were similar between rontalizumab and pbo groups. However, rontalizumab vs pbo SRI response was 55% vs 31% in those on >10 mg prednisone at baseline (56% vs 23% and 54% vs 38% in the IV and SC groups, respectively). In a biomarker-defined pre-specified subgroup, ISM-Low subjects, rontalizumab vs pbo SRI response rates were 75% vs. 18%, and 75% vs. 62% in the IV and SC groups, respectively. The estimated treatment difference of SRI response in rontalizumab and pbo ISM-Low arms was 31% (90% CI: 9–51%, p=0.0285). A reduction in SS flare rates occurred in rontalizumab subjects vs. pbo: hazard ratio 0.61 (0.46–0.81, p=0.0040), driven by ISM-Low subjects. A greater percentage of subjects achieved prednisone reduction (≤10 mg/day) by week 24 in the rontalizumab ISM-Low group: 91% vs. 67% pbo. Incidence of adverse events (AE) was comparable between pbo and rontalizumab-treated subjects. The most common AEs were UTI, URI, headache, and nausea. There were more SAEs from SLE flares in the active group (n=10, 6%) vs. pbo (n=1, 1%), which occurred only in ISM-High subjects. Treatment emergent anti-therapeutic antibodies were uncommon (1/159, 0.6%) and did not appear to affect safety or PK.

Conclusion: Rontalizumab treatment in the absence of immunosuppressants was associated with improvement in signs and symptoms of SLE, flare rates and steroid burden at week 24 in a pre-specified biomarker defined group of ISM-Low moderate to severely active lupus subjects.

Taking Charge of Systemic Sclerosis: A Pilot Study of an Internet Self-Management Program. Janet L. Poole[1], Dinesh Khanna[2], Betty Skipper[3] and Cindy F. Mendelson[1]. [1]University of New Mexico, Albuquerque, NM, [2]University of Michigan, Ann Arbor, MI, [3]University of New Mexico, NM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease with serious implications for quality of life. The disease is challenging due to the variable course and potential for disability and morbidity. Persons living outside major metropolitan areas may be emotionally and geographically isolated from support groups, knowledgeable rheumatologists and other health professionals, and disease self-management education. We did a small study of 5 months duration to convert a previously developed self-management program to an internet format and pilot test the effects of the program on self-efficacy, health efficacy, management of care, pain, fatigue, functional ability and depression.

Methods: The intervention program consisted of an internet program with modules on scleroderma, coping, self-advocacy, fatigue and energy conservation, activities of daily living, mouth and teeth care, digestive tract

(including dysphagia), Raynaud's phenomenon, and exercises for the face, hands, arms and legs. Participants logged on to a password protected website and proceeded through the modules and learning activities at their own pace over 10 weeks. Participants were encouraged to log on to the discussion board, an interactive component of the website, and respond to questions posted for each module. Participants completed pre and post intervention questionnaires on perceived self efficacy (CDSES), health efficacy (heiQ), ability to manage care (PAM), functional disability (HAQ-DI), depression (CES-D), and pain and fatigue VAS's. T-tests analyzed differences in scores between the pre and post intervention questionnaires. Participants also completed an 8 question evaluation form about their satisfaction with the web site, program content, discussion boards and learning activities.

Results: Twenty one participants, recruited from the National Scleroderma Foundation website and a state chapter, completed baseline measures. Thirteen participants completed the study and completed post intervention measures. There were no demographic differences between people who participated vs. did not participate in the internet program. Of the participants who completed the program, the mean age was 52 years with mean disease duration of 7 years and mean education level of 16 years. Eighty four percent were female, 92% Caucasian, and 77% were married. Significant improvements were seen in mean scores for self-efficacy ($t = 2.31$; p =.039), ability to manage care ($t = 2.82$; p =.016), and health efficacy ($t = 2.28$; p =.042). Scores for pain and fatigue, functional ability and depression improved but not significantly. The evaluation of the program revealed mean scores ranging from 4.1 (action plans contributed to learning) to 4.9 (information presented clearly) on a 5 point scale.

Conclusion: The preliminary findings suggest that a self-management program delivered using an internet format can lead to statistically significant improvements in self efficacy, health efficacy, and ability to manage care. These results need to be confirmed with a larger randomized controlled trial with a longer follow-up period.

Changes in Leisure Participation in Persons with Systemic Sclerosis. Cindy F. Mendelson, Jessica Greaves and Janet L. Poole. University of New Mexico, Albuquerque, NM

Background/Purpose: Little attention has been devoted to understanding the difficulties and limitations people with systemic sclerosis (SSc) experience with leisure participation. A qualitative interview study was conducted to understand the barriers people with SSc experience participating in and selecting leisure activities.

Methods: Twenty-five people with SSc who met inclusion criteria were selected based on self-reported difficulty with leisure and willingness to participate in the study interview.

Interviews were conducted over the telephone and followed a semi-structured format. Interview questions focused on the meaning of SSc, leisure activities and the importance of those activities, the influence of SSc on leisure activities, and adaptations used to engage in leisure activities.

Interviews were transcribed verbatim. The major interview questions were used as a framework to guide the analysis. A research journal was used to track and identify thematic concepts as they emerged from the data set. An additional document was created to manage the quotes that immediately drew the attention of the analyst in order to prevent initial bias in forming core themes. After analyzing the major questions separately, the over-arching concepts were compared for redundancy or outliers. Attending to rigor was an important consideration. One analyst (JG) analyzed the data set and the research team members then reviewed the themes for clarity, redundancy, and that it was representative of the participants' voices. In order to avoid common pitfalls, qualitative analysis hazards such as premature closure, misinterpreting frequency, over-inscription of self, and capitalizing on outliers, were closely attended to.

Results: The participants were 92% female, 88% were white, mean age was 54 years, mean disease duration was 12 years, mean education level was 16 years, 100% of the participants reported Raynaud's Phenomenon, 73% had digital ulcers, and 96% reported GI involvement.

Three themes emerged from the analysis. *Barriers to Leisure Participation*, describes the challenges people with SSc experience when selecting and participating in leisure activities. *Decrease in Leisure Participation*, reflected a change in the amount of time spent participating in leisure activities. *Experience of Losing a Valued Leisure Activity*, showed the impact that loss

of leisure activities had on some participants' mental health and social engagement.

Conclusion: Our study found that the barriers to leisure participation reported by participants with SSc were similar to those reported in the literature by people with RA, except people with SSc experienced an additional barrier of Raynaud's phenomenon.. In conclusion, SSc disease symptoms affect the amount and types of leisure activities in which people with SSc participate.

The Impact of Sexual Difficulties in Women with Scleroderma and Interpersonal Relationships. Tanaka Ngcozana[1], Louise Parker[1], Christopher P. Denton[2] and Voon Ong[3]. [1]UCL Medical School and Royal Free Hosp, London, United Kingdom, [2]UCL, London, United Kingdom, [3]UCL Medical School, London, England

Background/Purpose: Sexual problems are common in women with systemic sclerosis (SSc). SSc is a complicated condition linked to a number of complications including sexual dysfunction. Sexuality is a vital part of life and it is a subject not usually broached. The aims of this study were to determine the prevalence of sexual problems in a large cohort of women with SSc, to evaluate the effects on sexual relationship, sexual activities and the difficulties faced by the women.

Methods: A total of 100 women with either limited (lcSSc) or diffuse (dcSSc) systemic sclerosis were invited to participate in a questionnaire survey. Each participant completed the validated Female Sexual Function Index (FSFI) questionnaire that assesses six domains: desire, arousal, lubrication, orgasm, satisfaction and pain. Additional psychological questions were included to examine sexual difficulties faced by the women in their interpersonal relationships.

Results: 50 women with SSc responded to the questionnaire. Mean age of the cohort was (mean ±SD, years) 56 ±1.41. 52% of the women who responded had diffuse subset while 40% had been diagnosed with the limited disease. The mean disease duration is similar for both subsets with (mean ±SD, years) 12±2.8.54% of the patients developed sexual difficulties after their diagnosis and the mean duration from SSc diagnosis to first sexual complaint was (mean, ±SD, years) 4.0±5.8.84% of the patients reported significant sexual problems in the overall FSFI domains. The pain domain fared the worst with 56% and 40% of the respondents did not have any sexual activity due to lack of lubrication. 60% of the patients revealed that their sexual complications had caused a significant strain in their relationships. 30% of the respondents admitted to not discussing their problems with their partners due to embarrassment, nonetheless 46% of the women reported to discussing the difficulties. Among those who discussed their problems with their partners 32 (64%) reassuringly stated that their partners understood the problems. 76% of the subjects reported that they had never been asked about sexual functioning by a health professional. However 52% revealed that they would have discussed their sexual problems if they were concerned, 38% would approach the nurse with their problem while 36% would discuss with their medical practitioners. Interestingly 72% of these women admitted to not raising any concern about their sexual problems.

Conclusion: Sexual functioning is an essential aspect of life for women with SSc. Our study revealed that most of the respondents had some form of significant sexual problems. It also showed that sexual impairment can have a significant negative impact for the affected women and their partners. Sexual health is a subject that is usually neglected by both patients and doctors yet it has been associated with psychological difficulties such as depressive symptoms. It is a subject worth exploring and actively enquiring in order to provide holistic care and improve our patients' quality of life.

The Utility of the Patient Health Questionnaire-9 to Assess Suicide Risk in Patients with Systemic Sclerosis. Ilya Razykov[1], Marie Hudson[1], Murray Baron[2] and Brett D. Thombs[1]. [1]McGill University, Montreal, QC, [2]Jewish General Hospital, Montreal, QC

Background/Purpose: Depression is common in rheumatic diseases, including systemic sclerosis (SSc). In the general population, depression is

associated with suicidal ideation, attempts and completion. The Patient Health Questionnare-9 (PHQ-9) is a self-administered and easily scored measure of depression symptoms that is increasingly used in medical settings. Item 9 of the PHQ-9 has been used in several studies, including with arthritis patients, to assess the prevalence of suicidal ideation. Item 9 asks patients "How often have you been bothered by thoughts that you would be better off dead or of hurting yourself in some way?" The item is ambiguous, however, because it includes both passive thoughts of death and more active ideas of self-harm. As a result, some researchers have advocated using the PHQ-8, which does not include Item 9. Thus, the objectives of this study were (1) to determine the proportion of SSc patients who responded anything other than "never" to Item 9 who endorsed active suicidal ideation in response to more direct questions during a structured clinical interview and (2) to assess the association between the PHQ-9 and the PHQ-8, which does not include Item 9.

Methods: Canadian Scleroderma Research Groups Registry patients were administered the PHQ-9 and the Composite International Diagnostic Interview (CIDI) depression module in a phone interview. Item 9 responses were compared to suicidal ideation and intent in the last year based on the CIDI. PHQ-8 scores were calculated by subtracting Item 9 scores. The association between the PHQ-9 and the PHQ-8 was computed using the Pearson correlation coefficient.

Results: Of 313 patients in the study, 30 (6.9%) screened positive for suicidal ideation on the Item 9. Of those, only 1 (3.3%) had thought about suicide in some detail as assessed by the CIDI at any time in the past year. No patients had an active suicide plan at the time of the interview. Correlation between PHQ-9 and PHQ-8 scores was r=0.998.

Conclusion: Item 9 does not appear to be an effective suicide screen. There is currently no evidence that screening for suicidality would prevent suicidal behaviour. If researchers or clinicians do screen for suicidality, direct questions about suicide should be asked. The PHQ-8 may be a better option than the PHQ-9 for assessment of depressive symptoms in SSc patients given the high association with the PHQ-9 and the ambiguous nature of Item 9.

Disclosure: I. Razykov, None; **M. Hudson**, None; **M. Baron**, None; **B. D. Thombs**, None.

Gender Differences of Concepts Important to People Living with Crohn's Disease and Their Coverage by Commonly Used Patient-Reported Outcome Instruments: Patient's Perspective Elevated by a Qualitative Study.
Mona Dür[1], Michaela Coenen[2], Josef S. Smolen[3], Clemens Dejaco[1] and Tanja A. Stamm[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Ludwig-Maximilians-University, Munich, Germany, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Crohn's disease (CD) has a major impact on functioning, health and well-being and patient-reported outcome (PRO) instruments have not been analysed from the perspective of patients with CD so far. The clinical setting often restricts the opportunities to focus on other health determining concepts aside disease activity. We aimed to explore which concepts determining health in a positive way are important to patients with CD, their coverage by patient-reported outcome instruments and to recommend appropriate ones for the future.

Methods: A qualitative study was conducted: Told life stories were analysed by the biographical narrative interpretative method, findings were linked to concepts determining health in a positive way. Furthermore the qualitative data were analysed regarding gender differences. Two systematic literature searches were done to identify relevant concepts and clinically relevant PROs. Concepts and the items of the PROs were linked to WHO International Classification of Functioning, Disability and Health (ICF) codes and compared to evaluate instruments' coverage.

Results: 15 people with CD with a median age of 46 years (IQR 34–60) and median disease duration of 15 month (IQR 8–30) participated. 14 participants mentioned self-efficacy, social support (93%) and 13 described job satisfaction (87%) as being important which were the three commonest concepts. Most of them experienced relations between their health behaviour and disease course, and tried to "gain control over their disease" by being self-efficient. While participation had more meaning for men, appreciation and resilience was more important for women. Work-life balance and secondary illness gain was hardly meaningful. The 9 patient-reported outcome tools (see table 1) covered 9 different ICF codes (see table 2).

Table 1. Characteristics of the identified patient-reported outcome instruments

Abbr.	Patient-reported outcome instrument	Content	Items	Response options	Time frame
BDI-II	Beck Depression Inventory-II	Depression	21	4 statements: increasing severity	Past, present, future
ESSI	ENRICHD Social Support Scale	Extent of social Support	7	Question 1-6 (None, a little, some, most or all of the time), Question 7 (yes/no)	present
HADS	Hospital Anxiety and Depression Scale	Anxiety, depression	14	Frequency: 4-point Likert scale (0=not at all, 4=definitely)	present
IBDQ-32	Inflammatory Bowel Disease Questionnaire	Health related quality of life	32	7 point Likert scale (1 = significant impairment, 7 = no impairment)	2 weeks
PSQ-R	Perceived Stress Questionnaire Recent	Perceived stress	30	4-point scale on frequency (1=almost never, 4=usually)	month
RFIPC	Rating form of Inflammatory Bowel Disease Patient Concerns	Worries, concerns regarding IBD	25	Visual analogue scale (0 = Not at all, 100 = A great deal)	present
SF-36	Short Form 36	Health related quality of life	36	Different response scales	4 weeks
SIBDQ	Short Inflammatory Bowel Disease Questionnaire	Quality of life	10	7-point Likert scale on frequency (1=all of the time, 7=none of the time)	2 weeks
STAI	State-Trait Anxiety Inventory	Anxiety about an event, and trait anxiety	40	Intensity 4-point Likert scale (1=not at all, 4 very)	Present

Table 2. Coverage of the linked concepts by patient-reported outcome tools

Concepts of health and wellbeing	ICF Codes	ICF Title	BDI	ESSI	HADS	IBDQ-32	PSQ-R	RFIPC	SF-36	SIBDQ	STAI
Coping	d240	Handling stress and other psychological demands	+				+				
Participation (societal)	d9	Community, social and civic life				+			+	+	
Reflecting about one's life in an optimistic way	b126	Temperament and personality functions			+		+	+			+
	b1265	Optimism			+		+				
Resilience	b1263	Psychic stability			+		+	+			+
Self-efficacy	b1641	Organization and planning									
	d177	Making decisions					+				
Social acceptance	e4	Attitudes	+			+		+			
Social support	e3	Support and relationships	+	+			+				

Conclusion: This is the first study elaborating the coverage of patient's perspective by commonly used patient-reported outcome instruments. The use of the *perceived stress questionnaire – recent* is recommended because it covered most concepts, as well as the use of *inflammatory bowel disease self-efficacy scale* due to the importance of self-efficacy for people with CD. Social support, self-efficacy and gender differences at several concepts should get more attention in clinical daily routine and in the research of people living with CD.

The Lumbo-Pelvic Muscles and Axial Spondyloarthritis: A Pilot Observational Study.
Janet Millner[1], Julie A. Hides[2], Patricia Lewis[3] and Jane Zochling[3]. [1]Royal Hobart Hospital, Hobart, Australia, [2]Australian Catholic University, Brisbane, Australia, [3]Menzies Research Institute Tasmania, Hobart, Australia

Background/Purpose: The importance of a physical approach in the management of axial spondyloarthritis (SpA) has been recognised for many years. It is supported by level 1a evidence including the 2008 Cochrane review into the effectiveness of physiotherapy in ankylosing spondylitis (AS), and by expert panel recommendations such as those of the Assessment of Spondyloarthritis group. The benefits of exercise have been shown to be still relevant even in patients who are stabilised with TNF blocking medication, and both subjective and measurable benefits can be much larger than that seen for other types of arthritis, and also non-inflammatory back pain. Despite this, there is a paucity of information about why exercise can be so beneficial, and about the specifics of exercise prescription. The aim of this study was therefore to provide pilot morphological data regarding any changes in lumbo-pelvic muscles, which may inform exercise prescription, and indicate further areas for research.

Methods: Twenty-three subjects with confirmed SpA or AS underwent an MRI scan of the lumbar spine and pelvis. The protocol aligned the transverse imaging plane with inferior aspect of the body of the 4th lumbar vertebra, in order to obtain measures of the cross sectional area (CSA) of specific lumbo-pelvic muscles. The digitised images were analysed by computer software to determine muscle size, symmetry and ratio of contractile to non-contractile tissue, using previously validated methods.

Results: Non-contractile tissue was observed within the fascial boundaries of the paraspinal muscles to some degree in all subjects. These changes were graded according to a previously validated five point scale as follows:

Number of Spinal Levels	Lumbar Multifidus		Lumbar Erector Spinae	
	Subjects ≥ Grade 2− n	Subjects ≥ Grade 2− %	Subjects ≥ Grade 2− n	Subjects ≥ Grade 2− %
0	0	0%	3	13%
1	8	35%	8	35%
2	8	35%	8	35%
3	3	13%	1	13%
4	1	4%	1	13%
5	3	13%	n/a	n/a

The prevalence of non-contractile tissue was not associated with measures such as body mass or metrology indices, but was inversely associated with self-reported physical activity levels (p). Additional measures of lumbar multifidus CSA at L5/S1 level demonstrated a mean functional to total muscle CSA of only 61% (range 18–88%).

Conclusion: This study provides new information on the morphology of the lumbo-pelvic muscles in SpA, and also confirms the applicability of this methodology in inflammatory back pain. The association of reduced functional muscle area with lower activity levels supports the concept of a specifically designed exercise intervention. Similar findings have been noted in non-inflammatory back pain, but points of difference are highlighted that need exploring. The study has therefore revealed some research gaps regarding muscle changes in SpA, which may be either secondary to the disease or part of the process.

Associations of Current and Early-Life Socioeconomic Positions with Risk of Self-Reported Doctor-Diagnosed Arthritis in a Family-Medicine Cohort of North-Carolinians. Antoine A. Baldassari[1], Rebecca J. Cleveland[1] and Leigh F. Callahan[2]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill, NC

Background/Purpose: Socioeconomic position (SEP) across the lifecourse has been convincingly identified as a determinant of health. In particular, mounting evidence suggests that low current and childhood SEP are associated with higher risks of cardiovascular disease and autoimmune disorders. In contrast, relatively few studies have investigated the relationship between SEP and arthritis, with childhood SEP being particularly untested as a potential risk factor for the disease. The purpose of this study is to determine the associations of childhood and current SEP with the presence of arthritis.

Methods: Our data came from the North Carolina Family Medicine Research Network (NC-FM-RN), a practice-based research network of 22 family medicine practice selected to represent the geographic and racial/ethnic diversity of North Carolina. In 2006, the Individual and Community Social Determinants of Arthritis Outcomes study invited NC-FM-RN participants to complete a phone survey assessing demographics, health status, chronic health conditions, health attitudes and beliefs, and perceptions of neighborhood environment. Participants who provided complete sociodemographic and relevant health information were retained in our sample (n = 1302). We created three-levels (high[referent], medium, low) summary measures for current and childhood SEP accounting for education, homeownership and occupational class, using parental SEP as a proxy for participants' childhood SEP. Logistic regression models were

carried out to assess the associations between arthritis status and SEP variables separately and together, adjusting for known covariates.

Results: Our sample included 929 females (70.65%) and 210 males (29.35%). The mean age was 56.94 years old (23–94), and 782 respondents had self-reported doctor-diagnosed arthritis. 485 (37.25%) participants received a high current SEP summary score, while 578 (44.39%) had a medium current SEP and 239 (18.36%) a low current SEP. Summary scores were lower for the childhood SEP measure: 195 (14.98%) participants scored in the high childhood SEP level, 447 (34.33%) did in the medium level, and 660 (50.69%) had a low childhood SEP. Arthritis was more likely in participants with medium current SEP, OR=1.41 (95% CI=[1.06, 1.88]), and low current SEP, OR=1.96 (95% CI=[1.32, 2.90]) and somewhat more likely in respondents with low childhood SEP, OR=1.32 (95% CI=[1.02, 1.71]). Childhood SEP was not associated with arthritis in the model including both current and childhood SEP as explanatory variables, while current SEP remained significantly associated with arthritis at both the medium and low levels.

Conclusion: Our results suggest that while there was a robust association between current SEP and arthritis susceptibility in our sample, the association of childhood SEP with arthritis was relatively weak. Studies should investigate whether our results consistently appear in larger populations with clinically documented arthritis. Additionally, further research could focus on arthritis-type specific associations with SEP, considering the broad range of joint disease encompassed by arthritis.

Rheumatoid Arthritis and Osteoarthritis in the Population: How Different Is the Impact? Christina H. Chan[1], Mayilee Canizares[1] and E.M. Badley[2]. [1]Division of Healthcare Outcomes and Research, Toronto Western Research Institute, Toronto, ON, [2]Division of Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: It is a common perception that rheumatoid arthritis (RA) is a more severe and debilitating disease than osteoarthritis (OA); however, there have been many recent advancements in treatment for RA including development of biologics, while treatment of OA remains largely focused on joint replacement surgeries which are only appropriate for end-stage OA. A recent national survey of a representative sample of Canadians reporting arthritis provided an opportunity to compare individuals reporting RA who see a rheumatologist and individuals reporting OA. Our objective was to describe and compare the arthritis-related characteristics and health care use of individuals reporting RA and OA.

Methods: Data were obtained from the 2009 Survey on Living with Chronic Diseases in Canada which included detailed information on a sample self-reporting arthritis as a long term chronic health condition (n = 4,565). Data were obtained on demographic characteristics, lifestyle (smoking, alcohol, physical activity), type of arthritis, number and site of painful joints (16 sites), pain and fatigue (severity on 1–10 scale and frequency), limitations in 5 areas of daily activities, general health, health care use (health professionals seen in the past year, use of medication, assistive devices and receipt of information and other support services), and self-management of arthritis. Two groups were examined: individuals who reported RA and have seen a rheumatologist in the past year (RA), and individuals who reported OA.

Results: An estimated 0.5% of Canadians reported RA and 5.1% reported OA. Those with RA were more likely to have symmetrical arthritis than those with OA. The two groups were similar in demographic and lifestyle characteristics, and there were no significant differences in the number of joint sites affected (RA: 5.1 95% CI 3.9–6.4; OA: 4.6 95% CI 4.3–4.8), severity of pain or fatigue, frequency of fatigue, or having any activity limitations. Compared to RA, the OA group reported better self-rated health but more frequent joint pain. A higher proportion of the RA group reported seeing primary care physicians, orthopedic surgeons, physiotherapists, pharmacists and mental health professionals compared to the OA group. Those with RA were more likely to report taking prescription medication (RA: 83%; OA: 40%), using assistive devices, and receiving information on how to manage their arthritis. Individuals with RA were less likely to exercise or control weight for arthritis.

Conclusion: Overall, the impact of RA among those who reported seeing a rheumatologist was comparable to the impact of OA in this representative sample of Canadians. This similarity is surprising given that RA is often perceived as a more severe form of arthritis. The findings could be a reflection of the benefits of specialist care and hence pharmacotherapy and access to

other support for disease management for RA, and the lack of effective treatment for OA. The similar joint site count for RA and OA also suggests that further attention should be paid to OA as a polyarticular disease.

Radiographic Osteoarthritis Severity Is Associated with an Increased Risk of Developing Knee Pain: Findings From the Osteoarthritis Initiative. Jingbo Niu, David T. Felson, Tuhina Neogi and Yuqing Zhang. Boston Univ School of Medicine, Boston, MA

Background/Purpose: While knee pain is a major complaint from subjects with knee osteoarthritis (OA), most epidemiologic studies have found only weak to moderate associations between knee radiographic OA (ROA) and presence of knee pain. These findings may be partly due to confounding by variation of pain sensitivity and tolerance between subjects. In addition, few studies have prospectively assessed the relation of severity of ROA to the occurrence of knee pain. To avoid across person differences in pain reporting, we performed a within-person knee-matched cohort study to examine the relation of Kellgren/Lawrence (KL) grade and joint space narrowing (JSN) to the risk of developing knee pain among participants of the Osteoarthritis Initiative (OAI).

Methods: The OAI is a multi-center longitudinal study focusing primarily on risk factors for the onset and progression of knee OA. Subjects aged between 45–79 years were recruited at four centers across the US. At baseline and yearly follow-up visits knee-specific pain was assessed, including a question about presence of knee pain, aching or stiffness in more than half of the past 30 days ("frequent knee pain"). KL grade (0–4) and JSN (0–3 using the OARSI atlas) were scored on PA view knee radiographs by experienced readers blinded to the time sequence. Included were subjects who had no frequent knee pain in either knee and had unequal KL grade at the 12-month visit in their two knees. They were considered as having incident frequent knee pain if it occurred in any of the later annual follow-up visits. Within each subject we compared risk of incident frequent knee pain in the knee with higher KL grade vs. that in the contralateral knee with lower KL grade. The two knees within a subject formed a matched set. We examined the association between KL grade and incident frequent knee pain using a Cox proportional hazards regression model adjusting for history of knee injury. We took the same approach to assess the relation of maximal JSN score to risk of the incident frequent knee pain.

Results: Included were 1093 subjects who had no frequent knee pain and whose KL grades differed between two knees (mean age: 63.0, 52.4% women), and 712 subjects who had no frequent knee pain and whose JSN score differed between two knees (mean age: 63.8, 52.4% women) at 12-month visit. Higher KL grade was associated with an increased risk of incident frequent knee pain. Compared with knees with KL grade 0, the risk ratios of incident frequent knee pain were 1.2, 1.4, 2.3, and 3.3 for each increased grade of KL grade, respectively (p for trend <0.001). Similar association was observed for JSN (Table).

Table 1. Severity of knee ROA and incidence of frequent knee pain incidence (%) of frequent knee pain among knees with more severe / less severe ROA, N of eligible subjects

Knee with higher KL grade (more severe ROA)	Knee with lower KL grade (less severe ROA)				Adjusted RR (95% CI)	p-value
	0	1	2	3		
0	N/A	N/A	N/A	N/A	1.0	
1	27.0 / 21.5, 270	N/A	N/A	N/A	1.2 (0.9, 1.6)	0.118
2	26.8 / 20.0, 190	35.6 / 30.0, 247	N/A	N/A	1.4 (1.1, 1.9)	0.020
3	27.3 / 7.6, 66	61.7 / 31.7, 60	49.4 / 27.6, 156	N/A	2.3 (1.6, 3.4)	<.001
4	66.7 / 10.0, 30	44.4 / 22.2, 18	66.7 / 40.7, 27	72.4 / 37.9, 29	3.3 (1.9, 5.5)	<.001

Knee with higher JSN score (more severe ROA)	Knee with lower JSN (less severe ROA)			Adjusted RR (95% CI)	p-value
	0	1	2		
0	N/A	N/A	N/A	1.0	
1	28.1 / 25.3, 324	N/A	N/A	1.1 (0.9, 1.5)	0.276
2	43.0 / 19.5, 128	50.6 / 27.6, 156	N/A	2.0 (1.4, 2.8)	0.001
3	63.4 / 9.8, 41	58.8 / 41.2, 34	72.4 / 37.9, 29	2.9 (1.7, 4.8)	<.001

Conclusion: The radiographic severity of OA is strongly associated with an increased risk of frequent knee pain. Contrary to the so-called structure symptom discordance, there is a dose-responsive relationship between structure and symptoms when between-person confounding is appropriately accounted for.

Doing Is Believing: Health Beliefs Before and After an Exercised-Based Rehabilitation Programme for Chronic Knee Pain. Mike Hurley[1] and Dr Nicola E. Walsh[2]. [1]St George's University of London, London, United Kingdom, [2]University of the West of England Bristol, Bristol, United Kingdom

Background/Purpose: An integrated exercise-based rehabilitation programme, *Enabling Self-management and Coping with Arthritis knee Pain through Exercise (ESCAPE-knee pain)*, improves pain and physical disability of people with chronic knee pain. Qualitative interviews were used to understand how and why *ESCAPE-knee pain* works.

Methods: 29 people involved in the quantitative study evaluating the *ESCAPE-knee pain* programme, were interviewed before and after participation on the programme. Semi-structured interviews were used to explore participants' experiences of living with knee pain, their understanding and beliefs about their condition, and management strategies adopted. The same participants were re-interviewed after completing the programme to explore their experiences of the programme, its impact on their beliefs about knee pain and their views about the management of their condition. A thematic analysis was conducted. Interviews were audio taped, transcribed verbatim, read several times by two researchers independently to familiarise themselves with the data, met to identifying themes and agree a coding scheme and resolve differences in coding and interpretation.

Results: Initially people had poor understanding and negative, fatalistic beliefs about the management or prognosis for knee pain. Following the programme the majority of participants had positive experiences, improvement in pain, physical and psychosocial functioning, greater knowledge and understanding of their condition and treatment options, and in their ability to use exercise to control symptoms. Beliefs about the causation and prognosis of knee pain were unchanged, but concerns about possible dangers of exercise decreased. They appreciated how exercise could reduce symptoms (treatment beliefs) and their confidence in their ability to use exercise to control symptoms (exercise self-efficacy) increased. These improvements were attributed to the content and structure of the programme, and the care and guidance of the physiotherapist.

Conclusion: *ESCAPE-knee pain* improves physical and psychosocial functioning of people with chronic knee pain by increasing people's treatment belief in safety, the utility of exercise to control symptoms and exercise self-efficacy, rather than alteration in their beliefs about causation or prognosis.

Independence At Home: Real or Perceived. Hazel L. Breland. Medical University of South Carolina, Charleston, SC

Background/Purpose: Rheumatic conditions are more prevalent among women than men and increase with age. Over 4 million African Americans affected are by rheumatic conditions and yet disparities and underrepresentation of this group exist in research studies. The burden of physical disability confronting older African American women can affect their ability to engage in everyday activities. Thus, performance-based data are needs in the home environment where effective patient management and aging in place occurs. However, differences exist between self-report and performance-based data. Therefore, the purpose of this descriptive, non-intervention study uses mixed methods to identify the degree of concordance between self-reported performance capabilities and real-time performance of criterion-referenced task situations within the home environment.

Methods: Eighteen community-dwelling African American females with rheumatic conditions (age 64.7, widowed = 38.9%, living with family = 50%, self-reported quality of life = "good") participated in brief qualitative interviews on the perception of participation in daily activities and home safety. During the in-home assessment, participants completed demographic questionnaires, the PASS-SR (self-report of performance capabilities, what they "could do" compared to what they "routinely do", and the PASS-Home (observational data of real-time performance of 26 criterion-referenced, standardized task situations). The PASS-Home includes 4 domains: basic ADL (dressing), physical and cognitive instrumental ADL (IADL-physical: sweeping & IADL-cognitive: managing home safety), and functional mobility (indoor walking). The interviews were audio-recorded and transcribed verbatim. Content analysis was used for initial codes and summary statements were generated for each code. Based on summary statements data were

aggregated into eight key themes. Data from the interviews, PASS-SR, and PASS-Home were integrated. Concordance was defined as the percent agreement between self-reported capability (PASS-SR) and performance-based (PASS-Home) data of task situations.

Results: Generally, participants reported that physical factors of rheumatic conditions negatively affected their lives with regard to symptoms triggers, physical problems, limitations on their activity, and safety concerns. Chores, daily living, and movement were the most prominent symptoms triggers. The primary safety concerns included falling, difficulty-using hands, and lack of proper safety equipment. Percent agreement between self-reported capability on the PASS-SR and performance-based data of the task situations (PASS-Home) ranged from 22.2% (4 of 18) for functional mobility-stair use to 94.4% (17 of 18) for IADL (current event) obtaining critical audio information from the media and IADL (money management) checkbook balancing. There were 9 of 26 task situations with less than 50% concordance.

Conclusion: Using mixed methods, we were able to examine real and perceived performance patterns among older African American women with rheumatic conditions. Participant perceptions of their independence were typically underestimated for functional mobility and physical IADL.

Physical Disability, Perceived Dependence and Depression in Older Women with Osteoarthriti. Kisoo Park[1], Monique A. Gignac[2] and E. M. Badley[3]. [1]Gyeongsang National University, Jinju, South Korea, [2]Arthritis Community Research and Evaluation Unit, Toronto Western Research Institute and University of Toronto, Toronto, ON, [3]Division of Health Care and Outcomes Research,Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON

Background/Purpose: Older women with osteoarthritis (OA) often report difficulty with tasks and needing to rely on others for assistance. In addition, depressed mood has been observed among individuals with arthritis. However, there is little research examining relationship physical disability and the perception of dependence with depression among women with arthritis. This study assessed whether both physical disability and perceived dependence relate to depression or whether perceived dependence in personal care activities, household activities, community mobility and valued activities is an intermediate step in the relationship between physical disability and depressive symptoms.

Methods: Data come from a cross-sectional survey of 209 women, aged 55 or older, with osteoarthritis (OA). Physical disabilities were examined in four domains: personal care, household activities, community mobility and valued activities. Perceived dependence was asked in each domain using the question 'Thinking about these activities, to what extent do you feel dependent?'. Responses were on a 5-point scale from 0 = 'not at all' to 4 = 'a great deal'. Depression was assessed using the Center for Epidemiological Studies—Depression Scale (CES-D). Mediation analyses occurred in four step and included regression analyses as outlined by Baron and Kenny.

Results: On average, participants reported mild or moderate disability and perceived dependence. 28.7 % of participants reported a depression score ≥ 16, which indicates depressive symptomotology. The results from step 1 show that, greater difficulty with each domain of physical disabilities was significantly related to greater perceived dependence. In step 2, greater perceived dependence was significantly associated with greater depressive symptoms in all domains. Step 3 analyses showed that greater physical disabilities in each domain were significantly associated with depression. The final step testing mediation indicated that personal care activities, household activities and community mobility were fully mediated by perceived dependence. That is, once dependence was taken into account, the relationship between physical disabilities and depression was no longer significant. Partial mediation was found for dependence and valued activity limitations. Both were significantly related to depression.

Conclusion: It is important to take into account the experience of perceived dependence as a mediator in understanding the relationship between disability and depression in the domains of personal care, household, and community mobility. However, for valued activities, both disability and perceived dependence are important in understanding depression. This may be because valued activities are discretionary and reflect a person's identity (i.e., what's important to them). Also, they are not always activities where others can provide assistance, making perceptions of dependence less relevant. To conclude, these findings point to the importance of taking into account an individual's reaction to their disability rather than just focusing on the severity of disability

Exploring the Influence of Patient Perceptions On Medication Escalation in Daily Practice. Jos Hendrikx, Wietske Kievit, Jaap Fransen and Piet L.C.M. van Riel. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: In rheumatoid arthritis (RA), patients' and physicians' perceptions of disease can differ and patients who are satisfied with their health do not tend to agree with escalation of drug therapy, even if disease activity is not low. It is hypothesized that patient acceptable symptom state, as well as perceived and expected change, influence patients' willingness to alter therapy, in addition to disease activity state.

Objective: To investigate the influence of patient perceptions and disease activity on escalation of drug therapy in RA patients.

Methods: Consecutive RA patients attending the outpatient rheumatology clinic received standard clinical assessment including the DAS28 and medication changes. In addition, patients were asked 4 items regarding: perceived health state transition, satisfaction with their health state, willingness to change therapy and expected health state transition until the next visit. To investigate explanatory factors, logistic models predicting actual escalation of medication in daily practice and predicting patients' self-reported willingness to escalate therapy were fitted by means of forward selection. Predictors for the models were: sex, age, rheumatoid factor, disease duration, DAS28 response since last visit, attained DAS28 level and the above mentioned patient perception items. Escalation of DMARD or biologic medication was defined as an increase in frequency and/or dose of medication, or starting a new one, between the current and next visit.

Results: In total 422 RA patients; 63.3% female, 67.1% rheumatoid factor positive were included in the analysis. Mean (SD) DAS28 at visit, age and disease duration in years were: 3.09(1.24), 58.6(12.95), 9.72(9.25), respectively. In total 185 (43.8%) patients had a DAS28>3.2, of whom 96 (59.1%) were satisfied with their health status if this would not change until the next visit, and a majority of patients 132 (71.4%) did not want to change their medication. Table 1 shows the final model for therapy escalation with a clear independent relationship of patient reported willingness to escalate therapy. Table 2 shows the model with willingness to escalate therapy as the outcome. All patient perception measures exhibited significant independent associations, of which patient satisfaction was strongest. Figure 1 shows a model of medication escalation in daily practice.
Conclusion: Patients' willingness to escalate therapy is strongly associated with actual escalation of therapy in daily practice, independent of clinical parameters. In turn, patients' willingness to escalate therapy is primarily associated with patients' satisfaction with their health state, perceived change and expected change. Treat to target interventions should address patients' perceptions of their disease, and the related health goals patients aim to achieve, next to the level of disease activity attained.

2636

Understanding Why Treat-to-Target Strategies Are Difficult to Follow.
Liana Fraenkel[1], Meaghan Cunningham[2] and Paul Falzer[3]. [1]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT, [3]VA Connecticut Healthcare System, New Haven, CT

Background/Purpose: Treat-to-target (T2T) refers to a set of decision strategies widely advocated for the optimal management of rheumatoid arthritis (RA). Despite considerable evidence that this approach leads to improved outcomes, T2T strategies are not consistently adopted. We hypothesize that patients' experience of illness complicates the decision to adjust treatment when indicated by recommended thresholds. While disease activity thresholds assess a single reference point (current level of disease activity), patients' appraisal of their illness depends on multiple reference points. Therefore, in addition to current experience, we also examine past and future reference points, i.e., how current illness compares with recalled past experience and the difference between current and expected future health states.

Methods: We conducted a prospective, repeated measures study in which 142 RA patients (mean age: 59, 86% female) were interviewed at baseline, 2, 4, and 6 months. Disease activity was measured using the RAPID-4. Patients' current experience was measured using current (8-item Brief Illness Perception Questionnaire), past (recent change in illness severity measured on a 5-point Likert scale) and future (discrepancy between the patient's current and desirable health states measured on an 11-point numeric rating scale) reference points. We used generalized estimating equations to examine illness perception items, recent change, and discrepancy as main effects and in combination with disease in predicting treatment adjustment. Models are adjusted for age, education, income, duration, and biologic use.

Results: We found that disease activity, three illness perception factors: illness consequences, concern, emotional impact and both past and future reference points predict future treatment adjustments. These illness experience factors are also significant as interactions and the interaction model provided a slightly better fit (QICC index) than the main effects model indicating that the combination of disease activity and the three temporal reference points predicts future treatment adjustments better than disease activity alone.

Table 1. Main Effect Model

Table 2. Interaction Model

Independent variables	Beta	Std error	OR	Lower	Upper	Wald chi square	p	QICC
Illness perceptions								
Consequences	**0.03**	**0.01**	**1.03**	**1.01**	**1.05**	**10.20**	**0.001**	**263.58**
Timeline	0.02	0.01	1.02	1.00	1.04	2.86	0.091	268.94
Control	0.00	0.02	1.00	0.97	1.03	0.06	0.810	271.34
Treatment	0.01	0.01	1.01	0.99	1.02	0.73	0.393	270.68
Identity	**0.03**	**0.01**	**1.03**	**1.01**	**1.04**	**8.00**	**0.005**	**265.32**
Concern	**0.03**	**0.01**	**1.03**	**1.01**	**1.05**	**9.10**	**0.003**	**263.92**
Understanding	0.02	0.01	1.02	1.00	1.05	3.76	0.052	267.12
Emotional response	**0.03**	**0.01**	**1.03**	**1.01**	**1.05**	**11.74**	**0.001**	**262.99**
Reference points								
Perceived change	0.06	0.02	1.07	1.03	1.11	10.37	0.001	263.37
Discrepancy	0.03	0.01	1.03	1.01	1.05	11.17	0.001	264.12

Conclusion: These findings indicate that recommended T2T thresholds may not adequately reflect thresholds used clinical practice. Physicians likely take patient experience of their illness into account in making treatment recommendations, making it more difficult to consistently adhere to T2T thresholds. Understanding the factors that impact on decision making, may help modify T2T strategies to improve their uptake and ultimately improve patient outcomes.

2637

Cost-Effectiveness and Cost-Utility Analysis of Treat-to-Target Versus Usual Care in Early Rheumatoid Arthritis: Results of the Dutch Rheumatoid Arthritis Monitoring Registry.
Marloes Vermeer[1], Wietske Kievit[2], Ina H. Kuper[3], Annemarie Braakman-Jansen[4], Hein J. Bernelot Moens[5], Theo R. Zijlstra[6], Alfons A. den Broeder[7], Piet L.C.M. van Riel[2], Jaap Fransen[2] and Mart A.F.J. van de Laar[1]. [1]University of Twente & Medisch Spectrum Twente, Enschede, Netherlands, [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Medisch Spectrum Twente, Enschede, Netherlands, [4]University of Twente, Enschede, Netherlands, [5]Ziekenhuisgroep Twente, Hengelo, Netherlands, [6]Isala Klinieken, Zwolle, Netherlands, [7]Maartenskliniek, Nijmegen, Netherlands

Background/Purpose: Treat-to-target (T2T) has proven to be more effective in achieving remission in early rheumatoid arthritis (RA) patients than usual care [1]. However, T2T has not been fully implemented in daily clinical practice yet. Moreover, it is unknown whether T2T is cost-effective. The objective was to analyze the cost-effectiveness and cost-utility of a T2T strategy aiming at remission (Disease Activity Score in 28 joints (DAS28) < 2.6) compared to usual care in early RA over the first two years of the disease.

Methods: Two early RA inception cohorts including patients who fulfilled the ACR 1987 criteria were compared. The T2T group (n=261) consisted of patients from the DREAM remission induction cohort and was treated according to a protocolized treatment strategy aiming at DAS28 remission. The usual care group (n=213) consisted of patients from the Nijmegen early RA inception cohort and was treated without DAS28-guided, protocolized treatment decisions. For both groups, direct medical costs were collected and compared with gain in effectiveness (DAS28 remission) and quality adjusted life years (QALYs) (EQ-5D utility estimated from the HAQ) over two years of follow-up.

Results: T2T produced a higher remission percentage (64.4% vs. 34.7%) and a larger gain in QALYs (median (IQR) 1.45 (1.24–1.55) vs. 1.39 (1.18–1.53), p=0.037) than usual care. The total mean (SD) costs per patient were € 4.791 (7.436) in the T2T group and € 3.727 (5.773) in the usual care group. The incremental cost-effectiveness ratio was € 3.591 per patient in remission. The incremental cost-utility ratio (ICUR) was € 19.410 per QALY. The figure presents the cost planes which show the relation between A) the differences in effectiveness and costs and B) the differences in utility and costs of T2T versus usual care. Anti-TNF therapy was given to more T2T patients (21.5% vs. 15.0%) and was prescribed earlier in the disease process, compared to usual care. Our data showed that after three years of follow-up, T2T probably becomes cost-saving.
Conclusion: This quasi-experiment showed that over the first two years of treatment, T2T is associated with higher costs but also with substantial higher effectiveness. We conclude that T2T is cost-effective in daily clinical practice.

Biologic Switching Among Patients with Rheumatoid Arthritis in the United States, 2004–2011. Ozgur Tunceli[1], Jeffrey R. Curtis[2], Tatia C. Woodward[3], Siting Zhou[1], Yen-Wen Chen[1] and Ancilla W. Fernandes[4]. [1]HealthCore, Inc, Wilmington, DE, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]MedImmune, LLC, Gaithersburg, MD, [4]MedImmune LLC, Gaithersburg, MD

Background/Purpose: While studies have assessed the efficacy of switching among biologic disease-modifying antirheumatic drugs (bDMARD), there is a lack of knowledge regarding the patterns of bDMARD use and switching in a real-world setting. The objective of this study was to describe and compare the characteristics and treatment patterns associated with RA patients who maintain their initial bDMARD (non-switchers) to: [1] patients that cycle from one anti–tumor necrosis factor (AT) to another and [2] patients that switch to a non-anti-TNF agent (NAT) in the year following bDMARD initiation.

Methods: Patients aged ≥18 with ≥1 diagnosis of RA between January 2004 and August 2011, from an administrative claims database, were included if they initiated a new anti-TNF treatment, did not have any bDMARD claims in the 12 months prior to bDMARD initiation, and were continuously enrolled for 12 months following bDMARD initiation. Patients who had ≥1 different bDMARD following initiation were classified as AT or NAT study group, depending on mechanism of action (MOA). AT and NAT groups were compared to non-switchers, using t-tests for continuous data and chi-square tests for categorical data. Cox Proportional Hazards model was used to examine time-to-discontinuation/switch while controlling for confounding factors.

Results: Among the 7,719 naïve bDMARD patients identified, 87% [n=6,698] maintained their initial bDMARD, 10% [n=792] cycled to a second AT and 3% [n=229] switched to a NAT.

Comorbidity profile of study groups was varied; the Deyo-Charlson Comorbidity Index for non-switchers [1.59] was higher than the AT group [1.49; P=0.033] and lower than the NAT group [1.78; P=0.038]. At baseline, the AT group had significantly lower proportions of cardiovascular disease, hypertension, dyslipidemia, and malignancy than the non-switchers [P<0.05]. The NAT group had higher rates of hypertension, diabetes and dyslipidemia than non-switchers [P<0.05].

At baseline, the AT group had significantly greater use of background medications than non-switchers [methotrexate (MTX): 75.5% vs 61.9%; P<0.0001, other non-biologic DMARDs (nbDMARDs):48.4 % vs 40.3%; P<.0001]. The NAT group also had greater use of MTX compared to non-switchers (61.9% vs 54.6%; P<0.0001) but not nbDMARDs.

The most common index bDMARD was etanercept [45%] and adalimumab [20%]. Among the AT group, the majority of patients switched to adalimumab [49%], followed by etanercept [25%], infliximab [20%] golimumab [4%], and certolizumab [3%]. For the NAT group, most common switch therapies were abatacept [43%], tocilizumab [38%], and rituximab [19%].

Mean duration of therapy on index bDMARD was 248 days, 145 days, and 127 days for non-switchers, the AT group and NAT groups, respectively. In adjusted analyses, the AT and NAT groups had similar discontinuation/switch rates (hazard ratio=1.13; P=0.15).

Conclusion: In the 12 months following bDMARD initiation, most RA patients maintained their initial bDMARD. Compared to non-switchers, the NAT group had higher comorbidities, suggesting that sicker patients are more likely to be switched to a different MOA. The use of MTX and nbDMARDs at baseline was not universal.

Residual Disease Activity in Patients with Early Rheumatoid Arthritis Who Were Classified As Being in Remission According to 8 Different Descriptions: Post Hoc Analysis of the Etude Et Suivi Des Polyarthrites Indifférenciées Récentes (ESPOIR) Cohort. Isabel Castrejón[1], Maxime Dougados[2], Bernard Combe[3], Francis Guillemin[4], Bruno Fautrel[5] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Paris-Descartes University, APHP, Cochin Hospital, Paris, France, [3]Hopital Lapeyronie, Montpellier, France, [4]Faculte de Medecin/BP 184, Vandoeuvre-les-Nancy, France, [5]APHP-Pitie Salpetriere Hospital / UPMC, Paris, France

Background/Purpose: No single gold standard for remission is available for rheumatoid arthritis (RA). All available descriptions, including 2 proposed by an ACR/EULAR committee, allow residual joint abnormalities and RA symptoms. Relatively little information is reported concerning these abnormalities in patients who meet various descriptions of remission.

Methods: The ESPOIR cohort of 734 patients with complete 6-month data was analyzed to identify those in remission according to 8 descriptions, 4 requiring a formal joint count: disease activity score (DAS28) ≤2.6, clinical disease activity index (CDAI) ≤2.8, and the 2 proposed by ACR/EULAR – Boolean dichotomy with tender joint count (TJC28), swollen joint count (SJC28), C-reactive protein (CRP) and patient global estimate (PATGL) all ≤1, and simplified disease activity index (SDAI) ≤3.3. Four additional descriptions are based on routine assessment of patient index data (RAPID3), an index of patient-reported function, pain and PATGL with remission (RAPID3R) described by a score ≤3 (0–30 scale), and 3 more stringent definitions that add a careful joint examination and physician global estimate (DOCGL): RAPID3R+J1 (RAPID3 ≤3 and ≤1 swollen joint); RAPID3R+J1D1 (RAPID3 ≤3, ≤1 swollen joint and DOCGL ≤1); and RAPID3R+J0D1 (RAPID3 ≤3, no swollen joint and DOCGL ≤1). Proportions of patients with TJC28, SJC28, CRP, DOCGL, PATGL, pain or fatigue >1, or HAQ function (FN) >0.5, and specific swollen joints (n=28) were computed for each remission description.

Results: Boolean dichotomy and RAPID3R+J0D1 indicated 13% of all patients in remission vs 16–19% by SDAI, CDAI, RAPID3R+J1 and RAPID3R+J1D1. RAPID3R (26%) and DAS28 (32%) were least stringent. TJC28 >1 was seen in 0% by Boolean criteria (by definition) vs 3–11% by SDAI, CDAI, DAS28; 13–16% by RAPID3R+J1, RAPID3R+J1D1, RAPID3R+J0D1; and 24% by RAPID3R. SJC28 >1 was seen in 0% by Boolean criteria, RAPID3R+J1, RAPID3R+J1D1 and RAPID3R+J0D1 (by definition); 2% by CDAI and SDAI; 16% by DAS28; and 27% by RAPID3R. CRP >1 was seen in <8%, and HAQ-FN >0.5 in 2–12% by all 8 descriptions. PATGL >1 was seen in 10–21% by all but Boolean (0% by definition) and DAS28 (49%); pain >1 in 9–23% by all but DAS28 (46%); and fatigue >1 in 47–65% by all 8 descriptions. Knees, shoulders and elbows were involved in <5% of patients by all 8 descriptions; wrists in <6%, MCPs in <9% and PIPs in <5%, except by DAS28 and RAPID3R. Most residual joint involvement was of MCPs or PIPs.

Table. Number (%) of 734 patients in the ESPOIR early RA cohort who are in remission according to each of 8 descriptions, and number (%) of patients within each description category having residual symptoms according to specific measures and joint counts

8 Descriptions of Remission in Rheumatoid Arthritis

N (% of all pts)*	Boolean	SDAI ≤3.3	DAS28 ≤2.6	CDAI ≤2.8	RAPID3 [RAPID3 ≤3]	RAPID3R + J1 [RAPID3 ≤3; SJC ≤1]	RAPID3R + J1D1 [RAPID3 ≤3; SJC ≤1; DOCGL ≤1]	RAPID3R + J0D1 [RAPID3 ≤3; SJC = 0; DOCGL ≤1]
	96 (13%)	127 (17%)	238 (32%)	138 (18%)	194 (26%)	141 (19%)	121 (16%)	100 (13%)
Measures: N (%) of patients in remission by each description								
TJC28 >1	0 (0%)	4 (3%)	26 (11%)	4 (3%)	46 (24%)	22 (16%)	18 (15%)	13 (13%)
SJC28 >1	0 (0%)	3 (2%)	38 (16%)	3 (2%)	53 (27%)	0 (0%)	0 (0%)	0 (0%)
CRP >1	0 (0%)	4 (3%)	14 (6%)	10 (7%)	14 (8%)	8 (6%)	7 (6%)	5 (5%)
DOCGL >1	7 (7%)	10 (8%)	90 (37%)	11 (8%)	44 (23%)	20 (14%)	0 (0%)	0 (0%)
PATGL >1	0 (0%)	24 (19%)	117 (49%)	29 (21%)	40 (21%)	25 (18%)	13 (11%)	10 (10%)
Pain >1	15 (16%)	29 (23%)	100 (46%)	29 (21%)	33 (17%)	19 (13%)	14 (12%)	9 (9%)
Fatigue >1	55 (57%)	75 (59%)	156 (65%)	81 (59%)	103 (53%)	76 (54%)	57 (47%)	53 (53%)
HAQ-FN >0.5	5 (5%)	12 (9%)	29 (12%)	13 (9%)	3 (1%)	3 (2%)	3 (2%)	2 (2%)
Swollen Joints: N (%) of patients in remission by each description								
Knees ≥1	0 (0%)	0 (0%)	7 (3%)	1 (1%)	9 (4%)	2 (1.5%)	1 (1%)	0 (0%)
Shoulders ≥1	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
Elbows ≥1	0 (0%)	0 (0%)	5 (2%)	0 (0%)	2 (1%)	0 (0%)	0 (0%)	0 (0%)
Wrists ≥1	5 (5%)	5 (4%)	19 (8%)	5 (4%)	22 (11%)	6 (4%)	6 (5%)	0 (0%)
MCPs ≥1	9 (9%)	11 (9%)	46 (21%)	10 (7%)	52 (27%)	13 (9%)	10 (8%)	0 (0%)
PIPs ≥1	3 (3%)	5 (5%)	24 (11%)	5 (4%)	14 (19%)	4 (3%)	4 (3%)	0 (0%)

*Top row indicates number (%) of 734 patients who are in remission according to each of 8 descriptions. All other values are number (%) of patients within each column (remission description category) who have residual symptoms.

Conclusion: At least 9% of patients in remission by any description had pain, and at least 47% fatigue. RAPID3R and DAS28 had the largest proportions of patients with residual abnormalities, while CDAI and stringent RAPID3-based remission descriptions are similar to the 2 proposed by ACR/EULAR. RAPID3-based descriptions do not require formal joint counts or laboratory data, but do require DOCGL and careful joint examination, and could be feasible in usual care.

Methotrexate Adverse Events in a Cohort of US Veterans with Rheumatoid Arthritis. Lisa A. Davis[1], Brooke Ivan Polk[2], Alyse D. Mann[3], Gail S. Kerr[4], Andreas M. Reimold[5], Grant W. Cannon[6], Ted R. Mikuls[7] and Liron Caplan[8]. [1]Univ of Colorado School of Med, Aurora, CO, [2]University of Colorado Medical School, Aurora, CO, [3]Denver VA Medical Center, Denver, CO, [4]Washington DC VAMC, Georgetown and Howard University, Washington, DC, [5]Dallas VA and University of Texas Southwestern, Dallas, TX, [6]George E. Wahlen VA Medical Center, Salt Lake City, UT, [7]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [8]Denver VA and University of Colorado School of Medicine, Aurora, CO

Background/Purpose: Methotrexate (MTX) is the most commonly used medication for patients with rheumatoid arthritis (RA), however, the frequency of MTX adverse events (AE) has not been fully described. We surveyed patients exposed to multiple MTX courses to characterize MTX-associated AEs.

Methods: A random sample of patients enrolled in the prospective Veterans Affairs RA (VARA) registry was selected. Medical records were reviewed for MTX-associated AEs from the time of MTX initiation until 120 days following MTX cessation. Separate MTX courses were defined by a gap > 90 days in the pharmacy data. The AEs abstracted included: dermatologic (alopecia, rash, photosensitivity, or nodulosis); gastrointestinal (oral ulcers/ stomatitis, nausea/vomiting/anorexia/dyspepsia, or diarrhea); hematologic (leukopenia <3,500, thrombocytopenia <100,000, or new-onset anemia [hemoglobin <13.5 g/dL in men and <12.0g/dL in women]); hepatic (transaminitis >upper limit of normal, fibrosis, or cirrhosis); infectious (clinical diagnosis defined by the treating physician); central nervous system (headache, dizziness/vertigo, fatigue within 48 hours of MTX, mood alteration, or memory impairment as defined by the patient or physician); respiratory (dry cough, dyspnea, or interstitial lung disease [ILD]); and other (AE defined by physician or patient as associated with MTX). Significant AEs (SigAE) were defined as an AE leading to drug discontinuation (operationalized as any AE preceding MTX cessation by ≤ 120 days).

Results: Of the 319 patients for whom records were abstracted (1196 total patient-years [PY] of observation), 642 AEs were recorded in 270 patients during 614 total courses of MTX. The first AEs (n=268) occurred over a course of 496.5 PY of observation, yielding an incidence rate of first AE of 0.54 per PY (95% CI 0.48–0.61). SigAE (n=93) had an incidence rate of 0.08 per PY. The most common AEs were hematologic (30.4% of all AE), with anemia the leading subcategory (27.9%) (see Table). The most common SigAE was respiratory (22.6% of all SigE) but the incidence of ILD was low at 4.1%.

Table. Adverse and Significant Methotrexate Adverse Events in VARA cohort

Adverse Event	All AE N = 642	%	SigAE n = 93	%
Dermatologic	16	2.49	0	0.00
Alopecia	3	0.47	0	0.00
Rash	6	0.93	0	0.00
Photosensitivity	1	0.16	0	0.00
Nodulosis	7	1.09	0	0.00
Gastrointestinal	79	12.31	11	11.83
Oral Ulcers/Stomatitis	19	2.96	1	1.08
N/V/Anorexia/ Dyspepsia	54	8.41	7	7.53
Diarrhea	11	1.71	3	3.23
Hematologic	195	30.37	20	21.51
Leukopenia	13	2.02	0	0.00
Thrombocytopenia	6	0.93	1	1.08
Anemia	179	27.88	19	20.43
Hepatic	168	26.17	17	18.28
Transaminitis	168	26.17	17	18.28
Fibrosis	0	0.00	0	0.00
Cirrhosis	0	0.00	0	0.00
Infectious Disease	81	12.62	12	12.90
Central Nervous System	15	2.34	1	1.08
Headache	4	0.62	0	0.00
Dizziness/Vertigo	1	0.16	0	0.00
Fatigue/Malaise	9	1.40	1	1.08
Depression/Mood	1	0.16	0	0.00
Memory Impairment	1	0.16	0	0.00
Respiratory	45	7.01	21	22.58
Dry Cough	15	2.34	5	5.38
Dyspnea	21	3.27	8	8.60
Interstitial Lung Disease	26	4.05	14	15.05
Other	46	7.17	11	11.83

*SigAE=significant AE; N=nausea; V=vomiting; N=total number of reported AE; n=total number of reported significant Aes

Conclusion: Among US veterans with RA, MTX has a high AE rate, with approximately one AE noted per patient over a two-year period of treatment. In contrast, the rate of SigAE mandating drug discontinuation is much lower. The most common SigAE was respiratory, which may reflect physicians' high level of concern for MTX- associated ILD. However, the incidence of ILD in the cohort was low.

Time-to-Improvement of Pain and Sleep in Clinical Trials of Pregabalin Treatment of Fibromyalgia. Lesley M. Arnold[1], Andrew Clair[2], Birol Emir[2], Lynne Pauer[2] and E. Malca Resnick[2]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Pfizer Inc, New York, NY

Background/Purpose: Fibromyalgia (FM) is a chronic condition characterized by widespread pain and tenderness. Sleep disturbance is common in patients with FM, and both pain and poor sleep quality can have a significant impact on patients' quality of life. Pregabalin is one of 3 drugs approved for the treatment of FM in the United States. Several placebo-controlled clinical trials have demonstrated that pregabalin treatment results in significant improvements in both pain and sleep in patients with FM.

Methods: This post-hoc analysis examined the time-to-onset (TTO) of improvement in pain and sleep quality in patients diagnosed with FM from four 8- to 14-week Phase III placebo-controlled trials of pregabalin at 150, 300, 450 or 600 mg/d. Pain scores were recorded in a daily diary on an 11-point numeric rating scale (NRS) ranging from 0 (no pain) to 10 (worst possible pain). Daily sleep quality was also reported on an 11-point NRS ranging from 0 (best possible sleep) to 10 (worst possible sleep). Daily pain and sleep quality scores were analyzed using analysis of covariance in the intent-to-treat population. The TTO of improvement in pain and sleep quality scores were calculated for all pregabalin dose arms that showed a statistically significant (p<0.05) reduction in their respective score at endpoint compared with placebo. TTO was defined as the first of 2 consecutive days for which the mean score was statistically significantly lower for pregabalin vs placebo.

Results: Across the 4 studies included in the analysis, there was a total of 12 pregabalin dose arms, with 2069 patients receiving pregabalin and 689 placebo. Patients had a mean age ranging from 48.0–49.7 years and the majority were women (93.1%). Mean baseline pain scores were similar for the pregabalin (range 6.8–7.0) and placebo groups (6.8). Mean baseline sleep quality scores were also similar for the pregabalin (range 6.3–6.4) and placebo (6.4) groups. Eight of 12 pregabalin dose arms were associated with a significant reduction in pain scores vs placebo at endpoint. TTO of improvement in pain occurred at day 1 of treatment for 7 dose arms (average reduction in mean pain score vs placebo, −0.36 for 300 mg/d, −0.55 for 450 mg/d, and −0.41 for 600 mg/d) and at day 2 for 1 arm (−0.59 for 300 mg/d). Eleven of 12 pregabalin dose arms were associated with a significant improvement in sleep quality score vs placebo at endpoint. TTO of improvement in sleep occurred at day 1 of treatment for these 11 arms (average reduction in mean sleep quality score vs placebo, −0.77 for 300 mg/d, −0.77 for 450 mg/d, and −0.71 for 600 mg/d pregabalin).

Conclusion: In patients with FM, statistically significant improvement in pain typically occurs within 2 days, and statistically significant improvement of sleep quality within 1 day, of initiating treatment with pregabalin.

Rate and Predictors of Work Disability in Fibromyalgia. Frederick Wolfe[1], Brian T. Walitt[2], Robert S. Katz[3] and Winfried Häuser[4]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Washington Hospital Center, Washington, DC, [3]Rush University Medical Center, Chicago, IL, [4]Technische Universität München, Munich, Germany

Background/Purpose: Fibromyalgia is a contested disorder whose diagnosis depends largely on self-report. It is reportedly also associated with a high rate of work disability, but there have been no detailed studies of work disability in fibromyalgia. In addition, disabled status is difficult to determine because there are no clearly observable abnormalities or reliable assessments methods to determine work disability. In this study we determined the rate of a work disability award and its predictors.

Methods: For up to 13 years, we studied a cohort of 2,322 fibromyalgia patients, who were between the ages of 21 and 64 years, using mailed and Internet questionnaires at 6-month intervals. 591 patients were receiving US Social Security disability (SSD) awards at entry to the cohort, and were not studied further. The remaining 1,730 constituted the study sample and were evaluated using Cox regression.

Results: For the entire sample (N=2,322) the prevalence of SSD was 34.8% (95% CI 32.9, 36.8). Over 13 years of follow-up of the non-disabled sample at study entry, a SSD prevalence of 25.5% was noted. The annual incidence rate for this group was 3.4% (3.0, 3.9%) annually and 25% of patients were disabled at 9.0 years (Figure 1). As shown in Table 1, a wide variety of univariate predictors (adjusted for age and sex) at the first observation were associated with future work disability, including younger age, abnormal mood, functional status as measured by the Health Assessment Questionnaire disability index (HAQ), increased BMI, current smoking, the polysymptomatic distress scale (PSD ("fibromyalgianess")), meeting ACR 2010 criteria, the SF-36 PCS and MCS scales, VAS fatigue, VAS pain, and rating one's self as being disabled or being unemployed. College education was protective against future SSD. In multivariable Cox regression, only HAQ disability (Relative Risk 2.5 (1.8, 3.6)), rating one's self as disabled (RR 5.9 (3.6, 9.7)), and being unemployed (RR 3.3 (1.9, 5.8)) were significant predictors of future SSD.

Table 1. Univariate predictors of SSD, adjusted for age and sex

Variable	Hazard Ratio (95% CI)
Disabled – self-report (yes/no)	10.5 (6.56, 16.67)
Unemployed (yes/no)	4.05 (2.34, 7.01)
FM Diagnostic criteria (+) (yes/no)	3.27 (2.27, 4.71)
Current smoking (yes/no)	1.70 (1.22, 2.35)
> High school education (yes/no)	0.71 (0.51, 0.98)
College education (yes/no)	0.46 (0.33, 0.66)
HAQ Disability (0–3)	4.77 (3.76, 6.04)
VAS Pain (0–10)	1.34 (1.25, 1.43)
Mood (0–10)	1.29 (1.21, 1.38)
VAS Fatigue (0–10)	1.22 (1.15, 1.30)
VAS Sleep disturbance (0–10)	1.18 (1.12, 1.24)
Polysymptomatic distress (0–31)	1.09 (1.07, 1.11)
Body mass index	1.04 (1.02, 1.05)
SF-36 PCS	0.92 (0.90, 0.93)
SF-36 MCS	0.96 (0.95, 0.97)

No ethnicity groups were statistically significant predictors.

Cox proportional hazards regression
Conclusion: The receipt of a SSD award is common in fibromyalgia, with an annual incidence of 3.4% (3.0, 3.9%). Although many variables were predictive of SSD in univariate models, only self-report of functional status and current unemployment and/or self-reported disability predicted future SSD. One explanation for the few predictors is that BMI, smoking, education and symptoms contribute to functional status, which then dominates all other predictors.

Grey Matter Decrease in Fibromyalgia Is Related to Pain Catastrophizing and Pain Sensitivity. Marta Ceko, Mary-Ann Fitzcharles, M. Catherine Bushnell and Petra Schweinhardt. McGill University, Montreal, QC

Background/Purpose: Fibromyalgia (FM) is commonly associated with catastrophizing, a set of negative emotional and cognitive processes related to pain. Catastrophizing is suggested to augment pain sensitivity through increased attention to pain and exaggerated emotional processing of pain. FM is associated with grey matter (GM) decreases in cortical medial frontal regions thought to be involved in attention to pain and pain modulation. We investigated the relationship between GM alterations and measures of pain, specifically hypothesizing that in fibromyalgia GM decreases in the medial frontal regions will be related to pain catastrophizing, as well as to pain sensitivity.

Methods: We recruited 29 female FM patients and 29 female controls matched for age, handedness, education, body mass index, physical activity, and socioeconomic status. All subjects underwent anatomical magnetic resonance imaging (MRI). Catastrophizing was assessed using the Pain Catastrophizing Scale; pain intensity and unpleasantness were assessed in response to a standardized pressure stimulus applied on the thumbnail. MRI data were preprocessed in SPM8. Voxel-wise GM differences were examined using independent sample t-tests while controling for age.

Results: Pain catastrophizing was higher in the FM patients (p<0.001), as was pain unpleasantness (p=0.011), with a trend for pain intensity (p=0.079). FM patients had decreased GM in the medial prefrontal cortex (MPFC), superior frontal gyrus, and premotor cortex (p<0.05 cluster-corrected). In FM patients, GM in the MPFC was negatively correlated with catastrophizing (p=0.022), pain intensity (p=0.048), and pain unpleasatness (p=0.020).

Conclusion: This study shows a three-way relationship between MPFC changes, catastrophizing and pain sensitivity, indicating that structural alterations in FM might contribute to the patients' phenotype.

Functional Magnetic Resonance Imaging of Working Memory in Fibromyalgia: Support for a "Competing Demands" Theory of Cognitive Function in Chronic Pain. Anson E. Kairys, Gabriela Ramirez, Eric Ichesco, Johnson P. Hampson, Richard E. Harris, Daniel J. Clauw, Tobias Schmidt-Wilcke and Jennifer M. Glass. University of Michigan, Ann Arbor, MI

Background/Purpose: The primary symptom of fibromyalgia (FM) is chronic widespread pain; however, patients report additional symptoms including decreased concentration and memory. Deficits are seen mainly in tests of working memory (WM) and executive functioning. WM is a cognitive system that involves the ability to store and manipulate mental information for a short period of time, as occurs in the 2-back task. Versions of this task have been used extensively in functional neuroimaging studies of WM. Chronic pain may interfere with cognitive performance, but the neural correlates of this interference remain unclear. We hypothesized that FMs would perform worse on the 2-back task relative to healthy controls (HC), with neural-based changes in blood-oxygen-level-dependent (BOLD) signal.

Methods: 16 FM patients completed a randomized double-blind two-period cross-over study of milnacipran versus placebo. Data reported here are from pre-drug baseline assessment. 13 age and gender matched healthy controls (HC) also participated. Participants performed five blocks of the 2-back task (with 0-back as a control) while in the fMRI scanner. All fMRI data were pre-processed using SPM5. Our regressors of interest (2-back and 0-back) were convolved with the hemodynamic response function and applied to voxel-wise statistics. Corresponding contrast images (2back>0back) were then entered into a 2nd level analysis (two-sample t-test) to delineate differences in brain activations between the groups. Regions of

interest showing significant changes in BOLD activation during the 2-back task were extracted and analyzed using SPSS 19.

Results: Behavioral results showed no overall difference between FM and HC groups on the 2-back task; however, there was an interaction with block $(F(4, 24)=2.8, p<.05)$, such that FM patients showed better accuracy during the first block, but did not improve over time. In contrast, HC subjects improved and by the final block were more accurate than FM patients. While performing the task in the scanner, FM patients displayed significantly less BOLD activity within the left-mid insula (FM<HC percent BOLD change mean difference -0.455 ± 0.194), right posterior insula (-0.057 ± 0.196), left cingulate cortex (-0.109 ± 0.134) and right primary somatosensory cortex $(-0.43 \pm 0.204$; all p<0.05 corrected). There was a significant positive correlation between BOLD activity in the left cingulate cortex and accuracy on the 2-back task (r=0.5, p=0.049), and a significant negative correlation between BOLD activity in the primary somatosensory cortex and pain severity (r=−0.546, p=0.029) in FM patients.

Conclusion: FM patients displayed reduced activity in the insula, cingulate, and primary somatosensory cortex during a working memory task, when compared to HCs. Behaviorally, FM patients showed no improvement in performance over time, whereas HCs improved. The results are consistent with a "competing demands" problem with neural resources in FM patients. It appears as though perception and processing of pain activates areas of the brain that are also involved in cognition, including inhibition and attention networks involved in cognitive executive function, making these networks less available for cognitive tasks.

The Transcription Factor Mohawk Plays an Important Role for Maintaining Human Anterior Cruciate Ligament Homeostasis. Hiroyuki Nakahara, Akihiko Hasegawa, Fumiaki Ayabe, Tetsuya Matsukawa, Koji Otabe, Tomo Yonezawa, Martin K. Lotz and Hiroshi Asahara. The Scripps Research Institute, La Jolla, CA

Background/Purpose: Recently Mohawk homeobox (MKX) has been discovered as a tendon and ligament specific transcriptional factor. MKX deficient-mice are shown to hypoplastic tendons throughout the body by down regulating changing type I collagen production in tendon cells. However, in human tendons or ligaments, little is known about the function of MKX. In this study, we demonstrated using human anterior cruciate ligament (ACL) tissues and primary cultured human ACL cells that MKX is an important regulator of human ligament homeostasis, and that its changes in the expression and function play an important role in ligament degeneration. The aims of this study are to characterize the expression of MKX in normal human knee joints and osteoarthritis (OA) affected knee joints and to investigate the role of MKX in human ligament homeostasis.

Methods: Human ACL specimens were obtained from the knee joints at cadaveric autopsy within 24–48 hours postmortem with approval of the Scripps Human Subjects Committee. 7 normal donors (mean±SD age 33.57±11.67years) and 8 donors with OA (mean±SD age 77.50±11.46 years) were analyzed and none of the donors had a history of knee joint trauma. All cartilage surfaces were graded macroscopically. ACL degeneration was assessed macroscopically and histologically using quantitative scoring systems. ACL tissues were analyzed for the expression of MKX by immunohistochemistry and quantitative RT-PCR assays. Primary cultured human ACL cells were stimulated with IL-1β to examine whether proinflammatory cytokine modulates MKX expression. Moreover, in order to examine the function of MKX on ECM production and differentiation in these cells, we performed the knocked-down by MKX specific siRNA and then, determined the expression of some genes involving in ECM and the differentiation using quantitative RT-PCR and western blotting analysis.

Results: The expression of MKX was remarkably decreased during developing OA. In addition, the expression of COL1a1, which is major component of ACL, is also decreased in OA group. In coincidence with the result of immunohistochemistry revealed that the percentage of MKX positive cells was significantly reduced in OA group. In primary cultured human ACL cells, the expression of MKX was significantly reduced by the treatment of IL-1β. The expression of genes involving in regulating ECM homeostasis such as COL1a1 and TNXb and transcriptional factor Scleraxis (SCX), which is specific regulator of the tendon/ligament

lineage, were down-regulated by IL-1β treatment. On the other hand, SOX9, which is involved in the modulation of chondrocyte like phenotype, was up-regulated by IL-1β treatment. The expression of COL1a1 and TNXb were decreased by MKX specific siRNA treatment, though that of SOX9 was increased. We didn't detect any significant differences in those of SCX, IL-6 and MMP13.

Conclusion: To our knowledge, this is the first report to investigate the MKX expression and function in Human ligaments. The present study demonstrates that the expression of MKX is down-regulated by an inflammatory response and MKX may play important roles in ligament homeostasis via regulating the expression of COL1a1, TNXb and SOX9 in human ACL cells.

Cost-Effectiveness of Tai Chi Mind-Body Exercise for the Treatment of Fibromyalgia. John B. Wong and Chenchen Wang. Tufts Medical Center, Boston, MA

Background/Purpose: Although fibromyalgia is associated with substantial annual direct medical and indirect productivity costs, the cost-effectiveness of treatments for fibromyalgia remains understudied. A randomized controlled trial of tai chi mind-body exercises versus wellness education and stretching found tai chi to be safe and effective, so our aim was to assess the cost-effectiveness of tai chi for fibromyalgia in this trial.

Methods: The analysis is based on a single-blind, 12-week randomized trial of classic Yang-style tai chi compared with wellness education and stretching control for the treatment of fibromyalgia in 66 patients with 24 week follow up (NEJM 2010; 363:743–54). Effectiveness outcomes from baseline to week 24 included Fibromyalgia Impact Questionnaire (FIQ) score, Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36) quality of life (QOL), pain score using the visual analog scale (VAS) and Health Assessment Questionnaire Disability Index (HAQ). Hourly costs were based on an Internet search with Tai Chi costing $17.50 ($10–$25) and stretching costing $12 ($9–$15). A systematic review of Medline from inception to 2011 for economic studies regarding fibromyalgia found annual direct medical care costs of $3700 equaling 1.7 to 2.9 times population controls and indirect costs that were 1.7 to 2.2 times direct medical care costs (ACR #902 Arthritis Rheum 2011;63 Suppl 10:S354–5). Statistical testing for differences used the two sample t-test and mixed models with time and group as categorical fixed factors. A linear regression related HAQ to mean direct care costs (R-square 0.96).

Results: The mean difference improvement with tai chi versus wellness education and stretching control in FIQ was 18.3 (95% CI 9.6–27.1, p<0.001); in SF36 QOL physical health was 7.0 (2.9–11.0, p=0.001) and SF36 QOL mental health was 7.3 (1.9–2.8, p=0.009); in VAS pain was 2.1 (95% CI 0.74–3.5, p=0.003); and in HAQ was 0.21 (95% CI 0.037–0.390, p=0.019). Assuming no reduction in health care utilization from tai chi, the incremental cost-effectiveness of tai chi versus wellness education and stretching was $4 (95% CI $2–$7) per 1 point improvement in FIQ; $9 (95% CI $5–35) per 1 point improvement in physical or mental QOL; $31 (95% CI $19–$89) per 1 point improvement in VAS pain score and $314 (95% CI $169–$1784) per 1 point improvement in HAQ. Assuming that the improved HAQ disability index decreases health care utilization, tai chi results in an estimated savings of $366 (95% CI $9–$724) per patient over 6 months. Assuming that the observed decreased HAQ disability index decreases health care utilization and productivity losses, tai chi results in an estimated savings of $775 (95% CI $80–$1474) per patient over 6 months.

Conclusion: Compared with wellness intervention and stretching, tai chi improves FIQ score, SF36 QOL, VAS pain score and HAQ significantly. Costs per unit improvement appear to be quite modest, and assuming that improvement in HAQ would lead to direct and indirect cost reductions, tai chi would be cost-saving. Confirmation of these results in a larger randomized controlled trial is needed.

Effects of Pain Expectations On Neuromuscular Control of the Spine in Patients with Chronic Low Back Pain and Healthy Participants. Yves Henchoz, Charles Tétreau, Jacques Abboud, Mathieu Piché and Martin Descarreaux. Université du Québec à Trois-Rivières, Trois-Rivières, QC

Background/Purpose: The mechanisms underlying the transition from acute to chronic low back pain (cLBP) are poorly understood. Physiological and psychological factors are implicated. Although significant associations have been found between neuromuscular control of the lumbar spine and the level of fear of pain, it is still unknown whether acute exposure to fear of pain alters trunk motor control. The objective of this study was to determine if experimentally induced pain expectations modulate trunk neuromuscular responses differently in subjects with and without cLBP.

Methods: This cross-sectional study included 22 patients with cLBP and 22 healthy participants. They performed 6 trunk flexion-extension tasks under three experimental conditions: innocuous heat, noxious stimulation with low pain expectation and noxious stimulation with high pain expectation. Noxious stimulation was generated by thermal cutaneous heat stimulations in the lumbar region (L4-L5), whereas low or high pain expectations were generated by verbal and visual instructions (see **Fig. 1**). After each task, experimental pain was evaluated using a numerical rating scale (NRS). Surface electromyography (sEMG) of erector spinae at L2-L3 and L4-L5 as well as lumbopelvic kinematic variables were collected during the tasks. Pain ratings, sEMG and kinematic variables were compared between groups and conditions using two-way mixed ANOVAs. Pearson's correlation coefficients were calculated in cLBP patients to determine whether the effects of expectations were associated with disability, pain catastrophizing, state and trait anxiety and fear avoidance beliefs.
Fig. 1. Study design

Results: Pain ratings were significantly different between high and low pain expectations conditions (P<0.001). This difference was similar between patients with cLBP (15.2 ±13.4) and control participants (13.3 ± 10.2). In patients with cLBP, the increase in sEMG activity in full flexion caused by expectation was related to higher pain catastrophizing, but not to disability, anxiety and fear-avoidance beliefs. Two-way mixed ANOVA yielded a significant "group × condition" interaction for sEMG in Full flexion (P<0.05). Planned comparisons revealed a stronger effect of pain expectation in healthy participants than in patients with cLBP. Lumbopelvic rhythm was significantly different between groups (P<0.05), but similarly affected by pain expectation.

Conclusion: As anticipated, the increase in sEMG activity caused by expectations was related to higher pain catastrophizing in patients with cLBP. Nevertheless, expectations of high pain resulted in neuromuscular adaptations that were weaker in patients with cLBP than in healthy participants. In conclusion, chronic pain appears to generate rigid and less variable movement patterns in patients with cLBP, which attenuate their response to acute fear of pain exposure.

Randomized Placebo-Controlled Trial of Local Steroid Injection for Moderately Severe Carpal Tunnel Syndrome. Isam Atroshi[1], Magnus Flondell[2] and Manfred Hofer[3]. [1]Lund University, Hässleholm, Sweden, [2]Lund University, Malmö, Sweden, [3]Kristianstad Hospital, Kristianstad, Sweden

Background/Purpose: Patients with idiopathic carpal tunnel syndrome (CTS) are commonly treated with local steroid injection but there is currently no evidence from placebo-controlled trials supporting efficacy beyond 1 month.

Methods: We conducted a randomized triple-blind placebo-controlled trial of first-time steroid injection into the carpal tunnel in patients with moderately severe CTS. Patients aged 18 to 70 years with primary idiopathic CTS, no severe sensory loss or muscle atrophy, and no previous steroid injection for CTS were randomized to 1 of 3 groups (37 patients in each): 80 mg Methylprednisolone, 40 mg Methylprednisolone, or saline (each also containing 10 mg Lidocaine). Patient-reported outcomes (CTS symptom severity scale, *Quick*DASH, SF-36 bodily pain, and SF-6D) were obtained and physical examination by a blinded assessor was performed at baseline and at 10, 24 and 52 weeks after injection. The primary end points were change in CTS symptom severity score at 10 weeks and rate of surgery at 52 weeks. Data from all patients were analyzed.

Results: During 1 year after injection surgery was carried out on 27 patients (73%) in the 80 mg Methylprednisolone group, on 30 patients (81%) in the 40 mg Methylprednisoline group, and on 34 patients (92%) in the placebo group. Patients who received placebo were significantly more likely to have surgery during 1 year after injection than patients who received Methylprednisolone; adjusted hazard ratio 2.0 (95% confidence interval 1.3–3.2, P<0.01). The change in the CTS symptom severity score from baseline to 10 weeks was significantly larger in both Methylprednisolone groups than in the placebo group.

Conclusion: In patients with moderately severe carpal tunnel syndrome first-time steroid injection into the carpal tunnel has a significant benefit in relieving symptoms up to 10 weeks and in reducing the need for surgery up to 1 year after treatment.

Trends in US Arthroplasty Rates 1991–2005: Patients with Inflammatory Arthritis Continue to Require Joint Replacement. Christina Mertelsmann-Voss[1], Ting Jung Pan[2], Stephen L. Lyman[3], Mark P. Figgie[2] and Lisa A. Mandl[2]. [1]Hospital for Special Surgery, Cornell University, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital Special Surgery, New York, NY

Background/Purpose: Overall rates of total joint replacement surgeries (TJR) have increased dramatically over the past decades. By contrast, TJR rates among patients with rheumatoid arthritis (RA) are reported to be decreasing. The magnitude of such change, and whether it applies to all types of inflammatory arthritis (IA), is not clear. This study evaluates rates of TJR among patients with IA, [RA, juvenile idiopathic arthritis (JIA) and spondyloarthropathies (SpA)] and compares them to TJR patients with non-inflammatory conditions.

Methods: Administrative hospital discharge databases from 10 states (AZ, CA, CO, FL, IA, MA, NJ, NY, WA, WI) and census data annual population estimates were used to calculate combined rates per 100,000 population of knee arthroplasty, total and partial hip arthroplasty, and total and partial shoulder arthroplasty from 1991 to 2005. ICD-9-CM codes were used to identify specific diseases.

Results: There were 2,839,325 arthroplasties from 1991 to 2005, of which 76,665 (2.7%) were in IA patients. The proportion of TJR attributable to IA nearly halved during this period (3.9% in 1991 vs. 2.0% in 2005). TJR rate for non-inflammatory conditions almost doubled from 124.5 in 1991 to 247.5 in 2005, while the rate in IA patients was fairly steady (range: 4.4–5.2). Stratifying by IA subtype, the TJR rate decreased slightly for RA (4.6 vs. 4.5, p-value<0.001) decreased by 40% for JIA (0.31 vs. 0.22, p-value<0.001), and increased by 40% for SpA (0.22 vs. 0.31 p-value<0.001). From 1991 to 2005, the mean age at TJR for IA patients across all disease subtypes increased: RA (63.4 yrs ±12.7 vs. 64.9 yrs ±12.8, p-value<0.001), JIA (30.9 yrs ±12.2 vs. 36.7 yrs ±14.9, p-value <0.001), and SpA (54.3 yrs ±16.1 vs. 60.4 yrs ±13.9, p-value

<0.001). In contrast, the mean age of non-IA decreased (71.5±11.8 yrs. vs. 69.0±12.0 yrs p<0.001). Among IA patients, neither age nor sex was statistically significantly related to TJR rates.

Conclusion: To our knowledge this is the largest cohort of TJR of patients with IA and the first study of TJR trends in patients with JIA and SpA. Surprisingly, TJR rates in RA showed minimal change despite the widespread introduction of methotrexate in the 1990s. JIA and SpA patients appear to be deferring TJR, with JIA patients requiring fewer procedures. Why SpA TJR rates increased is unclear. These data suggest there will be an ongoing need for orthopedists with expertise in operating on IA patients. Obtaining exposure during surgical training may be difficult, as the proportion of TJR cases due to IA is declining. Further research is needed to assess the effect of biologic medications, first introduced in 1998, on IA TJR rates.

The Meteor Trial: Preliminary Results of an RCT of Arthroscopic Partial Meniscectomy Vs. Physical Therapy in Patients greater Than 45. Jeffrey N. Katz[1], Christine E. Chaisson[2], Brian Cole[3], Laurel Donnell-Fink[1], Morgan Jones[4], Bruce Levy[5], Lisa A. Mandl[6], Scott Martin[1], Robert Marx[6], Anthony Miniaci[4], Joseph Palmisano[7], Emily Reinke[8], Clare Safran-Norton[1], Debra J. Skoniecki[9], Daniel Hal Solomon[9], Kurt P. Spindler[8], John Wright[1], Rick Wright[10] and Elena Losina[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Boston University School of Public Health, Boston, MA, [3]Rush University, Chicago, IL, [4]Cleveland Clinic, Cleveland, OH, [5]Mayo Clinic, Rochester, MN, [6]Hospital for Special Surgery, New York, NY, [7]Boston University School of Public Health, [8]Vanderbilt University, Nashville, TN, [9]Brigham & Womens Hospital, Boston, MA, [10]Washington University, MO

Background/Purpose: Patients who present with a symptomatic knee that has both osteoarthritis and a meniscal tear present a difficult treatment challenge. They may be treated nonoperatively or with arthroscopic partial meniscectomy (APM); there is limited data on the comparative outcomes of these treatments.

Methods: We conducted a randomized controlled trial in 7 US centers involving 351 subjects > 45 years old with symptomatic meniscal tear and osteoarthritic cartilage change, documented by magnetic resonance imaging (MRI). To be eligible, subjects must have exhibited meniscus related symptoms for at least 4 weeks. Enrolled subjects were randomized to APM with postoperative physical therapy (APM arm) or to nonoperative care including a standardized PT regimen focused on strengthening (non-operative arm). The primary analysis compared change in functional status (WOMAC) over 6 months across the 2 arms, using an intention to treat (ITT) approach. A secondary outcome was a binary variable defined as lack of improvement in WOMAC function of at least 8 points over 6 months (a clinically relevant change) OR unplanned cross-over (from nonoperative therapy to APM or from APM to nonoperative therapy). We carried 3 month observations forward to address missing 6 month outcome data.

Results: 174 subjects were randomized to APM and 177 to the nonoperative arm. The arms were balanced with respect to baseline function, radiographic severity, age and sex. The response rate at 6 months was 84% across both arms. In the ITT analysis, mean improvement in WOMAC function after 6 months was 19.4 points (sd 18.4) in subjects randomized to APM and 16.8 (sd 18.1) in those randomized to the non-operative arm (p=0.19). Of the 174 randomized to APM, 9 (5%) did not receive surgery by 6 months. Of the 177 subjects randomized to the non-operative arm, 53 (30%) crossed over and had APM by 6 months (Table). In the analysis of the secondary outcome, 26% of subjects randomized to APM vs. 51% of subjects in the nonoperative arm either did not improve by at least 8 points on WOMAC function or crossed over (p<0.0001; Table).

Table. Crossovers and functional outcomes at six months in the randomized arms

Randomized arm	No crossover		Crossover
	WOMAC improvement ≥ 8	WOMAC improvement < 8	
APM	129 (74%)	36 (21%)	9 (5%)
Nonoperative	86 (49%)	38 (22%)	53 (30%)

Conclusion: These preliminary trial findings suggest that in both the APM and the nonoperative arms, subjects experienced substantial improvement in functional status over six months, with no significant differences between the two arms in the ITT analysis. 30% of subjects randomized to nonoperative therapy underwent APM within the first six months. As with all RCT's the results should be generalized cautiously to clinical populations. These findings will aid physicians and their patients over 45 who present with knee symptoms in association with meniscal tears and osteoarthritis as they decide whether to elect APM or nonoperative therapy.

Associations Between Body Mass Index and Physical Activity Following Total Knee Replacement. Carol A. Oatis[1], Wenjun Li[2], Milagros Rosal[2], David Ayers[2] and Patricia D. Franklin[2]. [1]Arcadia University, Glenside, PA, [2]University of Massachusetts Medical School, Worcester, MA

Background/Purpose: In 2009 over 620,000 total knee replacement (TKR) surgeries were performed. That number is expected to increase to 3.5 million annually by 2030. On average, physical activity and functional ability remain diminished one year post TKR when compared to age matched controls. Many patients who undergo TKR are obese. The purpose of this study was to examine the relationship of preoperative body mass index (BMI) to objectively measured physical activity levels at 6 months post TKR.

Methods: Subjects were 179 participants of an NIH funded RCT of telephone support intervention following unilateral primary total knee replacement (TKR). Participants were stratified by BMI (< 30; 30–35; > 35). Participants were asked to wear an accelerometer (Step Activity Monitor™) at the ankle for four consecutive days (2 weekday; 2 weekend) before surgery and at 8 weeks and 6 months post operatively. The accelerometer monitored the number of steps taken daily. Valid wear days required a minimum of 10 hours of wear time.

Results: Participants were 68% female with a mean (SD) age of 65.1 (8.61). Mean (SD) BMI at baseline was 32.5 (5.24). All 179 participants wore the accelerometer preoperatively. 174, 163 and 168 participants had at least one valid wear day preoperatively, at 8 weeks and 6 months after surgery respectively. Mean days worn was 3.3 days. Participants with BMI > 35 (n=53) took fewer steps than those with BMI < 35 (n=121) preoperatively, at 8 weeks post surgery (BMI > 35, n = 46 and BMI < 35, n = 117) and at 6 months post surgery (BMI > 35, n = 50 and BMI < 35, n = 118) (p <.01) (Figure). At 6 months post surgery, mean steps (SD) were greatest in those with BMI < 30, 8845 (3731), fewer in those with BMI between 30 and 35, 8688 (3386), and fewest in those with BMI > 35, 7196 (3299). Change in daily steps from baseline to 6 months was similar across all BMI groups.
Conclusion: Subjects with grade 2 obesity or greater (BMI >35) are less physically active throughout the perioperative period of TKR than those with lower BMI. However high BMI does not preclude improvements in physical activity levels following TKR. An understanding of the association between obesity and physical activity can help inform patients' and clinicians' expectations for post-TKR gain and may focus interventions not only on the knee impairments following TKR but also on the modifiable risks to optimal gains in physical activity following TKR. Risk factors such as BMI may be addressed pre- and post-operatively.

Benefits of Aerobic Training in Patients with Ankylosing Spondylitis Are Not Coupled by Effects On Cytokines: A Randomized Controlled Trial. Fabio Jennings, Hilda A. Oliveira, Marcelo C. Sousa, Vaneska G. Cruz, Fabio S. Lira and Jamil Natour. Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background/Purpose: Ankylosing Spondylitis (AS) is a systemic inflammatory disease that causes deterioration of physical capacity. Although exercises remain essential in the treatment, the literature lacks research on the mechanisms by which exercises lead to clinical improvements in patients with AS. The purpose of this study was to evaluate the effects of aerobic exercise on functional capacity, mobility, disease activity, aerobic capacity, quality of life and cytokine levels (TNF-α, IL-1β, IL-6 and IL-10) in patients with AS.

Methods: Seventy patients with a diagnosis of AS, according to New York modified criteria and with stable drug treatment, were included. The patients were randomly allocated in two groups. The intervention group (IG) underwent 50 minutes of walking in the individual anaerobic threshold associated with stretching exercises 3 times a week for 12 weeks. The control group (CG) performed stretching exercises 3 times a week for 12 weeks. The outcome measurements were: functional capacity measured using BASFI (The Bath Ankylosing Spondylitis Functional Index), HAQ-S (Health Assessment Questionnaire for spondyloarthritis) and the 6-minute walking test (6MWT); mobility measured using BASMI (The Bath Ankylosing Spondylitis Metrologyl Index); disease activity by BASDAI (The Bath Ankylosing Spondylitis Disease Activity Index) and ASDAS (Ankylosing Spondylitis Disease Activity Score). Aerobic capacity was evaluated using an incremental cardiopulmonary exercise testing protocol by treadmill. TNF-α, IL-1β, IL-6 and IL-10 levels were measured using ELISA method. The evaluations were done by a blinded assessor immediately before the randomization, 6 weeks, and 12 weeks after the beginning of the exercise programs. It was used intention-to-treat analysis.

Results: Thirty-five patients were randomized to IG and 35 to CG. Two patients from CG and one patient from IG withdrew because of time availability. At baseline, the groups were homogeneous regarding all clinical and demographic characteristics. There were significant improvements in BASFI, HAQ-S, BASDAI and ASDAS scores in both groups (p < 0.05), but there was no difference between groups. There was no significant improvement of mobility and quality of life in both groups. The IG showed significant improvement in 6MWT compared to the control group (p < 0.001). There was significant increase in VO_2 peak and anaerobic threshold (AT) in IG after treatment. In CG, VO_2 peak and AT did not change after 12 weeks. There was significant difference between groups in absolute values of VO_2 peak (p=0.049) and O_2pulse (p=0.039) at 12 weeks. TNF-α, IL-1β, IL-6 levels did not change over time in both groups. IL-10 levels decreased in both groups after 12 weeks compared to baseline (p< 0.001), but there was no difference between groups.

Conclusion: Aerobic training and stretching exercises had beneficial effects on functional capacity and disease activity. Aerobic training, in addition to stretching exercises, increased walking distance and cardiopulmonary capacity in patients with AS. Aerobic exercise did not affect cytokine levels. More studies are need to understand the mechanisms by which exercises have a therapeutic role in AS.

Background/Purpose: Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) syndrome is a recently described early-onset autoinflammatory disease caused by autosomal recessive mutations in genes encoding the proteasome subunits, mainly the subunit β type 8 gene (*PSMB8*). It was previously shown that CANDLE patients present with increased expression of Interferon (IFN) regulated genes and unregulated stat1 phosphorylation on peripheral blood monocytes. We therefore suggested that drugs inhibiting Janus kinases (JAKs), mediators of IFN signaling, might be used as a treatment in CANDLE. The objectives of this study were to assess the interferon regulated genes expression in additional CANDLE patients and to describe the effect of oral treatment with JAK inhibition on IFN-induced genes in CANDLE patients.

Methods: Two new and 4 previously evaluated CANDLE patients had whole blood microarray analysis performed and their IFN signaling was compared with 5 healthy controls. Total RNA was extracted from PAXgene tubes blood samples and complementary DNA synthesis and target amplification were done. Affymetrix HU-133 Plus 2.0 gene chips were used for hybridization and data analysis was performed with GeneSpring 11.5 and Partek softwares. Patients and healthy control groups were compared using unpaired t test with Welch's correction. IFN regulated gene expression profiles were assessed before and after treatment with the JAK inhibitor baricitinib in 2 CANDLE patients.

Results: Compared to controls, two new CANDLE patients presented with increased expression of IFN-induced genes, as in the previously evaluated 4 CANDLE patients. We have found that 202 genes were >2-fold upregulated compared to the 5 healthy controls, of those 89 are IFN regulated. The difference between the expression values was strikingly marked for the following genes: *IFI27* (12.85 $\pm$ 0.85 vs. 6.10 $\pm$ 0.31, p<0.0001), *ISG15* (12.86 $\pm$ 0.35 vs. 9.60 $\pm$ 0.69, p=0.0002), *RSAD2* (12.75 $\pm$ 0.18 vs. 9.19 $\pm$ 0.70, p=0.0004), *SP100* (11.75 $\pm$ 0.12 vs. 10.89 $\pm$ 0.34, p=0.0062), *USP18* (9.95 $\pm$ 0.33 vs. 6.25 $\pm$ 0.68, p=0.0001), *DDX60* (11.71 $\pm$ 0.09 vs. 9.72 $\pm$ 0.33, p=0.0002), *EIF2AK2* (12.24 $\pm$ 0.21 vs. 10.64 $\pm$ 0.35, p=0.0001) and *GBP1*(12.02 $\pm$ 0.54 vs. 9.68 $\pm$ 0.43, p<0.0001). Upon treatment with the JAK inhibitor, 136 of the 202 up-regulated genes get down-regulated and 65 of those are IFN regulated genes. The others were genes that were associated with cytokine regulation including IL-22, IL-9, IL-15, IL-3, IL-2, GM-CSF, IL-17A. Of those 66 genes that did not change, 24 were IFN regulated genes. Interestingly, the expression of 37 proteasome-associated genes either increase or do not change with JAK inhibitor treatment.

Conclusion: We have found that CANDLE patients present a high expression of IFN-regulated genes and that this finding is present in all patients. This study also suggests that treatment with a JAK inhibitor is able to downregulate IFN induced genes as well as genes associated with the regulation of other inflammatory cytokines.

Genome-Wide Association Study of Methotrexate Response Identifies Novel Genes in a Large Cohort of European Juvenile Idiopathic Arthritis Cases.

Joanna Cobb[1], Erika Cule[2], Halima Moncrieffe[3], Edward Flynn[4], Anne Hinks[1], Fiona Patrick[3], Laura Kassoumeri[3], Simona Ursu[3], Maja Bulatovic[5], Marek Bohm[6], Bertrand D. van Zelst[7], Pavla Dolezalova[6], Robert De Jonge[7], Nico M. Wulffraat[5], Stanton Newman[8], Maria de Iorio[3], Lucy R. Wedderburn[3] and Wendy Thomson[1]. [1]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom, [2]Imperial College London, United Kingdom, [3]University College London, London, United Kingdom, [4]University of Manchester, Manchester Academy of Health Sciences, Manchester, United Kingdom, [5]University Medical Centre Utrecht, Utrecht, Netherlands, [6]First Faculty of Medicine and General Faculty Hospital, Prague, Czech Republic, [7]Erasmus Medical Center, Rotterdam, Netherlands, [8]City University London, London, United Kingdom

Background/Purpose: The drug methotrexate (MTX) is the first line treatment for many children with Juvenile Idiopathic Arthritis (JIA). Only 45% of children treated with MTX for arthritis achieve 70% improvement as defined using internationally agreed JIA core set criteria, and a proportion of children will not respond at all to MTX treatment. Currently there are no reliable predictors to identify children likely to fail to respond. In order to identify these children early, and thus target their treatment during the apparent short window of opportunity in which disease can readily be brought into remission, the Childhood Arthritis Response to Medication Study (CHARMS) was established. Growing evidence suggests that multiple genes contribute to the genetic component of treatment response in arthritis. With this in mind, and using the CHARMS cohort, this study aimed to perform a genome wide association study (GWAS) to identify genomic loci associated with response to MTX in JIA.

Methods: Genotyping of the Illumina OmniExpress Beadchip was performed in a large cohort of 792 JIA cases from the UK, Netherlands and Czech Republic. Single nucleotide polymorphisms (SNPs) failed QC based on a call rate <98% and/or cluster separation score <0.4. Samples failed QC based on a call rate <98%, in addition outliers of mean heterozygosity, related individuals and ancestral outliers (identified using principal components analysis) were removed. The final sample size after QC was 694 cases. The 6 core outcome variables (active/limited joint counts, ESR, CHAQ, parent/physician global assessments) were collected at baseline and 6 months. MTX response was defined using the internationally developed ACR-Pedi categories (non-responder, ACR-Pedi 30, 50, 70), as well as change in each of the core outcome variables individually. Analysis was performed using ordinal and linear regressions in R vers2.15 and PLINK vers1.07. Within the most highly associated regions, IMPUTE2 was used to increase genetic coverage.

Results: A total of 587,822 SNPs (all MAF $\geq$5%) across the entire genome were analyzed for each of the 6 core outcome variables as well as ACR-Pedi. 16 regions containing one or more SNPs with association with MTX response at $P < 1 \times 10^{-4}$ in more than one of the 7 analyses met criteria for further investigation including SNP imputation. The most highly associated SNPs were found near the genes *CACNA1I*, *PVT1* and *CFTR*. These findings are currently being validated within a US cohort of JIA cases with MTX response data available in the form of active and limited joint counts.

Conclusion: These results suggest a role for novel pathways in MTX response. Further investigations within associated regions to dissect the genetic basis of MTX response will move us towards our ultimate goal of prediction of response to MTX for children with JIA.

Rapid and Effective Response to Immunosuppression in Treating Macrophage Activation Syndrome Associated with a Heterozygous Dominant Negative Mutation in RAB27a Leading to Decreased Cytolytic Activity.

Randy Q. Cron, Mingce Zhang, Christina J. Bemrich-Stolz and Timothy Beukelman. Univ of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is an often fatal disorder of infancy resulting from homozygous mutations in proteins involved in cytolysis (e.g. MUNC13-4, RAB27a, Perforin 1, Syntaxin11, STXBP2). HLH treatment is an etoposide based aggressive chemotherapy, and associated mortality remains problematic. Secondary forms of HLH, or macrophage activation syndrome (MAS), frequently result beyond infancy from rheumatologic, infectious, and oncologic conditions. MAS is typically treated with immunosuppression, including high dose **C**orticosteroids, **C**yclosporine, and, recently, the IL-1 receptor antagonist, **A**nakinra (**CCA**). Of late, mutations in HLH associated cytolytic pathway genes have been identified in children with MAS. The importance of these mutations in the pathophysiology of MAS, and the appropriate treatment for MAS in these settings remains unclear.

Methods: Chart review was performed for a teen with MAS successfully treated with CCA. Cytolytic activity of a natural killer (NK) cell line was assessed following over-expression of a RAB27a mutant protein identified in this girl. Lentiviral expression vectors were generated with the RAB27a mutation, and a wild-type RAB27a sequence control, sequenced for authenticity, and introduced into the NK-92 human NK cell line by transduction. Transduced NK cells were analyzed for transgene expression by co-expression of green fluorescence protein, and tested for their ability to lyse calcein violet loaded K562 NK target cells at varying effector to target cell ratios.

Results: An 18-year-old girl presented with 2 weeks of fever (>102ºF) and abdominal pain. Exam revealed a febrile, semi-coherent female with hepatosplenomegaly. Extensive infectious, oncologic, and rheumatic diseases work-ups were negative. Laboratory findings revealed pancytopenia; severe hepatitis; coagulopathy; elevated ferritin, triglycerides, soluble CD25, and soluble CD163; increased CD163 staining of bone marrow; markedly decreased NK cell function; ESR of 10 mm/hr. Sequencing of HLH genes revealed a single copy RAB27a mutation (259 G>A, A87P) known to be associated with type II Griscelli syndrome/HLH. She met 8 of 8 HLH criteria and was treated for MAS with CCA. She markedly and rapidly clinically improved. Her ferritin fell from 8,446 to 201 ng/ml (<115), and her AST fell from 4,639 U/L to 176 U/L, within 4 days of CCA. Lentiviral transduction of wild-type RAB27a into the NK-92 cell line had no effect on cytolysis of K562 target cells *in vitro*, whereas over-expression of the 259 G>A patient mutation decreased cytolytic activity by ∼50%.

Conclusion: The distinction between HLH and MAS is becoming blurred as mutations in HLH genes are identified in patients with MAS. Perhaps later age of onset reflects heterozygous versus homozygous defects in cytolytic pathway proteins. Our data suggests single gene copy mutations can partially disrupt cytolytic activity through a dominant negative effect. Important treatment differences exist between protocols for HLH and MAS, and our patient's response to CCA immunosuppression suggests HLH associated genetic mutations presenting later in life may be responsive to less aggressive/toxic (non-chemotherapeutic) immunosuppression.

Elevated Serum Follistatin-Like Protein 1 Suggests an Interleukin-1 Independent Pathway for Inflammation in Patients with Cryopyrin Associated Periodic Syndromes.

Mark Gorelik[1], Daniel Bushnell[2], Raphaela T. Goldbach-Mansky[3], Hal M. Hoffman[4] and Raphael Hirsch[5]. [1]Univ of Pittsburgh Med Ctr Children's Hospital, Pittsburgh, PA, [2]Childrens Hospital Pittsburgh, Pittsburgh, PA, [3]Translational Autoinflammatory Diseases Section NIAMS NIH, Bethesda, MD, [4]University of California at San Diego, La Jolla, CA, [5]Childrens Hosp Pittsburgh, Pittsburgh, PA

Background/Purpose: Cryopyrin associated periodic syndromes (CAPS) are a group of IL-1β mediated autoinflammatory diseases characterized by fever, urticaria and conjunctivitis, and in severe cases, CNS abnormalities, hearing loss, and bone overgrowth. Patients treated with IL-1 targeted therapy have resolution of a majority of clinical symptoms, although bone lesions are known to progress despite treatment. Follistatin-like protein 1 (FSTL-1) is a pro-inflammatory protein secreted by mesenchymal cells, including osteoblasts. This study was performed to determine how serum FSTL-1 levels correlate with clinical and laboratory markers in the most severe form of the CAPS, Neonatal Onset Multisystem Inflammatory Disease (NOMID).

Methods: FSTL-1 serum levels were measured by ELISA in 10 patients at pre-treatment and post-treatment time points and compared to values from a group of 53 normal controls. FSTL-1 levels were correlated with ESR, CRP, as well as complete blood counts, and clinical characteristics, including presence of bony overgrowth at baseline. To gain insights into the expression of FSTL-1 relative to IL-1 blockade, FSTL-1 levels were measured in CAPS knock-in mice expressing an NLRP3 mutation, as well as in mice with the NLRP3 mutation on an IL-1 receptor knockout background.

Results: FSTL-1 serum levels were elevated in NOMID patients vs. normal controls (182 ng/ml vs. 139 ng/ml, p=0.037) and remained elevated after treatment with anakinra (160 ng/ml), even though other markers of inflammation, including ESR, high sensitivity CRP, WBC, and platelet counts all declined to normal levels. The highest levels of FSTL-1 were observed in patients with bony overgrowth at baseline as compared to patients without bony overgrowth (204 ng/ml vs. 149 ng/ml, p = 0.01), whereas FSTL-1 levels did not correlate with other clinical abnormalities. A trend of correlation was seen between FSTL-1 and high sensitivity CRP (Pearson r = 0.38, p = 0.08). Finally, FSTL-1 serum levels were elevated in mice expressing NLRP3 mutation compared to wild type controls (502 ng/ml vs. 201 ng/ml, p <0.001) and were similarly elevated in mice expressing NLRP3 mutation on an IL1 receptor knockout background (440 ng/ml, p = 0.07 vs. controls).

Conclusion: Serum FSTL-1 is elevated in patients with NOMID and FSTL-1 levels remain elevated despite anakinra treatment. Similarly, FSTL-1 levels are elevated in a mouse model of CAPS and remain elevated despite the absence of IL-1 receptor. Serum FSTL-1 levels are most elevated in NOMID patients with greater baseline bony overgrowth and remain elevated despite treatment with anakinra, suggesting that FSTL-1 may play a role or be a marker of bone abnormalities in this disorder.

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a rare inflammatory disease that is inherited as a complex genetic trait. While the pathophysiology of sJIA is poorly understood, there is evidence of both innate and adaptive immune involvement. We have undertaken a genome-wide association study (GWAS) of sJIA to elucidate pathways and molecular mechanisms that underlie this disease. The power of a GWAS is directly related to the size of the population studied. This confounds the application of GWAS to rare diseases, such as sJIA, where acquisition of even modestly-sized patient collections is very difficult. In an attempt to overcome the rare nature of sJIA, we have designed a meta-analytic GWAS to investigate sJIA collections from eight different countries.

Methods: We genotyped 823 children fulfilling ILAR criteria for sJIA and 442 healthy children using the Omni1M Quad SNP array. We obtained five *in silico* collections of control genotypes that were geographically-matched to five of the case collections, providing an additional 4037 controls for our analysis. After performing quality control operations to exclude low quality samples and markers, we combined case and control genotype data for each of the eight strata, retaining only markers that were present in both the case and control datasets. We used principal components analysis to identify and remove genetic outliers from each population. For each stratum, we created phased haplotypes with the ShapeIT software, we performed SNP imputation with IMPUTE2 software and the HapMap3 reference haplotypes, and we undertook association testing with SNPTEST software. Finally, genomewide association meta-analysis of the eight strata was performed using the GWAMA software.

Results: Genomewide association meta-analysis of 1,447,416 markers, applying the additive model to eight case-control strata, identified 49 regions that contained one or more marker with p < 5E-5. Fourteen of these genes reside within a 3 Mb segment of the major histocompatibility complex (MHC), spanning the MHC class II and III gene clusters. This sJIA-associated region also contains the only marker to exceed the genomewide significance threshold (rs615672, p = 2.64E-8; OR = 0.7, 95CI 0.62, 0.79), which lies between *HLA-DRB1* and *HLA-DQA1*.

Genomewide Association Meta-Analysis of Systemic Juvenile Idiopathic Arthritis. This plot demonstrates the $-\log_{10}$ p values generated by genomewide meta-analysis of eight sJIA case-control strata. The horizontal line at y = 7.3 represents the threshold for genomewide significance (p < 5 x 10^{-8}).
Conclusion: The markers most strongly associated with sJIA were found within the MHC locus, nearest to the *HLA-DRB1* and *HLA-DQA1* genes. However, these variants reside in a larger, 3 Mb interval that contains a range of genes involved in both innate and adaptive immunity. Interestingly, we have observed an almost complete absence of overlap between our 49 candidate loci and the known autoimmune and autoinflammatory loci. If this observation is upheld by additional investigations, then we may expect this study to identify novel pathways and mechanisms involved in sJIA, which may also represent novel therapeutic targets.

Correlation Between Mefv Genotype and Interleukin (IL)1β secretion and Role of the nlr Family Pyrin Domain Containing 3 (Nlrp3) Inflammasome in Patients with Familial Mediterranean Fever (FMF). Alessia Omenetti[1], Sonia Carta[2], Delfino Laura[2], Alberto Martini[3], Anna Rubartelli[4] and Marco Gattorno[1]. [1]Pediatrics II Unit G Gaslini Institute, Genoa, Italy, [2]Cell Biology, lST-San Martino, Genoa, Italy, [3]Pediatrics ll Unit, G Gaslini Institute and University of Genoa, Genoa, Italy, [4]lST-San Martino, Genoa, Italy, Genoa, Italy

Background/Purpose: Familial Mediterranean Fever (FMF) is an auto-inflammatory disease due to mutations of MEFV gene which encodes for

Pyrin. FMF does not behave as a pure recessive disorder but clinical manifestations may parallel the actual amount of mutant pyrin. In agreement with this concept, correlation between genotype and FMF symptoms has been described. Growing evidence suggests that aberrant interleukin (IL) 1β signaling occurs in FMF. However, whether genetic variants of the MEFV gene result in differences in $IL1\beta$ levels has never been explored. Moreover, the role of NLR family pyrin domain containing 3 (NLRP3) inflammasome in this contest is still largely unclear. Thus, we evaluated if $IL1\beta$ pathway activation (1) is enhanced in FMF; (2) correlates with the type of MEFV mutation; and (3) is mediated by NLRP3.

Methods: Twenty FMF patients (FMFp) were evaluated and compared with 14 MEFV healthy carriers (HC) and 30 healthy donors (HD). Among patients, 12 were genetically confirmed (i.e. carrying 2 mutations) while 8 had clinical manifestations even if carrying 1 single mutation in heterozygosity. Ten out of 20 FMFp were under colchicine treatment and all of them were in controlled disease activity. Monocytes were freshly isolated and studied at baseline and after LPS in vitro activation. Monocyte nucleofection with NLRP3 siRNA or appropriate Mock controls was performed in 23 subjects (i.e. 7 FMFp, 9 HC, 3 HD) using Nucleofector" Technology (Amaxa). $IL1\beta$ and IL1 receptor antagonist (ILRa) pattern of secretion (3–6-18h) was analyzed by ELISA assay. Differences in oxydative state were evaluated by assessing levels of reactive oxygen species (ROS) and the cysteine release, as markers of pro- and antioxidant responses, respectively.

Results: Monocytes purified from FMFp displayed enhanced $IL1\beta$ release. Interestingly, $lL1\beta$ secretion correlated with number and penetrance of MEFV mutations, with higher levels in the presence of 2 high penetrance mutations in FMFp, and 1 high penetrance mutation in HC, respectively. Silencing of NLRP3 activity in monocytes freshly isolated from patients and controls consistently inhibited $lL1\beta$ secretion. Contrary to what previously described in diseases caused by mutations that primarily affect the NLRP3 (i.e. Cryopyrinopaties) $L1\beta$ release in pyrin mutated monocytes was featured by a more physiological kinetics. Consistent with this finding, FMFp monocytes basally produced more ROS but had a conserved, although impaired, cysteine release. Finally, IL1Ra levels were comparable to HD.

Conclusion: MEFV mutated monocytes display enhanced $IL1\beta$ secretion, which correlates with the number of high-penetrance mutations. In contrast to what found in the animal model, $IL1\beta$ secretion in FMFp monocytes is NLRP3-dependent. Interestingly, contrary to what previously reported in NLRP3 mutated cells, monocytes carrying MEFV mutation (1) have conserved antioxidant machinery capable of restraining the oxidative stress, (2) do not show stress-related defect in protein synthesis, (including IL1Ra production) and (3) display a more physiological pattern of secretion of $lL1\beta$.

ACR Concurrent Abstract Session
Rheumatoid Arthritis - Clinical Aspects VII:
Prediction of Outcome in Rheumatoid Arthritis
Wednesday, November 14, 2012, 11:00 AM–12:30 PM

2659

An Expanded Repertoire of Anti-Citrullinated Peptide Antibodies Is Associated with Interstitial Lung Disease in Rheumatoid Arthritis.
Jon T. Giles[1], Sonye Danoff[2], Jeremy Sokolove[3], Robert Winchester[4], Dimitrios A. Pappas[5], Catriona Cramb[6], Geoffrey Connors[7], Stanley S. Siegelman[8], William H. Robinson[9] and Joan M. Bathon[1]. [1]Columbia University Medical Center, New York, NY, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]VA Palo Alto Health Care System and Stanford University, Palo Alto, CA, [4]Columbia University, New York, NY, [5]Columbia University, College of Physicians and Surgeons, New York, NY, [6]VA Palo Alto Heatlh Care System and Stanford University, Palo Alto, CA, [7]Division of Pulmonary and Critical Care Medicine, Yale University, New Haven, CT, [8]Department of Radiology, Johns Hopkins University, Baltimore, MD, [9]Stanford University, Palo Alto, CA

Background/Purpose: Interstitial lung disease (ILD) is an outcome with high morbidity and mortality in rheumatoid arthritis (RA). Citrullinated proteins are observed in these lung tissues; however, the association of specific anti-citrullinated peptide antibodies (ACPA) with ILD in RA is unknown.

Methods: RA patients underwent multi-detector computed tomography (MDCT) of the chest with interpretation by a pulmonary radiologist for ILD features [ground glass opacification (GGO), reticulation (R), honeycombing (HC), and traction bronchiectasis (TB)]. A semi-quantitative ILD Score (ILDS; range 0–32) for ILD features was calculated. Concurrent serum samples were assessed for anti-CCP (CCP2) and levels of a panel of antibodies against 4 non-citrullinated proteins [fibrinogen A, HSP60, apolipoprotein (Apo) A1, and Apo E] and 17 citrullinated full-length proteins or peptides within these proteins (see table for list) using a custom Bio-Plex bead array. Individual candidate citrullinated antigens were conjugated to spectrally-distinct fluorescently dyed beads. Peptide-conjugated beads were incubated with diluted patient sera, autoantibody binding detected with a phycoerythrin-conjugated secondary antibody, and levels of autoantibody binding quantitated on a Luminex 200 System. High level ACPA was defined at $\geq$ the group 75th percentile. Pulmonary function testing (PFT) was performed in 156 patients a mean of 21 ± 3 months later.

Results: Among 177 RA patients [60% female, 86% Caucasian, mean age 59 ± 9 years, 11% current smokers], any ILD features (i.e. ILDS>0) was observed in 57 (32%). Among those with any ILD, the median ILDS was 3 (range 1–10). A predominant pattern of GGO was observed in 22 (39%) and R/HC/TB in 35 (61%). PFT restriction or impaired diffusion was observed in 36 (23%).

Levels of CCP2 and all specific ACPAs were 46–273% higher among RA patients with vs. those without ILD (all p-values<0.05), and higher levels correlated with higher ILDS. In contrast, levels of non-citrullinated protein antibodies were not higher in those with ILD. The median number of high level ACPA was significantly greater for those with an ILDS$\geq$3 vs. those with an ILDS=0 (6 vs. 1; p=0.005, see Table). Each ACPA was associated, on average, with a 0.10 unit increase in ILDS (p=0.001), an association that remained significant after adjusting for features associated with ILD [age, gender, current and former smoking, DAS28, current prednisone and leflunomide use]. More high level ACPA were observed in R/HC/TB compared to ILDS=0, but the difference was less robust for GGO vs. ILDS=0 (Table). More high level ACPA were observed in those with PFT restriction or impaired diffusion compared to those without these PFT findings (Table).

Table. Number of High Level ACPA* (>75th Percentile) According to Computed Tomographic Features of RA-Associated Interstitial Lung Disease and Restriction and/or Impaired Diffusion on Pulmonary Function Testing

Outcome	Number of High Level ACPA**	p-value
ILDS = 0 (n = 120)	1 (0–5)	referent
ILDS 1 or 2 (n = 25)	3 (1–11)	0.073
ILDS $\geq$ 3 (n = 32)	6 (1–11)	0.005
ILDS = 0 (n = 120)	1 (0–5)	referent
GGO (n = 22)	3 (1–7)	0.23
R/HC/TB (n = 35)	3 (0–12)	0.041
No Restriction cr Impaired DLCO (n = 120)	1 (0–5)	referent
Restriction or Impaired DLCO (n = 36)	5 (1–11)	0.009

* ACPA levels measured included citrullinated versions of <u>fibrinogen A</u> and <u>4 specific fibrinogen A peptides</u>, <u>Apo A1</u>, <u>Apo E</u> and <u>1 specific Apo E peptide</u>, <u>enolase</u>, <u>vimentin</u> and <u>1 specific vimentin peptide</u>, <u>histones 2A</u> and B, <u>filaggrin</u>, <u>biglycan</u>, and <u>clusterin</u>
** Values depicted are median (interquartile range) with comparison using the Kruskal-Wallis test.
ACPA = anti-citrullinated protein antibody; ILD = interstitial lung disease; ILDS = expert read interstitial lung disease score; GGO = ground glass opacification; R/HC/TB = reticulation/honeycombing/traction bronchiectasis; DLCO = diffusing capacity for carbon monoxide

Conclusion: Our findings of a broader ACPA repertoire in RA ILD suggest a role for ACPA in the pathogenesis of ILD and/or implicate inflamed lung parenchyma as a source of ACPA generation.

Progressive Radiographic Joint Damage in Established Rheumatoid Arthritis: Common and Strongly Associated with Seropositivity. Siri Lillegraven[1], Nancy A. Shadick[2], Zarif Jabbar-Lopez[3], Anna Potapov[3], Michelle A. Frits[2], Christine K. Iannaccone[2], Espen A. Haavardsholm[1], Tore K. Kvien[1], Michael Weinblatt[2] and Daniel H. Solomon[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard School of Public Health, Boston, MA

Background/Purpose: During the last decade, rheumatoid arthritis (RA) research has mainly focused on early disease, as it has become apparent that early and aggressive treatment can change the long-term outcome of RA. However, most patients in clinical practice have established disease. Our objective was to describe the proportion of patients with established RA (≥ 5 years disease duration) who experience continued joint damage, and to identify its predictors.

Methods: We analyzed data from BRASS, an observational RA cohort. The data collection includes joint examinations, serological markers and patient reported outcome measures. Hand and wrist radiographs are acquired at baseline and 2 years and scored by van der Heijde-modified Sharp score (vdHSs). Patients with a disease duration ≥ 5 years and 2-year radiographic data (n=390) were selected, and progression of joint damage was defined as an annual change of ≥ 1 unit in total vdHSs. In univariate logistic regression models, we assessed the association between progressive joint damage and predictors such as age, gender, disease duration, treatment, DAS-28 category, subcutaneous nodules, seropositivity (classified as either negative for both RF and anti-CCP, positive for either RF or anti-CCP, or positive for both RF and anti-CCP), BMI and smoking. We then built a multivariate regression model, forcing DMARD treatment and disease duration into the model as covariates. Individual radiographic data stratified according to serological status were displayed in a cumulative probability plot.

Results: The median (IQR) age of the 390 patients was 60 (52, 67) years and the median disease duration was 17 (10, 27) years. 84% were female and 44% received biologic DMARD treatment. 16 % were negative for both RF and anti-CCP, 16 % were positive for either and 68 % were positive for both RF and anti-CCP. 44% (172) of the patients had progression of joint damage. Older age, longer disease duration, worse disease activity, seropositivity, normal BMI and no prior smoking had p-values <0.25 and were included in the model building. In multivariate logistic regression analyses, seropositivity was independently associated with joint damage. Positivity for either RF or anti-CCP had an OR (95% CI) of 5.0 (2.2, 11.1) and positivity for both serological markers an OR of 4.1 (2.1, 8.2) for subsequent joint damage. No other independent predictors were identified. Although the ORs for progressive joint damage were similar if patients were positive for one or both of RF and anti-CCP, patients who were positive for both RF and anti-CCP tended to experience more joint damage (**Figure**).
Figure. Cumulative probability plot displaying individual radiographic data. A tendency towards more rapid radiographic progression (VdHSS ≥ 5 units per year) is seen in patients positive for both RF and anti-CCP (16%) compared to patients positive for only RF or anti-CCP (9%), p-value 0.21.

Conclusion: Progression of joint damage is still common in RA patients with at least five years disease duration, even in a setting where 44% of the patients receive biologic DMARDs. Seropositivity is strongly and independently associated with joint damage.

Disease Activity Score 28-Joint Count: Are Erythrocyte Sedimentation Rate and C-Reactive Protein Versions Comparable? Roy M. Fleischmann[1], Désirée van der Heijde[2], Andrew S. Koenig[3], Ronald Pedersen[3], Annette Szumski[3], Lisa Marshall[3] and Eustratios Bananis[3]. [1]University of Texas, Dallas, TX, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Pfizer Inc., Collegeville, PA

Background/Purpose: Frequently DAS28-CRP is utilized instead of DAS28-ESR to assess rheumatoid arthritis (RA) disease activity; however, values for remission and low disease activity (LDA) for DAS28-CRP have not been validated.[1,2] Differences between remission rates could vary between 8–24% and therefore, the cut-off points should not be identical for the two measures.[3–5] The aim of this analysis is to examine the value of DAS28-CRP, which corresponds to the value of DAS28-ESR for cut-off points from 3 different patient populations.

Methods: Randomized patients from COMET (early, moderate-to-severe RA), TEMPO (established moderate-to-severe RA), and PRESERVE (moderate RA) who received etanercept (ETN) 50 mg weekly + MTX or MTX alone were included. DAS28-ESR and DAS28-CRP response rates were compared (COMET, TEMPO week 52; PRESERVE week 36) for each study and by treatment group utilizing the traditional ESR cut-off points for remission <2.6 and LDA ≤ 3.2; level of agreement was determined by kappa coefficient, sensitivity, and specificity. Remission and LDA cut-offs for DAS28-CRP were based on patients' final time point, with treatment groups and studies being pooled together before utilizing ROC analysis to obtain the new cut-offs that best correspond to ESR established cut-offs. DAS28-ESR and CRP, along with their unique components (0.70*ln[ESR] and 0.36*ln-[CRP + 1] + 0.96), were analyzed as continuous parameters using Spearman's correlation. DAS28-CRP cut-offs for the Asian population were examined and compared with the overall population.

Results: The percentage of patients meeting the definition of remission (<2.6) or LDA (≤ 3.2) was slightly higher for DAS28-CRP than DAS28-ESR for both treatment groups across all 3 trials (Table). The concordance in which patients achieved the same outcome for both DAS28-ESR and CRP LDA or remission ranged from 82–91%. Although, DAS28-ESR and CRP measures were highly correlated (range 0.80–0.90; $P<0.001$) for each study's final time point, their unique components were not highly correlated (range 0.35–0.50; $P<0.001$). New DAS28-CRP cut-offs were found to range from 2.4–2.5 for remission and 3.0–3.1 for LDA, depending on study and treatment with 2.52–3.05 providing the best overall results. Cut-offs determined from the Asian population showed some differences, especially LDA, compared with the overall population suggesting regional differences exist.

Table. Statistical Measures of Agreement for DAS28-ESR and DAS28-CRP by Study and Treatment

Disease Activity	ETN + MTX					MTX				
	DAS28-ESR	DAS28-CRP	Sensitivity	Specificity	Kappa Coefficient	DAS28-ESR	DAS28-CRP	Sensitivity	Specificity	Kappa Coefficient
COMET (Week 52)										
Remission (<2.6)	132/265 (50)	145/262 (55)	(89)	(78)	0.671*	73/263 (28)	85/250 (34)	(83)	(86)	0.658*
LDA (≤ 3.2)	170/265 (64)	187/262 (71)	(96)	(76)	0.756*	109/263 (41)	132/250 (49)	(94)	(83)	0.759*
TEMPO (Week 52)										
Remission (<2.6)	88/231 (38)	98/229 (43)	(86)	(84)	0.693*	39/228 (17)	53/228 (23)	(67)	(86)	0.458*
LDA (≤ 3.2)	122/231 (53)	128/229 (56)	(91)	(84)	0.754*	68/228 (30)	91/228 (40)	(87)	(80)	0.608*
PRESERVE (Week 36)										
Remission (<2.6)	525/826 (64)	523/826 (63)	(87)	(78)	0.645*	NA	NA	NA	NA	NA
LDA (≤ 3.2)	677/826 (82)	671/826 (81)	(94)	(77)	0.702*	NA	NA	NA	NA	NA

* $P<0.05$ corresponds to kappa coefficient of agreement between the two measurements. Sensitivity and specificity based on standard of DAS28-ESR LDA or remission. Values n/N (%). NA = not applicable as PRESERVE patients received open-label ETN 50 mg + MTX.

Conclusion: The percentage of patients achieving remission or LDA was lower for DAS28-ESR than DAS28-CRP when utilizing the same cut-off points for both measures. DAS28-CRP underestimates disease activity when utilizing cut-off points validated for DAS28-ESR and therefore, should be evaluated using different remission and LDA values. Studies are needed to validate proposed DAS28-CRP disease activity cut-offs.

Tightening up: Musculoskeletal Ultrasound Could Further Individualise Treatment Decisions in Early Rheumatoid Arthritis Patients Treated by a Step-up DMARD Escalation Regimen. James Dale[1], David Purves[1], Alex McConnachie[1], Duncan Porter[2] and Iain B. McInnes[1]. [1]University of Glasgow, Glasgow, United Kingdom, [2]Gartnavel General Hosp, Glasgow, United Kingdom

Background/Purpose: Treat-to-target (T2T) strategies have significantly improved outcomes in early rheumatoid arthritis (RA). Treatment escalation is usually guided by a disease activity score; however, modern imaging techniques demonstrate that many patients have sub-clinical synovitis without clinical joint swelling, and DAS28 scores can be elevated in patients without active RA. The TASER study (NCT00920478) is a randomized controlled trial comparing a standard T2T strategy with one guided by DAS28 and musculoskeletal ultrasound (MSUS)

Objective: To report the frequency of sub-clinical MSUS synovitis in patients randomized to the MSUS arm of the TASER study, and to determine how frequently treatment decisions could be affected by using MSUS.

Methods: DAS28 scores were calculated every month. MSUS was performed on patients in low disease activity (DAS28<3.2) and those with moderate disease activity (3.2≤DAS28<5.1) in the absence of clinically swollen joints (SJ ≤1). 14 joints (bilateral PIP2+3, MCP2+3, radiocarpal, MTP2+5) were assessed. Active disease was defined as >2 joints demonstrating any Power Doppler (PD) signal.

Analysis: Paired DAS28 and MSUS data from 319 assessments were pooled to determine levels of agreement between clinical and MSUS findings

Results: *Cohort:* 60% female, mean age 57 years (SD13), mean disease duration 5.1 months (SD2.8), 66% rheumatoid factor positive, 66% anti-CCP antibody positive, 32% erosive baseline Xrays.

Table 1. Comparison of DAS28 and MSUS findings; agreement is shown in italics, disagreement in bold

	Number of Instances	MSUS Findings N (%)		
		Active Disease	Inactive Disease	Overall Agreement
Remission (DAS28 < 2.6)	149	**42 (28%)**	*107 (72%)*	72%
Low disease activity (DAS28 < 3.2)	284	**78 (27%)**	*206 (73%)*	73%
Moderate disease activity (3.2≤DAS28<5.1) **AND ≤ 1 Swollen Joint**	35	*14 (40%)*	**21 (60%)**	40%

27–28% of patients in clinical remission/low DAS28, demonstrated evidence of sub-clinical synovitis. In 60% of patients with moderate disease in the absence of clinical synovitis there was no MSUS synovitis either. Overall, using MSUS or a DAS28>3.2 threshold for DMARD escalation would have reached the same decision on 220 out of 319 occasions (69% agreement).

Table 2. Frequency (%) of positive MSUS findings in individual joint areas

Joint Area (pooled data for both sides)	Synovial Hypertrophy N (%)	PD Signal N (%)
PiP2	30 (9%)	13 (4%)
PiP3	20 (6%)	3 (1%)
MCP2	105 (33%)	74 (23%)
MCP3	69 (22%)	42 (13%)
Radiocarpal	235 (74%)	179 (56%)
MTP2	212 (66%)	23 (7%)
MTP5	26 (8%)	16 (5%)

For all instances, mean SH score = 4.0 (SD3.5) and index = 2.2 (SD1.7). Mean PD score = 1.4 (SD1.8) and index = 1.1 (SD1.2)

Conclusion: Assessment of global disease activity using a limited MSUS joint set may allow further tailoring of DMARD therapy by: 1. supporting DMARD escalation in patients with active disease despite a reassuring DAS28 and 2. preventing DMARD escalation in patients with moderate DAS28 levels but minimal evidence of active disease. MSUS findings in the radiocarpal and index MCP joints were most likely to influence DMARD escalation decisions. Whether this approach will significantly improve outcomes remains to be proven.

A Variant in the Osteoprotegerin Gene Is Associated with Coronary Atherosclerosis in Patients with Rheumatoid Arthritis: Results From a Candidate Gene Study. Cecilia P. Chung[1], Joseph F. Solus[1], Annette Oeser[1], Chun Li[1], Paolo Raggi[2], Jeffrey R. Smith[1] and C. Michael Stein[1]. [1]Vanderbilt University, Nashville, TN, [2]Emory University, Atlanta, GA

Background/Purpose: Patients with rheumatoid arthritis (RA) have accelerated atherosclerosis. However, this association is not fully explained by traditional cardiovascular risk factors or markers of inflammation. Little is known about the association between genetic variation and atherosclerosis in this population. Therefore, we examined the hypothesis that in patients with RA selected candidate gene variants were associated with the presence of coronary atherosclerosis.

Methods: One hundred and forty patients with RA, enrolled in an ongoing study to evaluate the prevalence and risk factors of coronary atherosclerosis in RA, were studied. Patients fulfilled the 1987 American College of Rheumatology classification criteria for RA and were 18 years or older. Coronary artery calcium (CAC), a non-invasive measurement of coronary atherosclerosis, was measured by electron beam computed tomography. Genotyping was performed using the Illumina Goldengate platform on a custom panel of 714 single-nucleotide polymorphisms (SNPs) tagging 176 selected candidate genes. Candidate genes were chosen for relevance to autoimmune and cardiovascular risk. The association between the presence of CAC and the allele frequency of the SNP was assessed by logistic regression models, adjusted for age, sex, and race. To adjust for multiple comparisons, a false discovery rate (FDR) threshold was set at 20%.

Results: Patients with RA were 54±11 years old and predominantly Caucasian (89%) and female (69%). The presence of CAC was detected in 70 patients (50%). After adjustment for age, race, and sex, SNPs in tumor necrosis factor receptor superfamily member 11 b (*TNFRSF11B*), matrix metalloproteinase-3 (*MMP3*), interleukin-12 (*IL12*), matrix metalloproteinase-9 (*MMP9*), nucleotide-binding oligomerization domain-2 (*NOD2*), C-reactive protein (*CRP*), myeloperoxidase (*MPO*), resistin (*RETN*), interferon regulatory factor (*IRF*) and Fcγ receptor 2A (*FCGR2A*) were associated with the presence of CAC (Table). The variant rs2073618, which encodes an Asp3Lys missense change in the osteoprotegerin gene (*OPG, TNFRSF11B*), was significantly associated with CAC (OR= 4.09, p=0.00026) after FDR correction.

Table. Genetic Association with Coronary Atherosclerosis in Patients with RA

SNP	Gene	Major, minor allele	Minor allele frequency	Odds ratio* (95% CI)	p-value
rs2073618	*TNFRSF11B*	G,C	0.36	4.09 (1.93–8.70)	<0.001
rs522616	*MMP3*	T,C	0.29	4.43 (1.77–11.10)	0.001
rs2853694	*IL12B*	T,C	0.29	3.09 (1.53–6.24)	0.002
rs3918249	*MMP9*	T,C	0.49	0.36 (0.18–0.69)	0.002
rs17576	*MMP9*	A,G	0.45	0.34 (0.17–0.68)	0.002
rs3918253	*MMP9*	C,T	0.28	0.38 (0.20–0.72)	0.003
rs2274756	*MMP9*	G,A	0.16	0.24 (0.09–0.64)	0.004
rs751271	*NOD2*	T,G	0.49	2.57 (1.33–4.96)	0.005
rs650108	*MMP3*	G,A	0.41	2.82 (1.29–6.17)	0.009
rs1800947	*CRP*	C,G	0.04	5.93 (1.43–24.71)	0.014
rs9562414	*TNFSF11*	A,G	0.06	0.25 (0.08–0.79)	0.019
rs2107545	*MPO*	T,C	0.26	0.42 (0.20–0.89)	0.023
rs3745367	*RETN*	G,A	0.39	0.45 (0.22–0.91)	0.026
rs10954213	*IRF5*	G,A	0.47	0.50 (0.27–0.94)	0.030
rs633137	*TNFSF11*	T,A	0.08	0.34 (0.13–0.91)	0.031
rs2243828	*MPO*	A,G	0.23	0.43 (0.20–0.96)	0.040
rs1801274	*FCGR2A*	A,G	0.43	0.52 (0.28–1.00)	0.049

* Odds ratios for the comparison between minor and major allele.

Conclusion: Our results suggest that a potential functionally poly-morphism of the *TNFRSF11B* gene, which encodes osteoprotegerin, is associated with the presence of coronary atherosclerosis in patients with RA. Replication of this finding in independent validation cohorts will be of interest.

2664

A Multi-Biomarker Disease Activity (VECTRA™ DA Algorithm) Score Reflects Clinical Disease Activity and Tracks Responses in Patients with Rheumatoid Arthritis Treated with Either Adalimumab, Etanercept, and Infliximab. Shintaro Hirata[1], Douglas J. Haney[2], Guy Cavet[2], Rebecca Bolce[2], Wanying Li[2], Nadine Defranoux[2], David Chernoff[2], Kunihiro Yamaoka[1], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Crescendo Bioscience Inc., South San Francisco, CA

Background/Purpose: Anti-TNF therapy has become a standard therapeutic strategy for treatment of patients with rheumatoid arthritis (RA). A validated multi-biomarker disease activity algorithm (MBDA) blood test was used to provide objective biological information about RA. We studied the relationship between the MBDA score and disease activity measures including DAS28, SDAI, and CDAI in patients treated with anti-TNF therapy.

Methods: 147 patients who started anti-TNF therapy (49 adalimumab (ADA), 49 etanercept (ETN), 49 infliximab (IFX)) were enrolled. Twelve biomarkers were measured and combined in a pre-specified algorithm to generate a MBDA score between 1 and 100 at 0 (baseline) and 52 weeks after induction of anti-TNF therapy. Associations between MBDA score and DAS28/SDAI/CDAI were evaluated by Spearman correlation and by area under the receiver operating characteristic curve (AUROC). MBDA score changes in patients with EULAR responses were compared by t-test. Differences in the MBDA/DAS28 relationship between TNF inhibitors were evaluated by fitting linear models for DAS28 as a function of MBDA score, therapy and an MBDA/therapy interaction term.

Results: At baseline, patients' median age was 60 (interquartile range (IQR) 50–68), DAS28- 5.7 (5.0–6.5), MBDA- 64 (IQR 49–76) and disease duration 60 months (18–168). Methotrexate was used in 86% of patients, at a median dose of 8.0 (8.0–10) mg/week. There was a mean decrease + SD in DAS28 of 2.6 + 1.4 and in MBDA of 25 + 20 respectively. MBDA scores correlated with DAS28, SDAI and CDAI (ρ=0.64, 0.57, 0.50 respectively, all p<0.001) and distinguished low and moderate/high disease activity for all three clinical indices (AUROC =0.80, 0.76, 0.76 respectively, all p<0.001). No differences were found in the relationship between the MBDA score and DAS28 in patients treated with either ADA, ETN and IFX (p>0.05 for all comparisons). The mean decrease in the MBDA score was greater for patients with moderate EULAR response versus non response (−22 vs. 1, p<0.002) and greater for patients in good response versus moderate response (−30 vs. −22, p=0.009).

	ADA	ETN	IFX	all
n at Baseline	49	49	49	147
n at 52 weeks	49	49	49	147
Mean (±SD) MBDA at Baseline	61 ± 18	63 ± 17	59 ± 21	
Mean (±SD) MBDA at 52 Weeks	33 ± 15	37 ± 16	39 ± 18	
Mean (±SD) DAS28 at Baseline	5.4 ± 1.2	6.0 ± 1.1	5.9 ± 1.0	
Mean (±SD) DAS28 at 52 Weeks	2.8 ± 1.0	3.4 ± 1.2	3.1 ± 1.2	
Mean Change in MBDA (±SD): BL to 52 weeks	−29 ± 20	−26 ± 17	−20 ± 22	
Mean Change in DAS28 (±SD): BL to 52 weeks	−2.5 ± 1.4	−2.6 ± 1.4	−2.7 ± 1.3	

Conclusion: The MBDA score correlates with clinical disease activity measures in a cohort receiving anti-TNF therapy. The MBDA score tracks response in clinical disease activity in patients treated with different anti-TNF therapies, ADA, ETN or IFX.

Metabolic Reprogramming of Autoimmune T Cells in Rheumatoid Arthritis. Zhen Yang[1], Hiroshi Fujii[2], Shalini Mohan[1], Jorg J. Goronzy[1] and Cornelia M. Weyand[1]. [1]Stanford University School of Medicine, Stanford, CA, [2]Tohoku University, Sendai, Japan

Background/Purpose: In RA, autoimmunity precedes clinical symptoms by a decade and persists unabated even when downstream inflammation is well controlled; exposing lymphocytes to chronic stimulation and enforcing adaptation to persistent stress. T cells undergo rapid and extensive clonal expansion with a fairly unique need to greatly enhance metabolic activities and fulfill their energy needs by up-regulating aerobic glycolysis as well as autophagy. Glycolytic flux is mainly controlled by 6-phosphofructo-1-kinase, with its allosteric activator fructose 2,6-bisphosphate as a key regulator of the glycolytic pathway. The enzyme 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase isoform 3 (PFKFB3) generates fructose-2,6-bisphosphate and, hence, critically regulates the glycolytic rate under normal and pathophysiological conditions.

Methods: CD4$^+$CD45RO$^-$ T cells purified from the blood of RA patients (n=77) and age-matched controls were stimulated by TCR cross-linking. Glucose consumption, intracellular ATP and lactate production were quantified. Expression of 33 glycolysis-associated genes was profiled by RT-PCR. Protein levels of PFKFB3 and the autophagy marker LC3II were measured by Western blotting. Glycolytic flux and autophagic signaling were blocked through the PFKFB3 inhibitor N-BrEt or the autophagy inhibitor 3-methyladenine.

Results: Compared to control CD4 T cells, RA CD4 T cells respond to stimulation-induced metabolic needs with impaired glucose consumption (p=0.015), diminished ATP production (p<0.001)and reduced lactate release (p<0.001); all indicative of a defect in glycolytic flux. RA T cells express normal densities of glucose receptors but consistently fail to up-regulate PFKFB3 (p=0.012) and induce insufficient amounts of LC3II (p=0.032). Deficiency in glucose metabolism and autophagy is associated with increased apoptosis (p=0.003). This phenotype is reproduced in control T cells by knockdown of PFKFB3 or blocking autophagic signaling. Overexpression of ectopic PFKFB3 in RA T cells restores intracellular ATP (p=0.009) and lactate production (p=0.024) and conveys apoptotic resistance. Restoring PFKFB3 in RA T cells also rectifies the autophagic defect (p=0.024). Energy

deprivation is a stable phenotype of RA T cells, independent from disease activity and duration.

Conclusion: The inducible glycolytic rate-limiting enzyme PFKFB3 is repressed in RA T cells, resulting in deficient glucose utilization. The energy deprivation is aggravated by insufficient access to cell-internal energy resources and renders RA T cells apoptosis sensitive. Resetting the immune system in RA will require the repair of these metabolic abnormalities as they strain immune homeostasis and sustain chronic immune stress.

A Link Between B Cells and Bone Erosion in RA: RANKL Production by Memory B Cells. Nida Meednu, Teresa Owen, Hengwei Zhang, Christopher A. Cistrone, Lianping Xing and Jennifer H. Anolik. University of Rochester, Rochester, NY

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disorder that often leads to joint damage. Several lines of evidence suggests the role of B cells in joint destruction including the efficacy of B cell depletion therapy as a treatment and the presence of B cell aggregates in RA synovium and subchondral bone. The aim of this study was to investigate the mechanisms by which B cells contribute to joint destruction in RA.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from peripheral blood or synovial fluid by Ficoll-Hypaque density gradient centrifugation from healthy controls (HC) or RA patients. Purified B cells were obtained by CD19 magnetic isolation. Cells were stimulated with anti-CD40 (2.5 μg/ml) and PMA (20 ng/ml) for 48 hours. RANKL expression was detected by cell surface staining and multi-color flow cytometry. Several markers to identify B cells and for T cell exclusion were employed including CD19, CD27, IgD, CD95, CD21 and CD3. For osteoclast formation assay, purified B cells were cultured for 7 days with anti-CD40 and PMA in the first 48 hours. Normal bone marrow derived osteoclast precursors (OCPs) were co-cultured with stimulated B cells in the presence of M-CSF and 10ng RANKL for 4–7 days. Cells were stained with TRAP and multi-nucleated TRAP+ cells were enumerated.

Results: Upon stimulation of PBMCs with anti-CD40 and PMA, the percentage of RANKL+ B cells was significantly higher than cells cultured with medium alone (6.854±1.097 vs. 0.684±0.14, n=9, p< 0.001). The same result was observed with purified B cells (data not shown). CD27+ memory B cells (unswitched CD27+IgD+ and switched CD27+ IgD−) had a greater propensity to produce RANKL in comparison to CD27− B cells (9.41±0.62 vs. 4.93±0.69, p=0.0084). Flow sorting B cells into naïve, transitional, switched and unswitched memory cells further verified the propensity of memory B cells to produce RANKL. Notably, the majority of RANKL-expressing B cells appeared to express the activation marker CD95 (79.04±6.47% CD95+ vs. 20±6.47% CD95−, p= 0.001). We also observed that PB from RA patients contained elevated B cells of an activated memory phenotype (CD95+ on switched memory in RA [n=13] 50.6+19.5 vs. HC [n=14] 29.6+9.5, p=0.005). In accord with this activated memory expansion, the frequency of RANKL+ PB B cells after stimulation was higher in RA when compared to HC (18.4+5.1 vs. 6.9+0.8, p=0.09). Remarkably, RA synovial fluid B cells produced even higher RANKL (23.2+7.6%, n=4) and also spontaneously produced RANKL. Finally, B cells supported osteoclast differentiation, and RA B cells are more efficient than HC (n=4, p<0.05).

Conclusion: Our data support the hypothesis that B cells play a key role in RA disease pathology and joint destruction in part by RANKL production. Activated memory B cells are expanded in RA and have a propensity to produce RANKL, an important factor in bone resorption.

Activated Memory B Cell Compartment in Rheumatoid Arthritis: Impact of B Cell Depletion Therapy. Diana G. Adlowitz[1], Jennifer Hossler[1], Jamie Biear[1], Christopher A. Cistrone[1], Teresa Owen[1], Wensheng Wang[1], Arumugam Palanichamy[1], Ignacio Sanz[2] and Jennifer H. Anolik[1]. [1]University of Rochester Medical Center, Rochester, NY, [2]Emory University, Atlanta, GA

Background/Purpose: B cells are critical players in the orchestration of properly regulated immune responses. This is achieved through the finely regulated participation of multiple B cell populations with different antibody-dependent and independent functions, a balance that we postulate is perturbed in autoimmune diseases such as RA and may be corrected after B cell depletion therapy (BCDT).

Methods: B cells from 13 RA patients were analyzed by multi-color flow cytometry at baseline and longitudinally after BCDT. Expression of CXCR3, CD21, CD95, and anchor markers (IgD, CD19, CD27, CD38, CD24 and live/dead/T-cell exclusions) were used to subset memory B cells. Expression of MitoTracker Green extrusion, CD10, IgM, CD23 and anchor markers were used to subset transitional B cells. RA patients met ACR criteria for classification, and activity was assessed based on DAS28. Cytokine expression in distinct purified B cell subsets or total B cells in PBMCs were examined by flow cytometry after 88 hours stimulation (CpG 2006, anti-CD40, IL2, and BAFF) and 5 hr culture with PMA and ionomycin.

Results: In RA patients both CD27+IgD− switched memory (SM) and CD27−IgD− double negative memory (DN) contained higher fractions of CD95+ and CD21− activated B cells (DN CD95+: RA 28.9+3.9 vs. HC 10.7+1.2, p<0.0001; DN CD21−: RA 41.6+7.3 vs. HC 27.3+2.7, p=0.03). After BCD (1 month) the predominant B cell populations were memory (increase in DN from baseline 6.9+4.4 vs. 1 month 47.7+29.7, p=0.007; SM baseline 14.2+9.7 vs. 1 month 36.1+25.9, p=0.05). Notably, the residual memory B cells displayed a high fraction of CD95+ (DN 59.4+20.3, SM: 52.8+16.3) and CD21− (DN 94.6+2.9, SM: 73.1+22.2) compared to pre-depletion (CD95+: DN 28.9, p=0.03; SM: 38.7+18.0, p=0.1; CD21−: DN 41.6, p=0.0005; SM: 24.9, p=0.006;) suggesting some resistance of these activated populations to anti-CD20. Reconstitution occurred between 4 and 12 months with a variable distribution of transitional, naïve, and memory B cell subsets. At a reconstitution time-point (12 month), the fraction of activated memory remained high (CD95+ SM 91.4+4.6, p=0.001 vs. baseline; CD21− SM 70.4+12.4, p=0.009 vs. baseline), but there was a shift to a naïve/transitional dominant B cell compartment. The critical role of B cells as secretors of cytokines in a polarized fashion was highlighted by the propensity of CD27+ memory B cells to produce pro-inflammatory (TNF) over regulatory (IL10) cytokines (TNF: SM 28.2+5.4% vs. transitional 13.6+2.9, p=0.05; IL10: SM 3.5+0.7 vs. transitional 9.8+1.5, p=0.008). The effects of BCD on B cell cytokine secretion are under investigation.

Conclusion: Our results support the hypothesis that the clinical and immunological outcome of B cell depletion therapy depends on the relative balance of protective and pathogenic B cell subsets established after B cell depletion and upon B cell repopulation.

Interferon and B-Cell Gene Signatures Contribute to Diagnosis of pre-Clinical Rheumatoid Arthritis. Joyce Lubbers[1], Lotte A. van de Stadt[2], Saskia Vosslamber[1], John G. Wesseling[1], Dirkjan van Schaardenburg[2] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands

Background/Purpose: Diagnosis of the preclinical phase of rheumatoid arthritis (pre-RA) allows timely start of treatment with the potential to prevent disease progression. It is known that antibodies against citrullinated proteins (ACPA) and rheumatoid factor (RF) have diagnostic value to identify pre-RA. However, since only 20–40% of ACPA+/RF+ arthralgia patients develop arthritis within 5 years, better prognostic markers are needed. Recently we demonstrated involvement of interferon (IFN) response and B-cell gene signatures pre-RA. The objective of this study is to demonstrate the value of these signatures in the diagnosis of pre-RA.

Methods: Peripheral blood (Paxgene) was collected from 115 ACPA+/RF+ arthralgia patients from Jan van Breemen Research Institute | Reade Amsterdam. Patients where clinically followed for arthritis development with a mean follow-up time of 23 months (IQR 12–30). During this period 44 arthralgia patients developed arthritis within a median time of 8 months (IQR 5–13). IFN response and B-cell related gene expression was measured by multiplex qPCRs. An IFN score was calculated based on 7 highly correlating Type I IFN response genes. A B-cell score was calculated based on three highly correlating B-cell related genes. Cut-off levels for the IFN and B cell high or low definition was determined by the 95% CI of the levels in healthy controls. Cox regression analysis and Receiver Operating Characteristic curve analysis was used to demonstrate prognostic and diagnostic significance.

Results: Cox regression analysis revealed that an IFN[high] score was associated with arthritis development independent of ACPA status (RR 2.19, CI 1.007–4.739, P= 0.048). Inclusion of the B-cell score demonstrated that an IFN[low] score combined with a B-cell[high] score was associated with arthritis free survival (RR 0.375). To demonstrate the clinical utility of the IFN and B-cell signatures to separate pre-RA patients from arthritis free survival individuals we constructed an ROC-curve. The area under the curve (AUC) reached 0.802 (P=0.000), which is considered "good". Based on these data a cut-off could be chosen for the diagnosis of pre-RA with a specificity of 85% and a sensitivity of 52%.

Conclusion: These findings demonstrate the value of IFN and B cell gene signatures as biomarkers for the diagnosis of pre-RA.

This research was supported by the Center for Translational Molecular Medicine (CTMM) consortium "TRACER".

TLR7 Ligation Contributes to Monocyte Migration in Rheumatoid Arthritis. Nathan D. Chamberlain[1], Seung-jae Kim[1], Michael Volin[2], William Swedler[1], Suncica Volkov[3] and Shiva Shahrara[1]. [1]University of Illinois at Chicago, Chicago, IL, [2]Chicago College of Osteopathic Medicine Midwestern University, Downers Grove, IL, [3]University of Illinios at Chicago, Chicago, IL

Background/Purpose: The aim of the study was to characterize the expression of TLR7 in rheumatoid arthritis (RA) peripheral blood (PB) cells and to examine the pathogenic role of TLR7 ligation in RA.

Methods: Expression of TLR7 was determined in RA and normal (NL) PB monocytes and in vitro differentiated macrophages by real-time RT-PCR and/or flow cytometry. Next the endogenous TLR7 ligand was identified in RA synovial fluid and its ability to induce monocyte migration was determined by in vitro chemotaxis.

Results: Since we have previously shown that expression of TLR7 was elevated in RA synovial lining and sublining macrophages, we asked whether expression of TLR7 was increased in RA PB and synovial fluid macrophages compared to NL PB monocytes and differentiated macrophages. We show that expression of TLR7 was elevated 18 and 24 fold in RA synovial fluid macrophages compared to RA and NL PB differentiated macrophages respectively by real-time RT-PCR. Levels of TLR7 were 6 and 3 fold higher in RA monocytes compared to RA differentiated macrophages and NL monocytes. Interestingly, mRNA and endosomal expression of TLR7 are reduced when RA PB monocytes differentiate to macrophages. Ligation of TLR7 by a synthetic agonist in RA blood monocytes is responsible for production of high levels of TNF-a (3 ng/ml) and as such we demonstrate that levels of TLR7 and TNF-a in 35 RA monocytes strongly correlate with each other ($R^2=0.44$, $p=1.37\times10^{-5}$) and disease activity score (TLR7 and DAS28 correlation; $R^2=0.67$, $p=1.57\times10^{-9}$) suggesting a pathogenic role for TLR7 ligation in RA disease. In light of elevated levels of TLR7 in RA synovial fluid macrophages, we looked for TLR7 endogenous ligands in RA synovial fluid. We discovered that single strand (ss)RNA extracted from RA synovial fluid is a potential TLR7 endogenous ligand, since blockade of TLR7 ligation by TLR7 antagonist in RA monocytes greatly downregulates synovial fluid ssRNA mediated TNF-a transcription. To determine whether TLR7 ligation affects cell trafficking in the RA joint, monocyte chemotaxis was examined in response to a synthetic agonist to TLR7. We show that TLR7 ligation was chemotactic for monocytes beginning at 0.1 ng/ml of TLR7 agonist. Next, studies were performed to determine if the TLR7 ligation affects RA synovial fluid mediated monocyte extravasation. We document that blockade of TLR7 ligation or degradation of synovial fluid ssRNA is equally effective in reducing synovial fluid induced monocyte trafficking and that the combined therapy does not have an enhanced effect suggesting that ligation of joint ssRNA to TLR7 modulates monocyte extravasation through an overlapping pathway and it further points out that RA synovial fluid ssRNA is a potential TLR7 ligand.

Conclusion: We identify, for the first time, TLR7 endogenous ligand in RA joint and we also document a novel role for TLR7 ligation in RA monocyte migration.

Background/Purpose: Recent genome-wide association studies (GWAs) have identified >30 SNPs predisposing to Rheumatoid Arthritis (RA). These variants are helpful in unraveling the pathogenesis of RA. However, most therapeutic strategies target pathways of disease progression. Genetic factors account for a considerable proportion of variance in joint damage, but thus far only a few replicated severity factors are known and no GWAS has been performed. We aimed to increase the understanding of the processes underlying the inter-individual differences in joint damage in anti-citrullinated peptide antibodies (ACPA)-positive RA by performing a 3-staged GWAS on joint damage progression using high-quality radiological data, followed by *in vitro* and *ex vivo* studies.

Methods: Stage 1 was performed on 385 ACPA-positive RA-patients from the NARAC using Illumina HumanHap 550k BeadChips. Stage 2 concerned of 1,567 X-rays of 301 ACPA-positive RA-patients included in a Dutch cohort with 7 years follow-up. In stage 3, 861 X-rays of 742 North-American ACPA-positive RA-patients included in the NDB and Wichita-cohorts were studied. All X-rays were scored using the Sharp-van der Heijde method (ICCs all >0.9). The expression of SPAG16 variants was studied by RT-qPCR using a RA synovium cDNA library and cDNA derived from other RA tissues and fibroblast-like synoviocytes (FLS). Expression levels of MMP1 and MMP3 of FLS before and after stimulation with TNF-α (10 ng/ml) and IL1β (1ng/ml) were evaluated by RT-qPCR and ELISA (cell culture supernatants). Finally serum MMP3 levels were measured in RA patients of stage 2 using ELISA.

Results: In stage 1, the strongest association was observed for a cluster of SNPs at 2q34, the region of Sperm associated AntiGen16 (*SPAG16*, $P=4.55\times10^{-7}$, 0.77 fold progression rate per year per minor allele). Independent replication was obtained in stage 2 and 3, again observing a protective effect on damage progression ($P=2.16\times10^{-2}$ and 2.29×10^{-2} resp.). Apart from its role in spermatozoa, the function of SPAG16 is incompletely known. We detected SPAG16 isoforms in RA tissues and FLS. No relation between expression levels of SPAG16 transcripts in FLS and SPAG16 genotypes could be detected. However, the matrix degrading capacity of FLS may be affected. FLS of patients with the minor allele tended to express less MMP3 mRNA and secreted lower levels of MMP3 ($P=2.28\times10^{-2}$). Also after cytokine stimulation the minor allele was associated with less production of MMP3. Furthermore, RA-patients carrying the minor allele had lower serological levels of MMP3 ($P=4.59\times10^{-2}$) and lower MMP3 levels were associated with less progression of damage ($P=3.09\times10^{-3}$).

Conclusion: A genetic variant in *SPAG16* is associated with less production of MMP3 by FLS and protection against joint damage progression. These findings indicate a new pathway involved in joint damage in ACPA-positive RA.

Background/Purpose: Sjögren's syndrome (SS) is a common, clinically heterogeneous autoimmune disease characterized by exocrine gland dysfunction that involves both innate and adaptive immune responses. A complex genetic architecture has been hypothesized; however, genetic studies to date have been limited to candidate gene approaches. We sought to perform the first genome-wide association scan (GWAS) in an unbiased manner to identify SS susceptibility loci.

Methods: We used high-density Illumina OMNI1-Quad genotyping arrays in a discovery cohort of 424 European-derived SS cases and 2120 healthy controls for the GWAS discovery phase. Stringent quality control (QC) criteria, adjustments for population stratification, and standard GWA statistical methodologies were used to compare allele frequencies between cases and controls. A total of ~650,000 single nucleotide polymorphisms (SNPs) were tested for association to SS (P_{omni}). For replication, an independent set of 1194 SS cases and 2930 healthy controls were genotyped using the ImmunoChip (IC; P_{IC}) with ~26,000 overlapping SNPs with the GWAS after QC. Meta-analysis between the GWAS and IC was done using METAL (P_{meta}). Of the 1618 SS case, 133 also had gene expression data from the Illumina WG-6 microarray from whole blood. Expressed quantitative trait loci (eQTL) analysis was done using the MATRIXeQTL package in R. Probes and SNPs in a 50 kb region flanking 4 selected genes were analyzed.

Results: The most significantly associated region with SS was the major histocompatibility complex (MHC), with 1071 overlapping SNPs between the GWAS and IC exceeding a genome-wide significance (GWS) threshold of $5\times10E-8$. The peak association was observed in MSH5 (rs3117574 $P_{meta}=5.33\times10E-79$). Results across the extended MHC support association with multiple loci throughout this region. In the GWAS, 2 SNPs, rs485497 and rs4680536, were identified near IL12A with $P_{omni}<6\times10E-4$. Both rs485497 ($P_{IC}=1.88\times10E-7$) and rs4680536 ($P_{IC}=2.06\times10E-5$) replicated yielding $P_{meta}=4.81\times10E-10$ and $P_{meta}=1.69\times10E-8$, respectively. In addition, we observed associations surpassing GWS for the first time with loci previously implicated in SS, including IRF5 (rs10488631 $P_{meta}=5.25\times10E-13$), BLK (rs922483 $P_{meta}=1.50\times10E-8$), and STAT4 (rs10168266 $P_{meta}=3.59\times10E-8$). We also identified statistically significant eQTL in the IRF5 region with 13 SNPs at $P<5\times10E-8$. BLK also showed significant eQTLs with 8 SNPs at $P<7\times10E-4$. IL12A, IRF5 and STAT4 are involved in type I interferon responses. IL12A encodes the p35 subunit of IL12 and is secreted by monocytes and dendritic cells ultimately stimulating the production of IFN-γ. Interestingly, responses to IL12 are mediated through STAT4.

Conclusion: We present the first GWAS of SS identifying and confirming IL12A as a novel susceptibility locus. We also observed IRF5, BLK and STAT4 for the first time at GWS establishing them as risk loci for SS. We report eQTLs in the region of IRF5 and BLK in SS cases suggesting expression of these loci is important in the pathogenesis as has been reported in SLE. Collectively these genes illustrate the importance of both the innate and adaptive immune responses in the etiology of SS.

2672

Genome-Wide Association Analysis Reveals Genetic Heterogeneity of Sjögren's Syndrome (SS) According to Specific Subphenotypes and Ancestry. Lindsey A. Criswell[1], Kimberly E. Vivino[15], Zhao Yan[16], Steve Shiboski[1], Troy Daniels[17], John S. Greenspan[1], Caroline Shiboski[1] and SICCA[18]. [1]University of California, San Francisco, San Francisco, CA, [2]University of Washington, Seattle, WA, [3]Center for Inherited Disease Research, Baltimore, MD, [4]Rosalind Russell Medical Research Center for Arthritis, San Francisco, CA, [5]Washington University, St. Louis, MO, [6]National Institute of Dental and Craniofacial Research, Bethesda, MD, [7]Johns Hopkins University, Baltimore, MD, [8]Kings College London, London, United Kingdom, [9]Peking Univ Med Coll Hospital, East City Beijing, China, [10]University of Buenos Aires, Buenos Aires, Argentina, [11]Righospitalet, Copenhagen, Denmark, [12]Aravind Eye Hospital, Madurai, India, [13]Kanazawa Medical University, Ishikawa, Japan, [14]Kanazawa Medical University, Kanazawa, Japan, [15]Penn Presbyt Med Ctr, Philadelphia, PA, [16]Peking Union Medical College Hospital, Beijing, China, [17]UCSF Schools of Medicine & Dentistry, San Francisco, CA, [18]San Francisco

Background/Purpose: Our goal is to define the contribution of genetic factors to SS and related subphenotypes.

Methods: We studied 2,459 participants in the Sjögren's International Collaborative Clinical Alliance (SICCA) who were characterized for the Illumina HumanOmni 2.5-Quad marker set. SICCA participants were enrolled according to standardized protocols at 9 international sites, including Argentina (n=342), China (n=290), Denmark (n=446), India (n=65), Japan (n=354), the UK (n=203) and the US (total n=759 from 3 sites). Additional control data genotyped on the same platform were obtained from the Collaborative Genetic Study of Nicotine Dependence (COGEND, n = 1466). QC measures included filters based on SNP and sample missingness (≥2%), unexpected relatedness, non-Mendelian inheritance, and chromosomal regions of anomaly (> 10Mb). SICCA participants were classified according to ACR classification criteria for SS (AC&R 2012, 64; 475), including presence of focal lymphocytic sialadenitis (FLS) on minor salivary gland biopsy, presence of KCS based on ocular staining pattern (ocular staining score ≥3), and production of autoantibodies (SSA, SSB, ANA and RF). Principal components (PC) analysis was used to characterize each participant for genetic ancestry, and PCs 1 – 5 were included as covariates in all association analyses. The following phenotypes were examined: SS susceptibility (fulfillment of ACR criteria versus controls, including COGEND), presence of FLS, presence of KCS and autoantibody positive disease.

Results: Out of 2118 subjects with post-QC genotypes and sufficient clinical data, 1000 (47%) met ACR criteria for SS, and an additional 772 fulfilled at least 1 of the 3 criteria, including FLS, KCS or autoantibody positivity (SSA &/or SSB +, or both ANA ≥ 320 and RF +). A total of 1,445,406 SNPs passed all QC filters and were fully analyzed. For case-control analysis, 1,392,831 SNPs passed QC filters for both cohorts and were analyzed. Multiple variants within the MHC region on chr 6q and the IRF5-TNP03 region on chr 7 were strongly associated with SS susceptibility (lowest p values 1.9e-27 and 3.8e-13, respectively), and with autoantibody production (MHC p=1.7e-30, IRF5 p=3.2e-12) and FLS (MHC p=9.7e-12, IRF5 p=1.5e-10) within SICCA

subjects; furthermore the region of MHC association for autoantibody production was much broader (26–33Mb versus 30–33Mb). In contrast, we did not observe significant genetic associations with KCS, indicating genetic heterogeneity specifically related to the oral, ocular or systemic manifestations of SS. Among SICCA subjects, multiple PCs were strongly associated with some phenotypes examined, suggesting heterogeneity according to genetic ancestry. In particular, a PC separating Asian and European ancestry was strongly associated with autoantibody production (p < 4.5e-38).

Conclusion: These results demonstrate genetic overlap of SS with other autoimmune diseases, and highlight the genetic heterogeneity of the disease according to specific subphenotypes and ancestry. Future work including imputed genetic data and additional study subjects will provide more power for extending these findings and fully characterizing the genetic contribution to SS.

Sibling Relative Risk and Heritability of Sjögren's Syndrome: A Nationwide Population Study in Taiwan.

Chang-Fu Kuo[1], Matthew J. Grainge[1], Kuang-Hui Yu[2], Lai-Chu See[3], Shue-Fen Luo[2], Ana M. Valdes[4], I-Jun Chou[2], Hsiao-Chun Chang[2], Weiya Zhang[1] and Michael Doherty[1]. [1]University of Nottingham, Nottingham, United Kingdom, [2]Chang Gung Memorial Hospital, Taoyuan, Taiwan, [3]Chang Gung University, Taoyuan, Taiwan, [4]Dept of Twin Research and Genetic Epidemiology, St. Thomas' Hospital, King's College London, London, United Kingdom

Background/Purpose: Although familial aggregation has been found in many autoimmune diseases, the evidence for familial aggregation in Sjögren's syndrome is lacking. The aims of this study was to estimate familial relative risk (RR) and heritability of Sjögren's syndrome inthe general population of Taiwan.

Methods: Using data from the National Health Insurance Research Database in Taiwan, we conducted a nationwide cross-sectional study of 11,665,669 men and 11,332,220 women in 2010. We identified individuals with a full sibling affected by Sjögren's syndrome and compared the prevalence of the disease between individuals with and without an affected sibling. The identification of sibling of each individual was determined using the NIHRD registry for beneficiaries. This specifies relationships between the insured person who paid the insurance fee and his/her dependents, allowing first-degree relatives (father, mother, son, daughter, brother, sister, twin) to be identified directly. Full siblings were identified as individuals who shared the same parents. The marginal Cox proportional hazard model with an equal follow-up time for all subjects was used to estimate sibling relative risk (RR) and the 95% confidence interval (CI). This model was used to account for shared environment and case clustering within families with robust variance. The heritability of Sjögren's syndrome were estimated by multifactorial polygenic threshold which presumes a single, normally distributed disease liability resulting from a large number of unspecified genes and environmental factors, each with small and additive influences.

Results: There were 12,091 (men, 1,264; women, 10,827) patients with Sjögren's syndrome in the general population of Taiwan in 2010 (unadjusted prevalence = 0.53 per 1000). The mean age of patients with Sjögren's syndrome was 57.4 ± 14.1 years. Individuals with an affected sibling with Sjögren's syndrome had a higher prevalence of Sjögren's syndrome (5.03 per 1,000 people) than those without (0.53 per 1,000 people). The risk of Sjögren's syndrome in individuals with an affected sibling was 15.51 (95% CI, 5.85–41.12) times greater than that in individuals without an affect sibling. The heritability of Sjögren's syndrome was 0.54 (95% CI, 0.32–0.80).

Conclusion: This is the first population-based study to demonstrate that Sjögren's syndrome clustered within families. The results suggest a significant genetic contribution to the development of Sjögren's syndrome.

Background/Purpose: Sjögren's syndrome (SS) is a progressive autoimmune exocrinopathy characterized by symptoms of dry eyes and mouth present in 0.7–1% of Europeans. Dysregulation of interferon (IFN)-related pathways is well documented in SS and related autoimmune disorders, like systemic lupus erythematosus. To further characterize the expression of IFN-inducible genes in SS, we performed *cis*-expression quantitative trait loci (*c*-eQTL) analysis in SS cases to identify genetic variants regulating proximal IFN-regulated genes.

Methods: We first performed whole blood global gene expression profiling in 162 primary SS cases and 58 healthy controls of European ancestry. In total, 2410 genes were differentially expressed (DE) between SS cases and controls ($3.49 \times 10E$-$22 \leq q < 0.05$). Among pathways in which DE genes were identified, pathways involved in type I interferon-mediated signaling (31/70 genes; $p = 5.56 \times 10E$-14) were highly significant. The 31 genes were selected for use as phenotypic traits in *c*-eQTL analyses in 133 Caucasian SS patients through integration of gene expression data with genotypes from our SS genome-wide association study (GWAS, 424 cases / 2120 controls). Single nucleotide polymorphisms (SNPs) from GWAS data spanning 20kb flanking the target genes were tested for genetic association with expression levels by linear regression using Matrix-eQTL in the R Bioconductor suite.

Results: *C*-eQTL analysis identified SNPs within and flanking *HLA-C* (70 SNPs, $3.13 \times 10E$-$9 \leq q < 0.01$) and *OAS1* (26 SNPs, $6.29 \times 10E$-$9 \leq q < 0.01$) that are significantly associated with gene expression levels. Alleles of *HLA* genes are well-documented risk factors for the development of autoimmune disorders, including SS. *HLA-C* belongs to the highly polymorphic *MHC* class I heavy chain molecule, and is a major independent genetic determinant of psoriasis and rheumatoid vasculitis. Our GWA study also showed associations of *HLA-C* eQTL with SS susceptibility with the top $p = 1.72 \times 10E$-22 in rs2844612. The association of rs2844612 with *HLA-C* expression levels is independent of other non-*HLA-C* SNPs in the *MHC* region, such as *HLA-DRB1* and *HLA-DQB1*. Interestingly, the presence of both the risk alleles in *HLA-C1* and its receptor killer cell immunoglobulin-like receptor (*KIR*)-2DS2 (2 extracellular domains with short cytoplasmic domain) is significantly associated with dry eye disease in a Han Chinese population. *OAS1*, or 2′,5′-oligoadenylate synthetase 1, is a critical component involved in the innate immune response to viral infection through RNA degradation and the inhibition of viral replication. Mutations in *OAS1* have been associated with host susceptibility to viral infection. Evidence for association of the *OAS1* SNP rs10774671, a splice-site polymorphism associated with multiple sclerosis and type 1 diabetes, increased from $p = 3.39 \times 10E$-3 in our SS GWAS to $p = 6.29 \times 10E$-9 in the *c*-eQTL analysis.

Conclusion: Integration of results from genetic studies with gene expression data can help us to interpret downstream functional effects of SS susceptibility loci. These results provide promising novel candidate loci in and around *HLA-C* and *OAS1* for future functional studies to better understand SS pathophysiology.

Oral and Gut Microbiota Influence Immune Responses to Sjogren's Syndrome Associated Antigen Ro60. Agnieszka Szymula, Barbara Szczerba, Harini Bagavant, Shu-Man Fu and Umesh Deshmukh. University of Virginia, Charlottesville, VA

Background/Purpose: Autoantibodies reactive against Ro60 protein are often found in patients with Sjogren's syndrome. This study was undertaken to investigate the role of oral and gut microbiota in initiation of autoimmune responses against Ro60. We hypothesized that proteins derived from oral/gut microbes activate Ro60 reactive T cells, which then play a critical role in autoantibody generation.

Methods: HLA-DR3 restricted T cell hybridomas, reactive against Ro60 were generated, and employed to map and characterize T cell epitopes on Ro60. Pattern search and BLAST analysis was carried out to identify putative cross-reactive peptides from microbes in the Human Oral Microbiome Database. Several peptides were synthesized and their ability to activate Ro60 reactive T cell hybridomas tested. A recombinant microbial protein that contained the strongest mimicry peptide was generated and its ability to activate Ro60 reactive T cells analyzed. HLA-DR3 transgenic mice were immunized with this microbial protein and autoantibody responses against different autoantigens investigated.

Results: The HLA-DR3 restricted T cell hybridomas recognized 3 epitopes on Ro60, $Ro60_{221-250}$, $Ro60_{241-260}$ and $Ro60_{361-390}$. Pattern search analysis identified several hundred mimicry peptides originating from oral and gut microbes. Amongst these, peptides originating from von Willebrand factor type A (vWFA) protein were most potent in activating T cell hybridoma reactive against $Ro60_{361-390}$. Purified recombinant vWFA protein from Capnocytophaga ochracea (an oral microbe) activated Ro60 reactive T cells. Interestingly, whole E coli expressing vWFA protein were also able to activate Ro60 reactive T cells. These results show that peptides from vWFA protein are processed and presented by antigen presenting cells even in the presence of hundreds of other E coli proteins. Immunization of HLA-DR3 transgenic mice with recombinant vWFA protein readily induced autoantibodies reactive against Ro60, La (SSB) and Ro52 (SSA).

Conclusion: Our results clearly demonstrate that a microbial protein present in different commensall oral/gut bacteria can activate Ro60 reactive T cells and induce autoantibody responses against Ro60. Thus, we would like to propose that a dysregulated immune response against normal microbiome can be one of the pathways responsible for initiating autoimmune responses in Sjogren's syndrome. Considering that oral infections are a common problem in Sjogrens's syndrome patients, this pathway might also be involved in amplification of autoimmune responses in this disease.

Long-Term Humoral Autoimmunity to Ro60 in Primary Sjögren's Syndrome Is Driven by Clonal Succession. Rhianna Lindop[1], Isabell Bastian[1], Georgia Arentz[1], Lauren Thurgood[1], Andrew Whyte[1], Tim, K. Chataway[2], Michael Jackson[1] and Tom Gordon[1]. [1]Flinders Medical Centre and Flinders University, Adelaide, Australia, [2]Flinders University, Adelaide, Australia

Background/Purpose: Long-lived humoral autoimmunity to Ro60 is considered a hallmark of primary Sjögren's syndrome (SS), but the mechanism by which this immunity is sustained over decades remains unclear. Persistence of anti-Ro60 autoantibodies could be generated either by long-lived plasma cells residing in the bone marrow or by continual production of short-lived plasma cells. In the present study, these models were tested in humans for the first time by analysing serial molecular signatures of a recently reported public Ro60-specific clonotypic autoantibody (1).

Methods: Serial serum samples were collected over weeks to years from 8 patients with primary SS who expressed stable V_H3–23/ V_K3–20 Ro60 clonotypic autoantibody levels. Clonotypic IgGs were isolated by epitope-specific affinity chromatography and subjected to high resolution Orbitrap mass spectrometry. Variable regions of heavy and light chains were analysed by combined database and *de novo* amino acid sequencing. Alterations in autoantibody affinity were assessed by equilibrium binding analysis (Biacore).

Results: At each time point, patients expressed a single Ro60-specific monoclonal IgG1 kappa species, specified by a V_H3–23/J_H5 and V_K3–20/J_K2 pairing signature. However, near full-length V region protein sequencing showed a subtle turnover of clonotypes that was not detected by solid-phase immunoassay. The clonal turnover was characterised by 4–6 month cycles of clonal succession, with dominant clonotypes undergoing continual replacement by new somatically mutated clonal variants. Surprisingly, earlier clones never reappear in the periphery, and each new clone has a unique molecular signature. Affinities (K_D value) of successive clonotypes did not change significantly in the face of ongoing perpetual turnover. Autoantibody levels showed a cyclical rise and fall pattern every 3–4 months in keeping with this turnover model.

Conclusion: Analysis of the secreted autoantibody proteome demonstrates a dynamic process of clonal succession that masquerades as long-term Ro60 humoral autoimmunity. Surprisingly, the selection pressure for replacement clones is not based on affinity selection, indicating that an affinity ceiling is reached early in disease. Our findings are compatible with ongoing clonal expansion and exhaustion of short-lived autoreactive plasma cells, as opposed to a single event generation of long-lived plasma cells. The relentless generation of autoantibody clonotypes in primary SS by antigen-driven clonal selection has important therapeutic and diagnostic implications.

IL-23 Controls Autoimmunity by Facilitating Clearance of Apoptotic Bodies in the Marginal Zone in Lupus-Prone BXD2 Mice. Hao Li[1], Hui-Chen Hsu[1], Qi Wu[1], PingAr Yang[1], Jun Li[1], Daniel Cua[2], Mohamed Oukka[3] and John D. Mountz[4]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Merck Research Laboratory, Palo Alto, CA, [3]Seattle, WA, [4]University of Alabama at Birmingham and Birmingham VA Medical Center, Birmingham, AL

Background/Purpose: Failure to clear apoptotic bodies is a central pathogenic mechanism for SLE. We have observed that spontaneous systemic autoimmunity and lupus in BXD2 mice is associated with large germinal centers (GC) and development of highly pathogenic autoantibodies. The increased GCs in the spleen are promoted by increased Th17 cell, which is promoted by IL-23 in BXD2 mice. As anti-IL-23 therapy is under development for chronic inflammation and autoimmune diseases, we investigated the therapeutic potential of complete blocking IL-23 in BXD2 mice. We made an unexpected finding that complete deficiency of IL-23 accelerated and exacerbated systemic autoimmune disease in BXD2 mice.

Methods: Wild type (WT) BXD2 mice were treated with isotype control, anti-IL-17 or anti-IL-23 (100 ug iv Q3D $\times$ 3 doses). BXD2 mice were crossed to IL-23 p19 deficient ($p19^{-/-}$) mice to generate BXD2-$p19^{-/-}$ mice. Confocal microscope analysis and/or FACS analysis were carried out to determine the clearance of GFP$^+$ apoptotic cells (ACs), the percentages of PNA$^+$ GC B cells, SIGN-R1$^+$ marginal zone macrophages (MZMs), PDCA1$^+$ plasmacytoid dendritic cells (pDCs), CD68$^+$ red pulp macrophages, and IL-17$^+$ or IFNγ^+ CD4 T cells. ELISA assay was used to determine autoAb titers and protein urine levels in vivo. Quantitative RT-PCR was used to determine the expression of *Il23, Il23r, Ifna1, Ifna4, Ifna7,* and *Ifna11.* Depletion of MZMs was carried out by administration of clondronate liposome (167 ug/week $\times$ 8wk).

Results: Anti-IL-17 blocked development of GCs in BXD2 mice. Surprisingly, anti-IL-23 enhanced GC development and anti-dsDNA antibody production. Similarly, there was accelerated development of spontaneous GCs, production of anti-dsDNA antibody and IC deposition in the glomerulus of BXD2-$p19^{-/-}$ mice, compared with WT mice. While IL-23R was mainly expressed by MZMs, IL-23 was mainly produced by red pulp macrophages that were in close proximity to the MZM in the extra-follicular region of the spleen of BXD2 mice. Deficiency of IL-23 was associated with a dramatic reduction of MZMs in the spleen of BXD2-$p19^{-/-}$ mice. In contrast, expression of IL-23 by adenovirus in BXD2-$p19^{-/-}$ mice at early age prevented the loss of MZM and the initiation of glomerulonephritis. Clondronate liposome treatment mimicked the effects of $p19^{-/-}$, leading to depletion of MZMs, impaired clearance of ACs and severely accelerated autoimmune disease. This was associated with dramatically elevated serum levels of type I IFN genes including *Ifna1, Ifna4, Ifna7, Ifna11.* Although

there was diminished Th17 cells in BXD2-$p19^{-/-}$ mice, defective clearance of ACs was associated with greatly elevated production of type I IFNs by pDCs and IFNγ by Th1 cells.

Conclusion: Our results suggest a novel concept that IL-23 can act as a double edge sword to control the development and severity of autoimmunity. Overexpression of IL-23 may provoke autoimmunity through the induction/maintenance of Th17 yet a complete deficiency of IL-23 also induced autoimmunity through the loss of the MZM barrier that clears ACs and prevents follicular invasion of apoptotic autoantigens. Our results suggest that caution should be used when considering IL-23 blockade for treatment of autoimmune disease.

Novel Nuclear Export Inhibitors Deplete Autoreactive Plasma Cells and Protect Mice with Lupus-Like Disease From Nephritis. Teresa Owen[1], Wensheng Wang[1], Dilara McCauley[2], Laura Strojny[1], Jennifer Hossler[1], Javier Rangel-Moreno[1], Michael Kauffman[2], Sharon Shacham[2] and Jennifer H. Anolik[1]. [1]University of Rochester Medical Center, Rochester, NY, [2]Karyopharm, Therapeutics Inc., Natick, MA

Background/Purpose: Most therapies currently used to treat systemic lupus erythematosus (SLE) and B cell targeted therapies under development do not effectively target plasma cells and autoantibodies. We postulated that selective inhibition of nuclear export (SINE) with novel small molecule CRM1 antagonists, which have demonstrated potent activity for hematologic malignancies, may be useful in the treatment of SLE by targeting plasma cells and other immune cells critical to disease pathogenesis.

Methods: Nephritic NZB/W F1 lupus-prone female mice, with elevated serum anti-dsDNA antibodies and established proteinuria, were treated with the SINE KPT-251 (injections 5/7 days for 5 weeks) (initially 75 mg/kg $\times$ 3 weeks and then 50 mg/kg for 2 additional weeks) or vehicle control subcutaneously (n=10 per group). Spleen and bone marrow (BM) lymphocytes were harvested, stained with antibodies, and analyzed by flow cytometry. Plasma cells (PC) were identified with antibodies against intracellular kappa light chain. We monitored nephritis severity by measuring proteinuria (Uristix) and analyzing pathological changes in kidney histology. Serum auto-antibody levels (anti-dsDNA) were measured by ELISA. ELISpot was used to enumerate IgG- and dsDNA antibody secreting cells (ASC).

Results: KPT-251 SINE treatment of NZB/W F1 mice prevented nephritis progression with a statistically significant reduction in urine protein levels in the treated group (p<0.05 beginning at 3 weeks) and notably reduced the number of mice with significant proteinuria (77% of treated mice had low urine protein concentrations <100 mg/dL compared to only 10% of controls at 5 weeks) (p=0.003). Importantly, serum anti-dsDNA IgG levels were significantly reduced after KPT-251 treatment (>6-fold reduction, p=0.0017) with profound effects on antibody secreting plasma cells. We found a significant reduction in splenic plasmablasts (2.18-fold reduction, p=0.001), BM PCs (2-fold reduction, p=0.02) and plasmablasts (MHCII high) (2.24-fold reduction, p=0.003). Moreover, ASC numbers were notably decreased with nuclear transport inhibition. Total IgG and anti-dsDNA IgG ASC numbers in the spleen were drastically reduced after treatment (70% reduction, p=0.002). In bone marrow, there was a pronounced decline in IgG ASC numbers (81%), with a more dramatic effect on anti-dsDNA IgG ASCs (96% reduction, p=0.002).

Conclusion: These results suggest that nuclear transport inhibition preferentially affects auto-reactive PC and prevents SLE-associated nephritis. Therefore, these data support the further development of SINE drugs as a novel therapeutic approach for SLE.

Loss of Caspase 8 in Dendritic Cells Induces a Systemic Lupus Erythematosus-Like Disease That Is Independent of the Necroptosome. Carla M. Cuda[1], Alexander V. Misharin[2], Rana Saber[2], G. Kenneth Haines III[3], Jack Hutcheson[4], Chandra Mohan[4] and Harris R. Perlman[2]. [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Yale University, New Haven, CT, [4]University of Texas Southwestern Medical Center, Dallas, TX

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-organ, destructive autoimmune disease characterized by pathogenic autoantibodies. Though it is accepted that dendritic cells (DCs) play an important role in disease initiation, only recently have studies implicated DCs as a major factor in SLE persistence. DCs from SLE patients exhibit elevated expression of activation markers including co-stimulatory molecules and pro-inflammatory cytokines; however, the factors that are responsible for their aberrant activation is unknown. We recently identified that caspase 8, a cysteine-aspartic acid enzyme known to function in death receptor signaling, is a novel DC-specific inhibitor of inflammatory processes. While previous studies have shown that caspase 8 functions to initiate apoptosis and/or suppress necroptosis (through inhibition of RIPK1/3 signaling) in a multitude of cells, our data suggest that caspase 8 is not essential for the survival of DCs (apoptosis/necrosis), but rather inhibits the continuous activation of DCs, thereby preventing development of systemic autoimmunity.

Methods: Mice with caspase 8 flanked by loxP sites (Casp8$^{flox/flox}$. WT) were crossed with mice expressing Cre under control of the CD11c gene promoter (Cre^{CD11c}), which is expressed by dendritic cells. Flow cytometric analysis was employed to characterize DC populations in both mixed bone marrow chimeras and BrdU pulse assays. Bone marrow-derived DCs were cultured with TLR agonists $+/-$ necrostatin-1 to block RIPK1 activity. Luminex-based assays and ELISAs were used to detect cytokine and transcription factor DNA binding levels.

Results: Cre^{CD11c}Casp8$^{flox/flox}$ develop splenomegaly, lymphadenopathy, autoantibodies, glomerulonephritis, immune complex deposition in the kidney, exacerbated proteinuria levels, heightened amounts of serum pro-inflammatory cytokines (IL-12, IL-1β, and IFNα/β), and early mortality. Loss of caspase 8 in DCs does not affect their survival, as Cre^{CD11c}Casp8$^{flox/flox}$ mice present with increased DC populations, there are equal numbers of Cre^{CD11c}Casp8$^{flox/flox}$ and WT DCs in mixed bone marrow chimeras, there is no change in DC turnover rates using BrdU pulse assays, and bone marrow-derived DCs display similar levels of necrotic death independent of caspase 8 or RIPK1. Loss of caspase 8 in DCs does not affect their survival, but they are highly activated, leading to elevated levels of activated lymphocytes in a paracrine manner. The increased activation potential of Cre^{CD11c}Casp8$^{flox/flox}$ DCs may be controlled by toll-like receptors 7 and 9 (TLR7/9) since caspase 8-deficient DCs display a hyper-responsiveness to TLR7/9 ligation with increased DNA binding activity of interferon regulatory factor (IRF) and STAT1. Additionally, blocking RIPK1 signaling dampens the TLR7/9-induced secretion of pro-inflammatory cytokines in caspase 8-deficient DCs.

Conclusion: These results demonstrate that loss of caspase 8 in DCs initiates inflammatory phenotypes by a DC survival-independent novel mechanism. These data have implications for autoimmunity by elucidating previously unknown functions of a potentially useful target for therapy.

Disclosure: **C. M. Cuda**, None; **A. V. Misharin**, None; **R. Saber**, None; **G. K. Haines III**, None; **J. Hutcheson**, None; **C. Mohan**, None; **H. R. Perlman**, None.

Soluble Receptor for Advanced Glycation End Products Alleviates Nephritis in NZB/WF1 Mice. Sang-Won Lee[1], Kyu-Hyoung Park[1], Sungha Park[2], Ji-Hye Kim[1], Sung-You Hong[2], Soo Kon Lee[1], Donghoon Choi[2] and Yong-Beom Park[1]. [1]Yonse University College of Medicine, Seoul, South Korea, [2]Yonsei University College of Medicine, Seoul, South Korea

Background/Purpose: The receptor for advanced glycation end products (RAGE) is a pattern-recognition receptor that interacts with multiple ligands such as high mobility group box 1 (HMGB1) and is involved in various innate immune responses. The soluble form of RAGE (sRAGE) can bind to RAGE-ligands in the extracellular space, and thus competitively inhibit the binding of ligands to the membrane-bound form of RAGE (mRAGE), resulting in a reduction of the inflammation induced by NF-κB activation. We investigated the efficacy of different doses of the Fc-portion-conjugated sRAGE on nephritis in lupus-prone mice in comparison with the efficacy of combination therapy of mycophenolate mofetil plus prednisolone.

Methods: Twenty-eight female NZB/WF1 mice were divided into five groups (untreated; 0.5, 1, 2 μg of sRAGE; mycophenolate mofetil plus prednisolone). Proteinuria and histological damage were evaluated. Immune-complex deposition and the nuclear translocation of NF-κB in kidney tissues were assessed by immunofluorescence staining. Serum concentrations of anti-dsDNA and IgG subclasses were also measured. The population of T cells was evaluated using a fluorescence-activated cell sorter and ICAM-1 and VCAM-1 expression in kidney tissues was assessed by immunohistochemical staining.

Results: In comparison with untreated mice, mice treated with 1 or 2 μg of sRAGE showed significantly reduced proteinuria and improved histological renal damage, with efficacy comparable to that of combination therapy. Treatment with 1 or 2 μg of sRAGE significantly reduced immune-complex accumulation; decreased the serum concentrations of anti-dsDNA, IgG2a, IgG2b and IgG3; and interrupted the nuclear translocation of NF-κB in kidney tissues, leading to reduced ICAM-1 and VAM-1 expression. Furthermore, sRAGE effectively modified T cell populations.

Conclusion: sRAGE significantly improved nephritis in lupus-prone mice, with efficacy comparable to that of standard induction treatment for lupus nephritis. These data suggest that sRAGE have anti-inflammatory effects in lupus nephritis pathophysiology and could serve as a potent additional therapy for lupus nephritis.

Blocking the Serum Protease Inhibitor Activity of Plasminogen Activator Inhibitor-1 Protects Mice From Development of Glomerulonephritis in a Model of Lupus Nephritis. Brian Naiman[1], Tracy Delaney[1], Lily Cheng[1], Philip Brohawn[1], Chris Morehouse[1], Christopher Groves[1], Isabelle de-Mendez[2], Dominic Corkill[2], Anthony Coyle[3], Ronald Herbst[1] and Jane Connor[1]. [1]MedImmune, LLC, Gaithersburg, MD, [2]MedImmune, LLC, Cambridge, United Kingdom, [3]Pfizer, Inc. (formerly MedImmune LLC, Gaithersburg, MD, USA), Cambridge, MA

Background/Purpose: Lupus nephritis is an autoimmune disorder which is characterized by extracellular matrix accumulation driven by immune complex deposition and in which thrombosis and sclerosis play a role in the development of nephropathy. Plasminogen activator inhibitor-1 (PAI-1) is the major inhibitor of pro-fibrinolytic plasminogen activators uPA and tPA and its expression has been shown to be increased in renal biopsies obtained from patients with lupus nephritis. Several studies utilizing transgenic mice (KO or over-expressing) in models of lupus nephritis have demonstrated a role for PAI-1 in the kidney pathology associated with these models. The purpose of these studies was to evaluate the contribution of PAI-1 inhibition of PAs to pathological changes in the kidney in an accelerated model of mouse lupus nephritis.

Methods: An adenovirus encoding IFNa was injected into lupus-prone NZB/W mice resulting in an accelerated model of glomerulonephritis. A monoclonal antibody that selectively prevents the binding of PAI-1 to its target PAs was administered ip twice weekly beginning at the time of adv-IFNa administration. Effect of PAI-1 neutralization on development of proteinuria, gene and protein expression and histological changes in the kidney, and protein circulating in the plasma was assessed. Potential effects on immune cell expansion observed in this model were evaluated by FACS analysis. In vitro, the effect of blocking PAI-1 on extracellular matrix (ECM) degradation was evaluated in rat mesangial cells.

Results: PAI-1 was shown to be dramatically increased in the kidney (mRNA, IHC, ELISA) as well as in the plasma (ELISA) of diseased mice. Inhibition of the PAI-1/PA interaction via treatment with the anti-PAI-1 antibody provided dose-dependent protection against the development of proteinuria and changes in sodium excretion. These effects were associated with normalization of fibrinolysis, ECM, cytokine and chemokine genes as well as histological changes in the glomerulus of the kidney. Anti-PAI-1 treatment provided concentration-dependent degradation of ECM in rat mesangial cells providing further mechanistic support for the in vivo findings.

Conclusion: These data suggest that interfering with the PAI-1/PA interaction provides protection from the pathological changes in the kidney in this murine model downstream of immune complex deposition in the kidney.

2682

Calcium/Calmodulin-Dependent Protein Kinase IV Suppresses IL-2 Production and Regulatory T Cell Activity in Systemic Lupus Erythematosus. Tomohiro Koga[1], Kunihiro Ichinose[2], Masayuki Mizui[1], José C. Crispín[1] and George C. Tsokos[1]. [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background/Purpose: T cells from patients with SLE exhibit abnormal signaling upon TCR engagement and have an altered gene expression profile. Accordingly, the regulation of several transcription factors is distorted in SLE T cells upon activation. The activity of calcium/calmodulin-dependent protein kinase IV (CaMK4) is increased in T cells from patients with SLE and has been shown to reduce IL-2 production by promoting the effect of the transcriptional repressor cAMP responsive element modulator (CREM)-α on the IL2 promoter.

Methods: We crossed CaMK4 deficient ($CaMK4^{-/-}$) mice with MRL/MpJ-lpr/lpr (MRL/lpr) mice and examined survival rate, autoantibody levels, immune cells subpopulations, IL-2 production and regulatory T cells (Treg) activity. The suppressive capacity of Camk4-deficient and -sufficient Tregs was evaluated in in vitro co-culture assays. To determine the relevance of our findings to human SLE, we analyzed the effect of CaMK4 inhibition in T cells from patients.

Results: Here we show that T cells from MRL/lpr mice display increased levels of CaMK4 in the nucleus and Camk4 deficiency reduces the mortality of MRL/lpr mice in a statistically significant manner. The survival rate of MRL/lpr.Camk4$^{-/-}$ mice was 89% at 32 weeks of age compared to only 25% in the MRL/lpr group. The severity of the glomerulonephritis, as well as the levels of C3 deposits in the kidney and the extent of skin injury were notably decreased in MRL/lpr.Camk4$^{-/-}$ mice. We demonstrate that that absence of CaMK4 restores IL-2 production, curbs increased T cell activation, and augments the number and activity of Treg. Treg from MRL/lpr.Camk4$^{-/-}$ mice suppressed more efficiently the proliferation of CD4$^+$CD25$^-$ Camk4-sufficient T cells than Treg from wild type mice. Importantly, CaMK4 silencing in T cells from patients with SLE increases the generation of FoxP3$^+$cells upon stimulation in the presence of TGF-β.

Conclusion: Our results demonstrate the importance of the serine/threonine kinase CaMK4 in the generation and function of regulatory T cells in patients with SLE and lupus-prone mice and its potential to serve as a therapeutic target.

Interferon-Associated Cytokine and Chemokine Expression in Patients with Serologically Active Clinically Quiescent (SACQ) Systemic Lupus Erythematosus (SLE). Amanda J. Steiman[1], Murray B. Urowitz[1], Dominique Ibanez[1], Carolina Landolt-Marticorena[2], Dafna D. Gladman[3] and Joan E. Wither[4]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]University of Toronto, Toronto, ON, [3]Toronto Western Research Institute, University of Toronto, University Health Network, Toronto, ON, [4]Toronto Western Research Institute, University Health Network, Toronto, ON

Background/Purpose: Interferon-α (IFN-α) plays a prominent pro-inflammatory role in SLE. Studies suggest clinical/serologic discordance may illuminate SLE pathophysiology: peripheral IFN-α production is blunted in autoantibody-producing, clinically quiescent SLE mice despite abundant IFN-α-producing plasmacytoid dendritic cells (pDCs); continuous pDC stimulation yields reversible blunting of the IFN-α response in vitro. Thus SACQ patients, who exhibit persistent autoantibody production despite durable clinical quiescence, may provide unique insights. We thus measured IFN-associated cyto/chemokines in SACQ patients, compared to serologically and clinically active (SACA) and serologically and clinically quiescent (SQCQ) patients.

Methods: We defined SACQ and SQCQ as $\geq$2-year periods without clinical activity, with/without persistent serologic activity, respectively, by SLE Disease Activity Index 2000 (SLEDAI-2K), over which antimalarials were permissible; corticosteroids/immunosuppressives were not. SACA was defined as disease activity, by SLEDAI-2K, which compelled immunosuppression. Clinical and lab data were collected at each visit. Plasma cyto/

chemokines were measured by 65-plex Luminex panel, with the 16 most relevant selected *a priori* for analysis. Bonferroni correction was applied. Non-parametric univariate and logistic regression analyses were conducted. Given the vast range of cyto/chemokine levels, values were transformed by a factor of 10, 100, or 1000, as appropriate, to facilitate interpretation.

Results: We identified 25, 28 and 48 SACQ, SQCQ and SACA patients, respectively. IFN-α, IL-6, IL-10, IP-10 and MCP-1 levels were lower in SACQ vs SACA patients (p = 0.006, 0.0018, and <0.0001 (last three), respectively). There were no differences in cyto/chemokine levels between SACQ and SQCQ patients. IFN-α and IP-10 were moderately correlated (r=0.79). Disease duration at study start differed between SACQ and SACA patients (18.5±12.1 vs 7.4±7.3 yrs, p=0.0002) as did the proportion with anti-Ro, -La, and –RNP positivity (84.0 vs 53.6%; 48 vs 32.1%; 40 vs 28.6%, p=0.005, 0.004 and 0.023, respectively). There were no differences in clinical manifestations from disease onset between SACQ and SACA patients. Logistic regression revealed that increased levels of IL-10 (OR 7.35 [1.04,51.93]) and MCP-1 (OR 2.33 [1.23,4.41]) were associated with SACA status. Increased disease duration (OR 1.12 [1.03, 1.23] and anti-Ro positivity (OR 20 [2.38,166.67]) were associated with SACQ status. When SACA patients with disease duration <6 years were excluded, MCP-1 elevation remained associated with SACA (OR 1.95 [1.28,2.97] and anti-Ro positivity with SACQ (OR 7.14[1.47,33.33]. Regression analysis applied to SACQ vs SQCQ patients similarly revealed anti-Ro positivity was associated with SACQ status (OR 4.55 [1.23,16.67]).

Conclusion: IFN-associated cyto/chemokine profiles differed between SACQ and SACA, but not SACQ and SQCQ, patients. Elevations in MCP-1 and IL-10 were associated with SACA status; there were no cyto/chemokines associated with SACQ status. These findings warrant further pursuit to determine if they may facilitate clinical prediction.

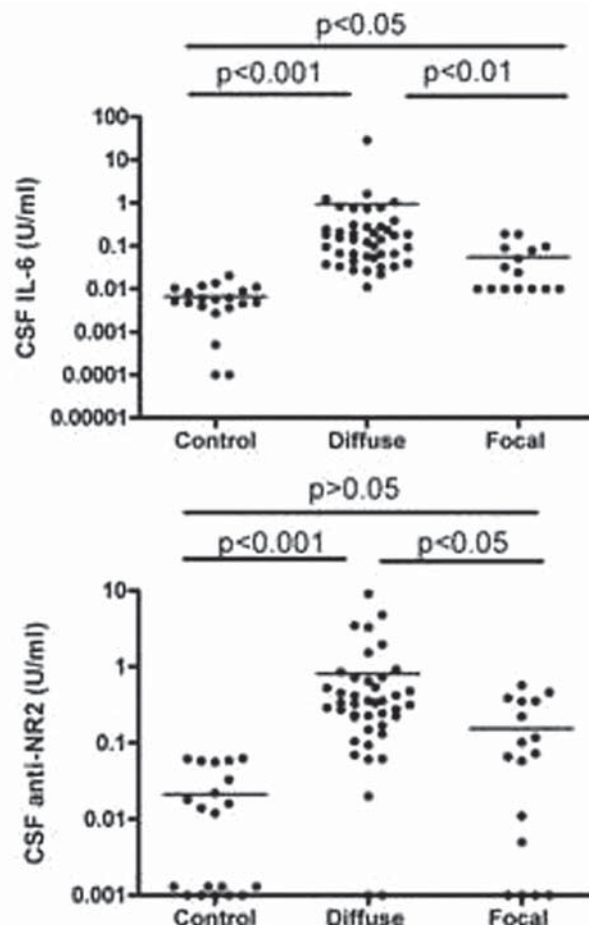
Cerebrospinal Fluid IL-6 and Anti-NMDA Receptor NR2 Antibodies As Surrogate Markers for CNS Disease Severity in SLE. Shunsei Hirohata, Yoshiyuki Arinuma and Eisuke Ogawa. Kitasato University School of Medicine, Sagamihara, Japan

Background/Purpose: Neuropsychiatricmanifestations occur in approximately one-half of patients with SLE and maycause substantial impairment of quality of life as well as disability. Among avariety of neuropsychiatric manifestations in SLE, acute confusional state (ACS) in diffuse psychiatric/neuropsychological syndromes (diffuse NP-SLE) is the mostserious one. Of note, cerebrospinalfluid (CSF) IL-6 was found to be elevated in patients with NP-SLE, including diffuse NP-SLE and focal NP-SLE. Moreover, recent studies have demonstrated that CSF anti-NMDA receptor NR2 antibodies (anti-NR2) are associated with diffuse NP-SLE. However, the relationship of CSF IL-6 and anti-NR2 with the severity ofNP-SLE remains uncertain. The currentstudies examined whether CSF IL-6 and ant-NR2 might be surrogate markers forthe severity of NP-SLE.

Methods: CSFsamples were obtained from 62 SLE patients who satisfied the 1982 ACR revisedcriteria when they showed active neuropsychiatric manifestations (44 patientswith diffuse NP-SLE and 18 patients with neurologic syndromes [focal NP-SLE])as well as from 20 control patients with non-inflammatory neurological diseases. CSF IL-6 was quantitated by bioassay using IL-6 dependent cell lineMH60. BSF2.CSF IgG anti-NR2 were measured by ELISAusing synthetic peptide containing the extracellular ligand-binding domain ofNR2.

Results: CSF IL-6 was significantly elevated in diffuse NP-SLE compared with that in focal NP-SLE orin control patients. CSF anti-NR2 were also significantly elevated in diffuse NP-SLE compared with those in focal NP-SLE or in control patients (figure). Moreover, CSF IL-6 levels as well as CSF anti-NR2 were also significantly higher in ACS than in diffuse NP-SLE other than ACS (cognitive disorder, mood disorder, anxiety disorder and psychosis). Finally, CSF IL-6 levels were significantly correlated with CSF anti-NR2in patients with NP-SLE (r=0.3732, p=0.0054).


Conclusion: These results demonstrate that CSF IL-6 as well as CSF anti-NR2 were most markedly elevated in ACS. The data therefore indicate that CSF IL-6 and anti-NR2 might be surrogate markers for the disease severity of NP-SLE. Finally, the positive correlation between CSF IL-6 and anti-NR2 suggest that anti-NR2 might be involved in the production of IL-6 within the CNS in SLE.

Overall and Cause Specific Mortality in Patients with Systemic Lupus Erythematosus. A Meta-Analysis of Observational Studies. Marko Yurkovich[1], Kateryna Vostretsova[2] and J. Antonio Avina-Zubieta[3]. [1]University of British Columbia, Vancouver, BC, [2]University of British Columbia, Vancouver, [3]Arthritis Research Centre of Canada/University of British Columbia, Richmond, BC

Background/Purpose: Systemic lupus erythematosus (SLE), is a chronic autoimmune condition. It has the potential to affect any organ system and can be associated with severe morbidity and mortality. Despite improvements in the management of SLE, patients with SLE still have higher mortality rates than the general population. Mortality rates in SLE have been shown to vary between countries and be higher in men. The purpose of this study was to determine the magnitude of risk from all cause and cause-specific mortality in patients with SLE compared to the general population through a meta-analysis of observational studies.

Methods: We searched MEDLINE and EMBASE databases from their inception to October 2011 with an experienced medical librarian. Observational studies that met the following criteria were assessed by two researchers: **(a)** pre-specified SLE definition; **(b)** overall and/or cause-specific deaths, cardiovascular disease (CVD), infections, malignancy and renal disease; **(c)** reported standardized mortality ratio (SMR) and 95% confidence intervals (CI). If data from a single study were reported in more than one article, only

the results from the most recent study were included in the meta-analysis. We assessed study quality based on a 12-point scale that included elements of previously published scales for observational studies. We calculated weighted–pooled summary estimates of SMRs (meta-SMR) for all cause and cause-specific mortality using the random effects model, and tested for heterogeneity using I^2 statistic using STATA.

Results: From 556 abstracts published over the last 65 years, we identified 12 studies (14 cohorts) evaluating the risk of all causeand/or cause-specific mortality, comprising a total of 27,210 patients with SLE, with a total of 4,989 observed deaths. Overall, there was a 300% increased risk of death in patients with SLE when compared to the general population. The jackknife sensitivity analyses showed that all the meta-SMRs remained statistically significant when studies were excluded one at a time, with point estimates ranging from 2.8 to 3.2. Mortality due to malignancy was the only cause-specific entity not increased in SLE (Table). We observed significant heterogeneity among the studies included in our study. However, results from the univariate meta-regression analysis using cohort type, quality assessment and sample type did not explain the heterogeneity.

Table. Mortality Risk in Patients with SLE compared to the general population

MORTALITY	No. of Studies	Number of SLE cases (number of deaths)	Meta-SMR
OVERALL	12	27,210 (4,989)	2.9 (2.3 – 3.8)
Females	6	19,062 (NA)	4.1 (3.1 – 5.3)
Males	6	2,661 (NA)	3.4 (2.6 – 4.5)
Cardiovascular	2	14,284 (1,285)	2.7 (1.8 – 4.0)
IHD	2	14,284 (687)	2.3 (1.3 – 4.0)
CVA	3	16,972 (177)	1.7 (1.1 – 2.6)
Malignancy	2	14,284 (383)	1.2 (0.6 – 2.4)
Infection	2	14,284 (67)	4.9 (3.9 – 6.3)
Renal disease	1	9,547 (34)	7.9 (5.5 – 11)

Conclusion: This is the first meta-analysis on SLE mortality using SMRs. Published data indicate that there is a 300% increase in the all-cause mortality in patients with SLE as compared to the general population. In addition, all cause-specific mortality rates, except for malignancy, were also increased with renal disease having the highest mortality risk.

Difference in Clinical Features and Mortality Between Pediatric-Onset and Adult-Onset Systemic Lupus Erythematosus. So-Yeon Park[1], Jeeseon Shim[2], Dam Kim[1], Ji-Young Choi[1], So-Young Bang[3], Chan-Bum Choi[4] and Sang-Cheol Bae[4]. [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Guri Hospital, Guri, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea

Background/Purpose: The aim of this study was to investigate differences in clinical features and outcomes including mortality between pediatric-onset systematic lupus erythematosus (pSLE) and adult-onset SLE (aSLE).

Methods: In total, 972 SLE patients were enrolled in the Hanyang BAE lupus cohort in Seoul, Korea, between February 1998 and December 2010. For mortality analysis, only 766 of the 972 SLE patients enrolled up to 2008 were included, because mortality data were prepared by data linkage with the available data from the Korean National Statistical Office. Mortality between the 2 groups was compared using the survival rates with Kaplan-Meier and the standardized mortality ratio (SMR). Multivariate linear regressions were used to determine the predictors of increased mortality.

Results: There were 111 (11.4%) pSLE patients and 861 (88.6%) aSLE patients. The female: male ratio in pSLE (3:1) is lower than that seen in aSLE (18:1). The duration of follow-up was similar in the two groups, with 5.7 years in the pSLE group and 5.6 years in the aSLE group. The frequency of malar rash, photosensitivity, renal disorder, neurologic disorder and immunologic disorder in ACR criteria were significantly higher in pSLE patients, whereas arthritis was more common in aSLE. The maximum value of the SLE Disease Activity Index (SLEDAI) scores (21.1 versus 9.6; p=0.0006), and the adjusted mean SLEDAI scores (AMS) during followup period were significantly higher in pSLE groups (5.2 versus 4.2; p=0.0006). The mean SDI scores were 0.9 in the pSLE group and 0.8 in the aSLE group, and pSLE

patients were more frequently affected in neuropsychiatric (14.4% vs. 8.4%; p=0.022) and renal system (18% vs. 9.3%; p=0.006).

Among 766 SLE patients (4,530 person-years), a total of 29 cases of death were confirmed. In pSLE, lupus-related deaths were most frequent (57.1%) whereas, deaths related infection were most common in aSLE (32.0%). The cumulative probabilities of survival at 5, 10 years were 97.6%, 89.3% in pSLE, and 98.2%, 96.4% in aSLE (log rank; p=0.035). Compared with an age-, sex-, and calendar-matched general population, the SMR of patients with pSLE and aSLE were 50.0 (95% CI 20.1–103) and 4.8 (95% CI 3.1–7.4), respectively. In multivariate regression analysis, pediatric onset lupus, shorter disease duration, higher disease activity, and higher disease damage were identified as predictor of mortality. In particular, the presence of neuropsychiatric damage (HR 3.8 vs. 96.6; p=0.0097) and hemolytic anemia (HR 2.5 vs. 22.5; p=0.0155) increased the mortality significantly in pSLE.

	Pediatric-onset (N=111, 11.4%)	Adult-onset (N=861, 88.6%)	P
Gender Women	86 (77.5%)	817 (94.9%)	<0.0001
Age (yrs)			
Age at Diagnosis	12.4 ± 2.5 (5–15)	29.4 ± 9.6 (16–68)	<0.0001
Time (onset to diagnosis)	0.7 ± 1.7 (0–10.9)	2.0 ± 3.7 (0–30.2)	–
Follow up period	6.4 ± 3.8 (0–13.7)	6.3 ± 4.1 (0–13.7)	–
Disease duration (at last followup)	9.5 ± 4.5 (1.2–18.8)	9.3 ± 5.2 (0–33.3)	–
SLEDAI score			
At enrollment	5.6 ± 4.6 (0–28)	5.4 ± 4.3 (0–22)	–
Maximum	21.1 ± 7.2 (0–45)	9.6 ± 5.3 (0–38)	0.0006
Adjusted mean SLEDAI	5.2 ± 2.9 (0–14.5)	4.2 ± 2.6 (0–18.4)	0.0006
SDI score			
At last followup	1.0 ± 1.6 (0–8)	0.9 ± 1.5 (0–9)	–
Renal SDI ≥ 1	20 (18.0%)	82 (9.5%)	0.0098
CNS SDI ≥ 1	17 (15.3%)	74 (8.6%)	0.0345
Mortality			
SMR	50.0 (95% CI 20.1–103)	4.8 (95% CI 3.1–7.4)	
5 years survival rates	97.6%	98.2%	0.035
10 years survival rates	89.3%	96.4%	0.035

Conclusion: This study demonstrates that the patients with pSLE have higher rate of major organ involvement and worse clinical outcomes with higher mortality. In particular, special attention will be needed when combined with neuropsychiatric damage or hemolytic anemia in pSLE.

Modular Microarray Analysis Fails to Reveal a Significant Biological Effect of Vitamin D3 Treatment in Patients Participating in a Double-Blind Randomized Placebo-Controlled Trial of the Effect of Vitamin D3 On the Interferon Signature in Patients with Systemic Lupus Erythematosus. Michaela Oswald[1], Cynthia Aranow[2], Diane L. Kamen[3], Meggan C. Mackay[4], Ellen A. Goldmuntz[5], Betty Diamond[6], Peter K. Gregersen[7] and ALE02 Study Team[8]. [1]The Feinstein Institute for Medical Research, Manhasset, NY, [2]Feinstein Institute for Medical Research, Manhasset, NY, [3]Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Charleston, SC, [4]The Feinstein Institute, Manhasset, NY, [5]NIAID/NIH Rm 6807, Bethesda, MD, [6]Feinstein Institute Med Rsch, Manhasset, NY, [7]Feinstein Institute Medical Research and North Shore-Long Island Jewish Health System, Manhasset, NY, [8]Bethesda, MD

Background/Purpose: Vitamin D modulates the immune response. Exposing normal PBMCs to activating SLE sera induces an interferon signature which can be inhibited by preexposure of the PBMCs to1,25 OH vitamin D. We explored effects of vitamin D supplementation on gene expression in whole blood in SLE using a modular microarray analysis. In addition to examining expression of IFN inducible genes, modular microarray analysis allows a comprehensive study of genes associated with inflammation, B cells, myeloid cells and others.

Methods: RNA was prepared from 40 stable, inactive, anti-DNA+ SLE patients with vitamin D deficiency and an IFN signature who were participating in a 12 week double-blind placebo controlled trial of daily vitamin D3 supplementation (0, 2000 or 4000 IU) at baseline and week 12, and 23 normal controls. A IFN signature was defined to be present if expression of 1 of 3 IFN responsive genes (Mx1, Ifit1, or Ifi44) determined using RT-PCR from whole blood RNA, was expressed at a level ≥ 4 SD, or if 2 of the 3 genes were expressed > 2 SD above the mean of normal controls. The Illumina HT12v4

platform was used for microarray analyses. Gene expression data were grouped using a modular framework for blood genomic analysis developed by Chaussabel et al. (Immunity 2008). Statistical significance for microarray modules was evaluated using a hypergeometric test. The 28 modules evaluated included modules for IFN as well as plasma cell, myeloid lineage and inflammation modules.

Results: Baseline characteristics of the three treatment groups were similar. Ten subjects had persistently low vitamin D levels (≤ 20 ng/ml) while 13 subjects achieved repletion (25 OH D $\geq$ 30ng/ml). Significant overexpression of IFN inducible genes and genes within the inflammation and myeloid modules was noted in all SLE subjects compared to controls at baseline and week 12. Expression of the T cell and other "undetermined" modules was decreased in the SLE group compared to controls. No significant changes in the IFN inducible module between baseline and week 12 were found within any treatment group. Examination of module 2_11 (an indeterminate group containing genes for kinases and RAS family members) was significantly decreased at week 12 compared to baseline in the high dose group only. When comparing the week 12 gene expression data from vitamin D repleted subjects to persistently deficient subjects, no significant differences in module expression (including the IFN module) other than a decrease in module 2_11 were noted.

Conclusion: There are highly significant differences in gene expression between lupus patients and controls with overexpression of IFN, inflammation and myeloid related modules. Vitamin D supplementation for 12 weeks failed to diminish expression of IFN inducible genes and with the possible exception of an indeterminate module (2_11), no major differences in modular expression was observed. Overall, module expression at week 12 between treatment groups was minimally different in this controlled clinical trial, with no significant biological changes distinguishing vitamin D repleted and deficient patients.

The Health Improvement and Prevention Program in Systemic Lupus Erythematosus Demonstrates Improvement in Mental Health and Framingham Risk Score At One Year. Paul R. Fortin[1], Ellie Aghdassi[2], Anne Cymet[3], Stacey Morrison[4], Willy Wynant[5], Janet E. Pope[6], Sara Hewitt[7], Christian A. Pineau[8], Carolyn Neville[9], Paula Harvey[10], Jean-Claude Tardif[11], Michal Abrahamowicz[12] and Deborah DaCosta[13]. [1]Division of Rheumatology, Centre de recherche du centre hospitalier universitaire de Québec, Faculté de médecine de L'université Laval, Quebec City, QC, [2]University Health Network Research Institute - Western Division, Toronto, ON, [3]University Health Network - Western Division, Toronto, ON, [4]The Toronto Western Hospital, Toronto, ON, [5]McGill University Health Centre and McGill University, Montreal, QC, [6]Western University of Canada, St. Joseph's Health Care, London, ON, [7]St. Joseph's Health Care, University of Western Ontario, London, ON, [8]McGill University Health Centre, Montreal, QC, [9]Royal Victoria Hospital, Montreal, QC, [10]Women's College Hospital, Toronto, ON, [11]Universite de Montreal endowed research chair in atherosclerosis, Quebec, QC, [12]McGill University, Montreal, QC, [13]Montreal General Hospital, Montreal

Background/Purpose: The Health Improvement and Prevention Program (HIPP) is a behavioral intervention aimed at improving health status and coping of persons with lupus while reducing cardiovascular (CVD) risk. Our purpose is to determine whether HIPP will improve health status, CVD risk and endothelial function at one year.

Methods: An unblinded RCT of HIPP compared to usual care assessed physical (PCS) and mental (MCS) component summary scores of SF-36, CVD risk derived from the Framingham risk score (FRS) and flow mediated dilatation (FMD) of the brachial artery. Patients with lupus and no previous CVD were recruited. SF-36, disease activity (SLEDAI-2K) and damage (SLICC-DI), CVD risk factors and FMD were collected at baseline. Those randomized to the NOW group attended four educational lectures and were administered a personalized risk modification program (disease education, CVD and osteoporosis risk reduction, exercise, and a psychological intervention where warranted). At one year, the LATER group crossed over and received HIPP while the NOW group resumed usual care. Repeated clinical assessments and FMD were performed at one and two years. Paired t-tests at the Bonferroni-corrected 2-tailed alpha=0.0125 were used to assess the statistical significance of the mean changes, estimated from data pooled from

the first year for the NOW group pooled with the second year for the LATER group in PCS, MCS, FRS and FMD. Additional analyses explored whether the changes observed at one year in the NOW group were sustained at two years.

Results: We randomized 288 patients; one withdrew at baseline leaving 287 for analysis. Mean age was 44 yrs, 70% were Caucasian, 53% married, 91% high school graduates, mean disease duration was 11.3 yrs, mean SLEDAI 4.04 and mean SDI 1.17. Two primary outcomes, the MCS and the FRS improved significantly at one year with a mean MCS score increase of 2.16 (95% CI: 0.75 to 3.58, p=0.003) and a mean FRS logit decrease of -0.06 (95% CI: -0.12 to -001, p=0.02) (Table 1). There was no improvement in PCS or FMD. Additional analyses at two years in the NOW group revealed that 1) the one-year benefit on MCS and FRS was lost at two years and 2) when compared to those without improvement in their MCS at one year, those with improvement in MCS did not benefit further in their PCS, FRS or FMD at two years.

Table 1. Differences after one year of the intervention HIPP in the NOW (1-year vs baseline) and LATER (2-year vs 1-year) groups

Primary outcome	PRE	POST	Mean of the differences	95% CI
SF-36 physical	40.89	40.87	-0.02	-1.11; 1.07
SF-36 mental	45.33	47.49	2.16	0.75; 3.58
Framingham logit	-5.79	-5.85	-0.06	-0.12; -0.01
FMD	0.117	0.109	-0.008	-0.028; 0.012

Conclusion: The HIPP behavioral intervention improves significantly the mental health and the Framingham risk score in lupus at one year but these are not sustained at two years. No reinforcement of the HIPP intervention was provided to patients of the NOW group in the second year. Given the chronicity and unpredictability of lupus, such a behavioral intervention should incorporate ongoing booster sessions and evaluate their effectiveness in maintaining the one year benefits of the Health Improvement and Prevention Program.

ARHP Concurrent Abstract Session
Factors Associated with Rheumatoid Arthritis
Wednesday, November 14, 2012, 11:00 AM–12:30 PM

2689

Quality of Sleep, Physical Activity and Fatigue in Patients with Rheumatoid Arthritis. A Cross-Sectional Study. Katrine Loeppenthin[1], Bente Appel Esbensen[1], Poul Jennum[2], Mikkel Østergaard[3], Tanja Thomsen[1] and Julie Midtgaard[4]. [1]Nursing and Health Science Research Unit, DK-2600 Glostrup, Denmark, [2]Danish Centre for Sleep Medicine, Department of Clinical Neurophysiology, DK-2600 Glostrup, Denmark, [3]Glostrup Hospital, Copenhagen, Denmark, [4]Health Care Research Centre, Copenhagen, Denmark

Background/Purpose: Sleep disturbances and fatigue are frequently experienced (40–70 %) in patients with rheumatoid arthritis (RA) and contribute to decreased quality of life and adverse health and behaviour consequences. However, little is known about the prevalence of poor sleep and its association to Physical Activity (PA) and fatigue. Understanding PA, fatigue and the impact on sleep disturbances could illuminate ways to promote sufficient sleep in RA patients. Thus, the aim of this study was to examine the association between sleep disturbance, PA, and fatigue.

Methods: A total of 500 RA patients from a rheumatology outpatient clinic were recruited consecutively to participate in an observational cross-sectional study. The self-administered questionnaire covered the Health Assessment Questionnaire (HAQ), Visual Analogue Scale (VAS) for pain and fatigue, Physical Activity Scale (PAS), Multidimensional Fatigue Inventory (MFI), Short Form SF-12v2, Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI) as well as demographic data and clinical data (comorbid condition, disease duration, disease activity).

Results: The response rate was 89%. All participants were between 22 and 88 years old (mean age of 58 years), and 80% were women. The mean disease duration was 14 years and mean DAS score was 2.7. The prevalence

of poor sleep quality was 61 %. Higher level of general fatigue, mental fatigue, physical fatigue, reduced activity and reduced motivation was reported in patients with poor sleep quality compared with patients with good sleep quality (P<0.0001). Sleepiness (P=0.0007), sleep duration, sleep latency, sleep disturbance and daytime dysfunction was also higher in patients with poor sleep quality then in patients with good sleep quality (P<0.0001). For the purpose of this study, the participants were divided into two categories. Poor sleep quality (PSQI global score >5) and good sleep quality (PSQI global score <5). More time spent on sedentary leisure time (P=0.0371) and moderately strenuous PA was reported in patients with poor sleep quality compared with patients with good sleep quality, but there were no significant differences between light PA and hard strenuous PA on sleep quality.

Conclusion: A high prevalence of sleep disturbances was observed. This study indicates that PA and fatigue play a significant role in self-reported sleep quality. Addressing sleep disturbances via pharmacological and behavioural interventions may have a critical impact on RA patients.

Assessment of Sleep Quality in Patients with Rheumatoid Arthritis. Ulku Ucar and Mehmet Tuncay Duruöz. Celal Bayar University Medical School, Manisa, Turkey

Background/Purpose: Rheumatoid arthritis is a chronic inflammatory disease affecting mainly diartrodial synovial joints. Fatigue and sleep disturbances are commonly seen symptoms in RA patients which are related to both inflammation and psychosocial factors. To evaluate the relation between fatigue and sleep disturbances together with clinical, functional and quality of life measures in RA patients.

Methods: Subjects fulfilling ACR 1987 revised criteria were consecutively recruited into the study. Patients with malignancy, fibromyalgia syndrome other systemic inflammatory diseases were excluded. Demographic, clinical, functional, laboratory, radiographic data of patients was recorded. The body mass index (BMI), severity of pain (VAS), severity of fatigue (VAS), disease duration (month) was evaluated. Disease activity, functional status and quality of life were assessed respectively with DAS 28, Duruöz Hand Index (DHI), Hand Functional Index (HFI), SF-36 and Rheumatoid arthritis quality of life (RAQOL) Pittsburgh Sleep Quality Index (PSQI) were used to measure patients' quality of sleep. Statistical analyses were performed with Pearson correlation coefficient and a value of p <0.05 was considered as statistically significant.

Results: Seventy patients (22 male) were recruited into the study. The mean of age 54,12±12,25 and the mean disease duration was 85,67 ± 95,79 months. The patient scores (mean ± SD) were: VAS severity of pain: 36,51±26,31 (mm), VAS severity of fatigue: 36,31±25,65 (mm), DAS 28: 4,27±1,49, DHI:12,67±14,37, HFI: 13,63±9,72, SF-36 vitality score: 47,06±22,39, RAQOL: 12,83±8,42, PSQI: 6,25±3,52. PSQI and VAS severity of fatigue showed significantly positive correlation with RAQOL (r=0,417, p<0,001) (r=0,577, p<0,001) and significantly negative correlation with SF-36 vitality subscale (r=−0,565, p<0,001) (r=−442, p<0,001) respectively. There was a weak but significant correlation between PSQI and VAS severity of fatigue (r=0,281, p=0, 02). PSQI showed no significant correlation with various demographic, clinical and laboratory features like age (p=0,904) disease duration (p=0,193), DAS 28 (p=0,812), VAS pain(p=0,309), DHI (p=0,415), HFI (p=0,074), ESR (p=0,507), CRP (p=0,693) (p>0,05).

Conclusion: Our findings confirmed that degree of fatigue and sleep quality of RA patients are mostly related with quality of life and vitality. Disease activity, laboratory parameters or functional status of patients are not significantly correlated with sleep quality. So treatment strategies that only target inflammation are not enough. Sleep disturbances and psychological factors should be evaluated separately.

Diet and Other Lifestyle Related Factors and the Risk of Developing Rheumatoid Arthritis. Björn Sundström[1], Ingegerd Johansson[2] and Solbritt Rantapää Dahlqvist[3]. [1]Umeå University, Umeå, Sweden, [2]Umeå Universitet, Umeå, Sweden, [3]Umeå University Hospital, Umeå, Sweden

Background/Purpose: There is a growing interest in the role of lifestyle in developing chronic diseases, such as rheumatoid arthritis (RA). Our aim was to investigate whether modifiable risk factors, such as an unfavorable lipid profile, smoking, obesity, diet, physical activity, and psycho-social factors, for example, education level, increase the risk of developing RA.

Methods: The register of patients with RA (1987 ACR criteria) at the Department of Rheumatology in the county of Västerbotten, northern Sweden, was co-analyzed with the register for the Västerbotten Intervention Project (VIP), which assembles data from clinical examinations in a community intervention program. Within this database, 146 patients (women, n=102, 70%) who had participated before onset of symptoms of disease and 438 controls matched for sex, were identified. Due to different versions of the food frequency questionnaire (FFQ) being used, the controls were also matched for FFQ version. From visits pre-dating the onset of symptoms, data on diet, physical activity, smoking, body mass index, serum levels of total cholesterol and triglycerides was retrieved from the database. The association between lifestyle factors and risk of developing RA was assessed by logistic regression analyses.

Results: Smoking and physically demanding work were associated with an increased risk of developing RA (OR=2.35 (1.54–3.59) and OR=1.17 (1.002–1.37), respectively), whilst higher education associated with a decreased risk (OR= 0.62 (0.39–0.98)). A median consumption of fish was 20 grams/day (IQR 11–28) and fruit/vegetables 150 grams/day (IQR 83–318) for the prediseased individuals was not significantly different from that of the controls. No significant associations for the risk of RA were found with the Healthy Diet Indicator score, or with food groups and macronutrients. Nor did body mass index and alcohol consumption affect the development of RA. Levels of serum cholesterol or triglycerides did not affect the risk, nor did the frequency of exercise.

Conclusion: In this nested case-control study no association between diet and risk for development of RA was observed. There was limited variability regarding dietary factors in the subject groups studied, which could reduce the detectibility within the populations studied. However, it can be concluded that smoking and the level of education, were more significant for the risk of developing RA than diet in this cohort of patients.

Factors Associated with Person-Perceived Disability in Adults Aged 18+ with Rheumatoid Arthritis. Yeliz Greenhill, Alison Hammond and Sarah Tyson. University of Salford, Manchester, United Kingdom

Background/Purpose: Rheumatoid Arthritis (RA) is associated with high risk of disability (1). Loss of independence is negatively correlated with the person's health and wellbeing (2). The International Classification of Health and Functioning (ICF) suggests that the relationship between impairment and disability is largely modified by social and environmental factors. Understanding the mechanisms of the disablement process can help to reduce or prevent the negative effects of RA on people's lives. This study aimed to establish key factors associated with person-perceived disability in adults with RA using the ICF as a framework.

Methods: Participants with RA over 18 years were recruited from 14 rheumatology clinics. They completed a postal questionnaire including demographic questions, life satisfaction, mood, pain, stiffness and fatigue numeric rating scales (0–10), the Evaluation of Daily Activities Questionnaire (EDAQ), SF-36v2, and RA Quality of Life scale (RAQOL). Person-perceived disability was measured by asking "Do you consider yourself to have a disability? (YES/NO)" Questionnaire items were linked to the ICF. The prevalence of perceived disability was calculated overall and for age and gender and tested using the χ^2 est. Univariable and multivariable logistic regression was used to assess associations between person-perceived disability and body functions and structures; activity limitation; personal and environmental factors. A parsimonious model of key factors associated with perceived disability was fitted using backwards-stepwise binary logistic regression. Adjusted odds ratios with 95% confidence intervals were calculated to determine the strength of association for each variable.

Results: 413 people responded (mean age: 60 years (SD: 11.5); 73% female; average disease duration: 13 years (SD: 10.7)); 242 (58%) of whom reported perceived disability, which was more common in women than men (p=0.04). There was no relationship with age (p=0.97). The parsimonious model was a reasonable fit for the data (χ^2 = 5.65, p=0.69). Key factors associated with perceived disability were: dissatisfaction with life (Adj. OR: 3.5; 95% CI 1.6, 7.8), low mood (Adj. OR: 2.9; 95% CI 1.3, 6.7), pain when moving (Adj. OR: 2.5; 95% CI 1.2, 4.9), and limitation in moving round outdoors/ shopping (Adj. OR: 1.3; 95% CI 1.2, 1.4). Additionally, the odds of reporting perceived disability were twice as high in those with RA duration >10 years compared to <10 years (adj. OR: 1.9 95% CI: 1.0, 3.9).

Conclusion: Half of adults with RA in this study considered themselves disabled. Psychosocial factors, pain and activity limitation contributed to disability across the age and gender range. Recognition of key factors associated with person-perceived disability could be helpful in rehabilitation, specifically focusing on improving: satisfaction with life (through enabling people to achieve occupational balance and meaningful goals); mood; and outdoor mobility; and reducing pain when moving. This might then help people to feel less disabled by RA.

Examination of a Multidimensional Model of Disability and Role Functioning in Patients with Rheumatoid Arthritis. Sarah R. Ormseth[1], Taylor Draper[1], M. Custodio[2], M.H. Weisman[3], M.R. Irwin[2] and Perry M. Nicassio[2]. [1]Loma Linda University, Loma Linda, CA, [2]UCLA, Los Angeles, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA

Background/Purpose: Disability and impairments in role functioning are common obstacles for many patients with RA. A combination of disease-related and psychosocial factors may contribute to limitations in functioning. The purpose of this research was to examine a model describing the interrelations among disease burden, mood disturbance, and disability as determinants of role limitations in patients with RA. It was expected that disease burden would be negatively associated with role functioning directly and/or indirectly through the potential mediators of mood disturbance and disability.

Methods: The data of 103 participants were drawn from baseline of a randomized comparative efficacy trial of psychosocial interventions for RA. In the hypothesized model, disease burden (total joint score and disease activity items from the Rapid Assessment of Disease Activity in Rheumatology) directly and indirectly predicted role functioning (physical role and social functioning from the Short Form-36) through negative mood (Center for Epidemiological Studies Depression Scale) and disability (large-limb gross movement and small-limb fine movement from the Health Assessment Questionnaire Disability Index). EQS 6.1 was used to evaluate the structural model. Data screening revealed a violation of multivariate normality, therefore, the ML robust test statistics, which correct for non-normal data, are reported.

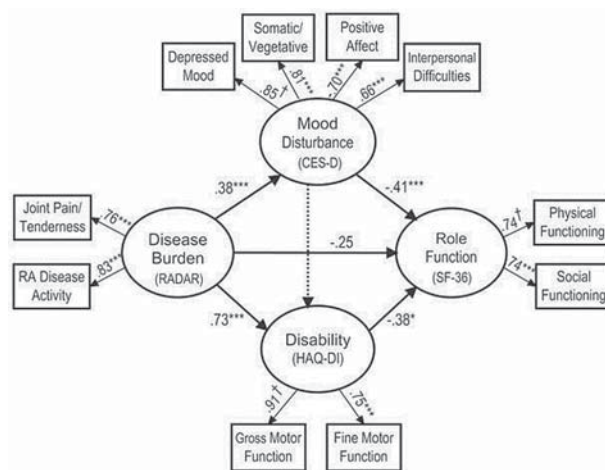
Results: The hypothesized model provided a good fit of the data, CFI =.975; S-B χ^2 29) = 38.12, p =.120; RMSEA =.056. However, the Wald test indicated removal of the path from mood disturbance to disability (β = −.08, p =.421). As such, along with theoretical plausibility, this path was removed. The fit of this more parsimonious model was similar, CFI =.976; S-B χ^2 30) = 38.60, p =.135; RMSEA =.053, and the final model is depicted in Figure 1. Greater disease burden predicted mood disturbance and higher levels of disability. In turn, mood disturbance and disability related to lower levels of role functioning. Partial support was found for the hypothesis that mood disturbance and disability mediate the relation between disease burden and role functioning. Specifically, as a sole predictor, the effect of disease burden on role functioning was significant (β = −.68, p <.001). Further, this effect was significantly reduced when mood disturbance (β = −.49, p <.001; Sobel Z = −2.33, p =.020) and disability (β = −.45, p =.007; Sobel Z = −2.08, p =.038) were entered in the model, indicating that each independently partially mediated the relation between disease burden and role functioning.


Figure 1. Structural model with standardized path coefficients.
Note. †pathway set to 1.0. Dotted line indicates path dropped from hypothesized model. RADAR = Rapid Assessment of Disease Activity in Rheumatology; CES-D = Center for Epidemiological Studies Depression scale; HAQ-DI = Health Assessment Questionnaire Disability Index; SF-36 = Short Form-36.
*p < .05; **p < .01; ***p < .001.

Conclusion: The findings from this study confirmed the importance of a multi-dimensional framework in evaluating disability and role functioning in RA using a structural equation approach. Mood disturbance and disability play major roles in explaining role limitations along with patient-reported disease burden.

Benefits of the Chronic Disease Self-Management Program in Low-Income African American Women with Systemic Lupus Erythematosus: Results of a Pilot Test. Cristina Drenkard[1], Charmayne M. Dunlop-Thomas[1], Kirk Easley[1], Gaobin Bao[1], S. Sam Lim[1] and Teresa J. Brady[2]. [1]Emory University, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA

Background/Purpose: Minorities with systemic lupus erythematosus (SLE) are at high risk of poor disease outcomes and may face challenges in effectively self-managing multiple health problems. The Chronic Disease Self-Management Program (CDSMP) is an evidence-based intervention that improves the health of people with chronic illnesses. We aimed to pilot test the benefits of the Chronic Disease Self-Management Program (CDSMP) for low-income African American women with systemic lupus erythematosus (SLE).

Methods: Four CDSMP 6-week workshops were delivered to 49 low-income African American women with SLE who received medical care for ≥6 months at a public lupus clinic in Atlanta, Georgia. We compared post- minus pre- CDSMP changes (from baseline to 4 months after the start of the intervention) in three general outcomes (health status, self-efficacy and self-management behaviors) using self-reported measures. Additionally, a fourth general outcome (outpatient and inpatient health care utilization) was assessed using electronic administrative records in the 6-month periods before and after the intervention. Paired t-tests or Wilcoxon signed-rank tests were used to compare the post-pre CDSMP change for each outcome measure.

Results: Significant improvements were observed in one of the three measures of health status (physical component summary of the SF-36), in the measure of self-efficacy, and three of the five measures of self-management behaviors outcome (cognitive symptom management, communication with physicians, and medication taking measure).

Post-pre-CDSMP Change of Self-reported Measures

Outcome Category	Measure	Post- minus pre-CDSMP Mean Change (SD)	p-value[a]
Health Status	Physical Component Summary*	2.4 (7.3)	0.032
	Mental Component Summary*	2.5 (10.2)	0.10
	CES-D^	−1.2 (10.1)	0.44
Self-efficacy	Self-Efficacy Managing Chronic Disease*	0.5 (1.7)	0.035
Self-Management Behaviors	Cognitive Symptom Management*	0.3 (1.0)	0.036
	Stretching/strengthening Exercise*	1.6 (74.4)	0.88
	Aerobic Exercise*	−6.4 (119.4)	0.72
	Communication with Physicians*	0.4 (1.0)	0.011
	Medication-Taking Measure*	0.4 (1.0)	0.012

[a] Paired t-test
*higher score = better, ^ lower score = better
Abbreviations: CES-D, Center for Epidemiologic Studies Depression Scale
The evaluation of the fourth outcome, health service utilization, showed that the median number of outpatient visits (lupus clinic and emergency room) decreased from 3 to 1 (p < .0001).

Conclusion: The CDSMP is a promising intervention for low-income African Americans with SLE. It is an inexpensive program with growing availability around the world that should be further evaluated as a resource to improve patient-centered outcomes and decrease health service utilization among SLE patients.

The Mary Kirkland Center for Lupus Care General Health Assessment Initiative for Systemic Lupus Erythematosus Patients. Monica C. Richey, Doruk Erkan and Kyriakos A. Kirou. Hospital for Special Surgery, New York, NY

Background/Purpose: Aiming to broaden the care of lupus patients beyond the standard lupus management, we launched a pilot general health assessment (GHA) initiative under the umbrella of our lupus center. The goal of this initiative was to systematically address potentially preventable lupus co- morbidities. The purpose of this analysis was to determine the one year impact of the GHA program on the care of our lupus patients.

Methods: The GHA program was implemented in September 2010 when our center's nurse practitioner (NP) started to meet with each SLE patient during their Friday Lupus Clinic visit. During this visit, a list of pre-determined general health measures, developed by our center based on ACR and USPSTF recommendations (Table), are reviewed with the patients in order to determine the need for further intervention. Following this initial visit, the center NP: a) facilitates the implementation of yet "uncompleted" measures, by either ordering directly the proper test/intervention and/or by communicating the need to the treating physician; and b) meets with the patients every 3–6 months (depending on the number of outstanding issues) to review the recommendations from the previous visit. For the purpose of this interim analysis, we compared the "completion" rates of GHA items between baseline and the 6–12 month visits (Chi-square test).

Results: 126 SLE patients completed a total of 315 visits between September 2010 and June 2012. Table demonstrates the proportion of GHA items that had been completed by patient's rheumatologists and/or primary care physicians before each NP visit at baseline, 6 months, and 12 months. There was a significant increase in the "completion" rates of the GHA items that were addressable at the time of the nurse practitioner visit, e.g., vaccinations. However, GHA items that required an extra appointment for the patient, e.g., mammogram, had a lower rate of success. The major reasons for "uncompleted" tests were: personal misconception of such tests; difficulty with making appointments and feeling overburdened with too many medical appointments.

GHA Items	Baseline n:126	6m Visit n:92	12m Visit n 54
Influenza Vaccination	82 (65%)	71 (77%)	**49 (90%)***
Pneumonia Vaccination	33 (26%)	32 (35%)	**32 (59%)***
PPD or Quantiferon	56 (44%)	**64 (69%)***	**51 (94%)***
HBsAg	71 (56%)	**77 (83%)***	**51 (94%)***
HBsAb	70 (55%)	**71 (77%)***	**51 (94%)***
Hep B Core	5 (4%)	**28 (30%)***	**32 (59%)***
Hepatitis C Antibody	75 (59%)	**70 (76%)***	**51 (94%)***
Vitamin D Level	113 (89%)	**90 (98%)***	**54 (100%)***
Eye Exam for HCQ °	113 (89%)	**90 (97%)***	53 (98%)
PAP Smear °	87/107 (81%)	71/77 (92%)	39/44 (88%)
Mammogram°	45/59 (76%)	**43/44 (97%)***	22/23 (96%)
Colonoscopy°	21/40 (52%)	21/30 (70%)	12/18 (67%)
DEXA°	61/114 (52%)	54/86 (60%)	**35/48 (67%)***
Calcium + Vit D	79 (65%)	64 (69%)	41 (76%)

° Addressed only if the test was indicated.
* p <0.05

Conclusion: Our lupus center general health assessment initiative demonstrates that additional visits with the center nurse practitioner at the time of patients' regular physician visits can improve the patient care. We will continue our efforts to increase patient education regarding the importance of general health assessment to prevent lupus-related co-morbidities; we will also work with physicians for improved coordination of care.

The Short Term Effect of Individualized Nutrition Counseling On Nutrients and Select Cardiovascular Risk Factors in Patients with Systemic Lupus Erythematosus. Sotiria Everett, Virginia Haiduc, Monica C. Richey and Doruk Erkan. Hospital for Special Surgery, New York, NY

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at a high risk for developing cardiovascular disease (CVD) due to increased prevalence of traditional and nontraditional CVD risks factors. The purpose of this study was to evaluate the 6-month effect of individualized nutrition counseling (INC) on SLE patients participating in an ongoing CVD prevention counseling program (PCP).

Methods: SLE patients attending a free-of-charge CVD PCP have been referred to a registered dietitian for INC following an assessment of their CVD risk factors. The INC incorporates patient-centered methods (tailored nutrition education, goal setting, and motivational interviewing) to facilitate dietary changes. In a preliminary 6-month analysis, we evaluated changes in select nutrients (calories, sodium, fat, saturated fat, cholesterol, omega-3 and omega-6 fatty acids, fiber, sugar and folate), diet habits, anthropometric measures (weight and BMI), and clinical outcomes (lipid levels and blood glucose levels). A one sample t-test on the difference in the means between baseline and 6-month data was conducted for nutrient, anthropometric measures, and clinical measures. A chi-squared analysis was conducted for categorical variables depicting dietary habits.

Results: From March 2009 to June 2011, 41 patients (female: 88%; mean age: 40.7 ± 12.6; African American/Hispanic: 73%; mean disease duration: 12.2 ± 8.2) attended INC (out of 71 referred). Hyperlipidemia was present in 18% of the patients, diabetes in 10%, and hypertension in 56%. Average weight was 85.98 kg ± 20.21, and BMI was 31.3 ± 7.56. In 6-month follow-up, patients: a) reduced their intake of sodium, total calories, and percent calories from fat and saturated fat (Table); b) had decreased weight (−1.64 kg, p = 0.025); and c) reported increases in eating a diet rich in fruits and vegetables (p < 0.001), a high fiber diet (p = 0.011), ≥ 2 servings of fish/week (p = 0.002), and a low cholesterol diet (p = 0.034). The analysis of patients with abnormal lipids, and/or glucose levels, at baseline did not show a clinically significant improvement.

	Baseline Mean (SD)	6-month[b] Mean (SD)	Mean difference (SD)	p-value
Calories (kcals)	1687.64 (SD = 515.59)	1522.91 (SD = 440.78)	−164.73 (SD: 568.71)	**.071**
%Calories from fat	32.93 (SD = 8.71)	28.18 (SD = .24)	−4.13 (SD: 9.88)	**.011**
%Calories from saturated fat	10.37 (SD = 4.19)	9.22 (SD = 3.32)	−1.15 (SD = 3.91)	**.068**
Cholesterol (mgs)	277.71 (SD = 204.23)	231.38 (SD = 49.74)	−46.34 (SD = 225.32)	.195
Sodium (mgs)	2518.28 (SD = 83.53)	2009.94 (SD = 977.74)	−508.34 (SD = 1359.82)	**.006**
Omega-6 Fatty Acids (grams)	9.02 (SD = .97)	8.53 (SD = .24)	−.49 (SD = 6.78)	.647
Omega-3 Fatty Acids (grams)	0.33 (SD =.66)	.29 (SD =.43)	.04 (SD =.81)	.739
Fiber (grams)	18.04 (SD = 8.62)	18.38 (SD = 9.33)	.34 (SD = 9.33)	.823
Sugar (grams)	82.52 (SD = 53.17)	76.72 (SD = 38.93)	−5.80 (SD = 51.93)	.479
Folate (mcg)	365.16 (SD = 193.66)	334.89 (SD = 211.13)	−30.27 (SD = 261.11)	.462

Conclusion: Our 6-month preliminary analysis suggest that individualized nutrition counseling using patient-centered methods is an effective method for promoting changes in nutrient intake, diet habits and, possibly, in anthropometric measures. The three-year longitudinal analysis of the patients receiving individualized nutrition counseling will determine the effectiveness of individualized nutrition counseling and if it can reduce prevalence of CVD risk factors.

FMS and SLE Patients Have Higher Treatment Expectations Than RA Patients. Robert S. Katz[1], Hannah Bond[2], Jessica L. Polyak[2], Lauren Kwan[2] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

Background/Purpose: It is anticipated that patients with high expectations for improvement of their medical condition may get frustrated when a significant degree of benefit does not occur with treatment. Medication and the non-medication therapy of fibromyalgia can be challenging. We asked fibromyalgia patients what their expectations were regarding past and current treatment.

Methods: Office patients were asked to complete a questionnaire about their expectations of treatment with respect to its general effect and its effect on pain, sleep quality, quality of life, and energy. Each item was rated 1–3 with 3 indicating the highest expectations. A total expectation score consisting of the mean of these expectation items was calculated. Patients also rated from 1–3 how challenging their rheumatic disease was with 3 as the most challenging rating. Three diagnosis groups were compared with respect to questionnaire responses: 91 FMS patients, 34 RA patients, and 14 SLE patients. The Kruskal-Wallis and Mann-Whitney tests were used to compare groups with respect to the items and total scores, and the Spearman correlation was used to test for linear association between the disease challenge rating and the total expectation score for each group, with a two-sided 0.05 significance level.

Results: Compared to RA patients, FMS patients considered their disease significantly more challenging (FMS 2.2 ± 0.7, RA 1.6 ± 0.8, $p < 0.001$) and had significantly higher general treatment expectations (FMS 1.8 ± 0.5, RA 1.2 ± 0.4, $p < 0.001$), significantly higher treatment expectations concerning pain (FMS 1.8 ± 0.6, RA 1.4 ± 0.5, $p = 0.010$), and significantly higher total treatment expectation scores (FMS 1.9 ± 0.4, RA 1.6 ± 0.4, $p = 0.009$). Compared to RA patients, SLE patients also had significantly higher general treatment expectations (SLE 2.0 ± 0.6, RA 1.2 ± 0.4, $p < 0.001$), significantly higher treatment expectations concerning pain (SLE 2.0 ± 0.7, RA 1.4 ± 0.5, $p = 0.011$), and significantly higher total treatment expectation scores (SLE 2.0 ± 0.6, RA 1.6 ± 0.4, $p = 0.037$). There were no statistically significant differences between FMS and SLE patients. For each group, a statistically significant positive Spearman correlation was found between the disease challenge rating and the total expectation score, so that higher expectation scores were associated with higher disease challenge ratings: FMS rho $= 0.37$ ($p = 0.001$), RA rho $= 0.50$ ($p = 0.005$), SLE rho $= 0.58$ ($p = 0.0498$).

Conclusion: Patients with fibromyalgia who have higher expectations for significant improvement may find be impossible to meet those expectations in many cases. A meaningful therapeutic relationship can help some patients cope with their illness better, but many fibromyalgia patients are currently frustrated by a lack of significant benefit from current therapy, especially those patients who have high expectations for improvement. Cognitive behavior therapy might help some patients with unrealistic expectations cope with their illness better.

Psychosocial Stress and Complement Activation Product C4d On Reticulocytes in Patients with Systemic Lupus Erythematosus. Xiaotian Chen[1], Yu Cheng[1], Chau Ching Liu[2], Amy H. Kao[2], Susan Manzi[3], Joseph M. Ahearn[3] and Carol M. Greco[1]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Allegheny Singer Research Institute, Pittsburgh, PA, [3]West Penn Allegheny Health System, Pittsburgh, PA

Background/Purpose: Although patients with SLE may report that psychosocial stress is linked with disease flares, research results on stress-disease activity associations are mixed. The lack of consistent results may be due to lack of true associations, difficulty in measuring stress, or to lack of precision in capturing the onset of SLE flares. Recently, the presence of complement activation products on circulating blood cells has emerged as a novel biomarker for diagnosis and disease activity in SLE. Complement activation products have been detected on reticulocytes, which are new blood cells that emerge from the bone marrow and are in circulation for just 1–2 days before becoming erythrocytes. Reticulocytes bearing complement activation product C4d (R-C4d) are potential biomarkers of new onset SLE disease activity. The purpose of this study was to evaluate the association between psychosocial stress, self-reported disease activity, and early signs of complement activation as measured by R-C4d in patients with SLE.

Methods: After completing informed consent, 123 SLE patients completed the 10-item Perceived Stress Scale (PSS), the Center for Epidemiologic Studies Depression scale (CESD), and the Positive Affect scale of the PANAS (Positive and Negative Affect Scale), as well as the self-report Systemic Lupus Activity Questionnaire (SLAQ) at up to 4 clinic visits. Reticulocytes were evaluated for presence of C4d using median fluorescence intensity (MFI) analysis by flow cytometry. R-C4d units were dichotomized at 3.35 MFI, a score indicative of abnormally elevated R-C4d level due to complement activation. Mixed regression modeling was used to evaluate concurrent associations between psychosocial variables, SLAQ, and R-C4d.

Results: The majority of participants were female (94%), non-Hispanic (96%), and non- African American (86%). The mean (SD) age was 45 (13) years. Mean (SD) SLAQ score was 11.4 (5.7) at study entry. R-C4d was concurrently associated with higher perceived stress; those with elevated R-C4d were 2.18 points higher on the PSS (p= 0. 01). There was a trend for lower Positive Affect scores to be associated with R-C4d (p= 0.06). Depressive symptoms (CESD), which averaged 16.2 (11.6) at study entry, were not associated with R-C4d (p = 0.25). SLAQ total score was not associated with elevated R-C4d (p = 0.58), but was associated with CESD (β=0.19, p<0.001), PANAS (β=−0.21, p<0.001) and PSS (β=0.2, p<0.001).

Conclusion: SLE patients with elevated levels of R-C4d had higher levels of perceived stress or feeling overwhelmed compared to patients without R-C4d elevation. This, in combination with the trend toward lower levels of positive affect, supports the idea of biological links between early SLE flares and perceptions of stress and malaise. The finding that CESD was not associated with R-C4d may be related to the breadth of depressive symptoms assessed by CESD, which range from social isolation to sleep problems in addition to sad mood. Whether psychosocial stress precedes or results from disease flares remains unknown given the concurrent measurements used in this study. Future studies should examine prospective links between stress and SLE disease biomarkers and should include physician ratings of SLE disease activity.

A Multi-Center Study of the Appropriateness of Anti-Neutrophilic Cytoplasmic Antibody Testing. Tarun S. Sharma, Vikash Sinha, Vino Unson, Saurav Acharya, Sahar Mohammadi and Amer Syed. Mount Sinai School of Medicine-Jersey City Medical Center, Jersey City, NJ

Background/Purpose: Anti Neutrophil Cytoplasmic Antibody (ANCA) test is an Indirect Immunoflorescence test used as an aid in the diagnosis of ANCA Associated Small Vessel Vasculitis (AASVV), namely, Wegener's Granulomatosis, Churg Strauss Vasculitis and Microscopic Polyangitis and its renal-limited variant (pauci-immune crescentic glomerulonephritis). In an effort to decrease the false positive ANCA tests and improve the clinical utility of this test, guidelines for ANCA testing were proposed in 1999. We aim to compare the trend of ANCA testing in practice with the proposed guidelines and thereby calculate the disparity in testing, if any, including the financial burden such testing would pose.

Methods: In this study, we assembled all the ANCA tests that were ordered on hospitalized patients during a 2 year period at 2 academic medical centers. A chart review (by a physician blinded to ANCA test results) was performed and the indications used by physicians for ordering each of the ANCA tests were then compared against the proposed guideline-indications for ANCA testing.

Table 1. Clinical Indications for ANCA Testing

Guidelines	Clinical Definition
1. Glomerulonephiritis, especially rapidly progressive	(A) Creatinine level >2.0 mg/dL (>176.8 μmol/L) (normal range, 0.7–1.3 mg/dL [61.9–114.9 μmol/L]) immediately prior to ANCA testing or (B) urinary red blood cell casts or hematuria with >5 red blood cells per high-powered microscopic field
2. Pulmonary hemorrhage, especially pulmonary renal syndrome	Hemoptysis or pulmonary hemorrhage
3. Cutaneous vasculitis with systemic features myalgias, arthralgias, or arthritis	Purpura, rash or livedo with concurrent fever, weight loss, myalgias, arthralgias, or arthritis
4. Multiple lung nodules	At least 1 nodule seen on any imaging study‡
5. Chronic destructive disease of the upper airways	Epistaxis or erosive changes seen on clinical examination or imaging studies not due to previous surgery
6. Long-standing sinusitis or otitis	(A) Hearing loss, blocked ears, or ear pain or (B) sinusitis or otitis specified as the reason for ANCA test ordering by the physician
7. Subglottic, tracheal stenosis	(A) Visualized on imaging studies or (B) tracheal stenosis specified as the reason for ANCA test ordering by the physician
8. Mononeuritis multiplex or other peripheral neuropathy	Sensory or motor changes, including cranial nerve palsies
9. Retro-orbital mass	Radiographic visualization of a mass lesion

Results: Of the 204 ANCA tests examined, only 98 were ordered using the guideline indications. The commonest of the non-guideline indications were Colitis (25%) and Liver disease (6%) whereas the commonest guideline indications were Acute Renal Failure (ARF) (54%) and hemoptysis (19%). All 3 positive test results were false positive and failed to meet the guideline indications to begin with. Among the commonest guideline indication of ARF, majority cases (75%) had an alternate obvious etiology for ARF at the time of ordering the ANCA test itself. All the non-guideline testing was ordered by primary care physicians, nephrologists and residents and led to an extraneous health care expenditure of over $25000 for the send-out lab test over the 2 year period.

Conclusion: In this study we conclude that the ANCA test has limited utility in the academic centers included in our study, mostly due to the use of non-guideline testing indications by physicians. Increased awareness regarding the appropriate use of the ANCA test among physicians is critical since it would not only assist in the diagnosis of AASVV, but also help increase the cost-effectiveness of this crucial test.

2012 ACR KNOWLEDGE BOWL

ARE YOU GAME to test your knowledge? Come and check out this year's **ACR Knowledge Bowl**!

This **jeopardy-game like session** is a must-attend event:

- **Preliminary round** – Sunday, November 11, from 12:30 – 1:45 PM

- **Final round** – Monday, November 12, from 11:00 AM – 12:30 PM

If you like a good competition, the Knowledge Bowl is your spot. **You don't want to miss this fun, challenging event.**

Washington, D.C.

ACR/ARHP 12
Annual Meeting
Pre-Meeting Courses: November 9-10, 2012
Scientific Sessions: November 10-14, 2012

Poster Printing and Hanging Service

Eliminate the hassle of traveling with your poster!
Order your poster through the ACR/ARHP poster printing service and we will ship, hang, take down and store your poster for you.

This year, the ACR has named Genigraphics, leading experts in large format color printing, as the official supplier of printed posters for the 2012 ACR/ARHP Annual Meeting. Genigraphics will create and ship your poster directly to the Walter E. Washington Convention Center. Genigraphics will also hang the poster at the meeting prior to the start of your poster session for no additional charge. After the session, they will take your poster down and make it ready for pickup at the Poster Service Counter, located in the poster hall.

To view poster templates and learn more about the ACR poster printing service, please visit **www.ACRannualmeeting.org**.

Washington, D.C.

ACR/ARHP Annual Meeting 12

Pre-Meeting Courses: November 9-10, 2012
Scientific Sessions: November 10-14, 2012
