Conclusion: Innovative care models have been developed to improve access to care for people with arthritis but these models mainly have focused on inflammatory arthritis and total joint replacement. Most models do not or in only a limited way address conservative management for people with the most common type of arthritis, osteoarthritis. It appears that current models of care are most organized at the level of specialist care, but not in primary care which is the gateway to early diagnosis, treatment and health promotion. Given the increasing prevalence of arthritis and that published data show that only a small proportion of arthritis care is specialist care, addressing this public health concern and provision of timely, appropriate care requires the development, implementation and evaluation of models of care for people with arthritis in general across the continuum of care.

1728

Capturing the Patient Experience: Patient Advisory Committee at Rush University Rheumatologists. Laura Wright[1] and John O'Toole[2]. [1]RUSH University Medical Center, Chicago, IL, [2]RUSH, Chicago, IL

Background/Purpose: The broad objective is to improve patient satisfaction. The purpose of this study is to determine if creating a Patient Advisory Committee (PAC) will lead to increased patient satisfaction which is measured quarterly via Press Ganey Medical Practice Report scores. Press Ganey (PG) produces the industry standard for measuring customer service satisfaction in healthcare. Our goal is to initiate changes in our Rush Rheumatology clinic based on the problems/solutions discussed during PAC meetings.

Methods: Distribute patient satisfaction survey to each patient prior to quarterly PAC meeting; Ask about interest in PAC; Create agenda; Hold quarterly meetings; Record patient input; Initiate changes based on patient input; Analyze effect of changes made based on PG scores

Results: *First PAC Meeting (3/1/11):* Patients can't get parking discount booklets sold in the medical center (accessibility); Met with parking administrator and received permission to sell the discount booklets at our front desk.

Patients want staff and physicians to more clearly identify their title and role; Met with faculty and staff to discuss titles and roles of providers, perceptions of patients.

Patients like that our physicians have latest information/technology, wash their hands in exam room, and take time to break down medical information; Relayed information to faculty/staff at meeting and via email summarizing the PAC meetings.

Patients want physicians to follow through with what they have said they will do such as calling back, sending information, sharing results (timely); Section Director discussed with faculty at weekly meeting and physicians discussed how to improve.

Patients would like administrative and clinical staff to participate in the PAC meetings; Administrative and clinical staff attended 2nd PAC meeting.

Patient expressed frustration with phone tree, difficulty reaching employees at front desk; Changed phone tree message and access to allow option to choose front desk staff.

Meeting End:Informed patients that RUSH is implementing EPIC electronic medical system, asked patients to notice any affect on their interaction with medical staff & comment at next visit.

Second PAC meeting (6/1/11): Patients like the After Visit Summary that is now printed at the end of their visit (Epic EMR implemented 4/5/11) and like that they don't have to request records. Feel more confident now that all of their providers can access their entire medical record; Shared information with faculty and staff and via email summarizing the PAC meetings.

Patients would like staff to call them to obtain information regarding past medical history and list of medications rather than taking up appointment time; Certified Medical Assistants testing in a very limited pilot program.

Conclusion: PG scores (to date) do not support initial improvement in "very good" responses via questionnaires. Many positive and enthusiastic patient comments about changes that have been made due to suggestions of patient advisory committee. Almost double the number of patients attended the second meeting. Patients are very appreciative of being "listened to" and included.

The Impact of Advanced Clinician Practitioner in Arthritis Care Program-Trained Extended Role Practitioners on Health Care Delivery: A Two Year Prospective Study. Carol Kennedy[1], Kelly Warmington[1], Leslie J. Soever[2], Laura A. Passalent[3], Sydney C. Lineker[4], Katie Lundon[1], Rachel Shupak[1] and Rayfel Schneider[5]. [1]St. Michael's Hospital, Toronto, ON, [2]Mount Sinai Hospital, Toronto, ON, [3]University Health Network, Toronto, ON, [4]The Arthritis Society, Toronto, ON, [5]Hospital for Sick Children, University of Toronto, Toronto, ON

Background/Purpose: The Advanced Clinician Practitioner in Arthritis Care (ACPAC) program is an innovative, clinical and academic, post-licensure program for experienced physical and occupational therapists. The program focuses on assessment, diagnosis, triage and independent management of selected musculoskeletal and arthritis-related disorders. In order to improve arthritis care through the implementation of a new clinical role, it is imperative to evaluate the extent to which ACPAC program graduates are delivering integrated and timely healthcare.

This study aimed to evaluate the impact of the Advanced Clinician Practitioner in Arthritis Care (ACPAC) program-trained extended role practitioner with respect to health care delivery. The research objectives were: 1) to measure access to ACPAC program-trained practitioners in Ontario, 2) to describe the role utilization of the ACPAC program-trained practitioner, and 3) to explore integration with internal/external services and other resources.

Methods: ACPAC program-trained practitioners (n=30) were recruited from 15 healthcare institutions across the province of Ontario, Canada. These included urban, rural, academic, non-academic, adult and paediatric settings. A longitudinal survey was completed at the end of each fiscal quarter in 2009 and 2010. Questions relating to system impact were developed through peer consensus. Descriptive statistics were used to summarize the data.

Results: The response rate varied from 83–97% over the 8 fiscal quarters of 2009 and 2010. The mean wait time from referral to initial assessment by an ACPAC program-trained practitioner varied from 14 to 26 days. Most respondents were working in an extended practice role (range 84–93%). These practitioners referred patients to a wide range of services (expressed as % of total patients seen in fiscal year 2009 [n=13407] and 2010 [n=14546]): 10% referred to internal services (publicly funded, privately funded but within); 18–20% to external/community services; 12–14% to medical doctors (general practitioners or specialists); 47–73% to other services (e.g. lab, imaging); and 22–24% to educational resources. Most ACPAC graduates (58–79%) reported acting under the auspices of medical directives to support their extended practice role. Most respondents ordered X-rays (82–88%), lab tests (64–74%) and diagnostic ultrasounds (43–55%). 70–80% reported recommending medication/dosage changes and 4–14% made these changes independently. 93–96% reported recommending joint injections and 8–18% were performing them.

Conclusion: Most ACPAC program-trained practitioners are working in extended practice roles and are performing tasks that have potential to improve access to care for patients with arthritis. Future evaluations will monitor the evolution of the graduates' extended roles and assess the impact of their care on patient outcomes.

The ACPAC therapist can potentially improve wait times for care and provide an interprofessional approach to managing patients with arthritis and other musculoskeletal disorders. This new human health resource may be an effective strategy to address the progressive decline in the number of arthritis care specialists.

1730

Patient Satisfaction with a New Healthcare Provider: Advanced Clinician Practitioner in Arthritis Care Program-Trained Clinicians. Kelly Warmington[1], Carol Kennedy[1], Sydney C. Lineker[2], Leslie J. Soever[3], Laura A. Passalent[4], Katie Lundon[1], Rachel Shupak[1] and Rayfel Schneider[5]. [1]St. Michael's Hospital, Toronto, ON, [2]The Arthritis Society, Toronto, ON, [3]Mount Sinai Hospital, Toronto, ON, [4]University Health Network, Toronto, ON, [5]Hospital for Sick Children, University of Toronto, Toronto, ON

Background/Purpose: In an effort to provide more appropriate and timely arthritis care, patients are being presented with new models of care and disease management. The Advanced Clinician Practitioner in Arthritis Care (ACPAC) Program is an innovative, clinical and academic education program for licensed physical therapists and occupational therapists. It focuses on the assessment, diagnosis and independent management of selected musculoskeletal and arthritis-related disorders.

As stakeholders in their own care, it is important to give patients a voice in determining the value of their care provider. Our objectives were to evaluate patients' satisfaction with the care received from ACPAC Program graduates and to explore factors associated with levels of satisfaction.

Methods: The patients (N=325) of 27 ACPAC program-trained therapists, seen during a face-to-face visit, were recruited from15 healthcare institutions across Ontario, Canada.

This was a cross-sectional study utilizing a self-report survey. The primary outcome measure was the Patient-Doctor Interaction Scale, modified to reflect patient-therapist interaction (PTIS). The PTIS subscales included: Providing Information (PI), Rapport (R), Meeting Patient Needs (PN). Secondary outcomes included satisfaction with services received (8 items from GHAA Consumer Satisfaction Survey); acceptability of wait times; overall satisfaction, and comparison with arthritis care received from other healthcare professionals.

Analyses included descriptive statistics and logistic regression methods. In the latter, the dependent variable was the PTIS (satisfied vs not satisfied). Fourteen independent factors were considered.

Results: The respondent mean age was 54 years (3–75), with most respondents female (72%), adult (82%) and living in urban areas (79%). The majority of respondents were not working (51%) and most had a diagnosis of an inflammatory (52%) or non-inflammatory (33%) condition.

The PTIS subscale scores [mean (sd); 1–5, 5=very satisfied] were high. PI: 4.5 (0.6), R: 4.6 (0.5), PN: 4.6 (0.5). Satisfaction with services received [1–5, 5=very satisfied]: item means ranged from 4.1–4.6. Wait time was acceptable: from referral (88% agree/strongly agree), and in clinic (87% agree/strongly agree). Overall satisfaction was high [1–5, 5=excellent]: 4.4 (0.7). The majority felt the arthritis care they received was comparable to (37%) or better than (61%) that provided by other healthcare professionals.

Higher levels of satisfaction were associated with acceptable wait times. A number of other factors were also associated with satisfaction across one or two subscales.

Conclusion: Patients seen by ACPAC program-trained practitioners were consistently satisfied across all PTIS subscales and secondary outcomes including access to care. Given the added involvement of this new human health resource in their arthritis management, patients are highly satisfied with the graduates' abilities and feel that their needs are being well addressed. Future work should focus on how the ACPAC program-trained therapists are improving patient care and filling gaps in this area of the healthcare system.

1731

Evaluation of Interprofessional Patient-Centred Collaborative Practice Behaviour and Perceptions Following An Intensive Continuing Education Development Initiative in Arthritis Care. Katie Lundon[1], Carol Kennedy[1], Kelly Warmington[1], Linda Rozmovits[2], Leslie J. Soever[3], Laura A. Passalent[4], Sydney C. Lineker[5], Rachel Shupak[6], Rayfel Schneider[7] and Lynne Sinclair[8]. [1]St. Michael's Hospital, Toronto, ON, [2]Consultant, Toronto, ON, [3]Mount Sinai Hospital, Toronto, ON, [4]University Health Network, Toronto, ON, [5]The Arthritis Society, Toronto, ON, [6]St. Michaels Hospital, Toronto, ON, [7]Hospital for Sick Children, University of Toronto, Toronto, ON, [8]Toronto Rehabiltation Institute, Toronto, ON

Background/Purpose: The Advanced Clinician Practitioner in Arthritis Care (ACPAC) program is an intensive one-year, academic and clinical training program offered to experienced physical and occupational therapists practising in diverse clinical settings across Ontario, Canada. These extended role practitioners both anticipate and are expected to work in the context of Interprofessional Patient-Centred Collaboration (IPC). This is motivated by the growing consensus that IPC practice improves patient care, access to care, patient safety and satisfaction. Purpose: To evaluate the IPC practice behaviour and perceptions amongst ACPAC program-trained practitioners and their teams.

Methods: This study used a mixed-method approach. Qualitative: Focus groups (n=3) for ACPAC practitioners (n=20 participated); Interviews (n=18) for their clinical colleagues and administrators. These were digitally audio-recorded for verbatim transcription, entered into HyperResearch software for textual data analysis. Transcripts were coded for anticipated and emergent themes using the method of constant comparison including searches for disconfirming evidence. Themes related to IPC were identified using components of Barr et al (2005) evaluation of interprofessional education (IPE) initiatives framework to evaluate behavior and modification of attitudes and perceptions, readiness for change in organizational practice and any benefit to patient. Quantitative survey completed by ACPAC practitioners (n=24): Bruyère Clinical Team Self-Assessment on Interprofessional Practice and a single-item rating of team's readiness for IPC practice. Descriptive statistics were used.

Results: Interviews and focus groups with ACPAC graduates and their clinical colleagues and administrators suggest these practitioners are generally effective at promoting and contributing to IPC within arthritis care settings. Varying degrees of IPC exist within their arthritis care teams. Barriers such as institution-specific lack of medical directives, remuneration conflicts, and role recognition issues were identified to impede role implementation. Quantitative survey: Seventy percent felt their team was actively working in an IPC practice model while just over 25% felt it was in the precontemplation (never thought about it) or contemplation phase (thinking about it), and the remaining 5% were prepared for action (making plans). Mean Bruyère subjective subscale scores were high (all >3, scale range 1–5=better perception of teams IPC practice) and lower (mean 4.6, scale range 0–9=more team practices associated with IPC) on the objective scale.

Conclusion: ACPAC program graduates are effective participants of, and contributors to IPC care at select sites. Their presence appears to both promote organizational change and impart general benefit to the collaborative care of patients with arthritis. However, ACPAC graduates are working on teams that are at varying stages of readiness for IPC practice. They appear to understand what is needed for IPC while fewer actual IPC team practices are in place. Intensive IPC components were recently added to the ACPAC curriculum to address this gap.

Key Words: *evaluation, advanced practice, arthritis care, IPC*

1732

An Overview of Clinical Performance by Advanced Clinician Practitioner in Arthritis Care Program-Trained Therapists: A Two-Year Prospective Study. Laura A. Passalent[1], Carol Kennedy[2], Leslie J. Soever[3], Kelly Warmington[2], Sydney C. Lineker[4], Katie Lundon[2], Rachel Shupak[5] and Rayfel Schneider[6]. [1]University Health Network, Toronto, ON, [2]St. Michael's Hospital, Toronto, ON, [3]Mount Sinai Hospital, Toronto, ON, [4]The Arthritis Society, Toronto, ON, [5]St. Michaels Hospital, Toronto, ON, [6]Hospital for Sick Children, University of Toronto, Toronto, ON

Background/Purpose: The Advanced Clinician Practitioner in Arthritis Care (ACPAC) Program is an innovative clinical and academic training program focused on assessment, diagnosis, triage and independent management of selected musculoskeletal and arthritis disorders. The aim of the program is to prepare experienced physical and occupational therapists for extended practice roles and to develop innovative models of arthritis care across diverse clinical settings. It is now critical and timely to evaluate the ACPAC program graduates' clinical performance. The specific objectives of this study were to examine the clinical performance of ACPAC program-trained therapists with respect to the following indicators: 1) referral source; 2) patient volumes and 3) patient diagnoses.

Methods: A longitudinal survey was administered to 30 ACPAC graduates working at 15 healthcare institutions across the Canadian province of Ontario. These included urban, rural, academic, non-academic, adult and paediatric settings. An electronic questionnaire was sent each quarter for the 2009 and 2010 fiscal years. Questions relating to clinical performance were established through peer consensus and were tested for face validity. Descriptive statistics were used to summarize the data.

Results: The mean response rate per quarter was 91.3% (range = 83.3% – 96.7%). ACPAC graduates saw a total of 13407 patients during the 2009 fiscal year and 14546 patients during the 2010 fiscal year. In 2009, the majority of patients were referred by a family physician (43.9%), followed by 35.8% of patients referred by a specialist. In contrast, 51.5% of patients were referred by a specialist in the 2010 fiscal year, followed by 37.3% referred by a family physician. Over the two-year period, new consults constituted 24.9% of all patients seen, of which 7.3% were paediatric. Just over half (55.6%) of patients seen by ACPAC program-trained therapist were for follow-up, with 17.5% of follow-ups specific to the paediatric population. The remaining patients underwent triage by ACPAC program-trained therapists. Approximately half (51.6%) of the patients seen had a diagnosis of osteoarthritis (OA), followed by rheumatoid arthritis (RA) (14.7%), juvenile idiopathic arthritis (11.1%) and the remainder having diagnoses related to various inflammatory and non-inflammatory arthropathies.

Conclusion: ACPAC program-trained therapists working in the province of Ontario are primarily seeing patients with OA or RA in a follow-up capacity, with most patients being referred by either a family physician or specialist. The above evaluation provides a snapshot of the clinical performance of the ACPAC program-trained therapist in terms of volumes, referral sources and diagnoses and identifies an evolving role in the triage of patients, which may improve access to care. The increase in referrals from specialists may reflect their growing awareness of the potential triage role offered by extended role practitioners. Knowing the clinical performance of this unique human health resource can help to shape strategic planning for health care clinical utilization and delivery of care.

Reduced Imprints of Receptor Editing At the Immunologlobulin κ and λ Light Chain Loci During Rituximab Treatment. Khalid Muhammad[1], Arumugam Palanichamy[1], Petra Roll[1], Stefan Kleinert[1], Thomas Dörner[2] and Hans-Peter Tony[1]. [1]University of Würzburg, Würzburg, Germany, [2]Charite Universitätsmedizin Berlin and DRFZ, Berlin, Germany

Background/Purpose: Transient B cell depletion by rituximab (RTX) has gained more importance in the treatment of rheumatoid arthritis (RA) in recent years. Although phenotypic reports on repopulation kinetics of B cell subsets are increasing, precise molecular analysis of the reconstituting immunoglobulin (Ig) genes are sparse. Detailed gene and mutational investigations are demanding to better understand the influence of RTX on Ig genes.

Methods: 708 individual CD19+CD27+ (memory) and CD19+CD27- (naive) B cells were analyzed from 2 RA patients at baseline and 7 months after RTX at B cell repopulation. Ig light chain variable kappa (Vκ) and lambda (Vλ) light chain gene rearrangements were amplified, sequenced and analyzed with a focus on receptor editing.

Results: The naïve as well as the memory repertoire repopulated polyclonally with a diverse use of variable light chain gene families and minigenes. In general, reemerging CD27+ Ig light chain genes displayed substantially higher mutations compared to baseline ($P<0.0001$ prior to RTX versus during reconstitution).. During reconstitution phase, B cells used significantly fewer Jκ distal Vκ genes (P=0.0006) together with a higher frequency of somatic hypermutation of rearrangements employing Jk5 compared to baseline in memory B cells. The use of Vλ rearrangements in regenerating B cells was also biased towards use of Vλ genes of the proximal cassette.

Conclusion: The data indicate that RTX therapy leads to the generation of distinct Vκ/Jκ and Vλ/Jλ gene repertoires consistent with replenishment of antigen-experienced B cells by germinal centers. At baseline, the imprints of receptor editing appeared to be more striking which indicates that a defect of receptor editing is not characteristic of RA and can be normalized by RTX.

1734

The Levels of Memory B-Cells with a Plasmablast-Like Phenotype Are Associated with Response to Anti-CD20 Treatment in Rheumatoid Arthritis. Gururaj Arumugakani[1], Andrew Rawstron[2], Reuben Tooze[1], Paul Emery[3] and Dennis McGonagle[4]. [1]University of Leeds, Leeds, United Kingdom, [2]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [4]University of Leeds and Leeds Teaching Hospitals, Leeds, United Kingdom

Background/Purpose: The advent of B-cell depletion therapy has significantly improved outcome of various autoimmune conditions including Rheumatoid Arthritis (RA), Lupus, Wegner's etc. The extent of B-cell depletion determined by high sensitivity flow cytometry is a key predictor of response and outcome. The pattern of B-cell reconstitution also appears to be important as clinical relapse does not occur in individuals with sustained B-cell depletion, and recovery of plasmablasts in the absence of other B-cell subsets predicts imminent relapse. Individuals with recovery of multiple B-cell subsets have a variable clinical course but those with a high proportion of memory cells within the reconstituting B-cell pool may have an increased risk of relapse. (Dass et al Arthritis Rheum. 2008 Oct;58(10):2993–9) The aim of this study was to identify the characteristics of B-cell subsets which contribute to relapse.

Methods: 79 samples from patients with autoimmune disorders and 28 disease controls were analysed by 10-parameter flow cytometry. An antibody backbone of CD19 and CD20 CD27, and CD38 were used to identify naïve,B-cells memory B-cells and plasmablasts in the backbone to define the initial subsets. 34 additional surface markers known to be expressed by B-cells were evaluated on selected RA cases and controls to identify the most informative subsets. Final assessment of the B-cell subset distribution was performed on 7 individuals prior to first anti-CD20 treatment and 6 individuals with relapsed disease prior to re-treatment.

Results: An iterative approach was used to select markers for further investigation, with an initial stage to detect markers with heterogeneous expression followed by further stages to identify combinations of markers which were complementary in the delineation of different B-cell subsets. Distinct populations could be identified by differential expression of 9 markers, 5/9 of these identified a population of CD38-negative memory B-cells which were otherwise phenotypically similar to plasmablasts. The proportions of these plasmablast-like memory B-cells were relatively low in control cases (median 18% of total memory B-cells, range 7–29%) but were more prevalent in rheumatoid cases prior to anti-CD20 treatment (median 26% of total memory B-cells, range 20–52%) although this difference did not reach statistical significance (Mann Whitney P=0.22). Individuals with relapsed disease requiring re-treatment had variable numbers of naïve B-cells but showed a highly significant increase in the proportion of plasmablast-like memory B-cells (median 55%, range 39–65%, Mann-Whitney P=0.007).

Conclusion: Extensive analysis of B-cell subsets in rheumatoid patients demonstrates heavy skewing of the memory B-cell pool in individuals relapsing after anti-CD20 treatment. Poor or unsustained response to anti-CD20 treatment is associated with the persistence and/or skewed reconstitution by both plasmablasts and plasmablast-like memory B-cells during and after anti-CD20 treatment.

1735

B Cell Depletion Therapy After Multiple Cycles of Rituximab in Patients with Rheumatoid Arthritis: B Cell and Plasma Cell Dynamics Measured Using Serology. Geraldine Cambridge[1], Maria J. Leandro[1], Jonathan CW Edwards[1], Harvey M. Parsons[1], Marion C. Dickson[2] and Hayley Perry[2]. [1]UCL, London, United Kingdom, [2]GSK, Stevenage

Background/Purpose: Pharmacokinetic studies of rituximab-based B cell depletion in RA, allows analysis of elements important for clinical response and relapse. B cell return is mandatory for relapse but in up to 50% of patients, disease flare only occurs several months (or years) after B cell return. Whether Concordant or Discordant with B cell return, relapse is coincident with rises in serum autoantibodies and maturation of B cells into memory cells. Patterns of response and relapse are usually consistent over cycles in individual patients suggesting qualitative as well as quantitative differences in pathogenic B cell selection and maturation. The aim of this study was to use serological markers to identify relationships between maturation of B cells into memory and plasma cells at key points in repeat cycles (median 3, range 2–4) of treatment with rituximab in 24 patients with RA.

Methods: Analytes were tested at 4 time points within each cycle of therapy: baseline, depletion (CD19+Bcell <5cells/μl), repopulation (CD19+Bcell ≥ 5cells/μl) and relapse. Soluble CD23 (sCD23) was used as a measure of B cell maturation into (CD27+) memory cells and serum free light chains as a measure of plasmablast/plasma cell activity. Levels of isotypes of autoantibodies, RF and anti-CCP, of protective antibodies, and of BAFF over the same cycles of treatment were measured. Mann Whitney U and Wilcoxon tests were performed for independent and paired parameters.

Results: After Cycle 1, all analytes decreased significantly from baseline ($p<0.01$) except TT and PCP antibodies. When divided into Concordant and Discordant patients however, IgG and IgA anti-CCP and IgA-RF did not decrease significantly in the Discordant group. These patterns were repeated in the second cycle. When paired samples taken pre-rituximab and at relapse after 3 cycles were compared, significant decreases were found for IgM-RhF and IgM-CCP ($p=0.004$; $p=0.02$ respectively) and for IgG-CCP ($p=0.04$) and sCD23 ($p=0.05$) with a highly significant increase in BAFF levels ($p=0.008$); the drop in CRP approached significance ($p=0.055$). Linear regression analyses of Cycles 1 and 2 showed that IgM-, IgA- and IgG-CCP antibodies were strongly correlated at relapses in the Concordant patient group, whereas IgA and IgM classes of CCP and of RF were strongly correlated at relapses in the Discordant group ($R^2 > 0.72$). There was a statistically significant association between the log transformed sCD23 as time dependent covariate and time to relapse in Cycles 2 and 3 but not in Cycle 1.

Conclusion: The findings of these studies suggest that a critical level of maturation of different autoreactive B cell clones must be reached for relapse to occur. This is largely independent of BAFF levels. Differences were also found between the response of B cell clones in Concordant and Discordant patients during depletion and also at relapse. The temporal relationship between sCD23 and relapse further supports the concept that maturation of B cells into memory phenotype is linked to relapse, but the dissociation between B cell repopulation and relapse suggests that the specificity of maturing clones is also important.

1736

Value of Predictive B Cell Markers for EULAR Response to RITUXIMAB in Patients with Rheumatoid Arthritis (FIRST). Hans-Peter Tony[1], Petra Roll[1], Henrik Mei[2], Lara Gnuegge[3], Monika Kobialko[3], Thomas Dörner[4] and FIRST study team[5]. [1]University of Würzburg, Würzburg, Germany, [2]Charite Universitätsmedizin Berlin and DRFZ,, 10117 Berlin, Germany, [3]Roche Pharma AG, 79639 Grenzach-Wyhlen, Germany, [4]Charite Universitätsmedizin Berlin and DRFZ,, Berlin,, Germany, [5]Würzburg

Background/Purpose: FIRST is an exploratory, multi-center, open label, uncontrolled phase IIIb study evaluating the efficacy of Rituximab (RTX) in RA after inadequate response to a single TNFα inhibitor (TNFi). 302 patients were treated with 1000 mg RTX on days 1 and 15 and observed up to 2 years. In a substudy, it was intended to investigate B cell markers and to identify B cell populations predictive of response at week 16.

Methods: In the substudy (n=154) rheumatoid factor (RF), RF-isotypes, peripheral CD19+ B cells and CD19+ B cell subpopulations using marker combinations of IgD, CD10, CD38, CD27 and CD20 were determined. Their impact on EULAR response rates (ER) was analysed univariately and multivariately. Stepwise forward logistic regression including the significant ($p<0.1$) B cell markers (logarithms) was used with entry and stay criterion of 10%. Odds ratios (OR) and their 95% confidence intervals [in brackets] were determined for the final model.

Results: Baseline characteristics: n=154, age [mean ± s.d.] = 54.9 ± 9.9 years, female 77.9%, RF+ 71.4%, RFIgA 103.9 ± 118.7 [IU/mL]. At week 16 112 patients (72.7%) achieved ER (good response 26.6%). DAS28 changed from initial 5.8 ± 1.0 to 4.0 ± 1.2 (week 16). About half of the patients (49.4%) showed an improvement in ACR 20, 18.8% in ACR 50 and 6.5% in ACR 70. According to predictors identified, the observed ER were: for RF+ patients 80.0%, RF- 56.1%, RFIgA+ 81.4%, RFIgA- 63.5%, for normal or above normal CD19 B cells [%] (CD19+) 75.7%, for low CD19 [%] (CD19-) 62.2%.

Multivariate analysis (MVA) yielded higher ER for RFIgA+ ($p = 0.0154$, OR=2.576 [1.198, 5.540]) and for CD19+ [%] ($p = 0.0517$, OR=2.186 [0.994, 4.807]). Observed ER were 83.9% (RFIgA+/CD19+), 73.1% (RFIgA+/CD19-), 69.0% (RFIgA-/CD19+) and 47.4% (RFIgA-/CD19-). Further MVA intending to differentiate specific B cell subpopulations yielded that ER is influenced by "double negative" CD27-IgD- B cells (27-D-) ($p=0.0174$, OR=1.989 [1.129, 3.506]). Observed ER for CD27-IgD- B cells ($\geq 5/\mu L$) were 81.8% and for low CD27-IgD- B cells ($<5/\mu L$) 62.9%. Combining RF and CD27-IgD- B cells resulted in ER for RF+ patients with 90.9% (RF+/27-D-(≥ 5) and 72.5% (RF+/27-D-(<5)). In RF negative patients the RF-/27-D-(≥ 5) group achieved 61.9% and the RF-/27-D-(<5) group 41.2% ER.

Conclusion: Among the different B cell markers in addition to RF positivity, normal or high values of B cells (CD19) and higher values of "double negative" CD27-IgD- B cells proved to be predictive of better EULAR responses to a first course of RTX+MTX. This was true among RF+ as well as among RF- patients. Particularly in RF negative patients the determination of CD19+ or "double negative" CD27-IgD- B cells may prove useful to select responding patients.

1737

B Cell Activating Factor (BAFF) Binding Receptors (BBR) on B Cells: Characterization in Patients with Rheumatoid Arthritis (RA) Receiving B Cell Depletion Therapy (BCDT) Based on Rituximab (Rtx). Elena Becerra-Fernandez[1], Inmaculada de la Torre[2], Lara Valor[2], Maria J. Leandro[1] and Geraldine Cambridge[1]. [1]UCL, London, United Kingdom, [2]Gregorio Marañón Hospital, Madrid, Spain

Background/Purpose: Two pattern of response/relapse in patients with RA after Rtx have been identified: *Concordant* between B cell return and clinical relapse *(C-R)* and *discordant* between B cells return *(D-NR)* and clinical relapse *(D-R)*. **Aim:** To investigate BBR expression in relation to B cell return after depletion and relation to clinical relapse

Methods: Phenotype analyses of BAFF-R, TACI and BCMA expression on PBMC were performed using combinations of CD19, CD27, CD38 and IgD (% and mean fluorescence intensity-MFI) in normal controls (NC) (n: 5) and patients pre (n: 11) and after Rtx, classified as C-R at B cell repopulation (n: 11), D-R > 3 months after repopulation (n: 11) or D-NR after B cell return (n: 11).

Results: BAFF-R, TACI expression in patients with RA pre and after Rtx compared to NC: Mean % of naïve and memory B cells subsets expressing BAFF-R and TACI (as well as MFI) was lower for patients with RA compared to NC. Lower BAFF-R expression on naive B cell pool for C-R patients was related to relapse closer to B cell return. Main differences between D-R or D-NR was BAFF-R expression on the post-Germinal Center (GC) B cells. **BAFFR/BCMA ratio before and after Rtx:** Inverse correlation between BAFF-R and BCMA seem to be preserved before Rtx, but after Rtx:1) D-NR patients, still inactive, presented with higher BCMA expression and lower BAFF-R on their naive B cells, 2) C-R patients, active after Rtx, in whom their naive B cells presented with lower BAFF-R expression, but normal BCMA expression. **Phenotype pattern in RA patients pre and after Rtx**: C-R patients presented with lower % of naïve mature B cells when compared to D-R or -NR patients (54.15% vs 79.13% and 79.78%, $p=0.01$ and $p=0.02$, respectively) and also with higher % of plasmablasts (15.4% vs 2.3% and 0.77%, $p=0.07$, $p=0.03$, respectively). D-NR patients showed a tendency through lower % of plasmablast when compared to pre-treatment patients (0.7% vs. 3.9%, $p=0.07$). % of post GC B cell was uniformly decreased after Rtx when compared to pre-treatment patients. However, D-NR patients showed a tendency through lower % of post GC when compared to D-R patients (0.04% vs. 1.7%, $p=0.08$).

Conclusion: Patients C-R repopulated with higher % of plasmablasts, and their naïve B cell pool presented with lower BAFF-R. Patients D at B cell return, repopulated with higher naïve B cells, and although BAFF-R could be lower in their naïve population, there is a tendency through higher BCMA. D-R patients presented with higher post GC B cells than D-NR. TACI was uniformly low after Rtx. Different preferential survival for C-R though plasmablast and antibody production may explain shorter clinical response after B cell return in those patients vs. the D ones. TACI low expression + BAFF-R/BCMA deregulation may be related to delayed acquisition of memory B cell and low Igs after Rtx.

Post hoc results for normalized quadriceps femoris muscle strength. At 3 months following total knee arthroplasty (TKA), the muscle in the involved limb was weaker than that in the uninvolved limb ($P<.001$). By 1 year, strength in the involved limb improved ($P=.016$), but this limb continued to be weaker than the uninvolved limb ($P=.015$). Compared with control subjects, subjects 3 months following TKA had a weaker muscle in the involved limb ($P=.001$) but not in the uninvolved limb ($P=.092$). At 1 year following TKA, there were no differences (involved limb, $P=.096$; uninvolved limb, $P=.408$). Abbreviations: 3 mo=3 months following TKA, 1 y=1 year following TKA, NON=noninvolved (not surgically treated) limb, OP=involved (surgically treated) limb, BMI=body mass index, MVC=maximal voluntary contraction.

No Expression of An Alternative CD20 Transcript Variant in B Cells From Patients with Rheumatoid Arthritis. Marina Deschamp[1], Béatrice Gaugler[1], Philippe Saas[1], Christophe Ferrand[1] and Eric Toussirot[2]. [1]INSERM UMR645 - IFR 133, Besançon, [2]Rheumatology and CIC Biotherapy 506 and EA 4266 Pathogens and Inflammation, Besançon, France

Background/Purpose: Targeting B cells is an effective therapy in rheumatoid arthritis (RA). Rituximab (RTX) is a chimeric monoclonal antibody directed against the membrane CD20 protein present on B cells. Predictive factors for good response to RTX therapy in RA have been identified and included the presence of rheumatoid factors and anti -CCP antibodies. Recently, a spliced mRNA transcript of CD20 (ΔCD20) has been identified in B cell lines from patients with lymphoma and leukaemia (ref). This transcript is coding for a non anchored membrane protein and its expression is associated with resistance to RTX in patients with haematological malignancies. Objectives: to determine whether ΔCD20 is expressed by circulating B cells from patients with RA and whether it could be a factor for non response to RTX therapy.

Methods: 23 RA patients (17 F, age [mean ± SEM]: 60.1 ± 2.7 years; disease duration: 13.3 ± 1.7 years, positive rheumatoid factors: 19/23; positive anti-CCP antibodies: 19/23) and 20 healthy controls (15 F, age: 59.6 ± 2.5 years) were evaluated. Patients were under DMARDs, low corticosteroids (< 10 mg/j) or anti TNFa agents but none received or had received RTX. CD20 mRNA expression study was performed using RT-PCR assay allowing first to discriminate full length CD20 (membrane CD20) from ΔCD20 transcripts. A more sensitive RT-PCR assay, using a specific primer spanning the splice fusion area was then used to detect specifically only the ΔCD20 transcript.

Results: RA patients had mild active disease (DAS28 score: 3.3 ± 0.3; CRP levels: 6.8 ± 1.9 mg/l). Number of circulating B cells per μl was not different between RA patients and controls (mean ± SEM, range: 184± 22, 18–437 *vs* 211± 27, 63–408, respectively). Among all the 23 RA samples, although full length CD20 expression was always detected, we were unable

to detect ΔCD20, even with the more sensitive RT-PCR assay permitting to identify the spliced transcript form.

Conclusion: The present study showed that, on the contrary of leukemic or lymphoma B cells, RA B-cells do not express ΔCD20, suggesting that this transcript may be a molecular marker of malignancies rather than of auto-immune diseases like RA. Study of RTX-non responders or -escaping RA patients may be relevant to know if ΔCD20 expression may be detected under the pressure of RTX therapy.

B Cell Function and Cytokine Secretion After B Cell Depletion Therapy in SLE and Rheumatoid Arthritis. Arumugam Palanichamy, James Roger, Wensheng Wang, Jennifer Barnard, Jamie Biear, Chungwen Wei, Iñaki Sanz and Jennifer H. Anolik. University of Rochester, Rochester, NY

Background/Purpose: The physiological complexity of B cell subsets and functions has been highlighted by the variable success of rituximab (anti-CD20) based B cell depletion therapy (BCDT) in multiple autoimmune diseases including systemic lupus (SLE) and rheumatoid arthritis (RA). We have previously described that a B cell reconstitution with transitional cells is associated with sustained clinical remission while a quick resurgence of memory cells portends a poor outcome. One critical question that remains to be addressed is whether the benefit of BCDT is directly mediated by the expanded transitional cells, a putative regulatory subset, or instead reflects the absence of effector B cells or a combination of both.

Methods: B cells from SLE (n=11) and RA patients (n11) were analyzed by multi-color flow cytometry at various times after BCDT or in untreated subjects. An additional 10 subjects were studied at baseline, 2 month, 4 month, and q4 months after BCD. Expression of CXCR3, CD21, CD95, and anchor markers (IgD, CD19, CD27, CD38, CD24 and live/dead/T-cell exclusions) were used to subset memory B cells. Expression of MitoTracker Green extrusion, CD10, IgM, CD23 and anchor markers were used to subset transitional B cells. Cytokine expression in distinct B cell subsets was examined by flow cytometry after 48 hours CpG stimulation (5 ug/ml) and 5 hr culture with PMA and ionomycin (both 500 ng/ml).

Results: Early after BCD (<6 month) residual B cells were detectable and consisted predominantly of memory B cell populations: switched CD27+IgD- memory, CD27-IgD- memory, and plasma cells. The residual memory B cells displayed a high fraction of CD95+ and CD21- compared to pre-depletion suggesting some resistance of these activated populations to anti-CD20. In patients who had previously received rituximab but were being re-treated because of disease relapse, memory B cells were overwhelmingly CD95+, CD21-, suggesting that disease is driven by these effector memory populations. In previously rituximab naïve patients, reconstitution occurred with a variable distribution of transitional, naïve, and memory B cells, with a memory dominant profile more common in SLE and associated with a less robust clinical response. In memory vs. transitional dominant patients, there was a significantly higher fraction of activated, effector B cell populations (CD21– 51.2+21.9 vs. 12.5+7.6%; CD24– 58.5+9.7 vs. 20.5+15.9%, CD95+ 76.9+24.4 vs. 17.6+7.2%, CXCR3+ 17.2+4.8 vs. 6.6+4.5%, $p<0.05$). In RA the predominant IL10 producing B cell populations were naïve/transitional, but the unswitched memory had the highest relative content of IL10+ cells. In untreated SLE IL10 production shifted to include more memory B cell populations, whereas the naïve/transitional compartment became the predominant IL10 producer after BCD. IL10 production in the unswitched memory compartment also increased after BCD in this group (4.7+3.3 vs. 1.2+1.1, $p=0.03$).

Conclusion: Our results support the hypothesis that the clinical and immunological outcome of BCDT depends on the relative balance of protective and pathogenic B cell subsets established after BCD and upon B cell repopulation.

Rituximab for the Treatment of IgG4-Related Disease:Lessons From Ten Consecutive Patients. Arezou Khosroshahi, Mollie Carruthers, Vikram Deshpande, Sebastian Unizony, Donald B. Bloch and John H. Stone. Massachusetts General Hospital, Boston, MA

Background/Purpose: Patients with IgG4-related disease (IgG4-RD) share histopathological features that are similar across affected organs and typically have elevated serum concentrations of IgG4. IgG4-RD patients frequently require prolonged treatment with glucocorticoids. Traditional disease-modifying antirheumatic drugs (DMARDs) are generally ineffective. We assessed the clinical and serologic responses to B lymphocyte depletion therapy in ten consecutive patients with glucocorticoid- and DMARD-refractory IgG4-RD.

Methods: Ten patients with IgG4-RD were treated with rituximab (RTX) (1000 mg times two, 15 days apart). Clinical improvement was assessed by monitoring patients' ability to taper prednisone to discontinuation and to stop DMARDs; by serial measurements of total IgG and IgG subclasses; and by follow-up radiologic assessments guided by the patients' particular patterns of organ involvement. We also applied a prototype of the IgG4-RD Disease Activity Index and Flare Tool to these cases retrospectively.

Results: The patients' organ involvement included the pancreas, biliary tree, aorta, salivary glands (submandibular and parotid), lacrimal glands, lymph nodes, thyroid gland, and retroperitoneum. Nine of the 10 patients demonstrated striking clinical improvement within one month of starting RTX. One patient with advanced thyroid fibrosis associated with Riedel's thyroiditis and a history of disease in multiple other organ systems did not have improvement in her thyroid gland but her disease did not progress to involve new organs. All ten patients discontinued prednisone and DMARDs following RTX therapy. Significant decreases in IgG concentrations were observed for the IgG4 subclass only (Figure). Four patients were re-treated with RTX after 6 months because of either symptom recurrence and increasing IgG4 concentration at the time of peripheral B cell reconstitution (n = 2) or because of physician discretion (n=2). Repeated courses of RTX maintained their effectiveness, and serial RTX courses led to steadily lower IgG4 concentrations. Serum IgG4 concentrations appeared to be a reliable surrogate of disease activity for patients in whom they were increased at baseline.

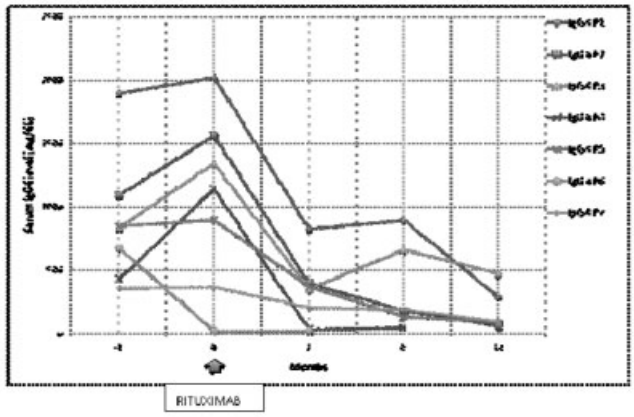

Figure. The graph is showing the serum IgG4 concentrations of 7 out of 10 patients with IgG4-RD who had elevated serum IgG4 levels at baseline 2 month prior to rituximab treatment to 12 months after treatment.

Conclusion: Treatment of IgG4-RD with RTX led to prompt clinical and serologic improvement in refractory IgG4-RD in all patients with active inflammation. Serial treatments with RTX may lead to progressive declines in serum IgG4 concentrations and better disease control. Serum IgG4 concentrations may remain low and clinical disease activity may remain quiescent even after B cell reconstitution in a significant proportion of patients.

Antibody Secreting Cells Arising After Vaccination From Anti-Cardiolipin Positive Individuals Can Produce Antibodies Which Are Bi-Specific and Bind to Both Cardiolipin and the Vaccinating Antigen. Kenneth Smith[1], Jennifer Muther[1], Angie Duke[1], Emily McKee[1], Patrick C. Wilson[2] and Judith A. James[3]. [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Chicago, Chicago, IL, [3]Oklahoma Medical Research Foundation and Oklahoma University Health Sciences Center, Oklahoma City, OK

Background/Purpose: While it is well known that certain bacterial infections may cause the presence of serum anti-cardiolipin antibodies in healthy controls, no one has previously dissected the presence of such antibodies on a 'per-antibody' basis. To this end, we have made antibodies from a serum anti-cardiolipin (aCl) positive, but otherwise healthy individual

after three separate vaccinations. These antibodies bind to the vaccinating agent as expected, however, several also bind to cardiolipin.

Methods: The OMRF Human Antibody Core Facility has developed a technology that allows us to make fully human monoclonal antibodies from any antigen currently approved as a vaccination in humans. This allows us to make large numbers of fully human full-length monoclonal antibodies which are highly specific to the vaccine antigen(s). This technology is based on the discovery of a population of B cells (ASCs), which arise 7 days after vaccination and produce antibody that is specific for the vaccine antigen. These cells can be sorted and their antibody genes cloned to express the antigen-specific antibody from each ASC.

Results: From this donor, we have characterized 49 antibodies to *Streptococcus pneumoniae* polysaccharides after vaccination with Pneumovax®23, 11 antibodies to S-OIV after vaccination with the monovalent swine flu vaccine, and 9 antibodies to VZV after vaccination with Zostavax®. Of the S. pneumoniae antibodies, two clonally related antibodies to cell wall polysaccharide, as well as an impressive clonal family of 7 antibodies to serotype 18C bind to cardiolipin (18%). Only one S-OIV antibody also binds to cardiolipin (9%), however it has a remarkable affinity of 8×10^{-9}M. Three VZV antibodies also bind to cardiolipin (33%).

All of the cardiolipin positive antibodies from this donor were also characterized using β2-GPI and qualitative ELISAs to other APS antigens (AESKU APS-Profil-GM kit). Although this donor's serum is not positive for β2-GPI antibodies, two VZV antibodies are weakly positive for β2-GPI. One of these two antibodies also showed clear binding to phosphatidylethanolamine.

Conclusion: The ability to analyze the immune response of a serum aCl positive individual on a 'per-antibody' basis indicates that it is possible in "healthy" and likely autoimmune patients for antigen specific antibodies to also bind to auto-antigen and such antibodies may arise after immune responses to a variety of immunogens.

Epratuzumab Inhibits Upstream B Cell Receptor Signaling and Modulates Ca^{2+} Flux Upon Activation. N. Sieger[1], K. Reiter[1], H.E. Mei[1], T. Shock[2], C. Daridon[1] and T. Dörner[1]. [1]Charité University Medicine Berlin, Berlin, Germany, [2]UCB, Slough, United Kingdom

Background/Purpose: CD22 is a surface molecule exclusively expressed on B lymphocytes that is involved in adhesion and B cell receptor (BCR) signaling. By recruiting a tyrosine phosphatase to its intracellular tail, it acts as an inhibitory co-receptor of the BCR via dephosphorylation of signaling molecules such as spleen tyrosine kinase (Syk). Phosphorylation of Syk is essential upon BCR engagement and is upstream of BCR-triggered Ca^{2+} flux. Epratuzumab, a humanized anti-CD22 monoclonal antibody, is currently being investigated in phase III clinical trials in systemic lupus erythematosus (SLE) patients. Although recent data show that the antibody affects B cell proliferation[1] as well as the expression of adhesion molecules and B cell migration,[2] its potential impact on intracellular signaling events has not been delineated. Therefore, the current study investigated the influence of epratuzumab on downstream kinases and BCR-induced Ca^{2+} flux in human B cells.

Methods: The *in vitro* effects of epratuzumab on BCR-induced Ca^{2+} signaling were evaluated by Ca^{2+} flux assays. Purified human B cells were pre-incubated with $F(ab')_2$-epratuzumab or medium alone for 60 min and were subsequently stimulated with anti-$F(ab')_2$ IgM and IgG. Intracellular Ca^{2+} concentrations were monitored by flow cytometry in B cells pre-loaded with Indo-1AM for a period of 10 min after activation. Additionally, the influence of epratuzumab on the phosphorylation of the BCR signaling molecules Syk and PLC-γ2 linked to Ca^{2+} flux was studied *in vitro* by flow cytometry.

Results: BCR activation induced an initial peak of Ca^{2+} flux within the first 10 s. Pre-incubation with epratuzumab moderately increased this initial peak. Notably, after the initial period, pre-incubation with epratuzumab strongly reduced Ca^{2+} flux in B cells, compared with controls treated with medium alone, which exhibited increased Ca^{2+}flux during BCR triggering over 10 min. At corresponding time points used to monitor Ca^{2+} flux, the phosphorylation status of Syk and PLC-g2 after BCR stimulation was measured. Pre-treatment with epratuzumab led to substantial reductions in the phosphorylation of Syk and PLC-g2 8 min after BCR stimulation, compared with controls. These differences in Syk and PLC-g2 were not found during the initial Ca^{2+}-peak at 10 s or after 1 min, consistent with the notion that they were not yet fully activated. Notably, effects on the phosphorylation of Syk and PLC-g2 were observed in $CD27^-$ naive and $CD27^+$ memory B cells.

Conclusion: These data indicate that epratuzumab exerts inhibitory effects on BCR signaling by reducing Ca^{2+} flux and Syk and PLC-g2 phosphorylation after BCR engagement. They are therefore consistent with the concept that targeting CD22 may reduce the characteristic B cell hyper-reactivity in SLE.

PTPN22 Risk Allele Interferes with the Removal of Developing Autoreactive B Cells in Humans. David Saadoun[1], Laurence Menard[2], Isabelle Isnardi[2], Yen-shing Ng[3], Greta Meyers[2], Clara Abraham[4], Roja Moyaghedi[5], Jane Buckner[6], Peter K. Gregersen[7] and Eric Meffre[8]. [1]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France, [2]Department of Immunobiology, Yale University School of Medicine, New Haven, CT 06511, USA;, New haven, [3]Department of Immunobiology, Yale University School of Medicine, New Haven, CT 06511, USA;, New Haven, [4]Department of Medicine, Section of Digestive Diseases, Yale University School of Medicine, New Haven, CT 06509, USA,, New Haven, [5]Department of Pediatrics, Weill Medical College of Cornell University, New York, NY 10021, USA,, New York, [6]Translational Research Program, Benaroya Research Institute, Seattle, WA 98101, USA,, Seattle, [7]Feinstein Institute Medical Reschearch, Manhasset, NY, [8]Yale University School of Medicine, New Haven, CT

Background/Purpose: Protein tyrosine phosphatase nonreceptor type 22 (*PTPN22*) gene polymorphisms associate with many autoimmune diseases; the major risk allele encodes an R620W amino acid change that alters B cell receptor (BCR) signaling involved in the regulation of central B cell tolerance.

Methods: To assess whether the *PTPN22* riskallele affects the removal of developing autoreactive B cells, we tested by ELISA the reactivity of recombinant antibodies isolated from single B cells from asymptomatic healthy individuals carrying one or two *PTPN22* risk allele(s).

Results: We found that new emigrant/transitional and mature naive B cells from *PTPN22* risk allele carriers contained high frequencies of autoreactive clones compared to non-carrier donors, revealing defective central and peripheral B cell tolerance checkpoints. Hence, a single *PTPN22* risk allele has a dominant effect on altering autoreactive B cell counterselection before any onset of autoimmunity. In addition, gene array experiments analyzing mature naïve B cells displaying *PTPN22* risk allele(s) revealed that the association strength of *PTPN22* for autoimmunity may not only be due to the impaired removal of autoreactive B cells but also to the upregulation of genes such as *CD40, TRAF1* and *IRF5*, which promote B cell activation and have been identified as susceptibility genes associated with autoimmune diseases.

Conclusion: We demonstrated that the *PTPN22* risk allele interferes with the removal of developing autoreactive B cells and allows the accumulation of large numbers of self-reactive mature naïve B cells in the periphery.

1744

Syk Inhibition with Fostamatinib Leads to Transitional B Lymphocyte Depletion. Chungwen Wei, Paul M. Barr, Julia Schaefer-Cutillo, John Jung, James Roger, Jennifer L. Kelly, Alex Rosenberg, Jonathan W. Friedberg and Iñaki Sanz. University of Rochester, Rochester, NY

Background/Purpose: The protein tyrosine kinase syk (spleen tyrosine kinase) is a critical component of B cell receptor (BCR) signaling, and plays an important role in both the maturation and survival of the B cell lineage. Syk deficient murine models demonstrate a developmental block at the transitional B cell stage and an absence of B cells in peripheral lymphoid organs. Promising results have been generated using an orally administered small molecule inhibitor of syk, fostamatinib, in the treatment of lymphoid malignancies as well as autoimmune diseases such as rheumatoid arthritis and immune thrombocytopenic purpura. However, the mechanism of action of syk inhibition in alleviating the symptoms of autoimmune diseases and its effects on B cell homeostasis remains to be elucidated.

Methods: Patients were obtained from a prospective phase 1/2 clinical trial with support from Rigel Pharmaceuticals, and blood samples were collected at baseline, 1 month and 2 months after treatment with fostamatinib. PBMCs from eleven patients, all with relapsed or refractory B-cell lymphoid malignancies [7 diffuse large B cell lymphoma (DLBCL), 2 follicular lymphoma (FL), 2 mantle cell lymphoma (MCL)], were analyzed by

multi-color flow cytometry. Mitotracker Green extrusion and the staining of CD19, IgD, CD27, CD38, CD24 as well as CD3/live/dead exclusion allow the identification of B cell subsets defined by the expression of IgD and CD27 and the fine discrimination of naïve and transitional B cells. P-values were calculated using the non-parametric Wilcoxon signed rank test for paired samples. To account for the 8 independent hypotheses tested, a Bonferroni adjusted threshold was used for statistical significance ($p<0.006$).

Results: In these patients, $CD19^+$ B cells remained unaffected after 2 months of treatment with fostamatinib. In addition, the fractions of the four core subsets defined by IgD/CD27 within the B cell population remained relatively stable. However, the early transitional (T1/T2) cells were rapidly depleted within the first month of treatment ($p=0.0029$) and continued to decline over the second month ($p=0.0039$). There was also a significant but lesser magnitude decrease in the late transitional (T3) cells at 2 months ($p=0.02$), with a concomitant increase in the naïve population ($p=0.0059$). The decrease in the T1/T2 population was also observed when absolute cell counts for the B cell subsets were calculated ($p=0.0039$). No association was identified between infections or clinical responses and the degree of transitional B cell depletion.

Conclusion: We demonstrate that short-term use of fostamatinib impairs B lymphocyte development at the transitional B cell stage without affecting mature B cell populations. These results provide mechanistic insights of action of syk inhibition in autoimmune diseases. Further, it suggests that prolonged administration may impair development of mature B cells and ultimately functioning of the humoral immune system. As development of syk inhibitors and other agents targeting molecules downstream of the B cell receptor proceeds, careful monitoring for infectious complications is warranted.

1745

Carbamoylation of Vimentin in Patients with Rheumatoid Arthritis: Identification of a Novel Protein Modification with a Possible Link to Disease Pathogenesis. Holger Bang[1], Karl Egerer[2], Anette Krämer[1], Eugen Feist[2] and Gerd R. Burmester[2]. [1]Orgentec Diagnostika GmbH, Mainz, Germany, [2]Charité - Universitätsmedizin Berlin, Berlin, Germany

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is believed to result from a multistep process, in which - based on a particular genetic background—environmental triggers initiate or modify specific immune reactions including anti-citrullinated peptide/protein antibodies (ACPA) generation. Especially, smoking has been identified as an important environmental factor potentially leading to protein modification resulting in an autoimmune response in the setting of a disturbed immune system. The aim of the current study was to investigate the possible role of a newly identified modification process, the carbamoylation of vimentin, in causing autoantibody production and immune responses in patients and animal models.

Methods: Human vimentin was carbamoylated and/or citrullinated by non-enzymatic and enzymatic posttranslational modifications. Corresponding ELISA assays were established and sera from human healthy individuals, RA patients in different stages of disease and with different DMARD treatments and disease controls (systemic autoimmune diseases such as SLE and Sjören′ syndrome) were analyzed. Rabbits were immunized with carbamoylated vimentin and mutated citrullinated vimentin (MCV), and antisera were tested for binding to cyclic citrullinated peptides (CCP), vimentin and its modified analogs. Induction of rheumatoid factor in treated animals was characterized as well. Cell models were used to identify pathways for induction of modified vimentin under inflammatory conditions.

Results: Carbamoylated vimentin (carbVim) shows a > 90% homocitrulline content in double mass spectrometry and sequencing analysis. Rabbits immunized with carbVim produced high affinity antibodies against carbVim and, to a lesser extent, against MCV. These antisera also bound human IgG and to a low extent immunoglobulin from other animal species. In 110 RA patients, sensitivities of 86,8 % and 69,2 % were calculated for the anti-MCV and anti-carbVim assays, respectively. Sera from healthy persons and disease control groups showed a comparable specificity for both assays (anti-MCV 97% and anti-carbVim 91%) and none had anti-vimentin abs. A significant correlation of ACPA positivity lacking rheumatoid factor with presence of anti-carbVim abs was documented in early RA patients (91 %). In cell models, modified vimentin was generated among inflammatory (TNF or IFN) or environment stress (hydrogen peroxide) conditions and cross react with abs from RA-patients or immunized animals.

Conclusion: Environmental triggers such as smoking together with inflammatory conditions involving destructive enzymes may result in carbamoylation of vimentin with a possible impact on its function as stress fiber, cell homing or adhesion protein. Anti-homocitrulline responses develop in the early stages of RA, where carbamoylated vimentin represents a major target of autoantibodies in RA patients. These results also suggest a critical reevaluation of the polyclonal immune response of RA patients, so far described as exclusively citrulline specific and may provide diagnostic options for the early detection of patients even before clinical onset of RA.

1746

Early Rheumatoid Arthritis (ERA) Has Lower Levels of Plasmablasts and Memory B Cells Compared to Long-Standing Rheumatoid Arthritis (LSRA) and Responds to Conventional Therapy with a Normalization of B Cell Subsets Abnormalities. Anna Laura Fedele, Barbara Tolusso, Silvia L. Bosello, Silvia Canestri, Elisa Gremese and Gianfranco Ferraccioli. Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy

Background/Purpose: B cells have been shown to be important players in RA chronicity and B cell depletion has been shown to be effective in RF seropositive patients. The aim of the study was to evaluate B cells subpopulations distribution in ERA and LSRA patients and their possible association with clinical or immunological data at baseline or with response to conventional therapy (ERA).

Methods: 53 ERA (88.7% females; mean age 53.2±15.1 years; 62% anti-CCP positive) and 49 LSRA, along with 30 healthy controls were studied. Baseline clinical and immunological characteristics and inflammatory status were assessed. Peripheral blood samples were analyzed by flow cytometry for the distribution of circulating B cell subsets by staining with surface markers CD19, CD45, CD38, CD27 and IgD and intracellular marker ZAP70. Plasma levels of IL-6 and BAFF were also determined with ELISAs. 22 ERA patients were followed for 6 months: they were treated with MTX (n=14) and MTX + TNF blockers (n=8).

Results: ERA patients showed an higher percentage of Bm2+Bm2' cells (48.8±20.9%) compared to LSRA patients (33.8±17.8%, *p=0.001*) and a lower percentage of eBm5 (10.0±7.3%) compared to LSRA (14.1±8.6%, *p=0.004*) and controls (16.0±7.1%, *p<0.001*). The percentage of CD19+/IgD-CD27- cells (7.5±4.8%) and CD19+/CD38+CD27+ cells (3.0±4.4%) was lower in ERA compared to LRSA (13.7±7.8%, *p<0.001*; 8.2±5.2%, *p<0.001*, respectively) and controls (16.2±9.1%, *p<0.001*; 8.0±3.5%, *p<0.001*, respectively). The percentage of CD19+/ZAP70+ cells (6.0±7.1%) was higher in ERA patients compared with controls (2.2±1.4%, *p=0.01*), while no difference was seen between ERA and LSRA. There were no differences in the distribution of B cell subpopulations between patients RF and anti-CCP positive and negative. ERA patients with baseline high DAS (>3.7) showed an higher percentage of CD19+/CD27+CD38+ cells compared to subjects with moderate DAS (*p=0.01*). The percentage of CD19+/ZAP70+ cells was higher in ERA patients with baseline plasma levels of BAFF>780 pg/ml (mean±2 SD of controls) (8.0±8.5%) compared to patients with levels of BAFF <780 pg/ml (3.0±2.3%, *p=0.08*). Plasma levels of BAFF correlated positively with percentage of CD19+/ZAP70+ cells (r=0.41, *p=0.002*) and of CD19+/IgD-CD27- cells (r=0.26, *p=0.05*). In ERA patients followed for 6 months, we observed DAS falling from 3.4 to 1.6 (*p<0.001*), an increased percentage of Bm1 cells (T0=21.4±17.8% vs T6=32.5±19.2%, *p=0.005*) and a fall in the percentage of eBm5 (T0=9.9±3.8% vs T6=6.5±4.7%, *p=0.01*) and of CD19+/ZAP70+ cells (T0=6.7±5.6% vs T6=3.8±3.1%, *p=0.02*), irrespectively of the type of therapy administered.

Conclusion: ERA differs from LSRA for higher levels of naive preswitch B cells, lower levels of memory B cells and plasmablasts. After six months of conventional treatment, a fall of memory B cells and ZAP70+ B cells and an increase of naïve B cells were observed. These results suggest that changing the inflammatory milieu in the early phases of the disease, leads to substantial changes in B cell subsets. Further studies are needed to define the molecular events linked to these effects. Early RA represents the best opportunity to normalize the immunological setting.

1747

Identification of Autoantibody Profiles by Monitoring Autoantibody Biomarkers in Rheumatoid Arthritis with Microarray Surface Plasmon Resonance Imaging. Joyce J.B.C. Van Beers[1], Angelique M.C. Segbers-Lokate[1], Wilma T.M. Vree Egberts[1], Richard B.M. Schasfoort[2] and Ger J.M. Pruijn[1]. [1]Radboud University Nijmegen, Nijmegen, Netherlands, [2]University of Twente and IBIS Technologies BV, Enschede, Netherlands

Background/Purpose: Autoantibodies against citrullinated proteins (ACPA) are specifically found in approximately 75% of rheumatoid arthritis (RA) patients. Citrullination is the post-translational conversion

of peptidylarginine into peptidylcitrulline, which is catalyzed by peptidylarginine deiminase (PAD) in a calcium-dependent manner. Several citrullinated antigens have been identified in the inflamed joints of RA patients. These include fibrinogen, alpha-enolase, vimentin and collagen type II. Accumulating evidence suggests a role of citrullinated proteins and ACPA in the pathophysiology of RA. The results of many studies indicate that the ACPA response is highly heterogeneous with diverse patterns of reactivity to distinct citrullinated epitopes. This study aimed to identify clinically meaningful ACPA profiles in RA patients using a microarray containing different citrullinated peptides in combination with surface plasmon resonance imaging (*i*SPR).

Methods: Several pairs of synthetic peptides (citrullinated and the corresponding non-citrullinated control) derived from known ACPA targets (e.g. fibrinogen, alpha-enolase, vimentin) as well as peptides isolated from synthetic citrullinated peptide libraries were used to generate ACPA target arrays. ACPA in RA patient sera were monitored by *i*SPR, which allows the simultaneous detection of autoantibody-peptide interactions in real-time. The present study was started using a 24-spot microarray and currently peptides are spotted using a continuous flow microspotter resulting in a 48-spot microarray.

Results: Using the 24-spot microarray, a total of 94 RA and 46 control sera were analyzed. The results confirmed the heterogeneous nature of ACPA in RA sera. RA patients displayed different patterns of co-occurrence of autoantibodies directed to distinct citrullinated peptides. The recognition of one peptide was very specific for RA and was observed in 62% of the anti-CCP2 positive RA patients. No reactivity was observed in the anti-CCP2 negative patients and a weak reactivity (2%) was observed in control patients. Another peptide showed reactivity in 68% of the RA patients, both anti-CCP2 positive (74%) as anti-CCP2 negative (54%) patients, whereas patients with other autoimmune diseases showed far less reactivity (13%).The median number of citrullinated peptides recognized by anti-CCP2 positive RA patients (4) was significantly higher than that of anti-CCP2 negative RA patients (1) and disease controls (1). The use of continuous flow microspotting instead of non-contact spotting is being optimized to increase the array size and to improve the quality and reproducibility of the microarrays.

Conclusion: Using microarray-iSPR we have shown that RA sera recognize various citrullinated peptides more frequently than other autoimmune disease sera. Sera from different RA patients frequently recognize different citrullinated peptides. Our data are consistent with the existence of different ACPA profiles that may have diagnostic and/or prognostic value. Microarray-*i*SPR represents a suitable system for multiplex autoantibody monitoring and allows the identification ACPA profiles.

Development of a High-Throughput, Multiplex Assay for Profiling the Autoantibody Fine Specificity in Rheumatoid Arthritis. Xiaoyan Zhao[1], P. Scott Eastman[1], Ferhan Qureshi[1], William C. Manning[1], William Robinson[2] and Lyndal K. Hesterberg[1]. [1]Crescendo Bioscience, Inc., South San Francisco, CA, [2]Stanford Univ School of Med, Stanford, CA

Background/Purpose: Rheumatoid Arthritis (RA) is an aggressive autoimmune disease that progressively destroys affected joints with frequent systemic complications. Production of autoantibodies, especially those against citrullinated proteins and peptides, is a hallmark of RA. The causal relationship between the development of autoantibodies and radiographic joint damage to this point remains unclear. To better understand this relationship, we developed autoantibody assays in a multiplex format against a panel of common and novel RA epitopes and applied the assays for profiling the fine specificity of these autoantibodies in RA.

Methods: Individual serum samples from 35 RA patients with different disease activities were evaluated for the presence of autoantibodies. Anti-cyclic citrullinated peptide (CCP) reactivity and rheumatoid factor (RF) status were assessed with commercial kits from Euro Diagnostica (CCP 2) and TheraTest Labs (RF). The reactivity of a panel of peptides derived from multiple proteins including both well known and novel antigens was also evaluated. Nine peptides were printed in a 3×3 grid on the bottom of a 96-well plate (Quansys Bioscience) and probed with RA patient samples. HRP-conjugated secondary antibody against human IgG, IgM or IgA was used to measure autoantibodies to specific peptides in a chemiluminescent format.

Results: The levels of anti-CCP antibodies ranged from >5,000 to below the cutoff (<25 arbitrary units) for CCP and from ~600 to 3 units for RF-IgA, suggesting a range of disease. Not surprisingly, levels of autoantibodies, when detected by anti-human IgG, reflected anti-CCP levels, predominantly to citrullinated fibrinogen and citrullinated filaggrin peptides. However, a wide range of anti-IgM/A responses were observed regardless of whether anti-CCP levels were high, intermediate or low. Interestingly, when anti-human IgA or IgM was used as detection, CCP negative and low CCP RA subjects frequently demonstrated strong positive reactivity to epitopes derived from citrullinated apoliporotein, citrullinated biglycan, native histone and/or native fibromodulin. While several of the IgM/A peptide reactivities overlapped with the IgG, in many instances the IgM and/or the IgA profiles demonstrated unique response patterns.

Conclusion: A high-throughput, multiplex assay has been developed to investigate the fine specificity of autoantibody reactivity against a broad variety of RA antigens including both citrullinated and native peptides. While anti-human IgG profiles reflected CCP levels, diverse levels of response were observed with anti-IgM and/or anti-IgA, including at low and intermediate CCP levels. Most studies to date have employed the CCP 2 assay, which uses a mixture of peptides, with mixed results. We observed that profiles of individual peptides may be different with different immunoglobulin isotypes. Thus evaluation of individual peptides in the context of immunoglobulin subtypes may provide insight into disease progression.

Anti-hnRNP Autoantibodies Detected in Inflammatory Rheumatic Diseases in Use to Close the Sensitivity gap left by Rheumatoid Factor and Anti CCP in Early Rheumatoid Arthritis. Bianka Marklein[1], Zoltan Konthur[2], Gerd-Rüdiger Burmester[3] and Karl Skriner[1]. [1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Max Planck Institute for Molecular Genetics, Berlin, Germany, [3]Charité - University Medicine Berlin, Berlin, Germany

Background/Purpose: Autoantigens are produced in bacteria ex-pressed purified using His-tag and Cm-sepharose under native and denaturated conditions. Bacterially expressed recombinant hnRNPs proteins were used in Elisa for confirming the data obtained by macroarray and immunoblotting. Anti-hnRNP-A/B and hnRNP D proteins were detected in a newly developed Elisa with patient sera and sera from animal model of SLE and RA

Methods: Autoantigens are produced in bacteria ex-pressed purified using His-tag and Cm-sepharose under native and denaturated conditions. Bacterially expressed recombinant hnRNPs proteins were used in Elisa for confirming the data obtained by macroarray and immunoblotting. Anti-hnRNP-A/B and hnRNP D proteins were detected in a newly developed Elisa with patient sera and sera from animal model of SLE and RA.

Results: Using a combination of three hnRNPs A2/D/DL, 76% of RA, 84% of SLE sera and 87% SKG mice which spontaneously develop chronic autoimmune arthritis, can be detected. Moreover hnRNP A2/A3/D/DL identified epitopes as well as identified citrullinated peptides (deduced citrullinated peptides thereof) were used to identify patterns associated with disease severity. No crossreactivity could be detected between the affinity purified anti-hnRNPDL and the highly related hnRNPD. A unique sequenz only found in hnRNP DL between aminoacid 81–120 was identified as indistinguishable for autoantibody binding. With citrullinated peptides out of a mutated form of hnRNPA3 and hnRNPA2/D/DL, 94 % out of 130 early RA sera can be identified but only in <10% of osteoarthritis and healthy control patients. With a combination of citrullinated forms of three hnRNPs (A2, D, DL) 98 % of the sera were tested positive in a cohort of 92 early RA patients (<12month). The hnRNP auoantibody response is dependent on Mod88, Tir8 and both TLR 7 and TLR9 costimulation tested with sera from TLR7, TLR9 deficient and double-deficient mice with an MRL-lpr/lpr background.

Conclusion: The hnRNP antibody response is Myd88, Toll 7 and 9 dependent generated. A combination of hnRNPs (A3/A2/DL/D) can be used to predict disease severity and partially close the sensitivity gap left by rheumatoid factor and anti CCP antibodies in early RA patients.

Substantial Influence of Rheumatoid Factor Positivity On the Peripheral Memory B Cells and Its Modulation by TNF Inhibition In Rheumatoid Arthritis. Petra Roll[1], Khalid Muhammad[1], Mathias Schumann[1], Stefan Kleinert[2] and Hans-Peter Tony[1]. [1]University of Würzburg, Würzburg, Germany, [2]Rheumatology, University of Würzburg, Würzburg, Germany

Background/Purpose: The role of B cells has been appreciated with the advent of B cell targeted therapies in patients with rheumatoid arthritis. However, alterations of peripheral B cell subsets have been described also under TNF inhibition. In this study, we focused on the influence of

rheumatoid factor positivity on the anti-TNF induced modulation of the peripheral B cell compartment.

Methods: Twenty six RA patients with inadequate response to methotrexate were included in a prospective study of weekly etanercept treatment. Immunphenotyping was performed at baseline, week 12 and 24.

Results: At baseline, rheumatoid factor (RF) negative patients had a significant higher percentage of overall CD27+ memory B cells compared to healthy controls (n=21) and RF positive patients. In detail, RF negative patients had 68.9% (25.6–86.6%) CD27+ B cells vs. 31.3% (12.9–56.9%, p=0.01) in HC and 28.8% (19–73.3%, p=0.02) in RF positive patients respectively. Within the CD27+ B cells compartment particularly pre-switch (CD27+/IgD+) memory B cells were significantly increased to 29.8% (15.8–51.1%) in RF negative patients compared to 14.9% (4.1–27.3%, p=0.0012) in HC and 10.4% (6–25.2%, p=0.001) in RF positive patients, respectively. Interestingly, relative and absolute numbers of CD27+ memory B cells increased significantly during anti-TNF therapy only in RF negative patients. Relative numbers increased from 68.9% (25.6–86.6%) to 73% (31.3–75.8%) at week 24 (p=0.03). Absolute numbers of CD27+ memory B cells showed a significant increase from baseline 49.3/μl (31.5–125.1/μl) to 77.1/μl (63.6–174.3/μl) at week 24 (p=0.01).

Conclusion: Peripheral accumulation of memory B cells, particularly pre-switch memory B cells, was observed in RF negative patients. Anti-TNF therapy leads significantly to increased memory B cells only in RF negative patients suggesting the peripheral memory B cell compartment being more amenable to TNF inhibition in these patients.

Dynamic Evolution of a Public Clonotypic Autoantibody Specific for Ro60: Perpetuating Humoral Autoimmunity Through Clonotypic Shift. Rhianna Lindop[1], Georgia Arentz[1], Tim, K. Chataway[2], Lauren A. Thurgood[1], Michael W. Jackson[1] and Tom P. Gordon[1]. [1]Flinders Medical Centre and Flinders University, Adelaide, Australia, [2]Flinders University, Adelaide, Australia

Background/Purpose: We have recently discovered a public Ro60-reactive clonotypic autoantibody specified by a unique V_H3–23/V_K3–20 chain pairing, by using positive epitope selection of human sera with anti-Ro/La responses and *de novo* sequencing of the purified autoantibody proteome (Lindop et al, Arthritis Rheum, in press). In the present longitudinal study, we use this unique clonotypic signature to trace the evolution of humoral autoimmunity directed against a member of the ENA family in human systemic autoimmunity.

Methods: Clonotypic V_H3–23/V_K3–20 IgGs specific for the immunodominant Ro60peg determinant (amino acids 193–236) were purified by epitope-specific affinity chromatography from serial serum samples of 5 patients with primary Sjögren's syndrome (ranges from 1 to 10 years apart). Direct variable (V)-region sequencing of heavy and light chains was performed by high-resolution *de novo* orbitrap mass spectrometric sequencing. Relative anti-Ro60peg binding affinities were compared by the KCSN elution method.

Results: Patient sera tested at each time point expressed a dominant Ro60peg-specific monoclonal IgG1 kappa species with a characteristic V_H3–23/V_K3–20 gene rearrangement signature, consistent with a common clonal origin for each patient. However, near full-length protein sequencing of serial samples from individual patients revealed that each clonotypic autoantibody, irrespective of the duration of disease, was subtly different from its predecessor, being specified by a unique pattern of somatic V-region mutations. Relative affinities of anti-Ro60peg clonotypic autoantibody variants were remarkably constant over years and even decades in the face of ongoing clonotypic shift, explained by preservation of key amino acid replacement mutations in the CDR regions critical for antibody binding.

Conclusion: Analysis of the autoantibody proteome has demonstrated for the first time a dynamic process of clonal evolution in systemic humoral autoimmunity, characterised by serial replacement of existing clonotypes with somatically mutated variants that presumably have a survival advantage over their predecessors. The selection pressures driving this process are not based solely on affinity for the autoepitope since the response reaches an affinity ceiling early in disease. The perpetual clonotypic shifts allow this secreted autoantibody to keep one step ahead of B-cell tolerogenic censuring mechanisms, resulting in life-long production of potentially pathogenic anti-Ro60 autoantibodies in patients with lupus and primary Sjögren's syndrome.

APRIL and BAFF Levels After Rituximab Treatment in Patients with Primary Sjögren's Syndrome: A Placebo-Controlled Clinical Trial. Rodney Pollard, Wayel H. Abdulahad, Minke G. Huitema, Annie Visser, Jiska Meijer, Hans Burgerhof, Fred Spijkervet, Cees GM Kallenberg, Arjan Vissink, Frans Kroese and Hendrika Bootsma. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by infiltrates of B- and T-cells in salivary and lacrimal glands, eventually leading to destruction of these glands. B-cell activating factor (BAFF) and proliferation-inducing ligand (APRIL), members of the tumor necrosis factor (TNF)-ligand family, are essential for development, maturation and survival of B-cells. To assess the effect of rituximab (anti-CD20) treatment on BAFF and APRIL levels in patients with pSS

Methods: In a randomised double-blinded placebo-controlled trial, pSS patients were treated on day 1 and 15 with either rituximab (n= 20) or placebo (n= 10). To minimise side effects (infusion reactions, serum sickness), all patients were pre-medicated with methylprednisolone and oral prednisone. Fresh blood samples were collected at various time points (before, 5, 12, 36 and 48 weeks following treatment). Age- and sex-matched blood samples were collected from healthy controls (n=10). In addition, paired incisional parotid biopsies were taken in 10 patients (5 rituximab, 5 placebo) before and 12 weeks after rituximab/placebo treatment. Percentages and numbers of B cell subsets were examined by four-color cytometry. BAFF and APRIL levels were assessed by enzyme-linked immunosorbent assay. BAFF expression in salivary glands was revealed by immunohistochemistry of parotid gland sections.

Results: Complete depletion of B-cells in serum was observed in the rituximab treated group, while B-cell levels remained unchanged after placebo treatment. B-cells reappeared in the rituximab treated group within 24 to 48 weeks after treatment. At baseline, both BAFF and APRIL serum levels were significantly ($p<0.01$) increased in pSS-patients in comparison to healthy controls. Strikingly, long-term elevated serum levels of BAFF (3.0–4.0 fold, $p<0.05$) were observed up to 36 weeks following rituximab treatment followed by a complete return to baseline levels by week 48. In contrast, BAFF serum levels were almost unchanged in the placebo group, except for a slight (0.5 fold, $p<0.05$) increase in BAFF levels at week 5 after treatment, likely due to methylprednisolone administration. APRIL levels in serum were hardly affected by the rituximab treatment, although there was a slight increase (0.25 fold, $p<0.05$) at 12 weeks after treatment, followed by a rapid return to baseline levels. Furthermore, at least 3 out of 5 pSS showed an increase in BAFF expression in parotid glands after rituximab treatment at tissue level.

Conclusion: These data show that both BAFF and APRIL levels are increased in serum of pSS patients, indicating that both cytokines could be involved in the pathogenesis of pSS, possibly by triggering the activation and differentiation of self-antigen-driven autoimmune B-cells. Importantly, we also demonstrate that there is a significant increase of BAFF in blood and salivary glands after rituximab therapy, whereas APRIL levels are almost unaffected by the treatment and remain elevated during the entire study period. This observation might be important for treatment strategies with biologicals affecting BAFF, T-cell co-stimulation and/or B-cell depletion. Extended data are in progress and will be presented at the ACR meeting.

1753

Expansion of Functionally Anergic Autoreactive CD21$^{-/Low}$ Marginal Zone B Cell Clones in Hepatitis C Virus Infection-Related Autoimmunity. Benjamin Terrier[1], Florence Joly[2], Philippe Benech[2], Michelle Rosenzwajg[3], Wassila Carpentier[4], Pascale Ghillani-Dalbin[5], David Klatzmann[3], Patrice Cacoub[5] and David Saadoun[6]. [1]Pitié-Salpêtrière Hospital, Paris, France, [2]Prediguard, Marseille, France, [3]Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Paris, France, [4]Plateforme génomique P3S, Paris, France, [5]CHU Pitié-Salpêtrière, Paris, France, [6]Department of Internal Medicine and Laboratory I3 "Immunology, Immunopathology, Immunotherapy", UMR CNRS 7211, INSERM U959, Groupe Hospitalier Pitié-Salpetrière, Université Pierre et Marie Curie, Paris 6, Paris, France, Paris, France

Background/Purpose: Homeostasis of peripheral B cell subsets is disturbed during chronic hepatitis C virus (HCV) infection, leading to the

occurrence of autoimmunity and B-cell lymphoproliferation. However, mechanisms by which HCV causes lymphoproliferation remain controversial.

Methods: 38 patients with HCV-related mixed cryoglobulinemia vasculitis (MC) and 35 patients with HCV infection without MC, before the initiation of therapy, and 20 healthy donors (HD) were included in the present study. Phenotypic analysis of B cells from peripheral blood using flow cytometry and sequencing and repertoire analysis using single-cell analysis were performed. Functional analysis of B cells, assessing B cell activation, calcium flux, proliferation and survival, was performed. Microarray gene expression profile analysis of clonal B cells compared to conventional B cells was performed on Illumina whole human genome chips.

Results: We report on significant elevated proportion of clonal $CD21^{-/low}$ marginal zone (MZ) B cells in the peripheral blood of HCV patients that correlates with the presence of autoimmunity and lymphoproliferation (24.3% in HCV-MC patients vs. 5.4% in HCV patients vs. 1.8% in HD; $p<0,0001$ each). We found an increase use in autoreactive BCRs using V_H1–69 and V_H4–34 genes in $CD21^{-/low}$ MZ B cells. $CD21^{-/low}$ MZ B cells showed impaired calcium-mediated signaling, did not up-regulate activation markers, and did not proliferate in response to B-cell receptor triggering using F(ab′)2 anti-IgM. $CD21^{-/low}$ MZ B cells were also prone to dye faster than their $CD21^{+}$ counterparts, suggesting that these autoreactive B cells were anergic. $CD21^{-/low}$ MZ B cells, in contrast, remained responsive to TLR9 stimulation. Gene array analyses comparing $CD21^{-/low}$ MZ B cells and conventional $CD21^{+}$ MZ B cells revealed the critical role of EGR2 and Cbl-b in the induction of anergy.

Conclusion: HCV infected patients who display high frequencies of autoreactive and unresponsive $CD21^{-/low}$ MZ B cells are more susceptible to develop autoimmunity and/or lymphoproliferation. These cells remain in peripheral blood controlled by functional anergy instead of being eliminated. Chronic antigenic stimulation through TLR stimulation may create a favorable environment for breaking tolerance and activating these cells in order to produce cryoglobulinemia and cause vasculitis and/or lymphoma.

1754

The Sympathetic Neurotransmitter Norepinephrine Inhibits Proinflammatory IL-7-Receptor Alpha Positive B Cells in Arthritis. Georg Pongratz, Judith Anthofer, Madlen Melzer and Rainer H. Straub. University Hospital Regensburg, Regensburg, Germany

Background/Purpose: Recent data show higher concentrations of IL-7 in synovial fluid of patients with rheumatoid arthritis (RA) as compared to osteoarthritis (OA). Among other cells in the inflamed synovium, IL-7 receptor (IL-7R) is expressed on synovial B cells but the role of these cells in arthritis is unclear.

Methods: Collagen type II induced arthritis (CIA) in DBA1 mice. ELISA to determine specific anti-CII antibodies. Isolation of naïve splenic B cells and in vitro culture. FACS analysis to determine IL-7R+ cells and intracellular pSTAT5. Immunohistochemistry to show pSTAT5+ and IL-7R+ B cells in RA and OA synovial tissue.

Results: Activation of naïve splenic murine B cells with CD40L and IL-4 in vitro increases IL-7R expression. To determine the role of IL-7R+ B cells in arthritis we treated arthritic mice with B cells that have been activated and stimulated with IL-7. Mice treated with IL-7 stimulated B cells developed more severe arthritis than controls. We also show that human RA and OA tissue contains IL-7R+ and pSTAT5+ B cells in synovial tissue. We know from former experiments that norepinephrine treated B cells show anti-inflammatory potential in arthritis. Therefore, B cells were activated in the presence of norepinehphrine and then stimulated with IL-7. Treatment of mice with these B cells did not show different severity of arthritis as compared to controls. As possible explanation for this observation we show that proper IL-7R signaling via STAT5 is inhibited in B cells pretreated with norepinephrine.

Conclusion: Taken together, these data indicate that IL7R+ B cells have a proinflammatory role in arthritis, which can be inhibited by the sympathetic neurotransmitter norepinephrine via inhibition of IL-7R signaling.

1755

Arthritogenic T Cells Regulate the Homeostatic Expansion of Antigen-Specific B Cells, and These B Cells or Antibodies Are Essential for the Development of Arthritis. Katalin Kis-Toth[1], Marianna Radacs[2], Tamas Kobezda[3], Willem van Eden[4], Katalin Mikecz[3] and Tibor T. Glant[3]. [1]Boston, MA, [2]Szegedi Tudomany Egyetem: JGYPK, Szeged, Hungary, [3]Rush University Medical Center, Chicago, IL, [4]Utrecht,, Netherlands

Background/Purpose: The original goals of this study were to prove whether the arthritogenic epitope-specific T cell receptor transgenic (TCR-Tg) $CD4^{+}$ T cell can transfer arthritis, and if so, what other 'costimulatory' components (e.g., B cells or antibodies) can contribute to an earlier onset or more severe arthritis. Unexpectedly, these highly specific arthritogenic TCR-Tg $CD4^{+}$ T cells were unable to transfer the disease alone, but supported the reconstitution of arthritogenic proteoglycan (PG)-specific B cell homeostasis, which appeared to be critical for arthritis induction.

Methods: PG (arthritogenic epitope)-specific TCR-Tg mice were generated earlier and their basic functions tested both *in vitro* and *in vivo*. $CD4^{+}$ T cells were separated from spleen of wild-type (WT) and TCR-Tg BALB/c (arthritic or non-arthritic) mice using the Pan T Cell Isolation Kit and B Cell Isolation Kit for negative selection. The purity and viability of $CD3^{+}/CD4^{+}$ T cells and $CD19^{+}/B220^{+}$ B cells were at least 98%. $CD4^{+}$ T cells (5×10^{6} cells in 200 μl PBS) were injected intraperitoneally into syngeneic BALB/c^{SCID} mice without or with PG antigen (100 μg with the first transfer), followed by a second transfer of (i) T cells from arthritic or non-arthritic WT or TCR-Tg mice, (ii) B cells from naïve, non-arthritic or arthritic BALB/c mice, or (iii) with IgGs purified from sera of arthritic or naïve animals. Two transfers were given at 7–10-day intervals. In reciprocal experiments, (i-iii) were injected first, which was followed by purified $CD4^{+}$ T cells from naïve or arthritic WT or TCR-Tg mice. Mice were scored for arthritis, and sacrificed 21–24 days after the second transfer for characterization of T and B cell markers, antigen-specific T cell responses, serum auto-antibodies (Abs) and cytokines.

Results: Neither PG-specific T or B cells, nor anti-PG Abs alone were sufficient for arthritis induction. In contrast, purified $CD4^{+}$ T cells (>98% purity) from TCR-Tg mice, if injected together with arthritogenic epitope-containing PG, induced arthritis in recipient SCID mice, but the onset and severity seemed to be dependent on selective proliferation of PG-specific autoAb-producing B cells. To further analyze the critical role of autoAbs in the development of arthritis, T cell transfer was followed by transfers of autoAb-producing B cells or autoAbs. TCR-Tg $CD4^{+}$ T cells controlled a highly selective homeostatic proliferation of autoAb-producing B cells, which their presence was critical for disease induction.

Conclusion: Anti-PG autoAbs bound to cartilage surface and co-localized with complement C3, might thus activate the complement cascade. They might also react with either intact or citrullinated G1 domain of PG, a domain structure which contains 12 potential sites of citrullination, and the G1 domain of human PG (injected together with the first transfer) heavily citrullinated in an age-dependent manner in human cartilage. At this moment, it remains an open question whether the homeostatic anti-PG B cell proliferation has been controlled primarily by highly specific TCR-Tg $CD4^{+}$ T cells, or the citrullinated G1 domain injected together with the first cell transfer, or both.

1756

$FasL^{+}$ Regulatory B Cells Are Expanded by Interleukin-5 and Induce Apoptosis in $CD4^{+}$ T Cells Via Cell-Cell Contact and Secretion of $FasL^{+}$ Exosomes. Matthew W. Klinker. Brian Alzua, Tamra Reed, Campbell Shaw, David A. Fox and Steven K. Lundy, University of Michigan, Ann Arbor, MI

Background/Purpose: We previously identified a subset of B cells that express the apoptosis-inducing molecule Fas ligand (FasL). Since little is known about $FasL^{+}$ B cells, we sought to characterize their surface phenotype, identify potential growth factors, and demonstrate their ability to directly induce apoptosis in $CD4^{+}$ T cells.

Methods: $CD19^{+}FasL^{+}$ murine splenocytes were assayed for expression of B cell markers and cytokine receptors by flow cytometry. The effects of cytokines on the expansion of $FasL^{+}$ B cells were tested *in vitro*. To measure the apoptosis-inducing function of $FasL^{+}$ B cells, they were cultured with TCR-transgenic $CD4^{+}$ T cells and T cell apoptosis was assayed via Annexin-V staining. A panel of human B cell-derived lymphoblastoid cell lines (LCLs) from RA patients and healthy controls was tested for FasL expression by immunoblot. A bead-based flow cytometry assay was used to test LCL culture supernatants for the presence of $MHCII^{+}FasL^{+}$ exosomes, and the ability of these exosomes to induce apoptosis in $CD4^{+}$ T cells isolated from peripheral blood was tested. A similar technique was used to analyze B cell-derived $FasL^{+}$ exosomes among murine splenic exosomes.

Results: $FasL^{+}$ B cells have the surface phenotype $IgM^{high}CD21^{high}$ $CD23^{+}CD5^{+}CD1d^{high}$, similar to that of IL-10-producing marginal zone precursor (MZP) B cells. In addition, $FasL^{+}$ B cells expressed high levels of the IL-5 receptor and *in vitro* culture of splenic B cells with IL-5 induced expansion of $FasL^{+}$ B cells and secretion of IL-10. These IL-5-stimulated B cells induced apoptosis in TCR-transgenic $CD4^{+}$ splenocytes, and this effect was greatly increased in the presence of the relevant antigen. In studies of

human B cells, it was found that all LCLs constitutively expressed FasL and secreted MHCII$^+$FasL$^+$ exosomes. LCL-derived exosomes induced apoptosis in autologous CD4$^+$ T cells in the presence of a superantigen. Finally, we found IgM$^+$FasL$^+$ exosomes in murine spleen extracts, suggesting that B cells secrete FasL$^+$ exosomes *in vivo*.

Conclusion: These data demonstrate that B cells can induce apoptosis in CD4$^+$ T cells, both by direct cell-cell contact and through the secretion of FasL$^+$ exosomes. The apoptosis-inducing properties of exosomes could extend the range of tissue compartments susceptible to the immunosuppressive effects of regulatory B cells. The ability to experimentally expand FasL$^+$ B cells through generation of LCLs and culture with IL-5 has many therapeutic implications in the treatment of rheumatoid arthritis and other T cell-mediated autoimmune diseases.

1757

Translational Medicine of a Selective Inhibitor of Btk in Rheumatic Diseases: Pharmacology and Early Clinical Development. Erica Evans, Richland Tester. Sharon Aslanian, Prasoon Chaturvedi, Russell Karp, Matt Labenski, Hormoz Mazdiyasni, Mariana Nacht, Michael Sheets, Kathryn Stiede, Steve Witowski, Heather Lounsbury, Russ Petter, Juswinder Singh and William Westlin, Avila Therapeutics, Waltham, MA

Background/Purpose: Dysregulated B cell activation and function has been demonstrated to be a critical component of the disease process in rheumatoid arthritis. The activity of Bruton's tyrosine kinase (Btk) is required for activation of B lymphocytes through the B Cell Receptor (BCR) signaling network. Due to a highly restricted expression pattern in humans (B cells, myeloid cells, mast cells), Btk is an exceptional target for a novel RA therapeutic. AVL-292 is a highly selective, orally active small molecule inhibitor of Btk in clinical development. This presentation summarizes therapeutic activity of AVL-292, including efficacy in preclinical models of RA and the results of a unique translational Phase 1a study that establishes the relationship between dose level administered, plasma drug concentration, and Btk molecular target engagement.

Methods: An ELISA assay has been developed to quantitatively determine the degree of AVL-292-Btk occupancy. In vivo activity of AVL-292 was evaluated in several models of RA including Collagen-Induced Arthritis in DBA1 male mice. AVL-292 was administered to healthy adult subjects in a Phase 1 clinical trial to assess the safety, pharmacokinetics, and Btk target occupancy in a double-blind, placebo controlled, single ascending dose study.

Results: AVL-292 covalently bonds to Cys481 on Btk and potently inhibited Btk in vitro in biochemical ($IC_{50} < 0.5$nM) and cellular assays ($EC_{50} \sim 3$nM) including isolated human B cells. The extent of Btk target occupancy directly correlated with inhibition of Btk enzyme activity and substrate phosphorylation. AVL-292 was disease-modifying in animal models of RA with 75% inhibition of the clinical score at an oral dose of 3 mg/kg that correlated directly with 75% Btk target occupancy. Complete inhibition of disease correlated with complete target occupancy at 10 mg/kg. In healthy human subjects, AVL-292 was found to be safe and well tolerated following oral administration at dose levels ranging from 0.5–7.0 mg/kg. All subjects that received an oral dose of 1.0 mg/kg of AVL-292 achieved >80% Btk occupancy. Mean peak plasma levels (Cmax 365 ng/mL) of AVL-292 were rapidly achieved (Tmax median 40 min) at this dose level. By 8 hours, plasma levels of AVL-292 ranged from 2.9–8.1ng/mL, whereas Btk occupancy was sustained at >73% in all subjects. 5 of the 6 subjects administered AVL-292 at 2.0 mg/kg achieved complete Btk occupancy. Cmax plasma levels in this dose level cohort (542ng/mL) were achieved at a Tmax of 60 min post dose administration. Btk occupancy was sustained through 24 hours even after plasma levels of AVL-292 had declined demonstrating that covalent inhibition of Btk with AVL-292 enables continued activity without requiring persistence of circulating drug.

Conclusion: Using this unique translational medicine approach the relationship between dose, plasma AVL-292 concentrations, and Btk molecular target occupancy has been established in humans. AVL-292 covalently bonds to Btk in a selective and potent manner leading to sustained inhibition of Btk that has the potential to translate to substantial clinical benefit for patients with RA and other autoimmune diseases characterized by aberrant B cell activation.

1758

A Bruton's Tyrosine Kinase Inhibitor Prevents Antigen-Driven B Cell Activation *In Vivo*. Micah Benson[1], Varenka A. Rodriguez[1], Tatyana Andreyeva[1], Sean Keegan[1], John R. Springer[2], Mark E. Schnute[2], Kyri Dunussi-Joannopoulos[1], Cheryl L. Nickerson-Nutter[1], Andrew L. Rankin[1], Melanie Ruzek[1] and John Douhan III[1]. [1]Pfizer, Cambridge, MA, [2]Pfizer, Inc, Cambridge, MA

Background/Purpose: Therapeutic targeting of B cells has proven effective for a multitude of human autoimmune indications. Most investigative and approved therapies are injected monoclonal antibodies that either deplete or inactivate B cells by targeting B cell surface moieties directly or by inactivating B cell modulating cytokines, with orally-available B cell modulating treatments currently lacking. Proximal to the intracellular signaling components of the B cell receptor (BCR) resides a network of adaptor proteins and protein tyrosine kinases that include the Tec family kinase Bruton's Tyrosine Kinase (BTK). The kinase activity of BTK is critical for transmitting signals received through the BCR to downstream signaling pathways that direct B cell activation. In this study, we assessed the ability of an orally-accessible BTK inhibitor to prevent antigen-driven B cell activation *in vivo*.

Methods: C57BL/6 mice were dosed orally with either vehicle alone or vehicle with BTK inhibitor at 10, 3, 1, or 0.3 mgs/kg as indicated. For the anti-IgD model, either 100mg of agonistic anti-CD40 (clone 1C10) or 200ml of goat-anti-mouse anti-IgD antisera (Ebioscience) were injected intraperitoneally (i.p) two hours after dosing. Mice were sacrificed between 4–18 hours later and splenic B cells analyzed. For mRNA transcript analysis, mature B220$^+$CD23$^+$ B cells were enriched to >93% purity by B cell negative selection followed by CD23 positive selection by antibody-coupled microbeads. Purified RNA was analyzed for mRNA transcript levels. To analyze the induction of B cell surface activation markers, B220$^+$ B cells were analyzed by FACS for CD86 expression levels. For the NP-Ficoll model, 100mg of NP-Ficoll were injected i.p. the day after dosing with either vehicle alone or vehicle with BTK inhibitor. BTK inhibitor was dosed daily for the duration of the experiment until day 7, whereupon anti-NP serum IgM and IgG3 titers were quantified by ELISA.

Results: We report that dosing with a BTK inhibitor suppressed, in a dose dependent manner, both anti-IgD driven B cell activation and NP-Ficoll elicited anti-NP IgM and IgG3 antibody titers in vivo. The suppression of anti-IgD driven B cell activation was manifested by suppression of the surface activation markers CD86 as well as suppression of mRNA transcripts (e.g. c-Myc, Bcl-xL, CCL3, CD98, EBI2, EGR1, EGR2 and IRF4), all markers otherwise rapidly induced upon engagement of the BCR with antigen. BTK inhibition had no impact on agonistic anti-CD40 driven B cell activation, indicating the specificity of the BTK inhibitor used in this study for the BCR signaling pathway. Lastly, inhibition of BTK prevented, in a dose-dependent manner, the generation of anti-NP IgM and IgG3antibodies upon immunization with NP-Ficoll.

Conclusion: Our results provide mechanistic insight into the role of BTK inhibition in a mouse model of in vivo BCR-driven B cell activation and support the concept that BTK kinase inhibitors represent a promising therapeutic approach for patients with B cell-dependent autoimmune disorders.

IL-10-Producing Regulatory B Cells (B10 cells) Inhibit Intestinal Injury In Mice. Koichi Yanaba and Shinichi Sato. The University of Tokyo, Tokyo, Japan

Background/Purpose: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by pathologic mucosal damage and ulceration, which can involve the rectum and extend proximally. Although the etiology and pathogenesis of UC have not yet been identified, an inappropriate activation of the mucosal immune system has been found to play an important role in the pathogenesis of mucosal inflammation. Oral administration of dextran sulfate sodium (DSS) solution to rodents is widely employed as a model of human UC, because it can cause acute inflammatory reaction and ulceration in the entire colon similar to that observed in patients with UC.

B cells mediate multiple functions that influence immune and inflammatory responses. Recently, it has been demonstrated that B cells and specific B cell subsets can also negatively regulate immune responses in mice, validating the existence of regulatory B cells. A potent subset of regulatory B cells with a phenotype of CD1d^{hi}CD5$^+$ was recently found to regulate contact hypersensitivity and experimental autoimmune encephalomyelitis in an IL-10-dependent manner. This regulatory B cell subset is called B10 cells to distinguish them from other regulatory B cell subsets that may exist and to identify them as the

predominant source of B cell IL-10 production. B10 cell subset is found within the spleen of naïve wild-type mice at 1–2% of the total B cell count, whereas CD19-deficient ($CD19^{-/-}$) mice have few, if any, B10 cells. At present, the contribution of regulatory B cells to DSS-induced colitis is unclear.

We examined the importance of regulatory B cells in DSS-induced colitis in $CD19^{-/-}$ and wild-type mice.

Methods: We treated $CD19^{-/-}$ and wild-type mice with 3% DSS for 7 days and quantitatively evaluated the severity of colitis.

Results: $CD19^{-/-}$ mice developed more severe colitis, both clinically and pathologically, than wild-type mice. Splenic B cell IL-10 expression was enhanced in wild-type mice during DSS-induced colitis and the enhanced IL-10 expression was restricted to the $CD1d^{hi}CD5^{+}$ B10 cell subset. By contrast, B cell IL-10 expression in mesenteric lymph nodes, Peyer's patches, and intestinal lamina propria did not change during DSS-induced colitis in wild-type or $CD19^{-/-}$ mice. Furthermore, blocking IL-10 receptor function enhanced the severity of DSS-induced colitis. Remarkably, the adoptive transfer of spleen $CD1d^{hi}CD5^{+}$ B cells from wild-type mice ameliorated DSS-induced colitis, whereas either splenic $CD1d^{hi}CD5^{+}$ B cells from $IL\text{-}10^{-/-}$ mice or non-$CD1d^{hi}CD5^{+}$ B cells from wild-type mice were without effect.

Conclusion: IL-10 production from $CD1d^{hi}CD5^{+}$ B10 cells regulated DSS-induced colitis. Further studies are needed to determine the precise mechanisms by which regulatory B cells attenuate the severity of colitis. Nonetheless, the current results may provide new insights and therapeutic approaches for treating UC.

B Cell Depletion Enhances T Regulatory Activity Essential in the Suppression of Arthritis. Susan Ashaye, Keith Hamel, Yanxia Cao, Yumei Wang, Tibor T. Glant and Alison Finnegan. Rush University Medical Center, Chicago, IL

Background/Purpose: B cell depletion is an effective therapy in Rheumatoid arthritis (RA), however, the mechanism responsible for suppression of disease is not clear. Autoantibodies are decreased in B cell depleted patients but the decrease does not necessarily correlate with clinical outcome suggesting that other mechanism may be effective. In a previous reported, we showed that in a murine model of arthritis proteoglycan-induced arthritis (PGIA) that B cell depletion inhibits autoreactive T cell responses. Recent studies of B cell depletion therapy also indicate a role for B cells in suppressing regulatory mechanisms. Here we tested where B cells inhibited both the expansion and the function of T regulatory (Treg) cells in PGIA.

Methods: B cells were depleted using in mice with PGIA an anti-CD20 mAb and Treg cell determined by Treg phenotype as $CD4^{+}$ $CD25^{+}$ $Foxp3^{+}$ by flow cytometry. T cell responses were measured by T cell proliferation and cytokine secretion.

Results: Treg cell percentages were elevated in B cell-depleted mice in comparison to control Ab treated. $CD4^{+}CD25^{+}$ cells from B cell depleted mice expressed increased amounts of Foxp3 and were significantly more suppressive than those from control Ab-treated mice. The depletion of Treg cells with an anti-CD25 mAb concurrent with B cell depletion therapy restored the severity of PGIA to levels equal to untreated mice. $CD4^{+}$ T cell recall responses to the immunizing antigen returned as measured by T proliferation and cytokine production.

Conclusion: These studies demonstrate B cells contribute to inflammation by inhibiting Treg cell expansion and function. B cell may inhibit T reg cells directly or indirectly by promoting preferential differentiation of naïve $CD4^{+}$ T cells towards a proinflammatory effector phenotypes rather than Tregs. Alternatively, the B cells act as APCs may expand the pool of autoreactive Teffs beyond the control of a Treg response. Further elucidation of the mechanisms utilized by B cells to suppress Tregs will have a major impact on the development of new therapies for the treatment of diseases.

Efficient Depletion of Autoreactive Plasma Cells within the Nephritic Kidneys in a Murine Model of SLE by Bortezomib. Charlotte M. Starke[1], Vilma Urbonaviciute[1], Silke Frey[1], Georg Schett[2] and Reinhard E. Voll[3]. [1]Clinical Research Group, Nikolaus-Fiebiger Center of Molecular Medicine, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Dept. of Rheumatology and Centre of Chronic Immunodeficiency, University of Freiburg, Freiburg, Germany

Background/Purpose: In autoimmune disorders such as systemic lupus erythematosus (SLE) self-reactive plasma cells (PCs) are known to contribute by diverse effector functions, for instance production of autoantibodies, to lupus pathogenicity. Glomerular deposits of immune complexes which are mainly composed of autoantibodies directed against nuclear components cause lupus nephritis, a severe manifestation of SLE-patients. Recently, we have shown that pathogenic autoantibodies are produced *in situ* within nephritic kidneys of lupus prone mice and that both short- and even more long-lived PCs are located in the renal tissue, indicating that a long-term production of renal autoantibodies is maintained by long-lived PCs. In contrast to short-lived PCs, the long-lived ones are extremely resistant to therapy. Therefore, novel therapeutic strategies targeting both short- and long-lived PCs are of particular importance.

Methods: NZB/W F1 lupus mice, displaying high titers of anti-double-stranded-DNA (dsDNA) antibodies and increased proteinuria, were treated short-term with either bortezomib (Bz) or Dexamethason (Dex) to evaluate possible depleting effects on specific leukocyte subsets within the nephritic kidneys by flow cytometry. To determine long-term effects, mice were analyzed after four weeks of initial therapy. Short- and long-lived PCs were differentiated using *in vivo* bromodeoxyuridine (BrdU)-labeling. ELISPOT assays were performed to quantify renal ASCs directed against antigen-specificities as dsDNA, histones and nucleosomes.

Results: We found a significant decrease of $CD138^{+}$ / intracellular κ/λ-L $chain^{+}$ PCs in renal tissue of Bz treated NZB/W F1 mice whereas treatment with Dex shows only a moderate depleting effect. Importantly, both short- and long-lived PCs as well as T lymphocytes were efficiently reduced after proteasome inhibition with Bz in the inflamed kidneys. In comparison, treatment with Dex solely depleted renal short-lived PCs and T leukocytes. Moreover, Bz short-term treatment markedly decreased not only renal IgG-antibody secreting cells (ASCs) but also potentially pathogenic anti-dsDNA, anti-histone and anti-nucleosome ASCs located in the nephritic tissue. Four weeks after initial therapy with Bz and subsequently a further therapy with Dex lupus mice showed beneficial effects in terms of the PC reconstitution in the kidneys. Interestingly, we observed that the IgG-secretion rate was significantly increased in renal IgG-ASCs when compared to IgG-secreting cells in spleen and BM.

Conclusion: Short- and long-lived PCs within the nephritic kidneys of NZB/W F1 lupus mice and can be efficiently depleted by treatment with Bz. Hence, the elimination of renal autoantibody-secreting cells by proteasome inhibition may critically contribute to beneficial effects in SLE-patients with lupus nephritis.

1762

TLR7 Overexpression Promotes Accumulation of Autoreactive CD19+ CD11c+ B Cells. Alice Wiedeman and Keith B. Elkon. University of Washington, Seattle, WA

Background/Purpose: 90% of patients with SLE are females yet the reasons for gender bias are incompletely understood. Recently, a novel CD11c+ B cell population was described that is expanded in older female mice (Age-Dependent B cells, or ABCs) and implicated in autoantibody production. Significantly, TLR7 appeared to be necessary for the generation of these cells since accumulation of ABCs was not observed in TLR7 deficient female mice. Since TLR7 has been strongly implicated in both mouse and human SLE, we asked what the effect of TLR7 overexpression would be on the numbers of ABC in male and female mice. We also asked whether type 1 interferon (T1-IFN) was responsible for driving expansion of these cells since TLR7 drives T1-IFN production and females have been shown to have increased type 1 interferon (T1-IFN) response to TLR7 ligands. Finally, we addressed whether the autoantigen (RNA) was responsible for driving the expansion of ABC in TLR7 Tg B cells.

Methods: Knock-in B6 mice that overexpressed TLR7 were kindly provided by S. Bolland. These mice were crossed to IFNaR knockout mice (to remove the effects of interferon-alpha signaling) or to RNAse transgenic mice (to diminish the source of antigen that is presumed to activate TLR7). ABCs were quantified by staining splenic B cells with anti-CD19 and CD11c mAbs by flow cytometry. Anti-RNA autoantibodies were quantified by ELISA.

Results: In wild-type B6 mice, an increased proportion of ABC was observed in female mice older than 6 months (2.70 vs 1.03%, $p<0.02$) confirming previous findings. However, in TLR7 transgenic mice, significantly more ABCs were observed in both female (4.52 vs 2.70%, $p<0.002$) as well as male (4.14 vs 1.03%, $p<0.004$) mice. Furthermore, these increases were markedly accelerated in time, being observed in mice as young as 3 months of age. Although TLR7 drives T1-IFN and this cytokine has a powerful effect on B cell activation, TLR7 transgenic mice deficient in IFNaR had only a modest reduction in ABC accumulation (4.53 vs 3.37%, $p< 0.04$). The % ABCs also correlated with levels of anti-RNA autoantibodies ($R^2=0.37$, $p<0.008$). When TLR7 transgenic mice were crossed to RNAse transgenic mice there was a partial reduction in the proportion of ABCs (4.53 vs 2.94%, $p<0.07$).

Conclusion: TLR7 overexpression in a non-autoimmune background accelerates the expansion of an unusual CD11c+ B cell population (ABC) in both male and female mice. These results suggest that gender specific factors act in concert with TLR7 pathways to promote the production of ABCs that are closely associated with autoantibody production. However, when TLR7 levels are increased by other mechanisms, the requirement for female hormones or other gender factors are not necessary. Since the expansion of ABC is only partially interferon-alpha-dependent, other mechanisms relevant to TLR7 activation or signaling also play a role. Since overexpression of RNAse in TLR7 transgenic mice reduced the proportion of ABC, and anti-RNA autoantibody levels correlated with the proportion of ABCs, the expansion of ABCs appears to be autoantigen driven. ABCs should be considered as a potential target for therapy to reduce autoantibody production.

Anti-DNA Antibody Production Is Restricted by the Germline Composition of DH Genes. Aaron Silva-Sanchez[1], Cunren Liu[1], Pratibha Kapoor[1], Yingxin Zhuang[1], Trenton R. Schoeb[1] and Harry W. Schroeder Jr.[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama-Birmingham, Birmingham, AL

Background/Purpose: Diversity genes (D_H genes) have a critical role in determining BCR specificity since they encode most of the CDR-H3 loop which is structurally located at the center of the antigen-binding site. The relevance of D_H genes has been overlooked due to the presumption that repertoire is randomly generated and only shaped by somatic events occurring during B cell maturation. D_H preferential use of reading frame (RF) 1, limited D-J recombination by inversion and presence of stop codons in RF3 contribute to narrow the physicochemical features of the mature BCR repertoire. One crucial feature of the WT repertoire is the poor representation of highly charged (R, K) amino acids. A probable explanation is that conserved DH sequences decrease the probability to produce potentially harmful self-reactive BCRs, e.g. anti-DNA BCRs containing CDR-H3s rich in arginine. In this work we hypothesized that D_H sequences encoding charged amino acids will favor the production of anti-DNA antibodies.

Methods: To test this hypothesis we used transgenic BALB/c mice with a single D_H gene encoding (in RF1) charged amino acids (DiD mice), mice with a single WT D_H gene (DFL16.1 gene, DFL mice), WT x DiD F1 ($DiD^{+/WT}$), WT x DFL F1 ($DFL^{+/WT}$), and WT BALB/c mice (considered to be resistant to anti-DNA antibody production). Cohorts of 9–16 female mice were followed for a period of ten months (2–12 months of age). Serum was obtained monthly and stored at −70°C until analysis. 1 year old mice were euthanized and the kidneys were collected for histological analysis. Total IgM, total IgG, anti-ssDNA and anti-dsDNA IgM and IgG was determined by ELISA. DNA reactivity was confirmed by Crithidia luciliae Immunofluorescence (CLIF) assay. Kidney sections were HE and PASH stained for histology analysis.

Results: At 12 months of age, sera from all groups showed similar concentration of anti-DNA IgM. Only mice containing the DiD allele had increased production of anti-DNA IgG. The increased production of anti-dsDNA IgG ranged from 3 to 8 fold increase when compared with WT average concentration, and the differences between $DiD^{+/+}$ and $DFL^{+/+}$ or $DFL^{+/WT}$ were statistically significant. Notably, DiD allele had increased anti-DNA IgG as soon as 5 months of age. Strains that do not contain the DiD allele have similar and homogeneous concentrations of anti-DNA IgG and IgM. A deleterious or additive effect of the DFL or DiD allele on the antibody production was discarded since the concentrations of total IgM and IgG showed no statistical differences among groups. DNA reactivity in $DiD^{+/+}$ and $DiD^{+/WT}$ samples was confirmed with the CLIF assay. Kidney histology did not revealed considerable alterations and most of the samples showed mild segmental sclerosis tipical of C57BL/6 mice.

Conclusion: These results show that D_H germline sequence shape preimmune BCR repertoire and this is reflected in B cell function. Importantly, tolerance mechanism in BALB/c mice acting on the BCR repertoire can be overcome by altering the D_H germline sequence. Also, our results suggest that the conserved D_H germline sequences have been selected to limit potentially auto-reactive BCRs and open the possibility to find new susceptibility genes in humans with D_H sequences encoding charged amino acids.

1764

A Novel Method to Evaluate Autoreactivity by Inducing Antibodies Secretion Allows the Study of Tolerance In Mice. Emiliano Marasco[1], Nataly Manjarrez Orduño[1], Peter K. Gregersen[2] and Betty Diamond[3]. [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Feinstein Institute Medical Reschearch, Manhasset, NY, [3]Feinstein Institute Med Rsch, Manhasset, NY

Background/Purpose: During maturation, B cells rearrange their V(D)J segments to produce functional immunoglobulins. Along the development pathway, there are checkpoints to censor B cells bearing autoreactive antibodies thus avoiding potential tissue damage. In systemic lupus erythematosus, the censoring at these tolerance checkpoints is not effective and autoreactive B cells enter the mature B cell pool, where they can be activated and induced to secrete pathogenic autoantibodies. Many transgenic models bearing autoreactive receptors have been developed to study the process of B cell tolerance and the pathogenesis of autoimmune diseases. However these manipulations can perturb the physiology of the system, leading us to build a model that might not fully apply to unmanipulated organisms. Here we present a different approach to study autoreactivity and censoring checkpoints of a native B cell repertoire in murine models of human autoimmune diseases.

Methods: B cells subpopulations in spleen and peritoneal cavity were sorted from BALB/c and NZB/W F1 mice and activated with a cocktail of TLR agonists and cytokines to induce the secretion of antibodies. After four days of culture, cells were harvested and seeded for ELISpot analysis. ELISpots were performed to evaluate the percentage of cells induced to secrete antibodies and the fraction of cells that secrete anti-DNA antibodies in each of the subpopulations. Finally, the percentage of autoreactive cells was normalized to the number of antibody secreting cells (ASC).

Results: Over 80% of each B cell subset was induced to secrete antibody. As reported in other models, we observe that autoreactivity decreases during development from the transitional to the mature follicular stage, while a large amount of autoreactivity can still be found in the marginal zone (MZ) and B1 cell pools. As expected B cells from NZB/W F1 mice, at every stage of development, contain a higher percentage of DNA reactive cells when compared to BALB/c mice, highlighting the altered censoring checkpoints present in this murine model of SLE.

Conclusion: To date, tolerance and autoreactivity checkpoints have been studied mainly through genetically modified mice. Here, we propose this method as a tool for the analysis of autoreactivity directly ex vivo. Our method allows us to measure the reactivity of antibodies to biologically and pathologically meaningful antigens in genetically unaltered animals within a reasonable timeframe. Consequently we propose this method to expand the knowledge acquired from transgenic models, and overcome the limitation of studying tolerance one B cell receptor at a time.

1765

Subtoxic Dose of Mercury Reduces Splenic Marginal Zone B Cells, Resulting in the Increase in Autoantibodies in Murine Mercury-Induced Autoimmunity. Takaji Matsutani[1], Miho Murakami[1], Hooi-Ming Lee[2], Hidehiko Sugino[2] and Norihiro Nishimoto[1]. [1]Wakayama Medical University, Ibaraki, Japan, [2]Osaka University, Suita, Japan

Background/Purpose: Mercury is one of the most abundant heavy-metal in the environment. It has been reported that high levels of serum anti-nuclear or anti-nucleolar autoantibodies were observed in peoples exposed to mercury in gold-mining area of Brazil. In rodent, *in vivo* administration of subtoxic dose of inorganic mercury ($HgCl_2$) can induce autoantibody production in susceptible strains of mice (Hg-induced autoimmune mouse model, HgIA). It is considered that the autoantibody production is T cell dependent and associated with particular MHC class II haplotype ($H\text{-}2^s$). However, it remain little known about the mechanism of autoantibody production by subtoxic mercury.

Methods: SJL mice ($H\text{-}2^s$) were treated with 10 ppm of $HgCl_2$ drinking water *ad libitum* for 4 weeks. Anti-nuclear or anti-nucleolar antibodies were measured with indirect immunofluorescence assay with Hep-2 slides. T cell subsets, CD4/CD8 ratio, activation markers ($CD69^+$, $CD62L^{low}$, $CD25^+$), and T cell receptor repertoires were analyzed in thymuses, spleens and LNs. Furthermore, splenocytes were surface stained with anti-CD19, IgM, IgD, IgG, CD21 and CD23, and analyzed with FACScalibur. Lymphoid follicle formation was evaluated with Immunohistochemical staining with anti-IgM and anti-MOMA-1 antibodies.

Results: Elevated numbers of B cells expressing surface IgG and increased levels of plasma IgG1-type anti-nucleolar antibodies were observed in HgIA mice. However, mercury administration had little impact on T cell profiles and repertoires *in vivo*. Interestingly, we found that mercury administration reduced splenic $CD21^{high}CD23^{low}$ marginal zone (MZ) B cells but not $CD21^{high}CD23^+$ follicular (FO) B cells. Such effects were not observed in resistant strains of mice. Immunohistochemcal staining confirmed the decrease of splenic MZ B cells localized in marginal zone of lymphoid follicle distinct from T cell area. Given T cell profiles were not altered in HgIA mice, it is possible that mercury can directly act on MZ B cells in a T cell-independent manner.

Conclusion: *In vivo* administration of subtoxic dose of mercury reduced splenic MZ B cells in HgIA mice. This suggests the possibility that mercury act directly on MZ B cells in a T cell-independent fashion, provoking B cells to produce autoantibody.

1766

Induction of Regulatory B Cells in Healthy Individuals and Patients with Systemic Lupus Erythematosus. Shun-ichiro Ota, Hiroaki Niiro, Naoko Ueki, Hirofumi Tsuzuki, Siamak Jabbarzadeh-Tabrizi, Yasushi Inoue, Yojiro Arinobu and Koichi Akashi. Kyushu University, Fukuoka, Japan

Background/Purpose: Recent evidence from B-cell depletion studies highlights the importance of antibody-independent roles for B cells in autoimmune diseases. In this respect, B cells can negatively regulate the disease process via production of an anti-inflammatory cytokine, IL-10, and thus is termed regulatory B cells (Bregs). The nature of human Bregs, however, remains somewhat elusive, due to a few conflicting previous results.

Methods: IL-10 expression in B cells was evaluated using real-time quantitative PCR and ELISA.

Results: We first determined IL-10 expression in $CD19^+$ B cells from healthy controls following stimulation of surface receptors for BCR, CD40, and TLR9, and found that CpG, a TLR9 ligand, is the most potent for Breg induction. Combined stimulation with BCR and CpG exerted synergistic effects on IL-10 production in B cells. Both naïve and memory B cells exhibited comparable levels of CpG-induced IL-10 expression. We next evaluated the effects of various chemical inhibitors of signaling pathways on CpG-induced Bregs. Among them, the inhibitors of the ERK, p38 MAPK, PI3K and STAT3 pathways significantly abrogated Breg induction. Combined stimulation with CpG and STAT3-activating cytokines induced higher levels of IL-10 production in B cells. We finally determined Breg induction in patients with systemic lupus erythematosus (SLE), and found that CpG-induced IL-10 production is significantly impaired in memory B cell subsets as compared with healthy controls. Intriguingly, sustained calcium signaling in B cells from healthy controls abrogated Breg induction in particularly memory B cells, which is reminiscent of SLE memory B cells. We are currently working on further underlying mechanisms of impaired induction of Bregs in SLE patients.

Conclusion: Our current findings could help to better understand a role of human Bregs in the pathogenesis of autoimmune diseases as well as to provide a novel clue to manipulate the generation of human Bregs for therapeutic application in the future.

1767

The Comprehensive B Cell Profiling Analysis of a Multicenter SLE Cohort. John Jung[1], Jamie Biear[1], Youqun Huang[1], Bridget Neary[1], Elides Marin[1], Jennifer Hossler[1], Elise Palmer[1], Sharleen Smith[1], Ehtisham Akhter[2], Tracey Sanford[1], Jie Xu[2], Michelle Petri[2], Alex Rosenberg[1], Jennifer H. Anolik[1], Chungwen Wei[1] and Iñaki Sanz[1]. [1]University of Rochester, Rochester, NY, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: B cell abnormalities in Systemic Lupus Erythematosus (SLE) are well-established contributors to disease pathogenesis. Past limitations such as pauci-color flow cytometry have limited a full characterization of this multifactorial disease. This study utilizes several multicolored flow cytometry panels to render a high-resolution footprint of the B cell profiles linked with comprehensive clinical parameters to identify distinct B cell signatures in SLE.

Methods: PBMCs were isolated and analyzed by flow cytometry from Healthy Controls (HC) (n=36) and SLE patients (n=161). B cell subsets were identified using the following markers: IgD, CD19, CD27, CD38, CD24, CXCR3, CD21, CD24, CD95, MitoTracker Green, CD10, IgM, CD23. SLE patients met ACR criteria for the classification of SLE, and were sub-categorized based on primary clinical manifestation. Disease activity and flares were measured by SELENA-SLEDAI and physician global assessment. All clinical and experimental data were imported into a customized database where multivariate methods were used to seek natural divisions based on the B cell profiles and relationship to clinical parameters.

Results: Our initial analyses show pronounced heterogeneity in SLE subjects. Multidimensional analysis of our multicolor panels can identify a total of 330 B cell subsets of which 132 demonstrate abnormal behavior with significantly different frequencies found between HC, SLElow (SLEDAI<=4), and SLEhi (SLEDAI>4) disease activity ($p<0.05$). SLE patients have a significant expansion of CD27- memory B cells and a contraction of unswitched memory subsets relative to HC subjects ($p<0.05$). Further characterization of memory B cells reveals additional signatures of active disease characterized by expansions of CD21low, CD24low, CXCR3hi, and CD95hi that correlate with higher number of autoantibodies, lower C3/C4 levels, higher disease activity, and flares ($p<0.0005$). Detailed analysis of the IgD+CD27- subsets show B cell subset shifts where overall the true naïve B cells contract and the transitional B cell compartments expand when compared to healthy controls ($p<0.005$). High dimensional multi-parameter analysis identifies multiple clusters of SLE subjects that can be sub-classified based on their B cell profiles and show similar clinical features. Further novel-analysis tools including heat-map displays and Principle Component Analysis confirm the added value of refined B cell phenotyping for superior segregation of HC and SLE subclasses.

Conclusion: Collectively, this study demonstrates that while SLE patients have variable B cell profiles, immune-profiling has the ability to identify clusters of SLE. Two year longitudinal studies of these subjects are currently under way to clarify whether the signatures corresponding to the different disease clusters have subset-specific changes to disease activity and predictive of disease progression. These profiles will be useful in understanding disease. Careful immunological studies of patients with SLE will increase our understanding of multiple aspects of human B cell biology and will be critical to providing the framework for the design and evaluation of current and future B cell targeted therapies.

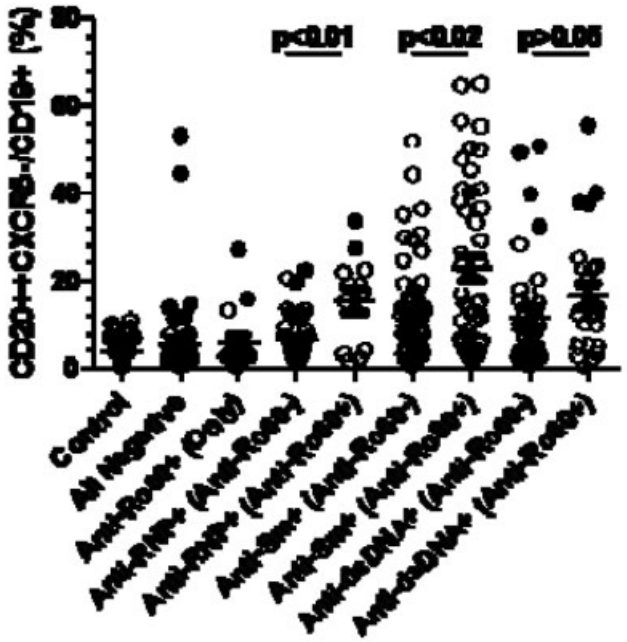
1768

A Novel Circulating CXCR5-CD20++ B Cell Compartment in Patients with Systemic Lupus Erythematosus. Eric S. Sobel, Edward Butfiloski, James Hunt, Mark Segal, Laurence Morel, Westley H. Reeves and Minoru Satoh. University of Florida, Gainesville, FL

Background/Purpose: Alterations in B cell homeostasis have been identified in patients with SLE and typically correlate with disease activity. Here, we describe a novel B cell compartment in our SLE cohort more related to autoantibody specificity.

Methods: A total of 131 patients with SLE were studied by 7- or 8-color flow cytometry, 81 of whom had two or more samples at least one year apart and 33 with multiple samples over a two to three year interval. A total of 47 controls were also studied. Clinical and serological data, including autoantibody characterization by immunoprecipitation, were available for all patients.

Results: In a subset of patients with lupus, there was a striking increase in a subset of CD19+ B cells that had the phenotype of CD20++CXCR5−. The mean percentage and standard deviation was $3.7\pm2.3\%$ for controls and was 12.8 ± 19.7 for all SLE samples. While there was a correlation between the percentage of this subset with disease activity ($9.4\pm11.3\%$ for SLEDAI <4 vs. $16.0\pm14.8\%$ for SLEDAI ≥4; $p<0.001$), a closer examination showed that there was a stronger correlation with autoantibody specificity (Figure). In patients negative for the specificities commonly available in clinical laboratories (anti-dsDNA, anti-Sm/RNP, anti-RNP, and anti-Ro60), the average percent of CD20++CXCR5− B cells was unchanged from the control population ($p>0.05$ by ANOVA). The outliers (shown in filled circles) were positive for either Ku or ribosomal P antibodies. In one case, the patient had seven unidentified bands. The presence of anti-RNP alone did not affect this population, but it doubled in the presence of anti-Ro60. In contrast, anti-Ro60 alone had only a minimal impact that did not achieve statistical significance. The few outliers also had additional known specificities (La, PCNA). The presence of anti-Sm characteristically had the biggest impact ($p<0.01$ by ANOVA compared to all negative) and this too was augmented by the co-presence of anti-Ro60 antibodies. The effect of anti-dsDNA was less clear. Although statistically significant ($p<0.05$ by ANOVA), most of the high positives had other specificities (primarily anti-Ku and anti-RNA helicase A), and the impact of anti-Ro60 was even less clear and did not reach statistical significance. Because of the striking similarity of our findings of specificity to the recently described novel class-switched IgD-CD27− memory B cell population, we examined the percent of these cells within our CD20++CXCR5−population. In patients with initial high levels of CD20++CXCR5- B cells, the IgD-CD27− B cells comprised a varying but substantial percentage (range 20–70%). This percentage fluctuated, but the overall trend indicated it was increasing over time.



Conclusion: Taken together, these findings suggest that this novel population is driven by TLR7-dependent pathways, and that the class-switched CD27- population may be the final product.

Effect of Mycophenolat Mofetil (MMF) on Clinical and Paraclinical Parameters in Systemic Lupus Erythematosus (SLE). Sebastian Eickenberg, Elisabeth Jung, Eva Mickholz and Annett M. Jacobi. University Hospital Münster, Münster, Germany

Background/Purpose: Although efficacy and safety of MMF were investigated thoroughly in SLE and experts consider MMF to be a therapeutic standard in lupus nephritis, few attempts have been undertaken to further delineate its mechanism of action in SLE—a disease characterized by enhanced B cell activation.

Methods: This consecutive investigation of our outpatients with SLE has been conducted for one year. During this time period 39 patients on MMF, 30 patients on aza and 38 patients currently not taking immunosuppressive drugs other than prednisolone and hydroxychloroquine (controls) were seen. Disease activity and manifestations, serologic and cellular parameters were recorded. To further delineate the effect of mycophenolic acid on naïve and memory B cells, *in vitro* assays were performed.

Results: Most Patients treated with MMF had a LN (90%, 57% in remission) compared to 2/3 of the aza-treated patients (45% in remission) and 38% (54% in remission) of the controls. Patients taking aza flared more frequently (47%, 71% LN) and showed a higher mean disease activity (SLEDAI: 7.1±5.5) than patients on MMF (23%, 44% LN, mean SLEDAI: 4.9±3.4) or controls (32%, 50% LN, mean SLEDAI: 5.6±5.6). These differences did not reach statistical significance and the three patient cohorts did not differ significantly with regard to all clinical manifestations recorded. However we observed a number of significant differences investigating paraclinical parameters suggesting that MMF has a favorable and distinct mechanism of action compared to other immunosuppressive drugs used in lupus patients. White blood cell count ($p<0.03$), B cell frequency ($p<0.005$) and B cell number ($p<0.002$) were significantly higher in patients taking MMF compared to those on aza. However B cell subset analysis revealed significantly lower numbers and frequencies of plasmablasts in patients taking MMF compared to those on aza ($p>0.0001$ und 0.001, respectively) or controls ($p=0.0002$ und <0.0001, respectively). On the contrary, MMF treatment was associated with a significantly higher frequency and number of transitional/regulatory B cells ($p<0.0001$ and <0.0001) as well as naïve B cells ($p<0.001$ and <0.0005) compared to treatment with aza. T cell subsets did not differ between patient groups. In line with these data, the results of our *in vitro* assays supported a preferential inhibition of B cells activated by CPG (Figure 1) or anti-CD40+IL-21.

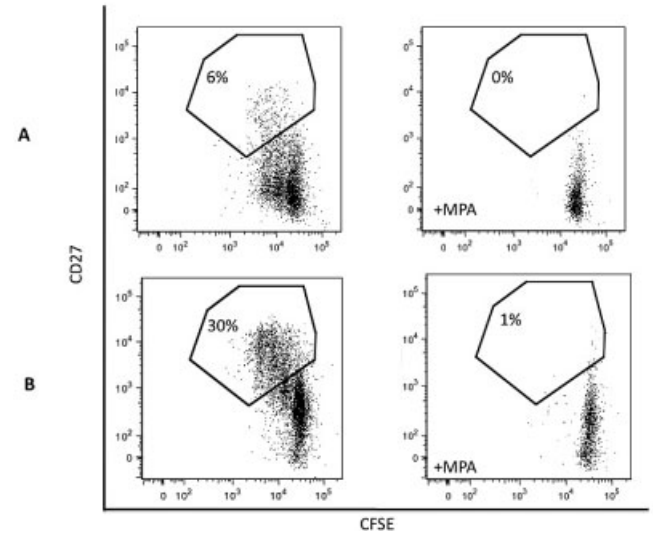

Figure 1. Naïve (A) and memory (B) B cells were isolated from the peripheral blood of healthy individuals and stimulated with CPG for 3 days with (right) or without mycophenolic acid (MPA, left). MPA abolished B cell division and plasmablast formation completely.

Conclusion: The specific inhibition of activated B cell subsets observed in this study might explain the favorable outcomes of previous clinical trials, since enhanced B cell activation is a common finding in patients with SLE.

Simultaneous Targeting of IL-1α and IL-1β by a Dual-Variable-Domain Immunoglobulin (DVD-Ig™) Prevents Cartilage Degradation In Preclinical Models of Osteoarthritis. Rajesh Kamath. Abbott Research Center, Worcester, MA

Background/Purpose: Interleukin-1 (IL-1) plays a major role in the development and progression of osteoarthritis (OA). IL-1α and IL-1β are two distinct cytokines that bind to the same receptor and are expressed in synovial membranes, cartilage, and synovial fluid of patients with OA. IL-1 induces structural changes (cartilage degradation, bone sclerosis & synovial proliferation) by inducing proteases and proinflammatory cytokines from all tissues (cartilage, bone and synovium) of the joint. The purpose of the study is to demonstrate a) blockade of both IL-1a and IL-1b with a combination of anti-mouse IL-1a and IL-1b monoclonal antibodies (mAbs) is efficacious compared to treatment with single mAbs in mouse models of OA, and b) to demonstrate that anti-IL-1a/b dual variable domain –Ig (DVD-Ig) produces similar efficacy as the combination of anti-mouse IL-1a and IL-1b mAbs.

Methods: The joint instability model (JIM) and destabilization of medial meniscus (DMM) model of OA were used to evaluate efficacy of IL-1 treatment. For JIM model, male Swiss Webster mice had anterior cruciate ligament (ACL) trauma on day 0 to transect the ACL and induce OA lesions. For DMM model, male sv129 mice were anesthetized on day 0 and then medial meniscotibial ligament which anchors the medial meniscus to the tibial plateau was transected to induce OA. Intraperitoneal (ip) treatments with IL-1 neutralizing antibodies [mouse anti-mouse IL-1α mAb, mouse anti-mouse IL-1β mAb alone, in combination, or anti-IL-1a/b DVD-Ig were initiated the day of the surgery and continued twice a week for either 3 weeks in JIM or 8 weeks in DMM models. Knees were harvested and histopathologic alterations were scored and characterized.

Results: In both JIM and DMM model, cartilage degeneration in animals treated with either anti-IL-1a (6 mg/kg) or IL-1b mAbs (6 mg/kg) was similar to vehicle control knees. However, a combination therapy with both antibodies (6 mg/kg each significantly decreased cartilage degeneration scores. We have recently reported on a novel dual-specific biologics approach, termed

DVD-Ig™ that can convert two pre-existing mAbs into a dual targeting agent by combining the variable domains of two mAbs via naturally occurring linkers. Anti–mIL-1α/β DVD-Ig (6 mg/kg) also significantly inhibited the progression of OA with comparable efficacy to the combination of the parental mAbs.

Conclusion: Our preclinical data demonstrate that combination of mouse anti-mouse-IL-1a and anti-mouse-IL-1b mAb as well as anti-mouse-IL-1a/b DVD-Ig™ molecules had significant beneficial effects on histopathological parameters of mouse OA. These preclinical proof of concept studies with anti-IL-1a/b DVD-Ig™ molecules form the basis for further investigation of therapeutic IL-1a/b DVD-Ig™ molecules in human OA patients.

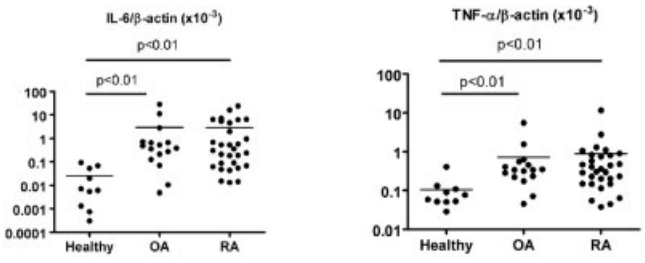
Enhanced Expression of mRNA for Interleukin 6 and Tumor Necrosis Factor-Alpha In CD34+ Cells of the Bone Marrow In Osteoarthritis. Shunsei Hirohata[1], Tamiko Yanagida[2], Tetsuya Tomita[3] and Hideki Yoshikawa[4]. [1]Kitasato Univ School of Med, Kanagawa, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan, [3]Osaka University Med School, Suita Osaka, Japan, [4]Osaka University Graduate School of Medicine, Osaka, Japan

Background/Purpose: Recent studies have disclosed that bone marrow lesions also play an important role in the pathogenesis of osteosrthritis (OA). Thus, bone marrow lesions have been consistently associated with an increased prevalence and severity of cartilage defects and metaphyseal expansion, both characteristics of the increasing severity of knee OA. Moreover, the development of new bone marrow lesions was associated with progressive knee cartilage pathology in asymptomatic middle-aged adults. However, the nature of bone marrow abnormalities in OA has not been determined. The current studies were therefore undertaken to explore the expression of mRNA for interleukin 6 (IL-6) and tumor necrosis factor-alpha (TNF-α) in bone marrow CD34+ cells in OA.

Methods: Bone marrow samples obtained from 16 patients with established OA (2 males and 14 females; mean age, 70.9 years) and from 30 patients with rheumatoid arthritis (RA) (5 males and 25 females: mean age, 59.4 years), who gave informed consent, during joint operations via aspiration from the iliac crest. CD34+ cells were purified from the bone marrow mononuclear cells by positive selection with magnetic beads. CD34+ cells from healthy individuals were also purchased from Bio-Whittaker, Walkersville, MD (8 males and 2 females: mean age, 24.9 years). The expression of mRNA for IL-6, TNF-α, NFkB1, FK506 binding protein 5, and Kruppel-like factor 5 in the CD34+ cells was examined by quantitative RT-PCR, and is evaluated as the ratio of the copy numbers to those of β-actin mRNA.

Results: The expression of mRNA for IL-6 and TNF-α in bone marrow CD34+ cells was significantly elevated in OA patients as well as in RA patients compared with that in healthy individuals (Figure). There was no significant difference in the expression of mRNA for IL-6 and TNF-α between OA bone marrow CD34+ cells and RA bone marrow CD34+ cells, although the expression of mRNA for several genes, including NFkB1, FK506 binding protein 5, and Kruppel-like factor 5, was significantly higher in RA bone marrow CD34+ cells.



Conclusion: These results demonstrate that bone marrow CD34+ cells in OA display the enhanced expression of mRNA for IL-6 and TNF-α, which might be a common sequela of inflammation of joints. The data also suggest that primary abnormalities in bone marrow CD34+ cells that lead to the enhanced mRNA expression for several genes other than these inflammatory cytokines might be a unique feature in RA.

Transcriptome Analysis Reveals a Robust Profile In Osteoarthritis Synovial Fibroblasts. Manuel J. Del Rey[1], Alicia Usategui[1], Elena Izquierdo[1], Vanessa Miranda[1], Juan D. Cañete[2], Francisco J. Blanco Sr.[3], Gabriel Criado[1] and Jose L. Pablos[1]. [1]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain, [2]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain, [3]INIBIC-CHUAC, La Coruna, Spain

Background/Purpose: Gene expression profiling in rheumatoid arthritis synovial fibroblasts (RASF) has not consistently demonstrated a unique phenotype and shows great heterogeneity. RASF gene expression changes have been usually defined by comparison to osteoarthritis SF (OASF) rather than healthy SF (HSF). The aim of this study was to analyze the transcriptome of OASF compared to both RASF and HSF.

Methods: Total RNA was extracted from 9 RASF, 11 OASF and 11 HSF lines (n=31) and cRNA was hybridized in Agilent G4112F platform (Whole Human Genome Microarray 44k). ANOVA with Benjamini and Hochberg multiple testing correction was used to determine the statistical significance of the differences in gene expression. Tukey post-hoc test was used to compare the three possible pairs after ANOVA. Cluster analysis was also performed with Cluster 3.0 software. Validation of microarray data was performed by quantitative RT-PCR of selected genes. Differentially expressed genes were analyzed to identify potential functional pathways using the Database for Annotation, Visualization and Integrated Discovery (DAVID).

Results: ANOVA showed 345 transcripts significantly different (down- or up-regulated) between the three different groups. Tukey post-hoc test identified the largest number of significant differences in OASF compared RASF or HSF (325/323 respectively), whereas only 39 transcripts were different in RASF compared to HSF. Cluster analysis of the 31 SF lines by similarity on gene expression patterns identified a single cluster including all OASF lines, whereas RASF clustered together with HSF into several clusters. The set of genes statistically different between OASF and HSF included several categories significantly different to the DAVID database, remarkably: genes related to cell-cell or cell-ECM adhesion and actin cytoskeleton regulation, growth factor and cytokine activities, synapse or neuroactive elements, and GTPase activity.

Conclusion: Cultured OASF display a more robust transcriptomic profile than RASF when compared to HSF which supports a role of SF in the pathogenesis of OA. These data also advise against the use of OASF as controls for SF studies.

1773

Destabilization of the Medial Meniscus As a Model to Study the Relationship Between Joint Degeneration and Pain. Rachel E. Miller, Phuong Tran, Nayereh Ghoreishi-Haack, Rosalina Das and Anne-Marie Malfait. Rush University Medical Center, Chicago, IL

Background/Purpose: Pain is the major symptom in osteoarthritis (OA), yet how this pain develops remains unknown. Our long-term goal is to quantitatively measure pain and dissect molecular pathways involved in pain generation in a mouse model of OA. We chose destabilization of the medial meniscus (DMM) in C57BL/6 mice because, unlike in other rodent OA models, the joint pathology in this model is slowly progressive over 16 weeks. Previous studies in our lab have found that mice receiving DMM surgery develop progressive mechanical allodynia in the ipsilateral hindpaw, as early as 2 weeks and progressing over 8 weeks post DMM (but not sham) surgery.

Methods: DMM or sham surgery was performed in the right knee of 10-week old male C57BL/6 mice. At 8 and 16 weeks post surgery, histopathology of the knees was evaluated according to OARSI recommendations. Additionally, at 4 and 8 weeks after surgery, whole knee joints were collected for protein extraction and ELISA. The LABORAS system (Metris, NL) was used to measure locomotor activity at 4, 8, and 16 weeks post surgery. At the same time points, innervating dorsal root ganglia (DRG), L3-L5, from DMM or sham-operated mice and age-matched naïve mice were collected for mRNA extraction for quantitative RT-PCR of nerve growth factor (NGF), monocyte chemoattractant protein (MCP)-1 and its receptor CCR2, and stromal cell-derived factor (SDF)-1. Finally, at 8 weeks post surgery, the response of DRG neurons to chemokines was recorded though intracellular Ca^{2+}-imaging, following standard protocols. In brief, DRG neurons were acutely isolated, plated on coverslips, cultured for 3–4 days, and loaded with a calcium indicator dye. The number of cells responding to chemokines was counted.

Results: Following DMM (but not sham) surgery, C57BL/6 mice developed cartilage degeneration and osteophyte formation by 8 weeks in the ipsilateral knee only, with progressive cartilage deterioration occurring up to 16 weeks. At 4 weeks post DMM, protein levels of MCP-1 and NGF were elevated in total joint extracts from the operated knee compared to naïve age-matched controls; by 8 weeks post DMM, levels of both proteins had returned to baseline. Additionally, locomotor activity (measured as total distance traveled) was relatively constant over the first 8 weeks, but was decreased in DMM mice at 16 weeks post surgery compared to age-matched naïve mice.

mRNA levels of NGF, MCP-1, CCR2, and SDF-1 in the innervating DRG were upregulated compared to naïve and sham age-matched controls, peaking at 8 weeks post surgery. Exposing isolated DRG neurons from DMM mice at 8 weeks post surgery to MCP-1 or to SDF-1 (200 or 500 ng/mL, respectively) resulted in an increased calcium response compared to naïve age-matched controls, indicating an upregulation of their respective receptors, CCR2 and CXCR4, on these cells.

Conclusion: Time-course experiments in the murine DMM model of OA enable us to quantify pain at different stages of disease. The upregulation of CCR2 and CXCR4 signaling pathways indicate that they likely play a central role in mediating painful osteoarthritis, similar to what has been reported in other neuropathic disease models; future work will address whether these pathways may serve as useful therapeutic targets.

IL-1beta Inhibits TNF-Mediated Differentiation of Human Osteoclast Precursors Grown in Presence of Fibroblast-Like Synoviocytes. Bohdan P. Harvey, Farhan A. Syed and Zehra Kaymakcalan. Abbott Laboratories, Worcester, MA

Background/Purpose: Inflammatory cytokines such as TNF-alpha (TNFa), IL-1beta (IL-1b) and IL-6 have been shown to contribute to osteoclastogenesis independently or in conjunction with M-CSF or RANKL, two key cytokines involved in osteoclast development. However, the role of TNFa as well as the other inflammatory cytokines in promoting the expression of these key osteoclastogenic factors in synovial tissue and the concomitant induction of osteoclast differentiation is poorly understood. In this study, we sought to determine whether TNFa, IL-1b or IL-6, separately or in combination, could induce human osteoclast differentiation directly in the presence of fibroblast-like synoviocytes (FLS).

Methods: Primary human osteoblasts or FLS from healthy or rheumatoid arthritis (RA) donors, were pre-treated with various combinations of TNFa, IL-1b, IL-6, soluble IL-6 receptor (sIL-6R), M-CSF and RANKL for 24 hr in the absence or presence of osteoprotegerin (OPG), a natural inhibitor of RANKL. Human osteoclast precursor cells were then added, and the co-cultures were continued for 7 days. Western blot analysis was performed on RA-FLS to evaluate RANKL protein expression. Osteoclast differentiation was determined by the appearance of large multinucleated cells staining positive for tartrate-resistant acid phosphatase (TRAP) and by bone-specific TRAP5b activity within culture supernatants.

Results: RA-FLS were found to express RANKL protein in response to either TNFa or IL-1b. Pre-treatment of osteoblasts or RA-FLS with a combination of TNF and M-CSF led to the appearance of TRAP+ multinucleated cells and an increase in TRAP5b activity; whereas, the combination of TNF and RANKL was ineffective in inducing osteoclasts, suggesting that TNF could substitute for exogenous RANKL but not M-CSF. Osteoclast differentiation was observed with FLS from healthy and RA donors and was found to increase in a TNF dose dependent manner. Addition of the RANKL inhibitor OPG caused a significant reduction in TRAP+ multinucleated cells without altering the level of TRAP5b activity. A greater degree of inhibition was observed with the addition of IL-1b alone or in combination with IL-6 and sIL-6R, since the generation of both TRAP+ multinucleated cells and TRAP5b were significantly reduced even in the presence of exogenous RANKL.

Conclusion: These findings suggest that in a co-culture system with FLS, TNFa can induce an early stage of osteoclast differentiation independent of RANKL as indicated by the expression of TRAP5b in the presence of OPG. This finding is in agreement with the literature describing TRAP5b as a marker of an immature osteoclast. However, the generation of multinucleated cells requires TNF-induced RANKL expression from the FLS since the number of TRAP+ multinucleated cells was reduced with OPG treatment. Surprisingly, IL-1b prevented both the expression of TRAP5b and the generation of TRAP+ multinucleated cells that was induced by either TNF or RANKL, suggesting that this pro-inflammatory cytokine can inhibit osteoclast development at an early stage.

1775

Norepinephrine (NE) Affects Mesenchymal Stem Cell (MSCs) Chondrogenesis and Accordingly the Self-Regeneration Capacity of Cartilage. Zsuzsa Jenei-Lanzl[1], Peter Angele[2] and Rainer H. Straub[3]. [1]Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Department of Internal Medicine, University Hospital Regensburg, Regensburg, Germany, [2]Department of Trauma Surgery, University Hospital Regensburg, Germany, Regensburg, Germany, [3]University Hospital Regensburg, Regensburg, Germany

Background/Purpose: It is known that sympathetic nerve fibers are present in healthy and osteoarthritic (OA) synovium and that the sympathetic nervous system mediates numerous effects on adult skeletal system. The presence of mesenchymal stem cells (MSCs) in healthy or arthritic cartilage has also been confirmed. In addition, MSCs migrating from synovium into the cartilage and differentiating into chondrocytes has been described. This might be the reason for increased MSC number in OA. The aim of this study was to investigate the effects of the most important sympathetic neurotransmitter norepinephrine (NE) on MSC chondrogenesis.

Methods: Human bone marrow derived MSCs were expanded in serum containing medium. After achieving confluence, 3D aggregates were formed and chondrogenesis was initiated by the use of a specific serum-free chondrogenic medium. Parallel to control conditions, aggregates were incubated with different concentrations of NE (10^{-9} to 10^{-6} M). Based on the first results aggregates were treated with specific β-adrenoceptor agonist (isoproterenol) or antagonist (nadolol). After 21 days, the quality of aggregate chondrogenesis was evaluated macroscopically, histologically and biochemically. Furthermore, specific adrenoceptors (α1 and β2) were detected.

Results: Aggregates treated with high NE concentrations (10^{-7} to 10^{-6}M) or with isoproterenol were smaller, showed a weaker staining of cartilaginous matrix and significantly reduced type II collagen synthesis than control aggregates or aggregates treated with lower NE concentrations or nadolol alone. Nadolol reversed the effects of NE and isoproterenol. In addition, acceleration of chondrocyte hypertrophy (increased MMP13 and type X collagen expression) was observed after NE and isoproterenol addition, which was reversed by nadolol. Presence of specific adrenoceptors (α1 and β2) was shown in the aggregates undergoing chondrogenesis.

Conclusion: The suppression of chondrogenesis by high NE or isoproterenol suggests that the β-adrenoceptors mediate this effect. This pathway might influence existing or migrating MSCs and play a role in OA development and manifestation. Further experiments are required to discover underlying signalling pathways, which might help to develop therapy options for the regeneration of injured or osteoarthritic cartilage tissue.

Adiponectin Is Associated with Joint Inflammation and Cartilage Degradation in Osteoarthritis. Anna Koskinen[1], Sami Juslin[1], Katriina Vuolteenaho[1], Riina Nieminen[1], Teemu Moilanen[2] and Eeva Moilanen[1]. [1]The Immunopharmacology Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland, [2]The Immunopharmacology Research Group, University of Tampere School of Medicine, Tampere University Hospital, and Coxa Hospital for Joint Replacement, Tampere, Finland

Background/Purpose: Adipocytokine adiponectin is known to regulate insulin sensitivity, energy metabolism and appetite. Recently, it has also been related to inflammation and arthritis. The aim of the present study was to investigate the association and effects of adiponectin on inflammation and cartilage destruction in osteoarthritic joints.

Methods: Blood and cartilage samples were collected from 35 male patients with OA undergoing total knee replacement surgery. Preoperative radiographs were evaluated according to the Ahlbäck grading scale for knee osteoarhtritis. Plasma concentrations of adiponectin and biomarkers of cartilage degradation, i.e. COMP (cartilage oligometric matrix protein)

and MMP-3 (matrix metalloproteinase 3) were measured by immunoassay. Cartilage samples were cultured for 42h, and amounts of adiponectin released into the culture media were measured and correlated to NO (nitric oxide), IL-6 (interleukin-6), MMP-1 and MMP-3 production. The effects of adiponectin on NO, IL-6, and MMP production in cartilage were studied in cell and tissue culture experiments.

Results: Plasma adiponectin concentrations correlated positively with biomarkers of cartilage degradation, i.e. with COMP (Pearson r=0.54, p<0.001, ln transformation) and with MMP-3 (r=0.34, p=0.046). Patients with the most severe radiographic findings (Ahlbäck grades IV-V) had higher circulating adiponectin concentrations as compared to patients with milder OA (grades I-III; p=0.012). OA cartilage was found to produce adiponectin and the amount of adiponectin released by cultured cartilage was also higher in samples from patients with the most severe radiographic findings (grades I-III vs. grades IV-V; p<0.001). In addition, adiponectin amounts released by cartilage in culture correlated positively with production of NO (r=0.34, p=0.049), IL-6 (r=0.39, p=0.021, ln transformation) and MMP-3 (r=0.36, p=0.037, ln transformation). Exogenous adiponectin, when added into the culture, enhanced production of NO, IL-6, MMP-1 and MMP-3 in primary human chondrocytes and in OA cartilage *in vitro* by a p38 MAP kinase dependent manner.

Conclusion: Adiponectin was found to correlate with OA biomarkers, with radiographic severity of OA and with production of catabolic/ inflammatory factors by cartilage *ex vivo*. In addition, adiponectin enhanced production of catabolic and inflammatory factors in OA cartilage and chondrocytes. These findings suggest that adiponectin is involved in the pathogenesis of joint inflammation and cartilage destruction in osteoarthritis and may be a target for disease-modifying drug development.

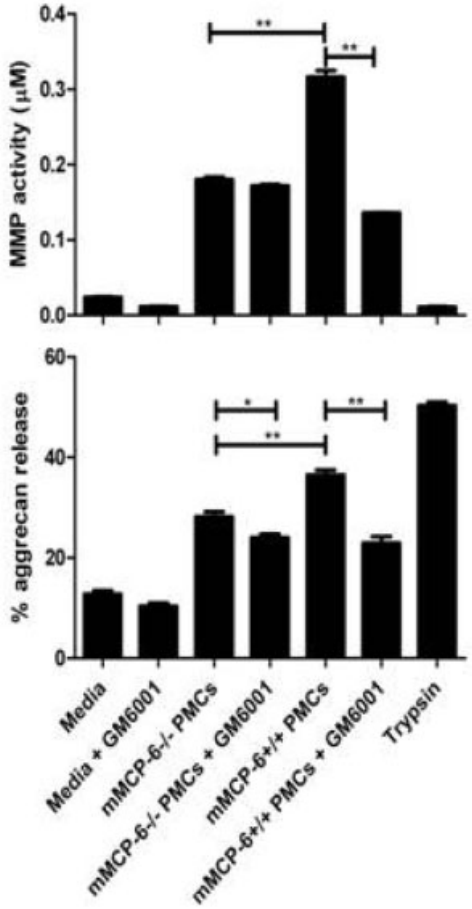
Mast Cell-Restricted, Tetramer-Forming Tryptases Are Novel Mediators of Articular Cartilage Aggrecanolysis by Activating Matrix Metalloprotease Zymogens. Natalia Magarinos[1], Katherine J. Bryant[1], Amanda J. Fosang[2], Richard L. Stevens[3] and H. Patrick McNeil[1]. [1]University of New South Wales, Sydney, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Brigham & Women's Hospital and Harvard Medical School, Boston, MA

Background/Purpose: The mast cells (MCs) in human and mouse synovium express hTryptase-β and its ortholog mouse mast cell protease (mMCP)-6, respectively. During experimental inflammatory arthritis, more aggrecan proteoglycan is lost from cartilage of mMCP-6-null C57BL/6 mice than wild-type C57BL/6 mice. We therefore used *ex vivo* cultures of mouse femoral head explants to explore the mechanism(s) of tryptase-mediated aggrecanolysis.

Methods: Mouse femoral head cartilage explants were freeze-thawed to devitalise chondrocytes, then cultured in the presence or absence of recombinant hTryptase-β or granule protein from peritoneal MCs (PMCs) isolated from mMCP-6$^{+/+}$ or mMCP-6$^{-/-}$ mice. Cartilage-derived aggrecan fragments in the media were measured using a glycosaminoglycan (GAG) dye-binding assay. Aggrecan degradation products were characterised by immunoblotting using antibodies that recognize the DIPEN neoepitope formed during matrix metalloprotease (MMP)-dependent aggrecanolysis. A fluorimetric assay was used to quantitate MMP activity in the cartilage explants. Activation of recombinant human proMMP-3 by hTryptase-β was determined by immunoblotting.

Results: Human and mouse MC tryptases induced significant release of aggrecan fragments from freeze-thawed femoral heads, indicating living chondrocytes were not required for tryptase-mediated aggrecanolysis. The finding that hTryptase-β and mMCP-6 failed to cleave purified aggrecan efficiently suggested that their aggrecanolysis activities were a result of activation of an aggrecan-degrading protease zymogen constitutively present in cartilage. In support of this conclusion, incubation of proMMP-3 with hTryptase-β *in vitro* resulted in conversion of the zymogen into its enzymatically active form. hTryptase-β caused release of 28% of aggrecan from articular cartilage within 24 h compared to 14% release from cartilage cultured in media alone (P<0.001). Similarly, the granule protein from mMCP-6$^{+/+}$ PMCs induced significantly greater release of GAGs (37%) compared to that obtained with the granule protein from mMCP-6$^{-/-}$ PMCs (28%) (P<0.01). Aggrecan fragments released into the media by hTryptase-β or mMCP-6$^{+/+}$ PMC granules possessed the DIPEN neoepitope, consistent with MMP-dependent proteolysis of aggrecan. Incubation of femoral heads with hTryptase-β or mMCP-6$^{+/+}$ PMC granules resulted in increased MMP enzymatic activity. Finally, the abilities of hTryptase-β and mMCP-6$^{+/+}$ PMC granules to induce aggrecanolysis were significantly inhibited by 72% and 57%, respectively, when cartilage explants were co-incubated with the MMP-inhibitor GM6001 (P<0.01).



Conclusion: The accumulated data suggest that tetramer-forming human and mouse tryptases participate in the early-stages of cartilage destruction in arthritis, in part, by activating latent MMPs that are constitutively present in cartilage's extracellular matrix.

1778

Calcium Mineral Deposition In the Cultures of Fibroblast-Like Synoviocytes. Yubo Sun, David Mauerhan, Atiya Franklin, Andrew Sun, Natalia Zinchenko, H. Norton, Edward Hanley Jr. and Helen Gruber. Carolinas Medical Center, Charlotte, NC

Background/Purpose: Calcium crystals are present in synovial fluid of ~75% of patients with osteoarthritis (OA) and up to 26% of patients with rheumatoid arthritis (RA). Recent findings, however, demonstrate that calcium crystals are present in all articular cartilage of patients with OA. Recent findings also demonstrate that more calcium deposits or crystals were formed in the monolayer culture of OA articular chondrocytes and OA meniscal cells than in the monolayer culture of those corresponding cells derived from control subjects. These newer findings indicate that pathological calcification occurs in all cases of OA and that pathological calcification is a cell-mediated process. In this study we hypothesized that fibroblast-like synoviocyte (FLS) also play a role in the formation and deposition of synovial calcium crystals.

Methods: Selected genes implicated in biomineral formation in hTERT-OA 13A FLS and hTERT-RA 516 FLS were examined for their expression using real-time RT-PCR. Calcium deposition in monolayer cultures of OA FLS and RA FLS was investigated using an ATP-induced ^{45}calcium deposition assay. Inhibition of calcium deposition by phosphocitrate, a calcification inhibitor, was also investigated using the ATP-induced ^{45}calcium deposition assay. Calcium mineral formation in monolayer cultures and micromass cultures of hTERT-OA 13A FLS and hTERT-RA 516 FLS grown under conditions promoting chondrogenesis (micromass formation) were examined with alizarin red staining.

Results: Several genes involved in biomineral formation, including ankylosis progressive homolog and ectonucleotide pyrophosphatase 1, were upregulated in hTERT-OA 13A FLS compared to hTERT-RA 516 FLS. Calcium deposition in monolayer cultures of OA FLS was significantly greater than that in monolayer cultures of RA FLS. Calcium minerals were detected in micromass cultures of hTERT-OA 13A FLS, but not in hTERT-RA 516 FLS. Examination using polarized microscope indicated that the majority of calcium minerals were basic calcium phosphate (BCP) crystal aggregates. Phosphocitrate, a calcification inhibitor, was found to potently inhibit OA FLS-mediated calcium deposition at concentrations of 0.1 to 0.5 mM.

Conclusion: OA FLS is not a passive bystander and may play an active role in the formation of synovial calcium crystals. Therefore, OA FLS may be valid target for OA intervention. Phosphocitrate may have other unidentified molecular targets whose identification may provide information important for the development of new novel drugs for OA therapy, and valuable for a better understanding of the disease mechanisms of OA.

1779

Infliximab Does Reverse Cytokine - Mediated Anti-Apoptotic Effects In CD14 $^{+}$/CD11b^{+} Circulating Monocytes - Implications for Osteoclastogenesis. Michael Seitz, Daniel Aeberli, Richard K. Kamgang, Willy Hofstetter, Deepak Balani and Peter M. Villiger. University Hospital, Bern, Switzerland

Background/Purpose: To study apoptosis in circulating CD14^{+}/CD11b^{+} monocytes treated with the chimeric TNFa antibody infliximab *in vitro* and *ex vivo*.

Methods: The induction of apoptosis in circulating CD14^{+}/CD11b^{+} monocytes from peripheral blood was investigated *in vitro* in cells from 16 healthy subjects and *ex vivo* in cells from 6 patients with ankylosing spondylitis (AS) that were treated with infliximab. The monocytes from healthy donors were exposed *in vitro* to interferon-g (IFNg) and tumor necrosis factor—a (TNFa) in the presence or absence of subsequent infliximab. Induction of apoptosis was detected by staining with annexinV and propidium iodide (PI). Osteoclastogenic potential of monocytes was tested *in vitro* by growing cells on dentin wafers.

Results: Treatment of monocytes from healthy donors with IFNg or TNFa caused a decrease in the number of CD14^{+}/CD11b^{+}/ annexinV^{+} monocytes ($p = 0.03$) and of CD14^{+}/CD11b^{+}/PI^{+} monocytes after TNFa exposure ($p=0.03$). This effect which was reversed by infliximab. Correspondingly, 2 days after the first infliximab infusion in AS patients, the numbers of CD14^{+}/ CD11b^{+}/annexinV^{+} and CD14^{+}/CD11b^{+}/PI^{+} monocytes increased, a change which was accompanied by a depletion of circulating monocytes. Based on their bone resorbing activity CD14^{+}/CD11b^{+} monocytes were further characterized as osteoclast precursor cells (OPC).

Conclusion: The findings of this study suggest that the anti-bone resorptive effects of infliximab are mediated by a rapid induction of apoptosis in OPC in patients with chronic inflammatory diseases.

New Alginate-Chitosan Hydrogel Beads with Anti-Inflammatory and Anabolic Effects on Human Chondrocytes. Frédéric Oprenyeszk[1], Christelle Sanchez[1], Jean-Emile Dubuc[2], Véronique Maquet[3] and Yves Henrotin[4]. [1]University of Liège, Liège, Belgium, [2]Clinical University Saint Luc, Bruxelles, Belgium, [3]KitoZyme SA, Herstal, Belgium, [4]Univ of Liege/ Pathology Inst, Liege, Belgium

Background/Purpose: Today there is no treatment to cure osteoarthritis (OA) or to delay effectively its progression. Current treatments are mainly based on the alleviation of painful symptoms but are unable to restore the cartilage. The development of new scaffolds for tissue engineering is a promising approach. Herein, we report the effects of alginate-chitosan hydrogel (AC) beads on the metabolism of chondrocytes.

Methods: Human chondrocytes were isolated from OA cartilage and then cultured either in AC beads or in alginate (A) beads. AC beads were prepared using ultra-pure chitosan (KiOmedine-CsU, KitoZyme, Herstal, Belgium) with molecular weight of 40 K (AC40) or 20 K (AC20) and alginate (Sigma Aldrich, Bornem, Belgium). The two polymer solutions were prepared separately before being mixed together. Cells were added to the polymer mixture and the cell-containing beads prepared by precipitation in a calcium chloride solution. The chondrocytes embedded in the beads (0.5 to 1×10^5 cells/bead) were then cultured in a well defined culture medium for 21 days. Cell viability was determined by quantifying the amount of lactate deshydrogenase (LDH) released in the culture medium. Interleukin (IL)-6 and −8, Matrix Metalloproteinase (MMP)-3 and aggrecan (AGG) were measured by specific sandwich enzyme-linked immunoabsorbent assays (ELISA). A spectrophotometric method based upon the Griess reaction was used to quantify nitric oxide (NO) product.

Results: Histological analysis of AC beads showed a homogeneous distribution of chitosan trabeculae in the alginate matrix and the presence of chondrocytes in contact with chitosan trabeculae. LDH level remained below the limit of detection over the culture duration suggesting that the AC had no cytotoxic effect. By comparison with cells cultured in A beads, chondrocytes cultured in AC40 or AC20 beads produced significantly higher amounts of AGG but lower levels of MMP-3, NO, IL-6 and IL-8 factors (Table 1).

Table 1. AGG, MMP-3, NO, IL-6 and IL-8 production of chondrocyte in AC40 and AC20 beads.

	AGG	MMP-3	NO	IL-6	IL-8
AC40	217.68 ± 72.24***	59.04 ± 30.04**	46.82 ± 6.21***	19.17 ± 14.8***	17.16 ± 3.37***
AC20	154.27 ± 15.23**	21.69 ± 16.64***	42.12 ± 20.20***	12.67 ± 2.58***	6.12 ± 3.37***

Results were represented as % of production of chondrocytes in A beads. Results were expressed as mean ± SEM (n=9). Comparison of mean values was performed by Student t parametric analysis. *** $p < 0.001$, ** $p < 0.01$ production of cells in AC beads was significantly different than production of cells in A beads.

Conclusion: AC beads reduce the production of inflammatory and catabolic mediators by OA chondrocytes and promote the synthesis of cartilage-specific matrix components. These particular effects indicate that AC beads are potential carriers for cell transplantation, and particularly to repair cartilage defects.

1781

Activation of Adenosine A_{2A} Receptors Prevents Wear Particle-Induced Osteolysis. Aranzazu Mediero[1], Sally Frenkel[2], Tuere Wilder[1] and Bruce N. Cronstein[3]. [1]NYU School of Medicine, New York, NY, [2]Hospital for Joint Disease, New York, NY, [3]New York Univ Medical Center, New York, NY

Background/Purpose: Prosthesis loosening is a common cause for joint prosthesis failure and necessitates further restorative surgery. Aseptic failure of cemented prostheses is associated with wear particle-induced inflammation and bone destruction mediated by osteoclasts. Adenosine A_{2A} receptors ($A_{2A}R$) mediate potent anti-inflammatory effects in many tissues and prevent osteoclast differentiation. We therefore tested the hypothesis that the selective $A_{2A}R$ agonist CGS21680 prevents osteoclast-mediated bone resorption at sites of prosthesis wear in a calvaria model of wear particle-induced bone resorption.

Methods: 52 C57Bl/6 (WT) and 18 A_{2A}KO mice age 6–8 weeks were anesthetized and a 1cm midline sagittal incision was made over the calvaria. 12 WT and 6 A_{2A}KO mice received no particles (Control), and the rest received 3mg of polyethylene particles (UHMWPE). 9 WT and 6 A_{2A}KO mice received 20μl of saline 0.9% at the surgical site, and the rest received 20μl of CGS21680 (1μM-1nM) every day. Animals were sacrificed after 14 days and calvaria were prepared for microCT, histological studies and cytokine assay.

Results: MicroCT analysis demonstrated pitting and increased porosity in untreated particle-exposed mice but treatment with CGS21680 significantly reduced the area of resorption in a dose-dependent manner (by as much as 41±11% of control resorption, $IC_{50} = 8.9$ nM, $p<0.05$). In CGS21680-treated mice the reduction in cortical bone was significantly less than in untreated-particle-exposed mice ($p<0.01$) and CGS21680-treated calvaria had significantly greater mean bone volume than did the untreated-group ($p<0.0005$). Histological examination of calvaria demonstrated a lymphohistiocytic infiltration in both particle-exposed groups that was significantly diminished by CGS21680 in a dose-dependent manner ($IC_{50} = 10$ nM). In contrast, CGS21680 did not affect inflammation or osteoclast-mediated bone resorption in A_{2A}RKO mice (p=NS for all measures above) Immunohistochemistry for RANK, RANKL, Cathepsin K, CD163, TNFα and Osteopontin revealed a marked increased in expression of these proteins in particle-exposed groups that was diminished by treatment with CGS21680. Similarly, CGS21680 treatment reduced TRAP+ osteoclasts in a dose-dependent manner ($IC_{50} = 10$ nM). There were decreased concentrations of IL-1β and TNFα in CGS21680 treated animals (Il-1β: Control: 168±11 pg/ml, Particle/Saline: 256±10 pg/ml, CGS21680: 101±7 pg/ml, $p<0.01$ respectively: TNFα: Control 85±8 pg/ml, Particle/Saline: 158±5 pg/ml, CGS21680: 111±3 pg/ml, $p<0.01$ and $p<0.05$ respectively).

Conclusion: Adenosine $A_{2A}R$ activation reduces inflammation and osteoclast-mediated bone destruction due to prosthetic wear particles in a dose-dependent manner. This suggests that site-specific delivery of the $A_{2A}R$-agonist could enhance implant survival, delaying or eliminating the need for revision arthroplastic surgery.

Heme Oxygenase-1 Lentiviral Transduction of Human Osteoarthritic Osteoblasts Down-Regulates Inflammatory, Degradative and Senescence Markers. Maria Isabel Guillen[1], Victoria Clerigues[1], Miguel Angel Castejon[2], Francisco Gomar[3] and Maria Jose Alcaraz[1]. [1]University of Valencia, Burjasot, Valencia, Spain, [2]La Ribera Hospital, Alzira, Valencia, Spain, [3]University of Valencia and University Hospital, Valencia, Spain

Background/Purpose: In previous works we demonstrated that the antioxidant enzyme heme oxygenase-1 (HO-1) protects against inflammatory and degenerative effects of IL-1β in osteoarthritic (OA) chondrocytes and synoviocytes. Osteoblasts play an important role in remodelling processes in OA. In this work we studied HO-1 effects on inflammatory, degradative and senescence markers in OA osteoblasts stimulated with IL-1β. Overexpression of HO-1 was performed by infection of these cells with lentiviral vectors.

Methods: The knee specimens were obtained from 46 patients with the diagnosis of advanced OA (71.5±7.1 years, mean ± S.E.M.) undergoing total knee joint replacement. The pieces of trabecular bone were obtained from the femoral condyles and tibial plateau, and cells were isolated after collagenase digestion. Osteoblasts were cultured in osteogenic medium and used at third passage. Lentiviral vector stocks were generated in HEK293T cells by calcium phosphate-mediated transient transfection of psPAX2, pMD2G and pWXL plasmids for 24 and 48h. The titers of lentiviral stocks were in the range of $3–5 \times 10^5$ IU/ml as determined by immunocytochemical analysis of HEK293T-infected cells. Osteoblasts culture was infected with LV-HO-1 flag or control empty vector, LV(−) for 24 h. After infection and culture in osteogenic medium for 2 days, osteoblasts were stimulated with IL-1β (10 ng/ml) for 24 h. HO-1 expression was measured by immunofluorescence using an anti-flag monoclonal antibody. PGE_2 was evaluated by RIA, IL-6, TNF-α, IL-10, matrix metalloproteinases (MMPs) and transcription factors NF-κB and AP-1 by ELISA, COX-2, mPGES-1, osteocalcin (OCN), osteopontin (OPN), collagen 1A1, collagen 1A2, osteoprotegerin (OPG), RANKL, and senescence markers (hTERT, caveolin and p21) by real-time PCR.

Results: Lentiviral vectors showed not toxicity on OA osteoblasts, evaluated by trypan blue exclusion test. The results showed that IL-b decreased HO-1 expression in cells treated with IL-1β and transfected with LV(−). However, in LV-HO-1 flag-transfected cells, IL-b did not alter the expression of HO-1. These effects were observed at protein and mRNA levels. IL-1β significantly increased the production of PGE_2, COX-2, mPGES-1, IL-6, TNF-α, MMP- 1, 2 and 3, with respect to basal conditions. In LV-HO-1 flag cells, all these mediators were significantly reduced. In contrast, HO-1 overexpression increased the production of IL-10, OCN, OPN, collagen 1A1, and the ratio OPG/RANKL, with respect to IL-1β control cells. The evaluation of senescence parameters showed that in cells transfected with LV-HO-1 flag hTERT was enhanced and caveolin decreased. The analysis of transcription factors showed HO-1 overexpression significantly reduced NF-κB activation in osteoblasts stimulated with IL-1β.

Conclusion: In this study we have demonstrated that HO-1 down-regulates the inflammatory response and cellular senescence besides exerting a positive effect on osteoblastic markers. HO-1 may be a novel therapeutic target in inflammatory and degradative processes in OA bone

1783

Human End-Stage Osteoarthritic Cartilage is Responsive to Transforming Growth Factor Beta and Contains a Population of Cells That Expresses SMAD2/3P and SMAD1/5/8P. Arjan P. M. van Caam, Esmeralda N. Blaney Davidson, Elly L. Vitters, Wim B. van den Berg and Peter M. van der Kraan. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Joint diseases such as osteoarthritis (OA) result in destruction of articular cartilage. Transforming Growth factor beta is considered as a protective factor in young cartilage while this function is lost upon aging. In chondrocytes, TGF beta can signal via phosphorylation of SMAD2/3 (via ALK5) or SMAD1/5/8 (via ALK1). In earlier studies we have found that in young healthy human cartilage (age < 10 years) only SMAD2/3 phosphorylation (SMAD2/3P) occurs and no SMAD1/5/8 phosphorylation (SMAD1/5/8P). Moreover, in human OA cartilage we showed a significant correlation between ALK1 and MMP13 expression. Our goal was to study the expression of SMAD2/3P and SMAD1/5/8P in chondrocyte populations in end-stage human OA cartilage and whether addition of exogenous TGF beta modulates the expression of MMP13 and ALK5 and ALK1 in this cartilage.

Methods: Human OA articular cartilage was obtained during knee joint replacement (n=20). Cartilage sections were stained for SMAD2/3P and SMAD1/5/8P using specific antibodies. In addition, human OA cartilage was incubated with 10 ng/ml TGF beta for 24h. Part of the cartilage explants were pre-incubated with the ALK5 inhibitor SB-505124 (50μM) for 6 hours. Expression of MMP13, ALK5 and ALK1 was analyzed by quantitative PCR.

Results: Staining for both SMAD2/3P and SMAD1/5/8P was observed in human OA cartilage. Strikingly, SMAD2/3P staining was mostly negative in histological intact cartilage areas while cells in damaged areas, mainly in chondrocyte clusters, were often strongly positive. Also staining for SMAD1/5/8P was most intense in cells surrounding damaged regions and chondrocyte clusters. Incubation of human OA cartilage with TGF beta significantly down regulated MMP13 expression. This effect was totally abolished by the ALK5 inhibitor SB-505124. TGF beta also significantly elevated ALK5 expression, and decreased ALK1 expression, and both these effects were completely blocked by pre-incubation with SB-505124.

Conclusion: Stimulation of human end-stage OA cartilage with high TGF beta concentrations down regulates MMP13 expression and modulates TGF beta type I receptors, increasing the ALK5/ALK1 ratio. These effects all run via SMAD2/3 (ALK5). We propose, based on these results and earlier findings, that during aging TGF beta loses its protective role by a loss of SMAD2/3 signaling in articular chondrocytes. This loss plays a role in the initiation of cartilage degradation. In end-stage OA cartilage the majority of cells does not display either SMAD2/3P or SMAD1/5/8P. However, neighboring severely damaged cartilage a population of chondrocytes is present, most probably involved in (unsuccessful) repair, that expresses SMAD2/3P and SMAD1/5/8P.

1784

A Single Injection of Adipose-Derived Stem Cells Protects Against Cartilage Damage and Lowers Synovial Activation in Experimental Osteoarthritis. Menno C. ter Huurne[1], Peter L.E.M. van Lent[1], Arjen B. Blom[1], Roxane Blattes[2], Yannick Jeanson[2], Louis Casteilla[2], Christian Jorgensen[3] and Wim B. van den Berg[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]INSERM U1031, Toulouse, France, [3]Hospital Lapeyronie, Montpellier, France

Background/Purpose: Synovial activation is evident in a substantial subpopulation of patients with early osteoarthritis (OA) and has been associated with pathophysiology and clinical symptoms of OA. Previous studies have shown that synovial activation is involved in mediating cartilage destruction during experimental OA. Recently it has been shown that Adipose-derived Stroma/Stem Cells (ASCs) express immunosuppressive characteristics. The aim of our study was to explore the effect of intra-articular injection of ASCs on synovial activation and cartilage destruction during experimental OA.

Methods: ASCs were isolated from inguinal fat surrounding the popliteal lymph nodes and cultured for two weeks according to standard procedures. Experimental OA was induced by injection of collagenase into murine knee joints, which causes instability and cartilage destruction. Collagenase-induced OA is characterized by thickening and activation of the synovial lining layer. ASCs were injected into knee joints at various time-points after induction of OA. OA phenotypes were measured within 8 weeks after induction. Total knee joints were isolated and processed for histology. Synovial activation was measured using an arbitrary scale (0 to 3) and cartilage destruction was measured in 4 different layers of the knee joint (medial and lateral tibia and femur) according to the scoring method of Pritzker et al.. Damage to the cruciate ligaments was scored using an arbitrary scale (0 to 5). Moreover, cartilage formation was assessed by quantification of proteoglycans in Safranin O stained sections, using an arbitrary scale (0 to 5).

Results: A single dose of ASCs (20×10^3 in mouse serum) was injected into the knee joint of mice, 7 days after induction of osteoarthritis. Histology showed that synovial activation was significantly inhibited at day 14 (9%) and day 42 (35%) when compared to serum treated joints. Destruction of cartilage was also significantly inhibited at day 14 (54%) and at day 42 (35%). Inhibition of cartilage destruction was particularly found in the medial tibia. Interestingly, ASC-treatment had a protective effect on the cruciate ligaments. At day 42, damage to the ligaments was reduced by nearly 50% in the ASC treated joints when compared to

controls. In line with that, 88% of the serum injected animals showed a dislocation of the knee joint, in contrast to only 25% of the ASC treated animals. Strikingly, new formation of cartilage was 50% lower in the ASC treated animals. In contrast to early treatment, injection of the same dose of ASCs, 14 days after induction of OA only showed a small inhibiting effect (11%) on synovial activation when measured at day 42. Although cartilage destruction diminished with 28%, these values did not reach significance at that time-point.

Conclusion: Our study indicates that a single injection of ASCs into the knee joints of mice with collagenase-induced osteoarthritis gives protection of synovial activation and cartilage destruction when given shortly (day 7) after induction of experimental OA, probably by protecting cruciate ligament destruction.

1785

Chondrocytes in a Subset of Osteo-Arthritic Patients with Reduced Nuclear FactorkappaB-p65 Levels Are Vulnerable to Apoptosis Induced by Tumor Necrosis Factor Alpha, Which Could Be Released by the Synovium. Onno J. Arntz, Eline A. Vermeij, Esmeralda N. Blaney Davidson, Shahla Abdollahi-Roodsaz, Miranda B. Bennink, Peter M. van der Kraan, Wim B. van den Berg and Fons Van De Loo. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: Chondrocytes play a central role in cartilage pathology as seen in rheumatoid arthritis (RA) and osteoarthritis (OA) patients by a deranged synthesis of extracellular matrix (ECM) components and the enhanced release of ECM destructive metalloproteinases (MMPs). Nuclear factor-kappaB (NF-kappaB) is an important transcription factor in the regulation of MMPs, but is also regarded as a survival factor in cells. We studied the levels of NFkappaB-p65(P65) in articular chondrocytes of osteoarthritis(OA), rheumatoid arthritis(RA), and mouse models and study the biological consequence regarding cell viability.

Methods: Levels of P65 were detected by immunohistochemistry and RT-qPCR levels in human cartilage of RA and OA patients, in murine cartilage of the spontaneous osteoarthritis mouse model (STR/ort) and cartilage from young (14 weeks) and old (>12 months) C57Black/6 mice. To study the functional consequences of decreased level of P65 in chondrocytes the murine H4 chondrocyte-cell line was stably transduced with a lentivirus expressing a short-hairpin RNA against P65 to reduce the P65 protein levels by a RNA interference approach. We selected several cell lines that expressed different amounts of P65 protein. To study the biological consequences, IL-1β, TNFα or conditioned medium of OA synovium was added to the murine chondrocyte-cell line with the lowest P65 level. Cell death was measured by Facs analysis of 7-AAD positive cells. In conditioned medium of OA synovium, levels of TNFα were measured by Luminex. P65 and an apoptotic marker (Caspase-3 active form) were detected by immunohistochemistry in serial paraffin sections of human OA cartilage explants from 6 different patients (4–10 section each patient). To study a relation between P65 in chondrocytes, synovial TNFα production and chondrocyte cell death, in 6 OA patients levels were detected in the same joint.

Results: A subset of OA patients showed low P65 levels (5 out of 10) compared to RA. In STR/ort mice levels were diminished more than 75% when joints became affected. Levels of P65 in normal young and old mice were equal. *In vitro*, adding TNFα to selected chondrocyte cell lines caused only cell death in the cell-line with low levels of P65. IL-1 had no effect on cell viability. Challenging the cell line with low P65 levels with conditioned medium from synovial tissue resulted in more than 60% chondrocyte death in 3 of the 5 OA patients. Synovial TNFα production was detected in the same samples that caused cell death. In human OA cartilage, chondrocyte P65 showed a significant negative correlation with Caspase-3 (an apoptotic marker) staining. Analyzing all parameters of a single joint in 6 OA patients showed that the combination of low endogenous P65 levels in cartilage and synovial TNF production caused chondrocyte cell death.

Conclusion: This study clearly demonstrated that low levels of P65 makes chondrocytes more vulnerable for TNFα, a cytokine which can be produced by the synovial tissue during OA, and that this transcription factor is downregulated in chondrocytes in murine OA and a considerable portion of OA patients.

1786

Adipokines Leptin and Adiponectin Correlate with Matrix Metalloproteinases and Interleukin-6 in Synovial Fluid From Osteoarthritis Patients and Enhance Their Production in Osteoarthritic Cartilage *Ex Vivo*. Katriina Vuolteenaho[1], Anna Koskinen[1], Sami Juslin[1], Riina Nieminen[1], Teemu Moilanen[2] and Eeva Moilanen[1]. [1]The Immunopharmacology Research Group, University of Tampere School of Medicine, and Tampere University Hospital, Tampere, Finland, [2]Coxa Hospital for Joint Replacement, Tampere, Finland

Background/Purpose: Adipokines leptin and adiponectin were first discovered to be produced by adipose tissue and to regulate energy metabolism and apetite. Interestingly, they have recently been found also in inflamed joints and related to the regulation of inflammatory responses. In arthritis, proteolytic degradation of cartilage is mediated by matrix metalloproteinases (MMPs) and interleukin-6 (IL-6) contributes to joint inflammation. In the present study, we investigated the effects of leptin and adiponectin on human OA cartilage, and further, assessed the association of leptin and adiponectin to MMPs and IL-6 in synovial fluid from osteoarthritis patients.

Methods: Cartilage samples for tissue culture were collected from OA patients undergoing total knee replacement surgery. The effects of leptin and adiponectin on MMP and IL-6 production in cartilage were studied in tissue culture experiments and in primary OA chondrocytes and the signaling pathways involved were studied by pharmacological means. Synovial fluid samples were obtained from 100 OA patients (62 females, BMI 30.8±0.6kg/m2, age 70.0±1.0 years; mean±SEM), and concentrations of leptin, adiponectin, MMPs and IL-6 were measured by immunoassay.

Results: Leptin and adiponectin enhanced production of MMPs and IL-6 in OA cartilage and in primary OA chondrocytes in vitro. Leptin-induced MMP-1, −3 and −13 and IL-6 productions were dependent on activation of MAP kinase JNK. In addition, p38 was involved in the leptin-induced MMP-1 and MMP-13 production and ERK1/2 pathway in MMP-1 production. Adiponectin enhanced IL-6, MMP-1 and MMP-3 production in OA cartilage culture was mediated by p38. In addition, Erk1/2 and JNK mediated adiponectin-induced production of IL-6 while contribution of these pathways to MMP-1 and MMP-3 production was smaller and did not reach statistical significance.

To evaluate if the stimulatory effect of these adipokines on IL-6 and MMPs in OA cartilage *ex vivo* could be translated *in vivo*, the concentrations of leptin, adiponectin, MMPs and IL-6 were determined in synovial fluid from OA patients. Synovial fluid leptin correlated positively with MMP-1 ($r=0.41$, $p<0.001$) and MMP-3 ($r=0.51$, $p<0.001$) as well as with IL-6 ($r=0.33$, $p=0.002$). There was also an association between adiponectin and IL-6 ($r=0.39$, $p<0.001$), MMP-1 ($r=0.31$, $p=0.004$) and MMP-3 ($r=0.27$, $p=0.011$).

Conclusion: The findings support the idea of leptin and adiponectin as catabolic and proinflammatory factors in the pathogenesis of OA, and as possible link between obesity and osteoarthritis.

1787

Adenosine A1 Receptor Blockade Inhibits Osteoclast Formation of Mouse Bone Marrow Cells by Downregulation RANKL Signaling. Wenjie He[1] and Bruce N. Cronstein[2]. [1]NYU, New York, NY, [2]New York Univ Medical Center, New York, NY

Background/Purpose: Adenosine is a purine molecule necessary for normal cell metabolism and growth. Previous work from our laboratory has uncovered a critical role for adenosine A1 receptors (A1R) in RANKL-stimulated osteoclast formation both in vivo and in vitro. In this study, we examined the effect of A1R blockade on RANKL-RANK signaling in osteoclast formation.

Methods: Osteoclasts were generated from bone marrow cells extracted from the femurs and tibiae of 4–6-week-old female C57BL/6 mice by exposure to macrophage colony-stimulating factor (M-CSF) and RANKL. The A1R specific antagonist, DPCPX, was added to bone marrow macrophages (BMMs) with RANKL for 5 days.

Results: A1R blockade inhibits the differentiation of BMMs into TRAP+ multinucleated cells by as much as 51% ($p<0.001$, $n=3$; $IC_{50}= 0.1\mu M$). Both western blot analysis of nuclear extracts and ELISA showed that A1R blockade markedly inhibits NF-kappa B activation: p65 nuclear translocation and p65 transcription activity ($p<0.05$, $n=4$). TRAF6, an adaptor protein that regulates RANKL signaling, was immunoprecipitated from BMMs and immunoblotted for TAK1, a serine/threonine kinase that, on activation, forms a complex with TRAF6 and subsequently activates NF-kappaB activity. A1R blockade by DPCPX diminishes TAK1 association with TRAF6 by 44.1% ($p<0.05$, $n=4$).

Conclusion: These results are consistent with the hypothesis that endogenously released adenosine, acting at A1 receptors, provides critical intracellular signals required for downstream activation of NF-κB, an event required for osteoclastogenesis. This study further supports the notion that adenosine A1 receptors may represent a novel therapeutic target to control bone resorption associated with postmenopausal osteoporosis or such pathologic conditions as Rheumatoid Arthritis.

1788

MAPK-Activated Protein Kinase-2 (MK2) Regulates Bone Homeostasis. Tobias Braun[1], Johannes Lepper[1], Gisela Ruiz Heiland[1], Georg Schett[1] and Jochen Zwerina[2]. [1]University of Erlangen-Nuremberg, Erlangen, Germany, [2]Hanusch Hospital, Vienna, Austria

Background/Purpose: Mitogen-activated protein kinase (MAPK)-activated protein kinase 2 (MK2) is an intracellular signal transduction molecule mediating inflammatory signals. Recent data indicate a strong link between the immune system and regulation of bone homeostasis. The aim of our study is to determine whether MK2 contributes to the regulation of osteoclastogenesis and bone turnover.

Methods: Osteoblasts and osteoclasts were generated from wildtype and $MK2^{-/-}$ mice ex vivo. Gene expression of osteoblast- and osteoclast- associated genes was determined by real-time PCR. Bone turnover was analysed by determination of serum levels of RANKL, OPG, CrossLaps and osteocalcin. Bone histomorphometry and μCT were used to determine bone turnover in vivo in wildtype and $MK2^{-/-}$ mice. A four-p point-bending test was used to evaluate bone quality of tibiae from wildtype and MK2- deficient mice. Finally, ovariectomy was performed in wildtype and MK2- deficient mice.

Results: MK2- deficient osteoclast precursor cells showed impaired differentiation capacity ex vivo and expression of osteoclast- specific genes was reduced. MK2- deficient osteoblasts showed an increased expression of OPG in vitro. Bone histomorphometry and μCT analysis revealed an increased bone mineral density in MK2- deficient mice. Moreover, four point bending tests demonstrated a higher mechanical stability of MK2- deficient bones. In vivo, the number of osteoclasts was reduced in $MK2^{-/-}$ mice while there was no difference in the number of osteoblasts. Serum osteocalcin and CrossLaps levels were reduced MK2 deficient mice further indicating a low bone turnover. Moreover, serum levels of OPG but not RANKL were increased in $MK2^{-/-}$ mice. Loss of MK2 partially protected mice from ovariectomy- induced bone loss.

Conclusion: MK2- deficient mice have increased bone mineral density associated with impaired osteoclast- differentiation. Further, MK2 is involved in estrogen- related bone loss. Thus, MK2 plays an important role in bone homeostasis.

1789

Human MSCs Ameliorate Bone Erosion in TNF-Alpha Transgenic Mice. Joy M. Whitbred[1], Robert M. Lowe[2], Donald P. Lennon[3], Joseph Molter[4], Chris A. Flask[4], Tracey L. Bonfield[2], Arnold I. Caplan[3] and Nora G. Singer[1]. [1]Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [2]Department of Pediatrics, Case Western Reserve University, Cleveland, OH, [3]Skeletal Research Center, Case Western Reserve University, Cleveland, OH, [4]Department of Radiology, Case Western Reserve University, Cleveland, OH

Background/Purpose: Human Mesenchymal Stem Cells (hMSCs) are promising immune modulators with therapeutic potential to treat a wide variety autoimmune diseases. Pleiotropic hMSCs have shown tremendous promise as immunomodulatory therapeutic agents in mouse models of asthma, inflammatory bowel disease (IBD) and multiple sclerosis (MS). However, their role in modulating bone erosions in a mouse model with excess TNF-alpha driven arthritis (TNF-alpha Tg) has not been explored. The purpose of these studies was to quantify the effects of hMSCs on disease progression in TNF-alpha Tg mice using a sensitive imaging technique prior to the onset of clinically apparent symptoms and correlate with immunological and histological outcomes.

Methods: Interperitoneal (IP) injections of 1×10^6 hMSCs or PBS (sham injection) in TNF-alpha Tg or non-Tg control mice were administered every two weeks beginning at age 6.5 weeks and for 8 weeks thereafter. Isosurface CT renderings, joint measurements and clinical scores were recorded. Mice were sacrificed at age 14.5 weeks and histological analysis of joints was performed.

Results: Joint erosion was first detected using isosurface CT at age 8.5 weeks in TNF-alpha Tg compared with non-Tg and C57BL/6 controls. Differential disease progression was observed by CT at age 12.5 weeks in TNF-alpha Tg mice treated with hMSCs versus those that were sham-injected. Untreated 16 week old TNF-alpha Tg mice showed extensive bone erosions compared to controls using isosurface CT. As might be anticipated in the presence of constitutively expressed TNF-alpha, TNF-alpha Tg mice had some progression of arthritis despite hMSC treatment, as evidenced by joint measurements and clinical scores. Sham-treated TNF-alpha Tg mice had enhanced erythema and reduced range of motion at 14.5 weeks compared to those treated with hMSCs. Histologically, TNF-alpha Tg mice treated with hMSCs had an immature pannus development, with little or no infiltration of joint space and insignificant cartilage and bone erosions compared to sham-treated TNF-alpha Tg mice, where loss of proteoglycan, loss of joint architecture, and highly developed mature pannus was observed.

Conclusion: hMSC treatment attenuates bone erosion and joint damage in the TNF-alpha Tg model of arthritis. Isosurface CT imaging is useful to detect and quantify bone erosion at very early stages in TNF-alpha-driven arthritis. These studies provide proof of concept of the potential therapeutic efficacy of hMSC therapy in inflammatory arthritis. These data suggest that hMSCs could modulate the immune-mediated destruction of joints in early RA.

The Role of Mir-29 in the Chondrogenic Differentiation of Mesenchymal Stem Cells. D. Guerit[1], D. Philipot[2], P. Chuchana[1], JM Brondello[2], Christian Jorgensen[3] and Daniele Noel[2]. [1]INSERM U844, Montpellier, France, [2]UM1, Montpellier, France, [3]CHU Lapeyronie, Montpellier, France

Background/Purpose: Mesenchymal stem or stromal cells (MSC) are multipotent cells that can differentiate into different lineages, particularly osteoblasts and chondrocytes. The differentiation process of MSC is regulated by various molecules among which Sox9 and Runx2 are key transcription factors leading, respectively to chondrogenesis or osteogenesis. Recently, a new class of regulating factors, namely microRNAs (miRs), has been shown to be important for differentiation processes but few data are available on the identity of miRNAs regulating chondrogenesis. The objective of my PhD project is therefore to identify microRNAs involved in the chondrogenic differentiation of MSC.

Methods: We performed the analysis of miRNA arrays obtained from samples of MSC (day 0) and MSC-derived pre-chondrocytes (day 3). We then compared the expression of the modulated miRNAs to that of mRNAs originating from another transcriptomic analysis from similar samples at identical time points. Using prediction software, we observed that a little number of transcription factors can regulate the majority of miRNAs. Among transcription factors, the master gene of chondrogenesis Sox9 and also YY1, which is known to negatively regulate chondromodulin during chondrogenesis, might bind to 71 out of 75 miRNAs. In particular, Sox9 and YY1 putatively bind to the promoter region of miR-29 which is down regulated at day 3.

Results: We confirmed by real-time RT-PCR that the expression level of miR-29 continuously decreases until the end of the differentiation (day 21). Transfection of Sox9 or YY1 in the Stro-1A MSC cell line significantly reduced the expression of miR-29. Moreover, transfection of both factors almost abolished its expression suggesting that they negatively regulate miR-29 after binding to the promoter region. The effect of gain- and loss-of-function of miR-29 during the chondrogenic differentiation of MSCs by transfecting pre-miRs or antago-miRs confirms the role of miR-29 during chondrogenesis.

Conclusion: Our preliminary data show that, during chondrogenesis, miR-29 expression is down-regulated, probably through the interaction of Sox9 and YY1 on the miR promoter region. Because miR-29 has been described to regulate different targets (DKK1, sFRP2, Kremen2 and CDK6 whose expression decreases during differentiation), future experiments will investigate whether these target genes are modulated by miR-29.

1791

Activation of AMP-Activated Protein Kinase (AMPK) Alleviates Endoplasmic Reticulum (ER) Stress and Inhibits Catabolic Responses to Biomechanical Injury in Chondrocytes. Freyr Petursson[1], Xianling Zhao[1], Robert Terkeltaub[2] and Ru L. Bryan[1]. [1]UCSD/VAMC, San Diego, CA, [2]VA Medical Ctr, San Diego, CA

Background/Purpose: Many cell stresses trigger protein misfolding in the ER, and the consequent unfolded protein response (UPR) can either trigger redox stress, inflammation, and apoptosis, or, if successful, restores ER homeostasis by upregulation of chaperones and protein folding catalysts.

AMP-activated protein kinase (AMPK) is a master regulator of energy homeostasis and cellular metabolism. AMPK activity is decreased in osteoarthritic (OA) and aged chondrocytes/cartilage, and drops in chondrocytes stimulated by IL-1b and TNFa; conversely, activation of AMPK inhibits chondrocyte catabolic responses to IL-1b and TNFa (Arthritis Rheum 2011, epub). Here, we tested the hypothesis that activation of AMPK alleviates ER stress and catabolic responses in articular chondrocytes in response to inflammation and biomechanical injury.

Methods: Primary human and/or bovine knee articular chondrocytes were pre-treated with AMPK activators AICAR (0.5–1 mM) or A769662 (0.25–0.5 mM), or the AMPK inhibitor Compound C (10 mM) for 2 h before stimulation with IL-1b (10 ng/ml), TNFa (10 ng/ml), and the ER stress positive control inducer tunicamycin (TM, 2.5 mg/ml) for 18 h. Also, chondrocytes embedded in alginate molds were subjected to sublethal biomechanical injury (22% maximum axial compression, 12% amplitude, 0.5 Hz) for 16 hours. Knockdown of AMPKa1/2 in primary human knee chondrocytes was achieved via siRNA. The cell lysates from each condition were analyzed for protein expression of the UPR activation markers GRP78 and CHOP, and MMP-3 by SDS-PAGE/Western blot. The conditioned media was assayed for release of nitric oxide (NO) and sulfated GAG by Greiss reaction and dimethylmethylene blue (DMMB) assay, respectively.

Results: IL-1b and TNFa modestly induced GRP78, whereas TM strongly induced both GRP78 and CHOP protein expression in chondrocytes. These effects were blunted by AICAR and A-769662, but significantly enhanced by Compound C. Knockdown of AMPKa1/2 enhanced induction of expression of GRP78 and CHOP by TM in chondrocytes. Last, biomechanical injury rapidly induced GRP78 and CHOP in chondrocytes, and this response was inhibited by AICAR and A-769662. Under these conditions, AMPK activators blunted catabolic responses of chondrocytes (including induction of NO and GAG release and MMP-3 expression).

Conclusion: Activation of AMPK alleviates ER stress and inhibits catabolic responses in articular chondrocytes subjected to inflammatory stress and biomechanical injury. Targeted activation of AMPK by pharmacological means has therapeutic potential to protect chondrocytes from excessive catabolic responses in part by successfully alleviating ER stress.

Apolipoprotein E and Undercarboxylated Osteocalcin Are Associated with Bone Fragility but Not with Bone Mineral Density in Osteoarthritis Patients. Ana M. Rodrigues[1], Joana Caetano-Lopes[2], Ana Lopes[3], Ana Catarina Vale[4], Inês Aleixo[3], Inês P. Perpétuo[2], Ana Sofia Pena[3], Alexandra Faustino[3], Alexandre Sepriano[3], Joaquim Polido-Pereira[5], Elsa Vieira-Sousa[6], Bruno Vidal[7], JC Romeu[8], PM Amaral[4], Luis G. Rosa[4], José A. Pereira da Silva[9], Jacinto Monteiro[10], Maria Fátima Vaz[4], J. E. Fonseca[5] and Helena Canhão[5]. [1]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal, [2]Rheumatology Research Unit, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [3]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [4]Department of Mechanical Engineering, Instituto Superior Técnico, ICEMS, Lisbon, Portugal, [5]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisboa, Portugal, [6]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [7]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal., Lisbon, Portugal, [8]Hospital de Santa Maria, Lisbon, Portugal, [9]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal, [10]Orthopaedics Department, Hospital de Santa Maria, Lisbon, Portugal

Background/Purpose: Apolipoprotein E (apoE) gene polymorphisms and undercarboxylated osteocalcin (ucOC) and vitamin K have been associated with fragility fractures and low BMD in general population. The aim of this work was to study whether the effect of apoE gene polymorphisms, seric apoE levels and ucOC influence trabecular bone biomechanics and bone mineral density (BMD) in patients submitted to hip replacement surgery due to advanced primary osteoarthritis.

Methods: Patients were evaluated for established clinical risk factors for fracture. A dual X-ray absorptiometry (DXA) was performed. ApoE genotyping was performed at positions rs429358 and rs7412. Fasting blood samples were collected at the time of surgery to assess the following parameters: seric apoE, ucOC, Vitamin K, LDL cholesterol, triglycerides and bone turnover markers. Femoral epiphyses were collected and trabecular bone cylinders were drilled in order to perform compression mechanical tests and analyze bone strength and stiffness.

Results: Forty-four patients were studied (median 70 years of age, 55% women and 90% postmenopausal, BMI of 27.2 Kg/m2). 6.8% had prevalent fragility fractures, 36% had normal BMD and 64% were osteopenic. The apoE genotype distribution was in accordance with Hardy-Weinberg equilibrium and the E4 allele, previously documented as the risk allele, was present in 16% of the patients. This allele was significantly associated with lower trabecular strength ($p=0.004$) and stiffness ($p=0.070$), adjusted for age and gender, but not with BMD. Moreover, E4 allele was associated with higher levels of markers of bone formation: ALP ($p=0.067$), BSALP ($p=0.085$) and P1NP ($p=0.062$). We also found that ucOC was negatively correlated with strength ($p=0.077$) and stiffness ($p=0.047$), regardless of patients gender, age or vitamin K, but not with BMD. ApoE levels were also associated with strength ($p=0.056$; $R=-0.322$) and stiffness ($p=0.001$; $R=-0.513$).

Conclusion: Other studies have shown that advanced hip osteoarthritis can be associated with a higher BMD, but is not a protective factor for fragility fractures. Our observations suggest that in osteoarthritis patients apoE4 allele, seric apoE and ucOC are biologic risk factors for bone fragility in a more independent way from BMD than in the general population.

1793

Alarmins s100a8 and s100a9 Elicit a Higher Catabolic Response in Osteoarthritic Chondrocytes Compared to Normal Chondrocytes That Is Toll Like Receptor 4 Dependent. Rik Schelbergen[1], Arjen B. Blom[1], Martijn H.J. van den Bosch[1], Annet Sloetjes[1], Thomas Vogl[2], Johannes Roth[2], Wim B. van den Berg[1] and Peter L.E.M. van Lent[1]. [1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Muenster, Munster, Germany

Background/Purpose: S100A8 and S100A9 are classified as damage associated molecular patterns (DAMPs) or alarmins and are found in high amounts in the synovial fluid of rheumatoid arthritis (RA) and osteoarthritis (OA) patients. Previously, we found that S100A8 and S100A9 are associated with cartilage degradation in murine collagenase-induced OA. We also showed that S100A8 and S100A9 stimulate expression and activity of matrix metalloproteinases (MMPs) and pro-inflammatory cytokines in murine chondrocytes.

In the current study, we investigated whether and via which receptor S100A8 and/or S100A9 can have a catabolic effect on chondrocytes from OA patients. Furthermore, we compared the S100-effect on OA chondrocytes with non-OA chondrocytes.

Methods: In cartilage from end stage OA, we stained for S100A8 and S100A9 protein, MMP-1 and −3 and a cartilage breakdown epitope specific for MMPs (VDIPEN) using immunohistochemistry. Isolated chondrocytes from OA and non-OA donors were stimulated with S100A8 and S100A9 protein. mRNA levels of MMPs, cytokines and cartilage matrix molecules were determined with RT-qPCR, protein levels of MMPs and cytokines with Luminex. For receptor blocking studies, specific inhibitors for Toll-like receptor 4 (TLR4) (intracellular TAK242) and RAGE and carboxylated glycans (blocking antibodies) were used.

Results: In cartilage of OA patients, localisation of S100A8 and S100A9 protein was found close to chondrocytes and was associated with proteoglycan (PG) depletion, MMP1 and −3 and VDIPEN expression.

Stimulation of OA chondrocytes with S100A8 and S100A9 caused a significant upregulation of MMP1, −3, −9 and −13 at the mRNA level (5.7, 5.0, 4.0, and 3.1-fold respectively). The upregulation was confirmed on protein level for MMP-1, −3 and −13 (2.3, 3.1 and 3.6-fold respectively). Moreover, S100A8 and S100A9 caused a huge increase in cytokine and chemokine expression. IL-6, IL-8 and MCP-1 were all greatly increased by S100A8 and S100A9 at both the mRNA (15.1, 24.0 and 3.7-fold respectively) as well as the protein level (29.1, 49.7 and 7.7-fold respectively). Moreover, the expression of anabolic markers (aggrecan and collagen type II) was significantly reduced at the mRNA level (2.7 and 2.7-fold decrease respectively).

Blocking TLR4 almost completely inhibited the upregulation of MMP-3, IL-6, IL-8, MCP-1 and collagen type II by S100A9 in OA chondrocytes. In contrast, blocking of carboxylated glycans and RAGE did not alter the S100-effects.

Finally, the catabolic effect of S100A8 and S100A9 was significantly more pronounced in chondrocytes from OA patients when compared to non-OA. TLR4 mRNA expression was enhanced in OA chondrocytes, which might explain the increased sensitivity.

Conclusion: S100A8 and S100A9 have a catabolic effect on human chondrocytes that is dependent on TLR4. OA chondrocytes are more sensitive for S100-stimulation than normal chondrocytes.

This study underlines the potential of S100A8 and S100A9 as mediators of cartilage damage during OA.

Periostin, An Osteoblast Stimulating Factor, Regulates Cartilage Metabolism Via MMP-13 Activation. Mukundan Attur[1], Glyn Palmer[1], Yuki Tachida[2], Seiichiro Kumakura[2], Kohei Shimada[2] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Daiichi-Sankyo Co. Ltd.,, Tokyo, Japan

Background/Purpose: Periostin (POSTN), a gamma-carboxylated extracellular matrix protein originally identified as an osteoblast stimulating factor. This study investigates its expression in OA cartilage and regulation of chondrocyte metabolism.

Methods: Cartilage slices were obtained from the advanced OA patients (age 45–80 years) undergoing knee replacement surgery. Non-arthritic knee cartilages were obtained from autopsy patients within 24h (NDRI, Philadelphia). Predesigned TaqMan PCR primers were purchased from Applied Biosystems. Lentiviral shRNA targeting POSTN were purchased from Sigma. Matrix metalloproteinases proMMP-1 and proMMP-13 ELISA kits were from R&D Systems. Degradation products of type II collagen was measured using CTX II -based assay kit.

Results: We studied the expression of POSTN in pools (n=10) of OA and age-matched non-diseased cartilage using U133 Affymetrix microarray. POSTN was overexpressed 2–4 fold in OA cartilage ($p<0.035$) compared to non-diseased controls. Verification by real-time PCR confirmed POSTN upregulation. Surgical-induction of OA in rats by anterior cruciate ligament transection (ACLT) and destabilization of the medial meniscus (DMM) models also significantly increased POSTN (3–11 fold) from 2–8 weeks after surgery. In OA chondrocytes isolated from human tibial cartilage, POSTN mRNA levels, determined by qPCR, were inhibited 3-fold in the presence of inflammatory cytokines IL-1β and TNFα. In contrast, TGFβ-1 (2 ng/ml) significantly increased POSTN expression (2–40-fold). In functional assays, exogenously added (1–30 ug/ml) or overexpression of POSTN significantly increased MMP-13 expression and activity ($p<0.02$) in primary human OA, rat and bovine chondrocytes. Conversely; knock down of endogenous POSTN using targeted lentiviral shRNAs significantly decreased MMP-13 expression in the presence of TGF-β1. In OA cartilage explants cultures, PSTN increased cartilage degeneration, evidenced by increased release of collagen (C1, 2C) and GAG fragments in culture supernatants. To determine whether PSTN is a hypertrophic marker of chondrocytes we examined its expression in chondrogenesis assays using human bone marrow-derived MSCs and immature murine costal chondrocytes undergoing maturation. In both assays PSTN expression was upregulated in a time-dependent manner, and expression coincided with MMP-13, Alkaline Phosphatase and F-spondin. These findings suggest that PSTN expression is associated with chondrocyte terminal differentiation.

Conclusion: Together, these studies indicate that PSTN is a marker of OA cartilage and chondrocyte hypertrophy. In OA, PSTN may contribute to disease pathogenesis by promoting cartilage degradation via induction of MMP-13.

1795

Sirt1 Deficient Mice Exhibit An Altered Cartilage Phenotype. Odile H. Gabay Engel[1], Christelle Sanchez[2], Mona dvir-Ginzberg[3], Viktoria Gagarina[1], Eun Jin Lee[1], Kristien J. Zaal[1], Michael McBurney[4] and David J. Hall[1]. [1]NIH, Bethesda, MD, [2]Bone and Cartilage Research Unit, Liege, Belgium, [3]Hebrew University- Hadassah Ein Kerem, Jerusalem, Israel, [4]Ottawa Hospital, Ottawa, ON

Background/Purpose: Cartilage degenerative diseases such as osteoarthritis, are age-related. The histone deacetylase Sirt 1 has been shown as an anti-aging protein. We previously demonstrated that Sirt 1 regulates apoptosis and cartilage-specific gene expression in human chondrocytes. Sirt 1 is also a potent inhibitor of the matrix metalloproteinases. To determine if Sirt 1 plays a protective role on cartilage homeostasis *in vivo*, we investigated Sirt1 KO mice to characterize their cartilage and try to understand the mechanisms underlying a phenotype, such as cartilage breakdown or apoptosis.

Methods: Articular cartilage was harvested form hind paws and knees of 1-week to 6-month old mice carrying wildtype, null or point mutations affecting the Sirt1 gene. The cartilage was processed for histology, immunohistochemistry, or used to establish cultures of chondrocytes.

Results: We found that articular cartilage tissue sections from Sirt1 KO mice at any age exhibited low levels of type 2 collagen, aggrecan and glycosaminoglycans. In contrast, protein levels of MMP-8, MMP-9 and MMP-13, were elevated in the SirT1 KO mice, leading to an increase of cartilage breakdown. The apoptotic process was shown to be elevated in these mice. Moreover, PTP1b, protein tyrosine phosphatase b, a chondrocyte proapoptotic protein elevated in OA, was elevated in the Sirt 1 KO mice.

Conclusion: The findings from this animal model demonstrate that Sirt1 KO mice present an altered cartilage phenotype: The apoptotic process and the cartilage breakdown were elevated in these mice.

1796

Rac1 and NADPH Oxidase Regulate NFκB Activity and MMP-13 Expression in Chondrocytes in Response to Integrin Activation. Richard F. Loeser, Elizabeth A. Erickson and David A. Long. Wake Forest University, Winston-Salem, NC

Background/Purpose: Matrix fragments, including fibronectin fragments (FN-f) that signal through the $\alpha5\beta1$ integrin, accumulate in the matrix during the development of OA stimulating chondrocyte cytokine, chemokine and MMP production. The signaling pathways activated by FN-f require generation of reactive oxygen species (ROS) as second messengers. The small GTPase Rac1 can mediate ROS generation through regulation of the NADPH oxidase (NOX) complex. We tested the hypothesis that Rac1 and NOX are required for FN-f stimulation of MMP-13 expression by articular chondrocytes and determined the mechanisms involved.

Methods: Human articular chondrocytes, isolated from normal ankle cartilage obtained from adult tissue donors or OA knee cartilage removed during joint replacement, were cultured in primary high density monolayers or in alginate beads. Serum-free cultures were treated with a recombinant FN-f that activates the $\alpha5\beta1$ integrin. Rac1 was inhibited with the specific inhibitor NSC23766 (100μM) or knocked-down by use of siRNA and NOX was inhibited with VAS 2870 (25μM). Rac 1 activity was increased using an adenoviral construct expressing constitutively active (CA) Rac 1. MMP-13 protein was measured by immunoblotting or ELISA of conditioned media and expression by real-time PCR. ROS production was quantified by detection of DCFDA fluorescence, a reactive oxygen species sensitive dye. MAP kinase activation was measured by immunoblotting with phospho-specific antibodies and NFkB activity using a promoter-reporter assay and immunoblotting for p65 translocation into the nucleus. Rac activity was measured by an activity-based ELISA kit and using a specific antibody that recognizes active (GTP bound) Rac.

Results: Chemical inhibition of Rac1 or transfection with Rac1 siRNA significantly reduced basal and FN-f stimulated ROS production by normal chondrocytes. The Rac inhibitor, the NOX inhibitor and Rac siRNA each blocked FN-f stimulated MMP-13 expression and production, while expression of CA Rac1 increased MMP-13 production. The Rac inhibitor also significantly reduced basal MMP-13 production by OA chondrocytes and blocked FN-f stimulation of MMP-13 production by cells cultured in alginate. Confocal microscopy revealed active Rac1 in a perinuclear distribution. Neither NOX or Rac inhibition had an affect on FN-f stimulation of MAP kinase phosphorylation. However, NOX inhibition blocked FN-f stimulated p65 phosphorylation. Both Rac and NOX inhibition blocked p65 translocation into the nucleus and reduced NFkB promoter-reporter activity. The basal activation of Rac1 was higher in OA chondrocytes than normal chondrocytes and immunocytochemistry revealed active Rac1 in OA but not normal cartilage in situ.

Conclusion: These results demonstrate for the first time that Rac1 and NOX regulate MMP-13 expression in response to integrin activation by FN-f. The findings are consistent with a role for NOX in NFκB activation via p65 phosphorylation followed by translocation to the nucleus which required Rac1 activity. The presence of activated Rac1 in OA but not normal cartilage together with the findings that Rac1 can positively regulate NFκB and MMP-13 suggests Rac1 may be an important mediator of matrix destruction in OA.

1797

Disease-Specific Induction of Fibroblast Activation Protein Alpha in Rheumatoid Arthritis. Christina Wunrau[1], Marianne Heitzmann[1], Corinna Wehmeyer[1], George Kollias[2], Thomas Pap[1] and Berno Dankbar[1]. [1]University Hospital Muenster, Muenster, Germany, [2]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece

Background/Purpose: The progressive destruction of articular cartilage and bones are hallmarks of rheumatoid arthritis (RA) and osteoclast differentiation and migration constitutes critically to process. The Fibroblast Activation Protein alpha (FAPa) is an integral membrane serine protease that plays a major role in cell migration, wound healing, and metastasis. Based on recent studies that have implicated membrane- bound serine proteases in osteoclast migration, we sought to study the expression of FAPa in RA as well as in tumor necrosis factor alpha transgenic (hTNFtg) mice and analyze its role in osteoclastogenesis under inflammatory conditions.

Methods: The *in vivo* expression of FAPa was determined by immunohistochemistry in human synovial tissues of RA and osteoarthritis (OA) patients as well as in hind paws of hTNFtg mice, which develop an RA-like destructive arthritis. The *in vitro* expression of FAPa was analyzed in freshly differentiated osteoclasts cocultured with osteoblasts, RA or OA fibroblast like synoviocytes (FLS) by PCR. Osteoclast differentiation was verified by tartrate-resistant acid phosphatase (TRAP) staining. The *in vitro* collagenolytic activity of preosteoclasts was evaluated by western blot analyses of degraded collagen type I.

Results: RA synovial tissues demonstrated a high expression of FAPa throughout the tissues whereas in OA samples FAPa was expressed only in the lining layer. *In vitro*, no expression of FAPa was found in differentiated preosteoclasts and osteoclasts, but coculture experiments showed that RA FLS, but not OA SF or osteoblasts, induce the expression of FAPa in preosteoclasts and osteoclasts. Consistent with the selective induction of FAPa in osteoclasts by RA-FLS, FAPa expression was detected in osteoclasts at the invasion front of the hyperplastic synovial tissues in the joints of hTNFtg mice. FAPa expressing preosteoclasts showed an MMP independent cleavage of native collagen type I.

Conclusion: The disease-dependent expression pattern of FAPa by osteoclasts in human RA and TNFtg mice suggest a role for FAPa in bone erosion in RA. The selective induction of FAPa in preosteoclasts and osteoclasts by RA-FLS indicate that FAPa may be regulated through the interaction with the pannus tissue. Furthermore, the collagenolytic activity of the FAPa expressing preosteoclasts point to a possible additional role of this serine protease in osteoclast precursor migration.

1798

Theragnostic Nanosomes for Detection and Treatment of Early Osteoarthritis and Cartilage Damage. Karen A. Hasty[1], Hongsik Cho[2], Eugene Pinkhassik[3] and John M. Stuart[4]. [1]University of Tennessee Health Science Center, VA Medical Center, Memphis, TN, [2]University of Tennessee Health Science Center, Memphis, TN, [3]University of Memphis, Memphis, TN, [4]VA Medical Center, University of Tennessee Health Science Center, Memphis, TN

Background/Purpose: Osteoarthritis (OA) is a common condition with few preventive therapies. One obstacle to developing therapies is a reliable method of detecting and measuring progression in the early stages of disease when intervention may prove more beneficial. This application uses fluorescent, targeted nanosomes (200 nm liposomes) developed as a theragnostic delivery system. The nanosomes incorporate a monoclonal antibody (Mab) to native type II collagen (CII) and a near infrared emitting fluorescent dye (NIF) that can be quantitatively visualized *in vivo*. CII in normal cartilage is not available for binding and is only unmasked when the surface of the cartilage is damaged. We show targeted nanosomes selectively bind exposed CII and can be quantitated using an external imaging system in both inflammatory and degenerative arthritis.

Methods: Animal All animal studies were approved IACUC protocols at the University of Tennessee Center for the Health Sciences. Dunkin-Hartley guinea pigs ranging in age 3–24 month were obtained from The Jackson Laboratory. To induce inflammatory arthritis in mice, DBA/1J mice were immunized with CII in complete Freund's adjuvant and observed until the onset of inflammation. Two months after inflammation subsided, mice were injected with NIF-MabCII nanosomes or control NIF-MabCon nanosomes.

Results: *In vivo* imaging was done at 24 hours post-injection using a Lumina II, In Vivo Imaging System (IVIS), (Caliper Life Sciences, MA) with an Indocyanine Green (ICG) Filter set (excitation 710–760nm, emission 810–875 nm). With imaging, older guinea pigs showed a significant difference between intraarticularly injected nanosomes with MabCII and those bound to control Mab. The NIF-MabCII showed a high degree of binding and exhibited fluorescence corresponding to joint degradation. This binding is proportional to the histopathological stage of cartilage damage in the joint. The administered nanosomes conjugated to a control antibody showed minimal binding. A minimal amount of binding was also observed in the young guinea pig for both control and experimental nanosomes. IVIS imaging of the dissected joint tissue surrounding the joint in both young and old samples showed no soft tissue fluorescence. Dissection showed binding of the NIF-MabCII-nanosomes was principally to the medial condyle. Histopathology of the joint showed the young joint had limited degradation while older joints displayed osteoarthritis with characteristic cartilage damage. IVIS imaging showed that nanosomes labeled with NIF-MabCII targeted directly to knee joints of animals that had previously shown evidence of CIA, when injected intravascularly or intraarticularly. Controls were negative.

Conclusion: Specific binding of nanosomes conjugated to type II collagen antibodies in joints with spontaneous OA and those damaged by CIA was seen. Collected data indicated the amount of nanosome binding is proportional to the level of cartilage damage. Adding drugs or cytokines inside the nanosomes may offer a method for diagnosis and treatmetn of early OA before clinical presentation of the disease.

Sclerostin Levels in Rheumatoid Arthritis and Its Relationship to Disease Activity and Radiographic Joint Damage. M. Vis[1], K. Britsemmer[2], A.C. Heijboer[1], N. Bravenboer[1], D. van Schaardenburg[2] and W. F. Lems[1]. [1]VU University medical center, Amsterdam, Netherlands, [2]Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands

Background/Purpose: Joint erosions are the hallmark of rheumatoid arthritis (RA). They are caused by an increased bone resorption. However there in no increased bone formation to prevent or heal these erosions. The Wnt pathway is important in the control of bone formation through regulation of osteoblast activity. Sclerostin is an important regulator of the Wnt pathway by blocking Wnt binding to its receptor and thereby inhibiting bone formation.

In this study we investigated whether sclerostin levels are increased in RA patients compared to healthy controls and whether there is an association with disease activity and radiographic damage.

Methods: Female patients from the Amsterdam Early Arthritis Cohort (EAC) were studied. Data and samples at 1 year after inclusion were used in this study. Consecutive patients were selected from the database on the basis of high or low disease activity (DAS-28 $<$ or $>$ 3.2) until both groups consisted of 25 patients. Ten healthy female students and 10 healthy postmenopausal women served as healthy controls. Sclerostin was measured using ELISA (Biomedica, Wien, Austria).

Results: In the 50 RA patients, mean age was 57 ($\pm$13), mean disease duration 6 months ($\pm$4), median Sharp van der Heijde score 2.5 (0–110) and mean DAS-28 3.6 ($\pm$1.2). Sclerostin levels were 28.7 pmol/l (12.1) in all RA patients, 30.7 pmol/l (12.9) in post menopausal women and 9.6 pmol/l (5.9) in healthy female students, which was significantly lower than the other 2 groups. ($p < 0.001$) In the RA patients sclerostin levels were significantly correlated with age (r 0.29, $p<0.05$) and inversely with DAS-28 (-0.28, $r<0.05$). No correlation was found between Sharp van der Heijde scores and sclerostin levels ($p=0.453$).

Conclusion: Sclerostin levels are low in healthy pre-menopausal women compared to healthy postmenopausal women and female RA patients.In female RA patients sclerostin levels are associated with age and inversely with disease activity. These data indicate that the decreased bone formation in active RA is not caused by increased sclerostin levels.

1800

A Novel Method of Basic Calcium Phosphate Crystal Quantification in Synovial Fluid Using a Tetracycline Binding Assay. Jonathan Kushi[1], Claudia Gohr[1], Brian Jubeck[1], Peter A. Simkin[2] and Ann K. Rosenthal[1]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]University of Washington, Seattle, WA

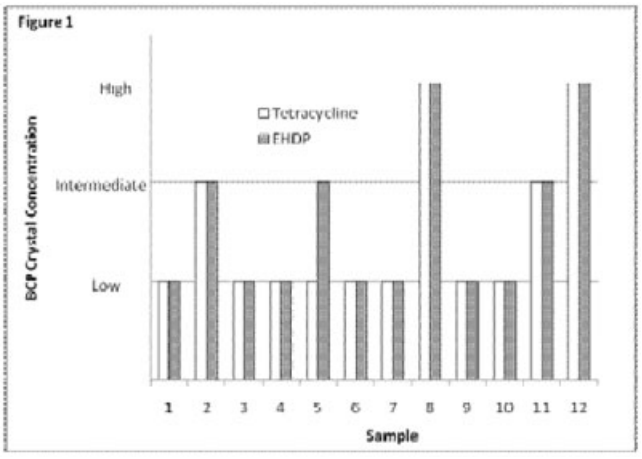
Background/Purpose: Basic calcium phosphate (BCP) crystals are known to play an important role in osteoarthritis; however, analysis of these crystals has been previously limited by difficulties with detection. Tetracycline, which is known to bind hydroxyapatite, has also been shown to qualitatively identify BCP crystals using fluorescence microscopy. We have developed an assay to quantify BCP crystal concentration in synovial fluid using tetracycline binding. This assay was run in parallel with the well

established Carbon-14 labeled etidronate (EHDP) binding assay as a basis for comparison.

Methods: Synovial fluid was collected from osteoarthritis patients and screened for visible crystals under polarizing microscopy. Crystal-negative samples were treated with hyaluronidase and trypsin and spun down. Pellets were divided equally to be run in both the tetracycline and EHDP assays. The first sample portion was incubated with oxytetracycline for 60 minutes at 37°C. Fluorescence of the fluid was measured using an excitation spectrum of 450/50 nm and emission spectrum of 540/35 nm. Synthetic BCP crystals at known concentrations were also measured for fluorescence to derive a comparative standard curve. The remaining sample portion was incubated with C-14 EHDP using established methods and measured in the scintillation counter to estimate percentage bound. A standard curve for the EHDP assay using synthetic BCP crystal was also generated.

Results: The tetracycline binding assay produced a linear standard curve with an r^2 value of 0.99 using BCP concentrations from 25–250 mg/ml. This standard curve was consistently reproducible with similar correlation coefficients. Twelve fluid samples were measured and an estimated BCP concentration was derived from the tetracycline standard curve. Fluorescence values within the upper tertile of the standard curve were determined to be of high concentration, the lower tertile of low concentration and the middle tertile of intermediate concentration. Samples from the EHDP assay were also stratified and assigned high, low and intermediate concentrations based on percent bound values.

In the tetracycline binding assay, 2 samples were of high concentration, 8 were of low concentration and 2 were intermediate. The EHDP assay demonstrated similar results in 11 of the 12 samples with stratification into identical tertiles as the tetracycline assay (2 high, 7 low and 2 intermediate). One sample did not correlate, measuring low concentration in the tetracycline assay, but intermediate in the EHDP assay (Figure 1).



Conclusion: Tetracycline binding can be used to estimate BCP crystal concentration in synovial fluid. This method is reproducible and comparable to an existing standard, C-14 EHDP binding. Tetracycline has advantages over EHDP in that it is both non-radioactive and readily available.

Revisiting Chemical and Morphological Diversity of Calcium-Containing Crystals in Human Osteoarthritic Menisci. Christelle Nguyen[1], Frédéric Lioté[1], Didier Hannouche[2], Valérie Bousson[3], Frédéric Velard[1], Michel Daudon[4], Dominique Bazin[5] and Hang-Korng Ea[1]. [1]UMR-S 606, INSERM & Paris Diderot University; PRES Sorbonne Paris-Cité; Lariboisière Hospital, Paris, France, [2]Orthopaedic Surgery Department; Lariboisière Hospital (AP-HP); Univ. Paris Diderot, Sorbonne Paris-Cité, Paris, France, [3]Radiology Department; Lariboisière Hospital (AP-HP); University Paris Diderot, Paris, France, [4]Service de Biochimie A; Necker Hospital (AP-HP), Paris, France, [5]Laboratoire de Physique des Solides; Paris Sud University, Orsay, France

Background/Purpose: Calcium-containing crystals (CC), including basic calcium phosphate crystals (BCPs) and calcium pyrophosphate crystals (CPPs) are associated with destructive forms of osteoarthritis (OA). Mineralization of several joint structures, including articular cartilage and menisci, is an indissociable process of end-stage OA, that occurs independently of ageing. We aimed to assess prevalence and biochemical composition of mineral phases in human OA menisci, and to determine their morphological aspects.

Methods: Fourteen patients (12 females and 2 males) who underwent total knee replacement (TKR) surgery for primary OA were prospectively included. A 24-year-old woman who underwent TKR for chondrosarcoma, and a 28-year-old man who had meniscectomy for medial meniscus tear served as non-OA control subjects. Clinical data and preoperative knee plain radiographs were retrieved from clinical charts. Specimen included lateral meniscus and medial meniscus, when this latter was available. For each meniscus, 2 samples were collected, consisting in 1-mm-thick slices. Slices were cut tangentially to the surface of the meniscus center part, within its superficial and deep layers, respectively. Menisci calcifications prevalence and semi-quantification were obtained using digital contact radiography (DCR). Biochemical composition was assessed using Fourier-transform infra-red (FTIR), while morphological aspects were determined using scanning electron microscopy (SEM).

Results: Mean age and body mass index at the time of TKR were 73.7 (8.6) years, and 29.3 (7.4) kg/m^2, respectively. Preoperative X-rays, available for 9 patients, found uni-, bi- or tricompartmental knee OA in 3 (33.3%), 5 (55.5%) and 1 (11.1%) cases, respectively. In all cases, the compartment mainly affected was medial femoro-tibial, and mean Kellgren and Lawrence score was 3.7 ± 0.5. Overall, 19 menisci (14 lateral and 5 medial) were harvested and analysed. Visual assessment found macroscopic menisci calcifications in 10 OA out of 14 patients (71.4%). Using DCR, CC were detected in all 19 OA menisci, whereas CC were not detected in non-OA control menisci. The mean overall mineral content represented $9.0\pm5.3\%$ of total volume (range 3.2–24%). FTIR analysis confirmed the presence CC in all 19 OA menisci specimens. CC were identified as CPPs only in 10 menisci (52.6%), as BCPs only in 6 (31.6%) and as both BCPs and CCPs in 3 (5.2%). Mean overall CPPs content represented $12.1\pm16.3\%$ and mean overall BCPs content represented $2.9\pm5.4\%$. In all cases, identified BCPs were characterized as carbonated apatite. Finally, by SEM, 2 different morphological aspects were identified: 1/spherical structures, typical of biological apatite, resulting from an agglomeration of nm-scale cristallites surrounded by proteins, in the BCPs-containing samples; 2/ acicular or cubic structures of different sizes, in the CPPs-containing samples.

Conclusion: CC are constantly found in human OA menisci at the time of knee joint replacement. Cartilage calcifications in human OA menisci are mainly identified as CPPs. Furthermore, CC morphological aspects are specific to the crystal type.

Inhibition of p38 Signaling Negatively Affects Chondrogenesis *in Vitro*, but Does Not Inhibit Ankylosis in a Model of Ankylosing Spondylitis. Kirsten Braem, Frank P. Luyten and Rik Lories. KU Leuven, Leuven, Belgium

Background/Purpose: Mitogen activated protein kinases (MAPKs) convert various extracellular stimuli onto different cellular responses and mediate distinct effects on a wide array of biological processes. Among the various MAPKs subfamilies, p38 plays an important role in bone formation, but it is also involved in the catabolic actions of pro-inflammatory cytokines interleukin 1 (IL1) and tumor necrosis factor α (TNFα). Ankylosing spondylitis (AS) is characterized by chronic inflammation of the spine and joints as well as progressive ankylosis leading to loss of function and disability. In spite of increasingly successful control of inflammation with TNFα inhibitory agents, structural progression of disease appears not to be affected by these drugs, suggesting that the processes of inflammation and ankylosis are at least partially independent. Bone morphogenetic proteins (BMP) have been identified as key players in onset and progression of ankylosis. BMP associated intracellular signaling cascades (SMAD and p38 MAPK signaling) play a role during chondrogenesis and osteogenesis *in vitro* and *in vivo* . Here, we studied the inhibition of p38 on chondrogenesis *in vitro* and *in vivo* with specific attention to its potential role in ankylosing enthesitis.

Methods: Male DBA/1 mice from different litters were caged together at the age of 8 weeks. From week 10 onwards to week 17, mice were injected daily with SB203580 (50 μg/g body weight) or DMSO vehicle control. In a second set of experiments, mice were injected daily with SB203580 or DMSO after the first symptoms appeared in each mouse and sacrificed 3 weeks later. Mice were evaluated for prospective signs of arthritis and toe joints were analyzed by histology to assess disease severity. For *in vitro* experiments, human periosteum-derived progenitor cells were cultured in pellets and stimulated with BMP2 or TGFβ1 in the presence or absence of

SB203580, IL1 or TNF. Chondrogenic differentiation was evaluated at day 7 using quantitative PCR marker analysis. Canonical SMAD and alternative MAPK signaling were studied by performing western blot analysis.

Results: p38 inhibition by SB203580 downregulated chondrogenic markers (*COL2*, *COL10*, *ACAN*) in periosteal progenitor cell pellet cultures stimulated by TGFβ1 or BMP2. This inhibition was also found with pro-inflammatory cytokines IL1 and TNF. In contrast, the *in vivo* experiments resulted in an increased clinical incidence of peripheral arthritis and pathology severity score in mice receiving SB203580, reflecting progression towards ankylosis.

Conclusion: p38 activation occurs both downstream of pro-inflammatory cytokines and TGFβ superfamily members. *In vitro* inhibition of p38 negatively affects chondrogenesis, demonstrating that not only the SMAD signaling pathways but also the alternative activation of MAPKs including p38 contribute to chondrogenesis. In a mouse model of ankylosing spondylitis, such an inhibitory effect is not found. Additionally, increased incidence and disease severity in preventive experiments as well as shifts in disease stages in a therapeutical experimental setup suggests that p38 inhibition may have deleterious rather than beneficial effects.

1803

Human Chondrocyte Behaviour During In Vitro Over Expression of Normal and Mutated HFE, the Hemochromatosis Gene. Vanessa Martelli[1], John A. Di Battista[1], Pantelis Panopalis[1], John Antoniou[2], Michael Sebag[1], Brian Gilfix[1] and Henri A. Ménard[1]. [1]McGill University Health Center, Montreal, QC, [2]Jewish General Hospital, Montreal, QC

Background/Purpose: Clinical hereditary hemochromatosis type I (HH-I) is defined as the progressive accumulation of iron in organs and is caused by missense mutations in the HFE gene. In population studies, there are two prevalent mutations the C282Y and the H63D. Rheumatic complaints of the osteoarthritis (HHOA) phenotype are the leading clinical manifestations of HH-I. Yet, little is known about the expression in chondrocytes of proteins regulating iron metabolism. Our study verified their presence and explored variations of OA-related biomarkers in normal vs. HFE-mutation-carrying cultured human chondrocytes and, in normal chondrocytes transfected with normal or mutated HFE under basal conditions or cytokine stimulations in a variable culture medium/serum iron environment.

Methods: Cultured chondrocytes were derived from tissues obtained at total knee replacement (TKR) of patients not carrying (OA) or carrying mutations (HHOA).Levels of MMP-1, MMP-3, MMP-13, iNOS and COX-2 (referred to as an "activation profile") were measured in normal chondrocytes transfected with plasmids containing normal or mutated HFE.

Results: Ferroportin, Divalent Metal Transporter 1, ferritin and transferrin receptor 1 were all identified by PCR in human chondrocytes. In vivo mutated chondrocytes spontaneously expressed in vitro, significantly higher levels of the "activation profile" compared with cells obtained from age-matched patients with idiopathic primary OA. The in vitro transfection of a construct expressing the wild type (normal) HFE gene into normal donor-derived chondrocytes had similar effects on basal or cytokine-induced MMP-13 or COX-2 expression as cells transfected with an empty vector or under mock transfection conditions. However, transfecting plasmids with HFE containing the mutations, generated through site directed mutagenesis, resulted in a 3 to 7-fold increase in MMP-1/MMP-13/COX-2/iNOS expression levels under basal and cytokine-induced conditions. Those effects were similar in the presence of normal vs. elevated iron concentrations in the culture medium.

Conclusion: These data albeit preliminary, constitute the first attempt to define in chondrocytes the molecular mechanisms driving the characteristic HHOA and the role that HFE mutant genotypes may play in this regard. Our companion clinical observations as well as published population-based data suggest that many patients with the so-called "silent" H63D HFE mutation have early rheumatic symptoms while presenting a normal biochemical phenotype. It follows that given its high frequency that mutation may be a major, still insufficiently recognized, genetic risk factor for OA. We are currrently trying to repair in vitro the HHOA phenotype of the chondrocytes using normal HFE gene therapy.

Blockade of Delta-like1 Suppresses Osteoclastgenesis and Arthritis. Chiyoko Sekine[1], Akemi Koyanagi[1], Noriko Koyama[1], Katsuto Hozumi[2], Shigeru Chiba[3] and Hideo Yagita[1]. [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Tokai University School of Medicine, Japan, [3]University of Tsukuba, Tsukuba, Japan

Background/Purpose: Osteoclastogenesis plays an important role in the bone erosion of rheumatoid arthritis (RA). Recently, Notch receptors have been implicated in the development of osteoclasts. However, the responsible Notch ligands have not been identified yet. This study was undertaken to determine the role of individual Notch receptors and ligands in osteoclastogenesis.

Methods: Mouse bone marrow-derived macrophages or human peripheral blood monocytes were used as osteoclast precursors and cultured with RANKL and M-CSF to induce osteoclasts. Osteoclasts were detected by tartrate-resistant acid phosphatase (TRAP) staining. K/BxN serum-induced arthritic mice were treated with anti-mouse Delta-like 1 (Dll1) blocking monoclonal antibody (mAb).

Results: Blockade of a Notch ligand Dll1 with mAb inhibited osteoclastogenesis and, conversely, immobilized Dll1-Fc fusion protein enhanced it in both mice and humans. In contrast, blockade of a Notch ligand Jagged1 enhanced osteoclastogenesis and immobilized Jagged1-Fc suppressed it. Enhancement of osteoclastogenesis by agonistic anti-Notch2 mAb suggested that Dll1 promoted osteoclastogenesis via Notch2, while suppression by agonistic anti-Notch1 mAb suggested that Jagged1 suppressed osteoclastogenesis via Notch1. Inhibition of Notch signaling by a γ–secretase inhibitor suppressed osteoclastogenesis, implying that Notch2/Dll1-mediated enhancement was dominant. Actually, blockade of Dll1 ameliorated arthritis induced by K/BxN serum transfer and reduced the number of osteoclasts in the affected joints.

Conclusion: The differential regulation of osteoclastogenesis by Notch2/Dll1 and Notch1/Jagged1 axes may be a novel target for amelioration of bone erosion in RA patients.

Induction of Tyrosine Hydroxylase (TH) and Modulation of Cytokine Release by Hypoxia in Mixed Synovial Cells of Patients with Rheumatoid Arthritis and Osteoarthritis. Silvia Capellino[1], Zsuzsa Jenei-Lanzl[1] and Rainer H. Straub[2]. [1]1Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Department of Internal Medicine, University Hospital Regensburg, Regensburg, Germany, [2]University Hospital Regensburg, Regensburg, Germany

Background/Purpose: It is known that the microenvironment of inflamed joints is hypoxic and that hypoxia induces tyrosine hydroxylase (TH) *in vivo* . Furthermore, in previous studies we have shown that TH-positive, catecholamine-producing cells are present in inflamed synovial tissue. Therefore, the aim of our study was to investigate whether hypoxia is responsible for TH expression and how hypoxia-induced catecholamines influence the inflammatory response in arthritis.

Methods: Synovial tissue was obtained from rheumatoid arthritis (RA) and osteoarthritis (OA) patients. Synovial cells were isolated by enzymatic digestion and cultivated under normal or hypoxic conditions. After 24 hours, cells were stained for TH. In order to determine effects caused by TH, cells were incubated with the competitive TH-inhibitor alpha-methyl-p-tyrosine (αMPT). In addition, different concentrations of catecholamine receptor (α- and b-adrenergic, D1/D5, D2,D3,D4 dopamine) or adenosine (A1aR, A2aR) receptor antagonists were applied. After 24 hours, supernatants were collected and cytokine (TNF, IL-6, IL-8, IL-10) concentrations were determined.

Results: Hypoxia increased the number of TH positive cells compared to cells cultured under normoxia. Compared to normoxic conditions, hypoxia exhibited inhibitory effects on IL-6, IL-8, and IL-10, whereas TNF was unaffected in OA. In contrast, hypoxia increased IL-6 and IL-8, but inhibited IL-10 and TNF in RA. These effects are partly dependent on locally produced catecholamines. Thus, TH blockade by αMPT reversed hypoxia-induced inhibition of IL-6 and upregulation of IL-8 in OA cells. In RA cells, αMPT reversed hypoxia-induced upregulation of IL-8. Moreover, specific catecholamine receptor antagonists were able to reverse hypoxia-induced influences on IL-8 and TNF in both OA and RA cells. Interestingly hypoxia-induced IL-8 increase was reversed by D1/D5 blockade.

Conclusion: This study demonstrates that hypoxia induces TH production in synovial cells, especially in RA patients. In addition, our results show that IL-6 and IL-8 are stimulated in RA by hypoxia. This is probably due to the activation of catecholamine pathway, especially of dopamine, as the blockade of dopamine D1/D5 receptors reverses IL-8 upregulation. In summary, these results suggest that hypoxia influences the inflammatory response in RA synovial cells by modulating local production of catecholamines.

Synovial Tissue Cytokine Expression in Rheumatoid Arthritis and Associations with Lymphoid Neogenesis, Disease Activity and the European League Against Rheumatism Response. Juan D. Canete[1], Raquel Celis[2], Julio Ramirez[1], Sara Marsal[3], Gabriel Avila[3], Raimon Sanmarti[2] and Jose L. Pablos[4]. [1]Hospital Clinic, Barcelona, Spain, [2]Clinic Hospital, Barcelona, Spain, [3]Hospital Vall de Hebró, Grup de Recerca de Reumatologia, Barcelona, Spain, [4]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain

Background/Purpose: We analized wether LN is associated with specific patterns of inflammatory cytokine expression in synovial tissue (ST), and the potential association of cytokine expression with disease activity and response to therapy.

Methods: ST samples were obtained by arthroscopy from the inflamed knee of 62 RA patients, In twenty-one patients which started TNF blockers a second biopsy was obtained after a mean of 8+5 months of treatment. ST samples were immunostained with CD3 (T cell), CD20 (B cell), and MECA-79 (high endothelial vessels). Total ST mRNA was extracted and gene expression of CCR7, LT-beta, IL-7, IL-10, IL-17A, IL-21, IL-22, IL-23, TNF-alpha, IL-1b, and IL-6 was measured by quantitative real-time PCR. Clinical and biological data were collected at inclusion and after a median of 2.3 years of follow-up.

Results: 28 out of 62 patients (45.2%) had LN, which correlated with a significantly-higher expression of three key molecular markers of LN, CCR7, IL-7 and LT-beta ($p<0.037$, $p<0.038$, and $p=0.009$, respectively). LN-positive patients also had higher IL-23 ($p=0.035$) and higher DAS28 score, both at inclusion and at the end of follow-up ($p=0.055$ and $p=0.037$, respectively). In the group of patients with ST before and after TNF blockers, EULAR good response was associated with IL-10 reduction ($p=0.035$). In the entire group EULAR response correlated with IL-1b expression ($P=0.014$).

Conclusion: RA patients with LN are characterized by higher expression of key molecular markers of LN, IL-23 and higher disease activity. Significant reduction in IL-10 expression after therapy with TNF-blockers is associated with good EULAR response.

Mucocutaneous Flares As Opposed to Flares From Other Organs Have the Strongest Association with High Type I Interferon Levels in Patents with Systemic Lupus Erythematosus. Elzbieta E. Jacek[1], Mikhail Olferiev[2], Vinicius Domingues[3], Rolando Duculan[1], Nancy Pan[4], Mary K. Crow[4] and Kyriakos A. Kirou[5]. [1]Mary Kirkland Center for Lupus Research-Hospital for Special Surgery, New York, NY, [2]Mary Kirkland Center for Lupus Research, Hospital for Special Surgery, New York, NY, [3]Estacio de Sá University, Rio de Janeiro, Brazil, [4]Hospital for Special Surgery, New York, NY, [5]Mary Kirkland Center for Lupus Care, Hospital for Special Surgery, New York, NY

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) have elevated levels of type I Interferon (IFN-I) in their sera and in cross-sectional studies these levels correlate with disease activity. Here, we studied whether IFN-I levels correlate with any specific organ flares in a longitudinally followed cohort of SLE patients.

Methods: There were 30 patients in our study: 83% female, 56% Caucasian, 26% African/American, mean age of 29± 8.8. We collected serum from all visits of each patient and used it to stimulate reporter cells (WISH cells) which are sensitive to IFN-I, and relative expression of two IFN-I-inducible genes, IFIT1 and IFI44, was quantified using real-time RT-PCR. The IFN-I score was calculated by converting relative expression values to IFN units, using a standard curve acquired from dose response stimulations of WISH cells with 1–100 units of recombinant IFN-α. The IFN score was reported as median and Interquartile Range (IQ). Flares of the disease were identified using the SELENA-SLEDAI instrument, and organ involvement was determined by BILAG. The median IFN-I levels during patient visits with mucocutaneous, musculoskeletal, renal, general and all flares were compared to the median IFN-I levels during non-flaring visits. Analyses were performed using Nonparametric Wilcoxon matched-pairs signed rank test (for comparison of visits within the same patient) and Mann-Whitney test when assessing collective differences between flares of particular organs among all patients.

Results:

Paired analysis of visits within same patients	IFN Score (IQ Range)	p-value
All flares (n=30)	4.81 (1.41–18.31)	0.0027
No flare (n=30)	2.41 (1.03–6.31)	
Flares with mucocutaneous involvement (n=11)	5.19 (2.17–16.44)	0.0098
No flare (n=11)	2.53 (1.22–2.86)	
Pure mucocutaneous flares (n=10)	10.83 (3.74–19.42)	0.0039
No flare (n=10)	2.54 (1.03–2.99)	
Pure mucocutaneous flares (n=9)	10.96 (6.6–36.19)	0.039
Flares without mucocutaneous involvement (n=9)	7.68 (2.97–14.99)	
Flares with musculoskeletal involvement (n=7)	3.97 (2.26–16.05)	0.067
No flare (n=7)	1.58 (0.99–03.59)	
Pure musculoskeletal flares (n=7)	2.5 (1.55–10.34)	0.21
No flare (n=7)	1.26 (0.86–3.26)	
Renal flare (n=7)	2.18 (1.56–8.23)	0.46
No flare (n=7)	2.54 (1.16–4.60)	
Nonpaired analysis of all visits		
All flares (n=106)	3.95 (1.62–12.97)	0.0009
No flare (n=247)	1.56 (0.75–3.63)	
Pure mucocutaneous flares (n=12)	11.12 (2.1–26.33)	0.006
No flare (n=247)	1.56 (0.77–3.65)	
Pure mucocutaneous flares (n=12)	11.12 (2.1–26.33)	0.16
Flares without mucocutaneous involvement (n=84)	3.36 (1.57–9.79)	

Conclusion: IFN-I levels vary within SLE patients during the course of their disease and roughly correlate with flares of disease. Interestingly, IFN-I levels are highest with mucocutaneous flares but much less so with musculoskeletal and especially renal flares.These results indicate a special role of IFN-I in the pathogenesis of mucocutaneous flares in SLE patients.

1808

Atherogenic Properties of Rheumatoid Arthritis and SLE Plasma Are Attenuated by Interferon-γ Depletion. Allison B. Reiss, Iryna Voloshyna, Michael J. Littlefield, Elise Belilos, Kristina B. Belostocki, Lois A. Bonetti, Gary C. Rosenblum and Steven E. Carsons. Winthrop University Hospital, Mineola, NY

Background/Purpose: The risk of cardiovascular (CV) morbidity and mortality is profoundly increased in patients with SLE and RA, resulting in a significantly shortened lifespan. It is likely that immunologic derangements contribute to CV disease in these patients. We have discovered that SLE and RA patients manifest a pattern of disturbance in expression of cholesterol transport genes that is atheroma-promoting. Exposure of monocytes/macrophages to human RA or SLE plasma suppresses the cholesterol efflux proteins 27-hydroxylase (27-OHase) and ATP binding cassette transporter (ABC)A1, while the scavenger receptor CD36 that facilitates cholesterol uptake is augmented. As a result, plasma from RA and SLE patients severely disrupts cholesterol balance, leading to excess lipid accumulation and foam cell formation (FCF). We have shown that IFN-γ, a pro-atherogenic, pro-inflammatory cytokine, lessens ABCA1 and 27-OHase and enhances CD36 expression and FCF. This study examines whether depletion of IFN-γ from SLE and RA patient plasma alters the atherogenic properties of the plasma.

Methods: 27-OHase, ABCA1, and CD36 expression were evaluated in THP-1 human monocytes/macrophages, a pertinent model of atherosclerosis. Cells were incubated for 18h in medium containing 10% SLE, RA or control human plasma (CHP) or 10% of the same plasma after depletion of IFN-γ. IFN-γ depletion was accomplished by immunoprecipitation with human IFN-γ antibody overnight at 4°C. Following incubation, mRNA was isolated and reverse transcribed. The resulting cDNA was subjected to quantitative PCR using specific primers for each gene. PCR results were normalized to the housekeeping gene GAPDH. Cellular extracts were prepared for Western immunoblotting.

Results: Pooled plasma from SLE and RA patients was compared to CHP (CHP expression set at 100%). In THP-1 macrophages, 10% SLE and RA plasma decreased 27-OHase message by 36.2 ± 12.8% and 49.1 ± 14.7% (n=3, $P<0.01$) below CHP, respectively and ABCA1 fell by 58.3 ± 15.5% (n=3, $P<0.001$) and 48.3 ± 18.7% (n=3, $P<0.01$) below CHP, respectively. CD36 message level rose to 223.8 ± 98.0% and 176.7 ± 53.6% (n=3, $P<0.01$) of CHP, respectively. These same SLE and RA plasma samples, when depleted of IFN-γ, lost their ability to affect 27-OHase and ABCA1 so that levels did not significantly differ from those seen in CHP-exposed cells.

However, CD36 message remained elevated compared to CHP and was the same as with the undepleted RA and SLE plasma.

Conclusion: This study demonstrates pro-atherogenic properties of SLE and RA plasma that may promote atherosclerosis by interfering with cholesterol transport, leading to lipid overload. Removal of IFN-γ from the autoimmune plasma improves cholesterol homeostasis by restoring efflux proteins, but does not change the scavenger receptor CD36. This provides further evidence of the involvement of the immune system in atherogenesis. Novel therapeutic approaches to increased CV risk in patients with autoimmune disorders may be directed toward improved cholesterol balance by targeting IFN-γ or its receptor. This line of research is particularly urgent in light of studies showing little effect of statins, mainstay drugs in CV treatment, on subclinical atherosclerosis in SLE.

1809

Potentiation of TNF-Induced T Cell Chemokine Expression by Type I Interferon in Fibroblast-Like Synoviocytes: Target for JAK Inhibition. Sanna Rosengren, Gary S. Firestein and David L. Boyle. UCSD School of Medicine, La Jolla, CA

Background/Purpose: Interferon-beta (IFNβ) was recently evaluated in clinical trials for treatment of rheumatoid arthritis (RA). Although effective in some animal arthritis models, IFNβ therapy has limited benefit in RA. In fibroblast-like synoviocytes (FLS), IFNβ inhibits IL1β-induced MMP secretion. In contrast, we recently showed that IFNβ acts as an autocrine intermediate in TNF-induced expression of chemokines such as IP10, RANTES, and MCP1 by FLS. To reconcile these apparently contradictory findings, we systematically examined the effect of type I IFN on cytokine-induced gene expression in FLS and the effect of JAK inhibition.

Methods: RA FLS were isolated from arthroplasty tissue, cultured, and serum-starved prior to stimulation. Message levels were determined by qPCR, and protein levels in supernatants determined by ELISA or multiplex bead assay. qPCR results are expressed in relative expression units (REU).

Results: IFNβ (25000 U/ml) significantly decreased IL1β-induced MMP3, IL6, and IL8 expression at 18h. In contrast, when combined with TNF, IFNβ had no effect on IL8 expression, but potentiated IL6 expression and secretion (3.3±0.5 and 2.2±0.5 fold levels of those induced by TNF alone, respectively, p=0.001 and 0.04). In addition, a substantial synergistic effect of IFNβ was observed on TNF-induced IP10, RANTES, and MCP1 expression. For example, IP10 expression after TNF alone was 89±2 REU, IFNβ alone 8.7±1.3, and TNF+IFNβ 1140±170 (n=6, p<0.0001 for TNF+IFNβ compared to the summed values for each). IL1β-induced IP10 and RANTES expression was also potentiated by IFNβ. Similar results were observed at the protein level, and with another member of the type I IFN family, IFNa2 (5000 U/ml). The only gene product studied that was induced by TNF and inhibited by IFNβ was MMP3, whose expression after TNF alone was 10.6±5.8, IFNβ alone 0.03±0.01, and TNF+IFNβ 5.4±3.5 (p=0.02). The type I IFN chemokine and IL6 synergy was reversed by tofacitinib. For example, IFNa2+TNF-induced IP10 levels in medium were 18±4 fold compared to TNF alone, an effect that was inhibited 78±4% by tofacitinib. Of note, the inhibition of TNF-induced MMP3 expression by IFNa2 was not reversed by tofacitinib. MMP3 levels in tofacitinib-treated FLS were 0.56±0.08 and 0.57±0.08 fold that of TNF+vehicle after TNF and TNF+IFNa2 treatment, respectively (p=0.96).

Conclusion: Type I IFN differentially affects IL1β- versus TNF-induced gene expression in FLS. Several genes including IL6 are inhibited by IFNβ in IL1β-stimulated FLS, but only MMP3 is suppressed in FLS activated by TNF. On the other hand, synergy is observed with type I IFN on TNF-induced T cell chemokines and IL6. These findings might explain the anti-inflammatory effects by IFNβ in some animal models where IL1β plays a key pathogenic role and the lack of efficacy of IFNβ treatment in clinical trials in RA where TNF is more important. The Jak inhibitor, tofacitinib significantly reverses this synergy but does not alter the inhibitory effect by IFN on MMP3 suggesting additional therapeutic effects of JAK/STAT pathway blockade in RA.

IL-6 and TNF-α Enhance the Expression of U1C and Affect the Splicing of Functional Defective Angiopoietin-1 (*Ang1*) Gene Mediated by Anti-U1C Antibody in the Patients with MCTD. Tatsuki Okuyama[1], Yuka Kosugi[1], Koichiro Komai[1], Akira Hashiramoto[2], Kazuko Shiozawa[3] and Shunichi Shiozawa[2]. [1]Graduate School of Health Sciences, Kobe Univ., Kobe, Japan, [2]Graduate School of Health Sciences and Medicine, Kobe Univ. / The Center for Rheumatic Diseases, Kobe Univ., Hosp., Kobe, Japan, [3]Rheumatic Diseases Center, Konan Kakogawa Hospital, Kakogawa, Japan

Background/Purpose: Angiopoietin-1 (*Ang1*), the ligand of endothelial tyrosine kinase receptor Tie2, which induces cell proliferation *via* ERK and resistance for apoptosis-induction *via* Akt (Arth. & Rheum. 57 (7): 2170, '07). *Ang1* is strongly up-regulated in the lung of patients with mixed connective tissue disease (MCTD) accompanied by pulmonary hypertension (PH), indicating that *Ang1* may play a key role in the pathogenesis of PH associated with MCTD. We previously showed that the frequency of the splicing variant of *Ang1* mRNA with nt805GGT insertion (*Ang1*/ins) encoding 269Gly was significantly increased in the Japanese patients with MCTD and those with PH as compared with *Ang1*/del with nt805GGT deletion (Arth. & Rheum. 52 (9): S283, '05). We also found that *Ang1*/ins facilitated proliferation of pulmonary endothelial cells and potentially induced hyperplasia of smooth muscle cells as compared with *Ang1*/del (Arth. & Rheum. 58 (9): S659, '08 and 60 (10): S8, '09). On the other hand, *Ang1*/ins variant was relatively increased when anti-U1C or U1–70K Ab was introduced into human pulmonary artery smooth muscle cells (HPASMC) in the presence of IL-6 and TNF-α (Arth. & Rheum. 62 (10): S370, '10), while it was not in cases without cytokine stimulation. We here investigated the mechanism how IL-6 or TNF-α interferes with the splicing of *Ang1*.

Methods: Anti-U1A, U1C, and U1–70K Abs (LifeSpan Biosc. and Bio Acad.) were labeled with Alexa Fluor 488 (invitrogen) and introduced into HPASMC by using protein delivery reagentPolyplus transfection) and cultivated with 20ng/ml of IL-6 or TNF-α for 24 h. Intracellular localization of introduced fluorescein labeled Abs was observed by using fluorescence microscope and the amount of introduced Abs was determined by using FACS. In order to quantify U1RNP mRNA, total RNA of cytokine-stimulated HPASMC was extracted and amounts of U1A, U1C, U1–70K mRNA were quantified by real-time TaqMan® PCR. The nuclear protein extracted from cytokine-stimulated HPASMC was analyzed by Western blotting using specific Abs for U1RNP proteins. We also examined the concentration of IL-6 and TNF-α in the sera of patients with MCTD (n=12) by using ELISA (R&D systems).

Results: Features of intracellular localization and amounts of introduced Abs appeared to be similar between the cases with or without IL-6 and TNF-α, however, the expression of mRNA and the amount of U1C protein were both significantly increased in HPASMC under the stimulation with IL-6 and TNF-α ($P < 0.05$). The serum concentrations of IL-6 and TNF-α in the patients having *Ang1* /ins dominantly (average±1SD) was 17.47±3.88 pg/ml, which showed significant increase as compared with 10.55±2.05 pg/ml in the patients having *Ang1* /del dominantly ($P < 0.005$). "dominant" represents that *Ang1* /del or *Ang1* /ins expressed higher than twice of the other one.

Conclusion: IL-6 and TNF-α interfere with the expression of U1C, thereby increasing the potential for intracellular-introduction of anti-U1C Ab. The anti-U1RNP antibody found in the sera of patients with MCTD or MCTD with PH may interfere with the splicing of *Ang1* to increase *Ang1* /ins variants.

Chemerin/ChemR23 Expression and Pro-Inflammatory Effects in Synovitis of Patients with Rheumatoid Arthritis. Hirahito Endo, Makoto Kabraki, Yoshie Kusunoki, Natsuko Kusunoki and Shinichi Kawai. Toho University School of Medicine, Tokyo, Japan

Background/Purpose: Chemerin is an adipokine that stimulates chemotaxis of cells of the innate immune system. To evaluate the role of chemerin, and its G protein - coupled receptor ChemR23 in inflammatory arthritis such as rheumatoid arthritis(RA) and Osteoarthritis(OA) we analyzed using synovial tissues and osteoclastogenesis system.

Methods: Level of Chemerin in synovial fluids and plasma from 52 patients with RA and 20 patients with OA were measured by an specific ELISA. Reverse transcription-polymerase chain reaction (RT-PCR), real-time quantitative PCR, and *in situ* hybridization were performed to detect mRNA for ChemR23 in 30 patients with RA and 10 patients with OA. Chemerin measured by immunohistochemical methods in synovium of RA and OA. The effects of chemerin/chemR23 on matorix metalloproteanases (MMP) synthesis in cultured synovial cells were measured. Effect of active chemerin on osteoclastgenesis, osteoblastgenesis from murine bone marrow cells and monocyte-linageRAW264.7 were also examined.

Results: Chemerin showed significantly higher levels in RA synovial fluids (378.8±185.2 ng/ml) than OA synovial fluids (102.5±74.8 ng/ml). Expression of ChemR23mRNA were stronger in RA synovium than OA synovium (RA 27.3±2.6 AU, OA 8.6±3.8 AU, p<0.05). *In situ* hybridization for ChemR23 mRNA expressed in macrophage and fibroblast-like cells from lining layer of RA synovium. Plasma chemerin levels of RA were not

higher than that of OA (RA 89±16.7ng/ml, OA 100.2±15.8ng/ml). Expression of Chemerin induced by interleukin-1 from cultured synovial cells in a dose dependent and time dependent manner. Chemerin induced MMP1 and MMP3 synthesis in cultured RA synovial cells via ChemR23. Chemerin/ChemR23 also induced osteoclastogenesis via active extracellular signal regulated kinase(ERK)1/2 in receptor activator of NF-kB ligand(RANKL)-stimulated bone marrow monocyte and macrophage-linage cells. Chemerin induced tartrate acid phosphatase(TRAP) mRNA and MMP-9 in these cells. Chemerin suppressed osteoblastogenetic differentiation accompanied with adipogenesis from progenitor cells in murine bone marrow system. Chemerin/ChemR23 also promoted resorption capacities of RANKL stimulated macrophage-linage cells on calcium phosphate-coated culture plates.

Conclusion: ChemR23 is an important target of chemerin in synovial tissues of patients with RA. Chemerin in inflammatory synovitis produce locally in inflammatory arthritis such as RA. Chemerin/ChemR23 might be modulate the bone resorption via osteoclast differentiation in RA. These findings could leads to the development of new therapeutic approach for inflammatory arthritis such as RA.

Functional Characterization of An Allosteric Enhancer of the Adenosine A_{2a} Receptor That Inhibits Pro-Inflammatory Cytokine Production. Ajith A. Welihinda and Edward P. Amento. Molecular Medicine Research Institute, Sunnyvale, CA

Background/Purpose: Adenosine, an endogenous nucleoside, is produced at high levels at inflamed sites as a by-product of cellular activation and breakdown. Adenosine, mediates its immune suppressive activity primarily through the adenosine A_{2a} receptor ($A_{2a}R$), a member of the G-protein coupled receptor family of transmembrane receptors. High affinity $A_{2a}R$ agonists have demonstrated anti-inflammatory efficacy, however, their therapeutic utility is hindered by lack of adenosine receptor subtype selectivity upon systemic exposure. We sought to harness the inherent immune suppressive effects of adenosine by enhancing the responsiveness of $A_{2a}R$ to endogenously produced adenosine. Using a mutually exclusive array of cell-based assays, we examined a series of compounds originally derived from plant sources to identify potential $A_{2a}R$ allosteric enhancers. The present study describes allosteric properties of a representative compound.

Methods: Compounds that inhibited inflammatory cytokines by mononuclear cells without affecting known anti-inflammatory pathways were screened for the enhancement of $A_{2a}R$-mediated cAMP production in cells over-expressing the receptor. $A_{2a}R$ deficient $CD4^+$ T cells were used to identify those compounds whose anti-inflammatory activity depended solely upon the intact receptor. Binding affinity of $A_{2a}R$ was determined using [^{14}C]CGS21680. $A_{2a}R$-mediated G-protein activation was evaluated using [^{35}S]GTP-γS binding to $A_{2a}R$ membranes. Human monocytes were isolated from PBMCs by depleting other cell types. $CD4^+$ T cells were isolated from splenocytes by negative selection. Cytokine levels in culture media and intracellular cAMP levels were quantitated by ELISA.

Results: A subset of compounds potentiated cAMP production by CHO cells stably expressing the human $A_{2a}R$ only in the presence of adenosine. A representative compound, AEA061, was chosen to establish allosteric modulation as the basis of the activity. AEA061 enhanced both the potency and efficacy of adenosine at the $A_{2a}R$. Binding studies demonstrated that the compound increased the affinity as well as the B_{max} of the $hA_{2a}R$ to agonists. In addition, AEA061 elevated agonist-mediated G-protein activation as shown by increased [^{35}S]GTP-γS incorporation into $A_{2a}R$ expressing cell membranes. Consistent with the immunomodulatory role of the $A_{2a}R$, AEA061-dependent activation of the receptor attenuated TNF-α production stimulated by distinctly different signaling pathways in monocytes/macrophages. Moreover, AEA061 attenuated IFN-γ production by anti-CD3-stimulated wild-type $CD4^+$ T cells but not by $A_{2a}R$ deficient $CD4^+$ T cells.

Conclusion: Our observations support the hypothesis that AEA061 and its analogs allosterically modulate the $A_{2a}R$ to potentiate cAMP production. The allosteric enhancement of $A_{2a}R$ leads to inhibition of pro-inflammatory cytokines. The potential to enhance natural immune suppression through the adenosine-$A_{2a}R$ pathway may provide a means to focus anti-inflammatory activity at disease sites where adenosine is abundant. Allosteric modulation of A2aR presents a novel and unique approach for the treatment of RA and associated inflammatory conditions.

Mechanism of Fractalkine/CX3CL1 Synthesis and Shedding in Rheumatoid Arthritis Synovial Fibroblasts. Brian Jones, Maria Beamer, Ayesha Rahman, Wissam Ali Aboualaiwi and Salahuddin Ahmed. Department of Pharmacology, University of Toledo College of Pharmacy & Pharmaceutical Sciences, Toledo, OH

Background/Purpose: Tumor necrosis factor (TNF)-α and interferon (IFN)-γ together induce the production of fractalkine/CX3CL1 (FKN), a well known chemoattractant and cell adhesion chemokine, in rheumatoid arthritis(RA) synovial fibroblasts by an unknown mechanism. The present study was undertaken to determine the cellular mechanisms governing RA synovial fibroblast FKN synthesis and shedding so that highly targeted therapeutic approaches against it may be developed for RA.

Methods: Effect of TNF-α and IFN-γ, alone or in combination, on human RA synovial fibroblast FKN synthesis and shedding was determined over 6–72 hours by immunostaining, quantitative RT-PCR, and Western blotting methods. The role of enzymes ADAM17, ADAM10 and caspase-3, the signaling mediators such as mitogen-activated protein kinases (MAPK) and nuclear factor-κB (NF-κB) pathways were evaluated using signaling inhibitors. 20S Proteasome activity in the treated samples and the DNA-binding activity of NF-κB in the nuclear fractions were evaluated using the commercially available ELISA kits.

Results: In RA synovial fibroblasts, the combination of TNF-α/IFN-γ induced the cellular expression of FKN that peaked as early as 24 hours ($P<0.05$; $n=3$). Activation of ADAM17 expression, but not ADAM10, enhanced the proteolytic shedding of FKN, resulting in the release of soluble FKN (sFKN) that peaked around 48–72 hours of stimulation. TNF-α/IFN-γ-induced FKN expression and sFKN release were markedly inhibited in RA synovial fibroblasts by the pretreatment of GM6001 (an inhibitor of ADAM17) or MG132 (a proteasome inhibitor), but not Z-DEVD-FMK (an inhibitor of caspase-3), suggesting an important role of ADAM17 in the proteolytic shedding of sFKN. This observation was further supported by an increase in the proteasome activity by 40% in the samples treated with TNF-α/IFN-γ as compared to the untreated samples ($P<0.001$; $n=3$). Evaluation of the signaling pathways revealed that MG132 and SB203580 (a p38-MAPK inhibitor) selectively inhibited TNF-α/IFN-γ-induced sFKN production in RA synovial fibroblasts ($p<0.05$; $n=3$), suggesting the clinical importance of these pathways in mediating the synthesis and proteolytic processing of FKN. Importantly, we also observed a rapid phosphorylation and proteasomal degradation of IκBα and an activation of phospho-p38 expression within 1–5 minutes of TNF-α/IFN-γ stimulation, which further correlated with the increased DNA-binding activity of NF-κB in the nuclear fractions of the similarly treated RA synovial fibroblasts.

Conclusion: Our results provide the evidence of the role of ADAM17, p38-MAPK, and proteasome pathway in regulating TNF-α/IFN-γ-induced synthesis and proteolytic shedding of FKN. Selective inhibition of these molecular targets may be one of the potential therapeutic approaches to limit the pathological role of FKN in RA synovial fibroblast mediated inflammation and tissue destruction.

1814

Comparison of Anti-Interleukin-6 and Anti-Interleukin-6 Receptor Antibodies Using *In Vivo* Functional Systems. Stevan Shaw, Diane Marshall, Helen Neale, Kosmas Kretsos, Tim Bourne and Alastair Lawson. UCB, Slough, United Kingdom

Background/Purpose: The multi-step assembly of the interleukin-6 (IL-6) signaling complex offers the potential for several therapeutic points of intervention in the treatment of rheumatoid arthritis; for example, targeting the cytokine IL-6, the IL-6 receptor (IL-6R; gp80), or gp130. The objective of this study was to compare affinity-matched anti-murine monoclonal antibodies (mAbs) that target either the cytokine or the receptor in a range of *in vivo* assays.

Methods: Affinity-matched anti-murine reagents 54E07 mAb (anti-IL-6) and 440-1 mAb (anti-IL-6R; gp80) were evaluated for their ability to inhibit either murine IL-6 or CFA-induced serum amyloid A (SAA). IL-6 is also known to have a significant role in B-cell function; therefore, these antibodies (Abs) were evaluated for their ability to inhibit dinitrophenyl (DNP)-specific Ab production. Furthermore, these Abs were dosed to steady state and their capacity to inhibit collagen-induced arthritis (CIA) in DBA-1 mice was evaluated.

Results: 54E07 mAb produced a ≥90% reduction in the SAA response to both IL-6 and CFA at a dose of 0.1 mg/kg ($p < 0.01$ and $p < 0.001$, respectively). In contrast, doses of at least 1 mg/kg and 3 mg/kg of 440-1 mAb were required to significantly reduce the SAA response ($p < 0.001$ for both doses). *In vivo* inhibition of IL-6 by 54E07 mAb significantly reduced the DNP-specific IgG response by 72% at doses as low as 0.3 mg/kg s.c. ($p < 0.05$), whereas 440-1 mAb only achieved a significant reduction (80%) in DNP-specific Ab titer at a dose of 10 mg/kg s.c. ($p < 0.05$). In the murine CIA model, both 54E07 mAb and 440-1 mAb achieved a similar reduction (≥97%) in the clinical arthritis score at the same high dose exposure; however, at the same low dose exposure, only 54E07 mAb caused a significant reduction (67%) in clinical score versus controls.

Conclusion: These murine *in vivo* studies strongly suggest that targeting IL-6 cytokine rather than the IL-6 receptor is the more efficient therapeutic approach for the treatment of autoimmune diseases such as rheumatoid arthritis.

Oncostatin M Is a Potent Regulator of Interleukin-6 and RANKL Expression in Mouse Synovial Fibroblasts and Synergises with Interleukin-1. Benoit Le Goff, Brett A. Tonkin, Sofie Singbrant, T. John Martin, Evange Romas, Natalie A. Sims and Nicole C. Walsh. St Vincent's Institute of Medical Research, Melbourne, Australia

Background/Purpose: Oncostatin M (OSM) is a multipotent cytokine expressed in the synovium of rheumatoid arthritis (RA) patients. OSM alone, or in concert with pro-inflammatory cytokines like IL-1, can stimulate expression of genes that promote inflammation and joint destruction. This study determined the acute effects of OSM, IL-1, and their combination on expression of IL-6 and RANKL in synovial fibroblasts (SFs).

Methods: SFs were isolated from non-arthritic mouse hind paws from wild type and OSMR knockout (OSMR−/−) mice, and stimulated with mouse OSM (2 ng/mL), mouse IL-1 (10 ng/mL), or their combination for 1, 6 and 24 hours. Gene expression was assessed by quantitative RT-PCR. IL-6 protein expression was determined using ELISA, and flow cytometry was performed to identify receptor expression. To identify protein expression in vivo, immunohistochemistry was performed on paraffin sections of non-arthritic and arthritic knee joints from mice induced with antigen-induced arthritis.

Results: In wild type SFs, OSM and IL-1 both increased IL-6 mRNA expression, with induction by OSM being more rapid and sustained compared with induction by IL-1: 179 fold vs. 40-fold at 24 hrs. Profound synergistic upregulation of IL-6 mRNA expression was observed when submaximal doses of OSM and IL-1 were combined (>1000-fold at 6 and 24 hrs). At the maximum cytokine doses the combination of OSM and IL-1 resulted in the release of approximately 10ng/mL IL-6 protein into the culture supernatant after 24 hrs of treatment (>1200 fold increase compared to control). Both OSM and IL-1 increased RANKL mRNA expression by 6 hrs (9-fold and 4-fold, respectively) but only OSM further increased RANKL expression at 24 hrs (23-fold). Combining submaximal doses of OSM and IL-1 significantly enhanced RANKL expression by 24 hrs (up to 100-fold). Importantly cells lacking OSMR expression (OSMR−/−) showed no induction of IL-6 or RANKL mRNA expression in response to OSM treatment, but did respond to IL-1 treatment in a similar manner to matched wild type SFs. In wild type SFs, OSM stimulated expression of its co-receptors (OSMR, 6-fold at 6 and 24 hrs, and gp130, 3-fold at 24 hrs). Furthermore, OSM increased IL-1 receptor mRNA expression at 6 and 24 hrs (5-fold) and increased IL-1 receptor protein expression at 24 hrs as determined by flow cytometry. Finally, immunostaining showed protein expression of OSM and its co-receptors in the synovium in normal mouse knee joints; this expression was increased in antigen-induced arthritis.

Conclusion: Together our data shows that OSM, acting alone or in synergy with IL-1, is a potent regulator of IL-6 mRNA and protein expression in SFs. Furthermore this cytokine combination can act together to increase RANKL expression in these cells. The ability of OSM to increase expression of IL-1R at both the gene and protein level may contribute in part to its synergistic effects with IL-1 on SFs. The results highlight the potential for OSM, acting through OSMR, to significantly contribute to inflammation and bone destruction in arthritic joints. OSM signaling via OSMR is therefore a potential therapeutic target in the treatment of RA.

1816

Late Apoptotic Bodies Mediates Sterile Inflammation in Vitro and In Vivo Via IL-1alpha. Yael Berda-Haddad[1], Stéphane Robert[1], Paul Salers[1], Leila Zekraoui[2], Catherine Farnarier[3], Charles A. Dinarello[4], Françoise Dignat-George[1] and Gilles Kaplanski[1]. [1]INSERM U608, Marseille, France, [2]Faculté de Médecine-Timone, Marseille, France, [3]Hopital de la Conception, Marseille, France, [4]Denver, CO

Background/Purpose: A common paradigm is that apoptotic bodies (AB) are rapidly cleared from the circulation by macrophage phagocytosis delivering an anti-inflammatory signal. During systemic lupus erythematosus, due to a defect of macrophage-mediated phagocytosis, AB persist in the circulation becoming late AB leading to anti-nucleosome and anti-DNA antibodies appearance. We asked whether late AB may also mediate a pro-inflammatory signal.

Methods: AB were prepared in vitro using serial centrifugations from the supernatant of apoptotic human umbilical vein endothelial cells (HUVEC) induced by combination of serum starvation and TNF-alpha stimulation. The presence of IL-1alpha was studied by ELISA, FACS, immuno-gold electronic microscopy, Western blot (WB) analysis. The pro-inflammatory function of late AB was studied in vitro through their ability to induce endothelial chemokine secretion in co-culture with normal HUVEC and in vivo by intra-peritoneal injection in mice.

Results: AB were isolated from the supernatant of apoptotic HUVEC using their size (1–3 microns), co-labelling with annexinV and propidium iodide and the detection of histones. In vitro, in the absence of macrophages, these AB becomes late AB. IL-1alpha was detected by ELISA in AB lysates, FACS analysis on permeabilized AB and electronic microscopy. WB analysis on AB lysates identified both the 31 kDA IL-1alpha precursor and its 17 kDa mature form. During in vitro co-culture with HUVEC, late AB were able to induce IL-8 and MCP-1 which were completely inhibited by addition of anti-IL-1alpha and IL-1receptor antagonist (IL-1ra) but not by anti-TNFalpha or anti-IL-1beta. Mice intra-peritoneal injection of late AB induced increased production of neutrophilic chemokine and a neutrophilic inflammation which was completely prevented by treatment with IL-1ra.

Conclusion: During cell necrosis, cytoplasmic IL-1alpha is released though the porous cell membrane and induces sterile inflammation. On the contrary, during apoptosis IL-1alpha remains associated within the nucleus preventing its pro-inflammatory effects. We observed that IL-1alpha is associated within AB and maybe released from late AB to induce sterile inflammation, suggesting that IL-1alpha may play a pathogenic role in the inflammation of auto-immune diseases.

1817

Fatty Acid-Binding Protein (FABP)-4 Is Increased in Patients with Rheumatoid Arthritis and Correlates with Metabolic Rather Than with Disease Activity Status. Lucie Andrés Cerezo[1], Hana Hulejová[1], Zdenka Vernerová[2], Markéta Kuklová[1], Ondrej Pecha[3], Vlasta Pesáková[1], Karel Pavelka[1], Jiri Vencovsky[1] and Ladislav Senolt[1]. [1]Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [2]Department of Pathology, 3rd Medical Faculty, Charles Universityin Prague, Prague, Czech Republic, [3]Institute of Biophysics and Informatics, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic

Background/Purpose: FABP4 protein belongs to the family of fatty acid binding proteins (FABPs) which are known to bind fatty acids and are believed to coordinate lipid response in cells. FABP4 was initially detected in mature adipocytes and linked to metabolic disorders; however, recently FABP4 has been identified in macrophages and shown to modulate inflammatory cytokines production. The purpose of this study was to assess FABP4 expression pattern in synovial tissues, serum and synovial fluid from patients with rheumatoid arthritis (RA) and osteoarthritis (OA), and to study relationship between FABP4, disease activity and metabolic status.

Methods: Synovial tissues were obtained from patients with established RA (n=5) and from patients with osteoarthritis (OA) (n=5). Immunohistochemical analysis of synovial tissues was used to determine the expression of FABP4 protein. FABP4 levels in serum and synovial fluid were determined by ELISA (Biovendor, Czech Republic) in 40 patients with RA and 40 control patients with OA. Patients with RA were assessed for disease activity (CRP, DAS28) and autoantibodies (ACPA and IgM-RF). Serum lipids including triglycerides (TG), total cholesterol, high-density lipoprotein (HDL) and low-density lipoprotein cholesterol were measured.

Results: We found an increased expression of FABP4 protein in RA

compared with OA synovial membrane, particularly in inflammatory infiltrates. Similar patterns of FABP4 staining intensity were detected in endothelial cells and adipose tissues in RA and OA synovial membranes. The levels of FABP4 were higher in serum (29.22±2.69 vs. 19.61±1.33 ng/ml; p=0.002) and synovial fluid (23.96±1.91 vs. 18.04±0.99 ng/ml; p=0.008) of patients with RA than in patients with OA, even when adjusted to age, sex and BMI (p= 0.001 and p=0.005). The levels of FABP4 significantly correlated between serum and synovial fluid in RA as well as in OA patients. In addition, FABP4 was higher in females than in males and its serum (r=0.343, p=0.03) and synovial fluid (r=0.447, p=0.004) levels significantly correlated with BMI in patients with RA, but not with OA. When adjusted to age, sex and BMI, serum and synovial fluid FABP4 levels significantly correlated with total cholesterol (r=0.302, p=0.07 and r=0.383, p=0.02, respectively) and LDL cholesterol (r=0.357, p=0.045 and r=0.412, p=0.019, respectively) in patients with RA, but not with OA. On the other hand, there were not found any associations between FABP4 levels and clinical or laboratory markers of RA.

Conclusion: Increased FABP4 in RA synovial membrane, synovial fluid and blood circulation and its positive correlation with BMI, total and LDL cholesterol suggests that FABP-4 may be related to metabolic abnormalities rather than to disease activity in patients with RA.

Role of Liver X Receptors In the Regulation of Effector Functions of Fibroblast-Like Synoviocytes In Rheumatoid Arthritis. M.Teresa Arce-Franco[1], M. Jesus Dominguez-Luis[2], Ana Diaz-Martin[2], Ada Herrera-Garcia[3], Maria Eugenia Miranda-Carus[4], Sagrario Bustabad-Reyes[3], Antonio Castrillo[5] and Federico Diaz-Gonzalez[1]. [1]Rheumatology Service, La Laguna, Spain, [2]Hospital Universitario de Canarias, La Laguna, Spain, [3]Hospital Universitario de Canarias, La Laguna. Tenerife, Spain, [4]La Paz Hospital. IdiPaz, Madrid, Spain, [5]University of Las Palmas de Gran Canaria (ULPGC), Canary Islands, Las Palmas (Gran Canaria), Spain

Background/Purpose: Fibroblast-like synoviocytes (FLS) play an essential role as effector cells in the pathogenesis of rheumatoid arthritis (RA) through the proliferation, production of metalloproteinases (MMPs) and invasion of joint structures. However, until now none therapeutic approach has been designed to target FLS in RA. The liver X receptors (LXR) isoforms, α and β are members of the nuclear receptor superfamily of transcription factors activated by ligand. LXR-induced genes were mainly identified as genes involved in reverse cholesterol transport but several evidences suggest that they are also involved in the modulation of the inflammatory response. The main objective of this work was to study the presence of LXR subtypes and the implication of LXR agonists in the migration, proliferation and MMPs production by FLS from RA patients.

Methods: Six FLS cell lines were isolated by enzymatic dispersion of synovial membrane and cultured in DMEM high glucose from 6 RA patients undergoing knee replacement prosthesis. The presence of LXR isoforms on cultured FLS was studied by RT-PCR and Western Blot. Quantitative RT-PCR of ATP binding cassette A1 (ABCA1) and ABCG1, two LXR target genes, was used to determine the functional capability of LXR on FLS in response to the LXR synthetic agonists: T1317 and GW3965. The role of LXR in FLS chemotaxis was determined by two-compartment transwell assay. Cell growth was measured by a fluorescence-based proliferation assay. Collagenase activity was determined by a fibril degradation assay.

Results: FLS from patients with RA expressed in basal conditions both mRNA and protein of a and b isoforms of LXR. The LXR synthetic agonists T1317 and GW3965 induced ABCA1 and ABCG1 genes in FLS by qRT-PCR. FLS cultured in the presence of both LXR agonists showed a reduction in their proliferative capacity of 40±5% respect to the absence of agonists with or without TNF-α. In transwell experiments using SDF-1 as chemoattractant, both LXR agonists significantly inhibited in 40±7% the migration of cells. FLS cultured with TNF-α in the presence of LXR agonists showed a reduction in the expression of MMP-1 and MMP-9 of 2.5 and 12 times, respectively ((-$\Delta\Delta$Ct) method). Similarly, the collagenase activity induced by TNF-α in FLS supernatant decreased significantly (65±10%) by the presence of GW3965 respect to basal conditions.

Conclusion: FLS from RA patients express constitutively functional LXR. Agonists of these receptors show antiproliferative activity, reduce migration and MMP production in FLS. Taken together, these data suggest that LXR may be a potential therapeutic target for the control of synovitis in patients with RA.

Poly I:C, a Ligand for TLR3, Abrogates Stimulation of Fibrotic Response Induced by Transforming Growth Factor-β. Feng Fang[1], Kohtaro Ooka[2], Swati Bhattacharyya[3] and John Varga[3]. [1]Northwestern University, Chicago, IL, [2]Northwestern University, [3]Northwestern Univ Med School, Chicago, IL

Background/Purpose: Transforming growth factor β (TGF-β) is a potent inducer of collagen synthesis, myofibroblast differentiation and epithelial-mesenchymal transition (EMT), and is implicated in fibrosis. Toll-like receptors (TLRs) mediate immune cell responses to endogenous danger signals generated during tissue injury. Aberrant TLR signaling is implicated in chronic inflammation and autoimmunity, but its role in fibrosis is not understood.

Methods: TLR3 expression on skin and lung fibroblasts was determined by real-time qPCR and immunofluorescence microscopy. Regulation of collagen and α-smooth muscle actin (α-SMA) gene expression and TGF-β signaling by Poly I:C, a TLR3 ligand, were examined by real-time qPCR, Western blot, immunofluorescence microscopy and transient transfection assays. Gene expression changes induced by Poly I:C were examined at the genomewide level using Illumina microarrays.

Results: Poly I:C caused inhibition of collagen and α-SMA gene expression in a dose- and time-dependent manner, while the expression of TLR3 was substantially enhanced. Microarray analysis revealed that many genes related to TGF-β signaling pathway were down-regulated by poly I: C. In TGF-β-activated fibroblasts, poly I:C abrogated the stimulation of fibrotic responses, and attenuated Smad2/3 phosphorylation and Smad-dependent transcription. These effects were largely TLR3-independent. Gene expression profiling showed that poly I:C significantly up-regulated the expression of Type I interferon (IFN), and 291 IFN-regulated genes. Type I IFN was required for mediating the antagonistic effect of Poly I:C on TGF-β-inducible responses.

Conclusion: Poly I:C, a TLR3 ligand mimicking the effects of nucleic acids generated at sites of tissue injury, abrogated Smad-dependent fibrotic TGF-β responses through a TLR3-independent Type I IFN-dependent manner. IFN-inducible genes stimulated by Poly I:C might underlie the repression of collagen and α-SMA, while up-regulating many inflammatory gene (IL-6, IL-8 CXCL10). The nature of Poly I:C signaling in fibroblasts, and mechanism underlying the antagonistic cross-talk between the IFN and TGF-β/Smad signaling pathways, are currently under study.

Background/Purpose: Visfatin (PBEF, pre-B-cell colony-enhancing factor) is an adipocytokine that supports B-lymphocyte precursor maturation, and besides other functions, takes part in regulation of inflammation. Anti-histidyl-tRNA syntethase antibodies (anti-Jo-1) are the most frequent autoantibodies in polymyositis (PM) and dermatomyositis (DM). Recently we showed increased serum levels of B-cell activating factor of the TNF family (BAFF) in anti-Jo-1+ PM/DM patients and its association with disease activity. The aim of this work was to evaluate serum levels of visfatin in anti-Jo-1+ PM/DM, expression of visfatin in muscle tissue and investigate potential relation between visfatin, BAFF and disease activity.

Methods: Visfatin was detected by immunohistochemistry in muscle tissues of PM/DM patients (n=5/5) and compared with non-inflammatory control muscle tissues from patients with myasthenia gravis (n=5). ELISA was used for detection of serum levels of visfatin (BioVision), BAFF (R&D) and anti-Jo-1 (Orgentec) in 38 patients with PM (n=27) or DM (n=11) and in 25 age and sex matched healthy controls. 16 patients had paired serum samples from different time points available (median interval 13.4 months; min 7–max 73.6). Disease activity was evaluated by myositis disease activity assessment visual analogue scales (MYOACT) and by serum levels of CK, ALT, AST, LDH and myoglobin.

Results: Visfatin expression was increased in muscle tissues from patients with PM/DM compared with that in controls and the expression was particularly associated with endomysial and perimysial inflammatory cell

infiltration. Serum visfatin levels were significantly higher in myositis patients compared to healthy controls (1.94 [range 0.13–9.9] vs. 1.31 [0.1–5.2] ng/ml; $p<0.02$). Both visfatin and BAFF levels were associated with clinical muscle activity ($rs=0.39$ and 0.34, $p<0.02$ and $p=0.04$) and there was a trend for correlation with the global disease activity ($rs=0.28$ and 0.33, $p=0.09$ and 0.05). Visfatin significantly correlated with LDH ($rs=0.39$, $p<0.02$), whereas BAFF correlated with CK ($rs=0.51$, $p=0.001$), myoglobin ($rs=0.57$, $p=0.002$) and AST ($p=0.39$, $p=0.01$). Serum levels of visfatin were positively correlated with BAFF in myositis patients ($rs=0.44$, $p=0.006$), but negatively in healthy controls ($rs=-0.54$, $p=0.005$). No association of visfatin with anti-Jo-1 autoantibody levels was found while BAFF correlated with levels of anti-Jo-1 positively ($rs=0.85$, $p=0.001$). Visfatin levels decreased significantly (from 2.12 [0.7–9.4] to 1.16 [0.6–4.45] ng/ml; $p=0.01$) over time while the decrease of BAFF was not significant (from 1.69 [0.6–10.9] to 1.11 [0.7–4.8] ng/ml; $p=0.09$).

Conclusion: These results demonstrate that the serum levels of visfatin, similarly to BAFF, associate with disease activity in patients with myositis. Increased visfatin levels and expression in inflamed muscle tissues support its possible role in the pathogenesis of idiopathic inflammatory myopathies.

FMS-Like Tyrosine Kinase 3 Ligand/CD135 in Arthritis: A New Inflammatory System in Rheumatoid Arthritis? Maria I. Martins Ramos, Saïda Aarrass, Lisa G.M. van Baarsen, Danielle M. Gerlag, PP. Tak and Maria C. Lebre. Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Fms-like tyrosine kinase 3 ligand (Flt3L) is a potent endogenous growth factor for myeloid dendritic cells (mDC) and plasmacytoid dendritic cells (pDC). Its administration to mice and humans leads to dramatic increases of various DC subsets while Flt3L−/− mice show reduced DC numbers. Flt3L and its receptor (CD135) have been poorly studied in the setting of autoimmune diseases in general. Typically, CD135 is expressed on early myeloid and lymphoid progenitors and is activated by its soluble ligand, Flt3L.The highly differentiated cellular pattern in rheumatoid arthritis (RA) synovium made us hypothesise that Flt3L, with its ability to induce proliferation and differentiation, could be of importance in induction and/or progression of arthritis. This research aims to directly determine the functional role of FLT3/Flt3L in RA.

Methods: Patients with active RA, psoriatic arthritis (PsA), spondyloarthritis (SpA), osteoarthritis (OA), gout and healthydonors (HD) were included in this study. Soluble (s)Flt3L levels in synovial fluid (SF) and serum were determined by ELISA. Expression of membrane-bound (m)Flt3L and Flt3L receptor (CD135) in peripheral blood mononuclear cells PBMC) and SFMC were assessed by FACS. In addition, immunohistochemical analysis of Flt3L and CD135 was performed in RA, PsA, gout, OA and HD synovial tissues.

Results: SF levels of Flt3L in RA ($n=103$), PsA ($n=33$), and SpA ($n=32$), OA ($n=8$) and gout ($n=43$) were significantly higher compared to paired serum. In addition, Flt3L levels were significantly higher in RA, PsA and SpA SFs compared to gout SF. In peripheral blood (PB) monocytes, B cells and mDC the expression of mFlt3L in RA was higher compared to HD. Flt3L receptor expression was confined to monocytes and mDC and higher in RA SF compared to PB. Immunohistochemistry and immunofluorescence data showed the presence of Flt3L and CD135 in RA ST. Interestingly, microarray data of RA synovial tissue showed that CD135 expression is increased in patients with high inflammatory gene profile compared to low inflammatory gene profile. There is no different in Flt3L expression between RA and OA confirming the ELISA data. In addition, prednisone treatment reduced Flt3L serum levels in RA patients, and changes in Flt3L serum levels correlate with changes in DAS28.

Conclusion: The data presented in this study point to inflammatory role for Flt3L/CD135 system. Moreover, as the Flt3L/CD135 system is implicated in the generation of DC and B cells, inflammatory cells important in RA pathogenesis, this system might be of importance in RA. Achieving a detailed understanding of Flt3L function(s) in arthritis may lead to the development of novel immunotherapies for RA and other immune-mediated inflammatory diseases.

Efficacy of Influenza and Meningococcal Vaccinations in Healthy Subjects Exposed to Secukinumab 150 Mg: Preliminary Study Results. Andrea Chioato. Novartis, Basel, Switzerland

Background/Purpose: AIN457 (secukinumab) is a high-affinity, anti-human interleukin-17A antibody in trials for inflammatory conditions. IL-17A is produced by memory effectors CD4+ and CD8+ T lymphocytes and the IL-23-Th17 cell pathway is critical for protective immunity against bacterial infections[1]. As this compound will be used in rheumatic conditions, we wanted to determine whether the interference with the IL17 cytokine could influence the response to antigens in frequently used vaccinations. The objective of this study was to evaluate immune response in subjects treated with secukinumab after 2 vaccines, aimed to protect against influenza and meningococcal infection.

Methods: This was an open-label, parallel group, randomized, single-center study in healthy subjects (age 18–55 years, body weight: ≥50 kg, BMI 18–29 kg/m^2). Main exclusion criteria included previous vaccinations and history of significant systemic diseases. After measurement of antibody (Ab) titers at baseline, subjects were randomized to a single secukinumab 150 mg s.c. dose or no treatment (control group), followed two weeks later by influenza or meningococcal vaccinations. The primary efficacy were the responses to influenza (≥4-fold increase in Ab titer in ≥2/3 serotypes) and meningococcal vaccines (also ≥4-fold increase) at 4 weeks.

With a total of 50 subjects (25 in each group), the study had an overall power of >85% to demonstrate non-inferiority for both influenza and meningococcal vaccinations.

Results: 50 out of 112 subjects screened were randomized (1:1) to secukinumab or control groups. All subjects completed the study. Mean age was 31.5 years, mean weight 68.1 Kg. Response to influenza vaccination (≥4-fold in ≥2/3 serotypes) at 4 weeks was seen in 20/25 subjects (80 %) in both groups. Both treatments induced a comparable response to meningococcal vaccine, with 19/25 subjects (76%) generating titers with ≥4 fold increase from baseline at 4 weeks in the secukinumab group compared to 18/25 subjects (72%) in the control group (difference 4%, 90% CI −16%,24%). These results support the non-inferiority of secukinumab compared to control.

Conclusion: Blockade of IL-17 by secukinumab does not appear to interfere with the efficacy of influenza and meningococcal vaccinations, as assessed by the achievement of antibody protective levels after vaccination. A protective (≥4 fold) immune response to influenza and meningococcal vaccinations at 4 weeks was achieved in 76 to 80% of subjects exposed to secukinumab. Further studies may be needed to replicate the results in patients with long term exposure to secukinumab.

Adiponectin Isoforms Differentially Affect Gene Expression, Signaling Transduction and Migration of Rheumatoid Arthritis Synovial Fibroblasts. Klaus Frommer[1], Rosel Engel[1], Andreas Schäffler[2], Christa Büchler[2], Jürgen Steinmeyer[3], Markus Rickert[3], Stefan Rehart[4], Fabia Brentano[5], Steffen Gay[6], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany, [2]University of Regensburg, Regensburg, Germany, [3]University Hospital Gieβen and Marburg, Gieβen, Germany, [4]Markus-Hospital, Frankfurt, Germany, [5]University Hospital Zürich, [6]University Hospital of Zürich, Zürich, Switzerland

Background/Purpose: The pathogenesis of rheumatoid (RA) arthritis is determined by numerous factors. A new group of such factors are the so-called adipo(cyto)kines, proteins with cytokine-like properties, which are predominantly found in adipose tissue. Adiponectin (AdQ), the most abundant adipokine in human serum, is elevated in the synovial fluid of RA patients and positively correlates with RA disease severity. Adiponectin exists in several isoforms, which can induce different effects. We therefore analyzed the effects of adiponectin isoforms on gene expression, signal transduction and migration of RA synovial fibroblasts (SF).

Methods: Human RASF were stimulated with different AdQ isoforms and analyzed for changes in gene expression by Affymetrix® oligonucleotide microarrays and protein arrays. Real-time PCR and immunoassays were used to quantify mRNA expression and protein secretion, respectively. Media from AdQ-stimulated RASF were analyzed for their chemoattractive potential on

RASF using a two chamber migration system. Human phospho-kinase signaling arrays were used to examine signaling molecule phosphorylation after stimulation of RASF with four AdQ isoforms: full-length AdQ containing all isoforms (fl-AdQ), globular (g-AdQ), high-molecular/middle-molecular weight-enriched (HMW/MMW-AdQ), and trimeric (t-AdQ) AdQ.

Results: The individual adiponectin isoforms induced various molecules with a known or potential role in the pathogenesis of RA, but to a notably different extent: the least potent isoform was the trimer, while the most potent isoforms were g-AdQ and HMW/MMW-AdQ. We observed a variably increased expression of cytokines (e.g. mRNA: IL-11-fl-AdQ, 24.3-fold/ HMW/MMW AdQ, 441-fold), chemokines (e.g. protein: ENA-78-fl-AdQ, 22.5-fold/t-AdQ, 9.9-fold), proinflammatory molecules (e.g. mRNA: PTGS2-t-AdQ, 7.1-fold/g-AdQ, 26.1-fold), growth factors (e.g. mRNA: FGF10-fl-AdQ, 5.0-fold/t-AdQ, no change), proteins involved in bone-, and matrix-remodeling (e.g. protein: pro-MMP1-HMW/MMW AdQ, 35.2/ t-AdQ, 11.6). We further confirmed that the secretion of chemokines induced by AdQ in RASF increases the migration of RASF: up to 177% by fl-AdQ, 208% by HMW/MMW AdQ, 127% by t-AdQ and 212% by g-AdQ. Of note, AdQ itself did not act as a chemoattractant. Signaling array analysis revealed differential AdQ-induced signaling molecule phosphorylation (fl- / HMW/ MMW- / t- / g-AdQ), e.g. for p27 (T198) (3.4/3.4/1.5/6.3), paxillin (5.0/1.6/ −1.9/3.9), eNOS (1.6/1.8/−1.4/2.1), and Pyk2 (4.4/1.3/−2.1/5.5).

Conclusion: The data support the hypothesis that AdQ contributes to RA activity by inducing the secretion of proinflammatory molecules, matrix-degrading enzymes, and chemokines in RASF, which in turn most likely promotes the additional influx of RASF to sites of inflammation and cartilage degradation. The adiponectin isoforms have different potencies for eliciting these effects as well as for activating signaling molecules, which suggests that targeting specific isoforms or inhibiting the receptor binding of isoforms may be more promising for therapeutic approaches than inhibiting AdQ in general.

F-Spondin Mediates Catabolic Effects on Articular Chondrocytes Via Its Thrombospondin Repeat Domain. James Liu[1], Glyn Palmer[1], Yang Qing[2], Daniel Rifkin[2], Mukundan Attur[1] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York University School of Medicine, New York, NY

Background/Purpose: We have previously shown that the thrombospondin-related, extracellular matrix protein, F-spondin, is upregulated in osteoarthritis (OA), and induces the production of catabolic mediators, PGE2 and MMP-13 in cartilage explants in a TGF-b dependent manner. In this study, we characterize the role of individual protein domains of F-spondin in modulating its catabolic effects in chondrocytes.

Methods: OA chondrocytes were harvested from tibial cartilage obtained from OA patients with end-stage disease undergoing knee replacement surgery. Transient transfections were performed using TransIT-LT1 reagent (Mirus) and cDNAs encoding full length (FS1) or a truncated C-terminal (FS7) portion of F-spondin coding sequence. Levels of TGF-b1 (R&D systems) and PGE2 (Cayman Chemical) were determined by ELISA, MMP-13 expression was measured by qRT-PCR (Applied Biosystems). TGF-b activity was also measured in conditioned media supernatants by incubation with mink lung epithelial cells (MLEC) expressing a TGF-b-responsive luciferase reporter.

Results: Consistent with our previous observations of the effects of intact F-spondin in cartilage explants, overexpression of FS1 in cultured OA chondrocytes from 3 patients increased expression levels of MMP-13 ~100 % compared to mock-transfected controls. Similarly, FS1 also increased PGE2 levels by 25 % ($p<0.05$). Both effects could be mimicked by transfection with a construct encoding only the c-terminal TSR repeat domain FS7; MMP-13 and PGE2 levels were elevated by FS7 above control vector transfected cultures, ~50 % ($p<0.005$) and 71% ($p<0.05$), respectively. Since the F-spondin TSR domain harbors consensus sequences for latent TGF-b activation (WxxW and KRFK), we tested whether this domain mediates TGF-b activation in cultured chondrocytes. In OA chondrocytes, TGF-b levels in culture supernatants were increased 30% by FS1 and 70% by FS7 compared to controls. Similarly, measurement of active TGF-b using MLEC reporter cells showed that FS1 and FS7-transfected culture media supernatants stimulated luciferase activity 30% and 100%, respectively ($p<0.05$). Conversely, FS3 and FS5 constructs, which both contain TSR-domain deletions, did not stimulate TGF-b activity in MLEC cells. Evidence of enhanced activation of TGF-b was also demonstrated by increased SMAD signaling. Immunoblot of FS treated chondrocytes showed increased phosphorylation of SMAD 1, 5, 8 relative to mock transfected cells. Similarly, both FS1 and FS7 stimulated expression of a SMAD-luciferase reporter in OA chondrocytes.

Conclusion: Our data provide evidence that F-spondin, via its TSR domain, can act as a latent TGF-b-activating protein and enhance the catabolic activity of chondrocytes via induction of MMP-13 and PGE2. The TSR domain of F-spondin may therefore represent a novel therapeutic target for slowing cartilage breakdown in OA.

Adipokine Expression in Osteoarthritis Osteophytes. Susann Junker[1], Klaus Frommer[1], Grit Krumbholz[1], Angela Lehr[2], Stefan Rehart[2], Markus Rickert[3], Jürgen Steinmeyer[3], Georg Schett[4], Ulf Müller-Ladner[1] and Elena Neumann[1]. [1]Justus-Liebig-University of Gieβen, Bad Nauheim, Germany, [2]Markus-Hospital, Frankfurt, Germany, [3]University Hospital Gieβen and Marburg, Gieβen, Germany, [4]University of Erlangen-Nuremberg, Erlangen, Germany

Background/Purpose: Obesity is a recognized risk factor in osteoarthritis (OA) but little is known about the interaction between adipose tissue derived factors and bone formation. Adipocytes produce a variety of cytokine-like proteins, such as adiponectin, visfatin or resistin. While it is known that these adipokines are associated with the pathogenesis of rheumatoid arthritis and can be produced by other cell types such as fibroblasts, osteoblasts and osteoclasts, their role in osteophyte formation in OA has not been studied. Despite the mostly unknown mechanisms of osteophyte formation, there is growing evidence that inflammation and local stress contribute to this process. In this study, the expression of adipokines in osteophytes and their co-localization with cells of bone remodeling was analyzed.

Methods: Osteophyte tissue and cartilage was obtained from OA patients during joint replacement surgery. Serial sections of decalcified and deparaffinized osteophyte tissue were prepared. For histological overview, hematoxylin/eosin and Masson trichrome stainings were performed. Using these stainings, the osteophytes were scored and divided into grade one (early, small osteophyte, no ossification) to four (ossified osteophyte with cartilage). Immunohistochemistry was performed to identify sites and localization of adipokines using antibodies against alkaline phosphatase, vimentin, collagen type I, type II, adiponectin, visfatin, and resistin. TRAP stainings were performed to identify osteoclasts. Immunoassay analyses for visfatin were done with cartilage and isolated primary chondrocyte lysates.

Results: Adiponectin, visfatin and resistin were detectable in all osteophytes of OA patients (grade 1–4). Adiponectin was localized around blood vessels as well as in some fibroblasts in the connective tissue of non-ossified osteophytes (25% of fibroblasts). In ossified osteophytes (grade 2–3), resistin and visfatin showed a co-localization with osteoblasts at the border of newly formed, non-mineralized bone tissue and with osteoblasts and osteoclasts at sites of bone resorption. In osteophytes without ossification (no detectable osteoblasts and osteoclasts, grade 1), visfatin and resistin were detectable only in single cells. Quantitatively, more visfatin than resistin expressing cells could be observed (resistin: 10% vs. visfatin: 25% of cells). ELISA using chondrocytes and cartilage confirmed the visfatin expression in these cells on the protein level.

Conclusion: The co-localization of visfatin and resistin with osteoblasts and osteoclasts in advanced osteophyte formation (grade 2–3) suggests that they may be involved in bone neo-formation and remodeling of OA osteophytes. In contrast, adiponectin was lower in advanced stages of osteophyte formation (grade 2–3) but present in early osteophytes that mainly consist of connective tissue (grade 1). These results indicate that visfatin, resistin and adiponectin may be involved in osteophyte formation at different stages and most likely affect different cell types of cartilage and bone formation during these processes.

Increasing Serum IL-17F Levels in Pediatric Localized Scleroderma As Disease Enters Remission. Kathryn S. Torok[1], Katherine Kurzinski[1], Christina Kelsey[1] and Carol A. Feghali-Bostwick[2]. [1]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: A predominant lymphocytic infiltrate has been identified in scleroderma skin specimens, both localized scleroderma (LS) and systemic sclerosis (SSc). CD4+T cell staining in affected skin supports potential involvement of T-helper cell associated cytokines in the pathogenesis of scleroderma. SSc studies have supported the role of Th1, Th2 and

more recently Th17 cell lineages, finding their associated cytokines in the serum, and expressed in PBMCs and skin specimens. However, there is limited data regarding pediatric LS.This study was designed to evaluate the Th17 serum profile of pediatric LS patients longitudinally as their disease was treated and transitioned to remission.

Methods: Serum samples were obtained from 23 pediatric LS patients with 3 or more specimens with concurrent clinical outcome measures of disease activity, mLoSSI (modified Localized Scleroderma Severity Index) and PGA-A (Physician Global Assessment of Disease Activity). All patients had active disease at the time of first sample collection, defined clinically by the presence of new, expanding, and/or erythematous lesions. They were also naïve to systemic therapy at first visit. All patients clinically improved and entered remission during follow-up serum and clinical data collection. Ten pediatric healthy controls were used as comparison. A luminex panel evaluating Th17 associated cytokines IL-17A, −17F, −22, −23, −27 was performed. Nonparametric analyses were performed to compare cytokine levels between LS and healthy groups and between time points for the LS patients ($p < 0.05$).

Results: Serum levels of IL-17A, −21 and −23 at the baseline visit were significantly lower in the LS group compared to healthy controls (p-values 0.005 – 0.01). IL-17F and IL-22 were not significantly different between controls and LS group at baseline; however, as LS patients clinically improved with systemic treatment, IL-17F levels increased significantly from their previous visits and in comparison to controls. A smaller proportion of LS patients exhibited increasing levels of IL-22 and IL-27 over time. The disease activity scores decreased significantly from baseline to timepoint 2 (median 4.36 mos from baseline) and timepoint 3 (median 11.6 mos from baseline), signifying disease improvement and remission.

	IL-17F (pg/ml)		mLoSSI		PGA-A	
Group	**Median**	**IQR**	**Median**	**IQR**	**Median**	**IQR**
Peds LS Baseline visit	232.9	79.5–456.6	8	(4–12)	45	(33–68)
Peds LS Timepoint 2	336.8	177.3–556.0	0	(0–0)	0	(0–0)
Peds LS Timepoint 3	452.9	271.5–539.5	0	(0–0)	0	(0–2)
Healthy Control	133.3	68.0–232.0	.	.	.	.

Conclusion: Th-17 associated cytokines of LS patients at baseline, when the disease was most active, were either not significantly different or lower than pediatric healthy controls. As systemic treatment was initiated and the patients improved clinically, mirrored by significant improvement in validated clinical outcome measures of disease activity, the IL-17F serum levels increased in the majority of patients and IL-22 and IL-27 increased in a smaller portion of patients. This may represent Th-17 cell lineage as an important factor in disease remission. Further studies analyzing PBMC and skin expression of Th-17 associated cytokines is warranted.

1827

TWEAKing Cutaneous Manifestations In MRL-Lpr/Lpr Lupus Prone mice. Yumin Xia[1], Karin Blecher[1], Jing Wen[1], Jennifer S. Michaelson[2], Linda C. Burkly[2], Adam Friedman[1] and Chaim Putterman[3]. [1]Albert Einstein College of Med, Bronx, NY, [2]Biogen Idec, Cambridge, MA, [3]Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: TWEAK, a TNF superfamily cytokine, is synthesized as a membrane bound protein and processed into a soluble form that circulates to bind to its sole signaling receptor Fn14. The TWEAK/Fn14 pathway is upregulated in the context of injury and inflammatory disease, and has a variety of functions including the stimulation of inflammatory mediators, angiogenesis, and modulation of cell survival. Both keratinocytes and dermal fibroblasts express Fn14 and respond to TWEAK, as shown by the production of inflammatory mediators implicated in cutaneous lupus. In addition, TWEAK acts with other cytokines to induce keratinocyte death. On the basis of these studies, we hypothesized that TWEAK may be involved in the pathogenesis of cutaneous manifestations in the MRL-lpr/lpr (MRL/lpr) spontaneous mouse SLE model.

Methods: 129 Fn14 knockout mice were backcrossed 8 generations onto MRL-lpr/lpr (MRL/lpr) mice to generate MRL-lpr, Fn14 deficient mice (Fn14 KO). The development of cutaneous lesions in MRL/lpr Fn14KO mice was compared to MRL/lpr wild type (Fn14 WT) mice, and to the control strain MRL/+. Lesion scoring was based on erythema, scaling, alopecia, lesion thickness, and percent of body surface area involved, with the total score comprised of a weighted combination of the scores of each of these features. Skin biopsies were obtained for histology and immunohistochemistry.

Results: We evaluated cutaneous disease in age matched cohorts of MRL-lpr Fn14 WT and KO mice (30 weeks of age) in a blinded assessment. Lesional skin in MRL/lpr WT mice was found predominantly on the head and upper trunk, with erythematous plaques displaying crusted erosions and scarring alopecia. Eight of 11 MRL/lpr Fn14WT mice displayed signs of cutaneous disease, as compared to only 2/8 MRL-lpr Fn14KO mice and 1/10 MRL/+ mice that exhibited skin lesions (**Figure 1**). Cutaneous involvement in MRL/lpr Fn14WT mice was also significantly more severe as compared to MRL/lpr Fn14KO mice (lesion score of 4.4±1.4 in WT vs. 0.9±0.7 in KO; $p<0.03$), with no significant difference between MRL/lpr Fn14 KO and control MRL/+ mice ($p=0.35$). Skin histology in the MRL/lpr Fn14WT mice demonstrated parakeratosis and serous crust in the stratum corneum, epidermal acanthosis with necrotic keratinocytes, and infiltration of the dermis with lymphocytes and histiocytes, associated with thickened collagen and follicular plugging. In contrast, MRL/lpr Fn14KO and MRL/+ mice demonstrated no atypia with normal basketweaving of the stratum corneum, a 2–3 cell thick epidermis, and healthy dermal collagen. Immunohistochemistry confirmed T cell and macrophage infiltration of the skin in MRL/lpr Fn14WT but not Fn14KO mice.

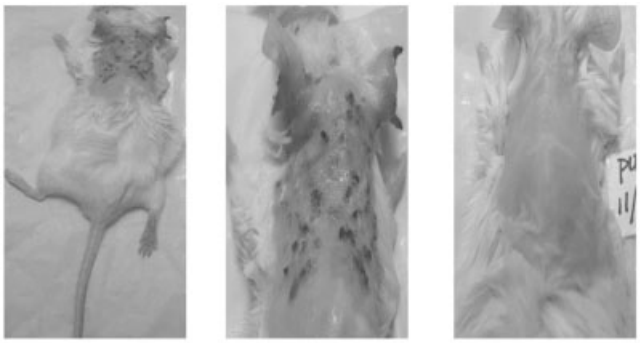

Figure 1.

Conclusion: Our data implicate the TWEAK/Fn14 pathway in the pathogenesis of cutaneous lesions in MRL/lpr mice, suggesting that targeting the TWEAK pathway may be a novel approach to treat cutaneous disease in lupus.

1828

Pro-Inflammatory Cytokine Measurement in Whole Blood Cultures Stimulated with Lipopolysaccharide Predicts Treatment Outcomes of Patients with Rheumatoid Arthritis Treated with Biologics. Ken Kayakabe[1], Takashi Kuroiwa[2], Noriyuki Sakurai[1], Hidekazu Ikeuchi[1], Anastasie K.T.[1], Toru Sakairi[1], Akito Maeshima[1], Keiju Hiromura[1] and Yoshihisa Nojima[1]. [1]Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan, [2]Jichi Medical University, Saitama Medical Center, Saitama, Japan

Background/Purpose: Although biological therapies targeting tumor necrosis factor (TNF)-α or interleukin (IL)-6 are highly effective for rheumatoid arthritis (RA), they are expensive and occasionally associated with severe side effects. Therefore, it is important to identify patients who respond or do not respond to the biologics. Possibility exists that such response is associated with each patient's capacity of pro-inflammatory cytokine production. Whole blood culture with lipopolysaccharide (LPS) stimulation is a valid low-cost method to measure cytokine synthesis in monocytes. To find predictors of response to biologics, we examined pro-inflammatory cytokine production in whole blood culture.

Methods: Whole blood was obtained from biologics-naïve patients with RA (n=41) before starting biologics (infliximab 13, etanercept 26, and adalimumab 2). At 6 months after initiation of biologics, whole blood was again drawn from 14 out of 41patients. Blood from 12 healthy volunteers were used as controls. We measured the concentration of TNF-α, IL-1β and IL-6 in supernatants of LPS-stimulated (at 1ng/ml, for 24 hrs) whole blood culture. Disease activity score (DAS28) was evaluated at baseline and 6 months after the therapy. Response to the therapy was defined by EULAR response criteria.

Results: The mean age of the patients was 55.9 yrs and 87.8% of them were female. The median of disease duration was 44.0 months. The mean DAS28 at baseline was 4.48. Rheumatoid factor and anti-citrullinated peptide antibodies were positive in 70.0% and 84.2%, respectively. The patients treated with methotrexate were 78.0% (mean 7.0 mg/week). Among patients examined, 32 were responders (good 14/moderate 18), and 9 were non-responders. All cytokines measured were significantly lower in RA patients than in healthy controls (the median and [interquartile range] of TNF-α: 30.4 [9.6, 149] vs. 256 [172, 406] pg/ml p=0.002, IL-1β: 6.9 [2.9, 75] vs. 256 [229, 371] pg/ml p<0.001, IL-6: 358 [65.3, 1975] vs. 1933 [1320, 2984] pg/ml p=0.004). In RA patients, IL-1β production before therapy was significantly lower in non-responders than in responders (3.48 [1.51, 9.41] vs. 10.0 [5.21, 93.1] pg/ml p=0.048). TNF-α and IL-6 were also lower in non-responders than in responders, but statistical significance was not observed (TNF-α: 23.0 [2.23, 66.5] vs. 31.5 [11.0, 224] pg/ml p=0.393, IL-6: 185 [45.3, 1257] vs. 366 [76.1, 2333] pg/ml, p=0.546). The area under the curve (AUC) from a receiver operating characteristic (ROC) curve analysis for the prediction of response using IL-1β was 0.717 (95% CI; 0.520 – 0.914). The sensitivity and specificity of IL-1β (cut-off value of 4.84pg/ml) were 78.1% and 77.8%, respectively. All cytokines were significantly higher after 6 month later of biologic therapy as compared with the respective baselines (TNF-α: 142 [38.0, 431] vs. 16.8 [7.45, 24.8] pg/ml p=0.004, IL-1β: 30.9 [7.11, 84.5] vs. 5.86 [1.02, 10.6] pg/ml p=0.001, IL-6: 1061 [385, 2286] vs. 122 [50.6, 275] pg/ml p=0.001).

Conclusion: This preliminary study suggests that IL-1β production in whole blood culture predicts the response to the biologic therapy. Cytokine production capacity is up-regulated by the biologic therapy. Larger studies to prove this concept are warranted.

1829

Mitochondrial Mutagenesis Correlates with the Local Inflammatory Environment in Arthritis. Leonard C. Harty[1], Monika Biniecka[1], Edward Fox[2], Jacintha N. O'Sullivan[3], Ursula Fearon[1] and Douglas J. Veale[1]. [1]Translation Rheumatology Research Group, Dublin, Ireland, [2]University of Washington, Seattle, WA, [3]Trinity University, Dublin, Ireland

Background/Purpose: To examine the association between levels of mitochondrial mutagenesis and the pro-inflammatory micro-environment in patients with inflammatory arthritis.

Methods: Fifty patients with inflammatory arthritis underwent arthroscopy and synovial tissue biopsies, synovial fluid and clinical assessment were obtained. A subgroup of patients (n=15) pre/post TNFi were also recruited. Normal synovial biopsies were obtained from 10 subjects undergoing interventional arthroscopy. Macroscopic synovitis/vascularity was measured by visual analogue scale (VAS). Cell specific markers CD3 (T cells), CD68 (macrophages) and lining layer thickness were quantified by immunohistology. TNFa, IL-6, IFNg, IL-1b and IL-8 were measured in paired synovial fluid by MSD multiplex assays. Synovial tissue mitochondrial mutagenesis was quantified using a mitochondrial random mutation capture assay (RMC). The direct effect of TNFa on oxidative stress and mitochondrial function was also assessed in primary RA synovial fibroblast cultures and mitochondrial mutagenesis, reactive oxygen species (ROS), mitochondrial membrane potential (MMP) and mitochondrial mass (MM) were quantified using the RMC assay and specific cell fluorescent probes.

Results: A significant increase in mtDNA mutation frequency was demonstrated in inflamed synovial tissue compared to control synovial tissue (p<0.05), an effect that was independent of age. mtDNA mutations positively correlated with macroscopic synovitis (r=0.52, p<0.01) and vascularity (r=0.54, p<0.01) and with sub-lining expression of CD3 (r=.46, p=0.046) and CD68 (r=.508, p=0.026). mtDNA mutation positively correlated with synovial fluid TNFa (r=0.74, p<0.01), IL-1b (r=0.65, p<0.05) and IFNg (r=0.72, p<0.05). mtDNA mutation frequency post TNFi therapy were significantly lower in patients with a DAS<3.2 (p<0.05). *In vitro* TNFa treatment significantly induced mtDNA mutations, ROS, MM and MMP in RASFCs (all p<0.05).

Conclusion: High mitochondrial mutations are strongly associated with synovial inflammation showing a direct link between mitochondrial mutations and key pro-inflammatory pathways.

1830

Relationship of Serum Tumor Necrosis Factor α, Tumor Necrosis Factor α Receptors and Tumor Necrosis Factor—Weak Inducer of Apoptosis to Clinical Parameters and Therapeutic Response in Rheumatoid Arthritis Patients Treated with Etanercept. Gunther Neeck[1], Helmut Dotzlaw[2] and Martin Schulz[2]. [1]Rheumazentrum Bad Doberan, Bad Doberan, Germany, [2]Center for Rheumatology, Bad Doberan, Germany

Background/Purpose: TWEAK has been shown to be a potent arthritogenic cytokine in the mouse model of collagen-induced arthritis. Serum levels of TWEAK increase in this model during the course of disease development, and treatment with an anti-TWEAK neutralizing monoclonal antibody reduces overall disease severity. It has been shown that TWEAK induces the expression of TNF α and that TWEAK-stimulated cell death is an indirect effect that is mediated by TNF α/TNF α receptor interactions. Our objective was to determine what relationships exist between the serum levels of TNF α, the TNF α receptors TNF-R1/-R2 and TWEAK with clinical response and disease biomarkers in a cohort of RA patients during the course of treatment with Etanercept.

Methods: Twenty patients with active rheumatoid arthritis according to the classification criteria of the American College of Rheumatology (ACR) that started Etanercept therapy due to an inadequate response to the treatment with conventional DMARDs were enrolled in the study. Patients received Etanercept 50 mg subcutaneously weekly during the course of the study. Clinical and laboratory assessments were conducted prior to injection at baseline and at 4 and 12 weeks into therapy with Etanercept. Quantification of sTNF-R1, sTNF-R2, sTWEAK, IL-6 and sTNF α in serum samples was performed using ELISA kits (R&D Systems, Wiesbaden, Germany) following the manufacturer's protocol.

Results: Etanercept therapy resulted in no sustainable effects on serum TNF-R1 and TWEAK levels during the observation period. A correlation between TNF-R2 concentrations was found with age and TNF-R1 prior to treatment with Etanercept, indicating a physiological relationship between the serum levels of TNF receptors 1 and 2. Circulating TNF α and TNF-R2 as measured using ELISA increased significantly during treatment with Etanercept. We could show that our anti-TNF-R2 assay was able to detect circulating Etanercept in serum.

Conclusion: We found no correlations between disease activity as measured using DAS28 and the levels of serum TNF-R1, TNF α and TWEAK at any of the time points during the course of treatment with Etanercept, suggesting that the levels of these factors had little measureable influence on the response to the treatment in this group of patients. The increase of serum TNF α during the course of treatment is related to the presence of high levels of TNF-R2 as measured using ELISA, since elevated TNF α is found in all patients except in two where no increased TNF-R2 was detected. The fact that patients with elevated levels of TNF α respond favorably to Etanercept suggests that this TNF α is biologically inactive, and is probably complexed with Etanercept in the serum. Interestingly, the two RA patients in which no increase in TNF α or TNF-R2 (Etanercept) could be measured during the course of treatment showed no reduction in the DAS28 after 12 weeks of therapy, suggesting that the measurement of TNF α / TNF-R2 might be useful in monitoring for compliance or for individual clearance times for serum Etanercept.

The Role of IL-17 in Systemic Lupus Erythematosus. Gil Amarilyo[1], Elaine Lourenco[2] and Antonio La Cava[3]. [1]University of California, Los Angeles, Los Angeles, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]Univ of California Los Angeles, Los Angeles, CA

Background/Purpose: T helper 17 cells (Th17), named after their signature cytokine IL-17, favor the development and progression of autoimmune diseases such as rheumatoid arthritis, Crohn's disease and multiple sclerosis. A role for Th17 cells in systemic lupus erythematosus (SLE) has been suggested by the finding that sera from lupus patients had abnormally elevated levels of IL-17 that correlated with disease activity, and by the observation that IL-17-producing T cells were present in kidney infiltrates of murine models as well as patients with lupus nephritis. Here we studied the role of IL-17 in the development of lupus-like disease induced by pristane in mice.

Methods: IL-17 knockout mice (on the B6 background) were compared with wild-type B6 mice (WT) for the development of lupus-like disease after intraperitoneal injection of the hydrocarbon oil pristane (which induces a

lupus-like disease characterized by the development of lupus-associated autoantibodies and glomerulonephritis). Total and percentage numbers of peripheral CD4, CD8 and related subsets including CD4+CD25+Foxp3+ regulatory T cells (Treg) were monitored ex vivo by flow cytometry at time 0, 3 weeks, 3 months, 5 months and 8 moths after disease induction in IL-17 knockout mice as compared to WT control mice.

Results: IL-17 deficient mice treated with pristane had reduced hypergammaglobulinemia and lower levels of anti-ssDNA and anti-chromatin antibodies in comparison with WT mice treated with pristane. The onset and the extent of glomerulonephritis were also delayed in the IL-17-deficient mice. Although IL-17 deficient mice had similar levels of CD4 and CD8 when compared to pristane injected wild type mice, they had significantly higher numbers of Treg by three months after pristane injection ($p<0.003$), and this number subsequently declined.

Conclusion: IL-17 deficiency reduced the development of lupus-like disease induced by pristane. These findings suggest a direct role of Il-17 in the SLE pathogenesis and may point towards a new drug therapy pathway for this disease.

1832

A Specific Microrna Pattern Discriminates Synovial Macrophages From Rheumatoid Arthritis and Osteoarthritis Patients. Andrea Diaz-Alderete[1], Vanessa Miranda[2], Ignacio Caballero[1], Manuel Tardaguila[1], Alberto Pascual-Montano[1], Jose L. Pablos[2] and Santos Mañes[1]. [1]Centro Nacional de Biotecnología- CSIC, Madrid, Spain, [2]Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid, Spain

Background/Purpose: Osteoarthritis (OA) and rheumatoid arthritis (RA) are chronic inflammatory diseases that can lead to joint destruction. OA is a degenerative disease of cartilage, RA is an autoimmune disease. Many pathological alterations in RA and OA are a consequence of aberrant hyperactivation of macrophages in the inflamed synovial membrane, and inhibition of their effector functions is a therapeutic strategy in both diseases. Little is known, however, about the specific genetic circuits that are differentially deregulated in RA and OA macrophages. microRNAs (miRNA) are a class of small, non-coding RNA molecules involved in fine-tuning gene expression at the post-transcriptional level. Deregulation of specific miRNA is associated with the onset or progression of human disease. We compared miRNA expression in macrophages from RA and OA patients to identify activation circuits specific for each pathological condition.

Methods: Synovial macrophages were obtained by centrifugation of synovial fluid of RA patients on Ficoll, or by collagenase I digestion of the synovial membrane of OA patients, followed by magnetic separation of CD14+ cells. The miRNA expression profile was initially evaluated in 3 RA and 3 OA samples using miRCURY LNA microRNA arrays; the miRNA identified were validated by real-time quantitative PCR (RT-qPCR) with specific probes in an independent set of samples. For bioinformatic analysis, we used 15 databases for predicted and observed miRNA targets. A statistical scoring system was applied to sort the most relevant pairs. A list of 215 high-confidence potential targets was selected and functional pathway analysis conducted on Ingenuity Pathway Analysis. Target expression was validated by RT-qPCR in purified macrophages and by immunohistochemistry in synovial membranes from RA and OA patients. Statistical analyses were performed with the Mann-Whitney U-test.

Results: Microarray analyses detected 19 differentially expressed miRNA (defined as 3.5-fold change; $p<0.02$) in macrophages from RA compared to OA patients. Of these, two up- and seven downregulated miRNA were validated by RT-qPCR in macrophages from 11 RA and 13 OA patients ($p<0.05$). Bioinformatics analysis was used to determine and prioritize potential miRNA-mRNA target pairs based on relevant biological context. A total of 215 high-confidence potential targets was selected, which defined a set of signaling pathways associated with the miRNA. Among them, the NF-kB ($p = 1.4 \times 10^{-15}$), IL-6 ($p = 1.2 \times 10^{-13}$), JAK/STAT ($p = 1.2 \times 10^{-9}$) and TNFR1 ($p = 9.3 \times 10^{-7}$) pathways were present. Finally, we validated the differential regulation of the NF-kB pathway in RA vs. OA macrophages. mRNA expression of IKKa (IkappaB kinase alpha; CHUK) was significantly lower in macrophages purified from RA compared to OA samples ($p<0.05$). Immunohistochemistry showed expression of IKKa protein in $CD68^+$ macrophages from RA and OA patients.

Conclusion: We identified a differential expression pattern of miRNA in synovial macrophages from RA compared to OA samples. This profile might be used to identify new targets and signaling pathways involved in each disease condition.

1833

The Influence of Interleukin-32γ on Osteoclastogenesis, with a Focus on Fusion-Related Genes. Bon San Koo, Yong-Gil Kim, Min Wook So, Chang-Keun Lee and Bin Yoo. University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea

Background/Purpose: We previously reported that interleukin-32γ (IL-32γ) has a direct effect on osteoclast differentiation and activation in vitro in the context of receptor activator of NF-κB ligand (RANKL) co-stimulation. However, the stage of osteoclast differentiation at which IL-32γ exerts its effect was not determined. We investigated the stage of osteoclast differentiation at which IL-32γ exerts this action, focusing on its effects on the fusion-related genes, dendritic cell-specific transmembrane protein (DC-STAMP) and the d2 isoform of vacuolar (H^+) ATPase (v-ATPase) Vo domain (Atp6v0d2).

Methods: Bone marrow-derived macrophages (BMMs) were isolated from mouse (C57BL/6J) femurs and tibiae. To determine the effects of IL-32γ and identify the most appropriate concentration for inducing osteoclast differentiation, we treated BMMs with different concentrations of IL-32γ (0, 12.5, 25, and 50 ng/ml) and then cultured them with M-CSF (30 ng/ml) and RANKL (50 ng/ml) for 4 d. To investigate whether IL-32γ affected the expression of NFATc1 and the fusion related-genes, DC-STAMP and ATP6v0d2, we performed RT-PCR from cells incubated in the absence or presence of IL-32γ. Lastly, to further investigate the stage of osteoclast differentiation during which IL-32γ acts, we added IL-32γ to our culture system at various times and incubated for 24 h.

Results: IL-32γ significantly increased osteoclast counts at concentrations of 25 and 50 ng/ml, producing the most effective induction of osteoclastogenesis at 25 ng/ml. We demonstrated that IL-32γ plays an important role in the fusion of preosteoclasts to yield multinuclear osteoclasts-particularly large osteoclasts (≥ 5 nuclei). The synergistic effect of IL-32γ on RANKL-induced formation of multinuclear osteoclasts was readily apparent when cells were treated with IL-32γ at days 1 and 2, considered to be the fusion stage of osteoclast differentiation. In addition, compared with controls, cells stimulated with IL-32γ highly expressed DC-STAMP on days 2 and 3, and NFATc1 was highly expressed on day 2.

Conclusion: On the basis of these results, we suggest that IL-32γ is a potent cytokine capable of promoting the differentiation of large osteoclasts in the context of co-stimulation with RANKL in a murine model. These effects could be related to up-regulation of the fusion-enhancing gene DC-STAMP via NFATc1 in the early stage of differentiation.

1834

Identification of Activated Cytokine Pathways in the Blood of Systemic Lupus Erythematosus, Myositis, Rheumatoid Arthritis, and Scleroderma Patients. Brandon W. Higgs[1], Wei Zhu[1], Laura Richman[1], David Fiorentino[2], Steven A. Greenberg[3], Bahija Jallal[1] and Yihong Yao[1]. [1]MedImmune, Gaithersburg, MD, [2]Stanford, Stanford, CA, [3]Brigham Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: To develop genomic signatures of seven cytokines involved in the pathogenesis of rheumatic diseases such as systemic lupus erythematosus (SLE), dermatomyositis (DM), polymyositis (PM), rheumatoid arthritis (RA), or systemic sclerosis (SSc) that could potentially help to identify patients likely to benefit from therapies that target these individual cytokines.

Methods: Over-expressed transcripts in the whole blood (WB) were identified from 262 SLE, 44 DM, 33 PM, 38 SSc and 89 RA subjects and compared to 24 healthy subjects using Affymetrix arrays. Cytokine-inducible gene signatures such as type I IFN, TNF-α, IL1β, IL-10, IL-13, IL-17, and GM-CSF were assessed in the WB of these subjects to identify subpopulations showing activation of specific cytokine pathways.

Results: Significant activation of the type I IFN pathway in a population of 5 diseases studied was universally observed. The TNF-α and IL-1β pathways were activated in subgroups of PM and RA subjects, respectively, with another subgroup of RA subjects showing activation of the IL-13 pathway. The GM-CSF pathway was activated in a subgroup of SSc subjects and the IL-17 pathway was activated in subgroups of all diseases except SLE.

Conclusion: A novel gene expression measurement of activated cytokines in five different rheumatic diseases is presented. Characterizing the cytokine pathways most activated in specific patient subpopulations has the potential to help to target the appropriate patient populations for corresponding anti-cytokine therapies.

1835

Systemic Lupus Erythematosus, Myositis, Rheumatoid Arthritis, and Scleroderma Patients Share Activation of a Common Type I Interferon Pathway. Brandon W. Higgs[1], Zheng Liu[1], Barbara White[1], Wei Zhu[1], Wendy White[1], Chris Morehouse[1], Philip Brohawn[1], Peter Kiener[1], Laura Richman[1], David Fiorentino[2], Steven A. Greenberg[3], Bahija Jallal[1] and Yihong Yao[1]. [1]MedImmune, Gaithersburg, MD, [2]Stanford, Stanford, CA, [3]Brigham Women's Hospital, Harvard Medical School, Boston, MA

Background/Purpose: To characterize the type I IFN pathway activation across systemic lupus erythematosus (SLE), dermatomyositis (DM), polymyositis (PM), rheumatoid arthritis (RA), and systemic scleroderma (SSc) subjects and evaluate the potential to develop a molecular diagnostic from the peripheral blood that reflects this activation in disease-affected tissues.

Methods: Over-expressed transcripts were identified in the whole blood (WB) of 262 SLE, 44 DM, 33 PM, 28 SSc and 89 RA subjects and compared to 24 healthy subjects using Affymetrix microarrays. A 5 gene type I IFN signature was assessed in these subjects to: 1) identify subpopulations showing both activation and concordance of the type I IFN pathway in the peripheral blood and disease-affected tissues of each disease, and 2) correlate this pathway activation in the WB with clinical measurements.

Results: A common set of 36 type I IFN-inducible transcripts were identified among the most over-expressed in the WB of all subjects. Significant activation of the type I IFN pathway in subgroups of each of the 5 diseases studied was observed. Baseline disease activity measurements correlated with a type I IFN gene signature in the WB of subjects with SLE, PM, and SSc, as did various serum autoantibody levels in SLE or DM subjects. This signature was also well correlated between disease-affected tissue and WB in subjects with SLE, DM, PM, or SSc.

Conclusion: The results indicate that in patient subsets of 5 rheumatic diseases, the IFN pathway is activated and identification of these subsets could play an important role in future therapies.

1836

Extracellular 14-3-3η: A Novel Mediator of Inflammation Associated with Selective Activation of Intracellular Pathways. Anthony Marotta[1], Yuan Gui[1], Aziz Ghahary[2], Ruhangiz Kilani[2] and Walter P. Maksymowych[3]. [1]Augurex Life Sciences Corp, North Vancouver, BC, [2]University of British Columbia, Vancover, BC, [3]University of Alberta, Edmonton, AB

Background/Purpose: Rheumatoid arthritis (RA) results from the interaction and convergence of mediators that contribute to pathological processes. The 14-3-3 family members are ubiquitously expressed intracellular chaperones. We previously demonstrated that the η isoform is specifically present extracellularly in the synovial fluid and matched serum of patients with inflammatory arthritis and that its expression significantly correlated with levels of MMP-1 and MMP-3. Recent data also indicates that serum 14-3-3η is highly specific for RA. We aimed to examine the role of extracellular 14-3-3η in the pathogenesis of RA by investigating its effects on 1) the activation of RA-relevant signaling cascades, 2) induction of pro-inflammatory mediators and 3) the effects of selectively targeting 14-3-3η with monoclonal antibodies.

Methods: Cells of the monocytic lineage (THP-1) were stimulated with 12.5ng/ml of recombinant human 14-3-3η and activation of relevant signaling targets was assessed by immunoblot analysis using phosphospecific antibodies. Activation of HL-60, PCS-201-010, Jurkat and Daudi cells was assessed by evaluating the phosphorylation status of MAPK/ERK following 15 minutes of stimulation with 12.5ng/ml. mRNA levels of IL-1β, IL-6, IL-8, CCL2/MCP-1, CCL4/MIP-1β, MMP-1, MMP-9, TNFα, RANKL were assessed in THP-1 cells following 18h incubation with a dose range of 0.10 to 100ng/ml of recombinant human 14-3-3η reflecting in vivo concentrations. For antibody targeting studies, recombinant human 14-3-3η was co-incubated with antibody (0.2 to 20mg/ml) for 18h and levels of transcripts were assessed.

Results: Stimulation assays showed that while monocytic, myeloid, and fibroblast cell lines were activated in response to 14-3-3η, T and B cell lines were not. Extracellular 14-3-3η, at concentrations found in RA patient serum (median 1.12ng/ml and range of 0.12 to 20ng/ml) activated key intracellular signalling cascades that regulate cell proliferation (MAPK/ERK), survival (AKT), inflammation (JAK-STAT), and tissue remodelling (SAPK/JNK). These cell stimulatory effects were specific yet distinct from other reported endokines/extracellular factors since neither the activation of p38MAPK nor NFκB was not observed with 14-3-3η stimulation. Furthermore, extracellular 14-3-3η at levels approximating median serum levels behaved as a potent inducer of IL-1β, IL-8, CCL2/MCP-1, CCL4/MIP-1β, MMP-1, MMP-9 and RANKL transcripts. Higher levels of 14-3-3η, though within the range found in vivo, were required for induction of IL-6 and TNFα. Targeting 14-3-3η with monoclonal antibody compounds attenuated these effects.

Conclusion: Extracellular 14-3-3η is a novel mediator that induces expression of several factors associated with the pathogenesis of RA. In contrast to other endokines that activate both p38MAPK and NFkB as well as up-regulate pro-inflammatory factors, 14-3-3η acts through alternate signalling pathways. Targeting 14-3-3η with monoclonal antibody compounds attenuates its inducing effects underscoring its novelty as a potential therapeutic target.

1837

Serum Galectin-3 Level in Patients with Scleroderma. Metin Ozgen[1], Suleyman Serdar Koca[1], Fatma Akbas[1], Nevin Ilhan[2], Baris Gundogdu[1] and Ahmet Isik[1]. [1]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [2]Department of Biochemistry, Faculty of Medicine, Firat University, Elazig, Turkey

Background/Purpose: Scleroderma (systemic sclerosis [SSc]) is an autoimmune disease of unknown etiology characterized by progressive multiorgan fibrosis. Activated fibroblasts are mainly responsible for fibrosis in SSc. Galectin-3, a β-galactoside binding lectin, plays many important regulatory roles in both physiological and pathological processes including proliferation, apoptosis, inflammation and fibrosis. Previous studies have demonstrated that galectin-3 contributes significantly to fibroblast activation and the development of fibrosis.

The purpose of this study was to asses the serum galectin-3 level and its association with disease activity and severity indexes in patients with SSc.

Methods: Thirty seven SSc patients, 23 systemic lupus erythematosus (SLE) patients (serving as patient control group) and 28 healthy volunteers were enrolled in this study. Disease activity and severity scores were detected with Valentini disease activity index and Medsger disease severity scale in the SSc group, and SLE Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborating Clinics/American Collage of Rheumatology (SLICC/ACR) damage index in the SLE group. The serum levels of galectin-3, vascular endothelial growth factor (VEGF), transforming growth factor (TGF)-β and interleukin (IL)-6 were determined.

Results: Compared with the control group, the galectin-3 levels were higher (Table) in the SSc and SLE groups. The galectin-3 levels were not correlated with the disease activity and severity indexes in both patient groups. But, the serum galectin-3 levels were higher in the active SSc and SLE subgroups than in the inactive SSc (4.6 ng/mL vs. 1.3 ng/mL p=0.015) and SLE (17.4 ng/mL vs. 6.5 ng/mL p=0.019) subgroups.

Table. Demographics and laboratory data in the study groups

	SSc	SLE	HC	P
Age (years)	46 ± 13	37 ± 10	42 ± 14	0.110*
Gender (Female/Male)	32/5	21/2	22/6	0.302**
BMI (kg/m^2)	24.2/5.1	25.2 ± 4.1	26.9 ± 4.8	0.980*
Disease duration (years)	4.19 ± 4.57	5.13 ± 4.38	—	0.079*
ESR (mm/h)	26 ± 20[b]	32 ± 26[c]	9 ± 4	0.001*
CRP (mg/L)	12 ± 20	6 ± 6	3 ± 0	0.056*
IL-6 (pg/mL)	11.4 ± 5.6	18.5 ± 20.4	14.9 ± 26.1	0.116*
TGF-β (ng/mL)	42.7 ± 14.8	32.8 ± 11.7	35.5 ± 12.2	0.085*
VEGF (pg/mL)	337 ± 242	210 ± 175[a]	330 ± 195	0.023*
Galectin-3 (ng/mL)	3.5 ± 4.9[a,d]	14.0 ± 11.6[c]	1.25 ± 1.08	0.001*

Data were presented as mean ± standard deviation. SSc: Systemic sclerosis, SLE: Systemic lupus erythematosus, HC: Healthy control, BMI: Body mass index, ESR: Erythrocyte sedimentation rate, CRP: C-reactive protein, IL: Interleukin, TGF: Transforming growth factor, VEGF: Vascular endothelial growth factor.
* ANOVA and ** Chi-square p value; Compared with control group: [a] p<0.05, [b] p<0.01, [c] p<0.001; Compared with SLE group: [d] p<0.001.

Conclusion: These results suggest that galectin-3 is involved in the pathogenesis of SSc characterized by fibrosis and SLE characterized by inflammation. Galectin-3, which is proposed as biomarker of fibrosis and inflammation by previous studies, may be a novel biomarker for activities of SSc and SLE.

1838

Atherogenic Effect of Inflammatory Cytokines in Chronic Inflammatory Diseases. Misato Hashizume and Masahiko Mihara. Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan

Background/Purpose: In patients with chronic inflammatory diseases such as rheumatoid arthritis (RA), the risk of cardiovascular disease (CVD) is increased. Inflammatory cytokines are considered of fundamental importance to atherogenesis. It was reported that high level scavenger receptor-A (SR-A) gene expression is associated with an increased incidence of cardiovascular events in acute coronary syndrome. SR-A is expressed on macrophages and facilitates the intracellular accumulation of oxidized LDL (oxLDL), resulting in the formation of atherosclerotic plaque. To explore whether inflammatory cytokines promote atherogenesis, we examined their effects on SR-A expression oxLDL accumulation.

Methods: THP-1 cells were induced to differentiate into macrophage-like cells (THP-1/macrophages) by culture with phorbol myristate acetate for 4 days. THP-1/macrophages were then stimulated for 24 h by serum from RA patients or healthy subjects, and IL-6 and TNF-α in the presence or absence of anti-IL-6 receptor antibody (tocilizumab, TCZ) or TNF-α receptor (p75)-Fc (etanercept, ETN). The level of SR-A mRNA was measured by real-time PCR. Cells were further incubated with oxLDL for a specific time. Intracellular accumulation of oxLDL was measured by Oil Red O staining and fluorescence.

Results: First, we determined the effect of TNF-α and IL-6 on the expression of SR-A and formation of atherosclerotic plaque. Either cytokine induced SR-A mRNA expression and increased intracellular oxLDL accumulation by THP-1/macrophages. ETN inhibited the induction of SR-A by TNF-α. Interestingly, TCZ inhibited SR-A induction by IL-6 as well as TNF-α because IL-6 induced by TNF-α increased SR-A expression. To test whether SR-A expression and the accumulation of oxLDL were induced by blood, THP-1/macrophages were cultured in the presence of serum from healthy subjects or RA patients. Serum from the latter but not the former induced expression of SR-A. Moreover, RA patients′ serum augmented the accumulation of oxLDL by THP-1/macrophages. Finally, in order to examine the effect of TNF-α and IL-6 on the induction of SR-A expression and the accumulation of oxLDL by RA serum, the sera were incubated with ETN or TCZ. Both agents were found to partially or completely inhibit the induction of SR-A expression and the accumulation of oxLDL stimulated by RA serum.

Conclusion: Inflammatory cytokines, TNF-α and IL-6 induce the expression of SR-A and accumulation of oxLDL. These cytokines are directly implicated in atherosclerotic plaque formation and progression. Our findings indicate that blockade of TNF-α and IL-6 has therapeutic potential for reducing CVD in chronic inflammatory diseases. We are now examining the expression of SR-A and plaque formation using macrophages from patients with chronic inflammatory diseases.

Follistatin-Like Protein 1 Promotes Arthritis by Enhancing Cytokine/Chemokine Gene Expression. Yury Chaly[1], Anthony Marinov[1], Leif Oxburgh[2], Daniel Bushnell[1] and Raphael Hirsch[1]. [1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Maine Medical Center Research Institute, Scarborough, ME

Background/Purpose: Follistatin-like protein 1 (FSTL-1) is a secreted glycoprotein that is over-expressed in the synovium of rheumatoid arthritis (RA) patients. We have previously shown that serum levels of FSTL-1 correlate with active disease in children with systemic juvenile idiopathic arthritis. We also demonstrated that over-expression of FSTL-1 exacerbated murine collagen-induced arthritis (CIA) while its neutralization suppressed CIA. The aim of the current study was to determine the mechanism by which FSTL-1 promotes arthritis focusing on FSTL-1 as a putative mediator of pro-inflammatory cytokine and chemokine synthesis.

Methods: CIA was induced in mice hypomorphic for FSTL-1 that were generated using a genetrap technique, resulting in a significant reduction of FSTL-1 protein expression. Arthritis was assessed by measuring paw swelling and using a qualitative arthritic index. Mesenchymal stromal cells (MSC) were isolated from the bone marrow of wild type and hypomorphic mice. To suppress FSTL-1 expression, mouse stromal ST2 cells were transduced with a lentivirus encoding mouse FSTL-1 short hairpin RNA. MSC and ST2 cells were stimulated with IL-1β, TNF-α and IL-17. Monocytic U937 cells, which do not normally express FSTL-1, were transfected with FSTL-1 and stimulated with phorbol myristate acetate (PMA) and lipopolysaccharide (LPS). The levels of FSTL-1, IL-6, IL-8 and monocyte chemotactic protein-1 (MCP-1) were assessed by ELISA.

Results: In CIA, a significant correlation was found between serum FSTL-1 levels and both paw swelling and the arthritic index ($r=0.399$, $p<0.01$; $r=0.496$, $p<0.05$, respectively). FSTL-1 up-regulated IL-6, IL-8 and MCP-1 production in PMA- and LPS-stimulated U937 cells. Knockdown of endogenous FSTL-1 expression suppressed IL-6 and MCP-1 production by stimulated stromal ST2 cells and MSC. FSTL-1 protein could be induced in vivo after treatment of mice with LPS.

Conclusion: These findings demonstrate that FSTL-1 directly up-regulates pro-inflammatory mediators important in the pathogenesis of arthritis and that serum levels of FSTL-1 correlate with severity of arthritis. Thus, FSTL-1 might be a useful biomarker of arthritis and a novel therapeutic target in chronic inflammatory diseases such as RA.

Decreased Interleukin-22 in Pulmonary Fibrosis: Potential Role As a Regulatory Cytokine. Minrui Liang[1], Xiangjun Chen[2], Jiu-Cun Wang[3], Min Guan[2], Haiyan Chu[4] and Hejian Zou[5]. [1]Huashan Hospital,Fudan University,Shanghai, Shanghai, China, [2]Huashan Hospital, Fudan University, Shanghai, China, [3]Fudan University, Shanghai, China, [4]School of Life Science, Fudan University, China, [5]Huashan Hospital, Shanghai, China

Background/Purpose: Idiopathic pulmonary fibrosis (IPF) is clinically characterized of pulmonary inflammation, fibrosis and loss of lung function. IPF is one of the major causes for mortality in most connective tissue diseases. Recent studies have demonstrated that Interleukin(IL)-22 has both proinflammatory and tissue-protective properties in certain inflammatory milieu. To better understand the pathogenesis of IPF with alveolar epithelial to mesenchymal cell transition (EMT) and excessive collagen deposition, we used bleomycin(BLM)-induced pulmonary fibrosis mouse models to explore a critical regulatory role for IL-22.

Methods: BLM-induced pulmonary inflammation and fibrosis was confirmed by hematoxylin and eosin(H&E) and Masson Trichrome staining. The relative expression of *collagen1a2, collagen3al, mmp2, mmp9, tgf-*β was determined by real-time RT-PCR. The expressions of α-SMA, E-cadherin (E-cad) and IL-22 in the lung tissues were meanwhile measured by immunohistochemisty(IHC) and western-blot. The secreting IL-22 in alveolar lavage fluid was quantitated by ELISA. The effects of recombinant IL-22 (rIL-22) on BLM treated A549 cells, with regard to the proliferation of A549 and production of α-SMA, were examined by CCK-8 and western-blot analysis.

Results: Pulmonary inflammation and fibrosis were observed by H&E and Masson Trichrome stainings in BLM-induced C57BL/6 mice, researching the peak at the third week. BLM induced mice then, undergo EMT, which was accompanied by the upregulation of myofibroblast phenotypic markersα-SMA and the downregulation of the epithelial phenotype marker E-cad. Our data showed that *collagen1a2, collagen3a1, mmp2, mmp9, tgf-*β in the lung of BLM induced mice increased, with significantly diminished IL-22 in the alveolar lavage fluid and lung tissue. In vitro, alvealor epithelial cell expressing IL-22R1 but not fibroblasts was determined as the main IL-22 target cell; IL-22 could induce the phosphorylation of STAT3, up-regulate the viability of A549 cell line and down-regulate the level of α-SMA induced by BLM.

Conclusion: Our study indicates a protective pathway during the pulmonary fibrosis possibly through inhibiting EMT regulated by IL-22.

Bridging ELISA As a Screening Assay to Monitor Immunogenicity in Routine Clinical Practice. Sandra Garcês[1], Jocelyne Demengeot[2], J. Canas da Silva[3] and L. Aarden[4]. [1]Instituto Gulbenkian Ciência; Hospital Garcia de Orta, Oeiras, Portugal, [2]Instituto Gulbenkian Ciência, Oeiras, Portugal, [3]Hospital Garcia de Orta, Almada, Portugal, [4]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

Background/Purpose: Drug immunogenicity can be a significant problem in the treatment of patients with therapeutic antibodies, such as TNF alpha inhibitors. The clinical and scientific relevance of monitoring immunogenicity in clinical practice have been recognized and recommended by the European Agency of Medicine (EMEA). However, its assessment is technically challenging and no consensus exists about the way immunogenicity can be monitored. Newly developed fluid-phase radio-immuno assays (RIA) have been presented as a kind of "gold standard" method to assess immunogenicity. However, RIA requires high doses of radioactivity and special conditions,

preventing its use as a routine assay. By contrast, enzyme-linked immunoassay (ELISA) it's a simple and cheap method, ideal candidate to be used as a high-throughput screening assay. Bridging ELISA has increased specificity over the conventional ELISAs methods. Several optimizations of this method were made so that it can become a good screening assay to monitor drug immunogenicity. We aim to test, in a same cohort of patients receiving infliximab, this bridging ELISA in comparison with a fluid-phase antigen-binding RIA to quantify anti-infliximab antibodies.

Methods: A total of 82 consecutive patients were evaluated (38 rheumatoid arthritis patients, 27 ankylosing spondylitis, 9 psoriatic arthritis and 18 patients with inflammatory bowel disease), 61 females, with a mean age of 41 (4.2) years, that were receiving Infliximab (3–5mg/Kg every 6 or 8 weeks) for a mean period of 3.5 (2.0) years. Blood samples were collected immediately before the next infliximab infusion. Anti-infliximab antibodies were quantified by 1) Bridging ELISA where the antibodies bind to the infliximab coated in a solid phase and revealed by the addition of biotinylated infliximab and by 2) fluid-phase RIA-ABA that uses a sepharose-immobilized protein A, IgG total and IgG4-specific, to bind IgGs in the patient's serum. Anti-infliximab specific IgGs are revealed by the addition of ^{125}I-labeled infliximab F(ab')2. A simple ELISA method was used to quantify serum infliximab levels., Therapeutic response was assessed according to validated criteria established for each disease.

Results: A total of 22 (27%) were tested positive for the presence of anti-infliximab abs using RIA, coinciding with the samples that were also positives in Bridging ELISA. Bridging ELISA cannot detect monovalent IgG4. No samples testing exclusively IgG4 specific anti-infliximab were detected. All patients (100%) with detectable anti-infliximab antibodies had undetectable serum trough drug levels and were not able to sustain the therapeutic response.

Conclusion: Bridging ELISA was able to detect the same positive samples as RIA. The presence of IgG4-specific antibodies did not alter the assay's ability in detecting positive samples, since exclusively IgG4-specific antibodies are unlikely to occur. By its simplicity Bridging ELISA is a suitable test to be implemented in routine clinical practice as a screening assay to monitor drug immunogenicity.

In Vivo Gene Transfer of IL-17A Induces Osteoclast Formation in a RANKL-Dependent Manner, Exacerbates Collagen-Induced Arthritis and Induces Epidermal Hyperplasia. Iannis E. Adamopoulos[1], Cheng-Chi Chao[2] and Eddie P. Bowman[3]. [1]UC Davis, Sacramento, CA, [2]Merck, Palo Alto, CA, [3]Merck, Palo Alto

Background/Purpose: Rheumatoid arthritis is an autoimmune disease where the interaction between the activated immune system and the skeletal system results in bone loss. We have previously shown that IL-17A upregulates the receptor RANK on human osteoclast precursors to increase their responsiveness to RANKL leading to increased bone loss *in vitro*.

Methods: In this study, we used minicircle-mediated gene transfer to evaluate the *in vivo* interplay between IL-17A and RANKL on bone metabolism.

Results: Chronic systemic IL-17A exposure induces neutrophilia *in vivo*, but was not sufficient to drive synovial inflammation in a naïve C57Bl/6 mouse. Systemic IL-17A exposure *in vivo* sensitized osteoclast precursors to sub-optimal RANKL levels resulting in elevated serum TRAP levels. The serum TRAP induction was independent of arthritis development. Moreover, systemic IL-17A exposure prior to collagen-induced arthritis sensitization severely exacerbated arthritis and bone loss, and led to epidermal hyperplasia.

Conclusion: Collectively our data suggest that IL-17A may play distinct roles in bone loss, joint inflammation and psoriasis making it a suitable candidate to combat psoriatic arthritis.

1843

FMS-Like Tyrosine Kinase 3 Receptor Inhibition Leads to Decreased Production of Interleukin 6 by Synovial Biopsies, Fibroblast-Like Synoviocytes and Monocytic Cells From Arthritic Patients. Maria I. Martins Ramos, Saïda Aarrass, Danielle M. Gerlag, PP. Tak and Maria C. Lebre. Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is characterized by inflammation of the synovial membrane and synovial lining hyperplasia, which results in erosion of cartilage and bone. Fibroblast-like synoviocytes (FLS) and macrophages play critical roles in this destructive process by producing inflammatory cytokines. Interleukin 6 (IL-6) is a key inflammatory cytokine in the pathobiology of RA and biological therapies targeting the IL-6 receptor have shown clinical benefit. Fms-like tyrosine kinase 3 ligand (FLT3L) plays a major role in dendritic cell (DC) biology. Flt3L can be detected in RA synovial fluid (SF) and serum and we have shown that Flt3L and its receptor are also expressed in other arthritic diseases. This axis exerts both pro-inflammatory and tissue destructive properties once in the joint cavity. Therefore we examined the effect(s) of a specific Flt3 inhibitor on IL-6 production by synovial biopsies from arthritic patients, cultured FLS and monocytic cells.

Methods: Synovial tissue biopsy specimens were obtained by arthroscopy and cultured in the absence or in the presence of a Flt3 specific inhibitor (50–100 nM, CEP-701) for 4 days. Monocytes were isolated from peripheral blood mononuclear cells (PBMC) by Ficoll gradient followed by Percoll gradient. Macrophages and DC were generated by culturing monocytes with GM-CSF or GM-CSF+IL-4, respectively. FLS and monocytic cells were cultured in the absence or in the presence of CEP-701 (50–100 nM). After 24h (monocytic cells and FLS) or after 4 days (synovial biopsies) IL-6 production was measured by ELISA.

Results: CEP-701 efficiently suppressed spontaneous production of IL-6 by synovial biopsies. As the main producers of IL-6 in the inflamed joint are synovial fibroblasts and macrophages we investigated the production of this inflammatory cytokine by these cells. Indeed, CEP-701 treatment blocked IL-6 levels in both FLS and monocytic cells.

Conclusion: Our findings suggest that therapies targeting Flt3L/Flt3 activity may be useful in suppressing inflammation in RA and other rheumatic diseases

1844

Anti-Inflammatory Activity of Apremilast Against T Cells, Chondrocytes, and Rheumatoid Arthritis Synovial Fibroblasts in Vitro. Lori Capone, Audry Rogovitz, Anita Gandhi and Peter Schafer. Celgene Corporation, Summit, NJ

Background/Purpose: Apremilast (APR) is a novel, orally available small molecule that specifically targets phosphodiesterase 4 (PDE4), thereby modulating multiple pro-inflammatory and anti-inflammatory mediators in both immune and non-immune cells. T cells secrete various cytokines and chemokines that play a role in RA and spondylarthritis. In addition, cytokines produced by chondrocytes and synoviocytes contribute to inflammatory joint diseases such as arthritis and in bone damage, and are increased in synovial fluid of spondylarthritis and RA patients.

Methods: To explore the modulation of various cellular responses involved in arthritis and joint damage, the effect of APR on inflammatory responses of primary human T cells, chondrocytes, and RA patient synovial fibroblasts was examined, and compared with that of other anti-rheumatic agents etanercept (ETAN), cyclosporine A (CsA), methotrexate (MTX), and prednisolone (PRED). Human peripheral blood total T cells from healthy donors were stimulated with anti-CD3 antibody. Total peripheral blood mononuclear cells were stimulated with Staphylococcal Enterotoxin B. Cytokine and chemokine protein levels were analyzed by cytometric bead array. Normal primary human chondrocytes and RA synovial fibroblasts were stimulated with IL-1β, IL-6 and IL-6R. IL-7 mRNA was measured by qRT-PCR.

Results: In T cells, APR inhibited production of all T cell cytokines and chemokines measured (IL-2, IL-4, IL-13, IFN-gamma, TNF-alpha, CXCL10, CCL3, and CCL4) with 50% inhibitory concentrations (IC50s) of 15–360 ng/mL. CsA also inhibited all analytes, with IC50s of 4.7–140 ng/mL. In contrast, ETAN potently inhibited TNF-alpha (IC50=1.5 ng/mL), and to a lesser degree IL-13 and IP-10 (16–62 ng/mL), but IC50s for all other analytes were >1600 ng/mL. Notably, ETAN and CsA inhibited TNF-α by 90–95%, while APR inhibited TNF-α by a maximum of 70%. In chondrocytes, APR significantly inhibited IL-7 gene expression (IC50=140 ng/mL) to a greater degree than ETAN or MTX, while IL-7 inhibition by PRED was greatest. APR showed a trend of inhibition of $\alpha v\beta 3$ integrin, ICAM-1 expression, and production of IL-8, MMP-3, and MMP-13 by chondrocytes. In stimulated RA synovial fibroblasts, APR inhibited IL-7 gene expression (IC50=1800 ng/mL), while PRED, MTX, and ETAN had no significant effect.

Conclusion: Treatment of human T cells with APR resulted in inhibition of IL-2, IL-4, IL-13, IFN-gamma, TNF-alpha, CXCL10, CCL3, and CCL4, with a predominant pattern of partial inhibition. In chondrocytes and RA synovial fibroblasts, APR inhibited IL-7 gene expression. These results illustrate the distinct pattern of modulation of inflammatory responses by PDE4 inhibition, compared to other classes of drugs.

C5orf30 a Candidate Susceptibility Gene in Rheumatoid Arthritis. Sachin Khetan[1], Munitta Muthana[1] and A. G. Wilson[2]. [1]Dr, Sheffield, United Kingdom, [2]Sheffield Uni /Medical School, Sheffield, United Kingdom

Background/Purpose: A recent genome wide associations study identified SNP rs26232 with risk of developing rheumatoid arthritis (RA) (1), in addition a recent study has reported association with radiological damage (2). The SNP rs26232 is located at chromosome 5q21 within the intron of a predicted gene *C5orf30* . The aim of this study is to determine the pattern of expression of *C5orf30* in rheumatoid synovium and cultured synovial cells.

Methods: Fresh synovial biopsies obtained from RA patients were used to isolate fibroblast-like synovial cells (FLS) following digestion with collagenase-1. Real time PCR was used to determine *C5orf30* transcript levels in FLS (stimulated with TNF, LPS & hypoxia) and in peripheral blood mononuclear cells (PBMC) isolated from RA patients and healthy individuals. *C5orf30* gene expression was also assessed in a panel of other cell types. To study protein expression we stained paraffin-embedded athroscopy sections with anti-*C5orf30*.

Results: The expression of *C5orf30* was confirmed at the mRNA level in many cell types including macrophages, keratinocytes, thymus and cancer cells including lung, breast, prostate and melanoma. *C5orf30* was also expressed in joint FLS and was found to be up-regulated following treatment with bacterial LPS (22 fold), hypoxia (26-fold) but not TNF-a (0.9 fold) when compared to untreated FLS. Interestingly, expression of *C5orf30* was detected at lower levels in PBMCs of patients than controls. Indeed, in some RA patients (14/23) this was undetectable. Immunohistochemistry, staining of patient arthroscopies revealed that *C5orf30* was strongly expressed in both the nuclear and cytoplasmic compartment of synovial lining cells.

Conclusion: *C5orf30* is expressed at both the transcript & protein level in synovial cells but not in circulating PBMC obtained from RA patients, suggesting that *C5orf30* is expressed in a tissue-specific manner. We are currently performing confocal microscopy to determine the subcellular localization of *C5orf30* expression in RA joints and mass spectrometry to work out the biology of this important marker in the pathogenesis and severity of RA.

Adult Prevalence of Systemic Autoimmune Rheumatic Diseases (SARDs) in British Columbia, Canada. J. Antonio Avina-Zubieta[1], Eric C. Sayre[1], Sasha Bernatsky[2], Allen J. Lehman[1], Kamran Shojania[1], John Esdaile[3] and Diane Lacaille[1]. [1]Arthritis Research Centre of Canada/ University of British Columbia, Vancouver, BC, [2]McGill UHC/RVH, Montreal, QC, [3]University of Calgary, Calgary, AB

Background/Purpose: There is a growing interest in the use of administrative health data to estimate the incidence and prevalence of systemic autoimmune rheumatic disorders (SARDs) such as systemic lupus erythematosus (SLE), systemic sclerosis (SSc), Sjögren's disease (SjD), and poly/dermatomyositis (PM/DM) [collectively called as connective tissue diseases CTD]; and, systemic vasculitides (polyarteritis nodosa, Wegener's disease, giant cell arteritis and Takayasu's disease). We estimated the prevalence and incidence rates of SARDs as a group and as individual diseases by sex in age 20+ years in the province of British Columbia (BC), Canada (population 3.3 million) using physician billing and hospitalization databases.

Methods: Our data included all visits to health professionals and hospital admissions covered by the comprehensive provincial medical services plan from January 1, 1990 until December 31, 2007 for all individuals > 18 years of age. SARDs was defined as: **(a)** ≥ 2 ICD-9/10 codes for SARDs ≥ 2 months apart but within a two-year period by any physician other than rheumatologists or **(b)** one ICD-9/10 code for SARDs by a rheumatologist (at any time), or **(c)** >1 hospitalization diagnostic code of SARDs. To improve specificity of our algorithm, we excluded individuals with at least two visits ≥ 2 months apart subsequent to the first SARD visit (second for a non-rheumatologist) with diagnoses of other non-SARDs inflammatory arthritides (e.g. rheumatoid arthritis, psoriatic arthritis, spondyloarthropathy) and those where a diagnosis of SARDs by a non-rheumatologist was non confirmed when seen by a rheumatologist. The prevalence estimates were calculated for the year 2007, based on the number of cases that had been identified during the study period (1996–2007) who remained alive as of December 31, 2007, with the denominator being the total number of BC residents at that time. SARDs cases were identified as incident cases for 1996–2007 if they had no prior visit for SARDs since 1990.

Results: The overall prevalence of CTD and systemic vasculitides in 2007 were 0.39% and 0.03%, respectively. The BC prevalence rates of CTD by sex and age are similar to those reported previously using Bayesian models (*males:* 176.3 versus 221.3 and *females*: 591.9 versus 605.9, for BC and Canada, respectively). The prevalence and incidence rates per 100,000 by disease, and sex in age 20+ are shown in the table below.

SARD DISEASE	Prevalence per 100K Males 20+	Prevalence per 100K Females 20+	Prevalence per 100K Total 20+	Incidence per 100K PY Males 20+	Incidence per 100K PY Females 20+	Incidence per 100K PY Total 20+
CONNECTIVE TISSUE DISEASES	176.3	591.9	388.6	20.1	67.5	44.3
SLE	30.4	193.9	113.9	3.6	24.2	14.1
SSc	6.4	35.6	21.3	1.5	5.6	3.6
SjD	5.5	36.4	21.3	1.7	6.8	4.3
DM	3.2	7.5	5.4	0.4	1.6	1.0
PM	8.0	10.3	9.2	1.1	1.8	1.4
SYSTEMIC VASCULITIDES	21.1	42.2	31.9	3.7	6.9	5.3
Polyarteritis nodosa	3.0	5.0	4.0	0.4	0.8	0.6
Wegener's disease	10.0	10.7	10.3	2.0	2.5	2.2
Giant cell arteritis	8.5	25.6	17.3	1.6	3.8	2.7
Takayasu's disease	0.6	2.8	1.7	0.2	0.5	0.4

Conclusion: CTD and systemic vasculitis rates in this study are comparable with epidemiologic studies on SARDs. Administrative data are a valuable source to study the epidemiology and surveillance of SARDs.

1847

The Georgia Lupus Registry: Differences in Age-Specific Incidence Rates Between Black and White Females with SLE. Cristina M. Drenkard[1], Gaobin Bao[1], Charles G. Helmick[2], C. Gordon[3], Rana Bayakly[4] and S. Sam Lim[1]. [1]Emory University, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]University of Birmingham, Birmingham, United Kingdom, [4]Georgia Department of Public Health, Atlanta, GA

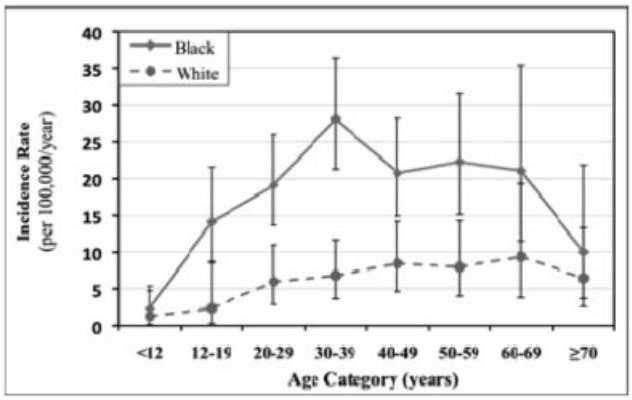
Background/Purpose: Although it is considered that SLE most often strikes women in their childbearing-ages, European studies have reported peak incidence among White women to occur above age 50. US studies have shown increased risk among younger Black females compared with Whites. However, age-specific risks by race in American women have been estimated from populations with relatively small number of Blacks. We aimed to describe age-specific incidence rates of SLE in Black and White females from a large population-based registry.

Methods: The Georgia Lupus Registry is a population-based registry designed to estimate the incidence and prevalence of SLE in Atlanta, GA. The state HIPAA exemption for surveillance allowed health care providers and facilities to provide access to protected health information without written patient consent. Sources of cases included hospitals (20), rheumatologists (35), nephrologists (10), dermatologists (20), commercial labs, and population databases. Trained abstractors reviewed >8,000 medical records. The catchment area was the two main counties (Fulton and DeKalb) that include Atlanta. Denominators were derived from the 2000 US Census Bureau Vintage 2009, for the period 2002–2004. The total population in the target counties for the period at risk was 4,742,264, of

whom 1,082,131 were White females (WF) and 1,239,819 Black females (BF). Average annual age-specific incidence rates per 100,000 and exact 95% confidence intervals assuming a Poisson distribution were calculated. BF and WF cases that were either definite (≥4 ACR Criteria) or probable (3 ACR Criteria with Final Diagnosis by Rheumatologist) were included in the analysis.

Results: Among a total of 332 incident cases, 215 were BF and 66 WF. The mean age at diagnosis was 39.4 and 46.3 years in BF and WF, respectively (p=0.009). The average annual incidence rate was 17.3/100,000 (95% CI 15.1, 19.8) for BF and 6.1 (95% CI 4.7, 7.8) for WF.

Average Annual Age-Specific Incidence Rates for females by race



Note: Vertical lines represent 95% CI

Conclusion: Our data support that Black females develop SLE at a younger age compared to White females. Incidence rates are similar at the extreme ages where female hormones are potentially less involved. However, the rates in Black females increase more dramatically at puberty and peak at 28/100,000/year between ages 30–39. White female rates have a more gradual increase and peak at 9.4/100,000/year between ages 60–69. Although SLE is often considered to be a disease that affects women in their reproductive years, these findings suggest that female hormones may be associated with lower threshold levels for the development of SLE in Blacks as compared to Whites. The development of lupus is likely to be influenced by both genetic and environmental factors that interact. More research into the mechanisms underpinning the racial disparities in susceptibility is warranted.

1848

Epidemiology of Systemic Lupus Erythematosus in a Large United States Managed Care Population. Daniel E. Furst[1], Ann Clarke[2], Ancilla Fernandes[3], Tim Bancroft[4], Warren Greth[3] and Serban R. Iorga[4]. [1]UCLA Medical School, Los Angeles, CA, [2]Montreal General Hospital, Montreal, QC, [3]MedImmune LLC, Gaithersburg, MD, [4]Innovus, Eden Prairie, MN

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder characterized by multiorgan involvement including skin, joints, kidney, heart, lungs and brain. Accurate data on the current incidence and prevalence of SLE are largely lacking, with ranges for incidence in the United States from 1.8–5.6 per 100,000 persons and prevalence from 53–150 per 100,000 persons. We investigated the incidence and prevalence of SLE in a large US managed care population by examining medical claims.

Methods: We conducted a retrospective study of SLE in a large US managed care database. Patients were included in the incidence cohort if they had a medical claim with SLE (ICD-9-CM diagnosis code of 710.0x) and an index date from 2003–2008 that satisfied the following criteria: 1) at least 1 inpatient claim or ≥2 office or ER visits at least 30 days apart with a diagnosis code for SLE; 2) ≥18 years of age on the index date; 3) continuously enrolled for 12 months before and after the index date; and 4) no SLE claims 12 months prior to index date. Patients were identified for the prevalence cohort using the same criteria, with the exception of requirement 4. Overall and annual incidence for the duration of 2003–2008 was estimated and age and gender adjusted to the US 2000 census population. Annual prevalence was calculated for each year from 2003 to 2008. Patients contributed to annual incidence only once (the earliest service date that met the above criteria was set as the index date), but could contribute to prevalence in multiple years. Sensitivity analyses were performed using select clinical characteristics (presence of a rheumatologist/dermatologist/nephrologists/neurologist visit) and/or treatments (presence of antimalarials/systemic corticosteroids/immunosuppressants).

Results: A total of 7301 patients were included in the incidence cohort (88% female, median age=48). During the period from 2003–2008, the overall age- and gender-adjusted SLE incidence rate was 24.06 cases per 100,000 person-years (95% CI, 23.36–24.75). The adjusted annual incidence of SLE ranged from 23.55 per 100,000 persons in 2003 to 29.19 per 100,000 persons in 2008. In the sensitivity analysis using clinical and treatment characteristics, the overall adjusted incidence rate was 21.69 cases per 100,000 person-years (95% CI, 21.04–22.35). A total of 15,396 patients were included in the prevalence cohort (90% female, median age=46). The annual prevalence of SLE (per 100,000 persons) varied from 81.07 in 2003 to 102.94 in 2008. The annual SLE prevalence was slightly lower in sensitivity analyses using clinical characteristics, and ranged between 67.90 in 2003 to 89.35 in 2008 per 100,000 persons.

Conclusion: While the prevalence of SLE in the US managed care population evaluated in this analysis was within the previously reported range for the United States, the incidence was several-fold higher. Due to the limitations inherent in claims analysis, such as possible miscoding and plan turnover, results should be interpreted with caution. Future research should also examine causes for the increased incidence observed in this population.

1849

Population-Based Incidence Estimates for Systemic Lupus Erythematosus in the USA, 2002–2005: Results From the Michigan Lupus Epidemiology and Surveillance (MILES) Program. Emily C. Somers[1], Wendy Marder[1], Patricia C. Cagnoli[1], Emily E. Lewis[1], Peter DeGuire[2], Caroline Gordon[3], Charles G. Helmick[4], Lu Wang[1], Jeffrey J. Wing[1], J. Patricia Dhar[5], James C. Leisen[6], W. Joseph McCune[1] and MILES Group[7]. [1]University of Michigan, Ann Arbor, MI, [2]MI Dept of Community Health, Lansing, MI, [3]University of Birmingham, Birmingham, United Kingdom, [4]Centers for Disease Control and Prevention, Atlanta, GA, [5]Wayne State University, Detroit, MI, [6]Henry Ford Hospital, Detroit, MI, [7]Ann Arbor, MI

Background/Purpose: The epidemiology of lupus in the USA has been characterized predominantly using homogenous populations from the tertiary care setting. We conducted this public health surveillance project to estimate systemic lupus erythematosus (SLE) incidence in a diverse population in Southeastern Michigan (source population ~2.3 million).

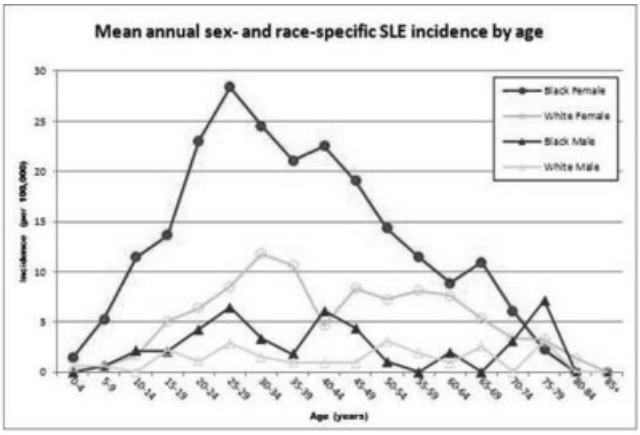
Methods: MILES is a population-based, active SLE surveillance program utilizing multiple sources of case-finding (eg, hospitals, private practice physicians, laboratories, etc) to identify SLE cases in the catchment area of Washtenaw (includes Ann Arbor) & Wayne (includes Detroit) Counties (2002–2005). Detailed record reviews are performed for all potential SLE cases meeting eligibility criteria. We recently completed case-finding and review activities, and final data cleaning steps are underway. The case definition for this analysis is: persons with a new diagnosis of SLE meeting ACR classification criteria (≥4) during 2002–2005, and who were residents of Washtenaw or Wayne Counties. Age-, sex- and race-specific denominators by county in Michigan were based on US Census data ("vintage 2009 bridged-race population files"). Mean annual incidence estimates and exact 95% CIs were calculated using SAS 9.2. Age standardization was performed using the 2000 US standard population.

Results: Among >13,000 records screened, 2482 cases met ACR classification criteria (≥4) for SLE: 2250 (90.7%) female; 944 (38%) white, 1410 (57%) black, 128 (5%) other race. Of these cases, 565 were newly diagnosed during the 4-year surveillance period. Incidence estimates are presented below (expressed per 100,000). Age-standardized mean annual incidence rates were 6.0 overall, 9.9 female, and 1.9 male. Peak incidence occurred at age 25–29 for black females and 30–34 for white females. Among males, due to the small sample size, age-specific patterns are less clear but appear more constant across ages.

Table 1. Mean annual SLE incidence per 100,000 (95% CIs) for Washtenaw and Wayne Counties, 2002–2005

Age	Average annual no. new cases	Overall population	Female	Male
0–4	1	0.6 (0.3, 1.1)	0.9 (0.3, 2.8)	0.3 (0.1, 0.9)
5–9	3	1.7 (1.0, 3.1)	2.9 (1.6, 5.5)	0.6 (0.2, 1.7)
10–14	8	4 (2.8, 5.8)	6.9 (4.7, 10.2)	1.3 (0.5, 3.1)
15–19	11	6.3 (4.7, 8.5)	10.4 (7.5, 14.5)	2.3 (1.2, 4.7)
20–24	14	8.5 (6.5, 11.1)	14.5 (10.9, 19.3)	2.5 (1.3, 5.0)
25–29	18	11.4 (9.0, 14.4)	18.5 (14.3, 23.9)	4.0 (2.2, 7.0)
30–34	18	10.2 (8.0, 12.8)	17.6 (13.8, 22.6)	2.3 (1.2, 4.7)
35–39	15	8.3 (6.4, 10.7)	15.1 (11.6, 19.8)	1.2 (0.4, 3.1)
40–44	13	7.1 (5.4, 9.3)	11.4 (8.4, 15.4)	2.6 (1.3, 4.9)
45–49	13	7.5 (5.7, 9.8)	12.5 (9.4, 16.7)	2.0 (1.0, 4.3)
50–54	11	6.9 (5.1, 9.2)	10.4 (7.4, 14.5)	3.0 (1.6, 5.7)
55–59	7	5.4 (3.7, 7.8)	9.1 (6.1, 13.6)	1.3 (0.4, 3.9)
60–64	4	4.7 (2.9, 7.6)	7.8 (4.7, 13.0)	1.2 (0.3, 4.7)
65–69	3	4.8 (2.8, 8.3)	7.2 (4.0, 13.1)	1.7 (0.4, 6.8)
70–74	2	3.3 (1.6, 6.6)	4.9 (2.3, 10.3)	1.0 (0.1, 7.1)
75–79	2	3.9 (2.0, 7.4)	3.6 (1.5, 8.7)	4.2 (1.6, 11.3)
80–84	0	0.6 (0.1, 4.2)	0.9 (0.1, 6.6)	0 (—)
85+	0	0 (—)	0 (—)	0 (—)
Total crude	***141***	***6.0 (5.7, 6.2)***	***9.8 (9.1, 10.7)***	***1.9 (1.7, 2.0)***
Total ASR*	***141***	***6.0 (5.9, 6.1)***	***9.9 (9.8, 10.0)***	***1.9 (1.8, 1.9)***

* ASR=age-standardized rate



Conclusion: SLE incidence in the diverse source population of Southeastern MI is estimated to be at the upper range of previously reported North American estimates, and slightly higher than previous European estimates. In contrast to recent European studies describing peak incidence among females around age of menopause, peak incidence in this population occurs during the reproductive years.Black females have highest risk of SLE, and the youngest peak age of incidence.

1850

Impact of Autoimmune Diseases on Health Status and Health Care Utilization. Pamela Shea Poynter, Kyoung-Suk Lee, Heather Bush and Leslie J. Crofford. University of Kentucky, Lexington, KY

Background/Purpose: Patients with autoimmune diseases are known to have reductions in health status and increased health care utilization compared with a healthy population. Few studies have compared patients with different autoimmune diseases and patients with other chronic diseases to determine the factors that drive these observations. The purpose of this study was to evaluate the impact of autoimmune diagnosis compared with other chronic diseases on self-report health perception and health care consumption.

Methods: This was a cross-sectional case-control study of participants in the Kentucky Women's Health Registry, a self-report longitudinal survey containing information on demographic variables, health behaviors, health care utilization, medical diagnoses, and health symptoms. The sample consisted of 10,684 women with different autoimmune disease diagnoses [n=794; rheumatoid arthritis (RA)=490; connective tissue diseases (CTD)=141; multiple sclerosis/myasthenia gravis (MS/MG)=80; inflammatory bowel disease (IBD)=83], asthma (n=1,664), hypertension (n=2097), and healthy controls (n=6,124). All analyses were performed using SAS Version 9.2. Univariate analyses were performed for all variables followed by multivariable logistic regression anlyses. Confounding factors in multivariable analyses included age, education, race, Appalachian residence, employment status, smoking status, marital status, insurance, social support, depression, anxiety, sedentary lifestyle, body mass index, and medical co-morbidities.

Results: Patients with autoimmune diseases had significantly poorer global health perception compared with the healthy control group with an adjusted odds ratio (aOR) of 4.49 (95%CI: 3.43, 5.88) versus an aOR of 1.71 (1.36, 2.16) for asthma and 1.77 (1.42, 2.21) for hypertension. There were striking increases in chronic fatigue [aOR 4.46 (3.54, 5.62)] and chronic pain [aOR 3.28 (2.65, 4.06)] in patients with an autoimmune diagnosis versus controls that were much more pronounced than with other chronic diseases. Furthermore, patients with autoimmune diseases were greater consumers of health care as measured by doctor visits [aOR 2.97 (2.43, 2.63) and ER visits [aOR 1.81 (1.43, 2.28) over the past 12 months. There were significant differences in health symptoms among the different autoimmune diseases. Notable findings were an increase in chronic fatigue among patients with MS/MG [aOR 2.28 (1.17, 4.45)] and a decrease in chronic fatigue among patients with IBD [aOR 0.44 (0.22, 0.87)] compared with RA patients. Patients with IBD also had a significantly lower risk for chronic pain [aOR 0.23 (0.12, 0.44)] than RA patients.

Conclusion: Autoimmune diseases have adverse effects on health status and health care utilization compared with other chronic diseases. The high prevalence of chronic fatigue and chronic pain appear to be important drivers of these effects. Among the autoimmune diseases, chronic pain in RA and chronic fatigue in MS/MG are the most important symptoms. Addressing these symptoms may provide important benefits to improve health status and reduce health care expenditures in patients with RA and other autoimmune diseases.

1851

Racial Disparities In Treatment Preferences Among Lupus Patients In An Urban Academic Center. Ernest R. Vina, Christopher M. Masi, Stephanie L. Green and Tammy O. Utset. University of Chicago, Chicago, IL

Background/Purpose: African American, compared to white, Systemic Lupus Erythematosus (SLE) patients have worse health outcomes. While racial differences in patient preferences for treatment decisions have been documented in other diseases, this phenomenon has not been explored in SLE. The objectives of this study are: 1) to determine whether there are differences between African American & white SLE patients' willingness to a) receive an immunosuppressive medication (i.e. cyclophosphamide, CTX) when indicated and b) participate in clinical trials involving novel, experimental medications; and 2) to determine whether demographic, psychosocial and clinical characteristics explain racial differences in either measure of medical management.

Methods: Data from 120 African American & 62 white lupus patients were evaluated. Structured telephone interviews were conducted to determine treatment preferences, as well as characteristics and beliefs that may affect these preferences. Chart reviews were conducted to evaluate clinical characteristics (SLE disease activity, damage index). Serial hierarchical multivariate logistic regression analyses were performed and their deviances from a saturated model were calculated.

Results: Compared to white SLE patients, African American SLE patients were less willing to receive CTX (84.9% vs. 67.0%, p=0.001). They were also less likely to have high income (p<0.005) and private insurance (p<0.005), and more likely to believe in prayer affecting health (p<0.005). Lupus patients willing to receive CTX were more likely to have private insurance (p=0.026), be married (p=0.011) and perceive CTX to be effective (p<0.001) and low risk (p=0.049). Multivariate logistic regression showed that white race (OR = 3.50, p=0.017), physician trust (OR = 1.05, p=0.071) and perception of effectiveness of treatment (OR = 1.40, p<0.005) were significant predictors of willingness to receive CTX. After adjustment for socioeconomic variables, the effect of race on willingness to receive CTX was no longer significant (OR 1.69, 95% CI 0.62–4.65)

In contrast, racial differences were observed in willingness to participate in a clinical trial but did not reach statistical significance (80.7% whites vs. 68.7% African Americans, p=0.096). A logistic regression model showed that internal health locus of control (OR 0.92, p=0.022), physician partici-

patory decision-making style (OR 1.03, $p<0.005$), lack of physician race preference (OR 2.28, $p=0.002$), marital status (OR 128.5, $p=0.012$), and the interaction between marital status & physician race preference (OR 0.39, $p=0.030$) were significant predictors of willingness to participate.

Conclusion: African American and white SLE patients did not differ in willingness to participate in a clinical trial. However, we found a decreased likelihood of accepting CTX in African American compared to white lupus patients. After controlling for socioeconomic factors, this racial disparity was no longer significant. Nevertheless, willingness to receive CTX was also associated with belief in its efficacy and trust in physicians, suggesting that education and improved trust can influence decision-making among SLE patients.

1852

Effort-Reward Imbalance in Patients with Systemic Lupus Erythematodes? Jutta G. Richter, Thomas Muth, Birthe Koerbl, Nicole Hoffmann, Tobias Koch, Johannes Siegrist and Matthias Schneider. Heinrich-Heine-University, Duesseldorf, Germany

Background/Purpose: Working life factors influence patients' (life) satisfaction and their well being. Effort at work is spent as part of a 'social contract' that reciprocates effort by adequate reward. Components of work-related rewards have been shown to matter for health. Research on ERI might contribute to the understanding of social and psychological factors related to the well-being of SLE patients (pts) with systemic lupus erythematosus (SLE). We studied psychosocial stress levels at work measured by the ERI model.

Methods: Within a cross sectional nationwide study a set of standardized self-administered questionnaires was applied to SLE pts. The ERI questionnaire assessed the effort-reward imbalance in SLE pts capable for work. Effort-reward ratio (ERR) scores >1 and the upper tertile scores of overcommitment (OCS) reflect relevant values. Data were analyzed in comparison to controls (c) not suffering from a rheumatic disease and recruited by the pts. Ethics committee approval had been obtained.

Results: 267 pts (95.9% female (f)) and 178 c (90.8% f) answered the questionnaires. Pts' mean age was 39.9 ± 9.5 (c 42.8 ± 9.8) years, mean disease duration 10.4 ± 7.3 years, 81.3% self-reported at least one comorbidity (range 1–10). 70.0% received at least one immunosuppressive medication (DMARD, range 1–3). 41.6% were on steroids $\leq$7.5mg and 15.7% on steroids $>$7.5mg. 33.0% took NSAIDS. Occupational status and self-categorized occupation groups (scog) did not significantly differ between pts and c.

77.8% of the pts (c 5.4%;$p<0.0001$) showed an ERR$>$1, significantly more female pts had an ERR$>$1 ($p<0.05$). Age, disease duration, functional capacity, number of DMARDs, steroid dosages, education, marital status, and scog did not significantly differ to those with ERR$\leq$1.

The OCS showed relevant values in 40.2% pts (f 40.0%, male 45.5%; c 25.2% (both p-values$>$0.05). Age, disease duration, functional capacity, number of DMARDs, steroid dosages, education, marital status, and scog were not significantly different to those with OCS in the lower tertiles.

Table 1. Effort & reward and overcommitment scores, ERR$>$1 and OCS upper tertil in pts and c

	Effort mean ± SD	Reward mean ± SD	ERR > 1 %	Overcommittment mean ± SD	OCS upper tertile %
Pts	15.5 ± 4.9	22.1 ± 9.9	77.8	14.4 ± 4.0	40.2
Female	15.6 ± 4.9	21.9 ± 9.8	79.2	14.4 ± 4.0	40.0
Male	14.0 ± 6.5	26.6 ± 11.7	37.5	13.5 ± 4.0	45.5
Controls	14.2 ± 4.1	46.8 ± 6.6	5.4	12.8 ± 3.9	25.2
Female	14.0 ± 4.0	47.0 ± 6.5	4.1	12.6 ± 3.8	23.2
Male	16.9 ± 3.9	43.8 ± 7.4	18.8	14.3 ± 4.1	43.8

Conclusion: This is the first study investigating the ERI in SLE pts. Compared to controls a significantly higher proportion of pts reported a relevant ERI. Analysis on direct and indirect mechanisms potentially involved in the relation between psychosocial work characteristics and SLE need further evaluations. However, although no cause and effect relationship can be established a reduction of stressful experiences in the framework of the worksites for SLE pts seems reasonable.

1853

Missed Work Days In Systemic Lupus Erythematosus. Jie Xu, Hong Fang and Michelle Petri. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: SLE has a profound effect on work productivity that is not captured in most analyses of medical care costs. We quantified the frequency and clinical associations of missed work days in SLE patients.

Methods: A medical resource use questionnaire that covered the last 3 months was distributed to 240 SLE patients. They were 89% female, 58% Caucasian, 32% African American. Exclusion criteria were diagnosis with SLE less than 6 months, age younger than 18 or older than 75, pregnant at baseline, and active HIV patients.

Results: 35.8% (86/240) had missed work days. The mean missed work days was 0.9 (range: 0–30) per month.

Table 1. Patient Characteristics Associated with Missed Work Days

Variable	No missed work days (%, N=154)	1–5 missed work days (%, N=55)	5+ missed work days (%, N=31)	P-value
Age at visit (years)				
≤3	24.68	40.00	32.26	0.092
>35	75.32	60.00	67.74	
Race				
African-American	28.57	30.91	48.39	0.18
Caucasian	60.39	61.82	38.71	
Other	11.04	7.27	12.90	
Education (years)				
≤12	20.78	25.45	25.81	0.69
>12	79.22	74.55	74.19	
Income ($)				
≤50K	36.36	41.82	58.06	0.08
>50K	63.64	58.18	41.94	
Smoking	5.19	12.73	16.13	0.054
Anti-dsDNA	71.43	60.00	45.16	0.012
Low C3	67.53	47.27	41.94	0.0032
Diabetes	3.25	10.91	16.13	0.01
Physical global assessment >1 (0 to 3 VAS)	9.09	12.73	29.03	0.009
SLEDAI '4	19.48	14.55	32.26	0.14
BMI>30	28.57	25.45	51.61	0.025
Vitamin D <15	3.90	7.27	16.13	0.035
Prednisone (mg)				
0	68.18	58.18	51.61	0.0008
1–9	27.27	27.27	19.35	
10+	4.55	14.55	29.03	

Conclusion: About one third of SLE patients had missed work days. Age, race, education, and income were not associated with missed work days. The physician global assessment of disease activity (but not SLEDAI) and prednisone $\geq$ 10 mg were associated with missed work days. Serologic measures (anti-DNA, low complement) were associated with missed work, but in a counterintuitive way (patients with no missed work were more likely to have high anti-dsDNA and low complement). A low vitamin D was somewhat associated. These data suggest that both control of disease activity and reduction in prednisone would reduce loss of work and indirect medical care costs.

1854

Life and Job Satisfaction in Patients with Systemic Lupus Erythematosus. Jutta G. Richter, Thomas Muth, Birthe Koerbl, Mia Vidakovic, Tobias Koch and Matthias Schneider. Heinrich-Heine-University, Duesseldorf, Germany

Background/Purpose: Life satisfaction (LS) is a psychological construct that has become an increasingly important outcome measure in healthcare and is a relevant indicator of job satisfaction. The objectives of the study were to investigate life and job satisfaction in patients (pts) with systemic lupus erythematosus (SLE) capable for work.

Methods: Within a cross sectional nationwide study a set of standardized self-administered questionnaires was applied to SLE pts. The questionnaire on life satisfaction (FLZ) measures ten domains of satisfaction (health, finances, job and profession, friends and relatives, leisure, home, partner/relationship, sexuality, children, self), the total score values general LS. According to questionnaire's analysis scores are expressed as age and sex standardized stanines (a method of scaling test scores on a normalized nine-point standard scale (1–9) with a mean of 5 and a standard deviation of 2). Data were analyzed in comparison to controls (c) not suffering from a rheumatic disease. Ethics committee approval had been obtained.

Results: 267 pts (95.9% female (f)) and 178 c (90.8% f) answered the questionnaires. Pts' mean age was 39.9±9.5 (c 42.8±9.8) years, mean disease duration 10.4±7.3 years, 81.3% self-reported at least one comorbidity (range 1–10). 70.0% received at least one immunosuppressive medication (DMARD, range 1–3). 41.6% were on steroids ≤7.5mg and 15.7% on steroids >7.5mg. 33.0% took NSAIDS. Occupational status and self-categorized occupation groups (scog) did not significantly differ between pts and c.

Compared to c significantly higher proportions of pts reported lower satisfaction in the domains health, job and profession, friends and relatives, leisure, sexuality, self and in the total score reflecting general LS (see table 1). Age, disease duration, number of DMARDs, steroid dosages, education, marital status, or scog were not significantly different in pts' general LS stanines (p-values>0.05). However, functional capacity differed significantly in stanines for general LS ($p<0.05$): more pts with stanines 1–4 had lower functional capacity.

Table 1. FLZ stanines in ten domains and for general LS

	SLE pts			Controls			
	Stanines 1–3% of pts (expected 23%*)	Stanines 4–6% of pts (expected 54%*)	Stanines 7–9% of pts (expected 23%*)	Stanines 1–3% of c (expected 23%*)	Stanines 4–6% of c (expected 54%*)	Stanines 7–9% of c (expected 23%*)	P values Pts vs C
Health	73.5	23.1	3.4	20.5	57.8	21.7	<0.01
Finances	26.7	52.5	20.8	20.5	52.8	26.7	n.s.
Job and profession	27.8	53.5	18.7	16.2	56.3	27.5	<0.05
Friends and relatives	31.5	46.6	21.9	20.0	53.8	26.2	<0.05
Leisure	37.5	47.7	14.8	22.2	58.6	19.2	<0.01
Home	14.0	56.8	29.2	11.2	48.8	40.0	<0.1
Partner/relationship	26.6	47.8	25.6	22.6	47.5	29.9	n.s.
Sexuality	43.0	44.3	12.7	21.1	52.6	26.3	<0.01
Children	31.6	41.9	26.5	20.9	39.6	39.5	<0.1
Self	35.7	47.9	16.4	19.2	60.9	19.9	<0.01
General LS (FLZ total score)	43.8	41.9	14.3	13.7	58.9	27.4	<0.01

*Expected from stanines' normal distribution, n.s. not significant

Conclusion: This first study of FLZ in SLE pts revealed significant less life, job and self satisfaction as well as satisfaction in other social domains. These domains are potentially modifiable by interventions that should predominantly target social and job related issues. Besides from already established assessments (e.g. HAQ, SF36) further clinical studies might gain from the additional assessment of LS as an outcome parameter.

1855

Impact of Systemic Lupus Erythematosus on Employment and Work Productivity in the US. Ellen Sulcs[1], Mechele Lee[2], Cindy P. Garris[3] and Priti M. Jhingran[3]. [1]Harris Interactive Inc., New York, NY, [2]Harris Interactive Inc., New York, [3]GlaxoSmithKline R&D, Research Triangle Park, NC

Background/Purpose: SLE is a complex, chronic autoimmune disorder characterized by fluctuating periods of disease activity affecting multiple organ systems. SLE patients experience a wide variety of symptoms including fatigue, rash, joint pain, kidney disease, central nervous system disease, and heart involvement. This study was conducted to evaluate the impact of SLE on patients' employment and productivity.

Methods: A cross-sectional cohort of employed and unemployed patients with SLE in the US, recruited through a patient advocacy association and the Harris Chronic Illness Panel, was surveyed online (IRB approved) between Dec 2010 and Mar 2011. Inclusion criteria were ≥18 years old, self-reported SLE diagnosis, and ≥1 SLE flare in prior 3 months requiring medical attention (taking medications, calling or visiting a physician, or going to the ER or hospital). A control group of employed patients without SLE recruited from HarrisPollOnline (HPOL) were demographically matched (age, sex, race, income, and education) to the employed SLE cohort. Controls met the above inclusion criteria excluding the SLE related criteria and were also surveyed online. Questions for the SLE cohort included perceived flare activity (a flare was defined as any time a patient perceived that their SLE symptoms intensified, whether mildly or severely), symptoms and impact of SLE on employment and work productivity. The control group answered similar questions about the impact of any health conditions on work. Impact on work productivity/daily activities was assessed over the past 7 days using a 10-point scale; anchors are at 0 (SLE/health conditions had no effect on my work/ regular daily activities) and 10 (SLE/health conditions completely prevented me from working/doing my regular daily activities). Employed and unemployed SLE patients were compared to controls by dependent sample T-tests.

Results: 546 SLE patients (281 employed, 265 unemployed) and 300 employed controls completed the survey; of the 300 control group respondents, 69% reported having ≥1 health condition(s). The unemployed SLE cohort was older than both the employed SLE group and control group (mean age 45.4 vs. 39.8 and 41.1, respectively; $p<0.05$). Of all surveyed respondents, 96% were female and 79% were Caucasian (no significant differences across groups). Of unemployed SLE patients, 75% attributed their unemployment to SLE, and 59% reported receiving disability benefits. Unemployed SLE patients reported experiencing a mean of 8.9 flares over 3 months compared with 5.7 flares for employed SLE patients ($p<0.05$). The employed SLE cohort reported more lost work hours per week due to SLE (6.9 hours) than the employed control group due to any health condition (1.6 hours)($p<0.05$). Mean work productivity rating was 4.5 for the SLE employed cohort vs. 1.3 for the control group ($p<0.05$). Likewise, mean daily activity rating was higher for both SLE cohorts (employed 5.6, unemployed 6.6) compared with the control group (1.8) ($p<0.05$).

Conclusion: Patients with SLE reported significantly reduced ability to work, work productivity, and daily activities. Further research is needed to quantify the economic impact of impaired work productivity due to SLE for patients, employers and society.

1856

Association of Body Mass Index, Race/Ethnicity and Gender in a Cohort of Systemic Lupus Erythematosus Patients with Diabetes and/or Hypertension. Jonea Lim[1], Nasir Mushtaq[2], Rachna Aggarwal[3] and R. Hal Scofield[4]. [1]Harold Hamm Oklahoma Diabetes Center, University of Oklahoma Health Science Center, Oklahoma City, OK, [2]University of Oklahoma Health Science Center College of Public Health, Oklahoma City, OK, [3]University of Oklahoma Health Science Center; Oklahoma Medical Research Foundation, OK, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: To determine the prevalence of diabetes mellitus (DM) and/or hypertension (HTN) in systemic lupus erythematosus (SLE) patients and its association with body mass index (BMI). To determine racial/ethnic and gender differences among SLE patients having DM and/or HTN.

Methods: In a large cohort of 2044 SLE patients we explored BMI, race/ethnicity and gender as risk factors for development of DM and HTN. All SLE patients met at least four 1982 American College of Rheumatology classification criteria. Chi square and regression techniques were used for this analysis. Statistical analysis was performed on 991 patients for whom we could confirm the diagnosis of DM and HTN after review of medical records of these patients. SAS version 9.1 was used for statistical analysis.

Results: Results of the descriptive analysis showed that 80% (n=789) had HTN, 7% (n=74) DM, and 13% (n=128) had both DM and HTN. Most of the participants (87%) were woman and the majority of them were White (44%) followed by African American (35%). The mean BMI of the sample was 28.93 (SD = 7.85) kg/m^2. Table 1 summarizes characteristics of the SLE patients participating in the study. Results of the univariate logistic regression models indicated that there was no statistically significant association of DM with gender or race as compared to those having HTN.

Table 1. Characteristics of the 991 SLE patients participating in the study

Variable	Overall	Diabetes	Hypertension	Both
Gender *n(%)*				
Female	860 (86.78)	68 (91.89)	686 (86.95)	106 (82.81)
Male	131 (13.22)	6 (8.11)	103 (13.05)	22 (17.19)
Race *n(%)*				
White	437 (44.10)	28 (37.84)	359 (45.50)	50 (39.06)
African American	344 (34.71)	22 (29.73)	271 (34.35)	51 (39.84)
AI/AN	40 (4.04)	6 (8.11)	31 (3.93)	3 (2.34)
Others	170 (17.15)	18 (24.32)	128 (16.22)	24 (18.75)
BMI *mean (sd)*	28.93 (7.85)	28.99 (7.91)	28.34 (7.61)	32.65 (8.35)

Comparison of exclusive DM and exclusive HTN did not show significant association with BMI, however when we compared all DM patients (exclusive DM and both DM and HTN) with exclusive HTN patients there was an association with BMI. SLE patients with higher BMI had increased odds (OR

1.045, 95%CI: 1.025–1.065) of having DM. There was no interaction between these variables and the results of the multiple logistic regression analysis showed similar estimates.

Crude and adjusted odds ratios suggested a statistically significant association between BMI and having both DM and HTN. SLE patients having higher BMI were 1.063 (95% CI: 1.040–1.087) times more likely to have both DM and HTN when adjusted for gender and race.

Results of analysis of variance indicated that the SLE patients having both DM and HTN had higher mean BMI than those who exclusively had DM (Mean difference = 3.659, 95%CI: 0.942–6.377) or HTN (mean difference = 4.314, 95%CI: 2.532, 6.097).

Conclusion: The impact of higher body mass index dominates race/ethnicity and gender association in developing DM and HTN among SLE patients.

1857

Everyday Stress, C-Reactive Protein, and Systemic Lupus Erythematosus. Amanda Eudy[1], Anissa I. Vines[1], Charles Poole[1], Carolina Lupus Study Investigators[2] and Christine G. Parks[3]. [1]University of North Carolina, Chapel Hill, NC, [2]USA, [3]NIH/NIEHS, Research Triangle Park, NC

Background/Purpose: Racial/ethnic and socioeconomic disparities in systemic lupus erythematous (SLE) are well described but not well understood. Psychosocial stress has known effects on immune function and may influence disease course in SLE. Elevated C-reactive protein (CRP), an inflammatory biomarker associated with psychosocial stress, has been seen in individuals of lower socioeconomic status (SES) and nonwhite race. We examined the relationship of self-reported disease activity in SLE with daily stress, squelched anger, and CRP, exploring potential differences by race or SES.

Methods: Data included of 72 Caucasian and 115 African American SLE patients diagnosed between 1995 and 1999, and enrolled in the Carolina Lupus Study (75% of the cases in the full cohort). CRP and self-reported disease activity were collected at baseline. Questions on day-to-day stress, squelched anger, recent flares (in past 3 months) and hospitalizations were asked at a 2001 follow-up interview. Age, sex, race and education adjusted logistic regression models estimated odds ratios (OR) and 95% confidence intervals (CI) for the associations of stress and anger with flare and hospitalization in the past 12 months. Student's t and ANOVA tests were used to compare log-transformed CRP by disease activity and hospitalization. We also considered factors associated with baseline CRP in linear regression models adjusted for age, sex, race and education. Stratified analyses explored modification by race and education (≤12 high school, >high school).

Results: Feeling the need to squelch anger was more common in both African Americans (26% vs. 10% Caucasians) and the less educated (28% vs. 14% >high school). Recent flare was reported by 58% (61% African American and 54% Caucasians). Overall, patients reporting a recent flare had higher daily stress (OR=1.8; 95%CI 1.0, 3.3) and felt the need to squelch anger more frequently (OR=1.8; 95% CI 1.0, 3.3). These associations did not differ by race and education, and the association of African-American race and anger squelching (OR=2.0; 95%CI 1.0, 3.3) persisted after adjusting for flare. Recent hospitalization was not associated with daily stress or squelched anger overall. Recent hospitalization was also associated with daily stress in Caucasians (OR=1.9; 95%CI 0.5, 6.4), but not in African-Americans (OR=0.6; 95%CI 0.1, 2.3). Higher baseline CRP was associated with recent flare, especially in African Americans and those with less education, and was associated with recent hospitalization in all groups.

Conclusion: Our findings support the idea that SLE disease activity may be related to stress and anger. They provide some evidence of racial/ethnic and socioeconomic differences in the experiences of daily stressors in SLE patients, though small sample size limited power for statistical comparisons. These data cannot directly address the role of stress as a cause or consequence of inflammation, but the observations support the need to better understand the interrelationships of anger, stress, and CRP levels as potential sources of socioeconomic health disparities in SLE.

1858

Stressful Life Experiences and Inflammation in the Carolina Lupus Study: An Open-Ended Query on Stress. Christine G. Parks[1], Anissa I. Vines[2], Amanda Eudy[3] and Carolina Lupus Study Investigators[4]. [1]NIH/NIEHS, Research Triangle Park, NC, [2]University of North Carolina, Chapel Hill, NC, [3]UNC Chapel Hill, Chapel Hill, NC, [4]USA

Background/Purpose: Psychosocial stress has been associated with disease activity in systemic lupus erythematosus (SLE), but knowledge is limited on biologic pathways relating stress to racial and socioeconomic health disparities in SLE. Here we describe open-ended reports of stressful experiences in a population-based study of participants in the Carolina Lupus Study. We also explore the association of the stressful experiences with C-reactive protein (CRP), an inflammatory biomarker previously related to SLE, stress, non-white race and low socioeconomic status (SES)

Methods: Participants included SLE patients (n=249; 64% African-American, 90% women; median age 37 years and 13 months since diagnosis) in North Carolina and South Carolina, and age, sex, and state-matched controls (n=329). In person interviews collected detailed participant characteristics and a blood specimen. Using an open-ended format, participants were asked to describe *up to* three stressful times in their lives and the age(s) of these experiences. Verbatim responses were later grouped by thematic subgroups of life events or chronic stressors. High sensitivity serum CRP was measured by ELISA. Odds ratios (OR) and 95% confidence intervals (CI) for reported stressful experiences in relation to SLE were estimated in regression models, adjusting for age, sex, state, race and education. In patients, we examined stress reporting in relation to log-transformed CRP, adjusted for age, sex, race, education, smoking, and recent flare. All analyses were also stratified to explore differences by race and education.

Results: Only 15% of participants (patients and controls) reported no stressors, but nearly 3-times as many African-American patients reported no stressors (17% vs. 6% in whites, p=0.01). The most common stressors were: death/major loss; relationship; health (cases); and job stressors. Caucasian patients reported more trauma, abuse, or accidents (p=0.02) versus African American patients, while higher education was related to job stress in all participant sub-groups. No other differences were seen in specific stressors by race or SES. Among Caucasians, SLE was associated with reporting at least one stressful experience (OR=3.4; 95%CI 1.3, 9.1). Among African Americans who reported stressors, patients described more health-stress than controls (OR=3.2; 95%CI 1.4, 7.0). In patients, higher CRP was associated with reporting at least one stressor (p=0.004) and more stressors reported p=0.03), independent of other risk factors (older age, African-American race, and low education). The association of patient-CRP levels with reporting at least one stressor was most apparent in African Americans, while higher CRP in Caucasians was associated with financial stress and lower education.

Conclusion: SLE patients may be more likely to report psychosocial stressors in general. Our results suggest stress may be related to inflammation in patients, but a causal role cannot be determined in these cross-sectional analyses. Observed racial differences in stress reporting and associations highlight a need for culturally-appropriate methods to assess stress in studies of SLE disparities.

1859

LupusPRO: Cross Cultural Validation Study for Lupus in the Philippines. S. Navarra[1], Rachel A. Mikolaitis[2], Joel A. Block[2] and Meenakshi Jolly[2]. [1]University of Santo Tomas Hospital, Manila, Philippines, [2]Rush University Medical Center, Chicago, IL

Background/Purpose: LupusPRO is a disease-targeted Patient Reported Outcome measure that was developed and validated from and among US patients with systemic lupus erythematosus (SLE). We herein report the results of the cross-cultural validation study of the English language version of LupusPRO among SLE patients in the Philippines.

Methods: The 43-item LupusPRO was pretested in 15 SLE individuals. It was then self administered to 106 SLE patients meeting ACR classification criteria (T1), along with generic tools SF36 and EQ5D visual analogue scale. A mail/drop back LupusPRO and change in health status item survey were given to the patients to be completed within 2–3 days (T2). Data on demographics, clinical and serological characteristics were collected. Disease activity was measured using Physician Global Assessment (PGA), SELENA-SLEDAI and LFA Flare (yes/no and severity of flare). Disease damage was determined using SLICC-ACR SLE damage index (SDI). Internal consistency reliability (ICR), test-retest reliability (TRT), convergent validity (corresponding SF36 domains), and criterion validity (against various general health and disease activity measures) were tested. All reported p values are two tailed.

Results: 121 SLE subjects (95% women) with at least high school level of English instruction medium education participated. Mean age ± SD was 34.7 ± 10.7 yrs and mean ± SD disease duration 6.2 ±4.9 yrs; 97% Asians, 75 % had more than high school education, and 42% were currently married. Mean ± SD PGA 0.81 ± 1.1, mean ± SD SLEDAI 5.3 ± 7.6 and mean ± SD SDI 0.8 ± 1.2. Table 1 outlines the psychometric properties. ICR and TRT were fair to excellent. Convergent validity ranged from moderate to strong. Criterion validity

was established against general health and/or disease activity measures on most domains. The tool was well received by the patients.

Table 1. Psychometric properties of LupusPRO among SLE patients in the Philippines

LupusPRO Domain	ICR	TRT	Convergent Validity (correlation coefficient r, p value)	Criterion Validity (p value)
Lupus Symptoms	0.66	0.95		LFA Flare (p 0.001), Flare severity (0.001), Patient-Change in Health (0.04), PGA (0.0001), SLEDAI (0.007), EQ5D VAS (0.001)
Cognition	0.79	0.95		Patient-Change in Health (0.03)
Lupus Medications	0.72	0.86		
Physical Health	0.88	0.90	Physical Function (0.35, 0.001), Role Physical (0.21, 0.02)	LFA Flare (0.04), Flare severity (0.01), Patient-Change in Health (0.0001), SF36-Overall Health (0.03),PGA (0.07), SLEDAI (0.0001), PGA (0.09)
Pain-Vitality	0.85	0.91	Bodily Pain (0.69, 0.001), Vitality (0.48, 0.001)	LFA Flare (0.05), Flare severity (0.09), Patient-Change in Health (0.0001),SF36-Overall Health (0.006), SLEDAI (0.004), PGA (0.03), EQ5D VAS (0.002)
Body Image	0.88	0.96		Flare severity (0.07), Patient-Change in Health (0.06), SF36-Overall Health (0.02), PGA (0.02), EQ5D VAS (0.02)
Emotional Health	0.88	0.93	Mental Health (0.46, 0.001), Role Emotional (0.33, 0.001)	Patient-Change in Health (0.06), EQ5D VAS (0.08)
Procreation	0.82	0.94		PGA (0.006), Patient-Change in Health (0.05)
Desires-Goals	0.86	0.89		Patient-Change in Health (0.01), SF36-Overall Health (0.04)
Social Support	0.80	0.95		SLEDAI (0.09), Patient-Change in Health (0.01)
Cope	0.72	0.91		SF36-Overall Health (0.006), EQ5D VAS (0.002)
Satisfaction Med Care	0.91	0.96		

Conclusion: English LupusPRO has fair psychometric properties among SLE patients in the Philippines. Validation studies on a Filipino version of LupusPRO are being planned.

1860

Spanish LupusPRO: Cross Cultural Validation Study for Lupus. Meenakshi Jolly[1], Joel A. Block[1], Rachel A. Mikolaitis[1], Daniel Wallace[2], Sergio Duran-Barragán[3], Ana M. Bertoli[4], Sergio Toloza[5], Ivana Blazevic[6], Luis M. Vila[7], Dilrukshie Cooray[8], Emmanuel P. Katsaros[9], Karina Marianne D. Torralba[10], Michael H. Weisman[11] and Graciela S. Alarcon[12]. [1]Rush University Medical Center, Chicago, IL, [2]Cedars-Sinai/UCLA, Los Angeles, CA, [3]UIECD, Guadalajara, Mexico, Guadalajara, Mexico, [4]Instituto Reumatológico Strusberg, Cordoba, Cordoba, Argentina, [5]Hospital San Juan Bautista, Catamarca, Argentina, [6]University of Buenos Aires, Buenos Aries, Argentina, [7]University of PuertoRico Medical Sciences Campus, San Juan, PR, [8]Harbor UCLA Medical Center, Torrance, CA, [9]Loma Linda Univ, Loma Linda, CA, [10]USC Keck Schl of Medicine, Los Angeles, CA, [11]Cedars Sinai Med Ctr, Los Angeles, CA, [12]University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: LupusPRO is a disease targeted Patient Reported Outcome measure that was developed and validated from and among US patients with Systemic Lupus Erythematosus (SLE). We herein report the results of the cross-cultural validation study of the Spanish translated version of the LupusPRO.

Methods: Forward and back translations of the 43 item English LupusPRO were undertaken and pretested in five individuals. The finalized Spanish version was applied to the SLE patients meeting ACR classification criteria of Hispanic ancestry from the US and Latin America. Demographic, clinical and serological characteristics were obtained and the SF-36 (Spanish) and Spanish LupusPRO (T1) administered. Disease activity was ascertained using the physician Global Assessment (PGA), SELENA-SLEDAI and LFA defined Flare (Yes/No). Disease damage was assessed using the SLICC-ACR SDI. A mail back Spanish LupusPRO to be completed within 2–3 days (T2) was also given. Internal consistency reliability (ICR), test-retest reliability (TRT), criterion validity (against measures of disease activity or health status) and convergent validity (corresponding domains of the SF36) were all tested. All reported p values are two tailed.

Results: 211 SLE subjects (90% women) were enrolled. Sixty-four percent had upto High School education, and 46% were currently married. The mean ± SD age (yrs) and disease duration were 38 ± 12 and 8.8 ±7.6. The mean ± SD PGA and SLEDAI were 0.78 ±0.76 and 3.9 ±4.4. The mean ± SD SDI were 0.61 ± 1.1. Psychometric properties are shown in the table.

Table. Psychometric Properties of Spanish LupusPRO

Domain	ICR T1	ICR T2	TRT	Conv. Validity (corr r, p)	Criterion Validity (p value)
Lupus Symptoms	0.67	0.73	0.94		LFA Flare (p 0.001), Flare severity (0.007), Patient-Change in Health (0.01), SF36-Overall Health (0.0001), PGA (0.0001), SLEDAI (0.01)
Cognition	0.91	0.93	0.9		LFA Flare (0.01), Flare severity (0.06), Patient-Change in Health (0.03), SF36-Overall Health (0.0001), PGA (0.0001),SLEDAI (0.04)
Lupus Medications	0.74	0.74	0.89		LFA Flare (0.04), SF36-Overall Health (0.001),PGA (0.002), SLEDAI (0.03)
Physical Health	0.87	0.93	0.95	SDI (−0.15, 0.04), PF (0.64, 0.001), RP(0.61, 0.001)	LFA Flare (0.001), Flare severity (0.01), Patient-Change in Health (0.0001), SF36-Overall Health (0.0001),PGA (0.0001), SLEDAI (0.0001)
Pain-Vitality	0.94	0.95	0.96	BP (0.78, 0.001), VT (0.73, 0.001)	LFA Flare (0.002), Flare severity (0.003), Patient-Change in Health (0.0001),SF36-Overall Health (0.0001), PGA (0.0001), SLEDAI (0.003)
Body Image	0.95	0.96	0.96		LFA Flare (0.001), Flare severity (0.002), Patient-Change in Health (0.06), SF36-Overall Health (0.0001), PGA (0.0001), SLEDAI (0.008)
Emotional Health	0.93	0.95	0.97	EH (0.67, 0.001), RE (0.64, 0.001)	LFA Flare (0.002), Flare severity (0.006), SF36-Overall Health (0.0001),PGA (0.001), SLEDAI (0.03)
Procreation	0.59	0.81	0.92		PGA (0.05)
Desires-Goals	0.88	0.93	0.93		LFA Flare (0.01), Flare severity (0.07), Patient-Change in Health (0.01), SF36-Overall Health (0.0001), PGA (0.001), SLEDAI (0.001)
Social Support	0.79	0.84	0.8		
Cope	0.71	0.6	0.88		
Satisfaction Med Care	0.86	0.5	0.8		

Conclusion: The Spanish LupusPRO has fair psychometric properties and is now available to be included in Latino-American clinical trials and in longitudinal studies for testing of responsiveness to change.

1861

Epidemiology of Systemic Sclerosis in a Large United States Managed Care Population. Daniel E. Furst[1], Ancilla Fernandes[2], Serban R. Iorga[3], Warren Greth[2] and Tim Bancroft[3]. [1]UCLA Medical School, Los Angeles, CA, [2]MedImmune LLC, Gaithersburg, MD, [3]Innovus, Eden Prairie, MN

Background/Purpose: Previous epidemiologic studies of systemic sclerosis (SSc) in the United States have reported an annual incidence of slightly fewer than 2 per 100,000 persons and a prevalence of 24–28 per 100,000 persons. As most prior studies of SSc epidemiology in the United States relied on data from about 10 years ago (or longer), an updated description of disease characteristics may help increase awareness among healthcare providers of this rare condition.

Methods: We conducted a retrospective study of SSc in a large US managed care database. Patients were included in the incidence cohort if they had a medical claim with an SSc ICD-9-CM code of 710.1x and an index date from 2003–2008 that satisfied the following criteria: 1) at least 1 inpatient claim *or* ≥2 office or ER visits at least 30 days apart with a diagnosis code for SSc; 2) ≥18 years of age on the index date; 3) continuously enrolled for 12 months before and after the index date; and 4) no SSc claims 12 months prior to index date. Patients were identified for the prevalence cohort using the same criteria, with the exception of requirement 4. Overall and annual incidence for the duration of 2003–2008 was estimated and age-gender adjusted to the US 2000 census population. Annual prevalence was calculated for each year from 2003 to 2008. Patients contributed to annual incidence only once (the earliest service date that met the above criteria was set as the index date) but could contribute to prevalence in multiple years. Sensitivity analyses were performed using select clinical characteristics (presence of rheumatologist / dermatologist / nephrologist visit) and treatments (presence of systemic corticosteroids / immunosuppressants use).

Results: A total of 1,529 patients were included in the incidence cohort (85% female, median age=52) and 2,739 were included in the prevalence

cohort (86% female, median age=52). From 2003–2008, the overall crude incidence rate for SSc was 4.57 cases per 100,000 person-years (95% CI, 4.34−4.80), and the overall adjusted incidence rate was 5.61 cases per 100,000 person-years (95% CI, 5.24–5.98). The adjusted annual incidence of SSc ranged from 5.37 per 100,000 persons in 2003 to 5.95 per 100,000 persons in 2008. In sensitivity analyses using clinical and treatment characteristics, the overall adjusted incidence rate was 4.74 cases per 100,000 person-years (95% CI, 4.40–5.07). The annual prevalence of SSc ranged from 13.47 in 2003 to 18.38 in 2008 per 100,000 persons. In sensitivity analyses using clinical characteristics, the annual prevalence was slightly lower, ranging between 11.17 in 2003 to 15.95 in 2008 per 100,000 persons.

Conclusion: These results suggest a higher SSc incidence and a lower prevalence in the managed care population evaluated in this study compared with other epidemiologic studies of SSc in the United States. Due to the limitations inherent in claims analysis, such as possible miscoding and plan turnover, results should be interpreted with caution. Future research should also examine causes for any observed difference in the epidemiology of SSc.

1862

Population-Based Prevalence Estimates of Myositis in First Nations Relative to Non-First Nations Canadians. Cheryl CM Barnabe[1], Lawrence Joseph[2], Patrick Belisle[2], Jeremy Labrecque[3], Lawrence W. Svenson[1], Steven M. Edworthy[1], Susan G. Barr[1], Marvin J. Fritzler[1], Christine A. Peschken[4], Brenda Hemmelgarn[1] and Sasha Bernatsky[3]. [1]University of Calgary, Calgary, AB, [2]McGill University Health Centre, Montreal, QC, [3]McGill UHC/RVH, Montreal, QC, [4]University of Manitoba, Winnipeg, MB

Background/Purpose: Canada's First Nations (FN) population has higher prevalence of rheumatoid arthritis, osteoarthritis, lupus and scleroderma relative to the non-First Nations (non-FN) population. Population-based prevalence estimates for autoimmune inflammatory myopathies considering race have not been previously reported. In addition, we examined the effect of demographic factors which may affect our estimates, given that they influence access to health services and thus identification of affected individuals in administrative healthcare databases.

Methods: Physician billing claims and hospitalization data (years 1994–2007), coded according to the International Classification of Diseases (ICD) system, were used to ascertain cases of polymyositis and dermatomyositis, using three case definitions: i) ≥1 billing code by a rheumatologist; ii) ≥2 billing codes by any physician, ≥8 weeks apart but within 2 years; or iii) one hospitalization diagnosis. A latent class Bayesian hierarchical regression model was employed to account for the imperfect sensitivity and specificity of these data sources in case ascertainment. We accounted for demographic factors, estimating prevalence for FN and non-FN populations by sex, age group, and location of residence (urban versus rural). FN status was determined by methodology derived by the provincial steward for health data to identify individuals registered with the Department of Indian and Northern Affairs of the Government of Canada.

Results: Contrary to other rheumatic diseases, the overall prevalence point estimate for myositis was lower in the FN population, at 25.0 per 100,000 persons, with a relatively wide credible interval (CrI) (95% CrI 13.4–49.0), compared to 33.8 per 100,000 (95% CrI 28.9–39.6) in the non-FN population. Except for rural FN females <45 years of age, all prevalence point estimates were higher in the non-FN population (Table 1), although the credible intervals overlapped. In non-FN we demonstrated higher prevalence estimates for females and older individuals, with similar trends in FN individuals. Trends were seen for higher myositis prevalence in rural locations.

Table 1. Myositis Prevalence Estimates (95% credible interval) for First Nations and non-First Nations Populations, per 100,000 people

	Females		Males	
	First Nations	Non-First Nations	First Nations	Non-First Nations
<45 years old				
Rural	27.7 (10.0–67.2)	19.2 (13.3–27.1)	2.1 (0.1–13.4)	5.7 (3.0–9.6)
Urban	4.5 (0.1–35.8)	13.4 (9.6–18.7)	4.8 (0.5–23.7)	4.2 (2.4–7.2)
>45 years old				
Rural	137.3 (55.9–345.6)	124.5 (97.5–161.9)	12.7 (1.1–54.7)	58.7 (43.5–78.9)
Urban	87.3 (4.8–415.9)	86.7 (70.6–107.6)	17.4 (0.2–153.9)	37.6 (28.5–49.5)

Conclusion: Female sex and older age were associated with higher myositis prevalence. We did not find higher myositis prevalence estimates in FN individuals, but our estimates are limited by the inability to capture Métis and non-treaty individuals of FN descent. There was an interesting trend for higher prevalence in rural areas, which raises potential hypotheses about genetic risk pools and/or environmental factors that might be triggers for autoimmune disease (e.g. pesticides, zoonotic pathogens, respirable silica etc.) as well as physician diagnosis and referral patterns. Further work is required to address these issues.

1863

Development and Content Validity of the Hand Disability in Systemic Sclerosis—Digital Ulcers (HDISS-DU) Scale. Dinesh Khanna[1], Serge Poiraudeau[2], Heather Gelhorn[3], Elke Hunsche[4], Kelly Papadakis[4], Loic Perchenet[4], Maria Stoeckl Mattera[5], Margaret Vernon[5] and Luc Mouthon[2]. [1]University of Michigan, Ann Arbor, MI, [2]Hopital Cochin, Paris, France, [3]United BioSource Corporation, Golden, CO, [4]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland, [5]United BioSource Corporation, Bethseda, Bethesda, US., MD

Background/Purpose: Digital ulcers (DU) are common, painful, debilitating manifestations of systemic sclerosis (SSc); they adversely affect hand function in daily activities. The Cochin Hand Function Scale (CHFS), originally developed for use in rheumatoid arthritis, is a self-administered hand functional disability questionnaire, containing 18 items related to daily activities. The objective of this research was to evaluate the content validity of the CHFS in patients with SSc and active DU, and to modify the instrument as needed.

Methods: A cross-sectional qualitative interview study was conducted in the US. Eligibility included a diagnosis of SSc and at least one recent, visible, active ischemic DU, for which the patient had seen a physician within the past 8 weeks. The study had 2 phases: Phase I consisted of 20 face-to-face semi-structured interviews, which focused on 2 parts: a) elicitation of emergent concepts relevant and important to DU-related hand function and b) cognitive debriefing of the CHFS. Based on findings and after having reached saturation of concepts, the original CHFS was modified and then cognitively debriefed in further qualitative interviews (Phase II, n=16) to confirm changes and the content validity of the modified instrument. IRB approval was obtained and all participants provided written informed consent. Interviews were recorded, transcribed, and analyzed using Atlas.ti (qualitative analysis software).

Results: The 36 patients had a mean age of 52.5 years (range: 18–73); 81% were female, and 83% Caucasian. Among the 35 participants with clinician-documented data, the mean number of active ulcers was 2.7; 89% and 71% had DU(s) on the dominant hand and submissive hand, respectively. Examples of commonly reported limitations due to DUs (in Phase I) included: activities using fingertips (e.g., using keyboard), washing dishes, cleaning, dressing, fitness activities, bathing/ showering, and grooming. Items in the original CHFS were modified and new items were added to cover the types of limitations patients reported in Phase I; specifically, 13 items were added, 4 items were deleted, and 12 items were modified and/or clarified to be more relevant to DU-related hand functioning. The revised instrument was called the Hand Disability in Systemic Sclerosis—Digital Ulcers (HDISS-DU) questionnaire. In Phase II, in which the HDISS-DU was cognitively debriefed, participants confirmed the clarity and relevance of the items, and the appropriateness of the recall period and response scales of the revised instrument. Only limited additional modifications to the instructions and response options were required; one item was deleted. The current version of the HDISS-DU assesses the impact of DUs on hand functioning through 26-items; patients are asked to rate their ability to complete common activities over the past 7 days.

Conclusion: The qualitative interview study suggests that the draft version of the HDISS-DU is a comprehensive, content valid instrument assessing the impact of DUs on hand functioning in patients with SSc. Future studies will be conducted for additional item reduction (if required) and assessment of psychometric properties of the HDISS-DU.

1864

Epidemiology of Idiopathic Inflammatory Myopathy in a Large United States Managed Care Population. Daniel E. Furst[1], Anthony A. Amato[2], Serban R. Iorga[3], Kavita Gajria[4] and Ancilla Fernandes[4]. [1]UCLA Medical School, Los Angeles, CA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Innovus, Eden Prairie, MN, [4]MedImmune LLC, Gaithersburg, MD

Background/Purpose: Prior studies have reported low incidence (0.1–1 per 100,000 persons) and prevalence (0.55–6 per 100,000 persons) of idiopathic inflammatory myopathies (IIMs) in the United States. However, updated estimates on the incidence and prevalence of IIMs have not been easily available.

Methods: We conducted a retrospective study of IIMs in a large US managed care database. Subjects were included in the incidence cohort if they had a medical claim with a myositis diagnosis (ICD-9-CM 710.3 [dermatomyositis/DM], 710.4 [polymyositis/PM], 728.81 [interstitial myositis]) and an index date from 2003–2008 that satisfied the following: 1) at least 1 inpatient claim or ≥2 office or ER visits at least 30 days apart with a diagnosis code for myositis; 2) ≥18 years of age on the index date; 3) continuously enrolled for 12 months before and after the index date; and 4) no myositis claims 12 months prior to index date. Subjects were identified for the prevalence cohort using the same criteria, with the exception of requirement 4. Overall and annual incidence for the duration of 2003–2008 was estimated and age-gender adjusted to the US 2000 census population. Annual prevalence was calculated for each year from 2003 to 2008. Subjects contributed to annual incidence once (the earliest service date that met the above criteria was set as the index date), but could contribute to prevalence in multiple years. Sensitivity analyses were performed using select clinical characteristics (presence of muscle biopsy or rheumatologist/neurologist/dermatologist visit) and treatments (presence of medications used to treat IIMs).

Results: A total of 1941 subjects were included in the incidence cohort (65% female, median age=49). For the duration of 2003–2008, the overall adjusted incidence rate for myositis was 6.57 cases (95% CI, 6.20–6.94) per 100,000 person-years. Similarly, the overall adjusted rates for PM, DM, and interstitial myositis were 3.79, 1.38, and 1.69 per 100,000 person-years, respectively. The adjusted annual incidence of myositis ranged from 5.81 to 7.89 per 100,000 persons from 2003 to 2008. From sensitivity analyses (using clinical/treatment characteristics), the overall adjusted incidence rate was 5.07 cases per 100,000 person-years (95% CI, 4.73–5.40). A total of 3112 subjects were included in the prevalence cohort (67% female, median age=49). The annual prevalence of myositis ranged from 13.99 in 2003 to 17.37 in 2008 per 100,000 persons. In sensitivity analyses (using clinical characteristics), the annual prevalence decreased slightly to range between 9.59 in 2003 to 13.61 in 2008 per 100,000 persons.

Conclusion: Our findings suggest that the incidence and prevalence of IIMs in the managed care database are higher than those previously reported. Due to the limitations inherent in claims analysis, such as plan turnover, additional research is needed to substantiate these results. Understanding the epidemiology of these rare conditions may help increase the awareness of healthcare providers and eventually contribute to early diagnosis and treatment of these debilitating conditions.

1865

Descriptive Epidemiology of Granulomatosis with Polyangitis (Wegener's), Microscopic Polyangitis, Polyarteritis Nodosa and Goodpasture's Syndrome in the United States. Martin M. Crane[1], Vincent X. Rabatin[2] and Alfred Mahr[3]. [1]GlaxoSmithKline, Research Triangle, NC, [2]GlaxoSmithKline, Research Triangle Park, NC, [3]Hospital Saint-Louis, Paris, France

Background/Purpose: Population-based registries for vasculitides in Europe have provided robust estimates for granulomatosis with polyangitis (Wegener's) (GPA), microscopic polyangitis (MPA), polyarteritis nodosa (PAN) and Churg-Strauss (CSS) syndrome but none for Goodpasture's syndrome (GS) are known to us. Contemporary estimates for the United States have been lacking. Herein we report incidence and prevalence rates for all but CSS based on an administrative claims database.

Methods: The HIPPA-compliant Thomson-Reuters Marketscan Commercial Claims and Encounters and the Medicare Supplemental and COB databases contain information (in-and out-patient encounters, prescription drugs, other services) for approximately 86 million (2.1 years mean follow-up) insured employees and their dependents covered by employer-sponsored plans and for Medicare-eligible and employer-paid supplemental insured individuals. The study population was defined as all subjects ≥ 20 years old having medical information for the entire 12 months of 2007 (N=17.2 million individuals). Prevalent disease in 2008–09 was defined as having at least two visits ≥30 days apart with the occurrence of a relevant ICD9 code (GPA [446.4]; MPA [446.20, 446.29]; PAN [446.0] and GS [446.21]) prior to the end of 2009. Incident cases were required to have at least two visits ≥30 days apart within the 2008–2009 time frame and no occurrences prior to 2008. Incidence is expressed as cases per million person-years at risk and prevalence as cases per million individuals. CSS could not be studied because of the lack of a well-defined ICD9 code and the code for PAN potentially includes other vasculitis entities.

Results: Unadjusted incidence of GPA, MPA, PAN and GS were 15.6/million (95%CI: 14.2, 17.1), 13.4/million (95%CI: 12.1,.14.8), 6.9/million (95%CI: 6.1, 8.0) and 1.6/million person-years (95%CI: 1.2, 2.1) based on 472, 405, 209 and 48 cases, respectively, and 30.2 million person-years of observation. Age-standardized incidence rates were slightly lower for GPA (14.9/million) and MPA (12.2/million) but virtually unchanged for PAN and GS. Gender-specific rates were higher in females for all diseases except GS (female-to-male ratio: 0.68); the highest female preponderance was observed for MPA (female-to-male ratio: 2.43). Incidence peaked in the 8th decade for GPA (38.9/million), the 6th decade for MPA (18.1/million), and the 8th and 9th decades for PAN (21.1/million) and GS (5.1/million). The year 2008–2009 prevalence rates were 123/million (95%CI: 118, 128) for GPA, 78.3/million (95%CI: 74, 83) for MPA, 51.0/million (95%CI: 47.7, 54.7) for PAN and 8.8/million (95%CI: 7.5, 10.4) for GS; respectively, based on 2113, 1346, 876 and 152 cases.

Conclusion: The incidence and prevalence of GPA and MPA in this US claims database were in the upper range of those reported for European populations. These data lend further support to the concept that rates of GPA and MPA have continued to increase in recent years, perhaps due to increased diagnostic awareness. Findings for the PAN group need probably to be viewed as a combination of several vasculitic entities. To the best of our knowledge, this is the first estimate of the frequency of GS from a large population.

1866

Prevalence of ANCA Associated Vasculitis and Polyarteritis Nodosa in Southern Sweden-Revisited 2010. Aladdin Mohammad[1] and Mårten Segelmark[2]. [1]Skåne University Hospital, Lund, Sweden, [2]Linköping University, Linköping, Sweden

Background/Purpose: Epidemiological studies have reported increasing incidence and prevalence of ANCA Associated Vasculitis [AAV: Granulomatosis with Polyangiitis (Wegener's) (GPA), microscopic polyangiitis (MPA), Churg-Strauss syndrome (CSS)] and polyarteritis nodosa (PAN) during the last two decades. In 2003 we found the highest prevalence ever reported (299/million)[1]. In the present investigation we have studied the development over the last 7 years.

Methods: The study area is a health care district in southern Sweden with a total population of 313,000 inhabitants (January 2010). Women made up 50.4% of the population. Patients with AAV and PAN who were living within the study area at the date of prevalence estimates were identified using hospital records (ICD-10) and a serology ANCA database. Diagnosis was verified by case records review. Patients were classified using the EMEA classification algorithm[2]. The date of point prevalence estimate was January, 1, 2010. The prevalence was calculated using the total number of patients fulfilled the study criteria as the numerator and the total population in the area as the denominator. The diagnosis delay was defined as time elapsed in months from the first possible symptoms of vasculitis to the date of diagnosis.

Results: Ninety-nine patients (48 female) with a median age of 67 years (range 21–90) fulfilled the study criteria and were alive at the date of point prevalence (Table 1). There were 51 patients with GPA; 38 with MPA; 6 with CSS and 4 with PAN. The point prevalence/million inhabitants was estimated to be 163 (95% confidence interval 118–208) for GPA, 121 (83–160) for MPA, 19 (4–34) for CSS, and 13 (0–25) for PAN. The prevalence was slightly higher in men than women (326 vs. 306/million).

Table 1.

	All n=99	GPA n=51	MPA n=38	CSS n=6	PAN n=4
Prevalence/million (95% CI)	316 (254–378)	163 (118–208)	121 (83–160)	19 (4–34)	13 (0–25)
Sex F/M	48/51	21/30	19/19	4/2	4/0
Age at diagnosis, median (range), yrs	57 (15–88)	55 (18–88)	60 (15–85)	60 (37–66)	60.5 (44–71)
Age at prevalence date, median (range), yrs	67 (21–90)	65 (21–89)	68 (33–90)	65 (52–70)	79 (63–83)
Time of follow-up, median (range), yrs	10 (0–43)	10 (0–26)	6 (0–43)	6.5 (2–16)	12 (8–34)
Diagnosis delay, median (range), months	3 (0–96)	3 (0–96)	2 (0–18)	3 (0.5–6)	5.5 (4–8)

Conclusion: The overall prevalence of AAV and PAN in southern Sweden is high (316/million) but has increased only marginally since the estimate in 2003 (299/million). For individual disease, the prevalence was stable for GPA and CSS, while decreasing for patients with PAN. However, the major difference was a 28% increases in the prevalence rate of MPA.

Informed Consent for Treatment of ANCA-Associated Vasculitis. Raluca Cozmuta[1], Peter A. Merkel[2] and Liana Fraenkel[3]. [1]St. Vincent Medical Center, Bridgeport, CT, [2]Boston University School of Medicine, Boston, MA, [3]Yale University School of Medicine, Veterans Affairs Connecticut Healthcare Systems, New Haven, CT

Background/Purpose: Treatment for ANCA-associated vasculitis (AAV) now frequently involves a choice between rituximab and cyclophosphamide. The decision can be extremely difficult and informed consent discussions between physicians and patients should rely on clear and consistent communication of the risks and benefits associated with each treatment option. To date, there are insufficient data fully describing the magnitude of risks associated with each of these treatments and no guidelines describing what experts consider as important to disclose to their patients. The objective of this study was to obtain expert ratings of 1) the risks associated with available treatment options for AAV and 2) the importance of disclosing specific adverse events (AEs).

Methods: We created a web survey in which we asked vasculitis experts (defined as physicians whose practices focus on vasculitis and physicians engaged in research in vasculitis) to rate the magnitude of risk for a list of AEs using prespecified response options ranging from 50% risk to 0% risk for rituximab and IV cyclophosphamide. Respondents were also asked to rate the importance of disclosing each AE on a 5-point scale.

Results: The survey was emailed to 167 vasculitis experts. Of these, 145 were successfully delivered. The survey was opened by 94 subjects and completed by 50. 77% were male, 49% were rheumatologists, and 39% were nephrologists. 90% were attending physicians and 4% were trainees. 67% reported spending the majority of their time in clinical practice, 31% in clinical research and 2% in basic research. 71% worked in a University hospital setting. 24% were from the US and 61% were from Europe. 80% reported seeing more than 10 patients with AAV in the previous year, 12% saw between 6 and 10 patients, and 8% saw between 1 and 5 patients. Experts' ratings of the probabilities of specific AEs varied significantly and are provided in the Table. The importance of disclosing these AEs according to the surveyed experts is illustrated in the Figure. The majority (75% or greater) of the experts surveyed felt that it was very or extremely important to disclose half of the AEs listed.

Table. Experts' Rating of Risks Associated with IV Cyclophosphamide (CTX) and Rituximab (RTX)

	30%+		20%–25%		10%–15%		5%		1%		1 in 500		1 in 1,000		1 in 10,000		1 in 100,000		0 (no risk)

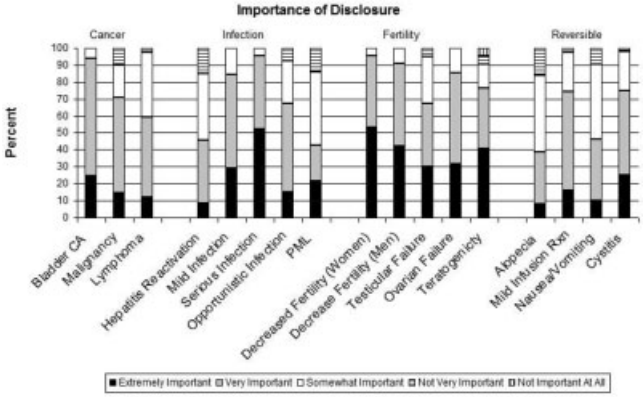
Most frequent responses per AE are bolded for both medications.



Conclusion: Experts vary significantly in the magnitude of risk they assign to AEs associated with treatment options for AAV. Further efforts are needed to develop consistent risk communication strategies for patients with AAV. There is currently fair agreement, however, on which risks are very or extremely important to disclose to patients.

1868

Increased Prevalence of Metabolic Syndrome and Higher Serum Leptin Levels in Patients with Psoriatic Arthritis. Devy Zisman[1], S. Nissan[1], Lihi Eder[1], J. Feld[1], M.A Rahat[1], Muna Elias[1], D. Rimar[1], A. Laor[1] and H. Bitterman[2]. [1]Carmel Medical Center, Haifa, Israel, [2]Carmel Medical Center, The Ruth and Bruce Rappaport Faculty of Medicine Technion, Haifa, Israel

Background/Purpose: To evaluate the prevalence of metabolic syndrome (MeS) in patients with psoriatic arthritis (PsA) compared to the general population and to determine its association with clinical biomarkers of inflammation and serum levels of pro- and anti-atherogenic adipokines.

Methods: Patients with PsA from a rheumatology clinic who met the CASPAR criteria were compared to control subjects without psoriasis and inflammatory rheumatic diseases, all of who were followed in a community clinic. All patients were interviewed regarding demographic data, concomitant diseases, medical treatment, smoking, physical activity and alcohol consumption. Blood pressure, body mass index (BMI), waist circumference and disease activity parameters were measured. Laboratory evaluation included fasting blood glucose level and lipid profile. The presence of MeS was determined according to the definition of the International Diabetes Federation criteria. Serum adiponectin and leptin levels were analyzed in 32 individuals in each group by ELISA. Continuous variables were compared by t-test, and a Chi square test was used for comparing discrete variables. Multivariate regression models compared the association of MeS, leptin and adiponectin with PsA in comparison to controls, after adjusting for potential confounders.

Results: 74 patients with PsA (average age of 57.6 years) were compared to 82 controls. The groups were comparable with regard to age, gender, smoking status, alcohol consumption, and physical activity, as well as personal and family history of atherosclerotic heart disease, hypertension, diabetes mellitus and hyperlipidemia. BMI was higher in PsA patients compared to the control group (29.6 vs. 27.8, $p=0.04$).

The prevalence of MeS was higher in PsA patients compared to the control group (54.8% vs. 36.6%, $p=0.02$). The difference remained statistically significant after adjustment for age, gender, ethnicity and smoking status (Odds Ratio=2.33, 95% confidence interval 1.16–4.69). No association was found between the occurrence of MeS and parameters of articular disease activity, severity of skin manifestation or treatment (anti TNFα agents, classical Disease Modifying Anti Rheumatic Drugs, steroids and non-steroidal anti inflammatory agents).

Leptin levels and leptin/adiponectin ratio were higher in PsA patients compared to controls (83.4 ng/ml vs. 51.7 ng/ml, $p=0.001$ and 6.3×10^{-3} vs. 4.1×10^{-3}, $p=0.015$, respectively). These differences remained statistically significant after adjustment for age and gender.

Conclusion: A higher prevalence of MeS was found in patients with PsA compared to the general population, accompanied by an increase in plasma concentration of leptin, the pro-atherogenic factor and the leptin/adiponectin ratio, thus pointing to an increased risk of vascular morbidity in PsA patients.

1869

Quantifying the Harmful Effects of Psoriatic Diseases on Quality of Life Outcomes—COMPASS III Study. Deepan Dalal[1], Yih Chang Lin[1], Danielle Brennan[1], Katherine Wolski[1], Neil Borkar[2], Neil J. Korman[2], Diane Dylinski[1] and M. Elaine Husni[1]. [1]Cleveland Clinic Foundation, Cleveland, OH, [2]University Hospitals—Case Medical Center, Cleveland, OH

Background/Purpose: Up to 30% of patients with Psoriasis (PsO) may suffer from concurrent Psoriatic Arthritis (PsA). Both, PsO and PsA have worse Quality of Life (QoL) outcomes compared to the general population, however, there is limited literature comparing the QoL outcomes between these diseases. We seek to investigate the differences in QoL outcomes between these 2 groups and its treatment implications.

Methods: The current study is a cross-sectional analysis of a cohort of 252 patients with PsO and PsA, recruited from 2 tertiary care centers. A self-administered questionnaire was used to collect demographic and validated QoL data. QoL outcomes were measured as follow:

a. SF-12 (Physical Composite Score (PCS) and Mental Composite Score (MCS))

b. Health Assessment Questionnaire (HAQ)

c. Dermatology Life Quality Index (DLQI)

The PCS and MCS scores were expressed as Mean±SD and compared using Student's t-test. The HAQ (Disability Index DI) and DLQI scores were expressed as Median (Q1, Q3) and compared using a Wilcoxon rank-sum test. All analyses were conducted in SAS version 9.2 (SAS Institute, Cary, NC).

Results: Of the 252 (125 males, 49.6%) patients enrolled in the cohort, 107 (42.5%) had PsA. The groups were comparable with regards to gender distribution and co-morbid diseases (stroke, MI, PVD, diabetes and other cardiovascular diseases). As anticipated, PsO patients were younger compared to PsA patients (45.9±15.4 v. 50.8±12.7 yrs, p=0.02). Also, patients with PsO received biologic/DMARD treatment less frequently, compared to PsA patients (31.0% v. 75.6%).

The PCS was significantly worse in patients with PsA compared to Pso, whereas the MCS was significantly worse in patients with PsO. The Disability Index (DI) calculated by HAQ was significantly worse in patients with PsA and the DLQI was significantly worse in patients with PsO. [Table 1]

Quality of Life Outcome	Psoriatic Arthritis (N = 107)	Psoriasis (N = 145)	P-value
SF-12			
a. PCS (Mean ± SD)	41.7 ± 11.6	49.3 ± 10.3	<0.001
b. MCS (Mean ± SD)	49.6 ± 9.6	46.6 ± 12.2	0.043
HAQ (Median [Q1, Q3])	0.4 (0.0, 0.9)	0.0 (0.0, 0.1)	<0.001*
DLQI (Median [Q1, Q3])	3.0 (1.0, 9.0)	6.0 (3.0, 10.0)	0.009*

* non-parametric analysis

Conclusion: As expected PsA had worse PCS and HAQ compared to PsO. This was despite the fact that the PsA received aggressive treatment more frequently. However, PsO patients had worse MCS and DLQI compared to PsA despite a presumed lower inflammatory component of skin alone compared to skin and joint combined. This may be related to disparity in the treatments received. These results warrant aggressive treatment of the PsA patients for prevention of functional decline. The study also suggests early and more aggressive treatment of PsO patients to prevent decline in the mental health quality of life.

1870

Trends In Lipid Profiles In Patients with Psoriasis: A Population-Based Analysis. Bharath Manu Akkara Veetil, Eric L. Matteson, Hilal Maradit-Kremers, Marian T. McEvoy and Cynthia S. Crowson. Mayo Clinic, Rochester, MN

Background/Purpose: Psoriasis is associated with an atherogenic lipid profile but it is unknown how this profile is affected by the onset of psoriasis. We performed a population based cohort study to determine the effect of psoriasis onset on serum lipid profiles.

Methods: We compared changes in lipid profiles in a population based incident cohort of 689 patients with psoriasis diagnosed between 1988 and 2008 and 717 non-psoriasis comparator subjects. All lipid measures performed clinically during the 5 years before and 5 years after psoriasis incidence/index date were abstracted. Random-effects models adjusting for age, sex and calendar year were used to examine trends in lipid profiles, accounting for multiple measurements for each subject.

Results: There were significant declines in total cholesterol (TC) and low density lipoprotein (LDL) levels during the 5 years before and the 5 years after psoriasis incidence/index date in both the psoriasis and the non-psoriasis cohorts, with a greater decrease noted in the TC levels (p=0.022) and LDL (p=0.054) in the non psoriasis cohort. HDL levels increased significantly both before and after psoriasis incidence date in the psoriasis cohort, but there was no change in HDL during the 5 years before index date in the non-psoriasis cohort. Although the trends between the psoriasis and non psoriasis cohorts were the same, TG levels were significantly higher in psoriasis compared to non-psoriasis subjects (p<0.001), and HDL levels were significantly lower in patients with psoriasis compared to non-psoriasis subjects (−1.9 mg/dL; p=0.013). HDL levels increased significantly both before and after psoriasis incidence in the psoriasis cohort but no significant change was noted during the 5 years before index date in the non-psoriasis cohort. The proportion of psoriasis subjects with elevated lipids did not change during the 5 years before psoriasis incidence but there was a significant decrease in the proportion of subjects with abnormal TC and LDL in the non-psoriasis cohort during the corresponding time period (p<0.01). Lipid trends were otherwise similar in both cohorts during the 5 years after psoriasis incidence/index date. There were no differences in prescriptions for lipid lowering drugs between the two groups.

Conclusion: Patients with psoriasis had a significant decrease in TC and LDL levels during the 5 years before psoriasis incidence. Higher mean TG and lower mean HDL levels were noted in the 5 years before psoriasis incidence. These changes are unlikely to be caused by lipid lowering treatment alone and require further exploration, as early intervention may positively impact cardiovascular morbidity and mortality in this patient population.

1871

Cardiovascular Risk In Psoriasis: A Population Based Analysis with Assessment of the Framingham Risk Score. Bharath Manu Akkara Veetil, Eric L. Matteson, Hilal Maradit-Kremers, Marian T. McEvoy and Cynthia S. Crowson. Mayo Clinic, Rochester, MN

Background/Purpose: Patients with psoriasis have an increased prevalence of traditional cardiovascular risk factors and increased risk of cardiovascular (CV) mortality. Psoriasis itself may be an independent CV risk factor, perhaps related to the pro atherosclerotic effect of chronic inflammation. The utility of risk stratification tools such as the Framingham risk score (FRS) to stratify patients according to their 10-year risk for CV events, and identify those who would benefit from risk lowering measures, is unknown in these patients. We performed a population based cohort study to examine CV risk in psoriasis and examine the performance of the FRS in assessing this risk.

Methods: We compared the predicted 10 year risk of death or myocardial infarction (MI) using the FRS, based on sex, age, total cholesterol, high-density lipoprotein, blood pressure, smoking, and diabetes, to the observed coronary heart disease (CHD) risk in a population based cohort of patients with psoriasis diagnosed between 1998 and 2008. Observed follow-up was truncated at 10 years after psoriasis incidence. For patients with <10 years of follow-up, the predicted risk of CHD was adjusted proportionately. Poisson regression models were used to obtain the standardized incidence ratio (SIR), which is the ratio of the observed CHD in psoriasis to the predicted CHD obtained from the FRS.

Results: The study included 1309 patients with psoriasis aged ≥30 years without prior MI. 74% of patients had all CV data required to compute FRS. The rate of occurrence of CHD was similar in those with and without FRS (logrank p=0.07). Among patients with predicted risk scores, the median FRS was 3.8% while the actual observed 10 year risk of CHD was 5.5%. A total of 44 patients developed CHD during follow-up, and the FRS predicted 47.7 CHD events among these patients. The SIR between the observed and predicted CHD risk, was 0.90 (95% CI: 0.67, 1.22; p=0.50). The SIR was not elevated for women or for men. Among patients aged <65 years, there were no apparent differences between observed and predicted CHD risk (SIR: 0.79, 95% CI: 0.51, 1.21). The observed risk of CHD was not different from the predicted risk in patients aged ≥65 years (SIR: 1.05; 95% CI: 0.69, 1.59).There were no significant differences in the SIR based on use of systemic treatment, and no apparent differences in the CHD event rate in patients on systemic treatment compared to those without.

Conclusion: Beyond traditional risk factors, psoriasis does not appear to be an additional risk factor for CHD. The Framingham Risk Score reasonably estimates CHD risk in both men and women and all age groups in patients with psoriasis, and can be used in risk stratification and identification of those most likely to benefit from early interventions to diagnose and treat cardiovascular disease.

1872

Learned Helplessness Predicts 2-Year Change in Functional Disability in Patients with Inflammatory Polyarthritis. Elizabeth M. Camacho[1], Suzanne Verstappen[1], Diane K. Bunn[2] and Deborah DPM Symmons[1]. [1]University of Manchester, Manchester, United Kingdom, [2]University of East Anglia, Norwich, United Kingdom

Background/Purpose: Learned helplessness (LH) is an attributional style. In patients with inflammatory polyarthritis (IP), LH may manifest itself when an individual feels they cannot have a positive impact on their own prognosis and as a result may not take measures to help themselves, for example non-compliance with medication, potentially resulting in a poor disease outcome. It may be possible to influence disease outcome by addressing LH. We investigated the directional association between LH and subsequent functional disability, examined how LH changes over 2yrs, and identified factors associated with LH, in patients with recent-onset IP.

Methods: The Norfolk Arthritis Register (NOAR) is an inception cohort of patients with recent-onset IP.This analysis included 446 patients with baseline symptom duration of ≤2yrs, who joined NOAR during 2004–07, and had ≥2yrs of follow-up. The Health Assessment Questionnaire (HAQ) and Rheumatology Attitudes Index (RAI) were completed by all patients at baseline and 2yrs later. The RAI is a 5-item measure of learned helplessness, with possible scores as any integer between 5–25. LH was defined using total RAI score (top quartile = high, bottom quartile = low). The relationship between LH and subsequent disability (measured as 2-yr change in HAQ score from baseline), was analysed using linear regression adjusted for baseline HAQ score. The level of LH was said to have changed from baseline if total RAI score had increased or decreased by ≥5 points at 2 years. Multinomial logistic regression, adjusted for baseline RAI score was used to identify factors associated with change in RAI score (increase vs. no change; decrease vs. no change). All analyses were adjusted for age and sex.

Results: At baseline, 230 (52%) patients had normal, 97 (22%) had low, and 119 (27%) had high RAI scores. Compared to patients with normal RAI scores, those with high LH showed a significantly greater increase in HAQ score over 2yrs (mean difference (MD): 0.21; 95% CI 0.05, 0.36) and those with low LH showed a comparable change in HAQ score (MD: −0.09; 95% CI −0.24, 0.06). From baseline to year 2, LH decreased in 223 (50%) patients, increased in 165 (37%) patients, and did not change in 58 (13%) patients. Increasing age at symptom onset was significantly associated with lower baseline LH (β per decade: −0.6; 95% CI −0.9, −0.3) and an increased likelihood of a reduction in RAI score over 2yrs (relative risk ratio (RRR) per decade 1.3; 95% CI 1.0, 1.5). Compared to patients of the highest SES, those of the lowest SES had significantly higher baseline LH on average (MD: 1.8; 95% CI 0.3, 3.3). Increasing BMI was associated with increasing LH at baseline (β per unit: 0.1; 95% CI 0.04, 0.2), and a lower likelihood of a reduction in RAI score over 2yrs (RRR 0.9; 95% CI 0.8, 1.0). Patients who were autoantibody positive were significantly more likely to have worsened LH at 2yrs than autoantibody negative patients (RRR RF+ 2.5; 95% CI 1.4, 4.6; RRR ACPA+ 4.0; 95% CI 2.1, 7.6).

Conclusion: LH predicted change in disability. For the majority of people LH changed over 2 years, and hence it should be regarded as a modifiable risk factor for disease outcome in IP.

1873

Adverse Pregnancy Outcomes Before Symptom Onset Are Associated with a Worse Disease Outcome in Women with Recent-Onset Inflammatory Polyarthritis. Elizabeth M. Camacho[1], Suzanne Verstappen[1], Mark Lunt[1], Diane K. Bunn[2] and Deborah P.M. Symmons[3]. [1]University of Manchester, Manchester, United Kingdom, [2]University of East Anglia, Norwich, United Kingdom,[3]The University of Manchester, Manchester, United Kingdom

Background/Purpose: A number of studies have suggested that female reproductive factors, such as parity or menopause status, may impact upon a woman's likelihood of developing rheumatoid arthritis (RA), and her subsequent disease severity. For example, there is some evidence that women with a history of adverse pregnancy outcomes (APOs) may be at greater risk of developing RA. Our aim was to investigate the relationship between pre-onset APO history (spontaneous abortion or stillbirth) and disease outcome (functional disability and disease activity) over time, in women with inflammatory polyarthritis (IP), a term which includes RA.

Methods: The Norfolk Arthritis Register (NOAR) is a primary-care-based cohort of patients with recent-onset IP; 1647 gravid women joined NOAR between 1990–2004. 46 women with subsequent pregnancies during follow-up and 12 women who only had pregnancies resulting in induced abortions were excluded from this cohort; 1586 women were included in the analysis. APO history was patient-reported and those with any history of APOs before symptom onset were further categorised into overlapping groups with one or more (1+), two or more (2+), or three or more (3+) APOs. Functional disability was assessed using the Stanford Health Assessment Questionnaire (HAQ) and, for a sub-group of patients for whom the relevant data were available, disease activity scores ($DAS28_{CRP}$) were calculated. Linear random effects models were used to examine differences over time in HAQ and DAS28 score, by APO history, initially unadjusted, and then progressively adjusted for: (i) age at symptom onset and symptom duration; (ii) socio-economic status and smoking status; (iii) oral contraceptive use; (iv) comorbid conditions.

Results: 397 (25%) patients reported at least one APO before symptom onset; 125 (8%) women had 2+ APOs and 47 (3%) had 3+ APOs. The rates of APOs in NOAR were largely comparable to those in the general population of the United Kingdom. The median age at IP onset was significantly younger for women with a history of APOs than women with no APOs (52 vs. 55 years). Results from the maximally adjusted models showed that on average, women with a history of 2+ APOs had significantly higher HAQ and DAS28 scores over time than women with no APOs (mean difference: HAQ 0.13; 95% CI 0.002, 0.26; and DAS28 0.56; 95% CI 0.01, 1.11). This relationship was more pronounced, in women with 3+ APOs (mean difference: HAQ 0.23; 95% CI 0.02, 0.43; and DAS28 0.98; 95% CI 0.23, 1.74).

Conclusion: Women with APOs before IP-onset had greater functional disability and more active disease over time than women with no APOs. There was a dose response effect whereby an increasing number of APOs was associated with an increasing negative difference in HAQ and DAS28 score, when compared to women with no APOs.

1874

Pregnancy Outcomes In Women Exposed to Adalimumab: An Update On the Autoimmune Diseases In Pregnancy Project. Diana Johnson, Yunjun Luo, Kenneth Lyons Jones and Christina Chambers. University of California, San Diego, La Jolla, CA

Background/Purpose: The fully human, anti-tumor necrosis factor monoclonal antibody adalimumab (ADA) is approved for the treatment of rheumatoid arthritis (RA), psoriatic arthritis, ankylosing spondylitis, Crohn's disease (CD), psoriasis, and juvenile idiopathic arthritis. The effect of ADA during pregnancy is unknown.

Methods: This report describes preliminary pregnancy outcomes from an ongoing study conducted by the Organization of Teratology Information Specialists (OTIS). In this prospective cohort, women treated with ADA for RA or CD during the first trimester of pregnancy are followed for 1-year postpartum. Outcomes are compared with a disease-matched group of women without ADA treatment during their pregnancies, and a control group of pregnant women who neither have an autoimmune disease nor have been treated with ADA. Additionally, OTIS collects information on ADA-exposed pregnancies that do not meet the cohort criteria, but are followed as a case series. These outcomes are presented separately as they have no comparison group.

Results: Between November 2004 and June 1, 2011, pregnancy outcomes have been collected on 161 women in the ADA-exposed cohort (60 RA, 101 CD); 79 women in the disease comparison group (68 RA, 11 CD), and 134 women in the healthy comparison group (Table 1). A total of 3.4% of women in the ADA-exposed RA group had a child with a major birth defect compared to 4.6% of women in the RA disease-matched group. A total of 14.1% of women in the ADA-exposed CD group had a child with a major birth defect compared to 10.0% in the CD disease-matched group. Major defects were reported in 4.1% of the healthy comparison pregnancies. The rate of spontaneous abortion in the ADA-exposed groups is 10.0% and 12.9% respectively compared to 4.4% and 9.1% in the disease comparison groups and 1.5% in the healthy comparison (Table 1).

Table 1. Pregnancy Outcomes of Women in the Cohort Study

Outcome	ADA-exposed RA (N=60)	ADA-exposed CD (N=101)	RA Disease Comparison (N=68)	CD Disease Comparison (N=11)	Healthy Comparison (N=134)
Live born–n (%)	53 (88.3)	85 (84.2)	62 (91.2)	9 (81.8)	120 (89.6)
Spontaneous Abortion - n (%)	6 (10.0)	13 (12.9)	3 (4.4)	1 (9.1)	2 (1.5)
Therapeutic Termination - n (%)	0	1 (1.0)	0	0	0
Stillbirth - n (%)	0	0	0	0	1 (0.7)
Lost to follow-up - n (%)	1 (1.7)	2 (2.0)	3 (4.4)	1 (9.1)	11 (8.2)
Preterm delivery - n (%)	7 (13.2)	17 (20.0)	11 (17.7)	1 (11.1)	6 (5.0)
Major Malformations - Live born infants - (%)	2/53 (3.8)	11/85 (12.9)	2/62 (3.2)	1/9 (11.1)	5/120 (4.2)
Major Malformations - All infants - (%)	2/59 (3.4)	14/99 (14.1)	3/65 (4.6)	1/10 (10.0)	5/123 (4.1)

Conclusion: Based on preliminary data, there is no evidence of an association between ADA exposure and major birth defects, or a specific pattern of malformation. It is difficult to draw conclusions regarding the ADA-exposed CD group without sufficient numbers in the CD disease comparison group. The proportion of pregnancies in the ADA-exposed cohort ending in spontaneous abortion is higher than the comparison groups; however, this difference may be due to earlier enrollment of ADA-exposed women, when the risk for miscarriage is highest. Formal comparisons with adjustments for confounders will be conducted when the target sample size has been achieved.

1875

Maternal Smoking and the Risk of Juvenile Idiopathic Arthritis. Susan Shenoi[1], Carol A. Wallace[1] and Beth A. Mueller[2]. [1]Seattle Children's Hospital, University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA

Background/Purpose: Environmental factors that act as triggers in a genetically susceptible host are one of the current postulated etiologies of Juvenile Idiopathic Arthritis (JIA). To date in adult studies cigarette smoking is the only consistent environmental risk factor demonstrated to have a strong association for severe seropositive Rheumatoid arthritis. JIA is a heterogenous group of chronic childhood inflammatory arthritides specifically targeting the synovium of joints. Maternal prenatal smoking may have several effects on the fetus and child due to the placental transfer of various chemicals including nicotine in tobacco smoke.

Objectives: To determine the association between JIA and maternal prenatal smoking.

Methods: This Washington State population-based case-control study used ICD-9 codes from outpatient hospital and clinic records to identify 1518 children <20 years of age with a diagnosis of JIA from 1987–2010. Controls (n=6072) were randomly selected from birth records of children without JIA, frequency matched on year of birth. Maternal prenatal smoking exposure data was assessed from subjects' birth certificates. Stratified analysis was used to estimate odds ratios (OR) and 95% confidence intervals (CI). Parental and infant factors were considered for their possible effects on the relationship.

Results: Mothers of JIA cases (10%) were less likely to have smoked prenatally than mothers of controls (16%, OR 0.69, 95% CI: 0.56 – 0.85, adjusted for maternal age, race and Medicaid recipient status. This association appeared to be restricted to children of white women, and was most marked for those whose mothers smoked 5 or more cigarettes per day.

Conclusion: Our study demonstrates a protective association between maternal smoking and JIA and should by no means be taken as encouragement for women to smoke during pregnancy. The risks of maternal smoking on the fetus, child and mother overall far outweigh any potential benefits. This association should encourage evaluation of other environmental risk factors and may help elucidate potential biologic mechanisms of this disease. Currently the effects of maternal smoking on inflammatory diseases remains unclear and future studies with more sensitive and specific identification of JIA cases and disease categories, and improved ascertainment of smoking status, will further elucidate this association.

1876

Prevalence of Depression and Concomitant Risk Factors in Children with Rheumatic Disease. Stacey E. Tarvin[1], Nicole M. Taylor[2], Christine M. Raches[2], Lisa M. Macharoni[2], Joseph E. Hansel[2] and Susan H. Ballinger[1]. [1]Riley Hospital for Children, Indianapolis, IN, [2]University of Indianapolis, Indianapolis, IN

Background/Purpose: Rheumatic disease impacts children emotionally, socially and physically. Children who perceive that their medical condition interferes with an ability to engage in social, educational, and family activities report more depressive symptoms. The aim of this study is to examine the prevalence of depression in children with rheumatic disease and to identify concomitant risk factors for depression. It was hypothesized that, compared to healthy peers, children with rheumatic diseases may have a higher risk of developing depressive symptoms.

Methods: Children with a primary rheumatic disease, ages 8–17 years, completed the Children's Depression Inventory (CDI) and parent-child pairs completed standardized measures documenting demographics, daily functioning (Childhood Health Assessment Questionnaire), pain (VAS), health-related quality of life (PedsQL Rheumatology module), and psychosocial variables (Family Environment Scale, Child Behavior Checklist, Youth Self Report). The primary rheumatologist documented a global assessment of disease severity (VAS) and disease activity for children with the diagnosis of juvenile idiopathic arthritis (active joint count and VAS), juvenile dermatomyositis (DAS), and systemic lupus erythematosus (SLEDAI). Children with primary pain disorders were excluded. Prevalence of depression was compared with the general child and adolescent population. Appropriate parametric statistics were completed to determine statistical significance of demographic variables. Pearson product moment correlations were run to determine relationships between depression, pain, quality of life, family conflict, physical functioning and disease severity. Hierarchal multiple regression analyses were run to determine which medical and psychosocial variables were significant predictors of depression, while controlling for demographic variables.

Results: One hundred eighteen patients were screened (80% female). Four percent of the population had clinically significant symptoms of depression while another 15% of the population was found to be "at risk" for symptoms of depression. Female gender ($p<.01$), usage of medication for depression ($p<.01$), and therapy for depression ($p<.05$) were the demographic variables that correlated with increased CDI scores and thus symptoms of depression. After controlling for demographic variables, total CDI score significantly correlated (adjusted $R^2 = .508$, $p<.01$) with child report of decreased quality of life and child perception of poor rule use and poor planning within the family. Years since diagnosis, disease specific activity scores, and physician global assessment did not correlate with increased CDI scores.

Conclusion: The prevalence and risk of depression among children with rheumatic diseases is comparable to previously reported data for a healthy population of children. Risk factors for depression are related to quality of life and family characteristics. Disease specific factors did not correlate with increased depressive symptoms.

1877

Disease Modifying Anti-Rheumatic Drugs Compliance Study. Kateryna Vostretsova[1], Pam Rogers[1], Darby JS Thompson[2] and Diane Lacaille[3]. [1]Arthritis Research Centre, Vancouver, BC, [2]Simon Fraser University, Vancouver, BC, [3]Arthritis Research Centre; University of British Columbia, Vancouver, BC

Background/Purpose: The efficacy of DMARDs for Rheumatoid Arthritis (RA) is well established; however, poor compliance may limit the effectiveness of DMARDs. People often have difficulty taking medications regularly, are often reluctant to take medications, or might experience side-effects, all of which can affect compliance. Few studies have evaluated compliance with DMARDs in RA. Reported compliance ranges from 58% to 91% with wide variation in how compliance is measured and defined. The purpose of this study was to evaluate compliance with DMARDs in RA. Specific objectives were to: 1) measure the degree of compliance with DMARDs in RA; 2) understand reasons for non-compliance; and 3) identify determinants of compliance.

Methods: We performed a cross sectional survey study. Participants were recruited from a random sample of 600 RA patients who had attended the Mary Pack outpatient arthritis treatment program which provides outpatient multidisciplinary arthritis services across the province. Eligibility criteria included having an MD diagnosis of RA, having

taken a DMARD in the preceding 6 months and ability to complete a questionnaire in English. Level of compliance was assessed using the Medication Adherence Report Scale (MARS) and reasons for non-compliance using the Adherence Questionnaire of Adult AIDS Clinical Trials Group (AACTG) adapted for arthritis. Determinants of adherence were assessed, using validated instruments where available, including RA measures (pain, HAQ, disease activity (VAS and RADAI), general health, co-morbidities, medications, private insurance, self-efficacy, social support, depression and satisfaction with health care.

Results: A total of 192 completed the questionnaire (74 ineligible or deaths, 37% participation rate) with 80% female, mean (SD) age 61.9 (14) years, RA duration 13.2 (11.5) years. Many were on combination therapy (70%), 39% were on biologics and 69% on Methotrexate. The mean (SD) score for MARS was 38.00(3.97), which indicates good adherence. Most frequent non-adherent behaviours were forgetting to take their DMARDs (55%), altering the dose (33%), deciding to skip a dose (29%), taking less than instructed (27%) and stopping for a while (22%). However these behaviours were mostly reported as infrequent (rarely or sometimes). Results from the AACTG demonstrated that forgetting, life events (i.e. being busy or away) and side-effects were the most common reasons for non-adherence. People used most frequently visual reminders and pill organizers as strategies to help adherence. Regression analyses using a Generalized Linear Model with Weibull distribution of MARS scores revealed that people who were younger, had longer disease duration, higher disease activity (VAS), worse physical function (HAQ), and those who experienced side-effects were less compliant.

Conclusion: Our results suggest that the overall level of compliance with DMARDs was good in this sample. Our findings are useful to clinicians to identify people at higher risk of non-compliance (younger people with early disease who are not doing well) in whom more time could be spent evaluating compliance to therapy and discussing underlying reasons for non-compliance.

1878

Improving the Assessment of Minimal Important Change by Combining Health State Transition Questions with Patient Acceptable Symptom State and Patient Willingness to Alter Therapy. Jos Hendrikx, Jaap Fransen, Wietske Kievit and Piet LC van Riel. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background/Purpose: The minimal important change (MIC) is the smallest change in a health related outcome measure which is perceived as important, and in the absence of side effects and excessive cost, would mandate a change in the patient's management. Transition questions used for the assessment of MIC ask for the amount of past health change. However, transition questions do not incorporate the importance of the health status reached nor a therapeutic consequence. Therefore, this study explored if combining the concepts of patient acceptable symptom state (PASS) and patient willingness to alter therapy (PatWAT) could improve methods for the assessment of MIC.

Methods: All rheumatoid arthritis patients visiting the outpatient clinic from December 2010 to June 2011 were given a questionnaire containing questions to measure health state transition, PASS and PatWAT. Trained research nurses measured the Disease Activity Score 28 (DAS28) during each outpatient visit. MIC was ascertained in the standard way by exploring the distributions of the actual DAS28 change in three transition categories: improved, unchanged and deteriorated. This was compared with a new classification system, based on the 3 health transition categories x 2 PASS subclasses x 4 PatWAT subclasses. The resulting 24 sub-categories were used to re-classify patients as either improved, unchanged or deteriorated in a manner reflecting the definition of MIC. The standard and new method for MIC assessment were compared using the area under the Receiver Operating Curve (ROC).

Results: In total data of 257 patients with at least two DAS28 measurements were available for analysis. Mean age was 59 years, 64.6% female, 73.3% rheumatoid factor positive, mean disease duration was 11 years and mean DAS28 score was 3.16. Of these patients 23.8% reported improvement, 43% no change, and 25% deterioration in health state as compared to their prior visit. The vast overlap in DAS28 change distributions when applying standard MIC assessment methods is shown in figure 1. When applying standard methodology to assess MIC the ROC had an area under the curve (AUC) of 0.64 for improvement in health and 0.74 for deterioration. 8% of the patients were re-categorized using the new strategy of combining the transition questions with PASS and PatWAT into a new classification scheme. The AUC for this method of MIC assessment was 0.65 for improvement and 0.76 for deterioration.

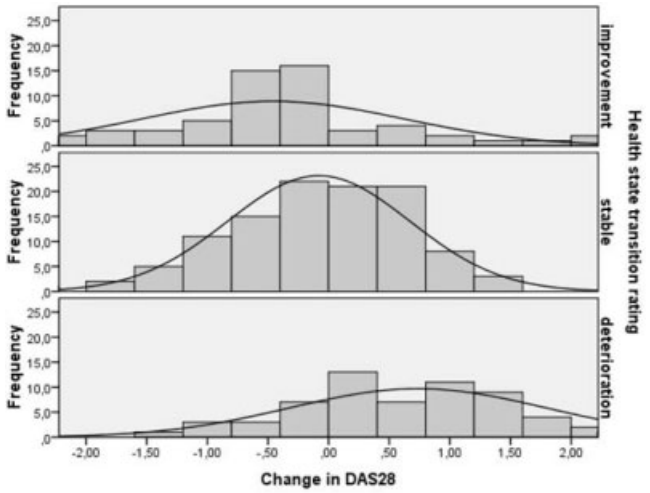


Figure 1. Distribution of DAS28 change scores according to health state transition ratings

Conclusion: The results show extensive heterogeneity in the perception of importance of change, which was minimally reduced with a new classification method that better reflected to concept of MIC. Apparently valuing health change is a highly individually determined process, expressing the need for innovative patient specific assessment methods that do more justice to each patient's unique disease course and resulting perspective on change.

1879

The Accuracy of Identifying Kidney Disease in Administrative Databases for Rheumatic Disease Research—A Systematic Review of Validation Studies. Bindee Kuriya[1], Ziv Harel[2] and Diane Lacaille[3]. [1]University of Toronto, Toronto, ON, [2]Division of Nehprology, University of Toronto, Toronto, [3]Arthritis Research Ctr Canada, Vancouver, BC

Background/Purpose: Administrative health care databases are an important resource to study the epidemiology of rheumatic diseases, their outcomes, and associated conditions. Among these, kidney disease is a frequent co-morbidity in people with rheumatic diseases and accurate classification of individuals with kidney disease is important for the control of confounding in risk models. Our objective was to assess the validity of identifying kidney disease in administrative health care data.

Methods: We conducted a systematic review of observational studies validating the accuracy of diagnostic and procedural codes for acute kidney injury (AKI), chronic kidney disease (CKD), and kidney disease requiring dialysis in administrative health care databases. Medline and Embase were searched for full length articles in English or French language from 1950 to November 2010. A hand search of eligible articles was done to identify additional relevant studies. All abstracts and articles were reviewed independently by 2 reviewers. The type of database, source population, index and reference standards used, and measures of diagnostic accuracy (sensitivity, specificity, positive and negative predictive value) were recorded. Quality of the articles was assessed using a newly developed tool for validation studies using administrative data.

Results: 23 studies among 17 databases in 5 countries were included for review. The diagnostic performance of administrative coding for AKI was reported in 7 studies, for dialysis in 4 studies, and validation of CKD in 16 studies. The number and type of diagnostic and procedural codes, and the ascertainment periods varied widely. The reference standards used were less variable and included documentation of kidney disease in the medical record or laboratory values of serum creatinine. Sensitivity for AKI and CKD varied widely (ranging from 3% to 83%) and was highest in study samples with underlying coronary artery disease. Sensitivity for procedure codes for dialysis ranged from 33% to 100%. No validation was performed exclusively among patients with rheumatic disease. Specificity and negative predictive values were uniformly high for all 3 conditions (range 88%–100% and 72%–100%). Positive predictive values were less consistent in AKI (15%–100%) and CKD (39%–100%) but higher in the validation of kidney disease requiring dialysis (84%–100%).

Conclusion: The existing literature demonstrates variable accuracy of diagnostic and procedure-based codes to identify kidney disease using administrative data. Sensitivity was generally poor for non-dialysis requiring

AKI and CKD, which would lead to an underestimation of true AKI and CKD but may be acceptable to identify kidney disease requiring dialysis. The variable PPV of codes especially for AKI and CKD put analyses using these codes at risk of misclassification. Researchers wishing to control for kidney disease in rheumatic disease research must take these findings into consideration to avoid bias arising from poor code validity.

1880

A Systematic Review of Validation Studies of Administrative Data Used to Identify Infections. Claire Barber[1], Diane V. Lacaille[2], Joan E. Wither[3] and Paul R. Fortin[4]. [1]Mount Sinai Hospital, Toronto, ON, [2]Arthritis Research Ctr Canada, Vancouver, BC, [3]Toronto Western Research Institute, University Health Network, Toronto, ON, [4]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: To conduct the first systematic review of the literature on the validation of algorithms identifying infections in administrative data for use in studies evaluating infections as either outcomes or covariates in population-based studies of rheumatic diseases.

Methods: Medline and Embase were searched using the terms "administrative data", infection", "outcomes", and "validation" between 1950 to November 2010. All abstracts were reviewed independently by 2 reviewers (CB & PF). A hand search of all articles reviewed was done to identify any other relevant work. Inclusion criteria: validation studies of administrative data in adult populations, and serious infections resulting in hospitalization or opportunistic infections. Exclusion criteria: language other than English or French and articles on HIV/AIDS. The quality of the articles was assessed using a validated tool (Benchimol et al. 2010).

Results: 106 articles were identified after exclusion of duplicates and 52 were excluded by title or abstract, 54 articles were included for detailed review and only 2 met our criteria for entry. A hand search identified a further 6 articles for a total of 8 studies suitable for inclusion: the majority (7/8) examined bacterial infections and 2 examined opportunistic infections. The majority of the studies were from the United States (6/8) and all but one study used ICD-9 codes (1/8 used ICD-10 codes). Six of the studies were of patients who were hospitalized, one included emergency visits and one study on opportunistic infections did have some outpatient data. In 3/8 papers the population studied was that of patients with rheumatoid arthritis. Only one of the studies on opportunistic infections reported the positive-predictive values (PPV) which was 58% (0.46–0.70), and increased to 73% (0.61–0.85) if candida infections were excluded. The studies on bacterial infections in general reported a moderate to high sensitivity and PPV for the diagnosis of infections using administrative data (sensitivity range 69.8–100%, PPV range 80.0–97.2%). Only 3/8 studies compared the diagnostic accuracy of different algorithms which revealed that more comprehensive algorithms that included a wider range of ICD-9 codes had the highest sensitivity for the diagnosis of infection.

Conclusion: Validated algorithms for the identification of infections using administrative data have a moderate to high sensitivity and positive predictive value and can be applied to population studies of patients with rheumatic disease to study this important co-morbidity.

1881

Consensus Statements Concerning the Use of Administrative Data in Rheumatology Research and Surveillance. Diane Lacaille[1], Lisa Lix[2], Sasha Bernatsky[3], Siobhan O'Donnell[4], Claire Bombardier[5] and Administrative Data Rheumatology Research & Surveillance. [1]Arthritis Research Ctr; University of British Columbia, Vancouver, BC, [2]University of Saskatchewan, Saskatoon, SK, [3]McGill UHC/RVH, Montreal, QC, [4]Public Health Agency of Canada, Ottawa, ON, [5]Institute for Work & Health, Toronto, ON

Background/Purpose: Administrative health databases (for remuneration & management) exist in each province & territory in Canada. They are a great resource for rheumatic disease surveillance & research, but standards are needed to ensure comparability of findings. Our purpose was to develop consensus statements in this regard.

Methods: We convened 52 decision makers, clinicians, & researchers to a 2-day workshop. Eight months in advance, participants were organized into working groups covering 3 themes: case definitions, methods, & co-morbidity/outcomes. Each conducted systematic & scoping reviews to define themes. At the workshop, Delphi-type consensus building techniques were used to develop statements for endorsement.

Results: 13 consensus statements were endorsed. Regarding case definitions for rheumatic diseases, these should be justified based on purpose, validity assessment, & feasibility; validation studies should adhere to published guidelines on conduct & reporting; and authors should acknowledge limitations of administrative data for case ascertainment

Regarding methods, authors must address confounding by indication; use appropriate methods to address other common confounders & biases; clearly define & justify exposure risk windows: and acknowledge limitations of administrative data.

For comorbidity/outcomes, our statements note that osteoporosis diagnostic codes should not be used alone due to low sensitivity. Hospital discharge data, & physician & procedure data when available, can be used to accurately identify hip fractures. Fractures not requiring hospitalization can be identified by combining physician billing diagnoses & procedure codes. For vertebral fractures, additional research is needed.

Regarding using administrative data (exclusive of cancer registries) to define cancer outcomes, authors should use an algorithm with good sensitivity & excellent specificity in a comparable population. Implications of imperfect case definition should be discussed.

Hospitalization diagnoses can be used to ascertain serious bacterial infections. Current data is not sufficient to recommend administrative data to identify opportunistic infections.

For cardiovascular disease, hospitalization data can be used to ascertain acute myocardial infarction, but there are significant limitations for congestive heart failure.

Regarding renal disease, administrative data can be used to identify kidney disease requiring dialysis. However, current data do not support using hospitalization data for acute or chronic kidney disease as a co-morbidity or outcome.

Conclusion: Our recommendations are consistent with other recent guidelines including the ISPOR report and the EULAR Points paper to address specific needs of rheumatic disease biologics registries. Our consensus statements include other issues as well, and some Canada-specific details. Their usefulness and implications for surveillance and research extends beyond Canada's borders.

Dissemination is in progress; for background documents see our current website archive https://connect.mcgill.ca/r41824168/

1882

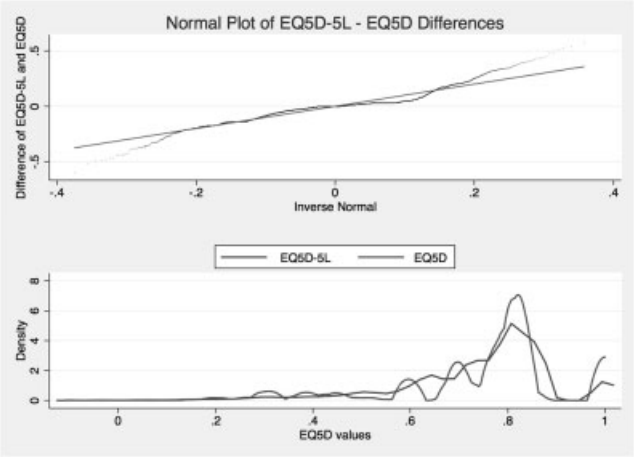
An Evaluation of the Extended Item Euroqol Compared with the Standard Euroqol. Kaleb Michaud[1] and Frederick Wolfe[2]. [1]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [2]National Data Bank for Rheumatic Diseases, Wichita, KS

Background/Purpose: The EuroQoL (EQ5D) is a widely used health-related quality of life utility scale that is frequently used in cost-effectiveness analyses. It is composed of 5 questions, 3 relating to function, 1 to pain, and 1 to mood. The EQ5D is limited because each question has only 3 levels: the worst possible condition, the best possible condition, and a single level in between. Since the worst level is rarely endorsed, each question effectively has two levels: perfectly normal or not perfectly normal. The limited range also results in a reduced sensitivity to change. The EuroQol Group recently developed a new scale (EQ5D-5L) in which each question contains 5 levels, thereby potentially increasing sensitivity and capturing a wider range of symptoms. A central question regarding the 2 scales is whether they yield similar results, and whether the new questionnaire has better performance characteristics.

Methods: We administered the EQ5D, EQ5D-5L and other rheumatic disease questions to 6,824 patients as part of a semi-annual long-term rheumatic disease outcome study.

Results: The Pearson correlation between the EQ5D questionnaires was 0.827, and Lin's concordance coefficient was 0.817. The average difference between questionnaires was 0.008, and the 95% limits of agreement was −0.206 to 0.190. The EQ5D-5L had a smoother and more continuous distribution, but questionnaires differed most at extreme values (Figure 1). The EQ5D-5L was more strongly correlated with all measures than the EQ5D (Table 1), and the EQ5D-5L provided a much better model fit as assessed by the Bayesian and Akaike Information coefficients. The EQ5D-5L/EQ5D mean (SD) values were: rheumatoid arthritis 0.751/0.761 (0.152/0.176), lupus 0.754/0.765 (0.172/0.189), fibromyalgia 0.666/0.666 (0.167/0.196) and osteoarthritis 0.745/0.751 (0.139/0.165). As suggested by Figure 1, the EQ5D has slightly higher scores compared to the EQ5D-5L in illnesses with better quality of life and equivalent scores in lower QOL disorders such as fibromyalgia.

Questionnaire	EQ5D-5L	EQ5D
EQ5D-L (0–1)	1.000	0.827
EQ5D (0–1)	0.827	1.000
Patient activity score (PAS) (0–10)	−0.781	−0.755
HAQ (0–3)	−0.709	−0.666
Global severity (0–10)	−0.673	−0.650
Pain (0–10)	−0.669	−0.665
Physical component score (SF–36)	0.665	0.629
Polysymptomatic distress scale	−0.648	−0.626
Fatigue (0–10)	−0.604	−0.576
Mood (0–10)	−0.525	−0.511
Sleep disturbance (0–10)	−0.494	−0.472
Mental component score (SF–36)	0.490	0.480
EuroQoL VAS (0–100)	0.484	0.456
Comorbidity Index (0–9)	−0.327	−0.309
Sex	0.067	0.050
Age (years)	0.061	0.039



Conclusion: The EuroQol scales provide similar mean scores and are well correlated. The EQ5D-5L provides a much better model fit, lower variance and greater correlation with clinical variables. The EQ5D-5L should be substituted for the older EQ5D version to provide a better assessment of health utility.

1883

Increased Ability to Meet Occupational, Home or Leisure Requirements in Patients Starting Biologic Agents. Anja Strangfeld[1], Diana Pantigoso[1], Peter Herzer[2], Hans Peter Tony[3], Elke Wilden[4], Joachim Listing[1] and Angela Zink[5]. [1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]University of Munich, Munich, Germany, [3]Rheumatology, University of Würzburg, Würzburg, Germany, [4]Rheumatologist, Köln, Germany, [5]Deutsches Rheumaforschungszentrum and Charité University Medicine, Berlin, Germany

Background/Purpose: During the course of disease, many patients with rheumatoid arthritis (RA) become increasingly unable to fulfill their daily life tasks. For employed patients, this is reflected in the number of days of sick leave or early retirement. For patients not employed it is less clear. Our objective was to evaluate the impact of functional disability on limitations in role fulfillment in both, employed and unemployed patients. Further we were interested in the improvement with the start of a biologic or non-biologic DMARD treatment.

Methods: Data from the German biologics register RABBIT with more than 9,550 patients included until June 2011. Enrolment in the cohort is possible with a start of a biologic treatment (BIOL) or a start with a conventional DMARD (CON) after DMARD failure. Among other information, patients assess their ability to meet usual occupational, home or leisure demands during the last four weeks. The propensity score method was used to adjust for differences in the baseline status between BIOL and CON patients. The outcome after 6 months was compared between the treatment groups within propensity score strata after adjustment for further differences in the baseline status by means of multiple logistic regression.

Results: 6,160 patients had at least 6 months of follow-up and were included in the analysis. Before enrolment more than a quarter of patients starting a biologic treatment and 17% in the control group had not been able to fulfill their daily role activities on more than 14 days within the last 4 weeks (Table).

Table. Percentage of patients not able to meet their daily demands before and after inclusion in the register/start of a new treatment (CON conventional DMARDs, RTX rituximab, ABA abatacept, TOC tocilizumab)

"On how many days during the last four weeks have you been unable to meet your usual occupational, home or leisure demands due to your rheumatoid arthritis?"	CON	Anti-TNF	RTX	ABA	TOC
> 14 days					
Before start of new treatment	17.3%	26.4%	28.1%	26.5%	33.1%
After 6 months	9.0%	11.0%	15.2%	16.5%	17.4%
7 to 14 days					
Before start of new treatment	22.9%	25.8%	27.0%	27.7%	23.1%
After 6 months	15.5%	15.5%	18.9%	20.6%	16.5%
On no day					
Before start of new treatment	29.0%	20.6%	17.2%	12.4%	18.2%
After 6 months	45.5%	42.2%	31.1%	19.4%	34.7%
Sum of patients included	1934	3224	711	170	121

All treatments increased the ability to meet occupational, home or leisure demands. Significant risk factors to remain limited in fulfilling daily activities after 6 months were higher number of days with limitations in activities, fatigue, comorbidities, and previous failure of a biologic treatment. Adjusted for these factors, the improvement was significantly higher for anti-TNF treatment compared to conventional DMARD treatment (adjusted odds ratio for >=7 days of being unable to meet requirements: 0.82 or for >=1 day: 0.75). Patients treated with other biologics who had longer disease duration and more previous treatment failures (including biologics) did not show significant differences from the patients in the control group.

Conclusion: Real-world patients who start treatment with biologic agents have significant constraints in fulfilling their daily role requirements. After six months, there is considerably less limitation, especially in those patients who receive their first biologic agent.

1884

Distribution of Tumor Necrosis Factor Inhibitor Use Across Indications in Sweden: Nationwide Register-Linkage Study. Martin Neovius[1], Jonas Eriksson[1], Julia F. Simard[1], Johan Askling[1] and ARTIS Study Group[2]. [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Stockholm, Sweden

Background/Purpose: Despite widening use of anti-TNF drugs, most long-term safety data come from patients with rheumatoid arthritis (RA). Similarly, most assessments of the societal benefits and costs of anti-TNF drugs are based on presumed distribution across indications. Few large studies have investigated the distribution of use across indications to determine which patients are actually using these drugs today. We estimated this distribution across indications using data from national registers.

Methods: All individuals in Sweden who were dispensed etanercept and adalimumab in 2009 were identified from the nationwide Prescribed Drug Register. Infliximab was excluded as it is primarily used in hospitals, not on prescription in ambulatory care, and therefore not registered on a patient level. The dataset was linked to the National Patient Register, which holds information on all inpatient and specialist outpatient visits, including associated main and subdiagnoses. On the basis of visit diagnoses in 2001–2009, patients were identified as having RA, ankylosing spondylitis (AS), psoriatic arthritis (PsA), psoriasis and/or inflammatory bowel disease (IBD).

Results: 12,142 unique patients exposed to etanercept (n=7,261) or adalimumab (n=5,402) were identified. The highest proportion of users had RA (59%), followed by PsA (17%), IBD (12%), other (10%), AS (10%), and psoriasis (7%). Rheumatic indications (RA, AS and PsA) constituted 77% of overall use. The distribution differed markedly for etanercept and adalimumab: only 2% of etanercept users had IBD compared to 24% of adalimumab users (Table).

Distribution of Etanercept and Adalimumab Use in the Swedish Population in 2009

Indication	N (%) Both (n=12,142)	Etanercept (n=7,261)	Adalimumab (n=5,402)
Rheumatology	9,375 (77%)	6,082 (84%)	3,722 (69%)
Rheumatoid Arthritis	*7,132 (59%)*	*4,763 (66%)*	*2,676 (50%)*
Ankylosing Spondylitis	*1,202 (10%)*	*625 (9%)*	*635 (12%)*
Psoriatic Arthritis	*2,039 (17%)*	*1,318 (18%)*	*852 (16%)*
Dermatology			
Psoriasis (excl PsA)	686 (7%)	473 (8%)	251 (6%)
Gastroenterology			
Inflammatory bowel disease	1,435 (12%)	179 (2%)	1,286 (24%)
Juveniles and/or Other Conditions	1,212 (10%)	819 (11%)	449 (8%)

Diagnostic categories not mutually exclusive. Therefore column percentage sums may exceed 100% due to overlap, i.e. patients having more than one diagnosis.

Conclusion: While long-term safety data are dominated by studies on patients with RA, RA accounted for only about half of anti-TNF users in Sweden in 2009. This surprisingly low proportion underscores the need for safety, cost and effectiveness studies in patients with diseases other than RA, especially as some of these patient groups display very different age-, sex-, and birth cohort-distributions, as well as dosing regimen.

Cross-Sectional Validation of the Patient Reported Outcome Measurement Information System Pediatric Scales in Juvenile Idiopathic Arthritis, Childhood Systemic Lupus Erythematosus, and Juvenile Dermatomyositis. Esi Morgan DeWitt[1], Heather Gross[2], Brian D. Stucky[3], Yang Liu[3], David Thissen[3], Daniel J. Lovell[1], Carol A. Wallace[4], James F. Fries[5], Bonnie Bruce[6], Egla C. Rabinovich[7], Laura E. Schanberg[7] and Darren Dewalt[2]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, [4]Childrens Hosp & Regional Med, Seattle, WA, [5]Stanford Univ Medical Center, Palo Alto, CA, [6]Stanford Dept of Medicine, Palo Alto, CA, [7]Duke University Medical Center, Durham, NC

Background/Purpose: The Patient Reported Outcome Measurement Information System (PROMIS) was created to develop patient-reported outcome measures using modern psychometric methods, including item response theory, to improve the assessment of self-reported health across many chronic diseases. PROMIS tools are publicly available (nihpromis.org). Our objective was to perform preliminary validation of PROMIS version 1.0 (v1.0) scales for pediatrics (8–17 years) in the more common childhood rheumatic diseases. PROMIS item banks and short forms were developed and initially validated in a sample of 4,129 children, 35% of whom had a chronic illness. This sample's overall mean HRQOL score of 74.5 on the PedsQL™ was lower than the mean of 83.8 for a healthy reference population. Pediatric PROMIS v1.0 scale scores were placed on a T-score metric such that the mean is 50, and standard deviation 10.

Methods: Participants with a physician confirmed diagnosis of juvenile idiopathic arthritis (JIA), childhood systemic lupus erythematosus (cSLE) or juvenile dermatomyositis (JDM) were recruited from rheumatology clinics. Participants were administered a combination of PROMIS short forms and/or complete item banks representing the following health domains: anger, anxiety, depressive symptoms, fatigue, pain interference, peer relationships, physical function – mobility, physical function – upper extremity. Demographics, clinical characteristics, and parental ratings of children's overall disease status and pain intensity were collected. Data were analyzed with descriptive statistics, correlations, ANOVA, and graphical display.

Results: 362 (JIA=269, SLE = 42, JDM = 23, overlap =28) participants were recruited from sites in California, North Carolina, Ohio, and Washington. Across the diagnostic categories, mean scores on parental ratings of overall well-being (0=very well, 10=very poor) were between1.28 (sd 2.43) −1.76 (sd 1.99), mean ratings of average pain over the past 7 days (0=no pain, 10=very bad pain) were between 1.04 (sd 2.12) −2.32 (sd 2.45), and the mean CHAQ score (0–3, 0=no disability) was 0.2475 (sd 0.44). Group mean scores were similar to the initial PROMIS v1.0 validation sample, or slightly better. There were no significant differences in scores across diagnostic groups, although scores of cSLE patients were numerically worse. Parental ratings had relative strong correlations with PROMIS fatigue, mobility and pain interference domains (Table). Compared to boys, girls demonstrated higher anxiety and depressive symptoms. School days missed correlated with higher fatigue and pain interference, and decreased mobility. The PROMIS mobility bank showed a modest decrease in ceiling effect compared to the CHAQ.

Table. Correlations between Child Outcomes and Parent Ratings

	Depressive Symptoms	Anxiety	Anger	Peer Relationships	Pain Interference	Fatigue	Dexterity	Mobility	CHAQ
Parent Rating of Pain	.310**	.326**	.405**	−.124	.559**	.448**	−.305**	−.463**	.325**
Parent Rating of how child is doing	.375**	.233*	.196	−.128	.519**	.435**	−.317**	−.435**	.293**

** Significant at .01, *Significant at .05; Parent Rating of Pain; 0 = No Pain; 10 = Very Bad Pain. Parent Rating of How Child is Doing: 0 = Very Well; 10 = Very Poor

Conclusion: The PROMIS v1.0 pediatric scales have undergone preliminary validation for use in JIA, cSLE and JDM and are ready for use.Longitudinal validation studies are underway.

Assesment of Disease Activity in Ankylosing Spondylitis: Comparison of Rapid3, Basdai, Basfi, and Asdas Scores in Routine Care. Muhammet Cinar[1], Sedat Yilmaz[1], Suleyman Serdar Koca[2], Hakan Erdem[1], Salih Pay[1], Yusuf Yazici[3] and Ismail Simsek[1]. [1]Division of Rheumatology, Gulhane School of Medicine, Ankara, Turkey, [2]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [3]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Quantitative assessment of disease outcome in ankylosing spondylitis (AS), as in all other rheumatological conditions, has been a major concern in rheumatology practice. There have been different methods validated and used for monitoring AS patients including, Bath ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI), and recently developed AS disease activity score (ASDAS). It is difficult to distribute multiple questionnaires to different patients in a reception area. A single questionnaire for all patients with rheumatic diseases may present advantages to introduce quantitative measurement into routine care. To this end, routine assessment of patient index data 3 (RAPID3) can be considered as a candidate index, which has been widely used and validated for RA and based on 3 multi-dimensional health assessment questionnaire (MDHAQ) components, patient function, pain and patient global assessment, each scored 0–10 for a total of 0–30. This study was conducted to compare the performance of RAPID3 in comparison with other validated measures in assessing patients with AS.

Methods: Patients seen consecutively at the rheumatology division of Gulhane School of Medicine, between May 1 and June 25, 2011 completed 3 questionnaires (BASDAI, BASFI, and MDHAQ) at each visit, and their physicians completed physician global assessments on VAS. CRPs were tested on the same date and used to calculate ASDAS-crp scores. Descriptive statistics and Pearson correlation coefficients were calculated for each measure.

Results: Fifty-one patients [88% male, mean (SD), age: 25.5 (8.4) years, disease duration: 2.8 (4.4) years] completed all assessments. Mean scores for BASDAI, BASFI, ASDAS-crp, and RAPID3 were 5.5 (2.1), 4.1 (2.4), 2.6 (0.9), and 14.5 (5.7) respectively. RAPID3 was strongly correlated with BASDAI, BASFI, and ASDAS-crp (r:0.84, r:072, and r:0.86, $p<0.001$ for each).

Conclusion: We found that RAPID3 on an MDHAQ, which had been in use for almost a decade in patients with rheumatoid arthritis, has a strong, positive correlation with the ASDAS-crp, a new composite index to assess disease activity in AS patients. Our results also confirmed the findings of a previous study (1) as showing very good correlation of RAPID3 with the outcome measures of BASDAI and BASFI in AS patients. An outcome measure that can be used in different patient populations may have the additional advantage of being easier to implement in a routine care setting.

Prevention of Latent Tuberculosis and Toxicity of Isoniazid in Patients Treated by Anti-Tumor Necrosis Factor Alpha in the Czech National Register. Katarina Hviscova[1], Liliana Sedova[1] and Karel Pavelka[2]. [1]Charles University, Prague, Czech Republic, [2]Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic

Background/Purpose: Anti-TNFα treatment has revolutionized the practice of rheumatologists all over the world, however has also raised new problems, particularly the increased risk of reactivation of latent tuberculosis (LTBI). This led to a need to screen for active and latent tuberculosis (TB) in patients before biological therapy is started. The Czech Rheumatology Society recommends performing PPD test, Quantiferon-TB Gold test and chest X-rays before the initiation of the treatment. Equally it is important to take detailed medical history focused on TB history, contact with active TB

and searching for symptoms that might point to TB infection (chronic cough, night sweats). If any of these results are abnormal before initiation or during the therapy, it is necessary to consult the pneumologist.

The Czech National Register of biological treatment in rheumatology (ATTRA) allows evaluating various parameters in patients with different diagnosis and during treatment by different drugs. In this retrospective study we have evaluated the toxicity of isoniazid (INH) in patients treated for LTBI before starting or during biological therapy.

Methods: In years 2001–2011 overall 1056 patients from Institute of Rheumatology in Prague were included in Czech National Registry of biological treatment in rheumatology ATTRA (656 RA patients, 335 AS and 65 PsA patients). In this group we have found 76 patients treated with INH and 8 of them were treated twice in this period. The aim of the study was to evaluate toxicity of INH in these cases, to evaluate the potential relationship with co-medication and to evaluate potential differences between the diagnoses.

Results: Out of 76 patients treated with INH, 44 were male and 32 female; 35 patients had AS, 26 had RA, 10 had PsA and 5 patients had undifferentiated spondylitis. Mean age in this group was 44 years (SD ± 13.3), median 40.5. More than 50% of patients had a long standing disease (duration for more than 10 years). In 34 cases the diagnosis of LTBI was made before the initiation of biological treatment and 47 cases of LTBI we have diagnosed during the biological treatment. Out of these 47 cases 3 patients have developed active TB and out of these 3 active TB cases 1 had developed TB though the patient was treated with INH before starting the biological treatment.

In a group treated with INH during biological therapy (47 cases) the mean time of treatment with biologics was 24.4 months (± 19.7), median of 16 months; most of the patients were treated with adalimumab (44 %) and infliximab (42%), only 12% with etanercept and 2% with abatacept. We had to withdraw INH in 7 cases; due to hepatotoxicity (n=4), due to allergy (n=2), due to optic neuritis (n=1).

Conclusion: In our group of 76 patients treated with INH we found increase of liver enzymes in 26. The most frequent situation was elevation of liver enzymes from 2 to 3 times more than normal range. In 8 cases we had to reduce the dose of INH or co-medication or we prescribed the hepatoprotective medication. Only in 4 cases we had to withdraw INH due to hepatotoxicity characterized by elevation more than 3 times. According to our results the risk of serious hepatotoxicity is only slightly increased.

Internet-Based Patient Registry and Biospecimen Collection: One Year Experience of the Arthritis Internet Registry. Kaleb Michaud[1], Kimberly Harp[1], Rebecca Schumacher[1], Stanley J. Naides[2], William F. Patten[2], Beth Axtell[3] and Robert M. Plenge[4]. [1]National Data Bank for Rheumatic Diseases, Wichita, KS, [2]Quest Diagnostics Nichols Inst, San Juan Capistrano, CA, [3]Arthritis Foundation, Atlanta, GA, [4]Brigham and Women's Hospital, Boston, MA

Background/Purpose: Observational cohorts that follow rheumatic disease patients longitudinally and obtain biospecimens can be extremely expensive and laborious to initiate. We sought to determine the feasibility of creating the Arthritis Internet Registry (AIR), an online-based cohort by combining the patient-study infrastructure of the National Data Bank for Rheumatic Diseases, the nation-wide availability of Quest Diagnostics Incorporated (QD) blood collection sites, and the patient outreach of the Arthritis Foundation.

Methods: Starting in July 2010, a website for AIR enrollment was created (http://www.arthritis-research.org/) and online advertising began on the Arthritis Foundation website asking visitors with arthritis to participate. After an initial consent, participants completed a questionnaire about their diagnoses and medical history to become enrolled. We obtained consent to contact their physicians about their diagnoses. Once the diagnoses were confirmed, we then requested consent to collect blood samples and mailed anonymous collection kits that they took to a nearby QD site for their blood draw. Samples were collected and analyzed by QD and stored at QD and academic sites.

Results: By June 2011, the AIR enrollment site had 3,331 unique visitors of which 923 patients from all 50 US states enrolled with 67% reporting rheumatoid arthritis (RA), 21% osteoarthritis (OA) and 12% were other rheumatic diseases (4% psoriatic arthritis, 2% lupus, 2% fibromyalgia, etc). After physician contact about diagnosis for 282 patients, 97.4% of participants reporting RA were confirmed and 1.8% had other inflammatory rheumatic diseases. There was no statistical association between RA screening questions and physician-confirmed diagnosis. Participants were primarily female (89%), younger (52 years), Caucasian (90%), married (66%), college educated (86%) and developed their condition almost 14 years prior. Overall pain, fatigue and clinical measures were moderate to high as shown in the Table. Blood specimens were collected for 163 patients, 125 were RA patients of which 51% were CCP+ and 50% RF+; of the 38 non-RA patients 5% were CCP+ and 8% RF+.

Table. Mean (SD) characteristics of 923 AIR participants at enrollment by diagnosis

	ALL (N=923)	RA (N=617)	OA (N=193)	Other (N=113)
Age (years)	51.7 (13.4)	50.1 (13.5)	57.5 (12.5)	50.3 (12.1)
Sex (% male)	10.6	9.2	11.9	15.9
Non–Hispanic White (%)	89.6	89.8	85.5	95.6
Education (years)	14.8 (2.4)	14.8 (2.3)	14.6 (2.9)	15.1 (1.8)
Married (%)	65.5	66.6	60.1	69.0
Smoker ever (%)	42.0	40.2	45.6	46.0
Disease duration (years)	13.7 (12.6)	13.5 (12.8)	14.5 (12.4)	13.2 (11.9)
HAQ–II (0–3)	1.01 (0.62)	0.99 (0.63)	1.07 (0.59)	1.07 (0.58)
Pain (0–10)	5.2 (3.0)	4.9 (3.0)	5.8 (2.8)	5.4 (2.8)
Patient global severity (0–10)	4.3 (2.6)	4.2 (2.6)	4.8 (2.7)	4.4 (2.5)
Patient activity score–II (0–10)	4.3 (2.3)	4.1 (2.3)	4.7 (2.2)	4.4 (2.1)
Fatigue (0–10)	5.8 (3.1)	5.8 (3.1)	5.6 (3.1)	6.4 (2.9)
GI severity (0–10)	2.9 (3.0)	2.9 (3.0)	2.7 (3.0)	3.4 (3.1)
Sleep disturbance (0–10)	5.2 (3.3)	5.2 (3.4)	5.3 (3.3)	5.4 (3.2)

Conclusion: Through the close cooperation of for-profit and non-profit organizations, AIR has proven that a large study of rheumatic disease patients with biospecimens can be created and conducted online. Continued recruitment, partnerships and patient-followup will be needed to determine the long-term research applications.

1889

Improving Clinical Trial Recruitment in a Real World Practice. Results From the Canadian Early Arthritis Cohort. Pooneh S.Akhavan[1], Vivian Bykerk[2], Ye Sun[3], Boulos Haraoui[4], J. Carter Thorne[5], Janet E. Pope[6], Carol A. Hitchon[7], Diane S. Ferland[8], Gilles Boire[9], Edward C. Keystone[10] and CATCH Investigators[11]. [1]University of Toronto, Toronto, ON, [2]Brigham & Women's Hospital, Boston, MA, [3]Mount Sinai Hospital, Toronto, ON, [4]Institut de Rhumatologie, Montreal, QC, [5]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [6]St. Joseph's Health Care, University of Western Ontario, London, ON, [7]University of Manitoba, Winnipeg, MB, [8]LaSalle, QC, [9]CHUS - Sherbrooke University, Sherbrooke, QC, [10]Rebecca MacDonald Centre for Arthritis and Autoimmune Disease, Mount Sinai Hospital, Toronto, ON, [11]Toronto, ON

Background/Purpose: Current clinical trials are not representative of characteristics of patients in clinical practice. A minority of patients in clinical practice meet current entry criteria for most trials. The objective was to evaluate whether using more liberal clinical trial entry criteria in a real world clinical setting will generate clinical outcomes comparable to the use of 'standard' entry criteria and will improve clinical trial recruitment.

Methods: Patients with early RA enrolled in the Canadian early Arthritis Cohort (CATCH), were evaluated. Patients were included in present study if: Age ≥ 18, met ACR 1987 criteria, initiating MTX at baseline, had ≥ 6-month follow up, did not receive biologics and had available ACR responses. Disease activity was assessed at baseline and 24 weeks.

Two "standard" enrolment criteria were defined: 1) ≥ 6 TJC68 and ≥ 6 SJC66 with either an ESR >28 or CRP >1.5 mg/dl, 2) ≥ 6 TJC28 and ≥ 6 SJC28 with either an ESR >28 or CRP >1.5 mg/dl. Five "liberal" criteria were defined as: 1) SDAI >11, 2) DAS28 >3.2, 3) ≥ 6 TJC28 and ≥ 6 SJC28 + elevated ESR or CRP (ESR >20 or CRP>1), 4)≥ 4 TJC28 and ≥ 4 SJC28 + ESR >28 or CRP >1.5 mg/dl, 5)≥ 4 TJC28 and ≥ 4 SJC28 + elevated ESR or CRP(ESR >20 or CRP>1). Proportion of patients eligible for enrolment based on each criteria were compared, their baseline characteristics, ACR and EULAR responses were compared.

Results: 312 patients were eligible for analysis. Percentages of patients who met each inclusion criteria are demonstrated in table 1. Patients in the first two liberal groups had the lowest proportion of elevated ESR/CRP(41% and 42% compared to >70% in other groups). ACR50 response rate was 56–57% in standard groups and 53–55% in liberal groups (except group 3). EULAR response rate was comparable among various groups.

Table 1. Comparison of percentage of patients who met each enrolment criteria (n=312)

	Standard 1	Standard 2	Liberal 1	Liberal 2	Liberal 3	Liberal 4	Liberal 5
Met enrolment criteria (%)	33%	28%	90%	88%	32%	33%	40%

Conclusion: Liberal trial entry criteria may improve recruitment from real world practice settings. Patients with a reduced joint count at entry (4 versus 6) and a greater than normal acute phase reactant were more likely to achieve the entry criteria with a significant proportion of patients having an elevated CRP. Entry criteria with 4 TJC28 and SJC28 with greater than normal acute phase reactant should be considered for future trials.

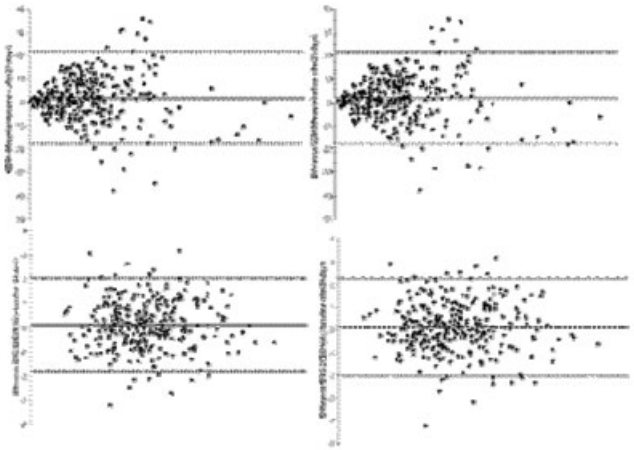
1890

Reproducibility of Composite Scores: Disease Activity 28-Joints Score, Simplified Disease Activity Score and Clinical Disease Activity Score In the Evaluation of Rheumatoid Arthritis(Ra) Disease Activity: Pursuit for A Gold Standard. Lissiane K. N. Guedes[1], Ana C. M. Ribeiro[2], Julio C. B. Moraes[2], Carla G.S. Saad[3], Nadia E. Aikawa[3], Eduardo F. Borba Neto[4], Sandra Pasotto[2], Jozelio F. Carvalho[3], Eloisa Bonfa[2] and Ieda Laurindo[5]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [4]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [5]Universidade de São Paulo, Sao Paulo, Brazil

Background/Purpose: to evaluate the reproducibility of the different composite indexes of evaluation of disease activity: DAS28 with 3 or 4 variables, SDAI and CDAI in an extreme clinical set-up designed to test the reproducibility of these tools.

Methods: 10 different physicians assessed classical parameters of disease activity in 340 adult patients with RA at baseline and after 21 days. The physicians were not uniformly familiar with the instruments; five applied these tools on regular basis and five, although experienced rheumatologists, were less familiar with these instruments. Patients were randomly allocated to each physician at baseline and after 21 days in such a way that less than 5% of the patients were assessed by the same physician at the two visits. No physician had acccess to the first evaluation. Acute-phase reactants were collected at baseline and after 21 days. All patients answered a YES/NO question regarding changes in the disease activity comparing their clinical status at baseline and after the 21 days. An affirmative answer or therapeutic changes, presence of infections, parenteral infusions or therapeutic intra-articular injection or arthrocenthesis during the 21 days of the study implied exclusion from the study.

Results: Data from 319 patients were analysed (failure to attend the second visit or incomplete laboratory data). The intraclass correlations between the different indexes were DAS28(4V)=0.681 (IC95% 0.615–0.737); DAS28(3V)=0.668 (IC95% 0.600–0.726); SDAI=0.601 (IC95% 0.524–0.668); CDAI(4V)=0.587 (IC95% 0.509–0.656) showing a similar intraclass reproducibility for all indexes with correlation coefficients between 0.5 and 0.7. Remarkably patient dependent outcomes (PGHA, pain and tender joints) did not change. After 21 days a statistically significant reduction in DAS28 was observed 3.68 (1.37) vs. 3.51(1.39, p=0.01)) but the difference 0.17 was well below clinical meaningful values. Interestingly the difference was only in the physician-dependent outcomes: number of swollen joints and global health assessment (IGHA); ESR/CRP values did not change. DAS 28 showed a slightly better performance also suggested by Bland-Altman graphics.



Conclusion: Reproducibility of the different composite scores was adequate, despite the most unfavorable artificial set-up of this study. DAS28 seems to perform slightly better.

1891

Doctor-Patient Involvement in Biologic Treatment Choice:the Benefits of a Collaborative Approach. Chris Martin and Katrina Johnson. The Research Partnership, London, United Kingdom

Background/Purpose: We recently conducted a market research study with rheumatoid arthritis (RA) patients (LWRA). Aim: to understand the link between RA patients' feelings and their history of biologic treatment.

We also collect patient chart data from a panel of rheumatologists (TKRA); using this dataset we investigated the demographic make-up of patients who are more likely to be pro-active about their RA treatment.

Methods: For LWRA, data were collected from 2,240 RA patients via online questionnaire, in March-June 2011, including disease history and experience of treatment. Of these, 739 were on biologic and were included here. Patients were asked who decided their biologic and were grouped: decided solely themselves (n=124); decided jointly with doctor (n=522); doctor decided entirely for them (n=93). Five key metrics were isolated, involving feelings about medication, relationship with doctor, dose-skipping (compliance), self-injection, and impact of disease.

For TKRA, we examined a subset featuring 5,829 RA patients reported from March-May 2011, and divided them into those who had made a request about biologic treatment vs. had not. This served as a proxy for the question about treatment decision-making.

Results: Patients who made a "**joint decision**" with the doctor about their biologic treatment felt more positive about medication, and had a stronger relationship with their doctor. When asked to agree with "My medication is making a positive difference to my life" on a 0–10 scale, co-deciders' mean was 7.8 vs. 6.9 for patients without joint ownership (i.e. either sole- or non-deciding), and for "My doctor gives me the help and support I need" co-deciders' mean was 8.2 vs. 7.4 for non-co-deciders. [All comparisons sig. at 95%+]

Patients who had **"no ownership"** over their treatment decision (i.e. doctor controlled decision) were less convinced about medication's effect on their lives, e.g. scoring 6.0 for "My medication helps me to live my life the way I want to" vs. 7.3 for patients with some ownership. This group also agreed less with the statement "my doctor provides support."

Patients with **"total ownership"** of the treatment decision disliked taking their medication more, e.g. scoring 5.7 for "I am unsure whether I want to be taking medication" vs. 3.6 for patients whose doctor had some influence, and were more likely to have skipped doses (76% vs. 47% for other patients). They skipped doses due to the belief their disease status had changed (self-diagnosis), 83% vs. 29% for doctor-influenced patients.

TKRA revealed that patients who make requests about their treatment are more severe: they have a higher DAS score (3.4 vs. 3.0) and more joints affected by RA (9.7 vs. 7.7), are further from diagnosis (9 years vs. 7.7 years) and received more DMARDs before starting biologic (2.9 vs. 2.5).

Conclusion: RA patients who felt their treatment decision was a result of "joint decision-making" between themselves and their doctor felt more positively about their RA disease and the impact the treatment was having on their lives. They were also less likely to skip doses.

In conclusion, a collaborative approach where both the doctor and RA patient make the decision, results in a more positive outcome for the patient.

1892

Older Age, Male Gender, Current Smoking and Worse Disease Activity Are Predictors of Respiratory Disease Mortality in Patients with Inflammatory Polyarthritis: Results From the Norfolk Arthritis Register. Suzanne MM Verstappen[1], Mark Lunt[1], Diane K. Bunn[2], Tarnya Marshall[3] and Deborah PM Symmons[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [2]Norfolk Arthritis Register, School of Medicine Health Policy and Practice Faculty of Health UEA, Norwich, United Kingdom, [3]Norfolk and Norwich University Hospitals Trust, Norwich, UK, Norwich, United Kingdom, Norwich, United Kingdom

Background/Purpose: Respiratory disease is one of the major causes of excess death in patients with rheumatoid arthritis (RA).Little is known about predictors of death due to respiratory disease in patients with RA. The aim of this study was to identify demographic and clinical predictors of mortality due

to respiratory disease in patients with inflammatory polyarthritis (IP) followed since 1990–1994.

Methods: Consecutive patients with early IP (≥ 2 swollen joints for ≥ 4 weeks) from a primary-care based inception cohort (NOAR), recruited between 1990–1994, were included in this study. Patients were assessed regularly since inclusion by a research nurse and flagged with the national UK death register during follow-up. All patients were followed until 31/12/2010 or death, whichever came first. Deaths with an underlying cause from ICD-10 Chapter J or lung ICD-10=C34.9 (lung carcinoma) were defined as being due to respiratory disease. Baseline clinical assessments included the DAS28 and the HAQ-score; blood was collected to determine C-reactive protein (CRP), rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA) and shared epitope (SE). The association of baseline disease and demographic characteristics, including smoking status, and death due to respiratory disease was assessed using Cox proportional hazards regression models (HR, 95% CI).

Results: 1,091 patients with IP were followed for 17194 person-years, during which a total of 69 patients died from respiratory disease (incidence rate: 4.0 per 1000 person-years, 95%CI 3.17 to 5.08). Twenty patients died with lung carcinoma as underlying cause (incidence rate: 1.16 per 1000 person-years, 95%CI 0.75 to 1.80) and 21 with chronic obstructive pulmonary disease as underlying cause (incidence rate: 1.22 per 1000 person-years, 95%CI 0.80 to 1.87). Older age, male gender and current smoking compared to never smoked were significant baseline demographic predictors of respiratory disease mortality (see Table). Satisfying the ACR criteria for RA, RF positivity, worse functional disability and high DAS28-score were baseline clinical predictors of respiratory disease mortality. There was no link between SE and respiratory disease mortality. In the multivariate regression model, age at onset and male gender were independent predictors of respiratory mortality.

Table. Predictors of mortality due to respiratory disease

	N patients with available baseline data	Univariate regression analysis HR (95%CI)	Multivariate regression analysis HR (95%CI)
Age at symptom onset	1091	1.12 (1.10 to 1.15)	1.13 (1.10 to 1.17)
Gender, *female (n)*	712/1091	0.56 (0.35 to 0.90)	0.52 (0.28 to 0.95)
HAQ-score	1079	2.02 (1.49 to 2.74)	1.48 (0.92 to 2.41)
DAS28	871	1.40 (1.15 to 1.70)	1.06 (0.82 to 1.39)
ACPA, *positive (n)*	183/810	1.66 (0.89 to 3.11)	
RF, *positive (n)*	267/952	1.98 (1.18 to 3.33)	1.74 (0.95 to 3.18)
RA, *1987 criteria (n)*	497/1091	2.30 (1.41 to 3.76)	1.48 (0.72 to 3.03)
Shared-epitope:	904		
No alleles		Ref	
One allele		1.52 (0.86 to 2.68)	
Two alleles		1.57 (0.73 to 3.37)	
Smoking status:	1090		
Never smoked		Ref	Ref
Ex-smoker		1.52 (0.81 to 2.84)	0.85 (0.41 to 1.78)
Current smoker		2.18 (1.16 to 4.12)	1.95 (0.88 to 4.29)

Conclusion: Both demographic, including current smoking but not smoking in the past, and baseline clinical variables assessed early in the disease of patients with IP are predictors of respiratory disease mortality.

1893

The Association Between Clinical and Lifestyle Factors and the Development of Inflammatory Polyarthritis and Rheumatoid Arthritis. *Results From the European Prospective Investigation of Cancer (Norfolk) Study and the Norfolk Arthritis Register.* Manjari Lahiri[1], Catharine Morgan[1], Robert N. Luben[2], Diane K. Bunn[3], Mark Lunt[1], Nick Warehan[2], Suzanne M.M. Verstappen[1], Deborah P. M. Symmons[1], Kay-Tee Khaw[2] and Ian N. Bruce[4]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [3]University of East Anglia, Norwich, United Kingdom, [4]A, Manchester, United Kingdom

Background/Purpose: Lifestyle factors implicated in the aetiology of inflammatory polyarthritis (IP) and rheumatoid arthritis (RA) are potentially modifiable. We investigated the association of smoking and other clinical and lifestyle factors with the risk of developing IP and RA.

Methods: A prospective population-based study, the European Prospective Investigation of Cancer in Norfolk, UK (EPIC-Norfolk), recruited participants from 1994–1997. All participants provided baseline data on smoking, alcohol intake, occupational class, body mass index (BMI), diabetes mellitus (DM), and (for women) parity and duration of breastfeeding. Individuals who subsequently developed IP were identified by linkage with the Norfolk Arthritis Register (NOAR), a primary-care based disease register with an overlapping catchment area. The primary outcome was development of IP. Secondary outcomes were development of RA (1987 ACR criteria) and seropositive IP (Anti-Citrullinated Peptide Antibody [ACPA] and/or Rheumatoid Factor [RF] positive). Using Cox proportional hazards with the robust option we performed a multivariable analysis adjusted for age, gender and all other variables in the model (Table). Interaction terms were tested, and were significant only between gender and pack-years of smoking.

Results are expressed as Hazard Ratios (HR) and 95% confidence intervals.

Results: 25,455 EPIC participants aged 40–79 years were followed for a median (IQR) of 14.2 (12.9, 15.3) years (342,916 person-years of follow-up). 184 developed incident IP, of whom 138 cumulatively fulfilled 1987 ACR criteria for RA. The median (IQR) time to onset of IP was 62.7 (27.8, 104) months. The median (IQR) age of IP onset was 65.2 (57.6, 73.2) years and 69.6% were women. 107/ 177 (60.5%) were seropositive. Pack-years of smoking was associated with an increased risk of IP and RA in men but not in women, and an increased risk of seropositive IP in both genders. Self-reported DM was associated with an increased risk of IP, RA and seropositive IP in the whole cohort, while alcohol intake and higher social class (categorised as professional, non-manual/ non-professional and manual) were inversely related to risk. BMI (categorised as normal or underweight, BMI < 25; overweight, BMI 25 to <30 and obese, BMI ≥ 30) was a predictor of IP, RA and seronegative IP, but not seropositive IP. In women, higher parity (categorised as 0, 1 or ≥2 children) was a risk factor, and a longer duration of breast-feeding was protective. (Table).

Table. Demographic and Lifestyle Risk factors for Inflammatory Polyarthritis (IP), Rheumatoid Arthritis (RA) and Seropositive IP

	IP (n = 184)	RA (n = 138)	Seropositive IP (n = 107)
Risk Factor	**Fully adjusted Hazard Ratio (HR) (95% CI)**	**Fully adjusted HR (95% CI)**	**Fully adjusted HR (95% CI)**
Smoking (Every 10 pack-years)	1.21 (1.08, 1.37)[+]	1.26 (1.10, 1.44)[+]	1.24 (1.10, 1.41)
Alcohol (Every 7 units/week)	0.86 (0.74, 0.99)	0.86 (0.72, 1.04)	0.86 (0.73, 1.01)
Body Mass Index			
Underweight/normal, BMI <25	1 (ref)	1 (ref)	1 (ref)
Overweight, BMI 25 to <30	1.08 (0.76, 1.54)	1.16 (0.78, 1.74)	0.73 (0.48, 1.13)
Obese, BMI ≥ 30	1.45 (0.95, 2.21)	1.49 (0.91, 2.42)	1.05 (0.61, 1.79)
Social class			
Manual	1 (ref)	1 (ref)	1 (ref)
Non−manual, non−professional	0.71 (0.53, 0.95)	0.65 (0.45, 0.93)	0.61 (0.41, 0.92)
Professional	0.36 (0.15, 0.89)	0.37 (0.14, 1.03)	0.24 (0.06, 0.97)
Diabetes mellitus	2.54 (1.26, 5.090)	2.16 (0.92, 5.07)	1.99 (0.69, 5.74)
Parity*			
0	1 (ref)	1 (ref)	1 (ref)
1	1.34 (0.54, 3.32)	1.10 (0.40, 3.01)	1.50 (0.49, 4.56)
≥2	2.81 (1.37, 5.76)	2.55 (1.19, 5.48)	2.43 (0.99, 6.00)
Breastfeeding (every 52 weeks)*	0.66 (0.46, 0.94)	0.71 (0.49, 1.03)	0.66 (0.41, 1.05)

[+] Men only. HR for women for every 10 pack-years of smoking = 1.00 (0.82, 1.21) for IP and 0.93 (0.74, 1.17) for RA
* Women only

Conclusion: We have identified several simply ascertained clinical and lifestyle factors which are potentially amenable to modification at a population level to reduce future risk of IP.

1894

Low Levels of Formal Education Generally Are As Significant As High Age and Long Duration of Disease to Identify Poor Clinical Status in Patients with Most Rheumatic Diseases. Isabel Castrejón[1], Yusuf Yazici[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: To analyze whether formal education level is associated with clinical status in patients with different rheumatic diseases, and to compare possible associations of low formal education level with high age and long duration of disease to identify poor clinical status, in patients seen in usual clinical care.

Methods: A database has been maintained on all patients seen at an academic rheumatology clinical setting since 2005, which includes demographic, patient self-report questionnaire, medication and laboratory data. All new patients seen between July 2005 and April 2011 were studied: 221 with rheumatoid arthritis (RA), 166 with systemic lupus erythematosus (SLE), 238 with osteoarthritis (OA) and 958 with other rheumatic diagnoses. Each patient in this setting (with any diagnosis) completes a 2-sided, 1-page MDHAQ (multidimensional health assessment questionnaire) at every visit while waiting to see the physician in the infrastructure of clinical care. The MDHAQ includes scales for physical function, pain, patient global estimate

(PATGL), fatigue, and a self-report RADAI painful joint count. RAPID3 (routine assessment of patient index data) is an index of physical function+pain+PATGL, each scored 0–10 (total 0–30). Patients were classified into 4 groups according to years of formal education: ≤12, 13–15, 16 and >17. Differences in self-report MDHAQ scores, RAPID3 scores, and ESR (erythrocyte sedimentation rate) were analyzed. Significance of formal education level to identify clinical status was compared to age and duration of disease in multiple linear regressions.

Results: Median age for all patients was 49 years (median age by diagnosis ranged from 39 years in SLE to 62 years in OA); 72% were female and 56% Caucasian. The median formal education level was 16 years. RA patients had higher scores (poorer status) for physical function, pain, PATGL, RAPID3 and RADAI joint count, compared to patients with other diagnoses. Patients with all diseases who had 12 years or fewer of formal education had significantly higher scores for physical function, pain, PATGL, RAPID3, RADAI, fatigue, and ESR. In most regressions, years of formal education explained variation in physical function, pain, PATGL, RAPID3, RADAI and fatigue scores, at higher levels of statistical significance (greater beta coefficients and lower *p* values) than age or duration of disease. Sub-analyses were similar in patients with RA, SLE, OA, and other diagnoses.

Median values of demographics, MDHAQ scores and ESR according to 4 groups classified by years of formal education.

		YEARS OF FORMAL EDUCATION				
	All patients (n=1,583)	≤12 (n=326)	13−15 (n=310)	16 (n=329)	>17 (n=618)	P*
Age (yr)	49	53.6	50.8	43.3	48	0.0001
Disease duration (yr)	1.15	1.14	1.50	0.88	1.17	0.31
Physical function	1.3	2	1.7	1	1	0.0001
Pain	5	6	5.5	3.5	3	0.0001
PATGL	5	5	5	4	4	0.0001
RAPID3	10.7	14	11.7	10	9.3	0.0001
RADAI (0−48)	6	9	7	5	4	0.0001
Fatigue	4	5.5	5	3.5	3	0.0001
ESR	14	18.5	14	13	12	0.01

* Overall statistical significance according to Kruskall−Wallis.

Conclusion: Formal education level is as significant as age and duration of disease to explain variation in clinical status measures, and should be included in all clinical trials and clinical care databases.

1895

Higher Fruit and Fructose Consumption Is Associated with a Reduced Risk of Inflammatory Polyarthritis and Rheumatoid Arthritis in Men. *Results From the European Prospective Investigation of Cancer (Norfolk) and the Norfolk Arthritis Register.* Manjari Lahiri[1], Catharine Morgan[1], Robert N. Luben[2], Marleen Lentjes[3], Diane K. Bunn[4], Mark Lunt[1], Nick Wareham[2], Suzanne M.M. Verstappen[1], Deborah P. M. Symmons[1], Kay-Tee Khaw[2] and Ian N. Bruce[5]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester, United Kingdom, [2]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [3]Cambridge, United Kingdom, [4]University of East Anglia, Norwich, United Kingdom, [5]A, Manchester, United Kingdom

Background/Purpose: We have previously shown that higher vitamin C and fruit intake is associated with lower risk of inflammatory polyarthritis (IP) (*Pattison et al. Ann Rheum Dis 2004;63:843–7*). However, it has been suggested that the effects of fruit may be more due to fructose-mediated effects on the uric acid – allantoin antioxidant system rather than vitamin C. We examined the association between dietary fructose, fruit and vitamin C consumption and the risk of developing IP/ rheumatoid arthritis (RA).

Methods: Dietary data were obtained from a prospective population-based study, the European Prospective Investigation of Cancer in Norfolk, UK (EPIC-Norfolk) which recruited adults aged 40–79 from 1994 – 1997. Individuals who subsequently developed IP were identified by linkage with the Norfolk Arthritis Register (NOAR), a primary-care based disease register with an overlapping catchment area. Dietary intake was assessed at baseline using 7-day diet diaries and coded by computer-software (DINER) for all IP cases and a random sample of 4000 EPIC participants and analysed as a case-cohort study. The primary outcome was development of IP. Secondary outcomes were development of RA (1987 ACR criteria) and seropositive IP (Anti-Citrullinated Peptide Antibody [ACPA] and/ or Rheumatoid Factor [RF] positive). Using Cox proportional hazards with the robust option, analyses were stratified for gender and adjusted for age, total energy intake and smoking.

Results: 25,639 EPIC participants of median (IQR) age 58.9 (50.8, 66.9) years were followed. During 342,916 person-years of follow-up, 184 developed incident IP of whom 168 had dietary diaries available. Of the random sample of 4000 (including 34 cases), diaries were available for 3961 without prevalent IP. A total of 4095 participants (168 cases, 3927 unaffected cohort) were analysed for this study. The median (IQR) age of IP onset was 65.7 (57.8, 73.4) years and 67.2% were women. 127 (75.6%) cumulatively fulfilled 1987 ACR criteria for RA, and 98/161 (60.9%) were seropositive. Men, but not women, in the top tertile of fruit and total fructose consumption were at lower risk of IP, RA and seropositive IP than those in the bottom tertile (Table). Vitamin C intake showed a weaker inverse association. Fruit remained a significant predictor of IP and seropositive IP when adjusted for vitamin C, but not when adjusted for fructose intake. It remained a predictor of RA when adjusted for either vitamin C or fructose.

Table 1. Association between Fruit intake, Dietary Fructose, Vitamin C and Inflammatory Polyarthritis, Rheumatoid Arthritis and Seropositive IP.

	Males (n = 1784) Fully adjusted* Hazard Ratio (HR) (95% CI)				Females (n = 2311) Fully adjusted* HR (95% CI)			
Food/Nutrient Group	Median (IQR) intake, top vs. bottom tertile, gm	IP (n=55/1729)	RA (n=36/1729)	Seropositive IP (n=33/1751)	Median (IQR) intake, top vs. bottom tertile, gm	IP (n=113/2198)	RA (n=91/2198)	Seropositive IP (n=65/2246)
Fruit consumption (top vs. bottom tertile)	266.3 (233.0, 343.1) vs. 34.2 (0, 61.6)	0.25 (0.10, 0.66)	0.07 (0.01, 0.54)	0.26 (0.08, 0.89)	275.4 (227.0, 345.8) vs. 42.9 (14.3, 66.6)	0.87 (0.53, 1.43)	1.03 (0.62, 1.70)	0.96 (0.54, 1.73)
Fruit servings (per serving)	–	0.64 (0.50, 0.81)	0.54 (0.39, 0.74)	0.65 (0.49, 0.86)	–	0.95 (0.85, 1.06)	0.96 (0.85, 1.08)	0.94 (0.81, 1.08)
Fructose (top vs. bottom tertile)	27.0 (23.6, 31.9) vs. 8.4 (6.2, 10.8)	0.31 (0.14, 0.68)	0.39 (0.16, 0.94)	0.44 (0.17, 1.13)	26.2 (23.2, 31.2) vs. 9.8 (7.1, 11.7)	0.65 (0.39, 1.09)	0.62 (0.35, 1.11)	0.63 (0.32, 1.27)
Vitamin C (top vs. bottom tertile)	131.0 (110.0, 162.0) vs. 44.0 (35.3, 50.9)	0.50 (0.25, 1.03)	0.33 (0.12, 0.89)	0.75 (0.30, 1.88)	130.2 (111.8, 160.7) vs. (34.3, 51.6)	0.68 (0.36, 1.31)	0.70 (0.34, 1.44)	0.70 (0.38, 1.32)

IP = Inflammatory polyarthritis, RA = Rheumatoid arthritis
* Adjusted for age, total energy intake and smoking
All intakes based on 7-day diaries. 1 serving of fruit = 80gm

Conclusion: Fruit intake is inversely associated with the risk of IP, RA and seropositive IP, an effect confined to men. Fructose appears to mediate this effect rather than vitamin C.

Response to Local Corticosteroid Injection In Carpal Tunnel Syndrome with Normal Electrodiagnostic Study. Domingo Ly-Pen[1], José Luis Andreu[2], Isabel Millán[3], Gema de Blas[4] and Alberto Sánchez-Olaso[4]. [1]SERMAS. CS "Gandhi" / Hospital "Ramón y Cajal", Madrid, Spain, [2]HU, Madrid, Spain, [3]HU "Puerta de Hierro Majadahonda", Madrid, Spain, [4]Hospital "Ramón y Cajal", Madrid, Spain

Background/Purpose: Electrodiagnostic testing (EMG) has usually been defined as the gold standard in carpal tunnel syndrome (CTS) diagnosis. Nevertheless, correlation between clinical symptomatology and EMG has shown to be very poor. In fact, clinical symptoms may precede EMG changes in months or years. There are very few papers about the clinical response to treatment of clinically typical CTS, but with normal EMG.

The aim of this study is to compare the clinical response to local corticosteroid injections (LCI) in clinically typical CTS, with normal and pathologic results in EMG.

Methods: We included patients older than 18 years, with typical symptoms of CTS (daily nocturnal pain, every night during at least 3 months). EMG was done on every patient. Wrists with abnormal EMG were randomised either to LCI or to surgical decompression. Wrists with normal EMG were rejected from our randomised study, and were treated with two LCI (two weeks between them). Follow-up was done at 3, 6 and 12 months. Primary outcome was visual analogue scale for pain (p-VAS), comparing wrists with abnormal EMG treated with LCI in our randomized clinical trial, with wrists with normal EMG that were all treated with LCI. Statistic signification was established by the Student′s t test, Mann-Whitney′s "U", the normal χ^2 test and with Yates′ correction. The study was approved by the ethics committees at our centers and all patients gave written informed consent.

Results: Forty four wrists were included in the group with normal EMG (NEMG) and 83 in the group with patologic EMG (PEMG).

Mean age was 49 years in the NEMG group and 54 years in the PEMG group (p = 0,063). The mean time of symptoms evolution was 26 weeks in the NEMG group and 38 weeks in the PEMG group (p = 0,33).

Mean p-VAS was 59 mm in the NEMG group and 42 mm in the PEMG group (p = 0,001). In the table we can see the percentage of wrists that reached a 20%, 50% and 70% reduction in p-VAS in the follow-up.

	Response 20%			Response 50%			Response 70%		
Months	3	6	12	3	6	12	3	6	12
NEMG	88%	85	90	81%	75	81	69%	61	62
PEMG	96%	87	87	89%	85	86	83%	79	79
p	0,199	0,706	0,910	0,186	0,205	0,551	0,076	0,03	0,07

Conclusion: Clinically relevant responses to local corticosteroid injections in CTS tend to be more frequent in wrists with pathologic EMG than in wrists with clinically typical symptoms of CTS, but with normal EMG.

1897

New Formulation to Improve Tendon Tissue Organization in Tendinopathies. Anna Torrent[1], Ramon Ruhí[1], Cristina Martínez[2], Mar Cid[2], Constanze Buhrmann[3] and Mehdi Shakibaei[3]. [1]BIOIBERICA S.A., Palafolls, Spain, [2]BIOIBERICA S.A., Barcelona, Spain, [3]LMU, Institute of Anatomy, Munich, Germany

Background/Purpose: Tendons are dense fibrous connective tissues that connect muscle to bone. The functional properties of the tendon are derived from the structure and components of the extracellular matrix (ECM). When diseased or injured, adult tendons do not heal to the same regenerative capacity of embryonic tissue, but exhibit a highly disorganized matrix that consequently affects normal tissue function. Collagen disorientation, disorganization and variations in the diameters of collagen fibrils are characteristics of a tendinopathic tendon. It is crucial to maintain the structure of the tendinous matrix for the ability of the tendon to resist mechanical forces and the repair response to injury.The aim of this study was to evaluate the potential effectiveness of a novel formulation (BIS033) including mucopolysaccharides on fibrillogenesis of collagen type I and tenomodulin (TeM) levels in the presence/absence of IL-1β in a 3-dimensional culture of human tenocytes.

Methods: Primary human tenocytes in 3-dimensional high density cultures were incubated for 0–14 days under different treatments. BIS033 is a nutraceutical formulation that contains mainly mucopolysaccharides. Tenocytes were either treated with BIS033, non-stimulated or stimulated with IL-1β or stimulated with IL-1β and BIS033.We evaluated the effect of this natural formulation on fibrillogenesis and on the tendon specific matrix glycoprotein called TeM in the presence or absence of IL-1β.The potential efficacy of BIS033 in the extracellular matrix (ECM) estructure, and especially in the orientation, organization and morphology of the collagen fibrils was investigated by Transmission Electron Microscopy (TEM).By Western Blot we evaluated whether incubation of tenocytes with the formulation could prevent IL-1β-induced upregulation of catabolic events leading to downregulation of production of matrix specific proteins such as TeM. This glycoprotein is highly expressed in normal, healthy tenocytes and is described in literature that there is a close correlation between TeM expression and the regular alignment of collagen fibers, further indicating that TeM is involved in the formation of organized tendon structures.

Results: Tenocytes treated with IL-1β underwent apoptosis and showed a completely disorganized extracellular matrix. The treatment with BIS033 was able to counteract the catabolic effects and cells looked healthy and with abundant and well organized extracellular matrix consisting of thick fibrils of collagen. Also tenocytes displayed high amount of euchromatin that indicates that cells were very active and with a high rate of protein biosynthesis. Western blot demonstrated a considerable prophylactic effect of BIS033 on human tenocytes co-treated with IL-1β on TeM synthesis. Additionally an anabolic effect of the formulation was observed: cells showed higher TeM levels compared to the untreated control cells.

Conclusion: These results indicate that the formulation BIS033 could be useful in the prevention and/or treatment of tendinopathies (tendinitis, tendinosis, etc). The administration of this product is believed to contribute to remodelling the tendon, which is crucial to return to its mature functional structure.

1898

Trochanteric Bursitis: Is there Ultrasonographic Evidence to Suggest Inflammation? P. Dundeva-Baleva[1], A. Abdel-Megid[1], A. Borham[1] and Naomi Schlesinger[2]. [1]UMDNJ/Robert Wood Johnson Medical School, New Brunswick, NJ, [2]UMDNJ-Robt Wood Johnson MS, New Brunswick, NJ

Background/Purpose: Trochanteric bursitis (Tb) is one of the most common soft tissue abnormalities in the hip region; affecting 10–25% of the population. Tb is a clinical diagnosis that includes lateral hip pain and tenderness around the greater trochanter. Power Doppler (PD) ultrasonography (US) is a sensitive method for demonstrating the presence of blood flow in small vessels. PD US enables visualization of synovial hyperemia. High frequency and PD US in combination are sensitive and reproducible tools for determining joint effusions and synovitis. The term Tb may be a misnomer given that three of the cardinal symptoms of inflammation: warmth, erythema and swelling are rarely seen in these patients. Could use of US help identify how commonly US and PD US changes suggestive of Trochanteric bursa inflammation are seen in patients with the clinical syndrome of Tb.

Methods: This study was a retrospective chart and US image review of patients seen in the Rheumatology clinic between 12/1/2006 and 2/1/2010 with a primary or secondary diagnosis of trochanteric bursitis (diagnosis codes CPT 76942 and/or 20610). Trochanteric bursa US images were reviewed for signs of inflammation (bursa swelling and capsule thickening), as well as PD US signals. Recorded were patients' past medical history and medications at the time of diagnosis and the response to intrabursal corticosteroid injections given by a Rheumatologist (AB,NS).

Results: 287 patient charts with CPT 76942 and 20610 were reviewed. Seventy five patients were found to have a diagnosis of Tb. Of these 75 patients; 52 underwent trochanteric bursa injections and had US images. 13 patients had bilateral trochanteric bursa images; 4 patients had the same bursa examined more than once. Total number of US images n=67, total number of PD US n=51.

The average age of the patients was 49 (range: 24–76) years. 50 (99%) patients were female; only two (1%) patients were male. Most patients had underlying osteoarthritis (OA) n= 23 (44%) and Fibromyalgia syndrome (FM) n= 26 (50%). Five (9.6%) patients with Tb had Sjogren's Syndome. 31(60%) patients diagnosed with Tb were on NSAIDs at the time of the diagnosis and 12(23%) on a neuropathic pain medication.

The Rt trochanteric bursa was most commonly involved (n= 44 (66%)). All (n=51 (100%)) of PD US were Grade 0 (normal: no evidence of inflammation). Only 2 of 67 (<1%) trochanteric bursa US images showed an effusion. None had bursal wall thickening. Pain relief was seen for an average of 4.5 months post-injection in 26 (50%) patients who had a follow up visit.

Conclusion: This is the first study to date examining the use of US and PD US as a means to review inflammation in patients with Tb. We found that patients with clinical Tb do not have US evidence to support a diagnosis of bursal inflammation. The right trochanteric bursa was commonly involved (dominant side in most patients). The involvement of mostly females is not surprising since females suffer more commonly from soft tissue rheumatism than men. Since we did not find signs of inflammation in the trochanteric bursa, we suggest that the most appropriate term to be used for what was previously known as trochanteric bursitis is **Trochanteric Pain Syndrome.**

1899

Stress Is a Key Modulator of Mood, Coping, Type of Control and Characteristic Symptoms in Females with Fibromyalgia. Katrina Malin[1] and Geoffrey O. Littlejohn[2]. [1]Monash Medical Centre, Clayton, Australia, [2]Monash Medical Center, Melbourne, Australia

Background/Purpose: Stress is an important feature of fibromyalgia [FM] with links to aberrant autonomic nervous system function, perturbed hypothalamic pituitary adrenal function and dysregulation of brain-related control over spinal cord sensory processing. However, it remains unclear how stress interacts with central processes such as personality, control styles, coping techniques and mood that in turn associate with the predictable phenotypic symptom characteristics of fibromyalgia, such as pain, fatigue, sleep and confusion. We aimed to identify the associations of stress with these central and "down-stream" variables in patients with FM.

Methods: We identified 98 women with fibromyalgia diagnosed according to standard ACR criteria. Applied questionnaires included Fibromyalgia Impact Questionnaire [FIQ], Perceived control of internal states scale (PCOISS), Mastery scale, the Coping Scale and Perceived Stress scale. Correlation and regression modelling were used to explore the relationships

between stress and the domains of coping, control, mood and personality as well as characteristic FM symptoms.

Results: Stress showed significant moderate to strong correlations with all the above "central' and symptom variables of FM [$p < 0.001$)]. There was a strong inverse correlation with measures of control [PCOISS and Mastery] and a strong positive correlation with mood, neuroticism, confusion and coping. When controlling for stress all variables, with the exceptions of internal control with mastery and neuroticism and confusion with mastery and coping, were not significant, indicating that stress impacts the majority of variables associated with FM. The regression model predicted ratings of stress as measured by disengagement (coping), pain, internal control, anxiety, confusion, mastery and neuroticism. Together they accounted for 75% of variance.The main significant independent elements were neuroticism (31%), mastery (29%), anxiety (23%) and disengagement (21%).

Conclusion: Stress associates with most of the central variables that have been identified as being important in fibromyalgia, as well as the phenotypic clinical characteristics. Strong predictors of stress were neuroticism, anxiety, behavioural disengagement and low mastery. Stress appears to have a pivotal role in modulating several key "up-stream" processes in fibromyalgia.

1900

Fibromyalgia and Parental Medical Histories of Depression and Alcoholism. Robert S. Katz[1], Ben J. Small[2], Sharon M. Ferbert[3], Patricia Kuenzi[1] and Susan Shott[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical School, Chicago, IL, [3]Advocates for Funding Fibromyalgia Treatment, Education and Research(AFFTER), Libertyville, IL

Background/Purpose: We investigated whether depression or alcoholism in parents is associated with an increased risk of fibromyalgia (FMS) in offspring. We had found in a previous study suggestions of an increased prevalence depression in the mothers and alcohol abuse in the fathers of fibromyalgia patients.

Methods: 115 FMS patients and 63 control patients with other rheumatic diseases answered a rheumatology office questionnaire that included questions about whether their mother or father had been diagnosed with or had symptoms of depression, alcoholism, or FMS. The chi-square test of association and Fisher's exact test were used to compare FMS and control patients with respect to percentages. The Mann-Whitney test was done to compare these groups with respect to age. A 0.05 significance level was used and all tests were two-sided.

Results: 81.7% of the FMS patients and 61.9% of the control patients were women ($p = 0.004$). The mean age was 48.1 ± 12.3 years for FMS patients and 50.7 ±13.6 for control patients ($p = 0.092$). 33.0% of FMS patients and 8.1% of control patients reported a depression diagnosis or symptoms in their mothers ($p < 0.001$). 26.3% of FMS patients reported a depression diagnosis or symptoms in their fathers, compared to 10.0% of control patients ($p = 0.013$). Although FMS patients were more likely than control patients to report an alcoholism diagnosis or symptoms in their mothers (9.6% vs. 4.8%. $p = 0.38$) and fathers (19.2% vs. 10.0%, $p = 0.18$), the differences were not statistically significant. FMS patients were significantly more likely than control patients to report a FMS diagnosis or symptoms in their mothers (26.4% vs. 3.2%. $p < 0.001$), but not in their fathers (6.2% vs. 0%, $p = 0.083$).

Conclusion: FMS patients were significantly more likely than control patients to report that their parents had a diagnosis or symptoms of depression, and significantly more likely to report that their mothers had a FMS diagnosis or symptoms. No statistically significant differences were found with respect to paternal FMS or maternal or paternal alcoholism.

1901

The Survey Diagnostic Criteria of Fibromyalgia Syndrome—Results From the German Fibromyalgia Syndrome Consumer Reports. Winfried Häuser[1], Eva Jung[1] and Frederick Wolfe[2]. [1]Technische Universität München, Munich, Germany, [2]National Data Bank for Rheumatic Diseases, Wichita, KS

Background/Purpose: A modification to the American College of Rheumatology (ACR) 2010 preliminary diagnostic criteria for the fibromyalgia syndrome (FMS) was developed for use in epidemiological and clinical studies. Patients satisfying the modified ACR 2010 diagnostic criteria meet the following 3 conditions: 1) Widespread Pain Index (WPI) ≥7 and Symptom Severity Score (SSS) ≥5 ("FMS 1") or WPI between 3–6 and SSS ≥9 ("FMS 2"); 2) Symptoms present at a similar level for at least 3 months; 3) Absence of another disorder that would otherwise sufficiently explain the pain. The feasibility and convergent validity of the survey criteria has not been tested previously. We assessed feasibility within a survey study and determined the concordance rates of FMS diagnosis according to survey, clinical and ACR 1990 criteria (convergent validity).

Methods: A questionnaire containing the WPI and SSS was included in the FMS consumer reports survey in Germany. Conducted between November 2010 and April 2011, the questionnaire was distributed by the two largest German FMS self-help organizations (German League for people with Arthritis and Rheumatism, German Fibromyalgia Association) to their members with self-reported FMS. In addition, 8 clinical institutions in different speciality areas (complementary and alternative medicine, pain medicine, psychosomatic medicine, rheumatology) and different levels of care distributed the questionnaire to consecutive patients with established or newly diagnosed FMS. The diagnosis of FMS was (re-) assessed by clinical criteria at all clinical institutions. Blinded clinicians from 4 centres performed the ACR 1990 criteria examination using the Okifuji tender point protocol (TPE).

Results: 1509 questionnaires were returned and 1291 (85.5%) to 1448 (95.9%) of the items of the survey questionnaire were answered. Data from 1446 persons were analyzed, of whom 1129 (78.1%) had been recruited by the self-help organisations. Women (n=1365) constituted 94.4% of the sample. The mean age was 54.4 (SD 9.8) years and the mean duration of chronic widespread pain was 16.8 (SD 11.0) years). The time since first diagnosis of FMS was 6.7 (SD 5.5) years. In 25 (1.7%) patients, FMS had been diagnosed for the first time. Of 1446 patients, 1182 (81.7%) met the FMS1-survey criterion and 60 (4.2%) met the FMS-2 criterion.

A TPE was performed on the 131 patients in the clinical centres with an established or initial diagnosis of FMS. Survey criteria were met by 111/(84.7%) of the patients. The 1990 classification criteria were met by 106 (80.9%)% of the patients. Survey and 1990 criteria were concordant in 100 (76.3%) of the patients.

Conclusion: The consumers reports study demonstrates the feasibility of survey diagnostic criteria in a patient survey of established or suspected FMS. The concordance rate of survey and ACR 1990 criteria was comparable to published data (75.2%) (Katz, A&R 54(1); 2006) and of defined clinical criteria and ACR 1990 criteria (86.6%) (HSuser, Clin J Pain 26(6): 2010). Survey criteria were designed to differ from the ACR 1990 classification criteria, and most disagreements were due to TP-counts <11 in patients meeting survey criteria. Feasibility and validity within a population survey needs to be determined.

1902

Prevalence of Fibromyalgia at the Medical Out Patient Clinic Kenyatta National Hospital. Sophia Dokwe and Omondi.G Oyoo. University of Nairobi, Nairobi, Kenya

Background/Purpose: Fibromyalgia syndrome is a disorder that is associated with significant morbidity. Despite its existence worldwide there is hardly any epidemiological data in Africa and none in Kenya. The prevalence of this disorder in the Kenyatta National Hospital medical out-patient and rheumatology clinics is unknown.

Objectives: To determine the prevalence of fibromyalgia, chronic regional pain and chronic widespread pain in patients attending the medical outpatient and rheumatology clinic at Kenyatta National Hospital; to investigate the frequency of fibromyalgia symptoms and to document the primary diagnosis and Cormobid conditions in the these patients.

Methods: A questionnaire that includes the 1990 American College Of Rheumatology criteria for diagnosis of widespread pain and fibromyalgia and the (FIQR) Revised fibromyalgia impact questionaire was administered on 384 patients with musculoskeletal pain.Consecutive sampling was used.

Results: The prevalence of fibromyalgia, chronic regional pain and chronic widespread pain amongst patients with chronic musculoskeletal pains (n = 384) in the medical outpatient clinic and rheumatology clinic of Kenyatta National Hospital was 13% (n = 50), 76% (n = 291) and 11% (n = 43) respectively. The overall three month prevalence of fibromyalgia in the general medical outpatient clinic was 1%,Chronic widespread pains 1.2% and Chronic regional pain 6.7%.The mean age of patients with fibromyalgia was 48.5 yrs SD 2.6 [95%CI 43.1–53.8]. Approximately forty four percent 44.2 % [95% CI 28.7–59.7] and [(34.9%) were widowed 95% CI 20.1–49.7]. More than half of fibromyalgia patients were unemployed [n =22 (51.2%) 95% CI 35.6–56.3] and 46.5 % [95% CI 30.9–62] were engaged in manual activity.There was a female predominance of 97.7% (n = 42). Mean duration of illness was 5.8 years SD 0.8 [95%CI 4.1 – 7.4]. Rheumatoid arthritis was the most frequent primary diagnosis at first consultation in the clinics [30.2% (n=13/43)]. Hypertension was the commonest Cormobid disease [53.5 %(n=23/43)] the mean total FIQR score for fibromyalgia patients was 55.94%

SD (2.85)95%CI 50.19–61.68. The most frequent symptoms were pain, fatigue, stiffness, depression, and unrefreshing sleep while balance problems, headache and increased sensitivity to the environment were the least reported symptoms.

Conclusion: Fibromyalgia is prevalent amongst patients with musculoskeletal complains in the Medical Outpatient and rheumatology clinics at the Kenyatta National Hospital. These patients present with severe fibromyalgia symptoms and frequently have other Cormobid illnesses. Primary diagnosis is often missed.

1903

Fibromyalgia in Systemic Lupus Erythematosus and Association with Fatigue and Disease Activity: Comparison of 2010 Versus 1990 Criteria. Vinicius Domingues, Hong Fang and Michelle Petri. Johns Hopkins University School of Medicine, Baltimore, MD

Background/Purpose: Up to 90% of SLE patients complain of fatigue. Fibromyalgia (FM) occurs more frequently in SLE than in the general female population, and is highly associated with fatigue. The American College of Rheumatology (ACR) diagnostic criteria for FM were revised in 2010. We compared the 1990 and 2010 criteria for FM, in terms of association with fatigue and SLE activity.

Methods: 174 patients (90% female, 55% Caucasian, 37% African/American, mean age at entry 47.3±13) participated. FACIT-Fatigue, Fatigue Severity Scale (FSS), Fatigue Visual Analog Scale (FVAS) and Multidimensional Assessment of Fatigue (MAF) were used to quantify fatigue. Pain Score was evaluated in a scale from 0 to 10 based on patient's self report. SLE disease activity was measured by Physician's Global Assessment (PGA) and SELENA-SLEDAI. FM status was assessed by both the 1990 and 2010 criteria (Widespread Pain index ≥ 7 and Severity Scale ≥5 or Widespread Pain Index 3–6 and Severity Scale ≥9).

Results: The prevalence of FM was 39% (1990 criteria) and 41% (2010 criteria). The 2010 FM criteria were associated with disease activity by PGA, but not SLEDAI. The 1990 FM criteria were not. Both FM criteria were highly associated with fatigue, by all measures.

	Fibromyalgia 1990	Fibromyalgia 2010
	p-value	p-value
FACIT	<0.0001	<0.0001
FSS	<0.0001	<0.0001
MAF	<0.0001	<0.0001
FVAS	<0.0001	<0.0001
Pain Score	<0.0001	<0.0001
PGA	0.2658	0.009
SLEDAI	0.7614	0.5303

Conclusion: The 1990 FM criteria are not associated with SLE disease activity, but the 2010 are associated with PGA. This may limit the utility of the new FM criteria in practice. Both FM criteria are highly associated with fatigue (by any measure used). The high prevalence of fatigue in SLE is important to recognize in clinical practice and clinical trials.

1904

Return of Pain and Functional Impairment After Discontinuation of Milnacipran in Patients with Fibromyalgia. Philip J. Mease[1], Daniel J. Clauw[2], Yimin Ma[3], Arlene Baldecchi[3], Joel M. Trugman[3] and Robert H. Palmer[3]. [1]Seattle Rheumatology Associates and Swedish Medical Center, Seattle, WA, [2]University of Michigan, Ann Arbor, MI, [3]Forest Research Institute, Jersey City, NJ

Background/Purpose: Fibromyalgia (FM) is a debilitating chronic disorder characterized by widespread musculoskeletal pain and a host of symptoms that include fatigue, sleep disturbances, stiffness, and cognitive dysfunction. These multiple symptoms have a substantial negative impact on physical, mental, and social patient functioning. The objective of this analysis was to evaluate the effect of discontinuing long-term (18–54 months) milnacipran treatment on functional outcomes in FM patients.

Methods: Patients completing a long-term (up to 3.25 years) open label (OL) extension study of milnacipran 50 to 200 mg/day were eligible to participate. After completing 4-weeks of OL milnacipran treatment, patients taking milnacipran ≥100 mg/day and achieving a ≥50% reduction in visual analog scale (VAS) pain score from pre-milnacipran exposure to current status were randomized 2:1 to double-blind (DB) treatment with milnacipran (ie, milnacipran continued) or placebo (ie, milnacipran withdrawn) for 12 weeks. Functional outcomes assessed included the change from baseline (randomization visit) in Fibromyalgia Impact Questionnaire-Revised (FIQR) total score, SF-36 Physical Component Summary (PCS) score, SF-36 Mental Component Summary (MCS) score, and SF-36 individual domain scores (physical functioning, role limit-physical, bodily pain, general health perception, energy/vitality, social functioning, role limit-emotional, and mental health). Assessments were made at 2, 4, 8, and 12 weeks postbaseline. Missing patient data were imputed by using the last observation carried forward (LOCF) approach.

Results: In patients in whom milnacipran was withdrawn (n=50), there was worsening in the FIQR total score at each of the 4 postbaseline visits compared with patients in whom milnacipran was continued (n=100) (P <.001, all visits). Similarly, patients in whom milnacipran was withdrawn demonstrated a decline in physical functioning, as measured by SF-36 PCS and SF-36 physical functioning scores, compared with patients in whom milnacipran was continued (P <.05, all visits, both outcomes). Worsening in mental function (SF-36 MCS scores) was significantly greater in the placebo vs the milnacipran group at 2 out of the 4 visits (P <.05). All of the SF-36 individual domains showed greater deterioration from baseline in placebo- vs milnacipran-treated patients at every postbaseline visit; in the case of SF-36 bodily pain, these differences reached significance at each visit (P <.05). Differences in the other SF-36 individual domains (except general health perception) were significant at one or more visits (P <.05).

Conclusion: These results further support the enduring efficacy of milnacipran for improving function in patients with FM, as demonstrated by the deterioration of functional outcomes following discontinuation of long-term treatment.

1905

Safety and Tolerability of Milnacipran in a 3-Year, Open-Label, Flexible-Dosing Study of Patients with Fibromyalgia. Lesley M. Arnold[1], Yimin Ma[2], Robert H. Palmer[2], Allan Spera[2] and Arlene Baldecchi[2]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Forest Research Institute, Jersey City, NJ

Background/Purpose: Milnacipran is a dual serotonin and norepinephrine reuptake inhibitor that is approved in the United States for the management of fibromyalgia (FM). Several clinical trials have shown the efficacy of milnacipran at doses of 100 to 200 mg/day in improving the multidimensional domains of FM, including pain, global status, physical functioning, and fatigue. This open-label study enrolled patients from previous milnacipran trials, some of whom had been taking milnacipran for over 1 year, to assess further its long-term safety and tolerability.

Methods: This was a multicenter, open-label, flexible dosing study of up to 3.25 years in duration. A total of 1227 patients with FM who successfully completed a previous milnacipran study were included in this safety analysis. Patients underwent a 2-week washout period, followed by a 2-week dose-escalation period of milnacipran to 100 mg/day. After 8 weeks of dose stabilization at 100 mg/day, patients could have their dose adjusted to between 50 mg/day and 200 mg/day, depending on tolerability and/or therapeutic benefit. Safety assessments included treatment-emergent adverse events (TEAEs) (not present before study drug was taken or that increased in severity during the study period) and vital signs (including weight). In order to adjust for the extended length of time in this study, rates of TEAEs per 100 patient-years were also determined.

Results: The completion rate was 47.7%, comprising 206 patients who reached the final visit and 379 who were enrolled when the study was terminated; discontinuations due to TEAEs were 20.9%. The mean duration of treatment was 563.1 days, with 35.4% of patients completing ≥2 years; total exposure to milnacipran was 1889.1 patient-years. The mean daily dose was 133.7 mg/day. TEAEs occurred in 88.3% of patients over the 3.25 year period, with the most commonly reported TEAEs (≥10%) being nausea (25.9%), headache (13.4%), hypertension (11.2%), and sinusitis (10.4%). Expressed as incidence per 100 patient-years (nausea, 16.8%; headache, 8.7%; hypertension, 7.3%; and sinusitis, 6.8%), these rates were not inconsistent with product labeling. Serious TEAEs occurred in 8.9% of patients. Mean changes from baseline in systolic and diastolic blood pressure (supine SBP and DBP, respectively) were +4.0 and +3.3 mm Hg, respectively. Mean change from baseline in supine heart rate was +5 bpm and in body weight was −0.3 kg. Potentially clinically significant (PCS) increases in supine SBP (≥180 mm Hg and increase ≥20 mm Hg) and DBP (≥110 mm Hg and increase ≥15 mm Hg) were observed in 0.3% and 1.1% of patients, respectively; PCS increases in supine heart rate (≥120 bpm and increase ≥20) were observed in 0.4% of patients. PCS increases and decreases in

weight (≥7% change) were observed in 13.3% and 18.5% of patients, respectively.

Conclusion: Milnacipran, at doses of 50 to 200 mg/day, was generally well-tolerated and safe for periods of up to 3.25 years. No new safety concerns were identified in this long-term study.

1906

Cannabinoid Use in Fibromyalgia Is Associated with Male Gender, Opioid Use and Drug Seeking Behaviour. Peter A. Ste-Marie[1], Mary-Ann Fitzcharles[2], Ann Gamsa[2], Pantelis Panopalis[2] and Yoram Shir[2]. [1]University of Montreal, Montreal, QC, [2]McGill University, Montreal, QC

Background/Purpose: In the absence of an ideal treatment for fibromyalgia (FM), and with only three drugs having FDA approval, FM patients often seek treatments outside of mainstream medicine. Although the endocannabinoid system plays a role in pain modulatory mechanisms, little is known about the effect of administered cannabinoids in chronic pain or FM. We have had the impression that some FM patients may be using cannabinoids, either prescribed or illicit for treatment of FM symptoms. These agents, mostly subject to regulation, are also not currently recommended for treatment of FM. The prevalence of use of cannabinoids in FM patients is unknown and warrants examination.

Methods: We have examined the use of cannabinoids, both licit and illicit, in patients referred to a tertiary care pain centre clinic with a diagnosis of FM between January 2005 and December 2010 by a retrospective chart review. Demographic and clinical information, education and work activity, mental health status as assessed by a psychologist, and other medication use were documented. Univariate comparisons of continuous variables were made using Student's t-tests, and for categorical variables chi-squared tests were used.

Results: Demographic and disease related information for 457 referred patients is shown in Table 1. Three hundred and two (66%) retained the diagnosis of FM, and 155 (34%) were assigned some other primary diagnosis (140 other medical diagnosis, 65 current serious mental health disorder, 51 with both). FM patients had a mean pain VAS of 6.4 and a Fibromyalgia Impact Questionnaire score of 65.7, and were using an average of 1.9 prescription medications for treatment of symptoms. Cannabinoids were used by 59 (13%) patients, 46 (78%) used illicit marijuana, 14 (24%) used prescription cannabinoids (13 nabilone, 1 dronabinol) and 1 used both. Cannabinoid users vs. non users were more likely to be male 22% vs. 7% (p=0.0006), be taking opioids 47% vs. 29% (p=0.007) and demonstrate drug-seeking behaviours 32% vs. 4% (p=0.009). There was a tendency for cannabinoid users to suffer from more unstable current mental illness and also to be unemployed.

Table 1. Demographic and disease information for 457 patients referred with diagnosis of fibromyalgia, stratified according to cannabinoid use

	All patients n=457	Cannabinoids n=59	No cannabinoids n=398	p value cannabinoids vs no cannabinoids
Age ± SD	47±11	45±10	48±11	NS
Gender/male, no (%)	40 (9)	13 (22)	27 (7)	0.0006
Education (in 436)				
Schooling not completed, no (%)	50 (11)	9 (15)	41 (10)	NS
High school, no (%)	132 (29)	16 (27)	116 (29)	NS
College, no (%)	156 (34)	22 (37)	134 (34)	NS
University, no (%)	98 (21)	10 (17)	88 (22)	NS
Unemployed, no (%)	308 (67)	46 (78)	262 (66)	NS
Disability, no (%)	165 (36)	23 (39)	142 (36)	NS
Diagnosis				
Fibromyalgia, no (%)	302 (66)	36 (61)	266 (67)	NS
Other primary diagnosis, no (%)	155 (34)	23 (39)	132 (33)	NS
Current mental illness, no (%)	110 (24)	20 (34)	90 (23)	NS
Opioids, no (%)	144 (32)	28 (47)	116 (29)	0.007
Drug-seeking behaviour	25 (6)	8 (32)	17 (4)	0.009

Conclusion: Cannabinoids were used by 13% of all patients referred with a diagnosis of FM, and $^1/_3$ of all males. Illicit marijuana was the most cannabinoid used. The concomitant use of opioids as well as an increased rate of drug seeking behaviour raises concerns regarding the true motive for this category of mostly self medication. Although cannabinoids may possibly offer a therapeutic effect for pain relief, caution regarding any recommendation for use should be exercised until these agents are subject to rigorous evaluation in view of concerns regarding psychological health and an association with other substance abuse.

1907

3-Year Efficacy of Milnacipran in Patients with Fibromyalgia: An Open-Label, Flexible-Dosing Study. Lesley M. Arnold[1], Yimin Ma[2], Robert H. Palmer[2], Allan Spera[2] and Arlene Baldecchi[2]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Forest Research Institute, Jersey City, NJ

Background/Purpose: Milnacipran is approved for the management of fibromyalgia (FM), a chronic disorder characterized by widespread pain and other symptoms that adversely impact function and health-related quality of life. Because FM is a chronic disorder, long-term efficacy is an important treatment goal. Previous studies have demonstrated the efficacy of milnacipran in managing FM symptoms for up to 1 year. This study extends those findings by evaluating the long-term efficacy of milnacipran for a period of up to 3.25 years.

Methods: In this open-label study, the treatment effects of milnacipran were evaluated in patients with FM (N=1227) over a period of up to 3.25 years (or until the study was terminated administratively). Patients successfully completing previous milnacipran studies were eligible for enrollment. This study comprised a 2-week washout period, a 2-week dose-escalation period (to milnacipran 100 mg/day), an 8-week dose-stabilization period (at milnacipran 100 mg/day), and a flexible-dose period (milnacipran 50–200 mg/day) for the remainder of the study. Key efficacy outcomes included mean changes from study baseline (after 2 week washout) in weekly recall VAS pain (0–100 mm scale), Patient Global Impression of Change (PGIC), Patient Global Disease Status (PGDS), SF-36 Physical Component Summary (PCS), and the Brief Pain Inventory (BPI). Efficacy analyses were reported for the intent-to-treat (ITT) population at the end of study (ie, last available assessment). Additional cohort analyses for weekly recall VAS pain were performed in order to assess the long-term effects of treatment in defined groups of patients treated for varying periods of time.

Results: For the ITT population, milnacipran-treated patients showed an improvement in pain, with a mean decrease from baseline in weekly recall VAS pain score of 17.6 mm. Additionally, improvements in BPI scores, global status (PGIC, PGDS), and physical function (SF-36 PCS) were all observed with milnacipran treatment for the ITT population. Because the number of patients with available data in the ITT population varied at each visit, we used weekly recall VAS pain to assess improvements over time in specified cohorts. In the cohort of patients completing ≥3 years (n=217), the observed pain improvement was reached by Month 3 and remained relatively constant throughout the entire study; weekly recall pain VAS scores improved by 23.9 mm in these patients at the final study visit (Month 36–38). Similar improvements from baseline in weekly recall VAS pain were observed over time and remained constant in the 2-year cohort (n=461) and the 1-year cohort (n=820).

Conclusion: The findings from this open-label study provide support for sustained long-term efficacy (in some cases exceeding 3 years of continuous treatment) of milnacipran in improving pain, global status, and physical functioning in patients with FM.

1908

Improvements in Fatigue Are Incompletely Explained by Improvements in Pain in Fibromyalgia Patients Treated with Milnacipran. Philip J. Mease[1], Robert H. Palmer[2], Yong Wang[2] and R. Michael Gendreau[3]. [1]Seattle Rheumatology Associate and Swedish Medical Center, Seattle, WA, [2]Forest Research Institute, Jersey City, NJ, [3]Cypress Bioscience, Inc., San Diego, CA

Background/Purpose: In addition to chronic widespread musculoskeletal pain, patients with fibromyalgia (FM) commonly report fatigue as a major symptom. Fatigue can contribute to diminished quality of life, impaired ability to work, and a perceived worsening of disease state. Pain has previously been shown to be significantly correlated with fatigue in FM patients; however, the extent to which the clinical domain of fatigue may change independent of changes in pain has not been well characterized.

Results from several clinical trials have shown that milnacipran significantly improves pain and fatigue in patients with FM. Based on pooled data from 3 of these studies, this analysis explores the relationship between pain and fatigue, including the effects of baseline fatigue severity on pain improvements and the influence of pain improvements on fatigue improvements in milnacipran-treated patients.

Methods: Data were pooled from 3 phase III studies in FM patients randomized to placebo (n=1133), milnacipran 100 mg/day (n=1139), or milnacipran 200 mg/day (n=837). After a dose-escalation phase, patients underwent

12 weeks of stable-dose treatment. Fatigue was measured by using the Multidimensional Fatigue Inventory (MFI; 20–100 scale) and pain was measured using a VAS pain scale (0–100). In order to evaluate the impact of baseline fatigue severity on pain improvement with treatment, pain improvement was assessed in patients stratified into tertiles based on their baseline MFI total score (ie, MFI ≤63; MFI >63 and ≤74; MFI >74). Pearson correlation coefficients were determined for the relationship between improvements in MFI total score and improvements in pain VAS. Path analysis was used to describe the direct and indirect effects of milnacipran treatment on fatigue.

Results: Milnacipran-treated patients had significantly reduced pain VAS scores ($P < .05$, vs placebo) in all baseline fatigue subgroups. However, regression analysis revealed that in the milnacipran 100 mg/day group, patients who exhibited greater fatigue at baseline demonstrated a slightly reduced pain response compared with those with less fatigue at baseline ($P = .066$); this dependency was not seen in the 200 mg/day dose group ($P = .69$). Overall, improvements in MFI total score correlated only moderately well with improvements in pain (milnacipran, $r = 0.4729$; placebo, $r = 0.3898$). Path analysis suggested that 28.1% of the observed milnacipran treatment effect on fatigue could be explained by a direct effect on fatigue, not mediated by an indirect effect on pain.

Conclusion: These results suggest that milnacipran treatment improves pain in FM patients regardless of baseline levels of fatigue, although patients with higher levels of fatigue may gain additional benefit from a higher milnacipran dose. Additionally, milnacipran had a substantial direct effect on fatigue that was not attributable to improvements in pain. Taken together, these results suggest that neither of these domains can be taken as a surrogate for the other, and that both are domains that should be assessed independently.

1909

Alcohol Consumption and Symptom Severity in Patients with Fibromyalgia. Terry H. Oh, Chul H. Kim, Connie Luedtke, Jeffery Thompson and Ann Vincent. Mayo Clinic, Rochester, MN

Background/Purpose: To examine the associations between alcohol consumption and symptom severity in patients seen in a fibromyalgia treatment program.

Methods: We assessed alcohol consumption in 946 patients with fibromyalgia based on a self-reported alcohol history taken as a part of a comprehensive social history. The subjects were divided into 4 groups according to alcohol consumption by the reported number of drinks per week: none, low (≤3/week), moderate (>3–7/week) and heavy (>7/week). Multiple linear regression models were used to compare numeric rating of pain scores, number of tender points, and scores on the Fibromyalgia Impact Questionnaire (FIQ) and the Short Form-36 Health Status Questionnaire (SF-36) among the 4 groups while adjusting for potential confounder.

Results: The majority, 546 (57.7%), of the subjects reported no alcohol intake. The alcohol consumption of the remaining groups was distributed as follows: low in 338 (35.7%), moderate in 31 (3.3%) and heavy in 31 (3.3%), respectively. Employment status ($p<0.001$), education level ($p=0.009$) and BMI ($p=0.002$) differed significantly across the 4 groups with more employment among low and moderate drinkers, higher level of education in moderate drinkers, and lower BMI in moderate and heavy drinkers.

After adjusting for age, employment status, education level and BMI, we found significant group differences in number of tender points ($p=0.01$), FIQ total score ($p=0.004$), FIQ subscales of physical function ($p<.001$), work missed ($p=0.002$), job ability ($p=0.009$), and pain ($p<.001$), as well as SF-36 subscales of physical functioning ($p<.001$), pain index ($p<.001$), general health perception ($p=0.009$), social functioning ($p=0.008$) and physical component summary ($p<0.001$) with generally lower dysfunction and higher levels of quality of life for those with low and moderate alcohol consumption.

Post hoc analysis among the 4 groups showed that low and moderate drinkers had significantly better scores than none drinkers on the FIQ physical function and job ability scales and better SF-36 scores on physical functioning, pain index and physical component summary scales. Also, low drinkers had better scores on the FIQ work missed and SF-36 general health perceptions and social functioning scales. Moderate drinkers had better FIQ total scores and heavy drinkers had better scores on the SF-36 physical functioning scale than none drinkers. Furthermore, moderate drinkers had significantly lower FIQ pain subscale scores than all other groups and a lower number of tender points than low drinkers.

Conclusion: In patients with fibromyalgia, low and moderate alcohol consumption appears to be associated with lower levels of dysfunction and higher levels of quality of life when compared to none drinkers. Furthermore, moderate alcohol consumption was associated with better FIQ pain scale score when compared to none, low and heavy alcohol consumption.

1910

Six-Month Treatment Patterns and Outcomes for Patients with Fibromyalgia. Rebecca Robinson[1], Kurt Kroenke[2], David A. Williams[3], Yi Chen[4], Madelaine M. Wohlreich[5], Bill McCarberg[6] and Philip J. Mease[7]. [1]Eli Lilly and Company, Indianapolis, IN, [2]Indiana University Regenstrief Institute, Indianapolis, IN, [3]Univ of MI Hlth System-Lobby M, Ann Arbor, MI, [4]i3, Ann Arbor, MI, [5]Lilly USA, Indianapolis, IN, [6]Kaiser Permanente, Escondido, CA, [7]Seattle Rheumatology Associate, Seattle, WA

Background/Purpose: Fibromyalgia (FM) is a chronic condition in which long-term treatment and prognosis are variable. Here we describe medication use and outcomes over 6 months for patients starting a new course of medication for FM.

Methods: Data were analyzed from REFLECTIONS, a prospective, observational study of patients treated for FM in the United States and Puerto Rico, conducted between 7/2008 and 4/2011. Treatment status and outcomes were collected from patients using structured telephone interviews at baseline, and 1, 3, 6, and 12 months. Repeated measures models were used to assess changes in Brief Pain Inventory (BPI) severity (4 items) and interference (7 items) over time while adjusting for confounder variables (demographics, clinical characteristics, physician characteristics, and symptom severity) for the total sample and for select medication cohorts. Satisfaction measures (4) were compared, using chi-square tests with pairwise comparisons, to assess differences across medication cohorts.

Results: Patients (N=1700) were mostly female (94.6%) and Caucasian (82.9%), with these baseline characteristics (mean [standard deviation]): age 50.4 (11.9) years, duration of FM 5.6 (6.3) years, BPI severity 5.5 (1.8), and BPI interference 6.1 (2.2). At 6 months, 1344 (79.1%) patients were surveyed and 1233 (72.5%) completed all 4 interviews. Patients initiated 145 unique drugs and averaged 4.80 (1.8) unique medications per patient over 6 months. Most patients initiated 1 drug (87.8%) by adding it to concomitant medications (77.8%). Medication cohorts included patients initiating duloxetine (DLX, 267, 15.7%), pregabalin (218, 12.8%), milnacipran (MLC, 135, 7.9%), and tricyclic antidepressants (TCAs, 70, 4.1%). Overall, 1-, 3-, and 6-month assessments demonstrated significant least-squares mean reductions for pain severity (.18,.27, and.29, respectively) and interference (.54,.57,.65, respectively) (all $p<0.01$). Reductions in BPI severity and interference did not significantly differ between medication cohorts. At 6 months, the initiated baseline medication was discontinued in 35.5% of patients, continued in 36.6% of patients, and unavailable/unknown in 27.9% of patients. Predominant reasons for discontinuation were adverse events and lack of efficacy. At 6 months, patient satisfaction was good to excellent in 77.9% for treatment overall, 77.1% for medication(s) prescribed, 90.8% for doctor's interest in FM, and 92.4% for patient's rapport with the doctor. Patients initiating TCAs had lower rates of satisfaction across all measures compared with the other 3 medication cohorts, and significantly lower rates for overall treatment compared with DLX and MLC cohorts (all $p<0.05$). Patients initiating MLC had significantly higher rates of satisfaction for doctor's interest in FM and rapport with the doctor than patients initiating pregabalin and TCA (all $p<0.05$).

Conclusion: Over 6 months, patients experienced modest improvements in BPI severity and interference and continued to change treatments, yet measures of patient satisfaction with care were relatively high. This may underscore the importance of the doctor-patient relationship when treating FM.

1911

Subgrouping Chronic Pain Patients At a Tertiary Care Center Based on the Presence of Fibromyalgia Symptoms. Afton L. Hassett[1], Chad M. Brummett[2], Jenna Goesling[2], Kevin Rakovitis[2], Daniel J. Clauw[3] and David A. Williams[4]. [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan Health System, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: Most patients evaluated at tertiary care pain clinics present with chronic pain presumed to be of focal and peripheral origin; thus treatment often consists of targeted interventional strategies like epidural injections. However, there is a growing appreciation of the role for centralized pain like that observed in fibromyalgia. Pain that is more central in nature may require a different approach to treatment. The objective of this study was to identify subgroups of chronic pain patients whose pain was more like that observed in those with fibromyalgia.

Methods: 497 new patients presenting to the Back & Pain Center were included. All completed a series of self-report questionnaires, including the Brief Pain Inventory (BPI), PainDETECT and the ACR survey criteria for fibromyalgia. Exploratory and confirmatory K means cluster analyses for a 3-factor solution were conducted with 244 patients in each analysis. Variables including "fibromyalgianess" (a continuous scale of symptom severity based on the ACR survey criteria), neuropathic pain extent (total score on PainDETECT), pain severity and pain interference (BPI) were converted to Z scores for the analysis. Clinical data were entered into the APOLO Electronic Data Capture system and analyzed using PASW 18.

Results: Three subgroups characterized by severity of symptoms and pain interference were identified in the first analysis and confirmed in the second (Table 1). Analysis of variance demonstrated differences between the cluster means ($P < 0.0001$). One subgroup was characterized by high levels of fibromyalgianess, neuropathic pain, clinical pain severity and pain interference with functioning. The second group of patients had moderate levels of fibromyalgianess and neuropathic pain with less severe pain and pain interference. Lastly, the third subgroup had very low levels of fibromyalgianess and neuropathic pain with low pain severity and minimal pain interference.

Table 1.

Analysis 1	Cluster 1 (n=50)	Cluster 2 (n=115)	Cluster 3 (n=79)
Fibromyalgianess	1.386	−0.030	−0.697
PainDETECT	1.286	0.018	−0.904
BPI Pain Intensity	0.868	0.383	−1.136
BPI Pain Interference	0.947	0.308	.−1.035
Analysis 2	**Cluster 1 (n=83)**	**Cluster 2 (n=113)**	**Cluster 3 (n=48)**
Fibromyalgianess	0.841	−0.404	−0.779
PainDETECT	0.946	−0.238	−0.888
BPI Pain Intensity	0.713	−0.029	−1.159
BPI Pain Interference	0.805	0.021	−1.483

Conclusion: Our data suggest that widespread pain and concomitant symptoms associated with fibromyalgia captured in the ACR survey criteria (e.g., poor mood, cognitive problems, sleep disturbance) occur on a continuum and might help differentiate chronic pain patients in a tertiary care setting. The patients on the high end of the continuum tend to have greater pain that may be more central in nature, as well as higher levels of disability. Such patients may require a different treatment strategy than those on the low end of the continuum.

1912

Smoking and Fibromyalgia: The Need for a Multidisciplinary Approach to Treatment. Jenna Goesling[1], Chad M. Brummett[1], Kevin Rakovitis[1], Daniel J. Clauw[2] and Afton L. Hassett[3]. [1]University of Michigan Health System, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan Medical School, Ann Arbor, MI

Background/Purpose: Current data on smoking and fibromyalgia (FM) are limited, and thus the implications of smoking behavior for FM patients are not well understood. Therefore, a better understanding of smoking among patients with FM is important because despite nicotine's analgesic effects, most smokers typically report greater pain, worse overall functioning, and more symptoms of mood disorders compared to nonsmokers. The objective of this study was to evaluate the relation of smoking status on pain and mood in FM patients using data from a tertiary care pain clinic. We hypothesized that patients meeting FM survey criteria who smoke would be more likely to report greater pain severity and interference, as well as higher levels of anxiety and depression.

Methods: New patients seeking treatment for chronic pain at the University of Michigan's Back & Pain Center were included in this study. The American College of Rheumatology (ACR) survey criteria for FM were used to categorize patients. Current smoking status was determined based on the question "Do you smoke" (yes=current smoker, no=nonsmoker). Pain was measured using the Brief Pain Inventory and mood was assessed with the Hospital Anxiety and Depression Scale. Data were entered into the APOLO Electronic Data Capture system and analyzed using PASW 18.

Results: Among the 170 patients who met survey criteria for FM, 38.8% (66) reported being current smokers. 41% smoked a pack or more per day. In comparison, 23% (68) of patients who did not meet survey criteria for FM were smokers. Consistent with predictions, current smokers meeting survey criteria for FM reported greater pain severity ($F=9.32$, $p < 0.003$) and pain interference ($F=12.49$, $p < .001$) compared to non-smokers who met FM criteria. Further, current smokers reported higher levels of anxiety, ($F=15.04$, $p < 0.001$) and depression ($F=23.34$, $p < 0.001$) compared to non-smokers who met survey criteria for FM.

Conclusion: Smoking rates were higher among patients who met survey criteria for FM compared to patient's who did not meet FM criteria. When comparing only patients who met FM criteria, smoking was associated with greater pain, more interference, anxiety, and depression. These results suggest that smokers who met survey criteria for FM have several comorbid factors that likely interfere with functioning. In conclusion, a multidisciplinary approach to treatment of chronic pain among current smokers, especially in patients who meet FM criteria, should include both cessation advice and treatment for co-occurring mood disorders. It follows that further consideration of the complex relation between smoking, mood and pain may help inform treatment decisions and interventions among patients who meet survey criteria for FM. Future studies will focus on differences in post-treatment outcomes between smokers and non-smokers who meet FM criteria.

1913

Perspectives on Fibromyalgia From Trainees At An Academic Health Center. Jennifer Lobert[1], Xolti Morgan[1] and Lesley M. Arnold[2]. [1]University of Cincinnati, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

Background/Purpose: Fibromyalgia (FM) is a common disorder in the US with an estimated 2% prevalence in the adult population. There are no published studies on trainees' attitudes towards FM and the degree of confidence in diagnosing and managing the disorder. We hypothesized that despite recent advances in the understanding of the pathophysiology and treatment of FM, there is still uncertainty among some trainees about the legitimacy of FM as a medical disorder. We propose that this uncertainty is due to inadequate quality and quantity of education.

Methods: We conducted a survey of residents and fellows in all departments of a large academic medical center using an anonymous, secure, web-based survey that consisted of questions related to education about diagnosis and treatment of FM, experience with FM, and personal beliefs about FM. To determine which factors were significantly associated with considering FM to be a legitimate medical disorder we used the Chi-Square test and univariate odds ratios. Those variables that were significant at a p value <0.10 were included in a multivariate logistic regression model predicting which residents thought FM was a legitimate medical disorder.

Results: The survey was completed by 154 of 642 residents and fellows. Respondents were more likely than the overall group to be Caucasian, in the first 3 years of training, and in primary care. Only 36% believed that FM was a legitimate medical disorder. Respondents who believed that FM was a legitimate medical disorder were more likely to be confident in treating FM (OR 3.16, 1.4–6.9) and to believe that FM patients were not more difficult to manage than other patients (OR 2.5, 1.0–6.0). Those who were confident in treating FM were more likely to be in primary care and to have diagnosed and treated FM. They also reported satisfactory or better quantity and quality of education on diagnosis and treatment of FM. They understood the pathophysiology of FM and were comfortable discussing FM with patients and attendings.

Conclusion: Despite advances in the understanding of the pathophysiology and management of FM, a minority of residents and fellows at a large academic medical center believe that FM is a legitimate medical disorder. Those who believe in its legitimacy are more confident in diagnosing and treating the disease. Factors that contribute to increased confidence include regular exposure to patients with FM and adequate quantity and quality of the educational experience. Interventions aimed at increasing trainees' clinical experience with FM patients and improving the quantity and quality of FM education may enhance trainees' level of confidence in diagnosing and treating FM as a legitimate medical disorder. This, in turn, will increase the percentage of trainees who believe in the legitimacy of the disorder and lead to improved FM patient care.

1914

EpiFibro—A Brazilian Nationwide Databank in Fibromyalgia—Analysis of 500 Women. Roberto E. Heymann[1], Eduardo S. Paiva[2], Marcelo C. Rezende[3], Daniel Feldman[4], Milton Helfenstein Jr.[1], Jose E. Martinez[5], Jose R. Provenza[6], Aline Ranzolin[7], Luiz S. Ribeiro[8] and Eduardo J.R. Souza[9]. [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]Universidade Federal do Parana, Curitiba, Brazil, [3]Santa Casa de Campo Grande, Campo Grande, Brazil, [4]Universidade Federal de São Paulo, Sao Paulo, Brazil, [5]Pontifícia Universidade Católica de São Paulo, Sorocaba, Brazil, [6]Pontifícia Universidade Católica de Campinas, Campinas, Brazil, [7]Hospital das Clínicas - Universidade Federal de Pernambuco, Recife, Brazil, [8]Instituto de Previdência dos Servidores do Estado de Minas Gerais, Belo Horizonte, Brazil, [9]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil

Background/Purpose: Fibromyalgia Syndrome (FM) is common in Brazil, with a prevalence of 2,1%. Here we present the initial data from EpiFibro, a nationwide (9 states) databank of FM patients seen in the public and private settings, mostly in referral centers and FM experts offices.

Methods: We analyzed data from the first 500 women in the databank. All patients were seen by a rheumatologist, and all fulfilled the 1990 ACR criteria for FM. 55% of patients received the diagnosis in the moment of entering the databank, and 42.8% were follow-up patients.

Results: Patients seen in a public setting comprise 70% of this sample. They had a lower level of education, more diffuse pain at onset (77.71% vs. 55.49% in private patients), but they did not differ from private patients concerning the FIQ score (60.65 vs. 62.67).

Most patients were married (59.4%) and most of them did not complete middle level education (67%). 31% are employed, 21% are housewives and 34% are unemployed or retired. The house income for the great majority of patients (73.4%) was less than 2,000 reais/month (1,200 US dollars).

Concerning the patient's impression about what triggered FM symptoms, 39.4% blame a work injury and 51% recognized a depressive or anxiety episode as a trigger. Most of patients referred that their pain already started as diffuse pain (70.2%). The majority of patients first saw a General Practitioner or an Orthopedic Surgeon for their complaints.

Patients presented with 13.74 tender points in average. The main associated symptoms were sleep disturbances (86%), fatigue (84.6%), anxiety (77.2%), paresthesias (75%) and headache (72.6). The mean FIQ score was 60.82.

Patients that received their diagnosis as they entered the database (277 subjects) usually have had their pain for more than three years (74.37%), visited more than 3 doctors before the diagnosis was made(70%) and 44% of them saw a rheumatologist only after three years after looking for medical help. Their FIQ score was not different from the follow-up patients (65.23 vs. 62.87).

Conclusion: A preliminary analysis of the EpiFibro databank revealed that female FM patients in Brazil have a high impact of their disease measured by FIQ, high prevalence of associated symptoms, a low degree of education (this could be explained as public health care in Brazil is used mainly by the underserved) an their pain seems to be diffuse from the start.

1915

EpiFibro—A Brazilian Nationwide Databank in Fibromyalgia—2010 Fibromyalgia Criteria, "Fibromyalgianess" Score and FIQ Performances. Eduardo S. Paiva[1], Roberto E. Heymann[2], Marcelo C. Rezende[3], Daniel Feldman[4], Milton Helfenstein Jr.[5], Jose E. Martinez[6], Jose R. Provenza[7], Aline Ranzolin[8], Luiz S. Ribeiro[9] and Eduardo J.R. Souza[10]. [1]Universidade Federal do Parana, Curitiba Parana, Brazil, [2]UNIFESP - Universidade Federal de São Paulo, São Paulo, Brazil, [3]Santa Casa de Campo Grande, Campo Grande, Brazil, [4]Universidade Federal de de São Paulo, Sao Paulo, Brazil, [5]Universidade Federal de de São Paulo, São Paulo, Brazil, [6]Pontifícia Universidade Católica de São Paulo, Sorocaba, Brazil, [7]Pontifícia Universidade Católica de Campinas, Campinas, Brazil, [8]Hospital das Clínicas - Universidade Federal de Pernambuco, Recife, Brazil, [9]Instituto de Previdência dos Servidores do Estado de Minas Gerais, Belo Horizonte, Brazil, [10]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil

Background/Purpose: EpiFibro is a nationwide (9 states) databank of FM patients seen in the public and private settings, mostly in referral centers and in FM experts offices.

Methods: 500 women with FM, defined by the 1990 ACR criteria, were included in this analysis. 55% of patients received the diagnosis in the moment of entering the databank, and 42.8% were follow-up patients, and 70% of this sample was composed by patients from public hospitals.

Results: When the 2010 ACR criteria were applied in these patients, 88.5% of them fulfilled the criteria for diagnosis of FM -Widespread Pain Index(WPI) => 7 and Symptoms Severity Scale (SSS) =>5 OR WPI =>3–6 and SSS=>9. There was no difference when the group had the 1990 criteria previously or when entering the databank.

The mean WPI was 12.43 ± 4.51, the mean SSS was 9.07±2.48 and the "Fibromyalgianess Score" – WPI+SSS was 19.92±7.79. Patients that did not fulfilled the 2010 criteria had much lower scores in the WPI and in the SSS subscales:

	2010 CRITERIA NEGATIVE	2010 CRITERIA POSITIVE	P
WPI	5.98	13.29	0.001
SSS-FATIGUE	1.17	2.4	0.001
SSS-SLEEP	1.16	2.38	0.001
SSS-COGNITIVE	1.28	2.19	0.001
SSS-SOMATIC	1.63	2.63	0.001
SSS-TOTAL	5.21	9.6	0.001
FIBROMYALGIANESS	11.19	22.89	0.001

We also correlated the FIQ (Fibromyalgia Impact Questionnaire) with the 2010 criteria subscales, and found a good correlation with the SSS($r=0,53$, $p<0.001$), especially the fatigue sub-item ($r=0,48$, $p<0.001$). Interestingly, the "Fibromyalgianess" score had a lower, although positive, correlation with the FIQ ($r=0,39$, $p<0.001$).

Comparing patients seen in a public setting with those seen in private practice, we were also able to find a higher WPI: 13.25 vs. 10.52 in private patients, and as a consequence, this group had higher "Fibromyalgianess Score" and a greater proportion of patients being diagnosed as FM with the 2010 diagnostic criteria.

Conclusion: Analysis of the EpiFibro databank revealed that a high proportion of female FM patients in Brazil (88%) also fulfilled the 2010 ACR criteria for the diagnosis for FM, and we found that the FIQ score correlates well with Symptoms Severity Scale, especially with the fatigue subscale.

1916

A Randomized, Double-Blind Comparison of Duloxetine 30 Mg Once Daily (QD) and Placebo in Adult Patients with Fibromyalgia. Lesley M. Arnold[1], Shuyu Zhang[2] and Beth Pangallo[3]. [1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Eli Lilly and Company, Indianapolis, IN, [3]ELi Lilly and Company, Indianapolis, IN

Background/Purpose: Treatment with duloxetine 60 mg QD significantly reduces pain severity in adult patients with fibromyalgia (FM) with or without major depressive disorder (MDD). In previous FM trials, 1-week treatment with duloxetine 30 mg QD resulted in statistically significant pain reduction compared with placebo before duloxetine was increased to the target dose of 60 mg QD. The present study was conducted to evaluate further the efficacy and safety of duloxetine 30 mg QD dose in adult patients with FM with or without MDD.

Methods: This study was a double-blind, randomized, placebo-controlled, fixed dose 12-week trial of duloxetine 30 mg QD. Key inclusion criteria included fibromyalgia as defined by the American College of Rheumatology (1990) with or without MDD and baseline ratings of ≥4 on the average pain severity of the Brief Pain Inventory-Modified Short Form (BPI), which was the primary measure of efficacy. Secondary measures included the Patient Global Impressions of Improvement (PGI-I), the Fibromyalgia Impact Questionnaire (FIQ) total score, and response rate (>=30% or 50% reduction in BPI average pain). Discontinuation rates and treatment-emergent adverse events were also assessed.

Results: Of the 308 patients randomized, 155 received duloxetine and 153 received placebo. The mean age was 50.80 years and 95% of the patients were female. Duloxetine- treated patients did not have statistically significant BPI average pain reduction compared with placebo-treated patients (−2.04 vs. −1.70 respectively, $P = .202$). There was a significant improvement in duloxetine-treated patients compared with placebo-treated patients assessed by PGI-I endpoint score (2.97 vs. 3.35 respectively, $P = .019$) and the change from baseline to endpoint on FIQ total score (−14.62 vs. −9.75 respectively, $P = .009$). There were no significant differences between duloxetine- and placebo-treated patients in the 30% response rate at endpoint (49.7% vs. 43.1% respectively, $P = .238$) and the 50% response rate at endpoint (36.6% vs. 35.9% respectively, $P = .902$). The number of patients who completed the study did not differ between duloxetine and placebo treatment groups (78.1% vs. 71.9% respectively, $P = .237$), and nausea was the most common (>1%) adverse event leading to discontinuation

(1.3% vs. 0.7% respectively, $P = 1.00$).Treatment-emergent adverse events experienced by ≥5% of LY2216684-treated patients and at least twice the incidence experienced by placebo-treated patients were nausea, dry mouth, somnolence and insomnia.

Conclusion: The primary result of the study did not demonstrate the analgesic effect of the duloxetine 30 mg QD in the treatment of fibromyalgia with or without MDD. Duloxetine 30 mg QD was generally well tolerated, and there were no new safety issues identified.

1917

Therapeutic Massage on Pain Relief for Fibromyalgia: A Systematic Review and Meta-Analysis. Lingjun Kong[1], Raveendhara R. Bannuru[2], Weian Yuan[1], Ying-wu Cheng[1], Min Fang[1], Timothy McAlindon[2] and Chenchen Wang[2]. [1]Shanghai University of Traditional Chinese Medicine of Yueyang Hospital, Shanghai, China, [2]Tufts Medical Center, Boston, MA

Background/Purpose: Therapeutic Massage is widely used for musculoskeletal pain relief in Asia, yet evidence of its effect for fibromyalgia (FM) is scarce. A comprehensive review of the literature is an important step for understanding the benefits of Therapeutic Massage in FM. We systematically review literature for the effect of Therapeutic Massage on pain in subjects with FM.

Methods: We performed a comprehensive search of 6 Eastern and Western databases and reference lists from published articles through June 2011. We included randomized controlled trials (RCTs) and non-randomized studies with Therapeutic Massage for FM. The FM Impact Questionnaire (FIQ) or VAS was evaluated as an endpoint. We also reviewed the treatment effect on depression, stiffness and sleep quality. Study quality was assessed with Jadad criteria assessing randomization, blinding and drop out rates for each study. The differences between treatment groups were reported as mean change (95% CI, p-value). We also performed a meta-analysis for the effects of Therapeutic Massage on FM pain of the 4 RCTs which provided sufficient quantitative data.

Results: We identified 102 potentially relevant studies. Ten studies (7 RCTs) with a total of 372 subjects (76% female) met eligibility criteria. Mean age was 47 and mean symptom duration was 10 years. Of those, 3 trials used Swedish massage, 3 used Chinese massage (Tuina) and 4 used other massage methods.

Table 1 summarizes the RCTs evaluating the effect of Therapeutic Massage on FM pain (VAS scale). Mean treatment duration was 8 weeks (range 3–24). The overall quality of RCTs was modest (mean Jadad score=1.9). All studies reported an association between the therapeutic massage and improved clinical symptom of pain. The meta-analysis results showed that 4 studies with 3 to 10 weeks of therapy had a decrease in pain versus either other therapies or no treatment controls. The pooled effect size was −0.92 (95% CI, −1.28 to −0.56) favoring therapeutic massage. In addition, 4 studies reported an improvement in stiffness measured with FIQ. 3 studies reported an improvement in depression. No adverse events were reported.

Table 1. Randomized Controlled Trials Evaluating the Effect of Therapeutic Massage on FM

Author, yr Country	Age*	N	Therapeutic massage (Dose: #times/ #sessions)	Control (Dose: #times/ #sessions)	Duration (weeks)	Pain VAS Mean difference (95% CI)*	P-value	Quality (Jadad)
#Sunshine 1996 US	50	30	Swedish massage (30 min/ 10 sessions)	1) TENS	5	1) vs. TENS ↓3.1[b]	<0.05	4
				2) Sham TENS (30 min/ 10 sessions)		2) vs. Sham TENS ↓1.6[b]	<0.05	
Blunt 1997 Canada	49	21	Chiropractic management (12–24 sessions)	Standard care	4	↓13.3	ND	3
#Brattberg 1999 Sweden	48	52	Connective tissue massage (15 sessions)	Standard care	10	↓27.7 (24.3, 31.0)	0.006	2
Alnigens 2001 US	46	37	Swedish massage (45 min/ 10 sessions)	1) Standard care	24	1) vs. Standard care ↑0.12[b]	>0.05	1
				2) Standard care and telephone		2) vs. Standard care and telephone ↑0.2[b]	>0.05	
#Field 2002, US	51	254	Swedish massage and Shiatsu (30 min/ 10 sessions)	Progressive muscle relaxation (30 min/ 10 sessions)	5	↓ 0.9 (00, 1.8)	ND	2
Tang 2009 China	ND	60	Massage in pain spots (15 min/ 9 sessions)	Chinese classical massage (Tuina) (15 min/ 9 sessions)	3	↓ 0.9 (0.5, 1.3)	<0.01	2
#Wang 2010 China	40	90	Chinese classical massage (Tuina) (1 hr/ 20 sessions)	1) Acupuncture (30 min/ 20 sessions) 2) Amitriptyline hydrochloride	3	1) vs. Acupuncture ↓18.8 (15.1, 22.5) 2) vs. Amitriptyline	ND	1

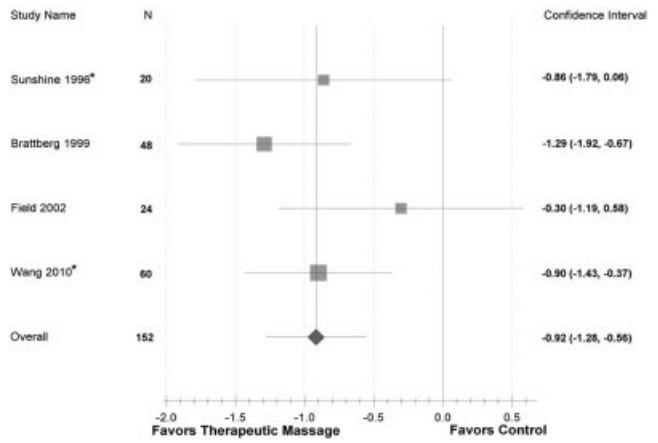

Figure 1. Meta-analysis for Effects of Therapeutic Massage on Pain of FM

Conclusion: The current body of evidence suggests that Therapeutic Massage may be helpful in the treatment of pain due to FM. The studies are very heterogeneous, and there is insufficient evidence for a definitive conclusion. Rigorous and well-controlled randomized trials are warranted.

Proteomic Profiling Following Immunoaffinity Capture of HDL Identifies Association of Acute Phase Proteins and Complement Factors with Pro-Inflammatory HDL in Rheumatoid Arthritis. Christina Charles-Schoeman[1], Yunan Miao[2], Junji Watanabe[3], Yuen Yin Lee[4], George Katselis[2], Terry D. Lee[2] and Srinivasa T. Reddy[3]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Beckman Research Institute of the City of Hope, Duarte, CA, [3]UCLA, Los Angeles, [4]UCLA, Los Angeles, CA

Background/Purpose: To utilize proteomic analysis to identify protein biomarkers associated with pro-inflammatory HDL in patients with active rheumatoid arthritis.

Methods: Liquid chromatography-mass spectrometry (LC-MS) was used to analyze proteins associated with immunoaffinity purified HDL from plasma of two sets of RA patients carrying distinct HDL (anti- or pro-) inflammatory properties (n=4 per group). Proteins were fractionated by Offgel electrophoresis and analyzed by LC-MS/MS equipped with a high capacity high performance liquid chromatography chip (HPLC-Chip) incorporating C18 reverse phase trapping and analytical columns. iTRAQ™ 8-plex reagent kit was used to test all eight HDL samples from RA patients in a single experiment. Sandwich enzyme-linked immunosorbent assays were used to validate select HDL-associated proteins in a second RA cohort (n=31).

Results: Seventy-eight proteins were identified in the HDL complexes. Twelve proteins were significantly increased in RA patients with pro-inflammatory HDL compared to RA patients with anti-inflammatory HDL.These proteins included acute phase proteins, including apolipoprotein J, fibrinogen, haptoglobin, serum amyloid A, and complement factors (B, C3, C9). Four of the proteins associated with HDL were validated in a second RA cohort.

Conclusion: Pro-inflammatory HDL in patients with RA contains a significantly altered proteome including increased amounts of acute phase proteins and proteins involved in the complement cascade. These findings suggest that HDL is significantly altered in the setting of chronic inflammation from active RA with resultant loss of its anti-inflammatory function. Since the inflammatory nature of HDL has previously been directly linked to CVD, and is also significantly correlated with disease activity in RA, characterization of the biomarkers reported here may identify novel molecular connections that contribute to the higher risk of CVD in RA patients.

1919

Association Between Interferon Alpha Gene Expression and Disease Characteristics in Systemic Lupus Erythematosus. Michelle Petri[1], Hong Fang[1], Wenzheng Hu[1], Jadwiga Bienkowska[2], Norm Allaire[2], John Carulli[2] and Matthew D. Linnik[3]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Biogen Idec Inc., Cambridge, MA, [3]Biogen Idec Inc., Solana Beach, CA

Background/Purpose: The interferon alpha gene signature occurs in 50 to 70% of SLE patients and has been strongly associated with ENA (Ro, La, RNP). We investigated the association of the IFN gene signature in a cohort of Caucasian and African-American patients.

Methods: 272 SLE patients (92% female, 59% Caucasian, 33% African-American, mean age 46.0 years) were enrolled in a prospective observational study. At baseline, the IFN gene signature was determined in peripheral blood RNA using Affymetrix chips, and was divided into low (<8, 42.6%) and high (≥8, 57.4%) groups. Clinical associations, based on the cumulative history and the same-day visit disease activity, were then determined. The results were based on the chi-square test (SAS Institute, Cary, NC, USA). P-values were then adjusted for race. A p-value ≤0.05 was considered statistically significant.

Table 1. Association between ACR criteria and IFN signature in SLE

Variable	Low IFN (%, N=116)	High IFN (%, N=156)	P-value	Adjusted P-value for Race
Malar rash	52.3	51.9	0.91	0.82
Discoid rash	14.7	19.2	0.32	0.30
Photosensitivity	58.6	51.3	0.23	0.45

Low C3	42.2	66.7	<.0001	0.0011
Low C4	32.8	58.3	<.0001	0.0002

Table 3. Association between same-day visit disease activity and IFN signature in SLE

Variable	Low IFN (%, N=116)	High IFN (%, N=156)	P-value	Adjusted P-value[§]
Physician Global Assessment (>1)	12.9	23.1	0.034	0.19
SLEDAI ('2)	46.6	66.7	0.0009	0.004
Modified SLEDAI* (>1)	34.5	46.8	0.042	0.2
Age at visit (years)				
≤ 30	7.8	15.4	0.057	0.17
> 30	92.2	84.6		
Urine Protein/Creatinine Ratio (≥0.5)	6.9	13.5	0.083	0.70
Anti-dsDNA	7.8	33.3	<.0001	<.0001
Low C3	5.2	18.0	0.0016	0.0012
Low C4	5.2	16.0	0.0053	0.0032
ESR (>20)	40.4	58.4	0.0034	0.034

* Modified SLEDAI (SLEDAI without low complement or anti-dsDNA)
§ Adjusted for race unless specified
£ Adjusted for race, prednisone dose and immunosuppressive (yes/no)

Table 4. Association between SLICC/ACR Damage Index and IFN signature in SLE

Variables	Low IFN (%, N=116)	High IFN (%, N=156)	P-value	Adjusted P-value for Race
Cataract	31.0	16.0	0.0033	0.0027
Cognitive impairment	12.9	5.1	0.022	0.02
Valvular disease	6.0	1.3	0.03	0.06
Muscle atrophy or weakness	5.2	1.3	0.076	0.068
AVN	7.8	17.4	0.02	0.018

Results: The high interferon alpha signature group was associated with non-Caucasian race, younger age, autoantibodies, and low complement. Clinical associations included leukopenia and pericarditis. The high IFN signature was not associated with clinical disease activity at the same day, once low complement and anti-dsDNA were removed from the SLEDAI.

Conclusion: IFN signature was strongly associated with Coombs positivity, leukopenia, autoantibodies, and low complement, but not with clinical disease activity. Surprisingly, SLE patients with this signature had a lower risk of developing some organ damage including cataract, cognitive impairment, valvular disease, and muscle atrophy/weakness.

1920

Association Between Plasma Cell Gene Signature and Disease Characteristics in Systemic Lupus Erythematosus. Michelle Petri[1], Hong Fang[1], Jie Xu[1], Wenzheng Hu[1], Ehtisham Akhter[1], Jadwiga Bienkowska[2], Norm Allaire[2], John Carulli[2], Laurence S. Magder[3] and Matthew D. Linnik[4]. [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Biogen Idec Inc., Cambridge, MA, [3]University of Maryland, Baltimore, MD, [4]Biogen Idec Inc., Solana Beach, CA

Background/Purpose: B cells, circulating plasma cells and tissue resident plasma cells contribute to the production of autoantibodies in SLE. The plasma cell populations have been suggested as an attractive therapeutic target. We investigated the association between clinical phenotype and circulating plasma cell signature in SLE.

Methods: 292 SLE patients (91% female, 59% Caucasian, 34% African-American, mean age 46.0 years) were enrolled in a prospective observational study. At baseline, the plasma cell gene signature (IGJ and TXNDC5) was determined in peripheral blood RNA using Affymetrix chips, and was divided into low (<7, 43.2%), medium (7 to 8, 28.4%) and high (>8, 28.4%) groups. Clinical associations, based on the cumulative history and the same-day visit disease activity, were then determined. The results were based on the chi-square test (SAS Institute, Cary, NC, USA). P-values were then adjusted for race. A p-value ≤0.05 was considered statistically significant.

Table 1. Association between cumulative history characteristics and plasma cell signature in SLE

Variable	Low PC (<7) (%, N=126)	Med PC (7–8) (%, N=83)	High PC (>8) (%, N=83)	P-value	Adjusted P-value for Race

Anti-RNP	19.8	23.2	33.7	0.07	0.47
Low C3	52.4	53.0	65.1	0.15	0.17
Low C4	43.7	42.2	56.6	0.11	0.11
Increased ESR	68.3	69.9	80.7	0.12	0.51

Table 2. Association between same-day visit disease activity and plasma cell signature in SLE

Variable	Low PC (<7) (%, N=126)	Med PC (7–8) (%, N=83)	High PC (>8) (%, N=83)	P-value	Adjusted P-value for Race
Physician global assessment >1	19.1	14.5	22.9	0.38	0.46
SLEDAI ≥2	53.2	55.4	66.3	0.16	0.53
Immunosuppressive use	45.2	22.9	32.5	0.0035	0.0008
Prednisone use	42.1	30.1	30.1	0.11	0.025
NSAID	27.0	31.3	15.7	0.053	0.079
Statin	31.0	15.7	16.9	0.012	0.039

Table 3. Association between SLICC/ACR Damage Index and plasma cell signature in SLE

Variable	Low PC (<7) (%, N=126)	Med PC (7–8) (%, N=83)	High PC (>8) (%, N=83)	P-value	Adjusted P-value for Race
Cranial/peripheral Neuropathy	14.3	10.8	3.6	0.045	0.045
Deforming/Erosive arthritis	5.8	11.1	0.0	0.0093	too few

Results: Elevated plasma cell gene signature was associated with leukopenia, anti-Ro, anti-La and the lupus anticoagulant, but not with the same day clinical activity by PGA or SLEDAI. It was negatively associated with neuropathy and arthritis damage but not associated with other organ damage (not shown in the table). Treatment with prednisone, immunosuppressive drugs and statins was associated with lower plasma cell gene signature.

Conclusion: Surprisingly, the plasma cell signature was not associated with a more severe clinical activity phenotype, but with leukopenia and ENA. Immunosuppressive, prednisone and statin therapy was associated with lower plasma cell gene signature. The lack of association with clinical activity calls into question whether circulating plasma cells are the optimum therapeutic target in SLE. However, our assay does not account for tissue resident plasma cells.

1921

Narrowing the *Protein Tyrosine Phospahatse-22* Locus in Mice with Cartilage Proteoglycan-Induced Arthritis Explores Disease-Promoting and Disease-Suppressive Sub-Loci Neutralizing Their *In Vivo* Arthritis Susceptibility and Severity. Timea Besenyei[1], Andras Kadar[1], Beata Tryniszewska[1], Vyacheslav A. Adarichev[2], Katalin Mikecz[1] and Tibor T. Glant[1]. [1]Rush University Medical Center, Chicago, IL, [2]Albert Einstein College of Medicine, Bronx, NY

Background/Purpose: Genome-wide screening of cartilage proteoglycan (PG)-induced arthritis (PGIA) in six different genetic combinations explored 29 QTLs (*Pgia1-Pgia29*), of which 8 showed high correlations with other arthritis models and GWAS of RA. We have selected *Pgia 26* locus on chromosome 3 (Chr3), because this is one of the most complex traits (after the MHC) regulating arthritis susceptibility and severity both in RA (*PTPN22* locus on human Chr1) and in PGIA (*Pgia26*). (Another study targets the Traf1/C5 locus on mouse Chr2 syntenic with human Chr9.) The goal was to narrow mouse Chr3 to as small as possible for candidate gene selection. Our hypothesis was that certain genes associated with these loci in murine autoimmune arthritis (PGIA) will correspond to genes involved in RA.

Methods: To achieve these goals, we intentionally excluded MHC (intercrossing arthritis–susceptible BALB/c and arthritis-resistant DBA/2 strains, both having the same H2d MHC), and replaced the entire genome with arthritis-prone BALB/c (congenic/sub-congenic stains) except the DBA/2 region of Chr3 (*Pgia26*).

Results: Eight subcongenic strains (n=355 animals) from Chr3 congenic (DBA/2 92.7–130 Mbp) and WT (n =102) mice were immunized for PGIA, scored, and serum markers such as autoantibodies (RF, ACPA, anti mouse PG), cytokines, *in vitro* T cell responses (PG-specific proliferation and cytokine production) were tested to select regions for further narrowing using interval-specific subcongenic strains.

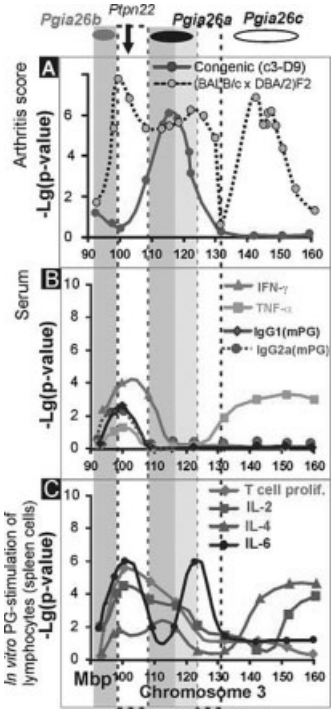

Figure 1. Linkage analysis for clinical and immune parameters in chr3 sub-congenic strains. Associations between traits and genotypes are presented as negative logarithms of p-values after Mann-Whitney U test [-Lg (p-value) on y-axis] (**Panels B and C**). Only traits (markers) that showed an association greater than $p < 0.01$ [-Lg (p-value) >2] are shown. Vertical shadowed areas indicate intervals of chr3 that were found to be associated with either arthritis promoting (*Pgia26b*) or arthritis suppressive (*Pgia26a*) effects using three independent analyses. Although we have localized the two major *Pgia26* loci, The intermediate region between the loci, however, does not seem to be "silent" either (white area throughout Fig. 1A–C).

Conclusion: We were able to distinguish between (i) a disease promoting region (both susceptibility and severity)(Pgia26b, Chr3: 92.799.5Mbp, approximately 40 genes in both human and mouse genomes), (ii) a disease suppressive locus (Pgia25a: Chr3: 109.2–115.8, ~20 genes) and (iii) regions appearing to control antigen (PG)-specific cytokine production and T cell proliferation (Fig. 1). The reduction of the sizes of these three "subloci" are in progress, and interval-specific subcongenic breeding pairs are established.

1922

Identification of microRNA-31 as a Novel Regulator Contributing to Impaired IL-2 Production in T cells From Patients With Systemic Lupus Erythematosus. Wei Fan[1], Yuanjia Tang[1], Bo Qu[1], Huijuan Cui[1], Xinfang Huang[1], Brandon W. Higgs[2], Yihong Yao[2], Bahija Jallal[2] and Nan Shen[1]. [1]Shanghai Ren Ji Hospital, Shanghai, China, [2]MedImmune, Gaithersburg, MD

Background/Purpose: MicroRNAs (miRNAs) act as fine tuner in the control of immune cells signaling. It was well-established as the abnormalities in signaling pathways related to interleukin(IL)-2 defect in lupus. miR-31 was identified as one of markedly underexpressed miRNAs in lupus patients. This study is aimed to investigate its role on IL-2 defect in lupus patients.

Methods: Quantitative analysis of miR-31 expression was done by TaqMan miRNA Assays. Transfection and stimulation of cultured cells followed by TaqMan qPCR, ELISA and reporter gene assays were conducted to determine the function of miR-31. Bioinformatics analysis, siRNA knockdown and western blotting were performed to validate miR-31 target and its function.

Results: miR-31 expression was significantly decreased and positively correlated with IL-2 expression in lupus T cells. Enforced expression of miR-31 in T cells increased, while knockdown of endogenous miR-31 reduced IL-2 production through changing the IL-2 promoter activity. RhoA as a miR-31 potential target was repressed by miR-31 in T cells. Of

note, siRNA-mediated knockdown of RhoA enhanced the IL-2 promoter activity then up-regulated IL-2 production. Consistently we also observed that RhoA expression was up-regulated and negatively correlated with miR-31 levels in lupus T cells. More importantly, manipulation of miR-31 expression in lupus T cells could restore IL-2 expression at both mRNA and protein level.

Conclusion: Our study reveals that miR-31 as a novel regulator can enhance the IL-2 production during T cell activation. Dysregulation of miR-31 and its target RhoA could be a novel molecular mechanism underlining deficiency of IL-2 in lupus patients.

1923

The Passenger Strand of MicroRNA-34a Is Epigenetically Silenced in Rheumatoid Arthritis Synovial Fibroblasts and Mediates Apoptosis Resistance Via Failure of XIAP (X-linked inhibitor of apoptosis protein) Inhibition. Fabienne Niederer[1], Caroline Ospelt[1], Joanna Stanczyk[2], Michelle Trenkmann[2], Emmanuel Karouzakis[2], Meike Dahlhaus[2], Beat A. Michel[2], Christoph Kolling[3], Renate E. Gay[2], Steffen Gay[2], Astrid Juengel[2] and Diego Kyburz[2]. [1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Center of Exp. Rheumatology, Zurich, Switzerland, [3]Schultess Clinic, Zurich, Switzerland

Background/Purpose: Synovial fibroblasts (SF) from patients with rheumatoid arthritis (RA) are considered to be key effector cells as they are linked to synovial hyperplasia due to their apoptosis resistant phenotype. We have noted that the passenger strand of microRNA-34a (miR-34a*) is less expressed in SF from patients with RA compared to osteoarthritis (OA) and that it can modulate apoptosis. Therefore, we assessed the regulatory mechanisms accounting for the altered expression of miR-34a* and analyzed how miR-34a* influences apoptotic pathways in RASF.

Methods: Total RNA was isolated from RASF and OASF (n=8 each) using the mirVana miRNA isolation kit and human miR-34a* expression was determined using TaqMan Real-time PCR analysis. To study the regulation of miR-34a* in RASF, we treated cells with the cytokines TNF-α (10 ng/ml, n=7) and IL-1β (1 ng/ml, n=4), as well as with different ligands for Toll-like receptors (TLR) such as bLP (TLR2, 300 ng/ml, n=4), pIC (TLR3, 10 μg/ml, n=5) or LPS (TLR4, 10 ng/ml, n=4) for 2, 8 or 24 hours. For methylation studies, the inhibitor of DNA methyltransferase, 5-azacytidine (5-aza), was added to the cell culture medium at a concentration of 0.1 or 1 μM for 7 days (n=6). Synthetic precursors (pre-miRs) and inhibitors (anti-miRs) for miR-34a* were used to study the effect of miR-34a* on the expression of XIAP after 72 hours by SYBR green Real-time PCR (n=5). Furthermore, apoptosis induction was assessed by Flow Cytometry 72 hours post transfection to study the influence of miR-34a* overexpression on FasL (200 ng/ml, n=6) and TRAIL (20 ng/ml, n=4) induced apoptosis in AnnexinV/PI stained RASF. Activation of caspase 3 was assessed by a colorimetric caspase 3 activity assay (Abnova) in miR-34a* overexpressing RASF (n=3).

Results: Neither TNF-α, IL-1β nor the different TLR ligands were found to influence the expression of miR-34a*. However, demethylation of RASF by 5-aza treatment strongly modulated the expression of miR-34a*, resulting in a 70 % induction of miR-34a* compared to untreated cells ($p<0.05$). Most interestingly, we detected miR-34a* to further enhance apoptosis in FasL (from 25 to 40%, $p<0.05$) as well as in TRAIL (from 15 to 20%, $p<0.05$) stimulated RASF compared to control transfected cells. Similarly, we found that overexpression of miR-34a* resulted in a 1.9 fold induction of FasL induced caspase 3 activation. We could further show that this pro-apoptotic effect of miR-34a* was dependent on the apoptosis inhibitor XIAP, as transfection of RASF with pre-miR-34a* and anti-miR-34a* resulted in 39 $\pm$ 26% reduced and 90 $\pm$ 52% increased mRNA levels of XIAP, respectively ($p<0.05$).

Conclusion: So far, research has focused on mature miRNA strands whereas the function of passenger miRNA strands has not been analyzed in RA. Our data provide for the first time evidence that the passenger strand of miR-34a is epigenetically silenced in RASF and is involved in the modulation of apoptosis pathways. As miR-34a* was found to be down regulated in RASF, it fails to effectively inhibit the apoptosis inhibitor XIAP, thereby resulting in reduced activation of caspase 3, thus contributing to the apoptosis resistant phenotype of RASF.

1924

Adoptive Transfer of Induced-Regulatory T Cells Effectively Attenuates Murine Airway Allergic Inflammation. Qin Lan[1], Wei Xu[2], Julie Wang[1], Hui-Ming Fan[3], Bernhard Ryffel[4], Wei Shi[2] and Song G. Zheng[5]. [1]University of Southern California, Los Angeles, CA, [2]The Saban Rrsearch Institute of Children's Hospital Los Angeles, [3]Shanghai East Hospital, Tonji University, Shanghai, China, [4]University and CNRS, 3b rue de la Ferollerie, F-45071 Orleans, France, [5]USC Keck School of Medicine, Los Angeles, CA

Background/Purpose: Both nature (nTreg) and induced-regulatory T cells (iTreg) are potent regulator of autoimmune and allergic disorders. Defects in Treg cells have been reported in patients with allergic asthma, and therefore replenishment of Treg cells might attenuate asthma. Here we investigated if adoptive transfer of iTreg cells generated ex-vivo could attenuate lung and airway allergic inflammation in murine model of asthma.

Methods: Naïve CD4+ T cells purified from spleen in C57BL/6 mice, were activated with anti-CD3/CD28-coated beads (1 bead: 3 cells) and IL-2 (50U/ml), in the presence (iTregs) or absence (CD4 control) of TGF-β (2ng/ml). C57BL/6 mice were immunized with OVA mixed with aluminum hydroxide (day 0) and challenged with OVA control through an intranasal (i.n.) route for three consecutive days (days 25, 26, and 27) to generate an acute allergic asthma model. 5×10^6 of iTreg cells or control cells were intravenously injected into mice on day 22, three days before antigen challenge. Pathological changes in airway and lung were observed by H&E, Discombe's Solution and Periodic-Acid-Schiff (PAS) staining. The intracellular expression of Foxp3, IFN-γ, IL-5 and IL-17 in CD4+ cells in spleens and draining lymph nodes was examined by flow cytometry. IgE in peripheral blood serum was measured by enzyme linked immunosorbent assay.

Results: Immunized mice given iTreg cells just before antigen challenge displayed markedly reduced airway résistance, eosinophil recruitment, mucus hyper-production, airway remodeling and IgE levels. This therapeutic effect was associated with increase of Treg cells ($CD4^+FoxP3^+$) in the draining lymph nodes, and with reduction of Th1, Th2, and Th17 cell response as compared to untreated and non-Treg cell treated controls.

Conclusion: Therefore, adoptive transfer of iTreg reduces the allergic response, which might be a novel and promising therapeutic approach to treat severe asthma.

1925

Correlations Between S100 Gene Expression Levels and the Local and Systemic Inflammatory Markers (matrix metalloproteinase-3, MMP3; erythrocyte sedimentation rate, ESR) in Rheumatoid Arthritis Patients. Hooi-Ming Lee[1], Hidehiko Sugino[1], Chieko Aoki[2], Miho Murakami[2], Takaji Matsutani[2], Takahiro Ochi[3] and Norihiro Nishimoto[2]. [1]Osaka University, Suita, Japan, [2]Wakayama Medical University, Ibaraki, Japan, [3]Osaka Police Hospital, Osaka, Japan

Background/Purpose: In humans, the S100 protein family is composed of at least 24 members and is thought to be involved in cell proliferation and differentiation via calcium regulation. Overexpressions of several S100 proteins have recently been reported in rheumatoid arthritis (RA). Thus, we performed a comprehensive gene expression analysis in RA patients to investigate the S100 gene expression levels and further investigating the correlations with clinical and laboratory markers.

Methods: Gene expression profiles of the peripheral blood from 112 RA patients with active disease (DAS28, 6.2 $\pm$ 0.9; CRP, 32 $\pm$ 24 mg/l; MMP3, 308.2 $\pm$ 225.3 ng/ml; ESR, 51.9 $\pm$ 26.1 mm/h; mean $\pm$ SD) and 45 healthy individuals (HI) were obtained using DNA microarray. S100 gene expressions were compared between the two groups using unpaired Mann-Whitney test. Clinical and laboratory markers including DAS28, serum MMP3 levels, and ESR of RA patients were obtained and correlations between expression levels of differentially expressed S100 genes and each marker were investigated using Spearman's rank correlation.

Results: The expressions of fifteen S100 genes were investigated. *S100A4, S100A5, S100A6, S100A9, S100A11*, and *S100A12* are significantly overexpressed in RA patients ($P<0.0005$). *S100G* were also increased ($P<0.005$) while *S100A2, S100A13, S100A16*, and *S100B* were underexpressed ($P<0.05$). There were no correlations between the expression levels of differentially expressed S100 genes and DAS28. However, the expression levels of *S100A6* and *S100A9* were found significantly correlated to MMP3 levels (Spear r = 0.25, 0.24, respectively; $P<0.05$), which may reflect joint inflammation and it is reported to be valuable for predicting bone damage progression, especially in the

early stage of RA, and *S100A12* was correlated to ESR, an inflammatory marker (Spear r = 0.21; $P < 0.05$).

Conclusion: We confirmed the previously described up-regulation of *S100A4* and *S100A12*, and also newly found up-regulation of *S100A5, S100A6, S100A9*, and *S100A11* in RA patients' peripheral blood. Correlation of *S100A6* /*S100A9* expression levels and serum MMP3 levels; *S10012* expression levels and ESR suggested their roles in inflammatory conditions in RA.

1926

Proteomic Characterization of Plasma Microparticles in Autoimmune Diseases. Christoffer T. Nielsen[1], Ole Østergaard[1], Line V. Iversen[1], Søren Jacobsen[2] and Niels H.H. Heegaard[1]. [1]Statens Serum Institut, Copenhagen S, Denmark, [2]Rigshospitalet - 4242, Copenhagen, Denmark

Background/Purpose: Circulating cell-derived microparticles (MPs) are a heterogenous population of submicron membraneous vesicles shedded from the cell-surface involved in cell-cell communication and immune regulation. We explored differences on the proteome level between MPs isolated from well-characterized patients with systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSc), and from healthy controls (HCs).

Methods: 12 SLE (6 active, 6 in remission), 6 RA (3 active, 3 in remission) and 6 SSc (3 with limited and 3 diffuse cutaneous SSc) patients were compared with 12 age- and gender-matched healthy controls. MPs from platelet-poor plasma were purified using centrifugation followed by tryptic digestion and analysis with liquid chromatography tandem mass spectrometry (LC-MS/MS) on an Orbitrap mass spectrometer. MP proteins were identified and spectral counts (SCs) were used as a semiquantitative measure of the abundance of each identified protein. Two independent statistical models, hierarchical clustering and principal component analysis (PCA) were applied to all the identified MP proteins and their associated SC values to search for disease classifiers.

Results: We identified a total of 343 unique protein entities in MPs. Of the, 143 were either membrane proteins or proteins otherwise associated with the cell membrane according to gene ontology analysis. 131 proteins represented extracellular proteins and included plasma proteins such as immunoglobulins, and other well-known opsonizing proteins including serum amyloid P component and C1q. Using both hierarchical clustering analysis and PCA, we were able to separate the different disease groups and identify several MP-associated disease classifying proteins as shown in Figure 1. Very high levels of MP-associated C1q and many forms of IgG and also galectin-3-binding protein, a protein mediating adhesion and sensing intracellular changes, were associated with MPs from the SLE group. Cytoskeletal proteins (multimerin-1 and myosin-9) and integrins (integrin-beta-3 and integrin alpha-IIb) were present in higher levels in the MPs from RA patients and HCs.

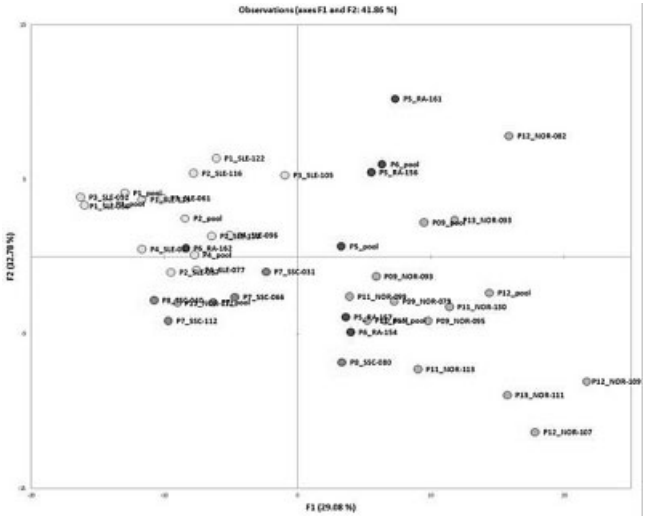

Figure 1.

Conclusion: Proteome analysis of plasma MPs in different autoimmune diseases reveals differentiating protein patterns with potential for biomarkers and supports MPs putative role in intercellular signalling and immune regulation.

1927

Feasibility of a Molecular Diagnosis of Arthritis Based on the Identification of Specific Transcriptomic Profiles in Knee Synovial Biopsies. Isabelle Focant[1], Daniel Hernandez-Lobato[2], Julie Ducreux[1], Patrick Durez[1], Adrien Nzeusseu Toukap[1], Dirk Elewaut[3], Frédéric. A. Houssiau[1], Pierre Dupont[2] and Bernard Lauwerys[1]. [1]Université catholique de Louvain, Brussels, Belgium, [2]Université catholique de Louvain, Louvain-La-Neuve, Belgium, [3]Gent University Hospital, Ghent, Belgium

Background/Purpose: Early diagnosis of arthritis is an "unmet medical need" in the field of rheumatology, as borne out by the number of publications addressing the issue. In particular, the delay in making a diagnosis of rheumatoid arthritis and initiating adequate therapy is associated with poor clinical, radiological and functional outcomes. In previous experiments, we performed transcriptomic studies on synovial biopsies from patients with arthritis using high-density oligonucleotide-spotted microarrays, and found that synovial gene expression profiles were significantly different according to the underlying disorder. Here, we wanted to explore whether these findings could translate into a useful diagnostic procedure.

Methods: Synovial biopsies were obtained from the knee of patients with a definite diagnosis of rheumatoid arthritis (1987 ACR criteria), seronegative arthritis or osteoarthritis (n=40), and from patients with undifferentiated arthritis (n=20). During each procedure, 6 to 8 biopsy fragments were stored overnight in RNALater at 4°, and next frozen at −80°. Biotinylated cDNA was synthesized and hybridized on customized low-density arrays, spotted with 100 diagnostic probes, house keeping genes and internal standards, in triplicates. Finally, the slides were scanned and the probe intensity data were collected for each sample. We performed the analyses by partitioning the microarray data into a training set and a testing set. The diagnosis of the samples in the testing set was generated using a nearest neighbor classification method, based on the Pearson correlation distance.

Results: In a first step of experiments, we looked whether the molecular diagnosis generated by the interpretation of the low-density microarray data matched the clinical diagnosis for the samples obtained from patients with a known diagnosis. We found that a right diagnosis was obtained in 73% of the samples. Because therapy can affect the gene expression profiles in the synovium and blur their diagnostic performances, we next restricted these analyses to the samples obtained from untreated patients. Doing this, we saw a slight improvement in the percentage of right molecular diagnoses, up to 75% of the cases. Next, we wondered whether addition of selected clinical symptoms could increase the accuracy of our model. Algorithms were developed that combine low-density array data and one or several relevant symptoms. Strikingly, the accuracy of the algorithm combining low-density expression data and 3 symptoms (presence of psoriasis, arthritis of the hands, presence of rheumatoid factors) was 92%. Finally, we performed the same analyses in 20 synovial samples obtained from UA patients. The combination of expression and clinical data resulted in a molecular diagnosis, which was confirmed in the 8 patients in whom a clinical diagnosis was made during the follow-up period after the biopsy.

Conclusion: Taken together, our data indicate that a diagnosis can be made in patients with UA based on the combination of gene expression data and selected clinical symptoms. As such, these results are particularly relevant from a clinical point of view, and open the perspective of valorization into a diagnostic test.

1928

Selective Inhibition of Epigenetic Factors Provide Potential New Tools for Arthritis Therapy. Timea Besenyei, Júlia Kurkó, Katalin Mikecz, Tibor T. Glant and Tibor A. Rauch. Rush University Medical Center, Chicago, IL

Background/Purpose: Rheumatoid arthritis (RA) is a degenerative inflammatory autoimmune disease that affects more than 1% of the human population. Currently, there is no ideal therapy for RA, but various types of treatments can provide alleviation of symptoms and modify disease progression. RA is considered to be a polygenic disease with strong immunogenetic components, because various immune cells (B and T lymphocytes, macrophages, dendritic cells) are involved. Besides of recently mapped genes, environmental factors can also contribute to the etiology of RA and increasing number of data proves that epigenetic factors are involved in autoimmune diseases. Therefore, enzymes that play roles in chromatin modification are plausible targets of RA therapy.

Methods: Applying specific *PCR arrays* we investigated the expression profile of 84 genes encoding key enzymes known to be specific modifiers of chromatin. Total RNA was isolated from lymphocytes from a murine model (proteoglycan-induced arthritis, **PGIA**) of RA and from mononuclear cells separated from RA patients and healthy controls.

Results: Fourteen chromatin modifying enzyme encoding genes showed arthritis-associated expression changes in arthritic mice. Six out of 14 genes showed elevated expression and eight were significantly down-regulated. Three of the up-regulated genes encode kinases involved in cell cycle regulation, while the other three are histone acetyltransferases. Application of selective kinase and acetyltransferase enzyme inhibitors was found to reduce the activity of the encoded enzymes and promote lymphocyte apoptosis both in ex vivo cell cultures and in vivo in arthritic mice. Preventive treatment of arthritis-prone mice and therapeutic treatment of established polyarthritis delayed the onset and attenuate severity of the arthritis.

Conclusion: Studies focused on human subjects revealed similar up-regulation of a set of enzymes in RA patients than in arthritic mice. Methotrexate (MTX) treatment lowered certain enzymes' expression levels in mononuclear cells of RA patients. Since MTX frequently does not provide ideal relief for RA patients, alternative treatment options including epigenetic enzyme inhibitiors can hold a great promise for next generation of RA therapies.

1929

Genome-Wide DNA Methylation Profiling Studies of Lymphocytes in Arthritic Mice. Tamas Kobezda[1], Katalin Olasz[2], Katalin Mikecz[1], Tibor T. Glant[1] and Tibor A. Rauch[1]. [1]Rush University Medical Center, Chicago, IL, [2]Pecs, Hungary

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disorder that mainly attacks synovial joints leading to inflammatory destruction of articular cartilage and bone. Although significant progress has been made in understanding of the genetics of the disease, a global characterization involving epigenomes in polyarthritis has not been yet performed. According to some recently published genome-wide DNA methylation study there is no detectable arthritis-associated DNA methylation changes in gene promoters in white blood cells. We challenged this observation by extending our genome-wide studies beyond the previously investigated CpG Islands.

Methods: Applying specific PCR arrays we investigated the expression profile of 84 genes encoding key enzymes known to be specific modifiers of chromatin. Total RNA and genomic DNA were isolated from lymphocytes from a murine model (proteoglycan-induced arthritis, **PGIA**) of RA and from mononuclear cells of RA patients and healthy individuals. DNA methylation alterations associated with the pathogenesis of arthritis was detected by Methylated CpG Island Recovery Assay (MIRA)-on-chip technique, and the accompanying gene expression changes were monitored by quantitative RT-PCR.

Results: PCR array studies identified eight genes showed arthritis-specific down-regulation in PGIA mice. Interestingly, enzymes involved in gene silencing were among the down-regulated genes including three DNA methyltransferases (Dnmts) and two histone deacetylases (Hdacs). Decreased expression of Dnmts is followed by a global demethylation in the lymphocyte epigenomes as we detected by an anti-5-methyl-citosin-based ELISA. To identify the exact genomic location of arthritis-associated hypomethylations we investigated all annotated mouse promoters and CpG islands by MIRA-on-chip method. The identified hypomethylated events were mostly localized outside of the CpG islands, in the so called, "CpG island shores". The detected demethylation was mostly followed by increased expression one of the nearby located genes. We further investigated expression changes of DNMTs in human mononuclear cells and found similar level of down-regulation of the above-mentioned genes than in PGIA model. This observation is a good promise to identify RA-specific DNA methylation changes in the human genome.

Conclusion: Arthritis-associated DNA methylation changes do exist and promote altered expression of genes. Our data shed light onto the molecular background of the known activated state of lymphocytes in arthritis, in the sense, that the low or inefficient expression of the inhibitors (i.e., DNMTs and HDACs) can contribute to the pathogenesis of RA.

1930

The *De Novo* Revision of TCRα but Not TCRβ Is Responsible for the Generation of Autoantibody-Inducing CD4$^+$ (*ai* CD4$^+$) T Cell That Causes Systemic Autoimmunity. Kenichi Uto[1], Ken Tsumiyama[1] and Shunichi Shiozawa[2]. [1]Kobe University Graduate School of Health Science, Kobe, Japan, [2]Kobe University Graduate School of Health Science and Medicine/ The Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan

Background/Purpose: We have repeatedly immunized mice normally not prone to autoimmune disease with the same antigen, and show that repeated immunization reproducibly causes systemic autoimmunity, i.e., systemic lupus erythematosus (SLE) (Tsumiyama K. *et al. PLoS ONE 4(12):e8382, 2009). Our studies show that autoantibodies are induced via de novo* T cell receptor (TCR) revision at periphery in spleen, giving rise to a novel T cell type we term an autoantibody-inducing CD4$^+$ T cell (*ai* CD4$^+$ T cell). The *ai* CD4$^+$ T cell not only stimulated B cells to generate varieties of autoantibodies but also helped final differentiation of CD8$^+$ T cell into cytotoxic T lymphocyte (CTL) *via* antigen cross-presentation to induce lupus tissue injuries. Here we investigated how *ai* CD4$^+$ T cell was generated in view of V(D)J recombination. The result showed that *ai* CD4$^+$ T cell was induced by *de novo* revision of TCRα but not TCRβ at periphery in spleen.

Methods: BALB/c mice were repeatedly immunized with staphylococcul enterotoxin B (SEB) by means of i.p. injection every 5 days. Expression of recombination-activating gene (RAG) 1/2, terminal deoxynucleotidyl transferase (TdT) and surrogate TCRα chain (pTα) in spleen were determined by using RT-PCR. GFP-positive cells in splenic Vβ8$^+$CD4$^+$ T cells of *rag1/gfp* knock-in mice were detected by using FACS. The rearranged intermediates of TCRα joining (Jα) regions from 1 to 61 and all TCRβ variable (Vβ) and diversity (Dβ) regions, which were blunt-ended DNA fragments flanked by recombination signal sequences, were detected in spleen by using ligation-mediated PCR. The histone modifications of TCR loci were examined by using ChIP assay.

Results: The V(D)J recombinase complex including RAG1/2, TdT and pTα was re-expressed in splenic T cells after immunization 8x with SEB. Expression of RAG1 gene was confirmed *in vivo* in *rag1/gfp* knock-in mice. Among varieties of Jα genes, the rearranged intermediate of TCR Jα12 gene was solely and specifically detected in splenic Vβ8$^+$CD4$^+$ T cells after immunization 8x with SEB. The studies encompassing gene regions Vβ2, 4, 16, 10, 1, 5.2, 8.3, 5.1, 8.2, 8.1, 13, 12, 11, 9, 6, 15, 20, 3, 7, 18, and 14 and Dβ1 and 2 genes, showed that rearranged intermediates of TCR Vβ and Dβ were never detectable, indicating that *de novo* revision of TCRα but not TCRβ takes place in spleen. Further, histone H3 of TCR Jα and Dβ regions but not TCR Vα and Vβ regions in splenic CD4$^+$T cells was heavily acetylated and trimethylated to the levels identical to those in thymus, indicating that the DJ region of splenic CD4$^+$T cells is constantly open to RAG1/2 and ready for TCR revision in terms of chromatin structure. The results indicate that these exists selection only for Jα chain to Jα12.

Conclusion: We show that the autoreactive (autoantibody-inducing) TCR of *ai* CD4$^+$ T cell is Jα12Vβ8 when SEB was used as a driving antigen. In view of our novel self-organized criticality theory, the structure of autoreactive TCR of *ai* CD4$^+$ T cell differs depending on driving antigen, which we investigate further. As to why TCRβ is not revised, possible explanations would be feedback inhibition of TCRβ but not TCRα revision because of locus conformation and subnuclear localization of TCRβ locus, or structural constraints of TCRβ chain against TCRα chain.

1931

The Transcriptomic Analysis From PBMC Is a Powerful Approach to Identify Specific Signatures Able to Predict Responses for Each TNFalpha Blocking Agent. Romain Normand[1], Olivier Vittecoq[2], Martine Hiron[1], Céline Derambure[1], Xavier Le Loët[2] and Thierry Lequerré[2]. [1]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France

Background/Purpose: The number of RA biological treatments is increasing but 30 to 40% of patients do not respond to TNFαblocking agents. One way to optimize the drug prescription is to identify predictive markers of drug responsiveness for each biologic agent. We already identified a gene combination able to predict infliximab responsiveness by transcriptomic analyses. The question is to know if this approach is enough sensitive to identify specific gene expression profile for the different TNFα blocking agents.

To identify specific gene expression profiles able to predict the response of RA patients treated with methotrexate (MTX)/adalimumab (ADA) or MTX/etanercept (ETA).

Methods: Twenty-nine RA patients were randomized to receive subcutaneously either ADA (40 mg each other week) or ETA (50 mg per week). Eighteen RA patients [average age: 49 $\pm$ 16 years old (yo), MTX: 14 $\pm$ 6 mg/week (w), initial DAS28: 5 $\pm$ 0.8] received ADA while eleven RA patients (age: 55 $\pm$ 15 yo, MTX: 18 $\pm$ 2 mg/w, initial DAS28: 5 $\pm$ 1) received ETA. The drug efficacy was evaluated with the DAS28 score after 3, 6 months and after one year of treatment according to the EULAR response criteria. A blood sample was carried out in patients just before the first injection of treatment in order to isolate peripheral blood mononuclear cells (PBMC) and extract total RNA. cRNAs were synthesized, amplified, labelled and purified using the Quick AMP labelling Agilent kits. Labeled cRNAs were hybridized to Agilent 4 $\times$ 44 K array and

scanned with an Agilent Scanner. Microarray data were extracted and normalized with the Feature Extraction software. Next, a supervised analysis was performed using t-test (GeneSpring GX software) in order to identify gene expression profiles able to separate perfectly responders (R) and moderate responders (MR) to each drug. The gene expression profiles obtained for ADA and ETA were further compared to know if we have a specific signature for each drug.

Results: Demographic, clinical and biological characteristics of all the patients were comparable whatever the treatment administered. From the 18 patients treated with ADA, a combination of 46 transcripts ($p<0.01$) was able to separate perfectly R (9/18) and MR (9/18). Among the 11 patients who have been treated with ETA, 3/11 were classified as R and 8/11 as MR. A combination of 2074 transcripts ($p<0.01$) was able to separate perfectly R and MR to ETA. When we compared these two combinations of transcripts, just an overlap of 3 transcripts was found between them, leading us to consider that the signatures obtained for ADA and ETA are drug specific.

Conclusion: We identified a specific drug signature able to separate perfectly R and MR to either MTX/ADA or MTX/ETA. This study has shown for the first time that the transcriptomic approach is a sensitive, relevant and powerful tool to identify specific predictive markers for each molecule, not only through the different classes of immunotherapies but also in a same class of drug such as TNFα blocking agents.

1932

Identification of a Set of 8 Proteins Able to Predict the Response to Methotrexate/Etanercept In Rheumatoid Arthritis Patients. Antoine Obry[1], Pascal Cosette[2], Philippe Chan Tchi Tsong[3], Jéremy Siemowski[4], Paul Morel[4], Olivier Boyer[1], Patrice Fardellone[5], René-Marc Flipo[6], Christian Marcelli[7], Xavier Le Loët[8], Thierry Lequerré[8] and Olivier Vittecoq[8]. [1]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]UMR 6270 CNRS, Plate-Forme d'Analyse protéomique de l'IFRMP23, Faculté des Sciences, University of Rouen, Rouen, France, [3]Inserm 982, Plate-Forme d'Analyse Protéomique de l'IFRMP23, Faculté des Sciences, University of Rouen, Rouen, France, [4]UMR 6270 CNRS, Faculté des Sciences, University of Rouen, France, [5]Rheumatology Department, Amiens University Hospital, Amiens, France, [6]Rheumatology Department, Lille University Hospital, Lille, France, [7]Rheumatology Department, Caen University Hospital, [8]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France

Background/Purpose: The number of biologic agents in RA is continuously increasing. However, clinicians observe that around 30 to 40% of treated patients fail to respond to TNFα blocking agents. One way to optimize the drug prescription is to identify predictive markers of drug responsiveness.

To identify a combination of proteins whose expression profile would predict the RA patients responses to the association of methotrexate (MTX) and etanercept (ETA).

Methods: A set of 10 patients with active RA (average age: 54 $\pm$ 16 years old, RA duration: 9 $\pm$ 9 years, MTX: 18 $\pm$ 3 mg/week, DAS28: 5.5 $\pm$ 1.0) was treated by a subcutaneous injection of ETA (50 mg/week). The clinical efficacy of these drugs was evaluated with the DAS28 score after 3, 6 and 12 months of treatment according to the EULAR response criteria. For proteomic analysis, a blood sample was carried out in patients prior to the first injection in order to extract peripheral blood mononuclear cells (PBMC). A relative quantification of protein expression from 7 samples of PBMC was performed by mass spectrometry, after labelling with stable isotopes (Isobaric Tags for Relative and Absolute Quantification: iTRAQ®). Protein identification and differential analysis between the samples from responders (R) and non-responders (NR) were made with the Spectrum Mill® software (Agilent). The statistical treatment using iQuantitator® has enabled the relative protein quantification for each patient. From 5 others samples of PBMC, a complementary approach based exclusively on mass spectrometry was implemented (the "label free approach"). "Label-free" quantification is based on extracted ion chromatograms to determine the differential expression. The differential analysis was achieved with SIEVE® (Thermofisher), a label-free dedicated software to compare LC/MS data from LTQ Orbitrap® (Thermofisher) analysis.

Results: Among the 10 patients, 6 out of 10 were classified as R.. When merging the 2 independent experimental approaches, we got consistent results for 8 overexpressed proteins and 2 underexpressed proteins among all patients responding to treatment.

Conclusion: For the first time, we identified a proteomic signature from PBMC able to predict MTX/ETA response. These proteins would thus represent valuable candidates for biomarkers of etanercept responsiveness that should be validated on a larger population. In addition, among the identified proteins, several proteins are also present in plasma, offering the possibility to explore their predictive value by ELISA tests.

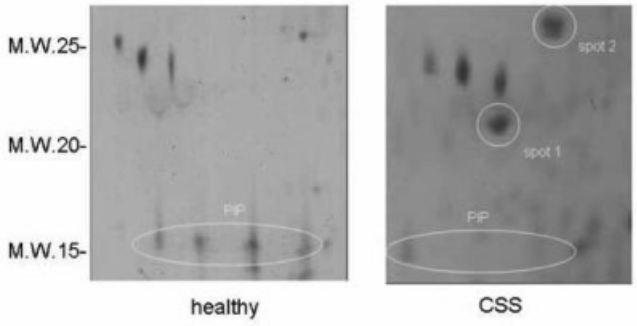
1933

Salivary Proteomics and Churg-Strauss Syndrome: A Phase IIa Case-Control Study Aimed At Identifying Novel Diagnostic Disease Biomarkers. Chiara Baldini, Daniela Martini, Sara Grossi, Nicoletta Luciano, Francesco Ferro and Stefano Bombardieri. Rheumatology Unit, Pisa, Italy

Background/Purpose: This is a IIa case-control study aimed at identifying novel proteomic biomarkers in whole saliva of patients affected by Churg-Strauss syndrome (CSS).

Methods: Consecutives subjects with a diagnosis of CSS (ACR criteria) and age- and sex- matched healthy volunteers were included in the study. Unstimulated WS samples were collected and analysed under standard conditions. Two-dimensional electrophoresis (2DE) was performed using the Immobiline-polyacrylamide system with pH 3–10L, 17 cm long IPG strips (Protean IEF Cell Biorad). The second dimension (SDS-PAGE) was performed by transferring the proteins to 15% polyacrylamide gel. The analytical gels were stained with Coomassie colloidal and images were analysed with PDQuest advanced software.

Results: Eighteen patients with a diagnosis of CSS (9 M: 9 F, mean age 62$\pm$14 yr, mean disease duration 7.8$\pm$5.3 yr) were enrolled. At the study entry, all the patients were in clinical remission (BVAS=2.5$\pm$2.9, VDI=2$\pm$1.1) with low dose steroids and weekly methotrexate ($<$ 15 mg/w). Asthma was poorly or partially controlled in 13/18 patients. Six CSS patients showed nasal polyposis and active rhinosinusitis. Two spots (Fig 1. spot n°1 e 2) with observed MW of $\sim$ 23 KDa/pI 4,3, and MW $\sim$ 30 KDa/pI 4,5 respectively, were detected in 16/18 and in 14/18 CSS cases and in none of the controls. A trend to prolactin-inducible protein precursor (PIP) decrease and fragmentation was observed in subjects with poorly controlled asthma (p-value 0.07) (Fig. 1).



Conclusion: In this preliminary study we described a different salivary proteomic profile in patients with CSS with respect to healthy controls. The identification by mass spectrometry (MALDI-TOF-MS) of the proteins differently expressed is now ongoing and will clarify the clinical and pathogenetic implications of our findings.

1934

BAFF and TACI Gene Expression Are Increased in Untreated Very Early Rheumatoid Arthritis Patients. Rita A. Moura[1], Helena Canhão[2], Joaquim Polido-Pereira[2], Ana M. Rodrigues[2], Márcio Navalho[3], Ana F. Mourão[4], Carlos M. Rosa[5], Catarina Resende[5], Raquel Campanilho-Marques[2], João Madruga Dias[2], João R. da Silva[5], Mário Bexiga[5], José A. Pereira da Silva[5], Luis Graca[6] and João E. Fonseca[7]. [1]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal, [3]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Radiology Department, Hospital da Luz, Lisbon, Portugal, [4]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa and Rheumatology Department, Centro Hospitalar de Lisboa Ocidental, EPE, Hospital Egas Moniz, Lisbon, Portugal, [5]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal, [6]Cellular Immunology Unit, Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [7]Lisbon Academic Medical Center, on behalf of Rheumatic Diseases Portuguese Register (Reuma.pt), Lisbon, Portugal

Background/Purpose: B cells play several important roles in Rheumatoid Arthritis (RA). Previous studies by our group have demonstrated that

very early RA patients have disturbances in peripheral blood memory B cells and increased circulating B-cell related cytokines. The main goal of the present work was to evaluate whether changes in the expression of genes related with B cell survival and activation were already present in untreated very early RA (VERA) patients (<6 weeks of disease duration).

Methods: The expression of a group of B-cell related activation and survival genes was quantified in peripheral blood mononuclear cells (PBMC) from VERA patients by real-time PCR and compared with untreated early RA (<1 year, ERA), established treated RA patients (RA) and other untreated early arthritis conditions (EA). Serum BAFF was quantified by ELISA.

Results: BAFF gene expression and serum levels were highest in VERA patients. The expression of BAFF-R increased with disease progression, while TACI was elevated since the first weeks of RA onset. Pax5 gene expression was also increased in all RA stages. CXCR5 was only elevated in established RA. No differences were observed in BCMA, AID, Blimp-1 and Bcl-2 expression.

Conclusion: Disturbances in the expression of B-cell related activation and survival genes, particularly BAFF and TACI, occur since the very early phase of RA and precede changes in BAFF-R. These alterations can potentiate the development of autoreactive B cells since the first weeks of RA onset.

L. Graca and J.E. Fonseca are joint senior authors.

SLC2A9 Gene Expression Is Associated with a Haplotype Tagging Polymorphism. Philip L. Riches, Samuel Gray, Omar Albagha and Stuart H. Ralston. University of Edinburgh, Edinburgh, United Kingdom

Background/Purpose: SLC2A9 expresses a novel urate transporter that has been consistently identified as an important regulator of serum urate and clinical gout. Although non-synonymous coding polymorphisms of SLC2A9 have been reported these have typically shown less significant associations with serum urate than non-coding variants, suggesting that non-coding polymorphisms within regulatory elements of the gene may be more important. We have explored the effect of a haplotype tagging polymorphism on the expression of SLC2A9 in human kidney and peripheral blood. In addition we have investigated the promoter activity of putative promoters of different splice variants of the gene.

Methods: The coding polymorphism rs16890979 was selected as a haplotype tagging marker known to be in strong linkage disequilibrium with intronic SNPs identified from genome wide association studies of serum urate (Kolz *et al*, PLoS Genetics 2009). TaqMan genotyping probes recognising either allele of rs16890979 were obtained from Applied Biosystems. RNA was extracted from whole blood or surplus tissue obtained from nephrectomy or joint replacement surgery using standard techniques. For the promoter-reporter assays 2kb fragments upstream of exon 1 of both short and long splice variants of SLC2A9 were cloned as well as a 2kb region immediately upstream of exon2 which is predicted to have regulatory potential. Promotor constructs were transfected into HEK293 cells using a pGL3 basic vector with expression levels determined by measurement of firefly luciferase.

Results: In samples from patients heterozygous for the rs16890979 polymorphism consistent overexpression of SLC2A9 was observed with the minor 'A' allele relative to the major 'G' allele. Approximately 6 fold enhanced expression was observed in both peripheral blood and renal tissue. Similar levels of expression were observed in synovial tissue as were seen in renal tissue. Minimal promoter activity was observed in both putative promoter regions upstream of short and long splice variants but approximately 2 fold enhanced expression was seen within a 2kb region upstream of exon2.

Conclusion: Marked differential expression of SLC2A9 is associated with alternative alleles of the rs16890979 polymorphism suggesting that this marker is in linkage disequilibrium with a mutation influencing gene regulation. Modest promoter activity is identified in a region upstream of exon 2 of SLC2A9. Further work will be required to identify variants within this promoter region, as well as to look for further regulatory elements within SLC2A9. SLC2A9 is known to be expressed in the proximal tubule where it is expressed at both apical and basolateral membranes. Better understanding of the role of SLC2A9 in regulating serum urate and also better understanding of the regulation of urate transport in synovium may in time lead to novel strategies for the management of gout.

1936

Elevated Expression of MMP9 in Plasma of Patients with Symptomatic Knee Osteoarthritic: Correlation with Disease Severity and Progression. Mukundan Attur[1], Jeffrey D. Greenberg[2], John Todd[3], Quynh Ann Lu[3], Renita Ramirez[3], Cheongeun Oh[4], Jonathan Samuels[1], Svetlana Krasnokutsky[5] and Steven B. Abramson[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]New York University School of Medicine, New York, NY, [3]Singulex, Alameda, California, Alameda, CA, [4]New York University, New York, NY, [5]NYU Hospital for Joint Disease, New York, NY

Background/Purpose: Osteoarthritis is degenerative joint disease that leads to permanent joint damage and is a multi-factorial complex disease. It is well established that in OA cartilage and synovium that some of the metalloproteinases (MMP) are over expressed including MMP- 2, 9 and 13 and Tissue inhibitors of Matrix metalloproteinases (TIMP) are down regulated. There is currently great interest in the field of OA to identify biomarkers that provide a method for earlier diagnosis and identify patients at higher risk for disease progression. This study was designed to test the hypothesis that plasma levels of gelatinase(s) MMP-2 and 9 predict knee OA severity and progression based on radiographic findings.

Methods: 150 Symptomatic knee OA (SKOA) patients (mean age 63.09 ± 10.3, mean BMI 26.5 ± 3.6) fulfilling ACR criteria for knee OA were recruited as part of an NIH-funded 24 month prospective study. These patients were followed longitudionally for 24 months, x-ray were taken at visit 0 and 24 months. The blood samples were collected at baseline and every 6 months. Standardized semi-flexed radiographs were scored for overall Kellgren and Lawrence (KL) grade, osteophytes, joint space width (JSW) and subchondral sclerosis by the same radiologist. Plasma samples from visit 18 month of 128 OA patients (37% male) were assayed for gelatinase(s) MMP-2 and 9 using the highly sensitive Erenna Immunoassay system (Singulex, Inc). For radiographic severity, biomarker were evaluated between KL scores of 1, 2 with those with scores of 3, 4. Progression of knee OA was defined as a change between baseline and 24 month visit in narrowest joint space width (JSW) in signal knee.

Results: The mean plasma MMP2 and 9 (pro and total) levels were 83.0 ± 63.05 ng/ml, 30.7 ± 32.64 and 455.9 ± 290.09 (all ng/mL), respectively. Only total MMP-9 positively correlated with KL score both at baseline ($r=0.220$; $p<0.036$) and 24 ($r=0.249$; $p<0.015$) month. MMP-2 or proMMP9 levels did not correlate with either radiographic marker. We further analyzed association of tMMP9 level with radiographic severity and progression by JSN as defined in the methods. tMMP9 correlated with radiographic severity ($p<0.061$) at baseline, and with progressive joint space narrowing ($r= 0.228$; $p<0.015$). However, we did not observe significant association between tMMP9 and delta KL score in this 24 month study.

Conclusion: These findings indicate that elevated levels of total gelatinase −9 (tMMP9) are associated with radiographic severity of SKOA and predict an increased risk of progressive joint space narrowing (JSN). These observations, which suggest that tMMP9 is a candidate prognostic biomarker, merit further validation in larger cohort of SKOA patients.

1937

MicroRNA Expression in Vault Particles. Anne Rowzee[1], Mayank Tandon[1], Alessia Gallo[1], John Routsias[2], Athanasios G. Tzioufas[3] and Ilias Alevizos[4]. [1]NIDCR, Bethesda, MD, [2]National University of Athens, Greece, [3]School of Medicine, National University of Athens, Greece, Athens, Greece, [4]NIDCR/ NIH #10 1N110, Bethesda, MD

Background/Purpose: Vault particles are among the largest ribonucleic complexes found in the cell, however, they remain largely uncharacterized. A single protein, major vault protein (MVP), comprises nearly 70% of the 13 MDa mass of this hollow, barrel-shaped organelle. The major components of vaults have been implicated in many basic cellular processes and disease mechanisms, including viral infections, but the function and contents of vaults remain unknown. Our primary interest in vault particles is centered on their ability to bind and sequester small RNAs. A 98 bp RNA sequence named VTRNA is housed within the interior of vaults and has similar characteristics to microRNA precursors. Consequently, the objective of this study was to detect and characterize any microRNAs present in vaults.

Methods: Existing cell-fractionation protocols were optimized to isolate intact vaults from murine salivary glands. Western immunoblot analysis of MVP was then used to demonstrate that we are able to obtain a sample enriched in MVP and likely to contain intact vault particles. Total RNA extracted from isolated vaults both with and without prior RNase treatment was then evaluated by Bioanalyzer, qPCR, and microarray.

Results: Using these methods, specific microRNAs from within vaults were identified and demonstrated to be protected from RNase treatment.

Conclusion: Overall, we consider vaults to be an interesting organelle that is potentially important for regulation of microRNA processing and trafficking, or may function as a delivery vehicle for small nucleic acid sequences representing an additional mechanism of translational control.

1938

Regulation of Apoptosis and Matrix Metalloproteinase Expression by Small Ubiquitin Related Modifier-2/3 in Rheumatoid Arthritis Fibroblast-Like Synoviocytes. Svetlana Frank[1], Simon Strietholt[1], Christine Seyfert[2], Marvin A. Peters[3], Thomas Pauly[4], George Kollias[5] and Thomas Pap[6]. [1]Institute of Experimental Musculoskeletal Medicine, University of Muenster, Muenster, Germany, [2]Department of Orthopaedic Surgery, Zeisigwaldkliniken, Chemnitz, Germany, [3]Kerckhoff- Klinik GmbH, Justus-Liebig-University Gieβen, Bad Nauheim, Gieβen, Germany, [4]Department of Nephrology and Rheumatology, Heinrich-Heine University, Meerbusch, Germany, [5]Biomedical Sciences Research Center 'Alexander Fleming', Vari, Greece, [6]University Hospital Münster, Münster, Germany

Background/Purpose: Posttranslational attachment of SUMO to target proteins regulates diverse cellular functions, including transcription, nuclear translocation, stress response and protein stability. Previously, we could show that the increased expression of SUMO-1 in RA fibroblasts regulates the susceptibility to apoptosis through a SUMO-1/SENP1 dependent mechanism. As SUMO-2/3 constitutes a structurally similar but functionally distinct member of the SUMO family, we investigated the expression of SUMO-2/3 in human RA and in hTNFtg mice and studied its role in regulating both apoptosis and the expression of disease specific MMPs.

Methods: Synovial tissue samples were obtained from RA and osteoarthritis (OA) patients at joint replacement surgery and used for histological analysis as well as for the isolation of fibroblast like synoviocytes. Using specific antibodies in immunohistochemical and Western blot analyses, we studied the expression of SUMO-2/3 in fibroblasts from human RA as well as from hTNFtg and wt mice. Knockdown of SUMO-2/3 was performed using specific siRNA against both SUMO-2 and −3. The apoptotic response of the fibroblasts was measured using a Caspase-3/7 assay after induction of cell death with 100ng/ml Fas ligand over 13h. MMP-1, MMP-3 and MMP-13 production in FLS from RA and OA patients was measured by ELISAs following the stimulation with TNF-alpha and IL-1beta.

Results: Immunohistochemistry and Western blot analyses revealed a clear upregulation of SUMO-2/3 expression in all RA synovial tissue samples and in RA-FLS compared to OA control samples. In line with these data, tissue sections of hTNFtg mice, as well as FLS from these mice confirmed increased expression of SUMO-2/3. Moreover, SUMO-2/3 expression was increased after stimulation with TNF-alpha in RASF. Knockdown of SUMO-2/3 by siRNA sensitized RASF to Fas-mediated apoptosis. Interestingly, TNF-alpha and IL-1beta induced upregulation of MMP-3 and MMP-13 expression was significantly stronger after knockdown of SUMO-2/3 in RA- and OA-FLS. While the expression of MMP-1 was not affected.

Conclusion: From our data we conclude that posttranslational modification of target proteins by SUMO-2/3 and specifically increased levels of SUMO-2/3 in RA-FLS contribute to the resistance of these cells against Fas-mediated apoptosis. Moreover, they indicate that SUMO-2/3 is regulated by TNF-alpha as well as involved in the regulation and TNF-alpha stimulated production of MMP-3. Therefore, we hypothesize that SUMO-2/3 are novel players contributing to the specific activation of RASF and, thus, to the disease process of RA.

High Expression of GITR and OX-40 Receptors on Memory CD4+25+ T Cells in the Joint Fluid of Patients with Antibiotic-Refractory Lyme Arthritis. Nalini K. Vudattu[1], Elise E. Drouin[2] and Allen C. Steere[3]. [1]Massachusetts General Hospital and Harvard Medical School, Charlestown, MA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, Massachusetts, Charlestown, MA, [3]Massachusetts General Hospital and Harvard Medical School, Boston, MA

Background/Purpose: Patients with Lyme arthritis have an infection-induced synovitis, which resolves in most patients with appropriate antibiotic therapy. However, a small percentage of patients have persistent synovitis despite spirochetal killing with oral and IV antibiotics (called antibiotic-refractory arthritis), which results from a putative infection-induced autoimmune response. This human model is unique in being able to compare infection versus autoimmune activation of T cells in the same disease. In an initial study, we showed that both refractory and responsive patients have elevated numbers of IFNg+ CD4+ Teff cells in synovial fluid (SF). In addition, in refractory patients, lower numbers of CD4+CD25+ T cells (primarily FoxP3+ Treg cells) correlated with a longer duration of synovitis after antibiotic therapy. To better understand the difference between infection versus autoimmune activation of T cells, we compared herein the phenotype of these cells in patients with antibiotic-responsive or antibiotic-refractory Lyme arthritis.

Methods: PBMC and synovial fluid mononuclear cells (SFMC) were obtained in 15 patients with antibiotic-responsive arthritis (prior to antibiotic therapy) and in 16 with antibiotic-refractory arthritis (in the post-antibiotic period after spirochetal killing). The cells were assessed for expression of CD3, CD4, CD25, CD45RO, CCR7, GITR, HLA-DR, OX40, CXCR3 and a viable cell marker using 10-channel polychromatic flow cytometry. The levels of these markers were correlated with the clinical course.

Results: CD4+ T cells in SF were even more abundant and enriched in patients with antibiotic-responsive arthritis than in those with antibiotic-refractory arthritis (median value, 59% and 51%, P=0.03). In both groups, approximately 95% of these cells were CD4+CD25- Teff cells and about 5% were CD4+CD25+ cells (primarily Treg cells). However, in contrast with our previous smaller study, the lower percentage of Treg cells in SF in the refractory group did not correlate with a longer duration of arthritis after antibiotic therapy. Instead, compared with patients with antibiotic-responsive arthritis, CD4+25+ T cells in SF in patients with antibiotic-refractory arthritis had significantly higher expression of GITR (P=0.006) and OX-40 receptors (P=0.02), which are members of the TNF receptor superfamily that are known to be associated with inhibition of Treg function. Finally, almost all of both Teff and Treg cells (98%) had a memory phenotype.

Conclusion: The expression of GITR and OX-40 receptors on CD4+CD25+ Treg cells differed significantly between patients with antibiotic-responsive or antibiotic-refractory arthritis. These observations imply that Treg in patients with antibiotic-refractory arthritis are unable to effectively regulate activated Teff cells because of phenotypic differences, including receptor expression. Studies are currently underway to determine the functional differences between T cells in these patients.

***C Trachomatis* Is Present and Metabolically Active During the Remitting Phase in Synovial Tissues From Patients with Chronic *Chlamydia*-Induced Reactive Arthritis.** John D. Carter[1], Herve C. Gerard[2] and Alan P. Hudson[2]. [1]University of South Florida, Tampa, FL, [2]Wayne State Univ Schl of Med, Detroit, MI

Background/Purpose: Patients with chronic *Chlamydia* -induced reactive arthritis (ReA) often show a remitting-relapsing disease phenotype. We have some knowledge of the genetic behavior of chlamydiae in the synovium during active disease, but we know nothing concerning the organism's metabolic or other characteristics during quiescent disease. Such information may be extremely useful in understanding the signals that trigger active disease from quiescence. Here we present the first study of chlamydial load and gene expression in synovial tissues during the quiescent disease phase of *Chlamydia* -induced inflammatory arthritis.

Methods: Synovial biopsies from 4 patients with remitting chronic ReA were procured by the Parker-Pearson method and snap frozen. All synovial tissue samples were obtained from the knee and the patients had no evidence of synovitis in the knee or any other joint or organ at the time of tissue procurement. Nucleic acids from these synovial tissue samples were prepared by the hot phenol method and analyzed by real time PCR and RT-PCR.

Results of the analyses were compared with transcript and bacterial load values averaged from the knee synovial tissue samples of 10 patients in the active disease phase of chronic *Chlamydia* -induced arthritis ReA.

Results: Quantitative real time PCR assays indicated that relative bacterial load in the remitting phase samples was about 20% of that in samples from patients with active disease. Surprisingly, transcript levels from the authentic hsp60-encoding gene were equal to those seen in active disease in 2 samples and about 5-fold higher than those of active disease samples in 2 others. Transcripts from the 2 other paralog hsp60 genes were equal to or somewhat lower than those found in active disease. mRNA from the host encoding IL-10, TNFα, and IFNγ were about 4-fold lower than those seen in

samples from patients in active disease. MCP-1 and RANTES transcript levels were equal to or higher than those in active disease samples.

Conclusion: These results show that bacterial load in the joints of patients during the remitting phase of arthritis is much lower than those during active disease. However, transcripts encoding the highly pro-inflammatory hsp60 proteins are equal to or higher than those found in active disease, and the transcriptional response of the host is attenuated in terms of several cytokines and chemokines in the remitting samples. Clearly, these initial results indicate that the sequence of genetic events characterizing quiescent disease is complex and requires more study to understand how quiescence is maintained and what triggers the transition to active disease.

1941

Interferon-γ Release Assays In Rheumatic Patients: Baseline Study and In the Course of Anti-Tumor Necrosis Factor-α Agents. Melania Martínez-Morillo[1], Sonia Mínguez[2], Lourdes Mateo-Soria[1], Irene Latorre[1], José Domínguez[1], Dolors Grados[1], Beatriz Tejera[1], Susana Holgado[1], Alejandro Olivé[1] and Xavier Tena[1]. [1]Hospital Universitario Germans Trias i Pujol, Badalona, Spain, [2]Hospital General de Manresa, Manresa, Spain

Background/Purpose: IFN-γ release assays are useful methods for diagnosing LTBI (latent tuberculosis infection). It allow us to detect: a) false negative TST in anergic subjects, b) false positives in BCG-vaccinated patients and c) NTM (non-tuberculous mycobacterias) previously sensitized individuals. All in all, these tests contribute to detect additional cases of LTBI.

Our aim is to establish the usefulness of blood interferon-γ release assays in patients with inflammatory rheumatic diseases scheduled for anti-TNF-α treatment and at the follow up.

Methods: Prospective study including rheumatic patients starting an anti-TNF-α agent. All patients underwent TST (two step testing), a chest radiograph, QuantiFERON GOLD *in tube* (QFN-G-IT), and T-SPOT.TB. Both tests were repeated after a year of anti-TNF treatment in 21 patients. As control group, 35 adult individuals were included. Concordance between TST/T-SPOT.TB, TST/QFT and T-SPOT.TB/QFT were analyzed by Cohen's kappa test.

Results: We included 53 patients (18 male/35 female) candidates for anti-TNF-α (18 rheumatoid arthritis, 13 ankylosing spondylitis, 9 psoriatic arthritis and 13 miscellanea). Mean age was 49 ± 13 years and mean disease evolution was 8.8 ± 8 years. Twenty-four out of 53 patients (45.3%) were receiving systemic steroids, mean daily dose 9.1 ± 11.9 mg/day. BCG vaccination status was documented in 3 patients, 2 referred history suggestive of TB disease and other 3 patients had contact with a confirmed TB case in the past.

The results of our study are summarized in Table 1. The differences in the results between the IFN-γ tests were not significant ($p = 0.675$). Interestingly enough, neither T-SPOT.TB nor QFN-G-IT were significant in comparison to TST results ($p = 0.344$ and $p = 0.727$, respectively). Overall agreement between TST and T-SPOT.TB and QFN-G-IT was 77.35% (k=0.33; and k=0.40, respectively), and between both in vitro tests was 83.01% (k=0.57). Three patients with positive TST and negative T-SPOT.TB and QFN-G-IT, was positive on ELISPOT after stimulation with NTM sensitins. Positive TST, T-SPOT.TB and QFN-G-IT results were not affected by the immunosuppressive therapies. We found 4 conversions (1 patient convert T-SPOT and QFN, and 3 patients convert only T-POT) out of 21 cases evaluated after a year under anti-TNF-α agents. We also observed 2 reversions, one in a patient who had undergone prophylactic treatment for tuberculosis.

Diagnostic test	All rheumatic patients, n=53 (%)	Rheumatoid arthritis patients, n=18 (%)	All rheumatic patients 1 year after treatment with anti-TNF-α, n=21 (%)
T-SPOT.TB			
Positive	11 (20.8)	4 (22.2)	7 (33.3)
Negative	40 (75.5)	14 (77.8)	13 (61.9)
Inderteminate	2 (3.8)	0 (0)	1 (4.7)
QFN-G-IT			
Positive	9 (17)	4 (22.2)	4 (19)
Negative	40 (75.5)	13 (72.2)	17 (80)
Indeterminate	4 (7.5)	1 (5.6)	0 (0)
TST			
Positive	7 (13.2)	3 (16.7)	Not done
Negative	46 (86.8)	15 (83.3)	Not done

Conclusion: In those patients with a high risk of developing active TB, the combined use of TST and IFN-γ may be recommended to increase the overall number of LTBI diagnosis. Reversion is described in subjects who have made prophylaxis. More studies are needed to recommend prophylaxis in conversions.

1942

Xenotropic Murine Leukemia Virus-Related Virus Infection in Italian Patients with Chronic Fatigue Syndrome, Fibromyalgia or Rheumatoid Arthritis. Laura Bazzichi[1], Fabrizio Maggi[2], Francesca Sernissi[3], Pietro Scarpellini[3], Camillo Giacomelli[3], Arianna Consensi[3], Maria Linda Vatteroni[3], Mauro Pistello[3] and Stefano Bombardieri[1]. [1]Rheumatology Unit, Pisa, Italy, [2]University Hospital, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [3]University of Pisa, Pisa, Italy

Background/Purpose: A plethora infectious agents have been linked to Chronic Fatigue Syndrome (CFS) over the years but none stand out intense scrutiny. This long list of viruses has been recently updated with the xenotropic murine leukemia virus-related virus (XMRV). XMRV was convincingly linked to CFS in a Science manuscript authored by Lombardi and colleagues, who demonstrated the presence of the virus in 68 of 101 American patients (67%) versus 8 of 218 (3.7%) healthy controls. Unfortunately, this was followed by a number of papers claiming that XMRV was not detectable in similar cohorts of patients, creating a rift in the scientific opinion. Several explanation has been provided to support one or the other position, but the controversy is nowadays still open. This work was carried out to contribute to the scientific debate by expanding the number of CFS patients examined to the Italian population and by extending the analysis to other two chronic diseases, which are Fibromyalgia and Rheumatoid Arthritis, with basically unknown etiology and common symptoms.

Methods: Patients and controls were recruited at the division of Rheumatology, Pisa University Hospital from June 2010 to January 2011. The diagnosis of CFS was made according to the Fukuda criteria of 1994, while FM and RA patients fulfilled the American College of Rheumatology of 1990 and 1987, respectively. Samples were obtained from 145 patients (65 with CFS, 55 with FM and 25 with RA diagnosis) and 25 age-matched healthy controls. The virus was searched as viral genome and using a diagnostic algorithm including a nested polymerase chain reaction (PCR) and a single step TaqMan real-time PCR, both designed on XMRV *gag* . Amplifications were carried out with protocols set up by Lombardi and colleagues that were published in the Science paper.

Results: No sample was found XMRV RNA positive. The *gag* primers designed for the real-time PCR and the technique itself ensured sensitivity to detect XMRV RNA at least as high as the nested PCR. Yet, plasma samples that were first tested by nested PCR and then retested by real-time PCR were all consistently negative. Since these findings did not rule out that the samples might contain copy numbers of XMRV genome very low (as suggested by other reports) and below the detection threshold, most plasma samples were reanalyzed following ultracentrifugation to concentrate the XMRV virions, but again no positive signal was scored.

Conclusion: Despite having strictly followed methods and procedures described and further improved by the Science authors and used negative and positive controls as indicated, we were unable to find any XMRV sequence in plasma and PBMC. These results add to the ever-growing number of surveys reporting the absence of XMRV in CFS patients and thus further increasing skepticism on possible links between XMRV and CFS.

1943

Dexamethasone Reduces *Staphylococcus Aureus*-Induced Production of Inflammatory Cytokines and Matrix Metalloproteases in Primary Human Chondrocytes and Synovial Fibroblasts. Frank Hanses[1], Irina Fink[1], Susanne Graessel[1], Bernd Salzberger[1] and Martin Fleck[2]. [1]University Hospital Regensburg, Regensburg, Germany, [2]Asklepios Klinikum Bad Abbach, Bad Abbach, Germany

Background/Purpose: *Staphylococcus aureus* (*S. aureus*) is the most frequent pathogen involved in acute bacterial arthritis. Joint infections due to *S. aureus* are associated with a high rate of sequelae and poor functional outcome. We hypothesize that concomitant glucocorticoid therapy may reduce joint destruction during staphylococcal arthritis.

Methods: Primary human chondrocytes, synovial fibroblasts and osteoblasts were infected with viable *S. aureus* . The production of the inflammatory cytokines IL-6 and IL-8 (CXCL8), the secretion of matrix metalloproteases (MMP-1, MMP-3, MMP-13), expression of aggrecanases (ADAMTS4 and ADAMTS5), cell viability and numbers of intracellular bacteria were studied with or without co-incubation of dexamethasone for 5 days.

Results: Primary human chondrocytes produced significantly more IL-6 and IL-8 than fibroblasts and osteoblasts as well as high levels of matrix metalloproteases upon *S. aureus* infection. Co-incubation with dexamethasone led to a significant decrease in IL-6 and IL-8 production in all cell types. Additionally,

dexamethasone reduced the *S. aureus* -induced production of matrix metalloproteases MMP-1 and MMP-13 (but not MMP-3) by primary chondrocytes significantly. Similary, *S. aureus* -induced expression of the aggrecanases ADAMTS4 and ADAMTS5 was significantly reduced by dexamethasone. No differences in cell viability and intracellular numbers of *S. aureus* were observed between cells incubated with dexamethasone and controls.

Conclusion: The host immune system and tissue destructive substances contribute to permanent joint damage in *S. aureus* arthritis. Dexamethasone might modulate inflammation and tissue destruction leading to a better functional outcome following *S. aureus* arthritis.

1944

The Cellular Response to Vaccination against Pandemic 2009 Influenza A (H1N1) Virus Among Patients with Rheumatic Diseases. Ori Elkayam, Sharon Amir, Uri Arad, Jonathan Wollman, Ayelet Brill, Daphna Paran, David Levartovsky, Irena Wigler and Dan Caspi. Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background/Purpose: Antibody and cell mediated responses are both involved in the defense against virus. We have previously shown that vaccination against pandemic H1N1 using an adjuvanted H1N1v monovalent influenza vaccine induced an appropriate humoral response response in patients with rheumatoid arthritis (RA), Systemic lupus erythematosus (SLE), Ankylosing spondylitis (AS) and Psoriatic arthritis (PsA). The purpose of this study was to assess the cellular response to vaccination against pandemic H1N1 virus in patients with rheumatic diseases compared with healthy controls.

Methods: The study population comprised 43 patients (16 RA, 12 SLE, 10 PsA, 5 AS) and 10 healthy controls, all vaccinated by Novartis MF59-adjuvanted H1N1v monovalent influenza vaccine. Peripheral blood mononuclear cells were obtained before and 4 weeks after vaccination. Cell-mediated response was evaluated by flow cytometry for IFNg and interleukin 2 (IL-2) producing CD4+ and CD8+ T-cells, following *in vitro* stimulation with virus antigen.

Results: CD4 T cell-mediated immune response to A/H1N1: Following vaccination, the percentage of IFNg producing CD4+ cells increased in the SLE, PsA and AS groups while it was decreased in RA and healthy groups. The percentage of IL-2 producing CD4+ cells increased in all groups except PsA. Among patients on TNFa blockers, RA patients had a greater response compared to PsA patients. Notably, the percentage of cytokine producing T-cells (CD4 and CD8) in either, pre- and post-vaccination was higher among the healthy group compared to the 4 patients groups.

CD8 T cell-mediated immune response to A/H1N1: After vaccination, the percentage of IL-2 producing CD8+ cells increased considerably (6-fold) in the healthy control group, the response being significantly stronger compared to the entire patient population ($P = 0.02$) and to the RA group ($P = 0.05$). In contrast, except for a slight increase among the SLE and AS groups, no increase in IFNg producing CD8+ T cells was observed.

Conclusion: The cellular response of IL-2 producing CD8+ cells following vaccination against pandemic influenza H1N1 is impaired in patients suffering from RA, SLE, PsA and AS in comparison with healthy controls. The IFNg producing CD4+ and CD8+ T-cell response was similar in patients and controls.

1945

Circulating Levels of IL6, sIL6-r, sgp130 and Gamma-IFN in Patients with Hepatitic C Virus Related Arthritis (HCVrA) and Rheumatoid Arthritis (RA). Angelo Spanò[1], Loredana Postiglione[1], Paola Sabatini[2], I. Soriente[2], M.G. Sangiolo[1], V. Bruner[1], Raffaele Scarpa[1] and Antonio Riccio[1]. [1]Federico II University Medical School, Naples, Italy, [2]Umberto I Hospital, Nocera Inferiore, Italy

Background/Purpose: To evaluate serum concentrations of IL6, sIL6r, sgp130 and gamma-IFN in HCVrA and RA patients. To verify any possible difference in circulating levels of these cytokines involved in the pathogenesis of RA and HCVrA, both conditions sharing some immunological features.

Methods: 25 HCVrA (15 with polyarticular symmetrical, 10 with oligoarticular asymmetrical involvement), 27 RA patients (fulfilling ACR criteria) and a control group of 20 healthy subjects were examinated. In the HCVrA group, 10 patients presented hepatic damage (hypertransaminasemia), 11 were virus negative HCV-RNA PCR, 17 were positive for Rheumatoid Factor (RF), 13 for Antinuclear Antibodies (ANA), 3 for Anti-Cytrullinated peptide (ACPA), 12 for cryoglobulins. None of them received steroids or immunosuppressive and viral replications inhibitors drugs. In the RA group, 22 patients were positive both for RF and ACPA, 5 only for RF and 5 for ANA, 16 received Methotrexate (15 mg/weekly), 6 Leflunomide (20 mg/day), 5 cyclosporine (3 mg/Kg bw), none steroids.ELISA Methods were used to determine serum concentrations of IL6 and sIL6r (R&D Systems – Milan –Italy), sgp130 (Bioscience International Camarillo USA) and gamma-IFN (Arcus Biologicals – Modena – Italy). Mann-Whitney test and Spearman's rho were used for statistical analysis.

Results: High IL6 serum levels were found respectively in 71% of HCVrA (60 pg/ml) and 62% of RA patients (255,6 pg/ml), sIL6r levels resulted high in 37% of HCVrA patients (36,1 ng/ml) and in 46% of RA patients (40,9 ng/ml), sgp130 levels were increased in 75% of HCVrA (37,8 ng/ml) and in 69% of RA patients (417,5 ng/ml). All these values, as in HCVrA as in RA patients, were significantly higher in comparison to the median values reported in the control group. Gamma-IFN serum levels were founded decreased in 24% (0,2 IU/ml)of HCVrA patients and 15% (0,12 IU//ml) of RA patients. No direct correlation was found between these parameters with viraemia, RF and ANA positivity in HCVrA group, while a mild correlation was found between IL6, sIL6r and sgp130 with RF levels in RA group. Furthermore, no correlation results both in HCVrA and RA group between gamma-IFN levels and IL6, sIL6r and sgp130 levels.

Conclusion: Enhanced serum levels of IL6 and its receptors both in HCVrA and in RA indicate an increased synthesis and activity of this interleukins, supporting the hypothesis of similar immune pathogenetic mechanism for both diseases. Low gamma-IFN serum levels, found in a minority of HCVrA and RA patients and above all the lack of correlations between IL6 and gamma-IFN could be explained because of gamma IFN is regulated in a composite system by many different contributing factors non yet completely evaluated.

1946

Polyarticular Septic Arthritis: A Case Series. Rajni Kalagate[1], Sherilyn T. McCollum[1], Charles H. Pritchard[2] and Lawrence H. Brent[1]. [1]Albert Einstein Medical Center, Philadelphia, PA, [2]Rheumatic Disease Associates, Willow Grove, PA

Background/Purpose: Septic arthritis (SA) is typically a monoarticular disease. Polyarticular SA has been reported, especially in patients with underlying RA and SLE. In this study we present a series of patients with polyarticular SA and compare them with monoarticular SA. Purpose: To describe the demographics, risk factors, microbial etiology, articular involvement, and outcomes of patients with polyarticular SA compared with monoarticular SA.

Methods: Medical records of all patients with a diagnosis recorded as SA admitted to Albert Einstein Medical Center and Abington Memorial Hospital from 1988 to 2010 were reviewed. Data collected included age, sex, comorbidities, joint involvement, synovial fluid analysis, and relevant culture results (synovial, others). Patients mislabeled as SA or with incomplete data were excluded. The diagnosis of SA was defined as definite (clinically inflamed joint and positive synovial fluid culture), probable (clinically inflamed joint and negative synovial fluid culture but positive culture from another source), or possible (clinically inflamed joint and all cultures negative). If data for a specific parameter was missing, percentages were calculated using the total number patients with data as the denominator. Data analysis was performed using SPSS17.0.

Results: A total of 515 patients were identified with septic arthritis. Of these patients, 39 (7.5%) had polyarticular SA. The incidence of polyarticular SA remained stable over the 22 year period. There were no significant differences between polyarticlular and monoarticular SA patiens with regards to demographics and co-morbid conditions including RA and SLE. Clinical features which were significantly different between the polyarticular and monoarticular SA were: peripheral WBC count 17,400 vs. 15,000 ($p=0.06$); positive blood cultures 64% vs. 41% ($p=0.007$); length of hospital stay 15.2 vs. 10.7 days ($p=0.01$). 74% of polyarticular SA patients had positive synovial fluid cultures vs. 62% of monoarticular SA patients ($p=0.8$). The overall bacterial etiology was not significantly different between the two groups. In polyarticular SA patients, *Staphylococcus aureus* was the most common organism identified 55 %, of which 26% were methicillin-resistant. The other organisms identified were *Streptococcus pneumoniae* (8%) and *Streptococcus* group A and B (10%). The knee was most commonly involved in both groups. Polyarticular SA had more involvement of knee (69% vs. 48%, $p=0.01$), wrist (30% vs. 5%, $p=0.000$), elbow (18% vs. 5.3%, $p=0.002$), and shoulder (36 % vs. 10%, $p=0.000$). Polyarticular SA had a worse prognosis with death occurring in 18% vs. 4.7% in monoarticular SA ($p=0.001$).

Conclusion: The incidence of polyarticular SA was less than what has been previously reported (7.5% vs. 15%). There were no specific predisposing factors identified for polyarticular SA in our study. Involvement of the knee, wrist, elbow, and shoulder joints were more common. These patients were more likely to have positive blood cultures and a prolonged hospital course. Polyarticular SA is associated with a worse prognosis including a higher mortality.

1947

Four Novel MEFV Gene Mutations in a Population Where the Prevalence of Crimean-Congo Hemorrhagic Fever and MEFV Gene Carrier Status Is Very High. Gulay Ozgon[1], Aynur Engin[2], Gulen Hatemi[3], Serdal Ugurlu[3], Elif Akyayla[1], Mehmet Bakir[2] and Huri Ozdogan[3]. [1]Nesiller Genetic Lab, Istanbul, Turkey, [2]MD, Department of of Infectious Diseases, Medical Faculty, University of Cumhuriyet, Sivas, Turkey, [3]MD, Division of Rheumatology, Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey

Background/Purpose: Crimean-Congo hemorrhagic fever (CCHF) is a tick-borne disease caused by an arbovirus in the family Bunyaviridae, which is associated with high mortality. CCHF is common in mid Anatolia where FMF is also very prevalent (1.2%), thus MEFV gene carrier status is very high (44%).To test our hypothesis that a selective biological advantage obtained by a carrier state for MEFV mutations may enhance the host's ability to withstand CCHF, we studied the distribution of MEFV gene mutations in patients with CCHF.

Methods: MEFV gene mutations of exon 2 and 10 were detected with polymerase chain reaction (PCR) and direct sequencing in 100 patients with CCHF with a definite diagnosis of CCHF followed in Cumhuriyet University, Sivas / Turkey, (mean age 45.6±17, 58 M: 42 F) and in 91 healthy blood donors (HC) living in the same area.All CCHF patients were classified into two groups in terms of disease severity (mild and severe), according to the predictive factors for fatal outcome reported by Swanepoel et al(1).

Results: Four new mutations were found on exon 10 of 7 CCHF patients and none of the healthy controls. A database search for these novel mutations was negative. The loci of these new MEVF gene mutations on exon 10 are as follows: Q778L, R717Q, P754A and R737K. Q778L mutation was found in four patients, one had a mild whereas the remaining 3 had severe disease. Carrier of R717Q had a severe disease and died, however the carriers of P754A and R737K had mild disease course. All of these patients except the one who died were reevaluated for co-existence of FMF but none had any personal or familial history of FMF.

Conclusion: Here we describe 4 novel MEFV gene mutations in patients with CCHF from a geographical area where MEFV gene carriership is very high. We do not yet know whether these mutations have any effect on the host's ability to withstand an infection.

The Effect of CCR5-DELTA-32 Mutation On *Chlamydia*-Induced Reactive Arthritis. Jason P. Guthrie[1], Aasim Rehman[2], Herve C. Gerard[3], Jessica Stanich[4], Alan P. Hudson[3] and John D. Carter[5]. [1]Springfield, IL, [2]Tampa, FL, [3]Wayne State Univ Schl of Med, Detroit, MI, [4]Wayne State University, Detroit, MI, [5]University of South Florida, Tampa, FL

Background/Purpose: *Chlamydia trachomatis* is a known cause of reactive arthritis (ReA). Only a minority of the infected patients develop ReA, with an attack rate of about 5%. Chemokine receptor-5 (CCR5) mediates chemotaxis and is expressed with the Th1 phenotype on monocyte/macrophages. The CCR5 protein is a cell surface receptor that binds several chemokines. A 32 base pair deletion in the CCR5 (CCR5-delta-32 allele) abolishes receptor expression in homozygote, while CC5-delta-32 carriers would express less receptor than the wild type homozygote. Data suggest that the CCR5-delta-32 mutation might be important in determining disease activity in autoimmune conditions. We hypothesize that the CCR5-delta-32 allele may modulate disease susceptibility and chronicity in *Chlamydia* -induced ReA.

Methods: Patients who tested positive for *Chlamydia trachomatis* after either 1.) symptoms of an acute venereal disease or 2.) sexual contact with an individual known to be positive for the same organism were recruited from the regional communicable disease clinic and followed in a prospective fashion. At enrollment, informed consent and demographic details were obtained and two blood samples were collected. All patients were contacted at week 6 after their acute infection and queried for symptoms of arthritis, conjunctivitis, urethritis, dactylitis, or enthesitis. All patients who had new onset symptoms suggestive of *Chlamydia* -induced ReA at week 6 had follow up telephone interviews at weeks 12, 26, and 52 to follow the chronicity of the symptoms. All the collected blood samples were tested for CCR5-delta-32 mutation.

Results: 365 study participants were enrolled. Average age of the population was 25.3 years. There were 201 males (55%) and 164 females (45%). Of the enrolled patients, 231 (63%) were African Americans, 81 (22%) Hispanics, 48 (13%) Caucasians and 5 (1.3%) were others. We were able to follow up with 149 (40%) of patients at week 6. 12/149 (8 %) participants contacted at week 6 had symptoms suggestive of *Chlamydia* -induced ReA. None of these 12 patients had the CCR5-delta-32 mutation. Of the 12 patients that had symptoms at week 6, we were able to follow up with 7 at weeks 12, 26 and 52. All 7 had complete resolution of their symptoms by week 26 and remained asymptomatic at week 52. Overall 25/365 (6.8%) subjects were positive for the CCR5-delta-32 mutation. We were able to follow up with 11 (44%) of these 25 patients. None of them had symptoms suggestive of *Chlamydia* -induced ReA at week 6 follow up.

Conclusion: The CCR5-delta-32 mutation does not seem to play a role in *Chlamydia* -induced ReA disease susceptibility. Because none of the subjects with long-term follow-up developed chronic disease, the potential role this mutation might play in disease chronicity remains uncertain.

1949

Hyperuricemia, Its Prevalence and Correlation with Age, Gender, BMI, Co-Morbidities and Metabolic Syndrome in Anti- Retroviral Naive HIV Cohort. Nirupa J. Patel[1], Roy Rajan[1], Rebecca Clark[2] and Luis R. Espinoza[3]. [1]LSU Health Sciences Ctr, New Orleans, LA, [2]LSU Health Sciences Center, New Orleans, [3]LSU Medical Center, New Orleans, LA

Background/Purpose: The aim of this study was to determine the prevalence of hyperuricemia in the HIV infected population, and whether uric acid can be used as a marker of metabolic syndrome (MetS). Hyperuricemia mediates adipocyte specific pro-inflammation and increases insulin resistance as studied in the murine model of MetS. We incorporated BMI, triglyceride levels, and co-morbidities correlating with hyperuricemia to analyze the pattern of metabolic syndrome in this HIV+ cohort. Viremia induced increased cell turnover, loss of mononuclear cells, concomitant infections and increased oxidative stress can all be implicated factors for hyperuricemia in HIV patients. Anti-retroviral drugs can cause mitochondrial dysfunction, lactic acidosis, and hyperuricemia. Our study included all drugs naive patients.

Methods: We studied 283 consecutive patients seen in our HIV clinic over 18 months' duration. We selected newly diagnosed HIV+ patients who had an initial uric acid levels performed. These uric acid levels were correlated with age, gender, ethnicity, CD4 counts, HIV viral load, BMI, Triglycerides levels, and concomitant co-morbid conditions [Type II Diabetes mellitus (DM), Hypertension (HTN)]. We analyzed our data using logistic regression analysis. Significant variables at $p<0.1$ in univariate analysis were used in multivariate models. WHO criteria for MetS were used in our study. It defines as having BMI > 30kg/m2, triglycerides > 150mg/dl, Blood pressure > 140/90 mm Hg.

Results: 283 newly diagnosed HIV+ anti-retroviral naive patients were studied. Initial panels included uric acid levels. HIV+ patients in our study had mean age of 38.2 yrs (SD11.6yrs) and 68.9% were males. Ethnicities included African Americans 77.7%, Caucasians 18.4%, and unknown 3.9%. Their BMI median was 25.2 (range 13.3– 63.9). Uric acid of >7mg/dl was found in 18.4% of patients. Race, CD4 count, and viral load were not significant in univariate analysis. In the multivariate logistic model, hyperuricemia of >7mg/dl was significantly associated with increasing BMI and age, male gender and co-morbidities (HTN, DM or both) (Table 1). In our separate model of MetS, 3.2% of patients had all 3 variables of MetS and uric acid> 7 mg/dl. These 9 patients with all variables were significantly associated with OR of 12.7 and $p=0.002$.

In current study, only 1 patient had uric acid level < 2mg/dl and 1/9 patient had gout associated with MetS (having all 4 variables).

Table 1.

HYPERURICEMIA	ODDS RATIO	P VALUE	95% CONFIDENCE INTERVAL
BMI	1.09	<0.0001	1.04–1.15
AGE	1.04	0.003	1.01–1.07
GENDER	4.95	0.001	1.94–12.63
HTN/DM	2.20	0.032	1.06–4.55

Conclusion: In this study, the prevalence of hyperuricemia in HIV population was 18.4%. Our HIV+ MetS model showed a high association of hyperuricemia with MetS, increasing age and BMI along with male gender. Hyperuricemia, when present in HIV population, may be a harbinger and marker of MetS. Further trials and larger cohorts are needed to study MetS in this vulnerable HIV hyperuricemic population.

1950

Outbreak in Syphilis Presenting As Uveitis. Inés Pérez-Martín[1], David de la Hera[1], Ricardo Blanco[2], Javier Rueda[1], Carmen Bejerano[2], Orlando Pompei[1], Joaquín Cañal[1], Juan Ventosa[1], Manuel Gutiérrez-Cuadra[1], Vanesa Calvo[1], Javier Loricera[1] and Miguel Angel González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain

Background/Purpose: Increased incidence of syphilis has been observed in developed countries in the last decade. In some cases indistinguishable uveitis from that related to non-infectious autoimmune uveitis may be the presenting manifestation of syphilis.

Methods: We conducted a review of the patients seen at the Uveitis Unit of the Rheumatology Service of a University Hospital that were diagnosed as having ocular syphilis as the first manifestation of this infectious disease from 2006 to 2011. The diagnosis of syphilis was established by the following tests: RPR and TPHA. The ophthalmological examination included slit lamp examination, retinography and ocular coherence tomography.

Results: Ten patients (6 men/4 women) with a mean age 50±20 (range 20–79) years were diagnosed with ocular syphilis as the first manifestation of this infection. The ocular manifestations were the following: anterior uveitis (2 cases), episcleritis (1), panuveitis (6), and posterior uveitis (1). The course before the diagnosis varied from one case to another: It was acute in 6 cases, chronic in 1, and recurrent in 3 patients. In 5 cases the inflammation was bilateral. In addition to syphilis, several concomitant infection diseases were found in some patients (hepatitis B in 3 cases and HIV infection in 1 case). Prior to the diagnosis of syphilis 3 patients were misdiagnosed as having non-infectious uveitis and were treated with high doses of prednisone. When the diagnosis of syphilis was established 9 patients received penicillin G (2 million units/4h i.v. for 2 weeks) with marked improvement and no relapses. One patient initially treated with penicillin G benzathine (2.4 million units/week for 3 weeks) suffered a relapse that was successfully treated with penicillin G. In those cases of ocular syphilis manifested by anterior uveitis the patients also received topic treatment (steroids and mydriatic drugs). Improvement of inflammatory tests/findings such as tyndall, choroiditis or vitritis was observed following antibiotic therapy. It was associated with marked improvement of visual acuity in 7 of the 10 patients. However, in the remaining 3 patients there was a impairment of visual acuity due to complications, mainly retinal detachment

Conclusion: We observed an increased incidence of syphilis presenting as uveitis in our Uveitis Unit. High level of suspicion for this infection is required to establish an early diagnosis and appropriate treatment.

1951

Anti-Cyclic Citrullinated Peptide (Anti-CCP) Antibodies with Brucellosis. Bunyamin Kisacik[1], Musa Aydinli[1], Yavuz Pehlivan[1], Muhammet sait Dag[1], Mehmet Sayarlioglu[2] and Ahmet Mesut Onat[3]. [1]Gaziantep, Turkey, [2]Kahramanmaras, Turkey, [3]Gaziantep Universitesi, Gaziantep, Turkey

Background/Purpose: Brucellosis is a zoonotic disease with a high prevalence that remains world's most commonly seen bacterial zoonosis. The clinical manifestations of brucellosis are similar with various diseases like rheumatic diseases, neurologic diseases and other infectious diseases. Anti-cyclic citrullinated peptide (Anti-CCP) is a highly specific serological marker for rheumatoid arthritis. In this study we have analyzed Anti-CCP and rheumatoid factor (RF) levels of patients with brucellosis.

Methods: The study population consist of of 113 patients with brucellosis (male/female: 37/76), 63 patients with hepatitis B (male/female: 30/33), 59 patients with hepatitis C (male/female: 11/48), 46 patients with rheumatoid arthritis (male/female: 16/30) and 49 patients with healthy controls (male/female: 20/29).

Results: Mean ages of patients with brucellosis, HCV, HBV, RA and healthy control subjects were 32.2±10.1, 34.2±8.2, 35.1±9.5, 46,6±11.1, 33.1±7.6 respectively. Artalgia was detected in 20 of 113 patients with brucellosis; arthritis was detected in 74 of 113 patients with brucellosis which was the commonest involvement. Of the 113 patients, 23 patients were mono-arthritis, 44 patients were oligo-arthritis and 7 patients were poly-arthritis. The most commonly affected joints were knee (49 patients, two patients were bilaterally), ankle (33 patients, three patients were bilaterally), hip (15 patients, three patients were bilaterally) and wrist (14 patients, three patients were bilaterally) respectively.The results of the analyses reflect that, anti-CCP was positive in 11.5% and RF was positive in 8.8% of the patients.

Conclusion: This is the first study that demonstrates potential role of anti-CCP in the diagnosis of patients with brucellosis. After a comparative evaluation, we have found out that there was not a statistical significance concerning the Anti-CCP levels between the patients with brucellosis and healthy control.

1952

Human Papillomavirus Lesion in Systemic Lupus Erythematosus. Ricardo V. Juarez. Crespo Maria Elena, Buschiazo Emilio, Sanchez Wilde Maria Cristina., Salta, Argentina

Background/Purpose: A papanicolau test and a pelvic exam are important as a part of a woman's routine health care because it can detect cancer related abnormalities. Human papillomavirus (HPV) infection is the primary risk factor for cervical cancer and is the most common sexually transmitted infection. Previous studies have demonstrated an increase prevalence of atypical cervical smears in patients with Systemic Lupus Erithematosus (SLE). These patients probably, may be predisposed to HPV infection due to SLE itself or the use of immunosuppressant or both.

The aims of this study were to compare, la prevalence of abnormal pap smears in SLE patients and to compare it with a group of healthy controls.

Methods: We studied consecutive patients fulfilling ACR criteria for SLE, recruited from one rheumatology center included between 2007 to 2010. Healthy controls were recruited from the same community and were matched by age. Each individual provided detailed medical information, medication and biochemistry. Disease activity was determined using Systemic Lupus Erithematosus Activity Index (SLEDAI) and disease damage by Systemic Lupus Erithematosus Collaborating Clinics Damage Index (SLICC). All the patients were refered to the gynecologist to take a sample of pap smear and colposcopy study.

Results: Thirty-two patients and 33 healthy controls were included. The median age of the SLE women was 35 years (IQR: 27–43.7) with a median disease duration of 6 years (IQR: 3–9.75). The prevalence of abnormal pap (Class III) smear was 12.4% (n = 4) in SLE patient compared with 6.1% (n = 2) in controls, but this difference did not reach statistical significance.

The prevalence de squamous intraepithelial lesion (SILs) was higher in patients than in controls, but was not statistically significant (7 (21.8%) vs 3 (9.09%), p = 0.139). The distribution for Low – grade SIL (LGSIL) was 3 (9.4%) vs 1 (3%), p = 0.355 and for high grade SIL (HGSIL) was 4 (12.5%) versus 2 (6.1%), p = 0.427. One of the patients had florid papillomatosis. In SLE patients there was no association between the presence of an abnormal gynecologic exam and the use of any inmunosuppressive therapy, or higher levels of SLEDAI or SLICC.

Conclusion: Abnormal Pap smear was more frequent in SLE patients than in healthy controls, though it did not reach statistical significance, perhaps due to the small number of patients.

ACR/ARHP Poster Session C
Miscellaneous Rheumatic and Inflammatory Diseases II

1953

A Higher Than Expected Prevalence of Autoimmune Disease in a Cohort of Patients with Recalcitrant Leg Ulcers. Victoria K. Shanmugam[1], Amber Schilling[1], Anthony Germinario[1], Mihriye Mete[2] and Christopher Attinger[3]. [1]Georgetown University Hospital, Washington, DC, [2]MedStar Health Research Institute, Hyattsville, MD, [3]Georgetown Universtiy Hosptial, Washington, DC

Background/Purpose: Wound healing is a highly regulated process progressing through hemostasis, inflammation, proliferation and maturation

regardless of the inciting etiology of the wound. Arrest of the wound in the inflammatory stage is a recognized cause of delayed healing, but the role autoimmune diseases play in this process is unknown. The purpose of this study was to determine the prevalence of autoimmune diseases in a cohort of patients presenting to a tertiary wound healing center, and to compare time to healing and graft outcomes.

Methods: Retrospective chart review was completed on consecutive patients scheduled in the Center for Wound Healing between January 1 and March 31, 2009. Subjects who did not attend and those without an open wound were excluded.

Baseline demographic and descriptive data including ulcer location, duration and size were recorded. Presence of comorbid conditions including autoimmune diseases, diabetes and vascular disease was documented. Time to healing and outcome of surgical interventions were recorded.

Data was analyzed using unpaired t-test for continuous variables, and Mann Whitney U test and Chi-square test for categorical variables using GraphPad Prism (GraphPad Software, CA).

Results: Of the 520 patients scheduled for appointments in the study period, 340 were eligible for inclusion. The remaining 180 patients either did not attend, or did not have an open ulcer.

Prevalence of diabetes, venous and arterial disease was as expected, with diabetes present in 168 patients (49%), venous disease in 120 (35%) and arterial disease in 118 (35%). However, the prevalence of autoimmune disease was much higher than expected with 78 of 340 patients (23%) having associated autoimmune disease, including rheumatoid arthritis (28%), systemic lupus erythematosus (14%), livedoid vasculopathy (14%), scleroderma (11%), vasculitis (10%), seronegative arthritis (8%), and inflammatory bowel disease (7%).

Autoimmune disease-associated wounds were significantly larger at the first visit, and were associated with higher pain scores (Table 1). While there was no significant difference in number of wounds that healed, autoimmune disease-associated wounds took significantly longer to heal (10.31 compared to 14.58 months, p=0.01).

Table 1.

	Non-Autoimmune Wounds n= 262	Autoimmune Wounds n=78	*p*
Age, years (Mean +/− SEM)	63.89+/−1.0	67.77+/−1.89	0.07
Race			
Caucasian	136 (52%)	40 (51%)	0.92
AA	106 (40%)	32 (41%)	0.92
Hispanic	6 (2.3%)	2 (2.6%)	0.88
Other	14 (5.3%)	4 (5.1%)	0.94
Sex			
Male	143 (55%)	25 (32%)	0.0005
Female	119 (45%)	53 (68%)	
Wound Size, cm^2(Mean +/− SEM)	22.5+/−3.9	33.4+/−7.8	0.02
Pain Score (Mean +/− SEM)	2.48+/−0.2	3.32+/−0.4	0.07
Wound healed over followup period	107 (41%)	31 (40%)	0.90
Time to healing, months (Mean +/− SEM)	10.31+/−0.6	14.58+/−2.27	0.01

Surgical skin graft and skin graft substitute data was available on 163 grafts from 50 subjects. Outcome was categorized into response (>50% graft take at 30 days) or no response (<50% graft take at 30 days). Only 39% of grafts to autoimmune-associated wounds demonstrated response compared to 49% of grafts to non-autoimmune associated wounds (p=0.29)

Conclusion: The 23% prevalence of autoimmune disease in this cohort is higher than in the general population, and higher than previously reported. Autoimmune-associated wounds were larger and took longer to heal than non-immune wounds, suggesting these wounds may provide important insights in to pathogenesis of delayed wound healing.

1954

Prevalence and Significance of Previously Undiagnosed Rheumatic Diseases in Pregnancy. Véronique Ramoni[1], Roberto Caporali[1], Arsenio Spinillo[2], Fausta Beneventi[2], Margherita Simonetta[2], Elena Locatelli[2], Chiara Cavagnoli[2], Claudia Alpini[3], Giulia Albonico[3], Elena Prisco[1] and Carlo M. Montecucco[1]. [1]Rheumatology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [2]Obstetrics and Gynecology, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, Italy, [3]IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background/Purpose: The objective of this study is to evaluate the rates of previously undiagnosed rheumatic diseases during the first trimester of pregnancy and their impact on pregnancy outcome.

Methods: Pregnant women attending the ultrasonography clinic of our Hospital for their first-trimester ultrasound scan were screened with a two-steps approach using a self administered 10 items questionnaire and subsequent testing for autoantibodies (antinuclear, anti-double-stranded DNA, anti-extractable nuclear antigen, anticardiolipin, anti-beta2-glycoprotein I antibodies and lupus anticoagulant) and evaluation by a rheumatologist. Overall, complications of pregnancy evaluated included fetal loss, preeclampsia, gestational diabetes, fetal growth restriction, delivery less than 34 weeks, neonatal resuscitation and admission to neonatal intensive care unit. Pregnancies were prospectively followed by Rheumatologists and Obstetricians to assess fetal and maternal outcomes.

Results: During a 5-year period (May 2005 to April 2010) out of the 2458 subjects screened, 291 (11.8%) patients answered positively to the questionnaire and among them 143 (49.2%) tested positive for autoantibodies. After rheumatologic evaluation we identified 62 (2.5%) women with a diagnosis of undifferentiated connective tissue disease (UCTD) and 24 (0.98%) with a major autoimmune rheumatic disease. The prevalences were 7 (0.28%) for systemic lupus erythematosus and Sjogren's syndrome, 6 (0.24 %) for rheumatoid arthritis, 3 (0.12%) for anti-phospholipid syndrome and 1 (0.04%) for systemic sclerosis respectively. Fifty-seven subjects (19.6%) had insufficient criteria for a diagnosis of inflammatory rheumatic disease despite positivity for both questionnaire and autoantibodies testing. During pregnancy, 18 patients required treatment with steroid and/or hydroxychloroquine to treat cutaneous and articular manifestations: 10 (16,1%) had UCTD e 8 (33,3%) had a major autoimmune rheumatic disease. Eleven patients received low dose aspirin and/or low molecular weight heparin as prophylaxis. Mean maternal age was higher in women with previously undiagnosed rheumatic diseases compared to healthy controls, while in this same group mean gestational age and birth weigh was lower. In multiple logistic regression, after adjustment for maternal age, the odds ratios of overall complications of pregnancy were 3.1 (95% confidence interval = 1.61 to 5.82) in subjects with UCTD and 5.74 (95% confidence interval = 2.33–14.2) in those with definite diseases, respectively, compared to asymptomatic controls.

Conclusion: In our population approximately 2.5% and 1% of first trimester pregnant women had a previously undiagnosed UCTD and definite systemic rheumatic disease, respectively. These conditions are associated with significant negative effects on the outcome of pregnancy.

1955

Eosinophilic Fasciitis (Shulman Disease): New Insights Into the Therapeutic Management From a Series of 34 Patients. David Lebeaux[1], Camille Frances[2], Stéphane Barete[2], Bertrand Wechsler[1], Odile Dubourg[1], Jérôme Renoux[1], Thierry Maisonobe[1], Olivier Benveniste[1], Marc Gatfossé[3], Pierre Bourgeois[1], Zahir Amoura[1], Jean-Charles Piette[4], Patrice Cacoub[4] and Damien Sène[1]. [1]Pitie-Salpetriere Hospital, Paris, France, [2]Tenon Hospital, Paris, France, [3]Centre Hospitalier Coulommiers, Coulommiers, France, [4]CHU Pitié-Salpêtrière, Paris, France

Background/Purpose: Eosinophilic fasciitis (EF) is a rare connective tissue disease characterized by a symmetrical and painful swelling with a progressive induration the skin and soft tissues. The therapeutic management of EF is one of the most significant challenges, as there is consensus on the use of steroids (dose and duration) and the interest of immunosuppressive drugs (ISD). The aim of this study was to analyze and report the results of the therapeutic management of 34 patients with a biopsy-proven EF.

Methods: We reviewed 34 adult-patients with a biopsy-proven EF. The analyses focused on the clinical, biological and histological features and the therapeutic management, which included the treatment modalities, responses and associated prognostic factors.

Results: 1) Clinical, biological and histological features: Thirty-four patients were included with a diagnosis age of 53±15.4 years. They were featured by cutaneous manifestations (88%) including morphea (41%), myalgia (86%) and hypereosinophilia (85%). The inflammatory infiltrates included lymphocytes in all patients (100%) and eosinophils in 26 patients (76.5%). A fascia fibrosis was present in 14 patients (41.2%) and an interstitial myositis in 23 patients (67.6%). A dermal fibrosis (histological morphea) was present in 11/30 patients (36.7%).

2) Therapeutic management and results: Thirty-two patients (94%) were eligible for treatment evaluation and all received corticosteroids as a first line therapy with a prednisone mean daily dose at initiation of 0.77±0.29 mg/kg. Fifteen patients (47%) received methylprednisolone pulses prior to prednisone treatment. At the end of follow-up: (A) 18 patients (56.25%) received steroids alone with a 45±31 month-treatment mean duration; (B) due to the lack of a complete remission, 14 patients (43.75%) required an ISD as a second line therapy in association with the steroid treatment in a 16.9±20.3

month-mean time interval (median=6.5): methotrexate for 12 patients (85.7%) with a 24.7±23.3 month-treatment mean duration and azathioprine for two patients (14.3%).

A complete remission was achieved for 69% of patients, a remission with disability (non progressive sequelae) for 19% and failure for 12%. The lack of complete remission was associated with a diagnosis time delay above 6 months (OR=14.7) and the lack of methylprednisolone pulses (OR=12.9). The relative risk of requiring an ISD was 4.7 times and 4.4 times higher in presence of a morphea and in patients who did not receive methylprednisolone pulses, respectively. EF-associated morphea was associated with a more frequent ISD requirement, mostly methotrexate (OR=64.4)

Conclusion: Our study reports new insights into the therapeutic management of EF: 1) corticosteroids treatment remains the standard therapy for EF, taken alone or in association with an ISD; 2) methylprednisolone pulses at treatment initiation are associated with a better outcome and a lower need of ISD use; 3) an ISD, mostly methotrexate, might useful as a second line therapy, mainly in patients with morphea-like lesions. Naturally, these practical conclusions should be confirmed by a prospective and multicentre study.

1956

Some of Subgroups in Rheumatoid Arthritis Are Difficult to Differentiate with Polymyalgia Rheumatica by a Genome-Wide Gene Expression Analysis. Yoshinobu Koyama[1], Chinami Era[1], Motohiko Tanino[2], Daisuke Hidaka[1], Toshiyuki Ota[1] and Ayumi Uchino[1]. [1]Iizuka Hospital, Iizuka, Japan, [2]DNA Chip Research Inc., Yokohama, Japan

Background/Purpose: There are many similarities between polymyalgia rheumatica (PMR) and rheumatoid arthritis (RA), especially late-onset RA, which in some cases, may lead to significant diagnostic difficulties. Microarrays for gene expression analysis are the most powerful technologies developed in recent years. It has been applied in the search for diagnostic patterns by comparing gene expression with other diseases to reveal markers for diagnostic and prognostic classification. So far, the differences of transcription profiles between PMR and RA have not been elucidated. The objectives of this study was to: (i) investigate whether the cluster analysis for genome-wide gene expression profiles of peripheral blood was able to distinguish RA from PMR; (ii) identify the gene expression signature that may distinguish RA from PMR.

Methods: The study included 44 RA patients (age 62.8±12.1) and 10 patients of Polymyalgia rheumatica (PMR: age 67.4±10.3). The final diagnosis of RA or PMR was confirmed after at least one year following up. In order to clarify the signature of gene expression, peripheral blood was drawn from the patients who were newly diagnosed and exposed neither steroids nor anti-rheumatic drugs. The samples were prepared and subjected to RNA extraction using PAXgene system (QIAGEN). Messenger RNA levels were then measured using Agilent whole human genome 60K (single-color procedure) and the log-transformed raw intensity data were normalized with a quantile algorithm. Based on the difference in gene expression between RA and PMR ($P<001$ by t-test), 4076 probes were selected and subjected to an unsupervised hierarchical clustering with assessment of the statistical robustness using a software, clusterStab (Bioconductor).

Results: The hierarchical clustering showed that the optimal number of clusters was 5. The statistical robustness was calculated for each cluster as 90%, 95%, 100%, 100% and 100%, respectively. Although the 4th and 5th cluster consisted of RA only, PMR was nested and distributed in the 1st to 3rd clusters. The percentage of PMR was 60%, 29% and 18% in these clusters, respectively. The average age of RA patients in the 1st cluster was statistically higher as compare with that of RA patients in the 4th and 5th clusters ($P<0.05$, 68.3±3.2 vs. 60.0±16.0). Application of pathway analysis reveals that B cell receptor (BCR) pathway was up-regulated in the 4th and 5th clusters.

Conclusion: PMR is an inflammatory rheumatic condition, which is sometimes difficult to distinguish from RA especially in elderly onset. Although the required treatments or features of pathophysiology are basically different between RA and PMR, these diseases occasionally seems to be overlapped. Although we defined 5 subgroups for RA and PMR by genome-wide transcription profiles, RA and PMR could not be distinguished clearly. It may support a hypothesis that some of RA or PMR cases may consider as an "overlap syndrome". The finding that BCL pathway was up-regulated in the "only-RA" clusters may explain that some of RA subgroups are susceptibility to B cell targeting treatments.

1957

Biologics In Relapsing Polychondritis: a Literature Review. Fernando Kemta Lekpa[1], Virginia Byers Kraus[2] and Xavier Chevalier[1]. [1]Hopital Henri-Mondor, Creteil, France, [2]Duke University Medical Center, Durham, NC

Background/Purpose: Emergence of biologics holds much hope in the management of patient with connective tissue disease, especially relapsing polychondritis (RP), a rare and severe disease which may lead to destruction of elastic cartilages. Until now, there is no standardized therapeutic protocol for RP. Objectives**:** To evaluate the efficacy and safety of biologics in patients with active RP.

Methods: A PubMed search up to December 2010 was performed without language restriction. MeSH terms and keywords were used relating to RP and biologics and various synonyms. All papers reporting the efficacy and/or safety of biologics in RP were selected. Reference lists of included papers were also search.

Results: All publications relate to case series or isolated case reports. No randomized controlled trial has been performed. Thirty papers including 61 patients were published. These patients were treated with TNFα blockers (n= 42), rituximab (n= 11), ankinra (n= 5), tocilizumab (n= 2) and abatacept (n= 1). Efficacy of these biologics is summarized in table 1. Safety appears to be good. However, four deaths were recorded (2 sepsis, 1 postoperatively after aortic aneurysm surgery and 1 after accidental dislocation of the tracheostomy device).

Table 1. Efficacy of biologics in relapsing polychondritis

Biologic Agent	Efficacy (Number of Patients) Yes	Partial	No	Total (Number of Patients)
Anti-TNFα				
Infliximab	14	3	14	31
Etanercept	4	0	3	7
Adalimumab	2	0	2	4
Rituximab	0	2	9	11
Anakinra	4	0	1	5
Tocilizumab	2	0	0	2
Abatacept	1	0	0	1

Conclusion: The experience with biologics in RP is very limited, and their real efficacy and indications need to be better defined. Randomized controlled trials, although difficult to realize because of the rarity of RP, are needed to determine the real role of biologics in the treatment strategy of this orphan disease.

1958

HM-018, An Oral Small Molecule JAK Inhibitor, Ameliorates Experimental Autoimmune Encephalomyelitis (EAE) in Mice. Yu Cai[1], Wuzhong Shen[1], Qianqian Dong[1], Zhipeng Wu[1], Xiaoning Yang[1], Ping Ren[1], Youjun Yu[1], Hongxia Shen[1], Jia Li[1], Jian Wang[1], Yang Sai[1], James Yan[1], Wei Deng[1], Jianguo Ji[2], Weiguo Su[1] and Haoran Zhao[1]. [1]Hutchison Medipharma Limited, Shanghai, China, [2]Abott, Shanghai, China

Background/Purpose: Multiple small molecule kinase inhibitors have been developed and advanced into clinical trials for the treatment of rheumatoid arthritis (RA) and represent a new class of oral DMARD therapies with immense potential. Janus family of non-receptor tyrosine kinases (JAKs), INCB018424, INCB028050, and CP690550 have demonstrated rapid and dramatic improvement in clinical measures of autoimmune diseases —consistent with their respective preclinical experiments. However, the effect of JAK inhibition has not been examined in animals with EAE, the experimental animal disease model for multiple sclerosis—a life-long, potentially debilitating autoimmune condition of the central nervous system in man.

Methods: Using both in vitro and in vivo assays for establishing structure-activity relationships, compounds were synthesized and screened to identify the ones with excellent potency, selectivity, and drug-like properties. PLP or MOG-induced EAE in mice was used to assess compound's effect in vivo. Clinical evaluation was carried out daily while histopathological analysis of the spinal cord was performed at the end of compound treatment. Inflammatory cytokine mRNA levels in spinal cords were quantified using real-time PCR.

Results: HM-018 was identified as a structurally unique, orally bioavailable, pan-JAK inhibitor with nanomolar potency against JAK1 (9.5 nM), JAK2 (14.8 nM), JAK 3 and TYK2 (less than 50 nM). It demonstrated superb selectivity to a panel of >63 additional kinases. HM-018 potently inhibited

signaling of multiple cytokines including IL-6 and IL-2 in vitro or in vivo. Prophylactic or therapeutic administration of HM-018 at 1 to 10 mg/kg significantly inhibited the progression of EAE and EAE-associated histological change in the spinal cords of SJL/J mice induced by immunization with $PLP_{139–151}$ peptide. Consistent with data from SJL/J mice, significant efficacy, as assessed by improvements in clinical score and histological signs of disease, was also achieved in the therapeutic setting of the more aggressive $MOG_{35–55}$-induced EAE model in C57BL/6 mice at total daily doses of 3~30 mg/kg. Disease development was nearly prevented completely at 30mg/kg. Histopathological examination of spinal cords showed that disease scores for inflammation and the area of demyelination were both significantly decreased in HM-018 treated animals versus vehicle control group. In the mean time, a rapid and sustained inhibition of the expression of mRNAs encoding multiple inflammatory mediators was detected. Moreover, HM-018 did not inhibit cytochrome P450s and demonstrated excellent oral PK properties in rodents and dogs. HM-018 also exhibited a favorable safety profile including a negative AMES test and no adverse effect level (NOAEL) in rats.

Conclusion: We demonstrated for the first time that HM-018, a potent and selective JAK inhibitor with attractive oral drug-like properties, exhibited strong beneficial effects under both prophylactic and therapeutic conditions in EAE models. These results support further development of JAK inhibitors for the treatment of MS patients.

1959

Safety and Efficacy of Mizoribine in Patients with Connective Tissue Diseases Other Than Rheumatoid Arthritis. Ryo Rokutanda[1], Mitsumasa Kishimoto[1], Hisanori Shimizu[1], Atsushi Nomura[2], Yasuhiro Suyama[1], Yuri Ohara[1], Akira Takeda[1], Ken-ichi Yamaguchi[3] and Masato Okada[1]. [1]St. Luke's International Hosptal, Tokyo, Japan, [2]Chubu-Rosai hospital, Nagoya, Japan, [3]St. Luke's International Hospital, Tokyo, Japan

Background/Purpose: Mizoribine (MZR) is an immunosuppressive agent which inhibits lymphocyte proliferation via inhibitory effect on the synthesis of inosine monophosphate dehydrogenase. Although MZR has the similar mechanism of action with Mycophenolate Mophetil, its anti-viral activity, such as against Cytomegalovirus, makes it more preferable as add-on therapy on high dose corticosteroids. While its efficacy for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), autoimmune nephritis and suppression of rejection in renal transplantation is well established, few studies have examined the use of MZR for various other connective tissue diseases (CTDs). The primary objective of this study was to evaluate the safety and tolerability of using MZR in a heterogeneous sample of patients with various CTDs other than RA. A secondary objective was to examine the impact of MZR on treating CTDs.

Methods: We identified all patients who had ever been treated with MZR for CTDs at our institution during the period from January 2001 to May 2011. After excluding patients with RA, a retrospective review of medical records was performed. Collected data included age, sex, race, type of CTD, time since diagnosis of CTD, previous treatment, and the reason for starting MZR. For the safety evaluation, information about adverse events, duration of therapy, and reasons for stopping MZR were also recorded. To categorize the purposes of adding MZR to corticosteroids therapy, patients who received high doses of PSL (prednisolone, 0.5 mg/kg/day or more) were defined as the induction therapy group, while those who received relatively low doses of PSL (less than 0.5 mg/kg/day) were defined as the maintenance therapy group. Longitudinal changes in the PSL doses were analyzed in each patient group.

Results: A total of 64 patients (14 receiving induction and 50 maintenance therapy with MZR) were included. The patient population comprised 34 with SLE, 6 with Sjögren syndrome, 6 with ANCA-associated vasculitis. Mean patient age at the time of starting MZR was 49.8 ± 16.5 years and the follow-up period was 400 ± 417 days. During 70.2 patient-years of follow-up, only two adverse events were identified: one was stomatitis which resulted in stopping MZR, and the other was leukocytopenia which improved with an MZR dose reduction. During the observational period, 17 patients discontinued MZR for various reasons. The reasons for discontinuation of treatment were lack of improvement/worsening of CTDs in 47.1% (8/17 patients), withdrawal after achieving remission in 11.8% (2/17 patients), and loss to follow-up in 11.8% (2/17 patients). In terms of efficacy, doses of PSL were significantly decreased at last follow-up in both the induction (44.1 ± 16.2 vs 10.7 ± 10.2 mg/day, $p<0.01$) and the maintenance group (12.4 ± 7.6 vs 9.3 ± 6.4 mg/day, $p<0.01$).

Conclusion: MZR appears to be safe and well tolerated in patients with CTDs other than RA. In addition, MZR seemed to be a effective steroid-sparing agent when combined with corticosteroids.

1960

Idiopathic Hindfoot Problems As An Early Rheumatological Manifestation of Hereditary Hemochromatosis Type I. Elena Becerra-Fernandez[1], Pantelis Panopalis[2] and Henri A. Menard[3]. [1]University College London, London, United Kingdom, [2]McGill University Health Center, Montreal, QC, [3]Montreal General Hospital, Montreal, QC

Background/Purpose: Ankle involvement in the arthropathy of Hereditary Hemochromatosis type I (HH) has been considered rare, but the number of reports describing this condition has increased over the past few years, highlighting the importance of further investigations for degenerative arthritis in unusual sites. Furthermore, two phenotypes of polyarticular osteoarthritis (OA) have been recently described, one of which, Type II OA, affects joints typically involved in HH and has been linked to mutations in the HFE genes in patients that do not suffer iron overload. Recent reports show that ferritin concentrations in synovial fluid are higher in those patients, suggesting that osteochondral damage in both arthropathy of HH and Type II POA may have the similar etiology. Currently, HFE genotyping is not done if the clinical or biochemical phenotypes are absent. Since frank idiopathic hindfoot OA can be a clue to undiagnosed HH, we hypothesized that unexplained idiopathic hindfoot arthralgia and/or joint swelling could be the presenting symptom of pre-clinical HH.

Methods: We report a pilot case series of 10 patients who presented to our clinic with idiopathic hindfoot problems and had a positive result for a major (C282Y) or minor (H63D) mutation in the HFE gene.

Results: All patients presented hindfoot symptoms, consisting of unilateral or bilateral arthralgia or joint swelling. Only one of the patients had been previously diagnosed with HH, and our studies revealed a bilateral marked subtalar joint osteoarthritis. In four of the patients, HH was diagnosed thanks to the hindfoot symptoms in otherwise asymptomatic patients, since bloods revealed data consistent with iron overload, and gene typing confirmed the diagnosis, with homozygosity for the major mutation in patients 2–4, and heterozygosity for the major mutation in patient 5. Patients 6–10 did not show the biochemical phenotype and were all heterozygote for the minor mutation. Patients 6 and 7 were initially diagnosed as chondrocalcinosis, but had persistent symptoms in the MCPs 2 and 3 bilaterally and ankles. Patient 8 presented with bilateral ankle pain and subtalar OA on X-Rays. Patient 9 presented as a polyarthralgia with involvement of his left hindfoot. Patient 10 had been diagnosed and treated for seropositive rheumatoid arthritis but had persistent non inflammatory swelling and bilateral mechanical pain in ankles and MCPs 2–3 (Pseudo-RA vs coexistent HH + RA?).

Conclusion: Hindfoot rheumatic symptoms can be the first manifestation of HH, long before occurrence of organ failure. This highlights the importance of including HH in the differential diagnosis of arthritis of unknown origin or degenerative arthropathy of unusual sites, especially the hindfoot which may have been overlooked in the past. In patients without iron overload, the HFE mutation would seem to operate via a different mechanism. For the rheumatologist, HFE genotyping of patients with hindfoot problems of unknown origin is useful. Our observations and other publications suggest that patients with the so-called "silent" H63D HFE mutation have early rheumatic symptoms. It follows that given their high frequency, those mutations may be a still insufficiently recognized major genetic risk factor for OA.

1961

Tumor Necrosis Factor Receptor Associated Periodic Fever Syndrome: A Case Series with Characteristic Features. Qingping Yao. Cleveland Clinic, Cleveland, OH

Background/Purpose: Autoinflammatory diseases (AIDs) are characterized by seemingly unprovoked episodes of inflammation, without high titer autoantibodies or antigen specific T cells, and derive from genetic variants of the innate immune system. Tumor necrosis factor receptor associated periodic fever syndrome (TRAPS) is an autosomal dominant AID. This study aimed to analyze a small case series of TRAPS with characteristic phenotypic and genotypic features.

Methods: Three adult patients with autoinflammatory clinical phenotypes were seen by the author in the Rheumatology Clinic at the Cleveland

Clinic between January, 2009 and October, 2010. A retrospective and prospective study of these cases was performed.

Results: These patients presented with autoinflammatory phenotypes compatible with TRAPS by genetic testing. Patient 1 was a 58-year-old Jewish woman with photographic evidence of various skin disease, including previously unreported severe alopecia, self limiting episodes of fever, abdominal pain/diarrhea, oligoarthralgia and myalgia. Complaints of urinating foreign bodies prompted a diagnosis of ureteral strictures with atypical cells, indicating a sequela of long-term autoinflammation. Patient 2 was a 32-year-old Caucasian woman with recurrent erythematous macules and papules (Photo), polyarthralgia and oral lesions. She was also found to have Ehlers-Danlos syndrome type III (Photo) which may complicate the arthralgia. Both TRAPS and Ehlers-Danlos syndrome could share common gene mutations. Patient 3 was a 56-year-old Caucasian man who presented with 4 years of periodic episodes of the right upper quadrant pain with nausea and vomiting. Both patients 1 and 2 had TNF receptor superfamily 1A (TNFRSF1A) gene mutation, R92Q and the patient 3 had TNFRSF1A missense mutation, V20A. Therapeutically, the patient 1 responded well to a short course of high dose prednisone, the patient 2 was treated with nonsteroidal anti-inflammatory agents, and the patient 3 had minimal response to high dose prednisone and failed a trial of etanercept.

Conclusion: Our small case series study suggests that patients with TRAPS may present with unusual phenotypes. TRAPS generally has oligoarthralgia which should be differentiated from concurrent joint disease. TNFRSF1A VA20 mutation has been linked to the clinical phenotypes of this disease.

1962

Atypical Persistent Plaquelike Skin Rash of Adult Onset Still's Disease. Case Report and Review of Literature. Asha Muthalaly[1], Dennis C. Ang[2], Steven T. Hugenberg[3], Roy Sampson[1] and Agith Muthalaly[4]. [1]Indiana University School of Medicine, Indianapolis, IN, [2]Indiana University, Indianapolis, IN, [3]Indiana Univ Schl of Medicine, Indianapolis, IN, [4]St. James School of Medicine, Chicago

Background/Purpose: 25 y/o Malaysian woman with no past medical history presented to the hospital with a 2 month history of fevers, chills, night sweats, diffuse myalgia, lethargy and sore throat. She also had a diffuse pruritic persistent hyper pigmented rash on back, chest, distal extremities. The patient was diagnosed with adult-onset Still's disease (AOSD) based on Yamaguchi criteria and skin biopsy revealed spongiotic psoriasiform dermatitis with scattered necrotic keratinocytes and confluent hyperkeratosis. Our patient met criteria for diagnosis of prurigo pigmentosa based on clinical and histopathologic findings. There have only been two other reported cases. However, when a review of literature was performed of all known cases of persistent plaques associated with AOSD, it was found that prurigo pigmentosa may be associated more commonly with AOSD than previously thought.

Methods: Meta analysis of 10 articles reviewed (total of 21 patients with AOSD) with persistent papules and plaques

Results: The histopathologic findings reported are commonly found in different stages of prurigo pigmentosa. See attached table for details.

Diagnosis	Laboratory Data	Gross findings	Pruritic	Description of Histology	Pathologic Diagnosis	Response to treatment	Duration of disease
AOSD (Case 1 presentation)	Ana negative, RF factor negative, elevated ferritin, normocytic anemia, and leukocytosis	Diffuse persistent hyperpigmented rash on back, chest, distal extremities	Yes	Spongiotic psoriasiform dermatitis with scattered necrotic keratinocytes and confluent hyperkarotosis	Meets criteria for prurigo pigmentosa based on histopathologic findings	Complete resolution of rash and systemic symptoms with prednisone 20mg and started on methotrexate for maintenance	2 months
Case 2 AOSD	Leukocytosis,elevated LFTS, elevated ferritin	Persistent skin rash on upper chest and back and evanescent skin eruption on lower extremities	N/A	Mild acanthosis, slight spongiosis, exocytosis and dyskaratotic cells	Prurigo pigmentosa	Complete resolution of rash with prednisone 40mg.	3 weeks
Case 3 AOSD	Leukocytosis, elevated LFTS, elevated ferritin, normocytic anemia, RF, ANA negative	Popular eruption arranged in reticulate pattern and distributed on face, neck, trunk and legs	Yes	Mild hyperkaratosis, acanthosis and mild spongiosis of epidermis. Lymphocytic infiltrate	Prurigo pigmentosa	Responded to prednisolone 1mg/kd/d and then prednisone therapy	10 days
Case 4 AOSD	Elevated sed rate, negative ANA and RF, elevated ferritin	Popular eruption which then became hyperpigmented papules over thighs,prethial areas and upper back, forearms	Yes	Hyperorthokeratosis, with dyskaratotic keratinocytes, mild perivascular infiltrate composed of lymphocytes and occasional eosinophils	Dyskaratosis w/ no specific diagnosis	Initial prednisone therapy with no response then methotrexate and etanercept and switched to interleukin 1 receptor antagonist (anakinra)	unknown
Case 5 AOSD	Normocytic anaemia,elevated liver function tests, negative ANA, RF	Migratory plaquelike rash on lower legs then became fixed and spread symmetrically on arms, dorsal hands,upper chest and back	Yes	Foci of eosinophilic spongiosis, epidermis with scattered necrotic keratinocytes with dermal lymphocytic perivascular infiltrate	No specific skin diagnosis	Methylprednisilone for 3 days with resolution of rash and then prednisone oral daily with methotrexate	8 months
Case 6 AOSD	Anemia, leukocytosis, thrombocytosis, elevated ESR and CRP. Elevated ferritin. Negative	Generalized edematous pink, maculopapular and urticarial lesions in arms and chest	N/A	Parakeratosis, acanthosis, and scattered intraepidermal	No specific skin diagnosis	Rapid resolution of all systemic symptoms with the skin lesions	5 weeks

Conclusion: The typical salmon colored evanescent rash is observed in 87% of patients in AOSD with histopathology showing relatively sparse perivascular mixed inflammatory infiltrate containing some neutrophils. Prurigo pigmentosa is a distinctive inflammatory disease first described in Japan. Clues to diagnosis include impression of trunk centered "scratched urticaria" Usually involves back, chest and neck and may also involve proximal extremities and upper extremities. It is rarely diagnosed outside of Japan because of its unfamiliarity. Various mechanisms proposed have been friction, contact allergy, sensitivity to sunlight, endocrine disorders such as diabetes, and metabolic disorders such as ketosis. Early lesions have superficial infiltrate of neutrophils and spongiosis with a few necrotic keratinocytes. Fully developed lesions have lymphocytic predominate infiltrate. In late lesions the epidermis is slightly hyperplastic and parakaratotic. Pruritis of early lesions is severe, however resolving lesions are devoid of symptoms. The pathologic skin diagnosis of the cases reviewed was unclear in the majority of cases. Prurigo pigmentosa may be an unusual yet more common, but under recognized skin manifestation of AOSD of which rheumatologists need to be aware in clinical practice.

1963

Clinical and Genetic Features of Autoinflammatory Syndromes in Hispanic Patients: The Chilean Experience. Cristian Vergara[1], Arturo Borzutzky[1], Miguel A. Gutierrez[1], Sergio Iacobelli[1], Eduardo Talesnik[1], Maria Eugenia Martinez[1], Lilith Stange[1], Javier Basualdo[2], Viviana Maluje[3], Renato Jimenez[4], Elena Jarpa[5], Roberto Wiener[6], Javier Tinoco[6], Juan I. Arostegui[7], Jordi Yague[7] and Manuel Alvarez-Lobos[1]. [1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Universidad de Chile, Santiago, Chile, [3]Hospital FACH, Santiago, Chile, [4]Hospital Gustavo Fricke, Valparaiso, Chile, [5]Hospital Naval Almirante Nef, Vina Del Mar, Chile, [6]Hospital Militar, Santiago, Chile, [7]Hospital Clínic/IDIBAPS, Barcelona, Spain

Background/Purpose: Hereditary autoinflammatory syndromes (AIS) are rare genetic diseases characterized by recurrent episodes of inflammation. Little information is available concerning AIS in Latin American Hispanic population. The purpose of this study was to determine the clinical and genetic characteristics of AIS in Chilean population.

Methods: A multicenter retrospective study of Hispanic patients from Chile with genetically-confirmed AIS was performed. Inclusion criteria for Familial Mediterranean Fever (FMF) were the presence of the characteristic clinical features associated with at least one mutated *MEFV* allele, whereas the TNF receptor-associated periodic syndrome (TRAPS) inclusion criteria were the presence of long inflammatory episodes associated with *TNFRSF1A* mutations. We included 13 patients, eight with FMF and five with TRAPS, evaluated at rheumatology or pediatric rheumatology clinics between January of 2007 and December of 2010. No patients with other AIS were seen in the study period.

Results: All 13 patients were Chilean and had Hispanic Latin American ethnicity with no other known genetic backgrounds. Median age of onset of clinical symptoms was 8 years (range: 1–35) and 8 years (range: 0.3–21) for FMF and TRAPS, respectively. Median duration of fever was 3 days (range: 2.5–15) for FMF and 21 days (range: 9.5–30) for TRAPS. In FMF patients, fever was associated with abdominal pain (6/8), myalgias (5/8), arthritis (4/8), and rash (3/8). All FMF patients had at least partial response to colchicine therapy, with two patients fully resolving episodes of recurrent fevers. Reactive AA-type amyloidosis was not observed among this group of FMF patients. In TRAPS patients, febrile episodes were preceded by malaise and periorbital edema in two patients. During episodes symptoms accompanying fever were migratory myalgias (4/5), rash (3/5), arthralgias/arthritis (3/5), and abdominal pain (3/5). Two patients with TRAPS underwent surgery for acute abdomen. Fever episodes were responsive to high-dose corticosteroids in 4/5 patients with TRAPS. Genotyping of the *MEFV* gene in FMF patients revealed one patient with a homozygous M694V missense mutation, and heterozygous missense mutations in seven patients: M694V (n=3), E148Q, R717H, A744S, and A511V. Sequencing of the *TNFRSF1A* gene in TRAPS patients revealed heterozygous missense mutations in four patients: T50M, C30R, R92Q, and IVS3+30:G>A, and a 2-base pair deletion (IVS2–17_18del2bpCT) in one patient. Mutation in *MEFV* R717H and mutations in *TNFRSF1A* IVS2–17_18del2bpCT and IVS3+30:G>A are novel and have not been reported previously.

Conclusion: This study reports the largest series of genetically-confirmed AIS in Latin America, and adds evidence regarding the clinical and genetic characteristics of patients with FMF and TRAPS in Hispanic population. In this series, mutations identified in *MEFV* and *TNFRSF1A* genes include defects reported in other ethnicities and novel mutations.

1964

Use of Canakinumab in the Routinary Clinical Practice in Severe Cryopyrin-Associated Periodic Syndrome: One Year of Follow-up.

Roberta Caorsi[1], Loredana Lepore[2], Francesco Zulian[3], Maria Alessio[4], Achille Stabile[5], Martina Finetti[6], Alberto Martini[6] and Marco Gattorno[1]. [1]G. Gaslini Institute, Genova, Italy, [2]Ospedale-Infantile Trieste, Trieste, Italy, [3]University of Padua, Padova, Italy, [4]University of Naples Federico II, Napoli, Italy, [5]DipartimentoPediatria, Policlinico Gemelli, Roma, Italy, [6]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy

Background/Purpose: Preliminary studies have shown the efficacy of Canakinumab (Ilaris™) in patients with Cryopyrin associated periodic syndromes (CAPS). So far, few information is available about the optimal dosage and frequency of administration of Canakinumab, especially in children presenting a more severe phenotype. Aim of the study was to analyse the efficacy and optimal dose regimen of Canakinumab in CAPS patients in 12 months of routinely clinical practice.

Methods: 12 patients (F:M = 7:5, 9 children and 3 adults) with a clinical diagnosis of CINCA (6 patients), Muckle-Wells (MWS) overlapping with CINCA syndrome (3 patients) and MWS (3 patients) were analyzed. Nine out of them carried mutations of NLRP3 gene. All patients were previously enrolled in the CACZ885D2306 trial and followed in an open fashion for 12 months after the end of the study. Modifications of dose and/or frequency were performed according to the judgment of the physician in charge. Complete remission was considered as the absence of clinical manifestations and normal acute phase reactants. Patients with no clinical remission and elevation of acute phase reactants were considered in partial remission. Patients with clinical manifestations and elevation of acute phase reactants were considered in relapse or active.

Results: At the end of CACZ885D2306 trial (baseline) 7 patients (3 CINCA patients, 1 MWS/CINCA and 3 MWS) were treated with the initial dosage of 2 mg/kg (or 150 mg if weight was higher than 40 Kg) every 8 weeks. Five were in complete remission, 2 CINCA in partial remission. In 5 patients (3 CINCA patients and 2 MWS/CINCA) the dosage was increased to 4 mg/kg (or 300 mg) every 8 weeks. All of them were in partial remission. During observational study, modifications of dosage or frequency were performed in 7/12 patients. The 5 patients who required a higher dosage during the CACZ885D2306 displayed a persistent elevation of acute phase reactants associated, in 2 patients, with a mild clinical disease activity (mild rash, headache, arthralgia). In these patients the frequency of the administration of Canakinumab was gradually increased to 7 weeks (1 CINCA, 1 MWS/CINCA), to 6 weeks in 2 CINCA patients and every 4 weeks in 1 MWS/CINCA patient. At the end of the 12 months of observation 1 patient was in complete remission and 3 in partial remission. In one CINCA patient the treatment was discontinued due to persistence of disease activity and poor compliance. During the 12 month of follow-up other two patients (1 CINCA, 1 MWS) displayed a mild relapse of their diseases that required to increase the frequency of administration (6 and 7 weeks, respectively) without a modification of the dosage (2 mg/kg). In 5 patients (2 MWS, 1 MWS/CINCA and 2 CINCA patients) the treatment was not modified being effective in the control of the disease.

Conclusion: This study confirms the efficacy of Canakinumab in the control of disease activity in CAPS. However, paediatric patients and those with a more severe phenotype require higher and more frequent dosage than previously described

1965

Classification of Two Subtypes in Adult-Onset Still's Disease.

Hisae Ichida, Yasushi Kawaguchi, Tomoko Sugiura, Takahisa Gono, Kae Takagi, Yuko Ota, Ikuko Masuda and Hisashi Yamanaka. Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background/Purpose: Adult-onset Still's disease (AOSD) may be a clinical entity including heterogenous etiology and pathogenesis. Clinical characteristics are systemic inflammations of unknown origin with hyperferritinemia in the absence of any autoantibodies. We encountered patients with AOSD having severe polyarthritis corresponding with the classification criteria of rheumatoid arthritis (RA), although most of patients with AOSD showed mild arthritis in general. In the present study, we propose two clinical subsets in AOSD and investigate clinically significant characteristics of the two subtypes.

Methods: We retrospectively observed consecutive 73 patients with AOSD in our outpatient clinic from 1995 to 2008. We observed the medical records of all patients for more than 2 years. We classified all patients with AOSD into 2 subsets: RA-subtype who finally met the revised criteria of American College of Rheumatology clinical diagnostic criteria for RA; and nonRA-subtype who didn't met it at all.

Results: The levels of both serum ferritin and IL-18 were significantly higher in nonRA-subtype than those in RA-subtype. To define the optimal cut-off point with the highest diagnostic accuracy, we performed receiver operating characteristic analyses for distinct serum ferritin and IL-18 concentrations. In both less than 1500 ng/dl of serum ferritin and less than 44000 pg/ml of serum IL-18, the sensitivity of RA-subtype was 82% and the specificity was 82% (Table 1). The frequency of patients whose family had autoimmune diseases showed a tendency to be high in nonRA-type. NonRA-subtype was accompanied with some severe inflammatory complications (i.e.; pleuritis, DIC, HPS). Interestingly, in patients with RA-subtype only a patient had anti-CCP antibody and no patients had rheumatoid factor, which is completely different from patients with true RA. The treatments with methotrexate and/or salazosulfapyridine were more frequent in RA-subtype than those in nonRA-subtype. All patients treated with biologics belonged to RA-type. Tocilizumab were applied to two patients, resulting in attenuating inflammation in the two patients.

Table 1. Predictive values of serum ferritin and serum IL-18

	RA-subtype n, (%)	NonRA-subtype n, (%)	P-value OR (95% CI)
Ferritin < 1500 ng/dl	12/15 (80)	15/52 (29)	0.0005 10 (2.4–40)
IL-18 < 44000 pg/ml	10/11 (91)	14/34 (41)	0.0043 14 (1.6–125)
Ferritin < 1500 and IL-18 < 44000	9/11 (82)	6/34 (18)	0.0002 21 (3.6–123)

The P-value was estimated by Fisher's exact test. n: number

Conclusion: We concluded the existence of two subsets in patients with AOSD. Patients with high levels of IL-18 or ferritin were complicated with severe systemic inflammatory disorders (nonRA-subtype), and patients with low levels of them developed to severe arthritis (RA-subtype).

1966

Free Interleukin 18 As a Predictor of Remission and Flare up in Adult-Onset Still's Disease Patients.

Kyong-Hee Jung[1], Joo Hyun Lee[2], JinJu Kim[2], Jin Sook Lee[2], Won Park[1], Tae-Hwan Kim[2] and Dae-Hyun Yoo[2]. [1]Center for Rheumatism, Inha University Hospital, Incheon, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: Recent investigations have shown that the serum level of interleukint-18 (IL-18) is extremely high in adult-onset Still's disease (AOSD) patients. However, IL-18 binding protein (IL-18BP), a natural antagonist of IL-18, and free IL-18 in AOSD have not been studied yet. The aim of this study was to investigate the usefulness of free IL-18 in AOSD patients.

Methods: The levels of free IL-18 were compared between 66 AOSD patients and 90 controls (30 unaffected controls, 30 rheumatoid arthritis patients, and 30 ankylosing spondylitis patients). The AOSD patients were divided into active and inactive groups according to disease activity based on clinical and laboratory findings. The inactive patients were further subdivided into remission group (the absence of clinical symptoms and laboratory evidence of disease activity for at least 12 months) and maintenance group. We compared ESR, CRP, ferritin and free IL-18 in AOSD patients. We measured serum IL-18, IL-18BP using enzyme-linked immunosorbent assay and calculated free IL-18 by applying the law of mass action.

Results: AOSD patients showed significantly higher levels of free IL-18 than controls (mean±SD, AOSD 14762±30586 pg/ml, RA 402±449 pg/ml, AS 192±98 pg/ml, healthy controls 175±74 pg/ml, $p<0.001$). Like conventional activity marker such as ESR, CRP and ferritin, free IL-18 was significantly higher in active group than inactive group (active 20913±27691 pg/ml, inactive 4523±8993 pg/ml, p-value <0.001). Within the inactive group with normal ESR, CRP and ferritin, free IL-18 levels in the remission group were significantly lower than in the maintenance group (remission 710±714 pg/ml, maintenance 6884±10856 pg/ml, p-value=0.047). During follow up, 4 out of 14 inactive AOSD patients with higher levels of free IL-18 despite of normal ESR, CRP and ferritin had a disease flare up within 3 months.

Conclusion: Free IL-18 level was significantly high in AOSD patients despite compensation of IL-18BP. Free IL-18 could be useful in the assessment of disease activity especially in clinically inactive AOSD patients, a useful predictor of remission and flare up.

1967

Study Design of the β-Confident-Registry Aiming to Evaluate the Largest Cohort of Cryopyrin-Associated Periodic Syndromes Patients. Hal M. Hoffman[1], Ulrich A. Walker[2], Hugh Tilson[3], Jasmin B. Kuemmerle-Deschner[4] and Philip Hawkins[5]. [1]Division of Rheumatology and Allergy/Immunology, La Jolla, CA, [2]Dept. of Rheumatology at Basel University, Felix-Platter Spital, Basel, Switzerland, [3]University of North Carolina, North Carolina, [4]University Hospital Tuebingen, Tuebingen, Germany, [5]Department of Medicine, University College London Medical School, London, United Kingdom

Background/Purpose: Cryopyrin-associated periodic syndromes (CAPS) is an extremely rare inflammatory disorder with limited available clinical and especially long-term follow-up data. Canakinumab (Ilaris®) has recently been approved for the treatment of CAPS, however, data on longer-term follow-up in larger patient cohorts is warranted. We report here the design of a global observational registry for canakinumab. The registry is monitored by an external steering committee with expertise in auto-inflammatory disease and registry design. The primary objective is to monitor overall safety of routine care with canakinumab in a large cohort (N≥400) of CAPS patients. Secondary objectives include exploring growth and development patterns in children and to measure the long-term impact of canakinumab on disease progression.

Methods: CAPS patients receiving canakinumab as part of their routine care are included in this study for a minimum of 5-years follow-up. Data from routine clinic assessments is supplied at 6-monthly intervals via a web-based application. Selected safety events potentially associated with anti-IL-1 therapy such as serious infections, malignancies, hypersensitivity and disease activity/progression is analyzed. Signs and symptoms of systemic inflammation, neurologic and ophthalmologic status and the potential for canakinumab therapy to prevent amyloidosis and to ameliorate sensorineural deafness are assessed. Patterns of growth/development, pregnancies, outcomes of vaccination, dosing pattern and tolerability are ascertained. All patients are followed until the registry ends.

Results: Baseline data from the first 58 CAPS patients, including 15 pediatric patients (age <18 years), enrolled to date, are presented (Table). Updated data will be provided during the presentation at the congress.

Table. Baseline characteristics of CAPS patients enrolled in B-Confident-Registry study till date

	FCAS (n=10)	MWS (n=37)	NOMID (n=6)	Other (n=5)
Age <4 years, n	0	2	0	1
Age 4-<18 years, n	2	6	3	1
Age ≥18 years, n	8	29	3	3
Male, n (%)	3 (30.0)	20 (54.1)	3 (50.0)	2 (40.0)
NLRP3 mutation, n (%)	10 (100.0)	35 (94.6)	5 (83.3)	2 (86.7)
Disease duration (months, mean)	550	370	172	64
Prior IL-1 inhibitor treatment, n (%)	0	14 (37.8)	1 (16.1)	2 (40)
Rash/arthralgia/headache/ conjunctivitis (%)	100/100/ 50/80	97.3/97.3/ 78.4/75.7	100/100/ 83.4/66.6	80/100/ 20/40
History of anaemia (%)	10	8.1	50	0
Prior SAA value (mg/L, mean)	37	26	47	3

FCAS=familial cold auto-inflammatory syndrome; IL-1=interleukin-1; MWS=Muckle-Wells syndrome;
n=number of patients; NOMID=neonatal-onset multisystem inflammatory disease;
SAA=serum amyloid A

Conclusion: Baseline characteristics validate an expected disease background in all patients enrolled to date. Upon availability of larger data-sets, subanalyses will yield valuable insights into disease characteristics and modification properties and safety profile of canakinumab in this rare disease.

1968

Anti-TNFα Therapy in 15 Patients with Severe and Refractory Sarcoidosis. Inés Pérez-Martín[1], Ricardo Blanco[2], Javier Rueda[1], Carmen Bejerano[2], Orlando Pompei[1], M. Carmen González-Vela[1], Marcos A. González-López[1], Héctor Fernández-Llaca[1], Agustín Oterino[1], María J. Sedano[1], Mario Agudo[1], Víctor M. Martínez-Taboada[1] and Miguel Angel González-Gay[1]. [1]Hospital Universitario Marqués de Valdecilla. IFIMAV, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla-IFIMAV, Santander, Spain

Background/Purpose: Sarcoidosis is a systemic granulomatous autoimmune disease. Clinically it may range from a mild to a severe life-threatening disease.

Methods: We reviewed the medical records of patients seen at the Rheumatology Service of a University hospital that were diagnosed with sarcoidosis and treated with anti-TNFα therapy because of disease severity.

Results: We assessed 15 patients (8 women/7 men); mean age at disease diagnosis: 49±15 years (range: 28–69); mean duration of sarcoidosis before the onset of anti-TNFα therapy 74±95 months (range 12–360) **(TABLE).**

patient	age/sex	main clinical complication	immunosuppressive agents prior to anti-TNFα	prednisone dose at anti-TNFα onset	1st anti-TNFα/2nd anti-TNFα	immunosuppressive drug with anti-TNFα
1	64/F	lupus pernio	HQ/AZA/MTX	–	infliximab	MTX
2	46/M	general syndrome and myopathy	HQ/MTX	40mg/d	infliximab	MTX
3	48/F	uveítis	MTX	45mg/d	infliximab	MTX
4	33/F	uveítis	SZP/MTX	30mg/d	infliximab/ adalimumab	MTX
5	28/M	uveítis	AZA	40mg/d	adalimumab	AZA
6	30/M	uveítis	HQ/MTX	30mg/d	infliximab	AZA
7	69/M	bone marrow-pancytopenia	MTX	30mg/d	infliximab/ adalimumab	MTX
8	67/F	neurosarcoidosis	MTX	40mg/d	infliximab	MTX
9	65/F	neurosarcoidosis	MTX	40mg/d	infliximab/ adalimumab	MTX
10	54/M	uveitis	CyA	45mg/d	adalimumab	–
11	58/M	neurosarcoidosis	–	60mg/d	infliximab	MTX
12	54/F	neurosarcoidosis	MTX/AZA	45mg/d	infliximab/ adalimumab	MTX
13	29/M	neurosarcoidosis	–	60mg/d	infliximab	MTX
14	56/M	aortitis	MTX	30mg/d	adalimumab	MTX
15	62/F	neurosarcoidosis	–	30mg/d	infliximab	MTX

Abbreviations: HQ: hydroxichloroquine, MTX: methotrexate, AZA: azathioprine, CyA: cyclosporine A SZP: sulfasalazine, M: male, F: female

The main clinical complications that made necessary the use of anti-TNFα agents were: uveitis (5 cases), neurosarcoidosis (6), bone marrow involvement-pancitopenia (1), skin-lupus pernio (1), systemic-myopathy (1), and aortitis (1).

Most patients had been refractory to corticosteroids and at least one immunosuppressive drug. However, in 3 patients with neurosarcoidosis anti-TNFα agents were prescribed along with corticosteroids as the initial therapy. Besides high-dose prednisone, patients had received the following drugs: i.v. methylprednisolone (500–1000 mg for 3 consecutive days) (4 cases) methotrexate (10 cases), cyclosporine (1 case), azathioprine (3 cases), sulfasalazine (2 cases), and hydroxychloroquine (3 cases).

Anti-TNFα drugs were associated to an immunosuppressive agent (methotrexate, or azathioprine). Infliximab was the most commonly anti-TNFα drug used in this series- in 12 cases (3–5 mg/kg/i.v. at 0, 2, 6 and then every 4–8 weeks). Adalimumab was administered in the other 3 patients (40 mg/sc EOW or EW if necessary). Infliximab was discontinued in 2 cases because of inefficacy and in another 2 due to adverse events (severe rash and gastrointestinal intolerance, respectively). In these 4 cases, infliximab was switched to adalimumab. Adalimumab was discontinued in 1 of 7 cases because of development of a lupus-like syndrome. After a mean time of anti-TNFα therapy of 25 ± 20 months (range 1–72), complete clinical remission was achieved in 9 cases and partial improvement in the remaining 6 patients. Of major importance, in most patients anti-TNFα treatment allowed withdrawal or significant reduction of corticosteroid therapy.

The most common adverse events were infections. Three of them were severe: pneumonia by *P. jirovecii*, septic shock by *P. aeruginosa* and VV Zoster infection.

Conclusion: Infliximab and adalimumab appear to be effective and safe drugs in the management of severe and refractory sarcoidosis.

1969

Sonographic Detection of a Bifid Median Nerve and Persistent Median Artery Among Patients with Clinical Diagnosis of Carpal Tunnel Syndrome in Rheumatology Office. Francis Luk, Carolyn R. O'Connor, Humaira Hussain, Vincent Zarro and Angel E. Checa. Drexel University College of Medicine, Philadelphia, PA

Background/Purpose: Patients with carpal tunnel syndrome (CTS) are often managed in rheumatology by corticoid injections with or without ultrasound guidance. Although, there is an increasing use of new imaging techniques which permit the identification of the bifid median nerve (bmn) and persistent median artery (pma), the prevalence of these variants continue to be unclear. The pma is a potential source of complication by laceration during interventional procedures.

Methods: To determine the prevalence and sonographic characteristics of bmn and pma in patients with CTS, a total of 129 wrists of 77 consecutive patients (9 males, 68 females) with clinical diagnosis of CTS assessed by ultrasound in rheumatology office were studied. A longitudinal and transverse

scan of the volar aspect of the wrist was performed with a GE LOGIQ e machine equipped with a broadband linear transducer from 8 to 13 MHz. The cross sectional area of the median nerve was calculated with the ellipse at the scaphoid-pisiform level. In those cases with bmn both branches were measured separately. The functional status of the median artery was evaluated by the presence or absence of a Doppler signal.

Results: Out of 77 patients (129 wrists), 13 (14 wrists) showed bmn or pma. The mean age of those with bmn or pma was 52.5 (31–81) years, with a prevalence of 8.5% and 4.6% respectively. The bmn was more common in the left hand, and a greater lateral branch was the most characteristic sonographic pattern, observed in 70%. The average cross sectional area for bmn was 11.4 (range 6–18) square millimeters. The pma was associated with a bmn in three wrists, and it appeared as an isolated variant in 3 other wrists. The average diameter of pma was 1.4 (range 0.8–3.1) millimeters. In three of them, Doppler signal showed a functional artery.Doppler signal was absent in two pma's and in one artery, the Doppler was not explored. In those patients with pma but no Doppler signal, a non-functional cord-like remnant may be present.

Conclusion: Although studies of large populations are needed, the increased observation of bmn and pma by ultrasound in patients with CTS should be considered more than a medical curiosity. Because corticoid injection and surgery are common therapeutic modalities in patients with CTS, an ultrasound should be part of the initial work-up to detect their presence and avoid the potential complication of laceration, bleeding, and nerve damage.

1970

The Role of Sufficient Starting Dose of Steroids in Adult-Onset Still's Disease. You Jae Kim[1], Bon San Koo[1], Min Wook So[1], Wook Jang Seo[2], Ji Seon Oh[3], Yong-Gil Kim[1], Chang-Keun Lee[1] and Bin Yoo[1]. [1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Seoul Veterans Hospital, Seoul, South Korea, [3]University of Ulsan College of Medicine, Ulsan University Hospital, Ulsan, South Korea

Background/Purpose: To evaluate the clinical features, laboratory findings, response to therapy in patients with adult-onset Still's disease (AOSD) and to determine the prognostic factors related with unfavorable outcomes.

Methods: The medical records of 82 patients, diagnosed with AOSD from January 1992 through December 2009 at a single tertiary hospital, were retrospectively reviewed. The patients were divided into two groups according to the disease course, i.e. favorable (monocyclic course, n=33) and unfavorable (chronic or polycyclic and death, n=49). The clinical parameters were compared and the odds ratio (OR) for an unfavorable course was assessed.

Results: The mean age at onset was 36.7±14.9 years, and women accounted for 60 of the total 82 patients (73.2%). Thirty-three (40.2%) patients had monocyclic disease, 33 (40.2%) experienced disease relapse at least once, and 14 (17.1%) had chronic articular disease. The major clinical features were high spiking fever (96.3%), polyarthralgia (85.4%), skin rash (80.5%), myalgia (70.7%), and sore throat (68.3%). Polyarthralgia ($p = 0.01$), leukocytosis ($p = 0.08$), anemia ($p = 0.05$), the serum erythrocyte sedimentation rate (ESR, $p = 0.03$), lactate dehydrogenase (LDH, $p = 0.04$), and the ferritin levels ($p = 0.04$) showed a significant correlation with the unfavorable disease course. Interestingly, an insufficient starting dosage of prednisolone or its equivalent (less than 30 mg/day) was a significant predictive factor (OR 9.2, $p = 0.007$). Response rate is decreased with insufficient dose of steroids, patients within unfavorable group subsequently exhibited a longer mean time from the initiation of treatment to disease remission, i.e. 4.6±2.9 months and 9.0±9.1 months ($p = 0.04$). They also had a longer duration of steroid use ($p < 0.001$) and received more disease-modifying anti-rheumatic drugs ($p = 0.002$).

Conclusion: Analyzing the risk factors for a poor prognosis, an insufficient starting dosage of steroids, i.e. less than 30mg/day of prednisolone, was seen to be significantly related to chronic or relapsing disease course and longer steroid use. Patients may require early treatment with sufficient steroids to control the disease activity and achieve quicker remission.

1971

Off-Label Use of Biological Therapies in Systemic Autoimmune Diseases. Ana Carolina Araújo, Carla Noronha, Ana Grilo, Maria Francisca Moraes-Fontes, Nuno Riso and Manuel Vaz Riscado. Hospital de Curry Cabral, Lisbon, Portugal

Background/Purpose: Patients with systemic autoimmune diseases (AID) may not respond to first line immunosupressants or relapse after initial clinical remission. The emergence of biological therapies has increased therapeutic options despite the lack of controlled trials.

Methods: Retrospective study of data from our Autoimmune Disease Clinic's database on the use of biological agents in patients with systemic autoimmune diseases (AID). The analysis included a total of 14 AID and by June 2011, the Database included 133 patients who had been treated with biological agents (16 received infliximab, 29 rituximab, 73 etanercept, 1 golimumab, 6 tocilizumab and 37 adalimumab).

Results: Off-label use of biological agents in 21 patients with AID included systemic lupus erythematosus (eight cases with nephritis and neuropsychiatric manifestations), autoimmune thrombocytopenia (five cases), Behçet disease (two cases) and one patient in each of the following diseases (overlap syndrome consisting of Sjögren's Syndrome with rheumatoid arthritis, Wegener granulomatosis, adult-onset Still′s disease, Churg Strauss vasculitis, ulcerative colitis and SAPHO syndrome). Patients calling for off-label use of biological drugs were also refractory to conventional therapies obtaining partial or no response to high dose conventional immunosupressants (namely steroids, full-dose cyclophosphamide and highest tolerated methotrexate dose). Regarding SLE, most patients had already been on cyclophosphamide for at least six months without adequate disease control. Both ANCA-vasculitis patients experienced only a partial response to the traditional treatment with cyclophosphamide and steroids.

The favorable response to Rituximab is highlighted. Five patients required re-treatment once and of these, one patient required a further re-treatment. Three were SLE patients and two had immune thrombocytopenic purpura. Of note, the Behçet's disease patients showed none or very small improvement with anti-TNF blockade.

Conclusion: Current evidence on the use of biological therapies in patients with refractory AID is mainly based on uncontrolled, observational data. In our experience, the best results have been observed in the use of rituximab for refractory SLE nephritis and ITP. Lack of efficacy was demonstrated for infliximab in Behçet's disease. Until future controlled trials confirm the potential use of biological therapies in patients with refractory AID, it is hoped that we can gather national data in a registry for refractory AID, from which further evidence can be drawn to support their use.

1972

Subacromial Steroid Injection Do Not Seems to Increase the Rate of Full-Thickness Rotator Cuff Tear. Julio Ramirez[1], Isaac Pomés[2], Jaume Pomés[2] and Juan D. Cañete[3]. [1]Hospital Clinic, Barcelona, Spain, [2]Hospital Clínic, Barcelona, Spain, [3]Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain

Background/Purpose: Up to 35% of patients with shoulder pain have a full-thickness rotator cuff tear. Although it has been demonstrated a deleterious effect of corticosteroid on collagen, the impact of corticosteroid injection on rotator cuff tears remains unclear. The aim of this study was to evaluate whether corticosteroid injection increase the incidence of full-thickness rotator cuff tear. Secondary objectives were to determine the percentage of partial-thickness rotator cuff tears which become full-thickness rotator cuff tear along the study, as well as to evaluate changes in shoulder pain and function between two groups of local treatment.

Methods: This is a prospective, open-label, controlled study designed to include a total of 100 patients along two years. Patients with unilateral painful shoulder without previous local steroid injection were enrolled. Clinical and ultrasound assessment in the first (day 0) and the last visit (day 120) were performed, excluding patients with full-thickness rotator cuff tear at day 0.Patients were randomized to receive either a standard subacromial infiltration of 1 ml of triamcinolone acetate or 1ml of mepivacaine.A radiologist and a rheumatologist with expertise in musculoskeletal ultrasound performed the ultrasound scans and clinical examination, respectively, of the painful shoulder.

Results: 43 patients with shoulder pain were evaluated. 23 (53%) had full-thickness rotator cuff tear in the first visit and were excluded. 20 patients completed the study (15 women and 5 men, mean age 60 years): 14 received one injection of triamcinolone acetate and 6 patients one of mepivacaine.

After 4 months of follow-up, 4 full-thickness rotator cuff tears were found: 2/14 (14%) in the triamcinolone group, and 2/6 (33%) in the mepivacaine group. Among 8 patients who had a partial-thickness rotator cuff tear in the first visit, 3 developed a complete tear after 4 month: 1/4 (25%) in the triamcinolone group and 2/4 (50%) in the mepivacaine group.

5/6 patients (83%) in the mepivacaine group and 8 /14 (57%) in the triamcinolone group experimented a great improvement in shoulder pain. All patients recovered the normal range of movement after 4 months.

Conclusion: These very preliminary results suggest that around 50% of patients with chronic shoulder pain have full-thickness rotator cuff tear, and that subacromial steroid injection did not increase the expected rate of

full-thickness rotator cuff tear in a population with shoulder pain. Furthermore, subacromial injection with mepivacaine or triamcinolona seems to produce similar clinical results a 4 months of follow-up. These findings should be confirmed in a greater sample of patients.

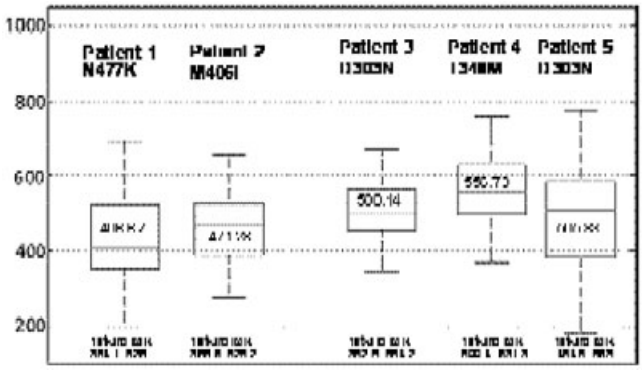
1973

Magnetic Resonance Imaging Cartilage Composition As a Potential Early Marker for Degenerative Joint Disease in Patients with Cryopyrinopathies. Clara Malattia[1], Martina Finetti[1], Maria Beatrice Damasio[2], Chiara Mattiuz[2], Gabriele Chiusano[3], Curzio Basso[3], Aldo Naselli[1], Alberto Martini[1] and Marco Gattorno[1]. [1]IRCCS G Gaslini, Pediatria II, Reumatologia, Genova, Italy, [2]IRCCS G Gaslini, U.O. Radiologia, Genova, Italy, [3]Dipartimento di Informatica e Scienze dell'Informazione, Università di Genova, Genova, Italy

Background/Purpose: Cryopyrinopathies (FCAS, MWS and CINCA) are autosomal-dominant disorders characterized by different mutations in a gene, NLRP3, encoding a protein called cryopyrin. Cryopyrin is expressed in granulocytes, dendritic cells, monocytes, B and T lymphocites; interestingly, high-level expression was also detected in chondrocytes. The most characteristic skeletal features observed in the most severe phenotype (CINCA) are represented by bone overgrowth that predominantly involves the knees and the distal extremities of hands and feet. These and other skeletal anomalies suggest a cartilage target. In these patients the cartilage burst causes deformity that leads to an early degenerative arthropathy. MRI has been established as the standard cartilage imaging modality, and techniques have been developed to visualize cartilage morphology and to analyze its biochemical composition. Delayed Gadolinium-Enhanced MRI of Cartilage (dGEMRIC) is a non-invasive molecular imaging technique that provides *in vivo* quantitative information about the fixed charged density of the articular cartilage, with is closely related to the glycosaminoglycane (GAG) concentration of the extracellular matrix. The purpose of the study was to investigate morphologic changes of the articular cartilage and to analyze its biochemical composition in patients with CAPS by using MRI.

Methods: 5 patients with CAPS (F:M = 3:2, mean age 11,4 years, range 6 – 16 years) with a clinical diagnosis of CINCA (N=2) or Muckle-Wells syndrome (N=3) were enrolled. The following *NLRP3* mutations were found: N477K, M406I, T348M, D303N (2 unrelated patients). All CAPS patients were receiving anti-IL-1 treatment with complete control of clinical and laboratory manifestations. MRI of the dominant knee was performed with a 1.5 Tesla MR scanner. The study included a morphologic and the ultrastructural assessment of the articular cartilage. The T1 maps were analyzed by using region of interest measurements. dGEMRIC values [in milliseconds] were determined after administration of contrast agent.

Results: The CINCA patients showed an evident frontal bossing with saddle back nose and late closure of the fontanel. No evident joint or skeletal abnormalities were observed in MWS patients. Clinical examination of the imaged knee was normal in all patients. No morphologic cartilage changes or inflammatory signs were detected by MRI. dGEMRIC values in the CINCA patients were lower than in MWS patients, suggesting a reduced GAG content in CINCA (figure).



Conclusion: dGEMRIC provides information beyond morphological changes in articular cartilage. Imaging of cartilage quality with dGEMRIC may provide pathophysiologic information relevant to disease progression and may be a promising tool for monitoring the effect of anti-IL-1 treatment on cartilage integrity. Evaluation of age-matched healthy controls is in progress.

1974

E148Q Is Not a Disease Causing Allele in Familial Mediterranean Fever in Populations Where FMF Is Prevalent. Servet Akar[1], Dilek Solmaz[2], Fatos Onen[1], Vedat Gerdan[2], Ozgul Soysal[2] and Nurullah Akkoc[1]. [1]Professor, Izmir, Turkey, [2]MD, Izmir, Turkey

Background/Purpose: About 200 sequence variations of the Mediterranean fever (*MEFV) gene* have been described. Even though the role of the three most frequent mutations located in exon 10 of the *MEFV* gene (M694V, V726A, M680I) in development of FMF has been widely recognized, the role of E148Q which was initially described as disease causing allele is yet controversial. Therefore the aim of this study is to assess the frequency of E148Q among FMF patients and healthy controls (HCs) based on the data from the published case control studies.

Methods: We conducted a systematic literature search using PubMed, Embase and The Cochrane Library. Search terms were "MEFV" and "MEFV gene". Hand searching of the reference lists of key articles and, hand/electronic searching of abstract books of the relevant conferences were performed. Statistical analysis was carried out using the Comprehensive Meta-Analysis statistical software (Biosta, Englewood, NJ, USA). Random-effects model was used.

Results: A total of 536 studies were identified of which 29 were retrieved for full review. Three of them assessed the frequency of MEFV variations in 11 ethnically different populations. A total of 13946 alleles of FMF patients and 9556 of HCs were included in the meta-analysis which yielded an overall odds ratio (OR) of 1.8 (95% CI 1.3–2.6) for E148Q in susceptibility to FMF. As the target populations in these studies show wide variation with regard to *FMF prevalence, a* subgroup-based meta-analysis was performed which revealed an OR of 1.3 (95% CI 0.9–1.8) and 6.1 (95% CI 3.3–11.3) in populations with high (Jews, Turks, Arabs and Armenians) and low prevalence (Greek, Japanese, Spanish and others), respectively (Figure 1). Homozygosity for E148Q was identified in 15/1875 FMF patients and 8/1878 healthy subjects in 17 studies which appropriate information was provided (p=0.144). On the other hand a clear association of M694V, M680I and V726A with FMF were observed in the pooled analysis.

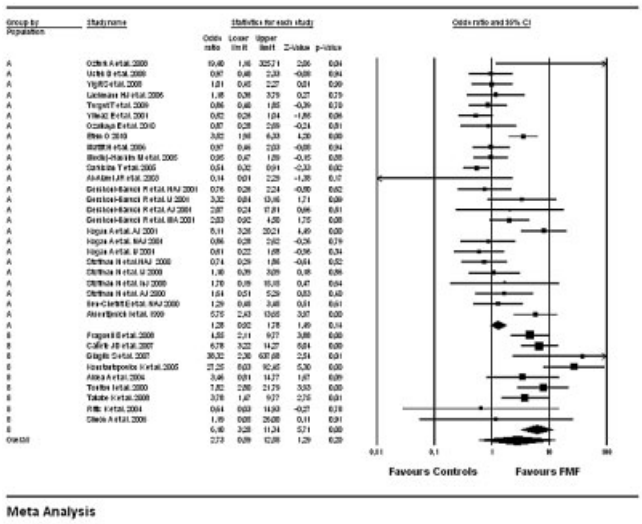


Figure 1. Odds ratios and corresponding 95% CI, for the association of the E148Q with familial Mediterranean fever in populations with high (group A) and low disease prevalence (group B).

Conclusion: Our results indicate that the presence of E148Q does not appear to be associated with an increased risk of FMF in populations with high disease prevalence whereas it may be associated with an increased risk in populations with low disease prevalence. However, in these latter populations further research is required to eliminate the role of over-emphasis on genetic testing which may lead to an over diagnosis of FMF.

1975

Long Term Follow-up of Infliximab Efficacy in Pulmonary and Extrapulmonary Sarcoidosis Refractory to Conventional Therapy. Eric Russell, Carolyn R. O'Connor and Humaira Hussain. Drexel University College of Medicine, Philadelphia, PA

Background/Purpose: Sarcoidosis is a multi-organ disorder histologically characterized by non-caseating granuloma formation. An etiology remains unclear, but TNF- a is known to play a crucial role and TNF- a blockade is a potential approach in the therapy of sarcoidosis. Infliximab, a chimeric monoclonal human mouse antibody against TNF- a has been shown to reduce the pulmonary and extrapulmonary manifestations of sarcoid, however, long term follow-up of sarcoidosis patients treated with infliximab has not been evaluated.

Methods: Subjects (18–85 years of age) with multi-organ sarcoidosis were identified retrospectively from the sarcoidosis clinic center of our outpatient office, in which infliximab had been prescribed due to failure of conventional therapy, between January 2000 to August 2010. Both symptomatic and clinical extra-pulmonary findings (constitutional, ocular, cutaneous, musculoskeletal, cardiac, neurologic, and renal) were evaluated pre-infliximab and post or concurrent infliximab therapy. When available, pulmonary assessment was evaluated using pulmonary function testing results also comparing pre-infliximab and post or concurrent infliximab therapy. Any adverse events of infliximab therapy were noted.

Results: All patients had biopsy-proven sarcoidosis and a clinical and/or radiographic presentation consistent with the diagnosis. Of the forty-five patients identified with sarcoidosis who received treatment with infliximab, cutaneous, lymphatic, neurologic, pulmonary and musculoskeletal sarcoidosis was recognized. Our data demonstrates that patients on long-term infliximab therapy had either sustained maintenance of disease improvement or cessation of disease progression as measured by patient description in addition to objective laboratory and/or imaging studies. Infliximab side effects or adverse events were rare.

Conclusion: Infliximab is effective and well tolerated in long-term control of pulmonary and extrapulmonary symptoms in patients with sarcoidosis refractory to other agents or in whom other agents were poorly tolerated due to side effects.

1976

Early Recognition of Hearing Loss in Muckle-Wells Syndrome. Jasmin B. Kuemmerle-Deschner[1], Assen Koitschev[2], Pascal N. Tyrrell[3], Katharina Ummenhofer[1], Peter Lohse[4], Sandra Hansmann[1], Stefan Plontke[5], Christiane Koitschev[6] and Susanne M. Benseler[3]. [1]University Hospital Tuebingen, Tuebingen, Germany, [2]Department of Otorhinolaryngology, Klinikum Stuttgart, Stuttgart, Germany, [3]The Hospital for Sick Children, Toronto, ON, [4]Department of Clinical Chemistry Groβhadern, University Munich, Munich, Germany, [5]Department of Otorhinolaryngology, University Hospital Halle (Saale), Halle (Saale), Germany, [6]Department of Otorhinolaryngology, University Hospital Tuebingen, Tuebingen, Germany

Background/Purpose: Hearing loss is the most common, debilitating long-term deficit in patients with Muckle-Wells syndrome (MWS). Standard audiology assessment includes the four pure tone average (4PTA) determining hearing thresholds at the four frequencies most relevant for speech discrimination (0.5, 1, 2, and 4 kHz). Inflammation in MWS results in early high-tone hearing loss at frequencies above 4Hz frequently undetected by standard hearing tests. Interleukin-1 (IL-1) inhibition can reverse hearing loss in MWS patients at an early stage. The aims of this study were to determine hearing thresholds of MWS patients at all frequencies, propose a MWS-specific audiology composite score (MWS-PTA) and compare the MWS-PTA with the standard 4PTA testing in MWS patients at baseline and following IL-1 inhibition.

Methods: A single center cohort study between 4/2008 and 8/2008 determined hearing thresholds in decibel (dB) at 0.5, 1, 2, 4, 6, 8 and 10 kHz by age-specific pure-tone audiometry in consecutive patients with clinically active and genetically confirmed MWS before and during treatment with the IL-1 receptor antagonist Anakinra and the fully human anti-IL-1β monoclonal antibody Canakinumab. The MWS-PTA was constructed including 0.5, 1, 2, 4, 6 and 8 kHz in all patients. The established parameter 4PTA was compared to the new parameter MWS-PTA regarding ability to discriminate hearing threshold differences before and with IL-1 inhibition.Change in summary score between baseline and follow-up was determined for mean right and left ear audiometry measures. Descriptive statistics and comparisons were performed using parametric and non-parametric methods when appropriate. The Shapiro-Wilk test for normality was used when testing observed distributions.

Results: A total of 23 MWS patients were included. These were 15 females and 8 males, median age at diagnosis 18.0 years (range 3–72). Mean audiometry scores at baseline were: PTA 40.7 ±27.8; MWS-PTA 49.2 ±30.7 and at follow-up: PTA 38.0 ±26.8; MWS-PTA 46.3 ±30.4. The difference in scores between timepoints were found to be significantly different from 0: PTA −2.7 ±6.1 p=0.01; MWS-PTA −2.9 ±5.0 p=0.01. Scores were found to be normally distributed at baseline and follow-up (Shapiro-Wilk all p>0.05). No statistically significant difference was observed for the change in scores between the two IL-1 blockers used in this study.

This was in accordance to the significant improvement of the clinical MWS-DAS (p=0,0005) and the inflammatory markers CRP, ESR and SAA.

Typical audiometry changes in MWS-patients appear as hearing loss in high frequencies which is in contrast to patients with hearing loss from other causes who usually have reduced hearing in frequencies relevant for speech discrimination, which detected by the 4PTA. The challenge is to establish a tool to detect early changes in MWS patients.

Conclusion: The MWS-PTA is a simple modification of the standard audiology assessment. It allows for early detection of hearing loss in patients with MWS. Early recognition and treatment of sensory neural hearing loss in MWS patient may enable physicians to prevent the debilitating long-term deficit in patients with Muckle-Wells syndrome.

Association Between Sports Participation and the Risk of Knee Osteoarthritis: A Systematic Review. Jeffrey B. Driban[1], Jennifer M. Hootman[2], Michael R. Sitler[3], Kyle P. Harris[4] and Nicole M. Cattano[5]. [1]Tufts Medical Center, Boston, MA, [2]Centers for Disease Control and Prevention, Kennesaw, GA, [3]Temple University, Philadelphia, PA, [4]Bucks County Community College, Newtown, PA, [5]West Chester University, West Chester, PA

Background/Purpose: Information regarding the relative risks of developing knee osteoarthritis (KOA) as a result of sports participation is critical for shaping public health communication messages and for informing KOA prevention strategies. The purpose of this systematic review was to investigate the association between specific sports participation and the risk of KOA. A secondary purpose was to attempt to separate out the effects of joint injury versus sport participation on the risk of KOA.

Methods: A systematic literature search was completed in March 2011 using 6 bibliographic databases (e.g., PubMed, OVID), by manual searches (4 journals), and reference lists (56 articles). Studies were included if they met 4 criteria: 1) a study aim was to investigate an association between sport participation and KOA; 2) the outcome measure was radiographic KOA, clinical KOA, total knee replacement (TKR), or placement on a waiting list for a TKR; 3) cohort study design; and 4) written in English. Study quality was assessed with the New-Castle Ottawa Scale (range 0–9; low < 4, high >4). One investigator extracted data (e.g., group descriptions, KOA prevalence, source of unexposed [NE] controls). Level of play was categorized as elite (national team/Olympic/professional) and non-elite (scholastic/recreational). Significant relative risks (RR) were defined as 95% confidence intervals (CI) that excluded 1.00. Sensitivity analyses were used to assess the influence of injury status among studies that excluded patients with a history of knee injury or stratified by history of joint injury and by source of NE controls.

Results: The overall prevalence of KOA in sports participants (n = 3192) was 8.4%; 9.1% among NE (referent group; n = 3485; RR [CI] = 0.9 [0.8 to 1.1]). NOS scores ranged from 3 to 6. Risk of KOA was similar for low and high quality studies. Specific sports with significantly higher risk of KOA were soccer (RR 4.4); as well as elite-level long-distance running (RR 3.2), competitive weight lifting (RR 6.4), and wrestling (RR 3.7). Sport participants were at an elevated risk of KOA compared to NE participants from local communities, hospital/medical practices, and sports (shooters), but at decreased risk compared to NE participants selected from national military service. Elite-sport participants (soccer or orienteering) without a history of knee injury were at greater risk for KOA than NE participants (studies excluding injuries: RR = 1.8; studies stratifying by history of injury: RR =

8.6). Nonelite-sport participants (soccer or American football) with no history of knee injury were at greater risk for KOA than NE participants (RR 3.6).

Conclusion: The risk of KOA is sport specific. Participants in soccer (elite and nonelite); as well as elite long distance running, weight lifting, and wrestling have increased risk of KOA and should be targeted for risk reduction strategies. Soccer, even in the absence of an injury is associated with increased risk of KOA; especially among elite participants. There are considerable gaps in the literature, including a lack of data on female sport participants, history of injury, and nonelite sport exposure.

1978

Physical Activity Levels and the Risk of Incident Radiographic Knee Osteoarthritis: The Johnston County Osteoarthritis Project. Kamil E. Barbour[1], Jennifer M. Hootman[1], Charles G. Helmick[2], Louise Murphy[1], Yiling Cheng[2], Kristina A. Theis[1], Barbara Do[2] and Joanne M. Jordan[3]. [1]CDC, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]UNC Thurston ARC, Chapel Hill, NC

Background/Purpose: Physical activity has been shown to reduce risk of cardiovascular disease, diabetes and hypertension; however the impact of physical activity on incident radiographic knee osteoarthritis (rKOA) remains unclear.

Methods: Using data from visits 2 (1999–2003) and 3 (2005–2010) Johnston County Osteoarthritis Project; we tested the association of physical activity with incident rKOA (mean follow-up 6.5 ± 1.9 years) among adults (n=641 without rKOA at visit 2) aged 45 years and older. Incident rKOA was defined as the development of a Kellgren-Lawrence (K-L) grade of ≥2 in either knee. Minutes per week of moderate-to-vigorous intensity physical activity (MVPA) were calculated at visit 2 using the Minnesota Leisure Time Physical Activity questionnaire. MVPA was categorized as meeting 2008 U.S. physical activity recommendations (>150 min/week) or not (<150 min/week). Weibull parametric regression estimated hazard ratios (HR) for interval censored data. Sampling weights at visit 3 and the Jackknife resampling method were used to account for the complex sampling design.

Results: Participants who reported ≥150 min/week MVPA had a non-significant 48% higher risk of incident rKOA (HR: 1.48; 95% CI: 0.99–2.22) compared with those with <150 min/week of MVPA after adjusting for age, race, sex, body mass index, education, diabetes status, and history of knee injury.

Conclusion: Results suggest that physical activity was modestly, but not significantly associated with incident rKOA. Further investigation is required to better understand the contribution of health-enhancing levels of MVPA with rKOA.

1979

Recent Heavy Physical Activities Trigger Knee Pain Exacerbation in Persons with Symptomatic Knee Osteoarthritis. Yuqing Zhang[1], Diane Wheaton[2], Jingbo Niu[1], Barton Wise[3], William Havey[4], Joyce Goggins[1] and David J. Hunter[5]. [1]Boston University School of Medicine, Boston, MA, [2]New England Baptist Hospital, Boston, MA, Boston, MA, [3]University of California, Davis School of Medicine, Sacramento, CA, [4]New England Baptist Hospital, Boston, MA, [5]Royal North Shore Hospital, Sydney, Australia

Background/Purpose: Subjects with symptomatic knee osteoarthritis (SxKOA) often experience recurrent pain exacerbation, with episodes lasting for days or weeks. Identifying the triggers for pain exacerbation and quantifying their effects are challenging because traditional study designs are ill-suited to answer this type of research question. We conducted an online case-crossover study to examine the relation of physical activity to pain exacerbation among subjects with SxKOA.

Methods: Subjects with a diagnosis of SxKOA (i.e., K/L> 2 and knee pain on most days on the past month) were recruited from the database of persons with SxKOA and followed for 3 months at 10 day intervals (control periods). Subjects were instructed to log on to the study website if they experienced a knee pain exacerbation during the follow-up period (hazard periods). Via the internet we collected data on triggers occurring during "***control periods*** " (i.e., periods without pain exacerbation) and "***hazard period"*** (i.e., period immediately preceding the pain exacerbation). *Pain exacerbation was defined as an increase of* ***100 units*** in a subject's WOMAC knee pain score (VAS 0–500) over the follow-up from his/her mildest pain score reported at the baseline visit. We collected data on potential triggers, including participation of various levels of physical activities (i.e., moderate, heavy and extremely heavy), on 1 day prior, 2 days prior, and 3–7 days prior to the index dates (i.e., date of pain exacerbation for hazard period, and date of data assessment for control periods). We examined the relation of heavy physical activities to the risk of pain exacerbation using the conditional logistic regression model.

Results: Of 52 subjects (women: 57.6%, mean age: 63 years, mean BMI: 29.3 kg/m^2) recruited in the study, 33 subjects (33 index knees) experienced at least one episode of knee pain exacerbation. Compared with no heavy/extremely physical activity, odds ratios of knee pain exacerbation was 2.7 10.8, and 0.03 for participation in heavy/extremely heavy physical activities on 1 day prior, 2 days prior, and 3–7 days prior to index date, respectively (Table).

Participation of Heavy/extremely Heavy Physical Activities prior to Index Date	Control periods	Case Periods	0.03 (0.01–0.14)
1 day			
No	122	51	1.0
Yes	48	31	2.7 (0.9–8.2)
2 days			
No	119	50	1.0
Yes	51	32	10.8 (1.9–61.4)
3–7 days			
No	105	65	1.0
Yes	65	17	0.03 (0.01–0.14)

Conclusion: Heavy physical activity occurred within 2 days was associated with an increased risk of knee pain exacerbation among patients with SxKOA. This finding suggests that individuals with SxKOA should avoid participation of heavy physical activity.

1980

Sedentary Behavior and Functional Performance Among Participants in the Osteoarthritis Initiative (OAI). Jungwha Lee[1], Rowland W. Chang[1], Larry Manheim[2], Pamela A. Semanik[3], Jing Song[2] and Dorothy D. Dunlop[2]. [1]Northwestern University, Chicago, IL, [2]Northwestern Univ Med School, Chicago, IL, [3]Rehabilitation Institute Chicago, Oak Park, IL

Background/Purpose: Physical activity offers important health benefits to adults, including those with lower limb osteoarthritis (OA). This study examined whether there is a graded relationship between objectively measured physical activity and functional performance among people with or at risk of knee OA.

Methods: Functional performance was assessed by gait speed measured in feet/speed based on the average speed over two 20-meter walk tests. Physical activity was objectively measured using accelerometers at the 48-month clinic visit in 1876 OAI participants (1076 with radiographic knee osteoarthritis (RKOA) in at least one knee and 800 participants without RKOA in both knees and at risk of RKOA at baseline). Accelerometer output is an activity count monitored for 7 consecutive days. Accelerometer data included at least 4 or more valid days for each participant. A valid day was defined as 10 or more wear hours in a day. Sedentary behavior, defined by activity counts/minute< 100, was used to calculate the percentage of daily wear hours spent in sedentary behavior. The association between gait speed and sedentary behavior percentage quartiles was examined by multiple regression models adjusting for socio-demographic factors (age, gender, income, education) and health factors (comorbidity, depressive symptoms, overweight/obesity, presence and severity of knee pain).

Results: Mean of average daily sedentary behavior percentage for participants was 40% (SD=5.5%). Functional performance measured by gait speed had mean ± SD of 4.36 ± 0.68 feet/second. Mean functional performance increased going from the highest sedentary quartile to the lowest (unadjusted mean gait speed 4.1, 4.2, 4.4, and 4.5 feet/second, respectively, P for trend <0.001). These trends remained significant in multivariate analyses after adjusting for socio-demographic factors and health factors (Table), and among subgroups with and without RKOA at baseline.

Adjusted Gait speed (feet/second)* by sedentary behavior quartiles** of adults with and without baseline radiographic knee OA after adjustment for age, gender, education, income***

	Sample Size (n)	Quartile 1**** (most sedentary)	Quartile 2	Quartile 3	Quartile 4 (least sedentary)	P for trend
Overall	1876	4.11 ± 0.03	4.38 ± 0.03	4.42 ± 0.03	4.47 ± 0.03	<.0001
Participants with Baseline RKOA	1076	4.04 ± 0.04	4.34 ± 0.04	4.37 ± 0.04	4.38 ± 0.04	<.0001
Participants without Baseline RKOA	800	4.22 ± 0.05	4.42 ± 0.05	4.56 ± 0.05	4.57 ± 0.04	<.0001

* Values are the mean ± SEM in average gait speed for sedentary behavior quartiles.
** Sedentary behavior quartiles are based on percentage of average sedentary minutes/day over wear hour (sedentary minutes: minutes of counts <100).
*** 4+ valid days of accelerometer monitoring; reference group are men aged 49–64 with 13+ education years and >$50k income.
**** Quartile 1 is the group with most sedentary behavior.

Conclusion: Despite the known benefits of physical activity to decrease disability, adults with or at risk for knee OA are largely sedentary. The OAI data indicate a strong relationship between greater levels of sedentary behavior and worse functional performance in adults with knee OA. These findings support guidelines that encourage adults with knee OA to decrease sedentary behavior regardless of current sedentary status.

1981

Differences in Patient Acceptable Symptomatic State (PASS) Thresholds and Minimal Clinically Important Improvement (MCII) for Pain At Rest and on Movement in Patients with Lower Limb Osteoarthritis. Serge Perrot[1], Philippe Bertin[2] and Philippe Ravaud[3]. [1]Hopital Hotel Dieu, Paris, France, [2]Chu Dupuytren, Limoges, France, [3]Hopital Hotel Dieu, Paris Descartes University, Paris, France

Background/Purpose: Two concepts have been developed to make patient assessment more clinically relevant: the patient acceptable symptomatic state (PASS)1, and the minimal clinically important improvement (MCII). Osteoarthritis (OA) is a painful disease in which pain intensity varies with activity. We compared PASS and MCII for pain at rest and on movement, in patients with painful lower limb OA.

Methods: A national multicentrer cohort study, in outpatients over the age of 50 years with painful knee or hip OA (pain VAS >3/10), visiting a GP and requiring treatment for more than seven days. During the visit, demographic characteristics were noted and PASS and pain were assessed at rest and on movement. This was a naturalistic study, with no specific recommendations made to the physicians, who were free to prescribe any type of analgesic or other drug. Seven days after the initial visit, patients were asked to complete a self-reported questionnaire, for the assessment of changes in pain and MCII.

Results: In total, 2414 patients (50.2% men, 67.3 ± 8.8 years old, BMI 27.9 ± 4.3, 33.5% with hip OA) were enrolled by 1116 GPs. Pain intensities were: 5.1 ± 1.9 at rest and 7.0 ± 1.4 on movement. The frequency of acceptability did not differ between knee (70.1%) and hip (68.3%) OA and was not affected by OA duration. PASS was estimated at 4 at rest and 5 on movement, with no difference between the hip and knee. After seven days of treatment, the perceived improvement in hip and knee OA was significantly correlated with initial acceptability ($p<0.001$). MCII was estimated at 1, both at rest and on movement, with no significant difference between hip and knee OA.

In knee OA, acceptability was more frequent in men under the age of 75 years, without synovial effusion, with pain (VAS< 6/10) on movement, in several professional categories (farmers vs others), and in patients specifically seeking an improvement in sporting activities.

In hip OA, pain acceptability was influenced only by pain at rest and on movement (more acceptable when below 6/10), and by BMI (more acceptable in non obese patients).

Conclusion: PASS thresholds are similar for hip and knee OA, but different at rest and in movement. MCII is similar in hip and knee OA, and at rest and in movement. In all situations, pain improvement is significantly associated with initial acceptability, whatever the treatment prescribed. The factors determining pain acceptability differ between hip and knee OA, demonstrating that these two conditions are distinct clinical entities. In both conditions, the determining factors should be assessed precisely, for the identification of additional factors and to improve personalized patient management.

1982

Relationship Between Aspects of the Pain Experience in Knee Osteoarthritis and Function and Disability. September Cahue, Joan Chmiel, Karen W. Hayes, Orit Almagor, Kirsten Moisio, Carmelita J. Colbert, Clifton Saurel, Yunhui Zhang and Leena Sharma. Northwestern University, Chicago, IL

Background/Purpose: It is widely accepted that knee pain influences physical functioning in knee osteoarthritis (OA), but how specific aspects of the pain experience relate to function impairment and disability is unclear. Our goal was to analyze separate aspects of the pain experience to determine which is most closely associated with measures of function and disability in persons with knee OA.

Methods: All participants had knee OA (osteophyte presence in at least one knee). Four aspects of the pain experience were evaluated: pain intensity (0–10 numeric rating scale); how much pain affected sleep (ICOAP item); pain after 20 m walk (0–10 rating scale); pain catastrophizing (Pain Catastrophizing Scale). Function was evaluated by: WOMAC function scale; Late Life Function Instrument (LL-FI), basic and advanced lower extremity function scales; 20 m walk time; time to complete 5 chair stands. Disability was evaluated by: Late Life Disability Instrument (LL-DI), activity frequency and activity limitation scales. Lower LL-FI and LL-DI scores are worse; higher WOMAC function, 20 m walk time, and chair stand time are worse. We used linear regression with function or disability as dependent variable, including each pain measure and age, gender, and BMI in each model, after screening for problematic multicollinearity. We calculated standardized regression coefficients [i.e., estimate of the expected change in standard deviation (SD) units in average value of dependent variable per SD change in predictor, after considering all other variables in the model] to compare the strength of association of different predictors with the outcome variable within the same model.

Results: The sample was 250 persons (mean age 64.8 yrs, BMI 28.6, 76% women). The table shows standardized coefficients for each model (bold and italicized when significant). Row variables and gender were included in each model. Pain intensity was associated with WOMAC function but no other measure, pain affecting sleep with almost all function measures but no disability measure, and pain after 20 m walk with self-report function measures. Pain catastrophizing was the only aspect to be associated with disability measures.

Standardized Coefficients from Multipredictor Regression Models

	WOMAC function	LL-FI, basic LE function	LL-FI, advanced LE function	20 m walk time	Chair stand time	LL-DI, activity frequency	LL-DI, activity limitation
Pain intensity	***0.10***	−0.05	−0.05	0.11	0.06	−0.05	−0.05
Pain affecting sleep	***0.36***	***−0.19***	***−0.14***	0.12	***0.18***	−0.05	−0.12
Pain after 20 m walk	***0.26***	***−0.20***	***−0.29***	0.11	−0.06	−0.06	−0.13
Pain catastrophizing	***0.25***	***−0.29***	***−0.18***	0.11	***0.22***	***−0.23***	***−0.30***
Age	0.04	***−0.17***	***−0.32***	***0.35***	***0.17***	0.05	0.11
BMI	***0.19***	***−0.21***	***−0.30***	***0.36***	0.03	−0.04	−0.08

Conclusion: When the four aspects of the pain experience were considered concurrently, pain catastrophizing was most consistently associated with measures of function and disability. Most closely associated with function measures were: pain affecting sleep, for WOMAC function; pain catastrophizing, for LL-basic function, chair stand time, and disability; and pain after 20 m walk, for LL-advanced function. These findings suggest that different aspects of the pain experience in knee OA may have unique relationships with function and disability. Ultimately, specific multidisciplinary attention to these aspects of pain may yield a more meaningful approach for the person with painful knee OA, and potentially have greater impact on function and disability over time.

1983

Relationship of Specific Pain Patterns in Knee Osteoarthritis with Severity of Pain and Functional Disability. Nehal Shah[1], Michael J. Hannon[2], WANG Zhijie[3] and C. Kent Kwoh[4]. [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh school of medicine, Pittsburgh, PA, [4]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA

Background/Purpose: Osteoarthritis is one of the most common causes of disability. Knee pain is the main reason for patients to seek care for knee osteoarthritis (OA), but the cause for knee pain is unclear. This study examines differences in pain and disability among specific knee pain patterns in knee OA.

Methods: This is an ancillary analysis of data from 4796 participants in the Osteoarthritis Initiative (OAI), a population-based cohort study designed to identify biomarkers of the development and/or progression of knee OA. Pain patterns in knee OA were characterized into localized, regional or diffuse using the Knee Pain Map, an interviewer-administered assessment of knee pain patterns based on pain in the past 30 days. Data on severity of pain and disability was obtained using Western Ontario and McMaster Universities (WOMAC) knee pain scale, including the scale scores(scaled from zero to 100, with 100 representing the most knee pain), and individual WOMAC items, from the OAI dataset at the 24 -month visit (Release 3.2.1). Data was analyzed using pain patterns as the dependent variable in multinomial logistic regression models, controlled for demographic characteristics, risk factors for knee OA and for clustering by knee.

Results: Of the 9383 knees studied, 19% had localized pain, 14.3% had regional pain, 8.8% had diffuse pain, and 58% had no pain. Controlling for demographic factors and participant characteristics, WOMAC knee pain, disability, and total scores were significantly different among knees with no

pain vs local, local vs. diffuse and regional vs. diffuse pain patterns ($p<.001$). For local vs. regional pain, only WOMAC disability ($p=0.013$) and the total WOMAC scores ($p=0.02$) were different. In multivariate analysis, the WOMAC knee pain score was different among those with no pain vs. those with only local pain ($p<.001$); and regional pain vs. diffuse pain ($p=0.02$). The WOMAC disability score was different among those with no pain vs. those with only local pain ($p<.001$); and those with local vs. diffuse pain ($p=0.03$). Individual items in the WOMAC differed among the various pain patterns in bivariate analysis, but none of the individual items remained significant in the multivariate analyses.

Conclusion: WOMAC pain and disability scores varied among the different knee pain patterns. Higher scores were associated with the diffuse pain pattern followed by regional and then the localized pain patterns, suggesting a gradient of disease severity across the pain patterns

1984

Relation of Knee Cartilage Loss to Pain and Functional Limitation: The Multicenter Osteoarthritis Study. Barton Wise[1], Jingbo Niu[2], Nancy E. Lane[3], Michael C. Nevitt[4], Daniel K. White[2], James Torner[5], Cora E. Lewis[6] and Yuqing Zhang[2]. [1]University of California, Davis School of Medicine, Sacramento, CA, [2]Boston University School of Medicine, Boston, MA, [3]UC Davis School of Medicine, Sacramento, CA, [4]University of California-San Francisco, San Francisco, CA, [5]University of Iowa, Iowa City, Iowa City, IA, [6]University of Alabama, Birmingham City, Birmingham, AL

Background/Purpose: Worsening radiographic knee osteoarthritis (OA) is associated with increased risk of incident severe functional limitation. While MRI is a more sensitive measure of changes in specific structures of the knee than radiographs, it is unclear if such improved sensitivity is significant when evaluating its association with worsening of pain and function.

Methods: The NIH-funded Multicenter Osteoarthritis Study (MOST) is an observational study of persons age 50 to 79 years with either symptomatic knee OA or at high risk of disease. Participants were evaluated at baseline and 60 months. A subset of MRIs acquired at baseline and 60 months from participants with unilateral whole knee OA at baseline or at 30 months but without endstage knee OA at either of those timepoints were assessed using the semi-quantitative Whole-Organ Magnetic Resonance Imaging Score (WORMS). Cartilage scores (range 0–6) were obtained for 14 subregions of the index knee for each subject. Cartilage loss at each subregion was defined as cartilage morphology score increase of $\geq$2 over 60 months. For each knee we summarized the number of subregions with cartilage loss. Knee pain worsening was defined as Western Ontario and McMaster Osteoarthritis Index (WOMAC) pain score (range 0–20) increased by $\geq$18% and an absolute increase of $\geq$2 over 60 months. Functional limitation worsening was defined as either an increase of WOMAC physical function (range 0–68) by $\geq$26% and an absolute increase $\geq$6.1, or objectively by a decrease in walking speed by $\geq$0.1 meter/second over 60 months. We used multiple logistic regression to examine the association between cartilage loss and worsening of pain and function adjusting for age, sex, BMI, race, clinic site, CES-D score, number of co-morbidities, K/L grade, and for function analyses WOMAC pain in contralateral knee.

Results: Of 210 subjects included in the analysis 60.5% were women, 26.7% had frequent knee pain (FKP) in the index knee, and 11.9% had FKP in the contralateral knee at baseline. Over a 60 month follow-up period, 109 (52.9%) knees had cartilage loss in at least one subregion, 28.1% had worsening WOMAC knee pain, 21.4% had self-reported worsening functional limitation, and 20.5% had functional limitation worsening by walking speed. As shown in the table, compared with those with no cartilage loss, increased number of subregions with cartilage loss was associated with higher odds of pain worsening (P for trend $<$ 0.01) and worsened functional limitation measured by WOMAC (P for trend = 0.04). However, no such relation was observed for worsening of walking speed.

# of subregions with cartilage worsening ≥2	WOMAC Pain Worsening		WOMAC Function Worsening		Walking Speed Worsening	
	Adj OR	95% CI	Adj OR	95% CI	Adj OR	95% CI
0	1.0		1.0		1.0	
1	1.64	0.70–3.65	1.06	0.41–2.75	0.65	0.24–1.81
2	2.28	0.89–5.87	1.09	0.37–3.17	1.62	0.59–4.45
3	2.76	1.01–7.59	1.50	0.49–4.59	1.36	0.42–4.43
4+	6.85	2.00–23.46	4.24	1.21–14.83	1.26	0.33–4.82
P for trend	< 0.01	0.04	0.45			

Conclusion: In this sample of subjects with unilateral radiographic OA, cartilage loss on MRI over 60 months is associated with worsening of pain and subjective physical function.

1985

Muscle Parameters and Function Self-Efficacy in Knee Osteoarthritis. Carmelita J. Colbert, Karen W. Hayes, Orit Almagor, Joan S. Chmiel, Alison H. Chang, Kirsten Moisio, September Cahue, Yunhui Zhang, Clifton Saurel and Leena Sharma. Northwestern University, Chicago, IL

Background/Purpose: Self-efficacy has been associated with physical function outcome in persons with knee osteoarthritis (OA). Efforts to understand factors contributing to self-efficacy may identify targets to improve self-efficacy. Little is known about how hip and knee motor activity relate to self-efficacy in knee OA. Quantitative gait analysis provides insight into dynamic muscle unit function during gait. We hypothesized that knee extensor, hip abductor, and hip external rotator strength and the knee extensor and hip abductor moments during gait are each associated with function self-efficacy.

Methods: 250 persons with knee OA were evaluated. Isokinetic knee extensor and isometric hip abductor and external rotator average peak torques were determined using a Biodex dynamometer. Quantitative gait analysis at self-selected walking speed was performed using external passive reflective markers and an 8-camera motion analysis system to calculate knee and hip joint moments (internal moments normalized to %BW*Ht). Self-efficacy was assessed using the Arthritis Self-Efficacy Scale function subscale. Data were also collected using: questionnaire adaptation of the Charlson index, Geriatric Depression Scale, WOMAC pain scale, Pain Catastrophizing Scale, and Physical Activity Scale for the Elderly. Multiple linear regression analysis was used to evaluate the association of self-efficacy (dependent variable) with each muscle factor. We used the worse (of the two limbs) value for the factor to derive the unadjusted regression coefficients and associated 95% CI, and the coefficient (95% CI) adjusting for age, gender, BMI, comorbidity, depressive symptoms, knee pain severity, pain catastrophizing, and physical activity.

Results: 250 participants had a mean age of 64.8 (SD 10.2), BMI 28.6 (5.6), and 189 (76%) were women. Mean self-efficacy score was 25.2 (5.4), hip abductor strength 57.5 Nm (17.7), hip external rotator strength 27.0 Nm (11.0), knee extensor strength 63.3 Nm (24.6), hip abductor moment during gait 4.1 (0.8), knee extensor moment during gait 1.25 (0.4). The table shows the coefficients (95% CI), with significant results bolded. In an additional model including knee extensor strength, hip abductor moment, and hip external rotator strength and the covariates noted above, knee extensor strength, hip abductor moment during gait, BMI, knee pain severity, and depressive symptoms were each significantly associated with self-efficacy (R^2 of this model 0.48).

Factors Associated with Function Self–Efficacy

	Unadjusted Coefficient (95% CI)	Adjusted Coefficient (95% CI)
Knee extensor strength (per 10 Nm)	**0.73 (0.47, 0.99)**	**0.80 (0.50, 1.09)**
Knee extensor moment during gait (per 1%BWxHT)	**2.73 (1.25, 4.21)**	**1.39 (0.03, 2.74)**
Hip abductor strength (per 10 Nm)	**0.69 (0.32, 1.06)**	0.25 (−0.16, 0.65)
Hip abductor moment during gait (per 1%BWxHT)	**0.86 (0.01, 1.70)**	**1.14 (0.41, 1.87)**
Hip external rotator strength (per 10 Nm)	**1.12 (0.52, 1.72)**	**1.25 (0.55, 1.95)**

Conclusion: Knee extensor strength and hip abductor moment during gait (as well as BMI, knee pain severity, and depressive symptoms) were independently associated with function self-efficacy in analyses adjusting for potential confounders. Longitudinal analyses will help to elucidate the direction of these relationships towards the goal of enhancing intervention to improve function self-efficacy in knee OA and lessen its deleterious consequences.

1986

Functional Impairment As a Predictor of Knee Replacement in the Multicenter Osteoarthritis Study. Barton Wise[1], Jingbo Niu[2], Nancy E. Lane[3], Michael C. Nevitt[4], David T. Felson[2], Jean Hietpas[5], Alesia Sadosky[6], James Torner[7], Cora E. Lewis[8] and Yuqing Zhang[2]. [1]University of California, Davis School of Medicine, Sacramento, CA, [2]Boston University School of Medicine, Boston, MA, [3]UC Davis School of Medicine, Sacramento, CA, [4]University of California-San Francisco, San Francisco, CA, [5]UCSF, San Francisco, CA, [6]Pfizer, Inc., New York, NY, [7]University of Iowa, Iowa City, Iowa City, IA, [8]University of Alabama, Birmingham City, Birmingham, AL

Background/Purpose: Functional impairment may influence an individual to receive a knee replacement (KR), but few studies have explored this assumption. We conducted a cohort study to evaluate the association between functional impairment and risk of KR over 30 months.

Methods: The NIH-funded Multicenter Osteoarthritis Study (MOST)

is an observational study of persons age 50 to 79 years with either symptomatic knee OA or at high risk of disease. We performed a repeated measures analysis using baseline Western Ontario McMaster (WOMAC) physical function score to predict the risk of KR from baseline to 30 months, and WOMAC score at 30 months to predict risk of incident KR from 30 months to 60 months. We examined the association between function and risk of KR using generalized estimating equations to account for the correlation between two knees within one subject and across the two periods of the repeated analysis. We calculated relative risk of KR over 30 months for groupings of WOMAC function using 0–5 group as referent. In the multiple binomial regression with log link we adjusted for clinic site, age, BMI, sex, race, education, depressive symptoms as measured by CES-D, comorbidity, ipsilateral K/L grade. We performed analyses with and without adjustment for ipsilateral visual analog scale (VAS) knee pain to assess whether an association between physical function or functional impairment and KR is independent from pain.

Results: Our sample consisted of 2,890 subjects with 5,780 native knees; 1,738 (60%) were women. 1,631 (57%) of subjects had a baseline WOMAC function score ≥10 (range 0–68).Over 60 months there were 445 incident KRs in 10506 knee-periods (4.3%). 311 (69.8%) were in women and 192 (43%) occurred in the first 30 month period. As shown in the Table, those with the highest function scores (greatest functional impairment; 40–68) had 18 times the risk of total knee replacement over 30 months compared with those with baseline function scores of 0–5 after adjustment for covariates other than pain (95% CI 8.4–38.3). Further adjustment for ipsilateral knee pain attenuated but did not eliminate the effect of function score on the risk of KR among those with the highest function scores (RR 7.2, 95% CI 3.3–15.9; P for linear trend <.0001).

WOMAC Function (0–68)	Knee-Periods (#)	TKR (#)	Adj RR (95% CI) (Basic Covariates)			Adj RR (95% CI)(Basic Covariates plus ipsilateral VAS pain score)		
			RR	95% CI		RR	95% CI	
0–5	3581	11	**1.0**			**1.0**		
6–9	1164	20	**3.9**	1.7	9.1	**3.5**	1.5	8.1
10–19	2405	97	**6.3**	3.0	13.0	**5.0**	2.4	10.3
20–29	1841	137	**9.4**	4.6	19.3	**6.1**	2.9	12.5
30–39	1056	117	**12.8**	6.2	26.5	**6.7**	3.2	14.2
40–68	459	63	**18.0**	8.4	38.3	**7.2**	3.3	15.9
P for linear trend				<0.001			<0.001	

Conclusion: Baseline physical function strongly predicts KR over a 30 month period. This relation is independent of concurrent knee pain severity.

1987

Clinical Characteristics and Medication Use of Patients with Knee Osteoarthritis Selected for Total Joint Replacement Surgery. T.N. de Boer[1], M.J.P.M. Stukstette[2], P.M.J. Welsing[1], A.M. Huisman[3], A.A. Polak[3], J.W.J. Bijlsma[1], Simon C. Mastbergen[1] and F.P.J.G. Lafeber[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]Sint Franciscus Gasthuis, Rotterdam, Netherlands

Background/Purpose: Costs related to total knee replacement (TKR) surgery, are tremendous and will increase further due to increasing prevalence of obesity and aging in developed countries. TKR is clearly effective in reducing pain and improving function in progressive knee osteoarthritis (OA). The outcome of revision surgery is less and even more costly. Postponing a first prosthesis and maintaining quality of life is at present the major goal in treatment of end-stage OA. Specific indications for TKR surgery are not clearly defined or evidence based. Generally accepted indications are pain and limitations in function in spite of the use of (non-)pharmacological interventions. However, substantial variations in referral behaviour between health professionals exist. Experts in the field believe that in many patients with severe OA conservative treatment options are not optimally prescribed. It seems plausible that TKR surgery can be postponed or even prevented. The aim of this explorative study is to obtain insight in characteristics and previous pharmacological management of end-stage knee OA patients submitted to TKR surgery, and to explore if patients without adequate pain medication still benefit from pain medication.

Methods: 172 successive patients referred for TKR were evaluated. Patients not using adequate analgesics, defined by no or occasional paracetamol (PCM), were randomized to an adequate dose of a NSAID (celecoxib; 2dd200mg daily or naproxen; 3dd250mg) or no medication for 6 weeks prior to surgery. Patient characteristics, severity of symptoms (WOMAC pain, stiffness and physical function), medication use in past year and radiological features (K&L and Altman) were collected. To calculate the percentage responders, modified OMERACT/OARSI responder criteria were used. A responder was defined by an improvement of ≥50% in function or pain, or an improvement of ≥20% in pain and function. The study was conducted according to the declaration of Helsinki and received ethics approval of the hospital.

Results: The year prior to TKR referral 26% (n= 44) of patients used daily NSAIDs, 27% (n=47) used daily PCM, or occasional NSAID, and nearly half (47%; n=81) used an occasional PCM or no medication at all. No differences in baseline characteristics or radiographic features were found between these three groups. Of the 81 patients not using adequate analgesics, 46 patients were randomized to NSAID treatment and 35 were randomized to no treatment. Patients without prior adequate pain medication treated for 6 weeks with an NSAID improved on average statistically significant in pain and stiffness (−5.7 [−10.9; −0.5] and −9.6 [−16.4; −2.8], resp. both $p<0.05$). 27% of patients could be classified as an actual responder.

Conclusion: In this explorative study most patients awaiting TKR experienced significant pain levels and limitations in activities, but surprisingly the majority did not use NSAIDs daily. Patients with inadequate medication, starting NSAID use daily, improved clinically significantly. Properly designed RCTs are warranted to study potential effects of adequate pain medication to delay the need for TKR surgery in case of severe OA, an area where rheumatologists can support orthopaedics.

1988

Psychological Predictors of Failure to Improve After Lower Extremity Joint Arthroplasty. Chad M. Brummett[1], Brian Hallstrom[1], Andrew Urquhart[1], Michelle Morris[1], Daniel J. Clauw[2] and David A. Williams[3]. [1]University of Michigan Health System, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Univ of MI Hlth System-Lobby M, Ann Arbor, MI

Background/Purpose: The lifetime risk for symptomatic knee osteoarthritis has been estimated at 45%, and the number of lower extremity arthroplasties conducted each year is anticipated to rise exponentially. The rate of failure to improve following arthroplasty is estimated to be between 20–40% for knees and 10% for hips. We present preliminary results of an ongoing study investigating the phenotypic predictors of failure to improve after lower extremity joint arthroplasty.

Methods: Patients scheduled for total hip and knee arthroplasty (THA and TKA) were recruited in the immediate preoperative area. The anticipated recruitment for the study is 2000 lower extremity total joint arthroplasty patients over a 5-year period. Patients completed a preoperative phenotyping battery of validated self-report questionnaires, including the Brief Pain Inventory and Hospital Anxiety and Depression Scale. Patients were then contacted at 1- and 3-months after surgery by phone and at 6-months postoperatively by mail with the same measures, as appropriate. At each follow up, patients were asked to rate the success of their surgery using the Patient Global Impression of Change (PGIC). Data were analyzed using PASW Version 18. THA and TKA patients were grouped for analysis of predictors of outcome. For comparisons of outcomes at 6-months, patients were categorized using the PGIC as treatment "Success" (+2 or +3) or "Failure" ([-3] – [+1]) for comparisons of baseline characteristics. Between-group comparisons were made using the Mann-Whitney test. A Bonferroni correction for multiple comparisons was conducted ($\alpha = 0.0125$).

Results: To date, 337 arthroplasty patients have been recruited with a recruitment rate of 83%. Retention rates are 96%, 91%, and 77% at 1-, 3-, and 6-months respectively. At 6-months (n = 211), 16% of patients were classified as failed therapy using the PGIC (TKA = 24.3% vs THA = 9.3%, p = 0.011). There were no significant differences in baseline pain score between patients classified as failed versus success (median 4.75 [IQR 3, 6.75] vs 4.75 [3.25, 6.0], p = 0.555) Patients classified as failed therapy reported higher baseline scores for depression (median 6.5 [IQR 5, 8] vs. 4 [2, 6], p = 0.012) and anxiety (7 [5, 8] vs. 5 [3, 7], p = 0.091). Patients in the Success group showed a trend towards a more positive affect on the positive subscale of the HADS (3 [1, 5] vs. 4.5 [3, 7], p = 0.052).

Conclusion: Preliminary data indicate that higher levels of depression are associated with poor outcomes in lower extremity joint arthroplasty. Anxiety and low positive affect show trends towards poor outcome. Recruitment is ongoing, and future analyses of predictors of success and failure will be conducted.

1989

Is the Impact of Knee Osteoarthritis Diminishing Because of Knee Replacements? the Multi-Center Osteoarthritis Study. Jingbo Niu[1], Michael C. Nevitt[2], Charles E. McCulloch[3], James Torner[4], Cora E. Lewis[5] and David T. Felson[1]. [1]Boston University School of Medicine, Boston, MA, [2]University of California-San Francisco, San Francisco, CA, [3]Department of Epidemiology and, San Francisco, CA, [4]University of Iowa, Iowa City, Iowa City, IA, [5]University of Alabama, Birmingham City, Birmingham, AL

Background/Purpose: Rates of knee replacement (KR) have increased so much that they may have an effect on the overall impact of symptomatic knee osteoarthritis (SxOA). Specifically, as more persons with severe knee SxOA get KR and get it at an earlier disease stage, only a limited number of persons with severely disabling SxOA are left in the population. Thus, there might be a secular trend of improvement in functional score among persons with SxOA. We described the secular trend of function among subjects with SxOA in the Muliticenter Osteoarthritis (MOST) Study in which > 300 subjects had KR over 5 years.

Methods: The MOST Study is a cohort study of 3026 persons with or at high risk of knee OA drawn from the community. Subjects had knee radiographs, filled out WOMAC surveys, and reported knee surgery every 30 months. Self reported KR was confirmed on radiographs or medical records. At each visit, a subject was defined as having SxOA if ≥1 knee had frequent knee pain plus K/L grade ≥2 at that time or had any KR prior to the visit. The WOMAC function score at 0M, 30M and 60M *among subjects who currently had SxOA at the visit* were compared by ANCOVA, adjusting for age, sex, BMI, clinical site, CES-D, comorbidity, number of painful joints in lower limbs other than knees, and number of SxOA knees. Analyses were done among Whites and Blacks separately, with age limited to 55–79 at all visits. GEE was used to adjust correlation between repeated measures within subjects. We repeated analyses excluding subjects (a) with bilateral KR and (b) with any KR. To mimic the function in a hypothetical sample in which no new KRs were done during follow-up, we set the post-KR WOMAC function scores to missing and imputed them based on the covariates above as well as race, baseline function score and K/L grade *among subjects with SxOA at 0M*.

Results: Subjects with SxOA (673 at 0M, 656 at 30M, and 616 at 60M) had similar characteristics (mean age 66–67 years, mean BMI 33 kg/m^2, 65–70% women, 82% Whites). Among them, the proportion of any KR (bilateral KR) were 12(0)%, 26(4)%, 44 (17)% in Whites, 8(0)%, 20(5)%, 33(14)% in Blacks at 0M, 30M, and 60M, respectively. The mean WOMAC function score was highest (worst) at 0M, not different at 30M, and significantly lower (better) at 60M compared to 0M in both Whites and Blacks (change from 0M = −5.8 and −3.9 respectively). After excluding subjects with bilateral KR or any KR, the improvement between 0M and 60M disappeared among Blacks (−0.7 to −1.6, p=0.22 to 0.63), but remained among Whites (−3.2 to −3.8, p<.0001). Post-KR function score was imputed among 469 subjects. Their observed mean WOMAC function decreased during follow-up, 24.2, 22.1, and 19.1, which became 24.2, 24.0, and 24.2 after imputation, suggesting no change in function without KR.

Table 1. WOMAC function score among subjects with knee symptomatic osteoarthritis (higher score is worse function)

	Whites			Blacks		
	0M	30M	60M	0M	30M	60M
Subjects with SxOA						
N	555	541	520	118	115	96
Crude	24.4 (23.5, 25.4)	22.9 (21.9, 23.9)*	18.2 (17.2, 19.2)*	30.6 (28.6, 32.6)	29.2 (26.7, 31.7)	27.1 (24.3, 30.0)*
Adjusted**	26.0 (25.1, 26.9)	25.8 (24.7, 26.9)	20.2 (19.1 21.3)*	32.1 (29.9, 34.2)	31.1 (28.9, 33.2)	28.2 (25.8, 30.6)*
Subjects with SxOA, excluding those with bilateral KR						
N	555	518	433	118	109	83
Crude	24.4 (23.5, 25.4)	23.5 (22.5, 24.6)	20.0 (18.9, 21.1)*	30.6 (28.6, 32.6)	29.8 (27.2, 32.3)	29.5 (26.7, 32.3)
Adjusted**	26.5 (25.6, 27.4)	26.5 (25.4, 27.6)	22.7 (21.5, 23.8)*	31.8 (29.7, 33.9)	31.3 (29.1, 33.4)	30.2 (28.0, 32.4)
Subjects with SxOA, excluding those with any KR						
N	489	398	290	108	92	64
Crude	25.2 (24.2, 26.1)	25.3 (24.2, 26.4)	22.0 (20.7, 23.2)*	31.7 (29.7, 33.7)	31.6 (29.0,34.2)	31.6 (28.6, 34.5)
Adjusted**	26.8 (25.8, 27.7)	27.5 (26.3, 28.6)	23.6 (22.3, 24.8)*	31.8 (29.6, 34.0)	32.5 (30.3,34.7)	31.1 (28.7, 33.4)

* P-value <0.05 compared to baseline.
** Adjusting age, sex, BMI, clinical site, CES-D, comorbidity, number of painful joints in the lower limbs, number of knees with SxOA.

Conclusion: A trend for better WOMAC function over time among subjects with SxOA suggests that KR has decreased the overall impact of SxOA on function. This decreased impact was less in Blacks probably due to their lower rate of KR.

1990

Gait Biomechanics As Predictors of Hip Osteoarthritis Progression. Kharma C. Foucher[1], Bryan R. Schlink[2], Najia Shakoor[1] and Markus A. Wimmer[1]. [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL

Background/Purpose: While it is generally believed that osteoarthritis (OA) progression may be exacerbated by abnormal loading patterns during daily activities, the underlying processes have not been fully characterized for hip OA. While reduced hip range of motion and peak external moments during walking are associated with OA severity[1], it is not known how gait may relate to disease progression. This study was a preliminary investigation of the relationship of baseline gait characteristics and radiographic hip OA progression.

Methods: We evaluated 11 subjects with hip OA (60±7 y; 1.7±0.1 m; 87±18 kg; 7 male). Speed, stride length, cadence, %gait cycle spent in stance, dynamic range of motion, and 3D peak external moments were averaged from 3 trials collected at subjects' self-selected normal walking speeds. A single observer assessed OA severity using the modified Kellgren-Lawrence (KL) grade from baseline and 1–2 year f/u hip radiographs. Disease progression (P group) was defined as increased KL grade or THR during the study period. All other subjects were assigned to the 'stable' (S). To assess between-group differences we calculated effect sizes (ES) from the means and standard deviations of the WOMAC scores, demographic and gait variables. We focused on variables with medium (≥0.5) and large (≥0.8) effect sizes[2].

Results: 6 of 11 subjects showed OA progression (Table). Baseline KL grade and WOMAC scores were unrelated to progression. P group subjects walked with longer steps and spent less time in stance, and had higher peak flexion and external rotation moments, but lower peak adduction moments.

Table. Baseline characteristics (N or mean ± standard deviations) and group comparisons for subjects who did and did not show radiographic OA progression. Bold text indicates variables for which group differences had medium or large effect sizes.

	Progression group	Stable group	Group comparisons KL grade and Gender: Chi-square p value Other variables: Effect size with 95% confidence interval
KL Grade	KL 1: N=1 KL 2: N=2 KL 3: N=3 KL 4: N=0	KL 1: N=0 KL 2: N=1 KL 3: N=2 KL 4: N=2	0.387
# Men/# Women	3/3	4/1	0.383
WOMAC	550±303	561±561	−0.03 (−1.21, 0.58)
Age (years)	60±8	61±6	−0.14 (−1.32, 0.47)
Height (m)	1.71±0.13	1.75±0.11	−0.33 (−0.94, 0.28)
Mass (kg)	83.3±22	91.6±11	−0.46 (−1.08, 0.15)
Speed (m/s)	1.22±0.19	1.16±0.10	0.48 (−0.23, 0.99)
Stride length (m)	**1.33±0.14**	**1.26±0.14**	**0.50 (−0.11, 1.11)**
Cadence (steps/min)	110±10	111±12	−0.09 (−0.70, 0.52)
Percent time in stance	**58.7±1.4**	**59.6±1.1**	**−0.71 (−1.33, −0.08)**
Dynamic range of motion (degrees)	22.5±4.3	23±8.5	−0.08 (−0.68, 0.53)
Peak flexion moment (%Body weight × Height)	**5.9±1.4**	**4.8±1.4**	**0.79 (0.16, 1.41)**
Peak extension moment (%Body weight × Height)	2.25±0.79	2.12±0.91	0.15 (−0.45, 0.76)
Peak abduction moment (%Body weight × Height)	1.95±1.1	1.65±0.56	0.33 (−0.28, 0.94)
Peak adduction moment (%Body weight × Height)	**2.97±0.99**	**3.61±0.89**	**−0.68 (−1.3, −0.05)**
Peak external rotation moment (%Body weight × Height)	**0.443±0.13**	**0.227±0.17**	**1.15 (0.5, 1.81)**
Peak internal rotation moment (%Body weight × Height)	0.43±0.23	0.523±0.13	−0.48 (−1.10, 0.13)

Conclusion: Several variables distinguished subjects with OA progression. These subjects adopted a gait pattern in which they spent less time bearing weight on their diseased hip; however this adaptation was seen along

with increased peak flexion moments (a large impulsive load that may be detrimental to cartilage). The reduced external adduction moment seen in the P group suggests more substantial overall abductor dysfunction compared to those with stable disease, however the higher external rotation moment indicates a relative overactivity of the anterior portions. Larger longitudinal studies are needed to confirm these findings and elucidate the underlying mechanisms. However, this preliminary work suggests that gait analysis may be used to help predict disease progression, and may provide specific biomechanical targets for intervention, such as those currently being evaluated for knee OA.

The Relationship of Toe-Out Walking to Clinical Characteristics of 1st Metatarsophalangeal Joint Osteoarthritis in Older Adults: The MOST Study. K. Douglas Gross[1], Howard J. Hillstrom[2], Jingbo Niu[3], Michael C. Nevitt[4], Cora E. Lewis[5], James Torner[6] and David T. Felson[3]. [1]MGH Institute of Health Professions, Boston, MA, [2]Hospital Special Surgery (HSS), New York, NY, [3]Boston University School of Medicine, Boston, MA, [4]University of California-San Francisco, San Francisco, CA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA

Background/Purpose: The 1st metatarsophalangeal joint (MTPJ) is the most common site of OA in the foot. While clinical diagnostic criteria have not been defined, characteristics of 1st MTPJ OA include frequent joint pain, hallux valgus malalignment, and limited joint dorsiflexion during gait (functional hallux limitus). The degree to which a person toes-out when walking is of interest to OA investigators because of the desirable effects that toe-out has in reducing load on the medial knee. However, evidence suggests that toe-out may also increase load on the 1st MTPJ, possibly putting this joint at greater risk of OA. This study determined the cross-sectional relationship of toe-out with clinical characteristics of 1st MTPJ OA, including joint pain, alignment, and dorsiflexion in a population of older adults at risk of OA.

Methods: The Multicenter Osteoarthritis Study (MOST) includes older adults who have or are at risk of knee OA. At the 60-month exam, we inquired about frequent 1st MTPJ pain, measured hallux valgus alignment from foot photos, and measured peak 1st MTPJ dorsiflexion and mean toe-out angle using a 4.9 meter instrumented GAITRite walkway and 60 Hz videos during 3–4 self-paced walking trials. Using the quintile distribution among pain cases to form cutpoints, we applied logistic regression to determine the relative odds of 1st MTPJ pain within categories of increasing toe-out while adjusting for age, sex, BMI, and walking velocity. Generalized estimating equations (GEE) accounted for inclusion of two feet from a subject. Using linear regression with GEE, we compared mean hallux valgus alignment and mean 1st MTPJ dorsiflexion within these categories while making similar adjustments.

Results: 2027, 534, and 626 participants with available 60-month exam data contributed 4054, 1066, and 1247 feet to assess the relation of toe-out to 1st MTPJ pain, alignment, and dorsiflexion, respectively. Mean toe-out was 6.8 +/− 5.6 degrees, mean hallux valgus alignment was 20.6 +/− 10.2 degrees, and mean 1st MTPJ dorsiflexion was 39.6 +/−10.8 degrees. After adjustments, the odds of 1st MTPJ pain and the means of hallux valgus alignment were similar across categories of increasing toe-out (p for trend = 0.36 and 0.22, respectively). Mean 1st MTPJ dorsiflexion decreased (p for trend = 0.04), but only slightly (≤ 2 degrees) (see table).

Table. Relative odds of 1st MTPJ pain, mean hallux valgus alignment, and mean 1st MTPJ dorsiflexion within categories of increasing toe-out during walking.

	1st MTPJ Pain N=4054 feet, 2027 ppts			Hallux Valgus N=1066 feet, 534 ppts		1st MTPJ Dorsiflex N=1247 feet, 626 ppts	
Toe-Out Categories	N of feet	N (%) painful	Adj. OR* (95% CI)	N of feet	Adj. Mean* (95% CI)	N of feet	Adj. Mean* (95% CI)
Lowest −10.3°, 2.3°	825	109 (13.2)	1.0 (ref)	198	21.0° (19.6, 22.4	225	40.7° (39.5, 41.9)
2nd 2.4°, 5.8°	904	111 (12.3)	1.0 (0.8, 1.3)	256	21.4° (20.2, 22.6)	301	39.4° (38.4, 40.5)
3rd 5.9°, 8.5°	810	114 (14.1)	1.1 (0.8, 1.4)	244	21.0° (19.9, 22.2)	268	40.2° (39.1, 41.3)
4th 8.6°, 11.7°	744	107 (14.4)	1.2 (0.9, 1.5)	194	20.9° (19.7, 22.1)	240	39.8° (38.6, 40.9)
Highest 11.8°, 32.6°	771	110 (14.3)	1.1 (0.8, 1.4)	174	19.7° (18.3, 22.1)	213	38.7° (37.4, 40.0)
p for trend			p=0.36		p=0.22		p=0.04

* Adjusted for age, sex, BMI, and walking velocity.

Conclusion: Increased toe-out during walking was not associated with increased prevalence of 1st MTPJ pain or increased hallux valgus malalignment. While greater toe-out was associated with slightly reduced 1st MTPJ dorsiflexion, the magnitude of this association was small and its relevance to OA etiology remains equivocal. Based on these findings, gait training to increase toe-out among adults with medial knee OA could be considered without substantial concern for OA characteristics at the 1st MTPJ.

1992

Relationships Between the Peak Adduction Moment and Symptoms During Walking in Knee Osteoarthritis Patients with Valgus Knee Brace: A Cross-Sectional Study. Paul Ornetti, Clementine Fortunet, Davy Laroche, Claire Morisset, jean-Marie Casillas and jean-Francis Maillefert. Dijon University Hospital, Dijon, France

Background/Purpose: The use of valgus knee brace has been recently recommended in the OARSI guidelines to decrease pain and functional impairment. Symptomatic effects are thought to be mediated by distracting the medial compartment via external valgus forces applied to the knee, which could be evaluated by the peak knee adduction moment.However, there is limited evidence regarding the symptomatic benefits of valgus knee brace in knee OA patients and their correlations with the peak adduction moment. Objective: To evaluate the clinical efficacy and biomechanical effectiveness of a new valgus knee brace (developed and provided by PROTEOR) with a rotating shift axis

Methods: *Design*: 5-week prospective open-labeled therapeutic trial in outpatients with symptomatic painful medial knee OA. *Inclusion and exclusion criteria*: age between 40 et 80, pain of at least 40 (100 visual analog scale (VAS)) on a daily basis for at least one month during the last three months, evidence of medial femoro-tibial OA on plain antero-posterior X-rays (Kellgren and Lawrence stage ^{3} 2), predominance of pain and radiographic OA in the medial part of the knee. *Outcome measures.* Three-dimensional (3D) Vicon gait analyses were performed at weeks 0 and 5 for all patients. Primary outcome measure was pain severity as measured on VAS. Secondary outcome measures were patient global assessment (PGA) on VAS (0–100), KOOS function activity of daily life (0–100, worst to best), gait parameters (gait speed, step length and walking frequency) and peak adduction moment. *Statistical analysis:* comparison of pre and post-treatment clinical and 3D gait data was performed using the Wilcoxon paired test and calculation of effect size (ES). Correlations between change in symptoms and peak adduction moment were calculated using Spearman correlation coefficient.

Results: Twenty patients (16 women and 4 men, mean age 64.2±10.2 years, mean body mass index 27.2±5.4 kg/m^2) were included. The mean VAS pain (63.0 to 29.8, $p < 0.001$, ES=2.34), VAS PGA (64.3 to 34.0, $p < 0.001$, ES=1.85) scores improved significantly from baseline to week 6, as well as KOOS function activity of daily life (ADL): 44.5 to 67.8, $p < 0.001$, ES=1.83; 85% of patients (17/20) considered their state as improved or very improved at week 6. NSAIDs and analgesic drug intake decreased significantly at week 6 ($p=0.018$ and $p=0.004$, respectively). No serious side-effects were observed. The gait speed and step length were significantly increased at the end of the study ($p<0.05$). The reduction of peak adduction moment was correlated with the improvement in pain ($r = 0.67$, $p<0.002$) and physical function ($r = 0.57$ for KOOS ADL, $p<0.01$).

Conclusion: The preliminary results demonstrate a good clinical efficacy of a new valgus knee brace in medial compartment knee OA patients. This efficacy is statistically correlated with the reduction of the peak adduction moment on the knee medial compartment.

1993

Consequences of Knee Buckling: The Multicenter Osteoarthritis Study. Uyen Sa D. Nguyen[1], David T. Felson[1], Jingbo Niu[1], Yanyan Zhu[1], Daniel K. White[1], Neil Segal[2], C.E. Lewis[3], Margaret Rasmussen[4] and Michael C. Nevitt[4]. [1]Boston University School of Medicine, Boston, MA, [2]University of Iowa, Iowa City, [3]University of Alabama, Birmingham City, AL, [4]University of California-San Francisco, San Francisco, CA

Background/Purpose: Recent studies suggest that knee buckling, a feeling of sudden "giving way" of the knee, is a common symptom in people with knee pain and knee osteoarthritis (OA). People may avoid physical activity out of fear of falling if their knee buckled, possibly leading to decreased physical function. Little is known about the psycho-social or physical consequences of knee buckling. We examined the association of buckling with fear of falling, decreased balance confidence, and decreased physical function. We further explored whether people whose knees buckled

repeatedly were at a greater risk for these outcomes than people whose knees did not buckle.

Methods: We used data from the 60-month visit of the Multicenter Osteoarthritis Study (MOST), an NIH funded longitudinal study of persons with or at high risk of knee OA. During clinic visits, participants were asked if their knees buckled or gave way in the past 12 months and if so, whether they buckled in the past 3 months and the frequency of such buckling. Repeated bucklers were defined as people who had 2 or more buckling episodes in the past 3 months. Participants were also asked about fear of falling, and balance confidence (ABC Balance Scale, range: 0–100, with poor confidence defined as ≤ 67). Low physical function was defined as WOMAC function score ≥ 28.0[1], and impaired walking speed as <1.22 m/s.[2] Poisson regression was used to estimate the prevalence ratio (PR) and 95% confidence interval (CI) for the cross-sectional association between buckling and each of the outcomes of interest, adjusting for age, sex, BMI, number of co-morbidities, severity of WOMAC knee pain score, radiographic OA (ROA) and quadriceps strength.

Results: Of 2,299 persons with buckling frequency and outcome data (60% female, 39% ≥ 65 years, mean BMI: 31), 24% had knee buckling in the previous year, 34% had a fear of falling, 14% had low confidence in their balance, 14% had low WOMAC physical function, and 50% had impaired walking speed. Overall, knee buckling was significantly associated with fear of falling, poor balance confidence, and poor WOMAC physical function, independent of knee pain and other confounders (Table). The associations were greatly attenuated after adjustment of covariates, particularly knee pain. Additionally adjusting for ROA and quadriceps strength did not further alter the estimates of association. Moreover, the magnitude of the association was slightly higher for repeated bucklers than non-repeated bucklers, especially for poor physical function. There was no association between buckling and impaired gait speed once confounders were adjusted.

Table. Association between Knee Buckling and Outcome of Interest All subjects and by Repeat or Non-Repeat Bucklers

	Knee Buckling			
Outcome of interest	**Any Buckling**	**Repeated Buckling**	**Non-Repeated Buckling**	**No Buckling**
Fear of Falling	N=552	N=310	N=240	N=1742
% with Fear of Falling	49.6	55.8	41.7	29.2
Unadjusted PR (95% CI)	17 (1.5, 1.9)	1.9 (1.7, 2.2)	1.4 (1.2, 1.7)	REF
Adjusted PR (95% CI)	1.3 (1.2, 1.5)	1.4 (1.3, 1.6)	1.2 (1.0, 1.4)	REF
Low Balance Confidence	N=552	N=310	N=242	N=1742
% with Balance Score ≤ 67	30.1	35.5	23.1	8.8
Unadjusted PR (95% CI)	3.4 (2.8, 4.2)	4.0 (3.3, 5.0)	2.6 (2.0, 3.5)	REF
Adjusted PR (95% CI)	2.0 (1.6, 2.5)	2.2 (1.7, 2.7)	1.8 (1.4, 2.3)	REF
Poor Physical Function	N=533	N=295	N=238	N=1727
% with WOMAC function ≥28.0	31.0	37.3	23.1	8.6
Unadjusted PR (95% CI)	3.6 (2.9, 4.4)	4.3 (3.5, 5.3)	2.7 (2.0, 3.5)	REF
Adjusted PR (95% CI)	1.3 (1.0, 1.6)	1.3 (1.1, 1.7)	1.2 (0.9, 1.6)	REF
Impaired Gait Speed	N=536	N=299	N=237	N=1704
% with Gait Speed < 1.22m/s	60.6	67.6	51.9	46.7
Unadjusted PR (95% CI)	1.3 (1.2, 1.4)	1.4 (1.3, 1.6)	1.1 (1.0, 1.3)	REF
Adjusted PR (95% CI)	1.0 (0.95, 1.1)	1.1 (1.0, 1.2)	0.9 (0.8, 1.1)	REF

Adjusted for Sex, Age (<65 vs. ≥), BMI, Comorbidity, WOMAC Knee pain severity. Additionally adjusting for ROA and quadriceps strength did not further alter the estimates of association.

[1] Ayis S et al. J Rheum 2007:34:1905–12
[2] White et al. AC&R 2010;62:938–43

Conclusion: Independent of knee pain and other confounders, knee buckling was significantly associated with fear of falling, poor balance confidence, and poor physical function. Future studies should examine the longitudinal effect of buckling on psycho-social and physical outcomes.

1994

Is Medial Knee Osteoarthritis Associated with Adverse Effects At the Ankles? Berna Goker[1], Abdurrahman Tufan[1], Roy H. Lidtke[2] and Joel A. Block[2]. [1]Gazi University Medical School, Ankara, Turkey, [2]Rush University Medical Center, Chicago, IL

Background/Purpose: Primary ankle osteoarthritis (OA) is considered to be uncommon, however, an association of radiographic ankle OA with symptomatic knee OA has recently been reported (McDaniel G, PMID 21310252), and lateral ankle pain is common in patients with knee OA. We hypothesized that the the tibio-femoral malalignment and lateral shift observed in medial knee OA would be associated with radiographic OA of the ankle.

Methods: 90 subjects with symptomatic medial knee OA (K-L grade 2–3, ambulatory pain >30 mm on a 100 mm VAS) were included. Full limb mechanical axis and AP X-rays of the ankles were obtained. Joint space width (JSW) of the medial and lateral tibiotalar joints were measured using a validated method (Goker B, PMID 19381746). Also, in addition to the knee alignment angle, the tibial lateral shift, defined as the distance between the center of the intercondylar notch of the femur and midpoint of the tibial plateau, was measured, using Image J software (US NIH, Bethesda, MD, http://rsbweb.nih.gov/ij/). Pearson's correlations were calculated to analyze the relationship between the ankle JSW and the other radiographic parameters. $p < 0.05$ was considered significant.

Results: The mean±SD tibial lateral shift was 5.18±2.45 mm, and was inversely related to the lateral ankle JSW (r=-0.27, p=0.01). In contrast, there was no relationship with the medial ankle JSW (r=-0.16, p=0.12). Also, the knee alignment angle (mechanical axis) was not associated either with medial or lateral ankle JSW (r=0.11, p=0.23 and r=0.16, p=0.12, respectively).

Conclusion: Radiographic JSW is a measure of cartilage loss, and is directly related to strucutral OA progression. These findings of an association between the magnitude of lateral tibio-femoral shift in knee OA and narrowing of ankle JSW suggest that the aberrant loading of the knee in OA has structural implications at the ankle, and may explain the previously described association between medial knee OA and radiographic ankle OA.. The clinical significance of this finding, and its relationship to lateral ankle pain in patients with knee OA, needs further study

1995

The Association of Vibratory Perception with Foot Plantar Pressures: The MOST Study. Najia Shakoor[1], Howard J. Hillstrom[2], K. Douglas Gross[3], Ke Wang[4], David T. Felson[5], Neil Segal[6], Cora E. Lewis[7] and Michael C. Nevitt[8]. [1]Rush University Medical Center, Chicago, IL, [2]Hospital Special Surgery (HSS), New York, NY, [3]MGH Institute of Health Professions, Boston, MA, [4]Boston University, Boston, MA, [5]Boston University School of Medicine, Boston, MA, [6]University of Iowa, Iowa City, [7]University of Alabama, Birmingham City, Birmingham, AL, [8]University of California-San Francisco, San Francisco, CA

Background/Purpose: Somatosensory alterations at the lower extremities have previously been recognized in osteoarthritis (OA), including deficits in vibratory perception. It is hypothesized that these sensory deficits may increase mechanical loading of tissues and joints in individuals with knee OA and that the mediator of this may be increased plantar pressures at the foot.Here, we evaluated the association between vibratory perception and plantar pressures in a large cohort study of knee OA.

Methods: The Multicenter Osteoarthritis Study (MOST) is a NIH-funded longitudinal study of persons with or at increased risk of knee OA. Those with total knee replacement or diabetes, defined by the use of medication, were excluded in this analysis. At the 60-month visit, participants underwent bilateral evaluation of vibratory perception threshold (VPT), using a biothesiometer. The applicator tip was placed at the dorsum of the 1st MTP joint. Voltage was initially set at "0" and then increased by 1 volt/second until the participant acknowledged sensation. This was defined as the VPT.Plantar pressures were captured using a high resolution digital pedobarograph (EmedX) during 5 self-paced walking trials for each foot. Peak pressures (N/cm2) and pressure-time integrals (Ns/cm^2) were evaluated in each anatomical region of the plantar foot using a masking algorithm. The hallux and medial and lateral heel were chosen as anatomic areas of interest that may be susceptible to increased pressures during the push off and weight acceptance phase of stance, respectively. Categories of "low", "normal", and "high" VPT, in order of better to worse vibratory sense, were formed at < or > 1 standard deviations from the mean. Mean plantar pressures were compared between these three VPT groups while adjusting for age, sex, race, body mass index, clinical site, and walking speed. Generalized Estimating Equations (GEE) accounted for the inclusion of two feet from a single subject.

Results: 1560 participants (2926 knees) were included in this analysis (59.3% female with a mean age (±SD) of 67±8 years). Results are summarized in Table 1 and demonstrate a "dose-response" trend, such that with worsening vibratory perception, increased hallucial peak pressures were observed as well as increased pressure-time integrals at the hallux and lateral and medial heel.

Table.

	Hallucial peak pressure (N/cm^2)	**Hallucial pressure-time integral (Ns/cm^2)**	**Medial heel pressure (N/cm^2)**	**Medial heel pressure–time integral (Ns/cm^2)**	**Lateral heel pressure (N/cm^2)**	**Lateral heel pressure-time integral (Ns/cm^2)**
"Low" VPT	63.3 (59.8, 66.9)	17.8 (16.6, 18.9)	33.6 (31.6, 35.5)	9.4 (9.0, 9.9)	30.2 (29.0, 31.4)	8.6 (8.3, 9.0)
"Normal" VPT	64.7 (63.1, 66.3)	18.2 (17.7, 18.8)	36.4 (35.4, 37.4	10.4 (10.0, 10.7)	32.1 (31.5, 32.7)	9.3 (9.1, 9.5)
"High" VPT	71.4 (68.4, 74.4)	20.5 (19.4, 21.6)	37.4 (35.3, 39.5)	10.8 (10.1, 11.4)	32.8 (31.3, 34.2)	9.6 (9.2, 10.1)
P for linear trend	**<0.001**	**<0.001**	0.132	**0.049**	0.153	**0.034**

Conclusion: Vibratory sense deficits have previously been observed in OA compared to age-matched controls. The role of these alterations in the OA disease process and OA mechanics is not clear. These results suggest that those with lower vibratory perception have increased plantar loading, indicating that sensory deficits may have mechanical associations in persons with or at risk of knee OA.

1996

Associations Between Pain on Movement, Range of Movement and Radiographic Change in Osteoarthritis of the Knee. Roger Hilfiker[1], Peter Juni[2], Eveline Nüesch[2], Paul A. Dieppe[3] and Stephan Reichenbach[1]. [1]Universtiy of Bern, Bern, Switzerland, [2]University of Bern, Bern, Switzerland, [3]University of Exeter, Plymouth, United Kingdom

Background/Purpose: Patients with osteoarthritis are at higher risk of death compared with the general population, and the presence of a walking disability is one major risk factor. Based on gait analyses, full extension of the knee is important for walking. We determined whether limitations in the range of motion (ROM) of the knee joint were associated with the presence of pain independently of structural damage as detected on radiographs.

Methods: Data from the follow-up study of the Somerset and Avon Survey of Health (SASH), a community-based prospective cohort study, were used. Passive knee flexion and extension were measured using a goniometer, and patients were asked whether the passive movements were painful [no/yes]. Knee radiographs were read for K&L grades [0–4], osteophytes [0–3] and joint space narrowing [0–3]. After adjustments for sex, body mass index (BMI), and radiographic characteristics, we evaluated whether extension and flexion deficits were associated with pain. Data were analysed at joint level using linear regression models with robust standard errors to account for clustering of knees within patients. We then explored potential interactions between the presence or absence of pain and the association of radiographic changes with limitations in ROM.

Results: 820 patients (1639 knees) had complete information for knee range of motion, radiographs and pain. 41.2% of the knees had a K/L grade of 0 or 1. The median range of knee extension was 0° (range −15° (hyperextension) to 50° (extension deficit)) with a mean extension deficit of 1.4° (sd 4.9). Passive extension caused pain in 322 knees (20%). The median knee flexion was 125° (range 40° to 158°) and mean flexion was 125° (sd 13.5). Passive flexion caused pain in 486 (30%) knees.

Extension deficits were more pronounced in individuals with pain on passive extension (difference after initial adjustment: 2.8°, 95% CI 1.9° to 3.8°). This difference was similar after adjustment for K/L (2.5°, 95% CI 1.5° to 3.5°). The association between K/L and extension was more pronounced in patients with pain on passive extension (extension deficit per K/L grade: 1.4°, 95% CI 0.6° to 2.1°) than in those without such pain (0.4°, 95% CI 0.2° to 0.7°), with a positive test for interaction (p=0.024).

Flexion was more restricted in individuals with pain on passive flexion (difference after initial adjustment: −5.9°, 95% CI −7.6° to −4.3°). This difference was slightly lower after adjustment for K/L (−4.4°, 95% CI −6.1° to −2.7°). The association between K/L and flexion was also more pronounced in patients with pain on passive flexion (reduced flexion per K/L grade: −2.4°, 95% CI −3.5° to −1.3°) than in those without such pain (−1.5°, 95% CI −2.2° to −0.8°), with a non-significant test for interaction (p=0.174).

Conclusion: Pain on extension and flexion were both associated with ROM, even after adjustment for radiographic severity. The presence or absence of pain on passive extension modified the association of ROM with K/L grade, with a more pronounced association in the presence of knee pain. For flexion, pain did not modify the association between radiographic severity and ROM. Pain and extension deficits may both be possible targets for preventing or ameliorating walking disability.

1997

Radiographic Joint Damage and Not Clinical Characteristics Are Related to the Actual Cartilage Damage in Severe Knee Osteoarthritis Patients. T.N. de Boer[1], Simon C. Mastbergen[1], A.M. Huisman[2], J.W.J. Bijlsma[1] and F.P.J.G. Lafeber[1]. [1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Sint Franciscus Gasthuis, Rotterdam, Netherlands

Background/Purpose: Clinically, osteoarthritis (OA) is characterized by joint pain, tenderness, limitation of movement, crepitus, occasional effusion, and local inflammation. Pain, joint deformation, and stiffness of the joint capsule may lead to severe restriction of function, and in the long term to disability. In end-stage disease specific indications for total knee replacement (TKR) surgery are not clearly defined. The decision to proceed to TKR is based upon the clinical parameters like pain and limitation of movement accompanied by radiographic characteristics. Because there are no clearly defined indications for TKR surgery, patients with little radiographic damage (K&L grade 1 or 2) frequently undergo TKR surgery. The aim of this study is to evaluate whether pre-operative radiographic characteristics, better than clinical characteristics, relates to actual cartilage damage of patients with end-stage knee osteoarthritis.

Methods: 172 successive patients with severe knee OA selected for TKR seen at a peripheral hospital in the Netherlands were evaluated (age 67.4; female/male ratio 119/53). Patient characteristics, radiographic features of OA (K&L score, Altman joint space narrowing and osteophytes) and severity of symptoms (WOMAC pain, stiffness and physical function) were assessed shortly before surgery. During joint replacement surgery, cartilage and synovial tissue were obtained and evaluated by macroscopy, histology, and biochemistry, blinded to the clinical and radiographic characteristics. The study was conducted according to the declaration of Helsinki and received ethics approval of the hospital.

Results: The average K&L score of this population was 3.1 (range 1–4). The average Altman scores for this population were 2.5 (range 0–3) for the joint space narrowing and 3.2 (range 0.8–6) for the osteophyte score. Both the K&L score and the Altman osteophyte score were statistically significant associated with the actual macroscopic cartilage damage [R=0.865, p=0.006/ R=0.801, p=0.005, respectively]. The Altman joint space narrowing showed also an association with the macroscopic cartilage damage [R=0.482, p=0.067]. The cartilage histology and the PG content showed no evident correlation with either of the radiographic parameters. The Altman osteophyte score was also significantly associated with the macroscopical synovial inflammation [R=0.466, p=0.029] and histological synovial inflammation [R=0.374, p=0.039]. None of the clinical parameters did relate to any of the actual structural cartilage damage of synovial inflammation.

Conclusion: The present study demonstrates that there is a good correlation between K&L score and actual cartilage damage in end-stage knee OA considered for replacement surgery. This indicates that radiographs give a good indication of the actual severity of joint damage. Osteophytes, dominating the overall K&L score, also on their own (Altman score) correlate with actual cartilage damage as well as actual synovial inflammation. Because no relations between clinical parameters and actual joint damage were found it might be concluded that radiographic joint damage is underestimated in the selection of patients considered for prosthesis surgery.

1998

Peri-Articular Apparent Bone Volume Fraction Is Associated with Numerous Patient Characteristics in Knees with Osteoarthritis: Data From the Osteoarthritis Initiative. Jeffrey B. Driban[1], Lori Lyn Price[1], Anna M. Tassinari[1], Grace H. Lo[2] and Timothy E. McAlindon[1]. [1]Tufts Medical Center, Boston, MA, [2]Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Boston, MA

Background/Purpose: Recent evidence suggests that peri-articular bone changes are integral to knee osteoarthritis (OA) pathophysiology. Peri-articular trabecular morphology changes have been associated with radiographic knee OA severity and may identify individuals at risk for knee OA progression. However, it is unclear how patient characteristics are associated with peri-articular trabecular morphology in knees with OA. The purpose of this study was to evaluate the association between patient characteristics and apparent bone volume fraction (aBVF), one measure of trabecular morphology, in knees with OA.

Methods: The sample comprised 421 participants in the Osteoarthritis Initiative (OAI) progression cohort who at the 30- or 36-month OAI visit had 3-tesla magnetic resonance imaging (MRI) that included a coronal 3D Fast Imaging with Steady State Precession (FISP) trabecular morphometry sequences of one knee (right knee unless contraindicated). We used a trabecular morphometry program (calcDCN, University of California-San Francisco) to measure aBVF in the medial tibial plateau. aBVF was calculated in 20 consecutive central slices within a 15 mm × 3.75 mm region of interest placed in the peri-articular medial tibia and then averaged. Intra-tester reproducibility was high (ICC = 0.99). We used three multiple linear regression models to evaluate patient characteristics associated to aBVF: 1) individual-level model (sex, race, age at time of MRI, body mass index at time of MRI, college, income, and history of smoking), 2) individual-level model with history of knee injury/surgery model, and 3) model 2 with knee-specific variables of radiographic severity (joint space narrowing [JSN] and joint space width [JSW] at 300 mm).

Results: Participant and knee-specific characteristics are reported in the table. Average (± s.d.) peri-articular aBVF was 0.10 ± 0.07. All three regression models were statistically significant ($p < 0.001$). Individual-level variables accounted for 12.0% of the variance in aBVF. The combination of individual-level and knee-specific variables accounted for 22.2% of the variance in aBVF. Females were characterized by lower aBVF in all three models. In contrast, Caucasians and patients with a higher body mass index had higher aBVF in all three models. History of knee injury/surgery and greater radiographic severity in the medial compartment (higher JSN score, lower JSW) were associated with higher aBVF. Age at the time of the MRI was only related to aBVF when radiographic severity was included in the model.

Conclusion: Among individuals with knee OA, peri-articular morphology is influenced by multiple individual-level (sex, race, body mass index) and knee-specific variables (knee injury/surgery, OA severity). Increases in aBVF were associated with individuals with higher body mass index and history of knee injury/surgery, Caucasians, and markers of local knee OA severity.

Table. Characteristics Associated with Peri-articular Apparent Bone Volume Fraction

Variable	Descriptives Mean ± SD or % (n)	Individual-Level Model (R^2 = 0.120)	Individual-Level + Injury/Surgery Model (R^2 = 0.134)	Individual + Knee Specific Model (R^2 = 0.222)
Female	46.3 % (195)	**−0.037 (0.007)***	**−0.036 (0.007)***	**−0.038 (0.007)***

1999

Safety of Diclofenac Sodium Topical Solution Compared with Oral Diclofenac for Osteoarthritis of the Knee in Patients Aged ≥65 Years: Pooled Analysis From 2 Controlled Trials. Sanford H. Roth[1] and Philip Fuller[2]. [1]Arizona Research & Education, Paradise Valley, AZ, [2]Covidien, Hazelwood, MO

Background/Purpose: Despite proven efficacy of oral nonsteroidal anti-inflammatory drugs (NSAIDs) for the management of osteoarthritis (OA), chronic systemic exposure to oral NSAIDs in patients aged ≥65 years is of concern due to documented increased risk of gastrointestinal (GI) and cardiovascular adverse events (AEs). Compared with oral NSAIDs, topical NSAIDs produce significantly less systemic exposure and may result in fewer and less severe systemic AEs. Clinical trials have shown that diclofenac sodium topical solution (TDiclo) with the penetration enhancer dimethyl sulfoxide (DMSO) is effective and well tolerated in the management of OA of the knee. This pooled analysis was conducted to characterize the safety profile of TDiclo vs oral diclofenac (ODiclo) in patients aged ≥65 years with radiologically confirmed symptomatic OA of the knee.

Methods: Data were pooled from two 12-week randomized, double-blind, multicenter trials of TDiclo that included an ODiclo comparator, in patients with primary OA of the knee. Safety assessments included AE monitoring, recording of vital signs, dermatologic examination of the study knee, and clinical laboratory evaluation. AEs were evaluated for statistical significance by system organ class (SOC); specific AEs were evaluated in the SOCs showing significant difference in AEs between treatment groups.

Results: A total of 927 patients were included; 427 (46%) were aged ≥65 years (223 TDiclo; 204 ODiclo). In this age group, significantly fewer GI-related AEs occurred with TDiclo (24.7%) vs ODiclo (42.6%; $P<0.0001$); the most common were dyspepsia (9.4% vs 24.0%; $P<0.0001$), diarrhea (6.7% vs 14.2%; $P=0.011$), and upper abdominal pain (5.8% vs 17.2%; $P=0.0002$). Application-site AEs were significantly more common with TDiclo (28.3%) vs ODiclo (3.4%; $P<0.0001$); the most common application-site AE was dry skin (TDiclo 21.5%; ODiclo 1.5%; $P<0.0001$). Overall incidence of cardiovascular AEs was low but was not statistically significantly different between groups (TDiclo 1.8%; ODiclo 4.4%; $P=0.159$).

Conclusion: The results of this analysis demonstrate that TDiclo was associated with a significantly lower incidence of GI-related AEs compared with ODiclo and may therefore represent a viable therapeutic option for older patients.

2000

Prevention of Celecoxib Induced Gastrointestinal Events by Concomitant Therapy with Rebamipide, Gastro-Protective Drug. Masahiro Hasegawa[1], Kyosuke Tanaka[1], Noriyuki Horiki[1], Hiroki Wakabayashi[1], Yoshiyuki Takei[1], Atsumasa Uchida[1], Akihiro Sudo[1] and GLORIA study group[2]. [1]Mie University Graduate School of Medicine, Tsu City, Mie, Japan, [2]Tsu City, Mie, Japan

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) can induce ulcer complications such as bleeding and perforation. Substitution of NSAIDs with a selective cyclo-oxygenase-2 (COX 2) inhibitor reduces the risk of gastroduodenal ulcer complications. However, gastroduodenal ulcer induced by COX 2 inhibitor was reported. In Japan, no randomized prospective gastrointestinal outcome trials have been designed to examine the benefit of combined treatment with a COX 2 selective inhibitor (celecoxib) and any kinds of anti-ulcer drug yet. Rebamipide, increases gastric mucous and stimulates the production of endogenous prostaglandins, has been frequently prescribed as gastroprotective agent in Japan. We aimed to confirm the hypothesis that combined treatment with celecoxib and rebamipide would be more effective than celecoxib alone for prevention of gastrointestinal endoscopic events.

Methods: This prospective, randomized, open-label blinded end point study was conducted from August 2008 to July 2011 in Japan. Patients with rheumatoid arthritis, osteoarthritis, and low back pain enrolled to this study. Gastroduodenal mucosal damage was evaluated using endoscopy before treatment and at the end of the study. The patients presented peptic ulcers before treatment were excluded. Patients were randomized to two groups: mono-therapy group (100 mg celecoxib twice daily) and combination group (100 mg celecoxib twice daily and 100 mg of rebamipide three times a day). These patients were tested for the presence of *Helicobacter pylori*. The primary endpoint was designed to endoscopic gastrointestinal events as occurring peptic ulcer within three months. Statistical analyses were performed using chi-squared test, Fisher's exact test, or Mann-Whitney U-test.

Results: Seventy-three patients were eligible. Seven patients were withdrawn. Thirty-five patients were assigned to the mono-therapy group, and 31 were in the combination group. No differences were found between the groups in terms of the demographics; age, gender, diagnosis, concomitant of aspirin, and past history of peptic ulcer. The prevalence of gastrointestinal events was 7/35 (20%) in the mono-therapy group, and 0/31(0%) in the combination group ($p=0.012$). Gastroduodenal ulcers were detected in six patients. No correlations were observed between the presence of *Helicobacter pylori* or past history of peptic ulcer and gastrointestinal events.

Conclusion: Use of celecoxib during three months induced gastrointestinal events in 20% in the present study and preventive strategy for gastrointestinal ulcer should be investigated. Combination treatment was more effective than celecoxib alone for prevention of gastrointestinal events in the present study, and our hypothesis was verified. Rebamipide could be candidate option for the prevention of COX 2 inhibitor induced gastrointestinal events.

2001

GI-REASONS: A Novel 6-Month, Prospective, Randomized, Open-Label, Blinded End Point (PROBE) Trial. Byron Cryer[1], Chunming Li[2], Lee S. Simon[3], Gurkirpal Singh[4], Martin Stillman[5] and Manuela Berger[2]. [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Pfizer Inc, New York, NY, [3]SDG LLC Consulting, West Newton, MA, [4]Stanford University School of Medicine, Palo Alto, CA, [5]Hennepin County Medical Center, Minneapolis, MN

Background/Purpose: The GI Randomized Event and Safety Open-Label NSAID Study (GI-REASONS) was a novel prospective, randomized, open-label, blinded end point (PROBE) study that measured adju-

dicated clinical outcomes throughout the GI tract. It was designed to assess if celecoxib use in patients with osteoarthritis (OA) at moderate GI risk (≥55 y) is associated with a lower incidence of clinically significant upper and lower GI events compared to nonselective (ns)NSAIDs, with/without proton-pump inhibitors (PPIs), in standard US clinical practice.

Methods: Patients were randomized 1:1 for 6 months to receive celecoxib or any nsNSAID, stratified by *H pylori* status. The primary end point was a composite of adjudicated clinically significant upper and lower GI events. Aspirin use was not permitted. Treatment doses could be adjusted per US prescribing information. Patients randomized to the nsNSAID arm could switch between nsNSAIDs; however, crossover between treatment arms was not allowed. PPIs and histamine-2 receptor antagonists (H_2RAs) were prescribed at the providers' discretion.

Results: 4035 celecoxib and 4032 nsNSAID patients with OA were randomized and included in the ITT analyses. Baseline demographics were similar. Overall, significantly more nsNSAID users met the primary end point at 6 months (OR, 1.82; 95% CI 1.31–2.55; $p=0.0003$; Table 1). The most commonly used nsNSAIDs were meloxicam (42%), naproxen (21%), diclofenac (20%) and nabumetone (14%). 2596 celecoxib (64.3%) and 2611 (64.8%) nsNSAID users completed the study. 189 patients were lost to follow-up (LTFU; 2.1% celecoxib and 2.6% nsNSAID). Attributing the primary end point to all LTFU patients (worst-case sensitivity analysis), celecoxib remained superior (OR 1.46; 95% CI 1.18–1.82; $P=0.0006$). AEs, SAEs and discontinuations were similar in both treatment groups. 23% of celecoxib and 24% of nsNSAID patients used a PPI (P=NS). Moderate to severe abdominal symptoms were experienced by 94 (2.3%) celecoxib and 138 (3.4%) nsNSAID patients ($P=0.0035$).

Table 1. Clinically Significant Upper and Lower GI Events: Primary Analysis

		Celecoxib		nsNSAID	
		N	Patients With Event n (%)	N	Patients With Event n (%)
All patients		4035	54 (1.3)	4032	98 (2.4)
***H pylori* status**	**Positive**	1401	25 (1.8)	1386	34 (2.5)
	Negative	2634	29 (1.1)	2646	64 (2.4)
OR (95% CI); P value		1.82 (1.31–2.55); $p=0.0003$			

Conclusion: Celecoxib use had a lower risk of clinically significant upper and lower GI events than nsNSAIDs. A major strength of this study is its PROBE design. Simple inclusion and exclusion criteria allowed for a broad patient population of moderate GI risk. Switching among nsNSAIDs and allowing for dose adjustments, along with use of PPIs and H_2RAs as needed, more closely reflects daily clinical practice. GI-REASONS demonstrates the superiority of the GI safety profile of celecoxib throughout the GI tract in patients treated in a "real-world" setting.

2002

COX-1 Affinity Determines NSAID - Aspirin Interactions. Inger L. Meek[1], Jeannine Kasemier[1], Harald E. Vonkeman[1], Kris Movig[1] and Mart AF van de Laar[2]. [1]Rheumatology Center Twente, Medisch Spectrum Twente & Twente University, Enschede, Netherlands, [2]Medisch Spectrum Twente & Twente University, Enschede, Netherlands.

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) and acetylsalicylic acid (ASA) are often prescribed concurrently in patients with osteoarthritis. Both drugs inhibit the same COX-enzymes, and thus may interact. Preceding pharmacodynamic studies confirm significant inhibition of ASA's antiplatelet effect by concurrent use of ibuprofen or indomethacin, but show conflicting results for naproxen. ASA's cardioprotective antiplatelet effect is entirely COX-1 dependent, which may explain the limited interaction between ASA and COX-2 selective NSAIDs. The aim of this study was to examine the interaction between ASA and different selective and non-selective NSAIDs on thrombocyte function.

Methods: Single blind, prospective, placebo controlled, ex-vivo, serial crossover trial of three-day cycles separated by washout periods of at least 12 days in healthy volunteers, evaluating interaction on ASA's antiplatelet effect by naproxen, ibuprofen, meloxicam, or etoricoxib taken two hours before ASA. Ex vivo platelet function, expressed as closure time (CT) in seconds, was measured using the Platelet Function Analyzer 100 (PFA-100). CT-prolongation during a cycle reflects the platelet inhibitory effect. ASA nonresponse was defined as CT-prolongation <40% in the placebo cycle, ASA nonresponders were excluded from the study. The effect of different NSAIDs on CT-prolongation was evaluated by Wilcoxon signed-rank test.

Results: Ibuprofen and naproxen show inhibition of ASA's antiplatelet effect below the nonresponse threshold. Etoricoxib and meloxicam show no relevant change in ASA thrombocyte inhibition.

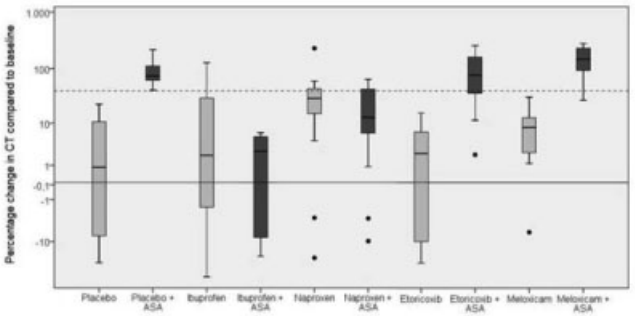

Figure 1. The y-axis shows percentage CT change after use of NSAID or placebo alone (grey boxes) and in combination with ASA (dark boxes) on a loglinear scale. ASA nonresponse threshold (<40% CT-prolongation from baseline) is indicated by the dotted line. The continuous line represents baseline reference.

Conclusion: COX-1 affinity determines the interaction between NSAIDs and ASA on thrombocyte function: aggregation and clotting. Ibuprofen and naproxen, but not etoricoxib or meloxicam, taken two hours before ASA significantly inhibit ASA's antiplatelet effect.

2003

Effects of Opioid and Neurotoxin Analgesics on Pain Behaviors and Function Over Time in Mice with Collagenase-Induced Osteoarthritis. Hollis E. Krug[1], Christopher W. Dorman[2], Sandra Frizelle[2] and Maren L. Mahowald[3]. [1]Minneapolis VA Health Care System and University of Minnesota Medical School, Minneapolis, MN, [2]Minneapolis VA Health Care System, Minneapolis, MN, [3]University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, MN.

Background/Purpose: Osteoarthritis pain remains a significant health problem due to a growing elderly population, increasing longevity, and lack of safe and effective therapies. Understanding the origins of chronic arthritis pain is important for developing effective therapies. Osteoarthritis pain does not correlate well with radiographic severity, and loss of function in patients with osteoarthritis may result from pain, from altered biomechanics or from toxicity of analgesics. In order to better understand the relationship between osteoarthritis, pain and function, we measured different types of pain behaviors in mice with osteoarthritis as a function of age, duration of arthritis and in response to different analgesic treatments.

Methods: Osteoarthritis was produced by intra-articular (IA) injection of 10 μl collagenase (10 IU) into the left knee of 4-week-old C57Bl6 male mice. Arthritic mice were compared to uninjected naïve mice of the same age at 4 weeks and 6 weeks after collagenase injection and to arthritic mice treated with IA analgesics. Analgesics tested were IA morphine sulfate (0.7 mg/kg in 5 μl) or IA Botulinum toxin type A (BoNT/A) (0.02 IU 3 d before testing). Pain behavior measures included evoked pain response to firm palpation of the knee for 1 minute, spontaneous nocturnal wheel-running, mechanical withdrawal thresholds by Von Frey filament testing and digitized video gait analysis using DigiGait™ (Mouse Specifics, Inc, Quincy, MA). The nonarthritic knee was the internal nonpainful control.

Results: Evoked pain responses in arthritic knees were increased at both 4 and 6 weeks after collagenase injection, but this response was 65% greater at 4 weeks than at 6 weeks. Arthritis caused an increased swing/stride ratio measured by gait analysis and increased mechanical allodynia in the arthritic limb by Von Frey filament testing at both 4 and 6 weeks. Spontaneous nocturnal wheelrunning was reduced in both the 4 and 6 week arthritic groups, as well as in 6 week naïve mice. Both BoNT/A and Morphine were effective analgesics at 4 and 6 weeks as measured by evoked pain but did not normalize gait function at either time point. Only morphine normalized the threshold for mechanical allodynia to Von Frey filament testing at 4 weeks, but IA BoNT/A was more effective at 6 weeks.

Conclusion: Arthritis pain produced by IA injection of collagenase in mouse knees produces pain that can be measured at 4 weeks and persists to 6 weeks. Both opioids and BoNT/A given IA are effective analgesics when pain is measured by evoked pain behavior. Changes in functional measures such as gait analysis do reflect the development of arthritis pain but are not clearly normalized by analgesia and may be due not only to pain but to biomechanical changes in the joints. Chronic osteoarthritis

pain produces mechanical allodynia, one indication of peripheral sensitization. Mechanical allodynia may be decreased by opioids if arthritis pain is not longstanding but IA BoNT/A may be more effective for sensitization due to arthritis that is more chronic. More work needs to be done to determine which pain behaviors best measure chronic pain in murine arthritis and are sensitive for detecting analgesia in order to use preclinical models for testing potential new analgesics.

2004

Validation of the Longitudinal Reproducibility of Medial Joint Space Width Quantification in Knee Osteoarthritis. Berna Goker[1], Tayfun Akalin[1] and Joel A. Block[2]. [1]Gazi University Medical School, Ankara, Turkey, [2]Rush University Medical Center, Chicago, IL.

Background/Purpose: Quantification of the radiographic tibio-femoral joint space width (JSW) is a widely used method to evaluate progression of osteoarthritis (OA) and remains the only structural outcome accepted by the US FDA to demonstrate OA disease modification. The aim of this study was to validate the short and long term reproducibility of measurements using Image J (US NIH, Bethesda, MD, http://rsbweb.nih.gov/ij/) in medial knee OA. In addition to being a freely available public access software, it provides a flexible platform for optimizing measurement views for JSW quantification that can be readily learned in only a few minutes.

Methods: 42 patients with symptomatic medial knee OA (Kellgren-Lawrence grade 2–3, pain on ambulation >30 mm on a 100 mm visual analog scale) were assessed. Semi-flexed fluoroscopy-guided PA knee radiographs (Schuss view) were obtained. Medial knee JSWs, defined as the narrowest interbone distance, were measured independently by two observers, one of which was an experienced observer and the other was a first time Image J user. Inter-observer variability (before and after one hour training) and intra-observer variability, at short term (3 weeks) and long term (4 years) were calculated by using coefficient of variation (CV), as well as intraclass correlation coefficient (ICC).

Results: The index knees (most painful) of 37 patients were analyzed. Patients with lateral compartment OA and medial JSW less than 1 mm were excluded (5 patients). Intra-observer variability at 3 weeks was similar to that at 4 years (Table). One hour training resulted in significant improvement in inter-observer variability.

	CV (%)	ICC
Inter-observer variability		
Before training	6.6	0.89
After training	4.4	0.98
Intra-observer variability		
Experienced observer		
Short term (3 weeks)	3.5	0.98
Long term (4 years)	3.8	0.97
First-time user after training		
Short term (3 weeks)	3.8	0.98

Conclusion: Quantification of the medial JSW of the knee in patients with OA using Image J is reproducible. This method is convenient to apply and requires only brief training to obtain high reproducibility. Moreover, these data confrim that quantitative JSW measurements provide meaningful information, as the method yields results that are stable over a several year period.

2005

Validity of within-Grade Scoring of Longitudinal Changes of MRI-Based Cartilage Morphology and Bone Marrow Lesion Assessment—the MOST Study. Frank Roemer[1], Michael C. Nevitt[2], David T. Felson[3], Jingbo Niu[1], John Lynch[4], Michel Crema[1], Cora E. Lewis[5], James Torner[6] and Ali Guermazi[7]. [1]Boston University, Boston, MA, [2]University of California-San Francisco, San Francisco, CA, [3]Department of Clinical Epidemiology, Boston University School of Public Health, Boston, MA, USA, Boston, MA, [4]San Francisco, CA, [5]University of Alabama, Birmingham City, Birmingham, AL, [6]University of Iowa, Iowa City, Iowa City, IA, [7]Boston Medical Center, Boston, MA.

Background/Purpose: Semiquantitative MRI scoring systems for knee osteoarthritis (OA) typically define longitudinal change in cartilage morphology and bone marrow lesions (BMLs) within a subregion in terms of at least one full-grade change between time points. In order to increase the sensitivity to detect change, we introduced the practice of scoring within- (or "partial-") grade changes for WORMS cartilage and BML assessment. The aim of this study was to examine the validity provided by within-grade scoring of cartilage and BMLs in comparison to full-grade assessment using baseline and 30 months follow-up MRIs from the MOST study.

Methods: The Multicenter Osteoarthritis (MOST) Study is a longitudinal study of subjects with knee OA or at risk of OA. The present analysis included all knees with available baseline and 30 months MRI and radiographic readings. MRIs were read according to the modified WORMS scoring system including scoring of within-grade and full-grade or greater changes for cartilage and BMLs. The sensitivity and specificity of MRI-defined cartilage loss to detect increase in X-ray defined joint space narrowing was assessed using cartilage scores applying within-grades plus full grades vs. full grades only. The ability of baseline knee malalignment and meniscal damage to predict compartment-specific structural progression was assessed using ordinal logistic regression adjusting for age, sex and body mass index. Progression was defined as cartilage loss and BML worsening considering half grade scoring only vs. full grade scoring only.

Results: 1867 knees were analyzed. Sensitivity and specificity to detect progression of joint space narrowing by ≥ full grade cartilage worsening were 0.55 and 0.86, respectively, and by ≥ partial grade worsening were 0.66 and 0.81, respectively. Severe meniscal damage predicted both partial grade and ≥ full grade worsening of cartilage loss and worsening of BMLs in a comparable fashion (Table 1). Any varus malalignment predicted both within-grade and full grade worsening of BMLs in the medial compartment. Malalignment similarly predicted half (and full) grade WORMS medial cartilage loss. Results were comparable for valgus malalignment. Severe meniscal damage predicted within-grade and full grade worsening of cartilage and BMLs in a comparable fashion.

Table 1. Medical[1] mensical damage and its relation to cartilage loss and BML worsening in the medial tibio-femoral compartment

Meniscal damage (predictor) (max. score in medial compartment)	Cartilage loss in medical compartment (outcome)				[2]Adjusted OR (95% CI)	
	Total number of knees	Knees with no change (%)	Knees with half grade worsening only (%)	Knees with ≥ full grade worsening (%)	Outcome: half grade worsening vs. No change	Outcome: ≥ full grade worsening vs. No change
0	1224	1002 (81.9)	43 (3.5)	179 (14.6)	1.0	1.0
1	78	48 (61.6)	6 (7.7)	24 (30.8)	1.0 (0.3, 3.7)	1.8 (0.8, 3.9)
2	243	139 (57.2)	26 (10.7)	78 (32.1)	2.1 (0.9, 4.6)	2.1 (1.3, 3.5)

3 and 4	320	157 (49.1)	34 (10.6)	129 (40.3)	9.6 (3.6, 25.1)	5.1 (3.2, 8.2)

[1] Results for lateral compartment comparable and not shown
[2] Adjusting for age, sex, BMI

Conclusion: Recording of within-grade subregional changes between time points for WORMS cartilage scores increases sensitivity for the detection of X-ray defined wosening of joint space narrowing by only slightly decreasing specificity. Both, within-grade and full-grade or more cartilage and BML changes are predicted by baseline malalignment and meniscal damage. Scoring of partial grade changes increases number of compartments and subregions showing change and the association of partial grade changes with risk factors and outcomes suggests that they are clinically relevant.

2006

Similar Reliability of DESS and TSE Magnetic Resonance Imaging Sequences in the Assessment of Bone Marrow Lesions in Knee Osteoarthritis Patients: Data From the Osteoarthritis Initiative Cohort. Jean-Pierre Raynauld[1], Lukas M. Wildi[1], François Abram[2], Thomas Moser[3], Manon Girard[2], Johanne Martel-Pelletier[1] and Jean Pierre Pelletier[1]. [1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Notre-Dame Hospital, Montreal, QC, [2]ArthroVision Inc., Montreal, QC, [3]Department of Radiology, University of Montreal Hospital Centre (CHUM), Notre-Dame Hospital, Montreal, QC

Background/Purpose: To assess bone marrow lesions (BML) in a head to head comparative study using a T2/T1-weighted steady-state gradient echo (DESS) and a fluid-sensitive intermediate-weighted turbo spin echo (TSE) sequence and the sensitivity to change over time of these sequences. Using a subset of the Osteoarthritis Initiative (OAI) cohort (public MR image sets), we assessed the BML prevalence, lesion size, and change over time comparing data from a TSE to a DESS magnetic resonance imaging (MRI) sequence.

Methods: A subgroup of 144 patients (mean age 61.3 ± 9.8, mean BMI 30.0 ± 4.3, 51.4% were female) was selected from the OAI cohort of progressors who all had DESS and TSE MRI acquisitions at baseline and 24 months. BML were assessed blindly using a semi-quantitative score (scale, 0–3) for the global knee, as well as the medial and lateral compartments. Intra-reader reliability was assessed on a subset of 51 patients. Statistical analysis used a Spearman rho for intra-reader correlation, and a Fisher exact test or Wilcoxon signed rank test for comparison between DESS and TSE where appropriate.

Results: Intra-reader reliability was very good: Spearman rho for DESS sequence were 0.89 for the global knee, 0.91 for the medial compartment, and 0.78 for the lateral compartment; for the TSE sequence, 0.85, 0.86, and 0.77 were found respectively. The prevalence (presence or absence) of BML at baseline was only slightly greater for TSE compared to DESS sequences and this difference did not reach statistical significance (global knee, 80.6% vs. 79.2%; medial compartment, 70.1% vs. 68.1%; lateral compartment, 53.5% vs. 48.6%, respectively; p=ns). As expected, the mean BML score at baseline was lower for DESS than TSE sequences (2.7 ± 2.4 vs. 3.4 ± 3.0 for the global knee respectively, 1.7 ± 1.9 vs. 2.2 ± 2.3 for the medial compartment, and 0.9 ± 1.2 vs. 1.2 ± 1.6 for the lateral compartment, all p≤0.006). However, change at 24 months was similar for DESS and TSE sequences for the global knee (increment of 1.1 ± 1.7 vs. 1.0 ± 2.2 respectively, p=0.18) and for the lateral compartment (0.5 ± 1.0 vs. 0.6 ± 1.5, p=0.33), but superior for DESS in the medial compartment (0.6 ± 1.5 vs. 0.4 ± 1.6, p=0.03).

Conclusion: This is the first report of a direct comparison between DESS and TSE MRI sequences in the assessment of BML and their changes over time. Contrary to common belief, these results demonstrate a similar sensitivity to assess BML prevalence as well as their changes over time in the global knee and lateral compartment, and a slightly superior evaluation of changes over time for the DESS in the medial compartment. These data show that the use of the DESS sequence may have an advantage in clinical trials since, in contrast to the TSE sequence, it could be used for both BML and cartilage volume assessments.

The Childhood Myositis Assessment Scale (CMAS) Total Score in Healthy Children, Age 4–5 Years, is 46, Not 52. Rebecca Quinones[1], Gabrielle Morgan[1], Maria Amoruso[1], Deli Wang[2] and Lauren M. Pachman[3]. [1]Children's Memorial Hospital, Chicago, IL, [2]Northwestern University's Feinberg School of Medicine, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL

Background/Purpose: JDM is a systemic vasculopathy primarily affecting the neck flexors and proximal muscles of both the upper and lower extremities, as well as the child's core strength. Previous national epidemiology studies have documented that the mean age diagnosis is 6.7 years (boys, girls) but 25% are age 4 or less at the time of their first visit to the physician. We had observed that treated children with JDM who had achieved a disease activity score for muscle weakness of "0", still had an average CMAS score of 46, raising the question: "Could healthy children, age 4–5, ever achieve a CMAS score of 52?" Hypothesis: The "normal" total value for CMAS of 52 is not attainable by healthy children who are 4–5 years of age.

Methods: To evaluate healthy boy and girls, age 4.0–4.9 years of age, the validated CMAS 14 point scale was used. The CMAS was administered by the same evaluator, who had been trained in the CMAS administration. The study is descriptive and Spearman rank correlation coefficient was used for age comparisons and Mann-Whitney for comparisons of items by gender.

Results: The test population of 28 healthy children was recruited after obtaining IRB approved consent (IRB#2010–14188). The group was composed of 14 boys and 14 girls, age 4.0–4.9 years. Their mean age was 4.4 years +/−0.3 years. The racial composition was: 68% White/Hispanic, 32% non-White, non-Hispanic. As a group, they achieved a total mean CMAS score of 46.6 ± 2.3 SD. There were no significant differences between boys and girls, and their scores were unaffected by their height or weight. The greatest variation in the scores involved those that were effort dependent. Item 1, neck raise score yielded a mean of 28.12 seconds ± 19.17 SD, CMAS score=2.5 ± 0.9/5. For item 3, the leg lift score =55.27± 36.94 SD seconds; CMAS score=3.1, ± 1.1/5. Finally, item 8, arm raise score=57.73 ± 6.53 seconds, CMAS score3.8 ±0.4/4. The remainder of the CMAS items were very consistent between the boys and the girls.

Conclusion: Healthy children age 4–5 are not able to achieve a total CMAS of 52, expected of older children. In fact, children of this age, both boys and girls were remarkable consistent, both performing at a CMAS mean level of 46. These data suggest that young children with JDM, who are between 4–5 years of age and who reach a score of 46, are in fact performing in a normal fashion, and should not be considered to be impaired.

The Pediatric Automated Neuropsychological Assessment Metrics Has Reproducibility and Criterion Validity in Childhood-Onset Lupus. Hermine Brunner[1], Aimee Baker[1], Adlin Cedeno[2], Jennifer L. Huggins[1], Anna Carmela P. Sagcal-Gironella[3], Jun Ying[4], Marisa Klein-Gitelman[2] and Tresa Roebuck-Spencer[5]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Children's Memorial Hospital, Chicago, IL, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]University of Cincinnati, Cincinnati, OH, [5]University of Oklahoma, Norman, OK

Background/Purpose: The Childhood-onset Systemic Lupus Erythematosus (cSLE) *Neuropsychological Battery* (AC&R 2010; 62: 1029–33) was introduced to standardize neuropsychological testing (NPT), specifically probing the domains *Attention, Working Memory, Psychomotor Speed, Visuoconstructural Ability (VCA)*. The Pediatric Automated Neuropsychological Assessment Metrics (Ped-ANAM) software was developed to measure cognition in children ≥ 10 years. Performance on the Ped-ANAM subtests is assessed by accuracy (AC = % of correct answers), mean reaction time for correct responses (MNc), & throughput (TP), the number of correct responses per minute. The *purpose of this study* was to (1) assess the reproducibility & (2) investigate the criterion validity of the Ped-ANAM, using the *cSLE Neuropsychological Battery* as external standard.

Methods: cSLE patients and best-friend controls underwent NPT and completed the Ped-ANAM twice in one day. Neurocognitive dysfunction (NCD) was graded as per the performance on standardized tests that are part of the NPT [no-NCD: all z-scores > −1; mild/moderate NCD: at most two z-scores < −1 but > −2 or one z-score < −2; severe: at least three z-scores < −1 or two z-scores < −2].

Results: Among 37 cSLE & 37 controls (87% females), 23 (39%) had NCD. Most subtests had good reproducibility especially for tests of higher cognitive complexity (Table 1). Deficits in *Working Memory* resulted in lower AC on the subtests CS, PRT, & Spatial (all $p < 0.05$). Deficits in *Psychomotor Speed* resulted in worse performance on CS-Delayed, CS, Logical, MG & Spatial (all $p < 0.03$). Deficits in *Attention* resulted in worse performance on all subtests but MG & PRT (all $p < 0.04$), and deficits in *VCA* resulted in worse performance on Logical, MS & Spatial (all $p < 0.02$). Compared to others, the severe NCD group showed lower AC on several subtests (Table 2) with corresponding faster reaction times indicative of inefficient responding. In contrast, the severe NCD group was significantly slower on tests of simple reaction time (SRT1, SRT2) that did not require cognitive demands.

Table 1. Test-Retest reliability of the Ped-ANAM using TP as an example*

Ped-ANAM subtests	Cognitive Domain/ Function	All (n = 74)	Control (n = 37)	SLE (n = 37)	SLE without NCD (n = 28)	SLE with NCD (n = 9)

	Spatial Processing (Spatial)	91.50 ± 0.91	90.76 ± 1.28	83.11 ± 2.74	0.005	0.014
	Memory Search (Memory)	92.00 ± 1.24	91.07 ± 1.73	87.33 ± 3.72	0.237	0.364
	Simple reaction time, 1st trial (SRT1)	100.00 ± 0.00	100.00 ± 0.00	100.00 ± 0.00	–	–
	Simple reaction time, 2nd (SRT2)	99.94 ± 0.07	99.89 ± 0.09	100.00 ± 0.20	0.772	0.608
Mnc [i.e., mean reaction time for correct response]	Code substitution delayed (CS delayed)	1.20 ± 0.06	1.27 ± 0.08	0.77 ± 0.17	0.015	0.008
	Code substitution (CS)	1.13 ± 0.05	1.22 ± 0.06	1.01 ± 0.14	0.415	0.155
	Running Memory Continuous Perfor. Test (CPT)	0.59 ± 0.02	0.63 ± 0.03	0.54 ± 0.06	0.478	0.193
	Logical Relations (Logical)	1.54 ± 0.08	1.72 ± 0.11	1.48 ± 0.24	0.813	0.356
	Matching to Sample (MS)	2.06 ± 0.09	2.51 ± 0.12	1.85 ± 0.26	0.440	0.024
	Matching Grids (MG)	1.71 ± 0.08	2.10 ± 0.11	1.83 ± 0.24	0.615	0.310
	Mathematical Processing (Math)	1.55 ± 0.10	1.70 ± 0.14	1.88 ± 0.30	0.307	0.594
	Procedural Reaction Time (PRT)	0.59 ± 0.02	0.61 ± 0.02	0.56 ± 0.05	0.501	0.347

Conclusion: The Ped-ANAM has good reproducibility and criterion validity. Severe NCD is associated with significant differences in the performance of several Ped-ANAM subtests with a propensity for lower accuracy as tests increased in cognitive complexity. These results are in line with our earlier research.

2009

Therapeutic Approaches for the Treatment of New Onset and Flared Juvenile Systemic Lupus Erythematosus with Active Renal Disease: An International Multicenter PRINTO Study. Paivi Miettunen, Angela Pistorio, Angelo Ravelli, Sheila Oliveira, Maria Alessio, Ruben Cuttica, Dimitrina Mihaylova, Graciela Espada, Srdjan Pasic, Elisabetta Cortis, Seza Ozen, Oscar Porras, Flavio Sztajnbok, Alberto Martini and Nicolino Ruperto. IRCCS G. Gaslini, Pediatria II, PRINTO, Paediatric Rheumatology, Genova, Italy

Background/Purpose: To evaluate in a prospective international cohort of juvenile systemic lupus erythematosus (JSLE) with active renal disease (ARD) response to therapy over a 24-month period.

Methods: ARD was present in 240 (78.3% female) out of 557 patients with JSLE, age < 18 years (yr): 134 new onset JSLE (N-JSLE) and 106 flared JSLE (F-JSLE). Disease activity parameters and therapeutic approaches were analyzed at baseline, 6, 12 and 24 months, in 4 geographic areas. Response was assessed according to the PRINTO/ACR JSLE criteria, serum creatinine and glomerular filtration rate (GFR). Logistic regression was used to identify potential prognostic indicators at baseline for poor renal outcome at 24 months, defined as end stage renal disease (ESRD) or urinary protein >=3.5 grams/24 hours.

Results: The mean age at disease onset was 13.1 (SD 2.8) yr for N-JSLE and 10.2 (SD 2.9) yr for F-JSLE, with mean disease duration of 0.3 (SD 0.2) yr for N-JSLE and 4.2 (SD 2.9) yr for F-JSLE. A total of 143/240 (59.6%) patients had all 4 time point assessments available. At baseline, new and flared patients had similar renal activity, but N-JSLE had higher SLE activity overall, with more serositis, hematological, mucocutaneous and musculoskeletal manifestations. Corticosteroids were initiated at similar median doses: 1.0 mg/kg/day in N-JSLE and 0.8 mg/kg/day in F-JSLE. Pulse steroids were initiated in 33.6% of N-JSLE and 40.6% of F-JSLE. Cyclophosphamide was the most common (41.2%; 99/240) immunosuppressive medication, followed by azathioprine (25%; 60/240).Mycophenolate mofetil and azathioprine were used more commonly in F-JSLE. Latin American patients received more pulses and higher doses of oral steroids when compared to Western Europe. Use of cyclophosphamide was similar in all 4 regions. Seventy eight % (103/132) of N-JSLE compared to 57.4% (58/101) of F-JSLE (p=0.0007) reached at least PRINTO/ACR 70 level of response at 6 months, which increased to 87.1% in N-JSLE and 77.2% in F-JSLE at 24 months (p=0.12). The median serum creatinine and GFR were within normal range at all time points; all other measures showed statistically significant improvement over time in both groups (p <=0.0002). ESRD developed in 6 patients. Urinary protein >=3.5grams/24 hours was present in 50/240 patients at baseline and in 7/143 patients at 24 months. No predictors for poor renal outcome were identified. Twelve patients (5%) died, 10/12 before 12 months, and 7/12 of sepsis. Corticosteroids were discontinued in 20/143 by 24 months.

Conclusion: Despite higher overall lupus activity at baseline, N-JSLE and F-JLSE improved similarly over 24 months. ESRD was rare. Some differences in therapeutic approaches exist worldwide.

2010

Race, Ethnicity and Gender Affect the Severity of Renal Outcomes in Patients with Pediatric Systemic Lupus Erythematosus: An Analysis of the CARRAnet Data At Baseline Visit. Ornella J. Rullo[1], Deborah K. McCurdy[1], Ora Yadin[1], Alice DC Hoftman[1], Jennifer M.P. Woo[1], Emily von Scheven[2] and CARRAnet Investigators[3]. [1]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [2]UC San Francisco, San Francisco, CA, [3]Durham

Background/Purpose: The onset of SLE in adolescence has been associated with increased organ damage compared with adult-onset SLE. However, differences between ethnic and racial groups in young SLE patients have not been fully described. We hypothesize that U.S. pediatric SLE (pSLE; diagnosis < 18 years) patients of not uniquely European descent have more severe renal outomes compared to patients of European descent, independent of socio-economic factors.

Methods: CARRAnet registry data of pSLE patients including demographic, socio-economic status and renal biopsy data were correlated with each other and with renal outcome: chronic kidney disease (CKD stages I-V; Kendall correlation). The stages of CKD reflect functional chronic kidney damage with assessment of glomerular filtration rate [GFR; determined by MDRD or Schwartz (for age < 12 years) formulas]. The independent effect of each relevant factor on renal outcome in pSLE with biopsy-proven lupus nephritis (LN) was calculated with use of multiple regression models.

Results: Of 368 pSLE patients enrolled in CARRAnet with baseline demographic and clinical data, 159 patients have undergone renal biopsy (Table 1). In combined non-white and Hispanic pSLE LN, there is an enrichment of CKD (p = 0.003; Table 1) and a trend towards end-stage renal disease (ESRD, 5% vs 0%, p = 0.06; Table 1). Non-white/Hispanic and male gender were independently associated with CKD (OR 1.21 and 1.26, respectively, p < 0.05; Table 2) by multivariate logistic regression of subjects with biopsy-proven LN. Although non-white/Hispanic and white (excluding white Hispanics) pSLE differed in multiple socio-economic parameters including median household income and percentage of families below poverty line at diagnosis (both based on 1999 U.S. Census data using 3-digit zip code at diagnosis), and current reported income (p < 0.01), there was no correlation between these parameters and GFR (p > 0.1). Furthermore, there may be a negative correlation between renal biopsy and time to rheumatologic care in both white and non-white pSLE (Spearman r = −0.1; p = 0.07).

Table 1. Clinical and demographic features of the CARRAnet SLE registry

	White	Non-white†	p-value*
Female:Male	301:67		
White:Non-white†	97:269		
Disease duration at baseline visit, mean (years)**	3.2	3.6	0.5
SLE renal involvement, total number‡	33	126	
Prevalence of renal involvement, %	34	47	0.08
SLEDAI at baseline visit, median	2	4	0.02
SLEDAI-renal component scored at baseline visit, %	12	21	0.047
Prevalence of moderate/severe chronic kidney disease, %††	0	9	0.003
Prevalence of end-stage renal disease‡‡	0	5	

† Non-white is defined as people who self-identified as not uniquely of white race, including: Americans of Asian, native American, African and/or Hawaiian/Pacific Islander descent; and/or of Hispanic ethnicity
** Increased disease duration is correlated with increased rates of CKD (r = 0.2; p = 0.002); however there is no difference among these comparator groups in disease duration
‡ Chronic Kidney Disease Stages I–V, and with biopsy-proven renal disease
†† GFR < 60 ml/min/1.73 m2; CKD Stage II–V
‡‡ Dialysis or renal transplant endorsed in registry; CKD Stage V
* Calculated using Fisher's exact test, except disease duration (t-test) and median SLEDAI at baseline (Mann-Whitney test)

Table 2. Factors independently associated with CKD by multivariable logistic regression in patients with SLE renal disease from the CARRAnet registry

	OR	(95% CI)	p value
Age at baseline CARRAnet visit	0.99	(0.97, 1.03)	0.9
Male gender	1.26	(1.04, 1.53)	0.019*
Time since diagnosis	1.09	(0.98, 1.2)	0.105
Community poverty rate at diagnosis†	0.99	(0.99, 1.01)	0.3
Non-white race/Hispanic ethnicity‡	1.21	(1.02, 1.43)	0.023*
Time to first pediatric rheumatology visit††	0.97	(0.94, 1.01)	0.074
Current family income	0.99	(0.95, 1.04)	0.6

† Percentage of families below poverty level in the subject's zip code area at the time of diagnosis, based on 1999 U. S. Census data
‡ Subjects self-identifying as non-white and/or not uniquely of white race plus subjects of Hispanic ethnicity
†† From the onset of symptoms
* denotes p value < 0.05

Conclusion: The risk of CKD or ESRD in patients with pediatric-onset SLE renal disease is increased based on non-white race and/or Hispanic ethnicity (OR 1.21) and male gender (OR 1.26), independent of demographic and socio-economic factors. The trend towards shorter time to pediatric rheumatology care in patients of all groups requiring renal biopsy suggests adequate access to health care. Long-term follow-up data will be required to fully assess the impact of specific race/ethnicity and socio-economic factors on renal outcome.

Background/Purpose: Childhood-onset Systemic Lupus Erythematosus (cSLE) is a phenotypically diverse disease with the potential for adverse neuropsychological (NP) effects due to chronic disease or central nervous system involvement. Best-friend controlled studies are one effective approach to delineate the impact of disease upon cognition. The BRIEF (Behavior Rating Inventory of Executive Function), CBCL (Child Behavior Checklist-Parent Report), CDI (Child Depression Inventory), and SAND-C (Subjective Awareness of Neuropsychological Deficits Questionnaire for Children) are validated questionnaires which assess various aspects of NP and behavioral functioning.

Methods: For cSLE patients & same-sex, similar-aged best-friend controls completed the CDI, SAND-C, BRIEF & CBCL. To diagnose neurocognitive dysfunction (NCD), neuropsychological testing (NPT) was performed, using a standardized cSLE NP Battery as previously published by our group (Arthritis Care Res. 2010; 62:1029–33).

Results: This interim analysis included 37 cSLE patients and 37 controls (87% females). Mild, moderate or severe NCD was present in 14%, 14% or 11% of cSLE patients and in 30%, 5% or 5% of controls. As summarized in Table 1, ratings of executive functioning (BRIEF) in the cSLE and control groups were comparable but school functioning (CBCL) was rated more poorly with cSLE. Table 2 provides a comparison among cSLE patients with consideration of their NCD-status. The presence of NCD had little impact on the NP and behavioral functioning of children and adolescents with SLE, with the exception of self-esteem which was rated as more problematic in the NCD cSLE group. Perceived neurocognitive functioning (SAND-C) was similar in the cSLE and control groups, irrespective of NCD-status.

Table 1. cSLE versus Best-Friend Controls adjusted for race, ethnicity and income

Features/Questionnaires		A. All cSLE*	B. Best-friend Controls	P-values (A vs. B)

	E. Negative Self-esteem	**41.86 ± 0.85**	**46.13 ± 1.62**	**0.028**
	Total Depression Score (A–E)	43.31 ± 1.46	48.00 ± 2.78	0.358
SAND-C - Perceived Cognitive Function*		2.95 ± 0.065	2.71 ± 0.12	0.169

* None of the patients had neuropsychiatric damage
† Higher scores signify better functioning, T-Scores with a mean of 50 and SD of 10 (here: SEM of 1.64)
‡ Higher scores signify better/ worse performance; T-Scores with a mean of 50 and SD of 10 (here: SEM of 1.64)
μ Higher scores signify higher depressive features
** Higher scores signify better cognitive function; healthy children mean ±SEM: 2.91 ± 0.08

Conclusion: Compared to controls, school functioning seems to be worse with cSLE but the disease has comparatively little systematic effect on reported executive or behavioral functioning. If NCD is present, cSLE patients may have more negative self-esteem. Confirmation of these results in a larger cohort is necessary to substantiate these preliminary observations.

2012

The PRINTO Provisional Definition of REMISSION In Juvenile Dermatomyositis. Dragana Lazarevic[1], Angela Pistorio[1], Paivi Miettunen[1], Angelo Ravelli[1], Clara Malattia[1], Clarissa Pilkington[1], Nico Wulffraat[1], Stella Maris Garay[1], Michael Hofer[1], Pierre Quartier[1], Pavla Dolezalova[1], Inmaculada Calvo Penades[1], Virginia P.L. Ferriani[1], Gerd Ganser[2], Ozgur Kasapcopur[1], Jose Antonio Melo-Gomes[1], Malgorzata Wierzbowska[1], Alberto Martini[1] and Nicolino Ruperto[1]. [1]IRCCS G. Gaslini, Pediatria II, PRINTO, Paediatric Rheumatology, Genova, Italy, [2]Sankt Josef Stift, Sendenhorst, Germany

Background/Purpose: To define a definition of remission in juvenile dermatomyositis (JDM) that is stringent but achievable and could be applied uniformly as an outcome measure in clinical trials.

Methods: 275 patients in active phase of JDM <18 years, median disease duration 7.7 months, were evaluated at baseline and 24 months. Out of 275 patients, all patients (38/275) who were off treatment at 24 months were defined as being "inactive" and were included as the "gold standard" group. A random sample of 76 patients who were in an active phase of JDM at baseline and on medications at 24 months, were selected as the "comparison group". Literature was reviewed for definitions of remission and then other definitions were tested which included PRINTO core set variables, muscle enzymes, and other JDM activity measures. Accuracy measurements were calculated: sensitivity (Se), specificity (Sp), Cohen's kappa (k≥0.8 almost perfect).

Results: Seven best single variables with kappa≥0.8 were Manual Muscle Testing (MMT)=80 (se:0.89, sp:1.00, k:0.92), followed by MMT≥78 (se:0.94, sp:0.97, k:0.92), Physician Global Assessment of Muscle Activity (PhyMAVAS)=0 and Physician Myositis Activity Assessment (MYOACT)≤0.2, Physician Global Visual Analogue Scale (PhyGloVAS)≤0.2, Childhood Myositis Assessment Scale (CMAS)≥48, and Disease Activity Score (DAS)≤3. The most accurate combination of variables included 4 variables with 3 out of 4 required to be present: creatine phosphokinase≤150, CMAS≥48, MMT≥78, PhyGloVAS≤0.2 (se:0.97, sp:1.00, k:0.98).

Conclusion: The combination definition performed the best overall in defining inactive disease/remission in JDM and could be used for the evaluation of global response to therapy in future clinical trials.

2013

Determination of Pediatric Doses of Colchicine for Familial Mediterranean Fever on the Basis of Population Pharmacokinetics. Yackov Berkun[1], Eldad Ben-Chetrit[1], Suman Wason[2], Robert Faulkner[2] and Stephen Levenstein[3]. [1]Hadassah Hebrew University Medical Center, Jerusalem, Israel, [2]URL Pharma, Philadelphia, PA, [3]GCP Clinical Studies Ltd., Rosh Ha'Ayin, Israel

Background/Purpose: Define appropriate dose of colchicine (COL) in children age 2–4 yrs with familial Mediterranean fever (FMF), this study sought to determine steady-state pharmacokinetics of multiple doses of oral COL in pediatric FMF patients ages 2 to <16 yrs compared to adult FMF patients 16 to 65 yrs. Optimal starting doses of COL in pediatric FMF patients were determined.

Methods: Outpatients were given a new oral pediatric formulation of Colchicine, USP (Pediatric Granules, 0.3 mg) in 3 phases: 7-day up-titration phase (if required), fixed-dose 14-day phase culminating in pharmacokinetic (PK) blood sample on Days 14 and 15 (PK period); and flexible-dose phase for safety assessment (90-day total treatment duration, exclusive of up-titration). Approximately 10 male and female FMF patients in each age group were targeted for enrollment. Sample size was determined from population PK analysis of COL plasma data obtained from Phase 1 studies in healthy adults administered multiple oral doses of COL.

Colchicine Pediatric Granules Dosing

Age Group	Daily Dose	% of Referenced Daily Dose
≥2 – <4 years old	0.6 mg	50%
≥4 – <6 years old	0.9 mg	75%
≥6 – <12 years old	0.9 mg	75%
≥12 – <16 years old	1.2 mg	100%
Adults ≥16 to ≤65 years	1.2 mg	Reference

COL-naïve patients were to have a 1-wk dose up-titration period prior to attaining full target dose. After the PK period, the daily dose could be adjusted as needed for the balance of the study.

Blood was collected on Days 14 and 15 with plasma analyzed for COL. Sampling time windows for collection of PK samples were 0.25–0.5 hrs, 1.5–2.5 hrs, 3–5 hrs, 7–9 hrs, and 24 hrs post-Day 14 dose. Population PK modeling to a 3-compartment model with zero-order absorption was performed on COL plasma data to derive individual patient PK parameters.

Descriptive Statistics of C_{max} and AUC by Age Group

ONCE-DAILY DOSING

		Age Group				
		2–<4 yrs	4–<6 yrs	6–<12 yrs	12–<16 yrs	≥ 16 yrs
N		5	4	11	8	6
C_{max} (ng/mL)	Mean (SD)	8.6 (2.24)	11.2 (3.17)	7.9 (2.46)	6.9 (2.39)	7.2 (2.10)
	Range	6.7–12.5	8.4–15.6	5.2–12.1	3.8–11.0	4.9–9.6
AUC_{0-24} (ng·h/mL)	Mean(SD)	38.6 (7.40)	57.3 (21.3)	41.1 (12.38)	41.3 (8.68)	50.7 (18.55)
	Range	27.1–46.0	38.4–87.9	28.4–62.1	31.4–55.3	35.5–78.3

TWICE-DAILY DOSING

		Age Group				
		2–<4 yrs	4–<6 yrs	6–<12 yrs	12–<16 yrs	≥ 16 yrs
N		2	1	4	0	2
C_{max} (ng/mL)	Mean(SD)	–	–	9.6 (4.1)	–	3.1 (0.9)
	Range	6.1, 7.6	8.1	6.4–15.6	–	2.2–4.7
AUC_{0-24} (ng·h/mL)	Mean(SD)	–	–	55.2 (33.71)	–	42.7 (12.2)
	Range	33.1, 42.2	63.7	30.1–104.8	–	31.4–73.3

Results: The most common adverse event (AE) was breakthrough attacks of FMF (n=17) with no apparent trend by age. Consistent with the known COL safety profile, the most common AEs were GI disorders (abdominal pain, diarrhea, vomiting) which were mild and resolved with the majority untreated.

Conclusion: COL was safe when given as an age-appropriate dosage form in recommended doses and the safety profile in children 2 yrs of age is comparable to that seen in older children and adults. Results showed similar C_{max} (rate of absorption) and AUC (exposure) seen across the 2-<4, 6-<12, 12-<16 yr and adult age groups indicating that administration of half of the adult daily dose in children aged 2-<4 yrs, three-quarters of the adult daily dose in children aged 6-<12 yrs, and full adult dose in those aged 12-<16 yrs are most appropriate starting daily doses.

In the 4-<6 yr old group, the administered dose, which was three-quarters of the adult daily dose, provided exposures 30% higher than adults. The starting dose of COL in this age group should be reduced to half the adult dose (0.6 mg/day).

2014

Performance of the Systemic Lupus Erythematosus Responder Index in Juvenile Systemic Lupus Erythematosus. Rina Mina[1], Marisa Klein-Gitelman[2], Shannen L. Nelson[3], B. Anne Eberhard[4], Gloria C. Schanberg[13], Marilynn G. Punaro[14], Kathleen M. O'Neil[15], Nicolino Ruperto[16], Daniel J. Lovell[10] and Hermine Brunner[10]. [1]Cincinnati Children's Med Ctr, Cincinnati, OH, [2]Children's Memorial Hospital, Chicago, IL, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [5]Nationwide Childrens Hosp, Columbus, OH, [6]MetroHealth Medical Center, Cleveland, OH, [7]The Hospital for Sick Children, Toronto, ON, [8]University of Chicago, Chicago, IL, [9]Medical College of Wisconsin, Milwaukee, WI, [10]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [11]Childrens Hospital of New York, New York, NY, [12]BC Childrens Hospital, Vancouver, BC, [13]Duke University Medical Center, Durham, NC, [14]Texas Scottish Rite Hospital, Dallas, TX, [15]Okla Univ Health Science Ctr, Oklahoma City, OK, [16]PRINTO-IRCCS, Genova, Italy

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogeneous disease where changes in many organ systems must be concomitantly considered when assessing the overall disease course. In a recent RCT, the SLE Responder Index (SRI) proved to be a robust measure of improvement in adults with SLE; the SRI has yet to be evaluated in juvenile SLE (jSLE). The purpose of this study is to determine the concurrent validity of the SRI in assessing improvement in jSLE.

Methods: The SRI defines response (improvement) in SLE as the presence of all of the following: 1) ≥ 4-point reduction in SLEDAI score; 2) no new BILAG A or no more than 1 new BILAG B domain score; and 3) no worsening in the physician assessment of global disease activity (PGA) by ≥ 0.3 points in the 3-point PGA. Using prospectively collected data from 1443 unique visits of 331 jSLE patients, concurrent validation of the SRI was done by comparison with three external standards [i.e. physician assessment of overall disease activity (MD Likert scale: major improvement vs. not), patient/parent assessment of overall well-being (Parent Likert scale: much improved vs. not), and change in systemic steroid dose (decreased vs. not). Modified versions of the SRI using worsening of 1 cm and 2 cm in the 10 cm-PGA visual analog score, and ≥ 2-point reduction in the SLEDAI were evaluated as well. Agreement of the SRI with the ACR/PRINTO Provisional Criteria for Improvement of jSLE (PCI_{SLE}) was examined using Kappa statistic.

Results: Using chi-square statistics, the SRI has a sensitivity of 51% and specificity of 95% in determining the presence of major improvement using the MD Likert scale as external standard. The sensitivity of the SRI was lower when considering the Parent Likert scale or the change in systemic steroids as external standards. The modified versions of the SRI and the PCI_{SLE} had similar sensitivities and specificities as the SRI *(see Table 1)*. Agreement between the SRI and PCI_{SLE} was fair *(see Table 2)*.

Table 1. Performance of the SLE Responder Index (SRI) in assessing improvement in jSLE

Response Criteria	Physician Assessment of Overall Disease Activity Major Improvement vs. No Major Improvement	Patient Assessment of Overall Well-being Much Improved vs. Not Much Improved	Change in Systemic Steroids¶¶ Decreased vs. Not Decreased
SRI: Responder vs. Non-Responder	p-value < 0.0001¶	p-value = 0.0001	p-value = 0.05

Sensitivity	37%	14%	7%
Specificity	95%	95%	94%
Positive Predictive Value	21%	37%	59%
Negative Predictive Value	98%	84%	43%

¶ p-values are for association of responder/non-responder vs. major improvement (improved)/not major improved (not improved) under consideration of the external standards and definitions of SRI used
¶¶ Change in systemic steroids—Improved is defined as any decrease in oral steroids and cessation of intravenous pulse steroids
‡ Event defined as major improvement in MD Likert scale, much improved in Parent Likert scale, and decreased systemic steroids
± SRI_{PGA1}—Modified SRI where PGA-10 cm VAS (i.e. no worsening by 1 cm) instead of the PGA-3 point VAS is used as a part of the response criteria
∫ SRI_{PGA2}—Modified SRI where PGA-10 cm VAS (i.e. no worsening by 2 cm) instead of the PGA-3 point VAS is used as a part of the response criteria
∫∫ SRI_{MCID}—Modified SRI where Responder is defined by improvement of the SLEDAI by 2 points, no worsening of the PGA-10 cm VAS by 1 cm, and no new BILAG A or no more than 1 new BILAG B
μ PCI—Responder is defined as improvement of at least 2 of the core response variables (CRV) by ≥ 50%, with worsening by >30% in no more than 1 one of the remaining CRV (CRV: PGA-10 cm VAS, parent-global, validated disease activity score, proteinuria, Child Health Questionnaire-Physical Summary Score)

Table 2. Agreement of SLE Responder Index (SRI) with modified versions SRI and PRINTO/ACR provisional criteria for improvement in jSLE¶

Responder Tool	Kappa coefficient (95% Confidence Interval)			
	SRI	SRI_{PGA1}	SRI_{PGA2}	SRI_{MCID}
SRI	–	0.66 (0.58–0.73)	0.66 (0.59–0.74)	0.39 (0.33–0.45)
SRI_{PGA1}	0.66 (0.58–0.73)	–	0.80 (0.74–0.86)	0.49 (0.43–0.54)
SRI_{PGA2}	0.66 (0.59–0.74)	0.80 (0.74–0.86)	–	0.34 (0.29–0.41)
SRI_{MCID}	0.39 (0.33–0.45)	0.49 (0.43–0.54)	0.34 (0.29–0.41)	–
PCI	0.30 (0.20–0.40)	0.45 (0.34–0.55)	0.40 (0.29–0.51)	0.32 (0.25–0.39)

¶ For LEGEND, please see Table 1

Conclusion: The SRI has excellent specificity, but only fair sensitivity in identifying overall major improvement in children with jSLE. Thus, if used in clinical trials, the SRI tool may require larger sample sizes to detect important differences between treatment groups.

Background/Purpose: APPLE assessed atorvastatin's efficacy in reducing carotid intimal medial thickening (CIMT) progression in pediatric SLE (pSLE). While the primary endpoint of reduced mean-mean common CIMT progression was not met, observed trends of near significance in several CIMT segments suggested atorvastatin may reduce CIMT progression. Secondary analyses were performed to determine whether treatment effect was consistent across subgroups defined by LDL, high-sensitivity c-reactive protein (hscrp), age, pubertal status, SLE duration and medication adherence.

Methods: APPLE is a randomized, placebo-controlled, multicenter trial randomizing 221 subjects with pSLE (age 10–21 years) to 36 months of atorvastatin or placebo. CIMT was measured by standard protocol at 0, 12, 24 and 36 months. Fasting lipids and hscrp were measured centrally. Subgroups were defined as LDL < or >/= 110 mg/dL, hscrp < or >/= 1.5 mg/dL, age < or >/= 15.5 yrs, SLE duration < or ^{3} 24 months, adherence < or >/= 75%. Prepubertal status was defined by self-reported Tanner stage < 4. An additional combined subgroup of post-pubertal subjects with hscrp ^{3} 1.5 mg/dL vs. others was defined.

The statistical approach replicated primary APPLE efficacy analysis comparing CIMT progression rates between treatment groups based on

test of interaction between treatment group and time in a longitudinal linear mixed effects model. Similar models were used to assess non-CIMT outcomes. Indicator variables were included for subgroup level as well as two- and three-way interactions between subgroup, treatment group and time between subgroup level, treatment group and time. All statistical analyses were 2-sided, and the level of significance for all analyses was 0.05.

Results: Differences in treatment effects between hscrp subgroups were identified for mean-mean common (p=0.029) and mean-mean near wall (p=0.014). In both cases, the reduction in CIMT progression associated with atorvastatin assignment was more pronounced in the elevated hscrp subgroup. Similar differences were identified by pubertal status for mean-mean bifurcation (p=0.019) mean-max near wall (p=0.027) and mean-mean near wall (p=0.021), and by adherence for mean-mean far wall (p=0.035) and mean-mean near wall (p=0.028), where reduction in CIMT progression with atorvastatin assignment was more pronounced among post-pubertal or more adherent participants. No significant differences in treatment effects were observed between subgroups defined by LDL, age or SLE duration. The combined pubertal and high hscrp subgroup atorvastatin group had lower CIMT progression rates in five of 12 CIMT segments: mean-mean common (p=0.005), mean-mean (p=0.008), mean-mean bifurcation (p=0.023), mean-max near wall (p=0.029), and mean-mean near wall (p=0.002).

Conclusion: These exploratory results need to be confirmed and interpreted cautiously as multiple comparisons were performed. APPLE secondary analyses showed a trend of lower CIMT progression rates in the atorvastatin-treated pubertal and elevated hscrp subgroups, particularly in the combined pubertal subjects with high hscrp, suggesting that this subgroup may benefit from statin therapy.

2016

Ovarian Reserve in Juvenile Systemic Lupus Erythematosus Patients without Amenorrhea. Nadia E. Aikawa[1], Adriana M. Sallum[2], Rosa M.R. Pereira[3], Eloisa Bonfa[4], Lisa Suzuki[5], Vilma S.T. Viana[1] and Clovis A. Silva[6]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo-SP, Brazil, [3]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil, [4]University of Sao Paulo, Sao Paulo, Brazil, [5]Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil, [6]Instituto da Criança, Hospital das Clínicas, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil

Background/Purpose: Intravenous cyclophosphamide (IVCYC) use is a cause of premature ovarian failure in juvenile systemic lupus erythematous (JSLE). Assessment of markers of ovarian reserve is therefore of great interest in these patients and may allow a more accurate prediction of immunosuppressor-related risk to future fertility. Therefore, the objective of this study was to assess ovarian reserve using a combination of tests in JSLE patients without amenorrhea.

Methods: Twenty-seven consecutive JSLE female patients and 13 healthy subjects without amenorrhea (cessation of menstruation for more than 4 months after menarche) were evaluated prospectively for at least 6 months. Ovarian reserve was concomitantly assessed by serum levels of the following hormones (third to fifth day of the menstrual cycle): follicle stimulating hormone (FSH), luteinizing hormone (LH) and estradiol by fluoroimmunoassay, and inhibin A, inhibin-B and anti-mullerian hormone (AMH) by enzyme-linked immunosorbent assay in duplicated samples. Ovarian size was measured by abdominal ultrasonography. Demographic data, disease activity score (SLEDAI), disease cumulative damage (SLICC/ACR-DI) and treatment of JSLE patients were also analyzed.

Results: The median of current age and body mass index were similar in JSLE patients and controls (16.5 vs. 15years, p=0.31; 23 vs. 22.4kg/m^2, p=0.48). The age at menarche was significantly higher in JSLE patients that presented their first menstruation after disease onset *versus* controls (12.9 vs. 12years, p=0.044), whereas the frequencies of Tanner pattern 4 or 5 was similar in JSLE and controls (63% vs. 92%, p=0.07). The median levels of serum FSH (5.1 vs. 5.6IU/L, p=0.57), LH (2.7 vs. 3IU/L, p=0.8), estradiol (44.5 vs. 34pg/mL, p=0.37), inhibin A (0.3 vs. 0.1pg/mL, p=0.94), inhibin B (23.5 vs. 29.3pg/mL, p=0.58) and AMH (1.4 vs. 1.4ng/mL, p=0.7) were comparable in patients and controls. The median of ovarian volumes was also similar in JSLE versus controls (4.5 vs. 4.7cm^3, p=0.1416). Eleven patients were under IVCYC with median duration time between the last dose and study entry of 2.5 years (range 0–7.7). Further evaluation of ovarian reserve revealed that the median levels of serum FSH was significantly higher in JSLE patients under IVCYC (n=11) compared to those without this treatment (n=16) (6.4 vs. 4.6IU/L, p=0.023), however the lower inhibin B and AMH levels, and ovarian volume in the former group did not reach statistical significance (10.8 vs. 27.6pg/mL, p=0.17; 0.6 vs. 1.5ng/mL, p=0.28; 3.5 vs. 4.6cm^3, p=0.231; respectively). LH (2.7 vs. 2.9IU/L, p=0.43), estradiol (50 vs. 38pg/mL, p=0.34) and inhibin A (1.1 vs. 0pg/mL, p=0.49) levels were comparable in both groups. No correlation was found between FSH levels and duration of IVCYC use, inhibin A, inhibin B, AMH, SLEDAI and SLICC/ACR-DI in JSLE patients (p>0.05).

Conclusion: Our study suggest that ovarian reserve after cyclophosphamide treatment may be hampered in spite of menstrual cycles reinforcing the importance of gonadal function protection during the use of this alkylating agent. Further studies are necessary to determine the relevance of this subclinical condition for lupus fertility.

2017

Maternal Autoimmunity and Neonatal Brain Abnormalities: Cerebral Dysmaturation, Diencephalon Abnormalities, and Lenticulostriate Vasculopathy. Jennifer D. Frankovich[1], Patrick D. Barnes[1], Christy I. Sandborg[1] and Eliza F. Chakravarty[2]. [1]Stanford University, Palo Alto, CA, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: Case reports have suggested that neurologic disease may be part of the spectrum of neonatal lupus (NLE) in infants presenting with classical features of NLE, including diffuse cerebral hypomyelination, hydrocephalus, and vasculopathy. We report a similar spectrum of neurological findings in 9 infants born to mothers with lupus and associated autoimmune diseases in the absence of classical features of NLE (heart block, rash).

Methods: We report 9 infants born to mothers with lupus and associated autoimmune conditions, with evidence of idiopathic cerebral dysmaturity on brain MRI followed at a single center from birth through 3 years.

Results: Maternal autoimmune diseases include lupus (6), lupus nephritis (4), autoimmune thyroiditis (5), antiphospholipid antibody syndrome (3), Sjogren's or Ro/La antibodies (4), and ulcerative colitis (1). Only 2 of the 9 mothers received immunosuppression during pregnancy: cyclosporine (1) and low dose prednisone (2). Three mothers were diagnosed with autoimmune disease shortly after their infant was born. Median gestational age was 35 weeks (range 28–38 weeks). Median birth weight was 2350 grams (range 890–3260). ***Cerebral dysmaturity*** was seen in all 9 infants, which was primarily manifested as diffuse hypomyelination relative to adjusted gestational age at the time of MRI. Cortical dysmaturity was seen in 5 infants: polymicrogyria (1), coarse gyral pattern (1), wide sylvian fissures (1), and prominent Virchow-Robin Spaces (2). Ventriculomegaly was appreciated on 6 of the infant MRIs. ***Diencephalon abnormalities*** include optic tract hypoplasia (3), basal ganglia abnormalities (3), colossal or septum pellucidum abnormalities (5). ***Vasculopathy:*** Four head ultrasounds were available for review, and all 4 indicated lenticulostriate vasculopathy. Four infants also had brain calcifications consistent with prior hemorrhage and or vasculitis. ***Clinical neurological manifestations through 3 years*** include: static encephalopathy and death (2), persistent muscle tone abnormalities (6), seizures (3), persistent feeding abnormalities (4), delayed cognitive and language development (2), behavior abnormalities (2), macrocephaly (1), microcephaly (1), persistent congenital nystagmus and strabismus (1), opsiclonus and myoclonus (1), hyperekplexia (1).

Conclusion: A spectrum of cerebral and diencephalon abnormalities were present in infants born to mothers with lupus and associated autoimmune conditions. Lenticulostriate vasculopathy, previously reported in this setting, is of particular interest as these blood vessels supply the diencephalon and the germinal matrix (which gives rise to neurons and cells that myelinate the brain). While a causal connection between maternal autoantibodies or autoimmunity and these abnormalities cannot be firmly established, these neonatal neurologic abnormalities may be the result of passive autoimmunity. Clinicians should consider evaluation for maternal autoimmunity in cases of idiopathic cerebral dysmaturation, hypomyelination, or lenticulostriate vasculopathy.

2018

Long-Term Methotrexate Efficacy in Juvenile Localized Scleroderma. Francesco Zulian[1], Cristina Vallongo[1], Fabio Vittadello[1], Annalisa Patrizi[2], Maria Alessio[3], Anna Belloni Fortina[1], Silvana Martino[4] and Giorgia Martini[1]. [1]University of Padua, Padova, Italy, [2]University of Bologna, Bologna, Italy, [3]University of Naples Federico II, Napoli, Italy, [4]University of Turin, Italy

Background/Purpose: Recent studies reported that methotrexate (MTX), appears beneficial in juvenile localized scleroderma (JLS) but little is known about its long-term efficacy. We assessed the long-term efficacy of MTX in a cohort of patients with JLS.

Methods: We prospectively followed a cohort of patients with JLS who were enrolled in a double-blind, randomized controlled trial[1]. Oral MTX was used at a dose of 15 mg/m^2 once a week (max 20 mg) for at least 24 months; prednisone (1 mg/Kg/day, max 50 mg), as bridging therapy for 3 months was added. A target lesion was evaluated clinically, with infrared thermography and using a computerized scoring system with skin score rate (SSR) evaluation[2]. Response to treatment was defined as: no new lesions; SSR$<$1; decrease lesion temperature by at least 10% compared to baseline. Treatment failure was defined by appearance of new lesions, SSR$>$1, or increased lesion temperature. As far as outcome, partial remission (PR) was defined when the state of responder was maintained ON treatment for at least 6 months, complete remission (CR) when the state of responder was maintained OFF treatment for at least 6 months.

Results: 65 patients have been treated with MTX during the open-label phase of the study. Seven patients were lost to follow-up. Of the remaining 58 patients, after a mean follow-up of 43 months (median 36; range 6–72 months), 48 (82.8%) were responders, 10 (17.2%) relapsed by 24 months since MTX start. Among the responders, 35 (60.4%), after a 27.5 months of MTX treatment for (median 24, range 18–30) maintained CR for 25 months after stopping treatment (median 24, range 6–48), none relapsed. 13 patients (22.4%), after a mean follow-up of 20.5 months (median 15.5, range 6–45), were in PR. Among the ten MTX-refractory patients, 4 had linear subtype (2 limb, 2 ECDS), 4 had mixed subtype (2 linear-circumscribed, 2 linear-pansclerotic) and 2 generalized morphea. MTX-related side-effects were seen in 28 patients (48.3%), were generally mild and rarely required treatment discontinuation.

Conclusion: Long-term methotrexate therapy is a safe and effective treatment for JLS. Three months of combined MTX and glucocorticoid bridging therapy and MTX duration of treatment longer than 24 months ensure prolonged disease remission.

Diagnostic Evaluation and Medication Usage in a Cohort of Subjects with Juvenile Dermatomyositis Recruited within the First 11 Months of the Children's Arthritis and Rheumatology Research Alliance Registry. Angela B. Robinson[1], Mark F. Hoeltzel[2], ML Becker[2], Dawn M. Wahezi[3], Adam M. Huber[4], Brian M. Feldman[5], Ann M. Reed[6] and Juvenile Myositis CARRA Subgroup for CARRAnet Investigators[7]. [1]Rainbow Babies and Childrens Hospital, Cleveland, OH, [2]Children's Mercy Hospital, Kansas City, MO, [3]Children's Hospital Montefiore, Bronx, NY, [4]Dalhousie University, Halifax, NS, [5]The Hospital for Sick Children, Toronto, ON, [6]Mayo Clinic, Rochester, MN, [7]Varies by Investigator

Background/Purpose: Juvenile dermatomyositis (JDM) has been difficult to study due to the low incidence of disease. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) initiated a multi-center observational registry to create a clinical database for the major rheumatic diseases of childhood, including JDM. Initial data from the JDM cohort (prevalent and incident cases) enrolled in the first 11 months of this ongoing study are described here.

Methods: Children under 21 years of age with onset of JDM prior to 16 years were included. Subjects or their guardians gave consent for the study. IRB approval was obtained at each enrolling site. JDM was diagnosed by modified Bohan and Peter criteria. Clinical data were collected from the subjects, guardians, and providers using both general and JDM-specific case report forms at the time of enrollment. Data regarding demographics, diagnostic assessment, and medication exposure were collected. Data were pooled and stored in a secure centralized database and de-identified prior to analysis.

Results: Between May 28, 2010 and May 3, 2011, 198 subjects meeting modified criteria for JDM were enrolled from 40 sites in the US. Diagnostic studies commonly used include muscle biopsy, electromyography (EMG), and magnetic resonance imaging (MRI). All subjects had evidence of inflammatory myopathy by at least one of these modalities, with MRI being more sensitive than EMG or muscle biopsy (Table 1). Two or more studies were performed in 103 subjects, with 50.5% of the subjects exhibiting at least one non-diagnostic study. When evaluating medication use, 100% of subjects were treated with corticosteroids and 97% of subjects received methotrexate, suggesting that these medications are almost universally prescribed for JDM. Medication usage in order of frequency is presented in Table 2.

Table 1. Evaluation of diagnostic modalities in JDM

	N (%)
Muscle biopsy (n = 194)	
Performed	102 (52.6)
Consistent with JDM	78 (76.5)
Non-diagnostic	24 (23.5)
EMG (n = 192)	
Performed	62 (32.3)
Consistent with JDM	33 (53.2)
Non-diagnostic	29 (46.8)
MRI (n = 191)	
Performed	172 (90.1)
Consistent with JDM	152 (88.4)
Non-diagnostic	20 (11.6)
Combination of ≥2 studies (n = 194)	
Performed	103 (53.1)
3 studies consistent with JDM	1 (1.0)
2 studies consistent with JDM	66 (64.1)
1 study consistent with JDM	36 (35.0)

Table 2. Medication usage within the CARRAnet JDM cohort (N=198)

	Current use	Previous use	Ever used	Missing
All corticosteroids	94 (48.5%)	100 (51.5%)	194 (100.0%)	4
Daily corticosteroids	91 (47.2%)	98 (50.8%)	189 (97.9%)	5
Methotrexate	125 (65.1%)	62 (32.3%)	187 (97.4%)	6
Pulse corticosteroids	23 (12.0%)	104 (54.5%)	127 (66.5%)	7
Hydroxychloroquine	71 (37.4%)	38 (20.0%)	109 (57.4%)	8
Intravenous gammaglobulin	38 (19.3%)	50 (25.4%)	88 (44.7%)	1
Mycophenolate mofetil	27 (13.8%)	11 (5.6%)	38 (19.4%)	2
Cyclosporine A	8 (4.1%)	16 (8.2%)	24 (12.2%)	2
Rituximab	3 (1.5%)	15 (7.6%)	18 (9.1%)	1
Cyclophosphamide	0 (0.0%)	4 (2.0%)	4 (2.0%)	2

Conclusion: MRI was the most common diagnostic modality used and demonstrated the highest diagnostic sensitivity for JDM. Overall, the false negative rates of muscle biopsy, EMG and MRI were higher than expected. This may raise concerns about the underlying diagnosis or adequacy of these investigations, but may also be a more accurate representation of true false negative rates. Corticosteroids and methotrexate appear to be standard first line medications used by US pediatric rheumatologists for JDM. Pulse corticosteroids, intravenous gammaglobulin, and hydroxychloroquine were prescribed in about half of the enrolled subjects and further investigation of these subject characteristics is warranted.

2020

Influenza A H1N1/2009 Vaccine in Juvenile Dermatomyositis: Reduced Response in Patients Under Immunosuppressive Agents. Vanessa R. Guissa[1], Nadia E. Aikawa[2], Adriana M. Sallum[1], Lucia M.A. Campos[3], Rosa M.R. Pereira[4], Eloisa Bonfa[5] and Clovis A. Silva[1]. [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo-SP, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [4]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil, [5]University of Sao Paulo, São Paulo, Brazil

Background/Purpose: We recently evaluated in adults the immunogenicity and safety of the 2009 non-adjuvanted influenza A/H1N1 vaccine

in a large cohort of autoimmune rheumatic diseases, including those with dermatomyositis (Ann Rheum Dis 2011;70:1068–73). However, there are no data regarding immunogenicity and the safety of this immunization in juvenile dermatomyositis (JDM). We therefore, evaluated in these patients vaccine immunogenicity and adverse events, as well as, disease safety and the possible influence therapy in antibody response.

Methods: 30 JDM patients and 81 healthy controls were vaccinated with non-adjuvanted influenza A/California/7/2009 (H1N1) virus-like vaccine. All participants were evaluated pre- and 21 days post-vaccination and serology for anti-H1N1 was performed by hemagglutination inhibition (HI) assay. Seroprotection (percentage of subjects with HI antibody titer ≥ 1:40), seroconversion (percentage of subjects with either a pre-vaccination HI titer < 1:10 and a post vaccination HI titer ≥ 1:40 or a pre-vaccination HI titer ≥ 1:10 and a minimum four-fold rise in post-vaccination HI antibody titer) rates, geometric mean titres (GMTs) and factor increase (FI) in GMT (ratio of the GMT after vaccination to the GMT before vaccination) were analyzed. Muscle enzymes levels and JDM scores [disease activity score (DAS), Manual Muscle Test (MMT-8) and Childhood Myositis Assessment Scale (CMAS)] were evaluated before and after vaccination. Adverse events were also reported.

Results: JDM patients and healthy controls were comparable regarding median current age and female gender [15.5 (9–21) vs. 15 (9–21) years, p=0.511; 63 vs. 51%, p=0.286]. After immunization, seroconversion rates were significantly lower in JDM patients compared to controls (86.7 vs. 97.5%, p=0.045), whereas seroprotection (p=0.121), GMT (p=0.992) and FI in GMT (p=0.827) were similar in both groups. Clinical and laboratorial evaluations revealed that DAS [0 (0–11) vs. 0 (0–14), p=0.993)], CMAS [52 (45–52) vs. 52 (41–52), p=0.804], MMT [80 (74–80) vs. 80 (79–80), p=0.986], CPK [124 (49–533) vs. 102.5 (33–481), p=0.339], AST [20 (10–45) vs. 23 (11–36)UI/L, p=0.246], ALT [32.5 (12–72) vs. 31 (11–63)UI/L, p=0.826] and LDH [187 (93–469) vs. 179 (83–446)UI/L, p=0.907] remained stable throughout the study. Regarding therapy, seroconversion rates among JDM patients under current prednisone (p=0.005), methotrexate (MTX) (p=0.004), MTX and cyclosporine (p=0.005) and immunosuppressants other than MTX (p=0.039) were significantly lower compared to healthy controls. Local and systemic vaccine adverse events were uniformly mild and with similar frequency in patients and controls (p>0.05).

Conclusion: This first study of non-adjuvanted influenza A/H1N1 2009 virus immunization in JDM patients revealed a reduced immunoresponse particularly associated with immunosuppressive agents. The observed overall vaccine and disease safety supports its recommendation and suggest that a booster may be appropriate to improve antibody response. (ClinicalTrials.gov, #NCT01151644)

Creation of a Cohort of French Patients with Chronic Recurrent Multifocal Osteitis: Preliminary Results. Julien Wipff[1], M.-A. Dumitrescu[2], Mathie Lorrot[3], Albert Faye[2], S. lacassagne-Compeyrot[4], B. Bader Meunier[4], R. Mouy[4], Carine H. Wouters[5], Marine Desjonqueres[6], S. Jean[7], V. Despert[7], A. Duquesne[6], I. Lemelle[8], P. Pillet[9], M. Grall-Lerosey[10], Pierre Quartier[11] and Chantal Job-Deslandre[12]. [1]Paris descartes Universityn Rheumatology A, Cochin Hospital, Paris, France, [2]Paris, France, [3]Paediatry, Robert Debré hospital, Paris, France, [4]University Paris Descartes, Paediatry, Necker hospital, Paris, France, [5]University Hosp Gasthuisberg, Leuven, Belgium, [6]Hopital Femme Mere Enfant, Groupement Hospitalier Est, Lyon, France, [7]Paediatry, CHU, Rennes, France, [8]Paediatry, CHU, Nancy, France, [9]Paediatry, CHU, Bordeaux, France, [10]Paediatry, CHU, Rouen, France, [11]Hôpital Necker-Enfants Malades, Paris, France, [12]Hopital Cochin, Paris Cedex 14, France

Background/Purpose: Chronic recurrent multifocal osteomyelitis (CRMO), also known as chronic nonbacterial osteomyelitis, is an orphan disease that manifests by recurrent flares of inflammatory bone pain with or without fever. Its frequency seems to be underestimated and it often leads to consequential residual impairments. The aim of this study is to collect the French cases of CRMO in order to precise clinical, biological, radiological and histological features.

Methods: Creation of a French national database of cases of CRMO. In the absence of validated international diagnostic criteria, our inclusion criteria were: patient with at least one lesion of aseptic osteitis highlighted by imaging techniques (MRI or isotopic bone scan) and beginning before 18 years. Exclusion criteria were: onset after 18 years, other diagnosis (malignancy, infection, enthesitis related arthritis).

Results: 70 patients were included (46 females and 24 males) mean aged 15.71±4.61 years. Mean age at diagnosis was 10.9±3.90 years. The mean time between first symptom and diagnosis was 22.63±34.14 months. 19/70 (27%) patients had unifocal symptom, mainly located on lower limbs (n=7) [leg (n=3), thigh (n=2) and ankle (n=3)]. For the other patients, the mean number of clinical locations was 2.33±1.3 mainly in lower limbs. 30/70 patients had inflammatory skin appearance opposite the osteitis, 14/70 had fever and 37/70 had biological inflammatory syndrome.

Imagery plain radiographs and/or bone scan and/or MRI) showed 2.67±1.67 lesions per patients and confirm multifocal involvement in 8/19 cases with clinical unifocal symptom.

Bone biopsy was performed in 45/70 and was followed by antibiotherapy in 15 cases, including 10 without bacteriological proof NSAIDs were given as first line therapy to 68/70 patients. In case of failure second line treatment were bisphosphonates for 4 patients and anti-TNFalpha for 3.

Only 23 patients were considered in remission at the last visit after a mean follow-up of 50.66 ± 44.2 months. 16/70 patients had sequellae including localized deformations (n=8), growth retardation (n=6) or vertebral fractures (n=2).

Conclusion: Our first results confirm that the use of imagery (bone scan, MRI) can demonstrate the multifocal pattern of osteitis in patients with clinical monofocal lesion. This confirmation may avoid a bone biopsy which is invasive in these young patients. NSAIDs remained first line treatments with remarkable efficiency. Bisphosphonates and anti-TNFalpha are second line treatment options only if NSAIDs failed to improve symptoms.

2022

Recurrent Arthritis As the Sole Presenting Manifestation of Hereditary Autoinflammatory Syndromes. Giulia Vigo[1], Giorgia Martini[1], Fabio Vittadello[1], Isabella Ceccherini[2], Laura Obici[3] and Francesco Zulian[1]. [1]University of Padua, Padova, Italy, [2]G. Gaslini Institute, Genova, Italy, [3]IRCCS Policlinico S. Matteo, Pavia, Italy

Background/Purpose: Hereditary autoinflammatory syndromes (HAS) are a group of rare monogenic inherited conditions characterized by recurrence of symptoms of whom fever is the most frequent. We analyze the prevalence of recurrent arthritis in a cohort of patients with HAS.

Methods: We performed a retrospective study on 302 patients with periodic and recurrent fevers referred to a single tertiary center in 17 yrs of activity. Patients with recurrent arthritis were identified and fully investigated. On the basis of the clinical features and genetic tests, patients were divided into two groups: 275 PFAPA syndrome and 27 HAS (11 FMF, 3 TRAPS, 3 HIDS, 3 CAPS, 7 Undefined).

Results: Patients with monogenic HAS showed a later disease onset (63.4 months vs 27.9) and a higher frequency of abdominal pain (60% vs 16.4%), headache (32% vs 7.3%) than PFAPA. Recurrent arthritis, defined as episodes lasting less than 7 days, was found in 11 patients with HAS (40.7%): 4 had FMF, 2 TRAPS, 3 HIDS, 2 CAPS. No patient with arthritis was found in the PFAPA group. Interestingly, five out of 11 patients (3 FMF, 2 HIDS) had unexplained recurrent arthritis as unique manifestation of the disease for a long time. Arthritis consisted in episodes of joint swelling, pain and limitation of movement involving, asymmetrically, large joints. In three patients most episodes occurred after infections. During the disease-free intervals, acute-phase reactants (CRP and SAA) persisted elevated. Genetic analysis showed heterozygous missense changes of the MEFV gene in three patients (A289V father and daughter, P369S) and of MVK gene (V250I/G336S, I268T) in the other two. Before genetic confirmation, attacks resolved spontaneously or under NSAIDs treatment in few days. After genetic confirmation, four patients have been treated with colchicine and all responded.

Conclusion: Unexplained recurrent arthritis may be the unique manifestation of a monogenic HAS and should be added to the list of possible differential diagnosis of the so called "palindromic arthritis". Elevation of acute-phase reactants, during the arthritis-free intervals, might be a suspicion finding to address a genetic test for HAS. Colchicine may represent the drug of choice in this condition.

2023

Description of the Localized Scleroderma Subgroup of the CARRA *net* Registry. Eveline Y. Wu[1], Egla C. Rabinovich[2], Kathryn S. Torok[3], Suzanne C. Li[4], Robert C. Fuhlbrigge[5] and CARRANet Investigators[6]. [1]Duke Univ Med Ctr, Durham, NC, [2]Duke University Medical Center, Durham, NC, [3]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [4]Hackensack Univ Med Ctr, Hackensack, NJ, [5]Childrens Hospital, Boston, MA, [6]Stanford

Background/Purpose: Localized scleroderma (LS) is a chronic inflammatory and fibrosing skin disease. We present baseline data on the juvenile LS (jLS) cohort from the Childhood Arthritis and Rheumatology Research Alliance (CARRA*net*) registry, a United States observational longitudinal study of pediatric rheumatologic disorders.

Methods: We performed a cross-sectional baseline analysis of registry data for jLS.

Results: Data were available on 119 children. 80% were female and 90% were Caucasian, of which 11% were Latino. Mean age at onset was 7.8 years (± 4.1), yet first evaluation by a pediatric rheumatologist was 9.9 years (± 4.1). Mean disease duration at time of data collection was 4.8 years (±3.8). Reported subtypes were 67 (56%) with linear scleroderma (LiS: 44 trunk/limbs, 23 face/scalp), 22 (18%) with circumscribed morphea (13 deep, 11 superficial), 6 with generalized morphea, 4 with eosinophilic fasciitis, and 1 with pansclerotic morphea. There were 19 (16%) cases of mixed morphea. Features of activity included erythematous/violacious color (37), lesion extension (30), induration at lesion perimeter (29), and warmth (22). Damage included subcutaneous atrophy (88), hyperpigmentation (87), dermal atrophy (82), hypopigmentation (60), induration at lesion center (58), and hair loss (43). Musculoskeletal features of damage included muscle atrophy (27), joint contracture (25), hemifacial atrophy (10), and limb shortening (9). Eight children (7%) had arthritis. ANA positivity was found in 50% of tested patients, otherwise there were no consistent laboratory or imaging abnormalities.

	Antinuclear Antibody	Elevated IgG	Eosinophilia	Abnormal Aldolase	Abnormal Creatine Kinase	Abnormal CNS Imaging	Abnormal GI Study
Positive	46 (50.5%)	8 (12%)	18 (17.2%)	8 (13.6%)	4 (5.6%)	2 (4.5%)	3 (12%)
Negative	45 (49.5%)	59 (88%)	85 (82.5%)	85 (86.4%)	67 (94.4%)	42 (95.5%)	22 (88%)
Unknown	27	51	15	59	47	75	93
Total	**118**	**118**	**118**	**118**	**118**	**119**	**118**

Mean visual analog scale (VAS) physician global assessment of activity was 1.71 and mean CHAQ score was 0.17. By VAS (0–10), mean parent/subject score of overall well-being was 1.92 (±1.94) and pain was 1.30 (±1.91). Health related quality of life was reported as excellent in 30, very good in 54, good in 30, and poor in 3 subjects. A worst ever and current ACR functional class > I was reported in 24.2% and 11.2%, respectively. Medications used are listed below.

	Oral methotrexate (MTX)	Subcutaneous methotrexate (MTX)	Mycophenolate mofetil (MMF)	Intraveneous corticosteroids (CS)	Longterm daily corticosteroids (CS)
Subjects (%)	66/113 (58%)	91/113 (81%)	23/113 (20%)	58/93 (62%)	57/91 (63%)
Current Use	33	47	17	16	20
Past Use	33	44	6	42	37

Conclusion: jLS is reported more frequently in females and Caucasians in the CARRA*net* registry. LiS is the most common lesion subtype, representing 56% of all patients. 50% of the jLS cohort is ANA positive. Subcutaneous and oral MTX and pulse and long term daily CS are the most commonly used medications for treatment, followed by MMF. There is over a 2 year delay from symptom onset and referral to pediatric rheumatology. There is significant morbidity with 25% reporting limitation in functional capacity and only 25% reporting an excellent health related quality of life.

2024

Parents' Attitudes towards Research and Research Study Participation in Pediatric Rheumatology (PR). America Uribe[1], Lori B. Tucker[2], Louise Masse[1], Jaime Guzman[1] and David A. Cabral[3]. [1]BC Children's Hospital, Vancouver, BC, [2]BC Childrens Hospital, Vancouver, BC, [3]University of British Columbia, Vancouver, BC

Background/Purpose: To improve the outcome for children with rare PR diseases, it would be optimal for all patients to be treated in the context of a clinical study or clinical trial. In our clinic, we have fostered a milieu of integrated clinical care and research, in part through regular distribution of a Research newsletter for families. For our patients, we aimed to describe their parent's attitudes towards research in general, and to determine factors associated with their decisions to allow their child to participate in research studies

Methods: Parents of children attending the BC Children's Hospital tertiary PR clinics for at least 6 months, who were able to read English, were surveyed (April-June 2011) using a questionnaire. The questionnaire was developed using a three-stage process; a)13 family interviews to develop themes and itemized questions; b) items refined by members of the PR clinic team (4 MD, 2 RN, 1 PT, 1 OT, 1 SW) and a second group of 17 parents; c) the questionnaire was piloted (including re-test reliability) on a subset of 25 parents. Descriptive statistics were used.

Results: 124 of 163 eligible parents completed the survey (75.8% mothers). Patients' diagnoses were 78 (62.9%) JIA, 12 (9.7%) SLE, 7 (5.6%) vasculitis, 4 (3.2%) scleroderma, 20 (16.1%) other; median (range) age 14 (1–17) years. For 86 families (69.4%), English was the primary language at home. A majority of parents (N=110; 88.7%) reported to have looked for information related to the treatment/diagnosis of their child; 39 (35.5%) of these sought information specifically about research into their child's condition. 100 (80.6%) parents were open to participating in a research project; 107 (86.3%) considered it was important to carry out that research related to their child's disease, and a majority (85.0%) indicated their preference for this research to be done at our clinic. Sixty-two (50.0%) surveyed families had been invited to join a research study in the past (93.5% of these joined/6.5% declined). Factors influencing parent's decision of allowing their child to participate in a research study are shown in Table.

Table.

Factors influencing participation in a research study, n (%)	Study participation		
	More Likely	Less Likely	No difference
Child is doing well	20 (16.1)	26 (21.0)	**78 (62.9)**
Child is not doing well	57 (46.3)	18 (14.6)	48 (39.0)
My child is young	20 (16.4)	12 (9.8)	**90 (73.8)**
Study adds time to clinic visit	8 (6.6)	44 (36.4)	69 (57.0)
Study visits/procedures can be coordinated with regular clinic appointments	**91 (74.6)**	6 (4.9)	25 (20.5)
Involves additional visit to the hospital	2 (1.7%)	**88 (73.3)**	30 (25.0)
Study involves additional work at home	9 (7.3)	41 (33.3)	73 (59.3)
Study collects personal data	26 (21.1)	7 (5.7)	**90 (73.2)**
Study involves a blood draw	5 (4.2)	48 (40.0)	67 (55.8)
Study requires testing of a new medication/treatment	7 (5.7)	**82 (66.7)**	34 (27.6)
Side effects of new medication are unknown	2 (1.7)	**111 (91.7)**	8 (6.6)
Study includes the possibility of receiving placebo	6 (5.0)	59 (48.8)	56 (46.3)
Study drug/intervention is randomly assigned	5 (4.1)	**77 (62.6)**	41 (33.3)
Double-/single-blinded study	6 (4.9)	**68 (55.7)**	48 (39.3)
Study benefits child directly	**99 (79.8)**	1 (0.8)	23 (18.5)
In-person invitation instead of phone or paper invitation	50 (41.0)	12 (9.8)	60 (49.2)
Study will provide compensation (coupons/out-of-pocket expenses)	49 (40.0)	2 (1.6)	72 (58.5)
Family knows the investigators	57 (47.5)	2 (1.7)	61 (50.8)
Family feels satisfied with information given about study goals and procedures	**84 (68.9)**	1 (0.8)	37 (30.3)
Study results will be available quickly	**92 (74.8)**	6 (4.9)	25 (20.3)
Child is willing to join the study	51 (41.5)	3 (2.4)	**69 (56.1)**
Child is not willing to join the study	6 (4.9)	**85 (69.7)**	31 (25.4)

Conclusion: The majority of our patient's parents were interested in joining research studies and believed it was important to carry out research related to their child's condition. Parents in this study identified that studies involving additional visits to the hospital, testing of a new medication (with potential unknown side effects), randomized assignment of study intervention and blinding procedures were deterrents for study participation. Perceived direct benefit to child, study visits/procedures coordinated to regular clinical appointments, and feeling well informed about the study were facilitators of participation in research. Addressing these factors may increase enrolment to research studies in PR.

2025

Long-Term Mental Health Outcomes in Pediatric-Onset Systemic Lupus Erythematosus. Erica F. Lawson[1], Aimee O. Hersh[2], Laura J. Julian[1], Laura Trupin[3], Emily von Scheven[3], Patricia P. Katz[4] and Edward Yelin[1]. [1]University of California San Francisco, San Francisco, CA, [2]University of Utah, Salt Lake City, UT, [3]UC San Francisco, San Francisco, CA, [4]Univercity of California San Francisco, San Francisco, CA

Background/Purpose: Neuropsychiatric syndromes are prevalent in pediatric-onset systemic lupus erythematosus (pSLE), but the long-term risk of mood disorders in adults with pSLE is unknown. We aim to describe the prevalence of depression among adults with pSLE, and to compare subjects with pSLE to subjects with adult-onset SLE (aSLE) using the UCSF Lupus Outcomes Study (LOS).

Methods: Data derive from the 2009 cycle of the LOS, an annual longitudinal telephone survey of diverse English-speaking subjects with confirmed SLE. Subjects age 18–60 years (N=625) were included. Subjects were classified as pediatric-onset if age at diagnosis was < 18 years (N=86). Mental health was assessed with the Center for Epidemiological Studies Depression Scale (CESD), the ACR Committee on Neuropsychiatric Lupus' suggested measure of depression in SLE, using validated cutoff values. Outcome variables included CESD > 23 (indicative of major depression) and CESD > 19 (indicative of a mood disorder). We used logistic regression

analysis to compare pSLE and aSLE with and without adjustment for other characteristics that could affect depression risk. Age, gender, ethnicity, marital status, poverty, the presence of renal disease, self-reported disease activity according to the Systemic Lupus Activity Questionnaire (SLAQ) score, and physical disability according to the SF-36 Scale of Physical Function (SF36-PF) were included as predictors.

Results: Mean age of subjects was 45±10 years, and 93% were female. Ethnicities included Caucasian (60%), Hispanic (10%), African American (10%), Asian (12%) and other (8%). Subjects with pSLE were more likely to be ethnic minorities (p=0.003). Mean age at diagnosis was 14±2.9 years for subjects with pSLE and 32±8.8 years for subjects with aSLE. Mean disease duration was 19±9.3 years for subjects with pSLE and 16±7.5 years for subjects with aSLE. Mean SLAQ score at the time of the survey was 11.4±8.0 for all subjects. The prevalence of mood disorders was similar among subjects with pSLE and aSLE (22% vs. 20% for major depression and 30% vs 36% for all mood disorders, respectively, p=NS). Subjects with aSLE were more likely to report a diagnosis of depression (35% vs. 25%, p = 0.08). In multivariate logistic regression analysis, there was no statistically significant difference in the odds of any mood disorder between the two groups. However, the odds of major depression among subjects with pSLE was more than double the odds of major depression for subjects with aSLE after adjustment for covariates (Table 1).

Table 1. Regression-adjusted ORs for the presence of any mood disorder or the presence of major depression among subjects age 18–60 with SLE*

Variable	OR for any mood disorder (95% CI)†	OR for major depression (95% CI)†
Pediatric-onset SLE	1.42 (0.73–2.74)	2.34 (1.06–5.17)
Age	1.01 (0.99–1.03)	0.99 (0.96–1.02)
Female	1.03 (0.46–2.28)	0.67 (0.25–1.77)
Ethnicity		
Caucasian	referent	referent
Latino	1.37 (0.73–2.56)	1.62 (0.77–3.42)
African American	1.11 (0.58–2.13)	1.68 (0.80–3.49)
Asian	1.08 (0.58–2.04)	1.40 (0.63–3.10)
Other	1.00 (0.47–2.14)	2.07 (0.88–4.85)
Married or Partnered	0.88 (0.45–1.03)	1.03 (0.82–1.72)
Poverty¶	1.75 (1.01–3.02)	1.10 (0.60–2.01)
Renal disorder	0.81 (0.51–1.27)	0.84 (0.47–1.48)
SLAQ	1.09 (1.05–1.13)	1.10 (1.06–1.14)
SF36-PF	0.97 (0.95–0.99)	0.95 (0.92–0.97)

* OR = odds ratio; 95% CI = 95% confidence interval; SLAQ = Systemic Lupus Activity Questionnaire (0–47); SF36-PF = SF-36 Scale of Physical Functioning (0–100).
† OR from logistic regression, adjusted for variables shown.
¶ Income below 125% of the Federal poverty level.

Conclusion: While subjects with pSLE are not at increased risk for all mood disorders, including mild depression, as compared to subjects with aSLE, onset of lupus in childhood may significantly increase the risk of major depression in adulthood. Appropriate screening and treatment for depression is important to maximize long-term quality of life and functional outcomes in patients with pSLE.

2026

Quality of Life and Psychosocial Aspects Among School Adolescents with Diffuse Chronic Musculoskeletal Pain in Brazil. AK Nascif[1], V. Valim[1], M. Dorio[2], JR Gomes[1], AFA Pereira[1], E. Zandonade[1] and Claudio Len[3]. [1]Universidade Federal do Espírito Santo, Vitória, Brazil, [2]Vitória, Brazil, [3]Universidade Federal de São Paulo / UNIFESP, Sao Paulo, Brazil

Background/Purpose: Diffuse chronic musculoskeletal pain (DCMP) is part of the pain amplification syndromes and is defined by the presence of pain in three or more body sites for at least three months, excluding other diseases that could explain the symptoms. Its prevalence on the pediatric age varies significantly among studies due to the diversity of populations, definitions and methods used, ranging from 1 to 15%. It is closely related to psychosocial disorders (behavioral and sleep disturbances, depression, anxiety, catastrophization and impaired self-perception). The aim of this study is to evaluate the prevalence, quality of life and psychosocial aspects of adolescents with DCMP.

Methods: All 175 adolescents from 16 to 17 years old from a public school in Vitoria, Brazil, were evaluated. The diagnosis of DCMP was based on medical interview and physical examination by a pediatric rheumatologist. For each case of DCMP, four healthy controls were selected, matched by gender and age. Self-applicable questionnaires were used for comparison: Children's Depression Inventory (CDI), Child Behavior Checklist (CBCL), Harter Self Perception Scale for Adolescents (HSPS-A) and the Pediatric Quality of Life Inventory™ Version 4.0 (PedsQL™ 4.0).

Results: Five adolescents were diagnosed with DCMP (prevalence 2.86%) and compared with 20 matched controls. The results of psychosocial aspects and quality of life are in table 1.

Table 1. Analysis of CDI, CBCL, HSPS-A and PedsQLTM 4.0 questionnaires from cases and controls.

Questionnaire		Results			
		Group	Mean	SD e	p-value
CDI a	Score	Case	7.20	5.40	**0.0411**

[a]Children's Depression Inventory; [b]Child Behavior Checklist; [c]Harter Self Perception Scale for Adolescents; e Pediatric Quality of Life Inventory™ Version 4.0; [e]Standard-Deviation

Conclusion: The prevalence and greater incidence of depressive symptoms in adolescents with DCMP are similar to the data available in the literature. The lack of difference in self-perception and self-evaluation of behavior possibly suggests a greater focus on their own pain and physical limitations instead of their mental health, since other studies show detriment of psychosocial aspects when reported by parents. Besides, DCMP patients have impaired quality of life, difficulty in interpersonal relationship and loss of functional capacity for daily life activities. Therefore, it is important to value DCMP as an entity that causes a negative impact on the patient's life and has to be tackled in a multidisciplinary and effective manner.

2027

Race Is a Risk Factor for Calcinosis in Patients with Juvenile Dermatomyositis: Early Observations From the Childhood Arthritis and Rheumatology Research Alliance Registry (CARRAnet). Mark F. Hoeltzel[1], ML Becker[1], Angela B. Robinson[2], Adam M. Huber[3], Brian M. Feldman[4], Ann M. Reed[5] and Juvenile Myositis CARRA Subgroup for CARRAnet Investigators[6]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Rainbow Babies and Childrens Hospital, Cleveland, OH, [3]Dalhousie University, Halifax, NS, [4]The Hospital for Sick Children, Toronto, ON, [5]Mayo Clinic, Rochester, MN, [6]Various

Background/Purpose: Previously established risk factors for calcinosis include duration of disease and the length of time to treatment, suggesting early aggressive treatment may be important in preventing calcinosis. Race has also been suggested to be a risk factor, but this observation was thought to be

secondary to delays in treatment and longer disease duration. We utilized the CARRAnet registry to investigate potential risk factors for calcinosis.

Methods: Children with juvenile dermatomyositis (JDM) in the CARRAnet registry were included in this analysis. Race and ethnicity were self-reported. Subjects with current or past calcinosis were identified. Potential predictors of calcinosis identified *a priori* included race, ethnicity, sex, ANA status, age, age of onset, duration of disease, and time to rheumatologic care. Bi-variable associations between clinical variables and calcinosis were evaluated by Chi-square test, Fisher exact test, two-sample t-test, or Wilcoxon Rank Sum test as appropriate. A multivariable logistic regression model was run with variables significantly associated in bi-variable analyses ($P<0.1$). All statistical analyses were conducted using JMP Stats version 8.0 (SAS Institute, Cary, NC).

Results: 198 subjects meeting modified Bohan and Peter criteria for JDM were enrolled from 40 U.S. sites. Four subjects were excluded due to lack of data regarding calcinosis or race. Twenty-three (12%) of the remaining 194 patients had a history of calcinosis. Seven of 26 (27%) subjects reporting African American (AA) ancestry and 16 of 168 (10%) subjects without AA ancestry had a history of calcinosis.

Bi-variable analyses revealed a significant association between calcinosis and AA ancestry [OR 3.5 95% CI (1.3, 9.6) $P=0.019$], disease duration in years [median (quartiles), 5.6 (4.0, 9.1) vs. 3.1 (1.7, 5.3) $P=0.0002$], and age at study visit in years [mean (± SD), 13.1 (± 3.5) vs. 10.8 (± 4.4) $P=0.015$]. Analyzing these three variables in a multiple logistic regression model revealed that AA ancestry [Adjusted OR 5.2, 95% CI (1.6 16.3) $P=0.005$], and disease duration [Adjusted OR 3.7, 95% CI (1.6, 9.0) $P=0.003$], were independent predictors of calcinosis.

When demographic variables and outcome assessments were compared between AA patients and non-AA patients, both CHAQ scores (mean (±SD), 0.58 (±0.68) vs. 0.3 (±0.54) [$P=0.002$]) and pain scores (mean (±SD), 2.4 (±0.4) vs. 1.5 (±0.2) [$P=0.045$]) were statistically significantly higher in AA patients, but there was no difference in age of onset, disease duration, or time to rheumatologic care.

Conclusion: Children of AA ancestry with JDM have increased odds of developing calcinosis. While longer disease duration remains a significant risk factor for calcinosis in the cohort as a whole, there was no difference in the disease duration of patients with AA ancestry and those without in the CARRAnet cohort, and AA ancestry remained a significant predictor after controlling for age and disease duration in multiple logistic regression modeling. These findings warrant further investigation to determine if the increased risk of calcinosis can be attributed to differences in genotype, disease phenotype, or treatment practices in the AA population.

2028

Anakinra for the Treatment of Hyper-IgD with Periodic Fever Syndrome in Children. Donald P. Goldsmith[1], Karyl S. Barron[2], Amanda K. Ombrello[3], Robert Lembo[3], Deborah Stone[3], Anne Jones[4], Dawn C. Chapelle Neal[5] and Daniel L. Kastner[6]. [1]Drexel University College of Medicine/St Christophers Hosp for Child, Philadelphia, PA, [2]NIAID-NIH, Bethesda, MD, [3]National Institutes of Health, Bethesda, MD, [4]NIH-NIAMS, Bethesda, MD, [5]NIAMS, Bethesda, MD, [6]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Background/Purpose: Hyper-IgD with Periodic Fever Syndrome (HIDS) is an autosomal recessive autoinflammatory disorder thought to result from increased inflammasome activation. Various therapeutic agents have been proposed but there is no established treatment. Recent in vitro data indicates increased caspase-1 activity leading to active IL-I beta release (*Kuijk LM et al.Blood 2008;112:3653*). In earlier case reports and small series (*Rigante d et al. Rheumatol Int 2006;27:97* and *van der Hilst JC et al. Medicine 2008; 87:301*) clinical benefit has been noted using the Il-1 blocker, anakinra. To further explore its efficacy we assessed the therapeutic response of a cohort of pediatric HIDS patients to anakinra.

Methods: This study is a retrospective chart review of 11 children with HIDS. Eleven of 25 patients followed in the NIH Periodic Fever Clinic with known MVK mutations and symptoms compatible with HIDS, ages 4–17, were treated with anakinra. Five children had only one mutation in the MVK gene. Seven were started on intermittent administration at the onset of a febrile episode and 4 were treated with daily administration. Dosage most often was initiated at 1mg/kg with further increases when needed up to 3–5mg/kg/day. Clinical response was assessed at each outpatient visit by interview and clinical examination with determination of a clinical score based on changes in fever (frequency, duration, and apex), G-I symptoms, arthralgias/arthritis, and rash.

Results: Intermittent Rx (7patients): In 3 children there was a sustained reduction in the severity and frequency of febrile episodes (complete response). In 3 there was a reduction of in the severity but an increased frequency of episodes (partial response). In 1 there was no response (this child later developed JIA associated with dyserythropoietic anemia).

Daily Rx (4 patients): In 1 child there was reduced episode severity and no change in episode frequency (positive response). In 1 child there was reduced severity but increased episode frequency (partial response). In 2 there was no response.

Side effects were confined to localized cutaneous reactions. Those treated with daily therapy were assessed initially as having more severe clinical manifestations. Of 3 total patients with no clinical response 2 had previously been treated unsuccessfully with etanercept. With this small number of patients we were unable to correlate a specific mutation pattern with therapeutic results.Of note, however was that all 3 children who experienced an increased frequency of episodes had single MVK mutations.

Conclusion: The majority (8 [72%]) of 11 children with HIDS demonstrated a beneficial response to anakinra therapy, 4 complete and 4 incomplete. However, an increased frequency of episodes was an unexpected finding associated with benefit. These data emphasize that predictable, complete and enduring response to treatment with currently available biologic agents remains elusive. In this regard our results are similar to the analysis of 13 patients (adults and children) with HIDS treated with anakinra as reported by van der Hilst JC et al *(Medicine 2008;87:301).*

2029

Mycophenolate Mofetil in Children with Lupus: Clinical Findings in Favour of Therapeutic Drug Monitoring. Brigitte Bader-Meunier[1], Camille Jurado[2], Bruno Ranchin[3], Stéphane Decramer[4], Michel Fischbach[5], Etienne Berard[6] and Franck Saint Marcoux[2]. [1]Hôpital Necker, Paris, France, [2]INSERM UMR –S850, Limoges, France, [3]Hôpital Femme-Mère-Enfant, Lyon, France, [4]hôpital Purpan, Toulouse, France, [5]Hôpital Hautepierre, Strasbourg, France, [6]Hôpital Lenval, Nice, France

Background/Purpose: The use of mycophenolate mofetil (MMF) in children with Systemic Lupus Erythematosus (SLE) is increasing. However, the clinical benefit of its monitoring has been scarcely studied, and little is known about its pharmacokinetics in this context. We have launched a non interventional study with analysis of clinical, biological and pharmacokinetic (PK) information obtained from paediatric inpatients with SLE already treated with a maintenance immunosuppressive therapy including MMF. The main purpose of the study was (i) to model mycophenolic acid (MPA; the active moiety of MMF) PK profiles; (ii) to explore the relationships between exposure indices to MPA and the clinical status.

Methods: Full-PK profiles of MPA were collected and the observed concentration-time curves were fitted using a one compartment open PK model where a potential secondary peak of absorption is taken into account. Clinical data were summarized using the consensually recommended Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and the disease was considered active for a score ≥ 6. The relationships between MPA through concentrations (C_0), Area Under the Curve (AUC) or AUC/dose values, and the activity of the disease were then explored using Receiver Operating Curve (ROC) and logistic regression analysis.

Results: According to the design of the study, indications of performing MPA PK profiles with the aim of calculating AUC values were based on clinical decisions made by the patients' physicians. Full-PK profiles of MPA were obtained at steady state from twenty six children aged from 10 to 17 years with SLEDAI score ranging from 0 to 20 (median: 4) and followed-up in five different French centres. The PK model fitted accurately the data and reported a high interpatient variability: $AUC_{0-12h} = 40.51 \pm 20.49$ mg.h/L. Trough concentrations were poorly correlated to the global exposure to MPA (AUC). Multivariate analysis found: (i) no relationship between C_0 and SLEDAI; (ii) that patients with an AUC_{0-12h} / dose < 0.058 mg.h/L/mg were more likely to have an active disease (OR= 4.8; 95CI: 0.9–25.0; $p = 0.067$).

Conclusion: A PK model enabling the description of MPA PKs in children given MMF for lupus treatment was developed. Preliminary results obtained in this small population showed a tendency to a relationship between the activity of the disease and a too low exposure to MPA at the time of PK sampling. Further data are needed (i) to develop PK tools that could estimate the AUC using a limited sampling strategy (i.e. Bayesian estimators) and (ii) to lead prospective trials testing the potential impact of the therapeutic drug monitoring of MMF based on the AUC.

Autoantibody Testing for Children on Biologic Therapies for Rheumatological Conditions: Results of Audit. Julie Duncan, Jill Heath, Eileen M. Baildam, Gavin Cleary, Michael W. Beresford and Liza J. McCann. Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom

Background/Purpose: Biologic agents may cause auto-antibody formation and drug induced lupus but no paediatric guidelines exist regarding monitoring of auto-antibodies. The UK Royal College of Nursing Guidance advises checking ANA and anti-dsDNA before starting biologic treatment and repeating anti-dsDNA if concerned. A large tertiary paediatric rheumatology centre in the UK, Alder Hey, tended to test an autoantibody profile (see table) 3–6 monthly for data entry for the British Paediatric and Adolescent Rheumatology (BSPAR) Biologics and New Drugs Registry (BDNR). Children receiving IV biologic administration often had automatic antibodies testing more frequently, sometimes 4–6 weekly.

Methods: A retrospective audit of a 2 year period, August 2008 to July 2010 was carried out to determine frequency of abnormal autoantibody results in children on biologic therapies at a large tertiary paediatric rheumatology centre. All patients on biologics were included with data on auto-antibodies collated using the hospital computer system. Data were analysed including frequency of abnormal results and a cost analysis of tests done. The results were used to devise a rational protocol for frequency of testing.

Results: 111 children were receiving biologic therapy and 2511 auto-antibodies were tested at a cost of over £26,000.

Diagnosis of patients receiving biologic therapies	No. of Patients
JIA	102
SLE	1
JDM	2
Scleroderma	2
Uveitis (without arthritis)	2
Systemic sclerosis	1
Sarcoid vasculitis	1

Antibody	No. of children with positive results/ No. children with antibodies checked [%]	No. of positive antibodies/ No. antibodies checked [%]	Comments
ANA	80/111 [72%]	431/540 [79%]	36 children [32%] ANA always +ve; 44 children ANA sometimes +ve but not always.
Anti ENA	4/109 [<4%]	18/501 [<4%]	Always non-specific. Negative on subsequent testing.
Anti dsDNA	1/111 [<1%]	2/510 [<1%]	Negative on subsequent testing.
ANCA	14/41 [34%]	25/66 [38%]	Always non-specific (non PR3/ MPO).
Anticardiolipin	6/98 [6%]	8/894 [<1%]	Negative on subsequent testing.

Conclusion: With the exception of ANA antibody, all other antibody tests were usually negative. Those that were positive tended to be non specific (ie. ANCA non-PR3/MPO; ENA no specific specificity) and/or were negative on subsequent testing. The results did not alter patient care yet costs are significant. This audit would suggest that antibody tests are checked too frequently at Alder Hey Hospital. A new protocol as a result of this audit recommends testing auto-antibodies annually in the absence of clinical signs / symptoms of lupus.

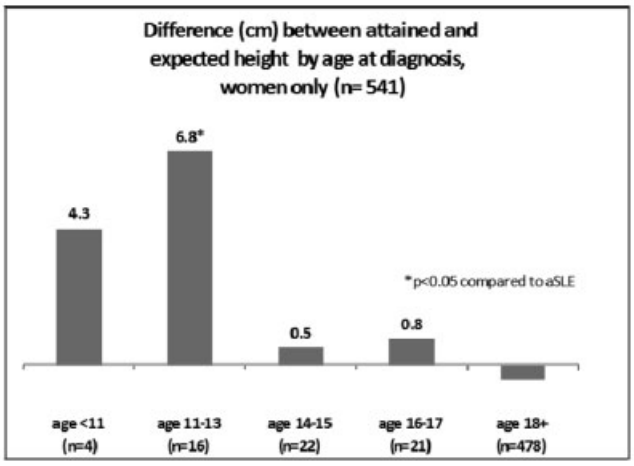
2031

Effects of Pediatric-Onset Systemic Lupus Erythematosus on Final Linear Height: Evidence From a Large Observational Cohort. Laura Trupin[1], Aimee O. Hersh[2], Jinoos Yazdany[3], Erica F. Lawson[1] and Emily von Scheven[1]. [1]UC San Francisco, San Francisco, CA, [2]University of Utah, Salt Lake City, UT, [3]University of California San Francisco, San Francisco, CA

Background/Purpose: Children with systemic lupus erythematosus (SLE) are at risk for decreased and delayed growth due to the effects of glucocorticoid exposure and the disease itself on skeletal bone development. However, due to lack of follow-up data, little is known about the final height attainment of patients with pediatric SLE. Using a large cohort of adults with SLE, we compared expected and actual heights for those diagnosed in childhood and adulthood.

Methods: Data derive from the 2007 cycle of the Lupus Outcomes Study (LOS), an annual telephone survey of diverse English-speaking adults with confirmed SLE. Subjects reported their current height and both parents' heights. Subjects aged 18–60 years with complete height data (N=580) were included. We defined pediatric-onset SLE (pSLE) as age at diagnosis < 18 years (N=72). Expected height was estimated by the Tanner formula, a validated measure for calculating midparental height. We used linear regression to compare the difference in expected and final linear height for pSLE and adult-onset SLE (aSLE) subjects, before and after adjustment for current age, gender, ethnicity, and end stage renal disease (ESRD). We examined expected vs. final height by age at diagnosis for pSLE women only, as there were too few men for a stratified analysis.

Results: Mean age of subjects was 43±10 years; 93% were female; 32% were ethnic minorities (9% Hispanic, 7% African American, 11% Asian, 5% other). PSLE subjects were younger ($p<0.01$), more likely to be nonwhite ($p<0.01$), and to report ESRD ($p=0.01$). Mean age at diagnosis was 14±3 years for pSLE and 34±10 years for aSLE subjects. Mean disease duration was 15±10 years for subjects with pSLE and 11±7 years for subjects with aSLE. Among pSLE subjects, the average difference between expected and final height was 2.4cm (95% CI 0.7–4.1), significantly greater than for aSLE subjects (−0.5cm; 95%CI −1.0–0.6; $p<0.01$). Thirty-one percent of pSLE subjects were ≥5cm below expected heights as compared to 14% of aSLE subjects, a difference seen in both men and women. Controlling for age, gender, ethnicity, and ESRD slightly increased the effect of pediatric onset disease on final height (adjusted mean: 2.8cm, 95% CI 1.1–4.4). No other variable in the model was associated with final height. Among women with pSLE, most of the effect on difference between expected and final height was seen in those diagnosed between age 11–13 years (see figure).



Conclusion: In this observational cohort of adults with SLE, we find a significant association between pediatric onset disease and shorter than expected adult stature. Patients who are peri-pubescent at disease onset may be at particular risk for growth delay. A larger, prospective cohort would allow for examination of the effects of disease activity and glucocorticoid use on final height attainment and better define which pediatric SLE patients are at highest risk for delayed or decreased growth.

2032

"Living Well" Chronic Disease Self-Management Program for Adolescents with Rheumatic Disease. Sheetal Vora[1] and Elizabeth L. Roth-Wojcicki[2]. [1]Medical College of Wisconsin, Milwaukee, WI, [2]Medical College of WI, Wauwatosa, WI

Background/Purpose: Chronic health conditions (CHC) in adolescents is a critical issue with estimates of 12–18% affected and with 6.5% experiencing disability. Childhood rheumatic disease contributes to increasing morbidity and costs of medical care and decreased health related quality of life (HQRL). Studies in CHC have demonstrated that self-management interventions that augment medical treatments improve health outcomes and HRQL. Evidence of the effectiveness of self-management therapies in adolescents has been sparse. The purpose of this research is to evaluate an adult self-management program (SMP) for its effectiveness in adolescents with rheumatic disease.

Methods: 15 adolescents, ages 13–20, together with their parents, followed in the rheumatology clinic at the Children's Hospital of Wisconsin (CHW) for greater than 3 months with a documented rheumatic disease were asked to participate. All were English speaking, and with no known cognitive delays. The program consists of 6 weekly sessions lasting 2 hours. To evaluate effectiveness of CDSMP, adolescents completed qualitative instruments including demographics, visual analog score of general health of adolescent by both parent and adolescent, general health symptoms (discouraged, worry, frustrated), self-management efficacy (SME), quantifying health service utilization, Peds QL Rheumatology and Peds QL Inventory teen reports. Data was collected at baseline, program completion and 3 months post program. Repeated measures analysis of variance with multiple comparisons corrections was used to identify changes from baseline.

Results: Demographics revealed that 60% were white, all were attending school, 60% came from a 2 parent household and 60% had the diagnosis of juvenile idiopathic arthritis, with the remainder either systemic lupus erythematosus or other defined rheumatic disease. Statistically significant variables found an increase in hospital and emergency visits ($p=0.029$) at each measurement; and increase in SME ($p=0.011$) and communication, a subscale of SME ($p=0.037$) from baseline to 3 months post program. Urgent care doctor visits, hospitalizations and missed doctor visits showed no significant (NS) difference. General health symptoms, discouraged and frustrated, showed improvement (NS) from baseline to 3 months post program only; worried improved successively (NS). Peds QL Inventory subscales; physical health showed no difference; emotional social and school functioning, and psychosocial health all showed improvement from baseline to 3 months post program (NS). Peds QL Rheumatology subscales pain and hurt, daily activities, treatment, worry and communication had no improvement.

Conclusion: CDSMP effectiveness in adolescents with rheumatic disease showed significant improvement in self-management efficacy and communication related to SME. General health symptoms and Peds QL Inventory subscales documented improvement despite an apparent increase in doctor hospital and emergency visits. Future plans include development of an adolescent SMP to improve self-management skills and allow for evaluation of health care utilization, health behaviors and status, and HRQL.

2033

Ethnic Differences of Early Disease Severity in Pediatric Systemic Lupus Erythematosus At An Urban Tertiary Care Center. Jennifer M.P. Woo[1], Peony Liu[2], Miriam F. Parsa[1], Gil Amarilyo[1], Alice DC Hoftman[2], Deborah K. McCurdy[2] and Ornella J. Rullo[2]. [1]University of California, Los Angeles, Los Angeles, CA, [2]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA

Background/Purpose: Systemic lupus erythematosus (SLE) can be characterized by increased incidence and disease severity in individuals of non-European descent. However, there exists a paucity of information describing disease manifestation at presentation and during the early stages of the disease process in pediatric SLE patients of different racial and ethnic backgrounds. We hypothesize that non-Caucasian pediatric SLE patients (pSLE) have an earlier, more severe disease course compared to Caucasian patients.

Methods: We retrospectively reviewed the medical records of 152 patients with pSLE (diagnosis $<$ 18 years) treated at an urban tertiary-care center between 2000 and 2010. Demographic and socioeconomic data were collected for each subject. ACR SLE criteria and SLE Disease Activity Index (SLEDAI) were evaluated at diagnosis, and any renal biopsy results were recorded. All subjects were assessed for cumulative steroid use, use of additional immunosuppressive agents, and urine protein-creatinine ratios at 12 months. Comparison of these data between Hispanic- (HA), Asian- (A), African- (AA), and Caucasian-(CA) American pSLE for was conducted using computed means, 95% confidence intervals, Student's one-tailed t-test, and Fisher's exact test.

Results: HA, AA, and A pSLE patients were diagnosed at a younger age than CA pSLE ($p < 0.05$; Table 1). Although the number of ACR criteria at diagnosis did not differ among the groups compared to CA, AA and HA were more likely to have arthritis at diagnosis than CA (44% and 37% vs 25%; $p = 0.007$ and 0.09, respectively). Furthermore, A and HA were more likely to present with proteinuria than CA (42% and 44% vs. 25%, $p = 0.02$ and 0.007, respectively) although prevalence of renal involvement by ACR criteria at SLE diagnosis only reached statistical significance in A vs CA (53% vs 38%; $p = 0.047$). Interestingly, increased rates of abnormal urine protein-creatinine ratios were observed at 12 months after SLE diagnosis in the HA and AA groups (64% and 40% vs. 25% in CA; $p < 0.0001$ and 0.03, respectively), but not in A (33%; $p = 0.3$ vs. CA). Over the first 12 months, significantly more HA, AA, and A required $>$150mg/kg of cumulative steroids compared to CA subjects ($p \leq 0.03$ for all) with additional immunosuppressive agents required for HA, AA, and A (Table 1). Of note, non-CA groups were significantly more likely to have government-assisted insurance and HA and AA tended to live in areas of significantly lower median family income compared to CA (Table 1).

Table 1. Clinical and socio-economic characteristics of CA, HA, AA and A rSLE patients.

	CA (n = 21)	HA (n = 68)	*p**	AA (n = 27)	*p**	A (n = 33)	*p**
Female:male	18.3	57.11		22:5		27.6

Sociodemographic							
Median household income, $‡‡	59,437	39,484	<0.0001	49,739	0.01	57,047	0.4
Insurance status, %			<0.0001		<0.0001		0.01
Uninsured	5	2		4		0	
Government	9	62		39		23	
Private	86	36		57		77	

CA-Caucasian; HA-Hispanic American; AA-African American, A-Asian American
* *p*-values taken in comparison to CA values and considered significant at $p < 0.05$
† % of patients requiring cumulative prednisone >150mg/kg in 1st year after diagnosis
†† Number of immunosuppressive agents required in addition to steroids and/or hydroxychloroquine in 1st year after diagnosis
‡ Urine PL/Cr >0.2 at 1 year after SLE diagnosis
‡‡ Based on 1999 US census figures for zip codes of patients at diagnosis

Conclusion: Pediatric patients of non-Caucasian background were diagnosed with SLE at a younger age, seemed to differ from Caucasian-American groups in SLE presentation, and had a potentially more severe early disease course, including increased immunosuppressive requirements. Prospective studies will help to clarify differences between these groups and to determine impact of socioeconomic factors.

2034

Clinical Characteristics of Children with Juvenile Dermatomyositis Recruited within the First 11 Months of the Children's Arthritis and Rheumatology Research Alliance Registry (CARRAnet). Mark F. Hoeltzel[1], ML Becker[1], Angela B. Robinson[2], Adam M. Huber[3], Brian M. Feldman[4], Ann M. Reed[5] and Juvenile Myositis CARRA Subgroup for CARRAnet Investigators[6]. [1]Children's Mercy Hospital, Kansas City, MO, [2]Rainbow Babies and Childrens Hospital, Cleveland, OH, [3]Dalhousie University, Halifax, NS, [4]The Hospital for Sick Children, Toronto, ON, [5]Mayo Clinic, Rochester, MN, [6]Various

Background/Purpose: Performing quality research in juvenile dermatomyositis (JDM) is difficult due to the rarity of the disease. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) initiated a multicenter observational cohort study to create a foundational clinical database for the major rheumatic diseases of childhood, including JDM. Initial data from the JDM cohort (prevalent and incident cases) enrolled in the first 11 months are described here.

Methods: Patients under the age of 21 yrs with onset of JDM prior to 16 yrs of age were included. JDM was established using modified Bohan and Peter criteria. IRB approval was obtained at each enrolling site. Subjects or their guardians gave consent, and clinical data were collected from the patients/guardians and medical providers using both general and

JDM-specific case report forms at the time of enrollment. Data regarding demographics, disease characteristics, diagnostic assessments, and medication exposure were collected. Measures of muscle strength, physical functioning, and quality of life were performed, including the Childhood Myositis Assessment Scale (CMAS), Childhood Health Assessment Questionnaire (CHAQ), Health Related Quality of Life measure (HRQOL), ACR Functional Class rating, global disease assessments, and pain scores.

Results: Over an 11 month period, 198 subjects with JDM were enrolled from 40 sites in the U.S. A summary of subject demographics and disease characteristics is provided in Table 1. At enrollment, the median (quartiles) CMAS score was 51 (46, 52), range from 0–52, the median CHAQ score was 0 (0, 0.5), range from 0–3, and the median physician and subject global assessment scores were 1 (0, 2), range from 0–8, and 1 (0, 3), range from 0–9, respectively. HRQOL rating, ACR functional class, and pain scores are represented in Figure 1.

Table 1. Demographics and Disease Characteristics

Characteristic	Number (%) of Subjects	Range, yrs	Characteristic	Number (%) with characteristic *ever*	Number (%) with characteristic *at enrollment*
Sex			Elevated muscle enzymes	190/196 (97%)	21/196 (11%)
Female	147 (74%)		Arthritis	74/190 (39%)	7/190 (4%)

Non-Hispanic	169 (60%)		Severe	–	2/197 (1%)
Hispanic	29 (15%)		Periungual telangiectasia	–	79/190 (42%)
1° Family hx of autoimmunity	35/179 (20%)		Malar or facial erythema	–	59/197 (30%)
Positive ANA	100/163 (61%)		Contractures	–	16/198 (8%)
Chronology	Median, yrs (quartiles)	Range, yrs	V or shawl sign	–	10/198 (5%)
Age	10.8 (7.7, 14.5)	2.4–21.0	Lipodystrophy	–	9/198 (5%)
Age of onset	6.2 (3.5, 9.3)	0.2–15.9	Skin ulcer	–	6/197 (3%)
Disease duration	3.7 (1.9, 5.9)	0.2–14.0	Gottron sign, papules, or heliotrope	–	89/198 (45%)
Time to rheumatologist	0.38 (0.16, 0.90)	0–5.1			

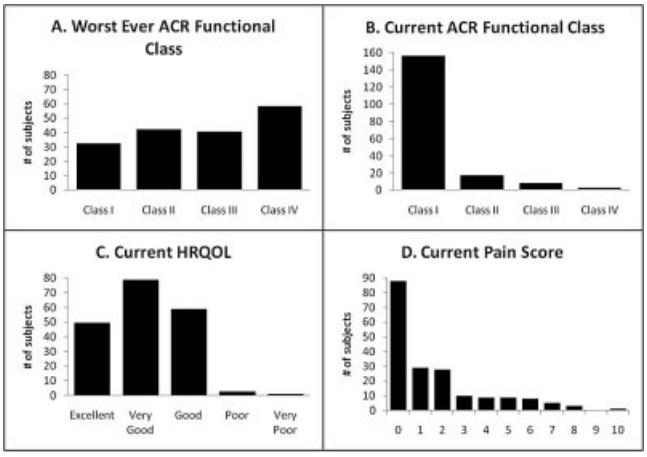

Figure 1.

Conclusion: The ongoing CARRAnet registry has collected clinical data on 198 children with JDM and has the potential to become one of the largest JDM cohorts in the world. Subject demographics are similar to other reported JDM cohorts from the U.S. and elsewhere. This is the first U.S. study to report prevalence of disease manifestations and functional and quality of life outcomes in a cross-sectional manner. The relatively mild disease severity observed at enrollment likely reflects the disproportionate number of prevalent cases collected to date, and is similar to other international cross-sectional JDM cohorts. This registry provides the infrastructure needed to advance clinical and translational research and represents a major step towards improving outcomes of children with JDM.

2035

Outcome of Babies Born to Mothers with Systemic Auto-Immune Diseases. Noemie Abisror[1], Arsene Mekinian[1], Eric Lachassinne[2], Pascale nicaise-Roland[3], Jerome Stirnemann[4], Loic de Pontual*[2], Lionel Carbillon[5] and Olivier Fain[4]. [1]Jean Verdier Hospital, Bondy, France, [2]Service de néonatologie et pédiatrie, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France, Bondy, France, [3]Unité Fonctionnelles d'Immunologie «Autoimmunité et Hypersensibilités», AP-HP, Hôpital Bichat-Claude Bernard, Paris, Paris, France, [4]Service de médecine interne, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France, Bondy, France, [5]Service de gynécologie-obstétrique, Université Paris 13, AP-HP, Hôpital Jean Verdier, 93140, Bondy, France, Bondy, France

Background/Purpose: To evaluate the neonatal complications, the long-term outcome and the immunological profile of babies born to mothers with primary antiphospholipid syndrome and lupus erythematosus.

Methods: Retrospective study from 2003 to 2010, assessing the clinical characteristics and psychomotor development, as well as biological data of children born to mothers with antiphospholipid syndrome (APS) (Group 1) and systemic lupus erythematosus (Group 2).

Results: Group 1 consisted of 45 children born to mothers (n=35) with a primary APS (median age 33 years [27–44]). The treatments during pregnancy were aspirin 100 mg (n = 31) and low-molecular weight heparin (LMWH) (n=35). Premature term < 37 weeks was present in 6 cases (13%). The median weight at birth was 3000 grams [920–4100], and 8 children had a weight < 2500 grams (18%) (table). The median follow-up was 11 months [1–72]. Since no thrombosis, or lupus were noted, an abnormal psychomotor development occurred in 5 cases [motor distal disorders (n=2) and autism (n =3)], associated with a language delay in 5 cases (11%). Three children with autism had persistent antibéta2GP1 IgG antibodies.

	APS group children (n=45)	Lupus group children (n=13)
Term	38 [32–41]	38 [37–41]
Term <37 weeks	6 (13%)	0
Birth weight (g)	3000 [920–4110]	3000 [2500–4000]
Birth height (cm)	49 [37–58]	49 [44–52]
Birth cranial perimeter (cm)	34 [30–39]	34 [32–50]
Apgar 1/5 minutes	10 [9–10]/10 [5–10]	10 [9–10]/10 [10]
Birth weight<2500 g	7 (18%)	0
Psychomotor development trouble	5 (13%)	0
Neonatal lupus	0	3 (23%)*
Follow-up (months)	11 [1–72]	9 [3–48]
Antinuclear antibodies	0 [0–80]	320 [0–1280]*
Anti-SSA antibodies	0	4 (31%)

*p<0.05

Group 2 consisted of 13 children born to mothers with systemic lupus (n=10) (median age 37 ([31–42]).) During pregnancy, treatments were aspirin 100 mg in association with low-molecular weight heparin (n = 6), hydroxychloroquine (n=8) and corticosteroids (n=8). Median birth weight was 3000 grams [2500–4000], and no preterm birth or weight<2500 g were noted (table). During follow-up of 9 months [3–48], three children experienced cutaneous neonatal lupus, but there were no thrombosis, or psychomotor development abnormalities. Antinuclear antibodies were present in 8 children (320 UI [0–1280]), and anti-SSA antibodies in 4 cases. Significant correlation was noted between antinuclear antibodies in mothers and children of group 2 (r =0.9; p = 0.01).

Comparing the characteristics of group 1 and 2, no significant difference was found with regard to the parameters at birth, during the follow-up or the presence of antiphospholipid antibodies. The children in Group 2 had more frequently antinuclear antibodies (p < 0.05), with median titers 320 UI [0–1280] in group 2 versus 0 [0–80] in group 1 (p = 0.0002).

Conclusion: Despite a significant rate of premature birth in babies born to mothers with APS, it does not seem to be increase of psychomotor development abnormalities. Nevertheless the presence of 3 cases of autism and of disorders in language acquisition should be analysed in a

study with a control group. The presence of anti-nuclear antibodies and neonatal lupus is more common in children born to mothers with lupus, inversely of children from APS mothers, in concern to antiphospholipid antibodies and thrombosis.

2036

Accrual Damage Assessment In Juvenile-Onset Systemic Lupus Erythematosus. Juan G. Ovalles, Julia Martínez-Barrio, Francisco J. López-Longo, Inmaculada de la Torre, Lina Martínez-Estupiñán, Juan C. Nieto and Luis Carreño. Gregorio Marañón Hospital, Madrid, Spain

Background/Purpose: Several studies have shown that patients with juvenile-onset systemic lupus erythematosus (JOSLE) develop more organ involvement and accrue irreversible damage at faster rates than adult SLE patients[1–4]. To investigate the frequency of cumulative organ damage in JOSLE and its association with demographic, clinical and immunological variables.

Methods: Data was obtained from a single-center inception cohort of 92 cases diagnosed at 18 years old or less between 1986 and 2006. Demographic, clinical and laboratory features were collected at disease onset and every 12 months with a minimum follow-up time of 1 year (median 12, 1–20). Damage was scored at the end of the study using SLICC/ACR Damage Index. Sera samples were tested for autoantibodies, complement and immunoglobulins. Student′s T, Chi-square or Fisher′s exact test was applied for bivariate analysis and multiple logistic regression for multivariate analysis.

Results: Overall, 68% patients had organ damage (SLICC/ACR≥1) with a mean score of 1.8. At disease onset renal involvement was associated with the presence of damage (p<0.002). Developing irreversible system damage was related to anaemia (p=0.006), thrombocytopenia (p=0.001), arthritis (p=0.01), neurologic (p<0.001), renal (p=0.002), hypertension (p=0.001) and musculoskeletal (p=0.02) manifestations during the follow-up. Also the accrual damage has shown relation with evolution time (p=0.009). The genre and mortality was no related to SLICC/ACR score (p>0.05). In logistic regression models, the occurrence of anaemia, arthritis, renal manifestations during follow-up and longer disease duration showed the strongest association with the presence of damage.

CHARACTERISTICS n=92	SLICC/ACR = 0 (n=29)	SLICC/ACR ≥ 1 (n=63)	p
At Disease Onset			
DEMOGRAPHIC FEATURES			
Sex Ratio (Female/Male)	8.6 (26/3)	5.2 (53/10)	NS
Age, Mean±SD	12.1±4.5	13.3±3.1	NS
CLINICAL MANIFESTATIONS (%)			
Renal	0 (0)	16 (25.4)	0.002
During Follow-Up			
Arthritis	20 (69)	57 (92)	0.01
Neuropsychiatric	2 (6.9)	35 (55.6)	<0.001
Renal	12 (41.4)	46 (73)	0.002
Hypertension	4 (13.8)	31 (49.2)	0.001
Musculoskeletal	3 (10.3)	21 (33.3)	0.02
Anaemia	12 (41.4)	45 (71.4)	0.006
Thrombocytopenia	1 (3.4)	21 (33.3%)	0.001
Disease Duration, Mean±SD	9.7 ± 5.6	14.8 ± 9.6	0.009
Exitus Letalis	0 (0)	7 (11.3)	NS

Best Predictor Logistic Regression Model for JOSLE patients with cumulative organ damage vs. patients without damage

	Odds Ratio	95% CI	p
Renal manifestations during follow-up	6.4	1.9–21.5	0.003
Anaemia	3.2	1.1–9.5	0.036
Arthritits	8	1.7–37.5	0.008
Evolution time	1.1	1.1–1.2	0.005

Conclusion: We found evidence of cumulative organ damage in 68% of the JOSLE cases. Damage was significantly more likely in patients who had experienced renal manifestations at diagnosis, had longer disease duration, anaemia, arthritis and renal manifestations during follow-up. Autoantibodies, in spite of being helpful for the diagnosis and prediction of SLE's activity, are not useful to predict damage.

2037

Low Vitamin D in Juvenile Onset Systemic Lupus Erythematosus: Association with Disease Activity and Low Bone Mineral Density. Luciana P.C. Seguro[1], Caio B. Casella[1], Liliam Takayama[2], Eloisa Bonfa[3] and Rosa M.R. Pereira[4]. [1]University of Sao Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]University of Sao Paulo, São Paulo, Brazil, [4]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil

Background/Purpose: Vitamin D plays an essential role in calcium homeostasis and bone health. There is also growing evidence that vitamin D may be involved in immunoregulation but there are few data regarding Juvenile onset SLE (JoSLE). This is the first study that evaluates vitamin D, bone mass and lupus activity concomitantly in this group of patients. The aim of this study was, therefore, to evaluate 25 hydroxyvitamin D (25OHD) levels in JoSLE patients and its possible association with disease activity, treatment, bone mineral density (BMD), body composition (BC).

Methods: Fifty-seven JoSLE patients were compared to 37 healthy controls. Disease activity was evaluated by SLEDAI. The serum concentration of 25OHD was used to measure the vitamin D reserves using a radioimmunoassay technique (DiaSorin, Stillwater, MN, USA). The intra and inter-assay variation coefficients were 16.6% and 22.6%. BMD and BC were measured using dual-energy X-ray absorptiometry (DXA).

Results: 25OHD levels were similar in patients and controls (21.44±7.91 vs. 22.54±8.25 ng/mL, $p=0.519$), despite vitamin D supplementation in 65% of patients and none in controls. The mean vitamin D supplementation was 429 UI/day. Patients with low levels of vitamin D (≤ 20 ng/mL) presented higher SLEDAI (3.10 ± 3.90 vs. 1.08 ± 2.50, $p=0.033$), lower C4 levels (12.79 ± 6.78 vs. 18.38 ± 12.24 mg/dL, $p=0.038$), lower lumbar spine BMD (0.798 ± 0.148 vs. 0.880 ± 0.127 g/cm^2, $p=0.037$) and whole body BMD (0.962 ± 0.109 vs. 1.027 ± 0.098 g/cm^2, $p=0.024$) compared with patients with vitamin D level >20ng/mL. BC was similar in both groups of patients (lean mass: 37.03 ± 7.79 vs. 38.40 ± 8.98 kg, $p=0.549$, fat mass: 18.17 ± 7.80 vs. 17.57 ± 6.67 kg, $p=0.764$) likewise the frequency of previous ($P=1.0$) and current use of glucocorticoids (GC) ($P=1.0$) and immunosuppressors (71 vs. 77%, $P=0.765$), and mean current daily dose of GC (14.19 ± 13.62 vs. 10.48 ± 15.78 mg/day, $P=0.345$).

Conclusion: Vitamin D insufficiency was associated with JoSLE flares and low bone mass independent of current CG dose, fat percentage and conventional vitamin D supplementation. This finding suggests that higher doses of vitamin D supplementation may be recommended not only for JoSLE with reduced BMD but also for those with active disease.

2038

Use of Urinary Metabolites to Distinguish Proliferative From Membranous Lupus Nephritis. Shannen L. Nelson[1], Rina Mina[2], Lindsey Romick-Rosendale[3], Hermine Brunner[4], Michael Bennett[2], Joshua D. Pendl[4], Michelle Petri[5], Adnan Kiani[5], Prasad Devarajan[2] and Michael Kennedy[6]. [1]Cincinnati Children's Hospital, Cincinnati, OH, [2]Cincinnati Children's Med Ctr, Cincinnati, OH, [3]Miami University, Ohio, Oxford, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Johns Hopkins University School of Medicine, Baltimore, MD, [6]Miami University, Oxford, Oxford, OH

Background/Purpose: Lupus Nephritis (LN) is a severe complication of many patients with childhood-onset Systemic Lupus Erythematosus. Kidney biopsy is currently the standard for assessing LN, but due to their invasive nature is not done on a routine basis. The identification of specific and sensitive biomarkers may allow for more timely diagnosis of LN allowing for more prompt treatment. Objective: To identify urinary metabolites that discriminate between proliferative and pure membranous lupus nephritis (LN) as defined by the International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification using nuclear magnetic resonance (NMR) spectroscopy.

Methods: Metabolic profiling was conducted using urine samples of patients with proliferative LN but without membranous features (Class III/IV; n=7) or pure membranous LN (Class V; n= 7). Patients with primary focal segmental glomerulosclerosis (FSGS; n=10) and proteinuria served as disease controls. For each patient, information about demographic and clinical data was obtained a random urine sample collected to measure NMR spectra. Data and sample collection for patients with LN occurred around the time of kidney biopsy. Metabolic profiling analysis was done by visual inspection and principal component analysis.

Results: Urinary concentrations of the metabolite taurine were significantly higher with Class V LN as compared to Class III/IV LN ($p < 0.01$) (see Figure 1). There was also a trend towards lower urinary concentrations of the metabolite citrate with Class V LN as compared to Class III/IV LN ($p < 0.1$). Urinary concentrations of the metabolite hippurate were significantly higher with Class V LN as compared to FSGS but not different from Class III/IV LN ($p < 0.001$).

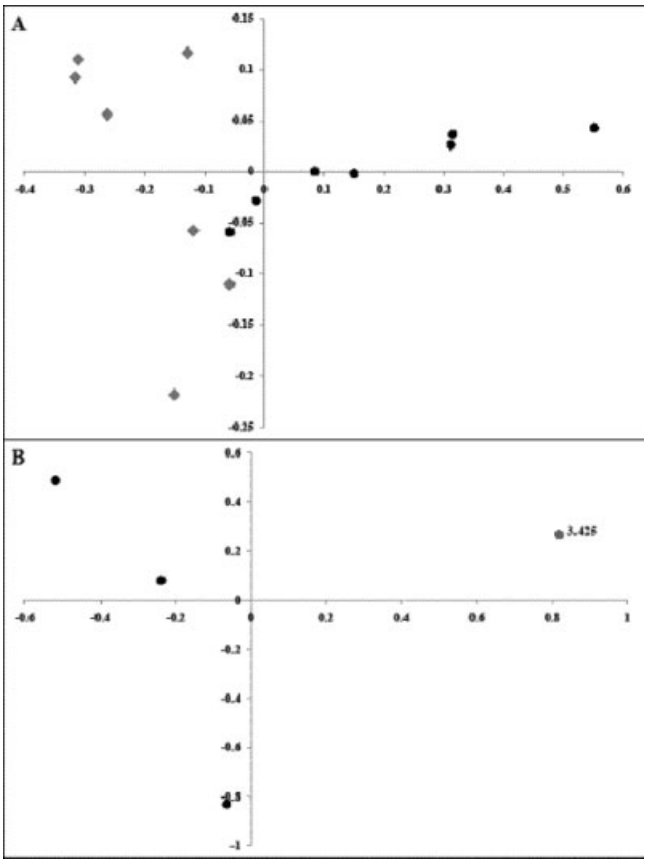

Figure 1. Principal Component Scores Plots of NMR-Spectra of Urine Samples with Proliferative and Pure Membranous Lupus Nephritis

Conclusion: This pilot study supports that there are differences in the urinary metabolite profiles of proliferative as compared to pure membranous LN. If confirmed in larger studies, these urine metabolites may serve as biomarkers to help discriminate between different classes of LN.

2039

Effectiveness of Anti-Tumor Necrosis Factor-α Agents in the Treatment of Refractory Juvenile Dermatomyositis. E.L. Boulter[1], L. Beard[2], Clive Ryder[3], Clarissa Pilkington[1] and Juvenile Dermatomyositis Research Group[4]. [1]Great Ormond Street Hospital, London, United Kingdom, [2]UCL Institute of Child Health, London, United Kingdom, [3]Birmingham Children's Hospital NHS Foundation Trust, Birmingham, United Kingdom, [4]London, United Kingdom

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare, chronic inflammatory disease. Anti-TNF-α agents are increasingly being used to treat disease that is refractory to other treatments. There is a lack of literature regarding the effectiveness of anti-TNF-α agents in JDM. The aim of the study was to describe the response of refractory JDM patients to anti-TNF-α agents.

Methods: The Juvenile Dermatomyositis National (UK and Ireland) Cohort Biomarker Study and Repository for Idiopathic Inflammatory Myopathies database was searched for patients treated with anti-TNF-α agents.

Results: INFLIXIMAB: 28/30(93%) patients had data available. Indicators for starting infliximab were: muscle weakness (70%), non-ulcerative skin disease (57%), calcinosis (33%), and nail fold changes (30%). All patients with a low CMAS (n=18) improved. Physician VAS improved in 20/26(77%), CHAQ score in 11/16(69%), skin disease in 19/23(83%), calcinosis in 6/13(46%) and muscle enzymes in 6/10(60%). Prednisolone dose decreased in 17/21(81%).

ADALIMUMAB: 10/11(91%) had previously been treated with infliximab. 6/10(60%) were changed to improve disease control: 4 had persistent skin disease, 2 improved; 3 had progressive calcinosis, 1 improved, 2 remained stable. 8/9(89%) maintained previous gains or made further improvement in other parameters other than skin and calcinosis.

ETANERCEPT: 4/7(57%) patients had data available. 2 improved, 2 were switched to infliximab, one for increasing calcinosis, one for compliance issues.

Conclusion: Infliximab provides clinical benefit to patients with JDM refractory to other treatments; particularly muscle weakness. Switching to adalimumab benefited some patients; gains made on infliximab were maintained in most cases.

2040

Treatment Delay in Kawasaki Disease—the Role of Non-Traditional Risk Factors. Nadia Luca[1], Joyce C. Y. Ching[1], Cedric Manlhiot[2], Brian W. McCrindle[2] and Rae SM Yeung[1]. [1]Hospital for Sick Children, Toronto, ON, [2]The Hospital for Sick Children, Toronto, ON

Background/Purpose: Duration of fever is the most important predictor of coronary outcome in children with Kawasaki Disease (KD). The aim of this study is to define a specific and comprehensive profile for patients at risk for a delayed diagnosis of KD, including non-traditional factors such as physician experience with KD and health service utilization.

Patients and Methods: All hospitals and pediatric cardiologists in Ontario were contacted for identification of patients diagnosed with KD over a 12 year period (1995–2006). The only tertiary hospital, with KD experts on-site, was the Hospital for Sick Children in Toronto. Data on demographic information, day of the week admitted, symptoms, clinical features, treatment, and coronary outcome were collected. Hospital caseload was defined as low (<20 cases of KD per year) or high (>20 cases per year). The primary outcome was the number of days of fever prior to treatment with intravenous immunoglobulin (IVIg). Secondary outcomes were the number of days between admission and treatment, and coronary outcome. Data analysis was performed using multivariable linear and logistic regression models. Estimates (est), with associated standard error, are reported, which represent the change in outcome associated with each increment of 1 unit (continuous) or the presence (binary) of the independent variable.

Results: 2378 children were included, 13% of which were treated after the tenth day of fever. Clinical features associated with a greater delay in treatment were consistent with previously reported traditional risk factors and included older age and fewer KD features. Patients at the extremes of age had a greater risk of coronary artery aneurysm (CAA) development.

Earlier year of diagnosis was associated with delay of 0.04 days in IVIg administration ($p<0.001$) and an increased incidence of CAA (est 0.07; $p=0.03$). Patients prescribed antibiotics had 0.67 days more fever at time of treatment ($p<0.001$). Children admitted to hospitals with lower KD caseloads had fewer days of fever at admission (est 0.0031; $p=0.005$), but had a greater delay between admission and IVIg treatment (est 0.002; $p=0.01$).

Children admitted on Sunday had 0.80 more days of fever at time of treatment with IVIg (est 0.80; $p=0.04$). In addition, admission on Sunday was associated with a delay of 0.30 days between the time of admission and treatment with IVIg (est 0.30; $p=0.04$). When the tertiary care centre was excluded both of these delays were more significant. When the tertiary care centre was analyzed separately, no pattern for day of the week was identified.

Conclusion: We have identified critical non-traditional risk factors including health care centre characteristics and caregiver factors as important contributors to delay in diagnosis and treatment of KD.

2041

Health Care Transition Improvement Utilizing Learning Collaborative and the New Six Core Transition Elements. Patience H. White[1], Peggy McManus[2], Jeanne McAllister[3] and Carl Cooley[3]. [1]Arthritis Foundation, Washington, DC, [2]National Alliance to Advance Adolescent Health, Washington, DC, [3]Center for Medical Home Improvement, Concord, NH

Background/Purpose: Transition for youth with special health care needs from pediatric to adult health care remains a challenge. Needs assessments of youth, families and pediatric and adult providers reveal the requirements for successful transition. Practice improvement processes have been successful in medical home initiatives and the timing is right for their application to assist practices to improve their health care transition processes in partnership with youth and families.

Methods: Got Transition?, the new federally funded National Health Care Transition Center, has brought together the collective knowledge, tools and supports to facilitate the use of quality improvement and collaborative learning methods in 3 US regions (Washington DC, Denver, Colo, Boston, Mass) to help practices improve health care transition for youth and their families. The learning collaboratives are using a new clinical report that provides explicit practice-level guidance that is jointly endorsed by the American Academy of Pediatrics, American College of Physicians and American Academy of Family Physicians. The six core elements for health care transition and the Health Care Transition Indices for both pediatric and adult practices have been created to bring the clinical report to life and make it operational. To date two of the three national learning collaboratives have been created in Washington DC and Denver, Colo. The learning collaboratives include pediatric, family medicine and internal medicine teams with physicians, residents, nurses, social workers and youth and family partners.

Results: The combined baseline results from the self rated transition indices for the 10 practices in Washington DC and Denver, Colo participating in the learning collaboratives showed the need for the learning collaborative process and practice level health care transition support. Each practice rated their ability on a scale of 0–8 on the transition indices for each of the 6 core transition elements. The rating scale uses 8 as being most prepared and 0 being the least prepared in a particular element on the transition indices. The average rating of the 10 practices in the 6 core elements for health care transition were as follows: policy/privacy development 2, knowledge and skills 2.25, identification population 2.1, transition preparation 2, transition plan 2.5, transfer 2.6. The clinical report, six core elements of transition, and the transition indices with the baseline results for each of the Washington DC and Denver practices and the lessons learned from the Washington DC learning collaborative in will be presented.

Conclusion: The learning collaborative process is a new approach for supporting practices to improve the quality of the care for their patients moving from pediatric to adult models of health care and can be utilized in both primary and subspecialty health care transition initiatives.

2042

Mycophenolate Mofetil (MMF) Versus Azathioprine As Maintenance Therapy Combined with Monthly Intravenous Cyclophsophamide (IVCY) in Juvenile Lupus Nephritis. Toshitaka Kizawa, Tomoyuki Imagawa, Tomo Nozawa, Masako Kikuchi, Tomonori Harada, Takako Miyamae and Shumpei Yokota. Yokohama City University, Yokohama, Japan

Background/Purpose: The treatment failure to IVCY (as induction therapy) with azathioprine (as maintenance therapy) still remains to be a big problem in juvenile lupus nephritis patients. There is a growing body of evidence for the use of Mycophenolate mofetil (MMF) for maintenance treatment of lupus nephritis intractable to IVCY plus azathioprine.

Methods: Accompanying with monthly IVCY (500 mg/BSA) as induction therapy for 12 months, MMF (initial dose 1,000 mg/day, increased to 1,500 mg/day) as maintenance therapy was initiated in 10 patients with juvenile lupus nephritis for the same period, and compared to IVCY plus azathioprine (2 mg/kg/day) in 14 patients. Small doses of prednisolone (PSL) were administered in both groups. The primary endpoint was the improvement of renal histology by ISN/RPS classification, serum C3, C4 and CH50 titers, and other serum markers of disease activity, SLEDAI and reduced PSL doses.

Results: Ten patients who treated with IVCY + MMF (2 males and 8 femailes) revealed a significant improvement of renal histology (5/7, 71.4%) compared to 14 patients (2 males and 12 females) treated with IVCY + azathioprine (4/10, 40.0%) after 12 months treatment (Figure). Oral PSL doses were less in IVCY + MMF group (8.7 mg/day) than IVCY + azathioprine group (11.1 mg/day). At 12 months later, both the titers of serum activity markers (C3, C4, CH50, creatinine, and albumin) and SLEDAI were found no differences between the two groups. Adverse events, cytopenia, abnormal liver function tests, and abdominal abnormalities were found in IVCY + azathiprine group but not in IVCY + MMF group.

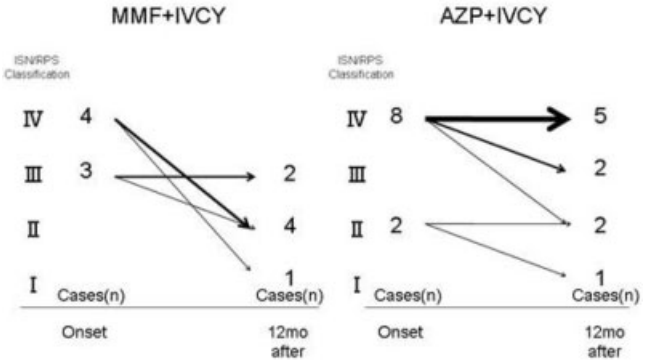

Figure.

Conclusion: MMF was well-tolerated, and efficacious as an induction therapy with monthly IVCY in patients with juvenile lupus nephritis.

2043

Inpatient Treatment Variation of Children Hospitalized with Complex Regional Pain Syndrome. Cara Hoffart[1], Pamela Weiss[2], Andrew J. Klink[3], David D. Sherry[3] and Chris Feudtner[4]. [1]The Childrens Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Division of General Pediatrics, Children's Hospital of Philadelphia; University of Pennsylvania Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA

Background/Purpose: Treatment for complex regional pain syndrome (CRPS) is comprised of intensive physical therapy, pain management, and psychological therapy. The pharmacologic and non-pharmacologic regimens used for CRPS treatment in children are incompletely characterized and optimal treatment is debated. The objective of this study is to characterize use of medications, physical therapy, and practice variation in CRPS treatment at U.S. children's hospitals.

Methods: We conducted a retrospective cohort study of children hospitalized between January 2004 and December 2009 with a discharge ICD-9-CM code for CRPS. We examined variation among 31 children's hospitals in the use of opioids and physical therapy services using multivariate mixed effects logistic regression models.

Results: During this 6-year study, we identified 644 individuals with 848 CRPS admissions. Physical therapy was prescribed for 583 patients (77.5%) during hospitalization. Pharmacologic drug therapy during admission included opioids (652 patients, 80.0%), non-steroidal anti-inflammatory drugs (493 patients, 60.5%), psychotherapeutics (511 patients, 62.7%), sedative hypnotics (206 patients, 25.3%), and anesthetics such as ketamine (245 patients, 30.1%). After adjustment for patient characteristics, hospitals varied significantly in their use of physical therapy, NSAIDs, anesthetics, psychotherapeutics, and sedative hypnotics ($p<0.001$). In contrast, hospitals did not differ significantly regarding administration of opioids.

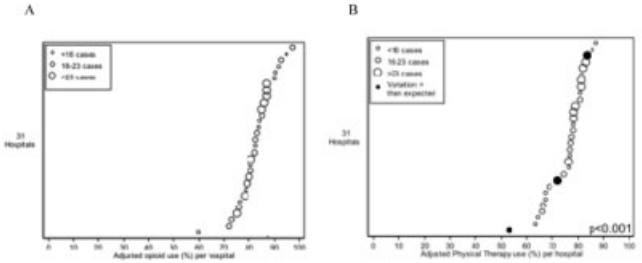

Figure 1. Use of Opioids (A) and PT/OT (B) among children's hospitals. There is no significant variation in opioid use across hospitals; however, the use of PT/OT is not uniform.

Conclusion: Significant variation in the inpatient treatment of CRPS exists across U.S. children's hospitals. Opioids are used consistently across hospitals in the majority of patients but the use of other drugs (psychotherapeutics, sedative hyponotics, anesthetics, NSAIDs) and PT/OT is not uniform. Future studies are warranted to evaluate whether these differences in treatment impact clinical outcomes such as duration and costs of hospitalization, readmission frequency, and further outpatient interventions.

2044

Children with Ehlers-Danlos Syndrome and Airway Dysfunction. Sanjay J. Khiani[1], Sara Lowe[1], Michael Zacharisen[1] and Sheetal Vora[2]. [1]Medical College of Wisconsin and the Children's Research Institute, Wauwatosa, WI, [2]Medical College of Wisconsin, Milwaukee, WI

Background/Purpose: Adults with hypermobility-type syndromes such as Ehlers-Danlos (EDS) have multiple issues including joint hyperextensibility, skin laxity/scarring, hearing, voice, speech, and swallowing disorders. Recent reports suggest a predominance of atopy and respiratory symptoms. Such information is not available in children. We report respiratory symptoms in children with EDS that complicates asthma or was erroneously diagnosed as asthma.

Methods: A series of 5 children with hypermobility-type EDS (1 and 3) presented to allergy/asthma clinic for evaluation of shortness of breath, chest tightness/pain, recurrent croup or chronic cough. At the discretion of their providers, evaluations included radiographic procedures, spirometry, videostroboscopy, rhinoscopy, largyngoscopy, methacholine challenge, airway fluoroscopy, and allergy testing.

Results: 5 children ages 9–14 years, 3 females, 2 siblings, all had recurrent respiratory symptoms and previously diagnosed as asthma. All had normal lung function with FEV1 96–124% of predicted. Only 2 had asthma confirmed with either reversible airway obstruction with albuterol or exercise pulmonary function test. One of these had 50% tracheal collapse and compression by aorta presenting as stridor. Two patients had environmental allergies confirmed by specific *in vitro* IgE or skin testing. Three patients had paradoxical vocal cord fold motion abnormalities on direct visualization with or without videostroboscopy. One had obstructive sleep apnea with 100% choanal obstruction by adenoid hypertrophy. Four of 5 had been diagnosed with GE reflux and 3 of these patients had g-tube placement and surgical intervention. Two patients had psychological issues such as anxiety and conversion disorder.

Conclusion: Children with EDS can have recurrent respiratory symptoms due to many etiologies including paradoxical vocal cord dysfunction, airway compression which may be erroneously attributed to asthma and possibly related to the underlying connective tissue abnormality.

2045

Cytomegalovirus in Pediatric Systemic Lupus Erythematosus: Screening and Therapeutic Implications. Evelyn V. Rozenblyum, Deborah M. Levy, Elizabeth Harvey, Diane Hebert and Earl D. Silverman. Hospital for Sick Children, Toronto, ON

Background/Purpose: Cytomegalovirus (CMV) is a beta-herpes virus. Its prevalence increases with age and infections may be severe or fatal in an immunocompromised host. Although there have been case reports of CMV in SLE patients, the relationship of CMV to SLE remains unclear as to which is the initial triggering disease. Determining the prevalence and outcome of CMV infection in pSLE would help establish the need for routine CMV testing prior to initiation of immunosuppressive therapy when indicated for pSLE. Currently, CMV is not routinely tested at the time of diagnosis of pSLE.

Objectives:

(1) Determine the incidence and prevalence of CMV infection at the time of diagnosis and during the course of pSLE.

(2) Determine if there are specific clinical and laboratory findings predictive of an active CMV infection.

Methods: Database review of all 540 patients seen in pSLE Clinic over a 20 year period identified 7 patients with SLE and concomitant CMV infection. Clinical manifestations, laboratory findings, virology studies and treatments were reviewed.

Results: CMV infection was detected in 7 adolescent patients; 6 (86%) at the time of diagnosis and one 5 years after diagnosis. Five were female and the mean age of the cohort was 14 years (10–17 years). All patients presented with fever, 6 had rash, 6 joint pain, 4 were nephrotic with peripheral edema and/or ascites, 3 respiratory symptoms, and 2 hepatomegaly. Six patients had nephritis and 2 required dialysis pre CMV detection. None of the patients were Caucasian- 4 patients were Asian (53%), 2 South East Asian (29%), and one Afro-Canadian (14%) ($p<0.01$ as compared to the total SLE cohort). Notable laboratory findings included: anemia in 6 (mean 101 g/L), lymphopenia in 5 with 3 patients having an absolute lymphocyte count of <500 cells (mean 1250 cells), hypoalbuminemia in 5 (mean 31 g/L) and mildly elevated liver function tests (LFTs) in 4. CMV was diagnosed by culture in 5 (urine in 3 and BAL in 2) and blood PCR in 2. All patients were on prednisone, 2 were on azathioprine and 1 was on cyclophosphamide prior to diagnosis of CMV infection. Six patients received gancyclovir and 5 Cytogam for CMV infection (1 patient received no therapy). All patients were maintained on prednisone throughout the treatment period. Six of 7 fully recovered without sequelae but one treated patient died during active CMV infection.

Conclusion: CMV infection was found in 6/540 (1.1%) patients at the time of diagnosis of pSLE. Non-Caucasian ethnicity, persistent fevers on prednisone, significant lymphopenia, abnormal LFTs and nephrotic syndrome were associated with CMV infection. We suggest routine testing for CMV at initial presentation of pSLE prior to immunosuppression.

2046

Alveolar Hemorrhage: Distinct Clinical Profile in Adult and Juvenile Systemic Lupus Erythematosus Patients. Daniel B. Araujo[1], Eduardo F. Borba Neto[1], Clovis A. Silva[1], Lucia M.A. Campos[1], Rosa M.R. Pereira[2], Eloisa Bonfa[1] and Samuel K. Shinjo[1]. [1]Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, [2]Disciplina de Reumatologia da FMUSP, Sao Paulo, Brazil

Background/Purpose: Alveolar hemorrhage (AH) is a rare and severe manifestation of systemic lupus erythematosus (SLE). Therefore, the aim of this study was to compare characteristics of AH in juvenile (JSLE) and adult SLE (ASLE) patients.

Methods: from January 1990 to January 2010, 28 out of 1785 SLE patients (13 JSLE and 15 ASLE) had AH in our tertiary hospital.

Results: JSLE and ASLE had comparable disease duration (2.6 ± 3.0 *vs.* 5.6 ± 7.0 years, $p=0.151$) with the mean age at AH diagnosis of 15.3 ± 2.7 and 28.7 ± 10.3 yrs for JSLE and ASLE, respectively. The frequency of AH events was significantly higher in JSLE [4.94% (13/263)] compared to ASLE patients [0.99% (15/1522)], $p<0.001$ and it was diagnosed at SLE onset in two (15.4%) JSLE and six (40.0%) ASLE patients $p=0.221$). Before AH event, the JSLE patients were using a higher mean dose of prednisone (>0.5mg/kg/day) when compared to ASLE 54% *vs.* 15%, $p=0.042$). Macrophage activation syndrome with macrophage hemophagocytosis was only observed in JSLE compared to ASLE patients with AH diagnosis (23% *vs.* 0%, $p=0.087$). Regarding outcomes, frequencies of death were significantly higher in JSLE than ASLE patients (69% *vs.* 13%, $p=0.006$), with a trend of higher frequency of mechanical ventilation use (85% *vs.* 47%, $p=0.055$). In spite of that, the mean drop of hemoglobin was significantly lower in JSLE patients (2.9 ± 0.9 *vs.* 5.5 ± 2.9 g/dL, $p=0.006$). All other demographical, clinical and laboratory features were alike in both groups ($p>0.050$).

Conclusion: This study revealed that AH is more prevalent in juvenile lupus with a worse outcome compared to adult SLE patients.

2047

CD146+ Endothelial Progenitor Cell Number Increases Following 36 Months of Atorvastatin Therapy in Children and Adolescents with SLE: The Atherosclerosis Prevention in Pediatric Lupus Erythematosus (APPLE) Cohort. Stacy P. Ardoin[1], Thomas Povsic[2], Laura E. Schanberg[3], Christy I. Sandborg[4], Huiman Barnhart[5], Eric Yow[5], Greg Evans[6], Kelly L. Mieszkalski[3], Norman T. Ilowite[7], Emily von Scheven[8], B. Anne Eberhard[9], Lisa F. Imundo[10], Yuki Kimura[11], Earl D. Silverman[12], Suzanne L. Bowyer[13], Marilynn G. Punaro[14], Nora G. Singer[15], David D. Sherry[16], Deborah K. McCurdy[17], Marisa Klein-Gitelman[18], Carol Wallace[19], Richard M. Silver[20], Linda Wagner-Weiner[21], Gloria C. Higgins[22] and Hermine Brunner[23]. [1]Ohio State University, Columbus, OH, [2]Duke University, Durham, NC, [3]Duke University Medical Center, Durham, NC, [4]Stanford University, Palo Alto, CA, [5]Duke Clinical Research Institute, Durham, NC, [6]Winston-Salem, NC, [7]Children's Hospital Montefiore, Bronx, NY, [8]UC San Francisco, San Francisco, CA, [9]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [10]Childrens Hospital of New York, Columbia University Medical Center, New York, NY, [11]Pediatrics, Hackensack, NJ, [12]Hospital for Sick Children, Toronto, ON, [13]James Whitcomb Riley Hospital, Indianapolis, IN, [14]Texas Scottish Rite Hospital, Dallas, TX, [15]Director, Division of Rheumatology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [16]Children's Hospital of Philadelphia, Philadelphia, PA, [17]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA, [18]Children's Memorial Hospital, Chicago, IL, [19]Childrens Hosp & Regional Med, Seattle, WA, [20]MUSC, Charleston, SC, [21]University of Chicago Hospital, Chicago, IL, [22]Nationwide Childrens Hosp, Columbus, OH, [23]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background/Purpose: Endothelial progenitor cells (EPCs) promote endothelial repair, and their number and function are reduced in adult SLE.

In the general population, statins decrease cardiovascular (CV) mortality, reduce EPC apoptosis and increase circulating EPCs. The impact of statins on EPCs has not been studied in SLE. We hypothesized that 36 months of statin therapy increase circulating EPC number in pediatric SLE (pSLE).

Methods: In the APPLE trial, 221 pSLE patients were randomized to receive atorvastatin or placebo. Carotid intima medial thickening (CIMT) was measured by b-mode ultrasonography using standard protocol. Lipids, high sensitivity c-reactive protein were measured after a 12 hour fast in a central laboratory. Samples were selected from subjects with CIMT and stored cell samples at 0, 12, 36 months (n=107).

Peripheral blood mononuclear cells (MNCs) were assayed using fluorescent antibodies against CD34, CD 133 and CD 146. Samples containing < 20,000 MNCs were excluded from analysis (n=35). EPC number was calculated as % of total MNC number.

Baseline characteristics were summarized using descriptive statistics. Differences between treatment groups were assessed with chi-square test, Fisher's exact test, or the nonparametric Wilcoxon test. Univariable relationships between CD 146+ cell subset and clinical variables were assessed, followed by multivariable linear regression modeling. All statistical analyses were 2-sided, and the level of significance was 0.05.

Results: At baseline, atorvastatin- (n=35) and placebo- (n=37) treated subjects had similar proportions of CD133+ CD34+, CD133+/34+ and CD146+ cells and did not differ according to age, gender, sociodemographics, BMI, renal status, disease duration or activity, or medications. In the placebo group, the proportion of CD133+, CD34+, CD133+/34+, and CD146+ cells did not change significantly over time. In the atorvastatin group, there were no significant changes from baseline in the CD133+, CD34+, CD133/34+ groups. The mean increase in proportion of CD146+ cells from baseline to 36 months was +1.48% (SD 1.0) in the atorvastatin group and +0.06% (SD 0.9) in the placebo group (p 0.011). In multivariable analysis, after covariate adjustment for age, gender, LDL, hscrp, prednisone dose, mean-mean CIMT, disease activity and damage, atorvastatin remained significantly associated with increase in CD 146+ cells (p 0.025; 95% CI 0.07, 1.04).

Conclusion: After 36 months of atorvastatin therapy, the proportion of CD146+ MNCs increased in the atorvastatin group but not in the placebo group. CD34+, 133+, 133+/34+ MNCs did not change significantly from baseline in either treatment group. Atorvastatin was independently associated with CD 146+ MNC increase in multivariable analysis. The CD146 marker is specific for EPCs but limitations include the following: EPC measurement is not widely standardized, normal values for adults and children are not defined, and clinically relevant magnitude of change in EPCs remains unknown. Despite these limitations, these exploratory analyses suggest that statin therapy may increase circulating EPCs, potentially enhancing capacity for CV repair in pSLE.

Serum Uric Acid Testing Patterns In Gout Patients: A Need for Improved Monitoring. Michael A. Becker[1], Bhavik J. Pandya[2], Jason R. Young[3], Xiangyang Ye[3], Sudhir Unni[3], Shawn Yu[2] and Carl V. Asche[3]. [1]University of Chicago Medical Center, Chicago, IL, [2]Takeda Pharmaceuticals International, Inc., Deerfield, IL, [3]University of Utah College of Pharmacy, Salt Lake City, UT

Background/Purpose: Hyperuricemia (serum urate level [sUA] >6.8 mg/dL) is the major pathogenetic factor in gout. Reducing sUA to subsaturating levels (usually recommended as <6.0 mg/dL) is an important goal for therapy. When goal range sUA is maintained long-term, urate crystal deposition ceases and even reverses, with eventual clinical benefits including reduction in gout flares, resolution of tophi, reduced pain, and improved physical function and quality of life. Monitoring of sUA is important for optimal long-term gout management, because it allows detection of the need for medication adjustment or confirms that chronic therapy is appropriate. Since stable levels of sUA are established within 2 to 4 weeks after initiation or escalation of oral urate-lowering therapy (ULT) with agents such as allopurinol and febuxostat, sUA measurement at biweekly to monthly intervals is an effective means to monitor ULT dose titration. Once goal range sUA is established, less monitoring is appropriate, but annual assessment of sUA in gout patients (pts) on ULT is frequently recommended. The purpose of this study was to evaluate current sUA testing patterns in gout pts in a real-world setting.

Methods: This retrospective study used an ambulatory care-based electronic medical record database with health records of primary care pts. Pts ≥18 years with diagnosis of gout (ICD-9 code 274.xx) and a prescription for allopurinol (ALLO) or febuxostat (FEB) from April 1, 2009 to Dec 31, 2009 and with 13+ months of database activity prior to and ≥6 months of activity after index date (first Rx of ALLO or FEB) were included. Pts with a diagnosis of neoplasm or with an Rx ≥2 ULTs on index date were excluded.

Results: The study included 17,542 ALLO-treated pts (mean age 65±12 years, 76% male) and 394 FEB-treated pts (mean age 62±13 years, 75% male). Of the 17,936 total pts included in the study, 7,998 (44.6%) had at least 1 sUA measurement in the year prior to index date. Only 4,721 (26.3%) pts had both a pre-index (within 1 year) and follow-up (anytime after index) sUA measurement. Of 564 ALLO-treated pts whose dose was adjusted at index date, 165 (29.3%) had a follow-up sUA measure reported. For those pts receiving a dosage escalation (378 patients), 95 (25.1%) had a subsequent sUA measurement compared with 70 of 186 pts (37.6%) who had the ALLO dose reduced. Median time to the first follow-up sUA was 56 days (mean: 67 days) for pts with a dose escalation and 73 days (mean: 71 days) for pts with a dose decrease. For the 394 FEB-treated pts, 216 (54.8%) had a follow-up sUA measure at a median time of 44 days (mean: 59 days).

Conclusion: Based on real-world data, sUA monitoring is not adequate for the majority of gout pts. As sUA measurement is the only immediate means to determine the effectiveness of therapy (clinical benefit is usually not apparent for many months to several years), improved sUA testing patterns could favorably influence the quality of care for gout pts by identifying those not at goal and allowing appropriate adjustments to ULT. The establishment of sUA testing pattern guidelines may improve testing patterns.

2049

Patient Reported Outcomes In a Single Community Based Rheumatology Practice—Outcomes Not As Good As We Think? Melinda K. Pemberton[1], Gary Runde[2] and Wendell D. Bronson[3]. [1]Heartland Clinic, St Joseph, MO, [2]Heartland Regional Medical Center, Saint Joseph, MO, [3]Heartland Clinic, St. Joseph, MO

Background/Purpose: Patient reported outcomes and benchmarking provide an opportunity for quality improvement initiatives. Collecting data in a community based clinical practice can be challenging. The Electronic Medical Record (EMR) makes patient reported outcomes readily recordable and queryable. We report RAPID 3 (routine assessment of patient index data) scores of all patients seen with RA who received care in 2010 in a single community based Rheumatology practice and identify opportunities for quality improvement and benchmarking.

Methods: A query of the EMR database identified 386 patients diagnosed with RA were seen between January 1, 2010 and December 31, 2010. The RAPID 3 was calculated at the time of each visit from patient reported questionnaires entered into the EMR. The EMR query identified the lowest and average reported RAPID 3 scores. RAPID 3 scores were reported in four groups (total range 0–30): 0–3 = remission, 3.01–6.0 = low disease activity, 6.01–12.0 = moderate disease activity, >12.01 high disease activity.

Results:

Total Patients = 386
68.9% Female (n=266)
31.1% Male (n=120)
Average Age = 63.3
Total Visits = 1202
Average # of visits/patient = 3.3

Average Reported RAPID3 RAPID3 Score	**#Patients**	**%Patients**
0–3	29	7.5%
3.01–6.0	42	10.9%
6.01–12.0	128	33.2%
>12	187	48.5%
TOTALS	386	100%

Lowest Reported RAPID3 RAPID3 Score	**#Patients**	**%Patients**
0–3	62	16.1%
3.01–6.0	63	16.3%
6.01–12.0	131	33.9%
>12	130	33.7%
TOTALS	386	100%

Conclusion: 31% of these patients were exposed to biologics agents for RA in 2010. The rate of remission using average and lowest RAPID 3 would be between 7.5–16%. High disease activity was reported 33–48% of the time. Our data suggests a low level of remission and a high level of moderate to severe symptomatology. Results of patient reported outcomes analysis in a community based Rheumatology practice differs from randomized controlled drug trial results. A snapshot of RA patient reported outcomes define sub groups receiving optimal therapy (RAPID 3 <3) and groups that might benefit from intensification of therapy or other interventions to reduce symptomatology (RAPID 3 >12). This or similar patient reported data may be useful in benchmarking between practices in the care of patients with Rheumatoid arthritis.

2050

Less-Experienced Rheumatologists Can Improve Agreement in the Detection of Clinical Synovitis Through Consensus in Rheumatoid Arthritis (RA). Peter Cheung[1], Vincent Andre[2], Natalie Balandraud[3], Gerard H. Chales[4], Isabelle Chary-Valckaneare[5], Emmanuel Chatelus[6], Emmanuelle Dernis[2], Ghislaine Gill[5], Melanie Gilson[7], Sandrine Guis[3], Thierry Marhadour[8], Gael Mouterde[9], Stephan Pavy[10], Francois Pouyol[11], Pascal Richette[12], Adeline Ruyssen-Witrand[13], Martin Soubrier[14], Maxime Dougados[15] and Laure Gossec[16]. [1]Hospital Cochin, Paris, France, [2]Centre Hospitalier, Le Mans, France, [3]Hopital de la Conception, Marseilles, France, [4]CHR—Hopital Sud, Rennes, France, [5]Hopital de Brabois, Nancy, France, [6]Hopital Hautepierre, Strasbourg, France, [7]CH Grenoble Hopital Sud, Grenoble, France, [8]CHU La Cavale Blanche, Brest, France, [9]Hopital Lapeyronie, Montpellier, France, [10]Hopital Bicetre, Paris, France, [11]Hopital de Roger Salengro, Lille, France, [12]Lariboisière Hospital, Paris, France, [13]Hopitaux de Toulouse, Toulouse, France, [14]CHU Clermont-Ferrand, Clermont-Ferrand, France, [15]Paris-Descartes University, Cochin Hospital, Paris, France, [16]Cochin Hospital, Paris, France

Background/Purpose: Synovitis assessment through evaluation of swollen joints (SJ) is integral in steering treatment decisions in RA, and in determining clinical remission. Studies indicate agreement in the assessment of SJ is low; there is limited data on practical methods of achieving consensus at the "joint level" among rheumatologists. The aim was to assess if a short collegiate consensus, would improve SJ agreement between rheumatologists, and whether this improvement was affected by experience.

Methods: 18 rheumatologists from French rheumatology University units participated in a half day national initiative. Clinicians were divided into groups of 4–5 and underwent two 30-minute rounds evaluating SJ in 9 RA patients with moderate disease activity, followed by short consensus discussions. Rheumatologists then assessed one additional patient as measurement of their final SJ agreement. Agreement was evaluated at the joint level, and according to level of experience of the rheumatologist; newly-qualified (<5 years), experienced (5–10 years) and very experienced (>10 years), expressed as kappa (k), proportion of positive agreement (synovitis) and negative agreement (no synovitis).

Results: In all, 9 male and 9 female rheumatologists participated, with median 9.5 years (Q1:Q3, 2.8:14.3) of experience. As seen in Table 1, there was only moderate agreement globally, with initial k=0.50 (95%CI 0.41–0.59) and no improvement over the 3 rounds. Rheumatologists agreed on the presence of synovitis 60% of the time and on the absence of synovitis 90% of the time, also with no improvement over the 3 rounds. When agreement was analyzed according to level of experience, SJ agreement of the "recently qualified" rheumatologists improved with k=0.28 (95%CI 0.05–0.51) going up to k=0.54 (95%CI 0.38–0.70) when compared to "very experienced" rheumatologists; and k=0.33 (95%CI 0.15–0.51) to k=0.47 (95%CI 0.31–0.64) when compared with "experienced" rheumatologists. The proportion of positive agreement (synovitis) between "recently qualified" and "very experienced" rheumatologists also increased from 40% to 64%. On the other hand, agreement between an "experienced" versus a "very experienced" rheumatologist was good initially, with k=0.74 (95%CI 0.61–0.87), but decreased over the subsequent 2 rounds.

Table 1. Agreement of swollen joints among the 18 rheumatologists and categorized according to level of experience

	Global	Recently qualified vs Experienced	Recently qualified vs Very Experienced	Experienced vs Very Experienced
Round 1				
Kappa (95%CI)	0.50 (0.41, 0.59)	0.33 (0.15, 0.51)	0.28 (0.05, 0.51)	0.74 (0.61,0.87)
Positive Agreement	60%	44%	40%	81%
Negative Agreement	90%	88%	87%	93%
Disagreement	31%	19%	21%	10%
Round 2				
Kappa (95%CI)	0.53 (0.46, 0.60)	0.49 (0.36, 0.63)	0.53 (0.37, 0.68)	0.42 (0.24,0.59)
Positive Agreement	61%	63%	63%	54%
Negative Agreement	87%	87%	88%	86%
Disagreement	33%	20%	17%	21%
Round 3				
Kappa (95%CI)	0.52 (0.44, 0.60)	0.47 (0.31, 0.64)	0.54 (0.38, 0.70)	0.42 (0.24,0.61)
Positive Agreement	58%	56%	64%	53%
Negative Agreement	90%	91%	90%	88%
Disagreement	33%	15%	15%	18%

Conclusion: "Recently trained" rheumatologists appeared to have improved their level of SJ agreement with a more senior rheumatologist although global SJ agreement for the study group did not change.

2051

A Clinical Microsystem Analysis of An Academic Rheumatology Practice Is High-Yield for Identifying Improvement Opportunities. Natalie B. Riblet, Alicia J. Zbehlik, Yvonne Y. Cheung and Daniel A. Albert. Dartmouth-Hitchcock Med Ctr, Lebanon, NH

Background/Purpose: The objective of this project was to complete a microsystem analysis of the Division of Rheumatology at Dartmouth-Hitchcock Medical Center (DHMC) as a basis for continual quality improvement work. We focused primarily on access and sufficiency of staffing as these problems are shared by many Rheumatology practices.

Methods: The Division of Rheumatology at DHMC is a referral-based, academic medical practice located in a tertiary care center in rural New Hampshire. In April and May 2011, we performed a detailed analysis of the Division of Rheumatology using a clinical microsystems approach. Data was obtained from the computerized Hitchcock Database Reporting System, a review of medical records, staff surveys and directly observations of routine clinic processes. Qualitative analysis included patient and staff interviews and a round-table discussion.

Results: Our findings indicate that access to the Division of Rheumatology is poor, with third next available new appointment being 107 days on May 1, 2011. Access acutely worsened with the introduction of a new electronic health record (EHR) in April 2011 from a baseline of 81 days on March 27, 2011. Stratified analysis of third next available appointment by staff provider clinical full time equivalent showed no statistically significant variation from the mean. Of approximately 12,500 patients seen annually, almost 3500 appointments were cancelled during 2010. Of these cancellations, 63% were due to inconvenient time or date. The initiation of an exit secretary to include patients in the scheduling process in January 2011 decreased the cancellations due to inconvenient day or time to 58%. Practice patterns included a lower than benchmark new patient to established patient ratio (17% DHMC vs. 38% benchmark), and fewer nurses per provider than Medical Group Management Association (MGMA) benchmarks (0.03 DHMC vs. 0.49 benchmark). Only one fifth of providers who responded to a survey during this time frame felt they had adequate nursing support. Clinic efficiency was negatively impacted by insufficient communication, providers leaving exam rooms to obtain paperwork and prescriptions, and lack of "huddles" to anticipate bottlenecks in flow. Formal data collection, analysis and display are not currently integrated into the daily work of the practice.

Conclusion: This analysis identifies multiple opportunities for improving access and work flows within the Division of Rheumatology at DHMC. Contextual factors such as adopting a new EHR may adversely impact patient access, at least temporarily. Interventions that include patients in the workflow such as an exit secretary may decrease redundant work. Incorporating meaningful use measures into the EHR's daily workflows may facilitate continual improvement and enhance patient care and outcomes. Access may be improved by adopting open access and patient initiated scheduling models. Microsystem analysis may benefit other Rheumatology practices by identifying high-yield targets for improvement and engaging stakeholders in improvement efforts.

2052

Scores for Sleep, Anxiety, and Depression on the Multidimensional Health Assessment Questionnaire (MDHAQ) in the Patient-Friendly HAQ Format Are Higher Than for Any of the 8 Traditional HAQ Queries to Identify Problems in Patients with Rheumatic Diseases. Isabel Castrejón[1], Yusuf Yazici[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: To compare scores for psychological queries concerning anxiety, depression and sleep in the patient-friendly HAQ format on a multidimensional health questionnaire (MDHAQ), compared to scores for the 8 MDHAQ activities from the traditional HAQ and 2 unique MDHAQ complex activities, "walk 2 miles" and "participate in sports and recreation", in 1,583 patients with rheumatic diseases, and subsets with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), osteoarthritis (OA), fibromyalgia, and other rheumatic diseases.

Methods: All patients seen at an academic rheumatology practice complete a 2-sided, 1-page MDHAQ at each visit while waiting to see the physician in the infrastructure of clinical care. Scores are available prior to the patient encounter, and are maintained in a longitudinal database. The MDHAQ includes 13 queries in the patient-friendly HAQ format on a 0–3 scale, concerning "Are you able to. . .?", with 4 response options: "without and difficulty" (=0), "with some difficulty" (=1), "with much difficulty" (=2), "unable to do" (=3). The 13 queries include 8 from the traditional HAQ—dress, arise, lift a cup, walk outdoors, hygiene, reach, grip, household chores; 2 complex activities unique to the MDHAQ–"walk 2 miles (3 kilometers)" and "participate in recreation"; and 3 psychological queries—"get a good night's sleep," "deal with feelings of anxiety or being nervous" and "deal with feelings of depression or feeling blue." Mean and standard deviation were calculated for responses to each of the 13 queries at baseline for all 1,583 new patients seen between 2005 and 2011, and subsets of 221 patients with RA, 166 with SLE, 238 with OA, 41 with fibromyalgia, and 917 with other diagnosis, using analysis of variance (ANOVA).

Results: In all patients, mean scores (on a 0–3 scale) for the 3 psychological queries concerning sleep (1.00), anxiety (0.64) and depression (0.54) were higher than, or in the range of highest scores for, all 8 traditional HAQ activities (Table). The only scores higher than seen for anxiety and depression in all patients were for unique MDHAQ items concerning ability to "walk 2 miles/3 kilometers" (1.00) and "participate in sports and recreation" (1.44). Similar trends were seen for all diagnoses, including "other rheumatic diseases" which does not include fibromyalgia, although scores for the 3 psychological queries were highest in patients with fibromyalgia.

Table. Mean MDHAQ scores for physical function, sleep, anxiety and depression in all 1,583 patients with rheumatic diseases, and according to diagnosis category (*p* determined by analysis of variance among all patient categories).

		All Patients (n = 1,583)	RA (n = 221)	SLE (n = 166)	OA (n = 238)	Fibromyalgia (n = 41)	Other (n = 917)	*p*
MDHAQ physical function items (0–3 scale)	Physical function items on traditional HAQ (0–3 scale)							
	Dress yourself	0.42	0.71	0.33	0.47	0.24	0.35	<0.001
	Get in/out of bed	0.48	0.76	0.40	0.50	0.51	0.42	<0.001
	Lift full glass to month	0.15	0.36	0.11	0.10	0.17	0.12	<0.001
	Walking	0.46	0.69	0.36	0.49	0.31	0.42	0.005
	Wash/dry yourself	0.34	0.60	0.26	0.32	0.15	0.30	<0.001
	Bend down	0.55	0.75	0.48	0.61	0.53	0.49	<0.001
	Turn faucets	0.22	0.56	0.15	0.18	0.12	0.17	<0.001
	Get in/out of a car	0.53	0.83	0.40	0.69	0.36	0.44	<0.001
	Walk two miles (3 km)	1.00	1.28	0.86	1.19	1.00	0.94	0.79
	Participate in sports/ recreation	1.44	1.70	1.17	1.62	1.25	1.39	0.96
MDHAQ function (0–10 scale)		1.85	2.74	1.51	2.03	1.54	1.68	<0.001
Get a good night's sleep (0–3 scale)		1.00	1.15	1.19	1.01	1.29	0.93	0.37
Cope with anxiety (0–3 scale)		0.64	0.70	0.84	0.59	1.12	0.60	0.49
Cope with depression (0–3 scale)		0.54	0.64	0.72	0.52	0.85	0.49	0.42

Conclusion: Three psychological queries as well as two complex activity queries on the MDHAQ that are not found on the HAQ appear to identify problems in patients with rheumatic diseases – including specifically in RA, SLE and OA – at higher levels than for most traditional activity queries from the HAQ. The MDHAQ is an informative screening tool for usual clinical care to assess and monitor patients with all rheumatic diseases.

2053

A Self-Report RADAI (Rheumatoid Arthritis Disease Activity Index) Count of Painful Joints Can Be Informative in Patients with Rheumatic Diseases Other Than Rheumatoid Arthritis. Isabel Castrejón[1], Yusuf Yazici[2] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: To analyze a self-report painful joint count based on the rheumatoid arthritis disease activity index (RADAI) [Stucki G, et al. Arthritis Rheum 1995;38:795–8], in patients with rheumatic diseases other than rheumatoid arthritis (RA), including systemic lupus erythematosus (SLE), gout, psoriatic arthritis (PsA) and osteoarthritis (OA), in comparison with RA patients, and with other measures of clinical status, in a usual care setting.

Methods: A database has been maintained on all patients seen at an academic rheumatology clinical setting since 2005, which includes demographic, patient self-report MDHAQ (multidimensional health assessment questionnaire), medication, and laboratory data. Each patient completes a 2-sided, 1-page multidimensional health assessment questionnaire (MDHAQ) at each visit while waiting to see the rheumatologist in the infrastructure of clinical care. RAPID3, an index of the 3 patient self-report RA Core Data Set measures – physical function, pain, and patient global estimate (each scored 0–10; total 0–30) – is scored on the MDHAQ by the rheumatologist prior to seeing the patient. The MDHAQ also includes a self-report joint count based on the RADAI, with scores for pain ranging from 0 ("no pain") to 3 ("severe pain") bilaterally for 8 specific joint groups, for a total of 0–48. A physician global estimate of status (DOCGL) also was scored by the rheumatologist, and erythrocyte sedimentation rate (ESR) was obtained. A random visit of 465 patients was analyzed including 174 with RA, 75 with SLE, 50 with gout, 53 with PsA and 113 with OA. RADAI self-report painful joint counts were compared to other MDHAQ measures, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), in patients with RA, SLE, gout, PsA and OA according to Spearman rank-order correlations.

Results: RADAI scores were correlated significantly with MDHAQ scores for function, pain, patient global estimate and RAPID3 in patients with each of the 5 different diagnoses (rho = 0.44–0.81, p <0.001; Table). RADAI was correlated significantly with DOCGL in patients with all diagnoses except SLE. RADAI was correlated with DOCGL at higher levels than with ESR and CRP in all diseases studied, including RA.

Table. Spearman correlations of RADAI self-report joint count with other MDHAQ scores and laboratory tests

	RADAI self-report painful joint score (range 0–48)					
	Total (n=465)	RA (n=174)	SLE (n=75)	Gout (n=50)	PsA (n=53)	OA (n=113)
DOCGL (0–10)	0.48*	0.54*	0.25	0.54	0.48	0.40*
PATGL (0–10)	0.67*	0.75*	0.50*	0.60	0.71*	0.50
Function (HAQ) (0–10)	0.67*	0.69*	0.60*	0.66	0.70*	0.50*
Pain (0–10)	0.74*	0.77*	0.64*	0.77*	0.80*	0.48*
RAPID3 (0–30)	0.77*	0.81*	0.63*	0.72*	0.80*	0.56*
ESR	0.15	0.25*	0.13	0.46*	0.28	0.15
CRP	0.18	0.22	0.06	−0.07	0.22	0.014

* p<0.0001

Conclusion: A self-report joint count derived from the RADAI can be informative in patients with many rheumatic diagnoses, including SLE, gout, psoriatic arthritis and OA, in addition to RA.

2054

Teens' Perception of Reproductive Health Counseling in Pediatric Rheumatology. Tova Ronis[1], Jennifer D. Frankovich[1], Christy I. Sandborg[1] and Peter Chira[2]. [1]Stanford University, Palo Alto, CA, [2]Indiana University School of Medicine, Indianapolis, IN

Background/Purpose: Psychosocial development during adolescence can be challenging for teens with rheumatic conditions. Unprotected sexual behavior is hazardous, especially for females on high risk teratogenic medications. Yearly screening of sexual health is recommended by the AAP and AMA and is

a proposed quality measure in JIA. Data from pediatric rheumatology patients regarding reproductive health counseling impact are lacking.

Methods: Females ages 13–20 seen at Stanford pediatric rheumatology clinic ≥2 visits for rheumatic conditions were prospectively enrolled during routine visits. Prior to study start, providers were instructed in the following: 1) HEADSS (home, education, activities, drugs, sexual activity, and suicide/depression) assessment; 2) reproductive health counseling; and 3) medical record documentation. Patients were invited to participate if providers indicated that the patient received the HEADSS assessment and the reproductive health counseling tool. At enrollment, patients completed a survey to assess perceptions of reproductive health counseling. Chart review assessed discussion documentation. Stanford IRB approved the project. Descriptive statistics are used.

Results: 90 females (aged 17 ± 2) participated (Table 1). 85 (94%) had a documented HEADSS. 23 (26%) were sexually active and 3 (3%) were considering sexual activity. 11 (12%) were followed by another provider for reproductive health care.

Table 1. Patient demographics and baseline information

Patient Characteristics	n	%
Total	90	100
Age (SD) (yrs)	17 ± 2	
Diagnosis		
JIA	41	45.6
SLE/MCTD/Sjogren's	36	40
Vasculitis	4	4.4
Juvenile Dermatomyositis	3	3.3
Scleroderma	2	2.2
Other	4	4.4
+ Pain syndrome	15	16.7
Disease duration (SD) (yrs)	5 ± 4	
Race		
Non-Hispanic white	45	50
Hispanic	22	24.4
Asian	17	18.9
Non-Hispanic black	3	3.3
Pacific Islander	1	1.1
Unanswered	2	2.2
Insurance status		
Private	70	77.8
Public	20	22.2
Medication use		
Remission off medications	5	5.6
History of high risk medication use	74	82.2
Current high-risk medications		
biologics	21	23.3
mycophenolate	17	18.9
methotrexate	16	17.8
azathioprine	11	12.2
leflunomide	2	2.2
cyclophosphamide	1	1.1
tacrolimus	1	1.1
none	13	14.4
Development		
Post-menarchal	88	97.8

Within the survey, 89 patients (99%) agreed reproductive health was discussed and 88 (98%) felt confidentiality was assured. 64 (71%) reported that pregnancy risks of medications were discussed. All patients agreed they felt comfortable enough with the provider to ask questions. 88 (98%) understood the need to take medications for disease control. 38 (42%) had recent concerns about reproductive health. 30 (33%) reported their provider recommended that they seek further reproductive health care and 9 (10%) were unsure. Of these 30 teens, 10 were already followed for reproductive health care, 2 said they would definitely go, 12 planned to go in the future, 5 were noncommittal, and 1 did not answer.

Conclusion: This first study investigating patient perception of reproductive health counseling in pediatric rheumatology shows that a significant number of teens (42%) had recent reproductive health concerns, indicating the importance of routine discussion and counseling, especially given the risks associated with unplanned pregnancy. Despite these discussions, teens reported feeling hesitant about pursuing further reproductive health care, highlighting the potential need for a formal referral process that providers can follow. Understanding patient motivation for seeking this type of care will improve the screening and counseling process and inform the development of provider guidelines.

2055

Placing Serious Infection Risk in Perspective: A Randomized Trial Evaluating a Patient Decision Aid to Reduce Focusing Illusion. Richard W. Martin[1], Newsha Lajevardi[1], Shruti Sevak[1], Andrew J. Head[1], Aaron T. Eggebeen[1] and Donald J. Tellinghuisen[2]. [1]Michigan State University College of Human Medicine, Grand Rapids, MI, [2]Calvin College, Grand Rapids, MI

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) increase the risk of serious infectious events (SIE). In rheumatoid arthritis (RA) the incidence varies by individual agent, but ranges from around 1–7/100 pt-year. A clinician counseling a patient who is choosing a new DMARD faces the dilemma of how to frame the discussion to avoid unfairly minimizing medication risks. Focusing illusion is an error in cognition where patients exaggerate the importance of a single factor on their health.[1] This study evaluates the hypothesis that presenting safety monitoring procedures simultaneously with SIE risk will reduce patient perception of drug riskiness and increase their likelihood to be willing to switch to a new DMARD.

Methods: We conducted a randomized controlled trial of 1438 RA patients seen in the past year in a community rheumatology practice. In a mail survey, patients were randomly assigned to read 1 of 4 variations of a hypothetical decision scenario where they were asked to consider switching DMARDs. The format of risk and safety information was derived from an existing DMARD patient decision aid.[2] The scenarios varied by the risk of DMARD related of SIE (1% vs. 8%), and if safety monitoring procedures to reduce risk of SIE were presented simultaneously (yes or no). After reading the scenario, each subject completed a 10 point Likert scale rating the riskiness and likelihood they would take the new DMARD.

Results: The response rate was 70%. Data was analyzed on 1002 respondents. Patient characteristics: female 75%, minority 6.5%, education less than high school graduation 12.6%, Medicaid 18.8%. Means: age was 61.6 years (range 18–93), duration of RA 13.1 years (range 0.5–68), CDAI 11.8 (range 0–54) and HAQ2 0.765 (0–3.0). 51% had started a new DMARD in the preceding 3 years. Multivariate analysis was conducted using 2-way ANOVA. There was a significant main effect of the presence of safety monitoring information but not level of risk on the perceived riskiness of the DMARD [($P< 0.007$) and ($P< 0.084$) respectively]. There were significant main effects of level of risk and presence of safety monitoring information on the likelihood that the patient would take would take the new DMARD [($P< 0.009$) and ($P< 0.005$) respectively]. A consistent pattern was seen where including monitoring procedures in the SIE risk presentation increased RA patient perception of riskiness and reduced the likelihood they would take a proposed DMARD. No significant interaction effect was present between risk level and contextual information on patient rating of either dependent variable.

Conclusion: Even when presented with SIE risk information reinforced with a natural frequency pictogram[3], RA patients differentiated poorly between the riskiness of a low vs. high risk DMARD. Presenting safety monitoring procedures simultaneously with SIE risk information, does not bias patients by reducing risk perception. Rather by presenting DMARD SIE risk in the context of proposed monitoring procedures may intensify patient deliberation of risk and lead to more conservative patient medication decisions.

Measurement of the Quality of the Patient-Physician Interaction in An Outpatient Rheumatology Clinic. Shawnta R. Pittman-Hobbs[1] and Andreas M. Reimold[2]. [1]UT Southwestern Medical Center, Dallas, TX, [2]Dallas VA and University of Texas Southwestern, Dallas, TX

Background/Purpose: Strengthening of the patient-doctor interaction is the basis of quality improvement efforts. Balancing a full schedule for the provider can come at the cost of longer wait times for the patient. The use of electronic medical records has added to potential distractions during a visit. Patients and providers can have different perspectives on the impact of computer use. Here we examine the impact on the perceived quality of the patient-doctor interaction with respect to time perception, communication, and use of electronic medical records.

Methods: This was a prospective observational study to measure quality of care in a VA rheumatology outpatient clinic. After verbal consent, written anonymous questionnaires were given to 144 patients who came for follow-up appointments over a 3 month interval. New patients were excluded. In addition, 20 surveys were administered to faculty, residents, and fellows involved in the patients' care.

Patients were asked 13 questions to rate the perceived wait time, the amount of time spent with the doctor, how well the doctor explained the plan of care, and how well the doctor listened while typing data into the EMR. Physicians were asked similar questions to rate the perceived patient wait time, their perception of how well they explained the plan of care, and if they felt distracted by entering data in the computer during the visit. The responses were rated on a scale of 1–5. Student's *t*-test was used to compare the averages of the two groups.

Results: The main outcome measures were the effects of the perceived wait time and of electronic medical record use on the reported quality of the physician-patient encounter. Perceived wait time was estimated at 30 to 60 minutes by 65.5% of the patients and 60% of physicians. Patients with longer wait times did not report a perceived lower quality of the encounter. Over 90% of both patients and physicians rated the amount of time spent discussing the plan of care as 4 (good) or 5 (very good). Half of physicians felt that entering information into the computer via electronic medical record was a distraction. However, 45% of physicians felt that they listened about the same to patients while entering data or not, while 40% felt that they listened less. This was in contrast to 58.1% of patients who felt that physicians listened about the same, 23.4% of patients felt that their physician listened more and 16.9% much more while entering data, whereas 1.6% felt the physician listened less. Differences were not statistically significant.

Conclusion: Physicians and patients agreed on the length of the wait time at the start of an appointment. Longer wait times did not correlate negatively with the patients' impression of their physician encounter quality. Use of the electronic medical record caused 40% of physicians to feel that they listen less to their patients while working at the computer, while only 1.6% of patients had this perception. These findings indicate that follow-up patients in rheumatology clinic perceive undiminished quality of care despite longer wait times or provider use of the computer during an encounter.

2057

Are United States Rheumatologists Interested in Using Electronic Mail in Patient Care? Concerns From a National Survey. Gregory Wilson[1], Chokkalingam Siva[2], Celso Velazquez[1], Karen L. Smarr[3], John Fresen[1] and Marius Petruc[1]. [1]University of Missouri, Columbia, MO, [2]Univ of Missouri Sch of Med, Columbia, MO, [3]Harry S Truman Mem VA Hospital, Columbia, MO

Background/Purpose: Numerous surveys have found patients expressing strong interest in email communication with their providers. However, no literature is available on the level of interest among rheumatologists.

Methods: 4895 U.S. clinical members of the American College of Rheumatology (ACR) with listed email addresses were surveyed. A SurveyMonkey link was provided by email. The survey contained questions on frequency of use, practice policies, and concerns surrounding the use of patient-provider email. Provider demographics and practice characteristics data were also collected. A total of 630 ACR members responded (13%). A small number of respondents skipped questions or answered questions inappropriately. Statistical analyses were performed using the R version 2.12.1 statistical package. Chi-square tests were performed to assess the relationships between several categorical variables and were assessed at 95% significance level (i.e. $p<0.05$).

Results: The majority of respondents do not use email at all to communicate with patients (n=334, 54%) and 34% do not plan to use it in the future. The most important concerns among all respondents were inappropriate use of email by patients, liability, and confidentiality (Table 1). Analysis of these three concerns revealed differences between users and non-users that were significant ($p<0.05$). Non-users (n=334), when compared to users (n=284), were extremely concerned about inappropriate use (61% vs. 38%), liability (56% vs. 36%) and confidentiality (50% vs. 35%). Regarding compensation, 32% of respondents indicated the insurance company and patient should pay for email consultations and 41% were unsure. A majority (83%) of respondents believed $30 or less would be an appropriate fee for a simple, clinical question taking ≤ 5 minutes. For clinical questions taking ≥ 10 minutes of time, 28% of respondents believed the reimbursement should be over $50. Rheumatologists from single specialty practices favored higher reimbursements compared to those from other practice types. Of all respondents, 92% do not distribute any written policy guidelines on email use to patients. Age, gender, and clinical experience did not impact the likelihood of use ($p > 0.05$), but there was a trend towards academic rheumatologists comprising the largest group of users (63%).

Table 1. Reasons for not using e-mail communication (n=590[a])

Concerns about:	1	2	3	4	5
Confidentiality	54 (9.2%)	58 (9.9%)	91 (15.5%)	129 (21.9%)	256 (43.5%)
Liability	48 (8.1%)	50 (8.5%)	71 (12.1%)	141 (23.9%)	279 (47.4%)
Reimbursement	133 (22.5%)	102 (17.3%)	112 (19%)	107 (18.1%)	136 (23.1%)
↓ Quality of care	117 (19.9%)	100 (17.0%)	130 (22.1%)	119 (20.2%)	123 (20.9%)
Inappropriate use	23 (3.9%)	50 (8.6%)	75 (12.8%)	134 (22.9%)	302 (51.7%)

1 = not important, 5 = extremely important, a = question skipped by 31 respondents

Conclusion: There appear to be significant concerns about email use among U.S. rheumatologists. This is likely an underestimation of the level of reluctance, since we surveyed only those with a listed email address. This survey identifies several concerns that are important to practitioners which may impede their use of email in patient care. Addressing these concerns may allow email to expand into the clinical setting as an effective method of patient-provider communication.

2058

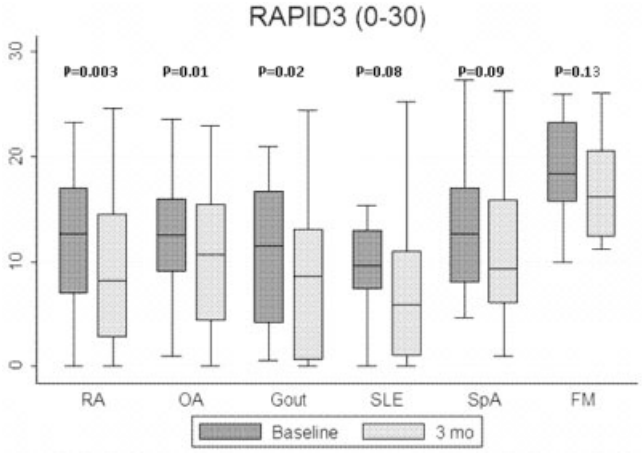
Routine Assessment of Patient Index Data-3 (RAPID3) Is Informative in Patients with All Rheumatic Diseases to Depict Patient-Reported Information As Quantitative Data, Rather Than As Narrative Descriptions. Isabel Castrejón[1], Martin J. Bergman[2], Yusuf Yazici[3] and Theodore Pincus[1]. [1]NYU Hospital for Joint Diseases, New York, NY, [2]Taylor Hospital, Ridley Park, PA, [3]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Patient history information is more prominent in clinical decisions in rheumatic diseases than in most chronic diseases, such as diabetes and hypertension, in which medical history information is considerably less important. Recording patient history information as quantitative, standardized, "scientific" data, rather than as narrative descriptions, may enhance clinical decisions and documentation of clinical changes in usual care of patients with rheumatic diseases. We analyzed scores for physical function, pain, and patient global estimate, and RAPID3 (routine assessment of patient index data) on an MDHAQ (multidimensional health assessment questionnaire) in patients seen in usual care with 6 diagnoses: rheumatoid arthritis (RA), osteoarthritis (OA), gout, systemic lupus erythematosus (SLE), spondyloarthropathy (SpA), and fibromyalgia (FM).

Methods: In one solo rheumatologist private practice setting, every patient (with any diagnosis) completes a 2-sided, 1-page MDHAQ at every visit while waiting to see the physician. RAPID3, an index of the 3 patient self-report Core Data Set measures – physical function, pain, and patient global estimate, each scored 0–10 (total 0–30)—is reviewed by the rheumatologist prior to seeing the patient. RAPID3 severity categories are >12=high, 6.1–12=moderate, 3.1–6=low, ≤3=remission. RAPID3 median and interquartile ranges, and the proportion of patients in each of the 4 categories of clinical status, were computed at first visit and 3 months later for 156 new patients in 6 groups according to diagnosis: RA (n=39), OA (n=41), gout (n=24), SLE (n=14), SpA (n=23), and FM (n=15). Statistical significance was assessed by analysis of variance (ANOVA) of all diagnoses, and *t* test to compare first visit to 3 month later.

Results: A decrease in median RAPID3 scores over 3 months was seen in patients with all 6 diagnoses studied: from 12.7 to 8.2 in RA, 12.5 to 10.7 in OA, 11.5 to 8.6 in gout, 9.7 to 5.9 in SLE, 12.7 to 9.3 in SpA, and 18.3 to 16.2 in FM (Figure). A higher proportion of patients improved from RAPID3 high/moderate severity to low severity/remission over 3 months in 5 of the 6 conditions (all but FM, in which all patients had high/moderate severity at both time points): from 15% at first visit to 49% at 3 months in RA, 19% to 34% in OA, 29% to 46% in gout, 14% to 50% in SLE, and 22% to 26% in

SpA. Changes over 3 months in median scores and in the proportion of patients in low severity/remission were statistically significant ($p<0.05$) for RA, OA and gout, but not for the other diseases.



Conclusion: RAPID3 appears useful in patients with all rheumatic diseases in usual clinical care to document clinical improvement according to a patient history, as quantitative scores rather than as traditional narrative descriptions.

2059

Ethical Issues in Rheumatology: A Survey of the American College of Rheumatology Membership. C. Ronald MacKenzie[1], Michele Meltzer[2] and Elizabeth A. Kitsis[3]. [1]Hosp for Special Surgery, New York, NY, [2]Jefferson Universtiy, Philadelphia, PA, [3]Albert Einstein College of Med, Bronx, NY

Background/Purpose: Despite the chronicity and complexity of rheumatologic disease, the literature pertaining to ethical considerations arising in the practice of rheumatology is negligible. In order to more fully understand the scope of ethical problems arising in the field, the Committee on Ethics and Conflict of Interest of the ACR polled the membership for their opinion. The goals of the survey were to learn: 1) the perceived frequency of ethical issues arising in rheumatology; 2) the identification of activities that pose ethical problems in rheumatolgic practice; 3) the extent of education that members have received in bioethics; and 4) member interest in additional learning activities related to bioethics.

Methods: A survey consisting of 14 closed-end and 4 open-ended questions was developed, pilot tested, and sent electronically to 5,500 US members of the ACR. A second offer for participation was sent to increase the response rate.

Results: Seven-hundred and seventy one (14%) members responded to the questionnaire. While there was general agreement that ethical issues arise in all areas of rheumatology, respondents believed that they arise more frequently in clinical research (61%) and clinical practice (44%) as opposed to basic research (26%). The 3 most common issues reported were the high costs of treatment to society (51%) or to patients (48%) and the practice of defensive medicine (45%). When asked to list the three most relevant ethical issues pertaining to rheumatologic practice, 10% of respondents reported conflict of interest in profiting from the over-utilization of infusions; 9% reported physician-pharmaceutical relationships; and 8% cited providing care for those with limited or no insurance. Industry-related activities identified as posing ethical problems include serving on boards of directors (76%) and serving on an industry-sponsored speakers bureaus (66%). Fifty-eight percent of respondents had received formal training in bioethics; 89% indicated an interest in additional education.

Conclusion: This survey suggests that ethical problems in rheumatology are of concern to the ACR membership. Further there is a perceived need for educational resources directed at helping members deal with such professional challenges. These results suggest that an active discourse and more formal education in bioethics should be a professional priority.

2060

Assessment of Cardiovascular Risk in Rheumatoid Arthritis: Comparison of Two Indices and Related Variables. José L. Rosales-Alexander, César Magro-Checa, Juan Salvatierra, Jesús Cantero-Hinojosa and Enrique Raya-Alvarez. University Hospital San Cecilio, Granada, Spain

Background/Purpose: Last year the European League Against Rheumatism (EULAR) developed a modified systematic coronary risk evaluation (mSCORE) index to guide in the cardiovascular (CV) risk management in patients with rheumatoid arthritis (RA) and other forms of inflammatory arthritis. In RA patients, the mSCORE is calculated according to the SCORE by the application of a multiplier factor 1,5 in those who meet some clinical criteria. EULAR recommends the use of the mSCORE when no local guidelines are available. In our country the SCORE table has been calibrated by our national Cardiology Society, although it is not systematically applied to our RA patients. For that reason we decide to compare the assessment of the CV risk in RA patients using the SCORE table calibrated for our population and the mSCORE following the EULAR recommendations as well as to analyze the correlation of several clinical and serological variables with these SCORE indices.

Methods: We included 161 consecutive patients diagnosed of RA according to the 1987 classification criteria of American College of Rheumatology (ACR) and followed in our outpatient clinics. We recorded demographic data, classic CV risk factors, previous ischemic events, clinical and laboratory parameters of disease activity like ESR, CRP, tender and swollen joint counts, DAS28, patient global assessment by visual analogue scale (VAS global), lipid profile and RA characteristics. We calculated the CV risk using the SCORE table calibrated for our population and the mSCORE following the EULAR recommendations. Data were collected in Excel 2007 and analyzed with the statistical software SPSS 15. Descriptive data were shown as percentages and mean ± standard deviation (SD). Differences between qualitative variables were assessed using Chi-squared test or McNemar's test and for comparing means we used the ANOVA Bonferroni adjustment. The limit of statistical significance was located in the α error of 0,05.

Results: Using the SCORE table calibrated for our population the mean ± SD score was 2,4 ± 2,9% and after the application of the mSCORE was 3 ± 4,2%. A change in the score occurred in 19 (55,8%) patients with intermediate risk being reclassified into high risk 18 (52,9%) and very high risk 1 (2,9%). Likewise 3 (17,6%) patients with high risk were reclassified into very high risk after applying the EULAR recommendations. It was observed that 58,8% of men had high and very high CV risk and that 61,9% of women had low CV risk. Of interest, in our study the levels of CRP and the values of the VAS global seemed to have a direct association with the final SCORE CV risk indices ($p<0,03$ and $p<0,02$ respectively) which suggest the influence of disease activity on the high CV risk associated to RA.

Conclusion: The use of the mSCORE index in RA patients involves an overestimation of the CV risk in comparison with the application of local guidelines, what could have implications in management of these patients. Of the analyzed variables, CRP and VAS global seem to affect the final CV risk scores, supporting the importance of a good control of the inflammation in RA.

2061

Measuring Quality of Care in Juvenile Idiopathic Arthritis: The Pediatric Rheumatology Care and Outcomes Improvement Network. Esi Morgan DeWitt[1], Timothy Beukelman[2], Beth S. Gottlieb[3], Nancy Griffin[4], Yukiko Kimura[5], Itara Barnes[6] and Murray H. Passo[7]. [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Univ of Alabama-Birmingham, Birmingham, AL, [3]Schneider Children's Hospital, New Hyde Park, NY, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, [5]Hackensack Univ Medical Ctr, Hackensack, NJ, [6]Atlanta, GA, [7]MUSC, Charleston, SC

Background/Purpose: Representatives from the ACR, ARHP, American Academy of Pediatrics, and American Board of Pediatrics (ABP) recently proposed 12 Quality Measures (QM) as a suitable baseline of data for the development of quality improvement projects. Implementation of the proposed QM set may improve the process of care, facilitate continuous quality improvement (QI), and eventuate in improved health outcomes of children with JIA.

Methods: The Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) is a multi-site QI learning collaborative formed to improve the outcomes of care of children with JIA and to accelerate adoption of evidence into medical practice. Our collaborative approach is based on the

Institute of Healthcare Improvement (IHI) Breakthrough Series Collaborative Model and utilizes the Model for Improvement to guide performance improvement activities. Using the ACR's Rheumatology Clinical Registry (RCR), PR-COIN is designed to aggregate data from participating pediatric rheumatology practices to study performance of sites on both process measures of care delivery and measures of patient outcomes to better understand which disease management approaches are optimal. Change strategies based on a chronic illness care model include pre-visit planning, population management, auditing, treatment protocols and preparing patients/parents in self-management techniques. Initial activities include collection of pre-intervention baseline data and training teams in performance improvement methodology, prior to testing change strategies at individual team sites. Teams will convene during three Improvement Learning Sessions over a 12 month period (June 2011, September 2011, April 2012) where they receive intensive training and coaching from QI experts. Between Learning Sessions, teams conduct tests of change using "Plan-Do-Study-Act" cycles, and submit data regarding their performance. Site specific and aggregate feedback reports are provided monthly to enable teams to assess progress on quality measures.

Results: 11 sites in the US and one in Canada are enrolled in the network which leverages a public website (pr-coin.org) with members only section for transparent sharing of data reports. The web-based JIA data entry system was created within the RCR. After completing an IRB approval process, subject data is entered into the RCR to populate run charts documenting performance on quality measures. QI measures have been embedded into some participating sites' electronic health records (EHRs) for more reliable data collection and with special programming, data may be uploaded from EHRs into the registry forms.

Conclusion: PR-COIN, by putting measurement of quality of care into practice, provides an opportunity for validation of recently published quality measures for process of care of JIA. QI learning networks organized in the IHI Breakthrough Series approach and utilizing the Model for Improvement to guide improvement activities may improve the quality of care of patients with chronic illness. The PR-COIN QI collaborative, which follows the IHI approach, offers an option to rheumatologists to meet part 4 QI project requirements for maintenance of certification by the ABP.

2062

Detection of Adverse Events in Routine Rheumatology Practice by a New Computer Application. Zulema Rosales[1], Ana B. Rodríguez-Cambrón[1], Lydia Abásolo[1], Leticia León[1], Oscar Fontsere[1], Cristina Vadillo[1], J.L. Fernández Rueda[1] and Juan A. Jover[2]. [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Hospital Clinico San Carlos, Madrid, Spain

Background/Purpose: There is a high risk of developing adverse events (AEs) in rheumatology practice due, mainly, to the immunosuppressive drugs used. Also, we must take into account the high workload and the difficulty of register AEs in daily clinical practice.

Our purpose was to describe the AEs collected in a routine practice of Rheumatology, by implementing a software system Reporting and Analysis for Incident Learning and Adverse Events (SNAIEA).

Methods: We performed an observational prospective study from October 1st 2010 to May 31st 2011. All patients seen, at least once, in the Rheumatology Service at the Hospital Clínico in Madrid since the introduction of SNAIEA were included. Primary endpoint: AEs collected by SNAIEA from patients attended during the study period. We also collected a) the severity (mild, moderate, severe, fatal), b) relationship to medication (Unlikely, Possible, Probable, Certain), c) causes of AE, d) the diagnosis of patients with some type of AE in that period, e) and drugs associated with these events. We collected demographic data (age and sex) of all patients. Statistical analyses: to estimate the incidence of adverse events we used survival techniques, expressing the incidence per 100 inhabitants per year (95% CI). A description of the sociodemographic, clinical, of the patients by frequency distribution and the mean and standard deviation or median and percentiles was completed. Analyses were performed using Stata statistical package 10.0.

Results: 7539 patients were attended during follow-up. Of these, 75% were female with a mean age of 61.92 ± 16 years. There were 241 AE (table 1) (84.6% female, mean age of 62.3 ± 15.3 years) during follow-up with an incidence of 8.5 % (95% CI: 7.5–9.7). The incidence of AE by sex was 9.5% (95% CI: 8.2–10.8) in females and 5.4% (95% CI: 3.9–7.5) in males. Of the AE, 5 were severe with an incidence of 0.2% (95% CI: 00.7–00.4). In 61% of the patients the relationship of the AE to medication was certain. The main diagnose in the patients with AE was Rheumatoid Arthritis (37%) followed by osteoarthritis (13%). The most frequent drugs causing AE were classical DMARDs (46.44%) followed by opioids (10.5%) and NSAIDs (9.6%).

AE	Number	Percentage (%)
Gastrointestinal	78	35.14
General Syndrome	27	12.16
Mucocutaneous	23	10.36
Laboratory Abnormalities	20	9.01
Neurological	18	8.11
Eye	16	7.21
Infections	14	6.31
Cardiological	10	4.50
Muscular	7	3.15
Fractures	6	2.70
Genitourinary	3	1.35

Conclusion: AEs in routine rheumatology practice are common; however the vast majority is mild. The most common adverse events were gastrointestinal. DMARDs are the drugs most associated with adverse events. Using SNAIEA has been a transition from the traditional manual model to the electronic analysis of AE, identifying those events, their severity and relationship to the medication, thus contributing to improving the quality of care.

2063

A Quality Indicator for Osteoporosis in a Japanese Hospital. Yasuhiro Suyama[1], Mitsumasa Kishimoto[1], Yuri Ohara[1], Ryo Rokutanda[1], Atsushi Nomura[2], Hisanori Shimizu[1], Ken-ichi Yamaguchi[1], Yukio Matsui[1] and Masato Okada[1]. [1]St. Luke's International Hospital, Tokyo, Japan, [2]Chubu-Rosai hospital, Nagoya, Japan

Background/Purpose: Bone fractures are the third most common reason why patients become bedridden in Japan and prevention is often more important than treatment, especially in patients with known risk factors. Quality indicators (QI) have received increasing attention in rheumatology and the ACR QIs for systemic lupus erythematosus include an indicator for glucocorticoid-induced osteoporosis. Furthermore, according to 2010 ACR recommendations for prevention and treatment of glucocorticoid-induced osteoporosis, patients on prednisolone as low as 7.5 mg daily or equivalent for more than 3 months should take anti-osteoporosis drugs. However, few studies have reported the effectiveness of the implementation of this QI measure for glucocorticoid-induced osteoporosis in the clinical setting.

Methods: We performed a retrospective review of medical records in our hospital, examining the number of patients with prescription for the equivalent of prednisolone 7.5 mg daily or more for at least 3 months each year from 1994 to 2010. The number of patients with prescriptions for a bisphosphonate (alendronate, risedronate, or zoledronic acid) and vitamin D analogue(Alfacalcidol)was also analyzed. The sample was categorized into 3 groups by gender and age. Group A comprised female patients over 50 years old who were recommended to take a bisphosphonate with vitamin D analogue; Group B was comprised of female patients less than 50 year-old taking the defined dose of steroid and who were recommended to take vitamin D analogue; Group C was male patients who were recommended to take a bisphosphonate with vitamin D analogue.Then we assessed the rate of following these recommendations in each group in each year.

Results: A total 2479 patients were included in this study. 1448 (58.4%) patients were female and the mean age of patients was 53.6±18.4 years. 528 (19.2%) patients underwent dual-energy x-ray absorptiometry scan during the study period. An average of 354 patients received the defined dose of steroid each year (316 – 381 patients/year). Analysis of data revealed that the rate of following the ACR recommendations were 40.1% in Group A (32.0% – 52.9% in each year), 41.8 % in Group B (26.1% – 58.4% in each year), and 11.4% in Group C (8.2% – 14.5% in each year)..

Conclusion: In our study, targeted anti-osteoporosis drug prescriptions per QI standards was found to be inadequate and the situation was worse in male patients. It is imperative to inform clinicians of the existence of evidence-based recommendations to combat steroid-induced osteoperosis and urge them to follow QI standards. Sequential analysis of QI would be an effective way to implement the recommendation in clinical practice, with the end goal of reducing the burden of preventable osteoporotic fracture.

2064

A Randomized Clinical Trial of a Comprehensive Behavioral Intervention in Systemic Lupus Erythematosus Demonstrates Improvement in Mental Health but Not in Physical Health, Cardiovascular Risk or Endothelial Function At One Year. Paul R. Fortin[1], Ellie Aghdassi[2], Anne Cymet[2], Stacey Morrison[3], Jiandong Su[3], Willy Wynant[4], Janet E. Pope[5], Sara Hewitt[5], Christian A. Pineau[6], Carolyn Neville[7], Paula Harvey[8], Jean-Claude Tardif[9], Michal Abrahamowicz[10] and Deborah DaCosta[11]. [1]Toronto Western Hospital, Toronto, ON, [2]University Health Network, Toronto, ON, [3]The Toronto Western Hospital, Toronto, ON, [4]McGill University, Quebec, QC, [5]St. Joseph's Health Care, University of Western Ontario, London, ON, [6]McGill Univ Health Center, Montreal, QC, [7]Royal Victoria Hospital, Montreal, QC, [8]Toronto General Hospital, Toronto, ON, [9]Universite de Montreal endowed research chair in atherosclerosis, Quebec, QC, [10]McGill UHC/RVH, Montreal, QC, [11]Montreal General Hospital, Montreal

Background/Purpose: The Health Improvement and Prevention Program (HIPP) in systemic lupus erythematosus (SLE) is the first randomized intervention aimed at the improvement of health status and coping while reducing risky behaviours for cardiovascular disease (CVD).

Methods: An unblinded RCT of the HIPP intervention (HIPP NOW) compared to usual care (HIPP LATER) assessed physical (PCS) and mental (MCS) component summary scores of SF-36, the CVD risk derived from the Framingham risk score (CVD risk) and the flow mediated dilatation (FMD) of the brachial artery. Patients with no CVD were recruited from three academic centres. After providing consent, SF-36, SLEDAI, SDI as well as FMD were collected. Those randomized to HIPP NOW were administered a personalized risk modification program by a nurse (disease education, CVD risk reduction {including smoking cessation}, exercise, psychological intervention). Repeated clinical assessments and FMD were performed at one year. A cross-over of the LATER group occurred at one year and all patients will be re-assessed at 2 years. We report here the one year results. Power calculations showed that 260 patients ensured 80% power to detect ≥10% improvement in the SF-36 MCS and PCS and 20% in CVD risk. Between groups differences (1year - baseline) were tested, separately for each primary outcome, using t-tests and multivariable linear regressions (MLR) adjusting for baseline values and for patients' characteristics associated with the outcome.

Results: We randomized 288 patients. There were no differences between groups for mean age (44 yrs), race (70% Caucasian), marital status (53% married), education (91% high school graduates), mean disease duration (11.3 yrs) and mean SLEDAI (4.04). The NOW group had a higher mean SDI (1.37 vs 1.00, p=0.03). Table 1 shows the results of the HIPP intervention at one year on the outcomes of PCS, MCS, CVD risk and the post-occlusive FMD change in brachial artery diameter.

	Unadjusted analyses			Adjusted analyses	
Outcome	Δ HIPP NOW (1 year-baseline)	Δ HIPP LATER (1 year-baseline)	p-value	$\beta_{study\text{-}group}$ in MLR (95%CI)	p-value study-group in MLR
SF36-physical	0.026	0.695	0.471	−0.10 (−1.80; 1.60)	0.909
SF-36 mental	1.837	−1.441	0.008	−2.67 (−4.84; −0.50)	0.017
CVD risk (logit)	−0.023	0.056	0.087	+0.08 (−0.01; 0.17)	0.067
FMD (% change)	−0.290	−0.205	0.922	+0.18 (−1.43; 1.79)	0.828

The MCS score increased during the first year of follow-up in the HIPP NOW group by 1.84 units but decreased in the LATER group by 1.44. The resulting un-adjusted difference (p=0.008 for the 2-tailed t-test) and the adjusted difference from MLR (2.67, 95% CI: 0.50 to 4.84, p=0.017) were both statistically significant. There was a trend toward improvement in CVD risk (p= 0.087 for t-test and p=0.067 for MLR). The differences in the other primary outcomes were not significant.

Conclusion: The HIPP intervention significantly improved the mental health but not the physical health in SLE as measured by the SF-36; other primary outcomes were not significant. Since SF-36 mental health improvement may precede changes towards healthier behaviour, this study will re-examine outcomes at two years.

2065

Cardiovascular Risk Assessment and Management in a Nationally Representative Sample of Routine Ambulatory Visits for Patients with Rheumatoid Arthritis and Systemic Lupus Erythematosus. Laura Tarter[1], Laura Trupin[1], Gabriela Schmajuk[2], Mary Margaretten[1], Edward Yelin[1] and Jinoos Yazdany[1]. [1]University of California San Francisco, San Francisco, CA, [2]Stanford University, Palo Alto, CA

Background/Purpose: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). We examined patient and physician factors associated with CVD risk factor screening in a nationally representative sample of routine ambulatory medical visits in the United States. Additionally, we analyzed management strategies among those with known CVD risk factors.

Methods: We studied the National Ambulatory Medical Care Survey (2005–2007), including all visits for patients > 17 years of age with SLE or RA presenting for routine (not acute) care. Data were recorded in standardized templates by the primary medical provider. We used logistic regression to examine the association between assessment of traditional CVD risk factors (hypertension, hyperlipidemia, diabetes, smoking and obesity) and patient sociodemographics, insurance status, and physician specialty (primary care provider, rheumatologist or other). We also examined the frequency with which physicians recorded addressing known CVD risk factors during routine visits (via lifestyle modification counseling (LMC) or pharmacotherapy).

Results: A total of 298 visits were included in the analysis (RA 72%, SLE 28%). Patients were 57.1 years old (SD 15.5), 78% female, 84% White, and 92% insured. Prevalence of CVD risk factors varied (hypertension 30%, hyperlipidemia 15%, diabetes 9%, smoking 8%, obesity 9%). Rates per visit of risk factor evaluation also varied (blood pressure measurement 88%, cholesterol measurement 12%, diabetes screening 11%, tobacco use assessment 58%, body mass index calculation 40%). In multivariate models adjusting for the number of visits to the reporting physician over the previous year, sociodemographic characteristics (age, sex, race/ethnicity) were not associated with receipt of CVD screening. Screening for hyperlipidemia and diabetes were more likely to be recorded for primary care visits than rheumatology visits (OR 5.04: 1.57–16.17; OR 4.54: 1.54–13.39). Patients with hypertension (n=60) were the most likely to have a management strategy recorded (60% received pharmacotherapy and 30% received LMC). In visits in which hyperlipidemia was recorded (n=30), 47% received pharmacotherapy and 40% received LMC. Cessation counseling was associated with only 6% of visits in which smoking was recorded (n=18).

Conclusion: In this nationally representative sample of ambulatory visits, screening for CVD risk factors in patients with RA and SLE occurred both during rheumatology and primary care visits; however, screening for hyperlipidemia and diabetes were more likely to occur during primary care visits. In patients with known CVD risk factors, a minority of visits were associated with relevant LMC or pharmacotherapy, suggesting opportunities for quality improvement.

2066

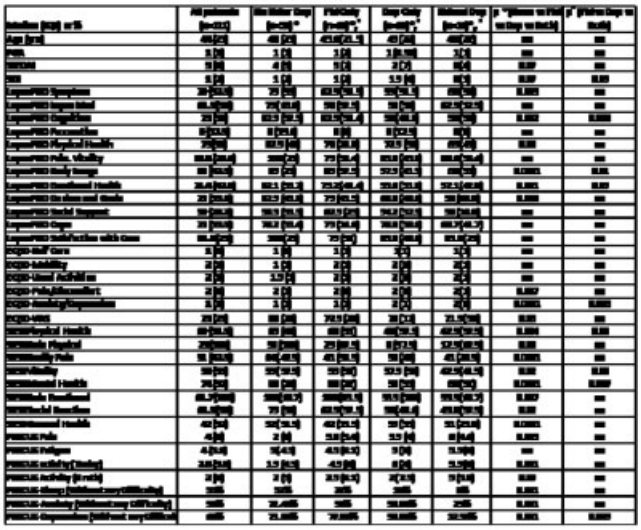
Is Having Fibromyalgia Worse Than Having Depression or Both in Lupus: Impact on Health Outcomes? Meenakshi Jolly[1], Jessica Cornejo[2], Rachel A. Mikoliatis[2] and Joel A. Block[1]. [1]Rush University Medical Center, Chicago, IL, [2]Rush University, Chicago, IL

Background/Purpose: Adverse effects of Fibromyalgia and Depression on health outcomes in Systemic Lupus Erythematosus (SLE) have been noted previously. Herein we present physician and patient reported health outcomes in SLE using wide variety of patient reported health outcome tools in rheumatology practice, and compare them (a) against a group without fibromyalgia and Depression, and (b) stratified by the presence of Fibromyalgia, Depression or both.

Methods: 111 SLE patients were administered patient reported health outcome tools prior to their routine clinic visit. The tools included LupusPRO, EuroQoL, MDHAQ (PINCUS) and SF36. Disease activity and damage were assessed using Physician Global Assessment (PGA), SELENA-SLEDAI, and damage Index (SLICC-ACR/SDI). In addition, patients provided their demographic, self reported history of fibromyalgia and Depression (Yes/No). These diagnoses were confirmed in all cases by medical chart review. Statistical methods include descriptive, non-parametric t tests and Chi square analyses. All p values noted are two sided.

Results: Age, PGA and SLEDAI were similar in all groups. Summary scores for the entire group and stratified by underlying co morbidity are shown in the table. Comparisons between SLE patients without fibromyalgia and depression with the other three groups showed significant differences on most tools. Differences in sleep, pain, fatigue, psychological and social health were noted on most tools. In addition, LupusPRO domains scores of symptoms, Cognition, Body Image and Desires and Goals showed significant differences in these four groups.

When we compared SLE groups with fibromyalgia, depression and both, we found fibromyalgia group to have better health outcomes than the other two groups. Notable differences were in the LupusPRO domains (Cognition, Body Image, Emotional Health), EuroQoL Anxiety/Depression, SF36 domains (Physical Function, Vitality and Mental Health) and MDHAQ (Depression item).



Conclusion: SLE Patients with depression have the worst patient reported health outcomes as compared to SLE patients with and without Fibromyalgia. Aggressive screening, counseling and appropriate intervention/s for such patients are indicated.

2067

Hydroxychloroquine Retinopathy in Inflammatory Arthritis: A Retrospective Analysis in Canadian Patients. Mohammed Osman[1], Heather Burnett[1], Alison Kydd[2], Paul Davis[1], Christopher Rudnisky[1], Matthew Tennant[1] and Elaine Yacyshyn[1]. [1]University of Alberta, Edmonton, AB, [2]University of British Columbia, Vancouver, BC

Background/Purpose: Antimalarial agents, hydroxychloroquine (HCQ, Plaquenil®) and chloroquine (CQ, Aralen®) have been linked to toxic ocular changes after prolonged use. The incidence of toxic changes is unclear for patients with inflammatory conditions, although prior studies show a low incidence (0.8–3.4%). In this study, we examined the frequency of true HCQ retinopathy in patients treated for various inflammatory conditions, with an abnormal mfERG.

Methods: Sixty-eight patients (age range 26 – 90 years) treated with HCQ between 2004 and 2010 were identified in this qualitative retrospective study. Patients with potential retinopathy were identified after having an abnormal multifocal electroretinogram (mfERG). Follow-up serial mfERG and complete ophthalmic assessments (visual acuity, dilated fundoscopy, automated Humphrey visual field (HVF)) were conducted to distinguish patients with HCQ retinopathy, as opposed to other conditions contributing to an abnormal mfERG. Repeated measures were completed 6 months to one year apart.

Results: Of the total number of patients identified with an abnormal mfERG, four female patients (age range 59–72 years) were identified with probable retinal toxicity (approximately 5.88 %) after 2.2, 4, 6 and 8 years of treatment with HCQ (mean dose 400 mg/d). None of these patients had ocular symptoms, although one of them had cataracts. Both patients using HCQ for more than 5 years developed Bull's eye maculopathy and had an abnormal HVF, while the other two were identified with serial mfERG and ophthalmic assessments. In addition, twenty-nine patients (age range 36–90 years) were found to have a persistently abnormal mfERG with no evidence of toxicity (approximately 42.6 %). Twenty-two patients had other ocular diseases (glaucoma, macular degeneration, diabetic retinopathy, cataracts, retinal pigment epithelial changes), and diabetes or hypertension (17 patients). Seventeen patients (age range 29–75 years) initially thought to have potential retinopathy were shown to have no evidence of antimalarial retinopathy after subsequent clinical and mfERG assessments.

Conclusion: We report a much higher rate of true postive abnormal mfERG than previously described in this select population of patients treated with HCQ. Of the sixty-eight patients, none of the patients with ocular toxicity were symptomatic and one of them developed ocular disease after only 2.2 years of treatment. Patients who have risk factors for potential toxicity, including duration of HCQ use, age, and other ocular diseases may benefit from mfERG screening, even in the absence of ocular symptoms. Our study highlights the important role mfERG may play in the early detection of patients at risk for developing antimalarial toxicity.

2068

Real-Time, Cohort-Based Clinical Decision Support Using a Novel Bioinformatics Platform to Assess Thrombotic Risk in a Critically Ill Pediatric Patient with Systemic Lupus Erythematosus. Jennifer D. Frankovich, Chris Longhurst, Scott Sutherland and Christy I. Sandborg. Stanford University, Palo Alto, CA

Background/Purpose: We often find ourselves in clinical situations where the medical literature is sparse or not applicable to our patients' unique medical milieu, particularly in pediatric medicine. Although previous groups have highlighted the secondary use of Electronic Health Record (EHR) data for clinical research, the following case highlights how this same approach can be used to guide real-time clinical decisions. We report the case of a 13 year old patient with SLE who presents with a 2 month history of heavy proteinuria complicated by mild pancreatitis and antiphospholipid (APL) antibodies. We feared that our patient had a high risk for thrombosis—but it is not commonplace to anticoagulate critically ill pediatric patients with these risk factors. Since the published literature was insufficient to guide us in the care of this complex patient, we used historical patient data to guide our decision to use anticoagulation.

Methods: We used an online tool to conduct a rapid automated review of EHR data from 98 historical SLE patients treated at our institution. The pediatric SLE cohort used for this chart review and the IRB approval were previously established. We predefined a list of 10 keywords that allowed us to rapidly identify risk factors and outcomes which were relevant to our patient's clinical situation. In all cases, the sentences surrounding the keywords were manually reviewed.

Results: 36/98 patients had heavy proteinuria (protein to creatinine ratio >2.5 g/dL) and 23 had heavy proteinuria which persisted >60 days. 9 patients had pancreatic dysfunction: 5 with clinical pancreatitis and 4 with subclinical pancreatitis. 53 patients had APL antibodies and were eventually started on aspirin. Among the 36 patients with heavy proteinuria, 9 (25%) developed thrombosis while acutely ill. Among the 9 patients with clinical or sub-clinical pancreatitis, 6 (67%) developed thrombosis while acutely ill. Only 11% of the patients with APL antibodies developed thrombosis. As compared to our lupus patients without these risk factors, the risk of thrombosis among patients with heavy proteinuria was high (RR 7.8, 95% CI 1.9–5.5) and even higher for those patients with heavy proteinuria lasting $>$ 2 months (RR 14.7, 95% CI 3.3–96). Risk of thrombosis among patients with pancreatic dysfunction was also high (RR 15.8, 95% CI 5–49). APL antibodies did not appear to be a risk factor for thrombosis in this cohort (RR 1.0, 95% CI 0.3–3.7). This chart review study was completed in 4 hours. Based on the high rate of thrombosis in patients with heavy proteinuria and pancreatic dysfunction, we decided to anticoagulate our patient within 24 hours of admission and prior to the administration of pulse methylprednisolone.

Conclusion: Real-time availability of data to guide decision making has already transformed other industries. The growing prevalence of EHRs, along with the development of sophisticated tools for real-time analysis of deidentified data sets, will further catalyze this data-driven approach to healthcare delivery. We look forward to the future of medicine in which our systems learn from every patient, at every visit, and help close the clinical decision-making feedback loop in real-time.

The Juvenile Systemic Sclerosis Clinic: An Interdisciplinary Approach. Marìa M. Katsicas, Erica Hammermuller, Betina Cervini and Ricardo A. Russo. MD, Caba, Argentina

Background/Purpose: Juvenile Systemic Sclerosis (JSS) is a rare, complex disease. Usually, patients with JSS receive specialized care from a multidisciplinary team in tertiary hospitals. In order to deliver high standard care, systematic clinical practice strategies should be designed. Based on these premises, we developed a JSS Clinic in the year 2008. We describe the structure and process of a JSS interdisciplinary Clinic, as well as outcomes observed

Methods: During the period 2008–2010, patients with a diagnosis of JSS entered a structured follow-up in a dedicated clinic. Clinic analysis was based on A) structure (teamwork members, databases, guidelines); B) process (tasks and activities related to patient care and evaluation of the JSS clinic); and C) clinical outcomes (skin thickness by Modified Rodnan Score, functional capacity by CHAQ and CMAS; quality of life (QoL) by PedsQL). The quality of the JSS clinic is assessed using a Quality Measure score (QM). This QM is a set of 20 items related to the timely assessment of lung-heart impact, outcome measures, drug adverse effects, cardiovascular risk factors, growth, autoimmunity, treatment appropriateness.

Results: The JSS clinic is the setting where patients diagnosed with JSS are regularly followed. A) Structure. The clinic team gathers monthly in the Day Hospital facility of a tertiary pediatric hospital. This interdisciplinary team includes: pediatricians (2), pediatric rheumatologists (2), pediatric dermatologists (2), pulmonologist (1), cardiologists (1), social workers (2), nutritionists (1), kinesiologists (1), psychiatrists (1) and nurses (1). Databases comprising clinical, epidemiological, and psychosocial variables, as well as electronic records of the clinic personnel and activities, were developed for this clinic and are regularly updated. Clinical guidelines including assessment of general, vascular, musculoskeletal, gastrointestinal, cardiopulmonary, renal and neurologic aspects of patients, as well as therapeutic recommendations. B) Process. Short reviews of the patients′ charts are distributed electronically to the team members 3 days prior to the clinic day. During the clinic, all patients are assessed according to guidelines. Outcome measures (Rodnan score, CMAS, CHAQ) are assessed at each visit; PedsQL is administered a once year. After the evaluation phase, team members discuss tailored work-up and therapeutic strategies for each individual patient. A final report is elaborated and sent both to our records and to the patients′ primary physician. C) Outcomes. Twelve patients (F:11, M:1) are currently included in the JSS clinic program, and they attend it every 3 months. Their age at onset is 96 (9–180) months; delay in diagnosis 21 (4–48) months. Medians at baseline: Rodnan score 21, CMAS 29 and CHAQ > 5: 5 patients. PedsQL Child Self-Report score: 68,45 and Parent Proxy-Report score: 71,71.

Conclusion: The JSS clinic is an interdisciplinary approach that allows a better quality of care, based on the interaction of participating members and the development and use of disease-specific guidelines. A systematic follow-up of patients with JSS is probably best accomplished in this setting.

2070

Lipid Testing Gaps in Patients with Rheumatoid Arthritis and Key Cardiovascular-Related Comorbidities. Christie M. Bartels[1], Amy J. Kind[2], Carolyn Thorpe[1], Christine Everett[3] and Maureen Smith[1]. [1]Univ of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Univ of Wisconsin and William S. Middleton VA, Madison, WI, [3]University of Wisconsin School of Medicine and Public Health, Madison, WI

Background/Purpose: For patients with rheumatoid arthritis (RA) and comorbid cardiovascular disease (CVD), diabetes or hyperlipidemia, secondary prevention through annual lipid testing is recommended to reduce morbidity and mortality from comorbidities. Given trends encouraging complex patients to receive care in "medical homes" we examined associations between regularly seeing a primary care provider (PCP) and secondary lipid testing in eligible RA patients.

Methods: We performed a retrospective cohort study examining a 5% random US Medicare sample (2004–2006) of beneficiaries over 65 years old with RA and concomitant CVD, diabetes, or hyperlipidemia (N=16,893). We examined the relationship between receiving secondary lipid testing in 2006, and having at least one PCP visit per year, 2004, 2005, and 2006, using multivariate regression.

Results: 90% of patients had prevalent CVD, 46% had diabetes, and 64% had hyperlipidemia, however, annual lipid testing was only performed in 63% of these RA patients. Thirty percent of patients saw a PCP less than once per year, despite frequent visits (mean >9) with other providers. Patients without at least one annual PCP visit were 16% less likely to have lipid testing. Increased age, complexity scores, and hospitalization predicted decreased lipid testing, while diabetes and hyperlipdemia increased lipid testing.

Conclusion: Despite comorbid CVD, diabetes, or hyperlipidemia, 30% of Medicare RA patients saw a PCP less than once per year, and one in three lacked annual lipid testing. Findings support advocating primary care visits at least once per year. Remaining gaps in lipid testing suggest the need for additional strategies to improve secondary lipid testing in at-risk RA patients.

2071

Safety, Tolerability, and Immunogenicity of Zoster Vaccine in Patients on Chronic/Maintenance Corticosteroids. Janie Parrino[1], Farid Marquez[2], Chester L. Fisher Jr.[3], Wolfgang Spieler[4], Tadeusz Tomala[5], Jon E. Stek[1], Amy F. Russell[1], Kathleen E. Coll[1], Shu-Chih Su[1], Jin Xu[1], Xiaoming Li[1], Katia Schlienger[1] and Jaffrey L. Silber[1]. [1]Merck Sharp & Dohme Corp., Whitehouse Station, NJ, [2]Palm Springs Research Institute, Hialeah, FL, [3]Health Research of Hampton Roads, Newport News, VA, [4]Rheumatology Specialty Practice, Zerbst, Germany, [5]Svelvik Medical, Svelvik, Norway

Background/Purpose: This study evaluated safety, tolerability, and immunogenicity of zoster vaccine (ZV) in individuals receiving chronic/maintenance systemic corticosteroid therapy (daily dose equivalent of 5 to 20 mg prednisone) for ≥2 weeks prior to enrollment, and ≥6 weeks postvaccination.

Methods: Three-hundred-nine varicella-zoster virus (VZV)-experienced adults ≥60 years old were randomized 2:1 to receive either ZV or placebo (P), stratified by prevaccination corticosteroid dose (5 to 10 mg; >10 to 20 mg) and age (60 to 69 yrs; 70 to 79 yrs; ≥80 yrs). Patients were vaccinated on Day 1 and followed for adverse experiences (AEs), exposure to varicella or herpes zoster (HZ), or development of varicella/varicella-like or HZ/HZ-like rashes for 42 days (primary safety follow-up period). Patients were followed for all serious AEs (SAEs) through Day 182 postvaccination (secondary follow-up period). Blood samples obtained immediately prior to vaccination and at Week 6 postvaccination were assessed for VZV antibody titer by glycoprotein enzyme-linked immunosorbent assay (gpELISA).

Results: During the primary safety follow-up period, 40.2% of patients in the ZV group and 30.3% of patients in the P group reported one or more AEs, with the difference due primarily to the different rates of injection-site AEs following administration of ZV (21.6%) and P (12.1%). The overall proportion of patients reporting systemic clinical AEs was similar between ZV (27.9%) and P (24.2%).

SAEs within 42 days postvaccination were similar for ZV (5.4%) and P (6.1%). One vaccine-related SAE (ophthalmic HZ, Day 16 postvaccination) was reported in the ZV group, and PCR testing confirmed the presence of wild-type (not vaccine strain) VZV. The percentage of patients who reported SAEs within 182 days postvaccination were similar for ZV (10.3%) and P (11.1%), with no vaccine-related SAEs reported between Day 43 and 182.

Geometric mean titer (GMT) at 6 weeks postvaccination was higher for ZV (531.1; 95% CI: 453.3, 622.1) than for P (224.3; 95% CI: 169.8, 296.2). Estimated geometric mean fold rise (GMFR) was 2.3 (95% CI: 2.0 to 2.7) for ZV and 1.1 (95% CI: 1.0 to 1.2) for P.

Conclusion: In adults ≥60 years old on chronic/maintenance corticosteroids: (1) ZV was generally well tolerated; (2) VZV-specific gpELISA antibody GMT at 6 weeks postvaccination was higher in ZV than in P; and (3) VZV gpELISA antibody GMFR from prevaccination to 6 weeks postvaccination was higher in ZV than in P.

2072

Factors Involved in the Decision to Take Medications to Prevent Rheumatoid Arthritis in First Degree Relatives of Patients with Rheumatoid Arthritis. A Discrete Choice Experiment. Axel Finckh[1], Monica Escher[2], Matthew H. Liang[3] and Nick Bansback[4]. [1]University Hospital of Geneva, Geneva, Switzerland, [2]University Hospital of Geneva, Geneva 14, Switzerland, [3]Brigham & Womens Hospital, Boston, MA, [4]University of British Columbia, Vancouver

Background/Purpose: The identification of biomarkers for RA and recent therapeutic advances suggest that it may be possible to identify persons at high risk, treat RA in its pre-clinical phase, and thereby prevent its occurrence. However to take a medication with potential side effects, for an unspecified period of time, possibly to prevent symptoms or disease, is extremely complex. No formative research has been conducted in presymptomatic individuals at high risk of developing RA to understand what factors

they might consider or what preventive treatment would be most acceptable to them.

Methods: We recruited individuals at increased risk of developing RA, namely first degree relatives of patients with RA, to participate in a screening study of preclinical RA. Before the results of biomarker tests were known, participants were invited to consider a scenario in which they were at high risk of developing RA and were offered preventive treatment. They were presented nine treatment profiles, each describing 4 attributes of possible treatments: reduction in risk of developing RA (80%, 20% risk reduction or only delay in RA development), risk of mild side effect (10%, 20%, or 40%), risk of serious side effect (<1%, 5% or 10%) and mode of administration (oral daily tablet, biweekly injections, or a single infusion cycle). The subjects were asked to choose the best and worst feature of each profile. The levels of each attribute were chosen using an orthogonal design. Conditional logit analysis was used to determine the relative preferences for each attribute level.

Results: Only 17 out of 48 subjects completed the questionnaire consistently. Most participants were female (83%), Caucasian (94%), and had one first degree relatives with RA (mean 1.2). Mean age was 49 years. The most important treatment attribute was preventive efficacy (reducing the risk of developing RA by 80%: B=1.99, p<0.01), which was given twice the weight of treatment safety (10% risk of a serious side effect: B=-0.72, p<0.01). A biweekly self-injection was valued worse (B=−0.44, p=0.06) than a 5% risk of serious adverse events (B=−0.09, p=0.06). A single infusion was the preferred mode of administration (B=0.01, p=0.003).

		Est	p
Reduction in risk of developing RA	0% but reduce for 1 year	−1.3582	0.00004
	20% reduction	−0.5888	0.06
	80% reduction	1.9986	0.023
Risk of mild side effect	40%	−0.1066	0.55
	20%	−0.5653	0.24
	10%	−0.0593	0.67
Risk of serious side effect	10%	−0.721	0.0034
	5%	−0.0872	0.056
	0%	1.0472	0.003
Mode of administration	Oral	−0.0499	0.33
	Injection	−0.4461	0.067
	Single Infusion cycle	0.0098	0.003

Conclusion: Our results suggest that efficacy of a preventive therapeutic intervention is the most important factor for individuals at risk of developing RA, followed by the risk of serious adverse events and the convenience and mode of administration of a particular therapy. In this pilot study, participants found it difficult to ponder the various treatment attributes. We suspect the lack of consistency reflects a real difficultly with the competing trade-offs inherent to therapeutic interventions in a primary prevention setting. The development of communication strategies are needed to help FDRs make these value judgments.

2073

Effect of Health Insurance Coverage on Quality of Care in SLE. Edward Yelin[1], Jinoos Yazdany[2], Laura Trupin[3], Chris Tonner[1], Patricia P. Katz[4], Gabriela Schmajuk[5], Joann Zell[6], Pantelis Panopalis[7], Lindsey A. Criswell[2] and Laura J. Julian[2]. [1]UCSF, San Francisco, CA, [2]University of California San Francisco, San Francisco, CA, [3]UC San Francisco, San Francisco, CA, [4]Univercity of California San Francisco, San Francisco, CA, [5]Stanford University, Palo Alto, CA, [6]National Jewish Health, Denver, CO, [7]McGill University, Montreal, QC

Background/Purpose: Quality indicators (QIs) for SLE care have recently been developed.[1] However, the extent to which the quality of SLE care varies between those with and without health insurance coverage and by the kind and source of insurance is unknown.

Methods: Cross-sectional analysis of data derived from the UCSF Lupus Outcomes Study, a prospective, longitudinal cohort study of 814 persons with SLE. Principal data collection was through annual structured telephone surveys between 2009–2010. Data on 13 SLE QIs covering diagnosis, monitoring, treatment, and preventive services were collected. Insurance status was categorized by presence of any insurance, source (public vs. private), and type (managed care [MC] vs. fee-for-service [FFS]); these variables were then combined into 5 mutually exclusive categories. We examined performance on each QI, and also performance on all indicators for which participants were eligible (pass rate). Logistic regression was used to estimate the impact of insurance status, with and without adjustment for demographic and socioeconomic characteristics, SLE and overall health status, specialty of main SLE physician, and total number of SLE physician visits.

Results: Participants were eligible for a mean of 5 QIs (range 2–12). Performance on individual QIs varied from 29% (assessment of cardiovascular risk factors) to 90% (sun avoidance counseling). The overall pass rate was 65% (95% CI 64%, 65%). In unadjusted and adjusted analyses, lack of health insurance was associated with lower pass rates and receiving care in public sector managed care organizations was associated with higher pass rates (see table). Poverty and being a member of a racial or ethnic minority were associated with lower overall pass rates in unadjusted but not adjusted analyses (data not in table).

	Insurance Status				
	None	Public-FFS	Public-MC	Private-FFS	Private-MC
	Cells are Pass Rates (95% CI)				
Unadjusted	.51 (.42, .60)	.66 (.64, .69)	.75 (.70, .80)	.64 (.61, .67)	.63 (.59, .67)
Adjusted*	.57 (.47, .66)	.66 (.63, .69)	.74 (.68, .79)	.64 (.61, .67)	.64 (.60, .67)

FFS= fee-for-service, MC=managed care
* Adjusted for age, gender, race/ethnicity, education, poverty status, disease activity, duration, number of physician visits, and specialty of main SLE physician

Conclusion: Lacking insurance was associated with lower quality of SLE care while having coverage in a public sector managed care organization was associated with higher quality. Health insurance status accounted for part of the effect of poverty and race/ethnicity on quality of care in SLE.

Adherence to Gout Guidelines in a Rheumatology Clinic. Richard Conway, Robert J. Coughlan and John J. Carey. Galway University Hospitals, Galway, Ireland

Background/Purpose: Gout is a common cause of severe acute and chronic debilitating arthopathy. Current drug treatments can reduce the frequency and severity of acute attacks, and eliminate or reverse long term sequelae of gout. Unfortunately many gout patients are poorly managed. Recently published guidelines have set treatment goals for gout management based on serum uric acid levels. A treat to target strategy in a subspeciality gout clinic has the potential to improve patient management.

The aim of this study was to evaluate adherence to recommended serum uric acid levels in the rheumatology outpatients department of a university teaching hospital.

Methods: We performed a retrospective study of all patients with a definitive diagnosis of gout attending our subspeciality gout clinic between 1st January 2010 and 31st December 2010. We evaluated adherence with two recently suggested uric acid thresholds, <5mg/dL and <6mg/dL. Patient management was judged to adhere to the guidelines if either 1) The latest serum uric acid level was less than the specified guideline targets, or 2) Uric acid lowering therapy was titrated upwards or the agent changed if the serum uric acid was above the guideline targets.

Results: 102 patients with a definitive diagnosis of gout attended the outpatients department between 1st January 2010 and 31st December 2010 and were included in the study. Median serum uric acid level was 5.57mg/dL (IQR 4.64mg/dL – 7.67mg/dL). With respect to uric acid lowering therapy, 86 patients (84%) were treated with allopurinol, 6 patients (6%) were treated with febuxostat (one of whom also received probenecid) and 1 with rasburicase. 9 patients (9%) were receiving no uric acid lowering therapy. In 80 patients (78%) the management adhered to a target guideline of <6mg/dL. In 66 patients (65%) the management adhered to a target guideline of <5mg/dL.

Conclusion: A treat to target approach has the potential to improve patient outcomes in the management of gouty arthritis. Our study shows encouraging results with the majority of patients on appropriate therapy, and reaching recommended targets, but there is room for improvement.

2075

Rheumatoid Arthritis: Patient Insights, Strategies and Expectations—Dual Survey Offers Physicians Unique Insight Into Patient Experience. Gerd R. Burmester[1], Theresa Lupton[2], JM Alvaro-Gracia[3] and Boulos Haraoui[4]. [1]Charité—Universitätsmedizin Berlin, Berlin, Germany, [2]Univ of Calgary Medical Clinics, Calgary, AB, [3]Hospital Universitario de la Princesa, IIS Princesa,, Madrid, Spain, [4]Institut de Rhumatologie, Montreal, QC

Background/Purpose: The 2009 Rheumatoid Arthritis: Patient Insights, Strategies + Expectations (RAISE) "Patient Needs Survey" identified gaps in patient-physician communications. The 2011 RAISE "Patient Experience Survey" allowed physicians to identify patients in their practice who could share their daily life with RA and user knowledge of TNF inhibitors (TNFi). Objectives: further define the best patient experience; identify + bridge gaps between actual patient experience and physician perceptions of patient experience; develop the foundation for an information-based program that opens a dialogue between patients and physicians about RA quality-of-life (QoL).

Methods: 47 rheumatologists from Spain, Canada, and Germany identified patients who met entry criteria: ≥18 years old + receiving a subcutaneous biologic for treatment of moderate-to-severe RA for ≥2 months. Patients completed a 30-minute survey via computer-assisted telephone interview. Survey topics: impact of RA on work and social interaction, optimism about QoL, experience with injection site reactions (ISRs), training and education on use of subcutaneous TNFi. All physicians saw aggregate country-level patient data, and those with participation of ≥5 patients also saw practice-level data. Physicians completed a survey that assessed their perceptions of patient needs—both before and after seeing patient data.

Results: 239 patients (78% female, mean age 52 yrs, mean 11 yrs since diagnosis) currently receiving etanercept (51%) or adalimumab (49%) completed the survey. 47 physicians reviewed country-level data (16/47 reviewed practice-level data) and completed a survey. *Patient Data:* 80% of patients felt their RA was moderately/very well controlled in the week pre-survey; 37% reported it significantly affected their daily activities. Two-thirds stated their physician was very aware of these difficulties, while 28% wished he/she asked about it more. Most patients (94%) experienced a degree of discomfort when injecting. The most common patient-reported ISRs were needlestick pain and burning, and 23% (55/239) have these sensations every time. 34% said the burning sensation is moderately or very bothersome and lasts 1.4 hours (mean). 13% have considered skipping injections because of ISRs. 60% reported discussing ISRs with their physician, with 36% of these conversations initiated by the physician. *Physician Data:* Before reviewing patient data, 64% of physicians said they initiated discussions about ISRs and believed that only 18% of their patients experience any ISR. Physicians believed needlestick pain was most common and burning was rarer (<10%) and probably not bothersome. Responding to patient data, 50% felt the incidence and bothersomeness of ISRs were somewhat worse than expected; 30% were motivated to change their approach to managing ISRs; and 75% were more likely to discuss ISRs with patients. 85% agreed that patient data provided new insights.

Conclusion: The RAISE Patient Experience Survey reveals gaps between patient reality and physician perceptions about TNFi treatment and living with RA. Education and dialogue will enable both physician and patient to benefit from improved management of RA.

2076

Implementation of An Electronic Interface for Medical Record Documentation in An Academic Pediatric Rheumatology Outpatient Clinic: An 18-Month Update. Jennifer M.P. Woo[1], Miriam F. Parsa[1], Gil Amarilyo[1], Nasim Afsar-manesh[1], Ornella J. Rullo[2] and Deborah K. McCurdy[2]. [1]University of California, Los Angeles, Los Angeles, CA, [2]Mattel Children's Hospital, University of California, Los Angeles, Los Angeles, CA

Background/Purpose: The transition to electronic medical records (EMR) from traditional paper clinic notes (PCN) reflects a nationwide effort to improve clinic efficiency, to standardize best practices, and to ensure that critical disease processes are documented. Commercial EMR platforms are designed to universalize medical records within a healthcare network; however, they may take years to be fully implemented at large sites and are not always designed to fully capture the specific elements that characterize subspecialty clinic exams. Our healthcare center currently utilizes a transitional EMR that requires physicians to document patient visits with PCN, which are then uploaded to the center-wide EMR by a central department. This process generates a lag period of up to 3 weeks, during which PCN are inaccessible electronically. In response, we created an EMR interface (EMRI) or electronic note. Its implementation in our outpatient pediatric rheumatology clinics began in June 2010 and allows physicians to document and upload their findings directly to the patient's center-wide EMR via laptop or computer in the exam room. Objective: To evaluate clinic workflow and to assess patient perceptions as we transition from PCN to a complete EMR system.

Methods: Our EMRI is a Microsoft Excel form with VBA macros, enabling physicians to compile an accurate measure of the patient's present health. Clinic efficiency is evaluated by monitoring the length of: 1) patient-physician interactions, 2) patient wait time, 3) time dedicated to follow-up charting, and 4) time required for clinic notes to be uploaded to the EMR. Patients or their parents are asked, via paper and/or internet survey, to anonymously assess the quality of care in clinic and their perception of EMRI use throughout the transition process. Data is collected and assessed in 6 month blocks (Block 1: months 1–6; Block 2: months 7–12; and Block 3: months 13–18) and will continue until our EMRI is fully integrated into clinical practice.

Results: One year has elapsed since the implementation of our EMRI, and approximately 56% of our weekly clinic notes are documented electronically. On average, EMRI notes become available within 12 hours of the clinic visit, whereas PCN notes require approximately 7 days ($p < 0.0001$). Compared to early PCN data, EMRI-use during block 2 significantly lessened patient wait time (48 vs. 23 min.; $p = 0.001$) and clinic visit length (85 vs. 51 min.; $p < 0.0001$). Patient-physician interaction time has continued to comprise approximately 50% of clinic visit duration. Of patients and parents surveyed during block 1 or 2 ($n = 31$; $n = 43$), 93% of both groups were receptive to the use of a clinical EMRI. In addition, 81% of patients/parents surveyed during block 2 believed that an EMRI would benefit the patient's quality of care compared to 67% of patients/parents surveyed during block 1 ($p = 0.1$).

Conclusion: The transition from PCN to EMRI notes can be tenuous, albeit necessary. Our preliminary data suggests EMRIs specific for targeted assessments (e.g. rheumatological evaluation) can improve medical documentation while increasing clinic efficiency, patient-physician interactions, and patient perception of quality of care.

The Use of Hydroxychloroquine in Patients with Rheumatoid Arthritis and Systemic Lupus Erythematosus: To Check or Not to Check Glucose-6-Phosphate Dehydrogenase Levels Prior to Its Initiation in Everyday Rheumatology Practice. Mercedes Quinones[1], Sharon Dowell[1], Archana Sharma[2], Raymond Flores[1], Marc Hochberg[1], Jamal Mikdashi[1] and Violeta Rus[1]. [1]University of Maryland School of Medicine, Baltimore, MD, [2]Maryland General Hospital, Baltimore, MD

Background/Purpose: Recent recommendations support the use of Hydroxychloroquine (HCQ) in Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE). There are no recommendations, however, regarding the utility of routinely checking serum Glucose-6-Phosphate-Dehydrogenase (G6PD) levels prior to the initiation of HCQ therapy. G6PD deficiency is the most common enzymatic disorder of red blood cells in humans and affects primarily those of African or Mediterranean descent. HCQ has been implicated as a potential inducer of hemolytic anemia in individuals with G6PD deficiency. Our aim was to identify the frequency with which serum G6PD levels are checked prior to the initiation of HCQ therapy and whether individuals with low G6PD levels suffered any adverse clinical events.

Methods: We conducted a retrospective chart review of our cohort of RA and SLE patients. A total of 170 patient charts were reviewed and we identified patients who were currently taking HCQ, taking it in the past, or had never taken it before. We identified the frequency with which serum G6PD levels were checked prior to starting HCQ. We identified those patients who had low G6PD levels and whether or not they had suffered any adverse clinical events, mainly hemolytic anemia. Descriptive statistics were used for data analysis.

Results: Of the 170 total patients, serum G6PD levels were checked in only 24 patients [14%] of the total study population. A total of 56 patients had a diagnosis of RA, 110 patients had a diagnosis of SLE, and 4 patients had a diagnosis of both RA and SLE. G6PD levels were checked in a total of 7 out of 60 patients with RA [11.6%] and 17 out of 114 patients with SLE [14.9%]. Of those patients in whom G6PD levels were checked, only 1 was found to have a low level [4.2%] without any adverse clinical events despite the long-term use of HCQ. With regards to ethnicity, 137 out of 170 patients were African-American [80.5%] and 29 out of 170 patients were Caucasian [17%]. Of those 24 patients in whom serum G6PD levels were checked, 21 out of 24

[87.5%] were African-American and 3 out of 24 [12.5%] were Caucasian. The 1 patient identified with low serum G6PD levels was African-American.

Conclusion: In our inner city outpatient population of patients with RA, SLE, or both, routine screening for G6PD deficiency prior to the initiation of HCQ therapy was done in only 14% of patients. One patient with RA was noted to have G6PD deficiency and was treated with HCQ with no adverse clinical events. This preliminary data supports the lack of any existing ACR recommendations for checking G6PD levels prior to the initiation of HCQ therapy in RA and SLE patients. Further data collection at our institution is currently in progress.

2078

A Pilot Cardiovascular Risk Reduction Clinic for Inflammatory Rheumatic Diseases. Kevin Martell, Michael Sean McMurtry, Finlay McAlister, Gabor Gyenes and Stephanie O. Keeling. University of Alberta, Edmonton, AB

Background/Purpose: A recent practice audit of 9 rheumatologists at a tertiary care site demonstrated poor cardiovascular (CV) risk management of inflammatory rheumatic disease (IRD) patients. Therefore the utility of a CV risk reduction clinic for these patients warrants investigation. This study established a new model-of-care independent of the standard rheumatology clinic and describes the original inception cohort.

Methods: Patients with moderate to severe inflammatory arthritis (IA) were invited to attend the "CV Risk Reduction Clinic for IRD" as part of a biologics surveillance program in northern Alberta. After initial postal screening of traditional CV risk factors & fasting labs (lipid panel, glucose), clinic attendees were evaluated with pre-specified case report forms including IA activity and traditional CV risk factors. Framingham & Reynold's risk scores were calculated & the European League Against Rheumatism (EULAR) CV risk multiplicative factor of 1.5 applied when criteria were met. Carotid intima media thickness (CIMT) measurements were measured on a separate visit for all consenting patients. Patients were offered dietician counseling, smoking cessation therapies, physiotherapy referrals, lipid lowering (according to 2009 Canadian Cardiovascular Society guidelines) & antihypertensive treatments. RA disease management was left for the attending rheumatologist. Descriptive statistics were calculated with Microsoft excel & the study approved by the University of Alberta ethics.

Results: Twenty-five patients (M:F 7:18) attended the clinic to date, mean age 55.8 (±13.5) years, with the following diagnoses: 19 (76%) RA; 2 (8%) juvenile idiopathic arthritis; 4 (16%) psoriatic arthritis. Fifteen (60%) patients were RF positive, 17 (68%) anti-CCP positive and 9 (36%) had rheumatoid nodules. Mean disease duration was 18±14 years, ESR 15 ± 12 mm/hr, CRP 5 ±4 mg/l & DAS28 2.5 ± 2.2. Radiographic erosions were noted in the hand and feet x-rays of 14 (58%) and 8 (38%) patients respectively. Traditional cardiovascular risk assessment confirmed four (16%) patients as active smokers, 10 (40%) with high cholesterol (LDL > 3.5 mmol/L), 2 (8%) with diabetes, 7 (28%) treated for systolic hypertension, 11 (44%) with family history of premature heart disease & 5 (20%) with personal history of CVD. The mean Framingham and Reynolds risk score of a CV event in the next 10-years was 10% and 2.2% & the mean Framingham applying the EULAR multiplicative factor (8 patients) was 8.0%. Mean CIMT measurement for any observed carotid artery was 0.70 mm (± 0.21; n=74 arteries), & number of arteries with significant thickness (>0.75 mm) was 27 with mean thickness of 0.96 ± 0.15 mm. Plaques were noted in 6 patients.

Conclusion: The CRRC-IRD provides a new model-of-care to evaluate and manage CV risk in a high-risk patient population. Future evaluations from this clinic model include (1) reviewing prospective CV outcomes from the clinic compared to standard-of-care, (2) applicability of different risk scores in IA (given the discrepancy of mean Framingham & Reynold's scores in this study) & (3) contributions of treat-to-target RA disease approach & (4) CIMT to CV risk assessment.

2079

A Screening Tool for Knee Osteoarthritis. C. Kent Kwoh[1], Michael J. Hannon[2], Stephanie M. Green[3], Ali Guermazi[4] and Robert M. Boudreau[3]. [1]University of Pittsburgh and Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Boston Medical Center, Boston, MA

Background/Purpose: This study was conducted to develop and validate a screening tool for knee osteoarthritis that could be administered on paper or thru a web-based interface.

Methods: Potential questions were identified through a literature review of risk factors for the development of radiographic knee osteoarthritis (ROA), examples from other OA screening questionnaires and an Expert Panel. A 42-item set of questions was created that included questions (yes/no) about participant characteristics, knee pain under varying conditions, and related symptoms.

The set of 42 questions was mailed to participants from 2/5 OAI Clinical Centers based on KL grade=0 in both knees (no ROA) or definite ROA (KL≥2 in at least one knee) at their enrollment visit. For the 951/1119 (85%) that responded, ROA status was updated (i.e., their most recent x-ray was read). Those that had a TKR were excluded. The final sample was 777 with 694 (89.32%) having ROA.

Classification and Regression Tree (CART) analysis was used to develop a screening tool using a test set and then validated on the remainder of the sample.

Results: The most predictive model yielded an ROC of.80 but translation of this model into an online screening tool would be relatively complex. Nodes with the least predictive power were pruned yielding a tree of seven variables with an ROC of 0.79, a specificity of 77.1% and sensitivity of 77.8%. The positive predictive value was 96.6%. The negative predictive value was low (29.4%), likely due to the low number of people without any ROA.

The most discriminating items were age, race (African-American (AA) or white), gender, BMI (obese or not), whether they had a history of knee surgery or talked to a doctor about having knee surgery, knee pain when squatting in the past year, stiffness in the knees lasting more than 20 minutes in the past year, swelling of the knees in the past year, and grinding or other noises in the past year.

ROA was very common (N = 268, 98.2%) in participants who had knee surgery or talked to their doctor about it. Among those participants who had not talked to their doctor, ROA was found in all of the participants in three nodes: AA participants ≥age 65 with no pain when squatting; white participants < 65 who were obese and had grinding in their knees; and white participants from 60 to 65 who were not obese but who had grinding in their knees. There was also a very elevated risk of ROA for the following: Anyone > 65 who reported pain while squatting (97.85%); Anyone over 65 who did not have pain when squatting but who was white and had stiffness (96.6%), and anybody under 65 who was AA (92.9%).

Risk of OA was more moderate only for white participants 65 and over who reported no stiffness and no pain when squatting (76.6%); white participants under age 60 who had grinding in their knee but were not obese (67.6%); and white participants under 65 with no grinding in their knee (58.2%).

Conclusion: We have developed and validated a knee OA screening tool. ROA risk was highest among those who were AA, older, heavier, and reported more knee pain symptoms.

Importance of E3 Ubiquitin Ligase Synoviolin In Fibrogenesis. Naoko Yagishita[1], Daisuke Hasegawa[1], Satoko Aratani[2], Yoshihisa Yamano[1] and Toshihiro Nakajima[2]. [1]St.Marianna University School of Medicine, Kawasaki, Kanagawa, Japan, [2]Tokyo Medical University, Tokyo, Japan

Background/Purpose: The symptoms of rheumatoid arthritis (RA) are based on the many processes; chronic inflammation, overgrowth of synovial cells, bone and joint destruction and fibrosis. To clarify the mechanism of outgrowth of synovial cells, we carried out immunoscreening using anti-rheumatoid synovial cell antibody, and cloned 'Synoviolin'. Synoviolin was highly expressed in the rheumatoid synovium, and confirmed that this molecule is one of the causative factors of arthropathy. Further analysis using

gene targeting approaches showed that in addition to its role in RA, Synoviolin is essential for embryogenesis. Synoviolin deficient ($syno^{-/-}$) mice exhibited severe anemia caused by enhancement of apoptosis in fetal liver, and the results suggested that the liver is sensitive organ for Synoviolin. Thus, this study aimed to explore the involvement of the Synoviolin in fibrosis process of RA using mice model of liver fibrosis.

Methods: The expression and localization of synoviolin in the liver were analyzed in CCl_4-induced hepatic injury models and human cirrhosis tissues. The degree of liver fibrosis and the number of activated hepatic stellate cells (HSCs) was compared between wild type (WT) and synoviolin heterozygote ($syno^{+/-}$) mice in the chronic hepatic injury model. We also analyzed the effect of synoviolin on collagen synthesis in the cell line from HSCs using siRNA-synoviolin and a mutant synoviolin in which E3 ligase activity was abolished. Furthermore, we compared collagen synthesis between WT and $syno^{-/-}$ mice embryonic fibroblasts (MEFs) using quantitative RT-PCR, western blotting, and collagen assay; then, we immunohistochemically analyzed the localization of collagen in $syno^{-/-}$ MEFs.

Results: In CCl_4-induced hepatic injury model, $syno^{+/-}$ mice are resistant to onset of liver fibrosis. The number of activated HSCs was decreased in $syno^{+/-}$ mice, and some of these cells showed apoptosis. Furthermore, collagen expression in HSCs was upregulated by synoviolin overexpression, while synoviolin knockdown led to reduced collagen expression. Moreover, in $syno^{-/-}$ MEFs, the amounts of intracellular and secreted mature collagen were significantly decreased, and procollagen was abnormally accumulated in the endoplasmic reticulum.

Conclusion: In conclusion, Synoviolin is involved in not only overgrowth process of synovial cells but also fibrosis process.

2081

Pemetrexed Ameliorates Experimental Arthritis in Rats. Metin Ozgen[1], Suleyman Serdar Koca[1], Ahmet Karatas[1], Adile Ferda Dagli[2], Fazilet Erman[3], Nuran Sahin[4], Kazim Sahin[4] and Ahmet Isik[1]. [1]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [2]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Turkey, [3]School of Health Sciences, Firat University, Elazig, Turkey, [4]Department of Animal Nutrition, Faculty of Veterinary Science, Firat University, Elazig, Turkey

Background/Purpose: Methotrexate (MTX) is considered as the 'anchor drug' and internationally accepted as the first choice in the treatment of rheumatoid arthritis (RA). Pemetrexed (PMTX) is an antifolate drug, as MTX. However, PMTX inhibits several folate-requiring enzymes, apart from MTX, and thus is termed a multitargeted antifolate.

The purpose of this study was to assess the efficacy of PMTX on collagen-induced arthritis (CIA) in rats.

Methods: Forty Wistar albino female rats were randomized to four groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis group, Group-III as the low dose PMTX group, and Group-IV as the high dose PMTX group were assigned. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant in Group-II, III, and IV rats. The doses of 0.2 and 1 mg/kg/week PMTX were intraperitoneally administered in Group-III and IV, respectively after the onset of arthritis.

Animals were sacrificed at the 15th day after the onset of arthritis. The trunk bloods and paws of the rats were obtained for further analysis. Tumor necrosis factor (TNF)-α, interleukin (IL)-17, malondialdehyde (MDA) levels and superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) activities in serum and articular tissue nuclear factor erythroid 2-related factor 2 (Nrf2) and heme oxgenase-1 (HO-1) expressions, perisynovial inflammation and cartilage-bone destruction were determined in the paws.

Results: When compared with Group-I, TNF-α, IL-17, and MDA levels were increased, and SOD, CAT, GPx activities and the expressions of Nrf2 and HO-1 were decreased in Group-II (Table). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in Group-II rats. PMTX treatment decreased the levels of TNF-α, IL-17 and MDA, and increased the activities of SOD, CAT, GPx and the expressions of Nrf2 and HO-1, and decreased the perisynovial inflammation and cartilage-bone destruction in the paws.

Table. Clinical and laboratory data in the study groups

	Group-I (Control) (n=10)	Group-II (Arthritis) (n=10)	Group-III (PMTX 0.2 mg/kg) (n=10)	Group-IV (PMTX 1 mg/kg) (n=10)
14th day arthritis score	–	1.4±0.7	1.9±1.3	1.4±0.5
29th day arthritis score	–	2.4±0.5	1.0±0.6[d]	0.4±0.5[e,f]
Inflammation score	–	4.0±0.0	3.2±0.9[c]	2.4±0.9[e]
Cartilage-bone destruction score	–	3.9±0.3	3.3±0.7[d]	2.0±0.0[e,g]
TNF-α (pg/mL)	25.6±5.0	62.7±12.9[b]	31.7±7.1[d]	30.7±10.4[d]
IL-17 (pg/mL)	29.5±8.3	65.7±8.9[b]	42.3±4.8[b,d]	47.0±5.6[b,d]
MDA (μmol/L)	0.58±0.23	1.60±0.20[b]	0.69±0.14[d]	0.70±0.16[d]
SOD (U/mL)	12.0±7.3	3.4±1.6[b]	6.5±2.7[b,d]	6.5±1.8[b,d]
CAT (nmol/min/mL)	0.33±0.07	0.12±0.08[b]	0.23±0.08[a,c]	0.13±0.1[b]
GPx (nmol/min/mL)	335±179	179±45[b]	292±126[c]	322±198[d]

Data were presented as mean±standard deviation. PMTX: Pemetrexed, TNF: Tumor necrosis factor, IL: Interleukin, MDA: Malondialdehyde, SOD: Superoxide dismutase, CAT: Catalase, GPx: Glutathione peroxidase.
vs Group-I: [a]p<0.05, [b]p<0.0; vs Group-II: [c]p<0.05, [d]p<0.01,[e]p<0.001; vs Group-III: [f]p<0.05, [g]p<0.01

Conclusion: This study is the first to show that PMTX prevents the development of cartilage-bone destruction in the CIA model. These results suggest that PMTX may be candidate of a novel disease modifying antirheumatic drug for the treatment of RA.

2082

Increased Density of Sympathetic Nerve Fibers in Metabolically Activated Fat Tissue Surrounding Human Synovium and Mouse Lymph Nodes in Arthritis. Christine Wolff[1], Luise Rauch[1], Torsten Lowin[1], Susanne Klatt[2] and Rainer H. Straub[1]. [1]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, Department of Internal Medicine I, University Hospital, Regensburg, Germany, [2]Laboratory of Exp. Rheumatology and Neuroendocrino-Immunology, University Hospital, Regensburg, Germany

Background/Purpose: The loss of sympathetic nerve fibers in inflamed tissue and secondary lymphoid organs has been detected during chronic inflammatory diseases such as rheumatoid arthritis (RA). However, it is unclear whether nerve fibers appear in higher density in surrounding non-participating normal tissue. Since fat tissue is often found in the proximity of inflammatory lesions, this study aimed to investigate density of sympathetic nerve fibers in and metabolic activation of fat tissue surrounding human synovium in rheumatoid arthritis/osteoarthritis (OA) and draining lymph nodes in arthritic and normal mice.

Methods: Synovial tissue samples were obtained from 10 OA and 10 RA patients, that underwent knee joint replacement surgery. DBA/1 mice were immunized with collagen type II (CII) in Freund's adjuvant (FA) on day 0 and boosted with CII in incomplete FA on day 21. When a score of 3 points was reached animals were killed and tissue subjected to further analysis. Stainings of sympathetic nerve fibers were performed by immunofluorescence. Presence of nerve repellent factors and beta-3adrenergic receptors was investigated using immunohistochemistry. Metabolic activation of fat tissue was estimated by occurrence of small-vacuoled adipocytes (Sudan-III staining), expression of beta3-adrenoceptors, and adipose tissue weight.

Results: Density of sympathetic nerve fibers was markedly increased in fat tissue surrounding RA compared to OA synovium. In adipose tissue adjacent to draining lymph nodes, density of sympathetic nerve fibers was higher in arthritic compared to normal animals. In human synovium and mouse draining lymph nodes, the two sympathetic nerve repellent factors semaphorin 3C and 3F were highly expressed. In arthritic compared to normal mice, fat tissue around lymph nodes was markedly lighter, adipocytes had more fragmented lipid droplets, and fat tissue demonstrated a high expression of beta3-adrenoceptors.

Conclusion: This study demonstrated an increased density of sympathetic nerve fibers in metabolically activated fat tissue surrounding human RA synovium and draining lymph nodes of arthritic mice. Since sympathetic neurotransmitters stimulate lipolysis, the repulsion of sympathetic nerve fibers from inflamed regions and their increased occurrence in fat tissue is probably an adaptive program to support the proinflammatory process by releasing energy-rich substrates.

2083

Gemcitabine Ameliorates Experimental Arthritis in Rats. Metin Ozgen[1], Suleyman Serdar Koca[1], Adile Ferda Dagli[2], Ahmet Karatas[1], Cemal Orhan[3], Mehmet Tuzcu[4], Nuran Sahin[3], Kazim Sahin[3] and Ahmet Isik[1]. [1]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [2]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Turkey, [3]Department of Animal Nutrition, Faculty of Veterinary Science, Elazig, Turkey, [4]Department of Biology, Faculty of Science, Firat University, Elazig, Turkey

Background/Purpose: T and B lymphocytes are known to have important roles in initiating and/or perpetuating synovial inflammation in rheumatoid arthritis (RA). Gemcitabine (2',2'-difluorodeoxycytidine, GEM), an antimetabolite drug, has anti-proliferative and apoptotic effects on T and B lymphocytes.

This study investigated the therapeutic potential of the GEM on collagen-induced arthritis (CIA) in rats

Methods: Forty Wistar albino female rats were randomized to four groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis group, Group-III as the low dose GEM group, and Group-IV as the high dose GEM group were assigned. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant in Group-II, III, and IV rats. The doses of 5 and 20 mg/kg GEM were intraperitoneally administered in Group-III and IV, respectively twice a week after the onset of arthritis.

Animals were sacrificed at the 15th day after the onset of arthritis. The trunk bloods and paws of the rats were obtained for further analysis. Tumor necrosis factor (TNF)-α, interleukin (IL)-17, malondialdehyde (MDA) levels and superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) activities in serum and articular tissue nuclear factor erythroid 2-related factor 2 (Nrf2) and heme oxgenase-1 (HO-1) expressions, perisynovial inflammation and cartilage-bone destruction were determined in the paws.

Results: When compared with Group-I, TNF-α, IL-17, and MDA levels were increased, and SOD, CAT, GPx activities and the expressions of Nrf2 and HO-1 were decreased in Group-II (Table). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in Group-II rats. GEM treatment decreased the levels of TNF-α, IL-17, MDA, and increased the activities of SOD, CAT, GPx and the expressions of Nrf2 and HO-1, and decreased the perisynovial inflammation and cartilage-bone destruction in the paws.

Table. Clinical and laboratory data in the study groups

	Group-I (Control)	Group-II (Arthritis)	Group-III (GEM 5 mg/kg)	Group-IV (GEM 20 mg/kg)
14th day arthritis score	–	1.4±0.7	1.4±0.5	1.7±0.4
29th day arthritis score	–	2.4±0.5	0.0±0.0[e]	0.0±0.0[e]
Inflammation score	–	4.0±0.0	1.8±0.6[e]	1.3±0.6[e]
Cartilage-bone destruction score	–	3.9±0.3	1.1±0.6[e]	0.5±0.5[e,f]
TNF-α (pg/mL)	25.6±5.0	62.7±12.9[b]	25.8±4.9[d]	30.8±5.5[d]
IL-17 (pg/mL)	29.5±8.3	65.7±8.9[b]	47.4±4.6[b,d]	44.7±5.6[b, d]
MDA (μmol/L)	0.58±0.23	1.6±0.2[b]	0.91±0.28[a,d]	0.76±0.32[d]
SOD (U/mL)	12.0±7.3	3.4±1.6[b]	4.9±1.3[b,c]	4.8±1.4[b]
CAT (nmol/min/mL)	0.33±0.07	0.12±0.08[b]	0.26±0.05[d]	0.30±0.07[e]
GPx (nmol/min/mL)	335±179	179±45[b]	362±208[c]	351±243[c]

Data were presented as mean±standard deviation. GEM: Gemcitabine, TNF: Tumor necrosis factor, IL: Interleukin, MDA: Malondialdehyde, SOD: Superoxide dismutase, CAT: Catalase, GPx: Glutathione peroxidase.
vs Group-I: [a]p<0.05, [b]p<0.01; vs Group-II: [c]p<0.05, [d]p<0.01,[e]p<0.001; vs Group-III: [f]p<0.05

Conclusion: GEM treatment suppresses inflammatory pathways and oxidative stress and ameliorates clinical symptoms and reduces histological scores in the experimental CIA model. These results suggest that GEM may be a potential therapeutic agent in inhibiting joint destruction in RA.

2084

A Novel, Highly Selective Syk Kinase Inhibitor Significantly Ameliorates the Severity of Arthritis in Rodents. Zhong Cui Sun[1], Yu Cai[1], Yan Qiu[1], Lei Fang[1], Xiaoming Dai[1], Zhipeng Wu[1], Ping Ren[1], Jianlin He[1], Changwu Lu[1], Yongjuan Yu[1], Jian Wang[1], Yang Sai[1], James Yan[1], Jia Li[1], Wei Deng[1], Weihan Zhang[1], Jianguo Ji[2], Weiguo Su[1] and Haoran Zhao[1]. [1]Hutchison Medipharma Limited, Shanghai, China, [2]Abott, Shanghai, China

Background/Purpose: SYK non receptor tyrosine kinase is a key mediator of signaling events downstream of a wide array of receptors important for immune function, including the B cell antigen receptor, immunoglobulin receptors bearing the Fcgamma chain, and other ITAM-containing C-type lectin and integrin receptors. In this study we seek to discover a highly potent and selective, orally available small molecule inhibitor for Syk kinase and evaluate its effects in rodent models of arthritis.

Methods: Using both in vitro enzymatic and cell-based assays and in vivo pharmacological assays for establishing structure-activity relationships, compounds were synthesized and screened to identify the ones with excellent potency, selectivity, and drug-like properties. Mouse collagen induced arthritis (CIA) was induced in DBA/1 mice by intradermal administration of chicken collagen type II (CCII) with complete Freund's adjuvant (CFA) on days 0 and 21. Paws were scored using a 0–4 scale with a maximum score of 16 for each animal. Rat adjuvant arthritis (AA) was induced in Lewis rats by intradermal administration of CFA on day 0. Paw volumes were measured daily after arthritis onset. In both models, HM-029 was administered by daily oral gavage.

Results: HM-029 was discovered as a potent and highly selective inhibitor of Syk. It has been tested against a panel of 24 representative tyrosine and serine-threonine kinases and exhibited good general selectivity against other kinases, including KDR, JAK, and Src kinases. In bone marrow-derived mast cells (BMMCs), HM-029 potently inhibited IgE receptor cross-linking stimulated phosphorylation of LAT, ERK, p38 and Akt. The secretion of IL-6, TNFa and IL-13 was blocked by HM-029 as well. In mice with collagen-induced arthritis, treatment with HM-029 after disease onset significantly reduced disease severity in a dose dependent manner. Consistent with its efficacy in mice, HM-029 administered to rats with established AA also ameliorated disease severity compared to vehicle group.

Conclusion: This study showed that HM-029, acting through selective inhibition of Syk activation, exhibited strong beneficial effect in rodent arthritis models. These results support the development of HM-029 as a promising new agent for the treatment of rheumatoid arthritis.

A Novel Role of h2-Calponin in the Development of Anti-GPI Serum-Induced Arthritis. M. Moazzem Hossain[1], Qi Quan Huang[2], Linda D. Hazlet[3], Sharon A. McClellan[3], Richard M. Pope[2] and J.-P. Jin[1]. [1]Departments of Physiology, Wayne State University School of Medicine, Detroit, MI, [2]Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Anatomy and Cell Biology, Wayne State University School of Medicine, Detroit, MI

Background/Purpose: Calponin is an actin cytoskeleton-associated regulatory protein. Three homologous isoforms (h1, h2 and h3) have been identified. H2-calponin is found in smooth muscle and several types of non-muscle cells, including monocytes and macrophages. H2-calponin inhibits proliferation and migration of various types of cells. Our previous study (Huang et al., *JBC*. 283:25887–99, 2008) demonstrated that h2-calponin KO mice showed reduced numbers of peripheral blood neutrophils and monocytes. In addition, the lack of h2- calponin significantly increased migration and phagocytotic activity of macrophages. In the present study, we investigated the role of h2-calponin in the development of anti-GPI serum-induced arthritis.

Methods: H2-calponin knockout (KO) and age- and genetic background-matched C57BL/6 wild type (WT) mice were intraperitoneally injected with 300 ml of anti-GPI mouse serum. Delta-ankle circumference and arthritis clinical score were determined at days 0, 2, 4, 7 and 9 after injection. The ankles harvested at day 9 post-arthritis induction were analyzed for histology by H&E staining. IL-1b concentration in ankle homogenates and serum collected from day 9 post-arthritis induction mice were determined by ELISA. Brewer's thioglycollate-elicited peritoneal macrophages from h2-calponin KO and WT mice were also examined for their cytokine production in response to LPS stimulation in culture using quantitative PCR.

Results: Injection of anti-GPI serum resulted significantly ($P<0.05$) lower Delta-ankle circumference and clinical arthritis score in h2-calponin KO mice in comparison to WT mice. H&E stained sections of ankle joints showed significantly ($P<0.05$) lower inflammation and bone erosion in h2-calponin KO group than that of controls. In contrast, there was no difference in IL-1b in joint tissues of H2-calponin KO and WT mice. Further, compared with the WT controls, h2-calponin-null macrophages demonstrated increased *in vitro* synthesis of IL-1b, IL-6, IL-10, IL-12, TNFa, MIP-2, IFNg, HIF-1a, and INOS both at baseline and upon LPS stimulation. The levels of TLR2 and VEGF-A in h2-calponin-null cells were also higher than WT cells at baseline but were not different after LPS stimulation. TLR4, TGF-b, VEGF-R1 and VEGF-R2 were unchanged in the KO macrophages.

Conclusion: The results demonstrated that h2-calponin plays a novel role in the development of anti-GPI serum-induced arthritis. The function of h2-calponin in regulating macrophage activity may form a basis for its role in inflammation and autoimmune responses. Since there was no reduction of IL-1b in joint tissue, a critical cytokine in this model of passive arthritis, the results may suggest that the mechanisms down stream of the induction of cytokines contributed to the reduction of arthritis development despite the elevation of IL-1b and TNFa. The increased phagocytotic activity of h2-calponin-null macrophages may facilitate the clearance of autoimmune complexes to reduce the severity of arthritis. Further studies are underway to investigate the underlying mechanisms and explore the value of inhibiting h2-caloponin expression for the treatment of arthritis.

2086

An Endogenous TLR2 Ligand Promotes Chronicity of Arthritis Which Is Modulated by Fas Signaling. Qi Quan Huang[1], Alexander Misharin[1], Robert Birtett[1], Carla M. Cuda[1], Christopher V. Nicchitta[2], Harris R. Perlman[1] and Richard M. Pope[1]. [1]Northwestern University, Chicago, IL, [2]Duke university Medical Center, Durham, NC

Background/Purpose: To define the role of non-apoptotic Fas-FasL signaling in the anti-GPI serum induced arthritis model and identify its association with TLR2 or TLR4-mediated macrophage activation.

Methods: Genetically modified mice were generated by crossing floxed Fas ($Fas^{f/f}$) mice with $LyzM^{cre}$ mice to obtain a mouse line deficient in Fas in myeloid lineage ($Fas^{f/f}$, $LyzM^{cre}$). Cell types in peripheral blood were determined by complete cell count and in peritoneal cavity by immunophenotyping. Expression of Fas, TLR2 and TLR4 on the surface of macrophages was determined by flow cytometry. Arthritis was induced by transfer of anti-GPI serum (300ml or 150ml/mouse) from K/BxN mice. The ankles harvested on day10 post-induction were analyzed for histology, cytokines, and gp96 expression, an endogenous TLR2 ligand. Cytokines and gp96 concentration in ankle homogenates were determined by ELISA. Resident peritoneal macrophages were cultured for 3–4 days, and activation following incubation with TLR4 (LPS) or TLR2 (Pam3) ligation was assessed by IL-6 and TNFa ELISA.

Results: When arthritis was induced by a low dose of anti-GPI serum (150 ml), arthritis was significantly reduced in both males and females, while at the higher dose (300 ml), and the reduction of arthritis was greater in the male $Fas^{f/f}$, $LyzM^{cre}$ mice, compared to littermate controls. The ankle homogenates from mice at day10 (300ml anti-GPI) demonstrated reduced IL-1b in both male and female $Fas^{f/f}$, $LyzM^{cre}$ mice compared with same gender littermate controls ($p< 0.05$), however, IL-1b was significantly ($p< 0.05$) lower in the ankles of male compared with female $Fas^{f/f}$, $LyzM^{cre}$ mice. We have demonstrated earlier that the 96 kD heat shock protein (gp96) is an endogenousTLR2 ligand which is increased in the joints of patients with rheumatoid arthritis. We observed that the expression of gp96 is strongly correlated with the course of anti-GPI serum induced arthritis in both $Fas^{f/f}$, $LyzM^{cre}$ ($r= 0.81$, $p<0.001$) and littermate controls ($r= 0.63$, $p<0.01$). gp96 concentration is greatly reduced in the ankles of male $Fas^{f/f}$, $LyzM^{cre}$ mice compared with the same gender littermate controls ($p< 0.01$) or female $Fas^{f/f}$, $LyzM^{cre}$ mice at day10. Resident peritoneal macrophages from the male mice demonstrated reduced IL-6 ($p<0.05$) and TNFa ($p<0.05$) production in response to Pam3, but not to LPS. The expression of TLR2 and TLR4 was not reduced in any myeloid cell in the $Fas^{f/f}$, $LyzM^{cre}$ mice. Supporting the role of gp96, treatment of wild type mice with a neutralizing antibody to gp96, ameliorated the chronicity of the arthritis in male but not female mice.

Conclusion: These observations demonstrate that Fas deficiency on myeloid cells results in reduced arthritis, which is more apparent in males. The local expression of the endogenous TLR2 ligand gp96 correlated with disease activity, and TLR2-mediated activation of macrophages from $Fas^{f/f}$, $LyzM^{cre}$ was reduced. Further, a neutralizing antibody to gp96 suppressed arthritis in male mice. These observations suggest that the local release of endogenous TLR2 ligands may contribute to the chronicity of anti-GPI induced arthritis and that this progression is enhanced by intact Fas signaling.

Suppression of Established Rat Collagen-Induced Arthritis and Inhibition of TNF-α with Small Molecule Aminopyridizines. Soo I. Choi[1], Lori D. Klaman[2], Weiling Chen[1] and Ernest Brahn[1]. [1]UCLA School of Medicine, Los Angeles, CA, [2]Transition Therapeutics, Toronto, ON

Background/Purpose: In rheumatoid arthritis (RA), activated macrophages and synoviocytes produce many key cytokines and mediators that contribute to the inflammation and joint destruction. Blocking proinflammatory cytokines such as TNF-α, IL-1β, and IL-6 has led to clinical and radiographic benefits in RA patients. TT301 and TT302 are unique, orally available, small molecules that can suppress proinflammatory cytokines and reduce inflammation in rodent models of multiple sclerosis and Alzheimer's disease. We report the effects of these compounds on inflammatory pathways *in vitro*, and in established rat collagen-induced arthritis (CIA) *in vivo*.

Methods: The in vitro effects of TT301 and TT302 on cytokine production were examined in stimulated primary synovial fibroblasts and RAW264.7 macrophages. Cells were preincubated with compound or vehicle in serum-free media and stimulated with LPS (5 mg/mL), IL-1β (5 mg/mL) or TNF-α (30ng/mL). Supernatants were analyzed by cytokine ELISA. *In vivo* studies used Lewis rats immunized with porcine type II collagen on day 0 to induce CIA. A total of 84 rats were immunized and 71 rats with arthritis by day 14 were randomized to vehicle controls or 5 treatment arms: TT301 (1 and 7 mg/kg) or TT302 (at 1, 7, or 15mg/kg). Based on the degree of joint involvement and soft tissue swelling, each limb was scored from 0–4, with a maximum total score of 16. At the end of study (day 28), plasma was harvested for multiplex cytokine profiles, the left hind limbs were fixed for immunohistochemistry, and the right hind limbs were microdissected/snap frozen to obtain pure synovium for gene expression profiles, gene hub, module, and network analysis. All 142 hind limbs were also evaluated with high resolution digital radiographs using a 0–3 scale (0=normal, 1=soft tissue swelling only, 2=minor erosions, and 3=marked erosions).

Results: In stimulated RAW264.7 macrophages and synovial fibroblasts, TT301 and TT302 dose-dependently inhibited the induction of key cytokines relevant to RA pathology including TNF-α, IL-6, and MCP-1. By protocol design, all Lewis rats that developed CIA between days 11–14 entered the study and were then randomized. The clinical severity was significantly lower than vehicle controls for both agents with a dose-response benefit (TT302 $p< 4 \times 10^{-6}$, $p< 8 \times 10^{-7}$, and $p< 4 \times 10^{-9}$ for 1mg/kg, 7mg/kg or 15mg/kg, respectively) (TT301 $p< 1 \times 10^{-6}$, $p< 2 \times 10^{-8}$ for 1mg/kg or 7mg/kg, respectively). Statistical differences, compared to controls, were typically noted within 48–72 hours after initiation of therapy and this was sustained. By the end of the study on day 28, TT302 and TT301 suppressed radiographic damage (TT302 $p< 1 \times 10^{-2}$, $p< 5 \times 10^{-4}$, and $p< 3 \times 10^{-8}$ for 1mg/kg, 7mg/kg or 15mg/kg, respectively) (TT301 $p< 7 \times 10^{-2}$, $p< 2 \times 10^{-8}$ for 1mg/kg or 7mg/kg, respectively). Cytokine profiles post-treatment demonstrated that TT301 and TT302 tended to lower circulating TNF-α levels. The analysis of joint immunohistochemistry and synovial gene expression profiles is ongoing.

Conclusion: TT301 and TT302 suppressed established CIA and inhibited TNF-α. The studies indicate that these novel small molecules might have therapeutic benefits in RA.

2088

Treatments with Glycogen Synthase Kinase-3β Inhibitor Mitigate the Severity of Arthritis in Mice with Collagen-Induced Arthritis. Yong-Jin Kwon, Tae-Yeon Kim, Sang-Won Lee, Yong-Beom Park, Soo Kon Lee and Min-Chan Park. Yonse University College of Medicine, Seoul, South Korea

Background/Purpose: Glycogen synthase kinase (GSK)-3β is a multifunctional serine-threonine kinase, which was originally identified as a rate-limiting enzyme involved in the control of glycogen metabolism. Recently, it has been shown that GSK-3β performs a critical function in the regulation of various signaling pathways involving inflammatory responses, and the mechanisms for these anti-inflammatory effects are thought to be primarily mediated via antagonizing the transcriptional activities of NF-κB. This study was performed to investigate the therapeutic effects of selective GSK-3β inhibitors; lithium chloride, 4-benzyl-2-methyl-1,2,4-thiadiazolidine-3,5-dione (TDZD-8) and 6-bromoindirubin-3'-oxime (BIO) on the severity of arthritis and inflammatory response in collagen-induced arthritis (CIA) mice.

Methods: DBA/1J mice were immunized with CII in Freund's complete adjuvant and administered with booster injection 3 weeks later to induce CIA. Mice were subsequently injected intraperitoneally with 0.1 mM and 10 mM of lithium chloride, TDZD-8, or BIO once daily between day 24 and day 45 postimmunization. Clinical assessment for arthritis scores and histopathological assessment of joint sections were performed. The infiltration of T cells and macrophages were determined by immunohistochemical staining for CD3 and F4/80 and the activity of osteoclast

was assessed by tartrate resistant acid phosphatase (TRAP) staining in joint sections from CIA mice. Serum levels of IL-1β, IL-6, TNF-α and IFN-γ were evaluated using ELISA.

Results: Histologic analysis of joints from vehicle-treated CIA mice showed severe synovial proliferation, significant infiltration of inflammatory cells, and bone erosion. Treatments of each GSK-3β inhibitors significantly attenuated the clinical and histological severity of CIA, compared with vehicle-treated mice, and these effects were shown in dose-dependent manners. The infiltration of T cells and macrophages were decreased in immunohistochemical analysis of joint sections and TRAP-positive cells were also down-regulated by treatments with GSK-3β inhibitors. The serum levels of IL-1β, IL-6, TNF-α and IFN-γ were significantly decreased by treatments with GSK-3β inhibitors in dose-dependent manners.

Conclusion: GSK-3β inhibitors treatment reduces inflammation and joint destruction in CIA, and suppressed the productions of various pro-inflammatory cytokines. These findings suggest that inhibition of GSK-3β can be an effective therapeutic agent in rheumatoid arthritis.

Pressure and Viscosity Measurements in Efferent Lymphatics to Better Understand the Mechanisms of Arthritic Flare and Response to Therapy. Echoe M. Bouta, Ronald Wood, Christopher T. Ritchlin and Edward M. Schwarzy. University of Rochester School of Medicine and Dentistry, Rochester, NY

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease distinguished by episodic flares in affected joints. Recently, we showed that altered lymph node volume and lymph drainage from the affected joint precede arthritic flare while novel therapies that target lymphatics are being developed. Unfortunately, methods to directly measure the lymphatic pressure and viscosity changes during and after arthritic flare and responses to therapy are not available for the established animal models of RA. Thus, the goal of this study was to develop quantification methods suitable for studying the lower limbs of mice during arthritic flare and in response to therapy.

Methods: Pressure measurements were performed by the insertion of a glass micropipette connected to a pressure transducer into the popliteal lymph node (PLN) of WT mice. Placement was confirmed by examining the temporal association of pressure changes with optical pulsations detected by near infrared-indocyanine green (NIR-ICG) imaging, and by an increase of signal intensity in the lymphatic vessels that occurred after injecting ICG into the PLN through the glass micropipette. Viscosity was measured by multi-photon fluorescence recovery after photobleaching (MP-FRAP) of FITC-dextran in lymphatic vessels afferent to PLN, after introducing the dye by footpad injection. The recovery time was measured to determine the diffusion coefficient of lymph, which was then used to calculate the viscosity of the lymph with the Stokes-Einstein equation.

Results: Correct placement of the glass micropipette into the node was achieved and verified by no evidence of leaking, increase of intensity in the surrounding lymphatic vessels and a detected pulse in the pressure measurement. Lymphatic pressure was determined to be ~14cm water. In vivo viscosity measurements could be verified by finding the diffusion coefficient of a solution of a known viscosity, and the viscosity of the lymph was determined to be ~2mPa s.

Conclusion: Here we describe novel methods to quantify lymphatic pressure and viscosity in lymphatic vessels and PLN of mice. Additional preliminary results with these methods to quantify lymphatic function during the acute and chronic phases of arthritis in TNF-Tg mice will be discussed together with translational modification that may facilitate elucidation of the mechanisms of arthritic flare in RA.

IL-6 Blockade Augments the Therapeutic Effect of MTX in Mice with Glucose-6-Phosphate Isomerase-Induced Arthritis. Hiroto Yoshida[1], Misato Hashizume[1], Keisuke Tanaka[1], Miho Suzuki[1], Takayuki Sumida[2], Isao Matsumoto[2] and Masahiko Mihara[1]. [1]Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan, [2]Division of Clinical Immunology, Doctoral Program in Clinical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan

Background/Purpose: Methotrexate (MTX) is a front-line drug for rheumatoid arthritis (RA), but progressive loss of efficacy is a major problem. Transporters are determinants of the pharmacological effect of drugs. MTX enters cells through the reduced folate carrier (SLC19A1). Here, we elucidated the relevance of SLC19A1 expression for MTX therapeutic effects using glucose-6-phosphate isomerase (GPI)-induced arthritis.

Methods: GPI-induced arthritis in DBA/1J mice was triggered by intradermal injection of recombinant GPI and pertussis toxin. MTX was given orally thrice weekly from the first day of immunization. Mice were injected once with 4 mg of rat anti-mouse IL-6R monoclonal antibody (MR16-1) intraperitoneally 10 days after immunization. Clinical symptoms of arthritis were evaluated visually on a scale of 0 – 3 for each limb. SLC19A1 mRNA in hind limbs was quantified by real-time PCR. Serum anti-GPI antibody, antigen-specific IL-17 production from splenocytes and serum cytokines were measured by ELISA. Synovial cells from arthritic mice were cultured with MTX, TNF-α and IL-6 for 3 days, and cell proliferation assessed by BrdU incorporation. To analyze gene expression, synovial cells were cultured with MTX, TNF-α and IL-6 for 24 h, after which SLC19A1 mRNA was quantified by real-time PCR.

Results: First, we examined the effect of MTX on GPI-induced arthritis. Whereas MTX reduced arthritis up to day 20 after immunization, its efficacy gradually decreased between day 20 and 30. Arthritic mice expressed less hind limb SLC19A1 than controls, and MTX decreased this further. Because TNF-α and IL-6 levels were elevated in the affected paws of mice with GPI-induced arthritis, we next examined the effects of MTX, TNF-α and IL-6 *in vitro*. Culture of synovial cells with MTX or IL-6, but not TNF-α, decreased the expression of SLC19A1. In the presence of IL-6, MTX further reduced SLC19A1 expression. Additionally, the inhibitory effect of MTX on synovial cell proliferation was reduced in the presence of IL-6. Although MR16-1 did not improve arthritis when injected at day 10, MTX and MR16-1 together reduced symptoms better than MTX alone. Injection of MR16-1 resulted in the return of SLC19A1 mRNA to normal levels. Combining MTX and MR16-1 increased SLC19A1 mRNA more than MTX alone. Antigen-specific IL-17 production by splenocytes from arthritic mice was higher than in controls. Unexpectedly, MTX treatment increased IL-17 production and a combination of MTX + MR16-1 did not reduce it. Anti-GPI antibody was present in the serum of arthritic but not control mice, and this was more strongly suppressed by MTX and MR16-1 than by MTX alone.

Conclusion: We demonstrated that MTX-treated arthritic mice was resistant to MTX along with continuous administration and reduced SLC19A1 expression in mice with GPI-induced arthritis. IL-6 blockade augments the therapeutic effect of MTX via up-regulation of SLC19A1 expression.

2091

Laquinimod Inhibits Disease Severity in Murine Collagen Induced Arthritis. Joel F. Kaye and Eran Blaugrund. Teva Pharmaceuticals Ltd, Netanya, Israel

Background/Purpose: Laquinimod (TV-5600; LAQ) is a synthetic compound being developed by Teva for the treatment of multiple sclerosis (MS). Laquinimod has demonstrated therapeutic effect in various experimental autoimmune models, including animal models of Guillain-Barré Syndrome, Inflammatory Bowel Disease, and Type I Diabetes. The mechanism of action of laquinimod in these models includes the reduction of leukocyte infiltration and modulation of the cytokine milieu. Furthermore, in a spontaneous model of SLE in MRL/lpr mice, laquinimod treatment inhibited many aspects of systemic lupus including arthritic joint swelling. These promising findings prompted the present study to evaluate whether laquinimod can inhibit disease severity in a mouse model of arthritis.

Methods: Male DBA/1OlaHsd mice were immunized with type II collagen in CFA on days 1 and 21. From day 18 (semi-established arthritis) mice were dosed orally (PO) daily (QD) with vehicle, LAQ (0.2, 1, or 5 mg/kg), methotrexate (0.5 mg/kg, MTX), or LAQ (0.2 or 1 mg/kg) in combination with MTX (0.5 mg/kg) until day 33. Efficacy evaluations were

based on animal body weights, daily clinical arthritis scores, arthritis scores expressed as area under the curve (AUC) and histopathology on fore paws, hind paws, and knees from all mice. Evaluation of serum anti-type II collagen antibody levels was also performed

Results: Clinical arthritis scores expressed as AUC were significantly reduced for mice treated with MTX (50% reduction), 0.2 mg/kg LAQ (32%), 1mg/kg LAQ (52%) or 5 mg/kg LAQ (69%). When treatment with MTX and LAQ was combined, clinical arthritis scores were reduced to 82% (0.2mg/kg LAQ) or 95% (1mg/kg LAQ), as compared to vehicle controls.

All paw histopathology parameters were significantly reduced toward normal, for mice treated with 1 mg/kg LAQ (61% reduction of summed scores), 1 mg/kg LAQ+MTX (96%), or MTX (46%) as compared to vehicle controls. Treatment with 1 mg/kg LAQ significantly reduced knee inflammation (51% reduction), pannus (59%), cartilage damage (62%), and summed knee scores (57%) as compared to vehicle controls. All knee histopathology parameters were significantly reduced toward normal for mice treated with 1 mg/kg LAQ+MTX (97% reduction of summed scores) as compared to vehicle controls.

Conclusion: Results of this study indicate that daily oral treatment with laquinimod (0.2, 1, or 5 mg/kg) had significant and dose dependent effect on the clinical and histopathalogical parameters associated with semi-established type II collagen arthritis in mice. In addition, combining laquinimod and methotrexate treatment resulted in an additive effect on all tested parameters.

2092

Blocking the Granulocyte Macrophage Colony Stimulating Factor Receptor Alpha Chain Prevents Mechanical Hypersensitivity in a Mouse Model of Inflammatory Pain. John P. Hatcher, Justine Whitworth, Ian K. Anderson, Iain P. Chessell and Matthew A. Sleeman. MedImmune Ltd, Cambridge, United Kingdom

Background/Purpose: Over the last decade the GM-CSF pathway has been proposed as playing a pivotal role in the pathology of rheumatoid arthritis (RA) by promoting macrophage and neutrophil activation, survival and differentiation. Consequently a number of clinical studies are underway in RA targeting either GM-CSFR or GM-CSF. Recently it has also been shown that GM-CSF may have a role in peripheral pain sensation in models of cancer pain. As refractory pain remains a significant problem in many individuals with RA, we have investigated the role of GM-CSFR blockade in a mouse model of inflammatory pain. Objective: In these studies we aimed to characterize the role of GM-CSFR alpha in inflammatory pain by blocking GM-CSF signalling using a neutralising antibody to the GM-CSF receptor.

Methods: Mechanical hypersensitivity was determined using a mouse incapacitance tester. Mice were placed into the apparatus such as each hind paw was located on one of two weight bearing sensors. Weight bearing was calculated by measurement of ipsilateral and contralateral weights in grams over a period of 4s. Following the establishment of baseline readings mice received a single intra-plantar administration of Complete Freunds Adjuvant (FCA) (30μl of 1mg/ml). 24 hrs later mice underwent pre-dose testing for changes in mechanical hypersensitivity as described above. Mice were then randomly allocated into treatment groups of 9/10 with approximately equal ipsilateral/contralateral ratios and were administered one of the following treatments; PBS vehicle (10ml/kg), CAT-004, the isotype control (30mg/kg) or CAM-3003, a GM-CSFR antibody (3, 10 or 30mg/kg). All doses were administered intra-peritoneally. Mice were re-tested for changes in mechanical hypersensitivity at 4hr, 1, 2, 3 and 7 days post dose as described above.

Results: FCA caused a mechanical hypersensitivity which manifested as a reduction in the ipsilateral/contralateral ratio when compared to naive readings. The administration of CAT-004 did not produce any significant reversal of the FCA induced hypersensitivity at any time point when compared to PBS vehicle control. CAM-3003 (3, 10 and 30mg/kg) caused a reversal of the FCA induced hypersensitivity (vs CAT 004 control) which reached significance 1 day post dose for all treatment groups. Significance was maintained out till 2 days post dose for the 30mg/kg group. No significant inhibition of mechanical hypersensitivity was observed following administration of 3mg/kg or 10mg/kg CAM-3003 when compared with isotype control (CAT-004).

Conclusion: This study demonstrates that inhibiting GM-CSF signalling is effective in a mouse inflammatory pain mouse model, supporting continued development of agents targeting GM-CSFR for this therapeutic area.

2093

Prophylactic Injection of Non-Citrullinated Alpha-Enolase Has Immunomodulatory Effects in Collagen-Induced Arthritis Mice. Clément Guillou[1], Gilles Avenel[1], Céline Derambure[1], Mathieu Verdet[1], Martine Hiron[1], Maude Maho[1], Xavier Le Loët[2], Sahil Adriouch[1], Olivier Boyer[1], Thierry Lequerré[2] and Olivier Vittecoq[2]. [1]Inserm 905 & Institute for Biomedical Research, University of Rouen, Rouen, France, [2]Department of Rheumatology, Rouen University Hospital & Inserm 905, Institute for Biomedical Research, University of Rouen, Rouen, France

Background/Purpose: Identification of autoantibodies associated with rheumatoid arthritis (RA) has been of major interest. In this context, we have previously identified for the first time α-enolase as a new auto-antigen in early RA*. Moreover, subsequent studies have shown that citrullination of α-enolase is crucial for its autoantigenicity. α-enolase is an evolutionary conserved protein implicated both in glycolysis pathway and as a plasminogen receptor. Here, we have evaluated, in the well-known collagen induced arthritis (CIA) model, the clinical and immunological effects of both recombinant non-citrullinated α-enolase and immunodominant peptides from human and bacterial species.

Methods: Different doses of α-enolase (10 and 100 μg) or immunodominant enolase peptide 1 from human [hEP1] or P*orphyromonas gingivalis* [pEP1] (1, 10 or 100μg) were intraperitoneally injected to 6 week-old DBA/1 mice one day prior to collagen II arthritis induction. Both clinical (weight, arthritis score, tarsal thickness) and biological (anti-collagen II and anti-α-enolase antibodies) were assessed during the 90 days follow-up period.

Results: Prophylactic injection of recombinant α-enolase was able to significantly prevent weight loss and to decrease the severity of arthritis evaluated by the arthritis score as well as the tarsal thickness. There was a dose-effect since 100 μg led to better results. Levels of anti-collagen II antibodies were significantly lower whereas titers of anti-α-enolase antibodies were significantly higher in mice treated with 100 μg of a-enolase compared to control mice. As regards to hEP1 and pEP1, we etablished a dose-dependant protective effect in CIA which is significant for pEP1. This protective effect is not due to once again a decrease of anti-collagen II antibodies titer.

Conclusion: Prophylactic treatment with recombinant α-enolase as well as immunodominant peptides has immunomodulatory effects in collagen-induced arthritis mice. The regulatory mechanisms induced by this protein seem to be partially due to a control of the production of anti-collagen II antibodies. Those results suggest that non-citrullinated α-enolase could constitute a potential new therapeutic approach in RA.

Preventive and Therapeutic Effects of Epigallocatechin-3-Gallate (EGCG) on Collagen-Induced Arthritis in Rats. Metin Ozgen[1], Suleyman Serdar Koca[1], Adile Ferda Dagli[2], Ahmet Karatas[1], Cemal Orhan[3], Hasan Gencoglu[4], Nurhan Sahin[3], Kazim Sahin[3] and Ahmet Isik[1]. [1]Department of Rheumatology, Faculty of Medicine, Firat University, Elazig, Turkey, [2]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Turkey, [3]Department of Animal Nutrition, Faculty of Veterinary Science, Elazig, Turkey, [4]Department of Biology, Faculty of Science, Firat University, Elazig

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disorder characterized by cellular infiltration and proliferation of synovium, leading to progressive destruction of the joints through the interaction between infiltrating cells and mediators they produce. A number of factors including inflammation and oxidative stress are believed to play a role in the development of chronic joint diseases. Epigallocatechin-3-gallate (EGCG) is a potent antioxidant, antiinflammatory, antiangiogenic, and antioncogenic compound derived from green tea.

The purpose of this study was to assess the preventive and therapeutic effects of EGCG on collagen-induced arthritis (CIA) in rats.

Methods: Forty Wistar albino female rats were randomized to four groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis group, Group-III as the prenventive EGCG group, and Group-IV as the therapeutic EGCG group were assigned. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant in Group-II, III, and IV rats. In Group-III, the EGCG treatment was started one day before the induction of arthritis, while in Group-IV, EGCG treatment was started after the onset of arthritis at day 14.

Animals were sacrificed at the 15th day after the onset of arthritis. The trunk bloods and paws of the rats were obtained for further analysis. Tumor necrosis factor (TNF)-α, interleukin (IL)-17, malondialdehyde (MDA) levels and superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) activities in serum and articular tissue nuclear factor erythroid 2-

related factor 2 (Nrf2) and heme oxgenase-1 (HO-1) expressions, perisynovial inflammation and cartilage-bone destruction were determined in the paws.

Results: When compared with Group-I, TNF-α, IL-17, and MDA levels were increased, and SOD, CAT, GPx activities and the expressions of Nrf2 and HO-1 were decreased in Group-II (Table). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in Group-II rats. The decreased levels of TNF-α, IL-17, MDA, and the increased activities of SOD, CAT, GPx and the expressions of Nrf2 and HO-1, and the reductions in perisynovial inflammation and cartilage-bone destruction in the paws were determined in Group-III and IV. Compared with Group-IV, the decreased 14th day arthritis score was significant while the 29th day arthritis score was relatively lower in Group-III.

Table. Clinical and laboratory data in the study groups

	Group I (Control) (n=10)	Group II (Arthritis) (n=10)	Group III (EGCG1) (n=10)	Group IV (EGCG2) (n=10)
14th day arthritis score	–	1.4±0.7	1.0±0.6	1.6±0.5[f]
29th day arthritis score	–	2.4±0.5	0.6±0.5[e]	0.9±0.3[e]
Inflammation score	–	4.0±0.0	3.0±0.5[e]	3.1±0.7[d]
Destruction score	–	3.9±0.3	2.4±0.5[e]	3.0±0.8[d]
TNF-α (pg/mL)	25.6±5.0	62.7±12.9[b]	44.6±18.8[b,c]	31.6±8.4[d]
IL-17 (pg/mL)	29.5±8.3	65.7±8.9[b]	44.8±4.5[b,d]	47.0±4.6[b,d]
MDA (μmol/L)	0.58±0.23	1.60±0.20[b]	0.96±0.43[d]	0.77±0.14[d]
SOD (U/mL)	12.0±7.3	3.4±1.6[b]	8.5±5.2[d]	10.6±5.0[e]
CAT (nmol/min/mL)	0.33±0.07	0.12±0.08[b]	0.27±0.04[e]	0.28±0.04[e]
GPx (nmol/min /mL)	335±179	179±45[b]	403±88[e]	461±99[a,e]

Data were presented as mean±standard deviation. EGCG: Epigallocatechin-3-gallate, TNF: Tumor necrosis factor, IL: Interleukin, MDA: Malondialdehyde, SOD: Superoxide dismutase, CAT: Catalase, GPx: Glutathione peroxidase.
EGCG1: The administrations of EGCG were started one day before the induction of arthritis.
EGCG2: The administrations of EGCG were started after the onset of arthritis.
vs.Group-I: [a]p<0.05, [b]p<0.01; vs. Group-II: [c]p<0.05, [d]p<0.01,[e]p<0.001; vs. Group-III: [f]p<0.05

Conclusion: These results suggest that EGCG may be of potential preventive and therapeutic value in inhibiting joint destruction in RA.

2095

Trichostatin A Induces CD8á Positive Tolerogenic Dendritic Cells, Regulatory T Cells in SKG Mice, and Ameliorates the Severe Arthritis. Kenta Misaki, Akio Morinobu, Jun Saegusa, Shimpei Kasagi, Masaaki Fujita, Yoshiaki Miyamoto, Fumichika Matsuki and Shunichi Kumagai. Kobe university graduate school of medicine, Kobe, Japan

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disorder, characterized by cellular infiltration of and proliferation in the synovium, leading to the progressive destruction of the joints. Dendritic cells (DC) play a pivotal role by triggering the immune responses in RA pathogenesis. Trichostatin A (TSA) plays a significant role of controlling gene transcription as a histone deacetylase inhibitor, and has been reported to regulate immune responses. Here we examined to elucidate the effects of TSA on the phenotype and function of DC and on arthritis in SKG mice.

Methods: Arthritis was induced in SKG mice by Zymosan A (ZyA) injection. TSA was administered and its effects on arthritis were evaluated by joint swelling and histological evaluation. IL-17A production in lymph node cells was determined by ELISA. Foxp3 expression in lymph node cells and the phenotypes of splenic conventional DC (cDC) were examined by flow cytometry. Bone marrow-derived DC (BM-DC) were generated with granulocyte macrophage colony-stimulating factor. The effects of TSA on cytokine production, cell surface molecules, indoleamine 2,3-dioxygenase (IDO) expression and T cell stimulatory capacity of BM-DC were examined by flow cytometry, ELISA, quantitative real-time polymerase chain reaction and Western blot, and the allo-mixed lymphocyte reaction, respectively.

Results: TSA, when administered before the onset of arthritis, prevented SKG mice from arthritis. TSA treatment also showed therapeutic effects on arthritis in SKG mice, when administered after the onset of arthritis. TSA treatment reduced IL-17A production and increased in the ratio of CD4+CD25+Foxp3+ cells among CD4+ cells in lymph node, suggesting that regulatory T cells are involved in the prevention of arthritis in SKG mice with TSA. In the CD8α+ splenic cDC subset, the expressions of CD86, CD80, and CD40 were significantly decreased in the TSA-treated group compared to the control group. In contrast, there were no significant differences in the expression of these molecules in the CD8α− cDC subset. Thus, TSA predominantly affects CD8α+ cDC *in vivo*. *In vitro*, TSA markedly suppressed ZyA-induced IL-12 and IL-6 productions, cell surface molecules by BM-DC and up-regulated IDO expression at mRNA and protein levels. TSA-treated BM-DC also showed less T cell stimulatory capacity.

Conclusion: TSA changes DC to a tolerogenic phenotype, induces regulatory T cells and ameliorates arthritis in SKG mice.

Brucellosis-Induced Murine Arthritis and Spondylolisthesis. Elizabeth T. Lyons[1], Diogo Magnani[2], Toni S. Forde[1], Gary Splitter[2] and Vyacheslav A. Adarichev[1]. [1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Wisconsin, Madison, WI

Background/Purpose: Approximately 500,000 people world-wide are infected with Brucella each year and most develop spondyloarthropathy by mechanisms which are poorly understood. Brucellosis is a zoonotic disease that remains endemic to many parts of the world and therefore presents a problem for public health due to possible transmission to domestic animals and humans. The goal of the study was to establish a murine model for human Brucellosis to better understand mechanisms of association between Brucella infection and spondylitis of lumbar and sacral spine in human patients.

Methods: BALB/c females were infected via i.p. injection with 100M *B.abortus S19* or *B.melitensis GR023*, then sacrificed 3 and 26 weeks post-infection. Bacterial dissemination was monitored using bioluminescence and histopathology. Axial skeleton from thoracic to tail, front and hinds paws, spleen, and liver were included in the evaluation. Histopathology slides were stained with hematoxylin & eosin, alcian blue, tartrate-resistant acid phosphatase. Immunohistochemistry was performed for IBA-1 marker and Brucella cell wall.

Results: *B.abortus* and *B.melitensis* demonstrated similar peaks of bacterial infection at day seven, but bacteria remained detectable in the intraperitoneal cavity, spleen, and skeletal tissues for several weeks post-infection. *In vivo* bioluminescence showed accumulation of luminescent *B.melitensis* in tarsal parts of front and hind paws and in knees, but the strongest signal was detected in the tail following the distribution of vertebrae. Upon immunohistochemical staining, intracellular bacteria were found in the spleen, liver, epiphysis and metaphysis of peripheral joints, as well as in the subchondral region of vertebrae. Three weeks post-infection, bacteria-infected cells were not found in the peridiscal space or in the joint cavity, but were located in the subchondral bone. Though bacteria could be seen in association with cartilaginous structures, infiltration by inflammatory cells was undetectable. At 26 weeks post-infection with Brucella spp, infected cells were not found in spleen and subchondral bone, but were visible only as a weak and very rare staining of granulomas in liver. Despite the general absence of infection at this time point, mice developed arthritis in ankle joints, spondylolisthesis, and torsion/rotation misalignment in caudal spine.

Conclusion: Acute infection with *B.melitensis* or *B.abortus* is not associated with arthritis or spondyloartyhropathy in this murine model. Inflammation in joints and changes in skeleton were found at later time weeks after the bacteria were already cleared from subchondral bone marrow. Therefore, Brucella-induced osteomyelitis demonstrated features which are typical to reactive arthritis.

2097

IL-23 Upregulates IRF5 and Polarizes Inflammatory M1 Macrophages to Promote Inflammation in a Mouse Model of Arthritis. Hao Li[1], Hui-Chen Hsu[1], Jun Li[1], Qi Wu[1], PingAr Yang[1], Daniel Cua[2] and John D. Mountz[3]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Merck Research Laboratory, Palo Alto, CA, [3]University of Alabama at Birmingham and Birmingham VAMC, Birmingham, AL

Background/Purpose: The pathogenic mechanism of IL-23 is often associated with expansion and maturation of IL-17 producing CD4 cells, but expression of IL-23 receptor (IL-23R) is not limited to T cells. Increased numbers of macrophages is an early hallmark of active arthritis. Expression of IL-23R has been identified on myeloid cells. The present study determines if IL-23 can regulate the pathogenesis of collagen II-induced arthritis (CIA) via its effects on inflammatory macrophages.

Methods: Chicken CII (cCII) was administered to IL-23 $p19^{+/+}$, p19 deficient ($p19^{-/-}$), $Il23p19^{+/+}$ *GFP-Foxp3,* and $Il23p19^{-/-}$ *GFP-Foxp3* mice on day 0 and was boosted on day 21. AdIL-17 was administered on day 10 to ensure equivalent circulating levels of IL-17. FACS analysis was carried out to determine the percentages of $Foxp3^{+}$ regulatory (Tregs) and IL-$23R^{+}$ macrophages in the draining lymph nodes (LN) of mice with CIA. ELISA and real-time PCR was carried out to determine the effects of IL-23 on cytokine

profiles of GM-CSF-induced inflammatory M1 macrophages or M-CSF-induced suppressor M2 macrophages both *in vivo* and *in vitro.*

Results: CIA was developed by IL-23 $p19^{+/+}$ mice whereas $p19^{-/-}$ mice stayed resistant to CIA despite no deficiency of IL-17. Accumulated $Foxp3^+$ Tregs were only observed in $Il23p19^{-/-}$ *GFP-Foxp3* (from 8% to 18%) but not $Il23p19^{+/+}$ *GFP-Foxp3* mice on day 45 of CIA. Dramatic expansion of macrophages (from 5% to 19% of total) especially IL-$23R^+$ macrophages (from 7% to 23% of macrophages) occurred only in $Il23p19^{+/+}$ mice on day 45 post cCII injection. Macrophages are the major producers of inflammatory cytokines including IL-6 and TNFα in the draining LN of $Il23p19^{+/+}$ mice that developed CIA. IL-23 suppressed the expression of anti-inflammatory cytokine by M2 macrophages including TGFb and IL-10 and promoted the expression of inflammatory cytokines including IL-6, TNFα and IL-17 by M1 macrophages *in vitro*. Interestingly, IL-23 promoted M-CSF polarized M2 macrophages into M1 macrophages by inducing the expression of *Irf5*, an M1 specific transcription factor. Coculture of IL-23 stimulated macrophages with naïve CD4 T cells prevented the development and function of Treg cells.

Conclusion: Our results suggest a novel function of IL-23 in promoting inflammatory responses that can perpetuate the development of CIA via its effects to promote the differentiation of inflammatory M1 macrophages. Upregulation of IRF5 can be a potential factor promoted by IL-23 to turn off the differentiation of M2 macrophages. One important function of IL-23-activated macrophages was to prevent the development of Treg cell by inhibiting the conversion from conventional T cells.

Metformin Attenuated An Autoimmune Arthritis in Animal Models of Rheumatoid Arthritis Via AMP-Activated Protein Kinase Activation. Kwi Young Kang[1], Inje Kim[2] and Ji Hyeon Ju[3]. [1]Division of Rheumatology, Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, South Korea, [2]Hallym University Kangdong Sacred Heart hospital, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul, South Korea

Background/Purpose: Metformin is one of the most widely used drugs for diabetes. However, metformin takes a growing interests for its anti-inflammatory property. This study was undertaken to evaluate the anti-inflammatory effect of metformin in collagen induced arthritis (CIA) mice.

Methods: CIA mice in which inflammatory arthritis was developing were treated with metformin. The effect of treatment on clinical disease activity and histological joint destruction were studied. Naïve T ells were differentiated to Th17 or regulatory T cell by various cytokine stimulation and metformin was treated at each culture conditions. FACS analysis and ELISA were used for delineating the effect of metformin on T cell differentiation. The expression of proinflammatory cytokines such as TNF-α, IL-1β and IL-6 was also evaluated in splenic macrophage of DBA1 mice after metformin treatment. We transfected adenoviral vectors which overexpressing or inhibiting AMP-activated protein kinase (AMPK) into macrophages before stimulation. By adenoviral transfection, we evaluated the association between inflammation and AMPK which is well known major mediator of metformin.

Results: Metformin-treated mice revealed milder arthritis score than CIA mice ($p=0.014$), in which less inflammatory cells and bone destruction were observed. Metformin inhibited the expression of proinflammatory cytokines, such as TNF-α, IL-1β and IL-6, from splenic macrophage in a dose-dependent manner. The inhibition of AMPK by adenoviruses expressing dominant-negative-AMPKα attenuated the production of proinflammatory cytokines from macrophages. Metformin suppressed Th17differentiation and enhanced Treg portion, further supporting its anti-inflammatory property.

Conclusion: These results suggest that metformin has the anti-inflammatory effect via AMPK activation, even if it was developed for diabetes drug. Therefore, metformin may have therapeutic application for the optimal treatment of patients who suffer from rheumatoid arthritis and diabetes together.

SH3BP2 "Cherubism" Gain-of-Function Mutation Exacerbates Inflammation and Bone Erosion in Collagen Induced Arthritis. Tomoyuki Mukai[1], Teruhito Yoshitaka[1], Keiichiro Nishida[2] and Yasuyoshi Ueki[1]. [1]University of Missouri-Kansas City, Kansas City, MO, [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama city, Japan

Background/Purpose: SH3BP2 is a signaling adapter protein in which gain-of-function mutations result in cherubism due to enhance TNF-α production in macrophages and RANKL-induced osteoclastogenesis. In addition to its important roles in myeloid cell functions, SH3BP2 has been reported to be required for optimal B-cell activation. Cherubism is an autosomal dominant craniofacial disorder in children characterized by the extensive growth of fibrous lesions containing TRAP-positive multinucleated cells, resulting in facial swelling and jaw bone destruction. However, it remains unclear whether SH3BP2 is involved in the pathogenesis of other forms of inflammatory bone diseases other than cherubism. In this study, we examined the role of SH3BP2 in the development of arthritis using collagen induced arthritis (CIA) model.

Methods: Wild type (WT) and SH3BP2 "cherubism" mutation knock-in heterozygous (KI/+) mice on the C57BL/6 background were immunized with chicken type II collagen in complete Freund's adjuvant. Clinical arthritis scores (max score=16) were determined by visual inspection of the paws up to 56 days. Synovial inflammation and bone erosion were evaluated by histological analysis. Bone volume of the talus and trabecular bone properties of the proximal tibia were quantified by micro-CT to evaluate bone erosion and systemic bone loss, respectively. Serum levels of anti-type II collagen antibody were measured by ELISA.

Results: The incidence of arthritis was increased in KI/+ mice compared to WT mice (50.0% vs 27.3%, n=10–11). The arthritis score in KI/+ mice was higher than WT mice (7.20 $\pm$ 4.09 vs 4.33 $\pm$ 0.58 at day 28). KI/+ mice exhibited persistent inflammation compared to WT mice (8.00 $\pm$ 4.00 vs 1.00 $\pm$ 1.73 at day 56). Histological analysis showed that synovial inflammation and bone erosion in KI/+ mice were more severe than WT mice. Micro-CT analysis revealed that bone volume of the talus in KI/+ mice was reduced compared to WT mice (6.84% and 1.71% reduced from control mice of each genotype, respectively). And bone volume/tissue volume of the tibia in KI/+ mice was also reduced compared to WT mice (58.4% and 23.6% reduced from control mice of each genotype, respectively). Serum levels of anti-type II collagen antibody in KI/+ mice (108,884 $\pm$ 73,927units/ml) were 2.5 fold higher than WT mice (43,181 $\pm$ 45,590 units/ml).

Conclusion: A gain-of-function mutation in SH3BP2 increased the incidence and severity of arthritis accompanied by more severe bone destruction in the CIA model. These data suggest that adaptor protein SH3BP2 plays a role in the induction and development of arthritis by controlling the production of autoantibody by B cells.

Skin Fibroblasts Are Potent Suppressors of Inflammation in Experimental Arthritis. C. Bouffi[1], C. Bony[2], Christian Jorgensen[3] and Daniele Noel[1]. [1]UM1, Montpellier, France, [2]INSERM U844, Montpellier, France, [3]CHU Lapeyronie, Montpellier, France

Background/Purpose: Fibroblasts possess *in vitro* immunomodulatory properties that are similar to those of multipotent mesenchymal stromal cells (MSC) but their role has been poorly investigated *in vivo*. Here, we compared the effect of MSC or skin fibroblast injection on the host immune response in the collagen-induced arthritis model.

Methods: Fibroblasts were isolated from the skin of DBA1 mice and immunophenotyped by flow cytometry. Their capacity to differentiate into chondrocytes, adipocytes and osteoblasts was evaluated after culture in specific inducing conditions. Immunosuppresssion was evaluated in concanavalin A-induced proliferative assay. In the CIA model, 10^6 fibroblasts were intraveinously injected at day 18 and 24 after collagen II immunization. Arthritis was evaluated by the measure of clinical signs (paw swelling and inflammation) and immunological parameters (dosage of collagen II-specific immunoglobulins, inflammatory cytokines and proliferation of T lymphocytes).

Results: We first confirm that skin fibroblasts isolated from DBA1 mice lack the capacity to differentiate into osteoblasts or chondrocytes but possess the capacity to differentiate into adipocytes. We also report that fibroblasts inhibit the proliferation of T lymphocytes in a concanavalin A-induced proliferative assay and secrete modulatory molecules, in particular PGE2 and NO. To assess their role *in vivo*, 10^6 fibroblasts were intravenously injected at day 18 and 24 after collagen II immunization of DBA1 mice. We show that similar to MSCs, the intravenous injection of fibroblasts efficiently suppress the clinical signs of arthritis and delay the disease onset. This effect is associated with a reduced inflammation and notably, increased levels of IL-5, IL-10 and IL-13 in the spleens of treated mice. To further characterize the mechanism of immunosuppression, we performed phenotypic analyses and could not detect any induction of $CD4^+CD25^+Foxp3^+$ Treg cells whereas a

population of $CD4^+IL\text{-}10^+$ T cells is slightly increased after fibroblast injection and significantly up-regulated after MSC administration.

Conclusion: Our study shows the therapeutic efficacy of systemic injection of syngeneic fibroblasts to reduce the clinical signs of arthritis and strongly suggests that fibroblasts induce a Th2 immune profile although we cannot exclude that IL-10 secreting Treg cells may be generated.

2101

Treatment of Collagen Induced Arthritis with Human Adipose-Derived, Bone Marrow-Derived and Cord Blood-Derived Mesenchymal Stem Cells. Kyu-Hyung Park, Ji-Hye Kim, Sang-Won Lee, Soo Kon Lee and Yong-Beom Park. Yonse University College of Medicine, Seoul, South Korea

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic joint inflammation. Mesenchymal stem cells (MSC) have a capacity to differentiate into mesenchymal tissues and also have an immunomodulatory property. We investigated optimizing treatment condition for collagen induced arthritis (CIA) model using human adipose (AD)-derived, bone marrow (BM)-derived and cord blood (CB)-derived MSC. And, we explored the mechanism of immune modulation by MSC in CIA.

Methods: We obtained clinically available human AD, BM and CB-derived MSC, and evaluated the therapeutic effect of MSC on RA inflammation using DBA/1 mice with CIA. CIA mice were injected intraperitoneally with 1×10^6 of three types of MSC for 5 days, or 2.5×10^6 twice times. Control group were injected with 35mg/kg of methotraxate (MTX) twice a week. Clinical activity of CIA mice with total joint score and paw thickness, the degree of inflammation, joint destruction and cytokine expression in the joint tissue, and serum levels of cytokines were evaluated. Micro-CT for joint was also performed. Treg (CD4+CD25+FoxP3+) cell were evaluated from lymph node and spleen of CIA mice by FACS.

Results: Both 5 times ($1\times10^6\times5$) and 2 times ($2.5\times10^6\times2$) injections of human AD-MSC, BM-MSC and CB-MSC showed significant improvement of clinical joint score and paw thickness, comparable to MTX. H & E slides from mice injected with three types of MSC or MTX showed much less joint inflammation and damage than untreated mice. MSC treated mice had decreased TNF-α, IL-1β, IL-6, COX-2 expression and increased TGF-β expression in the joint tissue. AD-MSC, BM-MSC and CB-MSC injection significantly decreased serum pro-inflammatory cytokines (IL-1β, TNF-α, IL-6, INF-γ) and increased the anti-inflammatory cytokine (IL-10). Micro-CT showed little joint damage in MSC or MTX treated groups. Treg cells (CD4+CD25+FoxP3+) were increased in the lymph node and spleen of mice treated with AD-MSC, BM-MSC and CB-MSC compared with untreated mice or MTX-treated mice.

Conclusion: In this study, human AD-MSC, BM-MSC and CB-MSC significantly suppressed joint inflammation of CIA mice. They upregulated anti-inflammatory cytokines and Treg cells. Our study suggests human AD-MSC, BM-MSC and CB-MSC could be an effective therapeutic approach for arthritis.

A Novel Mouse Model of Atherosclerosis in Inflammatory Arthritis. Shawn M. Rose and Harris R. Perlman. Northwestern University, Chicago, IL

Background/Purpose: Inflammatory arthritides, such as rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA), are associated with significant morbidity and increased mortality. Patients with RA are at increased risk for cardiovascular (CV) events, which contributes greatly to their higher mortality. This elevated CV risk is independent of traditional CV risk factors and may be related to increased systemic inflammation. Alarmingly, premature atherosclerosis is already evident in teenage children with JIA. Progress in understanding the relationship between inflammatory arthritis and atherosclerosis has been hampered by the lack of a suitable animal model. For the first time, we introduce an animal model that faithfully recapitulates both human diseases.

Materials & Methods: 12 week-old K/BxA^{g7} and C57BL/6 control animals were maintained on an atherogenic diet for 9 weeks. Arthritis severity was assessed weekly, beginning at 4 weeks of age. Serial measurements of joint width (mm), clinical inflammation score (0–3 scale, 4 paws), and a novel clinical joint destruction index (0–40 scale, paw joints, wrists, ankles) were obtained. Sudan IV staining of aortas from 21 week-old mice was performed to assess atherosclerosis. Atherosclerotic lesions were quantitated using Image-Pro morphometric analysis, with lesion area normalized to total aortic area (aortic sinus to iliac bifurcation).

Results: All three measures of arthritis were significantly greater in K/BxA^{g7} animals compared to controls ($p<0.001$). The mean percentage area of total aortic atherosclerosis was significantly ($p<0.001$) higher in K/BxA^{g7} mice (21.1 +/− 7.6) compared to controls (0.7 +/− 0.4).

Conclusion: K/BxA^{g7} mice develop spontaneous arthritis beginning at 4–5 weeks of age followed by severe aortic atherosclerosis when receiving an atherogenic diet. This exciting discovery will spur novel mechanistic studies linking arthritis and atherosclerosis. Our model will also be highly informative for developing new biomarkers and therapeutic agents for both diseases.

2103

Arthritic ApoE-Deficient Mice Are Protected From the Development of Atherosclerosis. Shawn M. Rose and Harris R. Perlman. Northwestern University, Chicago, IL

Background/Purpose: Rheumatoid arthritis (RA) is a chronic debilitating disorder characterized by reduced life expectancy. The shortened lifespan in RA is largely due to cardiovascular (CV) disease. This elevated CV risk is independent of traditional CV risk factors and may be related to increased systemic inflammation in patients with RA. Dyslipidemia is also likely to contribute to increased CV mortality, as altered lipid profiles have been described in patients with RA. Progress in understanding the relationships among inflammation, dyslipidemia, and atherosclerosis in RA has been hampered by the lack of a suitable animal model. We have generated a novel model, ApoE$^{-/-}$.K/BxA^{g7} mice, to address this question.

Materials & Methods: Arthritis severity was assessed weekly in ApoE$^{-/-}$.K/BxA^{g7}, K/BxA^{g7}, and ApoE$^{-/-}$ control animals, beginning at 4 weeks of age. Serial measurements of joint width (mm), clinical inflammation score (0–3 scale, 4 paws), and a novel clinical joint destruction index (0–40 scale, paw joints, wrists, ankles) were obtained. Atherosclerosis was assessed in aortic specimens from 21–23 week-old mice via Sudan IV staining. Atherosclerotic lesions were quantitated using Image-Pro morphometric analysis, with lesion area normalized to total aortic area (aortic sinus to iliac bifurcation).

Results: All three measures of arthritis were significantly greater in ApoE$^{-/-}$.K/BxA^{g7} and K/BxA^{g7} animals compared to ApoE$^{-/-}$ controls ($p<0.001$). The onset and severity of arthritis was similar in ApoE$^{-/-}$.K/BxA^{g7} and K/BxA^{g7} controls. Serum lipid levels were also comparable in ApoE$^{-/-}$.K/BxA^{g7} and ApoE$^{-/-}$ mice. Aortic atherosclerosis was significantly lower ($p<0.05$) in ApoE$^{-/-}$.K/BxA^{g7} animals compared to ApoE$^{-/-}$ mice whether the mice were maintained on standard chow or an atherogenic diet.

Conclusion: Our findings suggest that ApoE-deficiency does not affect the onset or severity of arthritis in the K/BxA^{g7} model of spontaneous arthritis. Strikingly, despite severe dyslipidemia, arthritis is protective for the development of atherosclerosis in these animals. Understanding the mechanisms behind this phenomenon will be imperative for developing novel therapies for cardiovascular disease in RA.

Rheumatoid Arthritis Clinical Aspects III: Clinical Features of Rheumatoid Arthritis; Disease Severity; Outcomes Research and Metrology

Tuesday, November 8, 2011, 9:00 AM–6:00 PM

2104

Chronic Kidney Disease in Rheumatoid Arthritis. Cynthia S. Crowson, LaTonya Hickson, Sherine E. Gabriel, James T. McCarthy and Eric L. Matteson. Mayo Clinic, Rochester, MN

Background/Purpose: Rheumatoid arthritis (RA) is associated with a variety of comorbidities including cardiovascular disease (CVD). Chronic kidney disease (CKD) is associated with CVD in the general population. It is unclear whether patients with RA are more likely to develop CKD than persons in the general population, or whether CKD plays a role in the increased risk of CVD in RA. We sought to elucidate the occurrence of CKD in a well characterized population of patients with RA.

Methods: A retrospective medical record review was performed on all incident cases of adult onset RA from a defined geographic population base that fulfilled criteria for RA in 1980–2007. A comparison cohort of patients without RA from the same population base of similar age and sex was also

examined. Patients in both cohorts were followed until 12/31/2008 and all available creatinine values were collected. Estimated glomerular filtration rate (eGFR) was obtained using the Modification of Diet in Renal Disease (MDRD) formula. CKD was defined as eGFR <60 ml/min/1.73m^2 and moderate CKD was defined as eGFR <45 ml/min/1.73m^2. The cumulative incidence of CKD was estimated adjusting for the competing risk of death.

Results: 813 patients with RA and a comparison cohort of 813 patients without RA were assembled (mean age 55.9 years; 68% female in both cohorts). There was no significant difference in the presence of CKD at time of RA incidence, $p=0.84$. Among patients with RA, 38% had an eGFR<60 and 11% had eGFR<45, similar to non-RA patients (38% and 9%, respectively) observed at the RA incidence/reference date. However, the 10 year cumulative incidence of CKD was significantly higher in patients with RA compared to non-RA (43% vs 32%, $p=0.008$). This difference occurred primarily in the first year after RA incidence. The 10 year cumulative incidence of moderate CKD was also higher in patients with RA compared to non-RA (18% vs 14%, $p=0.037$). This difference became apparent three years after incident RA. The development of CKD was associated with erythrocyte sedimentation rate (HR 1.1 per 10 mm/hr, CI 1.03–1.20, $p=0.008$) and CVD (HR 2.1, CI 1.4–3.2, $p<0.001$).

Conclusion: Patients with RA are more likely to develop CKD than patients without RA. Inflammation and CVD appear to play a role in the development of CKD in RA. Further studies are needed to improve understanding of these relationships.

Increased Activity of the platelet glycoprotein (GP) VI pathway in Patients with Rheumatoid Arthritis. Paul A. MacMullan[1], Eimear Dunne[2], Anne M. Madigan[1], Michael C. Berndt[2], Robert K. Andrews[3], Elizabeth E. Gardiner[3], Dermot Kenny[2] and G M. McCarthy[1]. [1]Mater Misericordiae University Hospital, Dublin 7, Ireland, [2]RCSI, Dublin 2, Ireland, [3]Monash University, Melbourne, Australia

Background/Purpose: Recent experimental evidence using an animal model of rheumatoid arthritis (RA) has shown that platelet-derived microparticles exacerbate joint inflammation following engagement of the platelet-specific glycoprotein (GP) VI receptor by collagen (1). We have previously shown that GPVI engagement by collagen causes shedding of the soluble extracellular domain of GPVI (sGPVI) (2). Therefore we set out to evaluate 1) platelet aggregation in response to collagen and 2) plasma sGPVI levels in patients with RA.

Methods: Patients with an established diagnosis of RA were recuited consecutively. Those with a history of cardiovascular disease or who were receiving anti-platelet therapy or thromboembolic prophylaxis were excluded. Disease activity was assessed using standard inflammatory biomarkers and the internationally validated DAS-28 score. Platelet aggregation in response to increasing doses of collagen was tested in RA($n=62$) patients and healthy controls ($n=80$). We also measured sGPVI levels by ELISA in double-spun plasma from a subset of these RA patients ($n=10$) and controls ($n=20$).

Results: Patients with RA ($n=62$) had a significantly decreased platelet response to submaximal doses of collagen compared to healthy controls ($n=80$)(logEC50 1.99 ± 0.09 vs 1.6 ± 0.04, $p<0.0001$). Plasma sGPVI levels were several fold higher in RA patients ($n=10$) compared to controls ($n=20$) (mean$\pm$s.d; 49 ± 14 *vs* 19 ± 8 ng/mL, $p<0.0001$). There was no gross correlation between disease activity indices, platelet count, demographic data or cardiovascular risk factors and either platelet collagen aggregation response or sGPVI levels.

Conclusion: Patients with RA have decreased platelet response to GPVI stimulation by collagen compared to controls. Furthermore, levels of sGPVI are dramatically elevated in RA. This implies enhanced activity of the platelet GPVI pathway in RA, a phenomenon that could contribute to the underlying thrombotic risk in this patient population.

Comparison of Respiratory Function in Patients with Inflammatory Polyarthritis and the General Population in the United Kingdom. Suzanne MM Verstappen[1], Mark Lunt[1], Robert N. Luben[2], Jackie Chipping[3], Nick Wareham[2], Kay-Tee Khaw[2], Ian N. Bruce[1] and Deborah PM Symmons[1]. [1]Arthritis Research UK Epidemiology Unit, The University of Manchester, Manchester Academic Health Sciences Centre, Manchester, United Kingdom, [2]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, [3]Norfolk Arthritis Register, School of Medicine Health Policy and Practice Faculty of Health UEA, Norwich, United Kingdom

Background/Purpose: Pulmonary complications are common in patients with inflammatory polyarthritis (IP) and its subset rheumatoid arthritis (RA). Limited data are available on spirometry measures in these patients and whether the results differ from the general population. The objective of this study was to compare lung function in patients with IP with that in a matched general population.

Methods: Patients with early IP ($\geq$ 2 swollen joints for $\geq$4 wks) from a primary-care based inception cohort (the Norfolk Arthritis Register), recruited between 1990–1994, underwent spirometry at 15 years follow-up. FEV1 and FVC were recorded. Spirometry measurements were compared with those obtained during the second health check (1998 and 2000) from participants of the European Prospective Investigation of Cancer (EPIC-Norfolk) cohort, representing the general population in Norfolk, UK. People with IP, RA or using DMARDs in the EPIC-Norfolk cohort were excluded from analysis. 379 patients with IP aged 32–82 years were matched with people from the general population (1:2) by gender, age and season when spirometry was performed. First, a random effect model was applied to test the difference in FEV1 and FVC between patients with IP and the general population univariately. Secondly, possible confounders were included in the model (smoking status and BMI).

Results: Of the 379 patients with IP, 79% fulfilled the 1987 ACR criteria for RA in NOAR. In both cohorts, mean age was 62 (SD 11) years and 68% were women. More people of the IP-cohort were ex-smokers (53.6% vs 42.7%) or current smokers (12.7% vs 7.6%) (Chi2, $p<0.001$) and they had a higher BMI (median 27.2 vs 26.2, $p<0.001$) than people from the general population. In addition, more patients with IP used drugs for COPD/asthma compared to people from the general population (12.4% vs 2.2%, Chi2 $p<0.001$). In univariate regression analysis, compared to the general population, patients with IP had significantly lower FEV1 (β=-0.0797, 95%CI -0.141 to -0.019). However, when adjusting for confounders, no difference in FEV1 between the IP population and the general population was observed ($\beta=-0.0417$, 95%CI 0.104 to 0.021). In univariate analysis, FVC was similar between the IP population and the general population ($\beta=0.0467$, 95%CI -0.031 to 0.124). After adjustment for confounders, IP patients had higher FVC compared to people from the general population ($\beta=0.0826$, 95%CI 0.027 to 0.163).

Conclusion: Obstructive lung disease is the prominent spirometric abnormality in patients with IP. Patients with IP had a higher prevalence of COPD and asthma and lower FEV1 than the general population. This difference appears to be due to confounders, predominately smoking status and high BMI, rather than the disease itself.

2107

C-Reactive Protein Associated with Depression in Patients with Rheumatoid Arthritis. Mary E. Margaretten, Laura J. Julian, Vladimir Chernitskiy, Jonathan D. Graf, Patricia P. Katz, John B. Imboden and Edward H. Yelin. University of California San Francisco, San Francisco, CA

Background/Purpose: Depression is common in patients with rheumatoid arthritis (RA) and leads to worse health outcomes. Systemic inflammation may contribute to depression in patients with chronic inflammatory diseases, and there is conflicting evidence regarding the association of the acute phase reactant, high-sensitivity C-reactive protein (CRP) with depression in patients with RA. Our objective is to determine if CRP is correlated with depression scores in a large, diverse sample of patients with RA.

Methods: This is a cross-sectional study from an observational, clinical cohort. Patients fulfill the ACR criteria for RA and are enrolled into the cohort from two rheumatology clinics, a county, public-hospital and a university medical center. Once enrolled, data are collected for patients at each clinic visit. The outcome variable is a score on Patient Health Questionnaire-9 (PHQ-9), a self-report questionnaire validated to correlate with a diagnosis of major depression. A PHQ-9 score of 5–9 is consistent with mild depressive symptoms, 10–14 moderate, 15–19 moderate-severe, and > 20 severe depressive symptoms. The primary independent variable is CRP; covariates included gender, age, clinic site, disease activity (DAS 28) score, disability (HAQ) score, prednisone, and disease-modifying anti-rheumatic drug (DMARD) use, defined as one or more of the following: methotrexate, hydroxychloroquine, sulfasalazine, azathioprine, leflunomide, anti-TNFa medications, or other biologic medications. The DAS 28 includes scores of tender and swollen joint counts, patient global disease activity rating scale, and erythrocyte sedimentation rate (ESR). For the analyses, we use generalized estimating equations with robust standard errors to take into account the repeated measures from an individual's multiple clinical encounters.

Results: There are 1,042 clinical visits for 495 patients included in the analysis. The average number of rheumatology clinic visits per patient was 2.0 (range 1–8). 37% of patients reported depression of at least moderate severity during at least one clinic visit. CRP, care at a public hospital rheumatology clinic, disease activity, and disability are associated with depression in this cohort of patients with RA. In the full multivariate model, CRP, younger age, care at a public hospital rheumatology clinic, and higher disability scores were associated with higher depression scores. For every 10-unit increase in a subject's CRP, there was a 2-point increase in depression score.

Predictors of Depression among 495 Patients with Rheumatoid Arthritis

	Univariate		MV* Adjusted	
	GEE Coefficient (95% CI)	p-value	GEE Coefficient (95% CI)	p-value
C-Reactive Protein	0.1 (.06, 1.6)	<.0001	0.2 (.01, .4)	0.05
Female Gender	−.54 (−1.6, 5.4)	.33	0.9 (−.06, 2.1)	.066
Age (years)	−.02 (−.05, .004)	.09	−.06 (−.09, −.03)	<.0001
Public Hospital	1.4 (.59, 2.2)	.001	0.4 (0.1, 0.9)	.02
DAS 28-ESR	1.4 (1.1, 1.6)	<0.01	0.50 (−0.2, 0.8)	0.11
HAQ Score	3.6 (3.1, 3.9)	<.0001	3.6 (3.1, 4.1)	<.0001
Prednisone Use	.05 (−.63, .74)	.88	−0.4 (−1.1, 0.3)	0.25
DMARD Use	−0.4 (−1.1, .18)	.17	−0.3 (−0.9, 0.7)	0.42

Multivariate model adjusts for all variables shown.

Conclusion: Among patients with RA, the acute phase reactant, CRP, correlates with depression scores beyond the contribution from RA disease activity and disability. It will be important for longitudinal studies to identify whether systemic inflammation is a modifiable risk factor for depression in patients with RA, and if so, more tailored treatment approaches for depression in RA would be possible.

2108

Using Genome-wide Single Nucleotide Polymorphism Analysis to Investigate the Possibility of the CYB5R Gene Promoting Interstitial Pneumonia in Rheumatoid Arthritis Patients. Takeshi Nakamura[1], Satoru Koyano[2], Keiko Funahashi[2], Takafumi Hagiwara[1], Takako Miura[1], Kosuke Okuda[3], Akira Sagawa[4], Takeo Sakurai[5], Hiroaki Matsuno[6], Tomomaro Izumihara[7], Eisuke Shono[8] and Tsukasa Matsubara[9]. [1]Matsubara mayflower hospital, Kato, Japan, [2]Research Institute of Joint Diseases, Kobe, Japan, [3]Matsubara Mayflower Hospital, Kato, Japan, [4]Sagawa Akira Rheumatology Clinic, Sapporo, Japan, [5]Inoue Hospital, Takasaki, Japan, [6]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [7]Izumihara Rheumatic and Medical Clinic, Kagoshima, Japan, [8]Shono Rheumatology Clinic, Fukuoka, Japan, [9]Matsubara Mayflower Hospital, Kato-shi HYOGO-KEN, Japan

Background/Purpose: Interstitial pneumonia (IP) is a serious complication for collagen diseases such as RA. However, the pathogenesis of IP remains to be elucidated.We investigated SNPs which seem to be closely correlated with the pathogenesis of IP using genome-wide SNP analysis of IP in RA patients.

Methods: A total of 330 RA patients from 6 hospitals in different regions of Japan were enrolled in the study. The diagnosis of IP was performed by three doctors, one physician and two radiologists, according to IP criteria. As a result, it was determined there were 67 IP patients and 263 non-IP patients. Genome-wide SNP genotyping was performed by HumanHap300K chip. Case-control analyses between 285,548 SNPs and the association with IP were examined by Fisher's exact tests and Bonferoni's correction.

Results: We detected one SNP which is strongly associated with IP and located adjacent to the cytochrome-b5 reductase (CYB5R) gene (p value: 0.0000000117, $p < 0.05$, after Bonferoni's correction). It is reported that CYB5R plays an important role in the resolution of superoxide. In this present analysis, we propose a hypothesis of the functional and/or quantitative reduction of the CYB5R gene which promotes the resolution of superoxide-,according to the SNP detected in this study, and the increase of superoxide may lead to the high susceptibility of IP in RA patients, even though further investigation is required to confirm this.

Conclusion: The pathway of superoxide generation may associate to advancement of IP observed in RA patients.

2109

Contraception Use in Women with Rheumatoid Arthritis. Megan E. B. Clowse[1], Eliza F. Chakravarty[2], Karen H. Costenbader[3], Christina Chambers[4], Frederick Wolfe[5] and Kaleb Michaud[6]. [1]Duke University Medical Center, Durham, NC, [2]Stanford University, Palo Alto, CA, [3]Brigham and Women's Hospital, Boston, MA, [4]University of California, San Diego, La Jolla, CA, [5]National Data Bank for Rheumatic Diseases, Wichita, KS, [6]National Data Bank for Rheumatic Diseases, University of Nebraska, Omaha, NE

Background/Purpose: Women of reproductive age are frequently prescribed potentially teratogenic medications making the use of effective contraception of utmost importance. Pregnancies conceived while taking these medications have a higher rate of miscarriage and the decision whether to continue the pregnancy can be difficult. The frequency of contraceptive use in women with RA is little studied and whether this rate if different for women taking potentially teratogenic medications is unknown.

Methods: A one-time reproductive health questionnaire was sent to women in a large prospective cohort. Premenopausal women who were not trying to conceive were asked to report the methods they had used to avoid pregnancy in the prior year. Forms of contraception were divided into three categories: ineffective (no method, abstinence, withdrawal, rhythm, and barrier methods); effective (hormonal contraceptives or an intrauterine device (IUD)); and sterilization (either the woman or her partner had surgically sterilization). Women could report multiple forms of contraception; they were classified according to the most effective method reported. The current medications from the most recent biannual cohort questionnaire were merged with the reproductive health questionnaire results. Medications were analyzed according to the FDA pregnancy classification indicating the degree of potential risk to a fetus from *in utero* drug exposure.

Results: 108 premenopausal women with RA completed this questionnaire. Ineffective contraception was used by 33% of women; including 16 who reported that they used no contraception, 11 who used abstinence, 4 withdrawal, 3 the rhythm method, and 9 who used barrier methods. Effective contraception was used by 22% of women; including 21 using hormonal contraception and 4 with an IUD. The remaining 45% were sterilized; including 22 with a tubal ligation and 26 with a partner with a vasectomy.

FDA class X medications (methotrexate and/or leflunamide) were taken by 56% of women. Of these, 28% used ineffective contraception, 23% used effective contraception, and 48% were sterile.

Hydroxychloroquine (FDA class C) was used by 19% of women, 30% of whom used ineffective contraception, 35% used effective contraception, and 35% were sterile. Sulfasalazine (FDA class B) was only used by 6 women, 1 using ineffective contraception, 2 using effective, and 3 sterile.

TNF-inhibitors (FDA class B) were used by 53% of the women. Of these, 40% used ineffective contraception, 25% used effective contraception, and 35% were sterile. Other biologics, which included abatacept and rituximab, (both FDA class C) were used by 13 women, of whom 23% used ineffective contraception and 77% were sterile.

Conclusion: Almost half of women with RA in this cohort took FDA class X medications and 29% of these women were using ineffective contraception, leaving them at high risk for pregnancy. This study highlights the importance of contraceptive education and prescription by rheumatologists to ensure that patients taking potentially teratogenic medications do not become pregnant.

2110

Ethnic Minority Rheumatoid Arthritis Consortium: A Clinical Registry of Minority Patients with Rheumatoid Arthritis. Gail S. Kerr[1], Yvonne R. S. Sherrer[2], Raj G. Nair[3], Edward L. Treadwell[4], Angelia D. Mosley-Williams[5], Asia M. Mubashir[6], Luis R. Espinoza[7], Jeffrey Huang[6], Christopher Swearingen[8] and Yusuf Yazici[9]. [1]Washington DC VAMC and Georgetown University and Howard University Hospital, Washington, DC, [2]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [3]Washington Hospital Center, Washington, DC, [4]E Carolina Univ Sch of Med, Greenville, NC, [5]John Dingell VAMC, Detroit, MI, [6]Howard University Hospital, Washington, DC, [7]LSU Medical Center, New Orleans, LA, [8]University of Arkansas for Medical Sciences, Little Rock, AR, [9]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY

Background/Purpose: Minority ethnic groups with rheumatoid arthritis (RA) are under-represented in clinical trials and chronic disease registries. Hence potential differences in clinical presentations, response to therapies, quality of life and outcomes are unknown. We describe a clinical registry and database, Ethnic Minority Rheumatoid Arthritis Consortium (EMRAC) that evaluates disease characteristics, comorbidities, treatments, and outcomes in "real-world" rheumatology settings serving ethnic minority patients.

Methods: RA patients satisfying ACR diagnostic criteria, of self-reported ethnicity, and seen at 8 US sites are enrolled. Collected data include patient demographics, comorbidities, disease related characteristics (MDHAQ, ESR, CRP, swollen and tender joint counts, composite disease activity indices). Analyses of overall differences in clinical variables between racial groups was performed using Kruskal-Wallis for continuous variables and Chi-square test for qualitative variables; post-hoc pairwise comparisons between groups were adjusted using Bonferonni correction ($p<0.008$ for significance).

Results: Since 9/2010, 338 RA patients have been enrolled (Table). Significant differences amongst ethnic groups were observed in age, duration of disease and education, RAPID3, biologic use and comorbidites.

Table 1. Demographic and Clinical Characteristics of Patients enrolled in EMRAC[#]

	Total	African-American	Caucasian	Hispanic	Other	p-value
n	338	102	105	82	49	
Age (years)	54.5 (15.7)	58.3 (15.5)	52.1 (16.1)	55.5 (14.3)	50.3 (15.6)	0.001
Duration (years)	7.5 (9.2)	8.2 (9.3)	7.4 (10.0)	8.8 (9.4)	4.2 (5.1)	0.004
Education (years)	14.1 (4.1)	13.7 (3.6)	15.5 (3.8)	11.9 (4.1)	16.2 (3.6)	<0.001
Female (N, %)	274 (83%)	91 (89%)	86 (82%)	61 (74%)	36 (84%)	0.072
RAPID3 [0–30] (N=310)	10.8 (7.1)	11.2 (6.9)	9.5 (6.9)	13.1 (7.1)	8.9 (7.2)	0.002
DAS28 [0–10] (N=56)	3.1 (1.4)	3.1 (1.1)	3.4 (1.9)	3.0 (2.0)	2.9 (0.8)	0.848
CDAI [0–76] (N=87)	10.4 (1.7)	10.4 (11.0)	13.0 (13.2)	10.9 (9.7)	6.0 (5.6)	0.559
Prednisone (N, %)	117 (35%)	41 (40%)	34 (32%)	28 (34%)	14 (29%)	0.487
DMARD (N, %)	266 (79%)	85 (83%)	78 (74%)	62 (76%)	41 (84%)	0.294
Biologic (N, %)	119 (35%)	22 (22%)	43 (41%)	40 (49%)	14 (29%)	0.001
Comorbidities (N, %)						
Hypertension	69 (20%)	37 (36%)*	12 (11%)	14 (17%)	6 (12%)	<0.001
Asthma	24 (7%)	5 (5%)	6 (6%)	10 (12%)	3 (6%)	0.226
Diabetes	30 (9%)	17 (17%)**	4 (4%)	8 (10%)	1 (2%)	0.003
Cigarette Use (Ever)	63 (19%)	22 (22%)	20 (19%)	14 (17%)	7 (14%)	0.721

Mean (SD) presented unless otherwise specified.
p-values reflect the overall test between all groups. Pairwise tests were done after the global tests were performed.
* Unadjusted OR = 4.4 (95% CI: 2.1, 9.4), p <.01, reference group = Caucasian
** Unadjusted OR = 5.1 (95% CI: 1.6, 16.0), p =.01, reference group = Caucasian

African Americans were older and received less education compared to Caucasians. African Americans also had longer disease duration, received less biologic agents, and more frequently had hypertension. Hispanics received less education compared to Caucasians and were the only ethnic group to demonstrate high disease activity via the RAPID3 assessment.

Conclusion: EMRAC provides data that can address important gaps in knowledge regarding patient characteristics, treatments, and outcomes in a diverse ethnic cohort. By so doing, EMRAC can inform efforts to improve the quality of care and treatment outcomes in this historically understudied population.

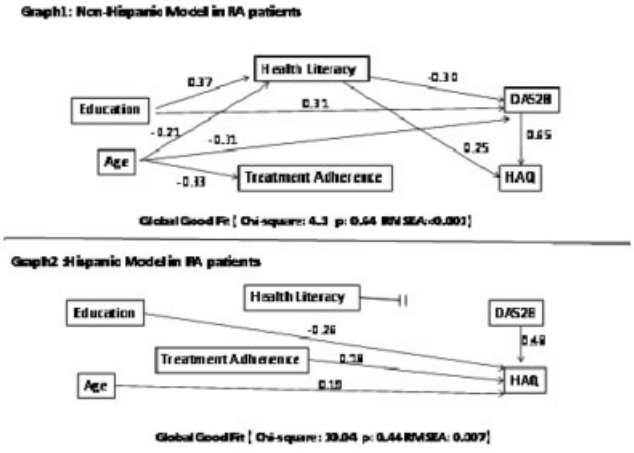
2111

Impact of Health Literacy on Treatment Adherence and Clinical Outcomes in Patients with Rheumatoid Arthritis. Maria F. Marengo[1], Michael A. Kallen[1], Sofia De Achaval[2], Vanessa Cox[1], Araceli Garcia[3], Marsha Richardson[4] and Maria E. Suarez-Almazor[5]. [1]UT MD Anderson Cancer Center, Houston, TX, [2]U.T. MD Anderson Cancer Center, Houston, TX, [3]UT MD Anderson, Houston, [4]UT MD Anderson, Houston, TX, [5]University of Texas. M.D Anderson Cancer Center, Houston, TX

Background/Purpose: Limited Health Literacy (HL) is associated with poorer health outcomes. Little is known about the effects of low HL among patients with Rheumatoid Arthritis (RA). The objective of our study was to measure the level of HL among patients with RA and determine its impact on disease activity and functional status.

Methods: This study was part of a 2– year prospective cohort study of 201 patients with RA; 170 RA patients completed the HL assessment. HL was measured using the numeracy score (0–50) from the Test of Functional Health Literacy (TOFHLA) and the reading comprehension score (0–50) from the TOFHLA-Short. A total score (total TOFHLA) was obtained (0–100, 0 worst HL). Patients were categorized as having low or adequate HL using the traditional cutoff (≥60). Patient information was assessed at BL, 12, and 24 months, including functional status (mHAQ), Disease Activity Index 28 (DAS28), and treatment adherence (AACTG). A conceptual model was developed, with demographic variables predicting HL and adherence, all of which predicted disease activity and functional status. Path analysis was conducted to test the model. Statistical analyses were carried out using STATA 11.1 and LISREL 8.8.

Results: 74.6% of patients were female, 52.7% Hispanic, 25% White and 21.4% African-American; mean age was 51y (±11.4), disease duration 7.5y (±5), DAS28 4.5(±1.6), MHAQ 0.87(±0.6) and AACTG 0.57 (±0.42). Mean total TOFHLA was 81.1(±19.2). Of 170 patients, 42 (24.7%) had low HL; these patients were more frequently female ($p=0.04$), Hispanic ($p<0.01$), with lower education ($p<0.01$) and higher DAS28 ($p=0.03$). In the path analysis, we found significant differences by ethnicity. For non-Hispanics, the model (Graph1) showed age had negative direct effects on HL, adherence, and DAS28, while education had positive direct effects on HL and DAS28. HL had a negative direct effect on DAS28. A dual effect was observed with HL on functional status: HL had a positive direct effect on HAQ, and a positive total effect via disease activity. For Hispanic, the model (Graph2) showed age and adherence had positive direct effects on HAQ, while education had a negative direct effect on HAQ, which itself was affected by a positive direct effect from DAS28. In the Hispanic subpopulation, age and education had no effect on HL, which had no effect on treatment adherence or clinical outcomes. Both overall path analytic models displayed good fit to the data (non-Hispanic chi-2= 4.3, p= 0.63, RMSEA<0.001 and chi-2= 10.04, p= 0.44, RMSEA=0.007).



Tuesday, November 8

Conclusion: Low HL was observed among 1 in 4 RA patients. The impact of HL on clinical outcomes differs by ethnicity. For non-Hispanic, limited HL is associated with worse functional status via disease activity. For Hispanics, worse functional status was associated with higher age and lower education, with no apparent impact of HL on treatment adherence or clinical outcomes.

2112

Rheumatoid Arthritis (RA) is Associated with Increased Mortality in Patients Undergoing Total Joint Arthroplasty. Kaleb D. Michaud[1], Edward Fehringer[2], Kevin Garvin[2], James R. O'Dell[3] and Ted R. Mikuls[3]. [1]National Data Bank for Rheumatic Diseases & University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Omaha VA and University of Nebraska Medical Center, Omaha, NE

Background/Purpose: Although total joint arthroplasty (TJA) is a commonly used procedure in rheumatoid arthritis (RA), risks and benefits of TJA in this specific population have not been well defined. The purpose of this study was to examine the association of RA with post-operative mortality following total hip, knee, shoulder and elbow arthroplasty.

Methods: Study subjects were enrolled in the Veterans Affairs (VA) Surgical Quality Improvement Program (VASQIP) undergoing TJA from fiscal years 1999 through 2006. Dispensed medications and ICD9 codes were indentified using links to the VA Pharmacy Benefits Management (PBM) database. Patients were classified as having RA if they had ICD9 code 714.0 plus use of a DMARD within 1 year before TJA; the osteoarthritis (OA) control group had ICD9 code 715. The association of RA with overall mortality through 2006 was examined using multivariate Cox proportional hazards regression, adjusting for age, gender, TJA type, calendar year, race, select baseline comorbidity / health behaviors (diabetes, COPD, dyspnea, congestive heart failure, cerebrovascular disease, renal insufficiency, anemia, alcohol use and current smoking), preoperative functional status, and ASA class. The effects of specific RA medications were examined using sequential models.

Results: There were 37,103 patients (n = 888 with RA) undergoing TJA, with total knee arthroplasty being most common (64%), followed by hip (33%), shoulder (2%), and elbow (0.2%). Patients were predominantly men (96%) and had a mean (SD) age of 64.4 (10.7) years. Glucocorticoid use was much more common in RA cases vs. OA (41% vs. 2%). There were a total of 4,093 deaths over a mean follow-up of 3.7 (2.3) years. After multivariate adjustment, RA was associated with a significantly higher mortality (HR = 1.48; 95% CI 1.24 to 1.76). This risk was attenuated after further adjustment for glucocorticoid use (HR = 1.23; 95% CI 1.02 to 1.49). Factors significantly associated with mortality in patients with only RA are shown in the Table. There was no association of other biologic or non-biologic DMARDs with mortality in RA-only sub-analyses.

Patient factor	Hazards Ratio (95% CI)
Glucocorticoid use	1.81 (1.28 to 2.53)
Age (year)	1.06 (1.04 to 1.08)
Chronic obstructive pulm disease	2.10 (1.39 to 3.19)
Congestive heart failure	4.05 (1.62 to 10.12)
Anemia, Hematocrit < 38%	1.57 (1.10 to 2.24)
Current smoking	2.03 (1.39 to 2.96)

Conclusion: RA patients have a higher long-term mortality risk than OA patients following TJA, a risk that is most pronounced among glucocorticoid users in addition to current smokers and those with select comorbid conditions. Perioperative interventions that target high risk patients with RA need to be evaluated and implemented with a goal of reducing postoperative mortality following TJA.

2113

Sex Differences in Cytokine Response of Patients with Rheumatoid Arthritis. Melissa A. Wells, John M. Davis III, Keith L. Knutson, Michael A. Strausbauch, Cynthia S. Crowson, Terry M. Therneau and Sherine E. Gabriel. Mayo Clinic, Rochester, MN

Background/Purpose: Sex differences have been observed in the incidences of autoimmune disorders as well as in the cytokine response to immune stimulation. However, very little is understood regarding sex differences in cytokine response in the setting of autoimmune disorders. We sought to explore the sex differences in cytokine response in patients with rheumatoid arthritis (RA).

Methods: We performed a cross-sectional analysis of data from a population-based cohort study of patients with RA. Patient information collected included age, RA duration, BMI, CRP, HAQ disability index, current smoking status, rheumatoid factor positivity, anti-CCP antibody positivity, and RA medication use. Peripheral blood mononuclear cells (PBMC) from subjects were stimulated with a variety of stimulants to determine their cytokine response. Stimulants included anti-CD3/anti-CD28, CpG oligonucleotides (CpG), combined cytomegalovirus and Epstein Barr virus lysates (CMV/EBV), phorbol myristate acetate with ionomycin (PMA/ionomycin), phytohemagglutinin, and combined Staphylococcal enterotoxins A and B (SEA/SEB). Collected supernatants were analyzed for 17 cytokines using multiplexed immunoassays. The data were normalized using mixed models with random effects for subject and plate, to adjust for assay effects. Males and females were compared using linear regression models on the ranks of the cytokine values (due to skewed distributions) with adjustment for the patient factors listed above.

Results: Our study included 234 females (mean age 59.6 years) and 83 males (mean age 63.3 years). Significant differences (p-value <0.05) were found between males and females after adjustment for disease activity, severity and treatment status for six of the cytokines using PMA/ionomycin and SEA/SEB as stimulants. Using PMA/ionomycin, the cytokine responses for granulocyte macrophage colony-stimulating factor (GM-CSF), interleukin-10 (IL-10), and IL-17 were increased in females compared to males. Using SEA/SEB, cytokine response in females was decreased compared to males for IL-12, IL-5, and interferon gamma (IFN-γ). Similar trends were noted for several other cytokines in response to PMA/ionomycin and SEA/SEB, but these comparisons did not reach statistical significance.

Conclusion: The involvement of T cells has been an important component to the pathophysiology and management of RA. Our understanding of subsets of T cells is still under development. In relation to sex, there are differences in the cytokine response for Th1 cells (IL-2, IL-12 and IFN-γ), Th2 (IL-5 and IL-13) and Th17 (IL-17). These results may shed light on sex differences in the incidence and characteristics of auto-immune disorders; and on sex differences in treatment response, especially as cytokine-targeted therapy continues to evolve.

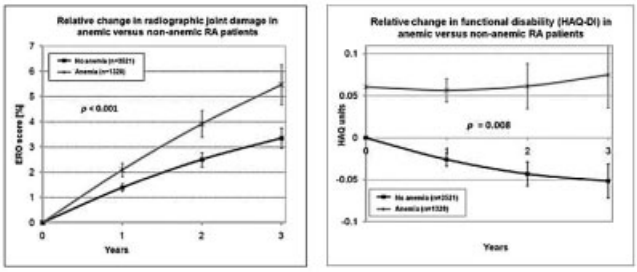
Anemia Is An Independent Indicator of Disease Progression In Rheumatoid Arthritis. Burkhard Moller[1], Doris Wisler[1], Frauke Foerger[1], Peter M. Villiger[1] and Axel Finckh[2]. [1]Inselspital-University Hospital, Bern, Switzerland, [2]University of Geneva, Geneva, Switzerland

Background/Purpose: To study the impact of anemia on disease specific outcomes and health related quality of life in rheumatoid arthritis (RA) patients.

Methods: In this longitudinal cohort study, we examined all patients with available consecutive hemoglobin assessments. Anemia was defined by hemoglobin <13 g/dl in men or <12 g/dl in women. We examined the impact of anemia on the evolution of the RA disease activity score (DAS28), erosive progression, functional disability (HAQ-DI), and health related quality of life (physical functioning and vitality scales SF-36) in longitudinal regression analyses, adjusting for potential confounders.

Results: 4377 patients (77% female, baseline median age 54 years) were followed over 2.8 years with a mean of 4.4 hemoglobin assessments. Median hemoglobin concentrations were 12.9 g/dl (interquartile range 12.0–13.7) in women and 14.2 g/dl (13.1–15.0) in men. At inclusion, anemia was present in 24% of patients and persisted in 63% of cases after one year. The incidence rate of new anemia was 7.6% per year. Anemia was significantly associated with high levels of DAS28 and the use of non-selective NSAIDs. Furthermore, anemia was independently associated with more progression of radiographic damage, functional disability, and lower health related quality of life, which persisted after adjustment for RA disease activity and severity. Figures represent the long-term evolution of radiographic damage and functional disability in RA patients with and without anemia. The lines represent the mean change over time

of radiographic damage (ERO) and functional disability (HAQ-DI). Vertical lines represent the 95% confidence intervals of the means. Analyses were adjusted for age, gender, rheumatoid factor, disease duration, baseline data of the erosion score, DAS28, HAQ-DI (only for ERO), SF36V and SF-36PF, and for co-morbidities, use of analgesics, conventional non-selective and cyclooxygenase-II selective (coxibs) nonsteroidal anti-rheumatc drugs (NSAIDs), corticosteroids, MTX, other synthetic disease modifying anti-rheumatic drugs, and TNF-α inhibitors.



Conclusion: Anemia in RA indicates an unfavorable course of the disease, which is not fully accounted for by DAS28 or other measures of disease severity. Anemia in RA requires a careful differential diagnosis and should prompt a more detailed disease activity assessment.

2115

Assesment of Physical Activity by Accelerometry: Relationship Between Physical Function and Disease Activity in Rheumatoid Arthritis Patients. Vanesa Hernandez-Hernandez[1], Esmeralda Delgado-Frías[1], Ivan Ferraz-Amaro[1], Jose A. Garcia-Dopico[2], Lilian Medina[2], Inmaculada Alonso[1], M. Teresa Arce-Franco[1], M. Jesus Dominguez-Luis[3] and Federico Diaz-Gonzalez[1]. [1]Rheumatology Service, La Laguna, Spain, [2]Central Laboratory, La Laguna, Spain, [3]Hospital Universitario de Canarias, La Laguna, Spain

Background/Purpose: In patients with rheumatoid arthritis (RA) the ability to perform activities of daily life may be deteriorated. However, the relationship between disease activity and global movement capability remains to be fully clarified in theese patients. The aim of this study was to determine to which extent RA features affect physical activity in these patients

Methods: 66 RA patients, without significant involvement of lower limbs, (56/10 female/male, age 53.6±9.6 years, disease duration 7.5±4.8 years) underwent physical activity monitoring through two methods: triaxial accelerometry output measured in vector magnitude (counts·min-1) and International Physical Activity Questionnaire (IPAQ) (MET-min/week). Patients were retested 6 months later to assess pre and post-test reliability. Demographic data, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Health Assessment Questionnaire Disability index (HAQ), Disease Activity Score (DAS 28), and quality of life through Functional Assessment of Chronic Illness Therapy (FACIT), and SF-36v2 Health Survey were performed at baseline and after 6 months of follow up.

Results: Univariate analysis showed that patients with higher DAS28 score express lower physical activity (coefficient beta 24.5 counts·min-1, (−46.7)–(−1.57)IC95%, p=0.03). These data remain statistically significant when adjusted for age, disease duration and body mass index. Similarly results were obtained for physical function (HAQ), showing a non-significant trend (coefficient,-35.2 counts·min-1,(−90.6)-(20.1) IC95%, p=0.07). Regard IPAQ questionnaire, the physical activity was also associated with HAQ (r^2=−0.41, p=0.00) and FACIT (r^2=−0.31, p=0.03) but not with DAS28 score. In fact, IPAQ and accelerometry did not correlate in RA patients (intraclass correlation index 0.01, (−0.29)-(0.32)IC95%, p=0.47). SF-36, both physical and mental component, did not showed relationship with physical activity by neither IPAQ nor accelerometry. Six months later reliability study showed that HAQ (coefficient beta −45.4 counts·min-1, (−70.9)–(−19.9)IC95%, p=0.00) and DAS28 (coefficient beta −15.9 counts·min-1, (−34.3)-(−3.35) IC95%, p=0.04) were still correlated with physical activity measured by accelerometry. This data suggest an optimal test-retest reliability. Multivariate analysis to construct the best explaining model for physical activity, assessed by accelerometry, in RA patients showed that disease duration, HAQ, DAS28 and ESR explain 29% of physical activity variation (r^2 adj=0.29).

Conclusion: Physical activity is related overtime to both disease activity and physical function in RA patients. Objective assesment of physical activity by accelerometry may be a valuable aspect to take into account in the evaluation of RA patients in clinical practice.

Gender Differences in Disease Characteristics in Rheumatoid Arthritis, Inflammatory Bowel Disease and Psoriasis: Evidence for a Greater Symptomatic Burden in Females. N. Lesuis[1], R. Befrits[2], Filippa Nyberg[3] and R. F. van Vollenhoven[2]. [1]Radboud University, Nijmegen, Netherlands, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Previous studies in rheumatoid arthritis (RA) have shown a gender difference in disease characteristics, with women generally having worse scores than men.[1] Similarly, in inflammatory bowel disease (IBD) health related quality of life is worse in females.[2] In RA, we previously suggested that biologics use differs subtly between men and women. For a third auto-immune disease, psoriasis (PSO), less is known on this subject. In our study we have compared gender differences in characteristics among RA, IBD and PSO.

Methods: Data on RA and IBD patients were obtained from two different registries at the Karolinska University Hospital, and data on patients with PSO were obtained from the published report by the Swedish psoriasis register [3]. For RA and IBD, demographic data and disease activity measures prior to biologic treatment start were compared for female vs male patients; for patients with PSO, data at inclusion in the register were used which corresponded roughly with the use of systemic (but not necessarily biologic) therapies for these patients. To compare differences between men and women, the Mann-Whitney U test or the students t-test was used for continuous variables, and the X^2 test for proportions.

Results: In total 4493 patients were included in the study (RA 1912; IBD 131; PSO 2450); in RA, the majority were women and in IBD and PSO the majority were men. In RA significant differences were seen in ESR, patients' global assessment, Tender Joint Count (TJC), Health Assessment Questionnaire (HAQ), Disease Activity Score (DAS28) and DAS28-CRP; all values were higher in women (table); in contrast, Swollen Joint Count (SJC) and CRP were nominally higher in the male patients. In the IBD patient group no statistically significant differences were seen in disease activity as measured with the Harvey Bradshaw index, but there was a trend towards higher scores on the Short Health Scale (SHS, disease-specific symptom survey) in women compared to men. For PSO, a high score on the Psoriasis Area and Severity Index (PASI) was noted in a significantly greater proportion of men, whereas a high Dermatology Life Quality Index (DLQI), ie, a worse quality of life, occurred more often in women. Overall, a greater proportion of men with IBD or PSO received biologic/systemic treatment, but for the biological treatment of RA this was not seen.

		Men	Women	p-value
RA	Swollen Joint Count	9.1	8.8	0.36
	Tender Joint Count	7.8	8.7	0.01
IBD	ESR	29.5	23.8	0.52
	SHS-Influence daily life	55.6	71.1	0.12
	Harvey Bradshaw	9.8	10.5	0.71
Psoriasis	PASI ≥10 (% pts)	35.3	27.0	0.00
	DLQI ≥10 (% pts)	27.7	37.7	0.00

Conclusion: Women with RA scored significantly higher on subjective disease activity measures than men, while SJC was comparable. A similar trend towards worse subjective disease symptoms despite similar measured disease activity is also seen in IBD and PSO, providing a framework for studies of gender differences in autoimmune diseases.

Early Rheumatoid Arthritis in Latin America. Low Socioeconomic Status Relates to High Disease Activity At Baseline. Loreto Massardo[1], Bernardo A. Pons-Estel[2], Mario H. Cardiel[3], Claudio Galarza-Maldonado[4], Mónica P. Sacnun[5], Enrique R. Soriano[6], Ieda Laurindo[7], Eduardo M. Acevedo-Vásquez[8], Carlo V. Caballero-Uribe[9], Oslando Padilla[10], Marlene Guibert-Toledano[11], Rubén A. Montufar Guardado[12], Sergio H. Jacobelli[13] and Daniel E. Furst[14]. [1]Catholic University of Chile, Santiago 114-D, Chile, [2]Hospital Provincial, Rosario, Argentina, [3]Hospital General "Dr. Miguel Silva", Morelia, Mexico, [4]Hospital Monte Sinai, Cuenca, Ecuador, [5]Hosp. Provincial, Rosario, Argentina, [6]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [7]Universidade de São Paulo, Sao Paulo, Brazil, [8]Hospital Nacional "Guillermo Almenara Irigoyen", Lima, Peru, [9]Continential Med Ctr, Barranquilla, Colombia, [10]Pontificia Universidad Catolica de Chile, Santiago, Chile, [11]Centro de Investigaciones Médico Quirúrgicas, Habana, Ciudad Habana, Cuba, [12]Instituto Salvadoreño del Seguro Social, San Salvador, El Salvador, [13]Universidad Catolica de Chile, Santiago, Chile, [14]UCLA Medical School, Los Angeles, CA

Background/Purpose: To determine the influence of social factors on disease activity at baseline in a large multinational inception cohort of Latin American (LA) patients with early rheumatoid arthritis (RA).

Patients and Methods: Patients with early RA (<1 year disease duration from first symptoms, ≥18 years old) were examined between 2004/05 and followed for 3 years. Patients attended 46 rheumatology centers in 14 LA countries. Clinical evaluation, ethnicity, socioeconomic status (SES) (Graffar's method), DAS28-ESR, HAQ-DI, and hand and feet radiographs were performed and recorded on an agreed data base (ARTHROS 6.1). Chi-square, Kruskal Wallis or Mann Whitney U tests (p value<0.01) were used for comparisons. Multivariate analyses were applied to evaluate the influence of all the above factors.

Results: Among the 1,093 patients who had been enrolled in July 2005, 85.3% were females. Mestizo (mixed European and Amerindians): 43%, Caucasians: 31%, African-LA (ALA): 19%, Amerindians: 4%, Others: 3%. 58% were in the lower or middle-lower SES; 41.7% had < 8 yrs of education; 44% had no or only some medical insurance coverage. Separated/divorced/widowed: 14%, and married/single: 86%. Age at onset: 46 (SD: 14) years; duration of disease at baseline 6.7 (SD: 3.2) months. Women and Mestizo, ALA, and Amerindian had earlier onset (5 years) than men or Caucasians ($p < 0.01$). Disease was clinically quite active- DAS28 score 6.0 (SD: 1.7) and moderately functionally disabling: HAQ-DI 1.29 (SD: 0.87). Surprisingly, joint erosions were present in only 25% (no stat. differences among ethnic groups).

ANCOVA multivariate analysis showed low/low middle SES, female sex and partial insurance are associated with both worse HAQ-DI and higher DAS28. Marital status was only associated with HAQ-DI, while older age was only associated with DAS28. Logistic regression analysis showed that older age, lack of insurance, and ethnic groups Amerindian and Other associated with the presence of erosions. When models included country of origin, differences between countries were found. (Cuba had highest HAQ-DI and DAS28 scores while Venezuela had lowest HAQ-DI and DAS28).

Conclusion: This report compares early RA patients from the four LA main ethnic groups. Women and LA ethnicities (Amerindian, ALA, Mestizo) had significantly younger RA onset. Higher HAQ-DI and DAS28 scores related to poor SES status, femaleness and partial insurance suggesting that poverty/low/ middle low SES influence are important factors in determining disease activity. A more genetic related background for erosions is possible.

Funding: supported by an unrestricted grant from Abbott Laboratories.

Forefoot Plantar Pressure and Gait Characteristic of Patients with Early Rheumatoid Arthritis: A Case-Control Study. Sze Man Lau[1], Chi Chiu Mok[2], Chi Hung To[2] and Wing Yuk Ip[3]. [1]Pok Oi Hospital, Hong Kong, Hong Kong, [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]University of Hong Kong, Hong Kong, Hong Kong

Background/Purpose: Foot and ankle symptoms are common in patients with established rheumatoid arthritis (RA). These are caused directly or indirectly by synovitis, subluxation and deformities of the foot joints. There is little information regarding the biomechanical features of the feet and gait of patients with early RA. We aimed to study the plantar pressure and gait characteristics of RA with early disease and their relationship with disease characteristics.

Methods: Patients who fulfilled the 1987 ACR criteria for RA and had disease duration of less than 4 years were recruited. Subjects without arthritis matched for sex and body mass index (BMI) were also invited as controls for comparison with patients. Barefoot plantar pressure (9 forefoot areas) and gait parameters including pressure time integral (total plantar pressure in a period of time) and the anterior progression of the centre of force over the plantar area from heel to mid-foot were measured by the Matscan ® pressure mapping system (TekScan, Inc, Massachusetts, United State) and processed by F-scan research STAM ver. 5.83 software. The Foot Function Index (FFI; 0–100 points; with subscales of pain, disability and activity limitation), Health Assessment Questionnaire Disability Index (HAQ), disease activity scores (DAS28) were obtained in patients with RA. Correlation analyses were performed between plantar pressures and various clinical and disease-related parameters.

Results: 47 consecutive RA patients (77% women; mean age 49.3 ± 11.1 years; mean BMI 23.3 ±3.6; disease duration 2.3 ± 1.1 years; DAS 28 score 3.29 ± 1.52) and 36 matched controls were studied. The median HAQ score of RA patients was 0.25 (IQR 0.63). Compared to control subjects, patients with RA had significantly lower forefoot peak plantar pressures (RA 249.9±44.1 vs controls 281.4±32.1 kPa; $p<0.001$) and pressure time integrals (RA 34.5±7.4 vs control 42.9±8.0 kPa·sec; $p<0.001$). The anterior progression of the centre of force from heel to midfoot was delayed (increase in time of walking on heel) in RA subjects but the difference was not statistically significant (RA 50% vs control 48% of stance). Correlation studies revealed that the peak pressure at the medial forefoot (hallux) was significantly and inversely associated with disease activity (DAS 28 score) ($r= 0.30$; $p= 0.04$), HAQ score ($r= -0.40$; $p= 0.005$), FFI score ($r= -0.32$; $p= 0.03$) and disability subscale of FFI ($r= -0.37$; $p= 0.01$). Overall, 40% of RA patient had abnormal pressure parameters (<2 standard deviations from the control group mean) of the forefeet.

Conclusion: In a substantial proportion of RA patients with relatively early disease, the centre of force of the plantar area of the feet is shifted to the heel during walking, which is likely contributed by pain and active synovitis of the feet and ankle joints. The altered loading of the feet and shifting to a heel-walking gait activates toe extensors which may further aggravate pain and deformities. Early identification of this gait drift and orthotic intervention to modify forefoot loading pattern may retard functional deterioration and deformity development in patients with early RA.

2119

The Effect of Patient Reported Pain on Disability Is Partially Mediated Through Depression in Vulnerable United States Hispanics with Rheumatoid Arthritis. Soha Dolatabadi[1], Rosalinda C. Moran[2], Galen Cook-Wiens[1], Ning Li[1], Michael H. Weisman[3], Perry M. Nicassio[4] and George A. Karpouzas[5]. [1]Cedars Sinai Medical Center, Los Angeles, CA, [2]Harbor UCLA Medical Center, Carson, CA, [3]Cedars Sinai Med Ctr, Los Angeles, CA, [4]UCLA, Los Angeles, CA, [5]Harbor-UCLA, Torrance, CA

Background/Purpose: US Hispanics with Rheumatoid Arthritis (RA) experience worse functional disability and quality of life compared to Caucasians. In a cross-sectional design, we previously characterized the predictors of such disability, assessed by Health Assessment Questionnaire-Disability Index (HAQ-DI); patient-reported pain was the most significant, followed by irreversible articular damage (IAD- defined as subluxation, arthrodesis, fusion, or prosthesis), disease activity (DAS28-3v-ESR), depression (evaluated by the physician Health Questionnaire- PHQ-9), joint replacement surgeries, and age. In the present report we examined the interactions and effects of pain, disease activity, depression and age longitudinally on disability. We additionally explored whether the effects of pain and disease activity on disability would be mediated through depression.

Methods: One hundred patients evaluated over 3 time points 6 months apart, in a single institution were studied. Regression models were constructed using pain and disease activity from time point 1 to predict depression at point 2; a subsequent model examined the ability of time 1 pain and disease activity to predict disability at time 3, with or without the addition of depression from time 2. Sobel test was used to address mediation of effects of pain and disease activity from time 1 on time 3 disability by time 2 depression. Additional modeling investigated the independent contribution of pain on disability, as well as the proportion of the effect of pain on disability that would be mediated by depression.

Results: Both pain and disease activity from time 1 were associated with depression at time 2 in decreasing order of significance (table 1). Pain from time 1 predicted disability at time 3 ($p=0.00002$);

Depression predicted disability at Time 3 after pain, but the effect of pain remained significant (p=0.0006); this suggested that depression partially mediated the effects of pain on disabililty. The Sobel test confirmed this mediation, and depression accounted for 35% of the effect of pain on disability. Disease activity at time 1 was not predictive of time 3 disability.

Regression 1	**Outcome: Depression (PHQ-9) at time 2**		
(time 1)	***b***	***95% CI***	***p*-value**
Pain-VAS	2.52	(0.9, 4.13)	0.0026
DAS28-3v-ESR	1.44	(0.16, 2.71)	0.0275
Regression 2	**Outcome: Disability (HAQ-DI) at time 3**		
(time 1)			
age	0.02	(0.003, 0.027)	0.016
Pain-VAS	0.44	(0.25, 0.64	0.00002
DAS28-3v-ESR	0.04	(−0.11, 0.2)	0.593
Regression 3	**Outcome: Disability (HAQ-DI) at time 3**		
(time 1)			
age	0.02	(0.006, 0.03)	0.0038
Pain-VAS	0.35	(0.15, 0.54)	0.0006
DAS28-3v-ESR	−0.01	(−0.17, 0.14)	0.858
PHQ-9	0.04	(0.01, 0.06)	0.0019
Sobel Test	***b* (SE) from Regression 1**	***b* (SE) of PHQ-9 from Regression 2**	***p*-value for Sobel test**
Pain-VAS	2.47 (0.81)	0.038 (0.012)	0.0273

Conclusion: Baseline self-reported pain is the most robust longitudinal predictor of disability in vulnerable US Hispanics with RA. Its effects are both direct (65%) and indirect, mediated through depression (35%). Therefore, future interventions addressing prevention of long-term disability in this group should target both depression and pain.

2120

The Public Health Impact of Risk Factors for Physical Inactivity in Adults with Rheumatoid Arthritis. Jungwha Lee[1], Dorothy D. Dunlop[2], Linda S. Ehrlich-Jones[3], Pamela A. Semanik[4], Jing Song[2], Larry Manheim[2] and Rowland W. Chang[1]. [1]Northwestern University, Chicago, IL, [2]Northwestern Univ Med School, Chicago, IL, [3]Rehabilitation Institute Chicago, Chicago, IL, [4]Rehabilitation Institute Chicago, Oak Park, IL

Background/Purpose: Physical activity offers important health benefits to adults, including those with rheumatoid arthritis (RA). This study investigated the potential public health impact of modifiable risk factors related to physical inactivity in adults with RA.

Methods: Physical activity was measured using accelerometers at the baseline visit of a clinical trial in 176 RA participants. Time spent in moderate-to-vigorous (MV) intensity activities was calculated to assess if participants were inactive (no MV minutes/week in bouts lasting 10 or more minutes). The cross-sectional relationships between modifiable risk factors (motivation for physical activity (strong vs. not strong), beliefs related to physical activity's benefits (strong vs. not strong), weight status (obese vs. not obese), pain (any vs. none), mental health (poor vs. not poor based on Mental Component Summary Score[MCS])) with inactivity were assessed by estimating odds ratios (OR) and attributable fractions (AF), controlling for potential confounding factors (age, gender, race, education, disease duration, and co-morbidity).

Results: Over two in five adults (42%) with RA were inactive. Modifiable factors most strongly related to inactivity were lack of strong motivation for physical activity (adjusted OR=2.85, 95% confidence interval [CI]=[1.31, 6.20]; adjusted AF=53.1%, 95% CI=[21.7, 74.6]) and lack of strong beliefs related to physical activity's benefits (OR=2.47, 95% CI=[1.10, 5.56]; AAF=49.2%, 95% CI=[7.0, 76.4]), controlling for age, gender, race, education, disease duration, and co-morbidity mobility limiting. Together, these two factors are related to almost 65% excess inactivity in this sample.

Conclusion: Despite known benefits from physical activity, adults with RA were substantially inactive (42%). Being inactive was strongly related to a lack of strong motivation for physical activity and a lack of strong beliefs in benefits from physical activity. These results support development of interventions that increase motivation for physical activity and that lead to stronger beliefs related to physical activity's benefits in order to reduce the prevalence of physical inactivity and improve health status in adults with rheumatoid arthritis.

Modifiable risk factor frequency, odds ratio, and attributable fraction for physical inactivity in adults with rheumatoid arthritis (n=176)

Modifiable Risk Factor	**Risk category on top**	**Frequency (%)**	**Adjusted Odds Ratio* [95% CI]**	**Adjusted Attributable Fraction* [95% CI]**
Motivation	Lack of strong motivation	60	2.85 [1.31, 6.20]	53.1 [21.7, 74.6]
	Strong motivation	40	Reference	
Belief	Lack of strong belief	67	2.47 [1.10, 5.56]	49.2 [7.0, 76.4]
	Strong belief	33	Reference

Aldosterone Is Not Increased in Patients with Rheumatoid Arthritis. Michelle J. Ormseth, Margaret Randels, Annette M. Oeser, Joseph F. Solus and C. Michael Stein. Vanderbilt Medical Center, Nashville, TN

Background/Purpose: Activation of the renin-angiotensin system and consequent increased aldosterone production is associated with adverse cardiovascular outcomes as a result of inflammation, fibrosis, and increased insulin resistance. There is no information about aldosterone in patients with rheumatoid arthritis (RA), a population with accelerated cardiovascular disease and increased prevalence of insulin resistance. We tested the hypothesis that aldosterone concentrations are increased in RA and associated with inflammation, insulin resistance, and markers of myocardial dysfunction in patients with RA.

Methods: We measured concentrations of serum aldosterone, high sensitivity troponin, brain natriuretic peptide (BNP), inflammatory cytokines, fasting insulin, glucose, and lipids, along with clinical variables in 35 patients with RA and 34 control subjects not taking any antihypertensive medications. We assessed the relationship between aldosterone and high sensitivity troponin and NT-proBNP, inflammatory cytokines, disease activity, and measures of insulin resistance using Spearman correlation analysis in patients with RA.

Results: Aldosterone concentrations were lower in patients with RA than controls (48.54 pg/ml [38.88–61.86] vs. 58.24 [50.75–76.49], p=0.01). Concentrations of markers of myocardial stress, high sensitivity troponin (p= 0.31) and NT-proBNP (p= 0.32), were not significantly correlated with serum aldosterone levels in RA. Similarly, interleukin 6 (IL-6) (p= 0.10), tumor necrosis factor alpha (TNFα) (p= 0.38), and RA disease activity (DAS28) (p= 0.57) were not associated with aldosterone. Finally, aldosterone was not correlated with markers of insulin resistance including fasting insulin (p= 0.33) and glucose (p= 0.77) and HOMA (p= 0.29).

Conclusion: Activation of the renin-angiotensin system does not appear to contribute to accelerated myocardial disease or insulin resistance in patients with RA.

2122

Clinical Characterization of Extensive Interstitial Lung Disease in Rheumatoid Arthritis Patients. Masaomi Yamasaki, Yoshiteru Haga, Makoto Inoue, Kumiko Tonooka and Naooki Katsuyama. St Marianna University, Yokohama City Seibu Hospital, Yokohama, Japan

Background/Purpose: To investigate clinical characteristics of interstitial lung disease (ILD) in rheumatoid arthritis (RA) patients, and to analyze whether high resolutional CT (HRCT) can predict the outcome of ILD in RA.

Methods: 340 patients with RA were treated at our hospital and followed up at least one year. All patients were performed chest radiological examinations at the initial presentation. The HRCT findings which include (1) ground glass opacity, (2) air-space consolidation, linear opacity including (3) septal line and (4) non-septal line, (5) honeycomb lung, (6) traction bronchiectasis, (7) pleural irregularity, and (8) pleural effusion were scored as the CT scoring system. The extent of involvement of each abnormality was assessed independently for each of the three

zones of each lung. The HRCT extent score was represented the sum of the score of each lung. HRCT parameters which include the extension score and the clinical features at the initial presentation were retrospectively analyzed.

Results: 162 out of 340 patients had abnormal chest radiological findings which included bronchiectasis, bronchitis and ILD (47.6%). 76 (26 male (39.3%), 50 female (18.2%)) out of 340 patients showed ILD at initial presentation (22.4%). 5 out of 76 patients had shortness of breath and showed a rapidly progressive ILD (6.6%). In HRCT findings, ILD in these 5 cases were widely spread at the initial presentation. The rest of 71 patients showed no progression of ILD and asymptomatic. However there were no difference in the HRCT findings which include nonseptal linear attenuation, ground-glass attenuation and air space consolidation between rapidly progressive ILD group and asymptomatic group, rapidly progressive ILD group showed more higher degree in honeycombing ($p=0.0003$) and extensive ILD ($p=0.0061$). Prognosis of the rapidly progressive ILD was variable. The rapidly progressive ILD are treated with immunosuppressive agent which include high dose steroid, cyclophosphamide, azathioprine, cyclosporineA (CsA) and Mycophenolate Mofetil(MMF) for IP. 2 patients treated with CsA and one patient treated with MMF shows improving of ILD on HRCT. But in other 2 patients were resistant to these immunosuppressive agents.

Table 1. HRCT findings at the initial presentation in RA-ILD

	asymptomatic ILD (n = 71)	rapidly progressive ILD (n = 5)	p value
nonseptal linear attenuation	91.5% (65)	100% (5)	0.4982
ground-glass attenuation	25.4% (18)	60.0% (3)	0.1258
honeycombing	16.9% (12)	100% (5)	0.0003*
air space consolidation	1.4% (1)	0.0% (0)	0.7894
extensive ILD (more than 4 areas of ILD)	16.9% (12)	80.0% (4)	0.0061*

Conclusion: HRCT findings focused on the extension score at the initial presentation is a useful predictor of the outcome of ILD in RA.

2123

Lobular Panniculitis: A Characteristic Skin Manifestation in Rheumatoid Arthritis. Takehiko Ogawa, Takehisa Ogura, Kana Ogawa, Ayako Hirata and Norihide Hayashi. Toho University Ohashi Medical Center, Tokyo, Japan

Background/Purpose: Although panniculitis has been described in various systemic inflammatory disorders such as systemic lupus erythematosus, sarcoidosis and Weber-Christian disease, but it has seldom been reported in RA. We encountered 8 RA patients with skin manifestations of which histologic findings revealed the lobular panniculitis. Those serial cases led us to investigate the incidence and clinical characteristics of lobular panniculitis occurring in RA.

Methods: We retrospectively reviewed the medical records of 8 patients with RA who developed lobular panniculitis. To investigate whether lobular panniculitis is characteristic of RA, we non-selectively recruited 100 RA patients without episode of panniculitis, and reviewed the patients' medical records for clinical manifestations and laboratory data. Patients were excluded if they had a rheumatic autoimmune disease other than RA or significant systemic involvement secondary to RA.

Results: Among the 8 patients with panniculitis studied (women/men: 6/2), those ages ranged from 30 to 78 years (58.1 ± 16.9 years) and duration of illness ranged from 2 to 15 years (8.9 ± 3.9 years). The cutaneous manifestations were edematous and tender erythematous indurations with partially hirsute, which were quite similar among those 8 patients and characteristic. Histologic studies revealed lobular panniculitis without vasculitis. In all 8 patients, the eruptions arose over the periarticular extensor surfaces of the forearms or the distal legs, which had the most active synovitis at the time. Compared with 100 RA patients without panniculitis, large joints including shoulder, elbow, wrist, knee and foot joints were more frequently affected in patients with panniculitis ($p=0.007$). Mean number of tender joints and swollen joints were significantly smaller ($P=0.002$), whereas patient's global assessment of disease activity, patient's global assessment of pain, mean values of CRP and the Disease Activity Score in 28 joints (DAS28) were significantly higher in RA patients with panniculitis ($p=0.007$, $p<0.0005$, $p=0.001$, respectively). The activities of arthritis and panniculitis were in parallel, and the skin manifestation and arthritis responded concurrently to treatments for RA.

Conclusion: Although lobular panniculitis has not been previously described as manifestation of RA, the present study demonstrates that panniculitis may be a characteristic and notable skin manifestation in RA.

2124

Low Levels of Vitamin D Level Are Associated with Greater Disease Activity and Disability in Patients with Rheumatoid Arthritis. Uzma J. Haque[1], Kevin R. Fontaine[2], Clifton O. Bingham[3] and Susan J. Bartlett[4]. [1]Johns Hopkins Hospital, Baltimore, MD, [2]John Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]McGill University, Montreal, QC

Background/Purpose: Low vitamin D levels are prevalent among persons with rheumatoid arthritis (RA). Some studies have shown an association between low vitamin D and increased disease activity and pain. Our goal was to estimate the prevalence of low vitamin D levels in a cohort of RA patients and estimate relationships between 25(OH)D levels, clinical and patient reported indicators of disease activity and disability.

Methods: Data are drawn from the baseline visit of an RCT to assess the effect of vitamin D repletion therapy in RA patients (currently underway). Patients who met ACR criteria were consecutively approached during routine clinic visits from Jan 2009 through April 2011. Joint counts and evaluator disease activity assessments were performed. CDAI scores were calculated as an indicator of disease activity. Patients completed the HAQ, AIMS2-SF and other selected additional questionnaires. 25(OH)D measures were conducted by one laboratory using the DiaSorin radioimmunoassay.

Results: Participants ($N=139$) were mostly female (79.9%) and white (79,1%) with a mean $\pm$ SD age of 53.4 ± 12.3 yrs, BMI of 30.5 ± 6.9 kg/m^2 and disease duration of 10.0 ± 9.0 yrs. Mean 25(OH)2 levels were 28.3 ± 11.1 ng/mL (range 6.3 – 72.8); mean 25(OH)D was < 30 ng/mL in all seasons except summer when it increased to 31.9 ± 11.2 ng/ml ($p=.429$). Overall, 60.2% had 25(OH)D levels < 30 ng/mL, and 21% $\leq$ 20 ng/mL. Patients with the lowest 25(OH)D levels had higher BMIs (33.6 ± 9.5 vs. 31.2 ± 6.2 vs. 28.5 ± 5.6; $p<.01$) but did not differ by age, sex, race or education. Patients with Vitamin D $\leq$ 20 ng/mL had significantly higher clinical (swollen and tender joints, CDAI) and patient reported (morning stiffness, pain, fatigue) indicators of disease activity and higher HAQ scores as shown in table. In a subset of participants ($n=90$) who completed the AIMS2-SF, very low vitamin D status also was associated with significantly more symptom reports.

Table 1. Clinical and Patient-Reported Disease Indicators in Patients with Rheumatoid Arthritis by 25(OH)D Level.

25(OH)D Levels (ng/mL)	≤ 20 N=29	20–30 N=54	>30 N=56	P value
Clinical Disease Indicators				
Swollen Joints	7.4 ± 9.3^a	3.7 ± 4.8^b	3.6 ± 5.2^b	.016
Tender Joints	12.3 ± 12.1^a	6.2 ± 10.0^b	6.1 ± 8.1^b	.012
CDAI	19.1 ± 15.6^a	10.0 ± 11.1^b	9.3 ± 10.3^b	.003
Patient Reported Indicators				
Morning Stiffness (min)	160^a	74^b	27^b	.015
Pain (100 mm VAS)	39 ± 29^a	24 ± 24^b	25 ± 22^b	.020
Fatigue (SF12 Vitality)	42.2 ± 9.9^a	49.1 ± 10.2^b	47.6 ± 9.3^b	.010
AIMS2-Symptoms	4.4 ± 3.1^a	$2.9 \pm 2.9^{a\dagger}$	2.3 ± 2.0^b	.033
Disability				
HAQ	1.01^a	0.62^b	0.68^b	.026

Conclusion: Despite increasing awareness of the importance of vitamin D for overall health, low levels appear to be common in RA patients. Low vitamin D status is associated with significantly higher clinical and patient reported indicators of disease activity and greater disability. The effect of repleting and maintaining adequate levels of vitamin D on RA disease activity, symptoms and disability remains unknown.

2125

Predictors of Assymetric Dimethyl Arginine in Rheumatoid Arthritis. Theodoros Dimitroulas[1], Aamer Sandoo[1], Jet JJCS Veldhuijzen van Zanten[2], Jacqueline P. Smith[1], George Metsios[1], Peter Nightingale[3], Antonios Stavropoulos-Kalinoglou[1] and George Kitas[1]. [1]Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, West Midlands, UK, Dudley, United Kingdom, [2]School of Sport and Exercise Sciences, University of Birmingham, Birmingham, UK, Dudley, United Kingdom, [3]Dudley, United Kingdom

Background/Purpose: Rheumatoid arthritis (RA) is associated with endothelial dysfunction and increased cardiovascular mortality. Assymetric dimethylarginine (ADMA) is a competitive inhibitor of nitric oxide synthase and has emerged as a novel cardiovascular risk factor. Previous studies have shown that ADMA levels are elevated in patients with RA. The aim of the present study was to investigate if demographic, inflammatory, or metabolic factors predict elevated ADMA levels in RA and to define the potential relationship between ADMA and *in vivo* assessments of microvascular and macrovascular endothelial function.

Methods: We studied 67 patients (age (mean ± standard deviation): 56 ± 12 years, disease duration median (25^{th} – 75^{th} percentile): 8 (3 – 15) years, 48 women) and 29 healthy controls (age (mean ± standard deviation): 42 ± 12, 21 women). Routine biochemistry tests, lipid profile, glycemic profile and inflammatory markers were measured in all patients and controls. ADMA levels were measured by ELISA. Microvascular endothelial-dependent (Acetylcholine) and endothelial-independent (sodium nitroprusside) function were examined using Laser Doppler Imaging. Macrovascular endothelial dependent function was assessed using flow-mediated dilatation, and endothelial-independent function using glyceryl-trinitrate-mediated dilataion. Arterial stiffness was characterised using pulse wave analysis.

Results: ADMA levels were significantly higher (p=.004) in RA patients compared with healthy controls after adjustment for age (difference = 0.088, 95% confidence interval 0.029–0.147). Linear regression analysis revealed that Insulin (β=.33, t (65) = 2.80, p =.007), HOMA (β=.36, t (64) = 3.01, p =.004) and QUICKI (β= -.12, t (64) = 3.03, p =.004) were independent predictors of elevated ADMA. ADMA levels did not correlate with demographic or disease characteristics. No correlation was found between ADMA and non-invasive assessments of endothelial function or with arterial stiffness.

Conclusion: The present findings suggest that insulin resistance, rather than inflammation or other classical CVD risk factors, predict elevated ADMA levels in RA. ADMA was not associated with assessments of endothelial function and these assessments should therefore be used independently for global assessment of vascular health. Further longitudinal studies are required to assess the long-term effect of elevated ADMA level in RA.

2126

Disease Activity Levels and Treatment Patterns Amongst Ethnic Minority Rheumatoid Arthritis Consortium Patients. Yusuf Yazici[1], Christopher Swearingen[2], Yvonne R. S. Sherrer[3], Raj G. Nair[4], Edward L. Treadwell[5], Angelia D. Mosley-Williams[6], Luis R. Espinoza[7], Asia M. Mubashir[8], Jeffrey Huang[8] and Gail S. Kerr[9]. [1]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]Centre Rheum Immunol Arthritis, Fort Lauderdale, FL, [4]Washington Hospital Center, Washington DC, DC, [5]E Carolina Univ Sch of Med, Greenville, NC, [6]John Dingell VAMC, Detroit, MI, [7]LSU Medical Center, New Orleans, LA, [8]Howard University Hospital, Washington, DC, [9]Washington DC VAMC and Georgetown University and Howard University Hospital, Washington, DC

Background/Purpose: Advances in therapeutic strategies for rheumatoid arthritis (RA) and focus on "treating to target" has led to increased use of disease activity measures in routine care. However, little data exists that examines disease activity in ethnic minorities. The Ethnic Minority Rheumatoid Arthritis Consortium (EMRAC) is a registry comprised of RA clinical measures obtained during routine care.

Methods: RA patients satisfying ACR diagnostic criteria, of self-reported ethnicity and seen at 8 US sites are enrolled. Collected data include patient demographics, comorbidities, disease characteristics and activity (MDHAQ, ESR, CRP, swollen and tender joint counts, composite disease activity indices). Patients enrolled in EMRAC were evaluated for treatment modalities, disease duration, and low/moderate/high disease activity as measured by RAPID3, CDAI, and DAS28. Ethnic groups were compared to Caucasians for each category of disease activity using Kruskal-Wallis for continuous variables and Chi-square test for qualitative variables; post-hoc pairwise comparisons between groups were adjusted using Bonferonni correction ($p<0.008$ for significance).

Results: More patients had data available for determination of RAPID3 than either CDAI or DAS28. Compared to Caucasians or Other racial category, Hispanic patients had significantly higher disease severity as measured by RAPID3; African Americans average RAPID3 was also higher, but was not statistically different from Caucasian or Other racial groups. No differences were seen in clinical remission by DAS28 or CDAI criteria, or in DMARD use between ethnic groups. However, significantly fewer African Americans were on biologic agents compared to Caucasians or Hispanics.

Table 1. Disease Severity and Treatments amongst Ethnic Groups in EMRAC

	African-American	Caucasian	Hispanic	Other	Total	p
N	102	105	82	49	338	
Dis Duration, mean yr (SD)	8.2 (9.3)	7.4 (10.0)	8.8 (9.4)	4.2 (5.1)	7.5 (9.2)	
RAPID3 (N=310)						**0.034**
High Severity [>12]	44 (48%)	34 (33%)	44 (59%)	13 (30%)	135 (44%)	
Moderate Severity [6.1–12]	20 (22%)	30 (29%)	16 (22%)	11 (26%)	77 (25%)	
Low Severity [3.1–6]	11 (12%)	13 (13%)	6 (8%)	8 (19%)	38 (12%)	
Near Remission [0–3]	16 (18%)	25 (25%)	8 (11%)	11 (26%)	60 (19%)	
Mean (SD) score [0–30]	11.2 (6.9)	9.5 (6.9)	13.1 (7.1)	8.9 (7.2)	10.8 (7.1)	**0.002**
DAS28 (N=56)						0.430*
High Severity [>5.1]	2 (6%)	2 (18%)	1 (14%)	0	5 (9%)	
Moderate Severity [3.21–5.1]	12 (34%)	5 (45%)	1 (14%)	1 (33%)	19 (34%)	
Low Severity [2.61–3.2]	9 (26%)	0	1 (14%)	0	10 (18%)	
Near Remission [0–2.6]	12 (34%)	4 (36%)	4 (57%)	2 (67%)	22 (39%)	
Mean (SD) score [0–10]	3.1 (1.1)	3.4 (1.9)	3.0 (2.0)	2.9 (0.8)	3.1 (1.4)	0.848
CDAI (N=87)						0.617*
High Severity [>22]	6 (11%)	2 (19%)	2 (17%)	0	10 (11%)	
Moderate Severity [10.1–22]	15 (27%)	3 (27%)	4 (33%)	3 (38%)	24 (29%)	
Low Severity [2.9–10]	24 (43%)	4 (36%)	3 (25%)	1 (13%)	32 (37%)	
Near Remission [0–2.8]	11 (20%)	2 (18%)	3 (25%)	4 (50%)	20 (23)%	
Mean (SD) score [0–76]	10.4 (11.0)	13.0 (13.2)	10.9 (9.7)	6.0 (5.6)	10.4 (1.7)	0.559
Prednisone (N, %)	41 (40%)	34 (32%)	28 (34%)	14 (29%)	117 (35%)	0.487
DMARD (N, %)	85 (83%)	78 (74%)	62 (76%)	41 (84%)	266 (79%)	0.294
Biologic (N, %)	22 (22%)	43 (41%)	40 (49%)	14 (29%)	119 (35%)	**0.001**

*Fisher's exact test reported instead of Chi-square test.

Conclusion: In a diverse ethnic cohort, significant differences in the patient-reported measure of RA disease activity and biologic treatment were noted. Further evaluation is needed to assess the reasons that may contribute to these differences among RA ethnic groups and their impact on long-term outcomes.

2127

The Impact of Morning Stiffness on Quality of Life in Early Rheumatoid Arthritis. Karin Britsemmer and Dirkjan van Schaardenburg. Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands

Background/Purpose: In early rheumatoid arthritis (RA), joint stiffness and pain are often most severe in the morning hours. Morning stiffness (MS) could impair physical functioning and may impact the quality of life (QoL). The aim of this study was to evaluate the relationship between MS and QoL.

Methods: Data of 286 patients (71% female, age 53 (13)) fulfilling the ACR 1987 criteria for RA either at baseline or at 1 year follow-up that had

data available were used for the analysis. Patients were treated with conventional DMARDs or TNF-α inhibitors as prescribed by the treating rheumatologist. Univariate and multivariate correlation/regression was used to evaluate the relationship between MS and QoL, and between MS and physical functioning, with disease activity as covariate. MS was expressed as duration in minutes, disease activity was measured by the 28-joint count disease activity score (DAS28) and the Health Assessment Questionnaire (HAQ) measured physical functioning. EuroQol measured quality of life, expressed as visual analog scale (VAS, range 0–100) and as profile result. Profiles were calculated according to a scoring formula based on unweighted coefficient (range −0.59 – 1,00)[1]. Measurements were at baseline and after 1-year follow-up. Statistical tests were performed at a one-sided alpha of 0.05, given the known relationship of patient symptoms with quality of life, the moderate discriminative characteristics of both duration of MS and EuroQol as measure, and the relative low power of regression models to detect interaction effects. Thus all results with a $p<0.10$ are regarded as significant.

Results: At baseline 84% of patients had MS of 15 minutes or more (mean 79 (69) minutes). Patients had active disease with a mean DAS28 of 5,0 (1.2) and were significantly impaired in physical functioning (mean HAQ 1.21 (0,73)). Quality of life was significantly impacted with EuroQol profile scores of 0,37 (0,29) and VAS results of 55 (20). Most patients had improved scores after 1-year (table 1). In univariate analysis MS was significantly correlated to EuroQol at both time points. More importantly, improvement in MS correlated strongly with improvement in EuroQol. This relationship maintained when adjusted for DAS28 for the separate time points, but weakened for the change scores. In all models MS was strongly correlated to HAQ even after adjustment for DAS28 (table 1).

Table 1. Descriptives (mean (SD)) and the measures of correlation (adjusted for DAS) between morning stiffness and quality of life

	Baseline	1 year FU	Change scores
MS (minutes)	79 (69)	35 (55)	−44 (87)
DAS28	5.0 (1.2)	3.2 (1.2)	−1.9 (1.4)
HAQ	1.21 (0.73)	0.80 (1.25)	−0.55 (0.69)
EuroQol Profile*	0.37 (0.29)	0.60 (0.29)	0.23 (0.33)
EuroQol VAS*	55 (20)	69 (19)	14 (23)
Correlation/regression coefficient			
EuroQol Profile	−0.136 (p=0.005)	−0.146 (p=0.008)	−0.095 (p=0.086)
EuroQol VAS	−0.089 (p=0.006)	−0.148 (p=0.087)	−0.036 (p=0.514)
HAQ	0.187 (p=0.002)	0.157 (p<0.005)	0.150 (p=0.006)

* an higher score means a better health state

Conclusion: MS is a frequent feature of early RA. It has an impact on quality of life and physical function that is independent of disease activity. Interventions directed at reduction of MS may have added value.

Complementary and Alternative Medicine Use in African Americans with Rheumatoid Arthritis. Ashutosh Tamhane[1], Gerald McGwin[1], David T. Redden[1], Elizabeth Brown[2], Andrew Westfall[1], Richard J. Reynolds[1], Laura B. Hughes[1], Doyt L. Conn[3], Beth L. Jonas[4], Edwin A. Smith[5], Richard D. Brasington[6], Larry W. Moreland[7], S. Louis Bridges Jr.[8] and Leigh F. Callahan[9]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Univ of Alabama at Birmingham, Birmingham, AL, Birmingham, AL, [3]Emory Univ School of Medicine, Atlanta, GA, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Med Univ of South Carolina, Charleston, SC, [6]Washington Univ School of Med, St. Louis, MO, [7]University of Pittsburgh, Pittsburgh, PA, [8]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [9]University of North Carolina, Chapel Hill, NC

Background/Purpose: Use of Complementary and Alternative Medicines (CAM) for rheumatoid arthritis (RA) has been increasing in the United States. Racial/ethnic differences with regard to CAM use have been reported but data on African-Americans (AAs) are limited. The study aimed to report the prevalence of CAM use in AAs with RA and compare the practices of those with late (>2 yrs) versus early (≤2 yrs) disease duration.

Methods: Self-reported data on CAM use (16 treatments, 9 activities, 5 providers) at enrollment was analyzed from the CLEAR registry.

Results: Of the 855 patients enrolled 85% were female and 418 (49%) had early disease. In late RA patients ever use of any of the CAM activities, treatments or providers was reported in 96%, 99%, and 51%, respectively and in early RA patients in 94%, 97%, and 51%, respectively. The most common treatment, activity, and CAM providers were heat treatment (80%), praying/attending church services (92%), and religious leaders (32%), respectively. Moderate (odds ratio ≥2) and significant ($p<0.05$) associations were observed for those with late disease and treatments such as ever using fish oils, or raisins soaked in gin while weak significant associations were observed for ever using household oils, heat treatments, gelatin, garlic, magnets, and special jewelry. Similarly, moderate significant association was observed for late disease and drinking alcohol. Those with late disease were significantly more likely to consult chiropractitioner but less likely to have visited religious leader.

Conclusion: Overall, CAM use was highly prevalent in this cohort.

2129

Effect of Treatment of Hypogonadism On Rheumatoid Arthritis In Male Veterans. Farah Mahmood, Robert W. McMurray and Dannette S. Johnson. G.V. Sonny Montgomery VA Medical Center and University of Mississippi Medical Center, Jackson, MS

Background/Purpose: It has been observed in previous studies that rheumatoid arthritis (RA) in male patients can affect the pituitary and hypogonadal axis. Men with RA have been shown to have a high incidence of testosterone deficiency. Low testosterone (T) can also predispose these patients to have more severe disease. We investigated the effect of hypogonadism therapy on rheumatoid arthritis activity in male patients.

Methods: In a subpopulation of the Veterans Affairs Rheumatoid Arthritis (VARA) registry, a group of men with a diagnosis of RA were previously found to be hypogonadal (total serum T < 250 ng/dl). Several of these men underwent treatment of their hypogonadism with testosterone replacement therapy (TRT) of testosterone cypionate 200mg IM every 8 weeks. Assessment of RA activity and treatment monitoring included: patient and physician global scores, tender and swollen joint counts, liver function tests, CBC, ESR and CRP. TRT monitoring assessments included: 30-second chair rise, 50-feet walk test, measurement of grip strength, Aging Male Symptoms (AMS) scale, as well as testosterone, prolactin, LH, and FSH measurements. The relationship of testosterone therapy on RA was evaluated using student's t-test and Wilcoxon matched-pairs test with Bonferroni correction ($\alpha=0.02$).

Results: The men with RA receiving TRT (n=14) had the following characteristics: 100% RF positive, age = 66.5 years (range 40–86 years), duration of disease = 14 years (range 2–31 years), mean T = 214 53 ng/dl. With TRT, 100% of patients had a decreased 50-foot walk time, 85% increased their 30-second chair rise, 92% decreased their DAS28, 50% had decreased CRP levels and 92% had decreased ESR. At 16 weeks of therapy, 50 % of patients met DAS28 remission criteria (DAS28<2.6). There was no significant change in RA therapy. There was a trend towards improvement in LH and FSH scores in almost 50% of patients. No adverse side effects of TRT were reported.

MEASURE (mean±SEM)	TIME (weeks) 0	8	16	P value (0–8 wks)	P value (0–16 wks)
Serum T (ng/dl)	213.4 ± 14.2	205 ± 25.9	310.9 ± 57.5	0.7	0.03
DAS28	3.8 ± 0.3	2.9 ± 0.3	2.6 ± 0.2	0.0002	0.0014
MD-HAQ	1.1 ± 0.1	1 ± 0.1	0.9 ± 0.1	0.5	0.3
Patient Global (mm)	44.2 ± 7.8	35.1 ± 4.8	33.8 ± 5.6	0.3	0.6
Physician Global (mm)	33.2 ± 6.4	23.7 ± 3	23.6 ± 3.9	0.15	0.3
ESR (mm/hr)	29.2 ± 5	22.2 ± 5	21.9 ± 6	0.4	0.017
CRP (ng/ml)	0.7 ± 0.2	0.4 ± 0.1	1.9 ± 1	0.09	0.9
HCT (%)	40.0 ± 1	41.2 ± 1.1	41.1 ± 1	0.09	0.1
50-Foot Walk (secs)	30 ± 2	22 ± 2	19.5 ± 2	0.0014	0.0011
30-sec chair (times)	8.3 ± 0.5	9.1 ± 0.5	10.8 ± 0.7	0.178	0.05
Grip–Right (mmHg)	55.5 ± 6.7	61.4 ± 6.6	86.07 ± 9.0	0.4	0.009
Grip–Left (mmHg)	56 ± 6.5	59.4 ± 6.4	78.9 ± 10.5	0.5	0.018
AMS Score	39 ± 3.4	31 ± 2.4	27.9 ± 2.7	0.0016	0.0017

Conclusion: In our population, TRT significantly improved RA disease activity and function in hypogonadal men with established RA. Symptoms of RA and hypogonadism overlap; men with RA should be screened for hypogonadism and TRT should be considered. Further investigation is needed to elucidate the aspects of immunoendocrine regulation of RA.

2130

Extra-Articular Manifestations of Rheumatoid Arthritis in An Ethnically Diverse Cohort: Prevalence and Clinical Associations. Nicole C. Richman[1], Jinoos Yazdany[1], Jonathan D. Graf[2], Vladimir Chernitskiy[1] and John B. Imboden[3]. [1]University of California San Francisco, San Francisco, CA, [2]Univ of Calif-San Francisco, San Francisco, CA, [3]University of California, San Francisco, CA

Background/Purpose: Prior studies report the prevalence of extra-articular manifestations of rheumatoid arthritis (ExRA) in predominantly Caucasian patients with rheumatoid arthritis (RA). The purpose of this study was to determine the prevalence and clinical associations of ExRA in an ethnically diverse, U.S. cohort of patients with RA.

Methods: This retrospective study analyzed 275 patients with RA seen at a public hospital between 2006 and 2010. All patients met the 1987 ACR criteria for RA. Outpatient records were reviewed to determine the presence of ExRA, including peripheral nodules, interstitial lung disease, serositis, scleritis, myocarditis, vasculitis, Felty's syndrome, large granular lymphocyte syndrome, and amyloid. A chi-squared test, t-test, or Fisher's exact test was used to determine whether or not there were differences in terms of sociodemographics (age at RA diagnosis, gender, and ethnicity), and clinical characteristics (rheumatoid factor, anti-cyclic citrullinated peptide antibodies, and radiographic changes on radiographs of the hands and feet) in patients with and without ExRA. Multivariate logistic regression was then used to examine the association between the same sociodemographics, clinical characteristics, and the presence of ExRA.

Results: We studied 129 (47%) Hispanic, 97 (35%) Asian, 27 (10%) African American, and 20 (7%) Caucasian patients with RA. The prevalence of ExRA was 21%. Peripheral nodules and interstitial lung disease were seen in 16.9% and 3.2% of patients respectively. Scleritis, pleural effusions, and pyoderma gangrenosum were seen in ≤1% of our patients. Other forms of ExRA were not observed. The prevalence of ExRA was significantly higher amongst Hispanic patients compared to Asian patients (27% vs. 13% p< 0.001). Patients with ExRA were more likely to be male (24% vs 11% p= 0.007) and positive for serum rheumatoid factor (RF) (97% vs 79% p= 0.003). In the adjusted model, RF positivity was shown to be associated with ExRA (OR= 10.9; 95% CI 2.16 to 55). Hispanic and Asian ethnicity were not shown to be associated with ExRA in the adjusted model. Age at RA diagnosis (46.7 years vs. 45.7 years), the presence of anti-cyclic citrullinated peptide antibodies (79% vs 76%), and radiographic changes on radiographs of the hands and feet (77% vs. 68%) were not significantly different in patients with and without ExRA.

Conclusion: ExRA in an in our cohort had a prevalence of 21% and manifested largely as peripheral nodules and interstitial lung disease. While ExRA was significantly more prevalent amongst Hispanic patients compared to Asian patients in our cohort, ethnicity was not associated with the development of ExRA in our adjusted analysis. Patients with ExRA were more likely to be RF positive and male, compared to patients without ExRA.

2131

Frequency and Clinical Characteristics of Osteoporosis in Patients with Rheumatoid Arthritis - a Comparison with Healthy Subjects. Seung Geun Lee[1], Young Eun Park[1], Seong Hu Park[2], Sung Il Kim[3], Seung Hoon Baek[4], Geun Tae Kim[5], Joung Wook Lee[6] and Jun Hee Lee[7]. [1]Pusan National University Hospital, Busan, South Korea, [2]Pusan, South Korea, [3]Pusan National University Hospital, Busan, South Korea, [4]Pusan National University Yangsan Hospital, Yangsan, South Korea, [5]Kosin University Gopsel Hospital, Pusan, South Korea, [6]Busan St. Mary's Medical Center, Busan, South Korea, [7]Ilsin Christian Hospital, Pusan, South Korea

Background/Purpose: To compare bone mineral density (BMD) and the frequency of osteoporosis between patients with the rheumatoid arthritis (RA) and healthy subjects and to determine risk factors for bone loss in female patients with RA.

Methods: In a cross-sectional study, clinical and demographic data were collected retrospectively from 317 patients with seropositive RA and 264 age- and sex-matched healthy subjects. BMD in the lumbar spine, femoral neck and total hip was measured with Dual-energy x-ray absorptiometry. A T-score of −2.5 or lower in postmenopausal women and men age 50 and older was defined as "osteoporosis", and a Z-score −2.0 or lower in females prior to menopause and males younger than age 50 was defined as "below the expected range for age" by WHO classification.

Results: The frequency of osteoporosis in the patients with RA was 18.5% at the lumbar spine, 7.1% at the femoral neck and/or total hip, and 22.0% in at least one of the evaluated sites and was significantly higher than in healthy subjects (18.5% vs 9.7%; p-value = 0.026, 7.1% vs 1.3%; p-value = 0.010, 22.0% vs 10.4%; p-value = 0.005). The occurrence of below the expected range for age in the patients with RA was also significantly higher than in the healthy subjects (8.7% vs 0.9%; p-value = 0.006). In 299 female patients with RA, age and body mass index (BMI) were significantly associated with the lumbar spine, femoral neck, and total hip BMD (age: $\beta = -0.005$; p-value < 0.001, $\beta = -0.003$; p-value = 0.005, $\beta = -0.003$; p-value = 0.012, BMI: $\beta = 0.016$; p-value < 0.001, $\beta = 0.011$; p-value < 0.001, $\beta = 0.014$; p-value < 0.001). Postmenopausal status was also related to decreased lumbar spine BMD ($\beta = -0.067$; p-value = 0.009). Of disease-related variables, the use of glucocorticoids, not the cumulative dose of glucocorticoids, was independently associated with reduction of total hip BMD ($\beta = -0.037$; p-value = 0.040).

Table 1. Clinical characteristics of the patients with RA and the healthy subjects

	Healthy subjects (n=264)	RA patients (n=317)	p-value
Male: Female	18: 246	18: 299	0.570
Age (years)	51.3 ± 9.4	52.8 ± 9.9	0.060
BMI (kg/m^2)	22.8 ± 2.9	22.6 ± 3.2	0.559
Median Disease duration (months)	NA	25.0 (IQR 6.0–94.0)	–
Median ESR (mm/hour)	NA	41.0 (IQR 19.0–77.0)	–
Median CRP (mg/dL)	NA	0.49 (IQR 0.12–1.77)	–
Number of GCs ever users (%),	NA	34.1	–
Cumulative GCs of dose (mg) of ever user	NA	2303 (367.5–5355)	–
Number of DMARDs users (%)	NA	97.8	–
Number of biologic agents users (%)	NA	1.3	–
Number of bisphosphonate users (%)	NA	24.3	–
L2-4 Spine			
BMD (g/cm^2)	1.13 ± 0.18	1.02 ± 0.17	<0.001
Z-score	0.39 ± 1.19	−0.24 ± 1.20	<0.001
T-score	−0.02 ± 1.38	−0.79 ± 1.42	<0.001
Femoral neck			
BMD (g/cm^2)	0.89 ± 0.12	0.83 ± 0.14	<0.001
Z-score	0.49 ± 0.94	0.34 ± 1.00	0.065

Total hip			
BMD (g/cm^2)	0.96 ± 0.13	0.85 ± 0.14	<0.001
Z-score	0.57 ± 1.02	0.26 ± 1.00	<0.001
T-score	0.09 ± 1.02	−0.41 ± 1.15	<0.001

RA = Rheumatoid arthritis; BMI = Body mass index; NA = not accessible; ESR = Erythrocyte sedimentation rate; CRP = C-reactive protein; GCs = Glucocorticoids; DMARD = Disease modifying anti-rheumatic drug; BMD = Bone mineral density

Table 2. Multivariable regression analysis of BMD in the 299 female patients with RA

	L2-4 spine BMD (g/cm^2)		Femoral neck BMD (g/cm^2)		Total hip BMD (g/cm^2)	
	β	SE	β	SE	β	SE
Age (years)	−0.005*	0.013	−0.003**	0.001	−0.003**	0.012
BMI (kg/m^2)	0.016*	0.003	0.011*	0.003	0.014*	0.003
Postmenopause	−0.067**	0.026	−0.031	0.020	−0.017	0.0002
ESR (mm/hr)	−0.0002	0.0002	0.0001	0.0002	−0.0002	0.0001
Disease duration (months)	0.0001	0.0001	−0.001	0.0001	6.66^{-6}	0.018
GCs ever user	−0.035	0.214	−0.032	0.017	−0.037**	0.022
Bisphosphonate use	−0.112*	0.026	−0.090*	0.021	−0.099*	0.073
R^2	0.406		0.310		0.307	

BMD = Bone mineral density; RA = Rheumatoid arthritis; BMI = Body mass index; ESR = Erythrocyte sedimentation rate; GCs = Glucocorticoids
* p-value < 0.001
** p-value < 0.005

Conclusion: The prevalence of osteoporosis in the patients with RA was 2.2 times higher than in the healthy subjects, and glucocorticoids use was a risk factor for generalized bone loss in the female RA patients.

2132

Low Vitamin D in Rheumatoid Arthritis Is Associated with Significant Limitations in Social Functioning. Susan J. Bartlett[1], Kevin R. Fontaine[2], Clifton O. Bingham[3] and Uzma J. Haque[4]. [1]McGill University, Montreal, QC, [2]John Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins Hospital, Baltimore, MD

Background/Purpose: Low vitamin D has been with linked increased disease activity, pain and disability in rheumatoid arthritis (RA). Little is known about the impact of low vitamin D in RA on participation in recreational and leisure activities (i.e., socializing and social function).

Methods: Data are drawn from the baseline visit of an RCT to assess the effect of vitamin D repletion in RA patients. Patients meeting 1987 ACR

criteria for RA and seen in a tertiary care clinic were consecutively approached during routine clinic visits from Jan 2009 through April 2011. Joint counts and evaluator disease activity assessments were performed and CDAI scores were calculated as an indicator of disease activity. Patients completed the HAQ, SF-12 and other selected questionnaires. 25(OH)D levels were measured by one laboratory using the DiaSorin radioimmunoassay. Multivariate linear regression was used to assess relationships among SF-12 social function (SF) and clinical and patient reported disease activity markers, disability and 25(OH)D.

Results: Participants (N=139) were mostly female (79.9%) and white (79.1%) with a mean ± SD age of 53.4 ± 12.3 yrs, body mass index (BMI) of 30.5 ± 6.9 m/kg^2 and disease duration of 10.0 ± 9 yrs. Mean 25(OH)2 levels were 28.3 ± 11.1 ng/mL (range 6.3 – 72.8); 60% had 25(OH)D levels < 30 ng/mL, and 21% ≤ 20 ng/mL. As compared with all others, patients with 25(OH)D ≤ 20 ng/mL had higher BMIs (29.8 ± 6.0 vs. 33.6 ± 9.5, respectively) and CDAI scores (9.6 ± 10.7 vs. 19.1 ± 15.6)(all p's<.03) but did not differ by age, sex, race or education. Mean SF was 48.2 ± 9.9 (range 16.2–56.6), significantly lower than population norms. In model 1 (adjusted for sex, BMI and disease duration), CDAI, HAQ, AM stiffness and pain were moderately and inversely related to SF; vitality and 25(OH)D were directly related to SF. In model 2 (fully adjusted), 25(OH)D remained a significant predictor of SF. Together, these factors accounted for a substantial amount of the variance in SF (F=13.97, p <.001; adj r^2=.56).

Table 1. Predictors of Social Function in Patients in with Rheumatoid Arthritis.

	Model 1* β	Model 2** β
CDAI	−.377†	−.167†
HAQ	−.572†	−3.286‡
25(OH)D (ng/mL)	.317‡	.135$^{\neq}$
SF12-Vitality	.573†	.349$^{\neq}$
Pain (100 mm VAS)	−.572†	−.109$^{\neq}$
Morning stiffness (min)	−.446†	−.008$^{\neq}$

*Adjusted for sex, BMI and disease duration; **Fully adjusted model; †p≤.001; ‡p≤.01; $^{\neq}$p≤.05.

Conclusion: Socializing and activity limitations have been previously reported in established RA. These data suggest that low vitamin D may also play an independent role in limiting normal social activities with friends, family, neighbors and other groups beyond disease activity, disability and patient-reported symptoms such as fatigue, pain and morning stiffness. The mechanism is unclear. Studies to evaluate the effect of repleting/maintaining adequate levels of vitamin D on RA on disease activity, symptoms and function are ongoing.

2133

Ocular Complication and Its Association with Disease Characteristics and Treatment Responses in a Cohort of 295 Rheumatoid Arthritis Patients. Zejin Zhu[1], Paul Maranian[2] and Harold E. Paulus[1]. [1]University of California, Los Angeles, Los Angeles, CA, [2]University of California, Los Angeles

Background/Purpose: To assess the prevalence of ocular complication and its association with disease characteristics and treatment responses over time in a disease-modifying antirheumatic drug (DMARD)-naive seropositive early rheumatoid arthritis (RA) cohort.

Methods: 295 patients with polyarticular disease who were DMARD-naive and had seropositive early RA (< 14 months) were recruited by the Western Consortium of Practicing Rheumatologists. Each patient was examined at study entry, 6 and 12 months, and yearly thereafter. Clinical, radiographic data, and ocular manifestation (keratoconjunctivitis sicca, xerostomia, episcleritis, scleromalacia, uveitis, salivary gland hypertrophy), presence of RA nodule, and serology markers were collected. We investigated the difference in baseline disease characteristics and treatment response in the presence or absence of eye manifestation.

Results: At baseline, 36 patients (12.2%) presented with ocular manifestation. Baseline disease characteristics were similar in the groups of RA patients with or without eye involvment. Patients with biologic DMARDs use was excluded from this study. Despite similar treatment, patients with ocular manifestations had worse disease progression over the 2-year follow up, as assessed by changes in Disease Activity Score 28/erythrocyte sedimentation rate (DDAS28-ESR4), changes in erosion score and joint space narrowing score. We also grouped the patients with Ksicca/xerostomia and/or salivary gland hypertrophy together to assume a diagnosis of secondary Sjogren's syndrome, and found this group of patients with worse disease progression and less response to DMARD therapy. The presence of rheumatoid nodules does not appear to predict the presence of ocular inflammation.

Conclusion: Ocular manifestation is not rare in rheumatoid arthritis; secondary sjogren's syndrome is by far the most prevalent ocular commorbidity. At baseline, early RA patients with or without eye manifestation had similar disease activity and joint damage. Responses to treatment over time were worse among patients with ocular manifestation in this cohort of patients treated with non-biologic DMARDs, despite similar treatment. We propose that aggressive treatment may be implicated in early RA patients with eye involvement to achieve better outcome.

2134

Role of Body Composition Phenotypes and Adiposity in Disease Activity, Endothelial Dysfunction and Radiological Damage in Rheumatoid Arthritis Patients. Esmeralda Delgado-Frías[1], Vanesa Hernandez-Hernandez[1], Ivan Ferraz-Amaro[1], Jose A. Garcia-Dopico[2], Lilian Medina[2], Antonieta Gonzalez-Diaz[3], Maria A. Gomez- Rodriguez-Bethencourt[3], Jose Ramon Muñiz[4], Ana I. Rodriguez-Vargas[1], M. Jesus Dominguez-Luis[1], M.Teresa Arce-Franco[1], M. Angeles Gantes-Mora[1] and Federico Diaz-Gonzalez[1]. [1]Servicio de Reumatología, Hospital Universitario de Canarias, La Laguna, Spain, [2]Servicio de Laboratorio Central, Hospital Universitario de Canarias, La Laguna, Spain, [3]Servicio de Medicina Nuclear, Hospital Universitario de Canarias, Spain, [4]Resonancia Magnética. IMETISA. Hospital Universitario de Canarias

Background/Purpose: The amount and distribution of fat and lean mass have important implications for health, and systemic inflammation may represent a risk for altered body composition. Rheumatoid arthritis (RA) is associated with changes in body composition and these changes may be factors potentially contributing to affect disease characteristics like endothelial dysfunction or radiological damage.

Methods: A total of 85 women, 44 RA patients and 41 age-matched controls were included in this cross-sectional study. Standards anthropometric measures were calculated. Demographic data, the 28-joint DAS (DAS-28) and disability using HAQ scores, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were collected. Quantification of visceral and subcutaneous abdominal fat area was determined using magnetic resonance imaging. Total and regional lean mass and fat mass were measured with dual energy X-ray absorptiometry. Lean mass of arms and legs, total body fat mass, truncal fat distribution, fat-free mass index, and presence or absence of sarcopenia and overfat were established. Radiological progression was defined in RA patients by the Sharp score. Endothelial dysfunction was assessed in patients and controls by brachial artery flow-mediated dilation (FMD) as the dilator response to 5 minutes distal cuff occlusion, and after sublingual nitroglycerine administration.

Results: RA patients showed endothelial dysfunction bias an inferior brachial artery FMD (6.3 vs 10.8 mm, p=0.03). Visceral and subcutaneous abdominal fat areas were not different between RA patients and controls when adjusted for age and body mass index. Abdominal fat through resonance imaging was not associated with endothelial dysfunction, DAS28, ESR, CRP or Sharp score. Only HAQ show a trend to be negatively related with subcutaneous abdominal fat (r^2=-0,358, p=0.07). Regard DEXA body composition parameters, overfat states tend to be more frequent in RA patients (chi^2=3.26, p=0.07). Disease duration was associated with an inferior fat mass (β coefficient −0.310 kg/years, p=0.03) and with changes in apendicular/truncal phenotypes: higher apendicular fat mass (r^2=0.41, p=0.01) and lower truncal fat mass (r^2=−0.40, p=0.02). Radiological damage through Sharp score was negatively correlated with fat free index and total lean mass (r^2=−0.39, p=0.04) showing that patients with fewer lean mass had higher radiological damage (adjusted for disease duration). This radiological damage was not associated with a specific apendicular or truncal fat mass phenotype. When patients were categorized as sarcopenic or not sarcopenic, radiological damage tends, in addition, to be high in the first group (26.0 vs 10.5 units, p=0.08). FMD was correlated with DAS28 but do not seem to be associated with any body composition phenotype. In our study endothelial dysfunction was not correlated with radiological damage.

Conclusion: Disease activity, radiological damage and disability scores are associated with unhealthy body composition in RA patients. Changes in body composition are partly explained by RA inflammation and these may influence the disease itself.

2135

Ultrasound Screening for Intestinal Lung Disease in Rheumatoid Arthritis. Sonja Kielhauser[1], Florentine Fuerst[1], Kerstin Brickmann[1], Peter Zechner[2], Norbert J. Tripolt[3] and Winfried B. Graninger[4]. [1]Med Univ Klinik Graz, Graz, Austria, [2]Cardiology, Graz, Austria, [3]Diabetology, Graz, Austria, [4]Medical University Graz, Graz, Austria

Background/Purpose: In rheumatoid arthritis (RA) patients, the occurrence of interstitial lung disease (ILD) is associated with an increased mortality due to loss of diffusion capacity and pulmonary hypertension. Thus regular screening for structural abnormalities of the lung is advised. In addition to standard radiological examination with computed x-ray tomography, ultrasound of the lung could serve as a non invasive and radiation-free ways of structural monitoring of the lung. We tested the reliability of lung sonography for the assessment of patients with RA who did not have clinical signs or symptoms of lung disease.

Methods: In a pilot study involving 64 patients with rheumatoid arthritis and 40 healthy volunteers, we screened the pleura and the pulmonary parenchyma for sonographic abnormalities. Patients with abnormal sonographic patterns were subjected to computed tomography of the chest.

Results: 28% of RA patients showed pleural nodules or B-line phenomena. In all of these patients CT scans showed signs of incipient interstitial lung disease. In 7% of the healthy controls, sporadic abnormalities were depicted by sonography. In this small study the use of methotrexate or TNF inhibitors was more frequent in the group of RA patients with radiographic and sonographic signs of interstitial lung disease.

Conclusion: Transthoracic ultrasound of the lung is suggested as a cheap and safe tool to screen patients with RA for incipient pulmonary structural changes.

2136

Genetic Predisposition of the Severity of Joint Destruction in Rheumatoid Arthritis; A Population Based Study. R. Knevel[1], Gerður Gröndal[2], Tom W.J. Huizinga[1], A. Willemien Visser[1], Helgi Jónsson[2], Arnór Víkingsson[2], Árni Jón Geirsson[2], Kristjan Steinsson[2] and Annette H.M. van der Helm-van Mil[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department of Rheumatology, Landspítali, National University Hospital Center for Rheumatology Research, Reykjavik, Iceland, Reykjavik, Iceland

Background/Purpose: The severity of Rheumatoid Arthritis (RA), generally measured by joint destruction, is highly variable between patients. Factors driving these inter-individual differences are unknown. The susceptibility to RA is partly heritable, whether the severity of RA is also influenced by genetics is not determined. Evaluation on the heritability of the severity of RA is basic to further studies on genetic factors. Estimating this genetic predisposition requires accurate information on the family nature of the studied patients. The objective of this study was to evaluate whether the severity of joint destruction in RA is heritable.

Methods: Iceland has a nation-wide unique genealogical database of 10 centuries and genome wide genetic data available of a large part of the population. The majority of the Icelandic RA population lives in the area of Reykjavik. We studied RA patients included in the RA research cohort of the Reykjavik National Hospital. 325 patients had complete radiographs of hand and feet (median disease duration of 10 years) and genealogic information. Of 267 patients genome wide genetic data were present. Radiographs were scored using the Sharp-van der Heijde method blinded to clinical data or data of relatedness and the yearly progression rate was assessed. The degree of relatedness between patients was estimated two-folded. First kinship coefficients (KC) on the genealogic data were expressed. Second the identical-by-descent (IBD) was estimated applying long-range phasing on the genetic profile of the patients.

Results: Significant associations between degree of relatedness and similarity in joint destruction rates were observed, for both methods of determining relatedness (P_{KC}=0.018, P_{IBD}=0.003). The estimated heritability was 45% using KC and 58% using the estimated IBD data.

Conclusion: The severity of joint destruction in RA is influenced by genetic factors.

2137

Longitudinal Determinants of Disability in Vulnerable United States Hispanics with Rheumatoid Arthritis. George A. Karpouzas[1], Soha Dolatabadi[2], Ning Li[2], Rosalinda C. Moran[3], Perry M. Nicassio[4] and Michael H. Weisman[5]. [1]Harbor-UCLA, Torrance, CA, [2]Cedars Sinai Medical Center, Los Angeles, CA, [3]Harbor UCLA Medical Center, Carson, CA, [4]UCLA, Los Angeles, CA, [5]Cedars Sinai Med Ctr, Los Angeles, CA

Background/Purpose: United States Hispanics with Rheumatoid Arthritis (RA) experience worse functional outcomes and quality of life compared to Caucasians. The determinants of disability however are not well established in large cohorts. In the present report we identified predictors of disability in a cross-sectional design, and validated their significance and contributions in a longitudinal design.

Methods: Two hundred and fifty one US-based Hispanics with RA from a single center were cross-sectionally evaluated. Disease activity (DAS28-3v-ESR), serologies, radiographs, treatments, Irreversible articular damage (IAD-defined as subluxation, arthrodesis, fusion, or prosthesis) and joint replacement surgeries (JRS) were recorded. Self-reported disability (Health Assessment Questionnaire Disability Index- HAQ-DI), patient- pain by visual analogue scale (pain-VAS), and depression (Physician Health Questionnaire-PHQ-9) were collected. Predictors of disability were identified using exploratory linear regressions with a forward selection based on observed significance level. Their impact over time was validated longitudinally in 114 patients with a subsequent clinical visit 6 months later, using linear mixed effects models; the predictors entered into the model as time-dependent covariates.

Results: Seven parameters were identified in the cross-sectional phase as determinants of disability (table); in decreasing order of significance, those included pain, IAD, disease activity, depression, JRS, fibromyalgia and age. In the longitudinal analysis, five of the seven parameters remained predictive. Again, patient-reported pain was the most significant, followed by depression, IAD, disease activity, and age. Disease activity and Disability at time 1 were highly correlated with themselves at time 2 (correlation coefficient r=0.61 and 0.6 respectively, p<0.0001 for both), while such correlations were weaker for pain and depression (r=0.33 and 0.48 respectively, p<0.001 for both).

	b	95% CI	p-value
Cross-sectional Phase (N=251)- Multivariable analysis			
Pain-VAS	0.33	(0.21, 0.45)	<0.0001
IAD	0.37	(0.18, 0.56)	0.0001
DAS28-3v-ESR	0.14	(0.06, 0.21)	0.0003
PHQ-9	0.03	(0.01–0.04)	0.0005
JRS	0.48	(0.14–0.81)	0.0054
Fibromyalgia	0.3	(0.06, 0.54)	0.0129
Age	0.01	(0.002–0.02)	0.0178
Longitudinal Phase (N=114)- Multivariable analysis			
Pain-VAS	0.31	(0.21, 0.41)	<0.0001
PHQ-9	0.03	(0.02–0.05)	<0.0001
IAD	0.35	(0.12, 0.57)	0.0029
DAS28-3v-ESR	0.09	(0.02, 0.17)	0.0168
Age	0.01	(0.002–0.02)	0.0227

Conclusion: Self-reported pain is the most important longitudinal predictor of disability in vulnerable US Hispanics with RA, followed by depression, IAD, disease activity, and age. All, except age, are amenable to targeted interventions and should be addressed in an effort to limit disability in these patients.

2138

Smoking Impact on Radiographic Progression in An Early Rheumatoid Arthritis Cohort. Virginia Ruiz-Esquide[1], Jose Alfredo Gomez Puerta[2], S. Cabrera[1], J. D. Cañete[3], M. V. Hernandez[2], Eduard Graell[4], Guadalupe Ercilla[1], Odette Viñas[1], M. J. Gómara[5], Isabel Haro[5] and Raimon Sanmarti[2]. [1]Hospital Clinic of Barcelona, Barcelona, Spain, [2]Hospital Clinic of Barcelona, Barcelona, Spain, [3]Hospital Clínic de Barcelona,, Barcelona, Spain, [4]Hospital Parc Tauli, Sabadell, Spain, [5]IQAC-CSIC, Barcelona, Spain

Background/Purpose: Smoking is a known predictor of rheumatoid arthritis (RA), but its effect in radiographic progression is still controversial.

To investigate the effects of cigarette smoking on radiographic progression in an early RA cohort two years after the beginning of DMARD therapy.

Methods: One hundred and fifty six patients (83% female) with early RA (disease duration < 2 years) treated with a similar therapeutic strategy with DMARDs and low-dose glucocorticoids were included. Several demographic, genetic (DRB genotype), clinical, laboratory and radiographic data were obtained at baseline and after one and two years of follow-up. Smoking was evaluated at study entry and patients were classified as past smokers, current smokers and non-smokers. Radiographic progression after one and two years of follow-up was evaluated in hand and feet radiographs using the erosion joint count (EJC) and Larsen-Scott score. Multivariate lineal regression analysis was performed.

Results: The frequency of current, past and non-smokers were 30.1%, 12.2% and 57.7% respectively. Only 14% of patients were heavy smokers (> 20 pack/year). Radiographic damage at one and two years was higher in current smokers compared with non-smokers, although only in the EJC at two years the difference was statistically significant (1.2±1.7 vs. 0.7±1.7, p=0.04). The Larsen score at two years was higher in current smokers than in non-smokers although the difference was not significant (7.4±12.9 vs. 4.2±6.7, p>0.05). In the univariate analysis taking Larsen-Scott score as the measure of radiographic damage, female sex, higher HAQ at disease onset, the presence of anticitrullinated antibodies, the shared epitope (SE) and the HLA-DRB*04 had a significant effect on radiological score. In the multivariate regression analysis adjusted for baseline radiographic damage, female sex, HLA-DRB*04 genotype and current smoking were independently associated with two year radiographic damage measured by the Larsen Score as well as with the EJC (Table). No significant differences were seen in clinical disease activity or rates of EULAR response at one and two years of follow-up between smokers and non smokers.

Table. Multivariate regression linear analysis for radiographic progression

Larsen-Scot score at 2 years	**B**	**SE**	**95% CI**	**p-value**
Smoking (past vs non smoker)	0.486	2.529	−4.52–5.49	0.848
Smoking (current vs non smoker)	4.274	1.910	0.49–8.05	**0.027**
Women	7.142	2.217	2.75–11.53	**0.02**
HLA-DRB*04 +	5.097	1.624	1.88–8.31	**0.002**
ECJ score at 2 years	**B**	**SE**	**95% IC**	**p-value**
Smoking (past vs non smoker)	−0.065	0.372	−0.8–0.67	0.861
Smoking (current vs non smoker)	0.603	0.282	0.05–1.16	**0.034**
Women	0.792	0.327	0.14–1.44	**0.017**
HLA-DRB*04 +	0.632	0.239	0.16–1.11	**0.009**

EJC: erosion joint count. B: regression coefficient SE: standard error. CI: confidence intervals.

Conclusion: In our early RA cohort, current smoking emerges as an independent factor for radiographic progression after two years of DMARDs.

2139

Environmental and Genetic Contributions to Disease Severity in North American Natives with Early Inflammatory Arthritis. Carol A. Hitchon, Christine A. Peschken, Trevor Mailley, Jillian Dooley, Peter Nickerson and Hani S. El-Gabalawy. University of Manitoba, Winnipeg, MB

Background/Purpose: North American Native (NAN) populations present with severe inflammatory arthritis at an early age. We sought to determine the influence of genetic predisposition as reflected by HLA DRB1 alleles and environmental factors such as smoking and socioeconomic status on the development and outcome of early inflammatory arthritis (EIA) in this group.

Methods: Patients with EIA (less than 1 year symptom duration: NAN =46 and nonNAN=269 (Caucasian =222,Metis =13 others =34) were assessed at baseline clinic visit. One year followup was available for 206 (NAN n=26 other n=174). Baseline disease activity (DAS28CRP3), functional status (mHAQ) and environmental exposures including self reported current smoking status, current alcohol use, a history of vaccination, flu-like illness, bacterial infection, travel, or trauma occurring within 6 months of symptom onset and socioeconomic status (years of education) were recorded. HLA-DRB1 alleles were determined by DNA sequencing. One year clinical outcomes included treatment response (EULAR criteria) and remission (DAS28CRP3<2.6).

Results: NAN were more likely to be current smokers (14/25 (56%) vs 53/216 (25%) p<0.001), less likely to use alcohol (7/18 (38%) vs 127/182 (70%) p<0.008) and had less formal education (7.9 vs 12.7 years p<0.0001). There were no significant differences between NAN and non-NAN in reported exposure to vaccines (3/12 vs 22/104), flu-like illness (3/12 vs 29/102), bacterial illness (2/12 vs 15/100) travel (2/12 vs 46/105) or trauma (1/11 vs 20/100). NAN were more likely to have any SE (30/39 (77%) vs 124/225 (55%) p<0.01) and less likely to have DERAA protective alleles (1/39 (3%) vs 40/225 (18%) p<0.015) than non-NAN. Smoking associated with ACPA in SE +ve subjects. In linear regression models predicting baseline DAS28CRP3 (included variables: years of school, smoking. any SE and DERAA) SE (B=0.5 p=0.02) and years of school (B=−0.05 p=0.02) were significant. At one year NAN were less likely to be in remission (6/26(23%) vs 83/174 (48%) p<0.02).In multivariate models including ethnic group, smoking (ever), education, and SE and DERAA, the presence of DERAA alleles were associated with remission (OR 3.2 CI 1.18–8.86, p<0.05).

Conclusion: In this cohort, environmental factors especially socioeconomic status as reflected by years of education is an important contributor to baseline disease activity. The presence of protective DERAA alleles is associated with a better clinical outcome.

Discrepancies Between Expert Reading and Standard Radiograph Report in Identifying Boney Erosions and Joint Space Narrowing in Patients with Rheumatoid Arthritis in the Veterans Affairs Rheumatoid Arthritis Registry. Maria P. Martes[1], Alan Erickson[2], Ted R. Mikuls[3], Alyse D. Mann[4], Liron Caplan[5], Dannette S. Johnson[6], J. Steuart Richards[7], Gail S. Kerr[7], Andreas M. Reimold[8] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Omaha VA and University of Nebraska Medical Center, Omaha, NE, [3]Omaha VA and University of Nebraska, Omaha, NE, [4]Denver VA and University of Colorado, Denver, CO, [5]Denver VA and University of Colorado, Aurora, CO, [6]Jackson VA and University of Mississippi Medical Center, Jackson, MS, [7]Washington DC VAMC and Georgetown University, Washington, DC, [8]Dallas VA and University of Texas Southwestern, Dallas, TX

Background/Purpose: The identification of radiographic changes—specifically boney erosions (BE) and joint space narrowing (JSN)—impacts the diagnosis and management of rheumatoid arthritis (RA). Little data addresses the validity of standard radiograph reports read by radiologists in identifying these key abnormalities. We compared standard radiograph reports in the Veterans Affairs (VA) computerized patient record system (CPRS) to the assessment by an expert reader (ER) trained to use the modified Sharp Score.

Methods: Bilateral hand X-rays of 302 RA patients enrolled in the Veterans Affairs RA (VARA) registry, a multi-center observational cohort, were assessed by an ER who noted the presence and absence of BE and JSN and quantified these abnormalities if present. A blinded chart abstracter (CA) reviewed the CPRS radiology report for the same X-ray and noted if BE or JSN were reported. CPRS reports that were discordant with ER findings were subjected to a second chart review by a different blinded CA. This review showed strong agreement with original CPRS chart interpretations (>95% for BE and >90% for JSN). Discrepancies between the two CPRS report reviews were adjudicated by a third independent CPRS reading. Demographic, clinical and radiographic features were compared in patients with discrepancies to patients with concordant readings in patients with BE and JSN by ER.

Results: The patients mean age was 64±11 years, 88% were male, RA disease duration was 13±11 years, and the majority was sero-positive for rheumatoid factor (84%) and anti-CCP (80%). As noted below, the two reading were concordant in 199 (66%) cases for BE and 180 (60%) cases for JSN. Only 77 (45%) patients with BE by ER and 112 (48%) patients with JSN by ER were not identified in the CPRS report by radiologists.

	Expert Reading				**Expert reading**		
CPRS reading	**Erosion(s)**	**No erosion**	**Total**	**CPRS reading**	**Narrowing**	**No Narrowing**	**Total**
Erosion(s)	96	26	122	Narrowing	122	10	132
No Erosion	77	103	180	No Narrowing	112	58	170
Total	173	129	302	Total	234	68	302
Sensitivity		55.5%		Sensitivity	52.1%		
Specificity		79.8%		Specificity	85.3%		
Positive Predictive Value		78.7%		Positive Predictive Value	92.4%		
Negative Predictive Value		57.2%		Negative Predictive Value	34.1%		

Neither concordant nor discordant reporting of BE or JSN in the CPRS report was associated with patient age, gender, disease duration, ethnicity, smoking history, serology, nor with most measures for clinical disease activity. Only CPRS noted BE was associated with high joint swelling counts (6.0±6.6 versus 4.0±5.0, p<0.05) at the time of X-ray. Comparison of the quantitative reading by the ER showed a higher likelihood of BE reporting in CPRS in patients with more severe BE (Chi square 21.3 p<0.001) and JSN (Chi square 9.6, p<0.05) scores; however no association was noted for the reporting of JSN in CPRS with severity of BE or JSN noted by ER.

Conclusion: These data show that there is underreporting of BE and JSN in routine CPRS radiograph reports of RA patients. While a positive

report in the CPRS can be considered valid, the absence of these findings does not possess sufficient validity to exclude the presence of BE and/or JSN. While the causes of discrepancy in radiographic findings require further study, current use of electronic medical records appears to have significant limitations.

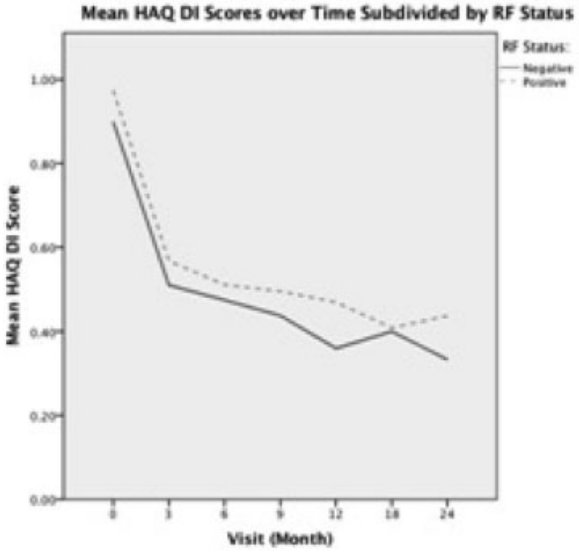
2141

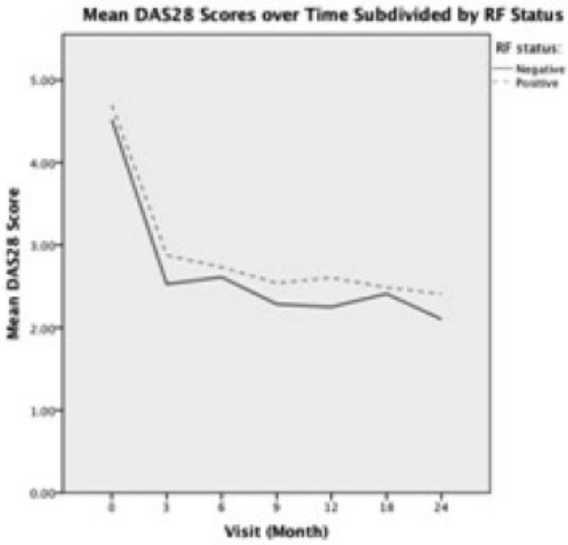
Function (HAQ) and Disease Activity (DAS) Varies by Rheumatoid Factor (RF) Status in Early Inflammatory Arthritis (EIA) with Stronger Associations in RF Positive Patients: Results From the CATCH Cohort. Tristan Boyd[1], Vivian Bykerk[2], Gilles Boire[3], Carol A. Hitchon[4], J. Carter Thorne[5], Edward Keystone[6], Boulos Haraoui[7], Diane S. Ferland[8], Janet E. Pope[9] and CATCH Investigators[10]. [1]University of Western Ontario, London, ON, [2]Brigham & Women's Hospital, Boston, MA, [3]CHUS - Sherbrooke University, Sherbrooke, QC, [4]University of Manitoba, Winnipeg, MB, [5]Southlake Regional Health Centre, Newmarket, Newmarket, ON, [6]Rebecca MacDonald Centre for Arthritis and Autoimmune Disease, Mount Sinai Hospital, Toronto, ON, [7]Institut de Rhumatologie, Montreal, QC, [8]LaSalle, QC, [9]St. Joseph's Health Care, University of Western Ontario, London, ON, [10]Toronto, ON

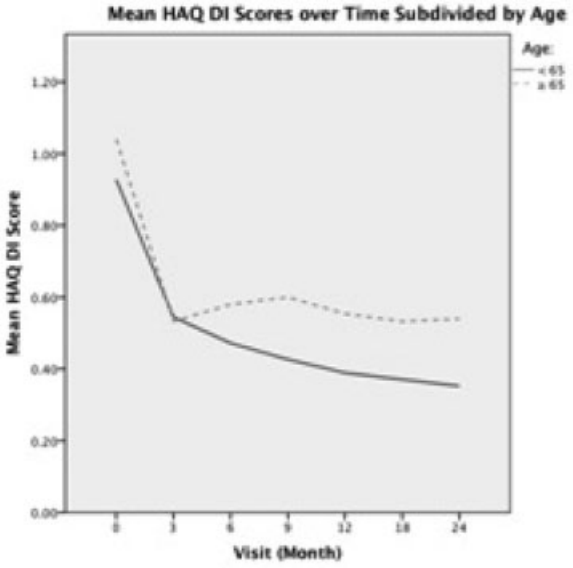
Background/Purpose: Our goal was to investigate the relationship between functional capacity and disease activity in early inflammatory arthritis (EIA) in a contemporary cohort and to determine if the correlations changed over time.

Methods: Data from patients (n=1,145) were collected from the Canadian Early Arthritis Cohort (CATCH), a multi-site observational cohort of EIA. HAQ and DAS28 were assessed at each visit. Correlations were done between HAQ and DAS every 3 months for the first year and then at 18 and 24 months. The relationship between HAQ and DAS in older and younger subjects (<65 versus ≥65) and in those who were RF positive or negative was studied.

Results: Mean symptom duration at first visit was 6.3 months. HAQ scores decreased over time from a baseline of 0.94 to 0.40 at 24 months (values were 0.55, 0.50, 0.47, 0.43, and 0.40 at 3, 6, 9, 12, and 18 months). Mean DAS28 scores also decreased over time from a baseline of 4.54 to 2.29 at 24 months (values were 2.72, 2.67, 2.44, 2.47, and 2.46 at 3, 6, 9, 12, and 18 months). Correlations between HAQ and DAS were significant at all time points ($p<0.01$) and varied over time. The strongest correlation between HAQ and DAS in the first 12 months occurred at the first visit (r=0.53, N=1,143), at which point many of the patients were untreated. At 6, 9, and 12 months the correlation was weaker (r=0.41, r=0.30, and r=0.40). Strong correlations were again noted at 18 months (r=0.57, N=321) and 24 months (r=0.59, N=214). The baseline correlation between HAQ and DAS was significantly different than correlations obtained at 3, 6, and 12 months ($p=0.02$, 0.01, and 0.01, respectively), but not statistically significantly different from values obtained at 18 and 24 months ($p=0.54$ and 0.43). Age did not change the association between HAQ and DAS {<65 years old (r=0.50, N=868) vs. ≥65 (r=0.48, N=254)}, but RF status did: RF+ relationship was larger than RF negative (r=0.63, N=636 vs. r=0.47, N=477).







Conclusion: Function and disease activity both improved after initiation of treatment and were related but in the first year most strongly linked at the first visit. Those with + RF had stronger associations.

2142

Progression of Joint Damage in a Rheumatoid Arthritis Cohort: Role of the HLA-DRB1 Shared Epitope. Jose Felix Restrepo[1], Inmaculada del Rincon[1], Daniel F. Battafarano[2] and Agustin Escalante[1]. [1]University of Texas Health Science Center, San Antonio, TX, [2]Brooke Army Medical Ctr, San Antonio, TX

Background/Purpose: A role for the HLA-DRB1 shared epitope (SE) in shaping the RA phenotype has long been suspected but not consistently observed. We used data from a large RA cohort to examine the association between the SE and the progression of joint damage, measured radiographically.

Methods: We recruited patients with RA attending a scheduled visit with a rheumatologist. We performed a comprehensive clinical evaluation, which include a radiograph of both hands and wrists. Patients were invited to attend annual follow-up visits which also included hand radiographs. These were scored for erosions and joint-space narrowing using the method developed by Sharp et al. We used generalized estimating equations (GEE) with the Sharp score as a dependent variable to examine association with joint damage. In particular, we tested SE × disease duration product terms to compare the rate of joint progression in patients with and without the SE.

Results: We recruited 779 RA patients. We obtained hand radiographs and typed for the SE in 718. Their median age was 57 (interquartile range 49, 64), disease duration 9 years (4, 17), and 509 were women (71%). These patients had 2,968 hand radiographs, or 4.1 films per patient, over 3,924 patient-years, or 5.5 years per patient. The mean Sharp score at the time of the

initial radiograph was 55 (range 0 to 294). It progressed at a rate of 4.5 Sharp units per year of RA duration (95% CI 4.3, 4.7). Among patients who did not have the SE, the rate of progression was 3.7 units per year (3.4, 4.1). In patients who were SE-positive patients, the progression rate was significantly more rapid, at 4.8 units per year (4.6, 5.0), $P \leq 0.001$.

Conclusion: These results suggest that joint damage progresses more rapidly among RA patients who have the SE than among patient who do not.

2143

Comparison of the Patient-Based Routine Assessment of Patient Index 3 in Usual Care of Rheumatoid Arthritis to the Physician-Based Disease Activity Score-28 Joint Count and Clinical Disease Activity Index. Daniel Lupash[1], Aarat M. Patel[2], Christine L. Amity[3], Lynne M. Frydrych[3], Derek Sippel[3], Donald M. Jones[3], Danielle Goudeau[3], Heather Eng[4], David Kyle[4], Melissa Saul[4], G.K. Balasubramani[4], Daniel H. Solomon[5], Stephen R. Wisniewski[4], Larry W. Moreland[1] and Marc C. Levesque[3]. [1]University of Pittsburgh, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr / Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [3]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [4]Univ of Pittsburgh, Pittsburgh, PA, [5]Brigham & Womens Hospital, Boston, MA

Background/Purpose: Studies support using quantitative measures of disease activity in the care of RA patients to improve patient outcomes. In addition, quantitative measures will soon be required by payers for full reimbursement for RA patient care. Despite Disease Activity Score-28 joint count's (DAS28) widespread use in clinical trials, it is challenging to use in clinical care because it requires a complex calculation, a blood test result (CRP or ESR), and a 28 joint assessment. Clinical Disease Activity Index (CDAI) avoids a complex calculation and ESR/CRP but still requires a 28 joint assessment. The Routine Assessment of Patient Index 3 (RAPID3) avoids these obstacles by assessing disease activity based on 3 patient-reported outcomes: physical function, pain, and global health status. This study compared RAPID3 as a measure of disease activity in the usual care of RA patients to DAS28 and CDAI.

Methods: 725 subjects in the University of Pittsburgh's Rheumatoid Arthritis Comparative Effectiveness (RACER) registry were evaluated. DAS28 was calculated using CRP. Correlations between DAS28, CDAI, and RAPID3 at a single visit were calculated. Next, comparisons of subjects classified by disease activity were performed. Finally, for 313 RA patients with follow-up visits, correlations were calculated for the change in DAS28, CDAI, and RAPID3 between visits.

Results: Spearman rank-order correlation results indicated that RAPID3 correlated with DAS28 (0.67, $p<0.001$) and CDAI (0.68, $p<0.001$) but not as strongly as CDAI correlated with DAS28 (0.93, $p<0.001$). RAPID3 and DAS28 categorization by disease activity were in agreement only 35% of the time, kappa score of 0.18. In contrast, CDAI and DAS28's categorization by disease activity were in agreement 54% of the time, kappa score of 0.41.

Table 1. DAS28 vs. RAPID3 Categorization of RACER Patients

	DAS28				
RAPID3	**Remission**	**Low**	**Moderate**	**High**	**Total**
Near Remission	102 (36%)	6 (6%)	9 (3%)	0 (0%)	117
Low	70 (24%)	15 (15%)	15 (6%)	4 (6%)	104
Moderate	74 (26%)	41 (42%)	85 (31%)	5 (7%)	205
High	41 (14%)	35 (36%)	161 (60%)	62 (88%)	299
Total	287	97	270	71	725

Kappa (95% CI) = 0.18 (0.17–0.19) (slight agreement)

Table 2. DAS28 vs. CDAI Categorization of RACER Patients

	DAS28				
CDAI	**Remission**	**Low**	**Moderate**	**High**	**Total**
Remission	96 (34%)	1 (1%)	0 (0%)	0	97
Low	174 (60%)	63 (65%)	27 (10%)	0	264
Moderate	17 (6%)	32 (33%)	164 (61%)	0	213
High	0	1 (1%)	79 (29%)	71 (100%)	151
Total	287	97	270	71	725

Kappa (95% CI) = 0.41 (0.37–0.44) (moderate agreement)

Of 287 subjects with a remission DAS28, only 102 had a near remission RAPID3 while 115 (40%) had a moderate or high RAPID3 (Table 1). When comparing these two groups, the 115 moderate to high RAPID3 patients had a higher Charlson Comorbidity Index (1.88 vs. 1.45, $p=0.002$) and lower SF-12 mental (47.38 vs. 52.03, $p<0.001$) and physical (34.5 vs. 49.1, $p<0.001$) health related quality of life than the 102 near remission RAPID3 patients; there were no differences in age, sex or disease duration between these groups. Pearson correlation results indicated that changes in RAPID3 between visits correlated significantly with changes in DAS28 (0.59, $P<0.001$) and CDAI (0.52, $p<0.001$) between visits, but not as strongly as changes in CDAI correlated with changes in DAS28 between visits (0.89, $p<0.001$).

Conclusion: DAS28 and CDAI were more strongly correlated than RAPID3 was correlated to CDAI or DAS28. Among subjects in DAS28 remission, 40% of subjects had discrepant RAPID3 and DAS28 associated with lower quality of life and more comorbidities. This suggests RAPID3 may lack specificity in a subset of RA patients as a measure of RA disease activity.

Background/Purpose: The recent formulation of 'treat to target' (T2T) recommendations on the management of rheumatoid arthritis (RA) (1) aim to improve patient outcomes. We aimed to investigate the additional role of ultrasound (US) to T2T clinical assessment.

Methods: An audit of 9 centres (8 countries) where musculoskeletal US is part of routine patient care was undertaken. Patients with active RA, requiring additional treatment and follow-up according to T2T recommendations were included. Clinical and US data were collected. US data from MCP 2–3, radiocarpal, intercarpal, MTP 5 joints and extensor carpi ulnaris tendon (where available) were analysed.

Results: At time of analysis, 93 patients had been audited. Baseline mean (SEM) characteristics included: Age 52.6 (15.5), disease duration 7.8 (11) years, DAS28 score 4.9 (1.5) and HAQ 2.4 (2.8). 78% were RF and 69%, ACPA positive. Thirty-five patients were on no DMARDS at baseline. At baseline, 81 % of patients had at least one joint PD signal.

The pre-defined disease activity target was achieved in 25% and 49% of patients at 3 and 6 months respectively. Therapy was modified in only 16–44 % of active patients; the main reason reported as "waiting for the previous treatment escalation to work" (13–76%) (Table 1).

At month 3, 50% of cases still had PD signal (38% PD≥2) in at least one joint despite achieving clinical target. Fifty percent of cases with clinical activity and PD signal did not receive any therapy modifications. Similarly at month 6, 53% of patients achieving clinical target still had PD signal in at least one joint with 20 % with PD≥2. Twenty-eight percent of patients received no treatment modification despite clinical disease activity and PD presence (Table 2).

Table 1. Summary of clinical assessments in each visit

CLINICAL ASSESSMENT	Month 1	M2	M3	M4	M5	M6
n	74	59	55	48	43	49
DAS28	3.8	3.5	3.4	3.1	3.1	3.2
HAQ	2.5	1.2	1	0.9	0.9	1
Clinical target achieved n (%)	11 (15)	17 (29)	14 (25)	22 (46)	17 (40)	24 (49)
Modification (in active group)	28/63 (44)	17/42 (40)	17/41 (42)	4/25 (16)	10/26 (39)	10/25 (40)
Type of modification						
Dose increase	25/28	10/17	8/17	2/4	4/10	1/10
Add DMARDS	1/28	2/17	4/17	2/4	3/10	7/10
Biologics	2/28	2/17	5/17	0/4	1/10	2/10
Additional steroids (n/active group)	4/63	6/42	4/41	2/25	3/26	2/25
Reason for no modification: Previous treatment to work n (%)	25/33 (76)	13/25 (52)	14/23 (61)	14/21 (67)	2/16 (13)	8/15 (53)

Table 2. PD findings according to clinical assessment at month 3 and 6.

Clinical target for disease activity	n	Any PD signal pos	Any PD signal neg	PD≥2 pos	PD≥2 neg
At month 3 (n=41)					
Achieved	8	4	4	3	5
Not-achieved	33	28	5	19	14
Modification	14	13	1	6	8
At month 6 (n=28)					
Achieved	15	8	7	3	12
Not-achieved	13	11	2	10	3
Modification	9	8	1	7	2

Conclusion: In this audit, therapy modifications were avoided in more than 50% of eligible RA patients at monthly visits, mainly due to waiting for the effect of previous treatments. A third to half of these cases also had PD signal, which has previously been demonstrated to be an independent risk factor for progression (2). US is a useful adjunct to clinical T2T approach and can inform patients who may particularly benefit from monthly treatment escalation.

Assessing the Individual Joint in Rheumatoid Arthritis (RA): Valid Detection of Synovitis in the MTP Joint Warrants Ultrasound Examination. Matthias Witt[1], Felix Mueller[1], Axel Nigg[1], Christiane Reindl[2], Hendrik Schulze-Koops[2] and Mathias Grunke[1]. [1]University of Munich, Munich, Germany, [2]Division of Rheumatology and Clinical Immunology, Med. Poliklinik, University of Munich, Munich, Germany

Background/Purpose: The clinical assessment of tender and swollen joints is a key outcome parameter in rheumatoid arthritis (RA). It has been shown recently, that the results of clinical joint examinations vary significantly among different examiners and depending on the joint region examined. Ultrasound examination has been proven to be more sensitive and reliable than clinical examination, but the sonographic evaluation of 68 joints is time-consuming and not feasible in daily clinical practice. The aim of this study was to compare the clinical and the ultrasonographic assessment of individual joints of patients with RA and to clarify, in which joints clinical examination alone is adequately reliable in the detection of arthritis and in which joints ultrasound confirmation is required.

Methods: 63 Patients with RA were clinically assessed for joint tenderness and swelling by performing a 66/68 joint count according to the EULAR technique. All patients were then independently examined by high resolution arthrosonography with an 18 MHz ultrasound probe and power doppler. For this analysis, clinical and ultrasonographic findings in each joint of the metacarpophalangeal (MCP), proximal interphalangeal (PIP) and metatarsophalangeal (MTP) joints were compared and sensitivities and specificities for each joint was calculated with ultrasound as reference. Sonographic findings consistent with inflammation in greyscale (GS) or power doppler (PD) mode were classified on a semiquantitative 0–3 scale as specified before.

Results: 633 MCP-, 641 PIP- and 628-MTP joints of 63 RA patients were individually assessed for signs of arthritis by clinical examination and ultrasonography. Sensitivities of clinical examination for the individual joints ranged from 7,9 to 48,4% (overall 31,6%) for MCPs, from 34,1 to 70,7% (overall 40,8%) for PIPs and from 4,8 to 33,9% (overall 19,4%) for MTPs. Overall specificities for MCPs, PIPs and MTPs were 90,5%, 91,3 and 94,9%, respectively. Taking just grade 2 and grade 3 ultrasound findings as reference, overall sensitivities of clinical examination adjust to 53,0%, 62,9% and 30,5% for MCP-, PIP- and MTP joints, respectively, with corresponding adjustments of sensitivities on the level of the individual joint. In both settings, sensitivities for each individual MTP as well as for all MTPs were signifiantly lower than for MCP- and PIP-joints.

Conclusion: In this independent multirater study evaluating clinical joint examination only low and hence insufficient sensitivities for the individual joints were observed in general, underlining the limitations of clinical examination even for the experienced rheumatologist. In comparison to the joints evaluated, MTPs were significantly associated with the lowest sensitivities overall and in the individual joint, while PIPs were associated with the highest sensitivities. These differences remained significant even if grade 1 ultrasound findings were excluded from the analysis. This indicates that more articular effusion is necessary in MTP joints for clinical detection of joint swelling and therefore a comprehensive assessment of arthritis requires ultrasound evaluation at least of the MTP joints.

2146

Quantifying the Contributors to Global Assessment of Rheumatoid Arthritis Disease Activity by the Patient and the Physician. Paul Studenic[1], Josef Smolen[2] and Daniel Aletaha[1]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: The perception of disease activity in RA often differs between physicians and patients, as can be realized by a disconnect between patient and physician global assessments (PGA, MDGA). In previous studies, swollen joint count (SJC) and pain were identified as main determinants of a higher MDGA and PGA, respectively. It is unknown, however, to what extent patients relate higher pain levels, and physicians higher joint counts, to their global assessments. We aimed to investigate how much variability of the PGA and MDGA are explained by pain, SJC and other core set variables.

Methods: We identified RA patients from an observational, prospective RA outpatient database, and obtained visual analogue scores (VAS) for PGA and MDGA. We performed a stepwise linear regression model, using PGA as dependent variable, and other core set variables as independent variables: pain scores on VAS, swollen and tender joint counts (SJC and TJC), functional scores by the Health Assessment Questionnaire Disability Index (HAQ), morning stiffness in minutes (MST), as well as C-reactive protein (CRP) and rheumatoid factor in units/ml (RF). We identified the variability of PGA explained by the variables selected by the model using a $p<0.05$ cutpoint for entry and $p>0.10$ for removal. We then repeated the same analysis using MDGA as the dependent variable.

Results: We identified 634 RA patients (80% female, 68% RF positive, mean disease duration: 7.7 years). In the stepwise model pain, HAQ scores, and SJC remained significant ($p<0.001$ for each), explaining 79.3% of overall PGA variability mostly conveyed by pain (77.9%; see figure), while 20.7% of variability remained unexplained. For MDGA as dependent variable in the stepwise model SJC, pain, TJC and CRP were significant ($p<0.0001$ for each) explaining 65.2% of overall MDGA variability, mostly represented by SJC (58.1%, see figure), leaving 34.7% unexplained.

When all variables were included in a linear model, 93.1% of PGA was explained, indicating that the joint effects of these additional insignificant variables contributed another 14%, leaving only ~7% of PGA variability unexplained. For MDGA such model explained 84.2% of variability (further contribution of 19% by the insignificant variables), leaving 15.8% of MDGA variability unexplained.

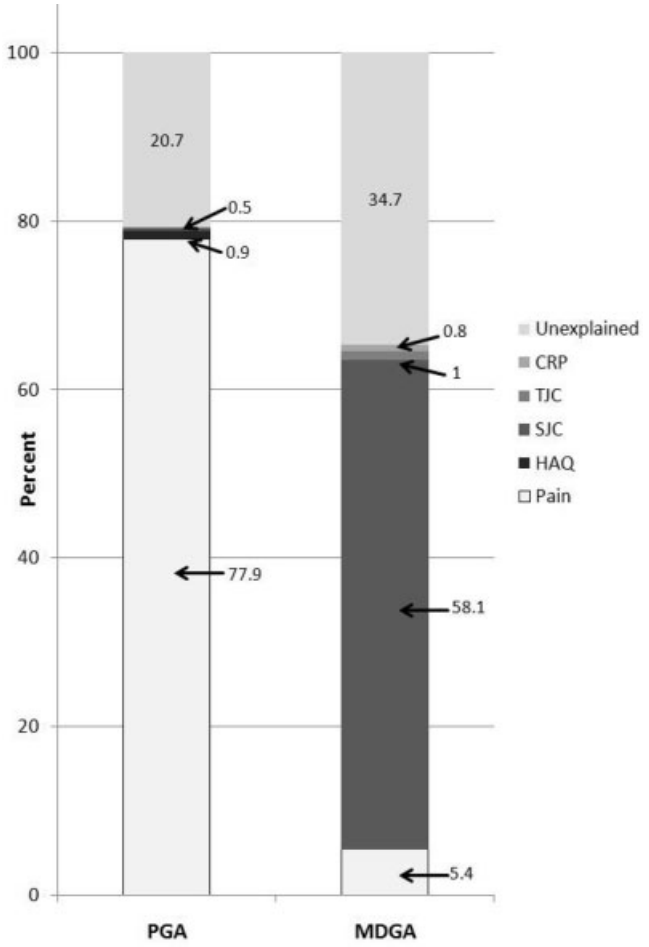

Figure 1. Components of patient global assessment (PGA) and physician global assessment (MDGA) in percent.

Conclusion: The single greatest determinant of patient global is pain, explaining ~80% of its variability. In contrast, the global assessment of disease activity by the MD, on the other hand, is largely a reflection of the number of swollen joints involved. The larger unexplained proportion of variability of the MDGA may indicate, that physicians take more aspects of RA disease activity into account than reflected in the core set measures, and supports its use as an additional measure of RA disease activity assessment.

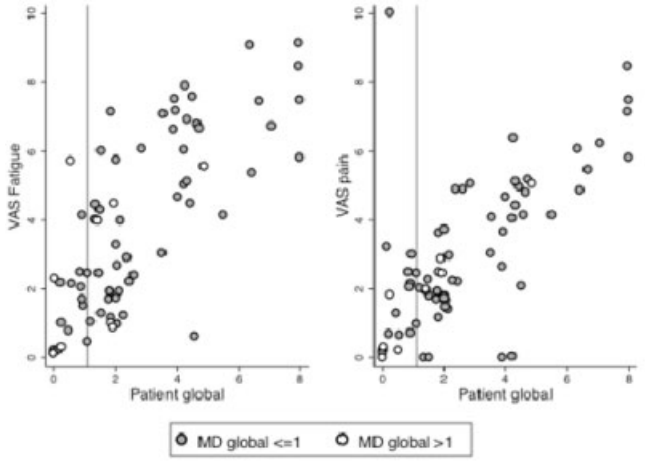
Validity and Reliability Problems with Patient Global As a Component of the American College of Rheumatology/European League Against Rheumatism Remission Criteria. Karim R. Masri[1], Frederick Wolfe[2], Timothy S. Shaver[3], Shadi H. Shahouri[4], Shirley Y. Wang[4], James D. Anderson[5] and Ruth E. Busch[6]. [1]Wichita, KS, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Arthritis & Rheum Clinics KS, Wichita, KS, [4]Arthritis & Rheum Clinic of KS, Wichita, KS, [5]Arthritis & Rheum Clinics KS, Leawood, KS, [6]Arthritis & Rheum Clinic, Wichita, KS

Background/Purpose: We have reported (A&R 2011) cross-sectional rates of remission in RA clinic patients of 7.5% using ACR/EULAR (AE) criteria, while 19.1% had Physician global scores $^{2}1$. AE clinical criteria require scores $^{2}1$ for tender and swollen joints and patient global (PtGlobal). Statistical analysis suggested that PtGlobal was the most important determinant of AE remission, but appeared to be unstable, shifting between observations. To understand the effect of PtGlobal, and what role it plays in AE remission, we studied its meaning and reliability and validity in consecutive patients who met AE joint criteria for remission.

Methods: We studied 73 consecutive RA clinic patients who met AE joint criteria for remission ($^{2}1$ swollen and $^{2}1$ tender joint), using the AE 28-joint count. Patients completed a VAS global, VAS fatigue and HAQ immediately before seeing the physician (MD), and completed a 2nd VAS global and questions about global severity immediately after the MD visit. MDs determined an MD global, clinical remission, and a complete tender and swollen joint count, including ankles and feet.

Results: Patient mean age was 60.0 (SD 15.1) years, and 41.7% were men. As expected, the VAS scores for pain, 2.9 (2.1), fatigue 3.7 (2.6) and patient global 2.7 (2.1) were low. Of patients meeting joint criteria for AE remission, 56 (76.7%) had PtGlobal >1, including 21.4% who reported no pain and 52.7% who indicated function or fatigue, not pain, were the main determinants of PtGlobal. Low back pain was also reported by 25% of this group. By contrast, 30.0% reported foot pain and 30.0% reported knee pain (compared with 7% on the MD examination) that may not have been identified in the physician's 28-joint count. There was no agreement beyond chance (kappa = 0.0, p=0.530) between ACR and MD remission, nor between high patient and physician global (global >1), kappa = −0.074, p=0.946. In addition to physician-patient disagreement (Figure 1), patients not meeting AE criteria frequently had high fatigue and high pain scores (Figure 1). Test-retest reliability of the patient global indicated an intraclass correlation coefficient (ICC) of 0.84.



Conclusion: PtGlobal has insufficient reliability for accurate measurement of remission in individual clinic patients. In addition, we identified problems with using PtGlobal as a measure of RA activity, for many patients who would otherwise be in AE remission were excluded because of non-RA activity factors, including low back pain, fatigue, functional limitations and low pain threshold. We also noted that physician joint counts may be biased downward by exclusion of foot and ankle pain that is not included in the 28-joint count or failure to identify knee joint activity. While the AE remission criteria appear to work well in clinical trials and groups of patients, problems with reliability and misclassification related to joint pain and patient global suggest caution in the use of the AE criteria in the individual patients.

Changes and Sex Differences in Patient Reported Outcomes in Rheumatoid Factor Positive Rheumatoid Arthritis—Results From a Community Based Study. Korosh Hekmat, Lennart TH Jacobsson, Jan-Åke Nilsson, Ylva Lindroth and Carl Turesson. Lund University, Malmö, Sweden

Background/Purpose: Patient reported outcomes are important measures of the burden of rheumatoid arthritis (RA) in the community. In order to assess changes in such outcomes over time, cohorts from well defined catchment areas should be studied. A comprehensive register of patients with RA from all rheumatology care providers in a single city was established in 1997 and has been continually updated. This register includes virtually all the RA patients in the area**.** The aim of this study was to analyze patient reported outcomes, including health related quality of life (HRQoL) in surveys of this population conducted between 1997 and 2008. Furthermore, we wanted to assess differences in treatment and outcome in male and female patients.

Methods: In 1997, 2002, 2005 and 2008, questionnaires were sent to the RA patients in the register (n= 1016 in 1997; n=916 in 2002; n=1625 in 2005; n=1700 in 2008). Response rates varied between 62 % and 74 %, and 72–74 % were women. Questionnaire data included current and previous medication, visual analogue scales (VAS, 0–100) for global assessment of disease activity and pain, disability measured using the Health Assessment Questionnaire (HAQ), and HRQoL as measured by the Short Form (SF)-36 questionnaire. Data on rheumatoid factor (RF) tests were retrieved from the databases of the two clinical immunology laboratories in the area. In the

present comparison, only patients with at least one positive RF test were included. The analyses were stratified by sex.

Results: The number of RF positive responders was 668 in 1997, 438 in 2002, 517 in 2005 and 454 in 2008. Current treatment with biologics, corticosteroids and methotrexate was more frequent in 2008 compared to previous surveys (Table). Patients reported less severe outcomes for all measures in the later surveys compared to 1997, and patients' global disease activity assessment and self reported pain were further improved in 2008 compared to 2005 (Table). There was a similar trend for the physical component score of SF-36, but no change in HAQ between the surveys conducted in 2005 and 2008 (Table). Treatment was similar in men and women, but improvements were greater in men, in particular with regard to VAS for pain [mean (M) 29 (95 % CI 25–33) in 2008 vs M 40 (95 % CI 35–46) in 1997 for men; M 41 (95 % CI 38–44 in 2008 vs M 48 (95 % CI 45–51) in 1997 for women].

	1997	2002	2005	2008
N	668	438	517	454
Disease duration years, mean	15.0	16.7	15.8	17.2
Female sex	497 (74%)	321 (73%)	368 (71%)	331 (73%)
Age; years, mean	61.9	63.9	62.9	63.8
Current treatment (95 % CI)				
Corticosteroids	19% (16–22)	30% (26–35)	26% (23–30)	31% (27–35)
Biologic	0	16% (12–19)	23% (19–27)	29% (25–33)
Methotrexate	20% (17–23)	44% (40–49)	56% (52–60)	58% (54–63)
Patient reported outcomes mean (95% CI)				
HAQ*	1.12 (0.50–0.75)	1.00 (0.50–1.62)	0.88 (0.38–1.38)	0.88 (0.38–1.5)
VAS global	44.8 (42.3–47.4)	40.0 (37.6–42.4)	41.8 (39.6–44.1)	37.6 (35.2–40,0)
VAS pain	46.3 (43.7–48.9)	41.1 (38.8–43.5)	40.8 (38.6–43.0)	38.2 (35.8–40.7)
SF-36 PCS	32.1 (31.0–33.1)	33.2 (32.2–34.4)	34.6 (33.6–35.7)	35.2 (34.0–36.4)
SF-36 MCS	45.4 (44.0–46.7)	46.7 (45.4–48.1)	47.9 (46.7–49.0)	47.1 (45.9–48.3)

*median (IQR)
PCS=physical component score
MCS=mental component score

Conclusion: In this community based cohort of patients with RF positive RA, treatment was more extensive in later surveys, and there was improvement in all patient reported outcomes. Patients reported less pain and less severe global disease assessment in 2008 compared to 2005. Despite similar treatment, male patients reported better outcomes and more improvement, in particular regarding pain, compared to female patients. This suggests that patient reported outcomes should be assessed separately in male and female patients with RA.

2149

Assessment of Foot Structure in Rheumatoid Arthritis by a Foot Digitizer Reveals Marked Deformities, Even in the Absence of Radiographic Erosions. Sophie De Mits[1], Dirk De Clercq[1], Jim Woodburn[2], Philip Roosen[1] and Dirk Elewaut[3]. [1]Ghent University, Ghent, Belgium, [2]Glasgow Caledonian University, Glasgow, United Kingdom, [3]Gent University Hospital, Ghent, Belgium

Background/Purpose: Foot involvement is a major feature of rheumatoid arthritis (RA), yet the rheumatoid foot is often neglected. There seems to be limited clinical interest which could possible lead to insufficiencies in treatment. The DAS28, frequently used in daily clinical routine, even omits the feet and ankles in the joint count. However, it is clear that the feet need the proper attention and care. The Ritchie Articular Index includes the feet but groups the joints, eg the MTP joints. Its 0–3 graded evaluation of the severity of the joint tenderness may be somehow subjective and complicated.

A foot digitizer, based on an optical laser scanning procedure, is a quick, easy to use and non-invasive device to collect objective data of the feet. It is proven to be a valid and reliable tool to use (1). The aim of this study is to determine if a foot digitizer can be a valuable tool for daily clinical routine to examine the feet in RA patients.

Methods: 106 RA patients and 135 matched healthy controls participated in the study. All patients had a confirmed diagnosis of RA based on the ACR criteria. Their disease duration ranged between 1 and 55 years, their DAS28 score between 1.3 and 6.6 and 49% had swollen and/or tender foot joints. The patients were included in a consecutive manner, irrespective of foot complaints being present or not. Ethical Committee Approval was obtained and all participants signed an Informed Consent.

3Dscans of the foot were made with a foot digitizer (Infoot USB, standard type, I-Ware Laboratory Co., Ltd, Osaka, Japan). The routine radiographs of the patients feet were checked for the presence of erosions.

Linear Mixed Models (IBM SPSS Statistics 19) were applied to compare the Infoot data between the controls, the patients with and without erosions. Post hoc analyses were performed with a Bonferroni correction.

Results: A majority of RA patients (62%) had signs of erosions at the feet. The impact of presence or absence of erosions of the foot yielded some remarkable results. Ball girth circumference and height of top of ball girth were significant smaller the erosive group ($p=0.002$) versus non-erosive and controls. Foot width was significantly smaller for both subgroups of RA patients ($p=0.009$ and $p=0.05$ respectively). Fibular instep length was larger for both erosive and non-erosive RA patients ($p=0.03$ and $p=0.24$). Differences in toes were also apparent: toe 1 angle is smaller in erosive RA versus controls ($p= 0.007$). The height of toe 1 was higher for both erosive and non-erosive RA patients. These findings were independent of gender, age, body weight, disease duration, DAS28 or presence of tender or swollen foot joints.

Conclusion: The results of the present study highlight a previously underappreciated impact of RA on foot structure, even in the absence of clinical signs of swelling or radiographic erosions. The Infoot digitizer offers a valuable tool to screen for such foot deformities at an early stage, before the presence of erosions. Importantly, the observed deformities could have implications for the shoe behavior of the patients. Hence, the digitizer can help in giving the proper shoe advise and consequently help in the daily management of RA.

Comparison of Rheumatoid Arthritis Patient Characteristics From Randomized Controlled Trials to a Registry Designed for Rheumatoid Arthritis Comparative Effectiveness Research. Aarat M. Patel[1], Christine L. Amity[2], Lynne M. Frydrych[2], Derek Sippel[2], Donald Jones[2], Danielle Goudeau[2], Heather Eng[3], David Kyle[3], Melissa Saul[3], Daniel Hal Solomon[4], Stephen R. Wisniewski[3], Larry W. Moreland[5] and Marc C. Levesque[2]. [1]Univ of Pittsburgh Med Ctr / Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [3]Univ of Pittsburgh, Pittsburgh, PA, [4]Brigham & Womens Hospital, Boston, MA, [5]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: The US federal government and several medical societies have recently endorsed more research targeted to comparative effectiveness studies of existing medical therapies as a way to optimize medical care, to lower health care costs and to provide research results that are more generalizable to a broader population than those typically included in randomized controlled trials (RCTs). We developed a Rheumatoid Arthritis Comparative Effectiveness Research (RACER) registry at the University of Pittsburgh Medical Center (UPMC) to provide a platform for comparative effectiveness study designs that incorporate electronic health record information, improve patient care and incorporate aspects of both randomized studies and real world observation. We determined whether there were significant differences between the characteristics of RACER subjects versus subjects from published RCTs.

Methods: RACER was established in February 2010 and consists of patients ≥18 years with a rheumatologist diagnosis of RA (n=820). At each clinic visit, self-administered questionnaires including a routine assessment of patient index-3 (RAPID3), short-form-12 (SF12), work productivity and activity impairment (WPAI), DAS28, and physician and patient visual analogue scales (VAS) for arthritis-related pain and global health are collected from subjects. Blood samples for determination of C-reactive protein (CRP), RF and anti-cyclic citrullinated peptide (CCP) levels are collected. We compared RACER descriptive statistics to similar data from all RA patients seen in the UPMC health care system in 2010 (n=2,610) and to published biological therapy RCTs identified by PubMed searches. We also compared the descriptive statistics of RACER subjects initiating new therapies to subjects in RCTs.

Results: RACER subjects had characteristics similar to RA patients evaluated throughout the UPMC system in 2010. RACER subjects that initiated new biologic or DMARD therapies (n=185) had somewhat higher disease activity scores, more work impairment and a lower physical quality of life but were otherwise highly comparable to other RACER subjects (**Table 1**). When compared to subjects in RCTs of biologic therapies, RACER subjects were older, had longer disease duration and lower disease activity. However, RACER subjects and subjects in RCTs had several similar characteristics including sex, race, RF positivity, functional ability (HAQ or mdHAQ) and quality of life (SF-12 or SF-36).

Table 1. Demographics of RACER Subjects (n=820)

	All RACER subjects (n=820)	RACER subjects that began a new DMARD/Biologic (n=185)
Age, yrs	59.8 ± 13.5	58.6 ± 13.4

African Am.	10%	11%
Other	1%	<1%
Duration, yrs	14.3 ± 12.4	14.2 ± 13.0
RA criteria Both 1987 and 2010	88%	94%
1987 ACR only	5%	4%
2010 ACR/EULAR only	4%	2%
Neither 1987 or 2010	2%	0%
ACR/EULAR Remission	17%	14%
Clinical Setting		
Academic	24%	29%
Private	76%	71%
RF, IU median	68	38
% Positive	77%	80%
Anti-CCP, IU median	46	60
% Positive	76%	79%
CRP, mg/dl	0.45	0.51
DAS28	3.2 ± 1.3	3.6 ± 1.5
SDAI	13.7 ± 11.8	17.9 ± 14.3
CDAI	12.9 ± 11.4	17.2 ± 13.9
RAPID3	3.5 ± 2.2	4.0 ± 2.2
WPAI Activity imp.	40.50%	48.60%
Time missed	6.20%	9.60%
Imp. working	27.60%	36.10%
Overall imp.	30.60%	39.30%
SF-12 MCS	36.1 ± 10.7	45.3 ± 11.7
PCS	46.7 ± 11.1	34.7 ± 9.8
Medications DMARD	47%	40%
Biologic	12%	15%
DMARD + Biologic	22%	29%
No DMARD or Biologic	8%	16%
NSAIDS	62%	56%
Corticosteroids	42%	45%
Opiates	36%	37%

All values are mean ± standard deviation unless otherwise written as median or percent. RACER: Rheumatoid Arthritis Comparative Effectiveness Research; ACR: American College of Rheumatology; EULAR: European League Against Rheumatism; RF: Rheumatoid factor; DAS28: disease activity score-28 joint count; SDAI: simplified disease activity index; CDAI: clinical disease activity index; RAPID3: routine assessment of patient index data 3; WPAI: Work Productivity and Activity Impairment; SF12: Short Form-12; DMARD: disease modifying anti-rheumatic Drug; MCS: mental component score; PCS: physical component score

Conclusion: The RACER cohort is representative of real world RA patients given the similarities between RACER subjects and non-RACER RA patients followed within the UPMC health care system. RACER subjects were typically older, had a longer disease duration and less disease activity than subjects in RCT's. This suggests that comparative effectiveness studies of different therapies tested in RACER subjects may yield different results compared to results from RCTs.

The Accuracy of Patient Reported Current and Past Medications Used to Treat Rheumatoid Arthritis in An Academic Institutional Registry. Sergio Schwartzman[1], Dana E. Orange[2] and Stephen L. Lyman[1]. [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, The Rockefeller University, New York, NY

Background/Purpose: Academic institutional registries are a valuable tool for collecting patient information. They have focused on research, specific drug safety and efficacy, and quality improvement. Patient self report has frequently been used in some registries. Validating data collected from patient reported registries has not always been straightforward. In an attempt to validate data from an academic rheumatoid arthritis registry with patient reported data, we conducted a study to assess the agreement between patient reported currently used medications at time of entry into the registry and prior history of medications used. Specific types of medications reviewed included DMARDS, corticosteroids and glucocorticoids.

Methods: At the time of analysis, 1 1/2 years after the date of 1st enrollment, 223 RA patients were enrolled in the registry. The baseline registry questionnaire requested patients to note both current and prior medications used to treat rheumatoid arthritis. Sample size was approximately 1/3 of the cohort. 67 randomly selected charts from 5 different physicians and 7 charts from the fellow's clinic were reviewed. The chart review was conducted by two rheumatologists blinded to the patient questionnaire responses. Kappa statistics with 95% confidence intervals were calculated as well as sensitivity, specificity, and positive predictive value (PPV).

Results: The study cohort consisted of 52 Females and 22 Males and the mean age was 57.9. There were 5 Hispanic or Latino, 7 Black or African American and 59 White patients. Educational level: Grade school-2, High school-11, College-24, Post Graduate-34. There was very good agreement between patient self report and medical chart review for both current and previous medications. For current medications kappa was 0.849 (0.794, 0.904) with a sensitivity of 84%, specificity of 89%, and PPV of 89%. For prior medications, kappa was 0.838 (0.794, 0.882) with a sensitivity of 88%, specificity of 97%, and PPV of 86%.

Conclusion: Self-reported current and previous medication used to treat rheumatoid arthritis appears to have excellent validity in this cohort of patients. These results may reflect a unique patient and/or physician population possibly due to a high education attainment in the patient cohort and the effect of a specialty hospital environment on physician documentation.

Discordant Autoantibodies and Clinical Outcomes In Rheumatoid Arthritis. Dannette S. Johnson[1], Alan Erickson[2], Grant W. Cannon[3], Gail S. Kerr[4], Liron Caplan[5], Andreas M. Reimold[6], John S. Richards[4], Pascale Schwab[7], Deana M. Lazaro[8], Nasim A. Khan[9], Bogdan Cherascu[10] and Ted R. Mikuls[11]. [1]G.V. Sonny Montgomery VA and University of Mississippi, Jackson, MS, [2]Omaha VA and University of Omaha, Omaha, NE, [3]Salt Lake City VA and University of Utah, Salt Lake City, UT, [4]Washington DC VA and Georgetown University, Washington, DC, [5]Denver VA and University of Colorado, Aurora, CO, [6]Dallas VA and University of Texas Southwestern, Dallas, TX, [7]Portland VA and Oregon Health & Science University, Portland, OR, [8]Brooklyn VA, Brooklyn, NY, [9]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, [10]Iowa City VA and University of Iowa, Iowa City, IA, [11]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Little attention has been given to the associations of discordant autoantibodies, RF and aCCP, with clinical outcomes in RA. We determined dual autoantibody status in a cohort of established RA patients and examined the associations of autoantibody status with RA disease characteristics.

Methods: U.S. Veterans in the Veterans Affairs Rheumatoid Arthritis (VARA) Registry with ≥ 2 clinical observations over 6 months had enrollment serum and DNA tested for aCCP, RF, and *HLA-DRB1* shared epitope (SE). Demographics, baseline and longitudinal clinical data were collected. Associations between aCCP, RF, and clinical outcomes were examined using linear and logistic regression adjusting for age and sex. Multivariate models also included demographics, disease activity and severity, comorbidity and therapies.

Results: Autoantibody status (n = 1097) was 81% RF positive and 76% aCCP positive (70% RF+/aCCP+, 11% RF+/aCCP-, 6% RF-/aCCP+ and 13% RF-/aCCP-). Patient characteristics based on dual autoantibody status are summarized in Table 1. SE, homozygous state, was more common in aCCP positive individuals than RF positive individuals regardless of whether patients were concordant for these values. Current smoking was lower among RF+/aCCP− patients than other patient groups. Multivariable associations of dual autoantibody status with measures of RA disease severity/activity are shown in Table 2.

Table 1. RA patient characteristics and prognostic factors based on autoantibody status

	Total (n = 1,097)	RF−/aCCP− (n = 146)	RF+/aCCP− (n = 115)	RF−/aCCP+ (n = 68)	RF+/aCCP+ (n = 768)	P-value
Age at enroll., yrs.	64 (11)	65 (12)	64 (10)	62 (12)	64 (11)	0.175
Male gender, %	91	89	90	85	92	0.323
Caucasian race, %	78	81	79	69	78	0.277
≥ H.S. education, %	83	84	83	87	82	0.755

1 copy	51	47	50	48	52	
2 copies	21	6	6	30	25	
Prednisone, %	62	53	63	64	63	0.158
Methotrexate, %	69	71	72	79	67	0.157
Biologic DMARD, %	47	36	47	45	49	0.022

Table 2. Multivariate associations of autoantibody status with clinical outcomes

Autoantibody Status	Erosions	Nodules	Sustained Remission*	Proportion of Follow-Up in Remission·
	Odds Ratio (95% CI)			β-Coefficient (95% CI), p-value
RF neg./aCCP neg.	Referent	Referent	Referent	Referent
RF pos./aCCP neg.	1.60 (0.69 to 3.70)	1.78 (1.04 to 3.03)	0.56 (0.23 to 1.38)	−0.03 (−0.10 to 0.03), p = 0.281
RF neg./aCCP pos.	2.53 (0.94 to 6.82)	2.50 (1.34 to 4.66)	0.74 (0.28 to 1.98)	−0.01 (−0.09 to 0.06), p = 0.725
RF pos./aCCP pos.	3.41 (1.79 to 6.53)	3.39 (2.26 to 5.09)	0.50 (0.26 to 0.97)	−0.10 (−0.14 to −0.05), p <0.001

* Sustained Remission - at least 2 consecutive observations, separated by ≥ 3 months, with DAS28 % 2.6.
· Proportion of Follow-Up in Remission - (a continuous measure, range 0–1) to account for differences in follow-up duration (time in remission credited only when remission was maintained for at least 2 sequential visits)

Conclusion: In this cohort, RF+/aCCP+ patients had more severe disease and worse clinical outcomes with less time in remission than RF-/aCCP- patients. Discordant autoantibody groups generally demonstrated associations with disease outcomes that were intermediate or equivalent to those observed in the corresponding sero- negative / positive groups, suggesting that these autoantibodies play an additive and possibly synergistic role in RA disease progression.Bottom of Form

Does Clinical Assessment of Swollen and Tender Joints Reflect Inflammatory Synovitis in Rheumatoid Arthritis? A Comparative Study of Physician, Nurse and Patient Clinical Assessments Versus Ultrasonography (US) As the Gold Standard. Peter Cheung[1], Laure Gossec[2], Adeline Ruyssen-Witrand[3], Catherine Le Bourlout[4], Maryse Mezieres[4] and Maxime Dougados[5]. [1]National University Hospital, Singapore, Singapore, [2]Cochin Hospital, Paris, France, [3]Hopitaux de Toulouse, Toulouse, France, [4]Hospital Cochin, Paris, France, [5]Paris-Descartes University, Cochin Hospital, Paris, France

Background/Purpose: Swollen and tender joints (SJ, TJ) enable physicians to detect and quantify synovitis in rheumatoid arthritis (RA). There are data indicating Power Doppler positive ("inflammatory") synovitis is predictive of damage. The aim was to assess if SJ and TJ derived by physician, nurse and patient are associated with synovitis that is "inflammatory" or "mechanical", and to assess if radiographic damage interferes in the assessment of joint counts.

Methods: A cross-sectional study of 50 RA patients was conducted, where joints were independently evaluated by patients themselves, a trained nurse and a physician for swelling and tenderness (presence or absence at each joint). The wrists, metacarpophalageal and proximal interphalangeal joints were analysed (22 joints). Separate assessments by US were performed with the following definitions as gold standards:

i) "Inflammatory" synovitis: B-mode (>/= Grade 1), PD signal (>/= Grade 1), or
ii) "Mechanical" synovitis: B-mode (>/= Grade 1), absence of PD signal

Radiographic damage was graded according to Larsen. Presence of swelling or tenderness at the joint level was compared with US-detected "inflammatory" or "mechanical" synovitis using sensitivities (Se), specificities (Spe) and positive likelihood ratios (LR).

Results: *Swollen joints (SJ)*: SJ reflected with a higher sensitivity, "inflammatory" than "mechanical" synovitis (Table 1). Physician and nurse-derived SJ best reflected "inflammatory" synovitis, with LR of 2.40 (95%CI 1.96–2.95) and 3.60 (95%CI 2.67–4.86) respectively, compared to patient-derived SJ (LR 1.84, 95%CI 1.46–2.32). *Tender joints (TJ)*: like SJ, TJ reflected more "inflammatory" than "mechanical" synovitis although the difference was not as great. Patient-derived TJ had the highest sensitivity for detecting "inflammatory" synovitis (Se=0.42). *Radiographic damage*: Physician and nurse-derived SJ continued to reflect "inflammatory" synovitis more than "mechanical" synovitis in joints with severe radiographic damage, while patient-derived SJ did not. Inversely, for TJ, patient-derived TJ has the best properties to reflect "inflammatory" synovitis in this situation (LR 2.31, 95%CI 1.37–3.88).

Table 1. Diagnostic performance of clinical synovitis compared to gold standard US for inflammatory synovitis and mechanical synovitis

	Inflammatory synovitis by US			Mechanical synovitis by US		
	Se	Spe	LR	Se	Spe	LR
Swollen Joint						
Physician	0.44	0.82	2.40 (1.96–2.95)	0.28	0.78	1.26 (1.00–1.60)
Nurse	0.29	0.92	3.60 (2.67–4.86)	0.09	0.86	0.66 (0.43–1.02)
Patient	0.32	0.82	1.84 (1.46–2.32)	0.20	0.79	0.92 (0.69–1.22)
Tender Joint						
Physician	0.25	0.86	1.87 (1.41–2.46)	0.17	0.84	1.09 (0.79–1.49)
Nurse	0.27	0.84	1.67 (1.28–2.16)	0.16	0.81	0.83 (0.60–1.14)
Patient	0.42	0.77	1.82 (1.50–2.21)	0.26	0.72	0.94 (0.74–1.19)

Conclusion: It appears clinical assessment in a way adjusts to "inflammatory" activity in RA. Physician and nurse-derived SJ, as well as patient-reported TJ (in severely damaged joints) reflect "inflammatory" synovitis rather than "mechanical" synovitis. Clearly a statistical significance is seen suggesting a relation between the clinical assessment and US derived inflammatory synovitis BUT the clinical relevance is questionable.

Patient Tolerability of Arthroscopic Synovial Biopsy Compared to MRI. Maria J. H. de Hair, Marleen G. H. van de Sande, Mario Maas, Danielle M. Gerlag and Paul P. Tak. Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Arthroscopy is extensively used for research purposes in inflammatory arthritis. A relatively new tool for evaluating and quantitating synovial tissue abnormalities is dynamic contrast enhanced (DCE) MRI. Since the latter technique is less invasive and might therefore be experienced as more positive by study patients, we compared both procedures in terms of patient's preference.

Methods: Twenty-eight early arthritis patients and 34 individuals of our preclinical rheumatoid arthritis (RA) cohort who did not have any evidence of arthritis upon physical examination and were positive for IgM-rheumatoid factor and/or anti citrullinated protein antibodies were included in the study. All study subjects underwent both DCE-MRI (closed MRI n=24 for both study groups and open MRI n= 4 and 10, respectively) and arthroscopic synovial biopsy of the same joint within one week. In the early arthritis patients an inflamed wrist (n=1), knee (n=15) or ankle (n=11) joint was examined and in the preclinical RA subjects a knee joint in all cases. Before and after both procedures, patients filled in questionnaires with questions about patient expectations and experience with regard to the procedures.

Results: Eleven early arthritis patients did not complete the questionnaire after follow-up, of which 64% did not have a preference for one of the procedures at baseline and 18% had a preference for either MRI or arthroscopy before they had undergone the procedures. Fourteen individuals with preclinical RA did not complete the follow-up questionnaire, of which 64% did not have a preference, 22% preferred MRI and 14% preferred arthroscopy. Of 17 early arthritis patients and 20 preclinical RA subjects both baseline and follow-up questionnaires were available. Of these early arthritis patients 47% did not have a preference for one of the procedures at baseline, compared to 35% preferring MRI and 18% preferring arthroscopy. For the 20 preclinical RA subjects these percentages were 35% for 'no preference', 60% for MRI, and 5% for arthroscopy, respectively. After both procedures were performed, there was a shift of

35% in the early arthritis patients from 'no preference' and MRI in favour of arthroscopy. Also in the individuals with preclinical arthritis, there was a shift towards arthroscopy of 20%, coming from MRI in 75% of these individuals. In both groups, none of the subjects who preferred arthroscopy at baseline changed to MRI and only 6 and 10%, respectively, changed to 'no preference'. In the subset of subjects who underwent MRI in the open scanner, there was not a stronger preference for MRI than in the total group and nobody changed to having preference for MRI after both procedures.

Conclusion: In early arthritis patients who underwent both procedures, arthroscopy is preferred by 47%, compared to 24 and 29% for MRI and 'no preference', respectively. For some patients with active arthritis, being immobile during MRI is quite uncomfortable. In preclinical RA subjects who did not have any sign of arthritis, 25% preferred arthroscopy, compared to 55 and 20% for MRI and 'no preference', respectively. The results support previous studies showing that arthroscopic synovial biopsy is well tolerated.

Polymorphisms in N-Acetyltransferase 2 Impact Rheumatoid Arthritis Risk Due to Cigarette Smoking in African Americans. Marshall Davis[1], Tricia LeVan[1], Karen Gould[1], Fang Yu[1], Geoffrey M. Thiele[1], Kimberly Bynote[1], Larry W. Moreland[2], Doyt L. Conn[3], Edwin A. Smith[4], Leigh F. Callahan[5], Beth L. Jonas[6], Richard Brasington[7], S. Louis Bridges Jr.[8] and Ted R. Mikuls[1]. [1]Univ of Nebraska Med Ctr, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA, [3]Emory Univ School of Medicine, Atlanta, GA, [4]Med Univ of South Carolina, Charleston, SC, [5]University of North Carolina, Chapel Hill, NC, [6]University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]Washington Univ School of Med, St. Louis, MO, [8]Marguerite Jones Harbert-Gene V. Ball, MD Professor of Medicine, and Director, Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

Background/Purpose: Cigarette smoking is associated with an elevated risk of rheumatoid arthritis (RA) in African Americans, a risk that is most striking for those with a cumulative exposure of 10 or more pack-years. Recognizing that the risk of developing other smoking-related conditions is impacted by genetic variation in genes encoding drug metabolizing enzymes (DMEs), we sought to examine whether the risk of RA attributable to smoking in African Americans differs based on the presence of select DME gene polymorphisms.

Methods: RA cases (n=727) and controls (n=268) were participants in the Consortium for the Longitudinal Evaluation of African-Americans with Early Rheumatoid Arthritis (CLEAR) registry. Participants were categorized as either heavy smokers (≥ 10 pack-years) or other (< 10 pack-years including never smokers). Tagging single nucleotide polymorphisms (SNPs) encoding N-acetyltransferase 1 (*NAT1*), *NAT2*, and epoxide hydroxylase (*EPXH1*) and a homozygous deletion polymorphism in glutathione S-transferase Mu-1 (GSTM1-null) were genotyped. RA risk was evaluated for each polymorphism using logistic regression adjusting for age and gender. Evidence of gene-smoking interactions was examined by calculating the attributable proportion (AP; additive interaction) due to interaction and by modeling the polymorphism-smoking product term (multiplicative interaction). A Bonferroni correction was used to adjust for multiple comparisons (n = 30 polymorphisms) and the level of significance was set at a p-value < 0.0017 (0.05 / 30). Haplotype analyses were constructed for *NAT2* SNPs yielding at least borderline evidence of interaction (p < 0.05). A secondary analysis was conducted to evaluate the same outcomes in cases that were positive for anti-citrullinated protein antibody (ACPA).

Results: There were no associations of RA risk with any of the individual polymorphisms examined and there were no significant interactions between heavy smoking and the GSTM1-null, NAT1, or EPXH1 polymorphisms after adjusting for multiple comparisons. In contrast, there were 3 *NAT2* tagging SNPs with evidence of at least borderline interaction with heavy smoking in RA risk (Table 1). The *NAT2* rs9987109 and rs1208 SNPs demonstrated significant additive interactions with heavy smoking. *NAT2* haplotype analyses were consistent with the individual tagging SNP analyses and interactions were similar for overall disease risk compared to the risk of ACPA-positive RA.

Table 1. Association of NAT2 polymorphisms with RA based on smoking history

Gene/ polymorphism	Minor allele status	Smoking history	Cases (no.)	Controls (no.)	OR	95% CI	P-value
NAT2							
rs9987109	Absent	Never, < 10py	245 (38.1)	93 (36.3)	1.00	–	–
	Present	Never, < 10py	220 (34.2)	116 (45.3)	0.73	(0.52, 1.01)	0.06
	Absent	≥ 10py	85 (13.2)	31 (12.1)	1.07	(0.66, 1.73)	0.79
	Present	≥ 10py	93 (14.5)	16 (6.3)	2.42	(1.34, 4.38)	0.003
						P_{muk} = 0.003	
						AP (95% CI) = 0.67 (0.39 to 0.95)	
						P_{odd} = 0.000003	
rs1208	Absent	Never, < 10py	162 (23.6)	75 (28.7)	1.00	–	–
	Present	Never, < 10py	334 (48.8)	139 (53.3)	1.07	(0.76, 1.51)	0.69
	Absent	≥ 10py	60 (8.8)	26 (10.0)	1.10	(0.64, 1.90)	0.73
	Present	≥ 10py	129 (18.8)	21 (8.0)	3.03	(1.76, 5.23)	0.00006
						P_{muk} = 0.01	
						AP (95% CI) = 0.61 (0.34 to 0.89)	
						P_{odd} = 0.00001	
rs721399	Absent	Never, < 10py	156 (24.1)	85 (33.9)	1.00	–	–
	Present	Never, < 10py	313 (48.3)	120 (47.8)	1.45	(1.03, 2.03)	0.03
	Absent	≥ 10py	63 (9.7)	9 (3.6)	4.13	(1.94, 8.78)	0.0002
	Present	≥ 10py	116 (17.9)	37 (14.7)	1.83	(1.15, 2.91)	0.01
						P_{muk} = 0.008	
						AP (95% CI) = −1.50 (−3.35 to 0.35)	
						P_{odd} = 0.11	

Conclusion: These results show that the risk of RA in African Americans due to heavy smoking is mediated by genetic variation in *NAT2*. These results may provide important insight into disease pathogenesis and the constituents of cigarette smoke that may drive RA risk in this understudied population.

Integrative Analyses Demonstrate That Rheumatoid Arthritis Risk Loci Impact Genes with CD4+ Effector Memory T-Cell Function. Xinli Hu[1], Hyun Kim[1], Eli A. Stahl[1], Robert M. Plenge[1], Mark Daly[2] and Soumya Raychaudhuri[1]. [1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA

Background/Purpose: Previous experimental animal model studies and observational human studies have implicated a wide range of immunological cell types ranging from mast cells to lymphocytes in rheumatoid arthritis (RA) pathogenesis. Now, with the recent discovery of a total of 39 RA risk-conferring single nucleotide polymorphisms (SNPs), there has been an increasing push to define how these loci relate to functional disease immunology. Here, we hypothesize that predisposing RA risk loci act upon a small number of pathogenic cell types and that the genes with critical functions in those cell types are likely to be near the identified disease loci. Utilizing a compendium of gene expression data in immune cell types as an objective proxy for cell-specific gene function, the present study seeks to identify the main immunological cell type that is implicated by these risk loci.

Methods: We implemented a statistical algorithm to identify potentially pathogenic tissue types, using a compendium of gene expression data; our algorithm evaluates each tissue for enrichment of specifically expressed genes within complex disease loci. First, our algorithm uses linkage disequilibrium properties to identify the potentially implicated genes by each associated SNP. Then, for each tissue, we assess the tissue specific expression of genes implicated by all associated SNPs. By comparison to randomly selected matched SNP sets, we are able to assign a significance score to each tissue.

Results: Using a gene expression data set of 223 murine immunological tissues from the Immunological Genome Consortium (http://www.immgen.org/) we demonstrate highly significant enrichment of four CD4+ effector memory T-cell genes within RA loci ($p<10^{-6}$). To independently validate the role of CD4+ effector memory T-cells in RA, we identified 436 loci with suggestive statistics in a recent GWAS meta-analysis ($p<0.001$) and completely independent from the 39 known RA loci. Separate analyses have shown that >5% of these loci are true RA loci (Stahl *et al* in review). We note enrichment for CD4+ effector memory T-cell genes within these loci as well ($p=1.25\times10^{-4}$); this enrichment can be explained by ~25 true RA risk loci. We further note that different cell types are implicated in other autoimmune diseases, for example we demonstrate enrichment of transitional B-cell genes in

systemic lupus erythematosus ($p=5.9\times10^{-6}$) and dendritic cells in Crohn's disease ($p=1.6\times10^{-5}$).

Conclusion: These results demonstrate that validated RA risk loci are near genes most specifically expressed in CD4+ effector memory T-cells more than other immune cell subsets. To understand how these loci act to confer risk of RA, functional studies must be conducted in the CD4+ effector memory T-cells to better elucidate disease mechanisms.

2157

The Hierarchy of HLA-DRB1 Shared Epitope Risk Genotypes Associated with Rheumatoid Arthritis in African-Americans Differs From That in Europeans. Altan F. Ahmed[1], Laura B. Hughes[1], Doyt L. Conn[2], Beth L. Jonas[3], Leigh F. Callahan[4], Edwin A. Smith[5], Richard D. Brasington[6], Larry W. Moreland[7], S. Louis Bridges Jr.[1] and Richard J. Reynolds[1]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Emory Univ School of Medicine, Atlanta, GA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of North Carolina, Chapel Hill, NC, [5]Med Univ of South Carolina, Charleston, SC, [6]Washington Univ School of Med, St. Louis, MO, [7]University of Pittsburgh, Pittsburgh, PA

Background/Purpose: HLA-DRB1 alleles encoding the shared epitope (SE) are associated with RA in persons of European ancestry (~60–70% of RA vs ~40% of controls have ≥1 SE allele). SE-containing alleles are also associated with RA in African-Americans (Af-Amer) but have a lower allele frequency than in Europeans (~43% of RA vs ~25% of controls). Several SE classification systems have been developed to define the relative contributions of individual SE alleles/combinations on susceptibility to RA, but these have not been tested in Af-Amer because of insufficient numbers of subjects. Here we evaluate the du Montcel classification system in 920 Af-Amer RA pts and 1,006 Af-Amer controls.

Methods: High-resolution HLA-DRB1 genotyping was performed in patients and controls from the CLEAR Registry and from local Birmingham controls. *HLA-DRB1* susceptibility (S) alleles are those with the amino acid sequence RAA at positions 72–74 (Table). S alleles are subdivided according to the amino acid at position 71 (S1: ARAA [S1A] or ERAA [S1E], S2: KRAA, S3: RRAA). The S3 alleles are subdivided further according to the amino acid at position 70 (S3D: DRRAA, S3P: QRRAA or RRRAA). S1A, S1E, and S3D are classified as low-risk (L) alleles. All other alleles are non-susceptibility alleles. To estimate the odds ratio of association of each genotype with RA, we fit log-linear models with case/control as the response, also stratified by autoantibody positivity, with levels of genotype as predictors.

HLA-DRB1 Alleles	Amino Acid Residue 70	71	72	73	74	Classification
0401, 1303		K	R	A	A	S2
0101, 0102, 0404, 0405, 0408, 10, 1402, 1406	Q/R	R	R	A	A	S3P
1501, 1502, 1503		A	R	A	A	L (S1A)
0103, 0402, 1301, 1302		E	R	A	A	L (S1E)
1102, 1103, 1202, 1305, 16	D	R	R	A	A	L (S3D)

Results: The genotype combination with the largest effect for Af-Amer RA was S2/S3P (OR 9.1, CI 3.4–24, $p=5.7\times10^{-6}$) followed by S3P/S3P (OR 3.2, CI 1.5–6.7, $p=1.9\times10^{-3}$), S2/L (OR 2.6, CI 1.9–3.6, $p=2.7\times10^{-9}$), S2/S2 (OR 2.3, CI 0.62–8.3, p=.20), S3P/L (OR 1.9, CI 1.5–2.4, $p=1.8\times10^{-8}$). When analyzing autoantibody positive patients only, the risk hierarchy was nearly identical, and the overall effect was slightly larger. In contrast, when stratifying by autoantibody negative patients, there was no association of genotype with RA ($c^2=1.9$, DF=5, p=0.86).

Conclusion: Among British RA the S2/S2 genotype provided the strongest association with RA, but was not associated with RA in Af-Amer. Therefore, the HLA-DRB1 risk hierarchy differs between Af-Amer and Caucasians. The much lower risk of the S2/S2 genotype is likely due to its low frequency (0.56%, both cases and controls) in Af-Amer. The lack of association among autoantibody negative patients further substantiates the role of the HLA in the pathogenesis of autoantibody positive RA. The results illustrate the importance of considering ethnic differences, which may include heterogeneous genetic admixture and/or allele frequency differences, when defining genetic susceptibility loci for RA and other complex diseases.

2158

Apolipoprotein M Polymorphism Is a Novel Risk Factor for Dyslipidemia in Rheumatoid Arthritis: A Possible Link Between Disease Susceptibility and Dyslipidemia. Yune-Jung Park[1], Jung-Hwa Lee[1], Hosung Yoon[2], Daejun Kim[1], Chul-Soo Cho[3] and Wan-Uk Kim[1]. [1]The Catholic University of Korea, St. Vincent's Hospital, Suwon, South Korea, [2]The Catholic University, Incheon, South Korea, [3]The Catholic University of Korea, Seoul

Background/Purpose: Chronic inflammatory diseases, including rheumatoid arthritis (RA), have been implicated in the increased risk of dyslipidemia. Apolipoprotein M (apoM) is a novel apolipoprotein predominantly associated with high-density lipoprotein cholesterol (HDL-C). In this study, we investigated the possible association of *APOM* polymorphism and dyslipidemia in Korean RA patients.

Methods: A genome-wide association scan (GWAS) was performed 100 RA patients and 600 controls using Affymetrix SNP array 5.0. Two-hundred fifteen well-characterized RA patients, who provided complete genotyping, were evaluated for this cross-sectional study. Fasting lipid profile, disease activity in 28 joints, inflammatory markers, and radiographic severity using modified Sharp method were also assessed.

Results: Through GWAS, APOM gene was identified as a novel SNP associated with RA (rs805297, odds ratio (OR)=2.28 [1.65–3.14], $P<0.001$). RA patients had increased frequency of *A* allele on apoM C-1065A compared to the controls (44.8 % versus 36.4 %, OR=1.40 [1.19–1.65], $P<0.001$). RA patients with APOM 1605 *A* carriers (*CA+AA*) had higher levels of total cholesterol and low-density lipoproteins, as well as lower levels of HDL-C and pre-b-HDL-C than those with CC genotype. After adjustment of gender, BMI, diabetes, medications, and inflammatory markers, APOM genotype was strongly associated with low HDL-C (OR=2.75 [1.17–6.5], $P=0.021$). Moreover, when subgroup analyses according to disease activity and Sharp score were performed, the association between APOM genotype and low HDL-C levels was still significant in all subgroups, indicating that APOM polymorphism may increase the risk of dyslipidemia, independent of disease activity and radiographic severity of RA.

Conclusion: The APOM C-1605A polymorphism is associated with an increased risk for developing RA and low HDL-C levels in RA patients. Reduced HDL-C level is independent of disease activity and severity, but it is significantly influenced by APOM genotype. These findings suggest that a certain genetic factor itself for RA could be fundamentally linked to dyslipidemia, increasing the risk of atherosclerosis.

2159

Increased Frequency of Complement *C4B* Deficiency in Rheumatoid Arthritis (RA): Interaction with the Shared Epitope (SE). William F. C. Rigby[1], Y.L. Wu[2], Moe T. Zan[3], Bi Zhou[2], Sanna Rosengren[4], Cheryl Carlson[5], Whitney Hilton[5], Jonathan D. Jones[6] and Chack-Yung Yu[7]. [1]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [2]Nationwide Children's Hospital The Ohio State University, Columbus, OH, Columbus, OH, [3]Dartmouth-Hitchcock Clinic, Manchester, NH, [4]UCSD School of Medicine, La Jolla, CA, [5]Dartmouth Hitchcock Med Ctr, Lebanon, NH, [6]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [7]7Center for Molecular and Human Genetics, The Research Institute at Nationwide Children's Hospital and The Ohio State University, Columbus, OH

Background/Purpose: There is an increased frequency of complement *C4A* deficiency in Systemic Lupus Erythematosus (SLE). We assessed the Copy Number Variation (CNV) of complement *C4A* and *C4B* genes in patients with Rheumatoid Arthritis RA

Methods: DNA from 299 patients and volunteers were analyzed for CNV of total complement *C4, C4A,* and *C4B* genes by Southern blotting and real-time qPCR. These results were analyzed by chi-square analysis and odds ratios calculated. The presence or absence of the shared epitope (SE) was determined on all seropositive RA patients (n=113) as well as seronegative RA, non-RA controls and healthy volunteers with heterozygous deficiency (0–1 allele) for C4B (n=44).

Results: Chi-square analysis revealed similar distribution patterns of total *C4* alleles in RA (n=160), non-RA (n=88) rheumatology patients and in normal volunteers (n=51). There was no trend to *C4A* deficiency as seen in SLE. RA patients exhibited a ~2-fold increase in the frequency (40%) of homozygous and/or heterozygous *C4B* deficiency (0 or 1 allele) relative to non-RA patients (21%) or healthy controls (22%). This *C4B* deficiency concentrated in the seropositive RA patients relative to seronegative RA (44% vs 31%). The odds of *C4B* deficiency were 2.99 (C.I. 1.58–5.65 p=0.0006)

in the seropositive RA patient relative to non-RA controls. These findings were confirmed using a larger healthy control cohort (n=513) as a comparator, where an odds ratio of 1.83 (C.I. 1.21–2.76) p=0.0056 was observed. The shared epitope (SE) was present in 94/113 (83%) of seropositive RA patients (Table 1), similar to previous reports. In the 50 seropositive RA patients with C4B deficiency, the SE was present in 48/50 seropositive RA patients (96%) relative to seropositive RA patients with >2 *C4B* alleles (46/63, 73%, p<0.0009). In the 44 individuals with complement *C4B* deficiency that did not have seropositive RA, the frequency of the SE was 55% (24/44), which is similar to that seen in in the healthy volunteers/non-RA controls (17/30) and the general population. Thus, the frequency of the association of SE with C4B deficiency was significantly greater in the seropositive RA patient population relative to non-seropositive RA controls, 96% vs 55%, p<0.0001. The same level of statistical significance was seen using only the non-RA/healthy volunteers as a comparator (p<0.0001). Thus, while SE appears to be linked to heterozygous C4B deficiency, this linkage is further strengthened in seropositive RA, suggesting a functional interaction.

Table 1. Incidence of C4B Isotype Deficiency Increased in Sero+ and SE+ RA

Group	SE frequency (%)	p value
Seropositive RA	**94/113 (83%)**	
C4B (<2)	**48/50 (96%)**	
C4B (>2)	**46/63 (76%)**	**p=0.0009**
Non-Seropositive RA		
C4B (<2)	**24/44 (55%)**	**p<0.0001**
Non-RA/Volunteers	**17/30 (57%)**	**p<0.0001**

Conclusion: *C4B* CNV exhibits a clear relationship with RA that approximates that seen between *C4A* CNV and SLE. Given this frequency and the strength of this relationship, this finding has broad implications for our understanding of RA.

2160

The STAT4 rs7574865 Polymorphism Is Associated with Differences in Disease Activity and Disability in Patients Wirh Early Arthritis. Ana M. Ortiz[1], Amalia Lamana[1], Alejandro Balsa[2], Blanca Rueda[3], Laura Nuño[2], Maria Eugenia Miranda-Carus[2], María F. González-Escribano[4], Miguel A. López-Nebot[5], Dora Pascual-Salcedo[2], Javier Martin[6] and Isidoro González-Alvaro[1]. [1]Hospital Universitario de La Princesa. IIS Princesa, Madrid, Spain, [2]Hospital La Paz. IdiPaz, Madrid, Spain, [3]Facultad de Ciencias de la Salud. Universidad de Granada, Granada, Spain, [4]Hospital Universitario Virgen del Rocío, Sevilla, Spain, [5]Hospital Universitario Virgen de las Nieves, Granada, Spain, [6]Instituto de Parasitologia y Biomedicina Lopez-Neyra (CSIC), Granada, Spain

Background/Purpose: The presence of shared epitope and the minor allele of single nucleotide polymorphisms (SNPs) of STAT4 (rs7574865) and PTPN22 (rs2476601) have been associated with an increased risk of developing rheumatoid arthritis (RA). However, it is not well established whether these genetic markers could also determine a more severe clinical course of RA. The objective was to determine whether the genetic variants of *STAT4* rs7574865 and *PTPN22* rs2476601 and the number of copies of the shared epitope in *HLA-DRB1* affect disease activity or disability in patients with early arthritis (EA).

Methods: We studied 596 patients (75% female, median age at onset 51 years) of the EA registers of Hospital U La Paz and La Princesa in Madrid, who were followed up 2 years with visits every 6 months. Demographic and disease variables (rheumatoid factor, anti-CCP antibody [a-CCP, Euro-Diagnostica ELISA. Arnhem, Holland]), HAQ and variables needed to the estimation of DAS28 were collected. The HLA-DRB1 alleles were determined by medium-resolution technique (PCR-SSO) and sequencing was only done for the determination of certain subtypes of DR4. Genotyping of rs7574865 and rs2476601 was performed using real-time PCR and specific Taqman probes (Applied Biosystems). Multivariate analysis was performed using generalized estimating equations for repeated measures using the function xtgee of Stata 10.1 for Windows (StataCorp LP, College Station, TX, USA). We used the method "backward stepwise selection" to achieve the best fitting model, removing from the initial model, which included all independent variables, all those with $p > 0.15$.

Results: Female gender (β coefficient = 0.50 ± 0.13; $p < 0.001$), older age ([by 10 year] 0.22 ± 0.03; $p < 0.001$), a-CCP positivity (0.22 ± 0.21; $p = 0.056$) and TT genotype of rs7574865 in STAT4 (0.71 ± 0.32; $p = 0.024$) were associated with greater disease activity as measured by DAS28. A trend towards greater disease activity was detected in active smokers (0.25 ± 0.23; $p = 0.074$), whereas no association was found between the value of DAS28 and the presence of shared epitope and a tendency to lower activity in the homozygous minor allele of SNP in PTPN22 (−0.74 ± 0.92; $p = 0.132$) was also observed. There was no additive or synergistic effect between the presence of a-CCP and STAT4. On the other hand, female gender (0.1 ± 0.08; $p < 0.015$), older age ([by 10 year] 0.03 ± 0.02; $p = 0.003$) and heterozygosity (0.08 ± 0.07; $p = 0.035$) or homozygosity (0.17 ± 0.15; $p = 0.022$) for the T allele of rs7574865 in STAT4 were associated with functional capacity.

Conclusion: Our data suggest that EA patients with the minor allele of SNP rs7574865 in STAT4, in addition to a higher risk of developing RA, would have a more severe disease with increased activity and disability. These data have not been observed for the presence of shared epitope or PTPN22 variant that confers increased risk of RA.

The Complexity of Anti-CCP Positive Rheumatoid Arthritis, in the Context of Gene-Environment Associations. Karin Lundberg, Camilla Bengtsson, Lena Israelsson, Nastya Kharlamova, Iskra Pollak-Dorocic, Rikard Holmdahl, Leonid Padyukov, Vivianne Malmström, Lars Alfredsson and Lars Klareskog. Karolinska Institutet, Stockholm, Sweden

Background/Purpose: Risk factors for rheumatoid arthritis (RA), such as *HLA-DRB1* 'shared epitope' (SE) alleles, *PTPN22* and cigarette smoking, associate with anti-CCP positive disease. By subdividing CCP positive patients based on reactivity to CEP-1, the immunodominant B cell epitope on citrullinated alpha-enolase, we have previously shown that SE, *PTPN22* and smoking mainly constitute risk factors for CEP-1 positive, rather than CCP positive RA[1]. In this study, we investigate gene-environment associations with different subsets of RA, based on presence of anti-CCP and specific anti-citrullinated protein/peptide antibodies (ACPAs), including antibodies to CEP-1 and citrullinated peptides from vimentin (Cit-vim), fibrinogen (Cit-fib) and collagen type II (CII Cit-C1).

Methods: Presence of antibodies were analysed by ELISA (Immunoscan CCPlus (Euro-Diagnostica) and in-house peptide ELISAs) in 1985 RA patients from the Swedish population-based case-control study EIRA. One hundred and fifty healthy controls were used to determine the 98th percentile cut-off for positivity. A positive and a negative control serum and a standard of pooled antibody-positive sera were included on each plate. Different RA subsets were compared with regard to risk factors, by calculating odds ratios with 95% confidence interval by means of logistic regression.

Results: Antibody frequencies were: CCP (63%); CEP-1 (36%); Cit-vim (37%); Cit-fib (28%); CII Cit-C1 (37%). Most patients showed reactivity to multiple citrullinated antigens, though single-positive subsets of patients were also identified for each specific ACPA. Associations with the risk factors correlated with the number of ACPAs present, as well as anti-CCP antibody levels. However, SE, *PTPN22* and smoking associated specifically with CEP-1 positive and Cit-vim positive RA, but not with Cit-fib and Cit-C1 positive RA.

Conclusion: Our data show the complexity of CCP positive RA and that this subset can be further divided based on the fine-specificity of the ACPA response. SE, *PTPN22* and smoking seem to predispose for the development of ACPA with multiple reactivities, rather than one single specificity. However, clear differences with regard to gene-environment associations with specific ACPAs can also be identified, suggesting different etiological pathways in different subsets of anti-CCP positive RA patients.

Genome-Wide Association Study and Comparison of Risk Alleles for Rheumatoid Arthritis in An Isolated Dutch Population. Joanne Nitiham[1], Kimberly E. Taylor[1], Yurii S. Aulchenko[2], Ben Oostra[2], Robert M. Plenge[3], Tom W.J. Huizinga[4], Peter K. Gregersen[5], Cornelia M. van Duijn[2] and Lindsey A. Criswell[1]. [1]University of California, San Francisco, San Francisco, CA, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]Brigham and Women's Hospital, Boston, MA, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Feinstein Institute Medical Reschearch, Manhasset, NY

Background/Purpose: Rheumatoid arthritis (RA) is a genetically complex autoimmune disease causing severe disability through joint destruction

and deformity. Alleles of the of the *HLA-DRB1* locus in the major histocompatibility complex (MHC) have long been known to increase risk of RA; recent genome-wide association studies (GWAS) have resulted in over 30 established loci associated with RA risk. However, effects of these loci are small and much of the heritability of RA is not explained. Isolated populations offer a unique opportunity for the study of genetic diseases, as certain disease-causing alleles may be enriched in such populations.

Methods: We performed Illumina 660W genotyping on 201 RA cases and 100 healthy controls from a genetically-isolated Dutch population, and utilized Illumina 317K genotyping on another 500 healthy controls from the isolate. After strict quality control, SNPs were imputed up to the HapMap2 using MACH, and SNPs retained with quality score > 0.8 and RSQ > 0.3. We also obtained genotypes for known RA risk SNPs from 2 cohorts: anti-CCP+ or RF+ cases (5,539) and healthy controls (20,169) from a pan-European study, and anti-CCP+ cases (157) and healthy controls (702) from a non-isolated Dutch population. First, we compared 49 RA risk SNPs in our anti-CCP+ cases (131) and controls (555) to those from the pan-European study, and to a subset of SNPs typed in the Dutch non-isolate. Second, we performed a GWAS of our full cohort using the software ProbABEL in order to account for imputed genotype probabilities and relatedness in the population. New SNP associations will be investigated in replication cohorts.

Results: Although 17 (35%) of the RA risk SNPs had evidence of different background (control) frequencies ($p<0.01$), only 6 SNPs had evidence of heterogeneity of odds ratios (ORs) ($p_{het}<0.1$) between the isolate and pan-European cohorts. A SNP of gene TNFRSF14/MMEL1 had a significantly stronger protective effect in the isolate, OR=0.62 (95% CI 0.44–0.87) versus OR=0.89 (0.85–0.94), $p_{het} = 0.037$. Comparison to the Dutch non-isolate supported that differences are due to isolate membership versus Dutch ancestry. In our GWAS, in spite of the relatively small size of this study, 58 SNPs in the MHC reached genome-wide significance ($p < 5\times10^{-8}$), with the top hit as expected in the *HLA-DRB1-HLA-DQA1* region. In addition there were 31 regions outside of the MHC with at least two signals with $p<5\times10^{-8}$, which have not been implicated previously.

Conclusion: For most established RA risk alleles this isolated Dutch population has similar risk distributions to that of a pan-European cohort, with some exceptions. Our GWAS has identified additional loci with preliminary evidence of association with RA in this population.

Vitamin D Receptor Polymorphism rs2228570 (FokI) in North American Natives with Rheumatoid Arthritis and Their Unaffected First Degree Relatives. Carol A. Hitchon[1], Ye Sun[2], David B. Robinson[1], Christine A. Peschken[1], Charles N. Bernstein[1], Katherine A. Siminovitch[2] and Hani S. El-Gabalawy[1]. [1]University of Manitoba, Winnipeg, MB, [2]Mount Sinai Hospital, Toronto, ON

Background/Purpose: North American Natives (NAN) have high prevalence rates for rheumatoid arthritis. Our previous studies of a Cree/Ojibway population in Central Canada have shown an early age of onset, high prevalence and titers of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) and shared epitope alleles in the background population. 25 OH Vitamin D (VitD) has immune effects of potential importance to RA pathogenesis and low serum levels have been associated with RA and disease activity in other populations. We sought to examine association of the RS2228570 (FokI) polymorphism of the VitD receptor gene with RA susceptibility in the NAN population.

Methods: We tested NAN RA patients (n=458) and unrelated controls without autoimmune disease (n=715) were tested for the RS2228570 (FokI) single nucleotide polymorphism of the vitamin D receptor gene. The genotyping data were analyzed using genotypic (DD vs Dd vd dd), allelic (D vs d), dominant (DD, Dd vs dd), and recessive (DD vs Dd, dd) models.

Results: The minor allele frequency in the unaffected control group was 0.43. Significant differences between affected RA patients (90/240/118) and unaffected controls (157/307/241) were found using the genotypic model (ChiSq 11.83; p=0.0027). Using an allelic modle, there was no significant difference between the RA patients and controls (OR 1.12 p=NS, CI 0.95–1.32). Analysis using the dominant model was significant (RA=330/118 vs Controls=464/241 OR 1.45 p=0.006 CI 1.12–1.89). No interactions were seen between the presence of ACPA, RF and VitD receptor polymorphisms in the RA population.

Conclusion: The RS2228570 (FokI) VitD receptor polymorphism is associated with RA in the NAN population. Since VitD is important in maintaining dendritic cell tolerance, polymorphisms of the VitD receptor may contribute to loss of self tolerance in RA.

The I50V *IL4R* SNP Is Associated with Increased Th17 Cell Frequency and Activity in Autoimmune Arthritis. Jan Leipe[1], Iryna Prots[2], Markus A. Schramm[1], Alla Skapenko[1] and Hendrik Schulze-Koops[1]. [1]Division of Rheumatology and Clinical Immunology, Med. Poliklinik, University of Munich, Munich, Germany, [2]Junior Research Group III, Nikolaus-Fiebiger Center for Molecular Medicine, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen

Background/Purpose: Th17 cells are increased in active rheumatoid and psoriatic arthritis (RA, PsA) and are thought to be the driving force of autoimmune inflammation in these diseases. On the other hand, a single nucleotide polymorphism (SNP) in the *IL-4R* gene (I50V, rs 1805010) has previously been associated with an aggressive destructive course of RA. In this regard, CD4 T cells expressing the V50 variant of the IL-4R are hyporesponsive to the activity of IL-4. Since Th17 cell development is negatively regulated by IL-4, here we investigated if the I50V *IL-4R* SNP is associated with the observed increase of Th17 cells in active RA.

Methods: *IL4R* genotypes for I50V SNP were determined in well-defined cohorts of patients with RA (n = 28) and PsA (n = 18); as well as in controls: healthy controls (n=21) and patients with osteoarthritis (OA, n=15) by TaqMan SNP assay. IL-17 serum levels and *ex vivo* Th17 cell frequencies were analyzed by multi-color flow cytometry and ELISA. To assess the inhibitory effect of IL-4 on Th17 cell development, we primed CD4 T cells for 72 h in the presence or absence of IL-4 and determined Th17 cell frequencies.

Results: Although the IL-17 serum level was not elevated in the overall cohort of RA or PsA patients, patients homozygous for the V50 allele variant demonstrated significantly higher IL-17 serum levels as compared to I50I or I50V patients and to healthy or OA controls. Accordingly, the frequencies of Th17 cells were significantly increased in the V50V groups of RA and PsA patients. When the IL-4 inhibitory effect on Th17 cell development was investigated *in vitro*, cells from V50V individuals responded weaker to IL-4 inhibition as compared to their I50I or I50V counterparts. In V50V cells, the diminished inhibitory effect of IL-4 on Th17 development was more pronounced in RA and PsA patients compared to controls and was even completely absent in some patients. Of note, clinical activity was consistently high in V50V patients during two years of follow-up despite similar treatment regimens.

Conclusion: Together, the data indicate that the V50 allele of the I50V *IL4R* SNP renders CD4 T cells insensitive to IL-4 *in vivo* and may thus contribute to the increased Th17 cell frequency and activity characteristic for RA and PsA.

Gene Polymorphisms of Signal Transducers and Activator of Transcription 4 and Tumor Necrosis Factor Receptor-Associated Factor 1 Predict Clinical Response to Disease-Modifying Anti-Rheumatic Drugs in Japanese Patients with Rheumatoid Arthritis. Tetsuya Nishimoto, Noriyuki Seta, Ryusuke Anan, Tatsuya Yamamoto, Yuko Kaneko, Masataka Kuwana and Tsutomu Takeuchi. Keio university, Tokyo, Japan

Background/Purpose: Several single nucleotide polymorphisms (SNPs) associated with pathophysiology of rheumatoid arthritis (RA) have been identified in recent genome-wide association studies. Although disease-modifying anti-rheumatic drugs (DMARDs) including biologic agents, such as anti-tumor necrosis factor (TNF) drugs, have excellent efficacy against RA, a substantial number of patients still show inadequate responses. The aim of this study is to identify genetic predictors of response to non-biologic DMARDs, especially methotrexate (MTX), and anti-TNF drugs in RA patients using database of a single-centre prospective cohort study of Japanese patients with newly diagnosed and DMARDs-naïve RA (SAKURA study).

Methods: Fc receptor-like protein 3 (FCRL3) (-169A/G), signal transducers and activator of transcription 4 (STAT4) (+56293G/T), cytotoxic T lymphocyte antigen 4 (CTLA4) (+49G/A), peptidyl arginine deminase type IV (PADI4) (+163A/G), interferon regulatory factor 5 (IRF5) (+198G/T), and TNF receptor-associated factor 1 (TRAF1) (+16860A/G) were genotyped using TaqMan® SNP genotyping assay. We enrolled 114 untreated newly diagnosed Japanese RA patients, and prospectively analyzed the association between the SNPs and clinical response to treatment with DMARDs including biologics or MTX monotherapy as a first line treatment using the 28-joint Disease Activity Score (DAS28) at 24 weeks after registration. Moreover, in 28 RA patients treated with anti-TNF drugs in combination with MTX as a first biologic agent, such as infliximab, etanercept and adalimumab, we prospectively analyzed the association between SNPs and the clinical response using DAS28 and Simplified Disease Activity Index (SDAI) at 24 weeks of treatment.

Results: There was no association between each SNP and disease activity at baseline. Of 114 RA patients enrolled, 69 (60.5%) were treated with MTX, 41 (36.0%) with other non-biologic DMARDs, and 19 (16.7%) with biologic agents at 24 weeks after registration, although 34 (29.8%) patients were treated with more than one agent. Among them, 51 (44.7%) achieved a good response based on the DAS28 response criteria. FCRL3 (-169A/G) G allele (47.2% versus 30.8%, P=0.011, OR 2.01, 95%CI 1.17–3.45) and STAT4 (+56293G/T) G allele (76.9% versus 58.3%, P=0.003, OR 2.37, 95%CI 1.33–4.21) were increased in patients with a good response, compared with those with a moderate or no response. In 46 RA patients received MTX monotherapy for 24 weeks from diagnosis, 24 (52.2%) achieved a good response, and STAT4 (+56293G/T) G allele (75.0% versus 45.5%, P=0.003, OR 3.60, 95%CI 1.49–8.70) was also increased in patients with a good response. Interestingly, in 28 RA patients treated with anti-TNF drugs in combination with MTX as a first biologic agent, TRAF1 (+16860A/G) A allele was increased in patients with a good response based on DAS28 (88.9% versus 60.0%, P=0.012, OR 5.33, 95%CI 1.35–21.02), and a remission based on SDAI (92.3% versus 66.7%, P=0.020, OR 6.00, 95%CI 1.18–30.62).

Conclusion: STAT4 (+56293G/T) and TRAF1 (+16860A/G) are possibly useful in predicting the clinical response to MTX monotherapy as a first DMARD and anti-TNF drugs as a first biologic agent respectively.

Fine-Mapping of Autoimmune Susceptibility Loci Using Immunochip Identifies Novel Susceptibility Loci for Psoriatic Arthritis. John Bowes[1], Pauline Ho[2], Eleanor Korendowych[3], Neil J. McHugh[3], Helena Marzo-Ortega[4], Jonathon Packham[5], Ian N. Bruce[1] and Anne Barton[1]. [1]Arthritis Research UK Epidemiology Unit, Manchester Academic Health Science Centre, The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research UK, Manchester, United Kingdom, [3]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [4]University of Leeds, Leeds, United Kingdom, [5]Haywood Hospital, Stoke on Trent, United Kingdom

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease that typically accompanies psoriasis vulagris (PsV). Both conditions are considered to be complex diseases with both genetic and environmental susceptibility factors. Genome-wide association studies (GWAS) have identified a number of genetic susceptibility loci for both diseases. Comparing GWAS results performed in many common autoimmune diseases has revealed an extensive overlap in the genetic liability between autoimmune diseases in general. Based on the observed sharing of susceptibility loci across autoimmune diseases, the aim of this project is to identify novel susceptibility loci for PsA by fine-mapping all the currently confirmed susceptibility loci for 12 autoimmune diseases.

Methods: Data was available for 929 PsA cases and 4537 healthy controls genotyped using the Immunochip Illumina iSelect array at the Sanger Centre (www.sanger.ac.uk). Control data was sourced from the WTCCC (www.wtccc.org.uk). This custom array was designed to comprehensively fine-map confirmed autoimmune susceptibility loci and contains 196,524 SNPs covering approximately 200 candidate regions. A strict SNP-focused quality control process was applied to the dataset followed by single point analysis using the Armitage test for trend.

Results: Association analysis of 182,883 high quality SNPs in 862 cases and 4306 controls robustly detected association to previously confirmed PsA risk loci; *HLA-C* ($p = 8.2\times10^{-35}$), *IL23R* ($p = 8.4\times10^{-8}$) and *TRAF3IP2* ($p = 2.8\times10^{-7}$), *IL12B* ($p = 6.5\times10^{-6}$). In addition we find convincing evidence to support association to a number of novel loci not previously reported for PsA, including; 17q21 ($p_{trend} = 3.3\times10^{-05}$, *SMARCE1)*, 18p11 ($p_{trend} = 2.0\times10^{-05}$, *PTPN2)*, 11q23 ($p_{trend} = 1.4\times10^{-05}$, *TREH)*, and 19p13 ($p_{trend} = 9.8\times10^{-05}$, *TYK2)*. Interestingly, we also find convincing evidence for association to the *CARD15* gene, supported by multiple SNPs.

Conclusion: The preliminary single point analysis of an autoimmune loci fine-mapping dataset identifies a number of potential novel loci for PsA susceptibility. Validation of these results is currently underway in an independent sample collection. Single-point analysis will be followed by analyses to indentify independent effects within the previously identified and newly discovered loci.

2167

The Potential Role of *PTPRD* Gene Copy Number Variation in Susceptibility to Rheumatoid Arthritis. Seung Cheol Shim, Donghyuk Sheen, Mi-Kyoung Lim, Jiyoung Kim, Soyoung Lee and Sangkwang Lee. Eulji University Hospital, Daejeon, South Korea

Background/Purpose: Since it is important to explore genetic variations associated with rheumatoid arthritis (RA), genome-wide association studies (GWAS) have led to the identification of RA genetic variants putatively associated with susceptibility. Recently, copy number variation (CNV) may also affect susceptibility to diseases, which have been already observed in diverse autoimmune diseases. Protein tyrosine phosphatase receptor D (PTPRD) is a member of the receptor-like PTP which expresses in the B cell lines and thymus and could be involved in the pathogenesis of autoimmune diseases. In this study, we investigated whether the variation of the *PTPRD* gene copy number related with susceptibility to RA.

Methods: To investigate whether the variation of the *PTPRD* gene copy number influence the pathogenesis to RA, blood samples and clinical records were obtained from 217 RA patients (184 females, 33 males) and 205 healthy controls. The genomic DNA of RA patients and healthy controls was extracted from leukocytes in peripheral blood using the Genomic DNA Extraction kit (iNtRON Biotechnology, Korea). To measuring the copy number of *PPTRD* gene, the quantitative real-time PCR (QPCR) was carried out using Mx3000P QPCR system (Stratagene, La Jolla, CA) and each sample for each gene was assayed in triplicate.

Results: The copy number of *PTPRD* gene in RA patients was compared with that in healthy controls. The proportion of the individuals with <2 copy of *VPREB1* was significantly higher in patients than in controls, while that of the individuals with >2 copy was lower in patients than in controls. The average relative copy number of the *PTPRD* gene in RA patients (1.14, 95 % CI (1.12–1.16)) was significantly lower than that in healthy controls (1.65, 95 % CI (1.12–1.16), $p < 0.0001$) (Figure 1). Furthermore, we also investigated association between copy number of *PTPRD* and RA phenotype such as RF factor and anti-CCP levels, which showed no association between copy number of *PTPRD* and both RA phenotypes.

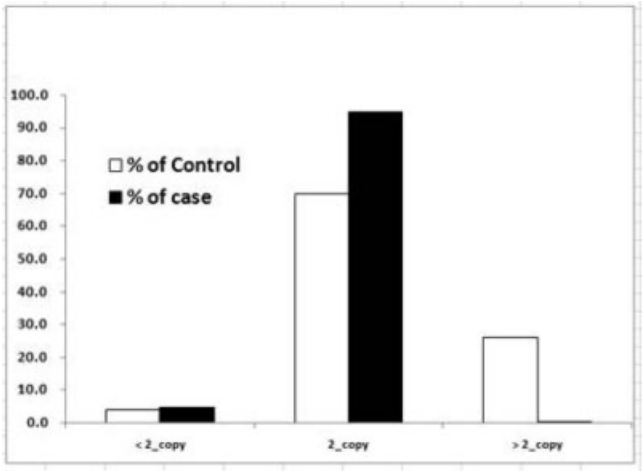

Figure 1. Relative gene copy numbers of *PTPRD* in RA patients and healthy controls. Relative amount of gene copy numbers of *PTPRD* in RA patients (n = 217) was compared to that in healthy controls (n = 205) by Quantitative PCR. Each of gene copy number was normalized to *HS6ST3* gene used as an internal control. The mean copy number of *PTPRD* in RA patients (1.14, 95 % CI (1.12–1.16)) was significantly lower than that in healthy controls (1.65, 95 % CI (1.12–1.16)) ($P<0.0001$). Bar show the mean ± SD for each group.

Conclusion: This is the first evidence showing the association between low copy number of the PTPRD gene and susceptibility to RA, which may help understanding the pathogenesis of RA and other autoimmune disorders like affecting maturation and differentiation of T cell and B cells.

2168

Exposure to Environmental Tobacco Smoke and the Risk of Rheumatoid Arthritis Among Nonsmoking Women. So-Young Bang, Hye-Soon Lee, Jae Hoon Kim, Joo-Hyun Lee, Jin Ju Kim, Young Bin Joo and Sang-Cheol Bae. Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: Smoking is the major known environmental risk factor for rheumatoid arthritis (RA). International meta-analyses have indicated that exposure to environmental tobacco smoke (ETS) results in significantly higher risks for many diseases as well as smoking. Although ETS may play an important role in the development of RA who never smoked, the association between exposure to ETS and RA has never been investigated.

The objectives of this study are to examine the prevalence of ETS in

nonsmoking women with RA, and to investigate whether ETS contribute to the development of RA.

Methods: A total of 1,450 women patients from BAE RA cohort, who fulfilled the American College of Rheumatology 1987 classification criteria for RA, and 897 healthy women were recruited in a Korean population. The RA patients (n =1,330) and controls (n = 868) were nonsmoking women. Four-digit HLA-DRB1 typing was performed by a conventional PCR-SBT method. Information about smoking and ETS history was obtained through a questionnaire by face-to-face interviews. Odds ratios (OR) with a 95% confidence interval (CI) were calculated by multivariate logistic regression.

Results: The frequency of smokers in Korean women (RA 8.3%, control 3.2%) was much lower than in Caucasian. The prevalence of ETS at home (> 3 day/week) was 21.0 % (n=279) in our RA cohort. The exposure to ETS (> 3 day/week) at home was associated with RA [OR 1.36 (95% CI: 1.05 1.75), p = 0.02] compared with the risk among nonsmokers exposed to ETS (< 3 day/week), when adjusted for age and HLA-DRB1 shared epitope alleles. Furthermore, the daily exposure to ETS at home [OR 1.68 (95% CI: 1.27 – 2.21), $p = 2.51 \times 10^{-4}$] increased the risk for RA compared with the risk among nonsmokers exposed to ETS (< 3 day/week) by multivariate logistic regression.

Conclusion: Exposure to ETS at home may confer an increased risk of RA among women who never smoked.

2169

Smoking and Oxidative Stress Interaction Is Associated with Rheumatoid Arthritis Risk. A Case–Control Study. Victoria Navarro Compán, Enrique Melguizo Madrid, Blanca Hernández Cruz, Christian Leyva Prado, Teresa Arrobas Velilla, Federico Navarro Sarabia and Concepción González Rodríguez. Hospital Universitario Virgen Macarena, Sevilla, Spain

Background/Purpose: The main objective of this study is to establish an association between smoking, oxidative stress and the development of rheumatoid arthritis (RA).

Methods: A case-control study, including disease-modifying antirheumatic drugs (DMARD) and glucocorticoids naïve early RA patients (1987 criteria) and healthy age, sex and smoke habit matched controls. Smoking was recorded by current habit and pack-year index. Oxidative stress was determined by measuring of plasmatic levels of malonildialdehyde (MDA), carbonyl protein (CP) and lipid hidroperoxide (LOOH). Statistical analysis was performed using the STATA 10.0.

Results: A total of 65 RA patients and 65 controls were included. Statistically significant differences between groups were found in antibodies and genetic variables associated with the disease. Pack-year index was associated with RA risk, OR of 4.0 and 6.5 for amount higher to 20.1 and 34 pack-year, respectively. Association was also observed between plasma LOOH and CP levels and RA risk, increased for levels higher than 27.1 mM (OR 2.4) for LOOH and 67 mM (OR 2.2) and 120 mM (OR 3.1) for CP. Negative association was observed between MDA levels and RA risk, OR 4.7 for MDA<7.7 mM.

7.8–8.6	8.2	8.0–8.3	20	8.3	8.1–8.5	17	1.18 (0.68–2.60)
8.6–10.0	9.1	9.0–9.9	7	9.1	8.7–9.8	22	0.32 (0.15–0.83)
>10.0	11.6	10.3–13.0	10	10.6	10.4–11.3	20	0.50 (0.22–1.11)

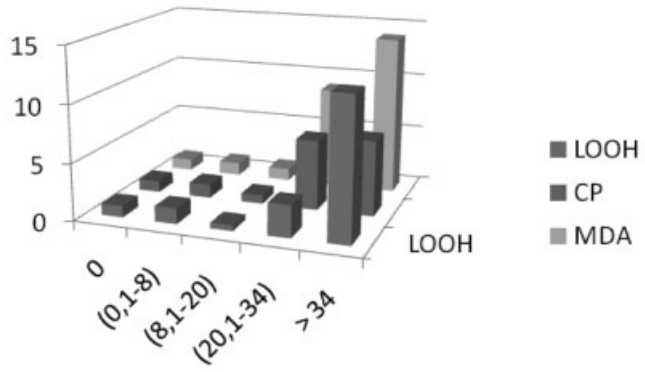

Figure 1. OR and corresponding 95% CI due to interaction for different amount of smoking (pack-years) and plasmatic levels of oxidative stress biomarkers (LOOH and CP).

The interaction of smoking and LOOH or CP increased RA risk, OR 12.3 for pack-years>34 for LOOH and OR 6.2 for pack-year>20.1 for CP. The interaction of smoking and MDA was associated with RA risk, OR 9.0 and 13.4 for pack-year>20.1 and >34 respectively.

Conclusion: The interaction between oxidative stress and smoking is associated with the RA risk.

2170

Smoking and Periodontal Status Are Associated with ACPA Fine Specificity and Levels of Inflammatory Cytokines in Rheumatoid Arthritis: The ARIC Study. Reuven Bromberg[1], Jeremy Sokolove[1], Lauren J. Lahey[1], Alvaro Alonso[2], Mark H. Wener[3], Vivian H. Gersuk[4], Jane Hoyt Buckner[4], James D. Beck[5], Bryan S. Michalowicz[6], Aaron A. Folsom[2], William Robinson[7] and Jerry A. Molitor[8]. [1]Stanford University, Palo Alto, CA, [2]Minneapolis, [3]University of Washington, Seattle, WA, [4]Benaroya Research Institute, Seattle, WA, [5]Chapel Hill, NC, [6]Minneapolis, MN, [7]Stanford Univ School of Med, Stanford, CA, [8]Univ of MN MMC108, Minneapolis, MN

Background/Purpose: Environmental factors predisposing to the development of rheumatoid arthritis (RA) include tobacco exposure (TE) and possibly periodontal disease (PD). Only TE has been clearly associated with risk for anti-citrullinated protein antibodies (ACPA). We sought (i) to determine whether periodontal disease (PD) was associated with an increased risk for development of APCA, (ii) to assess for interaction between TE and PD in the development of APCA, and (iii) whether this interaction was affected by presence of the HLA-DR4 shared epitope (SE).

Methods: We performed serum profiling of 16 putative RA-associated autoantibodies and 47 cytokines in 44 participants of the Atherosclerosis Risk in Communities (ARIC) study with a hospital discharge diagnosis of RA. Participants underwent detailed periodontal assessment (PD status: none or mild; moderate or severe). We evaluated levels of anti-cyclic citrullinated peptide antibodies by a second generation assay (CCP2) as well as breadth, amplitude, and specificity of ACPA targeted by RA patients with current or prior TE; moderate to severe PD; TE with PD; or neither TE or PD.

Results: The average number of ACPA subtypes closely paralleled the average CCP2 value and was higher among RA participants with TE and concurrent PD (Table 1). Small numbers particularly in non-smokers without PD (n=1), limited assessments to qualitative analysis.

Table 1.

	Average CCP2 titer (AU)	**Average # ACPA subtypes**	**n**
Tobacco exposure (TE)	7.55	1.1	11
Periodontal disease (PD)	53.4	2.0	12
TE and PD	224.3	11.5	20

Evaluation of individual ACPAs again suggested an interaction among smokers with PD as demonstrated by much higher levels of most ACPA subtypes among those with TE and PD compared with subjects with TE or PD alone. In most cases there were minimal differences between subgroups with TE or PD alone. An exception was anti-cit-fibrinogen autoantibodies which were elevated in both the TE and PD subgroups; with levels among those with TE approaching average levels of those with TE and PD combined. Among subjects positive for both TE and PD, HLA-DR4 status (7 positive, 12

negative) was associated with ACPA targeting citrullinated enolase, clusterin, and histone 2B.

Levels of 18 serum cytokines including TNFα, IL1β, IFN-γ followed a similar pattern to ACPA and were markedly elevated in the subgroup with combined TE and PD compared with TE or PD alone.

Conclusion: The presence of PD and TE was associated with increased breadth and amplitude of ACPA subtypes. This suggests a possible interaction between the presence of both TE and PD resulting in further increase in CCP2 titer, number of ACPA subtypes represented, and level of most individual ACPA subtypes. HLA-DR4 SE status appears to further influence the development of only a subgroup of ACPA subtypes. The relative lack of a combined effect between smoking and PD for anti-citrullinated fibrinogen antibodies supports a model in which these autoantibodies are formed in response to airway inflammation-induced citrullination of fibrinogen predisposing to autoantibody formation.

Relationships Between Smoking, HLA-DRB1 Risk Alleles and the Fine Specificity of Anti-Citrullinated Peptide Antibodies in Korean Patients with Rheumatoid Arthritis. Benjamin A. Fisher[1], So-Young Bang[2], Hye-Soon Lee[2], Joo-Hyun Lee[2], Muslima Chowdhury[3], Peter J. Charles[4], Patrick Venables[5] and Sang-Cheol Bae[6]. [1]Kennedy Institute of Rheumatology, Imperial College London, London, United Kingdom, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Imperial College London, London, United Kingdom, [4]Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom, London, England, [5]Kennedy Institute, Imperial College London, London, United Kingdom, [6]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea

Background/Purpose: In North European RA cohorts there is a gene-environment interaction between the HLA-DRB1 shared epitope (SE) and smoking as risk factors for development of disease-specific anti-citrullinated protein/peptide antibodies (ACPA). This is particularly strong for antibodies to citrullinated α-enolase and vimentin peptides. East Asian populations have a differing HLA-DRB1 profile and the aim of this study was to examine such associations in a large Korean cohort where the main risk alleles are *0405 and *0901.

Methods: Levels of antibodies were determined to citrullinated peptides from α-enolase (CEP-1), vimentin (cVim) and fibrinogen (cFib), in addition to CCP2, in 513 South Korean patients. Cut-offs were the 95th percentile of 75 healthy controls. Smoking was defined as never (n=417) or ever (n=96). The Mann Witney U Test was used to compare antibody levels. Logistic regression, adjusted for age and sex, generated odds ratios for RA in a case-control analysis with 1101 controls.

Results: Antibodies to CEP-1, cVim, cFib and CCP2 were positive in 46%, 64%, 75% and 87% respectively. The number of citrullinated peptides recognised, as well as the antibody level against each peptide, significantly increased with the number of copies of the SE. This effect was seen with the most prevalent DR4 allele, 0405, as well as for 0101/1001. However it was not observed with the major non-SE HLA risk allele in this population, 0901, or with smoking. In this population there was also a statistically significant association between the SE and anti-CCP2 negative RA. The SE conferred the strongest risks for subsets positive for both anti-CCP2 and either anti-CEP-1 or anti-cVim antibodies, in non-smokers (OR 14.5 and 17.7 respectively with 2 copies of the SE) as well as smokers (OR 17.6 and 30.8 respectively with 2 copies of the SE). However a gene-environment interaction between the SE and smoking was not limited to these subsets. Moreover, combinations of the SE and DRB1*0901 alleles (SE+*0901) were significantly associated with RA risk for subsets with anti-CCP2 and either anti-CEP-1, anti-cVim or anti-cFib antibodies, in the absence of smoking.

Conclusion: Within this population the SE governed the magnitude and breadth of the anti-citrullinated peptide antibody response. However the SE and smoking gene-environment interaction in relation to ACPA subsets differed from that seen in North European populations.

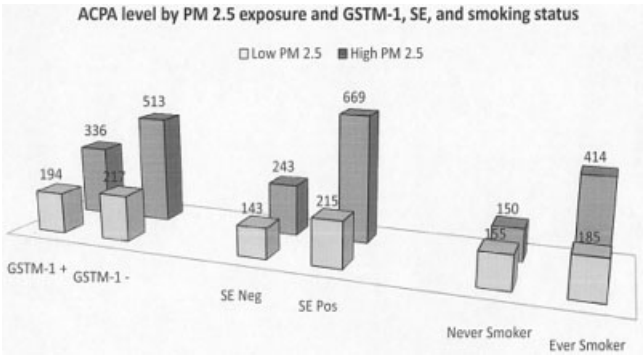
2172

Association of Particulate Air Pollution Exposure with Anti-Citrullinated Protein Antibody Elevation in Rheumatoid Arthritis Patients. Gary A. Kunkel[1], Ryan L. Ragle[1], Daniel O. Clegg[1], Ted R. Mikuls[2] and Grant W. Cannon[1]. [1]Salt Lake City VA and University of Utah, Salt Lake City, UT, [2]Omaha VA and University of Nebraska, Omaha, NE

Background/Purpose: Cigarette smoking is the major environmental risk factor associated with anti-citrullinated protein antibodies (ACPA) positive rheumatoid arthritis (RA), but other inhalational exposures have also been implicated. The purpose of this study was to explore the association of fine particulate air pollution exposure less than 2.5 micrometers in diameter (PM 2.5) with ACPA and to assess whether smoking history, homozygosity for the deletion allele in the enzyme *glutathione S-transferase Mu-1(GSTM-1 null),* and *HLA-DRB1 shared epitope (SE)* status impacted PM 2.5 association on ACPA.

Methods: PM 2.5 exposure was determined for 320 Salt Lake City RA patients enrolled in the Veterans Affairs Rheumatoid Arthritis (VARA) registry residing throughout the intermountain west. Yearly average PM 2.5 values from the nearest (as measured by patient zip code) State and Local Air Monitoring Station (SLAMS) were recorded from the United States Environmental Protection Agency (EPA) website. Associations of high versus low PM 2.5 exposure with ACPA level (as measured by second generation anti-CCP ELISA) were examined, with reference to smoking history, *GSTM1-null,* and *SE* status.

Results: Patients were greater than 90% male and Caucasian, age 65±10 years, positive for ACPA (78.2%) and rheumatoid factor (RF) (77.1%). The low and high exposure group's average yearly PM 2.5 exposures were 6.59±1.14 ug/m3 and 10.61±1.34 ug/m3, respectively. Significantly higher levels of ACPA were seen in the high PM 2.5 exposure group compared to the low exposure group (199±320 u/mL versus 342±665 u/mL, $p<0.02$). Analyses stratified by traditional risk factors including *GSTM-1 null* status, *SE* positivity, and never/ever smoking (figure below) suggest the possibility of interactions between pollution and these genetic and environmental factors. Former smokers constituted the group with the most apparent variation due to air pollution. The analysis of ACPA positivity, RF positivity, and RF showed similar trends but were not statistically significant with this small number of patients.



Conclusion: Particulate air pollution exposure appears to influence ACPA level in this small cohort, particularly in patients with genetic and/or environmental risk for ACPA positivity. Future plans will expand this work to involve other VARA sites to confirm these associations and expand the potential to further explore these genetic and environmental interactions.

2173

Childhood Residential Pesticides and Other Environmental Exposures in Relation to Rheumatoid Arthritis (RA) in Adulthood. Christine G. Parks, Aimee D'Aloisio, Lisa DeRoo and Dale Sandler. NIH/NIEHS, Research Triangle Park, NC

Background/Purpose: Experimental studies show important effects of immunotoxic exposures on the developing immune system, but few studies have addressed childhood environmental risk factors for RA. Here we examine whether childhood residential characteristics and proximity to potential environmental hazards are related to prevalence of rheumatoid arthritis (RA) in adult women.

Methods: The study sample included 50,884 women (ages 35 to 74; median age 55 years; 84% non-Hispanic white, 9% black, 8% Hispanic/other) enrolled 2004–2009 in the Sister Study, a national cohort study of environmental factors and health. Data were obtained from baseline questionnaires. Cases were defined as women reporting doctor-diagnosed RA with onset after age 16 years, who had a history of current or past use of disease modifying anti-rheumatic drugs (DMARDs) or steroids for RA, and bilateral joint swelling lasting 6 weeks or longer. Early life factors included characteristics of longest childhood residence up to age 14,

residential insecticide use and proximity of residence to of a variety of potential environmental hazards. Odds Ratios (OR) and 95% Confidence Intervals (CI) were estimated by logistic regression, adjusting for age and race/ethnicity. We also considered potential confounding by a previously developed score reflecting lower childhood socioeconomic status (SES), pack-years of smoking, and adult education level.

Results: We identified 424 (0.8%) women reporting RA diagnosed after age 16 (median = 47 years at diagnosis) who reported DMARD use or steroids for RA and bilateral joint swelling. Compared to 48,927 women without RA, cases were more likely to report frequent residential pesticide use (8% cases vs. 5% non-cases reported use at least every 1–3 months), personally applying pesticides (4% of cases vs. 2% non-cases reported applying them at least some of the time). After adjusting for age and race, a significant trend was seen for more frequent use of residential pesticides ($p=0.007$), with a strong, though imprecise, association for personally applying them all or most of the time (OR=5.2; 95%CI 2.4, 11.3). In adjusted models, cases also had significantly ($p<0.05$) higher odds of living near an oil refinery (OR=2.2), slaughterhouse or poultry processing plant (OR =1.9), landfill (OR=1.8), drycleaners (OR=1.4) or gas station (OR=1.4). The observed associations were not confounded by childhood SES score, smoking history, or adult educational attainment. No significant differences were seen for urban, town, rural, or farm residence, or water source.

Conclusion: These results suggest residential pesticide use and potential exposure to other environmental hazards in childhood are related to risk of DMARD-treated RA in adulthood. These results add to previous studies on residential insecticide use and RA, and suggest other relevant exposures may include hydrocarbons/solvents, animals/infections, or other types air or water pollutants. Future work will explore the extent to which the observed associations may also be related to ongoing adult exposures.

2174

Periodontal Disease Is Associated with Increased Risk of Incident Rheumatoid Arthritis in Never-Smokers: Results From the First National Health and Nutrition Examination Survey and Its Epidemiologic Follow-up Study. Ryan T. Demmer[1], David R. Jacobs Jr.[2], Bryan S. Michalowicz[2] and Jerry A. Molitor[3]. [1]New York, [2]Minneapolis, MN, [3]Univ of MN MMC108, Minneapolis, MN

Background/Purpose: Periodontal infections have been proposed as rheumatoid arthritis (RA) risk factors. This putative risk is typically confounded by tobacco smoking, which is a known environmental risk for both RA and Periodontitis. We examined whether signs of periodontal infection including gingivitis, periodontitis, and progressive tooth loss were associated with RA development in NHANES I & NHEFS, among never-smokers.

Methods: In 1971–1974, 9,702 men and women, aged 25–74 were enrolled and surveyed longitudinally at four time points (1982, 1986, 1987, and 1992). Of the total, there were 4,424 never smoking individuals without a baseline diagnosis of RA. Periodontal infection was defined by baseline tooth loss or the presence of gingivitis or periodontitis based on periodontal index values. Incident (n=218) RA cases were defined via self-report physician diagnosis, ICD-9 codes (714.0–714.9), death certificates, and/or RA hospitalization. Results were adjusted for age, gender, race and education.

Results: Missing $^{3}5$ teeth was positively associated with increased odds of incident RA. Relative to participants missing 0–4 teeth, the odds ratios(95%CI) for incident RA among never-smoking participants missing 5–8, 9–14, 15–31 or 32 teeth were 1.28(0.69,2.41), 1.56(0.81,3.01), 1.87(0.91,3.86) and 1.92(1.00,3.66), respectively (p for linear trend = 0.04). Odds ratios (OR) for incident RA among participants with gingivitis, periodontitis or those who were edentulous relative to periodontally healthy participants were 0.97(0.53, 1.77), 1.58(0.92, 2.74) and 1.47(0.87, 2.46), respectively (p for linear trend = 0.06).

Conclusion: Among never smokers, periodontal infection surrogates demonstrated weak, positive associations with incident RA, suggesting that periodontal infection may be a risk for RA, independent of smoking.

2175

Prevalence of Periodontitis Is High in Rheumatoid Arthritis Patients and Correlated to Disease Activity. Menke J. de Smit, Johanna Westra, Arjan Vissink, Berber Doornbos-van der Meer, Pieter A. Roelofs, Elisabeth Brouwer and Arie Jan van Winkelhoff. University Medical Center Groningen, Groningen, Netherlands

Background/Purpose: In a general population, the prevalence of severe periodontitis in adults is 10–15%. Co-existence of periodontitis and rheumatoid arthritis (RA) has been reported. These diseases have similarities in etiology, pathogenesis and risk factors. They are possibly linked by protein citrullination and subsequent ACPA response in genetically susceptible individuals. *Porphyromonas gingivalis* is a periodontal pathogen with the unique ability to citrullinate endogenous and human proteins, and human fibrinogen and alpha-enolase, which are auto-antigens in RA. This study aimed to assess the prevalence of periodontitis and the occurrence of *P. gingivalis* in RA patients, together with the correlation between markers of disease activity of RA.

Methods: In a cohort of 95 subsequent dentate RA patients attending our RA out patient clinic, the condition of the periodontium was investigated using the Dutch periodontal screening index for treatment needs (DPSI), which divides patients into category A (patients that require only oral hygiene instruction and calculus removal), category B (patients that require limited periodontal examination), and category C (patients that require extensive periodontal examination). RA disease activity was scored with the DAS28. Smoking and presence of HLA-SE (shared epitope) was determined. Serum was investigated for CRP-, IgMRF- and ACPAlevels. IgG- and IgM antibody titers to *P. gingivalis* were measured by ELISA. Subgingival microbial samples were taken to test for presence of *P. gingivalis*. In addition, ACPA titers in gingivocrevicular fluid (GCF) were measured.

Results: Twenty-seven % of the RA patients belonged to DPSI category C, which is significantly higher than the 12.5% DPSI category C subjects reported in a normal adult population (n=1503) of the same geographic area in the Netherlands ($p<0.0001$). The DAS score of the RA DPSI category C subjects was significantly higher compared to DPSI category A and B RA patients ($p<0.0001$), as were the CRP and IgMRF levels ($p=0.02$ and $p=0.01$). No significant differences in DAS scores between smokers and non- or former smokers were observed, neither when limiting this comparison to RA DPSI category C patients only. Likewise, no significant differences were found between these groups in presence or absence of the HLA-DR shared epitope, a known genetic risk factor for RA and a possible genetic risk factor for periodontitis. Subsequently, between these groups, no significant difference was found in ACPA titer.

Seventeen % of the RA patients were positive for *P. gingivalis,* of which 56 % belonged to DPSI category C. Patients positive for *P. gingivalis* had significant higher IgG anti- *P. gingivalis* titres ($p=0.002$). Also there was a positive correlation between ACPA and IgM anti-*P. gingivalis* levels ($p=0.017$), ACPA and IgMRF titer ($p<0.0001$), and ACPA titer in serum and GCF ($p<0.0001$).

Conclusion: In RA patients the prevalence of patients with periodontitis is significantly higher than a comparable normal adult population. Most strikingly, we found significantly higher DAS28 scores in RA patients with periodontitis, suggesting that periodontitis might attribute to disease activity in RA.

2176

Lung Changes Detected by High Resolution Tomography Are Present in ACPA Positive Rheumatoid Arthritis Patients Already At Disease Onset. Gudrun Reynisdottir[1], Sven Nyren[2], Anders Harju[1], Magnus Skold[3], Anders Eklund[1], Marianne Engström[1], Johan Grunewald[3], Lars Klareskog[4] and Anca Irinel Catrina[5]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [2]Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [3]Respiratory Medicine Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]D2:01, Stockholm, Sweden

Background/Purpose: We have previously shown that smoking increases citrullination in the lungs of healthy smokers and hypothesized that this process is an important step in the early development of rheumatoid arthritis (RA). To test this we investigated lung function in a cohort of RA patients with very early disease, already at the time of diagnosis and compared it with an aged, smoke and gender matched cohort of individuals without RA.

Methods: 82 patients, 56 female and 26 male, median age 60 (range 22–84) with symptom duration less than 1 year at the time of diagnosis and naive to DMARD treatment were included in the RA cohort. A second cohort of age, smoking and gender matched non RA individuals (n=43) were investigated with

an identical protocol. Lung function (X-ray, HRCT and dynamic spirometry) was tested in both RA and controls at baseline and repeated after 6 months in the RA group. All patients were started on anti rheumatic treatment according to clinical practice with 90% of the patients started on methotrexate. In a subgroup of patients bronchoscopy was performed at inclusion (n=18) and 6 months later (n=11) and BAL samples as well as mucosal large bronchial biopsies were retrieved. Presence of peptydilamino deiminase (PAD) enzymes were evaluated by immunohistochemistry

Results: 63% of the patients were ACPA positive, 26% were current smokers and 22% have reported a previous lung pathology. All patients had active disease with a mean DAS of 5.5±0.1 at inclusion that decreased significantly to 3.3±0.2 after 6 months. A majority of the patients (55%) had any type of changes on HRCT either focal or diffuse. Lung changes of any type were more frequent in RA as compared to non RA individuals (35%) with a higher prevalence of lung fibrosis (15/82 in the RA cohort and 0/43 in the control cohort). In the RA cohort 1 patient (1.2%) was diagnosed with lung cancer following HRCT screening while none in the control cohort. ACPA and RF but not smoking status associated with the presence of changes on HRCT. Immunohistochemistry demonstrated a significant increase in expression of both PAD2 and PAD4 in the lungs of current smokers independent of the ACPA status with no significant changes following 6 months of treatment.

Conclusion: Presence of ACPA associates with early lung HRCT changes in RA. We suggest that smoking (and other yet unidentified factors) promotes site specific citrullination (such as in lungs) leading to generation of ACPA immunity and lung changes very early in the disease process.

2177

Investigating the Cellular Composition of Lymph Nodes in Preclinical and Early Inflammatory Arthritis: A Feasibility Study. Lisa G.M. van Baarsen[1], Maria J. H. de Hair[1], Tamara H. Ramwadhdoebe[1], Marleen G. H. van de Sande[1], IJsbrand A.J. Zijlstra[2], Mario Maas[2], Danielle M. Gerlag[1] and PP. Tak[1]. [1]Division of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, [2]Department of Radiology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background/Purpose: Rheumatoid arthritis (RA) is an immune-mediated inflammatory disease of unknown etiology. To ultimately cure or prevent this chronic disease, it is critical to understand the earliest changes in the immune system that cause RA. Recent work has shown that systemic autoimmunity precedes inflammation in the synovium of RA patients. Animal models have suggested that changes in the lymph nodes may precede those in the synovial tissue. To provide insight into the immunological mechanisms involved in the pathogenesis of RA, we developed a method allowing us to obtain lymph node biopsies under local anaesthesia and investigated the cellular composition and distribution within lymph node tissue in individuals at risk of developing RA compared to early arthritis patients and healthy controls.

Methods: Six individuals without any evidence of arthritis upon physical examination who were positive for IgM rheumatoid factor and/or anti-citrullinated protein antibodies were included. For comparison 12 early arthritis patients (1x systemic lupus erythematosus, 1x psoriatic arthritis, 1x gout, 5x undifferentiated arthritis and 4x RA; disease duration <1 year, DMARD naïve), and 4 autoantibody negative healthy controls without joint complaints were included in the study. All study subjects underwent ultrasound-guided inguinal lymph node biopsy. Different T lymphocyte subsets were analysed by multi-color flow cytometry using labelled antibodies specific for CD3, CD4, CD8, CD45 and CD69.

Results: The procedure was well tolerated; no complications occurred. Different T cell subsets could be distinguished and differences between autoantibody positive individuals at risk of developing RA, early arthritis patients and healthy controls could be observed (Table 1). Interim analysis of these small study groups indicate an increase of activated CD69+ T cells in the early arthritis as well as in the at risk group compared to the control group. Interestingly, the CD4/CD8 distribution within the activated T cells was significantly changed in the early arthritis patients compared to healthy controls and the same trend was observed for the at risk group.

Table 1. Distribution of activated CD4+ and CD8+ T cells

CD45+CD3+	% CD69+	% CD4+ of CD69+	% CD8+ of CD69+
Subjects at risk of RA	14.80 (12–21)	78.45 (55–83)	12.55 (10–28)
Early arthritis	18.40 (9–48)	77.45 (84–94)*	15.00 (10–22)*
Healthy controls	10.70 (6–13)	91.20 (84–94)	4.4 (3–13)

Median (IQR); * $p<0.05$ Kruskal-Wallis test plus post Dunn's Multiple comparison test

Conclusion: Flow cytometry analysis of ultrasound-guided inguinal lymph node biopsies is a feasible method for investigating the cellular composition of lymph nodes in the earliest phases of inflammatory arthritis. These preliminary results suggest increased CD8+ T cell activation within lymph nodes of early arthritis patients as well as in autoantibody positive individuals at risk of developing RA. This method provides a unique tool to investigate the immunological changes in the lymph node compartment in the earliest phases of inflammatory arthritis. These data support the rationale for larger studies using more extensive panels of cellular markers.

2178

Type 1 Interferon Signature Predicts Development of Rheumatoid Arthritis. Joyce Lubbers[1], Mikael Brink[2], Lotte A. van de Stadt[3], Saskia Vosslamber[1], John G. Wesseling[1], Dirkjan van Schaardenburg[3], Solbritt M. Rantapaa-Dahlqvist[2] and Cornelis L. Verweij[1]. [1]VU University Medical Center, Amsterdam, Netherlands, [2]Umeå University, Umea, Sweden, [3]Jan van Breemen Research Institute / Reade, Amsterdam, Netherlands

Background/Purpose: Early recognition of development of rheumatoid arthritis (RA) allows timely start of treatment. It is known that antibodies against citrullinated proteins (ACPA) and rheumatoid factor (RF) have a predictive value for development of RA within 5 years. Since only 20–40% of $ACPA^+$ and/or RF^+ arthralgia patients develop RA better prognostic markers are warranted. Recently, we reported gene signatures in the peripheral blood that are relevant to the development of arthritis after a median of 7 months (van Baarsen, A& R, 2010). Gene signatures that are significantly associated with arthritis development involved interferon (IFN) activity. In this study we validate these findings and determine the predictive value of increased IFN activity in arthritis development.

Methods: For independent validation RNA was isolated from peripheral blood mononuclear cells (PBMC) from individuals of the Northern Sweden Health and Disease Study and the Maternity cohorts of Northern Sweden. RNA samples from 22 pre-onset RA patients (median disease duration before RA diagnosis was 3 years), 25 RA patients and 48 age and sex matched healthy individuals were analyzed. In addition, whole peripheral blood RNA of 106 $ACPA^+$ and/or RF^+ arthralgia patients who are clinically followed at Reade, Amsterdam, every year for RA development were used for diagnostic analysis. Gene expression levels of 6 IFN response genes were measured using the BioMark™ Dynamic Array system. An IFN score was determined by averaging the expression levels of these genes. Differences in IFN response score between the healthy controls, pre-onset RA and RA patients were analyzed using Mann-Whitney U test. The diagnostic potential was analyzed using Receiver Operating Characteristics (ROC)-curve analysis.

Results: To validate the presence of the IFN signature in an independent pre-onset RA cohort we analyzed the IFN score in pre-onset RA patients from the Northern Swedish Repository. Analysis of the IFN score in PBMCs from both pre-onset RA and RA samples revealed higher scores compared to HC (Mann-Whitney U test $p=0.0064$ and $p=0.0075$, respectively). No significant difference in the IFN score between pre-onset RA and RA samples was observed. To determine the diagnostic value of the IFN score for the development of arthritis we measured the IFN score in whole blood of $ACPA^+/RF^+$ arthralgia patients from the Amsterdam cohort after a median follow-up of 40 months. Out of 106 patients included 38 arthralgia patients had developed arthritis. Comparison of the IFN score at inclusion, between the arthritis converters and non-converters, confirmed the increased score in the arthritis converters (Mann-Whitney U test $p=0.0435$). ROC-curve analysis revealed an area under the curve of 0.601 ($p=0.043$), indicative for diagnostic potential of the use of the IFN score for diagnosing the pre-onset phase of RA.

Conclusion: Our results confirm the increased IFN response gene expression in the pre-onset stage of RA in an independent pre-onset RA cohort. Furthermore, we demonstrate the potential of using the IFN score for diagnosing the pre-onset stage of RA. Altogether, these results support the potential of using the IFN signature as a biomarker for early diagnosis of RA.

Identification of Shared Citrullinated Potentially Immunological Targets in the Lungs and Joints of Patients with Rheumatoid Arthritis. Jimmy Ytterberg[1], Gudrun Reynisdottir[1], Elena Ossipova[1], Aase Haj Hensvold[2], Anders Eklund[3], Magnus Skold[3], Johan Grunewald[3], Karin Lundberg[4], Vivianne Malmström[4], Per Johan Jakobsson[5], Roman Zubarev[4], Lars Klareskog[4] and Anca Irinel Catrina[1]. [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [2]Rheumatology unit, 171 76 Stockholm, Sweden, [3]Respiratory Medicine Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Rheumatology Unit, Karolinska Institutet; Karolinska University hospital, Stockholm, Sweden

Background/Purpose: We have previously demonstrated that smoking induces citrullination in the lungs of healthy smokers and we know that anti citrullinated protein antibodies (ACPA) develop in rheumatoid arthritis (RA) patients many years before disease onset. We hypothesized that shared citrullinated targets are present in the lungs and joints of RA affected individuals and sought to investigate this by full-proteome analysis of synovial and lung biopsies of RA patients.

Methods: Proteins were extracted from synovial (n=7, 5 females and 2 males, median age 58, 66.7% ACPA positive) and lung (n=6, 4 females and 2 males, median age 63, 66.7% ACPA positive) biopsies of RA patients. Synovial biopsies were obtained at the time of open surgery from patients with longstanding RA (mean disease duration 24 years). Large bronchi biopsies were obtained by bronchoscopy from patients with newly diagnosed RA (3 smokers and 3 non smokers) with symptom duration less than 1 year. The proteins were reduced, alkylated and digested with Lys-C, separated by reverse phase nanoflow chromatography and analyzed by LTQ Velos Orbitrap using multiple fragmentation methods. The data were searched against the human IPI database using the Mascot search engine and all citrullinated peptides were manually verified. Relative protein levels were quantified by label free approach using in-house written programs (Quanti), while the degree of modification was quantified manually. The final results were expressed as ratios of citrullinated versus non-modified peptides.

Results: Over 3300 peptides and 500 proteins were identified and quantified in the different samples. The overall protein profiles varied between patients. 5 of the identified proteins in the synovium (in total 8 sites) and 4 in the lungs (in total 4 sites) contained citrullinated residues. Two vimentin derived citrullinated peptides were present in a majority of synovial and lung biopsies with slightly higher citrullinated/unmodified peptides ratios in the smokers as compared to non-smokers (median ratio of 0.03 in smokers and 0.02 in non smokers for one of the peptides and a median ratio of 4.5 in the smokers and 0.04 in the non smokers for the second vimentin peptide). While non-modified and citrullinated fibrinogen a chain derived peptides were present in various amounts in the synovium, only the unmodified sites could be detected in the lungs of a subset of the patients (3 out of 6)

Conclusion: We demonstrate the presence of shared in vivo citrullinated proteins in the joints and lungs of RA individuals, providing further support for the important pathogenic link between joints and lungs in development of RA.

2180

A Disease-Modifying Role for Mucosal IgA Antibodies to Citrullinated Antigens? Anna Svärd[1], Alf Kastbom[2], Yngve Sommarin[3] and Thomas Skogh[4]. [1]Linköping University, Falun, Sweden, [2]Linköping University, Linköping, Sweden, [3]Euro-Diagnostica AB, Malmö, Sweden, [4]Linkoping University, Linkoping, Sweden

Background/Purpose: The aim of this pilot study was to investigate whether IgA antibodies to cyclic citrullinated peptides (CCP) can be detected in saliva of patients with established rheumatoid arthritis (RA) and if it relates to clinical manifestations.

Methods: Salivary samples were collected (by 'passive drewling') from 63 consecutive patients with established RA at a visit to the rheumatology outpatient clinic (Falun, Sweden), and from 20 healthy persons (hospital staff). The samples were centrifuged and kept frozen at −20°C until analysis. IgA-class anti-CCP antibodies in saliva were analysed by adaptation of a commercial ELISA (Immunoscan RA, *Euro-Diagnostica* AB, *Malmö*, Sweden) using polyclonal rabbit antihuman alpha-chain specific antibodies conjugated with horseradish peroxidase (DakoCytomation, Glostrup, Denmark) as secondary antibody.To ensure specificity of the reaction, a corresponding ELISA was set up to analyse IgA antibodies to control antigen (cyclic arginine peptide, CAP), and anti-CCP/anti-CAP ratios were calculated. Also, inhibition studies were performed by preincubation of sera with soluble CCP or CAP. Clinical and laboratory data on disease activity, *i.e.* C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and 28-joint count disease activity score (DAS28) as well as radiological outcome (occurrence or absence of erosions as judged by a radiologist in diagnostic routine) were achieved retrospectively via the patients' medical records.

Results: Background reactivity against CCP was found in virtually all patients and healthy subjects, whereas a positive anti-CCP/anti-CAP ratio (≥1.5) was found in 14 out of 63 RA patients (22%) and in one healthy subject (5%). Salivary IgA-reactivity with CCP was dose-dependently inhibited by soluble CCP (but not with CAP) in sera with anti-CCP/anti-CAP ratios ≥1.5. No IgG-reactivity to CCP was found in saliva, although all patients with salivary IgA anti-CCP tested IgG anti-CCP-positive in serum. Furthermore, less than half of those testing IgA-positive in saliva were IgA anti-CCP positive in serum, strongly arguing against passive leakage of anti-CCP antibodies from blood to saliva. The patients testing positive for salivary IgA antibodies had lower average disease activity measures (CRP, ESR, DAS28) at presentation and fewer developed bony erosions within six years after presentation (p=0.043, Fisher's exact test).

Conclusion: Salivary IgA antibodies to citrullinated proteins were found in a subset of IgG anti-CCP positive RA patients. In contrast to their serum counterparts, salivary IgA antibodies may associate with a milder/less destructive disease course. This accords with the notion that secretory IgA antibodies exert anti-inflammatory actions, and that they may be associated with induction of systemic tolerance (oral tolerance). The possible disease-modifying role of mucosal immunity to citrullinated proteins needs further investigation!

2181

The ACPA Recognition Profile and Sub-Grouping of APCA Positive Rheumatoid Arthritis Patients. Annemiek Willemze, Stefan Böhringer, Rachel Knevel, E.W. Nivine Levarht, Gerrie Stoeken-Rijsbergen, Jeanine J. Houwing-Duistermaat, Annette H.M. van der Helm-van Mil, Tom W.J. Huizinga, René E.M. Toes and Leendert A. Trouw. Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are the most predictive factor for the development of rheumatoid arthritis (RA). Epitope spreading towards more citrullinated epitopes occurs before the onset of RA. Here, we investigated whether specific subsets of RA patients can be distinguished on the basis of specific epitope recognition and determined the association of the ACPA fine specificity with clinical features of RA.

Methods: The reactivity of 661 RA patients, from the Leiden Early Arthritis Clinic (EAC), against several citrullinated antigens was determined by enzyme-linked immunosorbent assay (ELISA). Cluster analyses were performed to identify subgroups of patients on the basis of their ACPA-recognition profile and principal component analyses were performed to reduce data complexity. The association of the specific reactivities with clinical characteristics was studied.

Results: ACPA-positive patients displayed a heterogeneous ACPA-recognition profile. After performing a cluster analysis and a principal component analysis no apparent clustering of patients was found and on the basis of the reactivities analyzed, already 64 different subgroups could be identified. The extent of epitope recognition was associated with anti-CCP2-levels. The recognition of specific citrullinated epitopes was not associated with baseline characteristics. Likewise, patients with an extended fine specificity repertoire did not display differences in baseline characteristics or joint damage after 7 years of follow up using anti-CCP2 levels as a proxy, compared to ACPA-positive patients recognizing fewer peptides.

Conclusion: These data show that the ACPA-response is highly diverse with respect to recognition of specific epitopes. This diversity hampers further 'subgrouping' of ACPA-positive patients to define more homogenous patients groups that share baseline characteristics or radiological outcome.

Total Protein, Citrullination and Autoantibodies Are Elevated in Lungs of Patients with Established Rheumatoid Arthritis Compared to Controls: Pilot Study Results. Van Willis[1], Mark Parish[1], Lezlie A. Derber[2], M. Kristen Demoruelle[3], Jason R. Kolfenbach[4], Chris Striebich[3], Peter Sachs[3], David Lynch[5], Russell Bowler[5], Kevin K. Brown[6], V. Michael Holers[4] and Kevin D. Deane[3]. [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado AMC, Aurora, CO, [3]University of Colorado School of Medicine, Aurora, CO, [4]Univ of Colorado School of Med, Aurora, CO, [5]National Jewish Health, Denver, CO, [6]National Jewish Hospital, Denver, CO

Background/Purpose: Autoantibodies (Abs) to citrullinated proteins and other antigens may be a key part of the pathogenesis of articular as well as extra-articular disease in rheumatoid arthritis (RA). To evaluate the potential role of citrullination, antibodies to citrullinated protein antigens (ACPAs) and rheumatoid factor (RF) in RA-related lung disease, herein we evaluated levels of total and citrullinated proteins, anti-cyclic citrullinated peptide-2 (aCCP2) antibodies and RF isotypes in bronchoalveolar lavage (BAL) and sputa samples from subjects with established RA and interstitial lung disease (ILD), early RA with asymptomatic airways disease, and several control groups.

Methods: BAL samples from 5 patients with established RA-ILD (3 smokers), 5 with scleroderma (SSc)- ILD (2 smokers) and 32 healthy controls (20 smokers) were tested for levels of total protein (TP) (Pierce BCA method, Thermo Fischer Scientific Inc, USA) and citrullinated protein (CP) (colorimetric method, Knipp et al 2000). All BAL samples were tested by ELISA methods for aCCP2 (Axis-Shield, UK) and RF isotypes IgA, G, and M (INOVA, USA). aCCP2 testing was also performed on sputa samples from 5 additional patients with early seropositive RA (<8 mos. duration of symptoms) with asymptomatic airways disease without ILD per research-related lung high-resolution computed tomography, as well as sputa from 8 healthy controls.

Results: TP levels were increased in BAL from patients with RA-ILD and SSc-ILD compared to healthy controls ($p<0.01$) (Table). CP were present to some degree in most subjects, including controls; however, the highest median levels of CP were observed in subjects with RA-ILD ($p<0.05$) (Table). Patients with RA-ILD also had higher BAL aCCP2 and RF isotype levels compared to controls ($p<=0.03$) (Table). Finally, in the 5 patients with early RA and asymptomatic airways disease the median level of aCCP was significantly elevated compared to the 8 controls (35 vs. <1; $p<0.01$).

Median levels of total and citrullinated protein and rheumatoid arthritis (RA)-related autoantibodies in broncho-alveolar lavage (BAL) fluid

	RA-ILD (N=5)	SSc-ILD (N=5)	Healthy controls, never smokers (N=12)	Healthy controls, smokers (N=20)	P-value*
Total protein (pg/mL)	232	135	28	57	<0.01
Citrullinated protein (uM)	70	26	7	11	<0.01
aCCP2 (units)	100	<1	<1	<1	<0.01
RF-IgA (units)	62	3	7	29	<0.01
RF-IgG (units)	19	5	4	6	0.03
RF-IgM (units)	16	<1	<1	<1	<0.01

* Kruskal-Wallis testing comparing median BAL levels of autoantibodies across all groups

Conclusion: Levels of TP and CP are increased in the BAL of patients with RA-ILD compared to controls. This may represent increased protein generation in the lungs of these patients, and increased citrullination related to the inflammation of RA-ILD. Also, aCCP2 and RF isotype levels are increased in the BAL in patients with RA-ILD, and aCCP2 is increased in the sputa from patients with early RA and asymptomatic airways disease, suggesting that these autoantibodies may play a role in the pathogenesis of lung injury. Further studies are necessary in order to evaluate the types and citrullination status of lung proteins in RA patients, mechanisms of citrullination, and the potential pathogenic roles of aCCP2 and RF in lung injury.

A Serological Proteome Approach for Screening of Autoantigens From Korean Rheumatoid Arthritis Patients. Sung-Hoon Park[1], Ji Hun Kim[1], Seong-Kyu Kim[2], Jung-Yoon Choe[3], Sang-Hyon Kim[4], Yong-Hak Kim[5], Yeonkyung Park[5] and Mina Choi[5]. [1]Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegu, South Korea, [2]Arthritis and Autoimmunity Research Center, Catholic University of Daegu School of Medicine, Daegue, South Korea, [3]Arthritis and Autoimmunity Research Center, Catholic university of Daegu, School of mediine, Daegu, [4]Dongsan Medical Center, Keimyung University, Daegu, South Korea, [5]Catholic univeristy of Daegu, School of Medicine, Daegu, South Korea

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic, autoimmune, systemic inflammatory disease. An immunogenic autoantigen or antibody is still not clearly elucidated. We used a serological proteome approach in order to screen RA antigens and overview the underlying disease mechanism.

Methods: A whole cell extract of human osteosarcoma Cybrid rho(0) cells was used as a source of human antigens. Total proteins were analyzed by 2D gel electrophoresis and Western blotting with two pools of sera of female RA patients ($n = 6$; age = 35 ~ 59, mean ± SD = 46.2 ± 8.7) and healthy control women ($n = 6$, age = 30 ~ 58, mean ± SD = 43.3±11.1). Antigen spots showing >2-fold differences in Western blot data were identified from 2D gels, and trypsin-digested peptide extracts were analyzed on an LC-mass instrument. Proteins were identified by the X!Tandem search of mass data against a non-redundant database of human female (http://ppp.thegpm.org/) with high probability of $\log(e) < -2$ and false discover rate < 0.01, and were enlisted to analyze proteins associated with disease pathways.

Results: 2D gel and Western blot analysis with the sera of RA patients and healthy controls distinguished a total of 91 antigen spots, in which 49 spots were highly detected with the RA sera, and 42 spots with the normal sera. Protein entities were obtained from mass data of 46 RA and 39 normal spots, which accounts for 93.4% of the isolated spots from 2D gels. From identified spots, 25 RA and 17 normal spots had single proteins identified by two or more unique peptides. Analyses of protein association network (http://string-db.org/) and KEGG pathway database (http://www.genome.jp/kegg/pathway.html) showed that serologically identified RA factors were most probably related to a p53-signaling pathway leading to the control of cell cycle and apoptosis. In contrast, normal antigens were common components of glycolysis, DNA complex assembly, and splicesome.

Conclusion: A serological proteome approach was useful for screening of specific autoimmune factors associated with RA patients. The success rate of this approach was roughly 93.4% (85/91) from the mass data. However, it was accurately 46.2% (42/91) based on high resolution 2D gel and blot imaging system for identification of true antigens from single spots. Our study shows that RA factors may associate with some components of a p53-signaling pathway triggering cell cycle arrest and apoptosis. Further studies for verification and validation of these factors remain to be done.

Could Presence of Antibodies to Citrullinated Proteins Be More Strongly Associated to Bone Than Cartilage Destruction? Results From a 10-Year Prospective Study. Silje Watterdal Syversen[1], Pernille Bøyesen[2], Guro Løvik Goll[1], D. Van Der Heijde[3] and Tore K. Kvien[2]. [1]Oslo, Norway, [2]Diakonhjemmet Hospital, Oslo, Norway, [3]Leiden University Medical Center, Leiden, Netherlands

Background/Purpose: A more destructive disease course is a key feature of antibody positive RA. Although the strong association between ACPA status and radiographic progression is well established, the underlying mechanisms for this association are not known. The slightly higher disease activity in antibody positive patients can not alone ex-

plain this difference, but whether the antibodies are causually related to destruction of either bone or cartilage remains to be clarified. The aim of this study was to take advantage of clinical data from a long-term prospective study to establish whether ACPA status is related to joint destruction in general, or to either bone or cartilage destruction in particular.

Methods: The study population consists of patients included in the 10-year prospective EURIDISS study (n=238, disease duration <4 yrs. mean 2.3 yrs, 61% ACPA positive). A longitudinal data collection was performed including clinical data, serum sampling, conventional radiographs and assessment of bone mineral density (BMD). The radiographs were scored according to the vdH Sharp score with separate scores for erosions and joint space narrowing (JSN). Change in erosion score and JSN score over ten years are used as outcomes of bone and cartilage destruction. ACPA was measured by anti-CCP2 (INOVA®). Biomarkers of bone- (CTX-I (Nordic Biosience®)) and cartilage destruction (COMP (Anamar®) and C2C (Ibex®)) were assessed in baseline samples. Total and percentage change in BMD over 5 yrs were used as outcomes of generalised bone loss. Linear regression was performed both to assess the relation between ACPA status and progression in erosion and JSN score and change in BMD. Comparions between groups were performed by Mann-Whitney test.

Results: A positive ACPA status predicted 10-year progression both in the erosion and the JSN component of the vdHSS, but was more strongly associated to the change in the erosion component than to the change in the JSN score (standardized β 0.40 versus 0.26). ACPA positivity explained 16% of the change in erosion score, whereas only 6% of the change in JSN score could be attributed to ACPA status. Results remained when adjusting for markers of systemic inflammation. ACPA positive patients had higher baseline levels of the bone degradation marker CTX-I (0.43 ng/ml versus 0.33 ng/ml, $p < 0.01$), whereas levels of the two cartilage degradation markers (COMP, C2C) were similar in ACPA positive and negative patients. Furthermore, the generalised bone loss was higher in ACPA positive patients (6.8% loss in BMD versus 2.1% loss in BMD over 5 year, $p < 0.001$). A positive ACPA status explained 15% of the change in BMD, and remained the strongest predictor of long-term generalized bone loss, also when adjusting for gender and markers of systemic inflammation.

Conclusion: This study suggests that ACPA status might be more strongly associated to bone degradation than cartilage destruction, and furthermore raises the hypothesis that ACPA might act pathogeneic in the osteoclast mediated destruction of the joints by other mechanisms than just amplification of inflammation.

Rheumatoid Arthritis Patients Have Anti-Homocitrullinated Fibrinogen Antibodies. Mathias Scinocca[1], David A. Bell[1], Janet Pope[2], Ewa Cairns[1] and Lillian J. Barra[1]. [1]Schulich School of Medicine and Dentistry, London, ON, [2]Univ of Western Ontario, London, ON

Background/Purpose: Homocitrulline is generated by the chemical modification of lysine and is structurally similar to citrulline, the latter has been detected in the joints of RA patients using antibodies to modified citrulline (AMC). A recent study indicates that AMC cannot distinguish citrulline from homocitrulline. Antibodies to citrullinated peptides (ACPA), including citrullinated fibrinogen, are thought to be specific to RA and strongly linked to the Shared Epitope (SE), the major genetic risk factor for this disease. However, it is unclear whether RA patients also have antibodies to homocitrullinated peptides. Our specific objective was to determine the presence of anti-homocitrullinated fibrinogen antibodies (AHFA) in patients with RA and other rheumatic conditions and whether homocitrullinated peptides of fibrinogen are predicted to bind to the SE.

Methods: A commercial preparation of human fibrinogen (CalBiochem™) was homocitrullinated via a reaction with potassium isocyanate and confirmed by mass spectrometry. It was used in ELISA to detect AHFA and anti-citrullinated fibrinogen antibodies (ACFA) from patient serum (RA, Systemic Lupus Erythematosus (SLE) and Psoriatic Arthritis (PsA) meeting ACR criteria). All RA patients were anti-CCP2 positive.

Results: 85/103 lysines showed evidence of homocitrullination present in all three chains of fibrinogen, comprising 34 peptides predicted to bind to the SE using a modified algorithm by *Hammer et al.* Of these 34 peptides, 5 homocitrullinated peptides were previously shown to be capable of being citrullinated. Antibodies to this homocitrullinated fibrinogen were found in 16/46 RA patients (mean 12.73+/− 38.6 RU/ml), but only 1/37 PsA patients (mean 1.16+/−2.56 RU/ml), 1/37 age-matched normals (mean 1.43+/−2.37 RU/ml) and no SLE patients (n=37, mean 0.56+/−3.0 RU/ml); $p<0.0001$ for RA compared to others. 36/46 RA patients were also positive for ACFA and of these 14/36 were AHFA positive. All of the ACFA negative patients were also AHFA negative.

Conclusion: Fibrinogen can be extensively homocitrullinated and citrullinated. Both citrullinated and homocitrullinated fibrinogen appear to be autoantigens specific to RA.

2186

Heterogeneity in the Memory B Cell Compartment in the Bone Marrow in Human Rheumatoid Arthritis. Arumugam Palanichamy, Christopher A. Cistrone, Jennifer Hossler, Teresa Owen and Jennifer H. Anolik. University of Rochester, Rochester, NY

Background/Purpose: In addition to being the site of B cell development, the bone marrow (BM) contains mature lymphocytes that may participate in secondary immune responses including formation of germinal centers. However, the detailed phenotype, function, and regulation of mature B cell subsets in the BM microenvironment in humans is largely unexplored, particularly in the setting of autoimmunity.

Methods: BM aspirates and paired peripheral blood (PB) samples were collected from RA patients and age-matched normal controls (NC) (n=10). B cell subsets and effector molecules were defined using multiparameter flow cytometry by the expression of markers including CD19, IgD, CD27, Mitotracker G, CD10, CD38, CD24, B220, CD95, CXCR3 and CD21. In select experiments, B cells were enriched by rosette separation and single memory B cells from the switched (SM: IgD-, CD27+), unswitched (USM: IgD+, CD27+) and double negative memory (DN: IgD-, CD27-) subsets were sorted. Sorted naïve (IgD+, CD27-) B cells served as controls. B cell mRNA was reverse transcribed, immunoglobulin (Ig) genes were amplified by a nested PCR and products sequenced. Rearranged Ig gene products were compared to the closest germline fit on JoinSolver and a detailed mutational analysis was performed.

Results: Both NC and RA contained diverse mature memory B cell populations in the BM. The USM population in RA BM was decreased compared to NC BM (P=0.02) Analysis of activated, effector phenotype molecules on BM memory subsets showed significant levels of B220+, CD95+ and CXCR3+, with some RA subjects displaying a profound expansion of effector memory. Interestingly, the expression level of these molecules between BM and PBL subsets were closely comparable. However, in the RA DN compartment, the CD24- effector subset was larger in the BM (P=0.04, BM Vs. PB) and CXCR3+, CD95+ subsets represented in lower levels (P=0.001, BM Vs. PB). On the molecular level, the overall mutational frequencies in the SM, USM and DN Ig genes were similar between RA and NC BM. However, detailed mutational analysis revealed that all memory subsets in RA BM showed increased transversions compared to NC counterparts (P=0.001). Of note, SM and DN fractions from RA PB showed an elevated mutational frequency compared to NC PB (SM: 7.7% vs. 5.8%, DN: 4.5% vs. 2.8%). Moreover, similar to BM, RA PB also had elevated levels of transversions compared to NC PB ($P<0.05$ in all cases). Further analysis revealed a distinct pattern of nucleotide substitutions in RA BM and PB memory B cells compared to NC counterparts (e.g. predominant T/A to G substitutions in the RA BM SM B cells and T to C substitutions in RA PB SM B cells).

Conclusion: Tissue specific differences in the effector molecule expression on B cell subsets in RA suggests preferential homing or in-situ generation of these B cells in the BM. Elevated transversions in RA memory B cells may indicate increased activity of Uracil DNA glycosylase and warrants further investigation to understand the precise mechanisms underlying the mutational machinery in an autoimmune setting.

Tocilizumab and Tumor Necrosis Factor Inhibitors in Biologic Switchers: Similar Drug Survival and Safety with Different Infection Profile in Routine Practice. Kazuki Yoshida[1], Kazuo Matsui[1], Hiroto Nakano[1], Hideto Oshikawa[1], Masako Utsunomiya[1], Tatsuo Kobayashi[1], Makiko Kimura[1] and Mitsumasa Kishimoto[2]. [1]Kameda Medical Center, Kamogawa City, Japan, [2]St Luke's International Hospital, Chuo-ku, Tokyo, Japan

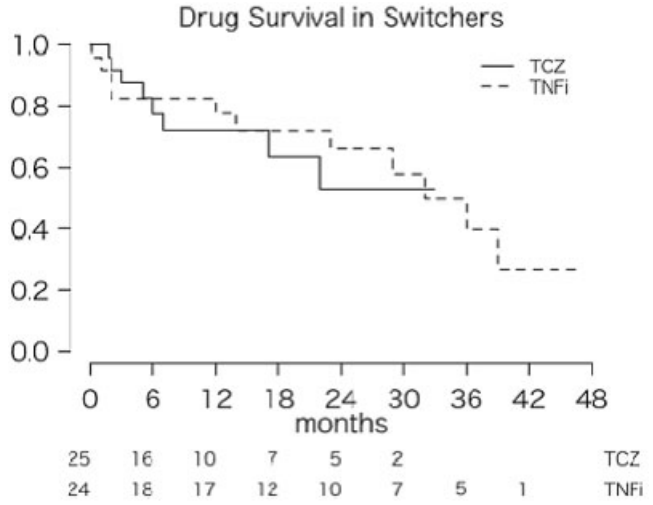
Background/Purpose: To compare the difference between tocilizumab (TCZ) and tumor necrosis factor inhibitors (TNFi) on safety and drug survival time.

Methods: We studied rheumatoid arthritis (RA) patients in the Cohort of Arthritis Biologic Users at Kameda Institute (CABUKI) registry from Jul/2003 to Apr/2011. Kaplan-Meier drug survival estimates of second-line TCZ and TNFi were analyzed with log rank test, and baseline predictors of poor drug survival were determined using multivariable-adjusted Cox regression models. We also examined the rates of serious adverse events (SAE; defined as hospitalization or IV antibiotic use) per 100 person-years (PY) of drug usage.

Results: We identified 260 patients who received TCZ (n=51) and TNFi (n=209, infliximab 102, etanercept 101, adalimumab 6). Among these patients, 49 patients who received second-line TCZ (n=25) and TNFi (n=24, infliximab 3, etanercept 19, adalimumab 2) were included for drug survival analysis. For multivariate models and SAE analysis, in addition to the second-line biologic users, 200 first-line (TCZ 19 and TNFi 181) and 11 third-line (TCZ 7 and TNFi 4) biologic users were also included.

No baseline characteristics were significantly different although second-line TCZ users had a shorter mean follow-up duration (TCZ 12.47 mo vs TNFi 19.71 mo, p=0.053) and a higher mean age (TCZ 60.68 yr vs TNFi 54.17 yr, p=0.118). Disease activity score-28 (DAS28) did not significantly differ between the groups (TCZ 5.1 ± 1.3 and TNFi 4.8 ± 1.1, p=0.423).

Drug survival was also comparable (p=0.732) between the second-line TCZ (77.5% at 6 mo; 72.3% at 12 mo) and TNFi (82.5% at 6 mo; 77.6% at 12 mo) users (Figure 1).



The reasons for drug discontinuation were: ineffectiveness (TCZ 50.0% vs TNFi 36.4%), side effects (12.5% vs 27.3%), patient preference (12.5% vs 9.1%), MD preference (12.5% vs 0%), and good response (12.5% vs 27.3%). Baseline factors affecting drug survival were BMI (HR1.06, [1.01, 1.10]), previous exposure to biologics (HR0.44, [0.27, 0.73]), and NSAIDs (HR0.59, [0.41, 0.84]).

Mean rates of SAEs were not significant different: 46.9/100PY for the TCZ group and 36.0/100PY for the TNFi group (p=0.621, t-test). Serious soft tissue infections, some requiring surgical interventions, occurred in 4 patients receiving TCZ (mediastinitis, orbital cellulitis, dog bite infection, joint injection site infection, and elbow bursitis), whereas only 3 patients receiving TNFi experienced such infections (vertebral osteomyelitis, septic arthritis, and cellulitis) although a larger number of patients were present in the TNFi group.

Conclusion: Drug survival was comparable between second-line TCZ and TNFi in routine practice. Although SAE rate was similar for both drugs, serious soft tissue infections may be more common among TCZ users. Both physicians and patients should be vigilant about this type of infection.

2188

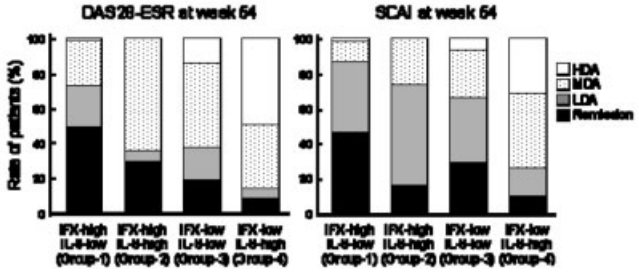
Clinical Efficacy of Infliximab Is Maximized When Both Circulating TNF and IL-6 Are Suppressed In the Treatment of Rheumatoid Arthritis—Results From the RISING Study. Tsutomu Takeuchi[1], Yoshihiko Tatsuki[2], Toshiro Yano[2], Toru Yoshinari[2], Nobuyuki Miyasaka[3], Tohru Abe[4] and Takao Koike[5]. [1]School of Medicine, Keio University, Tokyo, Japan, [2]Mitsubishi Tanabe Pharma Corporation, Osaka, Japan, [3]Tokyo Med & Dent Univ, Tokyo, Japan, [4]Saitama Medical School, Kawagoe-shi Saitama, Japan, [5]Sapporo Medical Center NTT EC, Sapporo, Japan

Background/Purpose: We have previously reported the practicability of the dose escalation of infliximab (IFX), an anti-TNF antibody, in MTX-refractory patients with rheumatoid arthritis (RA) in the RISING study (NCT00691028)*. Here, we show the analysis of the clinical response from the viewpoints of serum IFX level and plasma IL-6 level.

Methods: After the patients with RA refractory to MTX received 3 mg/kg IFX infusion at weeks 0, 2, and 6, they were randomly assigned for the administration of 3, 6, or 10 mg/kg IFX, every 8 weeks from week 14 to 46 in a double-blind manner (n=307). Disease activity was evaluated at week 54 by using DAS28-ESR or SDAI. Serum IFX and plasma IL-6 levels were measured by ELISA. Because the circulating TNF level could not be measured correctly in the presence of IFX, we used IFX level as the surrogate marker of the TNF level. For an index in TNF and IL-6 level, we stratified all patients who had complete data at week 54 (disease activity, IFX level and IL-6 level, n=271) into four groups: Group-1 (IFX-high/IL-6-low: suppression seen in both TNF and IL-6); Group-2 (IFX-high/IL-6-high: suppression in TNF only); Group-3 (IFX-low/IL6-low: suppression in IL-6 only); Group-4 (IFX-low/IL6-high: neither TNF nor IL-6 were suppressed). The cut-off values of IFX and IL-6 levels were determined as <1 μg/ml (the threshold level for clinical response of IFX) and <10 pg/ml (below the third quartile at week 54).

Results: Immediately after starting IFX treatment, the IL-6 level was markedly decreased. Median (IQR) IL-6 level at baseline (week 0) and at week 54 were 28.9 (12.8, 65.0) and 2.4 (0.9, 16.3) pg/ml, respectively, and the median reduction rate was 87%. IFX level closely and negatively correlated with the IL-6 level (rho=-0.58, p<0.001). Both IFX and IL-6 levels were closely correlated with disease activity as well as various components such as tender/swollen joint counts and patient global assessment. The number of patients in Group-1, 2, 3 and 4 were 134, 31, 48, and 58, and approximately half of the patients were in Group-1 (both TNF and IL-6 were suppressed). There is a significant difference in the clinical responses among Groups-1, 2, 3 and 4, and Group-1 exhibited the highest clinical response, especially clinical remission. Meanwhile, Group-4 (neither TNF nor IL-6 were suppressed) showed the lowest rate of response. Clinical response in Group-2 and Group-3 were intermediate values between those of Group-1 and Group-4 (Fig.). Similar results were obtained in the other components of disease activity.

Fig. The influence of serum IFX level and plasma IL-6 level on the disease activities at week 54.



Conclusion: IFX therapy remarkably suppressed not only TNF, but also the IL-6 level in RA patients. The clinical efficacy of IFX therapy was maximized when both circulating TNF and IL-6 were suppressed by the treatment.

Combination Therapy with Adalimumab+Methotrexate Significantly Improved Work Ability, Physical Function, Fatigue, and Other Patient-Reported Outcomes in Early Rheumatoid Arthritis: Results From a 26-Week Analysis. Paul Emery[1], Arthur F. Kavanaugh[2], Josef Smolen[3], Mary A. Cifaldi[4], Leonardo Chaves[4], Benoit Guerette[5], Vipin Arora[4] and Ronald F. van Vollenhoven[6]. [1]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [2]University of California San Diego, San Diego, CA, [3]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [4]Abbott Laboratories, Abbott Park, IL, [5]Abbott, Rungis, France, [6]The Karolinska Institute, Stockholm, Sweden

Background/Purpose: To compare work ability assessments and other patient-reported outcomes (PROs) in early rheumatoid arthritis (RA) patients treated with adalimumab (ADA)+methotrexate (MTX) vs. MTX+placebo (PBO) over 26 weeks.

Methods: OPTIMA (Optimal Protocol for Treatment Initiation With MTX and ADA in Patients With Early RA) was a Phase IV, double-blind, randomized, placebo-controlled trial. The overall study design has been described elsewhere[1]. This analysis evaluated the Period 1 (26 weeks) PRO, comparing ADA+MTX vs. MTX+PBO. Work outcomes were assessed with the Work Productivity and Activity Impairment (WPAI) questionnaire, percentage of employed patients, and Work Instability Scale (WIS). Other PROs evaluated included: Patient's Global Assessment of disease activity (PaGA; 100-mm visual analog scale (VAS]), Patient Assessment of Pain (PAP; 100-mm VAS), EuroQOL (100-mm VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and Patient Assessment Acceptable State (PASS; yes/no). The intent-to-treat population was analyzed and data were imputed using last observation carried forward. For continuous variables, treatment group homogeneity was assessed using 1-way ANOVA. Discrete variables were analyzed using chi-square or Kruskal-Wallis tests.

Results: There were no significant differences between treatment groups with respect to baseline demographics and disease characteristics or baseline PRO assessments, with the exception of employment status. Fewer patients in the ADA+MTX group compared with the MTX+PBO group were employed at baseline (49% vs. 55%; p=0.046). Significant differences between the ADA+MTX and PBO+MTX groups were observed for all PROs as early as Week 4. Improvements were maintained through Week 26. The table summarizes HAQ, PAP, FACIT-F, and WPAI results.

Patient-Reported Outcomes: Change From Baseline to Weeks 4 and 26

	ADA+MTX (N=515)	PBO+MTX (N=517)	P-Value
HAQ			
Change at Week 4 (mean±SD)	−0.64±0.61 (n=511)	−0.31±0.54 (n=512)	p<0.001
Change at Week 26 (mean±SD)	−0.89±0.74 (n=512)	−0.66±0.73 (n=512)	p<0.001
PAP			
Change at Week 4 (mean±SD)	−28.9±26.15 (n=512)	−15.6±22.70 (n=513)	p<0.001
Change at Week 26 (mean±SD)	−37.9±28.61 (n=513)	−28.0±29.33 (n=513)	p<0.001
FACIT-F			
Change at Week 4 (mean±SD)	8.1±10.28 (n=502)	4.4±8.70 (n=508)	p<0.001
Change at Week 26 (mean±SD)	10.5±11.82 (n=506)	8.3±11.12 (n=512)	p=0.001
WPAI Total Work Productivity Impairment			
Change at Week 4 (mean±SD)	−13.9±29.39 (n=205)	−5.4±24.32 (n=220)	p<0.001
Change at Week 26 (mean±SD)	−23.4±33.1 (n=215)	−16.5±31.20 (n=232)	p=0.002

Importantly, for those employed at baseline, more patients in the ADA+MTX group compared with the PBO+MTX group were still employed at Week 26 (85.9% vs. 76.3%; p=0.005). No differences were observed at Week 26 between the 2 groups among patients unemployed at baseline.

Conclusion: Patients who received ADA+MTX combination therapy were more likely to remain employed, be less impaired at work, and have less instability for future employment. They were also more satisfied with their health state, were less fatigued, and had better physical functioning than MTX-monotherapy patients. These data suggest that treatment with ADA+MTX for patients with early RA may improve their ability to retain employment and improve daily functionality and overall quality of life.

SC Abatacept Is Effective and Well Tolerated with Low Immunogenicity Following Temporary Withdrawal and Reintroduction in the ALLOW LTE (Evaluation of ABA Administered SubcutaneousLy in AduLts With Active Rheumatoid Arthritis: Impact of Withdrawal and Reintroduction). Jeffrey L. Kaine[1], Geoffrey S. Gladstein[2], Ingrid Strusberg[3], Manuel Robles[4], Ramesh Pappu[5], Ingrid Delaet[5], Miranda Pans[5] and Charles L. Ludivico[6]. [1]Sarasota Arthritis Center, Sarasota, FL, [2]New England Research Associates, Trumbull, CT, [3]Instituto Reumatológico Strusberg, Cordoba, Argentina, [4]Centro Médico Toluca, Metepec, Mexico, [5]Bristol-Myers Squibb, Princeton, NJ, [6]East Penn Rheumatology Association, East Stroudsburg, PA

Background/Purpose: Patients (pts) may temporarily stop rheumatoid arthritis (RA) biologic therapy, leading to reduced drug concentration and immunogenicity, with possible effects on safety and efficacy. We assess the impact of withdrawal and re-introduction of subcutaneous (SC) abatacept on safety, immunogenicity and efficacy up to Mth 15 of the ALLOW trial.

Methods: Pts with mild-to-moderate RA (receiving MTX for ≥3 mths) were enrolled in this randomized, double-blind, Phase III withdrawal trial. During Period I (3-mth, open-label [OL]) pts received 125 mg/week SC abatacept, plus an IV load (~10 mg/kg) on Day 1. Pts achieving DAS28-CRP reduction of ≥0.6 at Mth 3 (Period I responders) were randomized (1:2) in Period II to 3 mths SC abatacept or placebo (PBO). In Period III (3-mth, OL) all pts completing Period II received SC abatacept. Period III completers could enter the OL long-term extension (LTE) at the end of Mth 9, Period I non-responders (NR) could directly enter the OL LTE at the end of Mth 3. Pts continued to receive SC abatacept in the LTE. Safety was monitored in pts who received ≥1 dose of abatacept in the LTE. Immunogenicity (on-treatment and ≤85 days post-treatment by electrochemiluminescence) and disease activity (DAS28) are for pts entering the LTE (as-observed data), presented for 6 mths of the LTE up to Mth 15.

Results: Of 167 pts who entered Period I, 89.8% (n=150) entered the LTE: 113 Period III completers and 37 pts from Period I; 138 pts remained at time of reporting (Period I NRs=30; Period II SC abatacept=38, Period II PBO=70). 12 pts discontinued the LTE (seven Period I NRs, one Period II SC abatacept and four Period II SC PBO), the most common reasons being consent withdrawal (n=3) and other (n=4). Median (range) SC abatacept exposure was 18.9 (5–24) mths for Period I NRs and 18.7 (12–25) and 17.5 (11–22) for Period III SC abatacept and PBO groups, respectively. For pts entering the LTE, mean (SD) baseline (BL) RA duration was 7.3 (7.9) yrs and DAS28 was 4.7 (0.8). In the LTE, 12 (8.0%) SAEs occurred (none led to discontinuation) and one pt died (upper gastrointestinal bleeding). No serious infections or malignancies occurred; one pt had mild psoriasis. Local injection site reactions occurred in two (1.3%) pts. Immunogenicity was low: 4/142 (2.8%) pts treated in the LTE had positive immunogenicity (Period I NR, 1/36 [2.8%], Period II SC abatacept, 1/38 [2.6%] and PBO, 2/68 [2.9%]). Reduction in disease activity was maintained through the LTE (from Mth 9–15) in Period II SC abatacept and PBO groups, with increasing reductions from BL seen for Period I NRs (Fig). DAS28 remission rates (DAS28<2.6) at Mth 15 were 56.3 (18/32), 50.0 (19/38) and 57.1% (40/70) for Period I NRs, Period II SC abatacept and PBO.

	Number of patients with data available for DAS28 analysis			
	Month 3	Month 6	Month 9	Month 15
Period I NR	36	NA	36	32
Period II SC abatacept	39	37	38	38
Period II SC placebo	73	71	71	70

*Period I non-responders who achieved a clinical response (decrease in DAS28 of ≥0.6 from baseline) during the first 12 weeks of the long-term extension could then add a non-biologic DMARD if required

Conclusion: In ALLOW, 3-mth interruption and subsequent re-introduction of SC abatacept had no adverse impact on safety, immunogenicity or efficacy over 15 mths and was well-tolerated by the high proportion of pts continuing treatment in the LTE.

2191

Immunogenicity Is Low and Transient with Intravenous (IV) Abatacept Therapy: Results From a Large Pooled Analysis of 3985 Patients (pts) with Rheumatoid Arthritis (RA) and up to 8 Years' Exposure. Michael E. Weinblatt[1], Mark C. Genovese[2], Michael H. Schiff[3], Rene Westhovens[4], Rieke Alten[5], Ingrid Delaet[6], Marleen Nys[6], James Manning[6] and Joel M. Kremer[7]. [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]Stanford University, Palo Alto, CA, [3]Rheumatology Division, University of Colorado, Denver, CO, [4]University Hospital KU Leuven, Leuven, Belgium, [5]Rheumatology Schlossparkklinik, Berlin, Germany, [6]Bristol-Myers Squibb, Princeton, NJ, [7]Albany Medical College and The Center for Rheumatology, Albany, NY

Background/Purpose: Immunogenicity with some biologics has been associated with loss of efficacy and occurrence of adverse events (AEs)[1,2]. IV abatacept (ABA) has demonstrated low and transient immunogenicity in clinical trials (~3%) that does not impact safety or efficacy[3]. We further explore immunogenicity to ABA using a large dataset of pts with up to 8 years' ABA exposure.

Methods: Data from seven ABA RA clinical trials were included in immunogenicity assessments, including the short-term (ST) periods (6- or 12-months) of six double-blind, placebo-controlled studies (AIM, ATTEST, ATTAIN, ASSURE, 101 and 100) and one non-randomized, open-label study (ARRIVE), and their open-label long-term extensions. Pts had active RA, inadequate response/intolerance to MTX/DMARDs or biologics and were treated with monthly IV ABA (~10 mg/kg). Samples on or before the day of first ABA dose were excluded. Anti-ABA antibodies were detected using two ELISAs: one to the whole ABA molecule (CTLA4 and IgG1), and one to the CTLA4 region (T). Positive samples had titers ≥400 for anti-ABA or ≥25 for anti-CTLA4-T. Immunogenicity was defined as proportion of pts with antibody response while on-treatment (≤42 days post-last dose) or post-treatment. Persistent immunogenicity was defined as positive response on ≥2 consecutive visits. Data are as-observed for all ABA-treated pts.

Results: 3985 pts were included with up to 8 years' ABA exposure; 252/3985 (6.3%) pts demonstrated antibody response (Table). Antibody titers in positive pts were generally low (in the majority of pts, titers were less than 5000 for anti-ABA and less than 100 for anti-CTLA4-T) and did not appear to increase with continued treatment. Persistent immunogenicity and immunogenicity with missed doses was infrequent (Table); titers in these pts were also generally low. Serious adverse events (SAEs) related to study drug occurred in 32/252 pts who experienced immunogenicity, with no relationship identified between immunogenicity and SAEs, peri-infusional, acute infusional or autoimmune events, or hypersensitivity reactions. No consistent relationship with efficacy was identified; 83% (55/66) of ACR20 responders maintained this following positive antibody response, while 36% (10/28) of non-responders achieved ACR20 following positive antibody response.

Immunogenicity, n/N (%) patients with positive antibody response

	Total	Anti-abatacept	Anti-CTLA4-T
Overall	252/3985 (6.3)	178/3868 (4.6)	82/3985 (2.1)
On-treatment	187/3877 (4.8)	160/3762 (4.3)	32/3877 (0.8)
Persistent on-treatment	77/3214 (2.4)	74/3050 (2.4)	3/3212 (0.1)
Post-treatment follow-up	103/1888 (5.5)	52/1685 (3.1)	53/1887 (2.8)
Persistent post-treatment follow-up	31/1298 (2.4)	22/1149 (1.9)	9/1297 (0.7)
Patients with no missed doses	68/2272 (3.0)	60/2229 (2.7)	9/2272 (0.4)
Patients with one missed dose	28/742 (3.8)	27/707 (3.8)	1/742 (0.1)
Patients with ≥two missed doses*	40/863 (4.6)	29/826 (3.5)	13/863 (1.5)

* Includes patients who missed two or more doses (with one missed dose within 365 days) prior to any on-treatment serpositive antibody result; CTLA4-T= cytotoxic T-lymphocyte antigen-4-Tip

Conclusion: ABA demonstrated low immunogenicity; any immunogenicity was transient and with low titer that did not increase upon continued dosing. No consistent association was observed between antibody response and safety or clinical efficacy, with previous observations in a pooled dataset demonstrating no association with pharmacokinetics[3]. These findings confirm previous observations[3] in a large pt population with up to 8 years' exposure.

Tofacitinib (CP-690,550), An Oral Janus Kinase Inhibitor, As Monotherapy in Japanese Patients with Active Rheumatoid Arthritis: A 12-Week Phase 2b Study. Y. Tanaka[1], T. Takeuchi[2], H. Yamanaka[3], M. Suzuki[4], H. Nakamura[4], S. Toyoizumi[4], J. D. Bradley[5] and S. H. Zwillich[5]. [1]University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan, [2]Keio University School of Medicine, Tokyo, Japan, [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [4]Pfizer Inc., Tokyo, Japan, [5]Pfizer Inc., Groton, CT

Background/Purpose: To compare efficacy, safety, and tolerability of 5 doses of tofacitinib monotherapy vs placebo (PBO) for treatment of rheumatoid arthritis (RA) in Japanese pts with inadequate response to DMARDs.

Methods: This study was a 12-week (wk), double-blind, PBO-controlled Phase 2b study. Pts with active RA (≥6 tender/swollen joints, C-reactive protein [CRP] >7 mg/L or ESR > upper limit of normal [ULN]) were randomized to tofacitinib 1, 3, 5, 10, 15 mg twice daily (BID) or PBO. Continuation of stable doses of NSAIDs and corticosteroids ≤10 mg prednisone equivalent was permitted.

Results: 317 pts received at least one dose of study medication. Baseline demographics and disease characteristics were comparable across treatment groups: mean ages were 52.6 to 54.7 years (y); mean duration of RA was 6.4 to 11.0 y; mean tender joint count was 13.6 to 18.6; mean swollen joint count was 11.3 to 15.3; mean DAS28-4(ESR) was 5.9 to 6.4.

The primary endpoint, ACR20 response rate at Wk 12, was statistically superior for all tofacitinib doses compared with PBO and a clear dose-response was observed. ACR50 and ACR70 response rates at Wk 12 also showed a dose-response. Tofacitinib dosed ≥5 mg BID was statistically superior in rates of DAS28-4(ESR) <2.6 at Wk 12 with maximum effect observed at doses of 10 mg and 15 mg BID (Table 1).

Table I. ACR response rates. HAQ-DI and rates of DAS28-4(ESR)<2.6 at Wk 12

	Tofacitinib					
	1 mg BID N = 51	3 mg BID N = 49	5 mg BID N = 50	10 mg BID N = 49	15 mg BID N = 52	PBO N = 48
ACR20[a]† (%)	37.7**	67.9**	73.1**	84.9**	90.7**	15.4
ACR50† (%)	13.2	26.4*	46.2**	69.8**	72.2**	7.7
ACR70† (%)	7.6	13.2*	26.9*	49.1**	51.9**	1.9
HAQ-DI‡ (change from baseline)	−0.19**	−0.38**	−0.55**	−0.67**	−0.68**	0.18
DAS28-4[§] (ESR)<2.6 (%)	5.9	2.0	16.0*	42.9**	40.4**	2.1

For ACR20, ACR50 and ACR70, a step-down procedure was used with a significance level of 0.05 based on chi-square test
* p<0.05, **p<0.0001 vs PBO
[a] primary endpoint
† last observation carried forward; ‡longitudinal linear model; [sc]no imputation

The most common adverse events (AEs) were nasopharyngitis, hyperlipidemia, and increased LDL; most were mild in severity. Fifteen serious AEs (SAEs) were reported in 9 pts. Nine treatment-related SAEs were observed in 6 pts. There were no deaths in this study.

There were dose-dependent decreases in neutrophil counts. There was no severe anemia (hemoglobin value 7.0–8.0 mg/dL decrease from baseline). Dose-dependent increases in total, HDL, and LDL cholesterol and small increases in serum creatinine were also observed in this study. AST levels >3x ULN were observed in 1 pt in the PBO group, and ALT levels >3x ULN were observed in 1 and 2 pts in 1 mg BID and PBO treatment groups, respectively (Table 2).

Table 2. Summary of safety AEs. (SAEs and laboratory values)

	Tofacitinib					
	1 mg BID N = 53	3 mg BID N = 53	5 mg BID N = 52	10 mg BID N = 53	15 mg BID N = 54	PBO N = 52
Incidence of AEs (%)	21 (39.6)	23 (43.4)	29 (55.8)	32 (60.4)	28 (51.9)	23 (44.2)
Incidence of SAEs (%)	0	3 (5.7)	2 (3.8)	2 (3.8)	1 (1.9)	1 (1.9)
Incidence of severe AEs (%)	0	2 (3.8)	1 (1.9)	1 (1.9)	0	0
Incidence of discontinuation due to AEs (%)	0	1 (1.9)	2 (3.8)	3 (5.7)	0	2 (3.8)
LSM change from baseline at Week 12:						
Neutrophil counts ($10^3/\mu L$)	0.06	−0.98	−1.44	−2.10	−1.66	0.47
LDL cholesterol (mg/dL)	3.21	11.77	16.43	21.45	24.69	−0.24
HDL cholesterol (mg/dL)	5.04	10.81	17.73	21.94	21.11−0.94	
Number (%) of pts with abnormalities and normal baseline:						
AST > 3 × ULN	0	0	0	0	0	1 (2.0)
ALT > 3 × ULN	1 (1.9)	0	0	0	0	2 (3.9)

LSM, least squares mean

Conclusion: When used as monotherapy, tofacitinib dosed >1 mg BID demonstrated superior ACR20 response rates compared with PBO at Wk 12. Doses of tofacitinib 5, 10, and 15 mg BID demonstrated superiority to placebo in DAS28-4(ESR) < 2.6. The safety profile of tofacitinib monotherapy was manageable in Japanese pts with long-standing active RA.

2193

Use of Disease-Modifying Anti-Rheumatic Drugs for Rheumatoid Arthritis in Quebec, Canada. Jean-Pascal Roussy[1], Louis Bessette[2], Sasha Bernatsky[3], Elham Rahme[3], Jean Légaré[4] and Jean Lachaine[1]. [1]University of Montreal, Montreal, QC, [2]CHUL, Quebec, QC, [3]McGill UHC/RVH, Montreal, QC, [4]Arthritis Alliance of Canada, Neuville, QC

Background/Purpose: Disease-modifying anti-rheumatic drugs (DMARDs) are the cornerstone of rheumatoid arthritis (RA) pharmacotherapy and should be initiated promptly following RA diagnosis. Our objectives were 1) to describe the characteristics of RA subjects in Quebec, 2) to evaluate trends in DMARD use, and 3) to assess potential factors associated with DMARD use in newly diagnosed RA.

Methods: Data from the Quebec public healthcare system databases (RAMQ and MED-ECHO) were used to identify RA subjects and their claims for medical and pharmaceutical services between January 1st 2002 and December 31st 2008. Descriptive statistics were used to characterize the RA population. To describe the patterns of DMARD use and their evolution over time, cross-sectional analyses were performed on November 1st of each year. Finally, for the newly diagnosed subgroup, multivariable logistic regressions were used to identify potential correlates of DMARD initiation at 12 months, and Kaplan-Meier curves to define the probability of initiating a DMARD over time.

Results: A total of 32,533 subjects were included. The mean age was 67.5 years; 70.4% were female. Over the study period, the percentage of subjects on a DMARD increased from 42.0% (Nov 2002) to 43.2% (Nov 2008). In multivariable analyses, being followed by a rheumatologist (vs. a general practitioner) was shown to be the strongest predictor of DMARD initiation (OR=4.39; 95%CI: 3.80–5.08). The use of NSAIDs, corticosteroids, and opioids in the year prior to cohort entry and the calendar year of the cohort entry were also increasing the likelihood of DMARD initiation. Increasing age, comorbidity score, and the use of acetaminophen had a negative effect on DMARD initiation. When specifically looking at initiation of biologic DMARDs, the strongest predictor was calendar year of cohort entry (OR 2007 vs. 2002=10.78; 95%CI: 2.45–47.37). Of subjects newly diagnosed in 2002, 0.1% had a biologic initiated within one year, while for those newly diagnosed in 2007, the percentage was 1.3%. Being followed by a rheumatologist increased the likelihood of biologic initiation, whereas increasing age reduced that likelihood. At 12 months after RA diagnosis (i.e., after cohort entry), the probability of having initiated any DMARDs was 38.5%. That probability was higher (47.8%) in the subgroup followed by a rheumatologist. Over time, the probability of DMARD initiation improved. In 2008, the median time to DMARD initiation was 288 days.

Conclusion: From 2002 to 2008, the use of RA treatment in Quebec has evolved. Despite indications that practice is moving toward earlier and more aggressive management of the disease, initiation of DMARD therapies still appears sub-optimal. Improving access to rheumatologists could be an area of focus in order to enhance the quality of RA care.

2194

Remission Induction by Etanercept (ETN) Plus Methotrexate (MTX) Combination Therapy Versus ETN Monotherapy in Patients with Active Rheumatoid Arthritis Despite MTX Treatment. Hideto Kameda[1], Ukitaka Ueki[2], Kazuyoshi Saito[3], Shouhei Nagaoka[4], Toshihiko Hidaka[5], Tatsuya Atsumi[6], Michishi Tsukano[7], Tsuyoshi Kasama[8], Shunichi Shiozawa[9], Yoshiya Tanaka[3], Katsuaki Kanbe[10], Eri Sato[11], Hisashi Yamanaka[12] and Tsutomu Takeuchi[1]. [1]Keio University School of Medicine, Tokyo, Japan, [2]Rheumatic and Collagen Disease Center, Sasebo, Japan, [3]U Occupa & Environ Hlth, Kitakyushu, Japan, [4]Yokohama Minami Kyosai Hospital, Yokohama, Japan, [5]Zenjinkai Shimin-No-Mori-Hospital, Miyazaki, Japan, [6]Hokkaido University, Sapporo, Japan, [7]Kumamoto Hospital, Kumamoto, Japan, [8]Showa University School of Med, Shinagawa-ku Tokyo, Japan, [9]Kobe University Graduate School of Health Science and Medicine/ TThe Center for Rheumatic Diseases, Kobe University Hospital, Kobe, Japan, [10]Medical Center East, Tokyo Women's Medical University, Tokyo, Japan, [11]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [12]Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan

Background/Purpose: The JESMR study suggested clinical and radiographic superiority of ETN+MTX combination therapy to ETN monotherapy in patients with active rheumatoid arthritis (RA) despite MTX treatment.

Methods: To examine the difference in ACR/EULAR/OMERACT remission rates (Boolean and simplified disease activity index; SDAI) at 52 weeks between ETN+MTX combination versus ETN monotherapy.

Results: Demographic and clinical features between groups at baseline were similar. The rates of tender joint count ≤ 1, swollen joint count ≤ 1, physician's global assessment ≤ 1 and serum C-reactive protein (CRP) ≤ 1 mg/dl were significantly higher in the E+M group than the E group at week 52. The Boolean and the simplified disease activity index (SDAI) remission rates were 11.6% and 21.7% in the E group, respectively, while those were 21.9% and 32.9% (p=0.12 and p=0.19, respectively, versus the E group) in the E+M group. Non-remission by the Boolean or SDAI in the E group was identified as a high-risk group for radiographic progression by modified total Sharp score (ΔTSS), while remission in the E+M group resulted in radiographic non-progression.

	ETN	ETN+MTX	p value
% tender joint count ≤ 1	35	64	0.0007
% swollen joint count ≤ 1	39	59	0.02
% patient's global assessment ≤1	22	33	0.19
% physician's global assessment ≤1	35	56	0.012
% CRP ≤ 1 (mg/dL)	51	82	<0.0001
% Boolean remission	12	22	0.12
% SDAI remission	22	33	0.19
ΔTSS in Boolean remission; mean ± SD	1.1 ± 2.4	0.0 ± 2.9	0.16
ΔTSS in Boolean non-remission; mean ± SD	4.0 ± 11.1	1.0 ± 7.2	0.065
ΔTSS in SDAI remission; mean ± SD	1.8 ± 3.0	−0.4 ± 3.8	0.027
ΔTSS in SDAI non-remission; mean ± SD	4.2 ± 12.0	1.4 ± 7.5	0.11
% HAQ-DI ≤ 0.5 in baseline TSS ≤ 100	67	62	0.63
% HAQ-DI ≤ 0.5 in baseline TSS > 100	21	47	0.054

Conclusion: It is indicated that the continuation of MTX at the commencement of ETN and subsequent remission induction are associated with beneficial clinical and radiographic outcomes even in patients with active RA despite MTX treatment.

2195

Celecoxib, a Selective Cyclooxygenase-2 Inhibitor, Improves a Bone Resorption Marker in Postmenopausal Women with Rheumatoid Arthritis. Shigeyoshi Tsuji[1], Tetsuya Tomita[2], Takao Iwai[1], Takanobu Nakase[1], Masayuki Hamada[1], Hideo Kawai[1] and Hideki Yoshikawa[2]. [1]Hoshigaoka Koseinenkin Hospital, Hirakata city, Japan, [2]Osaka University Graduate School of Medicine, Suita Osaka, Japan

Background/Purpose: Celecoxib (CEL), a selective COX-2 inhibitor, has been reported to suppress osteoclastogenesis in vitro, reduce bone resorption in ovariectomized mice, and prevent bone destruction in adjuvant-induced arthritic rats. However, the effects of CEL on bone metabolism have not been demonstrated in clinical setting. Here, we prospectively investigated the effects of CEL on bone metabolism and inflammation in patients with rheumatoid arthritis (RA) who switched from nonsteroidal anti-inflammatory drugs (NSAIDs) to CEL.

Methods: RA patients who had been treated with NSAIDs for more than 12 weeks were switched to CEL without any other changes in previous medications. All patients gave informed consent before enrollment. Urinary type I collagen cross-linked N-telopeptide (uNTX), serum bone alkaline phosphatase (BAP), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and matrix metalloproteinase-3 (MMP-3) were evaluated before and 16 weeks after switching to CEL. Data are expressed as the mean ± SD, and Wilcoxon signed rank test was used in a statistical analysis with the significance level set at 0.05.

Results: Eighty-five patients were included in the study, and seventy-three of those were eligible for the efficacy analysis. Sixty-one were female, and the average age and affected period were 62.5 ± 10.3 and 17.2 ± 10.4 years, respectively. The most prevalently-used NSAID was loxoprofen sodium (49.3%), followed by diclofenac sodium (15.1%), meloxicam (13.7%), and etodolac (13.7%).

Sixteen weeks after switching to CEL, uNTX was significantly reduced to 34.9 ± 18.9 nmol BCE/mmol·Cr, compared with pre-treatment value of 41.0 ± 27.6 nmol BCE/mmol·Cr ($p = 0.042$) in female patients ($n = 60$). There was also a significant reduction in uNTX in postmenopausal females (from 39.0 ± 24.7 to 33.1 ± 18.6 nmol BCE/mmol·Cr, $p = 0.033$, $n = 52$), and postmenopausal females who did not use bisphosphonates (from 59.1 ± 28.3 to 46.2 ± 22.3 nmol BCE/mmol·Cr, $p = 0.011$, $n = 14$,). However, uNTX was not significantly altered in premenopausal females (from 53.8 ± 42.1 to 46.7 ± 17.1 nmol BCE/mmol·Cr, $p = 0.844$, $n = 8$) or males (from 26.1 ± 12.6 to 34.5 ± 33.9 nmol BCE/mmol·Cr, $p = 0.925$, $n = 12$). There were no significant changes in BAP, a bone formation marker, in any of these subgroups. Among various inflammatory markers, CRP was significantly decreased in the patients switched from NSAIDs to CEL (from 1.00 ± 1.36 to 0.92 ± 1.28 mg/dL, $p = 0.007$, $n = 73$), while ESR and MMP-3 remained unchanged (Table).

Table.

Changes in bone turnover and inflammatory markers after switching to celecoxib	n	Before switching	After switching	p value
Urinary NTX (nmolBCE/mmol·Cr)				
Female	60	41.0 ± 27.6	34.9 ± 18.9	p=0.042
Premenopause	8	53.8 ± 42.1	46.7 ± 17.1	p=0.844
Postmenopause	52	39.0 ± 24.7	33.1 ± 18.6	p=0.033
Bisphosphonate (+)	38	31.6 ± 18.7	28.3 ± 14.7	p=0.320
Bisphosphonate (−)	14	59.1 ± 28.3	46.2 ± 22.3	p=0.011
Biologics (+)	7	42.6 ± 20.7	34.8 ± 17.8	p=0.031
Biologics (−)	45	38.5 ± 25.4	32.8 ± 18.9	p=0.092
Corticosteroid (+)	25	43.4 ± 29.0	34.6 ± 21.2	p=0.068
Corticosteroid (−)	27	35.0 ± 19.7	31.7 ± 16.2	p=0.272
Male	12	26.1 ± 12.6	34.5 ± 33.9	p=0.925
BAP (U/L)				
Female	60	21.6 ± 9.3	20.8 ± 6.9	p=0.214
Male	12	21.3 ± 5.6	20.7 ± 4.0	p=0.925
CRP (mg/dl)	73	1.00 ± 1.36	0.92 ± 1.28	p=0.007
ESR (mm/hour)	52	35.7 ± 29.7	35.4 ± 27.7	p=0.996
MMP-3 (ng/ml)	72	168 ± 158	156 ± 123	p=0.483

MEAN±SD, Wilcoxon singed rank test

Conclusion: This is the first report to demonstrate that CEL significantly reduces uNTX, a bone resorption marker, in postmenopausal RA patients who switched from traditional NSAIDs to CEL, suggesting that CEL may suppress bone resorption through mechanisms other than cyclooxygenase inhibition. Further studies will be needed to determine whether CEL can prevent the long-term loss of bone mass in postmenopausal women.

2196

Safety of Rituximab in Combination with Other Biologic Disease-Modifying Antirheumatic Drugs in Rheumatoid Arthritis: 48-Week Data From SUNDIAL. William Rigby[1], Philip J. Mease[2], Ewa Olech[3], Mark Ashby[4] and Swati Tole[4]. [1]Dartmouth Medical School, Lebanon, NH, [2]Swedish Medical Center, Seattle, WA, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Genentech, Inc., South San Francisco, CA

Background/Purpose: Combination biologic therapy may be used in selected patients (pts) with an inadequate response (IR) to a single biologic. In addition, pts with an IR to rituximab (RTX) may receive other biologics while B-cell depleted. The objective of SUNDIAL (stage II) was to characterize the safety of RTX (single and repeat dose) in combination with biologic DMARDs in pts with RA.

Methods: An open-label study of adult pts with active RA and an IR to ≥1 biologic. Pts who received a biologic for ≥12 wks at a stable dose for ≥4 wks prior to baseline were treated with RTX (500 mg IV ×2) plus their current biologic (etanercept, adalimumab, infliximab, or abatacept) and non-biologic DMARD treatment at a stable dose. After 24 wks, pts with a DAS ≥2.6 were offered retreatment with RTX. Primary endpoint: proportion of pts developing a serious adverse event (SAE) within 24 wks of receiving the first course of RTX. Secondary endpoints included additional safety endpoints and efficacy at 24 and 48 wks. Missing values due to pt discontinuation were handled as non-responders. Some imputation was done for missing ACR components if the pt continued on study.

Results: The safety analysis population comprised 176 pts (mean age 53.6 yrs; 88% female, mean RA disease duration 10.6 yrs; mean baseline DAS28-ESR 6.21; baseline oral steroid use 39.2%; mean number of prior anti-TNFs 1.5). Pts received RTX with 18 different biologic/DMARD combinations: 110 (62.5%) biologics alone and 66 (37.5%) biologics with non-biologic DMARDs. The most common combinations were with adalimumab alone (n=46; 26.1%) and etanercept alone (n=37; 21.0%). Of the 176 pts, 160 (90.9%) completed 24 wks and 134 (76.1%) completed 48 wks. Between wks 24 and 40, 147 (83.5%) pts were retreated with RTX. Among the 147 retreated pts, rates of SAEs, infections, and serious infections were not increased compared with the overall study population at 24 or 48 wks (Table). No SAEs occurred during/within 24 h of any RTX infusion.

Table. Summary of safety data (Event rate/100 pt-yrs [95% CI])

	Safety population up to wk 24 (n=176) (Total pt-yrs=78.2)	Safety population up to wk 48 (n=176) (Total pt-yrs=147.1)	Retreated population up to wk 48 (n=147) (Total pt-yrs=134.5)
SAEs	21.7 (13.5–35.0)	22.4 (15.9–31.6)	16.4 (10.8–24.8)
Infections	165.0 (138.8–196.1)	144.8 (126.6–165.6)	145.7 (126.7–167.6)
Serious infections[a]	3.8 (1.2–11.9)	2.7 (1.0–7.2)	2.2 (0.7–6.9)

[a]SAE or any infection treated with an IV antibiotic.

ACR responses increased from wk 24 to 48 (ACR20: 30.1 to 47.2%; ACR50: 10.2 to 21.6%; ACR70: 5.1 to 9.1%). At wk 48, 61.4% of pts achieved EULAR moderate/good response; 22.1 and 7.0% achieved DAS28 low disease activity and remission, respectively. Mean HAQ-DI score improved by −0.32 from baseline at wk 48.

Conclusion: The overall safety profile of RTX used in combination with a biologic DMARD at 48 wks was consistent with that previously reported for RTX + methotrexate[1] and RTX + nonbiologic DMARDs.[2] Despite patterns consistent with clinical benefit, conclusions regarding efficacy results cannot be drawn due to the lack of a control group and differences in baseline characteristics compared with previous studies.

Switching of Biologic Disease-Modifying Antirheumatic Drugs During the First Year in Patients with Rheumatoid Arthritis in a Real-World Setting. Brian Meissner, Digisha Trivedi, Min You and Tony Hebden. Bristol-Myers Squibb, Plainsboro, NJ

Background/Purpose: Biologic disease-modifying antirheumatic drugs (bDMARDs) are commonly used to treat rheumatoid arthritis (RA). Although switching between bDMARD therapies is an accepted practice, there is a paucity of data describing the switching that occurs with these agents. Objective: To characterize bDMARD switching in a real-world RA population in the first year following initiation of therapy.

Methods: This observational, retrospective study utilized administrative medical and pharmacy claims from 01/01/2004 through 03/31/2010 of RA patients who were newly initiated on abatacept, etanercept, infliximab, or adalimumab. Switching of bDMARD therapy was characterized during the 12-month period following biologic initiation (post-index date). Switching was defined as a different bDMARD claim within a 100% gap in days' supply from the prior bDMARD claim. Days' supply for the bDMARD identified within the medical file was imputed based on the dosing frequency stated in the product label. Bivariate and multivariate statistical analyses were conducted to examine the characteristics of bDMARD switchers versus non-switchers.

Results: Of 10,281 patients initiated on one of the four bDMARDs studied, 7.8% switched from their index bDMARD to another within 1 year, specifically 8.9% of adalimumab, 8.5% of etanercept, 5.2% of infliximab, and 2.0% of abatacept patients. Those patients who initiated treatment with etanercept or adalimumab and switched within the first year primarily switched to a second anti-tumor necrosis factor agent (94.8%, 90%, respectively), although this was less frequent with infliximab initiators (44.6%). Among patients who switched to adalimumab, etanercept, infliximab, or abatacept as their second biologic, 18.1%, 12.9%, 12.8%, and 6.0% of patients switched to a third bDMARD, respectively, within the first year of therapy. Compared with non-switchers, bDMARD switchers incurred more hospitalizations (9.5% versus 7.2%; $p=0.015$), and higher monthly healthcare costs ($1,025 versus $796; $p<0.001$) prior to bDMARD initiation.

Conclusion: Less than 10% of RA patients who initiated therapy on adalimumab, etanercept, infliximab or abatacept switched to a second bDMARD in their first year of therapy, with switching associated with significantly more hospitalizations and healthcare costs than not switching. Further studies are required to determine why abatacept-treated patients had a lower frequency of switching than the other three biologics studied.

2198

Real-World Switching Patterns in Rheumatoid Arthritis Patients Receiving Abatacept, Adalimumab, Etanercept or Infliximab As Second-Line Biologic Therapy. Brian Meissner, Lisa Rosenblatt, Digisha Trivedi, Min You and Tony Hebden, Bristol-Myers Squibb. Plainsboro, NJ

Background/Purpose: A number of patients with rheumatoid arthritis (RA) switch from one biologic disease-modifying antirheumatic drug (bDMARD) to another, having previously switched from their initial bDMARD. There is a paucity of data characterizing this second-line bDMARD switch in these patients.

Objectives: To characterize, in a real-world RA population, bDMARD switching in the first year following initiation of second-line abatacept, adalimumab, etancercept or infliximab.

Methods: This observational, retrospective study utilized administrative medical and pharmacy claims from 01/01/2004 through 03/31/2010 of RA patients who were newly initiated on abatacept, etanercept, infliximab, or adalimumab. Patients were then followed forward to identify the first bDMARD claim (index date) that deviated from their initial bDMARD. Patients were required to have 6 months of continuous eligibility before, and 12 months after, the first bDMARD switch. The 12-month follow-up period was used to identify the rate of bDMARD switching among patients on second-line bDMARD therapy. Bivariate and multivariate statistical analyses were conducted to examine the characteristics of second-line abatacept versus second-line anti-tumor necrosis factor (TNF) patients.

Results: Of 3158 patients on a second-line bDMARD, 2478 (78.5%) had switched from one anti-TNF agent to another, 599 (20.0%) from anti-TNF to abatacept, and 81 from abatacept to anti-TNF (2.6%). Of these, 21.9% switched to a third bDMARD within 1 year, with 23.3% of second-line anti-TNF patients switching to a third agent compared with 15.9% of abatacept patients ($p<0.01$). Logistic regression demonstrated that patients on a second-line anti-TNF were more likely to switch to a third agent than patients on abatacept (odds ratio=1.69, 95% confidence interval: 1.33, 2.16), after controlling for age, gender, and pre-index comorbidity, hospitalization, and healthcare costs.

Conclusion: The majority of RA patients who switched from initial bDMARD stayed within the anti-TNF class. Approximately 20% of patients who switched to a second-line bDMARD subsequently switched to a third bDMARD, with those on an anti-TNF agent being significantly more likely to switch than those receiving abatacept. Further research is required to determine why abatacept-treated patients had a lower switching frequency than patients receiving an anti-TNF agent.

2199

Long-Term Safety of Rituximab in Rheumatoid Arthritis: Pooled Analysis of Patients in Clinical Trials with up to 9.5 Years of Treatment. Ronald F. van Vollenhoven[1], Paul Emery[2], Clifton O. Bingham[3], Edward Keystone[4], Roy M. Fleischmann[5], Daniel E. Furst[6], Nicola Tyson[7], Neil Collinson[7] and Patricia B. Lehane[7]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [3]Johns Hopkins University, Baltimore, MD, [4]University of Toronto, Toronto, ON, [5]University of Texas, Dallas, TX, [6]UCLA, Los Angeles, CA, [7]Roche Products Limited, Welwyn Garden City, United Kingdom

Background/Purpose: To evaluate the long-term safety profile of rituximab (RTX) in rheumatoid arthritis (RA).

Methods: A pooled observed case analysis of safety data from patients (pts) treated with RTX + methotrexate (MTX) in clinical trials. RTX re-treatment was based on clinical need and evidence of active disease (SJC and TJC ≥8 or DAS28 ≥2.6). Pts with >5 yrs' follow-up were analyzed as a subgroup (long-term population). Pooled data from pts treated with placebo (PBO) during the PBO-controlled phases of the trials were used to provide the PBO group.

Results: As of Sep 2010, 3194 pts (11962 pt-yrs) had received up to 17 courses of RTX over a period of 9.5 yrs. Repeat treatment data from pts exposed for >5 yrs were available for 627 pts (4418 pt-yrs). The PBO group comprised 818 pts (1107 pt-yrs) with a mean duration of follow-up of 1–1.5 yrs. The most frequent adverse event (AE) in RTX-treated pts was infusion-related reaction (IRR); 23.0% pts (734/3194) experienced IRR at first infusion of the first course; most were CTC grade 1 or 2 and were rarely serious. Other than IRR, the safety profile of RTX was similar to PBO and that of general RA populations.[1] Rates of AEs, serious AEs (SAEs), and infections remained stable over time and with multiple RTX courses. The rate of serious infection in RTX-treated patients, including pts through >5 yrs' follow-up, was comparable to that observed in the PBO population (Table). The most frequent serious infection was pneumonia (2% RTX pts). Serious opportunistic infections were rare (RTX 0.06/100 pt-yrs vs PBO 0.09/100 pt-yrs). There was no evidence of an increased risk of malignancy over the duration of follow up or with repeat RTX treatment courses. The rate of myocardial infarction (0.41/100 pt-yrs) was consistent with rates observed in the general RA population (0.48–0.59/100 pt-yrs).[1]

Table. Summary of adverse event rates per 100 pt-yrs

	RTX All-Exposure (n=3194; 11962 pt-yrs)	RTX Long-term (>5 yrs) (n=627; 4418 pt-yrs)	Pooled placebo (n=818; 1107 pt-yrs)
AE rate (95% CI)	263.10 (260.21–266.02)	254.12 (249.46–258.86)	315.43 (305.14–326.06)
SAE rate (95% CI)	14.40 (13.73–15.09)	14.30 (13.23–15.46)	13.82 (11.79–16.19)
Infection rate (95% CI)	81.64 (80.04–83.27)	75.41 (72.89–78.02)	90.39 (84.96–96.17)
Serious infection rate (95% CI)	3.94 (3.60–4.31)	3.26 (2.77–3.84)	3.79 (2.80–5.13)

CI = confidence interval.

Conclusion: Pooled long-term safety data from 3194 pts exposed to RTX in clinical trials for up to 9.5 yrs (11962 pt-yrs) show that RTX has remained well tolerated over time and over multiple courses. Increased duration of exposure to RTX treatment was not associated with any new safety signals, including in pts with >5 yrs' follow-up. The overall safety profile of RTX remains similar to that of the pooled PBO population and is consistent with published data for moderate to severe RA.

Eight Year Results of Disease Activity Steered Treatment in a Large Recent Rheumatoid Arthritis Cohort: Clinical and Radiological Outcomes.

Linda Dirven[1], M. van den Broek[1], N.B. Klarenbeek[1], K.H. Han[2], H.K Ronday[3], P.J.S.M. Kerstens[4], Tom W.J. Huizinga[1], Willem F. Lems[5] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Haga Hospital, The Hague, Netherlands, [4]Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands, [5]VU University medical center, Amsterdam, Netherlands

Background/Purpose: To compare 8-year clinical and radiological outcomes of four dynamic DAS steered treatment strategies (BeSt study) in recent onset rheumatoid arthritis (RA) patients.

Methods: 508 patients with recent onset RA were randomized to four treatment strategies: 1. sequential monotherapy, 2. step up combination therapy, 3. initial combination with prednisone, 4. initial combination with infliximab. Every three months, treatment adjustments were made based on DAS measurements (DAS >2.4: next treatment step; DAS ≤ 2.4 during ≥6 months: taper to maintenance dose, next if DAS <1.6 during ≥6 months: stop anti-rheumatic treatment). Functional ability (HAQ) was analyzed with a linear mixed model (LMM) with time, treatment and time*treatment as independent variables. Joint damage progression (Sharp-van der Heijde Score (SHS)) was assessed on X-rays of baseline and year 1, 2, 3, 4, 5, 6, 7 and 8 and scored by two independent readers (LD and MvdB), blinded for patient identity and in random order.

Results: After 8-years follow-up, 161 patients (32%) dropped out the study. Seventy-nine percent of the completers had a DAS ≤2.4 and 52% DAS <1.6 (remission), equally distributed among the four groups (table). Eighteen, 19, 17 and 15% of the patients in groups 1–4 were in drug free remission with a median (mean) duration of 45 (39) months. Six patients lost and twelve new patients achieved drug free remission in year 8, while eight patients with prolonged drug-free remission dropped out. The initial improvement of function, which occurred earlier in groups 3 and 4 than in groups 1 and 2, was maintained without deterioration over 8 years time in all groups. Over time (LMM), patients in group 4 have significantly better functional ability compared to group 2 (mean HAQ: 0.57 and 0.71). After initial differences in years 1 and 2 between the 4 groups, yearly radiological damage progression rates were low and similar between all groups, reflecting the efficacy of DAS-steered therapy. Differences in total damage after 8 years are no longer statistically significant. Mean SHS progression in patients in sustained drug free remission was 0.1 (median (IQR) 0 (0–0.03)) per person year drug-free. Toxicity was comparable between the groups.

Table. 8-year results of the BeSt study.

	Group 1 n=126	Group 2 n=121	Group 3 n=133	Group 4 n=128	p-value
DAS ≤2.4, (%)†	79	76	84	76	0.49
DAS <1.6, (%)†	49	56	57	47	0.48
DAS <1.6 drug free, %†	18	19	17	15	0.90
Still on initial treatment step, %†	29	22	45	66	<0.001
Mean HAQ during 8 years‡	0.69	0.71	0.63	0.57	<0.05*
IFX current use, (%)†	21	10	13	24	0.06
Lost to follow-up, n (%)‡	41 (33)	43 (36)	47 (35)	30 (23)	0.13
Missing data, no.	8	12	9	4	
SHS progression, median (mean)†					
Total, year 0–8	3.0 (14.6)	4.3 (13.9)	2.0 (8.5)	2.0 (8.3)	0.567
year 1	0.3 (4.9)	0.5 (2.3)	0 (1.1)	0 (1.0)	0.005
year 2	0 (2.6)	0 (1.1)	0 (0.8)	0 (0.6)	0.028
year 3	0 (1.2)	0 (1.5)	0 (1.1)	0 (0.6)	0.841
year 4	0 (1.1)	0 (1.3)	0 (1.1)	0 (0.8)	0.898
year 5	0 (1.3)	0 (1.6)	0 (1.3)	0 (1.2)	0.593
year 6	0 (1.5)	0 (1.2)	0 (1.4)	0 (0.9)	0.841
year 7	0 (0.6)	0 (1.7)	0 (1.6)	0 (0.7)	0.066
year 8	0 (0.4)	0 (1.0)	0 (1.3)	0 (0.7)	0.527

†completers analysis, ‡intention to treat. *LMM: group 2 vs 4, $p < 0.05$, group 1 vs 4, $p = 0.055$, all other, $p > 0.05$.

Conclusion: After a clinically relevant earlier functional improvement with initial combination therapy than with initial monotherapy, improvement was maintained in all groups without deterioration over time with continued DAS steered treatment aiming at DAS ≤ 2.4. In addition, radiological damage was very low, even after 8 years. The percentages of patients in clinical remission and in drug free remission were stabilized.

2201

A Phase I, Randomized, Double-Blind, Placebo-Controlled, Single-Dose, Dose Escalation Study to Evaluate the Safety, Tolerability and Pharmacokinetics of BIIB023 (Anti-TWEAK) in Subjects with Rheumatoid Arthritis.

Nicolas Wisniacki[1], Vishala L. Chindalore[2], Christine E. Codding[3], Maria W. Greenwald[4], Marianne L. Shaw[5], Sergey Fitilev[6], Olga Ershova[7], Xiao Hu[8], Timothy S. Zheng[9], Lakshmi Amaravadi[8], Ray Zhang[9] and Linda C. Burkly[8]. [1]Biogen Idec, Maidenhead, United Kingdom, [2]Anniston Medical Clinic PC, Anniston, AL, [3]Health Research of Oklahoma, Oklahoma City, OK, [4]Desert Medical Advances, Palm Desert, CA, [5]Duncansville, PA, [6]M. Sechenov Moscow Medical Academy, Moscow, Russia, [7]Clinical Hospital for Emergency Care, Moscow, Russia, [8]Biogen Idec, Cambridge, MA, [9]Biogen Idec Inc, Cambridge, MA

Background/Purpose: TNF-like weak inducer of apoptosis (TWEAK) and its sole signaling receptor FGF-inducible molecule 14 (Fn14) are highly upregulated locally in the end organ targets of inflammatory and autoimmune diseases. Inhibition of the TWEAK/Fn14 pathway has proved to be efficacious in multiple experimental models of these diseases by reducing inflammatory responses and pathological tissue remodelling. BIIB023 is a humanised anti-TWEAK monoclonal antibody currently in development for the treatment of lupus nephritis.

The objectives of this first in man study were to evaluate the safety, tolerability, PK and immunogenicity of single administration of BIIB023 in subjects with rheumatoid arthritis (RA). Exploratory objectives included the analysis of biomarkers for the assessment of target engagement and pharmacologic effect.

Methods: This was a multicenter, randomized double-blind, placebo-controlled, dose escalation study in subjects with RA. Fifty three subjects on stable regime of methotrexate received a single intravenous dose of BIIB023 of 0.03 to 20 mg/kg (n=38) or placebo (n=15) and were followed up for 70 days. Safety assessment included adverse events (AEs), serious adverse events (SAE), physical examination and laboratory analysis. Serum samples were collected for PK, immunogenicity and exploratory biomarker assessments.

Results: Single dose IV administration of BIIB023 demonstrated a favourable safety and tolerability profile with no dose-dependent safety finding observed in any of the dose groups. There were no severe or serious AEs or any subject discontinuation or withdrawal and no difference in infection rate between groups. No notable laboratory or physical exam/ECG findings were observed. The PK profile of BIIB023 revealed a t1/2 of approximately 24 days in the high doses of 10 and 20 mg/kg. A single subject (3%) tested positive for anti-drug antibody.

Serum soluble TWEAK concentrations, an indicator of target engagement, were suppressed to below the level of quantitation at the first timepoint assessed (6 hours after dosing) and returned to baseline levels at 3 to 4 weeks following a single dose of 10 mg/kg or 20 mg/kg BIIB023. Multiplex analysis of biomarkers revealed a trend toward down modulation in MCP-1, ICAM-1, A-SAA, BAFF, E-Selectin, IL-6, and IP-10 in the high dose cohorts (3 to 20 mg/kg) and was consistent with dose dependent activity of BIIB023 upon administration of a single dose.

Conclusion: Single dose administration of BIIB023 (Anti-TWEAK) showed a favourable safety and tolerability profile in subjects with RA and suppressed serum soluble TWEAK, a biomarker of target engagement, for up to 4 weeks. The PK profile of BIIB023 supports further development in inflammatory and autoimmune diseases and is currently being pursued for the treatment of Lupus Nephritis.

Response to Second-Line DMARDs and TNFi in Seropositive and Seronegative Patients in Early and Late Rheumatoid Arthritis Are Not the Same: Results From the CATCH Cohort and a Large, Established Rheumatoid Arthritis Database. Background/Purpose: To investigate differences in treatment response to second-line DMARDs and biologics (TNFi) in seropositive versus seronegative RA patients in early and established RA.

Methods: Patients from the CATCH ERA Cohort who had failed first line DMARD therapy and continued to second-line therapy were selected. These were defined as those on first-line therapy with DAS28>2.6 who added new DMARD(s). Patients treated with DMARDs before inclusion in the CATCH cohort were excluded from the analysis. The proportion achieving DAS<2.6 in next 6 months after the first addition of DMARD(s) were compared with regards to RF status and anti-CCP status. Similarly, patients with DAS28>2.6 adding biologic therapy were selected and the proportion achieving DAS<2.6 in the next 6 months were compared with regards to RF and anti-CCP status using Pearson Chi-square analyses. In an established RA Cohort[1] from an outpatient rheumatology practice, RA patients using TNFi were studied by response to treatment by RF status on HAQ-DI and pain change (on a 0 to 3 scale).

Results: CATCH Cohort: No significant difference was found in second-line DMARD response between RF+ and RF- groups as well as in anti-CCP+ and − groups. Proportion achieving DAS<2.6 at follow-up after initiating biologic therapy was significantly higher in anti-CCP− patients (14/22=63.6%) versus Anti-CCP+ patients (11/32=34.4%); p=0.034. The ERA changes in HAQ were not different in post DMARD and post TNFi when studying RF and CCP status (Table 1). Established RA Cohort: Mean one year HAQ-DI change was found to be significantly greater in 90 RF+ patients at −0.356 versus 38 RF- patients at −0.126 (p=0.043). Mean pain change was also found to be significantly greater in 77 RF+ patients at −0.725 versus 32 RF- patients at −0.332 (p=0.03) (Table 2).

Table 1.

Established RA TNFi Treatment	RF+	RF-	P value
N	178	60	
% Female	82%	72%	0.7
Age (SD)	57 (14)	56 (12)	0.6

	CCP +	CCP −	P Value		CCP +	CCP −	P Value
Patients adding first DMARD(s)	81	50		Patients adding first DMARD(s)	32	22	
% achieving DAS<2.6 at 1st FU	38.3%	24.0%	0.091	% achieving DAS<2.6 at 1st FU	31.2%	40.9%	0.465
% achieving DAS<2.6 at 2nd FU	60.5%	48.0%	0.162	% achieving DAS<2.6 at 2nd FU	**34.4%**	**63.6%**	**0.034**
HAQ Baseline (Adds)	0.821	0.794	0.835	HAQ Baseline (Adds)	0.830	0.607	0.348
HAQ 1st Follow up (Adds)	0.705	0.694	0.934	HAQ 1st Follow up (Adds)	0.680	0.613	0.776
HAQ 2nd Follow up (Adds)	0.647	0.686	0.813	HAQ 2nd Follow up (Adds)	0.647	0.722	0.778
Change in HAQ after 1st Follow up (Adds)	−0.144	−0.107	0.704	Change in HAQ after 1st Follow up (Adds)	−0.073	0.0875	0.418
Change in HAQ after 2nd Follow up (Adds)	−0.266	−0.160	0.331	Change in HAQ after 2nd Follow up (Adds)	−0.131	0.111	0.212

Conclusion: RF+ patients with established disease may be more responsive to TNFi therapy as measured by changes in HAQ and pain. Perhaps in established RA with DMARD failure, any biologic may have a blunted response in RF negative patients. However, anti-CCP negative patients may also be more responsive to TNFi therapy in ERA but other datasets may be needed to confirm these results. This may also be due to chance.

Better Retention Rate of Rituximab Vs Anti-Tnf Agents As Second Line therapy in RA Patients Failing a First Anti-Tnf Agents: Results From the Rhumadata® Registry. D. Choquette. Institute of Rheumatology of Montreal, Montreal, QC

Background/Purpose: A significant proportion of patient with rheumatoid arthritis treated with a first anti-tnf agent will eventually be exposed to a second biologic agent. The actual knowledge as to the best choice is another anti-TNF agent or an agent with a different mode of action such as rituximab remains controversial and often only explores the first three to six month after initiating the second agent.

Methods: We report three year follow-up of treatment with either a second anti-tnf agents, abatacept or rituximab in a cohort of RA patients having failed a first anti-tnf agent. Data initial extraction date is January 1st 2007. Data is extracted from the prospective Rhumadata ®electronic data collection system which compile over time demographics, diagnosis information, disease duration, anti-CCP and RF status, ESR &CRP, all DAS score, CDAI and SDAI, commonly used PRO's such as the HAQ, Patient global, fatigue evaluation, pain score at all visits. It also compiles all medications used for the treatment of RA with dose, frequency, duration, adverse events and reason for stopping.

Results: 119 patients are included in this analysis. All have failed a first anti-tnf agents. 34 received adalimumab (ADA) as second agent only, 17 rituximab (RTX), 25 etanercept (ETA), 15 infliximab (INF), and 28 abatacept(ABA). Baseline variables are shown in the table 1 (MEAN). % of patient still on treatment at 36 months in table 2.

Table 1. Baseline variables

TX	#PTS	RA/ YEAR	FEMALE	TJC	SJC	DAS28-4-ESR	DAS28-4-CRP	CDAI	FATIGUE (0–10 VAS)
ADA	34	14	74	5	6	3.12	3.47	16.84	5
RTX	17	20	82	8	9	3.79	4.23	23.15	6
ETA	25	15	80	11	10	3.90	4.36	24.85	5
INF	15	14	87	10	9	3.91	4.51	25.27	6
ABA	28	15	82	9	9	3.84	4.12	26.50	7

Table 2. % of patients still continuing therapy at 36 months

Biologic agents	% (p value)
Adalimumab	50% (p=0.03)*
Rituximab	76.5% (ref)
Etanercept	52% (p=0.05)*
Infliximab	33.3% (p=0.01)*
Abatacept	57.1% (p=0.1)*

* Fischer exact test –rituximab vs comparator

Conclusion: In this small sample of patients failing a first anti-tnf, rituximab at usual dosage seems to have better retention rate at 36 months than a second anti-tnf statistically and abatacept numerically.

2204

Effect of Tocilizumab on Hematologic Markers Implicates Interleukin-6 Signaling in the Anemia of Rheumatoid Arthritis. John D. Isaacs[1], Olivier Harari[2], Uwe Kobold[3], C. Bernasconi[4] and Janet S. Lee[5]. [1]Newcastle University, Newcastle Upon Tyne, United Kingdom, [2]Roche, Welwyn, United Kingdom, [3]Roche Diagnostics GmbH, Penzberg, Germany, Germany, [4]Roche, Basel, Switzerland, [5]Roche, Nutley, NJ

Background/Purpose: Infections trigger mechanisms that reduce iron availability to invading pathogens. The putative master regulator of this phenomenon is hepcidin, which inhibits intestinal absorption as well as mobilization from reticuloendothelial stores. Hepatic hepcidin expression is largely IL-6-signaling dependent.[1] These mechanisms also underlie chronic anemia in rheumatoid arthritis (RA).[2] Trials of tocilizumab (TCZ), an IL-6 receptor (IL-6R) inhibitor, show suppression of inflammation and increases in hemoglobin (Hb) in RA patients. We probed for associations between increases in Hb and hepcidin levels in RA patients treated with TCZ.

Methods: In the MEASURE study, patients with active RA and inadequate response to methotrexate (N=132) were randomized to TCZ 8 mg/kg IV or placebo (PBO) every 4 weeks (wks), both with weekly MTX. Serum hepcidin (HPLC–tandem mass spectroscopy assay[3]), markers of inflammation, and iron homeostasis were measured at screening, baseline, and through wk 12 of study. Descriptive methods and simple and multiple regression were used to evaluate data.

Results: Low Hb at baseline exhibited moderate correlation with acute phase reactants (C-reactive protein [CRP] and haptoglobin; Spearman rank correlation [P] −0.20 and −0.25, $P<0.023$ and $P<0.004$, respectively). Pre-treatment hepcidin was highly variable (0 – 63.1 fmol/uL), and levels correlated with acute phase reactants (CRP, HPT, ferritin [P: 0.34–0.64, $P<0.001$]), but not with Hb ($P=0.03$; $P=0.70$). Through 12 wks of treatment with TCZ (n=70) (but not PBO; n=62), increases in Hb and early and marked reductions in hepcidin and inflammation markers (CRP, haptoglobin, and ESR) were observed (Figure). Ferritin levels were reduced, reflecting the role of ferritin as an acute phase reactant; total iron binding capacity increased, reflecting an increased capacity of the blood compartment to store available iron. In TCZ-treated patients, an early drop in hepcidin (wks 1 and 2) correlated with a late increase in Hb (wks 4, 8, and 12) ($P>0.28$, $P<0.02$ for all comparisons). In multivariate analyses including all variables, the strongest predictor for TCZ-induced Hb increase through wks 4, 8, and 12 was fall in haptoglobin (multiple $R^2=0.26$, 0.31, and 0.45, respectively; $P<0.0001$).

Figure: Time course of median %-change in haematologic and inflammatory markers in the TCZ group,exclude early withdrawals (n=5) and patients who received escape therapy (n=12). CRP=C-reactive protein; TIBC= total iron binding capacity.

4. Hashizume M et al. *Rheumatol Int*. 2010;30(7):917–923.

Conclusion: TCZ induced a rapid and sustained fall in hepcidin, in association with suppression of inflammation markers. Association of early reductions in hepcidin with subsequent Hb increases is compatible with role of hepcidin in inflammatory anemia of RA.[4] These findings highlight the need for comparative data on the resolution of inflammatory anemia in RA pts, with TCZ vs. other therapies.

2205

Comparison of Disease Characteristics of rheumatoid arthritis patients in Remission According to the DAS Criteria Versus the New ACR/EULAR Criteria in a Real-World Patient Population. Denis Choquette[1], William G. Bensen[2], Maqbool K. Sheriff[3], John T. Kelsall[4], Milton F. Baker[5], John S. Sampalis[6], Susan M. Otawa[7] and Heidi Imhoff[7]. [1]University of Montreal Hospital Research Centre (CRCHUM), Notre Dame Hospital Montreal, Montreal, QC, [2]McMaster University, Hamilton, ON, Hamilton, ON, [3]Nanaimo Regional General Hospital, Nanaimo, BC, [4]Mary Pack Arthritis Centre, Vancouver, Vancouver, BC, [5]University of Victoria, Victoria, BC, [6]McGill University & JSS Medical Research, Montreal, QC, [7]Merck Canada Inc, Kirkland, QC

Background/Purpose: The commonly used remission criteria DAS-ESR and DAS-CRP rather define minimal disease activity than remission. ACR/EULAR recently developed new definitions of remission[1] (A/E criteria) that reflect more accurately a patient population in clinical remission. ACR/EULAR also endorses the definition of remission according to the SDAI (SDAI≤ 3.3). The purpose of this analysis is to compare the performance of the different remission criteria in a real-world Canadian patient population treated with infliximab (IFX).

Methods: BioTRAC is an ongoing, non-interventional study of patients (pts) starting IFX as first biologic or after having been treated with a biologic for less than six months. Pts with rheumatoid arthritis (RA) who have been enrolled for at least 6 months (mo) ago are included in this analysis. Remission rates at 6 mo are based on a modified ITT analysis, including all pts with sufficient information reported.

Results: A total of 775 established RA patients were included in this analysis. At 6 mo 33%, 28%, 17% and 8% of the pts achieved remission as defined by DAS28-CRP (≤2.6), DAS28-ESR (≤2.6), SDAI (≤3.3) or the A/E criteria, respectively.

In general, mean clinical parameters at 6 mo were higher in pts in DAS-CRP and in DAS-ESR remission compared to pts in SDAI or in A/E remission. The only exceptions were CRP, which was lowest in pts in DAS-CRP remission, and ESR, which was lowest in pts in DAS-ESR remission, reflecting the high weighing of the acute phase reactants in the DAS criteria. When comparing clinical characteristics at 6 mo between pts in SDAI and pts in A/E remission, mean CRP, ESR, Phys. Global Assess., DAS28-ESR, DAS28-CRP and SDAI score were comparable, while morning stiffness, HAQ, TJC, SJC, Pat Global Assess. were lower in pts in A/E remission (table 1). Pts in A/E remission at 6 mos consistently had the lowest HAQ over a 4 year period (as observed analysis), with mean HAQ<0.5, suggesting that pts achieving stringent remission criteria regain normal function and maintain it over 4 years.

Multivariate regression analysis showed that baseline characteristics predicting remission according to the different criteria at 6 mo did not differ greatly. Male gender and HAQ were the major prediction factors for remission.

Table 1. Clinical parameters at 6 mos according to remission criteria

Clinical parameters at 6 mos	DAS28 ESR > 2.6	DAS28 ESR <= 2.6	DAS28 CRP > 2.6	DAS28 CRP <= 2.6	SDAI > 3.3	SDAI <= 3.3	No ACR/ EULAR remission	ACR/ EULAR remission	All patients
	N/Mean	N/Mean	N/Mean	N/Mean	N/Mean	N/Mean	N/Mean	N/Mean	N/Mean
Morning Stiffness (min)	319/38.38	123/23.22	248/42.44	124/18.36	412/39.14	86/16.66	439/38.39	39/12.23	498/35.26
HAQ	317/1.26	121/0.60	249/1.27	121/0.66	412/1.21	81/0.48	437/1.17	39/0.32	493/1.09
ESR (mm/hr)	324/29.12	123/10.37	239/26.64	119/18.16	371/25.76	79/14.58	396/25.24	37/14.92	450/23.80

TJC (out of 28)	324/7.23	123/0.76	252/8.03	124/0.60	420/6.51	86/0.33	447/6.14	39/0.18	506/5.46
SJC (out of 28)	324/4.89	123/0.92	252/5.49	124/0.81	420/4.61	86/0.27	447/4.36	39/0.13	506/3.87
Pat GA (mm)	296/42.12	112/21.34	230/43.44	112/23.38	391/42.71	72/6.72	411/41.27	39/3.72	463/37.11
Phys GA (mm)	319/37.02	123/16.75	249/39.08	124/16.45	411/36.03	86/11.05	438/34.38	39/11.54	497/31.71
DAS28 CRP	261/3.74	94/1.89	252/3.96	124/1.86	312/3.61	64/1.60	332/3.49	39/1.60	376/3.27
DAS28 ESR	324/4.29	123/1.84	237/4.29	118/2.19	369/3.99	78/1.82	394/3.87	37/1.70	447/3.61
SDAI	324/18.90	123/4.31	252/20.50	1234/4.15	420/18.54	86/1.51	447/17.55	39/1.16	506/15.64

Conclusion: The results of this real-world study show that pts in DAS remission have higher disease activity than pts in SDAI or A/E remission. Although ACR/EULAR endorses both the SDAI as well as the A/E criteria, disease activity in pts in SDAI versus A/E remission was different in this real world pt population, with pts in A/E remission having lower disease activity. Stringent remission 6 mo after IFX initiation was associated with a normal functional outcome (mean HAQ<0.5) over 4 years.

Golimumab Treatment Inhibits Progression in Joint Damage in Patients with Psoriatic Arthritis Regardless of Baseline Disease Severity. Arthur Kavanaugh[1], Dafna D. Gladman[2], Anna Beutler[3], Chenglong Han[4] and GO-REVEAL Clinical Investigators. [1]University of California San Diego, San Diego, CA, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, [3]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [4]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA

Background/Purpose: To identify variables associated with radiographic joint damage in pts PsA treated with golimumab (GLM) or placebo (PBO) (standard therapy with MTX or/and NSAIDs) in a Ph3 randomized, PBO-controlled study (GO-REVEAL).

Methods: Adult PsA pts with ≥3 swollen & ≥ 3tender joints were randomized to subcutaneous placebo(PBO) or GLM(50 or 100mg) q4wks. At wk16, pts with <10% improvement in swollen & tender joint counts entered early escape in blinded fashion to GLM50mg (PBO pts) or GLM100mg (GLM 50mg pts). Starting at wk 24, pts remaining on PBO crossed over to GLM50mg. Changes from baseline in PsA modified vdH-S scores of hands and feet were compared at wks24&52 by stratification of baseline disease activity (DAS28>5.1 vs. ≤5.1) or CRP level (>0.6 vs. ≤0.6 mg/dL). Logistic regression model was used to adjust for covariates(age, gender, disease duration, body weight, baseline MTX use) when examining association of baseline DAS28 with joint progression from baseline to wk24 or from wk24 to 52. In logistic regression model, only patients who had no missing X-ray data were evaluated.

Results: 405pts were enrolled with mean(SD) total PsA modified vdH-S scores of 18.15(27.76) to 23.85(35.41) and baseline DAS28 score of 4.9 (1.0) to 5.0 (1.1). At wk24, GLM-treated pts had significantly less radiographic damage than PBO(mean change from baseline −0.09±1.32 vs. 0.27±1.26, p=0.015) or had no progression (change≤0) than PBO-treated pts (77.7% vs. 62.7%, p=0.003). These differences were greater among pts with high disease activity (DAS28>5.1) (p<0.01) or elevated CRP(CRP>0.6 mg/dL) (p=0.01) than pts with moderate disease activity or normal CRP. After adjusting for baseline characteristics using a regression model, higher baseline disease activity was significantly associated with radiographic progression at wk24 in PBO group (p<0.01), but baseline disease activity was not associated with radiographic progression in the GLM group. Similarly, disease activity at wk24 in all pts randomized to GLM or switched to GLM at wk24 was not associated with radiographic progression from wk24 to 54, suggesting that irrespective of disease activity at wk24, there was absent or nominal progression in joint damage at wk52.

Table. Pts with no radiographic progression (vdH-S score ≤0) at wk24 by baseline disease severity (DAS28) or baseline CRP concentration

Baseline DAS28	PBO N=109	GLM (50 or 100mg) N=285	Baseline CRP (mg/dL)	PBO N=112	GLM (50 or 100mg) N=290
<5.1	76.7%	81.2% (p=0.45)	≤0.6	71.7%%	81.3% (p=0.15)
≥5.1	53.1%	76.7% (p<0.01)	>0.6	61.0%	77.6% (p=0.01)

Conclusion: PsA pts with high arthritis disease activity or CRP level at baseline experience more joint damage if treated with standard therapy only. Adding GLM provides additional benefit in inhibiting radiographic progression, especially for pts with more severe disease activity. The beneficial effect of GLM on joint damage was also observed in pts with baseline DAS28 <5.1 or CRP ≤0.6 mg/dl but to a lesser degree than in pts with high disease activity.

2207

Optimism and Depressive Scores in Early Arthritis Patients Before and After Treatment with Methotrexate and a Tapered High Dose of Prednisone in the IMPROVED Study. L. Heimans[1], K.V.C. Wevers-de Boer[1], K. Visser[1], Tom W.J. Huizinga[1], H.K Ronday[2], M.L. Westedt[3], T.H.E. Molenaar[4], R.C. van der Mast[1] and C.F. Allaart[1]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haga Hospital, The Hague, Netherlands, [3]Bronovo Hospital, The Hague, Netherlands, [4]Groene Hart Hospital, Gouda, Netherlands

Background/Purpose: To assess depression and optimism scores in patients with recent onset arthritis, before and after four months of induction therapy with methotrexate and prednisone.

Methods: Patients with recent onset rheumatoid and undifferentiated arthritis were treated with MTX 25mg/week and 60 mg/day of prednisone immediately tapered to 7.5mg/day in seven weeks in the IMPROVED-study. At baseline and four months after start of treatment, patients filled out the Beck Depression Inventory (BDI-II) to assess depression symptom severity (range 0–63) and the Life Orientation Test Revised (LOT-R) to measure optimism (range 0–24). Comparisons were made between scores before and after treatment and between patients who did or did not achieve clinical remission, defined as a Disease Activity Score (DAS) <1.6. Linear multiple regression analysis was used to investigate the relationship between the two questionnaires, DAS and DAS components, visual analogue scales (VAS) for pain, general wellbeing and global health, age, sex, marital status, children, educational level, work, and previous medical history.

Results: 210 patients completed the LOT-R and 215 patients completed the BDI-II at both time points. Optimism and depression are related at baseline, but not after four months. Optimism significantly decreased, independent of whether remission was achieved. There was no significant difference in scores at baseline or after four months between both groups (p=0.823). Regression analysis revealed no significant relationship between disease activity and optimism scores. Only (higher) age was an independent predictor of (higher) absolute optimism scores after 4 months of treatment (p<0.001). Overall, the depression scores significantly improved. In patients who achieved remission, the scores after four months treatment were significantly lower than at baseline (from 6.9 to 4.8, p<0.001). In the non-remission group depression scores before and after treatment were similar (baseline 11.2 and 4 months 11.0, p=0.826). Independent predictors of depression scores after four months were a high depression score at baseline (B 0.48, p<0.001), a high DAS (B 2.17, p<0.001) and a history of metabolic disease (B 2.55, p=0.03). A higher baseline score predicted a smaller delta-BDI-II (B-0.51, p<0.001), higher VAS scores for general health (B 0.07, p=0.020) and general wellbeing (B 0.10, p<0.001) predicted a slightly increased delta-BDI-II.

Conclusion: Depression severity scores decrease in early RA and UA patients who achieve remission after 4 months of treatment with methotrexate and prednisone. However, optimism scores also decreased independent of whether remission was achieved and without strong predictors. This suggests that the change in optimism is not related to change in disease activity but maybe to shared characteristics related to diagnosis, trial participation or medication.

2208

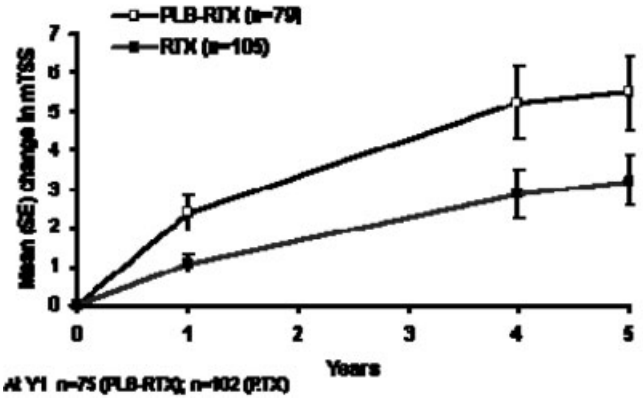
Sustained Inhibition of Structural Damage in Patients with Rheumatoid Arthritis and An Inadequate Response to Tumor Necrosis Factor Inhibitors Prior to Rituximab Treatment: 5-Year Data From the REFLEX Study. Edward Keystone[1], Stanley B. Cohen[2], Paul Emery[3], Joel M. Kremer[4], Maxime Dougados[5], James E. Loveless[6], Carol Chung[7], Patricia B. Lehane[8] and Helen Tyrrell[8]. [1]University of Toronto, Toronto, ON, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [4]Albany Medical College, Albany, NY, [5]Rene Descartes University, Paris, France, [6]St. Luke's Rheumatology, Boise, ID, [7]Genentech, Inc., South San Francisco, CA, [8]Roche Products Limited, Welwyn Garden City, United Kingdom

Background/Purpose: Rituximab (RTX) in combination with methotrexate (MTX) has been shown to inhibit progressive joint damage (PJD) in RA patients (pts) with an inadequate response to TNF inhibitors (TNF-IR) at 2 yrs (Cohen SB, et al. Ann Rheum Dis 2010;69:1158–61). This analysis assessed the impact of RTX treatment over 5 yrs on PJD in TNF-IR pts in the REFLEX open-label extension study.

Methods: In REFLEX, TNF-IR pts received background MTX and were randomized to placebo (PLB; n=209) or RTX (2 × 1000 mg, 2 wks apart; n=311). The study design has been described previously (Cohen SB, et al. Arthritis Rheum 2006;54:2793–806). Pts subsequently transferred to an open-label extension study to receive RTX repeat treatment as clinically required. This post-hoc analysis was conducted on ITT pts with an X-ray at baseline (BL) and at the 5-yr timepoint. Pts who were randomized at BL to PLB who may have subsequently received RTX as rescue therapy (PLB-RTX group) and pts originally randomized to RTX (RTX group) were included. X-rays of the hands and feet were read at BL and yrs (Y) 1, 4, and 5. All X-rays were rescored for this analysis using the Sharp-Genant method by trained radiologists who were blinded to treatment group assignment and order of the X-rays. Missing data were imputed using linear extrapolation of the progression observed from BL to the last value prior to the missing value. Linear interpolation was used between Y1 and Y4.

Results: The ITT population for this analysis comprised 79 PLB-RTX and 105 RTX pts. Among PLB-RTX pts, 71 were rescued with RTX during Y1, with an additional 6 pts rescued after Y1. BL demographics and disease characteristics were balanced between the groups, with the exception of RA disease duration (PLB-RTX 10.5 yrs; RTX 13.5 yrs). Pts in both groups received up to 12 RTX courses (mean = 5 courses over the 5 yrs). In both groups, the mean (SE) change in modified Total Sharp Score (mTSS) continued to decrease to Y5 (figure): change from BL at Y5 was 5.51 (0.95) for PLB-RTX pts and 3.21 (0.64) for RTX pts. Similar effects were observed for erosion scores and joint space narrowing. The annualized progression rate decreased from 2.08 (BL to Y1) to 0.89 (Y1 to Y4) and 0.25 (Y4 to Y5) in PLB-RTX pts, and from 0.91 to 0.56 and 0.33 for the same periods in RTX pts. Between Y4 and Y5, PLB-RTX pts showed similar rates of PJD to those originally randomized to RTX.

Figure: Mean change from baseline in mTSS



Conclusion: This 5-yr analysis of the REFLEX study demonstrates that RA pts with an IR to TNF inhibitors originally randomized to RTX treatment had enhanced inhibition of PJD at 5 yrs compared with pts originally randomized to PLB and later rescued with RTX. Both groups showed continued improvement in PJD inhibition over time, with pts originally randomized to PLB progressing more rapidly than pts originally randomized to RTX. A 1-yr delay in initiating RTX appears to lead to an increased rate of PJD. Differences between the groups remained out to 5 yrs.

2209

Evaluation of Remission Over 1 Year in Patients (pts) with Early Rheumatoid Arthritis (RA) Treated with Abatacept (ABA) Plus Methotrexate, According to Simplified Disease Activity Index (SDAI). Josef Smolen[1], J. Wollenhaupt[2], Juan J. Gomez-Reino[3], Walter Grassi[4], Manuela Le Bars[5], Corine Gaillez[5], Coralie Poncet[6], Ayanbola Elegbe[7] and Rene Westhovens[8]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Schön Klinik Hamburg-Eilbek, Hamburg, Germany, [3]Hospital Clinico Universitario, Santiago de Compostela, Spain, [4]Università Politecnica delle Marche, Ancona, Italy, [5]Bristol-Myers Squibb, Rueil Malmaison, France, [6]Docs International, Sèvres, France, [7]Bristol-Myers Squibb, Princeton, NJ, [8]UZ Gasthuisburg, Leuven, Belgium

Background/Purpose: In the AGREE study, a large proportion of pts with early RA and poor prognostic factors achieved DAS28 remission over 1 yr[1]. However, there is evidence that RA pts in DAS28 remission may experience residual disease activity as evidenced by tender/swollen joint counts (TJC/SJC) which, in turn, can lead to radiographic progression over time[2,3]. Recent ACR/EULAR recommendations advise the use of more stringent criteria, such as SDAI to define remission. SDAI does not have such heavy weighting for acute phase reactants as DAS28, but encompasses both physician and patient global assessments[4]. Here, we assess outcomes for ABA + MTX-treated early RA pts in SDAI remission through 1 yr.

Methods: During the 1-yr double-blind (DB) period of AGREE, MTX-naïve pts with early erosive RA (≤2 yrs), high disease activity (TJC ≥12, SJC ≥10 and CRP >0.45 mg/dL), and positivity for RF or anti-CCP were randomized 1:1 to ABA (~10 mg/kg) + MTX or placebo + MTX (MTX alone). DAS28 (C-reactive protein [CRP]) remission (co-primary Yr 1 endpoint) was defined as <2.6 (pts who discontinue considered non-responders) and SDAI remission as ≤3.3. All SDAI analyses were *post-hoc* (as-observed data). Clinical outcomes for patients in SDAI remission at Mth 6 and Yr 1 were determined.

Results: In total, 256 and 253 pts were treated with ABA + MTX vs MTX alone; 232 and 227 pts, respectively, completed Yr 1. Baseline demographics were similar between groups[1]; mean (SD) DAS28 (CRP) 6.3 (1.0) [n=256] vs 6.2 (1.0) [n=252] and SDAI 48.7 (14.9) [n=255] vs 48.1 (14.5) [n=252] for ABA + MTX vs MTX alone. At Mth 6, 72/256 (28.1% [95% CI: 22.6–33.6]) vs 39/253 (15.4% [11.0–19.9]) pts achieved DAS28 remission and 44/235 (18.7% [13.7–23.7]) vs 22/228 (9.6% [5.8–13.5]) SDAI remission, for ABA + MTX vs MTX alone. At Yr 1, 106/256 (41.4% [35.4–47.4]) vs 59/253 (23.3% [18.1–28.5]) achieved DAS28 remission and 70/219 (32.0% [25.8–38.1]) vs 21/215 (12.6% [8.1–17.0]) achieved SDAI remission for ABA + MTX vs MTX alone, respectively. For pts only achieving SDAI remission at Yr 1 but not Mth 6, mean (SD) SDAI at Mth 6 was 11.6 (11.3) for ABA + MTX (n=36) vs 11.9 (11.8) for MTX alone (n=18), suggesting low disease activity and improvements from baseline. Mth 6 and Yr 1 outcomes for ABA + MTX-treated pts in SDAI remission are shown (Table); pts in remission at Mth 6 and Yr 1 experienced low TJCs, SJCs, and HAQ-DI scores, among other SDAI components.

Table 1. Outcomes for abatacept plus methotrexate treated patients

Mean score (SD)	Patients in SDAI Remission at Month 6* (n=44)	Patients in SDAI Remission at Year 1†(n=70)
SDAI	1.53 (0.83)‡	1.63 (0.90)
TJC	0.18 (0.39)	0.19 (0.43)
SJC	0.14 (0.41)	0.11 (0.36)
PGA (0–10 cm VAS)	0.55 (0.45)	0.63 (0.57)
EGA (0–10 cm VAS)	0.35 (0.32)§	0.34 (0.34)
CRP (mg/dL)	0.32 (0.34)	0.36 (0.40)
ESR (mm/hour)	18.60 (11.95)#	19.10 (17.68)¶
HAQ-DI (0–3)§	0.18 (0.23)**	0.20 (0.34)††

Based on patients with both baseline and post-baseline data; *Outcomes at Month 6; †Outcomes at Year 1; ‡n=43; §n=43; #n=20;¶n=30;**n=42; ††Last observation carried forward; SD=standard deviation; SDAI=Simplified Disease Activity Index;TJC=28-joint tender joint count; SJC=28-joint swollen joint count; HAQ-DI=Health Assessment Questionnaire-Disability Index; PGA=Patient Global Assessment; VAS=visual analog scale; EGA=Physician Global Assessment; CRP=C-reactive protein; ESR=erythrocyte sedimentation rate

Conclusion: A large proportion of ABA + MTX-treated pts (32%) with early RA achieved stringent SDAI remission by Yr 1. Pts in SDAI remission at Mths 6 and 12 had little residual activity, as evidenced by SJC, TJC and HAQ-DI. Pts in SDAI remission at Yr 1 but not Mth 6 had low disease activity at Mth 6 suggesting that pts experiencing improvements can reach treatment goals with continued therapy.

GLPG0634 Shows Selective Inhibition of JAK1 and Maintained JAK-STAT Suppression in Healthy Volunteers. Frédéric Vanhoutte[1], René Galien[2], Eva Vets[3], Florence Namour[2], Béatrice Vayssière[2], Luc Van Rompaey[1], Bart Smets[1], Reginald Brys[1], Piet Wigerinck[1] and Gerben van 't Klooster[1]. [1]Galapagos NV, Mechelen, Belgium, [2]Galapagos SASU, Romainville, France, [3]SGS, Antwerp, Belgium

Background/Purpose: The four members of the Janus kinase (JAK) family of kinases, JAK1, JAK2, JAK3 and TYK2, are involved in signal transduction of inflammatory mediators, implicated in the pathogenesis of rheumatoid arthritis (RA). Small-molecule inhibitors of JAK1/2 and JAK1/3 have demonstrated therapeutic efficacy in clinical trials in RA.

GLPG0634 inhibits JAK1 with an IC_{50} of 10 nM in biochemical assays and shows efficacy in the therapeutic rat collagen-induced arthritis (CIA) model at 1 mg/kg once-daily oral dosing.

The JAK selectivity profile of GLPG0634 was further characterized using cellular- and human whole blood assays (WBA). The safety, tolerability and pharmacokinetic/pharmacodynamic (PK/PD) profile were evaluated in healthy volunteers. These data are presented here.

Methods: JAK inhibition by GLPG0634 was evaluated in a range of cellular assays with phosphorylation of STATs (pSTAT1, 5 and 6) induced by various ligands (IL, IFN, OSM and EPO) as read-outs.

Phase I clinical evaluation included single and multiple ascending oral dosing as capsules in 6 panels of 8 male healthy volunteers (2 on placebo). Two alternating panels took single doses from 10 to 200 mg, and 10-day dosing was performed in 4 consecutive panels for doses from 25 mg twice daily up to 200 mg once-daily. Safety was monitored continuously, and PK and PD (upon *ex vivo* stimulation, extent of STAT phosphorylation and/or JAK-STAT target gene expression) were evaluated at various timepoints on Days 1 and 10.

Results: In contrast to JAK2 pathways (EPO/pSTAT5, $IC_{50} > 10\ \mu M$), JAK1/JAK3 pathways were potently inhibited (IL4/pSTAT6, IC_{50}: 160 nM) in cells. Furthermore, GLPG0634 demonstrates 30-fold selectivity for JAK1 over JAK2 in cellular assays and WBA (IL-6/pSTAT1 over GM-CSF/pSTAT5).

In healthy volunteers, GLPG0634 was safe and well-tolerated for up to 10 days at 200 mg/day. Treatment-emergent adverse events (AEs) over all dose groups were mild and transient with a comparable incidence in GLPG0634- and placebo-treated subjects. Main AEs were headache, somnolence and abdominal discomfort. There were no relevant findings on hematology (including reticulocytes), biochemistry (including cholesterol and lipids) or other safety parameters (ECG and vital signs). A maximal tolerated dose was not reached. After both single and repeated dosing, PK was dose proportional, with an average elimination half-life of 6 hours. At 50 mg and higher doses, exposures were similar to or exceeded active exposures in rat CIA studies. Up from this dose level, dose-related PD effects on JAK1-related biomarkers (IL6-induced pSTAT1 and IFN-induced SOCS3 gene expression) were observed in blood from subjects exposed to GLPG0634. After once-daily dosing of 200mg, IL6-induced pSTAT1 still tended to be suppressed at pre-dose trough.

Conclusion: GLPG0634 potently inhibits JAK1 with a 30-fold selectivity over JAK2 in WBA. In healthy volunteers, GLPG0634 is well tolerated in the pharmacological active dose range, with a PK/PD relationship consistent with once-daily dosing. No signs indicative of anemia were observed after 10-days of dosing. These results support the progression of GLPG0634 into efficacy evaluation in RA patients.

2211

Evaluation of Anti-Tumor Necrosis Factor Levels and Anti-Tumor Necrosis Factor Antibodies in Rheumatic Diseases Treated with Infliximab and Adalimumab; Preliminary Results From a Local Registry.

José Rosas-Gómez de Salazar[1], Francisca Llinares-Tello[1], José M. Senabre-Gallego[1], Gregorio Santos-Soler[1], Carlos Santos-Ramírez[2], Esteban Salas-Heredia[1], Xavier Barber-Vallés[3], Mabel Sánchez-Barrioluengo[4], Juan Molina-García[1], Nuria Llahí Vidal[1] and Catalina Cano Pérez[1]. [1]Hospital Marina Baixa, Villajoyosa, Spain, [2]Hospital Marina Salud, Denia, Spain, [3]University Miguel Hernández, Elche, Spain, [4]Universitat Politècnica de València, Valencia, Spain

Background/Purpose: To analyse the clinical relevance of serum levels of infliximab (INF) and adalimumab (ADA) and the production of anti-INF (INF-Abs) or anti-ADA antibodies (ADA-Abs) from a local registry of patients with rheumatic diseases on treatment with INF or ADA.

Methods: We included 55 consecutive patients receiving treatment for more than 6 months with INF (25 patients) and ADA (30 patients). Clinical characteristics, clinical activity index (DAS in 28 joints for rheumatoid arthritis -RA- and psoriatic arthritis -PsA-; BASFI, BASDAI for ankylosing spondylitis -AE-) were recorded. Serum levels of INF or ADA and INF-Abs or ADA-Abs (ELISA kit. Promonitor®-INF, ADA. Proteomika, Derio. Vizcaya. Spain) were evaluated. Cut-off level for serum Abs for INF was >15 U/mL, and for ADA >8 U/mL and cut-off level for serum level of INF and ADA were <0.04 mg/L and <0.002 mg/L respectively.

Serum samples were collected at the time of infusion of INF or before injection of ADA, and stored frozen until analysis. Infusion reactions with INF were defined as any event appearing during infusion requiring either arrest of drug infusion or the administration of parenteral medication.

Patients were considered responders if they had at the same time of extraction, DAS28-ESR≤3 in RA or PsA patients; BASDAI≤4 in AE patients.

Results: We enrolled 55 patients, 36 were women; the mean age was 55±14 years. The diagnosis of patients was: RA (49%), AE (31%), PsA (15%) and others (5%). The average time of treatment for the whole population was 33.63 months and for INF and ADA was 41.5 months (range: 6–127) vs 25 months (range: 8–51) respectively. INF was the first anti-TNF received in 24 (96%) of the patients, and ADA was the first in 25 (83%) of the patients.

Antibodies were detected in 9 patients (18%): 5/25 patients (20%) INF-Abs and 4/30 patients (13%) ADA-Abs. In the ADA-Abs patients: all of them had low level of ADA, with a range level of Abs between 132–717.824 U/mL. Table 1 showed the characteristics in responders and non-responders patients. In the INF-Abs patients, only one patient had normal level (1.3 mg/L), and the range level of Abs was between 20–121.840 U/mL. Three patients had infusion reaction with INF, 2 of them with high level of Abs (1.282, 121.849 U/mL), and one patient without Abs.

Table 1. Characteristics in responders and non-responders patients.

	Responders (n: 17)	Non Responders (n: 8)	P
INF level, mean (range)	22.98±18,25 (3.60–73.21)	0.17±0.39 (0.04–1.14)	<0.005
INF-Abs	0%	62.5%	<0.001
DAS28-ESR	2.56	3.60	<0.001
	Responders (n: 15)	**Non Responders (n: 15)**	
ADA-level mean (range)	8,44±5.0 (2.42–21.30)	2,93±3,39 (0.002–11.28)	<0.005
ADA-Abs	0%	27%	0.02
DAS28-ESR	2.52	4.37	<0.01*

* Less than 5 values in same categories.

Conclusion: 1. Serum antibodies were detected in 20% of patients receiving treatment with INF and 13% of patients with ADA. 2. Patients responders have absence of Abs and significantly higher serum concentrations of anti-TNF than non-responders. 3. Immunogenicity can induce inefficacy in patients on treatment with anti-TNF.

2212

Open-Label, Pilot Study of the Safety and Clinical Effects of Rituximab in Patients with Rheumatoid Arthritis-Associated Interstitial Pneumonia.

Eric L. Matteson[1], Paul F. Dellaripa[2], Jay H. Ryu[1], Cynthia S. Crowson[1], Thomas E. Hartman[1] and Tim Bongartz[1]. [1]Mayo Clinic, Rochester, MN, [2]Brigham & Womens Hospital, Boston, MA

Background/Purpose: Clinically overt interstitial lung disease (ILD) is prevalent in 10–20% of patients with rheumatoid arthritis (RA) and has a significant impact on mortality. We sought to investigate the clinical effect of rituximab (RTX) in the management of progressive RA related ILD over a 48 week period of observation.

Methods: A total of 10 patients with RA ILD (4 with UIP, 6 with NSIP) were enrolled into this 48 week, open label treatment study. Treatment was with RTX at 1000 mg at time 0, and then repeated at week 2 and then again at weeks 24 and 26, with concomitant MTX. The primary endpoint was the safety of rituximab therapy, with secondary endpoints progression-free survival at 48 weeks.

Results: The study included 4 men and 6 women with mean age 64.7 years (min: 43, max: 80) who had RA (mean duration 13.8 years; min: 0.4, max: 43) and ILD (mean duration 3.2 years; min:0.2, max 7.5). Baseline pulmonary function included mean FVC 68% (min: 47%, max: 89%), mean DLco 47.6% (min: 28%, max: 73%), mean FEV1/FVC ratio 86.5 (min: 68.8, max 101), mean St. George's score 54.7 (min: 4.0, max 92.5). ILD changes were present in all patients at baseline. Mean SF-36 physical component score (PCS) was 23.2 (min: 11.4, 43.5), and the mean mental component score (MCS) was 47.8 (min: 324, max: 57.3).

Safety: One patient had an infusion reaction at week 0 and withdrew from the study. One patient was hospitalized for congestive heart failure at week 5, unlikely to be related to study drug, and later died at week 32 (complications following a traumatic hip fracture). Another patient died at week 6 (possible pneumonia).

Efficacy: By week 48, the DLco had worsened by at least 15% (at least ≥ 3 ml/min/mm Hg) in 1 patient, was stable in 4 patients, and increased by >15% of baseline in 2 patients. The FVC declined by at least 10% (and at least ≥ 200ml) in 1 patient, was stable in 4 patients, and increased by at least 10% in 2 patients. HRCT showed improvement in 1 patient and there were no changes noted on HRCT for the other 6 patients assessed at week 48. There was no clinically meaningful change in the St. George's respiratory score or SF36 parameters at week 48.

Conclusion: In this pilot study of 10 patients with RA associated advanced ILD treated with rituximab, there were significant adverse events including two deaths. Given the small number of patients, the relationship of these events to treatment vs. underlying disease is unclear. However, we didnot find a signal for clinical efficacy of this treatment for RA-ILD. Further research is needed to clarify whether this treatment has a role in management of RA-ILD in less advanced disease, or in specific histopathologic patterns of disease.

2213

Efficacy and Safety of Tocilizumab As Monotherapy or in Combination with Nonbiologic Disease-Modifying Antirheumatic Drugs: A 24-Week Randomized Study in a United States Population. Michael E. Weinblatt[1], Joel M. Kremer[2], John J. Cush[3], William F. C. Rigby[4], Lichen Teng[5], Natasha Singh[5] and Raymond L. Malamet[6]. [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]Albany Medical College and The Center for Rheumatology, Albany, NY, [3]Baylor Research Institute, Dallas, TX, [4]Dartmouth-Hitchcock Med Ctr, Lebanon, NH, [5]Roche, Nutley, NJ, [6]Genentech, South San Francisco, CA

Background/Purpose: The efficacy and safety of tocilizumab (TCZ) were studied in 5 pivotal randomized controlled trials (RCTs). We evaluated the benefit-risk profile of TCZ in patients (pts) with rheumatoid arthritis (RA) in an open-label, clinical practice study (ACT STAR).

Methods: This phase 3b, 24-wk, open-label, randomized, multicenter US study evaluated adults with active RA who had an inadequate clinical response or safety/tolerability issues with prior DMARD therapy. Patients on monotherapy (MONO) with biologic DMARD prior to baseline (BL) had biologic discontinued and replaced with TCZ MONO (8 mg/kg). Patients on MONO or combination (COMBO) with nonbiologic DMARDs were randomized to TCZ 4 mg/kg or 8 mg/kg and continued their current nonbiologic DMARD (discontinuing any prior biologic). At wk 8, pts on TCZ 4 mg/kg + nonbiologic DMARD who did not achieve ≥20% improvement in joint counts had TCZ dose increased to 8 mg/kg; beginning at wk 12, TCZ dose could be increased to 8 mg/kg per physician judgment. Study visits occurred at BL and 4 wks after each infusion; safety was primary study endpoint.

Results: The safety population included 883 pts (364 TCZ 4/8 mg/kg + nonbiologic DMARD; 381 TCZ 8 mg/kg + nonbiologic DMARD, and 138 TCZ 8 mg/kg). Over half of TCZ 4 pts were switched to TCZ 8 (n=211; 142 at wk 8). In the 3 groups, BL mean RA duration was 11.5, 10.5, and 13.5 years, respectively; pts using previous biologic DMARD were 65.4, 71.7, and 92.0%, respectively; pts using ≥2 previous anti-TNF agents were 25.8, 34.6, and 44.2%, respectively; and pts with normal CRP (≤0.3 mg/dL) were 28.3, 31.8, and 17.4%, respectively. AEs/SAEs/lab results are summarized in **Table**. SAEs/100 Pt-Yrs (95% CI) were comparable [29.1% (21.0, 39.2), 30.3% (22.2, 40.2), and 20.6% (10.3, 36.9)] for TCZ 4/8+DMARD, TCZ 8+DMARD, and TCZ 8 groups. The most common SAE was serious infections (SIEs, 3.6% [n=32]); tuberculosis was not reported. GI perforation was noted for TCZ 4+DMARD (n=3). At wk 24, CRP values were decreased 0.66, 0.91, and 1.54 mg/dL (all $P<0.0001$) from BL in the 3 groups, respectively. Efficacy outcomes (ACR20/50/70 response: 44.8/24.3/8.8%, 49.7/27.1/10.3%, and 47.9/24.5/7.4%, respectively; DAS28 remission: 20.6, 25.2, and 19.8%, respectively; and joint count response [≥20% improvement in tender and swollen joint counts] for BL CRP normal/elevated pts: 59.2/58.7%, 61.7/61.3%, and 46.7/59.4%, respectively) were similar for all groups in ITT population.

Table. AEs, SAEs, and Laboratory Abnormalities

Pts with ≥1 event/result, %	TCZ 4/8*+ DMARD n=364	TCZ 8+DMARD n=381	TCZ 8 n=138
AEs, %	80.8	81.1	82.6
SAEs, %	8.0	8.4	5.8
SAEs leading to TCZ discontinuation, %	3.0	1.0	2.2
Death, % (n)[†]	0.5 (2)	(0)	(0)
SIEs, %	3.6	3.9	2.9
Neutropenia (CTC Grade 3[‡])[µ], %	0.8	2.4	5.1
Platelet count (CTC Grade 3[‖]), %	0.6	–	–
ALT elevations (≤ULN at BL), %			
>1.5–3 × ULNM	7.9	13.2	6.1
>3 × ULN	2.1	1.9	1.5
TCZ or DMARD dose reduced/ interrupted/stopped after second ALT elevation, n/N (%)	18/33 (54.5)	34/60 (56.7)	9/13 (69.2)
Normalization following highest ALT elevation			
≥1–3 × ULN, n/N (%)	64/103 (62.1)	68/115 (59.1)	14/26 (53.8)
≥3–5 × ULN, n/N	3/8	2/6	0/4
≥5 × ULN, n/N	0	2/2	0
LDL-C ≥130 mg/dL (<100 at BL), %	8.0	6.7	3.2

* 211 pts switched from TCZ 4 to 8; [†]Cardiac death; cerebrovascular accident; [‡]ANC ≥0.5 – <1.0 × 10^9/L; no Grade 4 neutropenia; [µ]No apparent relationship between neutropenia and SIEs; [‖]Platelets ≥25.0 – <50.0 × 10^9/L; no Grade 4 thrombocytopenia.

Conclusion: The safety of TCZ MONO and COMBO therapy observed in this US clinical practice study was consistent with that seen in TCZ RCTs. Overall, similar rates of SAEs, SIEs, and laboratory abnormalities were observed among the 3 treatment groups. Efficacy among MONO and COMBO treatment groups was similar and comparable with the pivotal RCTs, suggesting a similar risk-benefit profile of TCZ MONO and COMBO therapy is observed in real-world practice.

2214

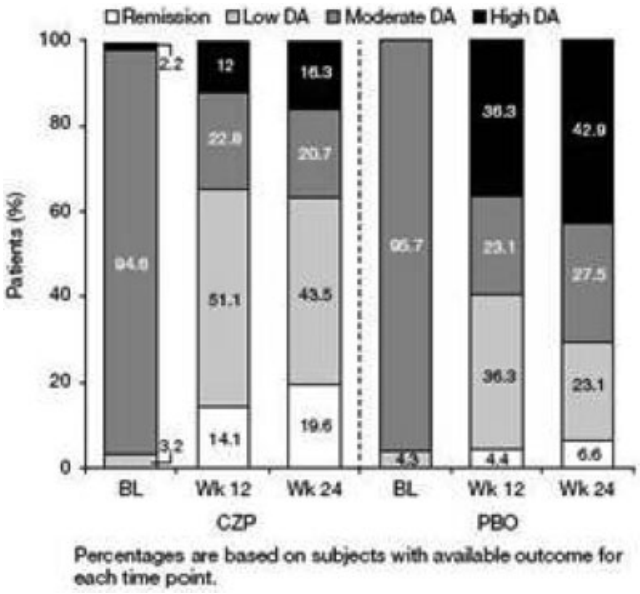
Efficacy, Safety, and Improvements in Work Productivity and Daily Activities with Certolizumab Pegol After Incomplete Response to Disease-Modifying Anti-Rheumatic Drugs in Patients with Low to Moderate Disease Activity. Josef Smolen[1], Paul Emery[2], Gianfranco Ferraccioli[3], Francis Berenbaum[4], Owen Davies[5], Oana Purcaru[5], Johann Ambrugeat[5], Barbara Bennett[6] and Harald Burkhardt[7]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [3]Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy, [4]Pierre and Marie Curie University, AP-HP St-Antoine Hospital, Paris, France, [5]UCB, Brussels, Belgium, [6]UCB, Smyrna, GA, [7]Johan Wolfgang Goethe University, Frankfurt am Main, Germany

Background/Purpose: We evaluated the efficacy, safety, and effects on work productivity and daily activity of certolizumab pegol (CZP) in combination with nonbiologic DMARDs in RA patients (pts) with low to moderate disease activity (DA).

Methods: CERTAIN (**CERT**olizumab pegol in the treatment of R**A**: remission **IN**duction and maintenance in pts with low DA) was a 52-wk, double-blind, Phase IIIb trial that enrolled pts with low to moderate DA (CDAI >6 and ≤16). Pts were randomized (1:1) to CZP (400 mg at Wks 0, 2, and 4, then 200 mg every other wk) or placebo (PBO) + existing DMARDs for an initial 24-wk phase (NCT00674362). Primary efficacy end point was % of pts in CDAI remission (≤2.8) at both Wks 20 and 24. CDAI/SDAI/DAS remission was assessed using NRI. Pts with CDAI remission at Wks 20 and 24 stopped CZP and were followed until Wk 52. Work productivity and daily activities were assessed using the Work Productivity and Activity Impairment Questionnaire (WPAI:RA). We report data for efficacy, safety, and WPAI:RA up to Wk 24.

Results: A total of 194 pts were randomized (mean age 54 y; 80% female) and 164 (84.5%) completed 24 wks. At BL, mean RA duration was 4.6 y and >90% of pts had moderate DA. Mean BL scores were SJC = 3.3, TJC = 3.8, CDAI = 13.4, HAQ-DI = 1.1, and DAS28(ESR) = 4.5. Significantly more CZP pts had CDAI remission at both Wks 20 and 24 than PBO pts (18.8% vs 6.1%, p=0.013 by logistic regression). At Wk 24, more CZP pts had CDAI remission/low DA (63.1% vs 29.7%) (Figure). CZP was associated with prevention of disease worsening; fewer CZP pts had moderate/high DA (37.0% vs 70.4%). Most of the effect of treatment with CZP was already seen at Wk 12, with similar numbers of pts in CDAI remission/low DA as at Wk 24. Mean CDAI/SDAI/DAS28 scores worsened in PBO pts (mean change from BL at Wk 24 CZP vs PBO: –4.01/–4.4/–1.12 vs 3.38/3.4/–0.07). Safety results at Wk 24 indicated that CZP was well tolerated with AE, serious AE, and serious infection rates comparable between CZP and PBO

(68.8% vs 67.3%; 5.2% vs 7.1%; 2.1% vs 1.0%). At BL, 32.4% pts were employed (29% in PBO vs 35.9% in CZP). Increased WPAI:RA mean scores at BL indicated an economic burden of low to moderate RA, especially in terms of overall work and daily activities (Table). Over the 24 wks, CZP pts reported on average greater improvements in absenteeism, presenteeism, overall work impairment, and daily activity, than PBO (Table).



Conclusion: In RA pts with longstanding low to moderate DA, the addition of CZP to nonbiologic DMARDs was well tolerated and associated with increased rates of remission, prevention of disease worsening, and improved work productivity and daily activity.

2215

Improved Quality of Life and Productivity in Patients with Moderate or Severe Rheumatoid Arthritis Actively Switched to Treatment with Infliximab From Adalimumab or Etanercept Therapy. Roy M. Fleischmann[1], Rebecca Bolce[2], Jim Wang[3], Mike Ingham[2], Raphael J. DeHoratius[2], Dennis Decktor[2] and RESTART Clinical Investigators. [1]MCRC, University of Texas, Dallas, TX, [2]Janssen Services, LLC, Horsham, PA, [3]Johnson & Johnson Pharmaceutical Research and Development, LLC, Belle Mead

Background/Purpose: The results from the RESTART study have shown that RA pts with active disease, despite treatment with SC anti-TNFα inhibitors, respond to infliximab (IFX). The dosing flexibility allowed in the IFX prescribing information allows for the treatment of continued active disease by adjusting dose for achievement of specific targeted clinical outcomes. The purpose of this study was to evaluate the effect of IFX on quality of life(Qol) and productivity in pts with moderate or severe RA actively switched from adalimumab (ADA) or etanercept (ETN).

Methods: This is a Ph4, multicenter, open-label, assessor-blinded, active switch study of IFX in pts with active RA who received MTX and had inadequate response (DAS28 score$\geq$ 3.6 and $\geq$6 swollen and $\geq$6 tender joints) to ADA/ETN. Pts were on stable dose of $\geq$7.5 mg/wk of MTX for $\geq$4 wks prior to screening. Pts receiving ETN were switched no less than 1wk and no more than 2wks after the last dose; pts receiving ADA were switched no less than 2wks and no more than 4wks after the last dose. Pts received open-label 3mg/kg IFX infusions at wks0, 2&6. Pts who either achieved/maintained EULAR response at wks14/22 remained on current IFX dose. IFX dose was increased by 2mg/kg for pts who did not achieve/lost response. Evaluations occurred at wk10 post induction and at wk26 following 2additional IFX doses at wk14&22. Pt functional status was assessed using the HAQ-DI at wk10&26. Health Status was evaluated using EQ-5D & SF-36. The EQ-5D includes a descriptive 5-dimensional system for evaluating current health status (each dimension has 3 response levels) and an alternative method using a standard 20cm VAS "feeling thermometer". Available algorithms allow scores on either dimension responses or the VAS to be converted to a pt quality adjusted life year(QALY) "utility" score. SF-36 requests pt health status over the prior 4wks and reports on 8 dimensions and2 summary component scales (Mental and Physical Health). Health economics data included medical resource utilization, time lost from work/school &employability at wk30.

Results: Data for 197/203pts enrolled were evaluable. 60.9% and 39.1% pts were previously treated with ETN or ADA, respectively. Baseline demographics and efficacy were reported previously. Mean HAQ score significantly improved from baseline (1.334,CI:1.252, 1.415) at both wk10 (-0.173,CI:-0.242,-0.105; $p<0.001$) and wk26 (-0.223,CI: -0.303,-0.143; $p<0.001$). % of pts who achieved significant improvement ($\geq$0.22 units) in HAQ score were 39.1% (CI:32.2%, 46.3%) at wk10 and 40.1% (CI:33.2%, 47.3%) at wk26. Change from baseline on all SF-36 domain scores significantly improved at both wk 10&26. Change in pt QALYs, taken from theEQ-5D also significantly improved over baseline (mean change of 0.106, CI: 0.073 to 0.140); $p<0.001$). Number of physician visits in previous 8wks decreased at wk30 from baseline. At wk30, no pts reported emergency room visits in the past 8wks. Pts assessed their productivity as significantly improved at wk30 vs. baseline (-1.42, CI:-1.86, -0.98; $p<0.001$).

Conclusion: RA pts actively switched from ADA or ETN to IFX, without a washout period, demonstrated a statistically significant & clinically important improvement in QoL, health status and productivity.

2216

Safety and Effectiveness of Adalimumab in Patients with Rheumatoid Arthritis During More Than 5 Years of Therapy Observed in a Phase 3b and Post-Marketing Observational Study. Gerd-Rüdiger Burmester[1], Marco Matucci-Cerinic[2], Xavier Mariette[3], Francisco Navarro-Blasco[4], Uemit Oezer[5], Sonja Kary[5], Kristina Unnebrink[5], Theresa Peterson[6] and Hartmut Kupper[5]. [1]Charité - University Medicine, Berlin, Germany, [2]University of Florence, Florence, Italy, [3]Université Paris-Sud Hôpital Bicêtre, Le Kremlin Bicêtre, France, [4]Universitario de Elche, Alicante, Spain, [5]Abbott, Ludwigshafen, Germany, [6]Abbott, Abbott Park, IL

Background/Purpose: In the phase 3b ReAct study, adalimumab (ADA) was added to pre-existing, inadequate, DMARD therapies in patients (pts) with long-standing, severely active rheumatoid arthritis (RA).[1] ReAlise was established to evaluate the long-term safety and effectiveness of ADA in pts who had completed ReAct. The objective of this analysis was to examine the long-term safety and effectiveness of ADA from the first injection in ReAct until the last observation (LO) in ReAlise (ie, >5 yrs).

Methods: Pts were eligible to enroll in ReAlise within 12 months of concluding participation in ReAct. Adverse events (AEs) were tabulated by 5 time windows after the first ADA injection. Standardized Mortality Rates (SMR) and Standardized Incidence Ratios (SIR) for malignancies were calculated for the completed treatment periods of all patients. For the calculation of SIR, the study results were compared with the NCI SEER database for all malignancies and lymphomas. For the calculation of SMR, study results were compared to an age- and sex-matched European cohort (WHO statistics, 2001). Effectiveness measures included the number (%) of pts with low disease activity (LDA) or remission (REM) as determined by simplified disease activity index (SDAI) $\leq$11 and $\leq$ 3.3, respectively, at 0.5, 1, 3, and 5 yrs and at LO after the first ADA injection using observed values.

Results: Among pts from ReAct, 52% (3435 of 6610) enrolled in ReAlise. In ReAct, the median age, DAS28, and HAQ-DI were 55 yrs, 6.1, and 1.73, respectively, at baseline. The median treatment duration was 2045 days (5.7 yrs); the minimum/maximum was 129 and 2681 days. The SIR was 0.64 (95% CI = 0.53–0.76) for all malignancies, and 1.99 (95% CI = 1.11–3.28) for lymphomas. The SMR was 0.71 (95% CI = 0.57–0.87). AEs are displayed in time windows after the first injection of ADA (**Table 1**). The number (%) of patients who achieved and maintained LDA and REM are shown in **Table 2**.

Table 1. Overview of Adverse Events (E[E/100PYs]) During More Than 5 years of Therapy with ADA

	Time windows after first injection of ADA					
	Overal N=6610 18272 PYs)	≤0.5 yr N=6610 (3059 PYs)	>0.5 to 1 yr N=5922 (2256 PYs)	>1 to 3 yrs N=4283 (6149 PYs)	>3 to 5 yrs N=2623 (4549 PYs)	>5yrs N=2000 (2260 PYs)
Serious AEs	2529 (13.8)	838 (27.4)	419 (18.6)	661 (10.7)	417 (9.2)	194 (8.6)
Fatal AEs	102 (0.6)	29 (0.9)	19 (0.8)	27 (0.4)	17 (0.4)	10 (0.4)
Serious Infections	518 (2.8)	162 (5.3)	83 (3.7)	154 (2.5)	81 (1.8)	38 (1.7)
TB[a]	35 (0.2)	11 (0.4)	11 (0.5)	8 (0.1)	4 (0.1)	1 (<0.1)
Sepsis	35 (0.2)	13 (0.4)	4 (0.2)	7 (0.1)	7 (0.2)	4 (0.2)
Malignancies[b]	121 (0.7)	19 (0.6)	16 (0.7)	45 (0.7)	25 (0.5)	16 (0.7)
Lymphoma	15 (0.1)	1 (<0.1)	0	9 (0.1)	4 (0.1)	1 (<0.1)
NMSC	43 (0.2)	8 (0.3)	2 (0.1)	17 (0.3)	11 (0.2)	5 (0.2)
Serious CHF	47 (0.3)	15 (0.5)	6 (0.3)	12 (0.2)	13 (0.3)	1 (<0.1)
Cerebrovascular AEs	56 (0.3)	13 (0.4)	5 (0.2)	16 (0.3)	15 (0.3)	7 (0.3)
Serious hematologic AEs	13 (0.1)	4 (0.1)	2 (0.1)	1 (<0.1)	3 (0.1)	3 (0.1)
Serious hepatic events	58 (0.3)	10 (0.3)	13 (0.6)	16 (0.3)	13 (0.3)	6 (0.3)

CHF, congestive heart failure; E, events; NMSC, non-melanoma skin cancer; PYs, patient-years; TB, tuberculosis. [a]Including 2 pts with a positive test for latent TB during ADA therapy. [b]Excluding lymphoma and NMSC.

Table 2. Number (%) of Patients with LDA or REM During ADA Treatment

	Time points after first injection of ADA				
	0.5 yr	1 yr	3 yrs	5 yrs	Last Observation
LDA	2372 (49)	1899 (56)	1364 (69)	062 (75)	3176 (50)
REM	781 (16)	747 (22)	616 (31)	503 (36)	1321 (21)

Conclusion: Long-term data from observational studies or registries are subject to bias since continued treatment often occurs in patients for whom the drug is efficient and well tolerated. However, in a setting that represents routine clinical practice, no new safety concerns, no increased risk of malignancy, and the expected risk of lymphoma were observed during a median follow-up of more than 5 years of treatment with ADA, representing approximately 20,000 PYs. Effectiveness of ADA was maintained during long-term observation.

2217

Long-Term Safety of Tocilizumab in Rheumatoid Arthritis Clinical Trials. Mark C. Genovese[1], Anthony Sebba[2], Andrea Rubbert-Roth[3], Juan Scali[4], Moshe Zilberstein[5], Liz Thompson[6] and Ronald F. van Vollenhoven[7]. [1]Stanford University Medical Center, Palo Alto, CA, [2]University of South Florida, Palm Harbor, FL, [3]University of Cologne, Cologne, Germany, [4]Durand University Hospital, Buenos Aires, Argentina, [5]Roche, Nutley, NJ, [6]Roche, Welwyn, United Kingdom, [7]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: Inhibiting interleukin-6 receptor (IL-6R) signal transduction by tocilizumab (TCZ) has been shown to effectively improve signs and symptoms and reduce joint damage in patients with rheumatoid arthritis (RA). The purpose of this analysis was to assess the long-term safety of TCZ in adult patients with RA.

Methods: Pooled data were assessed from clinical trials (OPTION, TOWARD, RADIATE, AMBITION, and LITHE), a clinical pharmacology study, and long-term extension studies (GROWTH95 and GROWTH96) as pertaining to patients who received ≥1 TCZ dose from initial exposure through February 17, 2010.

Results: A total of 4009 patients received TCZ; the median (mean [range]) duration was 3.6 (3.1 [0.0–5.1]) years, and the total observation time was 12,293 patient-years (PY). Rates of adverse events (AEs), serious adverse events (SAEs), and serious infections (Table) were consistent with those reported in the RA population.[1–5] The overall AE rate was 314.6/100 PY (95% CI: 311.5, 317.7); infections were the most frequent AE (103.7/100 PY, 95% CI: 101.9, 105.5), and the most common infections were upper respiratory tract infections and nasopharyngitis. The rate of AEs leading to withdrawal was 5.2/100 PY; the most common AEs leading to withdrawal were laboratory abnormalities (1.1/100 PY, transaminase elevations), infections (1.0/100 PY), and neoplasms (benign, malignant, or unspecified, 0.7/100 PY). The overall SAE rate was 14.7/100 PY (95% CI: 14.0, 15.4); infections were the most frequent SAE (4.6/100 PY; 95% CI: 4.3, 5.0). The rate of GI perforations was 0.24/100 PY (95% CI: 0.17, 0.37) and has remained consistent with that previously reported. Most of these events (59%, 17/29) were colonic diverticular perforations. Rates of myocardial infarction (MI) and stroke were 0.3/100 PY (95% CI: 0.2, 0.4) and 0.2 (95% CI: 0.1, 0.3), respectively, were stable over time (Table), and were similar to expected rates in the RA population.[3–5] Eight patients (0.1/100PY) experienced anaphylactic reactions and withdrew.

Table. Event Rate/100 PY (95% CI) Over 12-Month Periods

	0–12	13–24	25–36	37–48
AEs	418.4 (411.6, 425.2)	297.9 (291.8, 304.1)	273.3 (267.1, 279.6)	251.4 (244.8, 258.0)
SAEs	15.7 (14.4, 17.1)	13.9 (12.6, 15.2)	15.2 (13.7, 16.7)	14.4 (12.8, 16.0)
Serious infections	4.6 (3.9, 5.4)	3.9 (3.2, 4.7)	5.2 (4.3, 6.1)	4.9 (4.0, 5.9)
MI	0.3 (0.1, 0.5)	0.2 (0.1, 0.4)	0.3 (0.1, 0.6)	0.5 (0.3, 0.9)
Stroke	0.3 (0.1, 0.5)	0.1 (0.0, 0.3)	0.2 (0.1, 0.4)	0.1 (0.0, 0.3)

Conclusion: Rates of SAEs, serious infections, and cardiovascular events have remained stable with continued exposure to TCZ in long-term clinical trials.

2218

Comparison of Tocilizumab As Monotherapy or with Add-on Disease-Modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis and An Inadequate Response to Previous Treatments. Vivian Bykerk[1], Andrew Östör[2], José Andrés Román Ivorra[3], Jürgen Wollenhaupt[4], Andrea Stancati[5], Corrado Bernasconi[5] and Jean Sibilia[6]. [1]Brigham & Women's Hospital, Boston, MA, [2]University of Cambridge, Cambridge, United Kingdom, [3]Hospital Universitario La Fe, Valencia, Spain, [4]Schön Klinik, Hamburg, Germany, [5]Roche, Basel, Switzerland, [6]CHU Hautepierre, Strasbourg, France

Background/Purpose: Although combination therapy with a biologic agent plus a traditional disease-modifying antirheumatic drug (DMARD) is a well-established approach for the treatment of rheumatoid arthritis (RA) patients, little data exist on biologic monotherapy for patients for whom combination (biologic plus DMARD) therapy may not be appropriate (eg, due to methotrexate [MTX] intolerance). In the AMBITION trial, tocilizumab (TCZ) monotherapy showed significantly superior efficacy compared with MTX alone in patients who had not been exposed to or who never failed MTX. However, comparative data of TCZ monotherapy versus TCZ plus add-on DMARDs within the same study are limited. The objective of this analysis was to compare safety and efficacy measures in patients who received TCZ monotherapy versus patients who received TCZ plus DMARDs in the ACT-SURE study.

Methods: ACT-SURE was a phase 3b, open-label, single-arm, 6-month study in patients with inadequate responses to DMARDs (DMARD-IR) or tumor necrosis factor (TNF) inhibitors (TNFi-IR) who were receiving TCZ 8 mg/kg every 4 weeks, alone or in combination with 1 or more DMARDs at the investigator's discretion.

Results: Of 1681 patients in the safety and intent-to-treat populations, 14% (n=239) received TCZ monotherapy. Of monotherapy patients, 72% were TNF-IR; 37% of patients with add-on DMARDs were TNF-IR, and 22% of patients with add-on DMARDs received >1 DMARD. The most commonly used DMARD was MTX (79% of DMARD patients, of whom 74% had a weekly dose >10 mg and 47% >20 mg), followed by hydroxychloroquine (17%), leflunomide (13%), and sulfasalazine (13%). Baseline DAS28 was similar in both groups (6.2, 5.9). Safety in monotherapy/add-on DMARDs: withdrawal, 5%/5%; adverse event (AE), 82%/77%; serious AE (SAE), 8%/8%; AE leading to withdrawal, 5%/5%; infection, 38%/35%; serious infection (most common SAE), 2%/2%; grade 3 neutrophil decrease on at least 1 time point, 1.7%/3.3% (grade 4 decreases; only 1 case in add-on DMARDs, 0.1%); ALT elevation >60 U/L at any time point, 6%/9%; AST elevation >50 U/L at any time point, 1.7%/2.4%. At week 24, efficacy end points were comparable between groups (Table).

Week 24 Results, n/n (%)	TCZ Monotherapy	TCZ + DMARDs	p
EULAR good + moderate response	196/239 (82.0)	1206/1442 (83.6)	0.65
ACR50 response	104/239 (43.5)	680/1442 (47.2)	0.80
ACR70 response	57/239 (23.8)	386/1442 (26.8)	0.76
HAQ-DI reduction from baseline ≥0.22	143/209 (68.4)	912/1242 (73.4)	0.037
DAS28 <2.6	102/205 (49.8)	724/1250 (57.9)	0.70
CDAI remission	42/205 (20.0)	231/1243 (18.6)	0.18
SDAI remission	44/205 (21.5)	260/1218 (21.3)	0.31

p values are for the test of the "TCZ monotherapy = TCZ + DMARDs hypothesis" using logistic or linear regression models adjusted for previous treatment (DMARD-IR/TNF-IR) and baseline DAS28, CDAI, or SDAI. n/n = patients who responded/evaluable patients at week 24.

Conclusion: In a setting close to real life, TCZ monotherapy was highly efficacious at week 24; TCZ plus DMARDs provided similar results, suggesting that TCZ may be an appropriate treatment for patients who cannot tolerate MTX. The safety profile was similar for both groups.

2219

Effects of Tocilizumab Dose Escalation on Disease Activity in Adult Rheumatoid Arthritis Patients with Inadequate Response At 16 Weeks. Jeffrey R. Curtis[1], Sarika Ogale[2], Jenny Devenport[2] and Denise Lepley[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]Genentech, South San Francisco, CA

Background/Purpose: In the United States, current recommendations are to start tocilizumab (TCZ) at 4 mg/kg and to increase to 8 mg/kg, depending on clinical response. The objective of this analysis was to evaluate whether rheumatoid arthritis (RA) patients with inadequate response (IR) to TCZ after the first 16 weeks benefit from dose escalation (from TCZ 4 mg/kg [TCZ4] to TCZ 8 mg/kg [TCZ8]) or maintenance on their initial dose (TCZ8).

Methods: This post hoc analysis of clinical trial data included DMARD-IR (LITHE and OPTION) and TNF-IR (RADIATE) patients randomized to weekly methotrexate plus either TCZ4 or TCZ8 every 4 weeks for 24 weeks. Patients with inadequate response to treatment at week 16 (TJC and SJC improvement <20%) received blinded (LITHE) or open-label (OPTION and RADIATE) rescue treatment per protocol (TCZ4 to TCZ8, TCZ8 remained on TCZ8). Patients were grouped by initial TCZ dose and response at week 16: TCZ4 responders (no rescue); TCZ4 patients who dose-escalated to TCZ8 (TCZ4 rescue); TCZ8 responders (no rescue); TCZ8 rescue patients who received continued TCZ8 (TCZ8 rescue). Mean changes in DAS28 and CDAI from baseline to week 16 and from week 16 to week 24 were assessed, and paired within-person differences in DAS28/CDAI change between these 2 intervals were estimated. These analyses included patients with evaluable end points at baseline, week 16, and week 24.

Results: For TCZ4 patients who met criteria to receive rescue therapy/dose escalation to TCZ8 at week 16, significant improvements in DAS28 occurred between rescue and week 24 and exceeded pre-rescue improvements from baseline (Table). In contrast, TCZ8 rescue patients showed some improvement in DAS28 from baseline to rescue and had a numerically smaller magnitude of improvement from rescue to week 24 with continued therapy at the same TCZ dose (Table). Patients on both TCZ4 and TCZ8 doses who did not require rescue experienced the greatest improvements in DAS28 during the first 16 weeks (Table). Results from LITHE, in which week 16 rescue treatment remained blinded, showed patterns similar to the other two trials, which had open-label rescue. A pattern similar to that of TCZ4 rescue patients for DAS28 was seen for CDAI in all trials (data not shown).

Mean (95% CI) Change in DAS28	TCZ4 Rescue to TCZ8	TCZ8 Rescue to TCZ8	TCZ4 Responders	TCZ8 Responders
OPTION (DMARD-IR)	**n = 24**	**n = 17**	**n = 152**	**n = 168**
Change from baseline to week 16(D1)[a]	−0.22 (−0.70, 0.26)	−1.53 (−2.03, −1.04)	−2.57 (−2.80, −2.34)	−3.21 (−3.43, −3.00)
Change from week 16 to 24 (D2)[a]	−1.75 (−2.23, −1.28)	−0.99 (−1.95, −0.02)	−0.11 (−0.29, 0.07)	−0.23 (−0.39, −0.06)

Change from week 16 to 24 (D2)[a]	−2.04 (−2.44, −1.64)	−0.78 (−1.34, −0.23)	−0.09 (−0.30, 0.13)	0.14 (−0.37, 0.10)
Difference in change scores pre- and post-week 16 (D2-D1)[b]	−1.74 (−2.32, −1.16)[c]	0.14 (−0.57, 0.85)[d]	1.76 (1.45, 2.06)[c]	2.96 (2.56, 3.36)[c]
LITHE (DMARD-IR, blinded rescue)	**n = 47**	**n = 34**	**n = 292**	**n = 301**
Change from baseline to week 16 (D1)[a]	−0.39 (−0.60, −0.19)	−0.81 (−1.20, −0.42)	−2.33 (−2.48, 2.18)	−2.95 (−3.10, −2.8)
Change from week 16 to 24 (D2)[a]	−1.83 (−2.12, −1.55)	−0.96 (−1.40, −0.51)	−0.16 (−0.28, −0.05)	−0.33 −0.45, −0.21)
Difference in change scores per- and post-week 16 (D2-D1)[b]	−1.44 (1.85, −1.03)[c]	−0.15 (−0.79, 0.50)[d]	2.17 (1.95, 2.38)[c]	2.63 (2.41, 2.84)[c]

[a] At week 16, patients with IR could receive rescue. [b]Paired *t* test of differences, baseline-week 16 vs week 16–24. [c]$p<0.0001$, [d]$p>0.10$.

Conclusion: DMARD-IR and TNF-IR RA patients who did not achieve adequate response to TCZ4 and dose-escalated to TCZ8 at week 16 had significant improvements in DAS28 and CDAI scores at 24 weeks. For patients who fail to achieve adequate response to TCZ 4 mg/kg, physicians should consider dose escalation to TCZ 8 mg/kg. Patients who started on TCZ8 and who did not achieve adequate response at week 16 showed some incremental improvements in DAS28 and CDAI with continued TCZ8 treatment.

2220

Long Term Anti Tnfa Therapy for Inflammatory Rheumatic Disease Is Associated with Increased Bone Mineral Density and Paradoxical Elevation of TRAP5b Serum Levels. Eric Toussirot[1], Laurent Mourot[2], Emilie Grandclement[3], Daniel Wendling[4] and Gilles Dumoulin[3]. [1]Rheumatology and CIC Biotherapy 506 and EA 4266 Pathogens and Inflammation, Besançon, France, [2]University of Franche Comté, Besançon, France, [3]Department of Physiology, France, [4]Minjoz University Hospital, Besancon, France

Background/Purpose: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are inflammatory rheumatic diseases associated with increased risk of fractures, low bone mineral density (BMD) and increased levels of markers of bone resorption with normal or decreased values for bone formation markers. Anti-TNFa agents are very effective in treating clinical symptoms of RA and AS and suppressing inflammation. We evaluated the long term changes in bone mass and metabolic bone markers in patients with RA or AS while receiving anti-TNFa agent.

Methods: 20 patients (6 F) were evaluated (12 AS [modified NY criteria], age [mean ± SD]: 40.7 ± 16.1 yrs; and 8 RA [ACR criteria], age 60.5 ± 9.7 yrs; disease duration: 9.6 ± 9.8 yrs). They all received anti-TNFa agent (adalimumab: 12; etanercept: 6; infliximab: 2). At baseline and at 1, 3, 6, 12,18 and 24 months (M) after initiating anti-TNFa treatment, we measured both serum tartrate resistant acid phosphatase isoform 5b (TRAP5b, EIA, Quidel) and bone alkaline phosphatase (BAP, RIA, Beckman), as enzymatic markers of osteoclast and osteoblast, respectively, as well as serum beta CTX-I (EIA, IDS Nordic Bioscience), as marker of bone resorption. Serum osteocalcin (OC; RIA, Cisbio) and P1CP (Quidel) were measured as markers of bone formation. Osteoprotegerin (OPG, EIA, Quidel), an inhibitor of bone resorption was also evaluated. BMD at the lumbar spine and the hip was measured at baseline and after 6,12 and 24 M by DEXA (iDXA, Lunar). No patients had bisphosphonate treatment. Nine patients were under low dose corticosteroids (< 10 mg prednisone).

Results: All the patients responded to the treatment with clinical improvement and decline in erythrocyte sedimentation rate ($p=0.006$) and CRP levels ($p=0.003$). Compared to baseline, lumbar spine and hip BMD at M24 increased (+ 6.3% and + 2.4% respectively), with significant changes at the spine ($p< 0.001$). Beta CTX-I and OPG remained stable over the 24 M period while we observed a progressive and marked increase in TRAP5b (baseline: 1.21 ± 0.74; M24: 2.44 ± 1.05 U/L) ($p<0.001$). BAP also increased at M3 but not significantly. OC and P1CP similarly increased at M1 and M3 with significant change for P1C P ($p = 0.04$), then returning to baseline values.

Conclusion: This study confirms the beneficial effects of anti-TNFa agents on BMD, mainly at the lumbar spine. On the contrary of previous study, we did not observe a decrease in bone resorption markers (beta CTX-I) but we found a paradoxical increase in TRAP5b. By contrast, bone formation markers (BAP, OC) were unchanged or transciently increased (P1CP). These results suggest that anti-TNFa agents may increase osteoclast activity, but without stimulation of bone resorption since there was no parallel increase of beta CTX-I and no deleterious effect on BMD. We conclude that prolonged treatment with TNFa blocking agents has a favorable effect on bone mass in patients with RA or AS.

12 Month-Retrospective Analysis of Two Different Rituximab Retreatment Regimens in Rheumatoid Arthritis: Retreatment At Clinical Relapse Vs 6th Month Fixed Retreatment. Luca Quartuccio[1], Franco Schiavon[2], Domenico Biasi[3], Valeria Carraro[2], Viviana Ravagnani[4], Ilaria Dal Forno[4], Paola Masolini[1], Elisa Mansutti[1], Laura Corazza[1], Leonardo Punzi[5], Silvano Adami[4] and Salvatore De Vita[1]. [1]Rheumatology Clinic, DSMB, University of Udine, Udine, Italy, [2]Rheumatology Clinic, University of Padova, Padova, Italy, [3]Rheumatology Unit, University of Verona, Verona, Italy, [4]Rheumatology Clinic, University of Verona, Verona, Italy, [5]Rheumatology Unit, University of Padova, Padova, Italy

Background/Purpose: to describe two treatment regimens, retreatment at clinical relapse or fixed retreatment at 6th month with rituximab in rheumatoid arthritis (RA), focusing on clinical efficacy and costs at month +12.

Methods: 76 longstanding RA patients treated with rituximab at standard dose of 1 g ×2 were studied; 47 patients were retreated with rituximab (1 g ×2) at clinical relapse (retreatment at relapse group, ReR group), while 29 patients were retreated (rituximab 1 g ×2) at the end of the 6th month after the first standard cycle of rituximab (6 month fixed retreatment group, 6-R group). There were not differences as concerns the age and sex distribution between the two groups.

Results: There were significant differences as concerns the number of patients anti-TNF naïve (ReR>6-R, p=0.04), baseline DAS28 (ReR>6-R, p=0.01) and baseline HAQ (6-R>ReR, p<0.0001).

No differences were observed between the two groups as concerns DAS28 (p=0.6), EULAR moderate/good (ReR vs 6-R: 34/47 vs 20/29 (p=0.8), and ACRn response (ReR vs 6-R, 37/47 vs 26/29, p=0.3) at month +12.

Baseline HAQ was statistically associated with both EULAR good response [p=0.004 (OR 0.3, CI95% 0.1–0.7)], and ACR≥50 response at month +12 [p=0.001 (OR 0.3, CI95% 0.2–0.6)], independently from the retreatment regimen employed, by multivariate analysis.

Globally, a significant increase in utility (QoL) at month +12 vs baseline (p>0.0001) was observed, with mean QALY of 0.35 at month +12. Mean QALY at month+12 was 0.44 and 0.25 in ReR and 6-R group, respectively (p=0.01). A major QALY gain was observed in 6-R group than in ReR group (0.13 vs 0.07, p=0.006). Cost/QALY gain at month +12 was similar (p=1.0).

Conclusion: In RA patients, the identification of the best rituximab retreatment regimen remains an open question. Patients in the ReR group were more often TNF naïve, had a lower HAQ and higher DAS28. Similar results may be obtained with less intensive retreatment regimen in the first 12 months (i.e., retreatment at clinical relapse) in patients 1) naïve for TNF inhibitors, 2) with lower disability and 3) with higher disease activity.

The Comparative Efficacy and Toxicity of Initial Disease-Modifying Anti-Rheumatic Drug Choices for Patients with Moderate-Severe Early Rheumatoid Arthritis: A Bayesian Network Meta-Analysis. Glen S. Hazlewood[1], Cheryl CM Barnabe[2], George A. Tomlinson[1], Deborah Marshall[3] and Claire Bombardier[4]. [1]University of Toronto, Toronto, ON, [2]Univ of Calgary Foothills Hosp, Calgary, AB, [3]University of Calgary, Calgary, AB, [4]Institute for Work & Health, Toronto, ON

Background/Purpose: The choice of initial DMARD therapy in patients with early rheumatoid arthritis (ERA) is controversial. A systematic review of international clinical practice guidelines used to inform the 2011 Canadian Rheumatology Association Recommendations for the Management of RA identified four treatment options for patients with moderate-severe ERA: oral methotrexate (MTX) monotherapy, subcutaneous (sc) MTX monotherapy, combination therapy with MTX + other DMARDs, or MTX + anti-TNF therapy (TNF). The objective of this study was to compare the relative efficacy and toxicity of these treatment choices.

Methods: A systematic review of MEDLINE, EMBASE, Cochrane Central and 2009–2010 ACR/EULAR abstracts was performed to identify any randomized controlled trial evaluating the 4 treatment choices in adult patients with RA. The comparator arm was any DMARD or DMARD combination, as long as another trial was available to link the comparator to other trials within the network. Trials without an active comparator arm were excluded (i.e.- trials comparing the continuation of a failed DMARD to the addition of another DMARD). The primary efficacy and toxicity outcomes were ACR50 response and withdrawal (WD) due to toxicity. Secondary outcomes included WD due to inefficacy, total WD due to inefficacy or toxicity, ACR20 and ACR70 responses. Treatment effects relative to oral MTX were calculated through a Bayesian random-effects network meta-analysis, incorporating both direct and indirect treatment comparisons. Comparisons were made to estimates derived from Bayesian direct effect (non-network) meta-analyses.

Results: 16 trials were identified with the following treatment arms: oral MTX, sc MTX, combination therapy with MTX [MTX+ hydroxychloroquine/chloroquine (HCQ/CQ); MTX+sulphasalazine (SSZ); MTX+SSZ+HCQ] and MTX+TNF. There was a 99% and 100% probability that MTX+SSZ+HCQ and MTX+TNF respectively were superior to oral MTX monotherapy for ACR50 responses [MTX+SSZ+HCQ: OR 1.8 (95% Credible Interval (CrI): 1.1–3.0); MTX+TNF: OR 1.9 (95%CrI:1.4–2.7)]. Other DMARD combinations and scMTX monotherapy were not more effective than oral MTX. Similar results were found for ACR20 and ACR70 responses, although the ACR70 response for MTX+SSZ+HCQ showed only a trend towards superiority [OR: 1.6 (95%CrI: 0.8–3.7)]. MTX+SSZ+HCQ and MTX+TNF were associated with 64% and 92% probabilities respectively that treatment was associated with more withdrawals due to toxicity than oral MTX. No treatment was superior to oral MTX for total WD. Results were similar in analyses of direct treatment comparisons, however credible intervals were wider and an evaluation of ACR responses for MTX+SSZ+HCQ and MTX+HCQ relative to oral MTX was not possible due to a lack of studies directly comparing these treatment options.

Conclusion: Amongst currently recommended treatment choices for initial DMARD therapy in RA, there is a high probability that both MTX+SSZ+HCQ and MTX+TNF are more effective than oral MTX for clinically relevant outcomes. The incorporation of indirect treatment comparisons through the network meta-analysis permits inferences about ACR responses for MTX+SSZ+HCQ that are not possible through a traditional meta-analysis.

Impact of Comorbidities on TNF Inhibitor Persistence in Rheumatoid Arthritis Patients: An Analysis of Korean National Health Insurance Claims Data. Soo-Kyung Cho[1], Yoon-Kyoung Sung[1], Chan-Bum Choi[2], Jae Hoon Kim[3], Jin Ju Kim[4], Joo-Hyun Lee[4], Young Bin Joo[4] and Sang-Cheol Bae[1]. [1]Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Disease, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [3]Hanyang University Hospital for Rheumatic Disease, Seoul, South Korea, [4]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

Background/Purpose: The tumor necrosis factor (TNF) inbibitors have been shown to be effective in treating rheumatoid arthritis (RA) in several randomized controlled trials (RCTs). However, patients with RA in clinical practice might be different from those patients selected for clinical trials; for example, they may have different comorbidities, economic problems, and be taking other drugs at the same time. These differences may influence the efficacy and safety profile of TNF inhibitors. Comorbidity in particular increases the complexity of patient care and makes treatment decisions more challenging. Therefore, in clinical practice, it is important to recognize such comorbidities in RA patients and to consider them before initiating TNF inhibitor treatment. We conducted this study to evaluate TNF inhibitor persistence and the impact of comorbidity on treatment persistence in patients with RA.

Methods: In a Korean National Health Insurance claims database, patients with a diagnosis code of RA (M05 or M06) who started TNF inhibitor therapy between July 1, 2007 and June 30, 2008were enrolled. The study cohort was followed until December 31, 2009. Persistence was examined using Kaplan-Meier survival analysis, and multivariate Cox proportional hazard models were developed to examine the potential impact of comorbidities on drug persistence.

Results: A total of 388 patients were enrolled in the study cohort. The mean persistence rate in the overall population was 61% at 18 months. Drug survival rates for adalimumab and etanercept at 6 months were 82% and 85%, respectively, and 73% and 78%, respectively, at 12 months. Charlson comorbidity index (CCI) scores and comorbidities such as diabetes, chronic pulmonary disease, mild liver disease, and depression at initiation were not related with drug persistence, while peptic ulcer disease (PUD) lowered the risk of discontinuation of TNF inhibitors (HR 0.73, 95% CI: 0.55 to 0.97). Old age (HR 1.59, 95% CI: 1.09 to 2.33) and

prescription of inhibitors by an internist (HR 1.59, 95% CI: 1.02 to 2.48) were other factors associated with early discontinuation of TNF inhibitors.

Conclusion: The persistence rate of TNF inhibitors was 61% at 18 months. CCI score and other comorbidities were not related with early discontinuation of TNF inhibitors, while PUD was an independent contributing factor to TNF inhibitor persistence.

2224

Perioperative Use of Anti-TNF Medications in Patients with Rheumatoid Arthritis Undergoing Total Knee Replacement. Beverly Johnson, Susan M. Goodman, Michael Alexiades and Lisa A. Mandl. Hospital for Special Surgery, New York, NY

Background/Purpose: Anti-TNF medications are increasingly used in patients with rheumatoid arthritis (RA), and current guidelines recommend holding preoperatively. However, few studies examine actual practice and perioperative safety of TNF inhibitors. This study assesses the preoperative use of anti-TNF medications in RA patients undergoing total knee replacement (TKR), and examines if anti-TNF use increases six month adverse post-operative events or disease flares.

Methods: This is a retrospective chart review with follow-up. RA patients who had a TKR between June 2007 and May 2010 were identified from a large prospective single institution joint replacement registry. RA cases were identified by ICD-9 code (714.0) or self-report, and then confirmed by chart review. All registry patients receive a six month adverse events questionnaire which is validated by chart review or phone. For this study, patients received a RA focused questionnaire; medications were confirmed by chart review. We examined self-reported RA flare within one month of surgery and six month adverse events, including surgical site infection (SSI), pulmonary embolus (PE), deep venous thrombosis (DVT), pneumonia, any other infection or re-operation. We evaluated patterns of preoperative anti-TNF use, and compared differences in short term adverse events and post-operative flares between those on anti-TNF and non-users using a Chi-squared analysis. Analysis done with SAS version 9.2. This study was IRB approved.

Results: Of 728 cases reviewed, 194 patients were confirmed as RA (208 cases). Mean age was 61.7 years (SD+/− 11.9), female 86.6%, Caucasian 78.7% and 69.6% had some college education Anti- TNF was used in 86 cases (41.4%): etanercept 59.3%; adalimumab 20.9% infliximab 18.6% and golimumab 1.2%. 86% of the charts documented that anti-TNF should be held and of these, 54 (74%) recommended a specific stop time: mean of 2.4 (SD 2.4) weeks for etanercept (t ½ = 3–5.5 days), 4.6 weeks (SD 6.2) for adalimumab (t ½ = 10–20 days), and 4.9 (SD 2.15) weeks for infliximab (t ½ = 7–12 days). In anti-TNF vs. non-anti-TNF cases, non-biologic DMARDs or prednisone were used in 67.4% vs. 65.6%. 160 cases (77%) had six month data, and 120 (57.4%) responded to the RA questionnaire. There were 7 confirmed adverse events: 2 PEs, 1 DVT, 2 SSIs, and 2 re-operations. 4 / 7 were in the anti-TNF group (all SSIs and re-operations) and all of these were on etanercept. There was no significant difference between the anti-TNFs and non-anti TNF groups (p-value=.51). Self-reported RA flare was higher in the anti-TNF groups (22.4% vs. 16.9%), but the difference was not significant (p-value=.47).

Conclusion: Anti-TNF medication use was not associated with an increased risk of short term adverse postoperative events, though adverse events were rare. Anti-TNFs were held 2 to 4 weeks before TKR, without apparent regard for their pharmacologic half-lives. There appeared to be a non-significant trend towards increased post-operative flares in anti-TNF users. Larger studies should be done to examine if more pharmacologically based timing of anti-TNF withdrawal prior to surgery might minimize the risk of post-operative RA flare while maintaining the excellent safety of these medications.

2225

Undetectable Rheumatoid Factor Following Treatment with Rituximab- What Is Clinical Significance? Pravin Patil[1], Julia Flint[1], Elena Becerra-Fernandez[1], Inmaculada de la Torre[2], Geraldine Cambridge[1], Maria J. Leandro[1] and Jonathan CW Edwards[1]. [1]University College of London, London, United Kingdom, [2]Hospital Gregorio Maranon, Madrid, Spain

Background/Purpose: It is well established that rheumatoid arthritis (RA) patients with positive rheumatoid factor respond better to rituximab therapy. However, little is known whether the RF titre before or following rituximab therapy correlates with clinical response. In our cohort we observed that in a group of seropositive RA patients, RF as measured by agglutination assays can become undetectable following treatment with rituximab (seronegative). We studied the baseline characteristics of this group and their response to rituximab therapy in comparison to those patients who remained seropositive after the first cycle of rituximab.

Methods: All seropositive RA patients treated with rituximab in our centre from 2008 with at least one year follow up were included. Patients who lost seropositivity after the first cycle of rituximab were compared to patients who remained seropositive at this stage. Patients were assessed before treatment, 1 and 3 months after treatment and every 2 to 3 months thereafter. Serial assessments included CRP levels, CD19 counts, total immunoglobulin levels and RF by agglutination assay (RAPA). Anti-CCP antibodies were measured at baseline.

Results: Eighty-one patients were included in the study. The mean age was 56 years (range 20–86 years). 98% patients were anti-CCP positive at baseline. 23% of patients lost seropositivity after the first cycle of Rituximab, all within a year (n=19). These patients had lower baseline RF titres ($p<0.001$). There was no significant difference in number of patients being on concomitant DMARD in both groups. However, percentage of patients on steroids was significantly higher (13%) in those who remained with RF than those who lost seropositivity (5 %).

There was no significant difference between the groups in the baseline levels of C-reactive protein (CRP), total IgM and CD19 count. While all who lost seropositivity responded to rituximab therapy and achieved complete depletion of CD19 ($<0.005\times10^9$/L), six who remained with RF (9.5%) did not respond and required switching to another agent. Eight remaining with RF did not deplete well (CD19 count $>=0.005$). Nadir levels of CRP and total IgM following treatment were also similar.

The average number of months until B cell repopulation and clinical relapse was 5.4 and 7.33 respectively in patients who lost seropositivity compared to those who retained RF was 4.5 and 8.76.

Conclusion: This study suggests that those with low baseline RF titres are significantly more likely to lose seropositivity following treatment with rituximab. There was also a tendency towards a shorter and less robust response to rituximab in patients retaining seropositivity. However, larger studies are required to establish whether there is any correlation between the loss of seropositivity to RF with clinical response to treatment.

2226

Definition of Treatment Response in Rheumatoid Arthritis Based on the Simplified and the Clinical Disease Activity Index. Daniel Aletaha[1], José Martinez-Avila[2], Tore K. Kvien[3] and Josef S. Smolen[4]. [1]Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna, Austria, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]Krankenhaus Lainz, Vienna, Austria

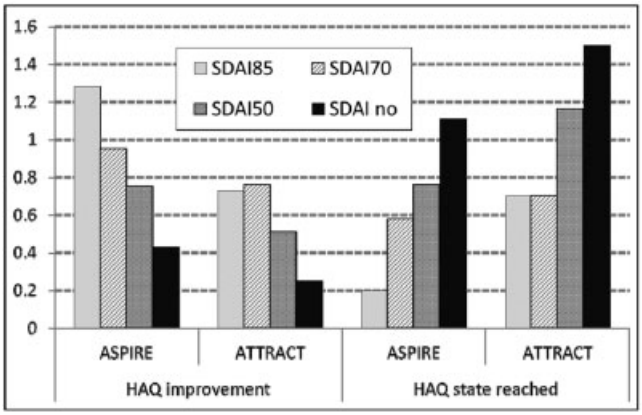
Background/Purpose: The Simplified and the clinical disease activity indices (SDAI, CDAI) have been introduced to assess disease activity in a simple way and have shown their merits in clinical practice. In clinical trials of rheumatoid arthritis (RA), however, treatment efficacy has traditionally been assessed through response rates. Currently, no validated response definitions for the SDAI and CDAI are available.

We aimed to define minor, moderate, and major response criteria for the SDAI based on the agreement with the traditional way of response assessment by the American College of Rheumatology (ACR) 20%, 50%, and 70% improvement definition.

Methods: We used data from two clinical trials on infliximab plus methotrexate (MTX) vs placebo plus MTX in early (ASPIRE) or established (ATTRACT) RA, and identified the three SDAI cutpoints based on the best agreement (by Kappa statistics) with the ACR20/50/70 responses. These cutpoints were then tested for face validity, construct, and discriminant validity in the trial datasets, and for construct validity and validity in regards to patients' reported perception of improvement in an observational dataset (NOR-DMARD).

Results: Based on agreement with the ACR response, the minor, moderate, and major responses were identified as SDAI 50%, 70%, and 85% improvement. These cutpoints had good face validity, with major response bringing the majority of patients into remission or near remission, moderate response bringing the majority into at least low disease activity, and minor response essentially warranting that no patient remains in a high disease activity state. Construct validity was shown by a clear association of increasing SDAI response categories with increasing levels of functional improvement, and better functional states reached (see

Figure). Also, the annual radiographic progression was greatest in SDAI non responders and increased across thes SDAI 50/70/85 response groups (mean: 5.9 vs. 3.9/2.2/-0.3). Across SDAI50/70/85 the sensitivities regarding patients' perceived improvement in NOR-DMARD decreased (73%/39%/22%) and the specificities increased (61%/89%/96%). Further, the identified cutpoints discriminated well between treatment arms in ASPIRE and ATTRACT. Results for the CDAI were not different to the SDAI, and thus the same cutpoints for definition of response were used.



Conclusion: New cutpoints for response have been defined for the SDAI and the CDAI, and have been assessed for their validity. These criteria expand the usefulness of the SDAI and CDAI for their application as endpoints in clinical trials beyond the definition of disease activity categories.

Golimumab 3-Year Safety Update: An Analysis of Pooled Data From the Long Term Extensions of Randomized, Double-Blind, Placebo-Controlled Studies in Rheumatoid Arthritis, Psoriatic Arthritis, and Ankylosing Spondylitis. Jonathan Kay[1], Roy Fleischmann[2], Edward Keystone[3], Elizabeth C. Hsia[4], Mittie K. Doyle[4], Benjamin Hsu[4], Michael Mack[5], Anna Beutler[5], Jürgen Braun[6] and Arthur Kavanaugh[7]. [1]University of Massachusetts Memorial Medical Center/University of Massachusetts Medical School, Worcester, MA, [2]University of Texas Southwestern Medical Center, Dallas, TX, [3]University of Toronto, Toronto, ON, [4]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC/Univ. of Pennsylvania School of Medicine, Malvern/Philadelphia, PA, [5]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA, [6]Rheumazentrum Ruhrgebiet, Herne, Germany, [7]University of California San Diego, San Diego, CA

Background/Purpose: Golimumab (GLM) has been assessed in rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) in randomized controlled trials. The purpose of this study was to present analysis of pooled data (cumulative control and uncontrolled periods) through approximately 3 yrs of follow-up from 5 ongoing GLM Phase 3 subcutaneous (SC) trials across rheumatological indications and through 1 yr in a completed Phase 2 RA trial.

Methods: SC placebo (PBO) or GLM (50mg or100mg) was administered q4wks in Phase3 and q2/4wks in Phase 2 clinical trials. After wk24/52, pts in the Phase 3 studies entered long term extensions (LTE) and received GLM 50mg or 100mg q4wks in an unblinded fashion. Dose escalation from 50mg to 100mg was allowed; no dose reduction was permitted. Concomitant medications included DMARDs, most frequently MTX. Adverse events (AE) were analyzed based on treatment received prior to the occurrence of the AE. Because pts could cross-over from PBO to GLM or increase GLM dose from 50mg to 100mg in cases of inadequate response in the Phase 3 trials, a pt may appear in more than one column. Due to the short duration of the PBO-controlled portion, comparisons between the GLM and PBO groups are limited.

Results: In combined Ph2/3 trials, 674 pts received PBO, 1317 GLM 50mg, and 1571 GLM100mg through 3 yrs. In Phase 3, 4.9%, 7.4%, and 10.5% of PBO, GLM50, GLM100mg pts, respectively, discontinued due to adverse events (AE) through 3yrs. In Phase 2, 5.9% of PBO and 8.0% of GLM pts discontinued due to AE through 1 yr. The incidences per 100 PY of deaths, serious infections (including tuberculosis and opportunistic infections), demyelination, and malignancies are presented (Table). Overall occurrence of injection site reactions was low; most were mild, and only 2 cases led to discontinuation. No GLM SC-treated pt developed anaphylaxis or a serum sickness-like reaction. Malignancies occurring during the 5 Phase 3 and 1 Phase 2 trials included skin cancers, solid tumors, and lymphoma. In comparison to the Surveillance Epidemiology and End Results (SEER) database for malignancies, the overall incidence of malignancies in GLM-and PBO-treated pts was similar to that expected in the general US population. The incidence of lymphomas per 100 pt-years of follow-up was greater in the GLM100mg dose group through 3yrs and higher than that expected in the general US population.

SIR (95% CI)	0.00 (0.00, 31.98)	1.71 (0.04, 9.55)	6.69 (2.45, 14.56)
Other malignancies			
Total pt/yrs of follow-up	357	2308	3398
Observed # of pts with event	2	18	14
Incidence/100 pt yrs (95% CI)	0.56 (0.07, 2.02)	0.78 (0.46, 1.23)	0.41 (0.23, 0.69)
Expected # of pts with event	2.05	12.32	19.34
SIR (95% CI)	0.98 (0.12, 3.53)	1.46 (0.87, 2.31)	0.72 (0.40, 1.21)

Includes GLM SC Phase2b in addition to 3RA, PsA, AS studies
* Based on data cut off as of Jan 25, 2010
SIR=standardized incidence ratio (observed/expected)

Conclusion: The safety profile of continued SC GLM exposure in this pooled analysis demonstrates that GLM was generally well-tolerated with overall low rates of discontinuation due to AEs. Safety profiles were generally similar between GLM dose groups with the exception of higher rates of serious infections, including tuberculosis and opportunistic infections, and lymphoma in the GLM100mg group. Results are confounded by LTE design in which pts could receive GLM100 mg after being exposed to GLM50mg with higher GLM dose used for pts with more active disease, and by limited exposure to PBO making the comparisons between PBO and active treatment groups of less value.

2228

Initial Combination Therapy with Adalimumab Plus Methotrexate Leads to Better Long-Term Outcomes in Patients with Advanced Rheumatoid Arthritis: Analysis of the Final 10-Year Results of An Open-Label Extension of a Phase 3 Trial. Edward Keystone[1], Désirée van der Heijde[2], Michael E. Weinblatt[3], Neelufar Mozaffarian[4], Benoit Guerette[5], Hartmut Kupper[6], Shufang Liu[4], Benjamin Wolfe[4] and Arthur Kavanaugh[7]. [1]University of Toronto, Toronto, ON, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [4]Abbott, Abbott Park, IL, [5]Abbott, Rungis, France, [6]Abbott GmbH & Co KG, Ludwigshafen, Germany, [7]University of California San Diego, San Diego, CA

Background/Purpose: DE019 was a phase 3, randomized, controlled trial (RCT) in which patients (pts) with active, advanced rheumatoid arthritis (RA) and an inadequate response to methotrexate (MTX) were randomized to 1 year (yr) of adalimumab (ADA) 40 mg every other week (eow), ADA 20 mg weekly, or placebo (PBO) injections; all received concomitant MTX. RCT results demonstrated the clinical and radiographic superiority of

ADA+MTX over PBO+MTX[1]. All pts completing the RCT were eligible to receive open-label (OL) ADA 40 mg eow +MTX for an additional 9 yrs. This post hoc analysis evaluated observed pt data to determine whether a 1 yr delay in initiation of ADA treatment results in differences in clinical, functional, or radiographic efficacy after up to 10 yrs of treatment.

Methods: Clinical and functional outcomes were assessed by the 28-joint disease activity score [DAS28(CRP)] and the disability index of the health assessment questionnaire (HAQ-DI), respectively. Radiographic damage was assessed using the modified total Sharp Score (mTSS) at baseline (BL) and yrs 1, 8, and 10; progressors were defined as pts with a change (Δ) in mTSS from BL >0.5. Differences in mean ΔmTSS between initial treatment arms were assessed using a constrained longitudinal data analysis. Safety was assessed in terms of adverse events for all pts exposed to ADA.

Results: Of the 619 pts initially randomized, 202 (32.6%; 80, 66, and 56 pts from the initial ADA 40 mg eow, ADA 20 mg weekly, and PBO arms, respectively) continued on OL ADA+MTX treatment through yr 10. Efficacy outcomes at yr 10 were not different between the 2 ADA arms; therefore, results for the ADA 40 mg eow arm are presented as representative of both ADA arms. Following the switch to OL ADA+MTX, the significant differences in clinical and functional responses observed during yr 1 (DAS28 =3.4 and 4.5; HAQ-DI =0.8 and 1.1 for ADA and PBO arms, respectively) were largely resolved following an additional 9 yrs of OL ADA+MTX treatment (DAS28 =2.4 and 2.7; HAQ-DI =0.7 and 0.8 for initial ADA and PBO arms, respectively). In addition, rates of radiographic progression became comparable between the treatment arms during OL ADA+MTX treatment (P =.22). However, pts initially randomized to ADA had significantly lower mean ΔmTSS compared with pts initially randomized to PBO (0.7 vs 6.2; P =.005), as well as a lower percentage of pts with radiographic progression (49.4% vs 61.1%). No new safety signals arose following up to 10 yrs of ADA exposure, and there was perhaps a trend towards fewer deaths than would be expected from a matched population [SMR (95% CI) =0.77 (0.52, 1.10)].

Conclusion: Following up to 10 yrs of treatment with ADA+MTX, pts with long-standing RA experienced safe and effective disease control. Initial treatment with ADA led to better outcomes than initial treatment with PBO, but the disparities in clinical and functional response rates observed during the RCT were largely ameliorated after treatment with OL ADA+MTX. Notably, radiographic damage remained lower in pts initially randomized to ADA, owing to the more extensive damage accrued during the RCT in PBO-treated pts.

2229

Patients with Early Rheumatoid Arthritis (RA) Who Respond Well to Methotrexate Monotherapy Have Less Metacarpal Bone Loss, Measured by Digital X-Ray Radiogrammetry (DXR), Than Those Who Need Add-on Therapy. Findings From a Randomized Trial. Hamed Rezaei[1], Saedis Saevarsdottir[1], Kristina Forslind[2], Pierre Geborek[3], Ingemar F. Petersson[3], Sofia Ernestam[4], Johan Bratt[4] and Ronald F. van Vollenhoven[1]. [1]The Karolinska Institute, Stockholm, Sweden, [2]Helsingborgs Lasarett and Lund University, Lund, Sweden, [3]Lund University, Lund, Sweden, [4]Karolinska University Hospital, Stockholm, Sweden

Background/Purpose: The aim of this study was to investigate metacarpal bone loss measured by digital X-ray radiogrammetry (DXR) in patients with early rheumatoid arthritis receiving different treatment regimens, and to evaluate if DXR-change rates during the first year correlate with radiological damage after 24 months.

Methods: In the SWEFOT trial, 487 patients (symptom duration <12 months) started methotrexate (MTX) 20 mg/week. After 3–4 months, patients with DAS28>3.2 were randomized to either sulfasalazine and hydroxychloroquine ("triple therapy") or infliximab ("anti-TNF"). Those with DAS28 ≤3.2 were followed in regular care ("MTX-responders"). Radiographic progression over 24 months was scored according to the van der Heijde modified Sharp score (SvdH). Metacarpal bone loss from 0–12 months was measured by DXR (Sectra, Linköping, Sweden), a method developed to allow measurement using routinely obtained digital x-rays. DXR bone loss >2.5 mg/cm2/month (10× upper limit of normal) is considered highly elevated and was used as cut-off in this study.

Results: Out of the whole SWEFOT population (n=487), the X-rays from 159 patients were of sufficient quality and correctly timed to be analyzed with the DXR method: MTX-responders 49 (31.0%), triple therapy 55 (34.5%), and anti-TNF 55 (34.5%).

The proportions of patients with DXR-change rate ≥ 2.5 mg/cm2/month in MTX responders, triple therapy, and anti-TNF were 4.1%, 22.2% and 16.4%, respectively (p=0.01).

Mean (SEM) radiological progression over 24 months according to SvdH-score was 6.72 (1.01), 7.40 (2.01) and 4.55 (0.66) for MTX monotherapy, triple therapy and anti-TNF, respectively (p=0.06 between triple therapy and anti-TNF).

Mean (SEM) radiological progression over 24 months in patients who did and who did not have a highly elevated DXR-change rate during the first 12 months was 10.38 (4.60) and 3.86 (0.58), respectively (p=0.006), and a significant difference was also seen for progression in the erosion score, 3.81 (1.98) vs. 1.23 (0.32) (p=0.02). Patients with highly elevated DXR change rate during the first 12 months had statistically significantly greater risk for a ≥5 increase in SvdH after 24 months (odds ratio 3.09, 95% CI =1.20–7.79, p=0.02). More progression occurred in the triple therapy group. (odds ratio 4.15, 95% CI=1.05–16.35, p=0.04).

Conclusion: DXR provides information on metacarpal bone loss in patients with RA. Non-responders to MTX (who went on to randomization in this trial) had a significantly greater risk for highly elevated BMD loss than MTX-responders despite the add-on therapies; and patients with highly elevated metacarpal bone loss had significantly greater x-ray damage after 24 months. Information from DXR may be complementary to that obtained by clinical assessments and standard radiography.

2230

Relevance of Involvement of Tofacitinib in T Cell Subsets to Clinical Courses in Patients with Rheumatoid Arthritis. Koshiro Sonomoto, Kunihiro Yamaoka, Satoshi Kubo, Keisuke Maeshima, Ippei Miyagawa, Kazuhisa Nakano, Norifumi Sawamukai, Kazuyoshi Saito and Yoshiya Tanaka. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background/Purpose: Tofacitinib, a Janus kinase (JAK) inhibitor, has demonstrated clinical efficacy on rheumatoid arthritis (RA). However the exact mechanism of action remains unclear especially in patients treated with tofacitinib. It is a key issue to elucidate the biological function of tofacitinib in RA patients, in order to increase not only the benefit but also safety. The purpose of this study is to clarify the mechanism of tofacitinib in clinical use of RA patients.

Methods: Twenty nine patients (24 women, mean age; 55.6 years, mean disease duration 73.9 months) with RA were enrolled in clinical studies of tofacitinib (6 treated with tofacitinib alone, 23 treated with tofacitinib with MTX) and were randomized to different doses of tofacitinib or placebo for the first 3 to 6 months and subsequently advanced to 5 mg or 10 mg BID of tofacitinib open label. Lymphocyte population analysis and proliferation of Carboxyfluorescein succinimidyl ester (CFSE) labeled CD4+ T cells at baseline (0 week) and 52 weeks were performed by flow cytometry.

Results: 25 patients out of 29 completed 52 weeks treatment with tofacitinib. MTX was administered in 23 patients and the average dose was 9.2 mg/week, oral corticosteroid was administered in 5 patients and the average dose was 4.4 mg/day. Four patients discontinued the treatment because of malignancy (n=2), bacterial infection (n=1) or incidental trauma (n=1). Tofacitinib improved disease activity measured by SDAI (36.0+-14.5 to 7.1+-7.2), and 12 out of 29 reached SDAI remission (<3.3), 9 patients fulfilled the Boolean remission criteria, and 14 patients reached DAS28-ESR <2.6. There was no change in the total lymphocyte counts nor lymphocytes subset profile at week 52. However, proliferation of CD4+ T cells induced by stimulation with anti-CD3 and CD28 antibodies *in vitro* was significantly reduced by administration of tofacitinib (p=0.02) and the decrease of proliferation of CD4+ T cells significantly correlated with both ΔCRP (p=0.02) and ΔSDAI (p=0.03). There was no statistical correlation between the decrease of CD4+ proliferation and incidence of the infections, although 21 events of infection (17 viral infection including 8 herpes zoster, 3 bacterial infection and 1 local fungus infection) were observed. In contrast, it is noteworthy that the number of CD8+ T cells at baseline was extracted as a predictive factors affecting incidence of infections by ROC analysis (odds ratio 5.33, 95% CI 1.02–27.8). Cut off value of CD8+ cells at baseline was <210/μl (sensitivity 0.67, specificity 0.82) to predict at least one infection per year. Moreover, all three patients who showed multiple infections had less than 141/μl CD8+ T cells at baseline.

Conclusion: Tofacitinib has demonstrated efficacy for the treatment of RA. These results indicate that the suppression of CD4+ T cell proliferation *in vitro* after the treatment with tofacitinib appears to contribute to the its mechanism of action in RA patients. In contrast, our results also suggest that patients with lower CD8+ T cell counts should be considered to possess a higher risk of infections.

Improvement in Disease Activity and Treatment Response Over 2 Years of Abatacept Treatment and Shifts to Improved Disease States in Patients with Early Rheumatoid Arthritis Who Switch From MTX. Rene Westhovens[1], Juan J. Gomez-Reino[2], Walter Grassi[3], Corine Gaillez[4], Manuela Le Bars[4], Coralie Poncet[5], Ayanbola Elegbe[6] and Jurgen Wollenhaupt[7]. [1]UZ Gasthuisburg, Leuven, Belgium, [2]Hospital Clinico Universitario, Santiago de Compostela, Spain, [3]Università Politecnica delle Marche, Ancona, Italy, [4]Bristol-Myers Squibb, Rueil Malmaison, France, [5]Docs International, Sèvres, France, [6]Bristol-Myers Squibb, Princeton, NJ, [7]Schön-Klinik Hamburg-Eilbeck, Hamburg, Germany

Background/Purpose: Remission is the primary RA treatment target; guidelines state the importance of maintaining the target disease state and measuring disease activity with validated, composite indices.[1] Biologics are recommended for early intensive treatment of early RA pts with poor prognostic factors; abatacept (ABA) has demonstrated significant clinical efficacy and reduction in irreversible structural damage progression vs MTX alone in these pts.[2,3] Using 3 composite disease activity indices, we explore if target disease states achieved with ABA + MTX are maintained/improved with continued treatment, and if MTX-treated pts can improve their disease state with addition of ABA.

Methods: Pts with erosive RA (≤2 yrs) were randomized to ABA + MTX (~10 mg/kg) or placebo + MTX (MTX alone) in the 1 yr double-blind (DB) period of AGREE. All DB-completing pts received open-label (OL) ABA (~10 mg/kg) in Yr 2. These *post-hoc* analyses of as-observed pt-level data include all pts who received ≥1 ABA dose in the OL period according to DB period treatment group (ABA + MTX vs MTX alone). Disease activity was defined by DAS28, SDAI and CDAI as High, Moderate and Low Disease Activity states (HDAS, MDAS and LDAS, respectively), and remission.

Results: Overall, 459 pts (232/256 ABA + MTX, 227/253 MTX alone) completed the DB period. All 459 pts were treated in the OL period; 433 pts completed Yr 2. At Yr 1, 32.1 and 33.2% of ABA + MTX pts achieved SDAI and CDAI remission, respectively, vs 12.5 and 16.1% of MTX alone pts. A similar trend was observed for DAS28 remission: 46.8 of ABA + MTX pts vs 26.9% of MTX alone pts at Yr 1. For MTX alone pts who switched to ABA + MTX at Yr 1, 51.9, 36.5 and 38.1% achieved DAS28, SDAI or CDAI remission at Yr 2, respectively, similar to pts from the original ABA group (56.9, 37.5, 39.0%, respectively). DAS28 and SDAI disease states at Yr 2 are shown for pts in LDAS or remission at Yr 1 (Table); ≥75% of pts achieving LDAS/remission at Yr 1 maintained or improved their disease status at Yr 2, regardless of initial treatment group. Addition of ABA at Yr 1 corresponded to a shift in 57 and 46% of MTX alone pts from LDAS to remission at Yr 2, according to DAS28 and SDAI, respectively. Similar trends to SDAI were observed for CDAI (data not shown).

Table. Abatacept plus methotrexate

		Year 1 DAS28 State, n (%)		Year 2 DAS28 State, n (%)	
	Total* (n=197)	HDAS DAS28 >5.1	MDAS DAS28 >3.2–5.1	LDAS DAS28 2.6–3.2	Remission DAS28<2.6
LDAS	31 (15.7)	0 (0)	6 (19.4)	9 (29.0)	26 (51.6)
Remission	89 (45.2)	0 (0)	4 (4.5)	8 (9.0)	77 (86.5)
		Year 1 SDAI State, n (%)		Year 2 SDAI State, n (%)	
	Total* (n=192)	HDAS SDAI >26	MDAS SDAI>11–26	LDAS SDAI>3.3–11	Remission SDAI ≤3.3
LDAS	65 (33.9)	0 (0)	6 (9.2)	38 (58.5)	21 (32.3)
Remission	58 (30.2)	0 (0)	1 (1.7)	13 (22.4)	44 (75.9)
Methotrexate	alone				
		Year 1 DAS28 State, n (%)		Year 2 DAS28 State, n (%)	
	Total* (n=181)	HDAS DAS28 >5.1	MDAS DAS28 >3.2–5.1	LDAS DAS28 2.6–3.2	Remission DAS28<2.6
LDAS	28 (15.5)	0 (0)	7 (25.0)	5 (17.9)	16 (57.1)
Remission	50 (27.6)	1 (2.0)	3 (6.0)	6 (12.0)	40 (80.0)
		Year 1 SDAI State, n (%)		Year 2 SDAI State, n (%)	
	Total* (n=178)	HDAS SDAI >26	MDAS SDAI>11–26	LDAS SDAI>3.3–11	Remission SDAI ≤3.3
LDAS	56 (31.5)	2 (3.6)	3 (5.4)	25 (44.6)	26 (46.4)
Remission	23 (12.9)	0 (0)	1 (4.3)	7 (30.4)	15 (65.2)

*Includes patients with data at both Year 1 and Year 2; DAS28=Disease Activity Score 28; HDAS=High disease Activity State; MDAS=Moderate Disease Activity State; LDAS=Low Disease Activity State; SDAI=Simplified Disease Activity Index

Conclusion: At Yr 1, greater proportions of ABA-treated pts achieved remission vs MTX alone according to DAS28, SDAI and CDAI criteria. Regardless of initial treatment group, the majority of pts in LDAS or remission at Yr 1 maintained or improved their disease state at Yr 2. According to all three indices, addition of ABA at Yr 1 to MTX corresponded to a shift in disease activity from LDAS to remission in ~50% of pts by Yr 2. These findings support the use of ABA + MTX in treating to target pts with early RA and poor prognostic factors.

Rate of Anti-Cyclic Citrullinated Peptide Antibody and Rheumatoid Factor Seroconversion in Patients with Undifferentiated Arthritis or Early Rheumatoid Arthritis Treated with Abatacept. Tom W.J. Huizinga[1], Paul Emery[2], Rene Westhovens[3], Manuela Le Bars[4], Corine Gaillez[4], Coralie Poncet[5], Ayanbola Elegbe[6] and Josef S. Smolen[7]. [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Leeds, Leeds, United Kingdom, [3]UZ Gasthuisberg, Leuven, Belgium, [4]Bristol-Myers Squibb, Rueil Malmaison, France, [5]Docs International, Sévres, France, [6]Bristol-Myers Squibb, Princeton, NJ, [7]Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background/Purpose: Autoantibodies are continuously generated in RA and the presence of anti-cyclic citrullinated peptide (anti-CCP) antibodies or rheumatoid factor (RF) in early RA suggest poor prognosis. Disrupting antigen presentation may interfere with autoantibody formation. As such, co-stimulation modulation with abatacept may lead to seroconversion. We evaluated anti-CCP and RF seroconversion in patients (pts) treated with abatacept or placebo in ADJUST (undifferentiated arthritis [UA] or very early RA) and AGREE (early RA), and assessed the clinical relevance of seroconversion.

Methods: In ADJUST, pts were DMARD-naïve, anti-CCP positive with UA/very early RA and had clinical synovitis of ≥2 joints; pts were treated with abatacept monotherapy or placebo to Mth 6, then withdrawn for 18 mths. In AGREE, MTX-naïve pts who had RA ≤2 yrs, were RF/anti-CCP positive with joint erosions on X-rays were treated with abatacept + MTX or MTX alone. RF and anti-CCP seroconversion was assessed at Mths 6 and 12 and data are presented for pts with positive results at baseline and the visit of interest. RF ≥15–20 IU/mL (dependent on assay) and anti-CCP >5 U/mL were considered positive. Efficacy subanalyses were performed for AGREE, but not for ADJUST due to low pt numbers.

Results: At baseline, 100 and 89% of all pts in ADJUST and AGREE, respectively, were positive for anti-CCP; 79 and 97% were positive for RF. Seroconversion from RF and anti-CCP positive to negative is shown for both studies (Table). For the overall abatacept + MTX population in AGREE, mean (SE) change in RF titers from baseline to Mth 6 was –133 (38.4) and to Mth 12 was –111 (45.2); change from Mth 6 to Mth 12 was 16.5 (12.7). For abatacept + MTX-treated pts in AGREE who converted from RF positive to negative from baseline to Mth 12, mean percentage reductions in tender and swollen joint counts were –75 (95% CI: –85, –66) and –76 (–87, –65) compared with –79 (–84, –73) and –84 (–87, –80) for those who remained positive at Mth 12. Mean changes in DAS28-CRP at Mth 12 were –3.0 (95% CI: –3.5, –2.6) vs –3.4 (–3.7, –3.2) for pts who seroconverted at Mth 12 vs those who remained positive.

		Month 6		Month 12	
		Seroconversion from aseline, n/N (%)	Treatment difference (95% CI)	Seroconversion from baseline, n/N (%)	Treatment difference (95% CI)
Proportion of patients with RF seroconversion (Positive to negative)					
ADJUST*	ABA	5/18 (27.8)	20.1 (−12.7, 48.5)	0/11 (0.0)	−12.5 (−52.7, 17.9)
	PBO	1/13 (7.7)		1/8 (12.5)	
AGREE	ABA + MTX	39/230 (17.0)	7.4 (0.8, 14.1)	41/222 (18.5)	3.9 (−3.5, 11.2)
	MTX alone	22/231 (9.5)		32/219 (14.6)	
Proportion of patients with anti-CCP seroconversion (Positive to negative)					
ADJUST*	ABA	2/22 (9.1)	9.1 (−9.3, 29.2)	2/15 (13.3)	13.3 (−19.6, 41.0)
	PBO	0/19 (0.0)		0/10 (0.0)	
AGREE	ABA + MTX	15/227 (6.6)	3.7 (−0.8, 8.2)	15/212 (7.1)	2.5 (−2.5, 7.6)
	MTX alone	6/208 (2.9)		9/198 (4.5)	

* Monotherapy (treatment withdrawn at Month 6); ABA=abatacept; PBO=placebo

Conclusion: Treatment with abatacept + MTX resulted in a greater proportion of pts with RF seroconversion vs MTX alone in early RA[1,2]. In pts with UA/very early RA, a similar effect on anti-CCP seroconversion was seen up to Mth 12, 6 mths after abatacept withdrawal, suggesting that abatacept may impact autoantibody formation. Pts experienced disease activity benefits with abatacept + MTX in the short-term regardless of RF seroconversion, although AGREE was not powered to evaluate this. Positivity for RF and anti-CCP is a prognostic marker of rapid progression of disease; therefore, further long-term analyses in larger populations are needed to determine whether seroconversion results in better long-term clinical and radiographic outcomes.

Comparative Effectiveness and Time to Response Among Abatacept, Adalimumab, Etanercept and Infliximab for the Treatment of Rheumatoid Arthritis in a Real World Routine Care Registry. Yusuf Yazici[1], Maria T. Filopoulos[2] and Christopher J. Swearingen[3]. [1]Division of Rheumatology, New York University School of Medicine and NYU Hospital for Joint Diseases, New York, NY, [2]NYU Hospital for Joint Diseases, New York, NY, [3]University of Arkansas for Medical Sciences, Little Rock, AR

Background/Purpose: With the availability of multiple biologic agents with different modes of action, and no head to head trials, it is of use to examine comparative effectiveness of these agents in real world registries to inform physicians how they might be used for the treatment of rheumatoid arthritis (RA).

Methods: Arthritis Registry Monitoring Database (ARMD) has been collecting prospective patient data since 2005 in all patients seen in routine care at New York University. For this analysis usage of the biologic medications abatacept, adalimumab, etanercept and infliximab along with self-reported disease activity and clinic measures were abstracted. Time to first response defined as an improvement in RAPID3 of at least 3.6 (clinically important difference) was calculated; change from biologic medication initiation to first response for self-reported disease activity and clinic measures was estimated. Differences in time to first response between biologic medications were estimated using Cox proportional hazards model.

Results: 3574 encounters were reviewed for this analysis. A total of 385 treatment courses were determined. 272 of the 385 courses represent the only biologic medication used by an individual; 40 individuals used two biologic medications at different times, while 11 had used three biologics. Abatacept had more patients achieve response (65%) characterized by a reduction in RAPID of 3.6 points or greater than adalimumab (64%), etanercept (62%) or infliximab (45%). Those patients treated with abatacept had 82% increased likelihood than those treated with infliximab to achieve response (HR=1.82, 95% CI: (1.00, 3.32), p=0.050) in an unadjusted Cox model; no other statistically significant differences between treatments were found. The difference between abatacept and infliximab was not maintained in a Cox model adjusting for age and duration. Increased duration of disease was associated with decreased likelihood of achieving a RAPID3 response. No difference in time to response among biologics was seen (Figure).

Table 1. Demographics and Outcome Measures at Initiation and Follow-up by Biologic Medication

	Abatacept Initiation	Change RAPID3 >=3.6 Present	Absent	Etanercept Initiation	Change RAPID3 >=3.6 Present	Absent	Infliximab Initiation	Change RAPID3 >=3.6 Present	Absent	Adalimumab Initiation	Change RAPID3 >=3.6 Present	Absent
N	114	61 (65%)	33 (35%)	148	77 (62%)	48 (38%)	38	13 (45%)	16 (55%)	85	42 (64%)	24 (36%)

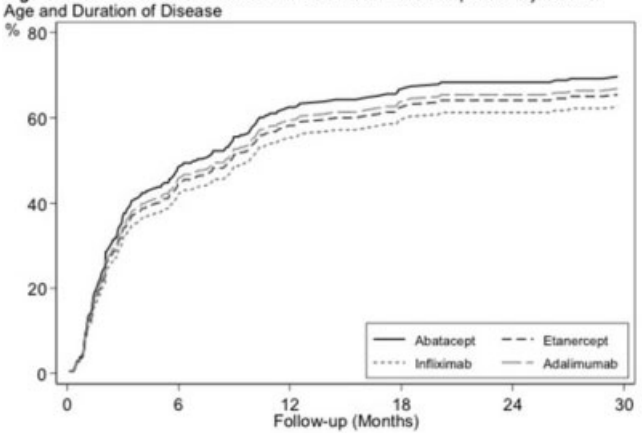
Figure 1. Cumulative Incidence of Time to RAPID ⌑3.6 Response Adjusted for Age and Duration of Disease



Conclusion: Our data suggest that overall efficacy of abatacept, adalimumab, etanercept and infliximab was similar. In addition no differences in time to response was shown among these biologic agents when treating RA patients. With no difference in clinical outcomes or response time, most treatment decisions may be based on ease of use, safety data and longterm survival of respective biologics agents when they are being considered for RA treatment.

Switching From Rituximab to Abatacept: Tolerance Data of 203 Patients Prospectively Followed up in the (Orencia) and Rheumatoid Arthritis (ORA) Registry. Jacques-Eric Gottenberg[1], Thierry Schaeverbeke[2], Philippe Gaudin[3], Liana E. Euller-Ziegler[4], Thao Pham[5], Rene-Marc Flipo[6], Alain G. Cantagrel[7], Eric Houvenagel[8], S. Redecker[9], Xavier X. Le Loet[10], Pascal Claudepierre[11], Isabelle Pane[12], Philippe Ravaud[13] and Xavier Mariette[14]. [1]Strasbourg University Hospital, Strasbourg, France, [2]Pellegrin Hospital, Bordeaux, France, [3]CHU Hôpital Sud, Grenoble Teaching Hospital, Echirolles, France, [4]L Archet Hospital (University), Nice CEDEX 3, France, [5]Sainte Marguerite Hospital, Marseille, France, [6]Hopital R Salengro CHRU, Lille CEDEX, France, [7]Hopital Purpan, Toulouse CEDEX 9, France, [8]St Philibert Hospital, Lomme 59462, France, [9]Hospital University Abbeville, France, [10]CHU de ROUEN, Rouen CEDEX, France, [11]Université Paris Est, Laboratoire d'Investigation Clinique (LIC) EA 4393, AP-HP, Hôpital Henri-Mondor, Rheumatology department, Creteil, France, [12]France, [13]Hopital Hotel Dieu, Paris Descartes University, Paris, France, [14]Université Paris-Sud, Le Kremline Bicetre, France

Background/Purpose: No tolerance data are available in patients with rheumatoid arthritis (RA) who switched from rituximab (RTX) to abatacept (ABA). RTX may have a persistent effect after its discontinuation, until B-cell repopulation, while the patients are already treated by ABA. This may result in some patients to a period of dual targeting of both B and T lymphocytes. We investigated tolerance of the switch from RTX to ABA using data from the "Orencia and Rheumatoid Arthritis" (ORA) registry.

Methods: The French Society of Rheumatology has developed the independent ORA registry, available on-line (www.ora-cri.org), in which data of tolerance and efficacy of ABA in refractory RA are currently being collected every 6 months for 5 years.

Results: From June 2008 to January 2010, 1st, 1000 RA patients have been prospectively included in the ORA registry. Among them, 203 patients (20.3%) received RTX as the last biologic before ABA initiation.

Median age of patients (74.9% of women, 73.5% RF-positive) was 59 years, median disease duration was 13 years. 5.0% of patients had a record of cancer and 35.2% had previously had severe or recurrent infections. Median number of prior synthetic DMARDs was 3. 85.2% of patients had been previously treated with anti-TNF.

Baseline disease activity and medications: before ABA, median DAS28ESR (assessed in 139 patients) was 5.5. 81.9% of patients were also treated with oral prednisone, with a median dosage of 10 mg/day. 30.2 % of patients were treated with ABA in monotherapy and 69.8% with a concomitant DMARD (methotrexate: 78.0%).

Follow-up: 190 patients have already had at least 1 follow-up visit. Median current follow-up duration is 1.8 years (342 patient/years).

Tolerance: 3 severe infusion-reactions resulted in ABA discontinuation. 6 deaths, including 2 resulting from a serious infection, occurred. 4 cancers

were observed (1.2/100 patient/years). 17 serious infections occurred corresponding to 5.0 serious infections/100 patient/years. In patients who did not receive RTX as a last biologic, the rate of serious infections was 6.1/100 patient/years.ABA was discontinued in 95 (46.8%) patients (10.5 % for severe adverse events, 73.7% for inefficacy and 15.8% for other reasons [adverse event and inefficacy, patient's wish, . . .])

Conclusion: In real life, switching from rituximab to abatacept is not unfrequent. In ORA registry, no increased risk of serious infections has been observed until now when RTX was the last biologic used before ABA, but a larger number of patients and a longer follow-up are required to confirmed these data.

First Year Radiological Erosive Progression Is a New Predictor of Further Erosive Progression in Early Arthritis: Results of the ESPOIR Cohort. Gabriel Tobon[1], Alain Saraux[2], Cédric Lukas[3], Frédérique Gandjbakhch[4], Xavier Mariette[5], Bernard G. Combe[6] and Valerie Devauchelle-Pensec[7]. [1]Unit of immunology, Brest, France, [2]Brest Occidentale University, Brest, France, [3]Montpellier 1 University, Lapeyronie Hospital, 371, Avenue du Doyen Gaston Giraud, 34295 Montpellier Cedex 5, France, Montpellier, France, [4]Hopital Pitié Salpétrière, Paris, France, [5]Université Paris-Sud, Le Kremlin Bicetre, France, [6]Hopital Lapeyronie, Montpellier, France, [7]Brest Occidentale University, Brest, France

Background/Purpose: One of a major goal in the treatment of recent arthritis is to prevent articular destruction. Several factors exist to predict joint destruction, but the rapidity of progression is never taken account.

Our objective was to determine if the first year radiological erosive progression (FIRE) is a predictor of further erosive progression (FURE) during the next two years in a cohort of early arthritis.

Methods: 813 patients with a diagnosis of recent arthritis of less than 6 months were included in the prospective French "ESPOIR" cohort. Standardized radiographs of hand wrist and foot in postero-anterior view (PAV) were performed at inclusion, one, two and three years. Inter and intraobserver variabilities were assessed. All the radiographs were examined by a blinded reader for modified Sharp score. The speed of progression was defined at one year (between M0 and M12) and after the next two years (between M12 and M36). The patients with a speed of annual progression of more than 2.5 in the erosion Sharp score were considered as high progressors.

Results: 535 patients have a complete set of radiographs. Among them 7% (35/500) received biological treatment before one year. None of them was FURE. For the 500 remaining patients without biologics, 55/500 (11%) were FIRE. During the first year, 37/500 (7.4%) did not have radiographic progression, 25% (124/500) were rapid progressor (> 5pts) Concerning classification criteria, only the presence of RF and the item 7 of the ACR criteria, or the serological item and the ACR/EULAR score of the ACR/EULAR criteria were associated with a FURE. Using logistic regression, the presence of RF or ACPA ($p = 0.023$), erosion at inclusion ($p=0.001$), the level of IL-6 ($p = 0.043$) and FIRE ($p = 0.002$) were associated with FURE. When items were combined, the FIRE criteria performed better than other criteria to predict further rapid progression.

Conclusion: The first year radiological erosive progression should be considered as a new predictor of further erosive progression in early arthritis None.

New, Provisional American College of Rheumatology and European League Against Rheumatism Remission Criteria: Results From 2 Randomized, Controlled Golimumab Trials in Patients with Rheumatoid Arthritis. Paul Emery[1], Edward Keystone[2], R. M. Fleischmann[3], M. C. Genovese[4], Lars Klareskog[5], Stephen Xu[6], Chenglong Han[7] and Elizabeth C. Hsia[8]. [1]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom, [2]University of Toronto, Toronto, ON, [3]University of Texas Southwestern Medical Center and Metroplex Clinical Research Center, Dallas, TX, [4]Stanford University Medical Center, Palo Alto, CA, [5]Karolinska Institutet, Stockholm, Sweden, [6]Centocor R & D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, [7]Johnson & Johnson Pharmaceutical Services, LLC, Malvern, PA, [8]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA

Background/Purpose: To assess wk24 remission rates from GO-BEFORE and GO-FORWARD using new, "provisional" criteria proposed by the American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) (Felson et al).[1]

Methods: This is a retrospective analysis from GO-BEFORE (methotrexate (MTX)-naïve RA pts) and GO-FORWARD (RA pts with inadequate response to MTX) through wk24. In GO-BEFORE (N=637) MTX-naïve pts and in GO-FORWARD (N=444) pts with active RA despite MTX were randomized to PBO+MTX, GLM100mg+PBO, GLM50mg+MTX, or GLM100mg+MTX, grps 1–4, respectively. In GO-FORWARD, pts with <20% improvement in SJC/TJC at wk16 entered early escape: PBO+MTX→GLM50mg+MTX, GLM 100mg+PBO→GLM100mg+MTX, GLM 50mg+MTX→GLM 100mg+MTX. GLM/PBO was injected q4wks. New ACR/EULAR remission was defined as follows: Definition A [Def A]-(TJC/SJC [28 joints], CRP mg/dL, and pt global assessment, each score ≤1) and Definition B [Def B]-SDAI score is the sum of (TJC/SJC [28 joints], pt global assessment, physician global assessment, and CRP mg/dL), scoring ≤3.3. Data handling rules were applied to wk24 analysis of data (Table).

Table. GO-BEFORE (MTX-naïve) and GO-FORWARD (MTX-inadequate response) Week 24 results using new, provisional ACR/EULAR remission criteriaμ

	Group 1 PBO+MTX	Group 2 GLM 100mg+PBO	Group 3 GLM 50mg+ MTX	Group 4 GLM 100mg+MTX	GLM 50 and 100mg + MTX
GO-BEFORE Wk 24-All pts*					
Definition A†	6.3 (10/160)	6.9 (11/159)	15.7** (25/159)	10.7 (17/159)	13.2** (42/318)
Definition B‡	8.1 (13/160)	7.5 (12/159)	15.1 (24/159)	15.7** (25/159)	15.4** (49/318)
GO-FORWARD Wk 24-All pts*					
Definition A†	1.5 (2/133)	6.0 (8/133)	12.4** (11/89)	10.1** (9/89)	11.2** (20/178)
Definition B‡	2.3 (3/133)	8.3** (11/133)	13.5** (12/89)	12.4** (11/89)	12.9** (23/178)

*% (n/N), ** p< 0.05, †Definition A-(TJC/SJC [28 joints], CRP mg/dL, and patient global assessment are all ≤1); ‡Definition B-Simplified Disease Activity Index score is the sum of (TJC/SJC [28 joints], patient global assessment, physician global assessment, and CRP mg/dL) is ≤3.3. μEarly escape (EE), pts wk16 values carried forward to wk24, last observation carried forward (missing data) and treatment failure rules applied. For GO-FORWARD-at wk16, pts in Grps 1, 2, and 3 with <20% improvement in SJC/TJC entered EE. Grp1: includes pts on PBO+MTX→EE to GLM 50mg+MTX (N=41); Grp2: GLM 100mg+PBO→EE to GLM 100mg +MTX (N=36); Grp3 GLM 50mg+MTX→EE GLM 100mg+MTX (N=15).

Results: Using new ACR/EULAR remission criteria (Def A and B), a significantly greater proportion of pts achieved remission in the combined GLM+MTX treatment grps vs grp 1 in GO-BEFORE and GO-FORWARD. A comparison between new criteria and previously published DAS28 remission criteria for the combined GLM+MTX treatment grps show: GO-BEFORE (13.2% (Def A)/15.4% (Def B) vs 26.7% (prev pub'd) and GO-FORWARD (11.2% (Def A)/12.9% (Def B) vs 28.7% (prev pub'd). As expected, the new, more stringent criteria resulted in lower remission rates vs DAS28 remission criteria. Def A and B had generally similar remission rates in both studies, with slightly lower numbers for Def A vs B. A comparison between individual treatment grps using the new criteria show: GO-BEFORE remission rates significantly greater in grp 3 for Def A and grp 4 for Def B, with grp 3 approaching statistical significance ($p=0.052$) (Def B) vs grp 1. In GO-FORWARD, significantly greater remission rates using Def A were achieved in grps 3 and 4, with grp 2 approaching statistical significance ($p=0.053$) vs grp 1, while significantly greater proportions of pts achieved remission in all GLM treatment grps vs grp 1 using Def B.

Conclusion: Significantly greater remission rates were achieved in the combined GLM grp vs grp 1 in GO-BEFORE and GO-FORWARD through wk24 based on new, more stringent ACR/EULAR criteria. Remission rates were generally slightly lower using Def A vs Def B.

A Twelve-Week Exploratory Phase II Trial of GLPG0259 Versus Placebo in Patients with Active Rheumatoid Arthritis and Inadequate Response to Methotrexate. Rene Westhovens[1], Filip De Keyser[2], Dmitro Rekalov[3], Evgeny L. Nasonov[4], Johan Beetens[5], Annegret Van der Aa[5], Piet Wigerinck[5], Florence Namour[6], Frédéric Vanhoutte[5] and Patrick Durez[7]. [1]University Hospital KU Leuven, Leuven, Belgium, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [3]Zaporizhzhia Regional Hospital, Zaporozhe, Ukraine, [4]Institute of Rheumatology, Moscow, Russia, [5]Galapagos NV, Mechelen, Belgium, [6]Galapagos SASU, Romainville, France, [7]Université Catholique de Louvain, Brussels, Belgium

Background/Purpose: GLPG0259, an inhibitor of the kinase MAP-KAPK5, blocked the release of mediators of inflammation (IL-6, TNFa) and cartilage erosion (MMPs) in disease-relevant cells and in synovial

cultures. In the mouse collagen-induced arthritis model, GLPG0259 reduced paw inflammation and prevented bone and cartilage erosion. Given these pre-clinical results, we explored the clinical development of GLPG0259 for the treatment of rheumatoid arthritis (RA). In Phase I trials GLPG0259 showed a favorable safety and a pharmacokinetic (PK) profile that supported once daily dosing. A Phase II dose-finding trial was then initiated to evaluate the efficacy and dose levels of GLPG0259 in RA patients.

Methods: This exploratory, Phase II, double-blind, placebo-controlled, multicenter trial was designed to be performed in a maximum of 200 randomized subjects with active RA who had an inadequate response to methotrexate (MTX). The trial consisted of two parts:

In Part A, thirty eligible subjects were randomized in a 2:1 ratio to receive either a once-daily 50 mg dose of GLPG0259 or placebo, in addition to a stable dose of MTX.

An interim analysis was performed at the end of Part A to assess the efficacy and tolerability of GLPG0259 versus placebo.

If the interim analysis at the end of Part A showed a clinical advantage of GLPG0259 over placebo, Part B would be initiated, with an additional 150 subjects randomized to GLPG0259 (50, 25 or 12.5 mg/day), or placebo.

Results: Here we present the results from Part A of the trial. In total 31 patients were randomized; one patient dropped-out before administration of study medication. The 30 remaining patients were allocated to 50 mg GLPG0259 q.d. (19 patients) or to placebo (11 patients) for 12 weeks. Both patient populations were comparable: they had an RA diagnosis established on average 7 years prior to participation in the trial, were on an average dose of MTX of 10–11 mg weekly for at least 12 weeks, had never taken biologics before and had comparable RF and anti-CCP seropositivity.

After 12 weeks of treatment 26% and 27% of GLPG0259 and placebo recipients, respectively, showed an ACR20 response. Sub-analysis of the ACR components showed no marked difference between the two treatment populations. A modest drop in CRP (26%) in the GLPG0259 group did not result in an improved ACR20 response.

Overall 9 patients (30%) presented with treatment-emergent adverse events (AEs); 8 (42%) on GLPG0259 and 1 (9%) on placebo. The GLPG0259-related AEs mainly affected the gastrointestinal tract (nausea, vomiting, gastrointestinal discomfort and xerostomia), consistent with the Phase I results.

Plasma concentrations of GLPG0259 were within the range observed in healthy volunteers dosed at 50 mg q.d. for 14 days.

Conclusion: The interim analysis of the results of Part A of this exploratory Phase II trial, involving 12 weeks of treatment with 50 mg q.d. GLPG0259 or placebo in patients with active RA and insufficient response to MTX, did not show any clinical benefit from GLPG0259. Therefore, Part B of the trial will not be initiated. This innovative trial design did, however, enable a quick determination of the lack of GLPG0259's efficacy in RA patients.

2238

Safety and Efficacy of Abatacept in Eight Rheumatoid Arthritis Patients with Chronic Hepatitis B. Paul S. Kim[1], Gerald Y. Ho[2], Pamela E. Prete[3] and Daniel E. Furst[4]. [1]University of California, Irvine, Orange, CA, [2]Arthritis/Osteoporosis Med Ctr, La Palma, CA, [3]Long Beach VA Med Ctr, Long Beach, CA, [4]UCLA, Los Angeles, CA

Background/Purpose: There are no previous studies on the use of abatacept in patients with chronic hepatitis B. This medical record review assesses the safety and efficacy of abatacept in eight patients with rheumatoid arthritis (RA) and chronic hepatitis B.

Methods: A retrospective analysis of 8 patients with RA and chronic hepatitis B treated with abatacept was conducted. The primary outcome was DAS 28 at each follow-up visit along with markers of hepatitis B reactivation including liver function tests as measured by aspartate aminotransferase (AST), alanine aminotransferase (ALT), and hepatitis B viral load.

Results: A total of 47 visits were recorded. Mean duration of follow-up of patients on abatacept was 19.1 months (SD 12.7, range 3–33). Analysis was limited to 18 months of follow-up (included 77% of all visits: 36/47). Four patients were started on antiviral prophylaxis for hepatitis B (3 on entecavir and 1 on tenofovir) with the initiation of abatacept while four patients were not. Among the 4 patients who received antiviral prophylaxis, RA improved as evidenced by a statistically significant decrease in DAS 28 scores from 5.2 (SD 1.7) at baseline to 2.9 (SD 1.4) at 18 month follow-up, $p = 0.025$. Also these 4 patients had no reactivation of hepatitis B with viral titers remaining within 1 log of baseline in the 2 where it was obtained. In the 4 patients without antiviral prophylaxis there was no significant decrease in the DAS 28 scores going from 4.8 (SD 0.9) at baseline to 3.9 (SD 0.34) at 18 month follow-up, $p = 0.318$, and all 4 experienced reactivation of hepatitis B with viral titers increasing more than 10-fold. There were no adverse events other than the hepatitis B reactivation.

Conclusion: In these preliminary data, the use of abatacept in patients with RA and chronic hepatitis B appears feasible if antiviral prophylaxis for hepatitis B is given concurrently. In these patients there were no non-hepatitis-related adverse effects. These data are encouraging and should lead to initiation of controlled trials of abatacept in hepatitis B.

2239

Higher Proportion of Rheumatoid Arthritis Patients Achieve Low Swollen and Tender Joint Counts and No Radiographic Progression with Etanercept Plus Methotrexate Versus Methotrexate Alone. Eustratios Bananis, Tahmina Ferdousi, Ronald Pedersen, Andrew S. Koenig and Thomas V. Jones. Pfizer Inc., Collegeville, PA

Background/Purpose: ACR/EULAR remission criteria for rheumatoid arthritis (RA) include achievement of 0 or 1 swollen joints (SJ) and 0 or 1 tender joints (TJ).[1] Recent studies have identified SJ count as a potential predictor of radiographic progression.[2,3] The Combination of Methotrexate (MTX) and Etanercept (ETN) in Active Early Rheumatoid Arthritis (COMET) trial demonstrated that treatment of early RA with MTX and ETN led to superior rates of DAS clinical remission and radiographic non-progression compared with MTX alone. This post hoc analysis of data from the COMET trial examines rates of achieving ≤1 SJ, ≤1 TJ and inhibition of radiographic progression (change in mTSS ≤0) at years 1 and 2 in response to treatment.

Methods: Overall trial methods have been previously described.[4,5] For this analysis, LOCF data, utilizing the DAS28 joint counts from the COMET trial, was assessed at years 1 and 2. Inhibition of radiographic progression was calculated for patients with valid radiographs that achieved ≤1 SJ and ≤1 TJ by treatment group.

Results: At year 1, a significantly higher proportion of patients achieved ≤1 SJ (70.9% vs 46.0%, P<0.02) or ≤1 TJ (64.2% vs 40.7%; P<0.02) when treated with ETN+MTX versus MTX alone, respectively (Table). Furthermore, a higher proportion of patients receiving ETN+MTX treatment that achieved ≤1 SJ (76.3% vs 65.5%, P=0.06) or ≤1 TJ (78.5% vs 55.9%, P<0.02) had no radiographic progression compared to MTX monotherapy at year 1 (Table). At 2 years, a significantly higher proportion of patients with continuous ETN+MTX therapy than MTX monotherapy had ≤1 SJ (80.6% vs 53.2%, P<0.02) or ≤1 TJ (70.4% vs. 53.2%, P<0.02), respectively. Similar to year 1 results, a higher proportion of patients receiving continuous ETN+MTX versus continuous MTX who achieved ≤1 SJ (87.7% vs 69.9%, P<0.02) or ≤1 TJ (85.5% vs 70.2%, P=0.062) had no radiographic progression at year 2 (Table). The proportion of patients with ≤1 SJ at year 1 and who had no radiographic progression after 2 years of continuous ETN+MTX therapy was significantly higher compared to those with ≤1 SJ at year 1 receiving 2 years of continuous MTX monotherapy (89.9% vs 65.2%, P=0.002). Similar results were seen in patients who achieved ≤1 TJ at year 1 after 2 years of continuous treatment (87.0% vs 62.8%, P=0.005).

Table. Patients who achieved ≤1 swollen joint or ≤1 tender joint and no radiographic progression at years 1 and 2 by treatment group

	Year 1		Year 2	
	ETN + MTX	MTX	ETN + MTX	MTX
≤ 1 swollen joint	188/265 (70.9)*	121/263 (46.0)	87/108 (80.6)*	50/94 (53.2)
≤ 1 swollen joint and mTSS ≤0†	135/177 (76.3)	74/113 (65.5)	71/81 (87.7)*	32/46 (69.6)
≤ 1 tender joint	170/265 (64.2)*	107/263 (40.7)	76/108 (70.4)*	50/94 (53.2)
≤ 1 tender joint and mTSS ≤0†	128/163 (78.5)*	57/102 (55.9)	59/69 (85.5)	33/47 (70.2)

All values n/N (%); *P<0.02 versus MTX monotherapy; †Includes only patients with valid radiographs

Conclusion: In this analysis, a significantly higher proportion of patients who were treated with ETN+MTX had ≤1 swollen joint or ≤1 tender joint at year 1 and 2 as compared to patients receiving MTX alone. Of the patients achieving ≤1 swollen joint or ≤1 tender joint, a higher proportion of patients receiving ETN+MTX had no radiographic progression versus MTX monotherapy. Combination treatment increases the proportion of patients achieving 2 major components of the new remission criteria and inhibits radiographic progression.

Efficacy of TNF Switch After Failure of One TNF Inhibitor – Results From a Nation-Wide Observational Study. Katerina Chatzidionysiou[1], Jonas Eriksson[2], Johan Askling[3] and Ronald F. van Vollenhoven[1]. [1]Karolinska Institute, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [3]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Solna, Sweden

Background/Purpose: The purpose of this study was to determine whether patients who failed one anti-TNF benefit from switching to another anti-TNF and whether the specific order of agents and reason for switch is significant.

Methods: Data from the ARTIS registry were used. Patients with RA, who received an anti-TNF [etanercept (ETA), adalimumab (ADA) or infliximab (INF)] as first biologic and subsequently switched to an alternative anti-TNF, were included in the analysis. Treatment segments were analysed according to DAS28 and HAQ reduction and EULAR response at 6 months after baseline. Treatment results were analysed for each biologic, by type of previous anti-TNF and reason for discontinuation (primary and secondary inefficacy or intolerance). Multiple treatment segments with the same anti-TNF were disregarded for this analysis.

Results: A total of 1080 patients were included. Of these, 520 switched to ETA, 466 to ADA, and 94 to INF. Complete data were available for appr. 50% of patients and were evenly distributed between groups. At baseline (BL= start of 2nd anti-TNF) no differences in age, sex, disease duration, RF, HAQ and concomitant NSAIDs were observed between groups. BL DAS28 (mean±SD) was significantly lower for ADA (4.79±1.32) than ETA (5.15±1.32, p<0.0001) and INF (5.13±1.22, p=0.04). INF was more often combined with DMARDs (81.9%) than ETA (69.3%, p=0.007) and ADA (65.7%, p=0.001), but less often with glucocorticoids (39.4%) than ETA (51.2%, p=0.02) and ADA (50.6%, p=0.03).

Significant clinical improvements were observed for the whole cohort of patients. DAS28 improvement at 6 months was 1.59±1.47 for ETA, 1.17±1.35 for INF and 1.00±1.32 for ADA (p=0.002 ETA vs. ADA, p=0.29 ETA vs. INF; p values adjusted for age, sex, BL DAS28, conc. DMARDs and glucocorticoids). HAQ improvement at 6 months = 0.26±0.52 for ETA, 0.14±0.50 for INF and 0.14±0.43 for ADA (adjusted p=0.42 ETA vs. INF, p=0.23 ETA vs. ADA). The percentages of EULAR Good/Moderate/Non-responders were 28/43/29% for ETA, 21/46/33% for INF and 17/45/38% for ADA (p=0.02 between groups). In table 1 the effectiveness of each anti-TNF by type and reason for discontinuation of the previous anti-TNF is summarized.

Table 1. Efficacy of the 2nd antiTNF assessed by DAS28 (mean±SD) and HAQ (mean±SD), reductions at 6 months from baseline, accordning to the type of previous antiTNF and reason for discontinuation. ([Number of patients])

1st antiTNF	2nd antiTNF	DeltaDAS28 6m mean±SD	p-value*	DeltaHAQ 6m mean±SD	p-value*
ETA	ADA	0.93 ± 1.21 [154]	0.34	0.12 ± 0.43 [164]	0.70
	INF	1.24 ± 1.40 [36]		0.18 ± 0.44 [36]	
ADA	ETA	1.39 ± 1.46 [121]	0.88	0.25 ± 0.44 [127]	0.25
	INF	0.91 ± 1.16 [10]		−0.02 ± 0.67 [10]	
INF	ETA	1.75 ± 1.47 [145]	0.30	0.26 ± 0.57 [145]	0.82
	ADA	1.16 ± 1.56 [63]		0.19 ± 0.43 [68]	
Reason discontinuation 1st antiTNF					
Intolerance	ETA	1.68 ± 1.47 [62]	0.85	0.30 ± 0.46 [61]	0.17
	INF	1.32 ± 0.90 [6]		0.20 ± 0.11 [5]	
	ADA	1.24 ± 1.79 [46]		0.06 ± 0.42 [53]	
Primary inefficacy	ETA	1.56 ± 1.45 [82]	0.13	0.25 ± 0.58 [87]	0.86
	INF	1.23 ± 1.33 [17]		0.13 ± 0.66 [19]	
	ADA	1.02 ± 1.03 [63]		0.16 ± 0.40 [65]	
Secondary inefficacy	ETA	1.65 ± 1.41 [83]	**0.02****	0.25 ± 0.48 [86]	0.92
	INF	1.04 ± 1.11 [12]		0.14 ± 0.50 [10]	
	ADA	0.99 ± 1.16 [59]		0.20 ± 0.45 [62]	

* Adjusted for BL age, sex, DAS28, conc. DMARDs and glucocorticoids.
** ETA vs. ADA p=0.005

Conclusion: In this large observational cohort, patients who failed anti-TNF therapy do benefit from switching to other TNF inhibitors. ETA as 2nd anti-TNF yielded significantly greater DAS28 reductions than INF and ADA, but due to the relatively large number of incomplete data this finding must be interpreted with caution. For patients who discontinued anti-TNF because of secondary inefficacy, switching to ETA appeared more effective than switching to ADA.

2241

A Safety Analysis of Oral Prednisone As a Pre-Treatment for Rituximab in Rheumatoid Arthritis. John D. Carter[1], Nancy Albritton[1], S. Alireza Zarabadi[2], Louis R. Ricca[3], Joanne Valeriano-Marcet[1], Frank B. Vasey[4] and Anthony Sebba[5]. [1]University of South Florida, Tampa, FL, [2]Tampa Arthritis Center, Tampa, FL, [3]University of South Florida College of Medicine, St Petersburg, FL, [4]Wayne State Univ. Health Ctr., Detroit, MI, [5]University of South Florida, Palm Harbor, FL

Background/Purpose: The administration of 100mg of methylprednisolone intravenously (IV) ½ hour prior to rituximab decreases the incidence and severity of acute infusion reactions (AIRs). However, the recommended pretreatment with IV methylprednisolone adds considerable time to the medication administration protocol; it also conveys potential risk. We present preliminary results of an assessment of oral prednisone as a pretreatment to rituximab.

Methods: This is a 6-month open-label assessment of 40mg of oral prednisone given ½ hour prior to rituximab as a prophylaxis against acute infusion reactions in patients with rheumatoid arthritis (RA). Subjects are ages 18–80 and either methotrexate (MTX) or TNF-antagonist inadequate responders and naïve to rituximab. All subjects have to be on concomitant methotrexate. Standard safety and laboratory exclusions applied. All subjects were treated with 40mg of oral prednisone ½ hour prior to their rituximab infusions. Rituximab was administered as per the standard RA protocol; i.e. 1000mg IV twice at days #1 and #15. The primary endpoint is AIRs in the first 24 hours after the initiation of their day #1 infusion. The severity, timing, and treatment (including rituximab dose modifications) of any AIRs are also recorded. Secondary endpoints include AIRs during the 24 hours following the day #15 infusion and any adverse events experienced during the 6 month study; efficacy measures (DAS-28 and HAQ-DI) were also followed as secondary endpoints.

Results: 65 subjects were screened and 50 subjects qualified. Baseline demographics include 42 females and 8 males, with 39/50 (78%) Caucasians, 5 (10%) Hispanics, 3 African-Americans (6%), and 3 other. The subjects' mean age was 52.2 years (range 27–80) and disease duration was 11.2 years (range 1–49). The average MTX dose was 16.2mg weekly and 30/50 (60%) have failed previous anti-TNF therapy (average number of TNF-antagonists used was 1.5). 22/50 (44%) subjects were on glucocorticoids at baseline with an average dose of 7.1mg prednisone daily; 36/50 (72%) subjects were seropositive. The mean DAS28 at screening was 5.64 and their HAQ-DI was 1.39. Regarding the primary endpoint, 15/50 (30%) of the subjects had AIRs within 24 hours of their day #1 infusion; 13 were mild in severity and 2 were moderate. There were only 6 (12.2%) AIRs within 24 hours of their day #15 infusion; all were mild. One of the day #1 AIRs required drug discontinuation (wheezing). Of the 47 subjects who have completed the entire 6 months of the study, 37 (79%) experienced an AE at some point during the trial. There were 3 SAE's (a-fib, asthma, suicide attempt) deemed not to be study-drug related. The DAS28 and HAQ-DI all improved significantly at weeks 8, 16, and 26 compared to baseline.

Conclusion: Historical controls demonstrate that 27–33% of RA subjects experience AIRs with their first rituximab infusion. Our data suggest a smaller dose of oral prednisone is an effective alternative to IV methylprednisolone as a pretreatment for rituximab in patients with RA.

Characterization of Long-Term Responders to First Treatment Course of Rituximab (RTX)—Results From the CERERRA Collaboration. Elisabeth Lie[1], Katerina Chatzidionysiou[2], Evgeny L. Nasonov[3], Galina Lukina[3], Karel Pavelka[4], Dan C. Nordström[5], Matija Tomsic[6], Cem Gabay[7], Ioan Ancuta[8], Piet LC van Riel[9], Juan J. Gomez-Reino[10], João E. Fonseca[11], Merete L. Hetland[12], Ulrik Tarp[13], Tore K. Kvien[1] and Ronald F. van Vollenhoven[2]. [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Karolinska Institute, Stockholm, Sweden, [3]Institute of Rheumatology, Moscow, Russia, [4]1Institute of Rheumatology, Department of Experimental Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [5]ROB-FIN, Helsinki University Central Hospital, Helsinki, Finland, [6]University Medical Centre Ljubjana, Ljubljana, Slovenia, [7]University Hospitals of Geneva, on behalf of the SCQM registry, Geneva, Switzerland, [8]Cantacuzino Hospital, Bucharest, Romania, [9]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [10]Hospital Clinico Universitario, Santiago, Spain, [11]Lisbon Academic Medical Center, on behalf of Rheumatic Diseases Portuguese Register (Reuma.pt), Lisbon, Portugal, [12]Copenhagen University Hospital at Glostrup, on behalf of DANBIO, Copenhagen, Denmark, [13]Aarhus University Hospital, Aarhus, Denmark

Background/Purpose: Most rheumatoid arthritis (RA) patients (pts) who respond to the first course of RTX need retreatment with a second course after 6 to 12 months due to increase in disease activity. However, some pts show a sustained clinical response for a longer period. Our objective was to characterize pts who showed a sustained response after the 1st course of RTX and compare them to those who were not long-term responders.

Methods: 10 European biologics registries provided anonymized data sets of RA pts treated with RTX in clinical practice for analysis of pooled data. Pts with available retreatment data were eligible for the current analyses. Long-term response was defined as no retreatment during the 1st year AND sustained response (ΔDAS28 < -1.2 vs. baseline) at months 6–12, in pts with at least 9 months follow-up. The comparator groupincluded pts retreated during the 1st year and/or without sustained response. Baseline (BL) characteristics, and year 1 and year 2 DAS28 states and changes were compared. Due to heterogeneity in timing of follow-up visits, overall mean DAS28 was calculated for the period 3–12 months and for year 2. The main effectiveness outcome was mean DAS28 during year 2. Predictors of long-term response were identified by univariate and multivariate logistic regression analysis.

Results: 209 pts were classified as long-term responders (LTRs) and 867 were non-long-term responders (NLTRs) (79% of NLTRs were retreated during the 1st year); 93% vs. 88% had >18 months follow-up time. In both groups, 83% were female, 81% received concomitant DMARDs and mean disease duration was 12 years. 84%/82% were RF pos. LTRs were significantly older (mean 55.1 vs. 52.2 years, p=0.005), were more often biologics naïve (51.0% vs. 40.4%, p=0.006) and had higher BL DAS28. Despite higher BL DAS28, % in low disease activity state (LDA) and remission (rem) were higher for LTRs through year 1, and mean DAS28 was lower (Table 1). The difference in mean DAS28 was more or less sustained through year 2, but % in LDA/rem. were similar for most time points. 34% of LTRs were retreated during year 2. Mean(SD) total number of RTX courses from baseline through year 2 was 1.6(1.0) for LTRs vs. 2.6(0.8) for NLTRs (p<0.001). Older age, biologics naivety, higher BL DAS28 and lower HAQ-DI were independent predictors of LTR (Table 2).

Table 1.

	Long-term responders	Non-long-term responders	p-value
BL DAS28	6.26	5.91	<0.001
Mean DAS28 months 3–12	3.66	4.39	<0.001
DAS28 ≤ 3.2 (LDA) months 6/12	36.4%/45.3%	19.8%/22.0%	<0.001/<0.001
DAS28 <1.6 (rem.) months 6/12	19.2%/22.7%	9.7%/11.5%	0.001/<0.001
Mean DAS28 year 2	3.78	4.13	0.01
ΔDAS28 BL to year 2	−2.37	−1.85	0.001
DAS28 ≤ 3.2 (LDA) months 18/24	28.3%/54.5%	25.8%/36.0%	0.70/0.02
DAS28 < 2.6 (rem.) months 18/24	13.2%/31.8%	13.1%/17.5%	0.98/0.03

Table 2.

	OR (95% CI)	p-value
Age	1.08 (1.00–1.16)*	0.051
Biologics naivety	1.58 (1.08–2.30)	0.018
BL DAS28	1.44 (1.19–1.73)	<0.001
BL HAQ-DI	0.70 (0.52–0.95)	0.024

* Per 5-year increase. Multivariate model, adjusted for sex and BL pain VAS. Hosmer-Lemeshow goodness-of-fit p=0.88.

Conclusion: Biologics naïve pts who were older and who had higher disease activity and less functional impairment at baseline were more likely be long-term responders to the 1st course of RTX, and these pts generally sustained a good clinical response through year 2.

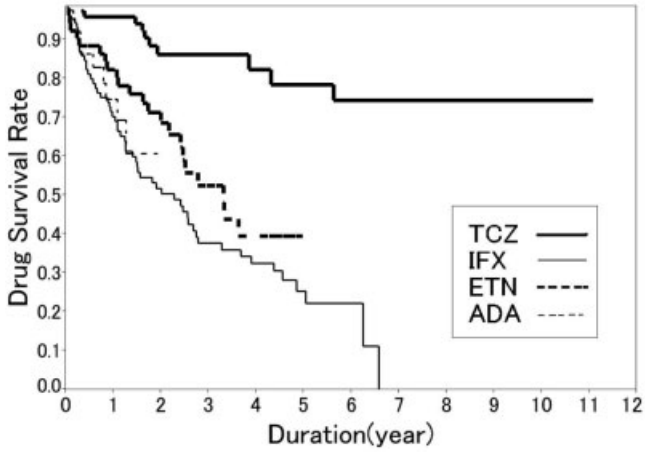
2243

Long-Term Tolerability of Tocilizumab for the Treatment of Rheumatoid Arthritis. Yoshihiro Hishitani, Toru Hirano, Yoshihito Shima, Atsushi Ogata, Masashi Narazaki, Keisuke Hagihara and Toshio Tanaka. Osaka University Graduate School of Medicine, Suita, Japan

Background/Purpose: Tocilizumab(TCZ),a humanized monoclonal anti-IL-6 receptor antibody, has been shown to have definite efficacy in patients with rheumatic arthritis(RA). However, long term utility of TCZ has not been well documented. And there are few reports comparing TCZ with anti-TNFα drugs. We observe patients with RA who are administered TCZ for up to 11 years. So we examined the tolerability of biologics, especially TCZ.

Methods: We retrospectively reviewed the medical charts of RA patients who were administered biologics from 1999 to 2010. We examined continuation rate andcause of discontinuation of biologics for the treatment of RA.

Results: We administered biologics to 200 RA patients by September 2010. And we were able to follow 192 cases to September 2010. TCZ,infliximab(IFX),etanercept(ETN),adalimumab(ADA) were administered to 78(51), 87(80), 53(43), 44(26) cases respectively (as the 1st biologics). TCZ and ADA were administered to elder patients than ETN. TCZ and ETN were administered to patients who had higer DAS-28 score than ADA. Concomitant dosage of methotrexate(MTX) was more in patients who were administered IFX (IFX group) compared to other groups. Disease duration and concomitant prednisolone dosage were not significantly different among the 4 groups. Median duration of administration of TCZ, IFX, ETN, ADA were 704,545,714,248days, respectively. The Kaplan-Meier curves of the continuation rate of the 4 drugs are shown in Figure. TCZ showed significantly higher continuation rate than anti-TNFα drugs (p<0.001). The cause and number of discontinuation of these 4 biologics are shown in Table. The rate of discontinuation due to lack of efficacy or loss of efficacy was significantly less in TCZ group than other groups. The rate of infusion reaction was significantly more in IFX group than other groups. The rate of discontinuation due to severe infection was not significantly different among the 4 groups.



Cause of discontinuation	TCZ	IFX	ETN	ADA
no efficacy	1	9	4	4
loss of efficacy	2	12	12	3
infusion reaction	1	12	2	0
severe infection	5	5	1	1
remission	0	5	1	1
miscellaneous	2	14	3	1
overall discontinuation	11	57	23	10
(Total cases)	(78)	(87)	(53)	(44)

Conclusion: In our cohort, TCZ showed long-term tolerability for the treatment of RA.

2244

A Multi-Biomarker Disease Activity Score (Vectra™DA algorithm score) Reflects Clinical Disease Activity and Tracks Response in a Japanese Rheumatoid Arthritis Population Treated with Anti-TNF Therapy. Shintaro Hirata[1], Douglas J. Haney[2], Guy Cavet[2], Lyndal K. Hesterberg[2], Norifumi Sawamukai[1], Kunihiro Yamaoka[3], Kazuyoshi Saito[1] and Yoshiya Tanaka[1]. [1]University of Occupational & Environmental Health, Japan, Kitakyushu, Japan, [2]Crescendo Bioscience, Inc., South San Francisco, CA, [3]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background/Purpose: Effective management of rheumatoid arthritis (RA) patients involves regular quantitative disease activity assessment. We set out to determine whether a multi-biomarker disease activity algorithm (MBDA), developed and validated in predominantly Caucasian populations, could assess disease activity and track changes in a Japanese RA cohort treated with anti-TNF therapy.

Methods: Patients were enrolled at the University of Occupational and Environmental Health, Kitakyushu, Japan. Each received anti-TNF treatment (50 adalimumab, 49 etanercept, 50 infliximab) in the course of their routine clinical care. Twelve biomarkers were measured using custom immunoassays on the Meso Scale Discovery MULTI-ARRAY platform and combined in a pre-specified algorithm to generate a MBDA score between 1 and 100. The association between MBDA score and DAS28 was evaluated by Spearman correlation and by area under the receiver operating characteristic (AUROC) curve for distinguishing DAS28 $\leq$ 3.2 from DAS28 $>$ 3.2. These analyses used a single randomly selected visit for each patient. MBDA score was evaluated as an independent predictor of disease activity in ordinary least squares regression with DAS28 as response variable and CRP and MBDA score (using only biomarkers other than CRP) as predictor variables. The ability of change in MBDA score to track clinical response was assessed by AUROC for good EULAR response at 1 year.

Results: At baseline, patients had median age of 60 (interquartile range (IQR) 50–68), median DAS28 of 5.7 (IQR 5.0–6.5) and disease duration of 60 months (IQR 18–168). MBDA scores distinguished low and moderate/high disease activity categories (AUROC = 0.80, 95%CI 0.72–0.87, $p < 0.001$) and were correlated with DAS28 (rho = 0.64, 95%CI = 0.54–0.73, $p < 0.05$). The MBDA score (with CRP removed) was independently predictive of DAS28 in a model including CRP (MBDA: $p < 0.001$, CRP: $p = 0.001$). 56% of patients had good EULAR responses at 1 year. Change in MBDA score from baseline to 1 year distinguished these responders from non-responders (AUROC = 0.68, 95%CI 0.58–0.76, $p < 0.001$).

Conclusion: The MBDA score reflects clinical disease activity and changes in the score are associated with clinical response in Japanese patients initiating anti-TNF therapy. The contributions of MBDA biomarkers other than CRP are independently predictive of clinical disease activity in a model also including CRP. These results are similar to those observed in predominantly Caucasian populations, suggesting that the behavior of the MBDA biomarkers is generally consistent between Japanese and Caucasian ethnic groups.

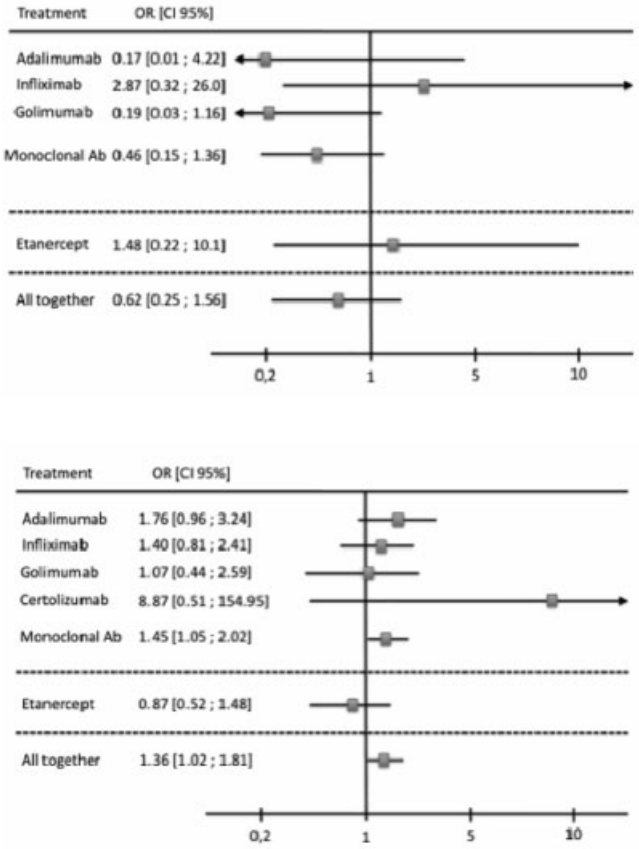
2245

The Risk of Serious Infection with and without Anti-TNF Therapy in Rheumatoid Arthritis and Ankylosing Spondylitis: A Meta-Analysis. Hélène Cormier, Thomas Barnetche and Thierry Schaeverbeke. Pellegrin Hospital, Bordeaux, France

Background/Purpose: In 2006, a meta-analysis of Bongartz et al. indicated that the rate of severe infections in rheumatoid arthritis is higher in patients treated with adalimumab and infliximab compared with patients treated with placebo. The difference was found to be not significant in ankylosing spondylitis with adalimumab, infliximab and etanercept (Fouque-Gombert et al.) Many randomized controlled trials have been published since 2006, included new anti-TNF: golimumab and certolizumab. Our objective was to assess the risk of infection with and without TNF blockers, with more power in RA and AS.

Methods: A systematic literature search was performed on Medline for randomized controlled trials from 1994 to December 2010. We included studies evaluating the five anti-TNF agents in rheumatoid arthritis and four anti-TNF agents in ankylosing spondylitis, using standard dosing regimens. The primary clinical outcome was the frequency of serious infections (infections requiring intravenous antibiotics and/or hospitalization). Statistical analyses were based on odds ratio for risk. We calculated a pooled odds ratio (Mantel-Haenszel methods) for serious infections in anti-TNF-treated patients vs placebo patients. We estimated effects for standard doses. Using these combined estimates, we calculated the absolute risk of serious infections for each product in RA and AS.

Results: 36 studies were included (9707 patients), 24 in RA (7702 patients) and 12 in AS (2005 patients). The frequency of serious infection is 2.2% (78/3487) in RA and 0.9% (7/707) in AS in patients not exposed to TNF blockers. The frequency of serious infection is 3% (125/4215) in RA and 0.6% (8/1298) in AS in patients exposed to TNF blockers. The pooled ratio for serious infection was 1.36 ($CI_{95\%}$= [1.02–1.81]) in RA and 0.62 ($CI_{95\%}$= [0.25–1.56]) in AS. Nevertheless, in RA, metanalysis of RCTs with etanercept compared with placebo shows that the increase in serious infections was not significant (OR=0.87; $CI_{95\%}$= [0.52–1.48]). In metanalysis of RCTs with monoclonal antibody therapy compared with placebo in RA, the difference is significant (OR=1.45; $CI_{95\%}$= [1.05–2.02], see Figure 1).



This difference of risk between etanercept and monoclonal antibodies is not observed with SA patients (see Figure 2).

Conclusion: There is an increased risk of serious infections in patients with RA treated by monoclonal antibodies. This difference is not significant in patients receiving etanercept. The risk of severe infections is low in patients with AS who receive placebo or TNF blockers, and no significant difference was demonstrated between these two groups.

2246

Rebalancing the IL-23/Th17 Axis and Regulatory T Cells in Arthritis by Depleting IRF5 $^{+}$ IL-23^{+} M1 Macrophages Using An Anti-Human DR5 Antibody. Jun Li[1], Hui-Chen Hsu[1], PingAr Yang[1], Qi Wu[1], Hao Li[1] and John D. Mountz[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham and Birmingham VAMC, Birmingham, AL

Background/Purpose: The abundance and activation of macrophages in the inflamed synovium significantly correlate with the severity of rheumatoid arthritis (RA). Macrophages are one of the major sources of IL-23 which potentially contributes to T cell subset plasticity including

Th17 cells and regulatory T cells (Tregs). Dysregulation of macrophages, the IL-23/Th17 axis, and Tregs have been implicated in the pathogenesis of RA. However, therapeutic strategies that can restore the homeostasis of these factors in RA are unknown. Death receptor 5 (DR5) is a pro-apoptotic protein, which mediates apoptosis upon cross-linking by a novel anti-human DR5 antibody, TRA-8. The purpose of this study was to investigate the immunomodulatory and therapeutic effects of TRA-8 by using macrophage targeted expression of a humanized DR5 transgenic (Tg) mouse with arthritis.

Methods: A humanized DR5 Tg mouse was generated using a 3kb mouse promoter/*Floxed* STOP/humanized mouse DR5 construct. Macrophages specific expression was achieved by crossing the DR5 Tg mice with lysozyme M-Cre mice. Arthritis was induced by intradermal injection of CII in CFA/IFA. TRA-8 (0.2 mg/mouse; I.V. weekly) was initiated on day 30 until mice were sacrificed 3 months post CII. Macrophages, Th17 and Tregs T cell subpopulations in the draining lymph nodes (LN) of DR5 Tg mice with and without TRA-8 treatment was analyzed by flow cytometry. *In vivo* joint macrophage activity was quantitated using an infrared cathespin imaging system. Expression of IRF5 and IL-23 protein in the $F4/80^+$ macrophages of draining LN was determined by 4-color imaging on Zeiss 710 confocal microscope. Clinical scoring and histological assessments of the joints were performed to evaluate the severity of arthritis.

Results: TRA-8 treatment resulted in a ~65% reduction of $CD11b^+$ macrophages in the draining LN of Tg^+ mice. Within the $CD11b^+$ cells, ~75% of the $Ly6C^+$ activated macrophages and ~90% of the $IL\text{-}23^+$ macrophages were eliminated by TRA-8 (2.4% to 0.23%, $P<0.05$). The depletion also leads to elevation of $CD4^+Foxp3^+$ Tregs (3.6% to 5.9%, $P<0.05$) and reduction of the $CD4^+IL\text{-}17^+$ Th17 cells (6.8% to 3.2%, $P<0.05$). Confocal imaging showed that there was a significant reduction of IL-23 and IRF5 expression (~85% and ~55% respectively) in macrophages after TRA-8 treatment, which suggested that TRA-8 specifically depleted M1 inflammatory macrophages. After TRA-8 treatment, joint histopathology showed a significantly decreased $MAC3^+$ macrophage infiltration, synovial hyperplasia, cartilage damage, and bone erosion (arthritis score: 9.8 versus 1.5, $P<0.01$). TRAP staining indicated that osteoclast formation in joints was inhibited by TRA-8 treatment. Cathepsin activity was significantly decreased (~62%) in DR5 Tg mice that received TRA-8 treatment. Neither systematic toxicities nor increased infection were found.

Conclusion: This study demonstrated that anti-human DR5 antibody (TRA-8) can specifically deplete the IL-23 secreting inflammatory M1 macrophages restoring the balance between Th17 and Tregs. Thus, anti-human DR5 antibody, currently in phase II cancer clinical trails, is a novel immunomodulatory agent and potentially effective for treatment of RA.

Systematic Review and Network Meta-Analysis of Combination Therapy for Methotrexate-Experienced, Rheumatoid Arthritis Patients: Analysis of American College of Rheumatology Criteria Scores 20, 50 and 70.
Michelle E. Orme[1], Iain Fotheringham[2], Stephen A. Mitchell[2], Dean Spurden[3] and Alex Bird[3]. [1]ICERA consutling, United Kingdom, [2]Abacus International, United Kingdom, [3]Pfizer Ltd, Surrey, United Kingdom

Background/Purpose: To determine the relative effectiveness of all UK licensed biological disease-modifying anti-rheumatic drugs (bDMARDs) for the treatment of rheumatoid arthritis (RA), in particular the concomitant use of bDMARDs with methotrexate (MTX) after failure of one or more DMARD.

Methods: A comprehensive systematic review was conducted to identify randomised controlled trials of bDMARDS for the treatment of RA in MTX experienced patients (defined as patients with an inadequate response to at least 1 cycle of MTX (6 months) or withdrawn from MTX due to adverse events). This analysis covers combination therapy (biological DMARD + other DMARD) in MTX experienced patients and:

Excludes studies in MTX naïve patients.

Excludes study arms evaluating biologic monotherapy, except if this results in only one remaining study arm for the meta-analysis (the biologic monotherapy arm is then included as the control for this study).

MTX monotherapy controls are included in the network and MTX is the reference treatment for the network meta-analysis (NMA).

Structured literature searches were conducted in MEDLINE, EMBASE, and the Cochrane Library, as well as hand searches of conference proceedings and reference lists. From this 13,649 citations were identified, of which 12,984 were excluded based on the title/abstract. After reviewing 665 full-text papers, there were 26 eligible studies that reported endpoints based on ACR criteria reported between 12 and 30 weeks. A network meta-analysis was conducted to estimate the relative effectiveness of treatments whilst preserving the randomised comparisons within each trial. A Bayesian network meta-analysis was conducted using a random-effects, logit model fitted to the binomial ACR20/50/70 trial data and was coded in WinBUGS. Direct probability statements are based on results from two chains of 20,000 samples.

Results: The table below summarise the network meta-analysis results for ACR 20/50/70.

Treatment	Log-OR vs MTX (95% CrI)	% pts achieving ACR20/50/70 (95% CrI)	Probability best
ACR70			
Etanercept 2×25mg/week + MTX	3.34 (1.11, 6.55)*	55.3% (12.8%, 97.3%)	62.59%
Certolizumab Pegol 200mg/2 weeks + MTX	2.61 (1.38, 3.96)*	41.4% (15.8%, 73.8%)	27.17%
Tocilizumab 8mg/kg/month + MTX	1.93 (0.76, 3.1)*	27.3% (9.2%, 54.5%)	5.2%
Golimumab 50mg/month + MTX	1.64 (0.26, 3.03)*	22.9% (5.8%, 52.6%)	3.48%
Abatacept 10mg/kg/month + MTX	1.49 (0.62, 2.41)*	19.3% (7.9%, 37.8%)	0.57%
Rituximab 2×1000mg + MTX	1.1 (−0.13, 2.39)	14.9% (4%, 36.9%)	0.51%
Adalimumab 40mg/2 weeks + MTX	1.34 (0.51, 2.19)*	17.1% (7%, 33.1%)	0.25%
Infliximab 3mg/kg/2 months + MTX	1.3 (0.49, 2.21)*	16.7% (6.9%, 33.2%)	0.24%
MTX	–	4.9% (3.2%, 7.1%)	0%
ACR50			
Etanercept 2×25mg/week + MTX	3.04 (1.65, 4.65)*	71.8% (40.9%, 93.6%)	77.79%
Certolizumab Pegol 200mg/2 weeks + MTX	2.29 (1.41, 3.22)*	57.1% (34.6%, 78.1%)	17.54%
Golimumab 50mg/month + MTX	1.65 (0.67, 2.63)*	42.1% (20.3%, 66.8%)	2.21%
Tocilizumab 8mg/kg/month + MTX	1.55 (0.65, 2.45)*	39.8% (19.9%, 62.6%)	1.27%
Rituximab 2×1000mg + MTX	1.42 (0.49, 2.38)*	37% (17.6%, 60.8%)	0.89%
Adalimumab 40mg/2 weeks + MTX	1.4 (0.77, 2.05)*	36.1% (21.5%, 53.2%)	0.15%
Infliximab 3mg/kg/2 months + MTX	1.34 (0.73, 1.97)*	34.8% (20.8%, 51.4%)	0.09%
Abatacept 10mg/kg/month + MTX	1.3 (0.65, 1.96)*	33.8% (19.5%, 51%)	0.08%
MTX	–	12.1% (9%, 15.9%)	0%
ACR20			
Etanercept 2×25mg/week + MTX	2.35 (1.34, 3.41)*	80.1% (60.6%, 92.8%)	44.94%
Certolizumab Pegol 200mg/2 weeks + MTX	2.42 (1.7, 3.16)*	81.7% (68.2%, 91.2%)	52.89%
Tocilizumab 8mg/kg/month + MTX	1.43 (0.68, 2.19)*	63% (43.9%, 79.7%)	0.89%
Golimumab 50mg/month + MTX	1.21 (0.38, 2.04)*	58% (36.7%, 77.1%)	0.45%
Abatacept 10mg/kg/month + MTX	1.16 (0.61, 1.71)*	56.9% (41.6%, 71.3%)	0.05%
Rituximab 2×1000mg + MTX	1.33 (0.56, 2.11)*	60.7% (40.8%, 78.4%)	0.61%
Adalimumab 40mg/2 weeks + MTX	1.26 (0.71, 1.81)*	59.3% (44.3%, 73.2%)	0.1%
Infliximab 3mg/kg/2 months + MTX	1.32 (0.81, 1.84)*	60.8% (46.5%, 73.9%)	0.08%
MTX	–	29.6% (23.7%, 36%)	0%

Abbreviations: CrI, credible interval (Bayesian probability interval); * $p<0.05$

Conclusion: In conclusion, in these selected studies, concomitant bDMARDs were significantly more effective than MTX alone in improving ACR 20/50/70 outcomes in MTX experienced patients. Out of the studies that met inclusion in our analysis, Etanercept had the highest probability of being the most effective concomitant bDMARD for achieving ACR 70 and 50 responses, whilst certolizumab pegol had the highest probability of achieving ACR 20 response.

2248

Fucosylation Inhibitor, 2-D-Gal, Promotes Human Synovial Fibroblast Apoptosis and Is a Potent Suppressor of Arthritis in a TNF-α Tg Mouse Model *In Vivo*.
Jun Li[1], Hui-Chen Hsu[1], PingAr Yang[1], Qi Wu[1] and John D. Mountz[2]. [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham and Birmingham VAMC, Birmingham, AL

Background/Purpose: Apoptosis plays a pivotal role in the pathogenesis of rheumatoid arthritis (RA). Resistance to cell death leads to the hyperplasic synovium and progressive joint destruction. Fucosylation is one of the most important glycosylation processes and altered fucosylation is involved in regulation of cancer cell death. However, the role of fucosylation in RA has not been extensively studied. The purpose of this study is to determine if fucosylation is involved in regulation of apoptosis of RA synovial fibroblasts (RASF) and to determine the therapeutic effects of fucosylation inhibition.

Methods: Thirty RA and 16 osteoarthritis (OA) subjects were recruited in this study. The study was approved by IRB, UAB. Synovial fibroblasts were isolated from synovial tissues obtained at the time of joint replacement surgery and synovial fragments of synovial fluid. Fucosylation of RASFs was labeled using the Click-it metabolic labeling kit. Apoptosis was measured by ATPLite and visualized by MitoTracker Deep Red FM staining. Total RNA was isolated from the synovial fibroblasts using Trizol reagent. Real-time PCR was performed using a Bio-Rad IQ5 thermocycler. For mouse study, the human TNF-α Tg mouse was obtained from Taconic. An α1–2-Fucosyltransferase (FUT1) inhibi-

tor, 2-Deoxy-D-Galactose (2-D-Gal, 200mg/kg body weight, every 3 days), Etanercept (5mg/kg body weight, every week), and combined therapy was administered via I.P. initiated at the age of 12 weeks. Clinical scoring and histological assessments of the joints were performed.

Results: There was no significant difference of tumor necrosis factor (TNF)-related apoptosis-inducing ligand (*Trail*), its receptors including *Dr4*, *Dr5*, *Dcr1*, *Dcr2* and regulators of TRAIL apoptosis $Flip_l$ and *ciap* between RASF to OASF. However, there is a higher expression level of α1–2-Fucosyltransferase (*Fut1*, P=0.016), α1–3/1–4-Fucosyltransferase (*Fut3*, P=0.018) and α1–3-Fucosyltransferase (*Fut6*, P=0.038), but not α1–6-Fucosyltransferase (*Fut8*, P=0.910) in RA compared to OA synovial tissues and fibroblasts. Interestingly, there is a very high correlation between *Tnf*α and *Fut1, Fut2* and *Fut3* (P=0.0001). *Fut1* also correlated with *IL-17a* (P=0.003) in synovial tissues. *Fut1* transcript abundance in synovial fibroblasts was highly correlated with the cell viability after TRAIL or anti-human DR5 treatment determined by ATPLite (R^2=0.81, P=0.00026), which was also confirmed by Click-it fucose labeling and MitoTracker confocal imaging. The human TNF-α Tg mice with established arthritis were treated with 2-D-Gal, Etanercept, and both for 4 weeks. 2-D-Gal treatment resulted in a significant ($p<0.05$) early decrease of joint swelling and sustained suppression of arthritis as determined by clinical scoring and histology, which was equivalent to that of Etanercept (P>0.05).

Conclusion: Our studies suggest that fucosylation is strongly correlated with TNF-α and IL-17, contributing to the inflammation and apoptosis resistance of RASF. Fucosylation inhibitor, 2-D-Gal, exhibited a compelling anti-arthritic effect which was equivalent to that observed with Etanercept. Fucosylation inhibition is a potential novel therapeutic strategy for RA.

Infliximab Is Associated with Improvement in Arterial Stiffness in Patients with Early Rheumatoid Arthritis—a Randomized Trial. Lai Shan Tam[1], Qing Shang[1], Edmund K. Li[1], Ka Lai Lee[2], Ying Ying Leung[3], King Yee Ying[4], Cheuk-Wan Yim[5], Emily W. Kun[6], Alexander M. Leung[7], Martin Li[1], Tena K. Li[1], Tracy Y. Zhu[1], Ricky K. Chui[1], Lorraine Tseung[1], Shui Lian Yu[1], Woon Pang Kuan[8] and Cheuk-Man Yu[1]. [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong, [3]North District Hospital, Hong Kong, Hong Kong, [4]Princess Margaret Hospital, Hong Kong, Hong Kong, [5]United Christian Hospital, Hong Kong, Hong Kong, [6]Tai Po Hospital, Hong Kong, Hong Kong, [7]Queen Elizabeth Hospital, Hong Kong, Hong Kong, [8]Hospital Selayang, Kuala Lumpur, Malaysia

Background/Purpose: Chronic inflammation is probably a driving force for premature atherosclerosis in Rheumatoid arthritis (RA). Whether effective suppression of inflammation could prevent progression of atherosclerosis would be worth studying. This study aimed to ascertain the efficacy of methotrexate (MTX) with infliximab compared with MTX alone in the prevention of atherosclerosis in patients with early RA.

Methods: A randomized, open-labeled study in which early RA patients (symptom onset < 2 years) with moderate to severe disease severity were treated with MTX with (Group 1, n=20) and without (Group 2, n=20) infliximab according to a standard treatment protocol for 12 months. Patients were assessed every 3 month. The main goal of treatment was to achieve remission (Disease activity score in 28 joints [DAS28] £ 2.6). Therapeutic regime was adjusted at each visit if the patient failed to achieve remission within 3 months according to the protocol. Progression of subclinical atherosclerosis will be measured by carotid ultrasound and arterial stiffness indexes as determined by pulse wave velocity (PWV) and augmentation index (AIx) at baseline and 12 months.

Results: Baseline clinical, demographic, cardiovascular risk factors and vascular assessment parameters (intima-media thickness [IMT], PWV and AIx) were similar between the 2 groups except Group 1 had a higher DAS28 score. At months 12, there was a significant decrease in PWV in Group 1 compared to baseline (15.3 $\pm$ 2.3 m/s versus 14.5 $\pm$ 2.6 m/s, $p<0.05$), while no significant changes were observed in Group 2 (14.6 $\pm$ 2.5 m/s versus 14.9 $\pm$ 3.2 m/s, p=0.341). Other vascular assessment parameters including the mean and maximum IMT and AIx remain unchanged in both groups. A higher proportion of patients in Group 1 achieved remission compared to Group 2 (4/20 [20%] versus 10/20 [50%], $p<0.05$). Most of the clinical and laboratory parameters of disease activities improved significantly in both groups compared to baseline, but there were no significant differences between the 2 groups at month 12. At month 12, the lipid profile was similar between the 2 groups although the fasting sugar level was significantly higher in Group 2 (4.9 $\pm$ 0.4 mmol/L 5.6 $\pm$ 0.6 mmol/L, $p<0.05$). Compared with baseline, the total cholesterol increased significantly in both groups and patients in Group 2 also had significant increase in LDL-cholesterol level. Fasting sugar and other lipid profile remained unchanged in both groups.

Conclusion: PWV, a marker of arterial stiffness, improved significantly in patients with early RA after 12-month treatment with MTX plus infliximab, compared to MTX alone, suggesting that effective suppression of inflammation using TNF-α inhibitors may prevent progression of atherosclerosis by improving vascular function in patients with early RA.

Golimumab Use and Sustained Clinical Response in Patients with Active Rheumatoid Arthritis Previously Treated with Anti-Tumor Necrosis Factor Alpha Agents. Josef Smolen[1], Jonathan Kay[2], Robert Landewe[3], Eric L. Matteson[4], Norman B. Gaylis[5], J. Wollenhaupt[6], Frederick T. Murphy[7], O. Zamani[8], Yiying Zhou[9], Elizabeth C. Hsia[9] and Mittie K. Doyle[9]. [1]Medical University of Vienna and Hietzing Hospital, Vienna, Austria, [2]University of Massachusetts Medical School, Worcester, MA, [3]Academic Medical Center, Amsterdam, Netherlands, [4]Mayo Clinic, Rochester, MN, [5]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [6]Eilbeck Hospital, Hamburg, Germany, [7]Altoona Ctr for Clinical Research, Duncansville, PA, [8]Rheumazentrum Favoriten, Wien, Austria, [9]Centocor R&D, a division of Johnson & Johnson Pharmaceutical Research & Development, LLC, Malvern, PA

Background/Purpose: To assess sustained clinical response in patients with active rheumatoid arthritis (RA) and previously treated with anti-TNF agent(s) who received treatment with golimumab (GLM) through wk100 in the GO-AFTER study.

Methods: GO-AFTER is a randomized, Phase 3, double-blind, PBO-controlled study of GLM in active RA ($\geq$4 tender and $\geq$ 4 swollen joints [TJC/SJC]) anti-TNFα experienced patients. Patients were randomized to PBO (Grp1), GLM 50 mg (Grp 2) or GLM 100 mg (Grp 3); injections were administered q4wks. Patients in Grps1 and 2 with <20% improvement in wk16 TJC/SJC escaped to GLM 50 mg and 100 mg, respectively. During the long-term extension, starting at wk24, all Grp1 patients crossed over to GLM 50 mg, Grp 2 patients continued GLM 50 mg or 100 mg per early escape status, and Grp 3 pts maintained dosing. After the wk24 database lock, patients were permitted to dose-escalate from GLM 50 mg to 100 mg at the investigator's discretion.

Results: From wk24 to wk100, ACR20 response was sustained in approximately 70% and 73% of patients in Grps 2 and 3, respectively and HAQ $\geq$0.25 improvement was sustained in approximately 81% and 75% of patients in Grps 2 and 3, respectively (Table). In addition, approximately 80% and 58% of pts in Grps 2 and 3, respectively achieved ACR 50 response and 71% and 55% of patients in Grps 2 and 3, respectively achieved ACR 70 response from wk24 through wk100, albeit with a smaller patient population. EULAR good and moderate response by DAS28 CRP was sustained in approximately 78% and 84% of patients in Grps 2 and 3 and by DAS28 ESR was found in 82% and 82% of patients in Grps 2 and 3, respectively from wk24 to wk100.

Table. Summary of results for sustained clinical response to golimumab from wk 24 through wk 100

	Group 1*	Group 2**	Group 3
No of randomized pts	150	147	148
ACR 20 response at wk 24 and at wk 100***,† ‡	–	38/54 (70.4)	40/55 (72.7)
ACR 50 response at wk 24 and at wk 100***,† ‡	–	20/25 (80.0)	15/26 (57.7)
ACR 70 response at wk 24 and at wk 100***,† ‡	–	10/14 (71.4)	6/11 (54.5)
EULAR response using CRP at wk 24 and at wk 100***,† ‡		55/71 (77.5)	62/74 (83.8)
EULAR response using ESR at wk 24 and at wk 100***,† ‡		55/67 (82.1)	63/77 (81.8)
HAQ improvement ≥0.25 at wk 24 and 100***,†‡	–	55/68 (80.9)	55/73 (75.3)

(n/N) %*Includes pts who early escaped at wk16 or crossed over at wk24 to GLM50 mg or dose escalated after the wk24 database lock to GLM100mg.**Includes pts who early escaped at wk16 or dose escalated after the wk24 database lock to GLM100mg.***excludes 16 pts from site 7465 (5 PBO, 6 GLM 50mg, 5 GLM 100mg) due to violations at the study site identified during the Sponsor's standard audit process. †observed data, ‡based on wk 24 responders who remained in the study at wk 100 for response rates at wk 100

Conclusion: Patients with active RA who received GLM 50mg or 100mg had sustained clinical response from wk24 through wk100.

Methotrexate Every Day Is Safe and Effective As Weekly Dosage. Ricardo Moreno-Valdes[1], Marco Ulises Martinez-Martinez[1], Enrique Cuevas-Orta[1], Jorge Alcocer-Varela[2] and Carlos Abud-Mendoza[3]. [1]Hospital Central,, San Luis Potosí, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico city, Mexico, [3]Hospital Central y Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosi, Mexico

Background/Purpose: Most of rheumatologists, under established guides with poor scientific support, emphasized that methotrexate (MTX), in rheumatoid arthritis, should be given weekly at low doses in one day (OD), with apparent less liver toxicity and better tolerance than given every day (ED). Studies have described that C reactive protein levels were lower and more constant with ED dosage. Objective: To compare patients with rheumatoid arthritis (RA) treated with MTX under OD with patients with RA treated with ED scheme.

Methods: We analyzed the files of consecutive patients with diagnosis of rheumatoid arthritis according ACR criteria, seen in two Mexican hospital centers. Patients with at least 1 year of disease evolution, treated with stable doses of methotrexate at least in the last 12 weeks were evaluated. Patients were divided into two groups, 80 patients were treated with methotrexate weekly in one day once or in two times with 12 hours between doses (OD or group 1) and 100 patients with low doses every day (ED or group 2). None of our patients were under another DMARD and patients continued taking low doses of steroids (equivalent to 7.5 mg of prednisone or less) and NSAID. We analyzed demographic characteristics, ACR response and disease activity, laboratory tests and adverse events.

Results: We did not find statistical demographic differences in the analyzed groups. Methotrexate dosage was the double in the group 2 with administration every day (equivalent to 2.5 mg/d vs. 1.3 mg/d). Group 2 achieve a better ACR 20, 50 and 70 responses vs. group 1, 81% vs. 60%, 55% vs. 32% and 42% vs. 15% respectively. Hemoglobin levels increased in group 2, and remain in same levels in group 1, C reactive protein and erythrosedimentation rate did not show modifications in group 1 patients, but C reactive protein and ESR diminished 25% and 18.3% respectively. Patients had similar elevation of liver function tests (24 patients in each group, none with 3x or more). Relapses occurred in 47% of patients under OD (Group 1) and in 14% of those with ED therapy (Group 2) ($p<0.01$). Methotrexate therapy was stopped in 18% of group 1 and in 2% of group 2 because adverse events. We did not find any differences related with glucocorticoid and NSAID doses.

Conclusion: Methotrexate given every day is associated to similar or better efficacy than weekly doses. Lower acute toxicity is founded in every day administration of MTX than when is used weekly. We recognized that is convenient a long and large randomized clinical trial, to define or ratify if methotrexate to diary dosage is as safe and effective as when is used weekly.

B Cell Biomarkers Allow Prediction of Improving Response on Repeat Cycles of rituximab. Sudipto Das[1], Edward M. Vital[2], Shouvik Dass[2], Maya H. Buch[3], Andrew Rawstron[2] and Paul Emery[4]. [1]NIHR Leeds Musculoskeletal Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]NIHR Leeds Biomedical Research Unit, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Leeds Institute of Molecular Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK, Leeds, United Kingdom

Background/Purpose: Rituximab is effective in rheumatoid arthritis but many patients do not achieve EULAR Good response. Previous studies have shown that repeat cycles of rituximab can improve responses in patients with non-response (NR) to the first cycle (C1). We therefore investigated the effect of repeat cycles of rituximab in C1 responders and the ability of known biomarkers to predict changing patterns of response.

Methods: 124 patients pooled from three clinical trials were treated with 2 × 1000mg of rituximab at baseline and then, in initial responders, on clinical relapse. DAS28 and EULAR response were calculated at baseline and 6 months after each cycle, compared to the original baseline. B cell naïve, memory and plasmablast subsets were measured by high flow assay as previously described.

Results: As previously reported, patients with NR after C1 were retreated at 6mo and most responded. Patients with EULAR MOD or GOOD in C1 were retreated following clinical relapse. Overall responses were better in C1 (see table).

Cycle 1 response	DAS28 at baseline (SD)	DAS28 after C1 (SD)	DAS28 after C2 (SD)	P (DAS28 after C1 vs. after C2)	EULAR response after C2		
					Non	Mod	Good
Moderate (n=44)	5.95 (1.02)	4.10 (0.77)	3.68 (1.08)	0.013	11.4%	54.5%	34.1%
Good (n=30)	5.53 (0.92)	2.31 (0.53)	2.71 (1.38)	0.118	16.7%	13.3%	70.0%

In MOD, B cell numbers were significantly lower at weeks 2–14 compared to C1, but in GOOD no difference was observed between cycles. Of 78 patients with positive RF at baseline, 28% became negative after C1 (seroconversion), and of these 90% remained positive after C2, although the titre was signicantly lower. There was no association between RF and B cell subsets at baseline, but seroconversion was associated with significantly lower B cell numbers at weeks 2–26.

Seroconversion was not associated with response in C1, but was associated with improving response in C2. In patients with C1-MOD and positive RF at baseline, 11/33 had seroconversion in C1, of whom only 1(9%) improved to GOOD in C2. Of 22/33 without seroconversion, 9(41%) improved to GOOD in C2 ($p=0.012$).

We compared DAS28 components, HAQ, RF and B cell subsets between patients with C1-GOOD who maintained (GOOD) or worsened (NR/MOD) response in C2. Patients with worsening response had lower baseline CRP ($p=0.002$) and higher memory B cells at repopulation ($p=0.094$) with no difference in severity of flare at relapse or time to retreatment.

Conclusion: Patients with potential for improved response on retreatment with rituximab may be identified by persistent RF. Greater repopulation of memory B cells before retreatment was associated with loss of response in C2.

2253

Pulmonary Adverse Events in a Cohort of Patients with Rheumatoid Arthritis Under Tnfa Blockers. Juan Antonio Martinez-Lopez[1], Fredeswinda Romero[1], Sandra Bermudez[1], Jorge J. González López[1], María Pérez Ferro[1], Sheila Recuero[1], Gema Díaz Moya[1], Maria A. Contreras[1], Gabriel Herrero-Beaumont[2] and Olga Sanchez-Pernaute[1]. [1]Jiménez Díaz Foundation University Hospital, Madrid, Spain, [2]Jiménez Diaz Foundation University Hospital, Madrid, Spain

Background/Purpose: Post-marketing surveillance of TNF blockers has confirmed an overall good safety profile. However, there have been increasing reports of either de novo developed or progression of pre-existent intersticial lung disease (ILD) in patients with rheumatoid arthritis (RA) treated with TNF blockers. They raise the concern of whether these therapies should be avoided in specific subsets of patients. Our aim was to analyse the occurrence of pulmonary events in our cohort of RA patients treated with TNF blockers.

Methods: All patients with RA from our Rheumatology clinics started on TNF blockers before April 2010 were included. A retrospective study of their clinical record was done.

Results: We evaluated 106 patients, with a total exposure to TNF blockers of 369 patient-year (median: 3.1 years). 17 patients developed a total of 31 relevant pulmonary events. Pulmonary events were classified as lung infections (18 cases), acute non-infectious pneumonitis (2 cases), ILD with fibrosis (5 cases), bronchospasm (1 case) and chronic obstructive lung disease (5 cases). The outcome was permanent disease in 9 patients and there was 1 death. In 6 cases, pulmonary symptoms led to discontinuation of TNF therapy. Both the disease duration (18 years, range 3–48) and the exposure to TNF blockers (74.6 patient-year, median: 3.8 years) were longer in the group suffering pulmonary events. Pre-existent lung disease was identified as a risk factor for the development of pulmonary events (RR 2.36, CI 0.79 – 6.89). The percentage of patients exposed to methotrexate was similar in both groups (88% compared to 81%, respectively). In the same way, no differences were found in the number of DMARD used, erosive arthritis, positive autoantibodies and smoking. The subgroup with pulmonary events had a higher rate of extra-articular manifestations (41% vs 24%) and Sjögren syndrome (41% vs 28%).

Conclusion: In our cohort, pulmonary events were a major cause of anti-TNF discontinuation. The pre-existence of lung disease and longstanding RA were the major risk factors for the occurrence of pulmonary complications. Since pulmonary processes can remain subclinical in early stages, we underline the importance of specifically seeking for respiratory lung diseases prior to the initiation of anti-TNF therapies in patients with RA.

Electrocardiographic Abnormalities in a Large Systemic Lupus Erythematosus Inception Cohort. Josiane Bourré-Tessier[1], Murray B. Urowitz[2], Mori J. Krantz[3], Lawrence Joseph[4], SLICC investigators[5] and Christian A. Pineau[6]. [1]McGill University Health Center, Montréal, QC, [2]Toronto Western Hospital and University of Toronto, Toronto, ON, [3]University of Colorado, Denver, CO, [4]McGill University Health Centre, Montreal, QC, [5]Toronto, [6]McGill Univ Health Center, Montreal, QC

Background/Purpose: Cardiovascular involvement is common in systemic lupus erythematosus (SLE) and can cause considerable morbidity and mortality. Myocardial ischemia, rhythm disturbances, and repolarization abnormalities including QT prolongation and increased QT dispersion (QTd) may be associated with an increased risk of sudden death. This study aimed to determine the early prevalence of electrocardiographic abnormalities in a large inception cohort of SLE patients.

Methods: We studied adult patients from 23 centers participating in the Systemic Lupus International Collaborating Clinics (SLICC) Prospective Inception Cohort for Atherosclerosis. Patients are followed prospectively and undergo a yearly assessment where demographics, disease activity (SLEDAI), disease damage (SLICC/ACR DI), laboratory data and 12-lead resting ECGs are collected. Baseline ECGs were manually interpreted by board certified cardiologists. QTd was defined as the difference between maximal and minimal QT-intervals. Proportions with QTc-prolongation crossing categorical regulatory thresholds (International Conference on Harmonization) and increased QTd (defined as $>$ 40 ms) were assessed.

Results: Of 785 patients evaluated at study entry, 744 had an interpretable ECG. At the time of their ECG, mean (SD) age was 35.6 years (13.8), 88.4% were women, and mean disease duration was 10.5 months (14.4). Mean SLEDAI was 5.41 (5.60) and mean SLICC/ACR DI was 0.50 (1.00). ST-segment changes were frequent: 30.9% were nonspecific and 3.5% had changes compatible with acute or chronic myocardial infarction. QTc prolongation, defined as $\geq$ 440 ms, was observed in 15.4%, while a QTc $\geq$ 480 ms was found in 1.1%. Mean (SD) QTd was 34.2 ms (14.7) and increased QTd, defined as greater than 40 ms, was found in 20.2%. A total of 5.4% manifested abnormalities compatible with left ventricular hypertrophy and 0.1% with right ventricular hypertrophy. Ventricular conduction disturbances were seen in a total of 4.3% of the patients. Other findings included supraventricular arrhythmias (1.5%; the majority were atrial flutter), premature ventricular contractions (1.5%), and atrioventricular heart block (0.7%).

Conclusion: Electrocardiographic abnormalities were frequent in this large SLE inception cohort. Despite a short disease duration, a significant proportion of patients manifested repolarization abnormalities possibly representing early signs of cardiac involvement. Performing ECGs in SLE patients may identify patients at a potentially higher cardiovascular risk, though additional studies assessing the utility of this strategy are needed.

2255

Initial Results for the LFA Collective Data Analysis Initiative (LFA CDAI): How Do Subjects From Lupus Clinical Trials Randomized to Standard of Care Respond Over Time? Kenneth C. Kalunian[1], Mimi Kim[2], Leslie M. Hanrahan[3], Jean-Claude P. Becker[4], Sabine Bongardt[5], Paul Brunetta[6], David Close[7], Jorn Drappa[7], Richard Furie[8], Bevra H. Hahn[9], Matthew Linnik[10], Jane E. Salmon[11], Neil Solomons[12] and Joan T. Merrill[13]. [1]UCSD School of Medicine, La Jolla, CA, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Lupus Foundation of America, Washington, DC, [4]Becker Clinical Reearch Consulting LLC, New York, NY, [5]UCB Biosciences, [6]Genentech, So San Francisco, CA, [7]MedImmune Inc., [8]North Shore-LIJ Health System, Lake Success, NY, [9]UCLA David Geffen School of Medicine, Los Angeles, CA, [10]Lilly Research Laboratories, [11]Hospital for Special Surgery, Weill Cornell Medical College, New York, NY, [12]Vifor Pharma, [13]Oklahoma Medical Research Foundation, Oklahoma City, OK

Background/Purpose: In the past two decades, more than a dozen investigational products have entered phase II/III clinical trials for lupus and failed despite adequate proof of concept studies in animal models and in vitro human studies. The Lupus Foundation of America (LFA) formed the LFA Collective Data Analysis Initiative (CDAI) to better understand these failures. Working and steering committees were formed, comprised of academic and industry lupus experts and an independent biostatistician with lupus expertise. Industry partners contributed blinded and deidentified data from their clinical trials. The first LFA CDAI project was to address the hypothesis that in the course of clinical trials in lupus, background medications may mask the effect of an investigational agent. To understand response rates of different background medications, pooled data from 5 industry sponsored clinical trials in lupus were utilized.

Methods: Data from the standard of care arms of 5 industry sponsored clinical trials (Total N=620) were combined to estimate response rates by background medication at different time points during follow up. Response was defined as an improvement by at least 1 step in any BILAG A and B at baseline without any new BILAG A. Background medications were classified into the following five groups: azathioprine (AZA), mycophenolate mofetil (MMF), methotrexate (MTX), cyclophosphamide (IVC), and other (including treatments such as antimalarials alone); corticosteroids usage was calculated for each treatment group. Separate subgroup analyses were also performed of nephritis patients only. The chi-square test was used to evaluate the null hypothesis that response rates are equivalent across treatment groups.

Results: Estimated response rates across background treatment groups ranged from 34%–65% at 12 weeks (p=0.06) and 28%–52% at 52 weeks (p=0.05). At both time points, the lowest response rate occurred in the MTX group. Mean steroid doses were 12.3–23.5mg at 12 weeks and 8.2–13.3 mg at 52 weeks and were significantly lower in responders compared to non-responders at 52 weeks (p=0.01) but not at 12 weeks (p=0.68). When the lupus nephritis trials were analyzed separately, using a more stringent response definition that required improvement in renal BILAG scores to C or better, response rates were 21% on IVC and 26% on MMF at 12 weeks and 34% on IVC and 42% on MMF at 24 weeks, the maximum duration of follow-up.

Conclusion: Lupus patients enrolled in clinical trials and randomized to standard of care arms are a proxy for real-life experiences of lupus patients who receive these standard therapies. The results of these analyses therefore provide a basis both for expected outcomes of lupus patients receiving standard of care in clinical practice and for lupus subjects in clinical trials randomized to these therapies. In addition, these data may be useful for investigators designing future clinical trials.

Incidence and Standardized Incidence Ratio (SIR) of Suicide in Southern Chinese Patients with Rheumatic Diseases in Hong Kong, China: 1999–2010. Chi Chiu Mok[1], Raymond Kwok[2], Ling Yin Ho[3] and Paul Yip[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]University of Hong Kong, Hong Kong, Hong Kong, [3]Tuen Mun Hospital, Hong Kong SAR, Hong Kong

Background/Purpose: Suicide is one of the most devastating complications of chronic medical illnesses, including rheumatological disorders. We studied the absolute incidence of suicide and its standardized incidence ratio (SIR) in six rheumatic diseases in Hong Kong as compared to the general population.

Methods: Patients with the diagnostic codes of systemic lupus erythematosus(SLE), rheumatoid arthritis(RA), ankylosing spondylitis(AS), psoriatic arthritis(PSA), systemic vasculitides(SV) and systemic sclerosis(SSc) registered in 37 public hospitals between 1999 and 2010 were identified from the hospital registry database. Patients who died of suicidal attempts within the same period were also retrieved. The SIRs were calculated by comparing the suicidal rate of patients with each disease with that of the general population, adjusted for age, with the 95% confidence intervals obtained by the exact Poisson method.

Results: In 2010, data on 10996 RA, 6296 SLE, 3034 AS, 2108 SV, 1192 PSA and 569 SSc patients were available in our registry. Between 1999 and 2010, 25 patients with these diseases committed suicide and died (15 SLE, 5 RA, 3 AS, 1 PSA, 1 SV and 0 SSc patients). There were 19 women and 6 men. The mean age of these patients at the time of suicidal acts was 48.8 $\pm$16.3 years. The methods of suicide were: jump from height (60%), overdose of medications (20%); hanging or strangulation (8%); drowning (4%); and uncertain method (8%). Three patients (12%) had documented history of suicidal attempts in the past. Of patients who committed suicide by overdose of medications, two were SLE patients who died of overdosage of hydroxychloroquine. The incidence of suicide per 100,000 patients was 31.6 for SLE, 17.1 for AS, 16.7 for PSA, 7.5 for SV and 6.9 for RA. The age-adjusted SIRs in female patients were 3.13 (95%CI [1.75–5.16]) in SLE, 2.72 (95%CI [0.07–15.2] in AS and 0.34 (95%CI [0.07–1.00]) in RA. The age-adjusted SIRs in male patients were 0.59 (95%CI [0.07–2.14]) in AS,

0.50 (95%CI [0.06–1.82]) in RA, 1.29 (95%CI [0.03–7.21]) in PSA and 0.82 (95%CI [0.02–4.56]) in SV.

Conclusion: Among the rheumatic diseases studied, only female patients with SLE have significantly increased relative risk of suicide by 2-fold as compared to the general population. More attention should be paid to mood problems in SLE patients and screening for depression should be performed during clinical visits.

Support Vector Machines Classification of Texture Parameters of White Matter Lesions in Systemic Lupus Erythematosus. Possible Mechanism to Distinguish Between Demyelination and Ischemia. Aline Lapa[1], Mariana P. Bento[1], Letcia Rittner[1], Gabriela Castellano[1], Heloisa Ruocco[2], Benito Damasceno[3], Lilian Costallat[4], Roberto Lotufo[4], Fernando Cendes[1] and Simone Appenzeller[5]. [1]State University of Campinas, Campinas, Brazil, [2]Medical Faculty of Jundiai, Campinas, Brazil, [3]Medical Faculty of Jundiai, Campinas, United Kingdom, [4]State University of Campinas, Campinas, United Kingdom, [5]State University of Campinas, São Paulo, Brazil

Background/Purpose: Texture analysis (TA) is a branch of image processing which seeks to reduce image information by extracting texture descriptors from the image. White matter hyperintensities (WMH) are frequently observed in systemic lupus erythematosus (SLE), however the etiology is still unknown. Ischemic and demyelination have been proposed as possible etiologies. Support vector machines (SVM) are a group of supervised learning methods that can be applied to classification or regression. SVM performs classification by constructing a set of hyperplanes in a high dimensional space that optimally separates the data into different categories. A classification task usually involves separating data into training and testing sets. The goal of SVM is to produce a model based on the training data which predicts the target values of the test data given only the test data attributes. Objective: To produce a training model that accurately differentiates WMH of multiple sclerosis (MS) and stroke from normal white matter. To determine attributes that best characterizes WMH in SLE and to analyze clinical and laboratory features that may differentiate SLE patients with demyelination from ischemic WMH.

Methods: TA was applied to axial T2-weighted magnetic resonance images (MRI) of 30 SLE, 30 MS, and 10 stroke patients and 30 normal controls, all age and sex-matched. The TA approach used was based on the Gray Level Co-occurrence Matrices (GLCM). The WMH were manually segmented for each subject, classified in periventricular and subcortical WMH and 256 texture parameters were computed for each lesion. A SVM classifier was developed based on texture features of normal white matter and WMH in MS and stroke patients. The classifier was then used to classify WMH in SLE patients. Nature of the classified WMH, demographic, clinical and laboratory features were included in a regression model to determine which variables could help to predict the nature of WMH in clinical practice.

Results: We achieve a accuracy rate of 0.9 on a database of 97 ROIs to training procedure, and 41 ROIs to testing procedure. Of the 24 periventricular WMH, 18 (75%) were classified as ischemic and 6 (25%) as demyelination. Of 44 subcortical lesions, 26 (59%) were classified as ischemic and 18 (41%) as demyelination. Age (odds ratio [OR] 1.7, 95% confidence interval [95% CI] 1.58–6.72), hypertension (OR=2.6; 95%CI 1.9–5.3) and positive antiphospholipid antibodies (aPL) (OR=1.9; 95%CI 1.2–7.3) were variables associated with stroke, whereas shorter disease duration (OR=3.1; 95%CI 2.2–7.5) and new onset of neurologic symptoms (OR=1.8; 95%CI 1.2–3.5) were associated with demyelination.

Conclusion: Although 75% of WMH were classified as ischemic in nature, we identified approximately 25% of demyelinating WMH in SLE. SMV of TA is a useful method to help to determine etiology of WMH in SLE. Age, hypertension and aPL were variables associated with ischemic; shorter disease duration and new onset neurologic symptoms were associated with demyelinating lesions in this cohort.

sIL-7R Is a Novel Marker of Disease Activity in Systemic Lupus Erythematosus Nephritis, Which Reflects Target Organ Involvement. Valérie Badot[1], Geneviève Depresseux[2], Frédéric. A. Houssiau[2] and Bernard Lauwerys[2]. [1]CHU-Brugmann & Université catholique de Louvain, Brussels, Belgium, [2]Université catholique de Louvain, Brussels, Belgium

Background/Purpose: The soluble form of the interleukin-7 receptor (sIL-7R) results from an alternative splicing of the full-length IL-7R mRNA. It is produced by fibroblasts, and, to a lesser extent, CD4 T cells, after stimulation with pro-inflammatory cytokines (TNF-alpha, IL-1beta alone or in combination with IL-17). We also previously demonstrated that sIL-7R serum levels are higher in rheumatoid arthritis patients compared to controls. We wondered whether sIL-7R production is dysregulated in systemic lupus erythematosus (SLE).

Methods: Serum sIL-7R titers were measured by sandwich ELISA, and transcriptomic studies were performed in PBMC from SLE patients and controls. IL-7R immunostaining was performed on frozen kidney sections from SLE nephritis patients.

Results: sIL-7R titers are significantly higher in the sera of patients with SLE nephritis (n = 17) compared to controls (n = 75) (mean SLE +/− SEM: 3,646.6 +/− 793.9 pmol/ml; mean controls +/− SEM: 688.1 +/− 60.5 pmol/ml; $p < 0.0001$). sIL-7R serum concentrations correlate significantly with SLEDAI scores ($r = 0.53$, $p < 0.05$), and significantly decrease under therapy, in parallel with disease activity scores (mean +/− SEM sIL-7R from 3,897.7 +/− 1,050.1 pmol/ml down to 967.4 +/− 129.0 pmol:ml, $p < 0.05$; mean +/− SEM SLEDAI from 22.9 +/− 2.3 down to 6.9 +/− 1.4, $p < 0.0001$ in 10 patients with follow-up measurements).

Strikingly, IL-7R gene expression is lower in SLE PBMC compared to controls, which indicates that the source of elevated serum sIL-7R titers is not to be found in SLE circulating cells. By contrast, we found a positive perivascular IL-7R immunostaining signal in kidney biopsies from patients with SLE nephritis.

Conclusion: sIL-7R is a novel marker of SLE disease activity. By opposition to conventional disease activity markers, sIL-7R is not produced by circulating cells, but by the target organ in SLE nephritis.

High-Sensitivity C-Reactive Protein As An Independent Risk Factor for Coronary Artery Disease in Systemic Lupus Erythematosus. Mandana Nikpour[1], Dafna D. Gladman[2], Dominique Ibanez[3], Paula Harvey[4] and Murray B. Urowitz[3]. [1]The University of Melbourne, Fitzroy, Australia, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, [3]Toronto Western Hospital and University of Toronto, Toronto, ON, [4]Women's College Hospital, Toronto, ON

Background/Purpose: In the general population, high sensitivity C-reactive protein (hsCRP), a non-specific marker of inflammation, is a predictor of coronary artery disease (CAD). Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with accelerated CAD. In SLE, hsCRP varies markedly over time due to changes in disease activity and treatment, casting doubt over its usefulness as marker of CAD in this patient population. We sought to determine whether hsCRP is an independent predictor of CAD among patients with SLE.

Methods: In a prospective cohort design, patients with serial measurements of hsCRP were followed for the occurrence of CAD events including angina and myocardial infarction (MI), which were defined based on a combination of clinical features, electrocardiographic and enzyme changes. Time-dependent proportional hazards regression models were used to determine the ability of hsCRP to predict CAD

Results: Four hundred and seventy two patients comprising 2,523 hsCRP measurements were included. HsCRP was significantly predictive of the twenty CAD events observed over a mean follow-up of 3.8 ± 5.4 years. The hazard ratio (HR) for each quartile increase in hsCRP level was 1.57, 95% confidence interval (CI): 1.02, 2.43, p=0.04. This association was independent of the Framingham ten-year risk score (HR 1.15, 95% CI: 1.05, 1.27, p=0.003) and time-adjusted SLE disease activity score (AMS; HR 1.12, 95% CI: 1.02, 1.22, p=0.01), which were also associated with CAD. Cut-point analysis using regression modeling revealed that an hsCRP level of 1.6 mg/L or greater was associated with significantly increased CAD risk.

Conclusion: Despite marked variability over time, even among patients with SLE, hsCRP level is significantly predictive of CAD, independently of the Framingham risk score and SLE disease activity score. This finding highlights the pivotal role of inflammation in the development of CAD in SLE, and makes a case for measuring hsCRP in routine CAD risk assessment of patients with SLE. SLE patients with hsCRP level ³ 1.6 mg/L are at significantly increased risk of CAD and represent a group in whom measures to prevent CAD events may include the use of statins.

2260

Effect of Raloxifene, a Selective Estrogen Receptor Modulator, on Disease Activity, Flare and Vascular Biomarkers in Patients with Systemic Lupus Erythematosus (SLE): A 12-Month Double-Blinded Randomized Controlled Trial. Chi Chiu Mok[1], King Yee Ying[2] and Kwok Man Ma[1]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Princess Margaret Hospital, Hong Kong, Hong Kong

Background/Purpose: To examine the effect of raloxifene on disease activity, flares, traditional risk factors and bone mineral density (BMD) in patients with SLE.

Methods: Subgroup data of postmenopausal female SLE patients who participated in a 12-month double-blinded randomized controlled trial of the effect of raloxifene on bone turnover and BMD in glucocorticoid-induced osteoporosis were extracted. Patients were randomized to receive either raloxifene (60mg/day) or matched placebo (one tab/day) on top of calcium and vitamin D. Disease activity was assessed by the SELENA-SLEDAI and physicans' global assessment (PGA; 0–3) every 3 months. Lupus flares were assessed by the SELENA flare instrument. The SLEDAI and PGA area under the curve (AUC) over 12 months and number of flares was compared between the raloxifene and placebo groups. In addition, the effect of raloxifene on homocysteine, soluble thrombomodulin (sTM), interleukin(IL)-6, high-sensitivity C-reactive protein (hsCRP) level and changes in traditional atherosclerotic risk factors was also evaluated.

Results: Sixty-two patients were studied (mean age 52.5±6.7 years; disease duration 9.3±7.6 years). The mean duration of menopause was 7.2±6.6 years. The mean duration of prednisolone treatment was 87±68 months and mean daily dose was 6.8±5.6mg. The mean SLEDAI score at entry was 1.8±2.3 and only 5(8%) patients had SLEDAI score of >=6. Thirty patients were randomized to raloxifene and thirty-two were randomized to placebo. Basic clinical characteristics were similar between the two groups. After 12 months, a significant gain in BMD at the lumbar spine was observed in raloxifene-treated patients (0.883±0.125 to 0.897±0.116g/cm^2; +1.6%,p=0.02) but not in the placebo group. Bone resorption and formation markers (urine DPD, P1NP, CTX and osteocalcin) decreased significantly in the raloxifene but not in the placebo group. The SLEDAI AUC (18.7±23 in raloxifene vs 20.3±19 in placebo; p=0.76) and PGA (2.2±3.5 vs 2.3±2.6; p=0.94) scores over 12 months were not significantly different between the two groups of patients. There were 3 episodes of mild / moderate flares of SLE (33% musculoskeletal, 33% dermatological) in the raloxifene group, compared to 9 episodes of mild / moderate flares (27% musculoskeletal, 45% dermatological) in the placebo group (p=0.11). The total and LDL cholesterol level of placebo-treated patients increased significantly but there were no significant changes in the raloxifene group. The systolic and diastolic blood pressure values did not change significantly in both groups of patients. The homocysteine level showed a trend of decrease in raloxifene-treated patients, but no statistically significant changes in hsCRP levels in both groups of patients were observed. Levels of IL-6 and sTM did not change significantly in either the raloxifene or placebo groups of patients. Treatment was well tolerated, with no thromboembolic complications reported.

Conclusion: Raloxifene is safe and well tolerated in stable SLE patients with no hypercoagulability factors. Raloxifene significantly improves lumbar spine BMD but does not cause an increase in lupus activity or flares.

2261

Transcriptional Patterns in Whole Blood Diagnostic of Systemic Lupus Erythematosus. Tracy Costello and Cole Harris. Exagen Diagnostics, Houston, TX

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease of heterogeneous presentation. As SLE can present with a wide range of symptoms, severity, and organ involvement, diagnosis can be difficult. Current laboratory tests suffer either from poor specificity or sensitivity. Improved laboratory tests are needed for earlier and more accurate diagnosis.

Methods: With the aim of providing a basis for development of improved tests, we sought to identify diagnostic gene expression patterns in whole blood from publicly available data. Two relevant datasets in the GEO repository (http://www.ncbi.nlm.nih.gov/geo) are described in the table below. Our analysis employed proprietary data mining software to identify diagnostic expression patterns in small subsets of genes. As shown in the table, a portion of GSE22098 data was used for identifying these patterns (training) and the balance for blinded validation (test). GSE8650 data was used primarily to confirm the results. Regression analyses investigated the relationship between the expression of the confirmed genes and SLEDAI in the SLE patients in GSE8650.

Results: In the pattern identification phase, 10,000 significant ($p<.05$ Bonferroni-corrected) 3-gene combinations were identified. A total of 5191 gene probes appear at least once in these combinations, however relatively few appear frequently. We identified the set of 38 gene probes, representing 35 unique genes, that appeared in more than 1% of the patterns. The combination utilizing the three most frequent genes (RH3HDM4, IFI44L, IFI27) achieved 95% sensitivity and 98% specificity in the training data, and 92% sensitivity and 100% specificity in the test data.

Across all 3-gene combinations from the 38-probe set, the means (range) of sensitivity and specificity in the training data were 96% (92–100) and 97% (90–100) respectively. In the blinded data, mean (range) sensitivity and specificity were 90% (76–96) and 97% (84–100).

In distinct analyses of GSE8650, we identified gene sets consisting of those genes frequently represented in significantly diagnostic 3-gene combinations for both SLE vs control and SLE vs SoJIA. Five genes appeared in frequent gene lists from GSE22098 and GSE8650 analyses: HERC6, LY6E, IFI44, IFI44L, and EPSTI1.

Univariately, all five genes were significantly associated with SLEDAI. In a multivariate linear regression analysis, we found that HERC6, LY6E, and EPSTI1 provide significant independent information.

GEO ID	Gene Probes	Controls (train/test)	SLE (train/test)	SoJIA (train/test)	SLEDAI
GSE22098	N=48803 Illumina	164 (115/49)	110 (85/25)	0	No
GSE8650	N=44928 Affymetrix	21 (14/7)	38 (26/12)	58 (39/19)	Yes

Conclusion: If validated in subsequent studies, patterns of expression in the listed genes can provide a basis for development of improved SLE diagnostics.

2262

Adjusted Framingham Risk Factor Scoring for Systemic Lupus Erythematosus. Murray B. Urowitz[1], Dominique Ibanez[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: There is a high prevalence of premature atherosclerosis among patients with SLE, with a risk 50 times of the general population. The traditional Framingham risk factor underestimates the risk for coronary artery disease (CAD) in patients with SLE. There has been discussion as to whether SLE should be considered equivalent to diabetes and therefore automatically be high risk, or whether some other adjustment to the scoring system is more appropriate. The aim of this study was to determine whether an adjustment to the Framingham risk factor scoring (FRS) algorithm would more accurate reflect the higher prevalence of CAD among patients with SLE.

Methods: Patients with SLE are followed regularly according to a standard protocol in an observational cohort study. Patients were included from the first visit where all the data required to calculate the FRS were available. Only patients without previous CAD or diabetes were included. Several modifications to the Framingham risk score were considered: 1) increasing the value of specific item (e.g. age, cholesterol values), 2) adding SLE as its own item with variable weights, or 3) enhancing the value of all items equally by multiplying each by 2. The latter was considered most appropriate since it retains the relative contribution of each of the various components. FRS was calculated for all patients with this modification. Patients with subsequent CAD were compared to those without CAD using the original and the modification. Descriptive statistics were used to characterize the patient population. T-tests were evaluated to compare the original and modified FRS between patients with and without subsequent CAD.

Results: 858 patients were included. There were 775 (90.3%) women, age at visit 38.2 ± 14, disease duration 9.5 ± 8.8. Total cholesterol 4.9 ± 1.4, HDL 1.5 ± 0.5, systolic blood pressure 119.8 ± 17.5 diastolic 74.9 ± 10.7, smokers 116 (13.5%). The overall FRS 10 year risk was 2.3 ± 3.6%. Table shows the calculated classic FRS and the modified FRS for the whole group.

	Classic FRS		Modified FRS	
Risk Category	**Number**	**%**	**Number**	**%**
Very low risk	806	93.9	678	79.0
Low risk	37	4.3	63	7.3
Moderate risk	11	1.3	23	2.7
High risk	4	0.5	94	11.0
Mod + high	**15**	**1.7**	**117**	**13.6**

Of the 858 patients 38 subsequently developed CAD and 787 did not. Of those who developed CAD the Classic FRS classified only 7.8% in the Moderate/High risk group and 1.4% in those without CAD. Using the modified FRS, this increased to 42.1% and 12.3% in patients with and without CAD respectively. The 10-year risk using the Classic FRS was 6.4 ± 7.2 in patients with CAD compared to 1.9 ± 3.5 in patients without CAD (p=0.0006). Using the modified FRS, the 10 year risk was 14.6 ± 14.9 for patients with CAD compared to 4.7 ± 9.0 for those without subsequent CAD (p=0.0003)

Conclusion: The modified Framingham risk score where each item is multiplied by 2 more accurately identifies patients at Moderate/High Risk of CAD (13.6%) and more accurately predicted subsequent coronary artery disease (Score of 14.6 vs 4.7) Therefore the modified Framingham risk score should be used to identify SLE patients for more intensive risk factor modification.

2263

Damage Accrual in Patients with Systemic Lupus Erythematosus Is Associated with Endothelial Function Detriment: A Prospective Cohort Study. Chiara Tani[1], R. Bruno[1], Anna d'Ascanio[2], Lorenzo Ghiadoni[1], Y. Plantinga[1], Rossella Neri[1], Antonio Tavoni[3], Linda Carli[1], Stefano Taddei[1], Stefano Bombardieri[2] and Marta Mosca[1]. [1]University of Pisa, Pisa, Italy, [2]Rheumatology Unit, Pisa, Italy, [3]AOUP, Pisa, Italy

Background/Purpose: Endothelial dysfunction is considered an initial step in the pathogenesis of atherosclerosis and an important predictor of future cardiovascular events. Flow-mediated dilation (FMD) is a reliable and non invasive technique to assess endothelial function (EF) Our aim was to study EF in a cohort of systemic lupus erythematosus (SLE) patients prospectively followed at our unit and to investigate its relation with disease activity and damage over time.

Methods: 38 female SLE patients without overt cardiovascular involvement were enrolled (mean age 35.8±8; 21– 55 years) and clinically followed-up for a mean of 4.45±1.5 years. Clinical history, traditional cardiovascular risk factors, laboratory parameters as well as a complete serological profile were recorded. Disease activity was evaluated with the ECLAM global score (a score >2 were arbitrarily used to defined "active disease") while SLICC/ACR-DI was used for scoring disease damage. An increase in SLICC/ACR DI or death were defined as poor outcome. FMD was assessed in the brachial artery by high-resolution ultrasound and computerized edge detection system (Quipu s.r.l., Pisa, Italy); FMD was defined as maximal % change in brachial artery diameter after reactive hyperemia induced by 5-min forearm ischemia. In addition, endothelium-independent dilation after administration of glyceryl trinitrate (25 μg s.l.) was also assessed. FMD assessment was performed at study entry and was repeated in a subgroup of 21 patients after a follow-up of 4.45±1.5 years.

Results: At enrolment, 18 patients (47%) presented an active disease and 7 (15%) an active renal involvement; 20 (53%) were inactive; mean FMD was 7.9±3.1% with no statistically significant differences between active (8.7±1) and inactive group (7.9±0.8; p=0.53), even after correction for age and disease duration. During the follow-up, 3 patients died and 12 accrued organ damage with cardiovascular complications in eight patients (21%) and progression to renal failure in 6 (15%). Interestingly, while basal EF did not predict the poor final outcome (death or damage accrual), its decline over time did. In fact, in the follow-up FMD showed a significant decline over time (from 8.0±3.2 to 5.9±3.3, P=0.04) while endothelial-independent dilation did not (from 9.2 ±3.5 to 8.6±4.9; p= 0.63). The decline was not different between active and inactive group; however, patients with poor outcome (n=7) showed a greater worsening in FMD over time (−4.1% vs −2.0%).

Conclusion: This study shows that in SLE patients damage accrual is associated with progressive loss of FMD, with preserved response to glyceryl trinitrate, suggesting a progressive detriment in EF. On the other hand, disease activity does not appear to influence EF. Rapid progressive worsening of EF over time could represent an early marker of poor outcome and its assessment by repeated measurement of FMD could allow its early and non invasive identification. In this perspective, EF preservation may be important in preventing damage accrual and life-threatening consequences and therefore could be viewed as a therapeutic goal.

2264

Transverse Myelitis and Its Relationship with Neuromyelitis Optica in the Michigan Lupus Cohort. Malini Venkatram[1], Patricia C. Cagnoli[1], Diana Gomez-Hassan[2] and W. Joseph McCune[1]. [1]University of Michigan, Ann Arbor, MI, [2]Univ of Michigan, Ann Arbor, MI

Background/Purpose: Background: Transverse myelitis (TM) is an infrequent but serious manifestation of Systemic Lupus Erythematosus (SLE) with a reported incidence of 1–2 % and significant morbidity and mortality. TM complicating SLE has been variously reported to be associated with optic neuritis, anti-phospholipid antibodies, and antibodies to Ro/SSA and more recently with antibodies to aquaporin 4.

Neuromyelitis optica (NMO) is a relapsing, autoimmune, demyelinating condition characterized by TM and ON & at least two of the following: 1)Brain MRI, non-diagnostic for multiple sclerosis; 2) Spinal cord lesion extending over >=3 vertebral segments 3) NMO Ig-G antibody.

NMO spectrum disorders refer to inflammatory conditions of spinal cord & optic nerve, associated with anti-NMO Ig-G that do not fulfill the classic definition for NMO.

We present the largest study of TM in SLE including testing for anti-NMO antibodies in patients who had stored sera from the time of onset of neurologic symptoms. We also try to investigate the relationship of TM in lupus with NMO/NMO spectrum disorders.

Methods: We conducted a retrospective study of all the patients satisfying 4 ACR criteria for SLE within the Michigan Lupus Cohort (MLC) & evaluated the clinical, laboratory & Imaging features in 23 patients with a history of TM. Available stored sera from the time of onset of TM were tested for IgG NMO antibodies.

Results: 2.7% (23/ 856) of patients in the MLC had TM of whom 9.5 % (2/ 23) had optic neuritis. Only 81.8% of all the pts demonstrated ANA positivity. At the time of the event, serologic markers for lupus activity were normal in 50 %of the patients. We did not observe the previously reported increased frequency of anti-phospholipid antibodies (8/23, 34.7%)%) or anti Ro/SSA antibodies (39.13%) compared to the general lupus population.

Sensory involvement was the commonest manifestation (93.7%) followed by motor (62.5%) and bladder involvement (50%). Paraplegia occurred in 21.05% & 17.6% were catheter dependent. All the pts received steroids & 81.25% received Cytoxan. Overall recovery was good mostly due to aggressive immunotherapy.

2/23 (9.5) % of pts with TM had optic neuritis and fulfilled criteria for NMO. 30% of pts with available serum samples demonstrated NMO Ig-G. Overall 36.3% were categorized as NMO disease (inclusive of NMO and NMO spectrum). Contrary to our expectation, none of the pts in NMO category had a severe involvement such as paraplegia or catheter dependency. There were no statistically significant differences between the two groups in imaging or serological characteristics. Recurrences were seen in 75%of NMO group vs none in non-NMO group (P<0.024).

Conclusion: In a large prospective cohort, TM occurred in 2.7% of patients & was not associated with antibodies to phospholipids or Ro/SSA. Majority of patients recovered after aggressive immunosuppression. There were no significant differences between the NMO and NMO groups. Recurrences of TM, but not severity of onset, were associated with NMO spectrum disorders.

Evaluation of Treatment Success in Systemic Lupus Erythematosus Clinical Trials: Development of the British Isles Lupus Assessment Group-Based Composite Lupus Assessment Endpoint. D. Wallace[1], V. Strand[2], R. Furie[3], M. Petri[4], K. Kalunian[5], M. Pike[6], L. Kelley[7] and C. Gordon[8]. [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Stanford University, Palo Alto, CA, [3]North Shore-LIJ Health System, Lake Success, NY, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]UCSD School of Medicine, La Jolla, [6]Massachusetts General Hospital, Fort ashington, PA, [7]UCB, Symrna, GA, [8]Medical School, Birmingham, United Kingdom

Background/Purpose: The evaluation of disease activity in systemic lupus erythematosus (SLE) clinical trials is challenging due to the multi-organ presentation of SLE, interindividual variability, unpredictability of disease course, medication effects, and interobserver rating differences. While composite endpoints have been widely adopted to study other diseases, single disease activity indices (DAIs) have been the

norm in SLE. The purpose of this study was to develop a composite responder index for use in SLE clinical trials.

Methods: An expert panel was consulted to review the characteristics of DAIs commonly used in SLE trials. These included the British Isles Lupus Assessment Group index (BILAG-2004), the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and the Physician's Global Assessment (PGA). Characteristics considered included basis of scoring and the number and types of items assessed. Following this review, the BILAG-based Composite Lupus Assessment (BICLA) was developed as a composite of multiple DAIs based on early epratuzumab clinical trial data. The BICLA requires patients to meet response criteria across three assessment tools.

Results: BICLA responders must achieve BILAG disease activity improvement with no worsening in BILAG or other DAIs and no treatment failure at any time point (Table). The BICLA was used to evaluate response in the EMBLEM™ phase II study (SL0007), a 12-week, randomized, double-blind, placebo-controlled study that recruited 227 patients with moderate to severe SLE. BICLA was sensitive to epratuzumab treatment response (epratuzumab 600 mg QW 45.9% response at 12 weeks; epratuzumab 1200 mg EOW 40.5%; epratuzumab 2400 mg cumulative dose 43.2%) with a limited placebo response rate (21%; p = 0.02 vs 2400 mg at 12 weeks). The use of BILAG as the primary component of the BICLA requires simultaneous improvement across all body systems with severe or moderate disease activity at baseline. BILAG gives balanced weight to all affected body systems and can reflect incremental improvements within a body system. The BICLA is also the 48-week primary efficacy variable in the EMBODY™ phase III studies (SL0009 [NCT01262365] and SL0010 [NCT01261793]) of epratuzumab in patients with moderate to severe SLE.

Table. Requirements for BICLA treatment response.

Improvement and	1. All BILAG level A scores at study entry improved to B/C/D and
	2. All BILAG level B scores at study entry improved to C/D
No worsening and	1. No single new BILAG A or two new BILAG B scores and
	2. No worsening of baseline SLEDAI total score and
	3. No worsening in PGA (< 10% worsening relative to baseline)
No treatment failure	Treatment failure defined as non-protocol treatment, e.g. new or increased immunosuppressants or antimalarials

Conclusion: The BICLA is a sensitive, clinically meaningful composite measure of SLE disease activity that requires disease improvement across all body systems with moderate or severe baseline activity without worsening or change in background medication, and which has discriminated between placebo and treatment responses in a phase II clinical trial. The three DAIs included in the BICLA require clinical assessment, physician assessment, laboratory assessment, and recording of medication use. Further analysis of data from studies using the BICLA composite endpoint may help to guide the design of future trials in SLE.

2266

Inpatient Mortality Related to Cerebrovascular Disease in Systemic Lupus Erythematosus: The Impact of Delay in Diagnosis of Neuropsychiatric Lupus. Jamal A. Mikdashi, Univ of Maryland Schl of Med. Baltimore, MD

Background/Purpose: Despite improvements in the process of care of stroke patients, mortality related to cerebrovascular disease (CVD) in systemic lupus erythematosus (SLE) patients during the first- ever stroke remains high when compared to patient with other causes for their first-ever stroke.

Purpose: To examine the predictors of inpatient mortality related to CVD in SLE and determine whether mortality associated with first-ever stroke is related to the disease effects, comorbidities or quality of care.

Methods: Inpatient mortality was examined in 143 SLE patients admitted to a tertiary care stroke center with validated first-ever stroke between January 2000 and January 2011. Mortality was defined as all-cause fatal event from day of first-ever stroke through the 28 day of follow up. Demographics, clinical manifestations and processes of care were compared between those who died (n= 14) and age- and gender –matched controls who survived the stroke event [3 controls for every patient] (N= 42). Risk factors predictive of mortality were determined using univariable analyses between survivals and non survivals. Multivariate analyses and Cox proportional hazards analyses of significant variables were examined to determine their contribution to mortality related to CVD. Severity of SLE disease activity (SLEDAI), damage (SDI) and stroke severity were adjusted for during analyses.

Results: Intractable disease activity and cumulative damage involving pulmonary and renal organs were higher in patients who died compared to those who survived the first-ever stroke. Both groups had comparable disease duration, ethnicity, socioeconomic features, smoking and alcohol use, stroke type (ischemic, hemorrhagic) and Charlson comorbidity score. Death related to cerebral vasculitis (50 %) appeared to be more common than death related to hemorrhagic (29 %) or ischemic stroke (21 %). The median time to diagnosis of neuropsychiatric SLE (NPSLE) was longer for patients who died as compared to patients who survived the stroke event [7days v 3 days; $p < 0.026$].

Table 1. Univariable analyses and Cox hazard analyses of factors associated with mortality related to CVD

Factors	Univariable Model Odds Ratio (95% Confidence Interval)	Proportional Hazard Model Hazard Ratio (95% Confidence interval)
Seizure	3.6 (1.1 – 12.3)	2.7 (1.0 – 7.6)
Cognitive impairment	3.7 (0.9 – 19.3)	2.1 (0.7 – 6.4)
Thrombocytopenia	4.8 (1.3 – 17.6)	3.3 (1.2 – 9.3)
Lupus anticoagulant	3.3 (0.9 – 15.4)	2.5 (0.8 – 7.0)
C Reactive Protein	1.2 (0.48 – 3.1)	0.9 (0.3 – 2.9)
Delay in NPSLE diagnosis	7.0 (1.8 – 27.1)	4.2 (1.4 – 11.6)

Conclusion: Despite the admission to a designated stroke center, mortality related to CVD in SLE remains significantly high. Quality improvement strategies targeting early diagnosis and timely intervention of neuropsychiatric SLE may reduce the associated morbidity and mortality among SLE patients.

2267

Predictors of Outcome in Peripheral Nervous System Manifestations of Systemic Lupus Erythematosus. Brandusa Florica[1], Jiandong Su[2] and Paul R. Fortin[1]. [1]Toronto Western Hospital, Toronto, ON, [2]The Toronto Western Hospital, Toronto, ON

Background/Purpose: Peripheral neuropathies (PN) in patients with systemic lupus erythematosus (SLE) are diverse and may cause significant functional impairment. The identification of factors that influence the outcome of PN is essential in decision regarding the timely treatment of potentially reversible nerve degeneration.

Methods: Data collected prospectively from the University of Toronto Lupus Clinic cohort was used to identify factors associated with improved neurological deficit (no need for assistance in self care). Potential predictors of improvement in PN were considered in univariate and multivariate logistic regression models. Also, the univariate and multivariate Cox proportional regression models were used to ascertain the results. The analysis included two groups of patients: those with SLE-related and those with PN not thought to be related to SLE. The statistical software used was SAS 9.13

Results: From 1533 SLE patients, 184 patients had PN diagnosed within 6 months of their first visit, with 105 patients with SLE-related PN and 79 with non SLE-related PN. Mean duration of follow up after PN diagnosis was 18.8 ± 11.0 years for SLE-related PN and 21.2 ± 11.0 years for non SLE-related PN. Patients with SLE-related PN had significantly higher SLEDAI at time of PN diagnosis ($p<0.0001$) and used more often steroids in the first year after PN diagnosis ($p=0.023$). SLE duration at PN onset and SLICC score were positively associated with improved outcome in patients with SLE-related PN, in the univariate logistic regression model, with OR (95%CI) of 0.949(0.909, 0.991) p =0.017 and of 0.730 (0.546, 0.977). Using multivariable Cox proportional model, the use of steroids in the first year after PN onset was the only factor that was independently associated with improved outcome in SLE-related [HR (95%CI) of 4.181 (1.254, 13.940) $p=0.019$] and with negative association for non-SLE related PN [HR (95%CI) 0.306 (0.127, 0.739) $p=0.008$]. Similar results were replicated using the multivariate logistic regression for non-SLE related PN [OR (95%CI) 0.137 (0.035, 0.538) p =0.004].

Conclusion: Clinical and laboratory characteristics of SLE patients at the time of PN diagnostic are not helpful to predict the outcome of the peripheral neurological manifestations. Steroid treatment in the first year after PN onset was associated with more patients improving in SLE related PN group and inversely in non-SLE related PN. Correct delineation of PN etiology is critical for timely intervention on nerve damage.

2268

Mortality Causes and Associated Factors in a Systemic Lupus Erythematosus Monocentric Cohort: Is the Systolic Pulmonary Artery Pressure a Risk Factor for Death? I. Rua-Figueroa, C. Erausquin, MD Fiuza, F. Francisco-Hernández, S. Ojeda, A. Naranjo, JC Quevedo, A. Acosta, R. Lopez -R and C. Rodriguez-Lozano. Hospital de GC Dr Negrin, Las Palmas GC, Spain

Background/Purpose: Despite improved prognosis, patients with SLE remain at increased risk for early death. Limited data are available in our country regarding the mortality of patients with SLE.

Objectives: To examine the mortality and associated factors in a monocentric Spanish

Methods: We studied 254 SLE (ACR 1997 criteria) patients under protocolized follow up in a rheumatology service. Acumulated clinical characteristic and damage accrual (ponderated SLICC/ACR/DI) (SDIp) and severity (Severity Katz Index) (SI) were recorded. The standardized mortality ratio (SMR), ROC analysis, with Hanley and McNeil contrast' for area under curve (AUC) comparisons and a multivariable analysis (logistic regression) were carried out.

Results: Mean age: 44.2±13.6; 92.1% female. The mean time (±S.D.) since the lupus diagnosis was 13.3 years (± 8.5); 19 patients (7.5%) died, 12 by SLE (63.2%). The most common cause of death was of respiratory origin (31.6%), followed by infection (26.3%), cancer (21%) cardiovascular (10.5%) and others (10.5%). SMR: 1.84 (1.48 females).The ROC curve cutoff for SDIp was >4 (sensitivity 66.6%; specificity 73.8% and + likelihood ratio (LR) 2.54 and for SI was >3 (S: 94.4%; E: 59.3%; +LR 2.31). There were no differences in AUC between SDIp (0.756; IC95% 0.698–0.808) and SI (0.820; IC95% 0.767–0.866) (p=0.632).The variables associated with mortality in the bi-variable analysis were: hospitalization by SLE, any time (66% vs 100% in deaths, OR 1,1; 95%CI:1.06–1.18; p=0.003), tobacco use (24.3 vs 47.4% OR 3.4; 95%CI:1.3–9.3; p=0.011), vasculitis (13.6 vs 42.1% OR 4.5; 95%CI: 1.7–12.1; p=0.001), severe thrombocytopenia (10.6% vs 26.3%; OR: 3.1; 95%CI: 1.04–9.6; p=0.033), hematocrit <30% (24.7% vs 73.7%; OR: 10.1; 95%CI: 3.2–32; p<0.0001), elevated **s**ystolic pulmonary artery pressure (SPAP) (2.6% vs 31.6%; OR:18.8; 95%CI: 5.2–67; p=0.0001), ischemic event (10.6% vs 26,3%; OR: 4,5; 95%CI: 1.4–14.2; p=0.005), cutaneus ulcers (4.3 vs 21.1 OR: 6.3; 95%CI: 1.7–22.7; p=0.002), major organ (52.8 vs. 84.2 OR: 6.9; 95%CI: 1.5–30.7; p=0.004), severe infection (29.8 vs. 78.9;OR: 8.7; 95%CI: 2.7–27.2; p=0.0001), antimalarials use (16.7% vs. 4.7%;OR: 0.2; 95%CI: 0.09–0.6; p=0.002), SI >3(OR: 24.6; 95%CI: 3.2–28.3; p<0.0001) and SDIp >0 (OR: 6.4; 95%CI: 1,4–28,3; p=0.006). Only hematocrit <30% (OR 10.3; 95%CI: 1.86–57.67, p=0.008) and elevated SPAP (OR 23.1; 95% CI: 3.24–165, p=0.002) were proven as independent factors in multivariate analysis.

Conclusion: Consistent with previous data, a strong association was found between anemia and mortality in SLE. However, the association with elevated SPAP, whatever cause, has not been previously recorded. We could not demonstrate a protective effect of antimalarials in the final model, perhaps by the very definition of the variable and/or the high percentage of patients treated with these drugs in our cohort. However, the protection against mortality was independent of severity, minimizing bias due to confounding by indication. This point needs to be explored further. Finally, our analysis doesn't reveal any differences between SDIp and SI as predictors of mortality.

2269

Anti-Nucleosome Antibodies Correlate with Temporal Fluctuations in Disease Activity in Systemic Lupus Erythematosus. Li Timothy[1], Stacey Morrison[2], Wendy Lou[3], Heather Reich[2], Ellie Aghdassi[4], D. D. Gladman[5], Murray B. Urowitz[1], James Scholey[2], Paul R. Fortin[1], Joan E. Wither[6] and Carolina Landolt-Marticorena[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]The Toronto Western Hospital, Toronto, ON, [3]University of Toronto, Toronto, ON, [4]University Health Network, Toronto, ON, [5]The Arthritis Program, Toronto Western Hospital and Division of Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, [6]Toronto Western Research Institute, University Health Network, Toronto, ON

Background/Purpose: The clinical course of SLE is characterized by unpredictable disease exacerbations. Current biomarkers (anti-dsDNA antibodies and complement (C3)) function poorly in forecasting these events. This limits their utility as reliable markers of disease activity, generating interest in the identification of novel biomarkers. Anti-nucleosome antibodies are increased in SLE patients and are associated with disease activity. The aim of this study was to examine the utility of anti-nucleosome antibodies as a flare-specific biomarker in SLE.

Methods: 51 SLE patients satisfying ≥ 4 ACR criteria and 49 healthy controls were recruited. Patients were followed over a 14-month period with at least 3 clinical and biochemical assessments over that time. Clinical data and blood samples were collected at the time of recruitment and at subsequent assessments to determine the SLEDAI-2K (S-2K). A modified S-2K (mS-2K) was calculated by subtracting the contribution of anti-dsDNA antibodies and complement from the global score. An ELISA was utilized to determine IgG anti-nucleosome antibody levels in patients and control with a threshold for anti-nucleosome positivity defined as values 3 SD above the mean for controls. Spearman's (non-parametric) rank correlation analysis was used to determine the correlation coefficient between variables. Logistic regression analysis was performed with outcome parameters defined as activity (mS-2K > 0) or no activity (mS-2K = 0). Analysis of longitudinally correlated data was assessed by mixed effects models. p values of less than 0.05 were considered statistically significant.

Results: Anti-nucleosome antibodies were significantly elevated in SLE patients versus controls ($p < 0.0001$). Anti-nucleosome antibody levels show a statistically significant positive correlation with anti-dsDNA antibodies ($r = 0.72$, $p < 0.0001$) and a negative correlation with C3 levels ($r = -0.42$, $p = 0.002$). A moderate positive correlation ($r = 0.32$, $p = 0.02$) was found between anti-nucleosome antibodies and disease activity. The ability of anti-nucleosome antibodies to discriminate between patients with active (mS-2K > 0) and inactive disease was determined using an ROC curve analysis. Examination of the area under the curve (AUC) for C3 (0.63), anti-dsDNA (0.69) and anti-nucleosome (0.61) antibodies demonstrated that all 3 biomarkers functioned in a comparable fashion. To determine the utility of these 3 parameters to mirror changes in disease activity a mixed effects regression analysis was performed. Models combining C3 and anti-nucleosome antibodies (AIC = 1188.6) outperformed models with C3 and anti-dsDNA antibodies (AIC = 1191.4). In a model (AIC = 1185.8) incorporating all 3 parameters only anti-nucleosome antibodies ($p < 0.0001$) remained statistically significant.

Conclusion: Anti-nucleosome antibodies outperform traditional biomarkers in tracking with changes in SLE disease activity supporting the incorporation of this serological marker in the monitoring of SLE. The current shift towards multiplex platforms for autoantibody determination will facilitate the inclusion of this parameter into clinical practice.

2270

The Substantial Negative Impact of Systemic Lupus Erythematosus on the Working Lives of Patients: Results of the Lupus European Online Survey. M. Schneider[1], C. Gordon[2], K. Lerstrøm[3], M. Govoni[4], E. Nikai[4] and D.A. Isenberg[5]. [1]Heinrich-Heine-University, Duesseldorf, Germany, [2]University of Birmingham, Birmingham, United Kingdom, [3]LUPUS EUROPE, Farum, Denmark, [4]UCB, Brussels, Belgium, [5]University College of London, London, United Kingdom

Background/Purpose: Previous studies have shown that SLE has a significant impact on patients' health-related quality of life (HRQoL). A significant proportion of employed SLE patients miss days of work or are permanently unemployed due to SLE.[1] An online survey was developed to understand better the impact of SLE on patients' daily lives and career. The survey used lupus-specific, validated patient-reported outcome (PRO) instruments.

Methods: The LEO survey was developed by a steering committee of SLE medical experts and a LUPUS EUROPE board patient representative. UCB representatives provided support and coordination. The survey was available between May and August 2010 in five European languages. It included patient-designed questions and lupus-specific, validated PROs assessing fatigue (Fatigue Severity Scale [FSS]: scores 1–7; higher score = greater fatigue; < 4 = normal), HRQoL (LupusQoL questionnaire: 8 domains; scores 1–100; higher score = better HRQoL), and work impairment (Work Productivity and Activity Impairment Questionnaire, Lupus V2.0 [WPAI]: 4 domains; higher percentage = greater loss of productivity). LUPUS EUROPE made the survey available to patients via e-mail, social media, patient organization websites and national SLE magazines. Responses were anonymous. Participants were not required to answer all questions.

Results: The survey was completed by 2070 respondents with self-reported SLE; of 1796 providing information about the effect of lupus on their career, most were aged < 45 years (67%) and were female (94%). Most respondents reported that SLE adversely affected their careers; among those aged 26–45 years, only one-third reported no effect. Among those whose careers were affected by SLE, mean total FSS was 6.2 in those requiring social or disability allowance (n = 330), 5.8 in patients requiring sick leave (n = 309), 5.7 in those who needed to

work flexible hours (n = 336) and 5.6 in those who had changed career (n = 183) compared with 4.5 (n = 565) in those whose career had not been affected. Among respondents receiving social or disability allowance, 95% reported fatigue (FSS score > 4 points). HRQoL was higher among respondents whose careers were not affected by SLE and lowest in those receiving social or disability allowance (Table). A negative impact of SLE on work productivity was seen in all 4 WPAI domains, and greater impairment was reported in respondents whose careers were affected by SLE (Table).

Table. Relationship between LupusQoL ad WPAI domains and self-reported effect of SLE on career

	Did SLE affect your career?				
LupusQoL domains (mean score ± SD)	**No influence on career**	**Sick leave**	**Social or disability allowance**	**Change career**	**Work flexible hours**
Physical health	n = 544 76.7 ± 20.8	n = 298 52.6 ± 24.0	n = 327 37.7 ± 22.7	n = 179 58.1 ± 20.3	n = 328 57.2 ± 20.4
Pain	n = 535 75.1 ± 24.8	n = 293 49.8 ± 28.9	n = 323 38.3 ± 27.8	n = 178 54.4 ± 25.1	n = 324 57.2 ± 27.8
Planning	n = 536 80.4 ± 24.1	n = 295 47.4 ± 30.3	n = 323 37.5 ± 27.8	n = 177 55.7 ± 27.8	n = 323 56.3 ± 29.3
Intimate relationship	n = 530 78.6 ± 28.7	n = 290 53.9 ± 32.8	n = 320 47.4 ± 33.6	n = 175 65.4 ± 29.8	n = 323 64.5 ± 30.1
Burden to others	n = 536 60.4 ± 30.4	n = 294 35.2 ± 30.4	n = 322 33.6 ± 30.4	n = 179 41.2 ± 29.5	n = 324 43.9 ± 31.0
Emotional health	n = 536 70.4 ± 22.9	n = 291 54.6 ± 24.0	n = 315 53.7 ± 24.3	n = 179 59.2 ± 24.0	n = 320 59.8 ± 24.1
Body image	n = 342 70.2 ± 25.6	n = 133 55.6 ± 30.2	n = 266 54.1 ± 28.2	n = 125 65.4 ± 28.0	n = 218 59.7 ± 30.1
Fatigue	n = 540 62.1 ± 25.5	n = 295 39.2 ± 24.8	n = 320 33.3 ± 23.3	n = 179 41.7 ± 23.6	n = 325 43.6 ± 23.0
WPAI dimensions (mean % of time impaired ± SD)					
Absenteeism	n = 268 3.8 ± 12.4	n = 82 35.0 ± 37.7	n = 37 31.3 ± 35.6	n = 91 10.0 ± 17.3	n = 193 16.6 ± 22.4
Presenteeism	n = 354 25.2 ± 19.4	n = 104 55.9 ± 27.4	n = 49 53.3 ± 26.3	n = 109 44.2 ± 22.3	n = 238 47.3 ± 23.0
Work productivity loss	n = 265 27.5 ± 20.5	n = 66 58.1 ± 28.4	n = 32 59.2 ± 28.4	n = 91 48.7 ± 25.0	n = 188 52.3 ± 24.9
Activity impartment	n = 552 39.2 ± 25.8	n = 300 64.7 ± 24.5	n = 325 70.6 ± 21.2	n = 178 57.9 ± 23.7	n = 327 58.4 ± 23.3

Conclusion: The LEO survey demonstrates that SLE adversely affects patients' careers and levels of productivity at work. Respondents who had to change work commitments because of SLE reported greater fatigue levels, worse HRQoL and greater loss of productivity. These results demonstrate the extensive burden of disease for patients, in terms of both quality of life and lost productivity.

Is the Heightened Lung Cancer Risk in Systemic Lupus Erythematosus Decreasing Over Time? Data From a Very Large International Multi-Centre Cohort. Sasha Bernatsky[1], Ann E. Clarke[2], C. Gordon[3], Jeremy Labrecque[1], Rosalind Ramsey-Goldman[4] and Systemic Lupus International Collaborating Clinic (SLICC).[5]. [1]McGill UHC/RVH, Montreal, QC, [2]Research Institute of the McGill Univ. Health, Montreal, QC, [3]University of Birmingham, Birmingham, United Kingdom, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Toronto

Background/Purpose: Previously we have demonstrated a small over-all increased cancer risk in SLE, with particularly heightened risk for non-Hodgkin's Lymphoma (NHL) and lung cancer. We recently updated our data, and present figures for over-all, NHL, and lung cancer risk in SLE versus the general population, for the years prior to 2000, and the period from 2000 onward.

Methods: We studied a very large multi-centre international cohort of clinically confirmed SLE patients. Patients at each center were linked to regional tumor registries to determine cancer occurrence. Standardized incidence ratios (SIRs) were calculated as the ratio of observed to expected cancers. Cancers expected were determined by multiplying person-years in the cohort by the geographically matched age, sex, and calendar year-specific cancer rates, and summing over all person-years.

Results: We studied a total of 16, 263 lupus patients from 1976 to 2009, from 53 centres. The total cohort was 90% female and the average follow-up was 9.3 years (a total of 150,984 patient-years). From the 1970's to 2000, there were 101,237 patient-years of follow up and from 2000 onward there were 49,747 patient-years of follow-up. The SIRs for prior to the year 2000, versus after 2000, are presented below.

	Prior to the year 2000					From the year 2000 onward				
	Observed	**Expected**	**SIR**	**95% CI**		**Observed**	**Expected**	**SIR**	**95% CI**	
Lung	73	54.6	1.34	1.05	1.68	28	29.5	0.95	0.63	1.37
NHL	50	14.1	3.54	2.63	4.67	30	8.3	3.63	2.45	5.18
All	550	457.5	1.20	1.10	1.31	302	254.8	1.19	1.06	1.33

Conclusion: The clear increase in lung cancer risk in SLE compared to the general population, which was demonstrated prior to 2000, was not as evident in more recent data. In contrast, the risk in SLE (compared to the general population) remained heightened for total malignancy incidence and NHL incidence. However, since our case ascertainment (and the general population cancer rates) rely on cancer registry records, the apparent trend could possibly also be related to systematic differences in classification of lung cancers, with a shift from ICD-9 to ICD-10 coding, if there is increasing non-differential misclassification of both lung cancers in SLE and the general population. Changes over time in race/ethnicity mix, smoking, and medication use are additional considerations, and these will be examined in future analyses.

Risk Factors Associated with Cataracts in Systemic Lupus Erythematosus Patients. An inception-Cohort Study. Mariana Chávez-Villa, Juanita Romero-Diaz, Claudia Recillas-Gispert, Carmen Lizana, Francisco Cárdenas and Jorge Sánchez-Guerrero. Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Mexico, Mexico

Background/Purpose: Cataracts have been reported as common finding in SLE patients. Its characteristics and lupus related risk factors are still poorly known. We aimed to identify the prevalence, time of onset, subtypes and risk factors associated with cataracts in an inception-cohort of SLE.

Methods: We included 123 patients (90% females) with SLE of recent-onset at enrollment. At entry, a standardized medical evaluation was done assessing lupus characteristics, medications, cardiovascular risk factors, and laboratory tests. Patients were seen every 3–6 months, and assessed for disease activity and medications. Every year, information was updated and a blood sample drawn.

At 4.9(3.0) years of follow-up, the patients were screened for ocular manifestations by 2 certified ophthalmologists who performed a full standardized ophthalmic examination. A composite slit-lamp evaluation based system for the clinical classification and grading of cataracts was performed. Cataracts features were classified morphologically by Lens Opacities Classification System (LOCS) III, and individual features were graded by comparison with standard diagrams mounted adjacent to the slit-lamp. The image degrading effect of the cataract was assessed using a resolution target projection ophthalmoscope.

Results: At enrollment into the cohort, mean (SD) age of lupus patients was 27.9 (8.9) years, lupus duration 5.4 (4.0) months, number of SLE criteria 5.7(1.3) and SLEDAI-2K score 6.5 (6.1). At ocular screening mean age of patients was 32.8 (8.6) years. Thirty nine patients (32%) were identified with cataract, females (90%). NC0NO0C0P1 (posterior subcapsular) was the most common subtype (41%). Cataracts were observed as early as age 21–30 years, and since the first years of diagnosis. Comparing patients with and without cataract, only hypertension was more often observed in patients with cataracts, no difference was observed in body mass index, diabetes mellitus, lipid profile, glucose, homocystein and hsCRP. Regarding SLE characteristics, patients with cataract had more often renal criterion, and higher modified SLICC/DI score. Photosensitivity was more frequent in patients without cataract. Age at diagnosis, disease duration, and autoantibodies profile did not differ between groups. The cumulative dose of prednisone was 28.2(17.8) and 19.1(13.8) grams, between patients with and without cataract, respectively (P=0.005), cyclophosphamide use 62% vs 32%, (P=0.003) and cumulative dose of cyclophosphamide was 9.6(17.7) and 4.6(9.9), (P=0.006). No difference was observed with the use of antimalarials and low-dose aspirin. Logistic regression analysis showed an independent association of cumulative dose of prednisone (OR 1.04, 95%IC1.0–1.07, p=0.02) and photosensitivity (OR 0.14, 95%IC 0.4–0.45,p=0.001) with cataract.

Conclusion: In this inception cohort of young lupus patients, at 4.9 years of follow-up, cataracts were observed in 32% of patients, from age 21–30 years, and since the first year of lupus. Cumulative dose of prednisone is an independent risk factor for cataract. Photosensitivity seems to be a protective factor in patients with lupus.

2273

Clinical and Psychosocial Factors Are Associated with Current Work Status and Missing Days At Work in a Large Population of Patients with Systemic Lupus Erythematosus (SLE). Stacey Morrison, Jiandong Su and Paul R. Fortin. Toronto Western Hospital, Toronto, ON

Background/Purpose: Our aim is to describe the work status of patients with systemic lupus erythematosus (SLE) and test for associations with (1) current work; and (2) missing days from work due to SLE in a North American registry of SLE patients.

Methods: A large registry collects information from (a) consenting SLE patients (age, gender, race, education, insurance, troublesome symptoms and work-related factors); and (b) their rheumatologist [ACR criteria, SLE duration, disease activity (SLEDAI, range 0–24), SLICC damage index (SDI, range 0–15)] at each visit. Descriptive statistics and univariate and multivariate (MV) regression analyses were performed.

Results: Data was collected from 1,242 individuals: mean (sd) age of 40.5 (13.2), 92% female, 48% Caucasian, 34% African American, 12% Hispanics, 74% with a college degree or higher. Four or more ACR criteria were met in 90% of the group with [median (IQR)] disease duration of 11.0 (11.0); SLEDAI of 2.0 (4.0); and SDI of 1.0 (2.0). Private insurance was reported in 60% of patients, 27% were work-disabled. There were 570 (48%) not working: 80% of these had worked previously with 20% having lost their job since their last visit and 14% looking for a job. Current work was reported by 52% of participants, 70% of these full time. One hundred and ninety (30%) had missed work due to illness since their last visit and 51% worried that SLE made it difficult for them to perform their job. Variables independently associated with work status and missing work are reported in Tables 1 and 2.

Table 1. Variables independently associated with current work

Variable	OR	95% CI	
Age (years)	0.99	0.98	1.00
Gender (male)	2.00	1.23	3.26
Private insurance	4.30	3.27	5.66
Race (African American)	1.39	1.04	1.87
Education	1.15	1.07	1.22
SDI	0.79	0.73	0.86

Further MV analysis of individual SDI items revealed that retinal damage, pulmonary hypertension and fibrosis, cardiomyopathy, osteoporosis, avascular necrosis and extensive skin scarring were adverse contributors to work status.

Table 2. Variables independently associated with missing days at work

Variable	OR	95% CI	
SLE duration (years)	1.03	1.00	1.05
Race (African American)	1.52	1.01	2.28
SLEDAI	1.07	1.01	1.12
Fatigue	2.81	1.85	4.26
Weakness	2.51	1.58	4.01
Difficulty thinking	2.03	1.23	3.36
Other troublesome symptoms	1.60	1.03	2.49

Conclusion: Work is a marker of vulnerability and is important in measuring health status. Factors independently associated with current work in SLE are younger age, male gender, African American race, higher education and less damage. Longer SLE duration, higher disease activity and several dimensions important to patients but often ignored by physicians (fatigue, weakness, difficulty thinking and other troublesome symptoms) are predictors of missing work. Improving work-related interventions, especially those focused on presenteeism may make this population less vulnerable to becoming work-disabled.

2274

The WHO Fracture Risk Assessment Tool ($FRAX^R$) Under-Estimates the 10-Year Fracture Risk in Chinese Patients with Systemic Lupus Erythematosus (SLE). Chi Chiu Mok, Chi Hung To and Kwok Man Ma. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: The WHO $FRAX^R$ tool was developed to evaluate the fracture risk of patients based on data derived from different ethnic groups so as to guide treatment decision. We compared the actual observed 10-year fracture incidence in a group of Chinese patients with long-standing SLE with the risk estimated by using the WHO $FRAX^R$ tool.

Methods: All patients who fulfilled ^{3}4 ACR criteria for SLE, aged ^{3}50 years and had disease duration of ^{3}10 years in the year 2008 were recruited. The 10-year risk of major fracture (without data on bone mineral density) was estimated by entering the WHO $FRAX^R$ tool covariates / risk factors described in our medical records in the year 1998. All these patients were screened for compression fracture of the thoracic and lumbar spine in the year 2008 using plain radiograph of the spine (antero-posterior and lateral). The grading of vertebral fracture as suggested by Genant was used to assess vertebral fractures (stage I, II and III). Data on non-vertebral fragility fracture in the same year were also collected by direct patient interview and medical record review. The actual observed incidence of vertebral and non-vertebral fractures in year 2008 was compared with the risk estimated by the WHO $FRAX^R$ tool based on the risk factors in the year 1998.

Results: 65 SLE patients were studied (92% women, age 56.6±6.3 years, disease duration 17.3±7.2 years in 2008). Thirteen patients (20%) had major fractures in 2008 (11 vertebral fractures – 5 Genant stage I, 4 stage II, 2 stage III; 3 multiple vertebral fractures; 2 fibular fractures). Six patients (9%) had symptomatic fractures at these sites. The frequency of risk factors for fragility fractures in 1998 used for the $FRAX^R$ tool in these patients was: chronic smoking (9%), use of glucocorticoids for more than 3 months (65%), premature menopause (6%), body mass index $<18 kg/m^2$ (5%), habitual drinking (0%) and history of parental fracture or personal fracture (0%). From the FRAX program, the mean 10-year fracture risk of this group of patients was estimated to be 2.0±2.1% (range 0.7% to 16%). The median 10-year fracture risk was 1.5% (IQR 1.2–2.4%). Even when symptomatic major fractures were considered only, the actual incidence (9%) was much higher than that estimated by the WHO $FRAX^R$ tool (2%).

Conclusion: The WHO $FRAX^R$ tool greatly under-estimates the 10-year incidence of fragility fractures in Chinese patients with SLE.

2275

Insulin Resistance and Its Association with Phospholipid Profile, Carotid Intimal- Medial Thickness and Carotid Plaque Area in Women with Systemic Lupus Erythematosus. Ellie Aghdassi[1], David WL. Ma[2], Lihi Eder[3], Amaris K. Balitsky[4], Stacey Morrison[5], Michael Frattasi[5], Jiandong Su[5], Shayan Ezatollahpour[5], D. D. Gladman[6] and Paul R. Fortin[7]. [1]University Health Network, Toronto, ON, [2]University of Guelph, Guelph, ON, [3]Toronto Western Hospital, University of Toronto, Toronto, ON, [4]The University of Toronto, Toronto, ON, [5]The Toronto Western Hospital, Toronto, ON, [6]The Arthritis Program, Toronto Western Hospital and Division of Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, [7]Toronto Western Hospital, Toronto, ON

Background/Purpose: Insulin resistance (IR) is associated with the metabolic syndrome and has been linked to inflammation and an increased risk for cardiovascular disease (CVD). The ratio of Phosphatidylcholine (PC) to Phosphatidyl-ethanolamine (PE) and the composition of PC and PE are important determinants of the cell membrane integrity and PC/ PE ratio may be a novel inflammatory marker. The purpose of this study was to estimate the prevalence of insulin resistance (IR) in women with Systemic Lupus Erythematosus (SLE) and to determine whether there are associations between IR and: PC/PE ratio, carotid intimal-medial thickness (cIMT) and carotid plaque area (cPA).

Methods: Consecutive SLE women, meeting the ACR criteria for classification of SLE were enrolled into this study. Data on demographic variables, cardiovascular risk profile, SLE disease activity index-2000 (SLEDAI-2K) and SLICC (Systemic Lupus International Collaboration Clinic)-damage index (SDI) were collected. Blood was collected after 12-hr fast and analyzed for glucose and insulin. Insulin resistance was calculated using the homeostatic model assessment formula (HOMA: {glucose (mmol/l) × insulin (mU/l}/22.5). HOMA >3 was considered IR. Phospholipid profile was determined in red blood cells (RBC) using thin layer and gas chromatography. cIMT and cPA were determined using B-mode ultrasonography only in a subset of patients (n=36). cIMT, cPA, SDI, SLEDAI-2K, demographic variables and CVD risk profiles were compared between patients with and without IR using student's t-test. Pearson correlation was used to determine associations.

Results: Among 78 subjects, 53 (67%) had IR (HOMA>3). Compared to those with HOMA<3, subjects with IR had higher: BMI [24.3 (6.5) vs. 27.2 (7.3) kg/m^2, p=0.09], systolic blood pressure [113.7 (8.5) vs. 123.0 (19.8) mmHg, p=0.02], waist circumference [76.2 (11.6) vs. 86.2 (15.0) cm, p=0.003], cPA [0.06 (0.06) vs. 0.19 (0.25) cm^2 p= 0.02] and were older [40.7 (13.9) vs. 50.6 (12.3) year, p=0.004]. PC to PE ratio was significantly

lower in those with IR compared to those without IR [1.37 (0.21) vs. 1.27 (0.17), p=0.024). SLEDAI, SDI and cIMT were similar between the two groups. However, there was a significant negative correlation between RBC PC content and: cIMT (r= − 0.35, p=0.03) and cPA (r= −0.32, p=0.46).

Conclusion: IR is prevalent in SLE patients and is accompanied by alterations in RBC phospholipid profile. Alteration in RBC phospholipids profile was associated with a higher cIMT and cPA. The data suggest that IR and alterations in phospholipids profile play a role in the pathophysiology of atherosclerosis in patients with SLE and warrants further investigations.

2276

Vitamin D Deficiency As Marker for Disease Activity and Organ Damage in Systemic Lupus Erythematosus: A Comparison with Anti-dsDNA and Anti-C1q. Chi Chiu Mok[1], Daniel Birmingham[2] and Brad H. Rovin[2]. [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Ohio State University Medical Center, Columbus, OH

Background/Purpose: Vitamin D has been shown to have in-vitro inhibitory effects on T and B cell functions. Low levels of 25-hydroxyvitamin D3 were found in patients with SLE and correlated with active disease. The objective of this study is to examine the sensitivity and specificity of vitamin D deficiency for predicting disease activity and damage of systemic lupus erythematosus (SLE) in comparison with anti-dsDNA and anti-C1q.

Methods: Consecutive patients who fulfilled ^{3}4 ACR criteria for SLE were recruited from an out-patient clinic during the summer months (May to August, 2008). Levels of 25-hydroxyvitamin D3 (enzyme immunoassay; Immunodiagnostic Systems Inc, Fountain Hills, AZ, USA), anti-C1q (ELISA kits, Euroimmun, Lubeck, Germany) and anti-dsDNA (ELISA kit, Eurodiagnostica, Arnhem, Netherlands) antibodies were measured. Relationship among these markers, concurrent disease activity and damage scores of SLE was studied by Spearman's rank correlation method.

Results: 290 SLE patients were studied (95% women; mean age 38.9±13.1years; SLE duration 7.7±6.7years). Clinical or serological lupus activity (SLEDAI^{3}1) was present in 225 (78%) patients at the time of venepuncture. Thirty-seven (13%) patients had SLEDAI score of 12 or more. The mean 25-hydroxyvitamin D3 level was 19.1±6.2 ng/mL (range 6.2–53.0). Vitamin D insufficiency (level <30ng/mL) was present in 277 (96%) patients. More serious vitamin D deficiency (level <15ng/mL) was found in 78 (27%) patients. Levels of 25-hydroxyvitamin D3 correlated inversely with the clinical SLE disease activity score (Rho=-0.26;p<0.001). The mean titers of anti-C1q and anti-dsDNA were 23.4±33 RU/mL (NR<20) and 143±153 RU/mL (NR<50), respectively. Levels of 25-hydroxyvitamin D3 correlated significantly and inversely with titers of anti-C1q (Rho= −0.14; p=0.02) and anti-dsDNA (Rho= −0.13; p=0.02). However, there was no significant relationship between levels of 25-hydroxyvitamin D3 and complement C3 (Rho=0.09; p=0.12) or C4 (Rho=0.09; p=0.13). Both 25-hydroxyvitamin D3 deficiency (specificity 0.78 and 0.79; sensitivity 0.44 and 0.38, respectively) and anti-C1q (specificity 0.82 and 0.82; sensitivity 0.59 and 0.45, respectively) were more specific but less sensitive than anti-dsDNA (specificity 0.47 an 0.47; sensitivity 0.86 and 0.76, respectively) for concurrent clinical renal and non-renal SLE activity. Levels of 25-hydroxyvitamin D3, anti-dsDNA or anti-C1q did not correlate significantly with the SLE damage scores.

Conclusion: 25-hydroxyvitamin D3 correlated inversely and significantly with clinical SLE activity, anti-C1q and anti-dsDNA titers, but not with complement levels or damage scores. Deficiency of 25-hydroxyvitamin D3 was as specific as anti-C1q, but less sensitive than anti-dsDNA, for detecting concurrent renal and non-renal clinical activity of SLE.

2277

Number of Breastfed Babies Inversely Related to Development of Systemic Lupus Erythematosus Compared to Controls. April Barnado[1], Lee Wheless[2], Anna K. Meyer[2], Gary S. Gilkeson[3] and Diane L. Kamen[4]. [1]Duke University Medical Center, Durham, NC, [2]Medical University of South Carolina, Charleston, SC, [3]Division of Rheumatologyand Immunology, Medical University of South Carolina, Charleston, SC, [4]Medical University of SC, Charleston, SC

Background/Purpose: Given the strong female predominance in Systemic Lupus Erythematosus (SLE), hormonal factors may play a role in its pathogenesis. Prior studies on breastfeeding and the development of SLE have found inconsistent results. Utilizing data from a longitudinal study of Gullah African Americans, we examined the effect of parity and breastfeeding on the development of SLE by comparing cases to controls.

Methods: Gullah African American cases and controls with at least one live birth were drawn from a longitudinal observational cohort started in 2002. In-person interviews, examination, labwork determination, and chart reviews confirmed the case/control status of each subject. We collected demographic, socioeconomic, and reproductive data, specifically live births occurring before SLE diagnosis in cases and all live births for controls. Weeks of breastfeeding were summed across all pregnancies. Categorical variables were examined by chi-square tests. Differences in the means of continuous variables were tested using Student's t-test. Logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (CI), adjusting for age and education. Two-sided p-values < 0.05 were significant.

Results: Mean age at SLE diagnosis was 34.6 years. Compared to controls (n = 207), cases (n = 120) had significantly fewer mean live births (2.3 vs 2.8, p<0.01). Cases had a similar mean age at first live birth (21.3 vs 22.3, p=0.13) and years of education (13.0 vs 13.0, p=0.97). Cases were as likely as controls to have breastfed (30.8% vs 24.2%, p=0.19) with similar mean weeks of breastfeeding (11.9 vs 15.4, p=0.54) and mean number of babies breastfed (0.5 vs 0.8, p=0.06). Number of live births was not associated with risk of developing SLE (Table 1, p for trend=0.70). There was a non-significant trend for a decreased risk of SLE with longer duration of breastfeeding (vs 0: 2–12 weeks OR 1.35, 95% CI 0.67–2.71; 13–51 weeks OR 0.50, 95% CI 0.19–1.26, p for trend=0.20). However, the number of babies breastfed was associated with a significantly lower risk of SLE (Table 1, p for trend= 0.02).

Table 1. Odds ratios (OR) and 95% confidence intervals (CI) for development of SLE compared to controls in an African American population. All estimates are adjusted for age and education.

	# of live births before diagnosis (p for trend = 0.70)	**# of babies breastfed before diagnosis (p for trend = 0.02)**
# of events	OR (95% CI)	OR (95% CI)
0	–	1.00
1	1.00	0.59 (0.31–1.13)
2	0.96 (0.52–1.75)	1.21 (0.47–3.12)
3	0.86 (0.43–1.72)	0.33 (0.06–1.73)
≥ 4	0.57 (0.24–1.36)	0.13 (0.02–1.03)

Conclusion: Number of live births was not associated with risk of developing SLE, with rates of breastfeeding low among both cases and controls in this cohort. Number of babies breastfed was protective against development of SLE. However, duration of breastfeeding was not associated with a significantly decreased risk of SLE, possibly because prolactin levels peak early in lactation and may offer a protective role that is less significant as levels slowly decline after a few months. These results suggest that early breastfeeding may be more clinically important than duration and need further investigation.

2278

Predictors of Preterm Birth and Preeclampsia in Systemic Lupus Erythematosus. Megan E. B. Clowse, Lisa G. Criscione-Schreiber and David S. Pisetsky. Duke University Medical Center, Durham, NC

Background/Purpose: Women with systemic lupus erythematosus (SLE) are at increased risk for preterm delivery and preeclampsia. While increased SLE activity is the best known predictor of adverse pregnancy outcome, markers of inflammation (CRP and ferritin), placental health (estradiol and alpha-fetoprotein), and renal function (uric acid) are good predictors of pregnancy complications in the general population. In this study, we investigated whether these markers could predict adverse pregnancy outcomes in women with SLE.

Methods: We prospectively enrolled pregnant women with SLE by the 1997 ACR criteria to assess SLE activity markers, inflammation, and placental health between 20 and 29 weeks gestation. SLE activity was measured using the SLE pregnancy disease activity index (SLEPDAI) and the physician's global assessment (PGA), as well as the anti-dsDNA antibody titer, C3, C4, blood counts, creatinine, and urine spot protein: creatinine ratio. The sedimentation rate (ESR), C reactive protein (CRP) and ferritin were used to measure inflammation. Measures of placental health were alpha-fetoprotein (AFP) and estradiol. Correlation analyses were used to examine the bivariate relationship between potential predictors with the gestational week of delivery and preterm birth; a p-value<0.05 was considered statistically significant.

Results: We enrolled 33 women, none of whom had antiphospholipid syndrome, and evaluated 33 pregnancies. One pregnancy resulted in a stillbirth. Of the live births, 10 (31%) were delivered preterm (<37 weeks gestation) and 5 (16%) were complicated by preeclampsia.

In this cohort, no markers of SLE activity correlated with gestational age at delivery. Low complement (C3) (r=-0.39), elevated urine protein: creatinine ratio (r=0.41), and SLEPDAI (r=0.35) all correlated with preeclampsia.

The renal changes associated with preeclampsia can lead to an increase in serum uric acid. In this cohort, the presence of an elevated uric acid at mid-pregnancy correlated with early delivery (r=-0.42) and preeclampsia (r=0.43).

Since estradiol levels can increase dramatically in pregnancy due to production by the placenta, a lower than expected estradiol level may indicate placental dysfunction. In this cohort, having a lower estradiol level at the mid-pregnancy visit correlated with an earlier delivery (r=0.52). AFP, also a marker of placental health, was not associated with gestational age at delivery in this study.

While CRP and ESR did not correlate with pregnancy outcomes, elevated ferritin was correlated with lower gestational age at delivery (r=-0.51) and preeclampsia (r=0.45).

Conclusion: In women with SLE, low estradiol or an elevated ferritin or uric acid level at mid-pregnancy may predict preterm birth. Furthermore, preeclampsia may be predicted by an elevated ferritin or uric acid, in addition to markers of SLE activity, including low complement, elevated proteinuria, and elevated SLEPDAI score. Although levels of estradiol, ferritin, and uric acid have not been previously associated with pregnancy complications in women with SLE, these markers may prove to be clinically useful in identifying pregnancies at particularly high risk for adverse outcomes.

2279

Nitrated Nucleosome Levels in Patients with Systemic Lupus Erythematosus – Associations with Ethnicity and Autoantibody Status. Sara Croca, Charis Pericleous, Karim Alber, Harry Yong, Ian Giles, David A. Isenberg, Anisur Rahman and Yiannis Ioannou. University College London, London, United Kingdom

Background/Purpose: Many different autoantibodies have been described in patients with SLE and serological assays have concentrated mainly on measuring autoantibody levels. Measuring levels of modified autoantigens may also be valuable. Nucleosomes from apoptotic debris are known to play a key role in pathogenesis of SLE, especially lupus nephritis. Nitration of histones within nucleosomes may be enhanced in patients with SLE by the presence of increased serum levels of reactive nitrogen species characteristic of inflammatory states. We developed a novel assay for measuring serum nitrated nucleosome (NN) levels. Here we report on results of this assay in patients with SLE and associations with ethnicity and autoantibody profile.

Methods: Multiple stored serum samples (mean 8 per patient) from a cohort of 49 patients with SLE were tested. The samples had been obtained over a mean (SD) follow-up period of 89 (46) months. NN levels were measured using a novel capture ELISA: serum added to a streptavidin plate pre-coated with a biotinylated anti-nitrotyrosine antibody followed by detection with a rabbit anti-histone-3 antibody and then an anti-rabbit IgG HRP conjugated antibody. OD values were converted to standard absorbance units (AU) by comparison to a positive control sample loaded on every plate. The mean absorbance value for each of the patients was calculated. Univariate analysis was used to investigate association between these levels and age, gender, ethnicity, disease duration and autoantibody status.

Results: The assay yielded reproducible results with an intra and inter-plate coefficient of variation of <10%. The mean age of the patients was 36 years (SD 13) and 81% were female. 23 were Caucasian, 18 Afro-Caribbean (A-C) and 8 other ethnicities. 17 patients had no NN at any time-point. In the other 34 patients, NN levels varied over time (mean 32.4 AU; SD 62.2; min 0; max 270.4). Age, gender and disease duration were not associated with NN level. A-C patients had significantly higher NN than other ethnic groups (p=0.03). Anti-Sm positivity was strongly associated with higher NN levels. Mean NN was 103.5 AU in anti-Sm positive and 7.75 AU in anti-Sm negative patients (p<0.0001). The apparent effect of ethnicity may be mediated via anti-Sm positivity since A-C patients were significantly more likely than other ethnic groups to be anti-Sm positive (p=0.04) and within the A-C group, anti-Sm positive patients had significantly higher NN levels than anti-Sm negative patients (p= 0.0004). There was no relationship between NN levels and positivity for anti-La, anti-Ro, anti-RNP or antiphospholipid antibodies.

Conclusion: NN were found in the serum of 65% of patients with SLE. Anti-Sm positivity and Afro-Caribbean ethnicity were associated with significantly higher NN levels. Studies to investigate the possible association of NN with anti-nucleosome antibodies are under way.

2280

Free Fatty Acids Are Associated with Metabolic Syndrome and Endothelial Activation but Not Inflammation in Lupus. Michelle J. Ormseth[1], Larry L. Swift[1], Sergio Fazio[1], MacRae F. Linton[1], Cecilia P. Chung[1], Paolo Raggi[2], Young Hee Rho[1], Joseph F. Solus[1], Annette M. Oeser[1], Aihua Bian[1], Tebeb Gebretsadik[1], Ayumi Shintani[1] and C. Michael Stein[1]. [1]Vanderbilt Medical Center, Nashville, TN, [2]Div.of Cardiology, Emory University, Atlanta, GA

Background/Purpose: Free fatty acids (FFAs) affect insulin signaling and are implicated in the pathogenesis of insulin resistance and atherosclerosis. Inflammatory cytokines increase lipolysis and thus raise levels of FFAs. Elevated FFAs can promote endothelial dysfunction, which may increase atherosclerosis risk. We hypothesized that increased inflammation is associated with increased FFAs resulting in insulin resistance and atherosclerosis in patients with systemic lupus erythematosus (SLE).

Methods: Clinical variables, serum FFAs, homeostasis model assessment for insulin resistance (HOMA-IR), and coronary artery calcium were measured in 167 patients with SLE and 90 controls. Inflammatory cytokines and markers of endothelial activation were measured in 115 of the SLE patients and 83 of controls. We compared FFAs in SLE and controls using Wilcoxon rank sum tests and further tested for independent association by adjusting for age, race, sex and BMI using multivariable regression models. Among patients with SLE, we assessed the relationship between FFAs and inflammatory cytokines, HOMA-IR, markers of endothelial activation and coronary artery calcium scores using Spearman correlation and multivariable regression analysis. Continuous variables are described as median [IQR].

Results: Patients with SLE and controls (both groups 87% female) were of similar age (40 years [30–48] and 42 [30–49], P=0.93), but BMI was higher in SLE (27.3 [23.6–32.6] vs 25.2 [22.5–30.1]. FFAs levels were higher in patients with SLE than controls (0.56 mmol/l [0.38– 0.71] vs. 0.44 mmol/l [0.32– 0.60], P=0.008), but association was not significant after adjustment for age, race, sex and BMI (adjusted P=0.074). Metabolic syndrome was present in 25.1% (42/167) of SLE patients. In univariate analysis, FFAs were increased among SLE with metabolic syndrome (0.665 mmol/l [0.47–0.80] vs. 0.52 mmol/l [0.37– 0.66], P<0.001). FFAs levels did not differ by current immunosuppressive medication use (all P value>0.05). In patients with SLE, FFAs were not associated with insulin resistance (HOMA-IR), inflammation (IL-6, TNFα), or atherosclerosis (coronary calcium score) (all adjusted P values >0.2), but were positively associated with levels of triglycerides (adjusted P=0.018), E-selectin (adjusted P<0.001) and ICAM-1 (adjusted P=0.004).

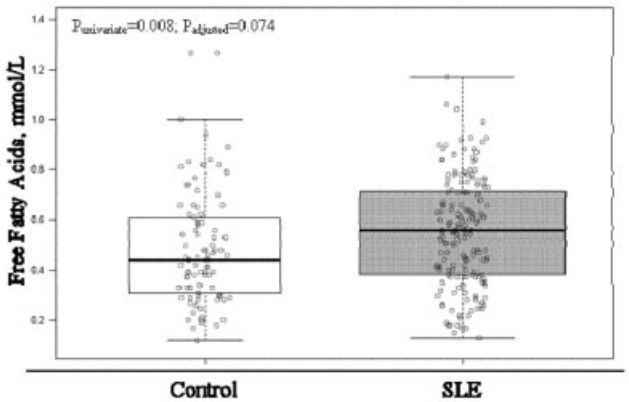

Figure 1. Free fatty acids concentration (mmol/L) in SLE and control subjects. *P univariate: Wilcoxon rank sum test; P adjusted: Multivariable linear regression was used for adjustment of age, race, sex and BMI.

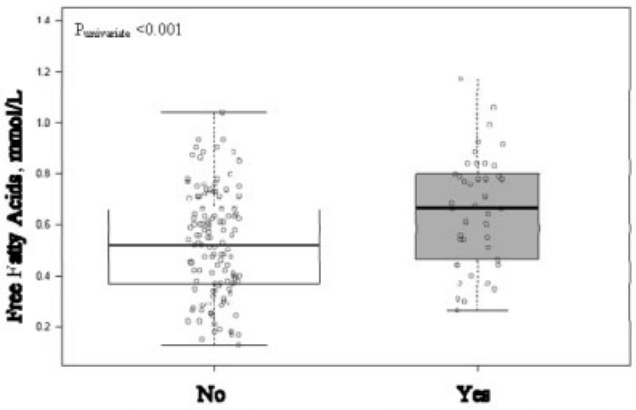

Figure 2. Free fatty acids concentration (mmol/L) in SLE patients without (No) and with (Yes) metabolic syndrome as defined by WHO criteria. *P univariate: Wilcoxon rank

Conclusion: FFAs are elevated in patients with SLE, particularly those with metabolic syndrome. FFAs in SLE are not associated with markers of generalized inflammation but are independently associated with triglycerides and markers of endothelial activation.

B Cell Depletion therapy and Pregnancy Outcome in Severe Refractory Autoimmune Disease. Pamela M.K Lutalo[1], Shirish Sangle[1], Rachel J. Davies[1], Munther A. Khamashta[2] and David P. D'Cruz[1]. [1]Louise Coote Lupus Unit, St Thomas' Hospital, London, United Kingdom, [2]Lupus Research Unit, The Rayne Institute, Kings College London School of Medicine, London, United Kingdom

Background/Purpose: Pregnancy is often associated with severe flares in active autoimmune diseases such as systemic lupus erythematosus (SLE) and ANCA positive vasculitis. Maternal and foetal outcomes are often poor if disease activity is not controlled prior to conception. We present an observational study of the antenatal and post-natal period of five women with severe, refractory autoimmune disease who received B-cell depletion therapy - Rituximab.

Methods: Four women with SLE and 1 woman with ANCA positive vasculitis fulfilling the ACR classification criteria who conceived following rituximab therapy were studied retrospectively. Three women had SLE complicated by aggressive crescentic WHO class IV lupus nephritis, 1 had SLE and immune thrombocytopenia (ITP) and 1 had ANCA positive vasculitis with an intra-orbital mass. All patients had previously failed or were intolerant to 3 or more immunosuppressive therapies. All received Rituximab (1gram) infusions on day 1 and day 15 after written informed consent. All immunosuppressive drugs, except oral corticosteroids and Hydroxychloroquine were stopped 2 weeks before the first infusion.

B-cell depletion was monitored by circulating CD19+ cell count on flow cytometry and patients were considered to have achieved B- cell depletion if absolute CD19 counts were $<$ 5 cell/ μL.

Results: Table 1. Baseline characteristics and pregnancy outcome

Table 1. Baseline characteristics and pregnancy outcomes

Pt	Age (yrs)	Race	Disease Duration (yrs)	AutoAb profile	Indication for BCDT	Previous therapy	Time of exposure before pregnancy (months)	Complications during pregnancy	Gestation age at birth (weeks)	Mode of delivery	BW (kg)	Neonatal Health
1	38	C	5	cANCA	WG, Intra orbital mass	Steroids HCQ, MTX, AZA, MMF, CyC, IVIG	10	Nasal septal perforation	40	C/S	2.9	Healthy neonate
2	39	C	10	dsDNA, Ro, La	SLE, Nephritis (IV+V)	Steroids HCQ, AZA, MMF, CyC, IVIG	18	Proteinuria > 3g/day at 21/40	31	C/S	1.17	Preterm low birth weight neonate
3	34	C	15	dsDNA	SLE, Nephritis (IV +V)	Steroids HCQ, AZA, MMF,	10	None	38	NVD	3.25	Healthy neonate
4	32	C	16	dsDNA	SLE, ITP	Steroids HCQ, AZA, IVIG, PE	22	None	40	C/S	3.2	Healthy neonate
5	32	AC	6	dsDNA, Sm, RNP, La, aCL	SLE, Nephritis (IV) APS	Steroids HCQ, AZA, CyC	8	Cutaneous lupus flare	38	NVD	3.3	Healthy neonate

Key: AC, Afro Caribbean; aCL anticardiolipin antibody; AutoAb autoantibody; AZA Azathioprine; BCDT, B-cell depletion therapy; BW (kg)birth weight in kilograms; C Caucasian; C/S Caesarean section; CyC Cyclophosphamide; dsDNA anti-double-stranded DNA antibody; HC Hydroxychloroquine; ITP, Immune thrombocytopenia; IVIG, Intravenous immunoglobulin; La anti-La antibody; MMF, Mycophenolate Mofetil; MTX, Methotrexate; NVD normal vaginal delivery; PE, plasma exchange NVD; RNP anti-RNP antibody; Ro anti-Ro antibody

Four women were Caucasian and 1 was Afro-Caribbean with a median age of 34 (range 32–39) years, median disease duration of 10 (range 5–16) years. All women responded to Rituximab therapy with a depleted B-cell count $<$ 1 cell/μL at 1 month and $<$ 5 cells/ μL 6 months post treatment. All women conceived within 22 months of treatment. Four women remained B-cell depleted throughout the course of their pregnancy. Median gestation period was 38 (range 31–40) weeks. Median birth weight of new born babies was 3.25 (range1.17–3.3) kg. All women had successful pregnancies with no congenital abnormalities. One new born (mother SLE with nephritis) needed observation in paediatric ITU for low birth weight.

Conclusion: A favourable pregnancy outcome is possible in women following B-cell depletion therapy with rituximab who have had previous refractory autoimmune diseases.

2282

Treatment of Hypertension and Hypercholesterolemia Is Not Successful in the Majority of Patients with Systemic Lupus Erythematosus. Elizabeth A. Pek[1], Dafna D. Gladman[2], Dominique Ibanez[1] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Patients with SLE demonstrate accelerated atherosclerosis and are at an increased risk of coronary artery disease. Previous quality improvement studies have demonstrated that increasing numbers of patients are being treated for hypertension and hypercholesterolemia. The objective of this study was to determine whether the initiation of treatment with antihypertensive or lipid lowering medications led to successful control of these risk factors.

Methods: Patients from the Toronto lupus cohort presenting within 1 year of SLE diagnosis and who received treatment with antihypertensive medications since 1985 and/or lipid lowering medications since 1995 were included. Success was defined as having met target blood pressure (BP), systolic BP $\leq$ 140 and diastolic BP $\leq$90 mmHg), serum total cholesterol (TC), TC $\leq$ 5.2 mmol/L or serum LDL, LDL $\leq$ 3.2 mmol/L during at least 90% of follow-up). Adjusted mean blood pressure and serum cholesterol values were calculated for one year prior to treatment initiation and for the duration of follow-up after treatment initiation.

Results: There were 441 inception patients seen after 1985 of which 234 (53%) had hypertension. Of these patients, 182 (78%) were initiated on anti-hypertensive therapy. 115 were included in our study (86% female, mean$\pm$SD age at treatment was 43.2$\pm$15.5, mean$\pm$SD disease duration at treatment was 2.8$\pm$4.2years). There were 287 inception patients seen after 1995 of which 195 (68%) had hypercholesterolemia. Of these patients, 56 (28%) were receiving appropriate treatment. 49 patients were included in our study (82% female, mean$\pm$SD age at treatment was 42.9$\pm$13.3, mean$\pm$SD disease duration at treatment was 3.2$\pm$3.6 years). Overall the adjusted mean systolic pressure decreased from 146.600$\pm$18.6 mmHg to 131.7$\pm$14.2 mmHg following treatment and the adjusted mean diastolic pressure decreased from 90.3$\pm$11.8 mmHg to 80.8$\pm$7.6 mmHg. However, only 39 of 110 patients (35%) met our criteria for successful treatment of hypertension. The adjusted mean total serum cholesterol and LDL decreased from 6.29$\pm$1.48 mmol/L to 4.76$\pm$1.01 mmol/L and 3.65 $\pm$ 1.29 to 2.56 $\pm$ 0.81 respectively. However, only 19 of 48 patients (40%) attained target total cholesterol levels while 25/40 (63%) attained target LDL levels during over 90% of follow-up.

Conclusion: Treatment of hypertension and hypercholesterolemia does not necessarily result in successful control of these risk factors in the majority of SLE patients. Further analysis will be important to discern the reasons for unsuccessful treatment and to compare CAD outcomes in patients who were successfully treated and those who were not.

Systematic Review and Meta-Analysis of the Association of Systemic Lupus Erythematosus and Malignancy. I.D. Dey[1] and David A. Isenberg[2]. [1]University College London Hospital, London, United Kingdom, [2]University College London, London WC1E 6JF, United Kingdom

Background/Purpose: There is a perceived increase risk of malignancy especially of Non-Hodgkin's lymphoma (NHL) in patients with Systemic Lupus Erythematosus (SLE). Many studies have investigated this association and the verdict is still open to debate. Also unclear is the possible role of immunosuppressive therapy and its contribution to this

risk. Previous studies have been limited by small cohort numbers and heterogeneous study groups. There have been new studies with larger cohorts of patients addressing these limitations but no systematic review has been done on the subject.

Methods: A systematic review of all relevant literature was conducted using Excerpta Medica Database (EMBASE), MEDLINE and PubMed databases, references of retrieved articles. Using keywords and MeSH terms relating to SLE, immunosuppressive medications and neoplasms. Cohort studies on SLE patients fulfilling the American College of Rheumatology (ACR) criteria were selected and data collated for review and meta-analysis. Meta-analysis was done using Relative risks (RR) with 95% confidence intervals to look for an association with malignancy with Comprehensive Meta-analysis software (CMA). Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines was used.

Results: 232 studies were identified after an initial search. 40 full text articles were selected after review of abstracts and application of inclusion and exclusion criteria. Of the 40 articles, final analysis was undertaken on 17 cohort studies selected for homogeneity after exclusion of case control, clinical series and duplicate centre studies.

The study review covers a period of 18 years from 1992 to 2010.

Out of 64135 patients, 2736 (4.26%) developed malignancy. Of the 17 cohort studies reviewed, eight reported significant association between malignancy and SLE. Nine of them did not show any association. Only one study revealed an association of overall malignancy with immunosuppressive medication. Seven did not show any association with medication use and nine studies were inconclusive or did not investigate this.

Meta-analysis indicates an association between malignancy and SLE.

Conclusion: Cohort studies to date seem to be equally divided on the issue of whether there is an increased incidence of malignancy in SLE patients. Meta-analysis of these studies however implies a positive association between malignancy and SLE.

Evidence of a link between malignancy in SLE and the role of immunosuppressive therapy in increasing that risk is inconclusive.

Keywords: Systemic Lupus Erythematosus, Lupus, Neoplasm's, Malignancy, Immunosuppressive therapy, Systematic Review, Meta-analysis.

Disclosure of Interest: Dr Ida Dey's fellowship training was supported partly by scientific training bursary from the European League against Rheumatism (EULAR).

Late Versus Early Development of Lupus Nephritis. Debra Dye-Torrington[1], Murray B. Urowitz[1], Dominique Ibanez[1] and Dafna D. Gladman[2]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Renal involvement is a common complication of Systemic lupus erythematosus, occurring in 50–60% of patients. A proportion of these patients will develop lupus nephritis as an initial presentation. The remaining patients will develop lupus nephritis later in the course of the disease. A recent longitudinal observational study of an inception cohort showed that of 107 patients who developed lupus nephritis 48(45%) did so after the first three years. 9% of these patients developed lupus nephritis after 10 years. In this study we compare the baseline characteristics of patients who developed early nephritis (within 3 years of entry into the clinic) with those who developed late nephritis (after 3 years) to determine predictors of late development of lupus nephritis.

Methods: Inception patients seen in clinic within one year of diagnosis of SLE were selected from a single centre cohort followed in an observational cohort study. Lupus nephritis was defined as sterile hematuria and/or pyuria, granular casts, proteinuria (>500mg/24hr), or elevated serum creatinine (defined as greater than 120μmols/l) on two or more consecutive visits attributed to SLE, or dialysis, transplant or WHO renal biopsy ≥ class 2. We identified patients who developed lupus nephritis after entry into the cohort. Early lupus nephritis was defined as those developing nephritis in the first 3 years. Patients developing lupus nephritis after three years were defined as having late lupus nephritis. The comparisons were done using t-test and chi-square test. Included in the model were sex, age at SLE diagnosis, race, SLEDAI-2K, steroids, antimalarial, immunosuppressant, complement and dsDNA at inclusion.

Results: 107 patients were identified from an inception group as having developed lupus nephritis in the course of their follow-up. This group was comprised of 89% female, 80% Caucasian. Mean (SD) age at SLE diagnosis was 34(13.9), mean (SD) SLEDAI -2K was 8.1 (7.4) and mean (SD) serum creatinine was 73.8(16.9). 51.0% had low complement and 49.5% had dsDNA antibodies. From this group, 59(55%) developed lupus nephritis within the first three years (early), while 48(45%) developed nephritis after three years. (Late). Comparison between early and late groups at first clinic visit showed that age at SLE diagnosis was younger in the early group Mean(SD) =30.9(12.2) compared to the late group.

Conclusion: Among patients who developed Lupus Nephritis after three years, age at diagnosis was the only significant predictor. Thus ongoing observation regarding renal involvement in SLE is important in all patients.

2285

Hospitalization in Patients with Systemic Lupus Erythematosus. Alhussain Asiri[1], Dafna D. Gladman[2], Anne G. MacKinnon[1] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: Patients with SLE may require frequent admission to hospital. Understanding the characteristics and risk factors of hospital admission of lupus patients would allow effective planning of services and resources utilization. We aimed to identify the causes and risk factors for hospital admissions and re-admissions of lupus patients to a network of three large teaching hospitals, and the outcomes of those admissions.

Methods: Patients who were admitted to the between January 2009 and December 2010, who had a diagnosis of SLE were identified and their information collected from electronic patient record. Simple calculations for percentages and means and P-values were performed.

Results: We identified a total number of 77 SLE patients admitted to hospital over the two year period with a total number of 165 admissions. SLE admissions represented 54% of total rheumatology admissions and 0.26% of total UHN admissions. The mean length of hospital stay in SLE patients was 14 days. When compared to patients in the lupus cohort seen during the same time period and not admitted to hospital, those admitted were more often Black, of younger age, shorter disease duration had a higher SLEDAI-2K and ACR/SLICC damage index. The main causes of admissions were disease flare 55 patients (71%) and infection in 16 patients (21%). Hospitalization outcome showed that in 27 patients (35%) the problem remained unresolved, 34 patients (46%) partially resolved and 14 patients (18%) had complete resolution of the primary problem. 22% had admission to ICU and 4% of patients died. 43 patients (56%) had re-admissions at least twice over 2 years. Mean hospital stay was 14 days for all admissions. Readmission causes were infections and non-resolved lupus flare in 44 % and 24 % respectively. Re-admissions for other medical or surgical causes accounted for 18% and 14% of the re-admissions respectively.

Conclusion: Admissions for SLE patients accounted for 54% of all rheumatology admissions. Major causes for admission are SLE flare and infection. There is a high rate of re-admission within a 2 year period. The major causes for re-admissions were infections and unresolved SLE flare. SLE patients utilize a significant proportion of rheumatology inpatient resources and services.

Few Pregnancies After Cyclophosphamide Treatment Despite Preserved Ovarian Function. Lindsey E. Harward[1], Kate Mitchell[2], Lisa G. Criscione-Schreiber[2] and Megan E. B. Clowse[2]. [1]Medical University of South Carolina, Charleston, SC, [2]Duke University Medical Center, Durham, NC

Background/Purpose: Cyclophosphamide (CYC), an alkylating agent used to treat severe autoimmune diseases, causes ovarian insufficiency. Our aims were (1) to retrospectively measure rates of ovarian protection used by women who underwent CYC therapy; (2) to measure the rate of ovarian failure in these women, (3) to measure how frequently women treated with CYC were able to complete their families and (4) compare pregnancy outcomes before and after CYC.

Methods: We enrolled women who had received CYC for rheumatologic disease before the age of 35. Participants completed a questionnaire about their reproductive health including information about their CYC treatment, desire for future children at the time of diagnosis, use of ovarian protection methods (leuprolide or oral contraceptives), current menstrual patterns, and information about each woman's pregnancy outcomes before and after CYC therapy. Additional information about dates of CYC treatment and cumulative dose was obtained from via chart review.

Results: This analysis included 23 women, mean age 32.9 years (range 21–45), who received CYC treatment at a mean age of 25.1 years (range 12–35). Diagnoses included SLE (19), scleroderma (1), granulo-

matosis with polyangiitis (Wegener's granulomatosis) (2), and SLE/scleroderma (1). The study group received an average cumulative CYC dose of 21,000mg (range 500 to 87,750 mg). CYC was given orally to 3 women, intravenously to 16, and by both routes to 4. CYC treatment lasted less than 6 months in 5 subjects (21.7%), 6–12 months in 7 (30.4%), and over 12 months in 11 (47.8%).

A form of ovarian protection was used by 10 subjects (leuprolide (7), oral contraceptives (3)). Cessation of menses occurred in 2 women prior to CYC and following CYC in 8 who had a mean age of 32.9 years at menopause, or 7.75 years (range 0 – 25) after CYC treatment. Of the remaining 13 women, 8 (34.8%) resumed regular menstrual cycles and 5 resumed irregular menstrual cycles following CYC. Women who had used ovarian protection had a higher rate of continuing regular menses (60%) than women who did not (15.4%, $p=0.02$).

The opportunity to have the number of children desired was limited by diagnosis prior to the completion of childbearing: 6% had the number of children desired when diagnosed prior to the completion of childbearing, compared to 57% diagnosed after childbearing ($p<0.01$) 10 women had never been pregnant. The remaining 13 women had 41 pregnancies (average 3.15 +− 1.8). Data was acquired for 39 pregnancies. Thirty-three pregnancies occurred before and 6 after CYC treatment. There were no significant differences in the number of live births, miscarriages, elective terminations, preterm births, or episodes of preeclampsia before and after CYC. No birth abnormalities were reported after CYC treatment.

Conclusion: The use of ovarian protective methods appears to improve the rate of regular menstruation in the years following treatment. However, menstruation may not indicate fertility, as despite menstruation, very few pregnancies occurred after treatment with CYC. Most participants in this study were unsuccessful in having the number of children they desired. This study highlights the need to study methods ovarian protections to determine whether they preserve fertility.

2287

Urinary Exosomal Microrna-192 and -195 As Potential Biomarkers of Renal Disease Activity in Lupus Nephritis. Hua Zhou[1], Gema Souto-Adeva[2], Donna Hardwick[2] and Gabor G. Illei[1]. [1]NIDCR/ NIH #10 1N110, Bethesda, MD, [2]NIH/NIAMS, Bethesda, MD

Background/Purpose: Urinary exosomes contain useful bioinformation and may serve as a novel source of biomarkers for kidney diseases. Renal microRNA (miR)-192 was increased in an animal model of diabetic nephropathy and increased expression of miR-195 was reported in kidney biopsies from class II lupus nephritis by microarray. The aim of the present study, was to explore whether miR-192 or miR-195 can reflect renal disease activity in lupus nephritis (LN) patients treated with Cytoxan.

Methods: Urine samples were collected from nine patients with active proliferative LN at baseline, 6 and 9 months post Cytoxan treatment. Urinary exosomes were isolated from 8 ml of urine sample in each urine collection by differential ultracentrifugation (520 × g for 10 min, 17,000 × g for 15min and 200,000 × g for 1hr at 4C). Total RNA was extracted from urinary exosomes with miRNeasy Kit. 25ng of total RNA were used in Taqman RT-PCR for analysis of miR-192, -195, and -27b (as the control of glomerular miRs due to abundant expression of miR-27b in renal medulla). The correlation among miRs and clinical parameters were analyzed by the Spearman correlation test, using the Prism 5 software package.

Results: The excretion of three urinary exosomal miRs significantly decreased at 6 and 9 months after cytoxan treatment compared to pretreatment in active LN patients. The level of urinary exosomal miRs did not correlate with urine concentration determined by urinary creatinine concentration. However, urinary exosomal miR-192 levels significantly correlated with urinary protein/creatinine (P/C, $r=0.56$, $p=0.031$) and so was urinary exosomal miR-195 ($r=0.60$, $p=0.018$). Albeit not significant, a similar trend was seen with urinary exosomal miR-27b and P/C ($r=0.31$, $p=0.26$). All three miRs correlated strongly with each other ($r=$ 0.68–0.8, $p<0.05$).

Conclusion: Urinary exosomes contain abundant miRs which can serve as a useful source for biomarkers. All three miRs decreased after cytoxan treatment. The difference in correlation between the level of miRs previously linked to diabetic nephropathy or lupus nephritis and miR-27b, which was used as a control, suggests a qualitative and not just quantitative change in exosomal miRs. However, the strong correlation among the three miRs tested supports the contrary and suggests that the correlation between miRs and proteinuria is a mere reflection of the improvement in the filtering function of the glomerular basement membrane. Further studies with a larger number of miRs are needed to assess the biomarker potential of urinary exosomal microRNAs in lupus nephritis.

2288

Nitrated Nucleosome Levels in Patients with Systemic Lupus Erythematosus—Associations with Disease Activity. Sara Croca[1], Charis Pericleous[1], Karim Alber[1], Harry Yong[1], Ian Giles[1], David A. Isenberg[2], Anisur Rahman[1] and Yiannis Ioannou[1]. [1]University College London, London, United Kingdom, [2]University College London, London WC1E 6JF, United Kingdom

Background/Purpose: Many different autoantibodies such as anti-nucleosome antibodies have been described in patients with SLE and serological assays have concentrated mainly on measuring autoantibody levels. Measuring levels of modified autoantigens may also be valuable. Since levels of reactive nitrogen species that promote nitration may rise with levels of systemic inflammation, we hypothesised that nitrated nucleosome (NN) levels may vary in parallel with disease activity. This abstract describes the result of longitudinal studies of NN levels and measures of disease activity in patients with SLE.

Methods: Longitudinal serum samples ($n=$ 398) were selected retrospectively from a cohort of 49 patients with SLE with a mean of 8 samples per patient (SD 2.16; min 3; max 14) and a mean follow-up of 89 months (SD 46; min 14; max 180). NN levels were measured using a capture ELISA. For all samples where data were available, we obtained anti-dsDNA and complement C3 levels and disease activity from a matching date and from the previous 3 assessments if these had occurred in the preceding 12 months. Using the British Isles Lupus Assessment Group (BILAG) index, we categorized the samples by disease activity as follows.

Current activity (on the date of the sample) was defined as high if global BILAG score was ≥5 and low if it was <5). Disease activity over the most recent 4 assessments was characterized as persistently low activity (all systems BILAG C, D or E) or persistently moderate-high activity (A or ≥1 B in any BILAG system on at least 2/4 occasions). 90% of all samples fell into one of those two categories and the rest were excluded.

Anti-dsDNA was defined as high or normal based on a cut-off of 50IU/ml. C3 was defined as low or normal based on a cut-off of 0.9g/l.

Results:

	Number of samples (*n*)	Mean (SD) NN level	*p*-value (high vs. low)
Persistently moderate-high activity	188	40.50 (51.7)	0.038
Persistently low activity	154	24.8 (72.3)	
BILAG< 5	204	25.6 (57.3)	0.045
BILAG≥ 5	171	37.9 (69.3)	
Anti-dsDNA			
High (>50IU/ml)	171	29,0 (48.1)	0.035
Normal(≤50IU/ml)	177	21.9 (38.6)	
C3			
Normal (≥0.9g/l)	207	20.8 (40.6)	<0.0001
Low (<0.9g/l)	138	31.6 (47.0)	

Conclusion: High NN levels were associated with high disease activity, high anti-dsDNA and low complement. In addition, flares in different organ systems may be associated with different levels of NN.

2289

Expression of Interferon-Inducible Genes Are Regulated by Sex Hormones and Gender in Systemic Lupus Erythematosus. Ravi Dinesh[1], Awlad Hossain[1], Bevra H. Hahn[1] and Ram P. Singh[2]. [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]David Geffen Schl of Med/UCLA, Los Angeles, CA

Background/Purpose: The goal of the present study was to determine the role of gender and the effect of sex hormones on the regulation of interferon genes in healthy individuals and in SLE patients, with particular attention to CD4+ regulatory T cells, which are fewer in number in women than in men in both the general population and in SLE patients.

Methods: Levels of interferon genes, sex hormones (17 b-estradiol, testosterone), cytokines, and chemokines were measured by real time PCR in peripheral blood cells, by ELISA in the serum/plasma of healthy donors, and

from the culture supernatant of peripheral blood mononuclear cells (PBMC) isolated from SLE patients and healthy controls. PBMC were immunophenotyped by flow cytometry, and mRNA gene expression studies were performed by real time PCR. Protein expression was analyzed by intracellular staining and by Western blot analysis. The *in vitro* effect of sex hormones 17 b-estradiol (60–100, 500pg/ml), and testosterone (100pg/ml) were studied by addition to cultures of sorted $CD4^{+}CD25^{hi}CD127_{lo}$ regulatory T cells for 24–72 hours. FACS/Western blot analyses of the cells were performed after culture.

Results: 1. Healthy women have significantly higher interferon related genes in PBMC ($p<0.02$) than healthy men.

2. Similarly, female BWF1 lupus mice have increased expression of interferon genes in spleen cells compared to age and sex- matched males.

3. Estradiol regulates interferon-inducible genes differentially in healthy controls and in SLE, with higher induction of IFN-inducible genes in the SLE population.

4. Estradiol increases proinflammatory cytokine generation, including positive correlation between plasma levels of estradiol and IL-21.

5. Plasma 17b-estradiol levels are significantly increased in female SLE patients compared to healthy females ($p<0.01$).

6. Testosterone (100 pg/ml) significantly increased FoxP3 expression in $CD4+CD25^{hi}$ cells from women with SLE ($p< 0.03$).

Conclusion: Women may be more susceptible than men to SLE and other autoimmune diseases in part because many healthy women have fewer CD4+ regulatory T cells, with less expression in PBMC of FoxP3 and more of interferon-regulated genes. In addition, women with SLE, compared to healthy women, have less ability to generate CD4+ Treg in response to physiologic concentrations of 17 b- estradiol, whereas testosterone metabolite increases the generation of Tregs. These data suggest that gender and sex hormones may influence susceptibility to SLE in part via their effects on regulatory T cells and interferon genes.

The Lupus Damage Index Questionnaire and Its Correlation with the SLICC/ACR Damage Index and the LupusQoL in a Spanish Multicenter Lupus Cohort. Is It Really Measuring Damage? José M. Pego-Reigosa[1], Íñigo Rúa-Figueroa[2], Teresa Otón-Sánchez[1], Manuela Fontanillo-Fontanillo[1], María Galindo-Izquierdo[3], Esther Uriarte-Isacelaya[4], Bruno Aspe-de la Iglesia[5], Laura Cáceres-Martín[2] and Félix Francisco-Hernández[2]. [1]Hospital do Meixoeiro, Vigo, Spain, [2]Hospital Universitario Dr Negrín, Las Palmas de Gran Canaria, Spain, [3]Hospital 12 de octubre, Madrid, Spain, [4]Donosti, Spain, [5]Vigo, Spain

Background/Purpose: Survival in patients with systemic lupus erythematosus (SLE) has improved over the last decades. Consequently, outcome measures such as accumulated damage and health-related quality of life (HRQOL) are gaining relevance. A self-assessed lupus organ damage instrument, the Lupus Damage Index Questionnaire (LDIQ), has been recently developed.

To study the correlation of accumulated lupus damage measured using the LDIQ with that measured using the SLICC/ACR damage index (DI). To analyze the correlation of both measures with SLE HRQOL measured using LupusQoL.

Methods: Multicenter cross-sectional study evaluating 156 patients with SLE. All patients completed the LDIQ and the LupusQoL. Four rheumatologists reviewed the clinical charts in order to calculate accumulated damage using SLICC/ACR DI. The correlation of the levels of damage measured using both instruments was calculated (Spearman's rho correlation coefficient). The correlation of damage with HRQoL measured using LupusQoL was calculated employing the same statistical test.

Results: One hundred and fifty-six patients (146 women and 10 men) were included in the study. The mean age (±S.D.) was 45.4 years (± 12.3). The mean time (±S.D.) since the lupus diagnosis was 15.5 years (± 8.9). The mean number (±S.D.) of lupus criteria was 5.6 (± 1.6) per patient. The mean time of years of study of the patients (±S.D.) was 11.1 (± 4.1).

The mean SLICC/ACR DI score was 1.1 (range 0–12) and the mean LDIQ score was 4.5 (range 0–18). The worst degree of agreement between SLICC/ACR DI and LDIQ was for renal damage (Spearman's $r = 0.13$, $p =$ n.s.). There was an important overestimation of neuropsychiatric damage (particularly neuropathy) by LDIQ compared to SLICC/ACR DI capturing 21 (15%) and 74 (49%) of the patients, respectively. The mean difference (±S.D.) between both damage scores was 2.7 (±2.5) and a clear trend towards lower differences was seen in the subgroup of patients with a longer period of education (>12 years) compared to that with <8 years. We found significant association of both damage scores with the number of lupus criteria and with the time since diagnosis of lupus. The global level of HRQoL was measured calculating the mean value of the eight domains that form the LupusQoL (the value ranges from 0–100 being 0 the minimum value and 100 the maximum value of HRQoL). The mean LupusQoL score was 64.0 (range 4.7–100). We did not find significant association of the LupusQoL scores with the time since the diagnosis and the number of lupus criteria that the patient fulfilled. The LDIQ scores had a significant correlation with the SLICC/ACR DI scores (Spearman's $r = 0.44$, $p < 0.001$) but a stronger significant negative correlation with LupusQoL scores (Spearman's $r = -0.48$, $p = 0.001$).

Conclusion: The correlation between the self-assessed LDIQ and SLICC/ACR DI is moderately high. The LDIQ tends to overestimate accumulated lupus damage (particularly renal and neuropsychiatric damage) compared with SLICC/ACR DI. This overestimation may be associated with a shorter period of education. The correlation of LDIQ scores with a HRQoL instrument scores such as LupusQoL is stronger than that with the traditional damage index scores (SLICC/ACR DI).

Anti-Dense Fine Speckled 70 Antibodies: Initial Study of Clinical and Laboratory Associations in a US Laboratory Patient Population. Gurpreet Rawat, Kathleen Hutchinson and Mark H. Wener. University of Washington, Seattle, WA

Background/Purpose: The recently recognized nuclear dense fine speckled immunofluorescence (IF) ANA pattern is associated with antibodies to the dense fine speckled 70 (DFS70) antigen. Presence of antiDFS70 may identify populations with a low prevalence of autoimmune rheumatic disease. A systematic evaluation of the associations of antiDFS70 has not been described previously in a U.S. clinical lab population.

Methods: Serum samples sent for ANA tests to our clinical laboratory were tested for ANA by a multiplex bead assay and HEp2 IF. Specimens with a positive IF ANA but negative for tested ANA subsets were identified. Randomly selected samples from that population were tested using a commercial anti-DFS70 ELISA and chart reviews were done on positive samples.

Results: 110 sera that were IFA positive but negative for ANA subsets were tested for anti- DFS70. Of those, 26 (24%) samples were positive.

Clinical data were available for 10 of the 26 DFS70-positive sera: 5 of the 10 were eventually referred to rheumatology. The IF ANA pattern was most commonly a mixed homogenous-speckled pattern (7/10). Three ANAs were homogenous alone. One serum had an ANA titer of 1:40, 4 had a 1:80 titer, 2 had 1:160 titer and 2 had 1:320 titer. One serum had an indeterminate RNP antibody, but no other ENA serologic abnormalities were present. Common clinical symptoms were arthralgias (6/10) and myalgias (3/10) with normal creatine kinase. 1 subject had documented synovitis. No other symptoms or signs of a connective tissues disease were present in the 10 subjects. One subject had transient lymphopenia and one subject had benign large granular lymphocytes. The ESR was elevated in 1/5 tested at 25 mm/hr. C-reactive protein was elevated in 3/5 tested, at 10.3, 14.3 and 20.9 mg/L. 2 subjects had echocardiograms: 1 normal, 1 with moderate diastolic dysfunction. One subject had pulmonary function tests showing mild restrictive disease. Diagnoses in the patients with DFS70 antibodies included 1 with multiple sclerosis, 1 with a history of ITP and 1 with hypothyroidism. There were no other autoimmune diseases noted. Other diagnoses included type II diabetes mellitus (2/10); obstructive sleep apnea (2/10); fibromyalgia (3/10); and polymorphic light eruption, migraines, and asthma in one subject each. There was no recorded history of atopic dermatitis, cystitis or malignancy (diagnoses previously reported with antiDFS70).

Conclusion: We found a moderate prevalence of antiDFS70 in sera ANA-positive by IF but without identified routine ANA subsets. Most of the positive samples were reported as having a combined homogenous-speckled pattern, similar to the recently described dense fine speckled pattern. Our positive sera had a range of ANA IF titers. None of our subjects had an identified autoimmune rheumatic disease. From this U.S. population, although small, we provide additional support for the proposal that sera with only DFS70 antibodies may help identify patients who do not have a rheumatologic disease despite a positive ANA IF test.

2292

The Workplace Activity Limitations Among Lupus Patients. Ali Al-Dhanhani[1], M. A. Gignac[2], Dorcas E. Beaton[3], Jiandong Su[4] and Paul R. Fortin[5]. [1]UAE University, Al Ain, United Arab Emirates, [2]Health Care and Outcomes Research, Toronto Western Research Institute; Dalla Lana School of Public Health, University of Toronto, Toronto, ON, [3]Ontario Workers Comp Institute, Toronto, ON, [4]The Toronto Western Hospital, Toronto, ON, [5]Toronto Western Hospital, Toronto, ON

Background/Purpose: Evidence in the literature suggests that people with lupus are at risk of work loss soon after diagnosis, but little is known about the experience of those people while at work. The objective of this study was to examine the extent of workplace activity limitations among persons with lupus and to determine factors associated with workplace activity limitations.

Methods: This is a cross sectional study using a mail survey of persons with lupus who attend a large single outpatient lupus clinic. We combined the survey data with the clinical data available for those patients from the clinic database. Eligible patient were those who read and wrote English and who were seen in the clinic in the previous two years. We used the workplace activity limitations measure (WALS), a 12-items scale that measures difficulty related to different activities at work. Through the survey, we collected data on demographics and health, work factors and psychosocial measures. Descriptive statistics, followed by univariate and multivariate (MV) regression analyses were performed.

Results: There were 604 eligible patients who were sent the survey. We had 362 responders (60% response rate). The mean age of respondents was 47.7 ± 15.0 and disease duration was 17.7±11.0. Eighty eight percent of responders were females. There were only 50% of respondent who were in the workforce. Among those who were not working, 52% reported not working because of lupus. In all the items of the WALS with one exception those who recently left the workforce had statistically significant more difficulty with work tasks compared to those who are currently at work table 1. Among working groups, 12% had difficulty in 9 items or more, compared to 43% among those who recently left the workforce. Those who left the work force had more difficulty in lifting, carrying or moving objects. Among those working, we document more difficulty crouching, bending, kneeling or working in awkward positions. In the multivariate analysis, factors associated with workplace activity limitations were age, disease activity, fatigue, health status measured by SF-36, job control, job strain, and working more than 40 hours/week.

Table 1. Percentage of people reporting difficulties in WALS items, a comparison between employed and not employed participants (but recently left the workforce in the previous five years) on the workplace activity limitations scale (WALS).

	Not employed (N = 65) %	Employed (N = 180) %	Difference (p-value)
1. How much difficulty would you have getting to and from work (e.g., subway, bus, car, walking) and getting to and from work on time?	32.3	17.9	0.0157*
2. How much difficulty would you have getting around the workplace (e.g., stairs, hallways, furniture)?	41.5	17.2	<0.0001*
3. How much difficulty would you have sitting for long periods of time at your job (e.g., more than 20 minutes)?	43.1	28.3	0.0293*
4. How much difficulty would you have standing for long periods of time at your job (e.g., more than 20 minutes)?	56.9	33.9	0.0012*
5. How much difficulty would you have lifting, carrying or moving objects?	64.6	42.2	0.0020*
6. How much difficulty would you have working with your hands (e.g., writing, typing, grasping small objects, holding a phone)?	52.3	27.2	0.0002*
7. How much difficulty would you have crouching, bending, kneeling or working in awkward positions?	60.0	57.8	0.7554
8. How much difficulty would you have reaching?	46.9	23.0	0.0003*
9. How much difficulty would you have with the schedule or hours of work that your job requires?	62.5	36.1	0.0003*
10. How much difficulty would you have with the pace of work that your job requires?	63.1	37.4	0.0004*
11. Overall, how much difficulty would you have meeting your current job demands?	60.3	36.7	0.0011*
12. As a result of your lupus, how much difficulty would you have concentrating or keeping your mind on your work?	63.1	38.6	0.0007*

Conclusion: People with lupus experience significant limitations and difficulty at work. Determinants of workplace activity limitations are mainly those related to health, and workplace related factors.

2293

Shrinking Lung Syndrome is a Multifactorial Process Featuring Reduced Lung Compliance and Extrinsic Ventilatory Restriction. Lauren A. Henderson[1], Stephen H. Loring[2], Ritu R. Gill[3], Katherine P. Liao[3], Matthew L. Stoll[4], Susan Kim[1], Paul F. Dellaripa[3], Deborah Rothman[5], Lawrence S. Zemel[6], Mary B. Son[1] and Peter A. Nigrovic[3]. [1]Children's Hospital Boston, Boston, MA, [2]Beth Israel Deaconess Medical Center, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Shriners Hosptials for Children, Springfield, MA, [6]Connecticut Childrens Med Ctr, Hartford, CT

Background/Purpose: The pathogenesis of shrinking lung syndrome (SLS) is poorly understood. We sought to identify the locus of pathology in SLS through detailed study of pulmonary physiology in affected patients.

Methods: SLS was defined to encompass patients with a systemic rheumatic disease who presented with dyspnea and all of the following: (1) decreased lung volumes on chest imaging; (2) pulmonary function tests demonstrating a restrictive ventilatory defect with normal diffusing capacity for carbon monoxide (DLCO), corrected for alveolar volume and hemoglobin concentration; and (3) absence of lung parenchymal pathology on chest computed tomography (CT). Patients who met these criteria and underwent pulmonary evaluation with esophageal manometry were identified. Demographic and clinical data were obtained from the medical records. Parameters examined included maximal inspiratory pressures measured by an esophageal balloon catheter (MIP_{es}) at defined lung volumes and static and dynamic lung compliances. Chest CT scans were reformatted to allow assessment of lung densities.

Results: Six SLS patients who underwent pulmonary evaluation were identified. All patients presented with dyspnea and had evidence of pleuritis manifested by pleuritic chest pain and/or pleural effusions. Chest imaging was free of parenchymal disease. Total lung capacities (TLC) ranged from 39% to 50% of predicted; however, corrected DLCOs were normal. Static and dynamic lung compliances were reduced in all patients. MIP_{es} were normal or near normal at functional reserve capacity (FRC), excluding overt respiratory muscle myopathy. In contrast, MIP_{es} at higher lung volumes were impaired in 5 patients, ranging from 12.2 to 23.7cm H_20 (normal: 25 to 35cm H_20), a finding consistent with an inability to fully expand the chest wall. Chest CT reformatting to assess lung density was available in 5 patients and showed increased lung densities. Re-evaluation after successful therapy in 1 patient showed improved MIP_{es} at FRC and TLC with no change in lung compliance.

Conclusion: In all patients studied, SLS manifested at least 2 concomitant pulmonary abnormalities: (1) reduced expansion of the chest wall upon inspiration, likely reflecting respiratory muscle inhibition by neural reflexes initiated by pleuritis; and (2) decreased lung compliance in the absence of radiographically evident interstitial lung disease, a well-recognized but poorly understood effect of chronic hypoventilation. Together, these findings suggest that SLS is primarily an unusual manifestation of pleural inflammation. Why some patients with pleurisy progress to SLS while others do not remains to be defined, but propensity to develop changes in lung parenchyma with hypoventilation is one intriguing candidate.

2294

Socioeconomic Status Is Associated with Disability in Pediatric Systemic Lupus Erythematosus. Mary Beth F. Son[1], Aimee O. Hersh[2], Hermine Brunner[3], B. Anne Eberhard[4], Emily von Scheven[5] and CARRAnet Investigators[6]. [1]Children's Hospital Boston, Boston, MA, [2]University of Utah, Salt Lake City, UT, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cohen Children's Hospital Medical Center, New Hyde Park, NY, [5]UC San Francisco, San Francisco, CA, [6]Durham

Background/Purpose: To evaluate socioeconomic status (SES), demographics, use of cyclophosphamide, and disease activity as predictors of disability in a diverse cohort of patients with pediatric-onset systemic lupus erythematosus (pSLE).

Methods: Cross-sectional data were obtained from the CARRAnet registry, a United States pediatric rheumatology database. Subjects included in the database were diagnosed with SLE at ≤18 years of age and were ≤ age 21 at enrollment. Disability was defined as a Childhood Health Assessment Questionnaire (CHAQ) score > 0 at enrollment. Multivariate logistic regression was used to determine predictors of disability. Gender, ethnicity, annual household income as a principal measure of SES, disease duration, previous or current treatment with intravenous cyclophosphamide as proxy for nephritis or cerebritis, and disease

activity at enrollment according to the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), were included as predictors.

Results: Data from 306 subjects enrolled at 44 sites were analyzed. Mean age at onset of symptoms was 12 ± 3 yrs (range 2.6–19.3 yrs). Mean disease duration was 3.6±2.7 years; 82% were female. Race/ethnicities included African American (33%), Caucasian (27%), Hispanic/Latino (22%), Asian (10%) and other (8%). 21% of the cohort had a household income of <$25,000/year. The median SLEDAI score at the time of enrollment was 4 (range 0–38). 32% had a current or prior history of treatment with intravenous cyclophosphamide. 131/306 (43%) subjects had disability defined as a CHAQ score>0; the mean CHAQ score was 0.23±0.43 and the median CHAQ score was 0 (range 0–3). In multivariate logistic regression analysis, low income was associated with disability (pseudo R2 = 0.088, Table 1).

Table 1. Regression-adjusted odds ratios for disability in the CARRAnet pediatric systemic lupus erythematosus cohort

Variable	Adjusted Odds Ratio (95% CI)
Disease Duration	1.00 (0.89–1.12)
Female	0.47 (0.21–1.07)
Ethnicity	
Caucasian	Referent
African American	1.23 (0.57–2.62)
Latino/Hispanic	1.30 (0.56–3.01)
Asian	0.49 (0.13–1.80)
Other	0.84 (0.23–3.1)
Household Income (in USD)	
≥75,0000	Referent
25,000–74,999	1.51 (0.69–3.30)
<25,000	2.69 (1.15–6.29)
SLEDAI	1.08 (1.01–1.15)
Cyclophosphamide Use	0.63 (0.33–1.22)

Conclusion: Disability was common in this cohort of pSLE subjects; the strongest predictor was SES as measured by household income. Additional studies are needed to better understand the relationship between SES and outcomes in pSLE.

2295

Performance of Complement C3, C4 and Anti-dsDNA Antibody in Predicting Disease Flare in Systemic Lupus Erythematosus: An Analysis of Data From 6035 Clinical Visits. Chi Hung To, Ka Lung Yu and Chi Chiu Mok. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To examine the performance of complement C3, C4 and anti-ds DNA antibody in predicting clinical disease flare in systemic lupus erythematosus(SLE).

Methods: SLE patients who were followed up in our clinics between 2000 and 2008 were studied. The date and clincial details of all visits during this period were retrieved from the electronic medical records. Disease flares (mild/moderate or severe), as defined by the SELENA-SLE flare instrument, were recorded. Disease activity scores during the flare episodes were measured by the SELENA-SLEDAI. The complements level C3, C4 and anti-dsDNA antibody titer checked within 4 weeks before the flare episodes (mild/moderate or severe) and the non-flare episodes were retrieved. Low C3 (LC3), very low C3 (VLC3), low C4 (LC4), and very low C4 (VLC4) were defined as 0.5–0.74g/L, <0.5g/L, 0.1–0.13g/L and <0.1g/L, respectively. Positive anti-dsDNA (PdsDNA) and highly positive anti-dsDNA (HPdsDNA) assay were defined as 50–300 IU/ml and >300 IU/ml respectively. The sensitivity, specificity, positive (PPV) and negative (NPV) predictive values of C3, C4 and anti-dsDNA in predicting disease flares were calculated.

Results: 218 SLE patients were studied. There were a total of 6035 clinical visits recorded. Among these, there were a total of 238 mild / moderate lupus flares, 178 severe lupus flares and 5778 non-flare episodes. The results were shown in table 1.

Table 1. Sensitivity, specificity, PPV and NPV of C3, C4 and anti-dsDNA antibody in predicting mild/moderate and severe lupus flares.

	Mild/Moderate Flares				Severe Flares			
	Sensitivity	Specificity	PPV	NPV	Sensitivity	Specificity	PPV	NPV
LC3	34.8%	63.2%	3.7%	95.9%	29.2%	63%	2.3%	96.7%
VLC3	43.1%	**87.5%**	12.3%	97.4%	51.1%	**87.4%**	11%	98.3%
LC4	19.1%	78.9%	3.7%	95.8%	19.2%	79%	2.8%	96.9%
VLC4	**49.1%**	74%	7.4%	97.2%	**52.9%**	73.9%	5.9%	98%
PdsDNA	**51.8%**	57.1%	5.1%	96.4%	**56.1%**	57.1%	4.1%	97.5%
HPdsDNA	28.4%	**89.1%**	10.3%	96.5%	26%	**88.8%**	7.1%	97.3%

Conclusion: The combination of complement C3, C4 and anti-dsDNA antibody is reasonably specific for predicting lupus flares in the preceding 4 weeks, especially for HPdsDNA and VLC3. However, these conventional markers are not sensitive for predicting lupus flares.

2296

Performance of Complement C3, C4 and Anti-dsDNA Antibody in Predicting Disease Flare in Individual Organ Systems in Systemic Lupus Erythematosus: An Analysis of Data From 6035 Clinical Visits. Chi Hung To, Ka Lung Yu and Chi Chiu Mok. Tuen Mun Hospital, Hong Kong, Hong Kong

Background/Purpose: To examine the performance of complement C3, C4 and anti-ds DNA antibody in predicting disease flare in individual organ systems in systemic lupus erythematosus(SLE).

Methods: SLE patients who were followed up in our clinics between 2000 and 2008 were studied. The date and clinical details of all visits during this period were retrieved from the electronic medical records. Disease flares in the five organ systems (cutaneous and musculoskeletal, serositis, hematologic flare, renal and neuropsychiatric) were defined by using the individual components of SLEDAI and the SELENA-SLE flare instrument and were recored during flare episodes. The complements level C3, C4 and anti-dsDNA antibody titer checked within 4 weeks before the flare episodes and the non-flare episodes were retrieved. Low C3 (LC3), very low C3 (VLC3), low C4 (LC4), and very low C4 (VLC4) were defined as 0.5–0.74g/L, <0.5g/L, 0.1–0.13g/L and <0.1g/L respectively. Positive anti-dsDNA (PdsDNA) and highly positive anti-dsDNA (HPdsDNA) assay were defined as 50–300 IU/ml and >300 IU/ml respectively. The sensitivity, specificity of C3, C4 and anti-dsDNA in predicting disease flare of individual organ systems were calculated respectively.

Results: 218 SLE patients were studied. A total of 6035 clinical visits were recorded. There were a total of 257 cutaneous and musculoskeletal flares, 119 hematologic flares, 108 renal flares, 26 serositis flares, 27 neuropsychiatric flares and 5778 non-flare episodes recorded. The results were shown in table 1.

Table 1. Sensitivity, specificity of C3, C4 and anti-dsDNA antibody in predicting disease flare of individual organ systems

	Cutaneous and musculoskeletal flare		Serositis flare		Hematologic flare		Renal flare		Neuropsychiatric flare	
	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity
LC3	35.9%	63.2%	23.1%	63.2%	34.5%	63.2%	28.7%	63.1%	28.6%	63.2%
VLC3	43.4%	**87.2%**	46.2%	**86.4%**	52.1%	**87.1%**	57.4%	**87.1%**	33.3%	**86.4%**
LC4	16%	78.9%	26.9%	79.1%	17.5%	78.9%	19.4%	79%	14.8%	79%
VLC4	**52.5%**	73.8%	34.6%	73.1%	**57%**	73.7%	55.3%	73.6%	34.6%	73.1%
PdsDNA	48.7%	56.9%	**66.6%**	56.8%	54.6%	56.9%	**61.1%**	57%	**60%**	56.8%
HPdsDNA	30.7%	**88.9%**	9.5%	**88.3%**	29.1%	**88.7%**	27.7%	**88.6%**	5%	**88.3%**

Conclusion: Anti-dsDNA lacks sensitivity in predicting serosal and neuropsychiatric lupus flares. Specificity for flares in any organ system is high for HPdsDNA and VLC3. The sensitivity of these conventional markers in picking up a lupus flare in any system is not impressively high. More sensitive novel biomarkers for predicting lupus flares are necessary.

2297

Digital Image Analysis Results Show High Reproducibility and Agreement with Human Interpretation on HEp-2 Cells. Gabriella Lakos, Carol E. Buchner, Cassandra C. Bryant, Pieter A. Baker, Rachel A. Rosenblum and Rufus W. Burlingame. INOVA Diagnostics, Inc., San Diego, CA

Background/Purpose: Evaluate the precision of the NOVA View® automated digital microscope system for anti-nuclear antibody (ANA) testing on HEp-2 cells based on nuclear light intensity units (LIU) and endpoint titration data. Additionally, compare the NOVA View results generated on 204 clinically defined sera to human interpretation of the same image captured by an automated camera and archived as a digital image.

Methods: For assessing intra-assay precision, four specimens with established patterns were assayed in the same run in 12 replicates. For inter-assay precision, five serum samples were tested in 25 runs that included two lots of HEp-2 slides, two lots of conjugates, and three operators. The %CV values were calculated based on nuclear LIU values generated by the NOVA View. Moreover, endpoint titers of four positive sera were established in 25 separate runs. To evaluate agreement, 204 clinically defined sera were processed for ANA testing on HEp-2 cells and then analyzed on the NOVA View automated system. A comparision of the nuclear LIU of the NOVA View with the reactivity obtained by human interpretation of the archived images was performed.

Results: The intra-assay and inter-assay precision was <20%. In the titration experiments, the same endpoint was found on average 15 times out of 25 runs

(range: 8–18), and the endpoint was one dilution lower or higher in the rest of the cases. Therefore, the 25 runs resulted in the same ± one dilution endpoint for all 25 runs for all four sera.

The qualitative discrimination by NOVA View was compared to the operator reactivity grading of the archived images. Depending on the chosen LIU cut-off values, the agreement between the automated and the human interpretation was 95.1% with a 100 LIU cut-off, and 96.1% with a 200 LIU cut-off, respectively. In the first setting there were 10 NOVA View positive/human interpretation negative results, while in the second setting there were 8 NOVA View negative/human interpretation positive results in the cohort.

Conclusion: Indirect immunofluorescence (IIF) testing on HEp-2 cells is considered the reference method for ANA detection. Lack of standardization of this method, however, still remains a concern. Sources of variability include the microscope and the interpretation by the operator. The NOVA View system offers automated evaluation of the IIF images, thereby decreasing sources of variability. Our results show that ANA detection by the NOVA View automated system is reproducible and reliable. The archived images can be stored and viewed or shared at any time. NOVA View provides the capability to quantify results which, in combination with high reproducibility, could provide the basis for ANA testing standardization.

2298

Serological and Clinical Associations of Anti-PCNA Antibodies in Systemic Lupus Erythematosus Detected by a Novel Chemiluminescence Assay. Michael Mahler[1], Marvin J. Fritzler[2] and John G. Hanly[3]. [1]INOVA Diagnostics, Inc., San Diego, CA, [2]University of Calgary, Calgary, AB, [3]Dalhousie University, Halifax, NS

Background/Purpose: Autoantibodies targeting proliferating cell nuclear antigen (PCNA) occur rarely in patients with systemic autoimmune rheumatic diseases, but are most commonly associated with systemic lupus erythematosus (SLE). The primary antigenic target is a 34 kDa protein that is part of the DNA polymerase delta multi-protein complex. The objective of the present study was to analyze the prevalence of anti-PCNA antibodies in SLE and various other diseases and healthy controls using a novel chemiluminescence immunoassay (CIA) and to evaluate a putative association with neuropsychiatric manifestations in SLE patients.

Methods: Sera or plasma from SLE patients (n=251), from individuals with various other diseases (n=257), and from apparently healthy blood donors (n=188) were tested for anti-PCNA antibodies by QUANTA Flash PCNA (research use only, INOVA Diagnostics) using commercially available recombinant human PCNA (Diarect AG, Freiburg, Germany) coupled to magnetic beads. SLE patient samples were also tested for other autoantibodies using the respective QUANTA Lite® ELISAs (INOVA Diagnostics). Statistical analysis (Fisher exact test, receiver operating characteristics (ROC) analysis) was done with ANALYSE-IT Version 2.03.

Results: Anti-PCNA antibodies were detected in 6% (15/251) of SLE patients, in 2.6% (1/38) of systemic sclerosis samples and in 4.3% (2/47) of rheumatoid arthritis patients. All other control samples were negative. Thus, the sensitivity for SLE was 6% (95% Confidence interval, CI 3.4–9.7%) with a specificity of 98.9% (95% CI 97.4–99.6%). The positive and negative likelihood ratios were 5.32 and 0.95, respectively. When SLE patients were compared to controls by ROC analysis, the area under the curve value was 0.88 (95% CI 0.85–0.90). Anti-PCNA antibodies were associated with anti-dsDNA (p=0.0250), anti-chromatin (p=0.0017) and anti-Ribosomal P antibodies (p=0.0058), but not with anti-RNP, anti-Sm, anti-SS-A (Ro60 and Ro52/TRIM21 mixture) or anti-SS-B.

Anti-PCNA antibodies, but none of the other autoantibodies were associated with lupus psychosis (p=0.0063). When NPSLE patients were compared to SLE without psychosis by ROC analysis, the AUC value was 0.83 (95% CI 0.65–1.00). At a cut-off of 20,000 RLU the sensitivity for NPSLE was 50.0% (95% CI 11.8–88.2%) and the specificity 95.1% (95% CI 91.6–97.4%). The positive likelihood ratio (LR) was 10.21 and the native LR 0.53.

Conclusion: Anti-PCNA antibodies are present in 6% of SLE patient sera, and are associated with anti-dsDNA, anti-chromatin and anti-ribosomal P antibodies as well as with lupus psychosis. In all of our samples, anti-PCNA antibodies were accompanied by at least one other autoantibody. Further studies using defined clinical subsets are required to verify the association between anti-PCNA antibodies and NPSLE.

2299

LupusPRO and Responsiveness to Changes in Health Status and Disease Activity Over Time. Meenakshi Jolly, Jessica Cornejo, Rachel A. Mikolaitis and Joel A. Block. Rush University Medical Center, Chicago, IL

Background/Purpose: LupusPRO is a disease targeted patient reported outcome measure for patients with Systemic Lupus Erythematosus (SLE). It has been developed from and validated among US patients with SLE. Herein, we sought to determine if LupusPRO domains (a) changed with changes in heath status and Disease activity and (b) if the direction of the changes observed paralleled the direction of changes in disease activity or health status longitudinally in SLE.

Methods: We utilized our observational longitudinal repository data of 69 SLE patients meeting ACR classification criteria. The data were collected as part of routine outpatient care of SLE patients at our center. wherein patients complete the LupusPRO along with a change in health status since previous visit (Likert responses range from −7 to 7). Disease activity was ascertained using the Physician Global Assessment (PGA) and the Lupus Foundation of America definition of Flare (Yes/No). Two visits data was available on all patients, while 28 and 13 patients had additional data from visit 3 and 4. Random Regression Model was used to analyze the relationship between LupusPRO domains and changes in disease and health related variables. Estimates of changes in domain scores were reported. P values less than 0.05 were considered as significance.

Results: The mean age (SD) of the patients was 43.9 (12.8) yrs. Ninety-Seven percent were women and 53% African-American, 21% Caucasian, 20% Hispanic and 6% Asian. Mean (SD) PGA and SLEDAI were 0.7 (0.8) and 3.6 (4.4). Mean (SD) SDI was 1.4 (1.8). Eighteen percent of patients were classified as having flare (LFA). Most of the domains seemed to be responsive to changes in disease and self reported changes in health over time. The changes in domains scores occurred in the expected directions (Table) and are summarized below.

Table. Estimates of Changes in the LupusPRO domains

LupusPRO Domain	PGA	LFA Flare	Change in Health Status
Symptom Scale	Unit Increase −9.99 p 0.0001	Yes −13.0 p 0.0001	Extremely Worse −10.7 p 0.03 Moderately Worse −13.0 p 0.0006 Minimally Worse −8.2 p 0.01 Extremely Better −9.6 p 0.06
Cognition			Moderately Worse −7.7 p 0.04
Lupus Medications	Unit Increase −4.9 p 0.04	Yes −8.5 p 0.02	Extremely Worse −16.9 p 0.004
Physical Health	Unit Increase −7.8 p 0.001		Extremely Worse −30.2 p 0.0001 Moderately Worse −16.2 p 0.003 Extremely Better 11.2 p 0.05
Pain Vitality	Unit Increase −9.7 p 0.002	Yes −13.5 p 0.004	Extremely Worse −37.6 p 0.0001 Moderately Worse −23.2 p 0.001 Minimally Worse −15.1 p 0.001 Extremely Better 14.9 p 0.03
Emotional Health			Extremely Worse −17.3 p 0.0006 Moderately Worse −8.3 p 0.02
Body Image			Extremely Worse −10.1 p 0.04
Desires & Goals			Extremely Worse −21.2 p 0.002 Moderately Worse −15.2 p 0.003 Minimally Worse −10.4 p 0.03
Social Support		Yes 10.2 p 0.04	Moderately Worse 10 p 0.08
HRQOL Summary	Unit Increase −3.7 p 0.003	Yes −3.8 p 0.04	Extremely Worse −10.9 p 0.0004 Moderately Worse −5.8 p 0.007 Extremely Better 8.5 p 0.03

Conclusion: LupusPRO domains seem to be sensitive to changes in disease and health status over time and in the expected directions in this observational non clinical trial non intervention based data repository from SLE patients. We did not experience the full spectrum of changes in disease activity and health status to better assess the responsiveness of the tool. However within the constraints of the study design data support responsiveness of the domains. Its inclusion into clinical trials for further responsiveness evaluations are now indicated. None.

2300

Analysis of Risk Factors for Relapses and Chronic Renal Failure in Lupus Nephritis: Long Term Follow-up of Biopsy Proven 172 Patients Followed at a Single Center. Bahar Artim-Esen[1], Yasemin Özlük[2], Isin Kilicaslan[2], Ahmet Omma[1], Özlem Pehlivan[1] and Murat Inanç[1]. [1]Istanbul University, Istanbul Faculty of Medicine,Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

Background/Purpose: Renal involvement is a major cause of mortality and morbidity in systemic lupus erythematosus (SLE) and carries a 10–25 % risk of chronic renal failure (CRF). In this study, we aimed to analyse the

characteristics and course of lupus nephritis (LN), determine the risk factors for flares and CRF.

Methods: An analysis of 172 patients with histopathologically proven LN registered and followed-up in our clinic (lupus clinic after 1993) between 1980 and 2010 was performed. Patients with adequate histopathologic and clinical data were selected for analysis. Biopsies were classified by both WHO and ISN/RPS 2003 systems by an experienced nephropathologist(IK). The association of clinical characteristics of the cohort with renal flares and outcome was investigated. Logistic regression analysis was done and Kaplan-Meier's method was used for survival analysis.

Results: Eighty-one % of the cohort was female. Duration of renal disease was 103±66 and follow-up was 100±67 months. Class IV nephritis was the most frequent (55%) followed by class V (15%), class III (11%), class II (10,5 %) and combined(6,6%). Cyclophosphamide was used for remission induction in 80 %. Remission was achieved in 90 %. CRF developed in 25 patients (14,5 %), 4 of whom were transplanted and 8 stayed on permanent dialysis. There were 53 flares in 38 patients and the most common type was proteinuric (60,4%). Comparison of patients with and without a flare revealed that in non-relapsing patients, cyclophosphamide was more significantly used for remission induction (85 % vs 60%, p<0,001) and more patients were on mycophenolate mofetil (MMF) for maintenance (38 vs 12%, p=0,004). When active and chronic lesions at renal biopsies were compared, the presence of fibrous crescents was significantly prevalent in the relapsing group (17 vs 2%, p<0,001). At multivariate analysis not being on MMF at maintenance, fibrous crescents at biopsy, lack of exposure to cyclophosphamide at remission induction and anti-Sm positivity were found to be risk factors for flare. Of patients with a flare, 31,6% developed CRF (vs 6,6 % in non-relapsing group, p<0,001). Comparison of patients who developed CRF to others, revealed that presentation with acute renal failure (ARF), hypertension and increased creatinine, occurrence of a flare, fibrous crescents at biopsy were more frequent in CRF + group (60 vs 19 %, p <0,001; 28 vs 10 %, p=0,009, 47 vs 8 %, p<0,001; 33 vs 12 %, p=0,03; 30 vs 2 %, p<0,001 respectively). Significantly less number of patients were on MMF at maintenance in CRF + patients (16 % vs 38%, p0,03). At logistic regression analysis, hypertension followed by fibrous crescents at biopsy and maintenance without MMF were found as risk factors for the development of CRF. Comparison of survival between patients with CRF to others showed significantly reduced survival in patients with CRF after 20 years (64 vs 90%; p=0,02).

Conclusion: Flares and chronic renal failure have a negative impact on the outcome. Cyclophosphamide usage for remission induction, MMF for maintenance and tight control of hypertension may reduce the risk of flares and development of CRF. Renal histopathologic features can be a predictive tool for renal outcome.

2301

Clinical Impact of Frequency of Visits in Systemic Lupus Erythematosus. Dafna D. Gladman[1], Dominique Ibanez[2] and Murray B. Urowitz[2]. [1]Toronto Western Hospital, University of Toronto, Toronto, ON, [2]Toronto Western Hospital and University of Toronto, Toronto, ON

Background/Purpose: The ACR committee on SLE guidelines recommends that patients with SLE be reviewed on a regular basis, with the frequency of visits based on the activity and severity of the disease and its complications. The aim of this study was to determine the optimal frequency of follow up visits in patients with SLE.

Methods: Patient selection: Patients followed in a large observational cohort lupus clinic from January 1, 2009 to December 31, 2010 who had at least 3 visits and at least 18 months of follow up were included. At each visit patients undergo a complete history, physical examination and laboratory evaluation. The following variables of interest that would not have been recognized by the patient were identified: proteinuria, hematuria, pyuria, casts, low haemoglobin, leucopenia, thrombocytopenia, elevated serum creatinine, positive anti-DNA antibodies and low complement. At each visit when one of these variables was detected, it was determined whether it was new, and whether other features of activity were present. Thus isolated new variables of interest were identified. Descriptive statistics were used.

Results: 515 patients met the inclusion criteria of having at least 3 visits and 18 months of follow up for a total of 3126 visits. The average length of time between visits was 3.8±1.0 months. There were 461 (89.5%) female, 315 (61%) Caucasian, 82 (16%) Black, 54 (11%) Asian, and 64 (12%) other. Age at SLE diagnosis 28.0± 12.6 (range = 6.0 to 79). At 1st clinic visit within the study period the mean age was 42.2 ± 15.1, disease duration was 14.2 ± 10.6 years (range = 0 to 56), SLEDAI-2K score was 4.1 ± 4.5 (range 0 to 34), with an adjusted mean SLEDAI of 3.87 ± 3.44 during the study period (range 0 to 180. The SLICC ACR damage index score was 1.51 ± 1.89 (range 0 to 11). Of the 515 patients, the variables of interest were the sole manifestation of SLE (ie SLEDAI-2k excluding new variable = 0) in 127 (24.7%) of the patients (in a total of 173 visits). Table 1 shows the frequency of the new isolated variables of interest in the patients and visits.

Variable	Number of visits with "new" (out of 173)	Number of patients with ≥1 visit with "new" (out of 127)
Cast	16	16
Hematuria	10	9
Proteinuria	15	15
Pyuria	42	35
Low complement	55	45
DNA antibodies	36	32
Thrombocytopenia	8	7
Leukopenia	7	7
Serum creatinine	9	8
hemoglobin	6	6

The commonest manifestations were renal, low complement and DNA antibodies but important manifestations such as thrombocytopenia, low haemoglobin and elevated creatinine were also seen.

Conclusion: 1 in 4 patients with SLE seen over a 2-year period will have a solitary silent variable of interest that could only be detected by routine laboratory follow –up. All patients with SLE should be followed with clinical and laboratory measures at 3 month intervals.

2302

Quality of Life Measures Are Not Associated and Have No Discriminative Validity in Lupus Patients for Different Levels of Disease Activity. Zahi Touma[1], Dafna D. Gladman[2], Dominique Ibanez[1], Shahrzad Taghavi-Zadeh[1] and Murray B. Urowitz[1]. [1]Toronto Western Hospital and University of Toronto, Toronto, ON, [2]Toronto Western Hospital, University of Toronto, Toronto, ON

Background/Purpose: A previous study showed that there is no superiority of LupusQoL over Short Form-36 in assessing lupus patients' quality of life with mild disease activity over 12 months. The utility of SF-36 and LupusQoL needs to be evaluated in patients with moderate to severe disease activity.

The objective of this study is to determine if among active lupus patients with moderate to severe disease activity, SF-36 and LupusQoL are associated with and have discriminant validity for different levels of disease activity.

Methods: This is a cross-sectional study conducted on lupus patients seen in a single center between September 2009–April 2011. At the baseline visit all patients had SLEDAI-2K ≥6. Patients completed both questionnaires on the baseline and follow-up visits.

We included the last available visit for each patient in the analysis. At the follow-up visit patients were grouped as follows: improved (if SLEDAI-2K decreased by ≥4) or same/worse.

We studied the association for each of the 8 domains of both questionnaires with SLEDAI-2K at the baseline and at the follow-up visit.

Discriminative validity was determined separately in the group who improved or was worse/same by comparing the mean scores for each of the 8 domains in both questionnaires at the baseline and the follow-up visit using t-test.

Results: 55 patients with SLEDAI-2K≥6 were indentified and included in the study. The demographics of the 55 patients are presented in table 1.

Table 1. Patients' characteristics

Sex	Female 48 (87%)/7 (13%)
Age at diagnosis (years)	28.1 ± 12.2
Age at 1st visit in the study (years)	39.1 ± 12.7
Disease Duration at 1st visit in the study (years)	10.9 ± 7.8
Race	
Caucasian	20 (36%)
Black	22 (40%)
Asian	6 (11%)
Others	7 (13%)
SDI at 1st visit in the study	1.5 ± 1.6
Prednisone at baseline visit: patients number (%)	46 (84%)
Anti-malarial number: patients number (%)	40 (73%)
Immunosuppressants: patients number (%)	40 (73%)

Mean SLEDAI-2K was 10.8±4.6 at the baseline visit and 8.4±5.0 at the follow-up visit. The length of the study was 4.8±2.3 months.

No association could be found between the 8 domains of both questionnaires and disease activity at both baseline and follow-up visits (Table 2) (all $p>0.05$).

Table 2. Association of LupusQoL and SF-36 with SLEDAI2K at baseline and follow-up visits

Domains	Baseline visits	Follow-up visits	Domains	Baseline visits	Follow-up visits
LupusQoL	**Correlation (p)**			**SF-36**	**Correlation (p)**
Physical Health	−0.02 (0.98)	0.06 (0.68)	**Bodily Pain**	−0.11 (0.43)	−0.01 (0.92)
Emotional Health	−0.20 (0.14)	−.020 (0.14)	**General Health**	0.14 (0.30)	0.18 (0.20)
Body Image	−0.11 (0.44)	−0.21 (0.12)	**Mental Health**	−0.16 (0.23)	−0.05 (0.70)
Pain	0.06 (0.66)	0.06 (0.65)	**Physical Functioning**	0.17 (0.22)	−0.02 (0.87)
Planning	0.04 (0.76)	0.04 (0.78)	**Role Emotional**	−0.16 (0.26)	0.02 (0.89)
Fatigue	−0.07 (0.61)	−0.005 (0.97)	**Role Physical**	−0.002 (0.99)	−0.12 (0.40)
Intimate Relationships	0.17 (0.27)	−0.06 (0.71)	**Social Functioning**	−0.16 (0.25)	−0.13 (0.34)
Burden to others	−0.25 (0.07)	−0.12 (0.40)	**Vitality**	−0.10 (0.48)	0.06 (0.65)
			PCS	0.13 (0.35)	−0.04 (0.77)
			MCS	−0.25 (0.07)	0.00 (0.95)

Both questionnaires showed no discriminative validity to different levels of disease activity; improved and same/worse (Table 3).

Table 3. Follow-up means comparing patients who improved (n=21) to patients who worsened/same (n=34)

	Improved n=21	Same/ worsened n=34	p values		Improved n=21	Same/ worsened n=34	p values
Disease Activity	**SLEDAI-2K**						
Baseline	12.7 ± 5.7	9.7 ± 3.4	0.04	Baseline	12.7 ± 5.7	9.7 ± 3.4	0.04
Follow-up	5.0 ± 4.3	10.4 ± 4.2	<0.001	Follow-up	5.0 ± 4.3	10.4 ± 4.2	<0.001
Domains				**Domains**			
LupusQoL	**Mean scores**				**SF-36**	**Mean scores**	
Physical Health	71.9 ± 26.0	62.2 ± 24.3	0.17	**Bodily Pain**	68.3 ± 27.3	61.8 ± 28.3	0.41
Emotional Health	77.8 ± 18.9	71.6 ± 25.0	0.34	General Health	48.4 ± 16.1	50.5 ± 23.7	0.72
Body Image	72.2 ± 21.8	66.0 ± 29.5	0.41	Mental Health	66.0 ± 15.2	68.3 ± 25.0	0.67
Pain	76.2 ± 26.1	69.1 ± 29.2	0.36	Physical Functioning	68.2 ± 28.3	58.8 ± 29.2	0.25
Planning	78.6 ± 28.5	73.8 ± 29.2	0.52	**Role Emotional**	60.0 ± 44.1	66.7 ± 43.2	0.59
Fatigue	64.7 ± 18.9	61.7 ± 26.8	0.67	Role Physical	50.0 ± 45.2	44.5 ± 45.7	0.67
Intimate Relationships	81.3 ± 21.4	56.3 ± 37.7	0.01	Social Functioning	73.2 ± 29.9	63.2 ± 29.3	0.23
Burden to others	64.5 ± 28.1	55.6 ± 26.6	0.25	Vitality	47.1 ± 18.1	52.2 ± 23.1	0.40
				PCS	43.1 ± 11.0	39.1 ± 11.7	0.22
				MCS	44.8 ± 11.0	47.6 ± 14.0	0.47

Conclusion: SF-36 and the LupusQoL are not associated with disease activity in this group of patients with moderate to severe disease activity. SF-36 and the LupusQoL have no discriminative validity to different levels of disease activity.

2303

The Influence of Age of Onset of Systemic Lupus Erythematosus and Disease Duration on Lupus Manifestations. Nayef Al Ghanim[1], Jiandong Su[2], Ellie Aghdassi[3], Wendy Lou[1] and Paul R. Fortin[4]. [1]University of Toronto, Toronto, ON, [2]The Toronto Western Hospital, Toronto, ON, [3]University Health Network, Toronto, ON, [4]Toronto Western Hospital, Toronto, ON

Background/Purpose: To investigate the influence of age of Systemic Lupus Erythematosus (SLE) onset and disease duration on the SLICC damage index (SDI).

Methods: Patients were identified from a single large lupus registry if they met four of the American College of Rheumatology classification criteria or 3 criteria and lupus histology on skin or kidney tissue. Patients were divided into two groups based on age of onset at diagnosis of SLE with Early onset (EOS) defined as those with SLE diagnosis between the ages 18 and 47 and Late onset SLE (LOS) at age 48 and more. We limited this study to an inception cohort defined as all those entered into the registry within one year of SLE diagnosis. Data on demographics, age at enrollment, SDI items and total score were collected. Chi-square tests were used to compare categorical variables. SLICC items were summarized by organ systems and then converted to a binary variable (0= negative, 1= score of 1 or more). The total SLICC scores in the two groups were compared using Wilcoxon Rank Sum test.

Results: Our sample included 653 patients with 514 EOS and 139 LOS. The majority of patients were female in both groups (88.1% in EOS vs. 82.0% in LOS; p=0.058). Caucasians were represented more in LOS (82.0% in LOS vs 69.9% in EOS; p=0.005). At 5 years follow-up, LOS patients were more likely to have cardiovascular manifestations (18% in LOS vs 6% in EOS. p=0.005). At 10 years follow-up, LOS patients have higher rate of ocular (28.9% vs 13.2%. p=0.01) and cardiovascular manifestations (23.7% vs 7.9%. p=0.005). There was no statistically significant difference in renal manifestations. Total mean SDI score was 1 in both groups at 5 and 10 years follow-up (p=NS). Comparing SDI manifestations over time (at the fifth versus the tenth year), EOS developed significantly more damage at the tenth year in ocular (9.8% vs 15.2%, respectively; p=0.01), cardiovascular (7.1% vs 10.7%; p=0.04), musculoskeletal (17% vs 26.8%; p=0.0009) and dermatological (3.6% vs 8%; p=0.02) organ systems. Similarly, LOS developed significantly more damage at the tenth year in musculoskeletal (9.1% vs 27.3%; p=0.04). In both groups, the total SLICC score increased from 0 to 1 over ten years (p=0.0005) and as expected, patients with longer follow-up have higher SLICC scores.

Conclusion: SLE damage reflects age of SLE onset diagnosis and disease duration.

2304

Prescribing Practices of Hydroxychloroquine World Wide. Seema Malani. SUNY Downstate Medical Center, Brooklyn, NY

Background/Purpose: Hydroxychloroquine (HCQ) has been used for the treatment of systemic lupus erythematosus (SLE) and other autoimmune diseases. Maculopathy is the most feared complication limiting its use. Our purpose with this survey was to determine if there is any correlation between the dosing practices of rheumatologists for HCQ and the incidence of maculopathy.

Methods: Approximately 1800 rheumatologists worldwide were invited to participate in an electronic survey with 20 questions pertaining to the use of HCQ. The survey included questions regarding use for various manifestations of SLE, side effects most noted and risk factors for maculopathy considered important by prescribers, and whether renal or hepatic function, ideal or actual body weight were taken into consideration while dosing HCQ.

Results: 582 physicians responded to the survey with 252 from North America, 151 from Europe, 109 from Asia, 66 from South America and Australia.

96% of respondants start HCQ at the time of diagnosis of SLE, 28.9% at the time of a flare and 51.6% would start even in established patients with SLE who were not on HCQ in the past. 98% of rheumatologists prescribed HCQ for arthritis with SLE, while 97.3% for cutaneous manifestations, 65.9% for fatigue, 39% for hematological indications and 26.7% for lupus nephritis (45.6% from Asia vs 22.5% from remaining respondants; p=0.000003). 52.1% would start HCQ in women planning pregnancy if symptomatic, while 31.2% even if no disease activity was present while 16.6% would not start at all. 79.8% and 61.3% stated that they would, however, continue HCQ if a patient with SLE becomes pregnant or is nursing while on it.

About 81% agreed that HCQ was beneficial for the overall survival of lupus patients. Of risk factors known for maculopathy, 79.1% considered underlying retinal or macular problems as the most significant, 49% a daily dose of more than 6.5 mg/kg actual or ideal body weight and about 32% each - age greater than 60 years, cumulative dose more than 1000 grams exposure, impaired renal function. Obesity and impaired hepatic function were not considered important by the majority.

54.2% used a fixed daily dose of 400 mg, while 31.1% adjusted the dose to actual body weight, 14.6% to ideal body weight. 33.3% and 23% adjusted for impaired renal and hepatic functions, respectively. However, there was no significant difference in maculopathy reported worldwide based on the dosing regimens with 86.6% reporting the incidence as less than 1%. GI side effects were the most common reported adverse events (74.8%) followed by skin pigmentation (72.4%), muscle weakness (27%), hematologic (11.6%) and cardiac (7.4%) effects. 94.8% of respondents from Asia and South America reported skin pigmentation vs 64.4% from the other continents ($p=1.38\times10^{-11}$).

Conclusion: The use of HCQ among rheumatologists worldwide did not differ and the dosing regimens did not affect the incidence of maculopathy. The indications and side effects appear to differ amongst the treating physicians especially from Asia and South America.

2305

Cluster Analysis of Autoantibodies in 852 Patients with Systemic Lupus Erythematosus From a Single Center: Four Main Clusters with Prognostic Implications. Bahar Artim-Esen[1], Erhan Çene[2], Yasemin Sahinkaya[1], Semra Ertan[1], Özlem Pehlivan[1], Sevil Kamali[1], Ahmet Gül[1], Lale Öcal[1], Orhan Aral[1] and Murat Inanç[1]. [1]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [2]Yildiz Technical University, Department of Statistics, Faculty of Arts and Sciences, Istanbul, Turkey

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with various serological and clinical manifestations. Associations between autoantibodies and clinical features have been described. Herein, we aimed to define autoantibody clusters and their clinical correlations in a large cohort of lupus patients.

Methods: We analysed 852 patients who attended our clinic (lupus clinic after 1993) between 1980 and 2010. Mean duration of disease was 115±85,9 months and 87% was female. Seven autoantibodies, namely anti-DNA, anti-Sm, anti-RNP, anticardiolipin IgG or IgM (aCL IgG/M), Lupus anticoagulant (LAC), anti-Ro, anti-La were selected for cluster analysis to identify subsets of lupus patients with similar autoantibody patterns. K-means cluster and Kaplan-Meier survival analyses were used.

Results: The frequencies of the selected autoantibodies in the cohort were as follows: anti-dsDNA 70%, anti-Sm 19%, anti-RNP 15%, Anti-Ro 24%, anti-La 11%, LAC 11%, aCL IgG/M 29%. Four clusters were identified by cluster analysis. Cluster 1 consisted of anti-Sm and anti-RNP, cluster 2 of anti-dsDNA only, cluster 3 of anti-Ro and anti-La and cluster 4 of aCL IgG/M autoantibodies. Although it did not reach statistical significance, LAC was more prevalent in cluster 4. Patients in cluster 1 when compared to 3 other clusters had significantly higher incidence of pulmonary hypertension (11%) and lower incidence of renal (12%) and neuropsychiatric involvement (7,9%). Cluster 2 had the highest incidence of renal involvement (43,2%) with diffuse proliferative nephritis dominating. In cluster 4, there were significantly more patients with neuropsychiatric involvement (42,9%), arterial (53,6%) and venous (54%) thrombotic events and autoimmune hemolytic anemia (33,3%). According to SLICC damage index, the highest frequency of damage was in cluster 2 (32,7%). Among SLICC damage items, there were significantly more patients with renal damage (43,1%) in cluster 2 compared to other clusters (11,1%, 15,3% and 30,6% in clusters 1, 3 and 4 respectively). Patients in cluster 4 had the highest percentage of damage due to arterial and/or venous thrombotic events. This cluster also had significantly more neuropsychiatric (40,2%) and cardiovascular (32,6%) damage compared to 3 other clusters. Comparison of 10 (98%, 92%, 95%, 88%) and 20 (98%, 87%, 88%, 80%) years survival in four clusters shows a trend towards reduced survival in Cluster 4 but the analysis did not reveal any statistical difference.

Table 1. Frequency of autoantibodies in clusters, n (%)

Autoantibody	Cluster 1 (n=136)	Cluster 2 (n=293)	Cluster 3 (n=240)	Cluster 4 (n=183)
Anti dsDNA	69 (50,7)	293 (100)*	98(40,8)	141 (77)
Anti Sm	135 (99,2)*	9 (3)	14 (5,8)	5 (2,7)
Acl IgG/IgM	43 (31,6)	0 (0)	21 (8,7)	183 (100)*
LAC	12 (8,8)	10 (4)	15 (6,2)	55 (30)
Anti RNP	121 (88,9)*	2 (0,8)	4 (1,6)	4 (2,1)
Anti RO	36 (26,4)	0 (0)	152 (63,3)*	17 (9,2)
Anti LA	14 (10,2)	2 (0,8)	71 (29,5)*	4 (2,1)

Conclusion: This study confirms the prognostic importance of autoantibodies and shows that disease subsetting according to autoantibody clusters may be useful in predicting the outcome of the disease. The cluster with only anti-dsDNA positivity in the absence of other important autoantibodies carries the highest risk for a major organ involvement and damage in our cohort.

Urine Protein-to-Creatinine Ratio in a Random Spot Urine Collection Is a Reliable Measure of Proteinuria in Lupus Nephritis. In Ah Choi, Eun Young Lee, Yeong Wook Song and Eun Bong Lee. Seoul National University Hospital, Seoul, South Korea

Background/Purpose: The accurate measurement of proteinuria is critical to the clinical management of lupus nephritis. The 24-hour urine collection has been commonly used to objectively measure the amount of proteinuria but is a laborious procedure for patients and is prone to cause collection error. Alternatively, spot urine ratio of protein to creatinine (P/Cr) has been introduced as an alternative representation of the 24-hour urine collection in various kinds of kidney diseases with proteinuria. However, it is not known whether spot urine P/Cr can replace 24hr urine protein in lupus nephritis.

Methods: This is a retrospective study investigating the association of random spot urine P/Cr and 24-hour urine protein in patients with biopsy-proven lupus nephritis. A total of 286 samples of random spot urine and concurrent 24-hour urine collections from 120 patients were analyzed. All the patients were diagnosed as systemic lupus erythematosus according to the revised criteria of American College of Rheumatology and were enrolled from Seoul National University Hospital between May 2004 and July 2010.

Results: In 286 selected samples, 24-hour urine protein excretion ranged from 42 mg/day to 36,080 mg/day. The range of 24-hour urine P/Cr was 0.04 to 49.72. Random urine P/Cr ranged from 0.06 to 51.40. There was a strong correlation between 24-hour urine protein excretion and random urine P/Cr ($r= 0.774$, $P<0.001$). A strong correlation ($r= 0.939$, $P<0.001$) was also found between 24-hour urine P/Cr and random P/Cr.

The spot urine P/Cr was correlated well with 24-hour urine protein when 24-hour urine protein was less than 8 g/day ($r=0.742$, $p<0.001$). However, the correlation was poor when it was more than 8 g/day ($r=367$, $p=0.134$).

Conclusion: This study shows that random spot urine P/Cr is well correlated with 24-hour urine protein when the 24-hour urine protein is less than 8 g/day. The result supports the use of random spot urine P/Cr in screening and monitoring of proteinuria in patients with lupus nephritis.

***Quasi*-homogeneous ANA-HEp-2 Pattern Reflects An Autoantibody Profile Intermediate to the Homogeneous and Dense Fine Speckled Nuclear Patterns.** Natália R. França[1], Alessandra Dellavance[2], Sílvia H. Rodrigues[3], Sandro F. Perazzio[4], Neusa P. Silva[5] and Luis Eduardo C. Andrade[3]. [1]Federal University, Sao Paulo, Brazil, [2]Universidade Federal de São Paulo and Fleury Health and Medicine Laboratories, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo and Fleury Health and Medicine Laboratories, Sao Paulo Brazil, Sao Paulo, Brazil, [4]Federal University of Sao Paulo, Sao Paulo, Brazil, [5]Escola Paulista de Medicina - Universidade Federal de São Paulo, Sao Paulo, Brazil

Background/Purpose: The indirect immunofluorescence assay on HEp-2 cells (ANA-HEp-2) yields different morphological patterns that reflect the distribution of the autoantigens recognized by a given sample. Thus the ANA-HEp-2 pattern may reflect the autoantibody profile present in the sample. We have recently observed a novel ANA-HEp-2 pattern, herein designated *Quasi-Homogeneous* (QH) pattern, which presents intermediary morphological features between the previously characterized nuclear homogeneous (Ho) and nuclear dense fine speckled (DFS) patterns. These three patterns have a common feature of staining the mitotic chromosome plates, what may induce misinterpretation. This study aimed to perform the clinical and immunological characterization of the QH pattern.

Methods: Serum samples were consecutively selected from the ANA-HEp-2 routine as follows: 60 samples displaying the QH pattern, 30 samples displaying Ho pattern, and 30 samples displaying the DFS pattern. All samples were tested for the presence of antibodies against native DNA, nucleosome, histones, cardiolipin, and extractable nuclear antigens (ENA). QH samples were processed in four different ANA-HEp-2 slide brands, in home-made slides with HEp-2 cells fixed with either methanol/acetone or paraformaldehyde, and tested in western blot against MOLT-4 cell total extract. Systemic autoimmune rheumatic diseases (SARD) were defined according to ACR criteria after clinical chart review and interview with clinicians.

Results: The QH pattern was reproducible in the four ANA-HEp-2 slide brands and in home-made HEp-2 cell slides fixed with the two different protocols. QH samples showed an intermediate frequency of antibodies against native DNA (7%), ENA (5%), nucleosome (35%) and histones (16.7%), in contrast with Ho samples, which showed high frequency of these autoantibodies (36.7%, 23.3%, 96.7% and 60%, respectively), and DFS samples in which these autoantibodies were consistently absent. In western blot, QH samples depicted heterogeneous reactivity with no apparent common band. QH serum samples were associated with heterogeneous clinical conditions, including SARD, non-inflammatory diseases, non-specific complaints, and even apparently healthy subjects. Association with SARD was higher for QH samples

(87.5%) than QH samples (41.6%) (p=0.004). The latter samples were more frequently associated with SARD than DFS samples (4%) (p=0.009). Therefore, QH samples held an intermediate position between the two other patterns in that the Ho pattern was strongly associated with SARD and the DFS pattern that held no association with SARD.

Conclusion: The QH ANA-HEp-2 pattern reflects a heterogeneous profile of autoantibodies and clinical manifestations intermediate to those represented by the Ho and DFS patterns, respectively. The distinction among these patterns is important for the appropriate interpretation of the ANA-HEp-2 results.

Cognitive Differences in Systemic Lupus Erythematosus Patients From the Western (Denver, CO) and Eastern (New York, NY) Regions of the United States. Elizabeth Kozora[1], Doruk Erkan[2], Sterling G. West[3], Christopher Filley[3], Aziz Ulug[4], Glendalee Ramon[2], Emily Duggan[1], Lening Zhang[1], JoAnn Vega[2] and Michael D. Lockshin[2]. [1]National Jewish Health, Denver, CO, [2]Barbara Volcker Center for Women and Rheumatic Diseases: Hospital for Special Surgery, New York, NY, [3]University of Colorado School of Medicine, Aurora, CO, [4]The Feinstein Institute for Medical Research, Manhasset, NY

Background/Purpose: Cognitive dysfunction can occur in over 50% of systemic lupus erythematosus (SLE) patients. During the analysis of two independent studies of SLE completed at two different regions of United States (US), we noticed significant differences in the cognitive test results. Thus, we decided to investigate the potential causes of this inconsistency.

Methods: SLE patients without prior or overt neuropsychiatric (NP) disorders from Western (Denver, CO) and Eastern (New York, NY) regions of the US were enrolled in two different but parallel cognition studies. Participants at both sites were screened similarly and evaluated with the same battery of cognitive tests recommended by the ACR (ad hoc ACR committee, 1999). Cognitive impairment was calculated using a reliable and valid index (range 0–12) with global impairment defined as impairment in four or more of the 12 scores (Kozora et al, 2004). The continuous variables were compared using a non-parametric Wilcoxon Rank Sum test and categorical variables with Fisher's Exact Test. Additional correlations were performed using Spearman coefficient.

Results: There were 84 patients enrolled from Western and 20 from Eastern regions with cognitive impairment rates of 24% and 60%, respectively (mean number of impaired cognition tests 2.6+2.3 versus 4.4+2.7, $p=0.005$). There were no significant differences between the groups in the demographics, depression level, SLE characteristics, and other co-morbidities except that Eastern participants had: a) significantly longer disease duration and higher ACR SLE criteria score (Table); and b) higher rates of malar rash, renal involvement, and immunologic disorder ($p<0.001$). There were no significant differences between the groups on measures of verbal memory/fluency, information processing, and visual learning/memory; however, Eastern participants were more commonly impaired in semantic fluency ($p=0.005$), visuomotor speed ($p=0.013$), and motor sequencing ($p=0.001$). We found a trend correlation between cognitive impairment and SLE disease duration ($p=0.07$) but not with total ACR SLE criteria score ($p=0.38$).

	Western (n: 84)	Eastern (n: 20)	P
Female (%)	94	100	Ns
Caucasian (%)	63	40	Ns
Mean Age (years)	36.7+8.7	36.5+11.7	Ns
Mean Education (years)	15.6+2.5	15.6+2.4	Ns
Mean ACR SLE Criteria	4.7+1.1	6.2+1.5	<0.001
Mean Diagnosis Duration (months)	90.2+78.7	154.8+122.9	0.005
Mean SLEDAI Score	4.2+6.3	3.7+4.6	Ns

Ns: not significant

Conclusion: SLE patients in the Eastern US, with significantly longer disease duration, showed greater cognitive impairment compared to patients in the Western US. The higher prevalence of medical complications in Eastern SLE patients might contribute to this difference. Although results should be interpreted cautiously due to varying sample size and baseline characteristics, our study provides a staring point to investigate different cognitive dysfunction patterns that may exist in different parts of the country.

Hypophosphatemia Is Associated with Nephrogenic Systemic Fibrosis: A Case-Control Study. Elana J. Bernstein[1], Tamara Isakova[2], Mary E. Sullivan[3], Lori B. Chibnik[4], Hasan Bazari[3], Myles Wolf[2] and Jonathan Kay[5]. [1]Hospital for Special Surgery, New York, NY, [2]University of Miami, Miami, FL, [3]Massachusetts General Hospital, Boston, MA, [4]Brigham & Women's Hospital, Boston, MA, [5]University of Massachusetts Medical School, Worcester, MA

Background/Purpose: Nephrogenic systemic fibrosis (NSF) manifests as hardening, tethering, and hyperpigmentation of skin; flexion contractures of joints; and extracutaneous fibrosis in individuals with chronic kidney disease (CKD) following exposure to gadolinium-based contrast agents (GBCA) during imaging procedures. Given that not all patients with CKD exposed to GBCA develop NSF, additional factors must be involved in its pathogenesis. Preliminary evidence suggests that there may be derangements of calcium and phosphorus metabolism in patients with NSF. Fibroblast growth factor 23 (FGF23) is a phosphorus and vitamin D regulating hormone. FGF23 levels increase markedly as glomerular filtration rate (GFR) decreases. Whether FGF23 excess contributes to the development of NSF is unknown.

This study investigated potential factors in addition to GBCA exposure that may be involved in the pathogenesis of NSF. We hypothesized that, compared to patients with stage 5 CKD who do not have NSF, those with NSF would manifest greater alterations in calcium, phosphorus, and FGF23 levels.

Methods: Twenty-nine adult subjects with stage 5 CKD undergoing hemodialysis or peritoneal dialysis were recruited from outpatient nephrology and rheumatology practices. Subjects were excluded if they had a history of a phosphate wasting disorder or untreated primary hyperparathyroidism. Cases consisted of 10 patients with stage 5 CKD and biopsy-proven NSF. Controls consisted of 19 patients with stage 5 CKD without NSF, 9 of whom had never previously been exposed to GBCA. Cases and controls were matched for age and sex. Blood was collected from all 29 subjects and analyzed for phosphorus, calcium, FGF23, and 25-hydroxy-vitamin D levels, in addition to other routine laboratory tests. Statistical analysis was performed using the student's t-test for differences in phosphorus, calcium, and 25-hydroxy-vitamin D levels between the 2 groups, and the Wilcoxon test for differences in FGF23 levels.

Results: Subjects were predominantly male (62%), and the majority identified themselves as Caucasian (79%). The mean age of subjects was 63 years (SD 12). Patients with NSF had significantly lower phosphorus levels compared to controls (3.4 ± 0.87 mg/dL vs. 4.49 ± 1.05 mg/dL, p = 0.01). Accounting for the use of phosphate binders did not alter these results. There were no significant differences in calcium (9.53 ± 0.92 mg/dL vs. 9.64 ± 0.58 mg/dL, p = 0.70), 25-hydroxy-vitamin D (29.53 ± 23.90 ng/mL vs. 26.90 ± 15.00 ng/mL, p = 0.74), or FGF23 (8468 ± 8560 RU/mL vs. 6956 ± 4785 RU/mL, p = 0.79) levels between NSF patients and controls.

Conclusion: This case-control study suggests that differences in phosphorus metabolism may exist between patients with stage 5 CKD and NSF compared to patients with stage 5 CKD without NSF. Further study of the possible pathogenic role of altered phosphorus handing in the development of NSF is therefore needed.

HLA-DRB5*01:05 Is a Risk Factor for Systemic Sclerosis with Interstitial Lung Disease. Toshio Odani, Shinsuke Yasuda, Ayaka Kubota, Hisako Nakagawa, Yuichiro Fujieda, Kotaro Otomo, Masaru Kato, Tetsuya Horita, Tatsuya Atsumi and Takao Koike. Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background/Purpose: Interstitial lung disease (ILD) is a serious complication of Systemic Sclerosis (SSc). Recently, a variety of markers including cytokines, disease-specific autoantibodies and genetic backgrounds have been reported to be associated with SSc. However, few studies have focused on association between specific markers and SSc-related ILD. We aimed to elucidate markers associated with ILD in patients with SSc.

Methods: This study was approved by the ethical committee of Hokkaido University Graduate School of Medicine. RNA was prepared from peripheral blood mononuclear cells (PBMCs) from 14 SSc patients. Fourteen samples were divided into 4 sets of RNA pools according to the presence or the absence of ILD, and to the treatment (conventional or hematopoietic stem cell transplantation), then were subjected to DNA microarray. The expression levels of *HLA-DRB5* in each individual were evaluated by real-time qPCR for 43 SSc patients (25 with ILD, 18 without ILD), 42 patients with other autoimmune diseases and 10 healthy controls. Genomic DNA samples were collected from147 healthy controls and 70 SSc patients who received high-resolution CT scan for the evaluation of ILD. *HLA-DRB5* genotype was analyzed by sequence specific primers method.
